Apps

Bit Error Rate Analysis

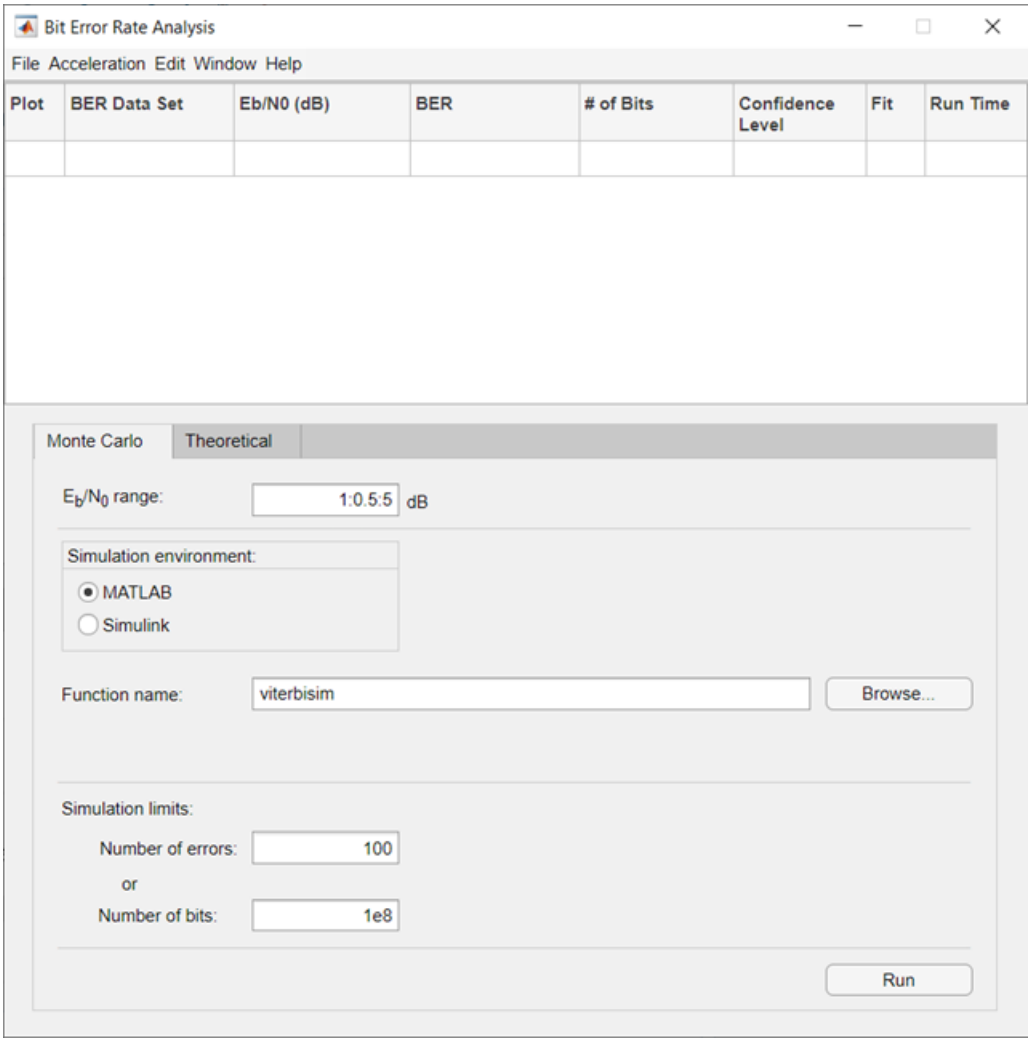
Analyze BER performance of communications systems

Description

The **Bit Error Rate Analysis** app calculates the bit error rate (BER) as a function of the energy per bit to noise power spectral density ratio (E_b/N_0). Using this app, you can:

- Generate BER data for a communications system and analyze performance using:
  - Monte Carlo simulations of MATLAB® functions and Simulink® models.
  - Theoretical closed-form expressions for selected types of communications systems.
  - Run systems contained in MATLAB simulation functions or Simulink models. After you create a function or model that simulates the system, the **Bit Error Rate Analysis** app iterates over your choice of E_b/N_0 values and collects the results.
- Plot one or more BER data sets on a single set of axes. You can graphically compare simulation data with theoretical results or simulation data from a series of communications system models.
- Fit a curve to a set of simulation data.
- Plot confidence levels of simulation data.
- Send BER data to the MATLAB workspace or to a file for further processing.

For more information, see “Analyze Performance with Bit Error Rate Analysis App”.



Open the Bit Error Rate Analysis App

- MATLAB Toolstrip: On the **Apps** tab, under **Signal Processing and Communications**, click the app icon.
- MATLAB command prompt: Enter `bertool`.

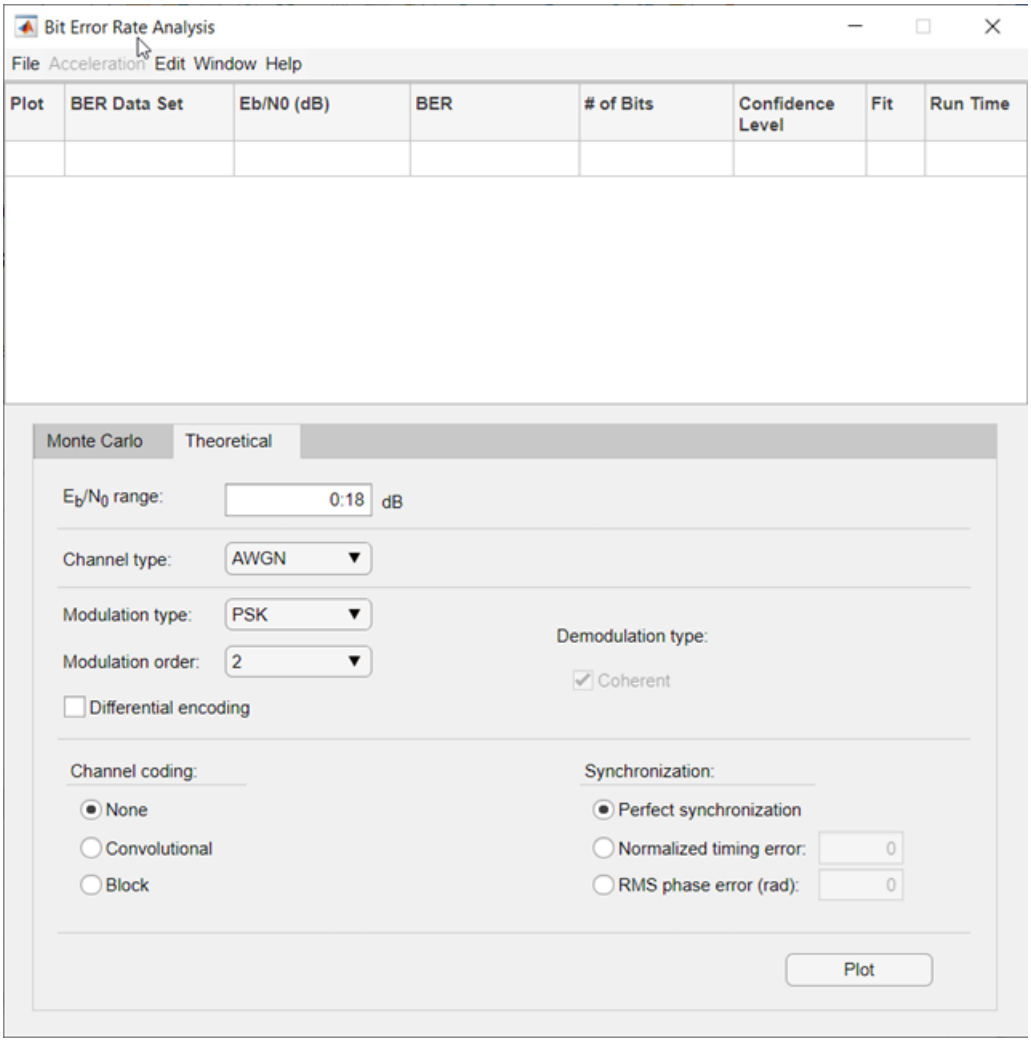
Examples

Compute BER Using Theoretical Tab

Generate a theoretical estimate of BER performance for a 16-QAM link in AWGN.

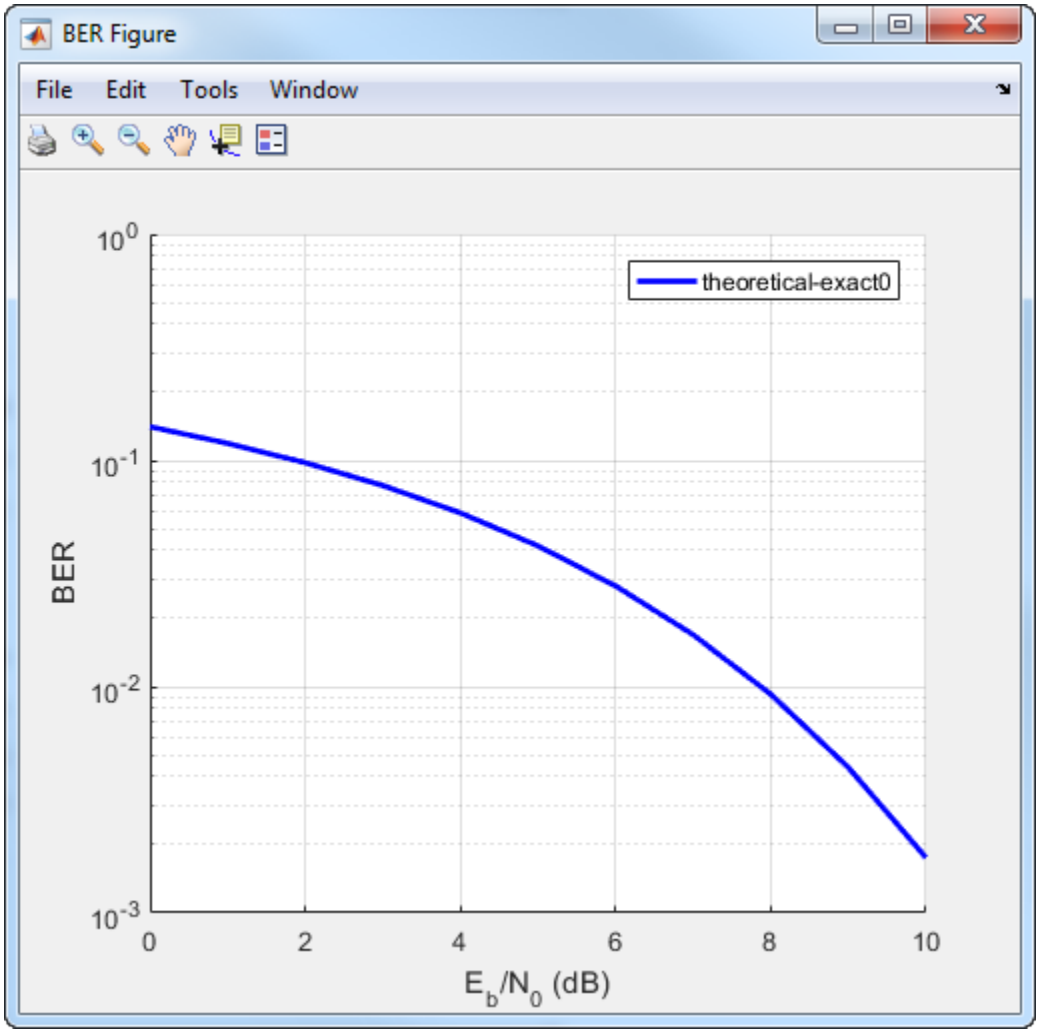
Open the **Bit Error Rate Analysis** app.

```
bertool
```



On the Theoretical tab, set these parameters to the specified values: **E_b/N_0 range** to `0:10`, **Modulation type** to `QAM`, and **Modulation order** to `16`.

Plot the BER curve by clicking **Plot**.



Compute BER Using Monte Carlo Tab and MATLAB Function Simulation

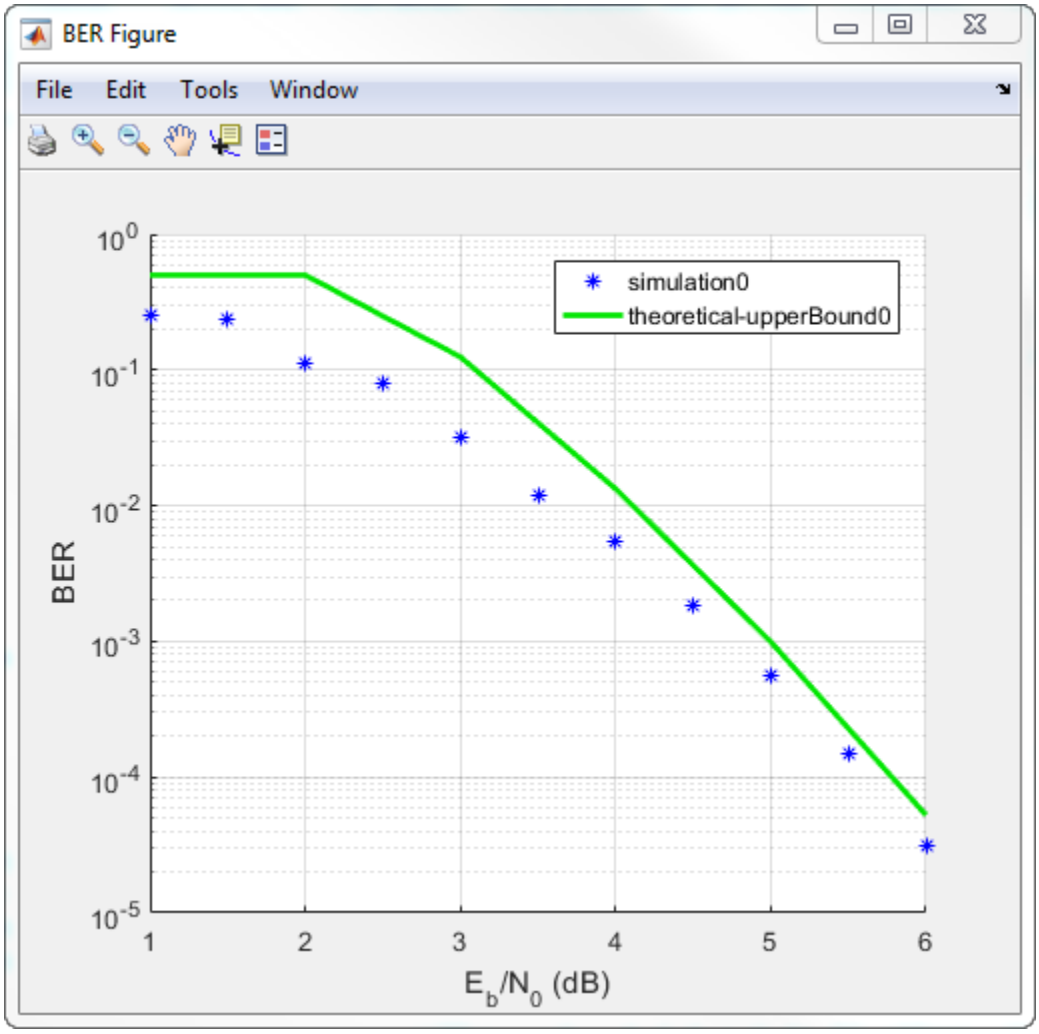
Simulate the BER by using a custom MATLAB function. By default, the app uses the `viterbisim.m` simulation.

Open the **Bit Error Rate Analysis** app.

```
bertool
```

On the **Monte Carlo** tab, set the **E_b/N_0 range** parameter to `1:.5:6`. Run the simulation and plot the estimated BER values by clicking **Run**.

On the **Theoretical** tab, set **E_b/N_0 range** to `1:6` and set **Modulation order** to 4. Enable convolutional coding by selecting **Convolutional**. Click **Plot** to add the theoretical upper bound of the BER curve to the plot.



Prepare MATLAB Function for Use in Bit Error Rate Analysis App

Add code to the simulation function template given in the “Template for Simulation Function” topic to run in the **Monte Carlo** tab of the **Bit Error Rate Analysis**.

Prepare Function

Copy the template from the “Template for Simulation Function” topic into a new MATLAB file in the MATLAB Editor. Save the file in a folder on your MATLAB path, using the file name `bertool_simfcn`.

Place lines of code that initialize parameters or create objects used in the simulation in the template section marked `Set up initial parameters`. This code maps simulation variables to the template input arguments. For example, `snr` maps to `EbNo`.

```
% Set up initial parameters.
siglen = 1000; % Number of bits in each trial
M = 2;         % DBPSK is binary
snr = EbNo;    % Because of binary modulation
```

```
% Create an ErrorRate calculator System object to compare
% decoded symbols to the original transmitted symbols.
errorCalc = comm.ErrorRate;
```

Place the code for the core simulation tasks in the template section marked `Proceed with simulation`. This code includes the core simulation tasks, after all setup work has been performed.

```
    msg = randi([0,M-1],siglen,1); % Generate message sequence
    txsig = dpskmod(msg,M);        % Modulate
    hChan.SignalPower = ...        % Calculate and assign signal power
        (txsig'*txsig)/length(txsig);
    rxsig = awgn(txsig,snr,'measured'); % Add noise
    decodmsg = dpskdemod(rxsig,M);      % Demodulate
    berVec = errorCalc(msg,decodmsg);   % Calculate BER
    totErr = totErr + berVec(2);
    numBits = numBits + berVec(3);
```

After you insert these two code sections into the template, the `bertool_simfcn` function is compatible with the **Bit Error Rate Analysis** app. The resulting code resembles this code segment.

```
function [ber,numBits] = bertool_simfcn(EbNo,maxNumErrs,maxNumBits,varargin)
%
%   See also BERTOOL and VITERBISIM.

% Copyright 2020 The MathWorks, Inc.

% Initialize variables related to exit criteria.
totErr = 0;  % Number of errors observed
numBits = 0; % Number of bits processed

% --- Set up the simulation parameters. ---
% --- INSERT YOUR CODE HERE.
% Set up initial parameters.
siglen = 1000; % Number of bits in each trial
M = 2;         % DBPSK is binary.
snr = EbNo;    % Because of binary modulation
% Create an ErrorRate calculator System object to compare
% decoded symbols to the original transmitted symbols.
errorCalc = comm.ErrorRate;

% Simulate until the number of errors exceeds maxNumErrs
% or the number of bits processed exceeds maxNumBits.
while((totErr < maxNumErrs) && (numBits < maxNumBits))

    % Check if the user clicked the Stop button of BERTool.
    if isBERToolSimulationStopped(varargin{:})
      break
    end

    % --- Proceed with the simulation.
    % --- Update totErr and numBits.
    % --- INSERT YOUR CODE HERE.
    msg = randi([0,M-1],siglen,1); % Generate message sequence
    txsig = dpskmod(msg,M);        % Modulate
    hChan.SignalPower = ...        % Calculate and assign signal power
        (txsig'*txsig)/length(txsig);
    rxsig = awgn(txsig,snr,'measured'); % Add noise
    decodmsg = dpskdemod(rxsig,M);      % Demodulate
    berVec = errorCalc(msg,decodmsg);   % Calculate BER
    totErr = totErr + berVec(2);
    numBits = numBits + berVec(3);
end % End of loop

% Compute the BER.
ber = totErr/numBits;
```

The function has inputs to specify the app and scalar quantities for `EbNo`, `maxNumErrs`, and `maxNumBits` that are provided by the app. The **Bit Error Rate Analysis** app is an input because the function monitors and responds to the stop command in the app. The `bertool_simfcn` function

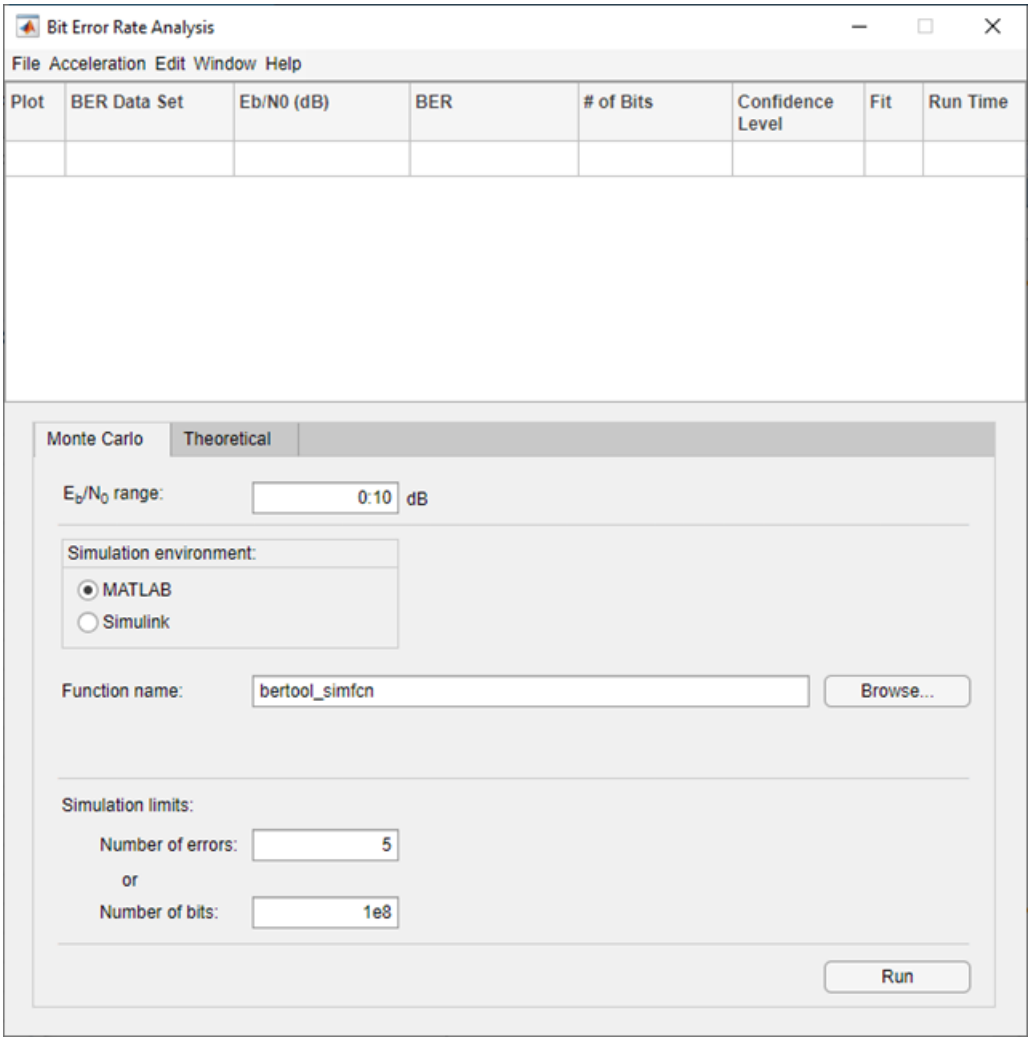
excludes code related to plotting, curve fitting, and confidence intervals because the **Bit Error Rate Analysis** app enables you to do similar tasks interactively without writing code.

Use Prepared Function

Run `bertool_simfcn` in the **Bit Error Rate Analysis** app.

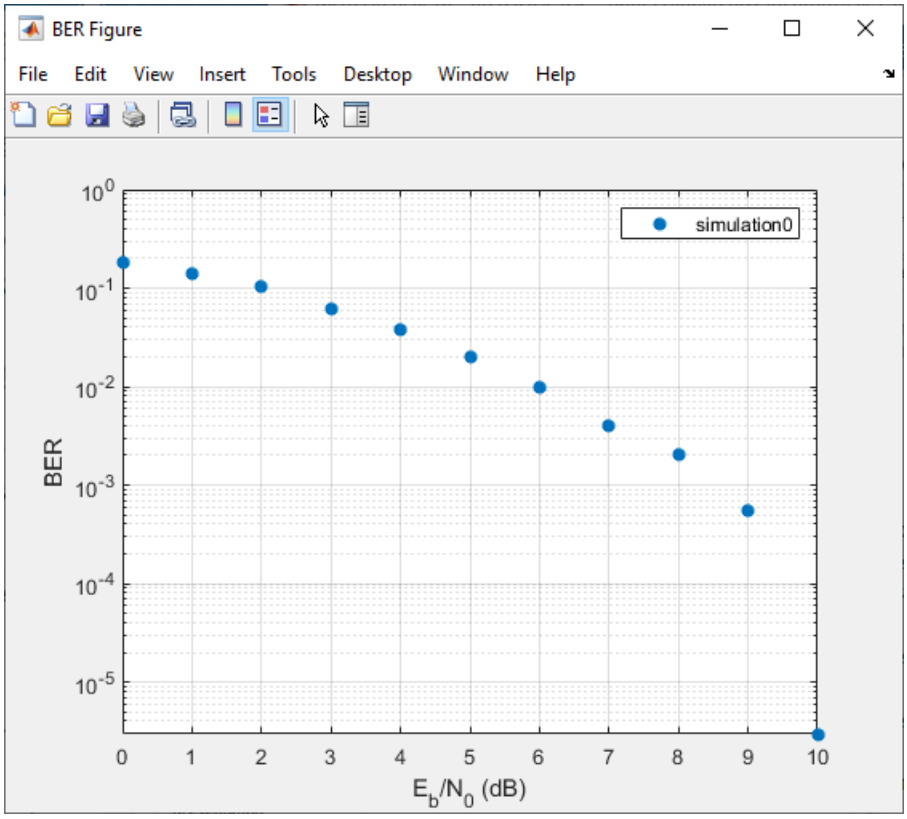
Open the **Bit Error Rate Analysis** app, and then select the **Monte Carlo** tab.

Set these parameters to the specified values: **E_b/N_0 range** to `0:10`, **Simulation environment** to `MATLAB`, **Function name** to `bertool_simfcn`, **Number of errors** to `5`, and **Number of bits** to `1e8`.



Click **Run**.

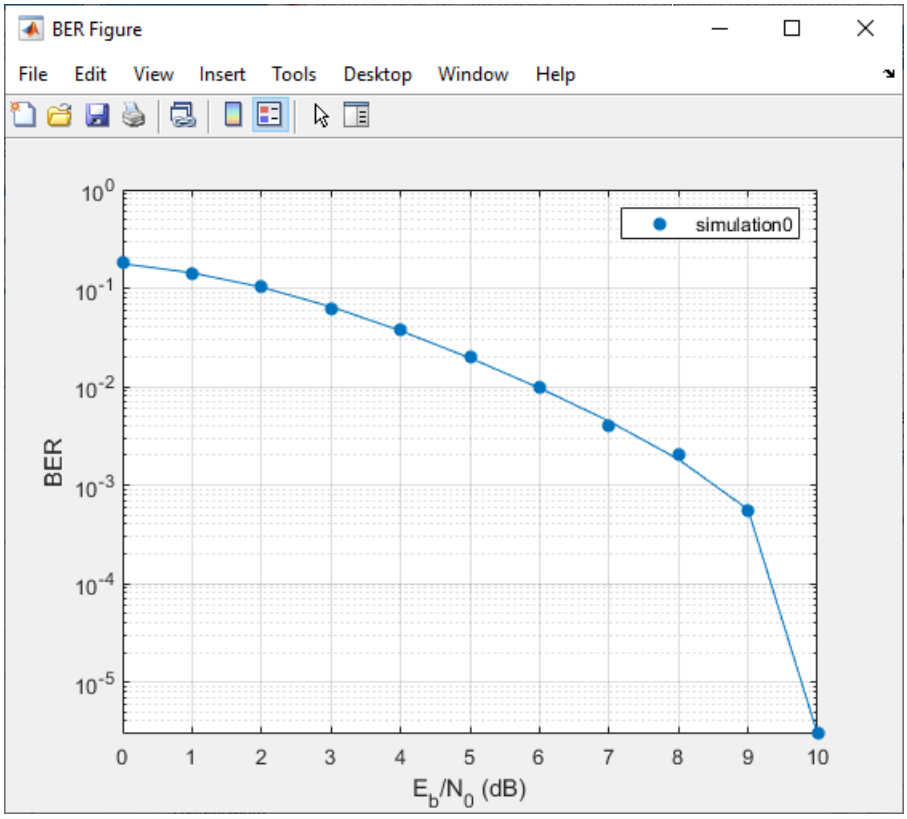
The **Bit Error Rate Analysis** app computes the results and then plots them. In this case, the results do not appear to fall along a smooth curve because the simulation required only five errors for each value in `EbNo`.



Fit a curve to the series of points in the BER Figure window, by selecting the **Fit** parameter in the data viewer.

Plot	BER Data Set	Eb/N0 (dB)	BER	# of Bits	Confidence Level	Fit
☑	simulation0	0 1 2 3 4 5 6 7 8 9 ...	0.169 0.127 0.105 ...	1000 1000 1000 1...	off	☑

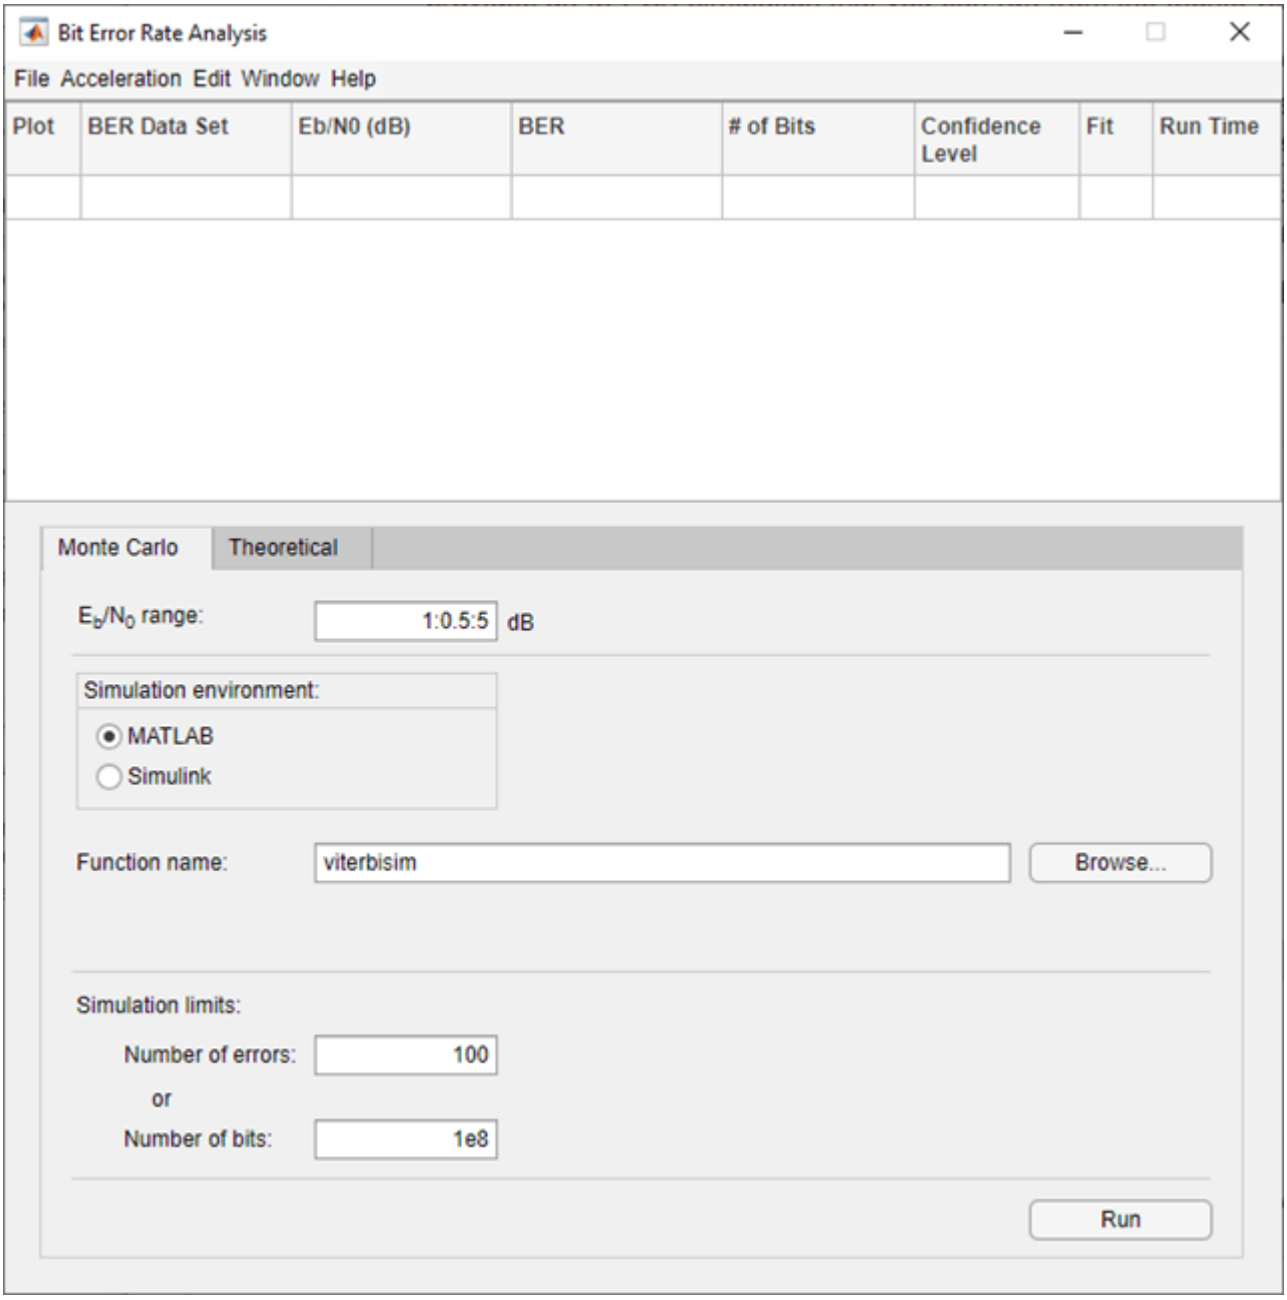
The **Bit Error Rate Analysis** app plots the fitted curve, as shown in this figure.



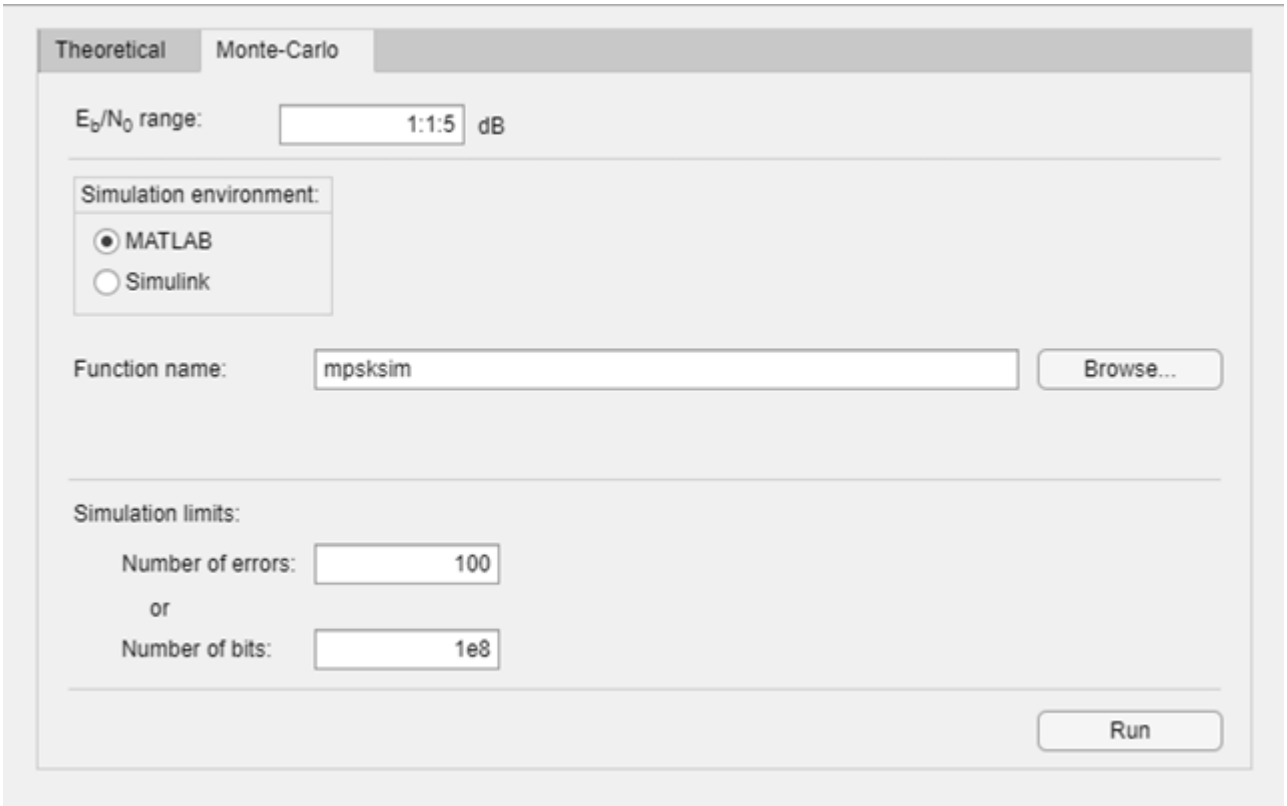
Compute Error Rate Simulation Sweeps Using Bit Error Rate Analysis App

Use the Bit Error Rate Analysis app to compute the BER as a function of E_b/N_0. The app analyzes performance with either Monte Carlo simulations of MATLAB® functions and Simulink® models or theoretical closed-form expressions for selected types of communications systems. The code in the mpsksim.m function provides an M-PSK simulation that you can run from the **Monte Carlo** tab of the app.

Open the **Bit Error Rate Analysis** app from the Apps tab or by running the `bertool` function in the MATLAB command window.



On the **Monte Carlo** tab, set the E_b/N_0 **range** parameter to `1:1:5` and the **Function name** parameter to `mpsksim`.



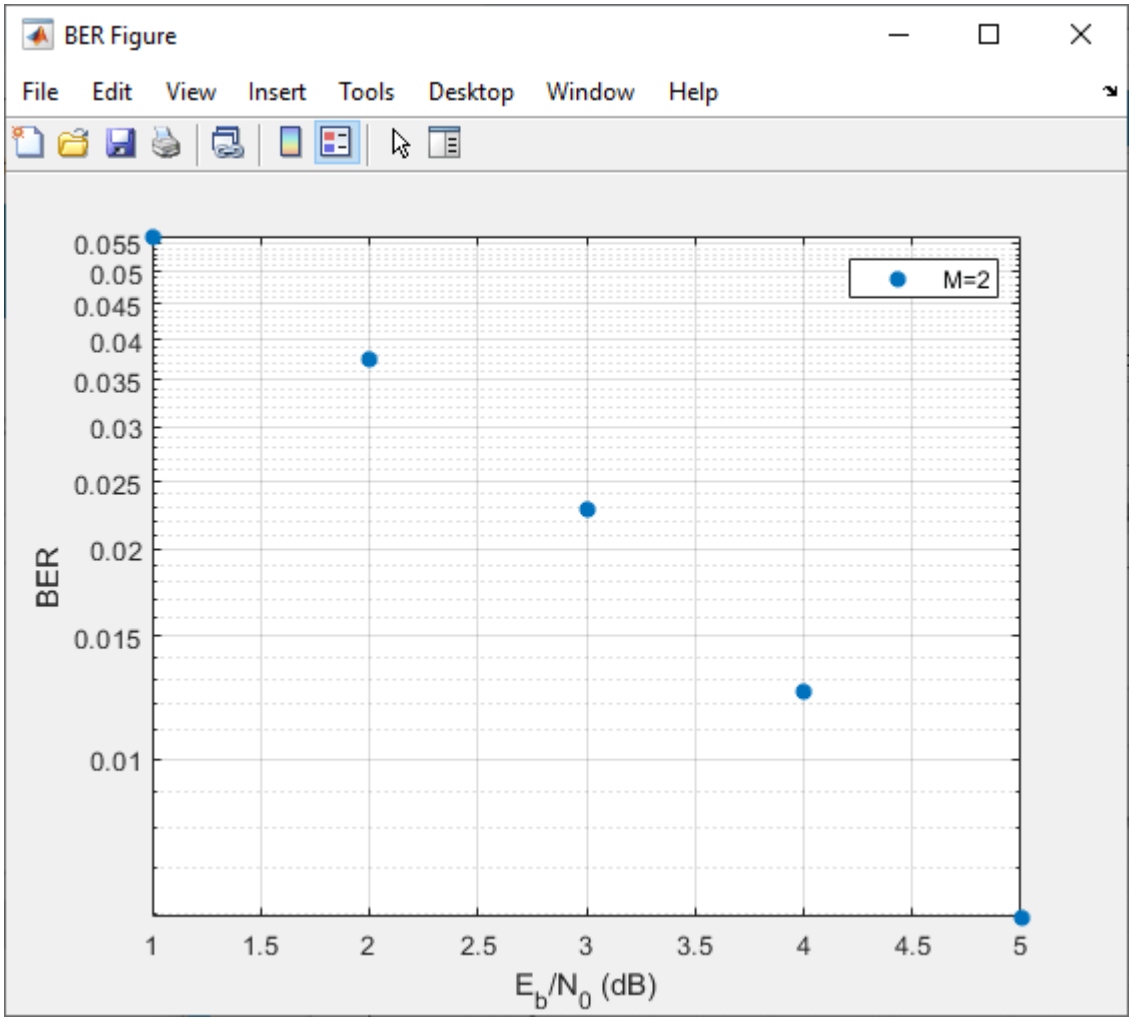
Open the `mpsksim` function for editing, set `M=2`, and save the changed file.

Run the `mpsksim.m` function as configured by clicking **Run** on the **Monte Carlo** tab in the app.

After the app simulates the set of E_b/N_0 points, update the name of the BER data set results by selecting `simulation0` in the **BER Data Set** field and typing `M=2` to rename the set of results. The legend on the BER figure updates the label to `M=2`.

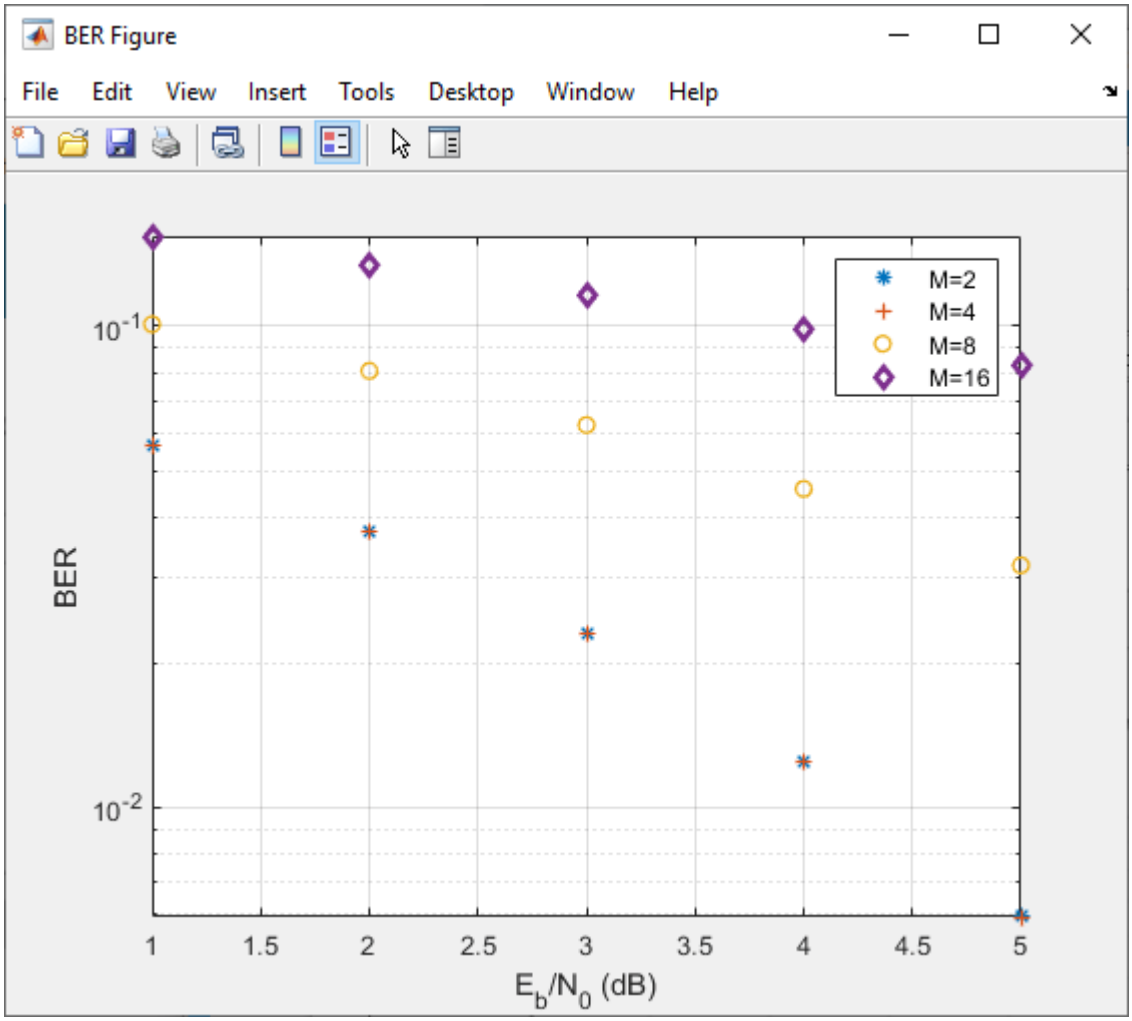
Plot	BER Data Set	Eb/N0 (dB)	BER	# of Bits	Confidence Level	Fit	Run Time
☑	simulation0	1, 2, 3, 4, 5	0.056284, 0.03751...	100002000, 100...	off	☐	00:00:44

Plot	BER Data Set	Eb/N0 (dB)	BER	# of Bits	Confidence Level	Fit	Run Time
☑	M=2	1, 2, 3, 4, 5	0.056284, 0.03751...	100002000, 100...	off	☐	00:00:44



Update the value for `M` in the `mpsksim` function, repeating this process for `M` = 4, 8, and 16. For example, these figures of the **Bit Error Rate Analysis** app and BER Figure window show results for varying `M` values.

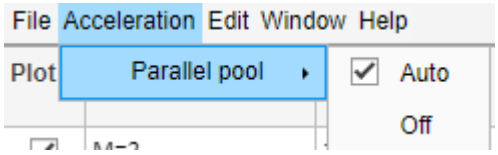
Plot	BER Data Set	Eb/N0 (dB)	BER	# of Bits	Confidence Level	Fit	Run Time
☑	M=2	1, 2, 3, 4, 5	0.056284, 0.03751...	100002000, 100...	off	☐	00:00:44
☑	M=4	1, 2, 3, 4, 5	0.056284, 0.03751...	100002000, 100...	off	☐	00:00:28
☑	M=8	1, 2, 3, 4, 5	0.10078, 0.080668...	100008000, 100...	off	☐	00:00:20
☑	M=16	1, 2, 3, 4, 5	0.15352, 0.13377, ...	100008000, 100...	off	☐	00:00:16



Parallel SNR Sweep Using Bit Error Rate Analysis App

The default configuration for the Monte Carlo processing of the **Bit Error Rate Analysis** app automatically uses parallel pool processing to process individual E_b/N_0 points when you have the Parallel Computing Toolbox™ software but for the processing of your simulation code:

- Any `parfor` function loops in your simulation code execute as standard `for` loops.
- Any `parfeval` (Parallel Computing Toolbox) function calls in your simulation code execute serially.
- Any `spmd` (Parallel Computing Toolbox) statement calls in your simulation code execute serially.



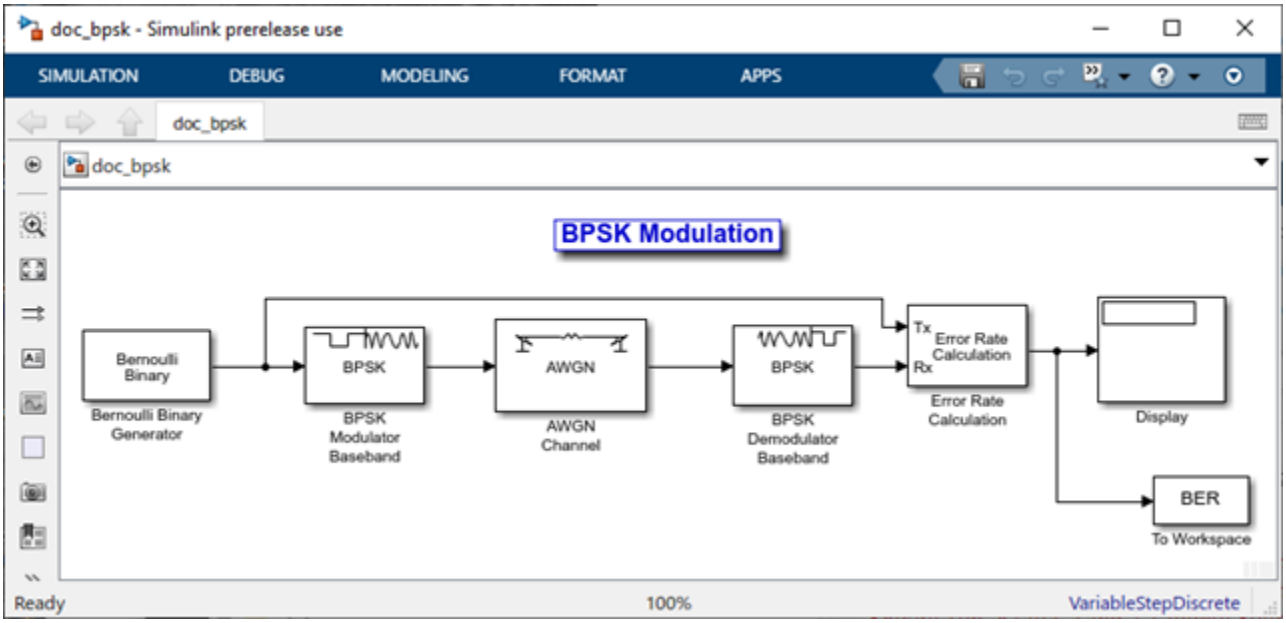
Prepare Simulink Model for Use with Bit Error Rate Analysis App

Use a Simulink simulation model to run in the **Monte Carlo** tab of the **Bit Error Rate Analysis** app. Compare the BER performance of the Simulink simulation results with theoretical BER results.

Prepare Model

Open the model by entering `doc_bpsk` at the MATLAB command prompt.

```
doc_bpsk
```



Initialize parameters in the MATLAB workspace to avoid using undefined variables as block parameters.

```
EbNo = 0;
maxNumErrs = 100;
maxNumBits = 1e8;
```

Ensure that the **Bit Error Rate Analysis** app uses the correct amount of noise each time it runs the simulation, by opening the dialog box for the AWGN Channel block and verifying that the **Es/No** parameter is set to `EbNo`.

Note For BPSK modulation, E_s/N_0 is equivalent to E_b/N_0.

Ensure that the **Bit Error Rate Analysis** app uses the correct stopping criteria for each iteration by:

- Opening the dialog box for the Error Rate Calculation block and verifying that **Target number of errors** is set to `maxNumErrs` and that **Maximum number of symbols** is set to `maxNumBits`.
- Verifying that the simulation stop time is set to `Inf`.

Enable the **Bit Error Rate Analysis** app to access the BER results that the Error Rate Calculation block computes, by ensuring that the **BER variable name** parameter in the app matches the

Variable name parameter set in the To Workspace block that connects to the output of the Error Rate Calculation block.

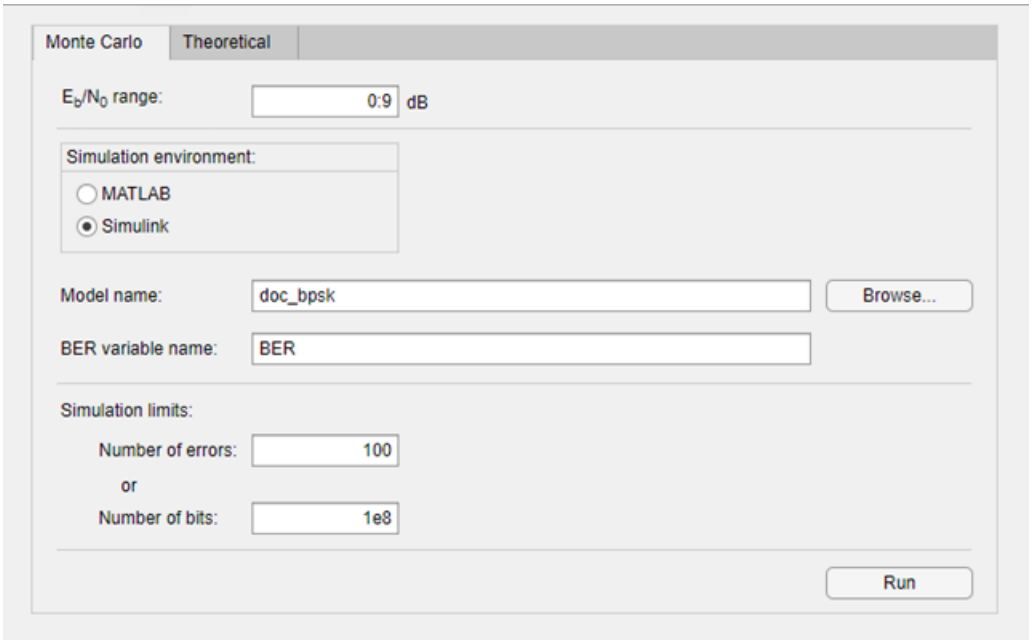
Tip Select the To Workspace block from the DSP System Toolbox™ / Sinks sublibrary. For more information, see "To Workspace Block Configuration for Communications System Simulations".

Use Prepared Model

Run the `doc_bpsk` model in the **Bit Error Rate Analysis** app.

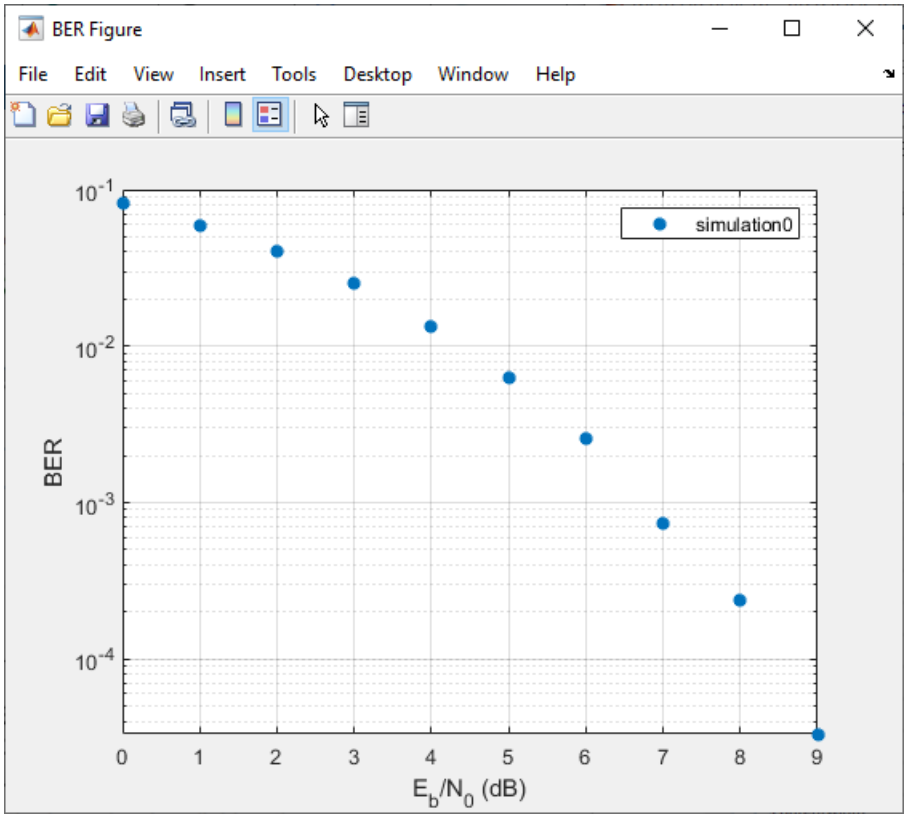
Open the **Bit Error Rate Analysis** app, and then select the **Monte Carlo** tab.

Set these parameters to the specified values: **E_b/N_0 range** to `0:9`, **Simulation environment** to `Simulink`, **Function name** to `doc_bpsk`, **Number of errors** to `100`, and **Number of bits** to `1e8`.

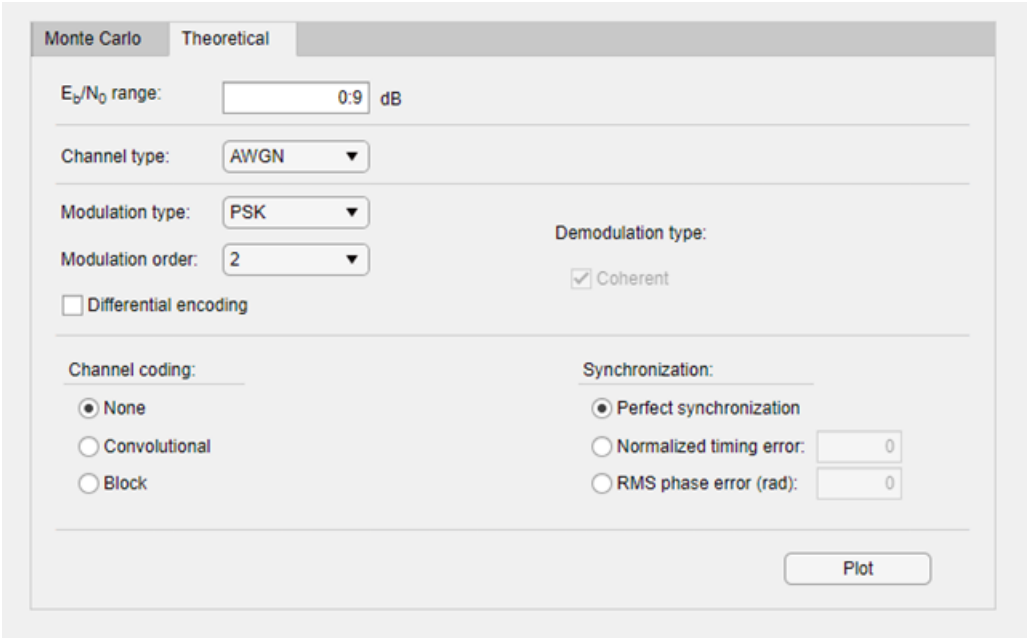


Click **Run**.

The **Bit Error Rate Analysis** app computes the results and then plots them.

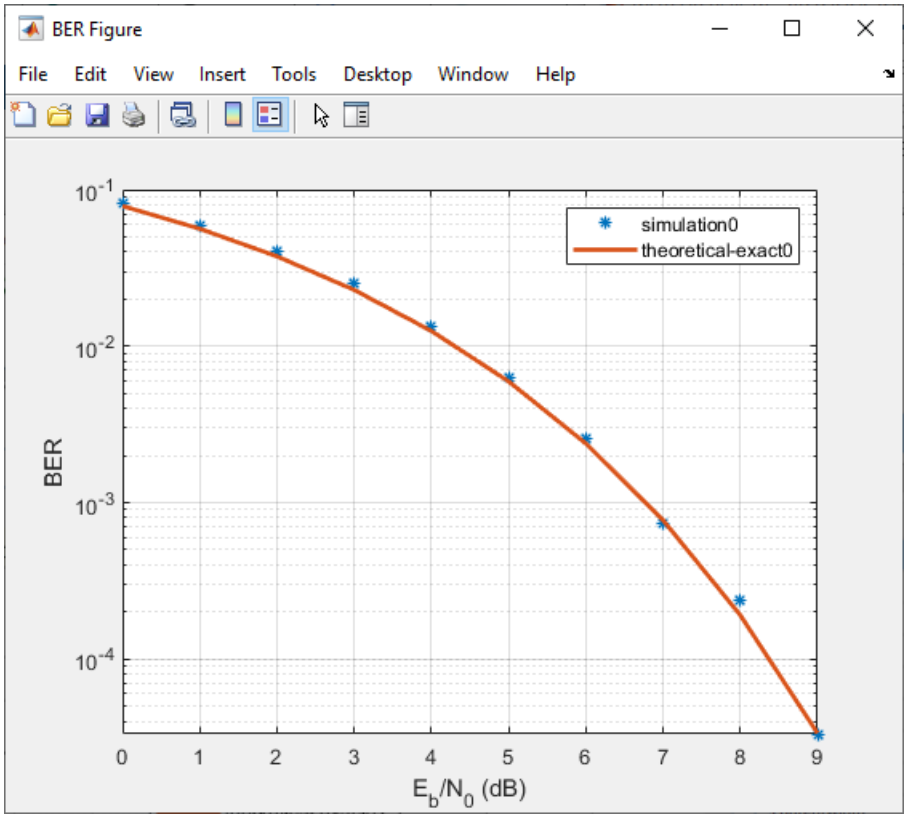


Compare these simulation results with the theoretical results, by clicking the **Theoretical** tab in the **Bit Error Rate Analysis** app and setting **E_b/N_0 range** to `0:9`.



Click **Plot**.

The **Bit Error Rate Analysis** app plots the theoretical curve in the BER Figure window along with the earlier simulation results.



Parameters

Theoretical

E_b/N_0 range — Range of E_b/N_0 values

`0:18` (default) | scalar | vector

Range of E_b/N_0 values over which the BER is evaluated, specified as a scalar or vector. Units are in dB.

Example: `5:10` specifies the evaluation of E_b/N_0 values over the range [5, 10] at 1 dB increments.

`Channel type` — Type of channel over which BER is evaluated

`AWGN` (default) | `Rayleigh` | `Rician`

Type of channel over which the BER is evaluated, specified as `AWGN`, `Rayleigh`, or `Rician`. The `Rayleigh` and `Rician` options correspond to flat fading channels.

`Modulation type` — Modulation type of communications link

`PSK` (default) | `DPSK` | `OQPSK` | `PAM` | `QAM` | `FSK` | `MSK` | `CPFSK`

Modulation type of the communications link, specified as `PSK`, `DPSK`, `OQPSK`, `PAM`, `QAM`, `FSK`, `MSK`, or `CPFSK`.

`Modulation order` — Modulation order of communications link
`2` (default) | `4` | `8` | `16` | `32` | `64`

Modulation order of the communications link, specified as `2`, `4`, `8`, `16`, `32`, or `64`.

`Differential encoding` — Differential encoding of input data
`off` (default) | `on`

Select this parameter to enable differential encoding of the input data.

`Correlation coefficient` — Correlation coefficient
`0` (default) | real scalar in the range [-1, 1]

Correlation coefficient, specified as a real scalar in the range [-1, 1].

Dependencies

To enable this parameter, set **Modulation type** to `FSK`.

`Modulation index` — Modulation index
`0.5` (default) | positive real scalar

Modulation index, specified as a positive real scalar.

Dependencies

To enable this parameter, set **Modulation type** to `CPFSK`.

`Demodulation type` — Coherent demodulation of input data
`on` (default) | `off`

- Select this parameter to enable coherent demodulation of the input data.
- Clear this parameter to enable noncoherent demodulation of the input data.

Dependencies

To enable this parameter, set **Modulation type** to `FSK` or `MSK`.

`Channel coding` — Channel coding type used when estimating theoretical BER
None (default) | **Convolutional** | **Block**

Channel coding type used when estimating the theoretical BER, specified as **None**, **Convolutional**, or **Block**.

`Synchronization` — Synchronization error
Perfect synchronization (default) | **Normalized timing error** | **RMS phase noise level**

Synchronization error in the demodulation process, specified as **Perfect synchronization**, **Normalized timing error**, or **RMS phase noise (rad)**.

- When you set **Synchronization** to **Perfect synchronization** no synchronization errors are encountered in the demodulation process.
- When you set **Synchronization** to **Normalized timing error**, you can set the normalized timing error as a scalar in the range [0, 0.5].
- When you set **Synchronization** to **RMS phase noise (rad)**, you can set the RMS phase noise level as a nonnegative scalar. Units are in radians

Dependencies

To enable this parameter, set **Modulation type** to PSK, **Modulation order** to 2, and **Channel coding** to **None**.

`Decision method` — Decoding decision method

`Hard` (default) | `Soft`

Decoding decision method used to decode the received data, specified as `Hard` or `Soft`.

Dependencies

To enable this parameter, set **Channel coding** to **Convolutional** or set **Channel coding** to **Block** and set **Coding type** to `General`.

`Trellis` — Convolutional code trellis

`poly2trellis(7,[171 133])` (default) | structure

Convolutional code trellis, specified as a structure variable. You can generate this structure by using the `poly2trellis` function.

Dependencies

To enable this parameter, set **Channel coding** to **Convolutional**.

`Coding type` — Block coding type

`General` (default) | `Hamming` | `Golay` | `Reed-Solomon`

Block coding type used in the BER evaluation, specified as `General`, `Hamming`, `Golay`, or `Reed-Solomon`.

Dependencies

To enable this parameter, set **Channel coding** to **Block**.

`N` — Codeword length

positive integer

Codeword length, specified as a positive integer.

Dependencies

To enable this parameter, set **Channel coding** to **Block** and set **Coding type** to `General`.

`K` — Message length

positive integer

Message length, specified as a positive integer such that **K** is less than **N**.

Dependencies

To enable this parameter, set **Channel coding** to **Block** and set **Coding type** to `General`.

d_{min} — Minimum distance of (N,K) block code

positive integer

Minimum distance of the (**N**,**K**) block code, specified as a positive integer.

Dependencies

To enable this parameter, set **Channel coding** to **Block** and set **Coding type** to `General`.

Monte Carlo

`Eb/N0 range` — Range of E_b/N_0 values
`1:0.5:5` (default) | scalar | vector

Range of E_b/N_0 values over which the BER is evaluated, specified as a scalar or vector. Units are in dB.

Example: `4:2:10` specifies evaluation of E_b/N_0 over the range [4, 10] at 2 dB increments.

`Simulation environment` — Simulation environment
MATLAB (default) | **Simulink**

Simulation environment, specified as **MATLAB** or **Simulink**.

`Function name` — Name of MATLAB function
`viterbisim` (default)

Name of the MATLAB function for the app to run for the Monte Carlo simulation.

Dependencies

To enable this parameter, set **Simulation environment** to **MATLAB**.

`Model name` — Name of Simulink model
`commgraycode` (default)

Name of the Simulink model for the app to run for the Monte Carlo simulation.

Dependencies

To enable this parameter, set **Simulation environment** to **Simulink**.

`BER variable name` — Name of variable containing BER simulation data
`grayBER` (default)

Name of the variable containing the BER simulation data. To output the BER simulation data to the MATLAB workspace, you can assign this variable name as the **Variable name** parameter value in a To Workspace block.

Tip Select the To Workspace block from the DSP System Toolbox / Sinks sublibrary. For more information, see “To Workspace Block Configuration for Communications System Simulations”.

Dependencies

To enable this parameter, set the **Simulation environment** to **Simulink**.

`Number of errors` — Number of errors to be measured before simulation stops
`100` (default) | positive integer

Number of errors to be measured before the simulation stops, specified as a positive integer. Typically, to produce an accurate BER estimate,100 measured errors are enough.

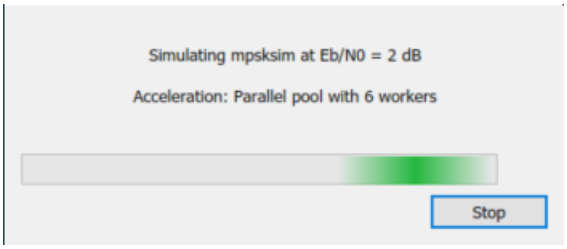
`Number of bits` — Number of bits to be processed before simulation stops
`1e8` (default) | positive integer

Number of bits to be processed before the simulation stops, specified as a positive integer. This parameter is used to prevent the simulation from running too long.

Note The Monte Carlo simulation stops when either the number of errors or number of bits threshold is reached.

Tips

- You can stop the simulation by clicking **Stop** on the Monte Carlo Simulation dialog box.



Version History

Introduced before R2006a

Semianalytic tab in the Bit Error Rate Analysis has been removed
Behavior changed in R2020b

The **Semianalytic** tab and functionality in the **Bit Error Rate Analysis** app has been removed. To generate semianalytic BER results, you can still use the `semianalytic` function.

For example, this code shows you how to use the `semianalytic` function to programmatically generate semianalytic BER results for a BPSK-modulated signal.

```
data = [0 1 1 0 0 1 1 1 1 0 1 1 0 0 0 0].';
bpskmod = comm.BPSKModulator
txSig = rectpulse(bpskmod(data),16);
rxSig = rectpulse(bpskmod(data),16); % Before receive filter
modType = 'psk';
modOrder = 2;
sps = 16; % samples per symbol
num = ones(16,1) / 16; % Filter numerator
den = 1 % Filter denominator
EbNo = 0:18; % dB
BER = semianalytic(txSig,rxSig,modType,modOrder,sps,num,den,EbNo);
semilogy(EbNo,BER)
```

Eye Diagram Analyzer

(Removed) Visualize and measure effects of impairments

Note **eyescope** has been removed. Use `eyediagram` instead.

Description

The **Eye Diagram Analyzer** app displays and measures the effects of various impairments. Using this app, you can:

- Visualize eye diagrams.
- Measure these quantities:
  - Horizontal and vertical eye openings
  - Random, deterministic, total, RMS, and peak-to-peak jitter
  - Rise and fall times
  - Signal-to-noise ratio
- Import and compare measurement results for eye diagrams of multiple signals.

Open the Eye Diagram Analyzer App

- MATLAB Toolstrip: On the **Apps** tab, under **Signal Processing and Communications**, click the app icon.
- MATLAB command prompt: Enter `eyescope`.

Programmatic Use

`eyescope` calls an empty scope.

`eyescope(obj)` calls the eye scope and displays object `obj`.

Version History

Introduced in R2008b

eyescope has been removed
Errors starting in R2020a

Eye Diagram Analyzer has been removed. Use `eyediagram` instead.

Wireless Waveform Generator

Create, impair, visualize, and export modulated waveforms

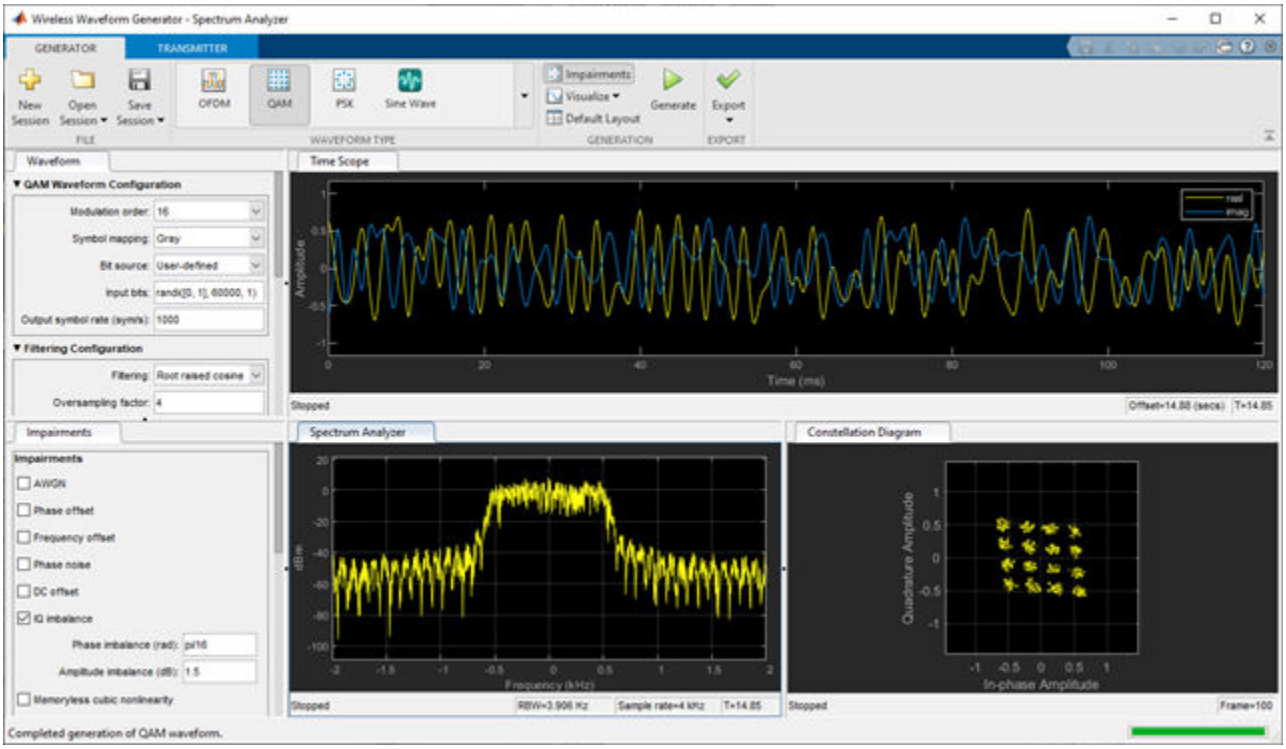
Description

The **Wireless Waveform Generator** app enables you to create, impair, visualize, and export modulated waveforms.

Using the app, you can:

- Generate custom OFDM, QAM, and PSK modulated waveforms.
- Generate sine wave test waveforms.
- Generate 5G NR uplink and downlink carrier waveforms. This feature requires “5G Toolbox”. For more information, see the **5G Waveform Generator** app reference page.
- Generate LTE modulated waveforms. This feature requires the “LTE Toolbox”. For more information, see the **LTE Waveform Generator** app reference page.
- Generate WLAN (802.11™) modulated waveforms. This feature requires the “WLAN Toolbox”. For more information, see the **WLAN Waveform Generator** app reference page.
- Generate Bluetooth modulated waveforms. This feature requires the “Bluetooth Toolbox”.
- Generate radar waveforms. This feature requires “Phased Array System Toolbox”.
- Generate ZigBee® and UWB (IEEE® 802.15.4z) modulated waveforms. This feature requires the Communications Toolbox Library for ZigBee and UWB add-on.
- Export the waveform to your workspace or to a `.mat` or a `.bb` file.
- Export waveform generation parameters to a runnable MATLAB script or a Simulink block.
  - Use the exported script to generate your waveform without the app from the command line.
  - Use the exported block as a waveform source in a Simulink model. For more information, see Waveform From Wireless Waveform Generator App.
- Visualize the waveform in constellation diagram, spectrum analyzer, OFDM grid, and time scope plots.
- Distort the waveform by adding RF impairments, such as AWGN, phase offset, frequency offset, DC offset, IQ imbalance, and memoryless cubic nonlinearity.
- Generate a waveform that you can transmit using a connected radio or lab test instrument.
  - To transmit a waveform by using an SDR, connect one of the supported SDRs (ADALM-Pluto, USRP™, USRP embedded series, and Xilinx® Zynq-based radios) to your computer and have the associated add-on installed. For more information, see “Transmit Using SDR”.
  - To transmit a waveform by using lab test instrument, connect one of the instruments supported by the `rfsiggen` function to your computer. For more information, see “Quick-Control RF Signal Generator Requirements” (Instrument Control Toolbox). This feature requires “Instrument Control Toolbox”.
  - To transmit your waveforms over the air at full radio device rates, use the Wireless Testbench™ software and connect a supported radio to your computer. For a list of radios that support full device rates, see “Supported Radio Devices” (Wireless Testbench). This feature requires “Wireless Testbench”. For an example, see “Transmit App-Generated Wireless Waveform Using Radio Transmitters” on page 1-49.

For more information, see “Create Waveforms Using Wireless Waveform Generator App”.



Open the Wireless Waveform Generator App

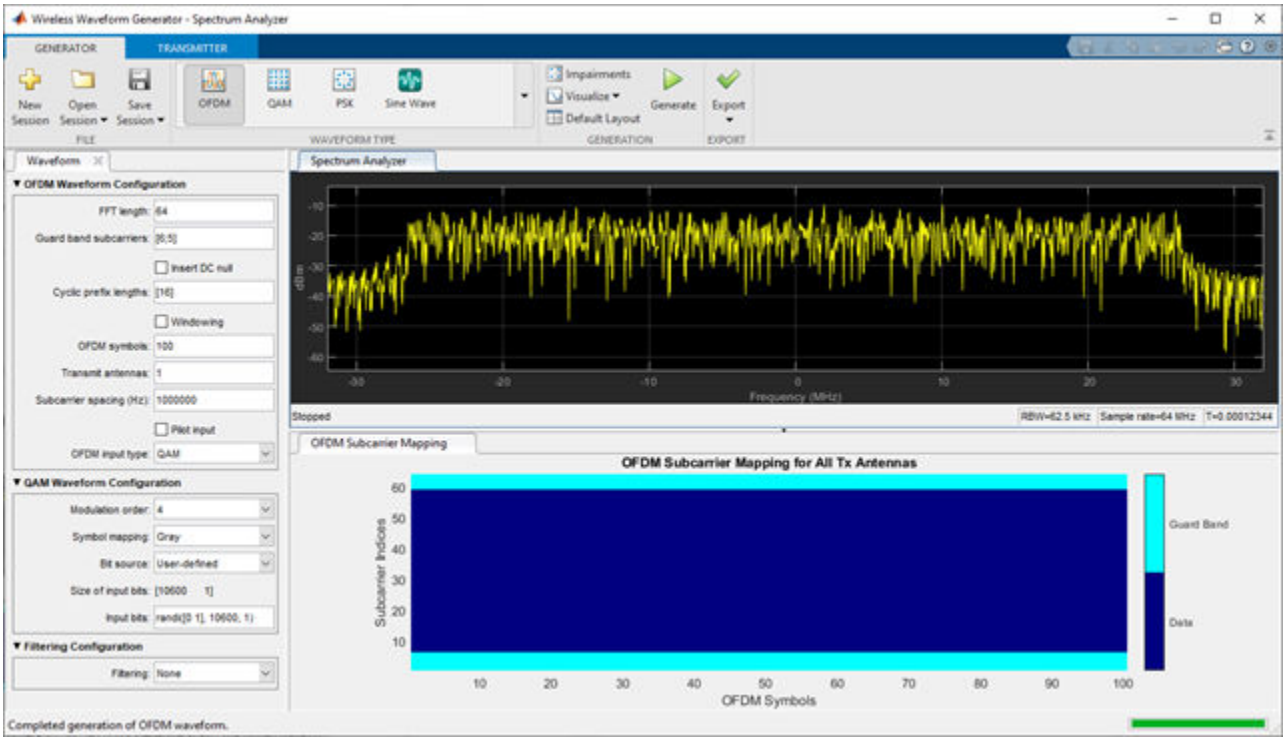
MATLAB Toolstrip: On the **Apps** tab, under **Signal Processing and Communications**, click the app icon. 
MATLAB Command Prompt: Enter `wirelessWaveformGenerator`.

Examples

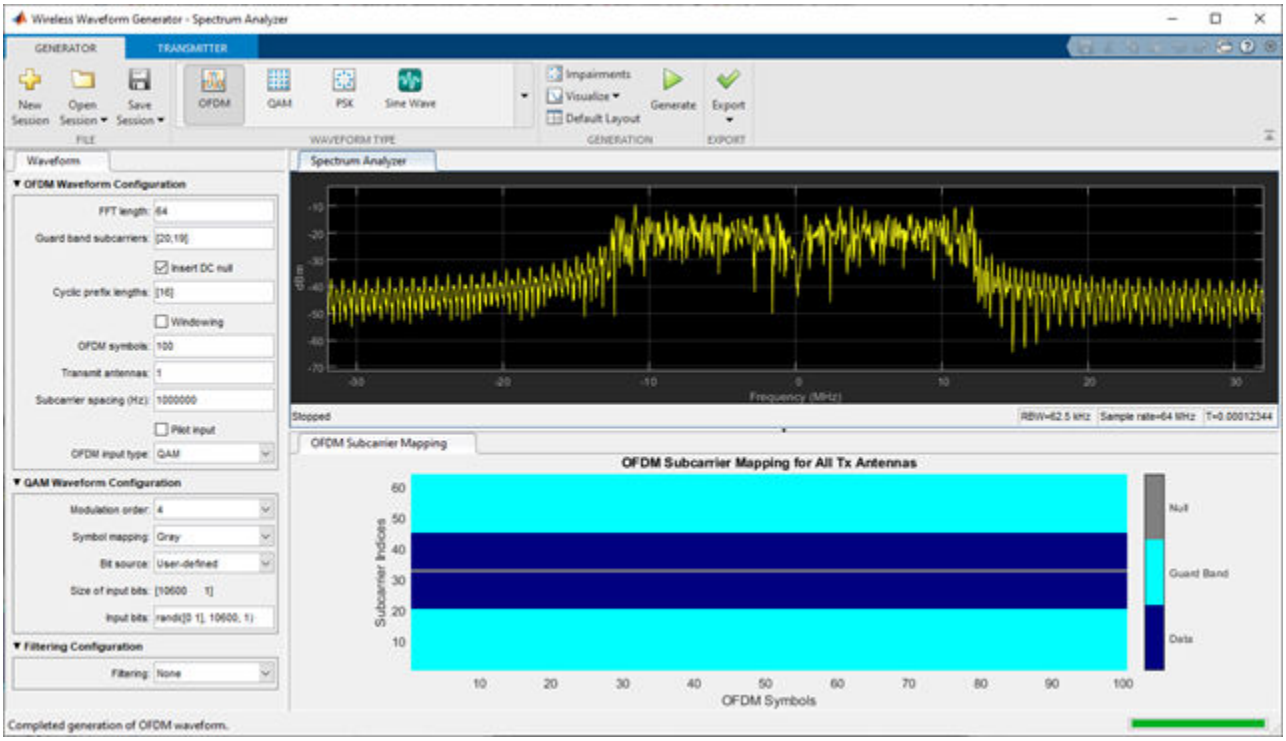
App-Based OFDM Waveform Generation

Open the **Wireless Waveform Generator** app and select 

from the **Waveform Type** tab to configure an OFDM waveform. Click **Generate** to generate the default waveform. The displayed waveform is an OFDM waveform with QPSK-modulated symbols.

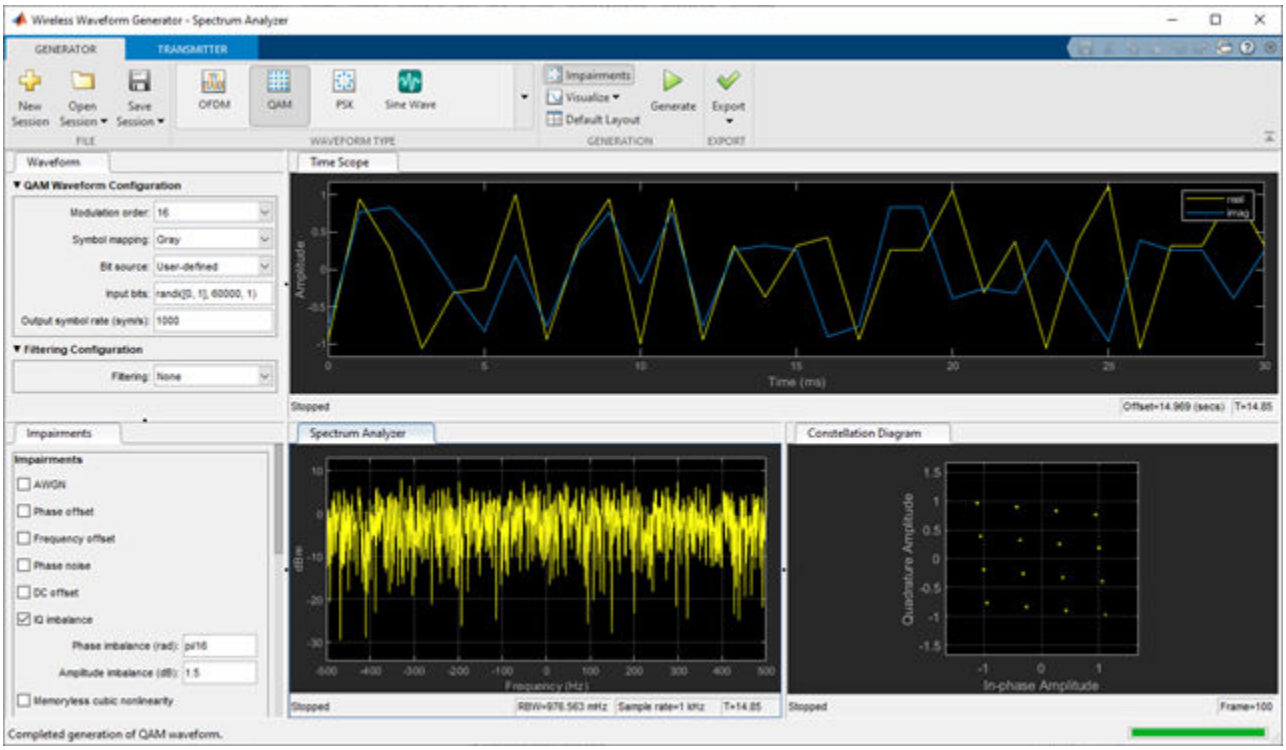


Click **Insert DC null** and increase the **Guard band subcarriers** to `[20;19]`. Click **Generate** again. The plotted waveform changes to reflect the updated configuration.

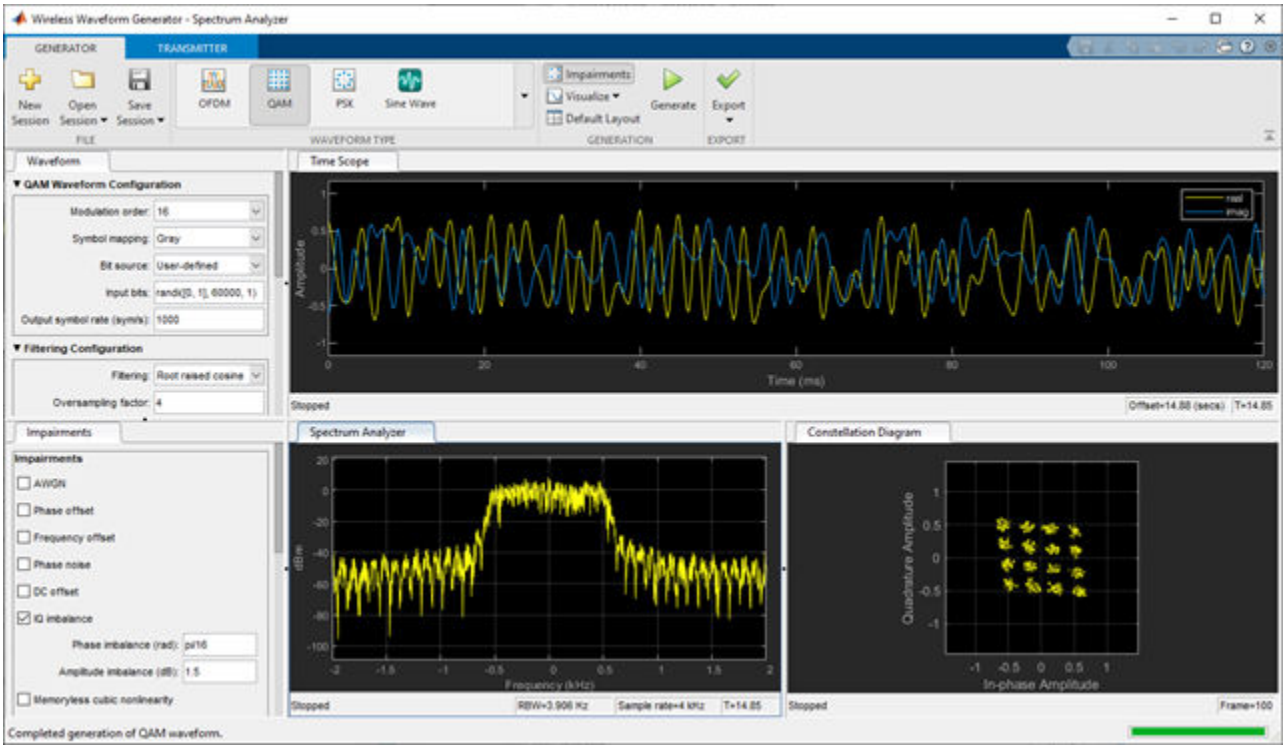


App-Based Impaired 16-QAM Waveform Generation

Open the **Wireless Waveform Generator** app and select 
from the **Waveform Type** tab to generate a QAM waveform. Update the default waveform settings to specify a phase imbalance of 11.25 degrees (`pi/16` radians) and an amplitude imbalance of 1.5 dB. Click **Generate** to generate the waveform.



Select the **Filtering** parameter and apply root raised cosine filtering. Click **Generate** again to generate a waveform using the current configuration. The plotted waveform changes to reflect the updated configuration.



App-Based 5G NR Waveform Generation

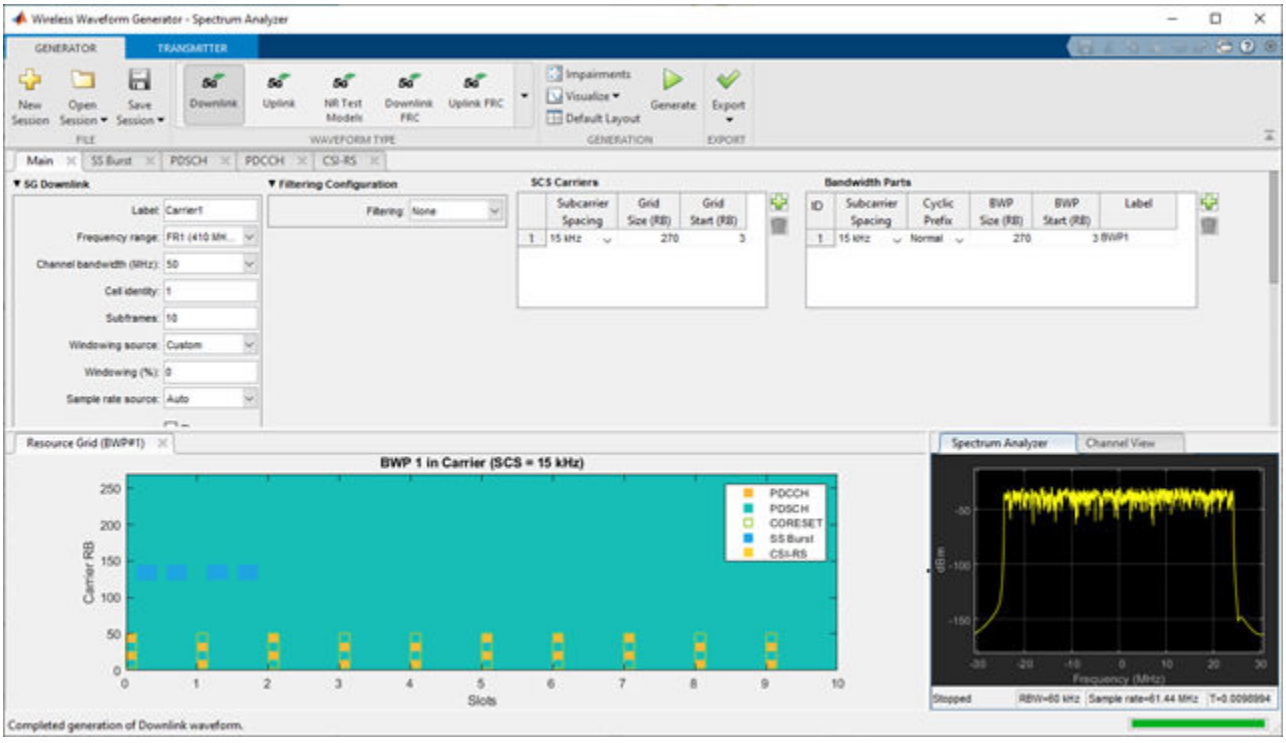
This example shows how you can generate 5G NR waveforms. For more information, see the **5G Waveform Generator** app reference page.

Open 5G Waveform Generator App

On the **Apps** tab of the MATLAB toolstrip, under **Signal Processing and Communications**, click the **5G Waveform Generator** app icon. This app opens the **Wireless Waveform Generator** app configured for 5G waveform generation. This feature requires “5G Toolbox”.

Generate 5G NR Waveform

This image shows the visualization results for 5G downlink waveform generation using default parameters.



App-Based LTE Waveform Generation

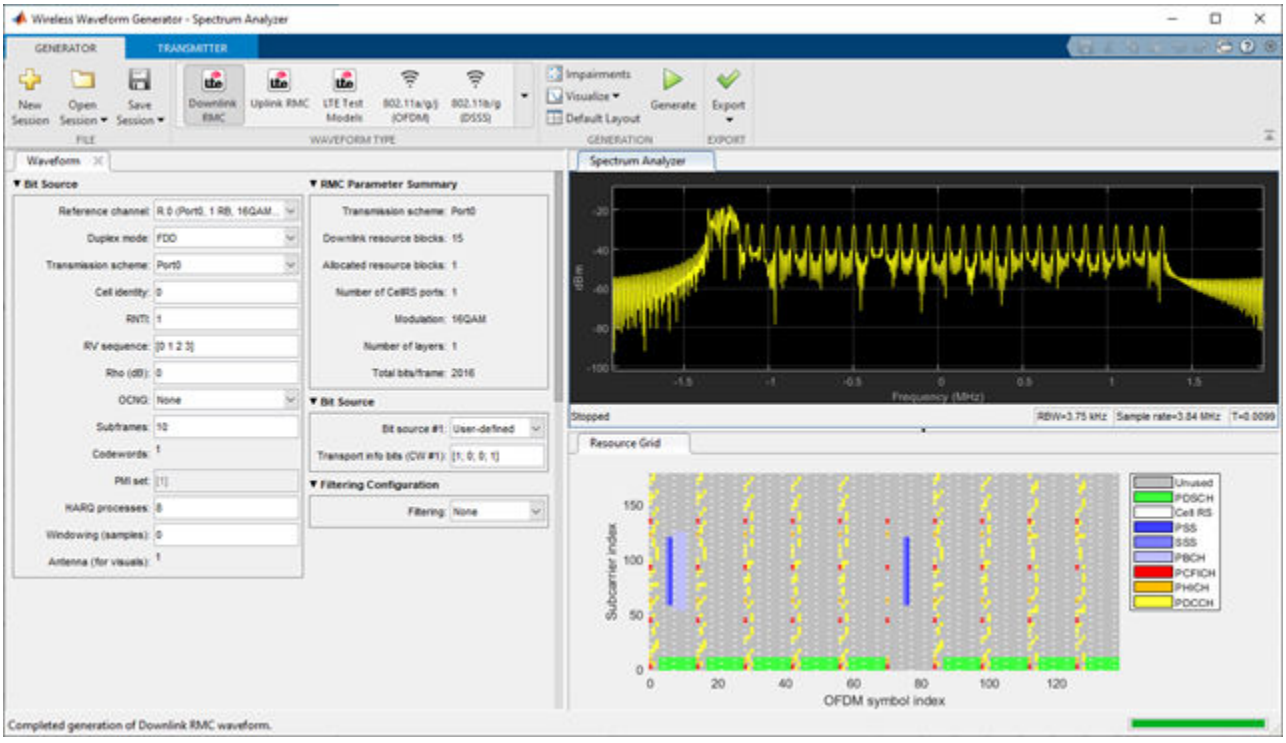
This example shows how you can generate LTE waveforms. For more information, see the **LTE Waveform Generator** app reference page.

Open LTE Waveform Generator App

On the **Apps** tab of the MATLAB toolstrip, under **Signal Processing and Communications**, click the **LTE Waveform Generator** app icon. This app opens the **Wireless Waveform Generator** app configured for LTE waveform generation. This feature requires the “LTE Toolbox”.

Generate LTE Waveform

This image shows the visualization results for LTE downlink waveform generation using default parameters.

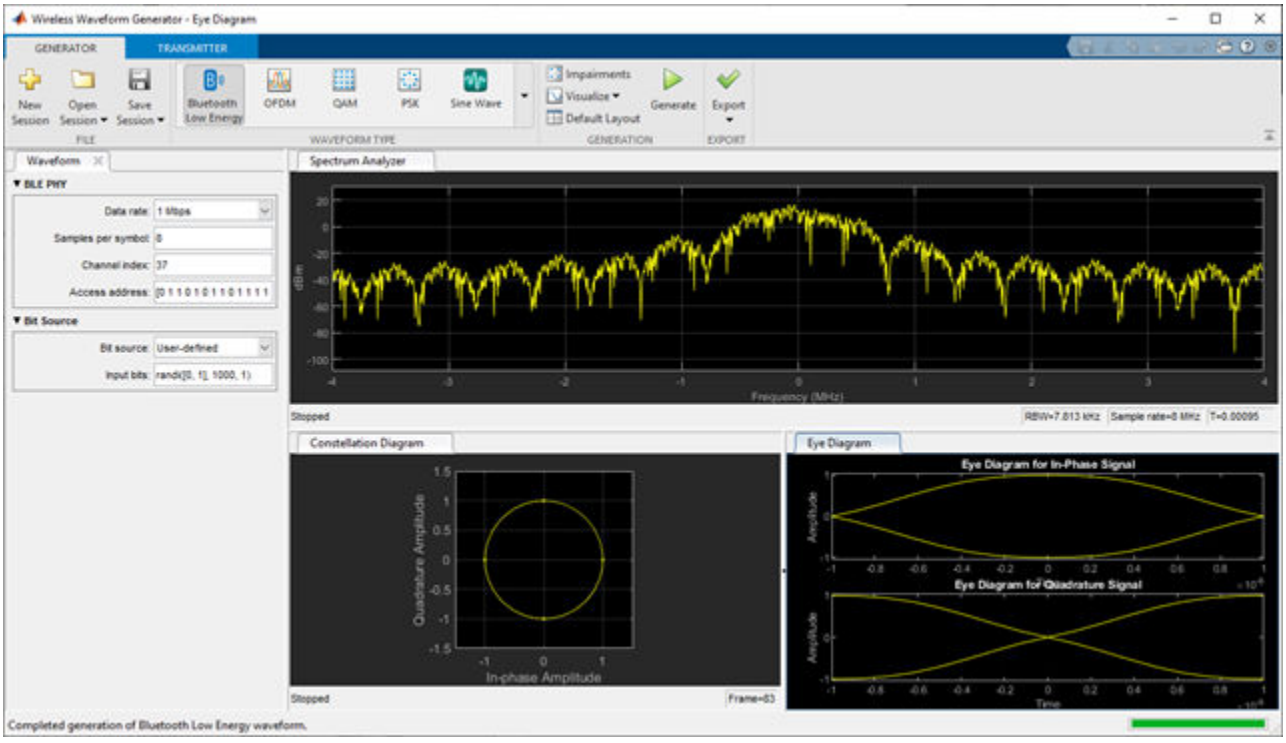


App-Based Bluetooth LE Waveform Generation

This example shows how you can generate Bluetooth® waveforms. This app opens the **Wireless Waveform Generator** app configured for Bluetooth waveform generation. This feature requires the “Bluetooth Toolbox”.

On the **Apps** tab of the MATLAB toolstrip, under **Signal Processing and Communications**, click the **Wireless Waveform Generator** app icon. This app opens the **Wireless Waveform Generator** app. In the **Waveform Type** section, click `Bluetooth Low Energy`. Click **Generate** to generate the Bluetooth low energy (LE) waveform.

This image shows the visualization results for Bluetooth LE downlink waveform generation using default parameters.



App-Based WLAN Waveform Generation

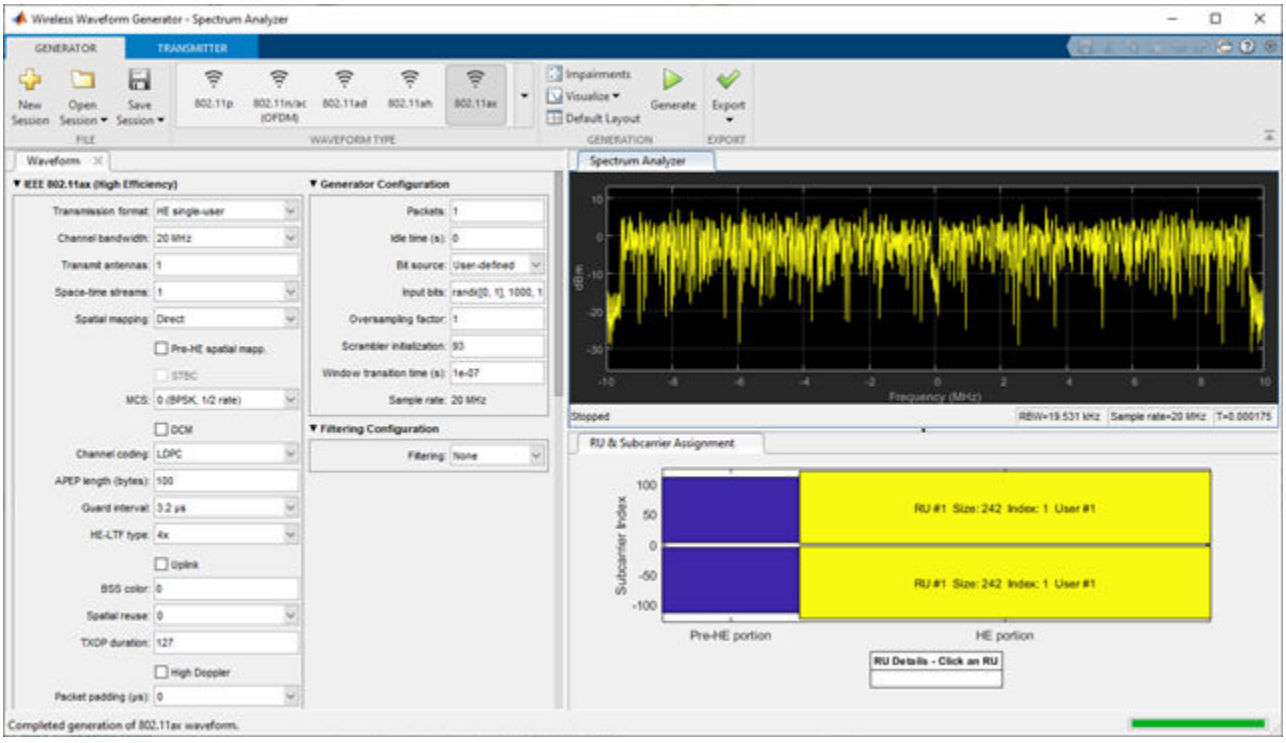
This example shows how you can generate WLAN waveforms. For more information, see the **WLAN Waveform Generator** app reference page.

Open WLAN Waveform Generator App

On the **Apps** tab of the MATLAB toolstrip, under **Signal Processing and Communications**, click the **WLAN Waveform Generator** app icon. This app opens the **Wireless Waveform Generator** app configured for WLAN waveform generation. This feature requires the “WLAN Toolbox”.

Generate WLAN Waveform

This image shows the visualization results for WLAN downlink waveform generation using default parameters.

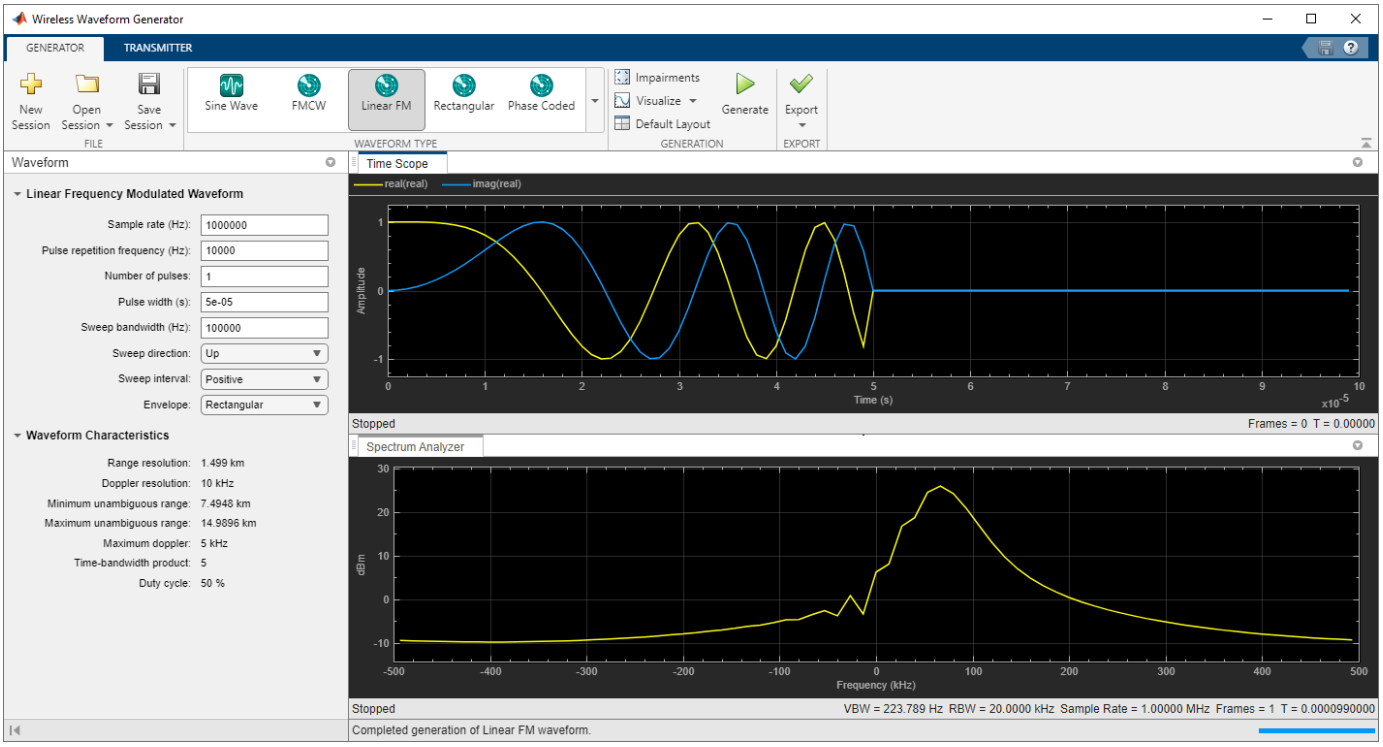


App-Based Linear FM Radar Waveform Generation

This example shows how you can generate radar waveforms found in the Phased Array System Toolbox™. For descriptions of radar waveforms, see the **Pulse Waveform Analyzer** app reference page.

To start, open the **Wireless Waveform Generator** app and select 

from the **Waveform Type** tab. Use the default waveform settings and click **Generate** to generate a single waveform.

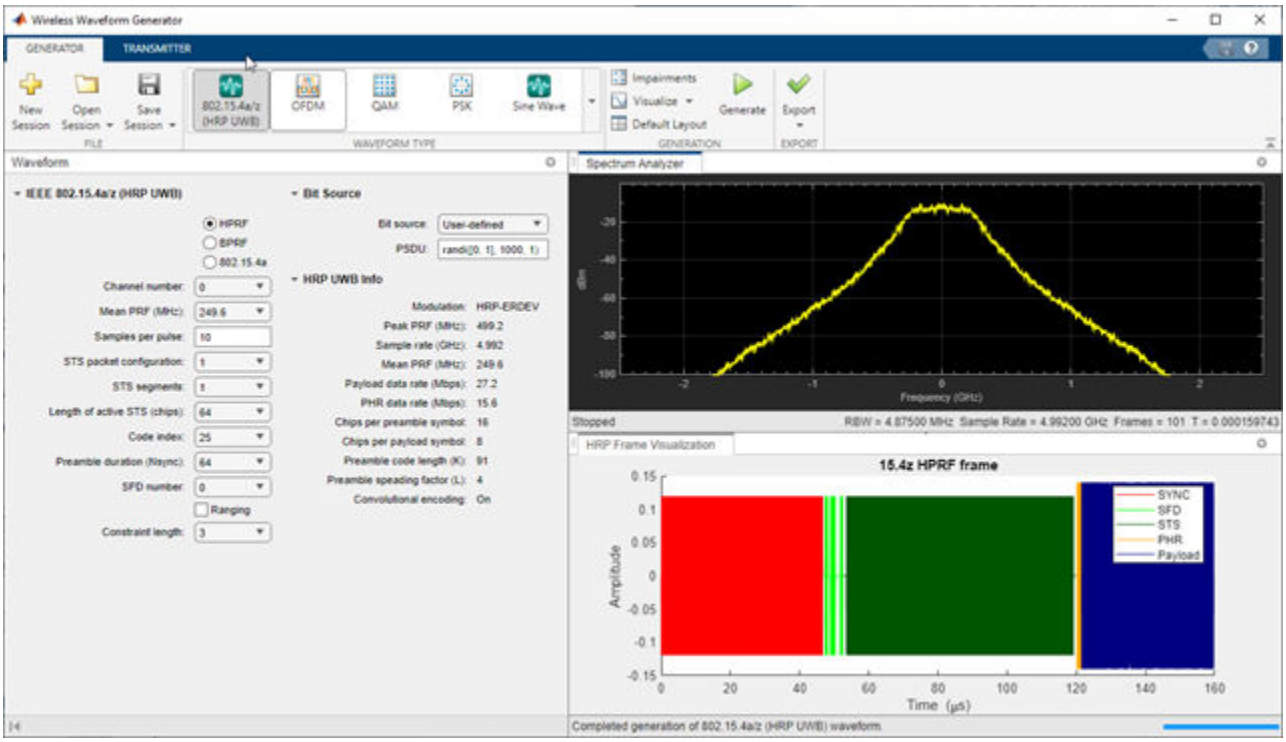


The app shows one linear FM pulse and the spectrum of the pulse.

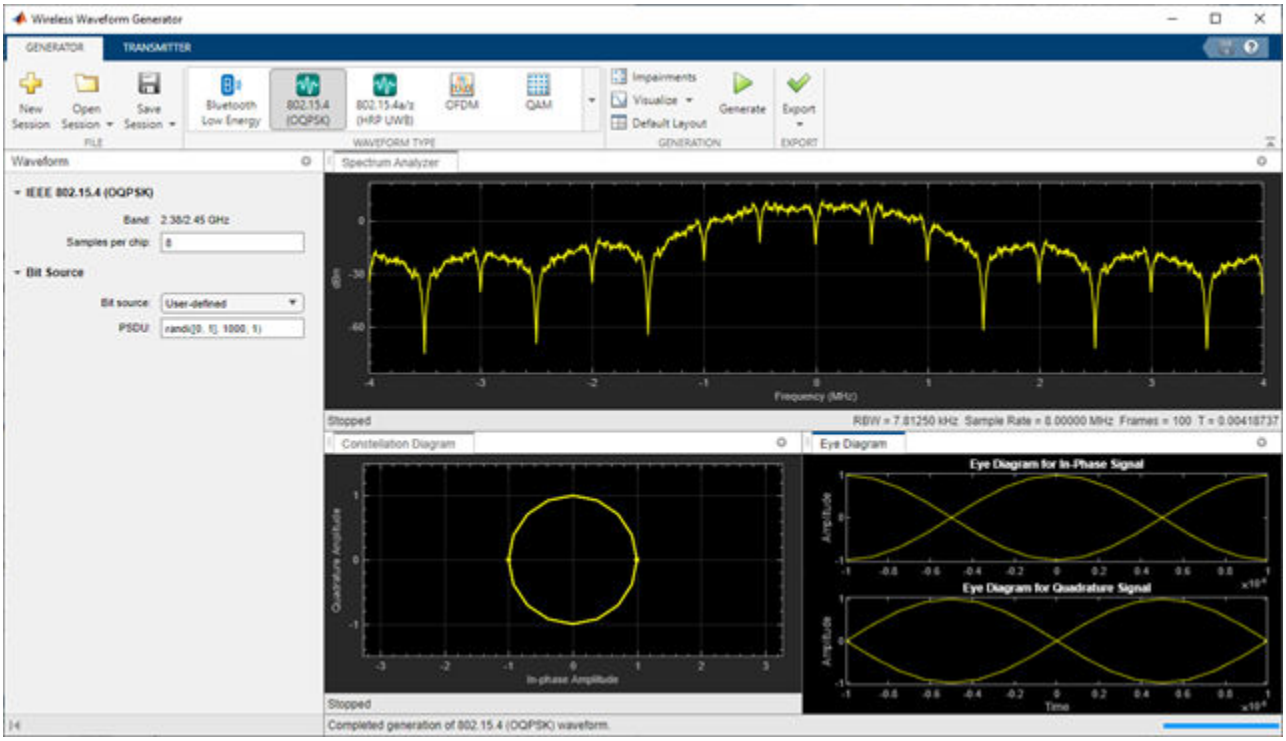
Next change the number of pulses in the waveform by setting the **Number of pulses** to 5 and then select **Generate** again. There are now five pulses displayed but the spectrum stays the nearly same.

App-Based 802.15.4 Waveform Generation

Open the **Wireless Waveform Generator** app and select 
from the **Waveform Type** tab to generate a UWB waveform. Use the default waveform settings. Click **Generate** to generate the waveform.



Select 
from the **Waveform Type** tab to generate an 802.15.4 OQPSK waveform, as used for ZigBee. Use the default waveform settings. Click **Generate** to generate the waveform.



Generate Wireless Waveform in Simulink Using App-Generated Block

This example shows how to configure and use the block that is generated using the **Export to Simulink** capability that is available in the **Wireless Waveform Generator** app.

Introduction

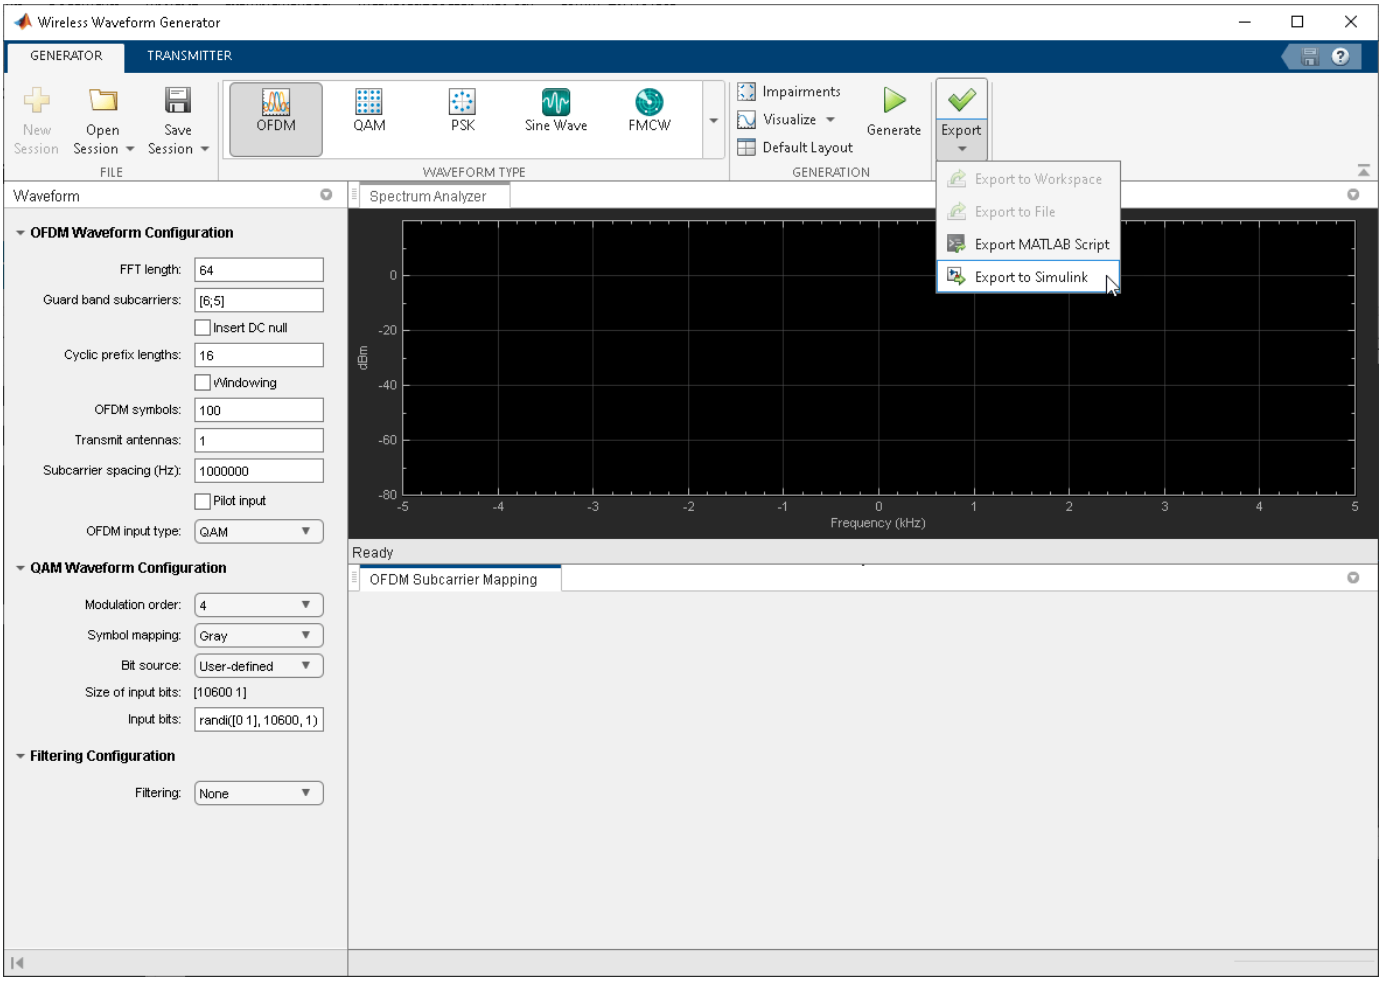
The **Wireless Waveform Generator** app is an interactive tool for creating, impairing, visualizing, and exporting waveforms. You can export the waveform to your workspace or to a `.mat` or `.bb` file. You can also export the waveform generation parameters to a runnable MATLAB® script or a Simulink® block. You can use the exported Simulink block to reproduce your waveform in Simulink. This example shows how to use the **Export to Simulink** capability of the app and how to configure the exported block to generate waveforms in Simulink.

Although this example focuses on exporting an OFDM waveform, the same process applies for all of the supported waveform types.

Export Wireless Waveform Configuration to Simulink

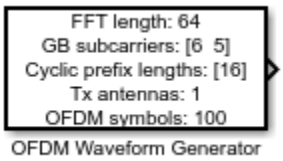
Open the **Wireless Waveform Generator** app by clicking the app icon on the **Apps** tab, under **Signal Processing and Communications**. Alternatively, enter `wirelessWaveformGenerator` at the MATLAB command prompt.

In the **Waveform Type** section, select an OFDM waveform by clicking **OFDM**. In the left-most pane of the app, adjust any configuration parameters for the selected waveform. Then export the configuration by clicking **Export** in the app toolstrip and selecting **Export to Simulink**.



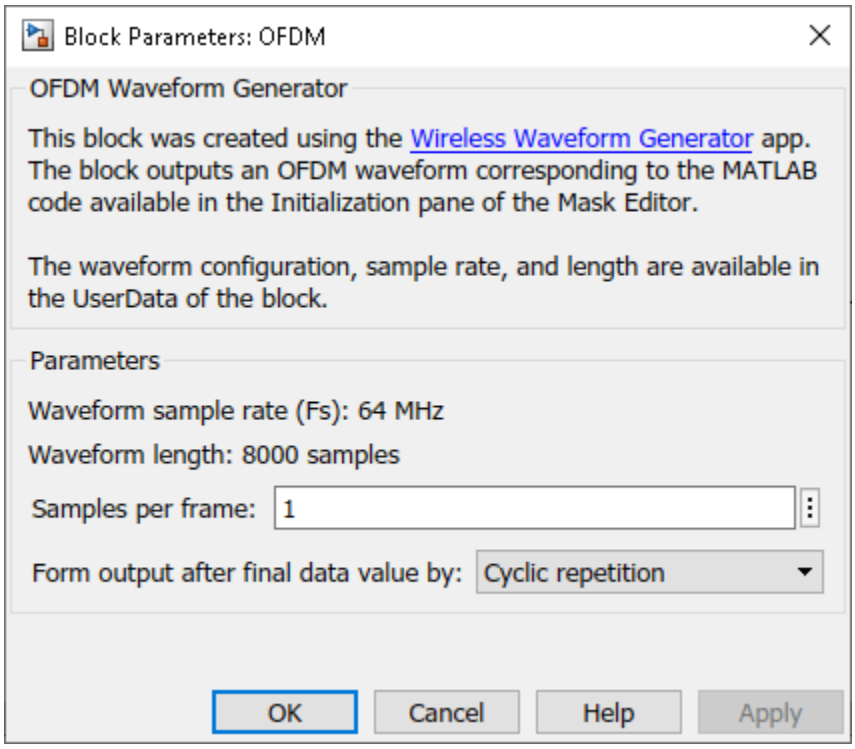
The **Export to Simulink** option creates a Simulink block, which outputs the selected waveform when you run the Simulink model. The block is exported to a new model if no open models exist.

```
modelName = 'WWGExport2SimulinkBlock';
open_system(modelName);
```



The **Form output after final data value by** block parameter specifies the output after all of the specified signal samples are generated. The value options for this parameter are `Cyclic repetition` and `Setting to zero`. The `Cyclic repetition` option repeats the signal from the beginning after it reaches the last sample in the signal. The `Setting to zero` option generates zero-valued outputs for the duration of the simulation after generating the last frame of the signal. The **Waveform sample rate (Fs)** and **Waveform length** block parameters are derived from the waveform configuration that is available in the **Code** tab of the Mask Editor dialog box. For further

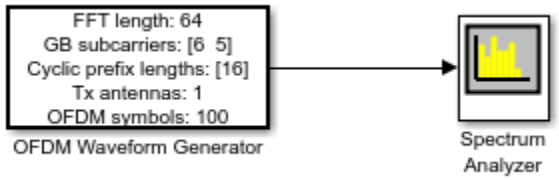
information about the block parameters, see Waveform From Wireless Waveform Generator App. This figure shows the parameters of the exported block.



```
close_system(modelName);
```

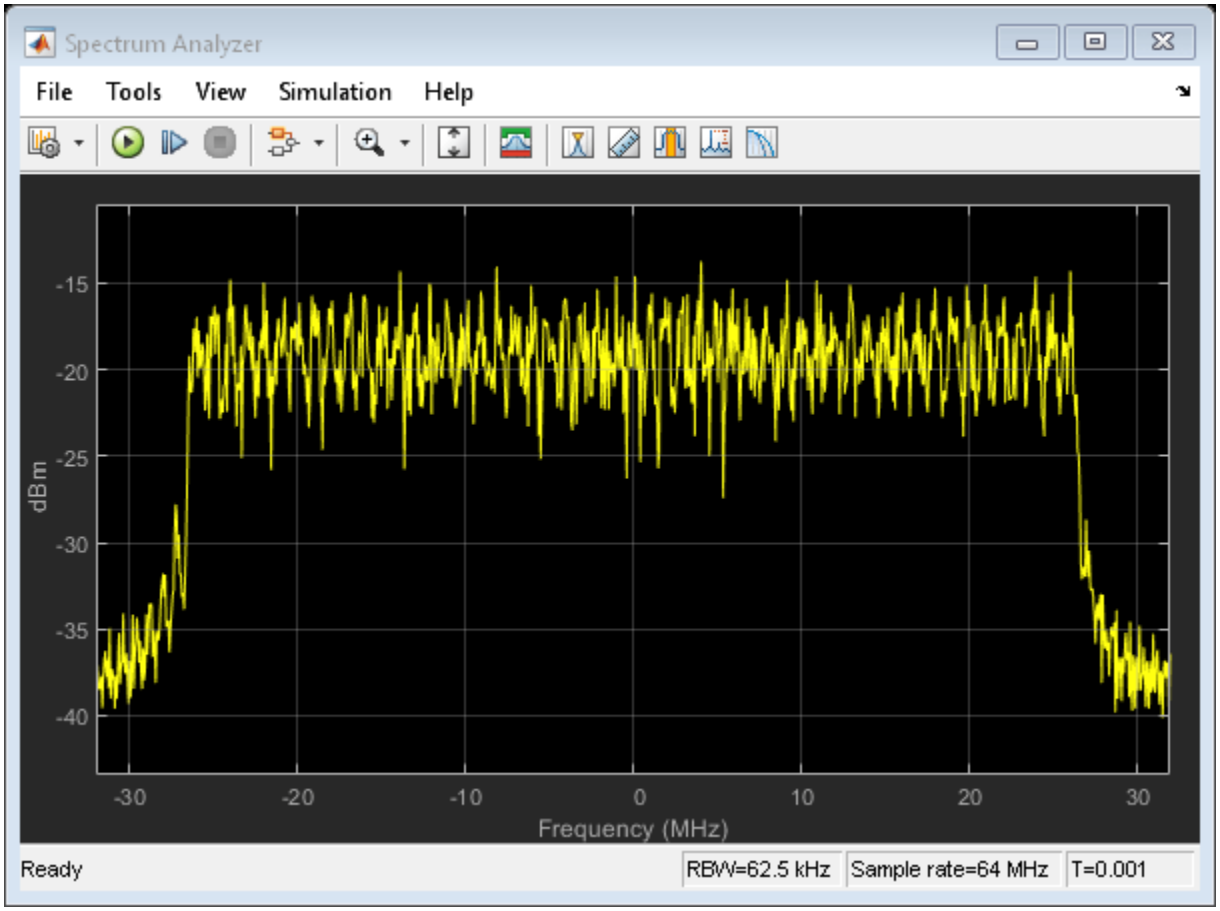
Connect a Spectrum Analyzer block to the exported block.

```
modelName = 'WWGExport2SimulinkModel';
open_system(modelName);
```



Simulate the model to visualize the waveform using the current configuration.

```
sim(modelName);
```



The Spectrum Analyzer block inherits the **Waveform sample rate (Fs)** parameter, which is 64 MHz.

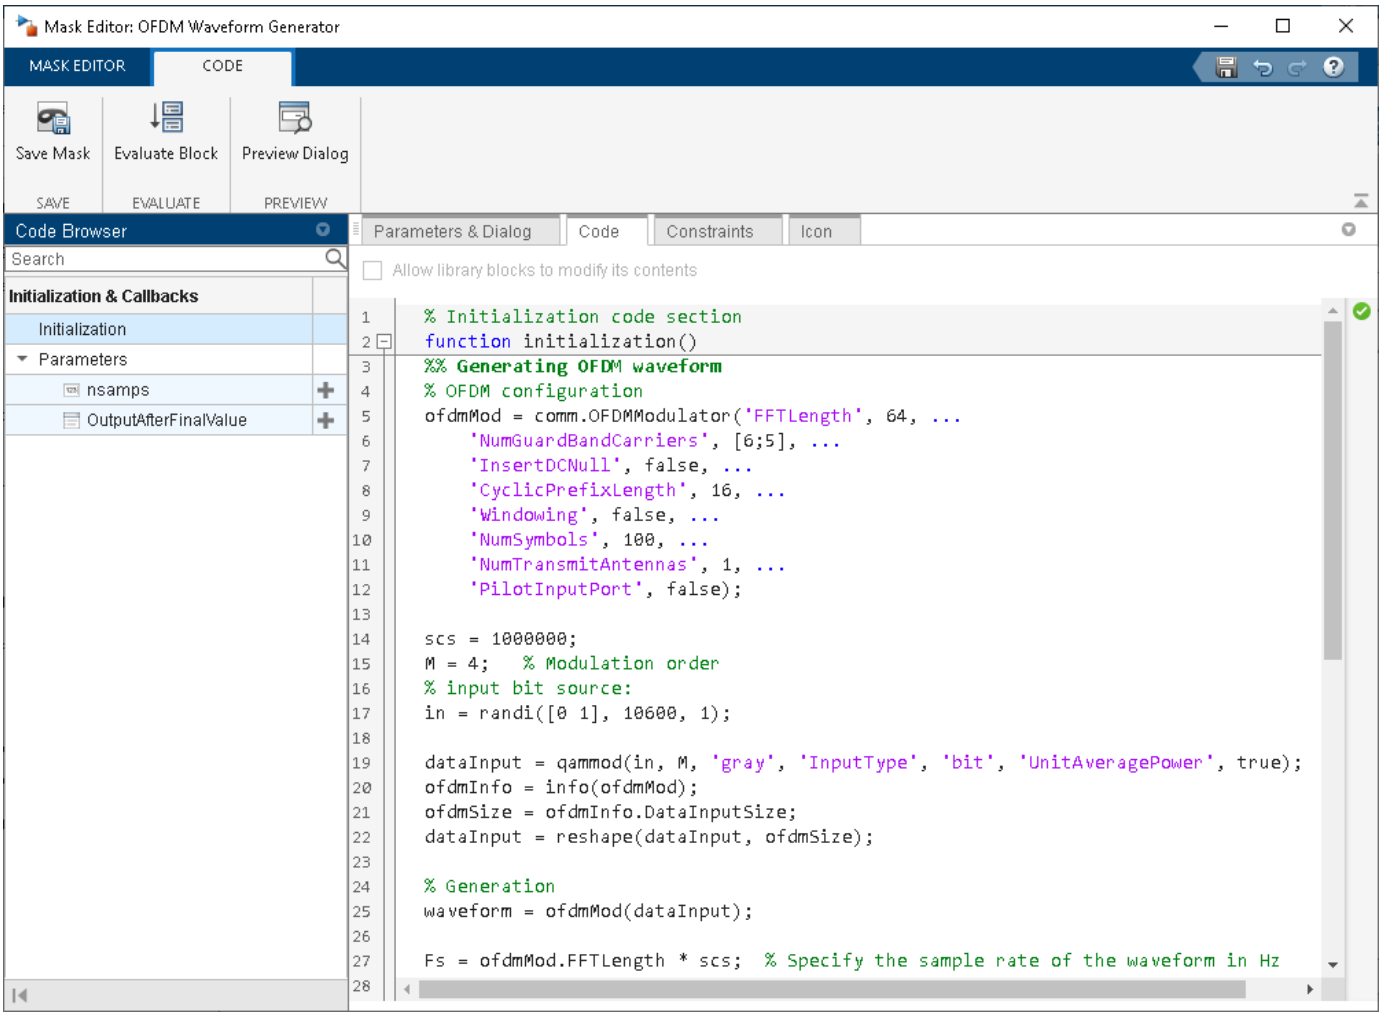
```
close_system(modelName);
```

Modify Wireless Waveform Configuration

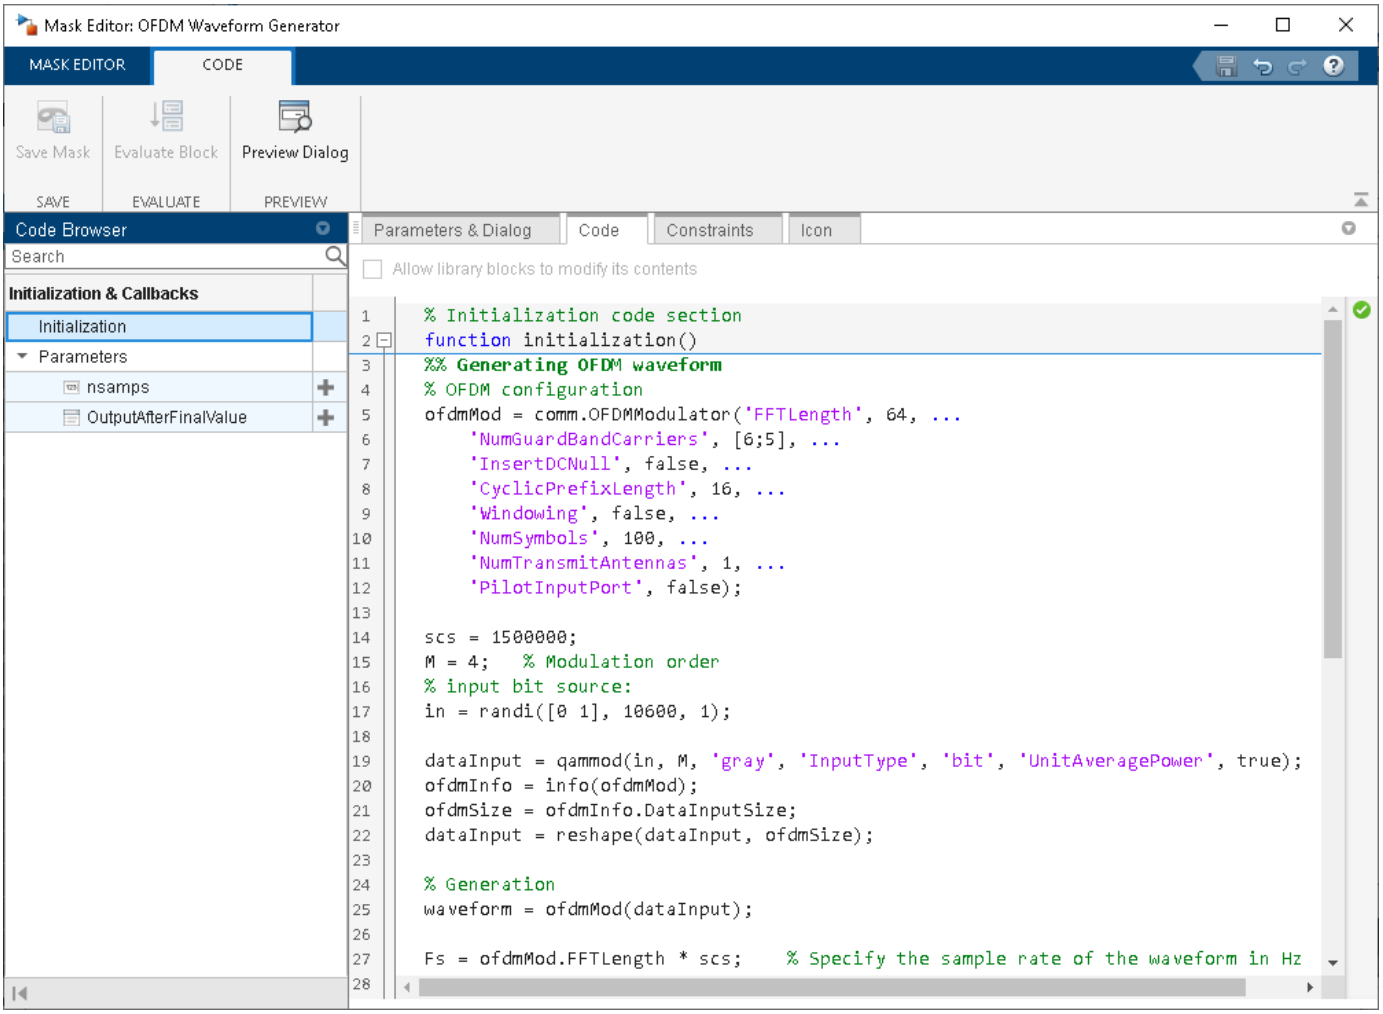
When you run the Simulink model, the exported block outputs the waveform generated in the **Code** tab of the Mask Editor dialog box for the block. The MATLAB code that initializes the waveform in this tab corresponds to the configuration that you selected in the **Wireless Waveform Generator** app before exporting the block. To modify the configuration of the waveform, choose one of these options:

- Open the **Wireless Waveform Generator** app, select the configuration of your choice, and export a new block. This option provides interaction with an app interface instead of MATLAB code, parameter range validation during the parameterization process, and visualization of the waveform before running the Simulink model.
- Update the configuration parameters that are available in the **Code** tab of the Mask Editor dialog box of the exported block. This option requires modifying the MATLAB code available in this tab so that the parameter range validation occurs only when you apply the changes. This option does not provide visualization of the waveform before running the Simulink model. Modifying the waveform parameters using this option is not recommended if you are not familiar with the MATLAB code that generates the selected waveform.

You can update the configuration in the **Code** tab of the Mask Editor. To open the Mask Editor, click the exported block and press **Ctrl+M**.

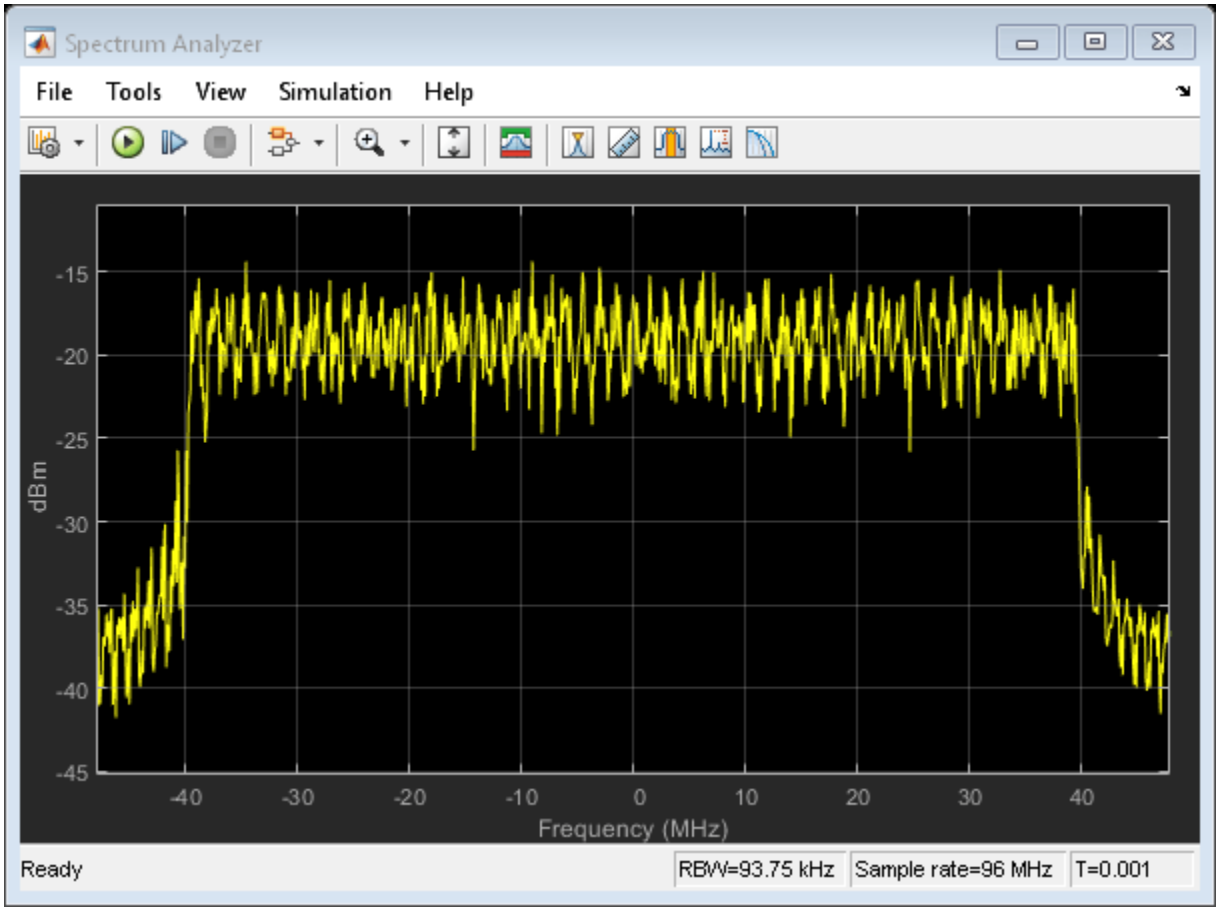


Use the MATLAB code that is available in the **Code** tab to update the parameters of your choice. For example, set the subcarrier spacing, `scs`, to 1,500,000 Hz.



Click **OK** to apply the changes and close the Mask Editor dialog box. Simulate the model to visualize the updated waveform.

```
modelName = 'WWGExport2SimulinkModelSCSModified';
sim(modelName);
```



The Spectrum Analyzer block now shows a sample rate of 96 MHz, which is 1.5 times the previous sample rate, as expected.

Share Wireless Waveform Configuration with Other Blocks in the Model

To access read-only block parameters and waveform configuration parameters, use the `UserData` common block property, which is a structure with these fields.

- `WaveformConfig`: Waveform configuration
- `WaveformLength`: Waveform length
- `Fs`: Waveform sample rate

You can access the user data of the exported block by using the `get_param` function.

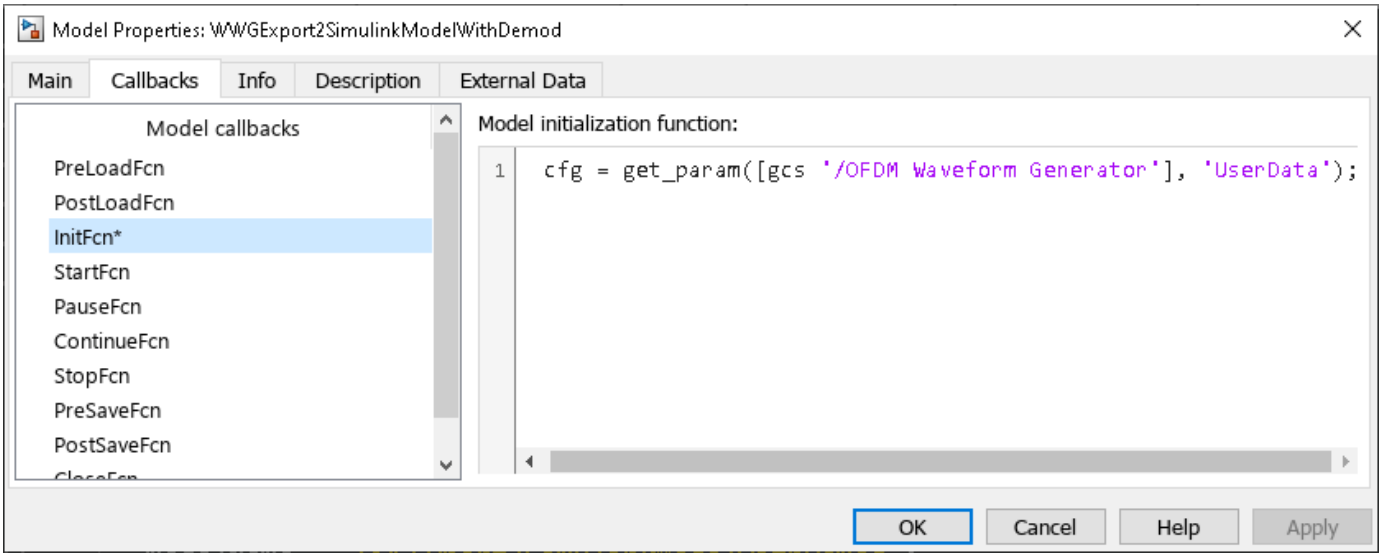
```
get_param([gcs '/OFDM Waveform Generator'],'UserData')
```

```
ans =

  struct with fields:

    WaveformConfig: [1x1 comm.OFDMModulator]
    WaveformLength: 8000
                Fs: 96000000
```

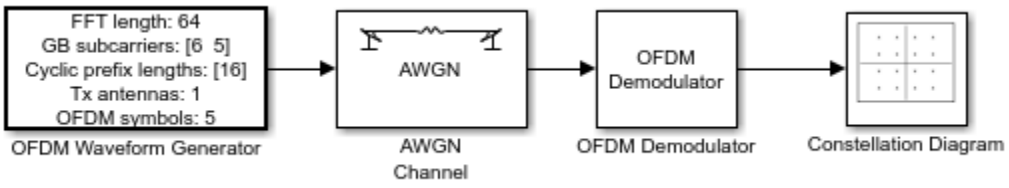
Store the structure available in the user data in a base workspace variable by using the `InitFcn` in the callback. The `InitFcn` callback is executed during a model update and simulation. To use this callback, click the **MODELING** tab, then click the **Model Settings** dropdown, and click the **Model Properties** option. In the **Callbacks** pane, select the `InitFcn` callback. Assign the user data to a new base workspace variable (for example, `cfg`).



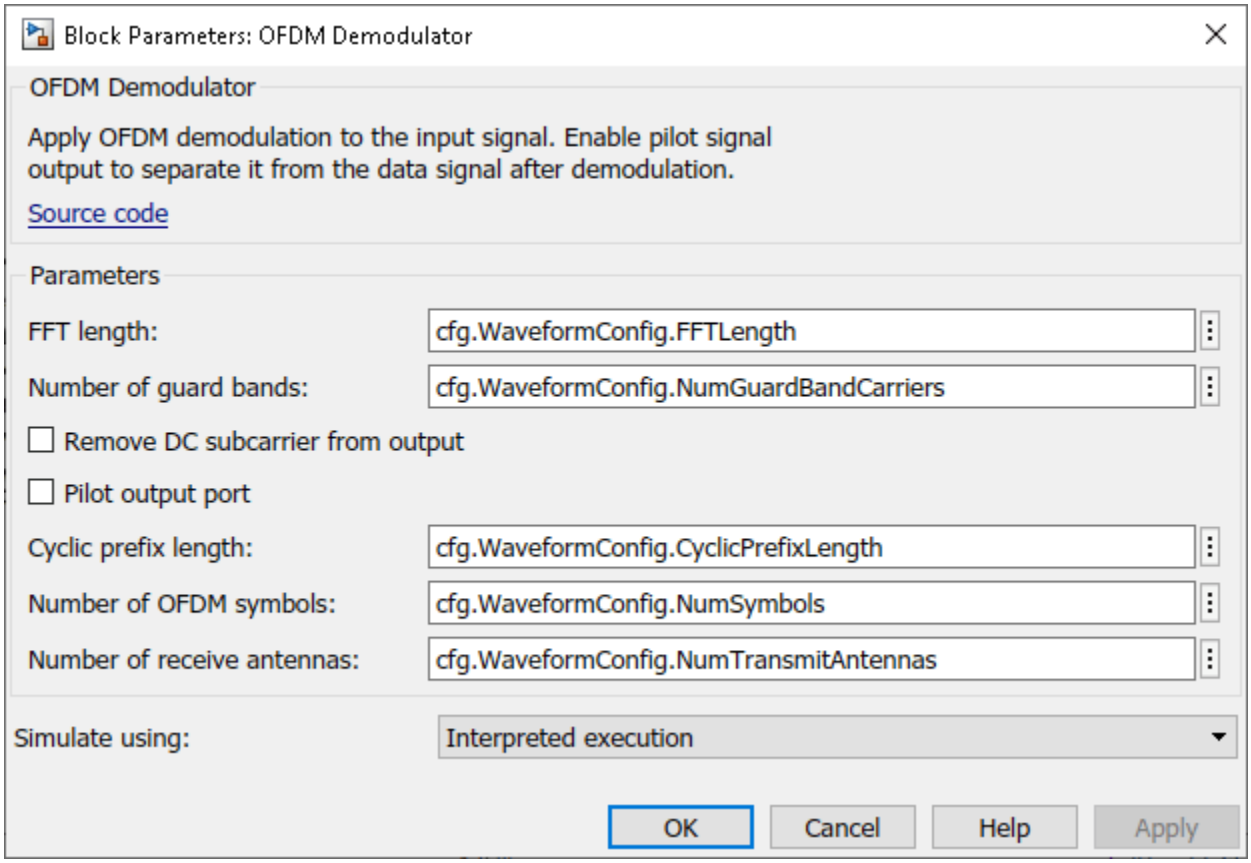
The parameters that are available in the user data of the exported block are updated every time you apply configuration changes in the **Code** tab.

To demodulate the OFDM waveform, add an OFDM Demodulator block to the model. Connect an AWGN Channel block between the OFDM Waveform Generator and OFDM Demodulator blocks to add white Gaussian noise to the input signal. Also add a Constellation Diagram block to plot the demodulated symbols.

```
modelName = 'WWGExport2SimulinkModelWithDemod';
open_system(modelName);
```

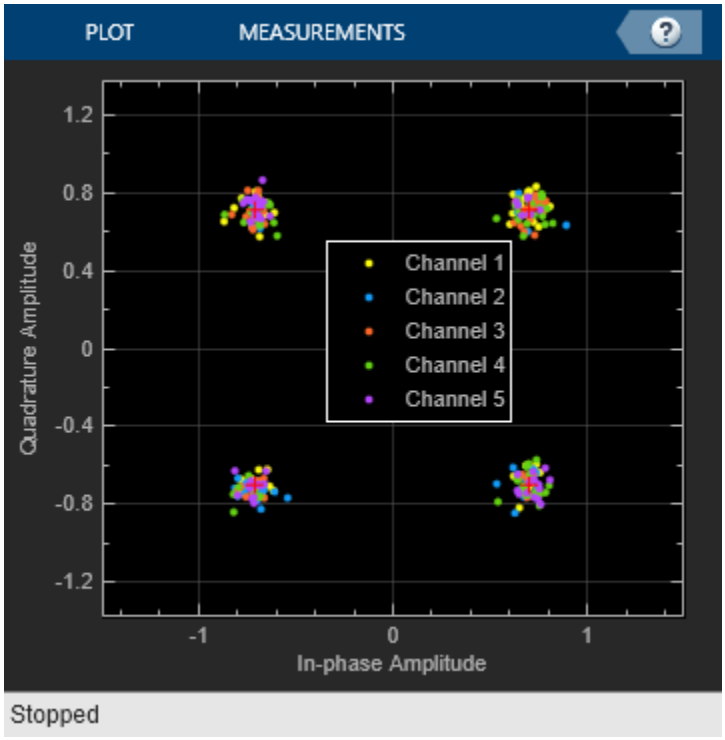


The parameters that are required to configure the OFDM Demodulator block must match the parameters that are used to configure the exported block, (otherwise, demodulation fails). To access the configuration parameters of the exported block, use the variable `cfg`. This figure shows the parameters of the OFDM Demodulator block.



Because the OFDM Demodulator block requires the entire OFDM waveform for demodulation, set the **Samples per frame** parameter in the exported block to `cfg.WaveformLength`. Simulate the model.

```
sim(modelName);
```

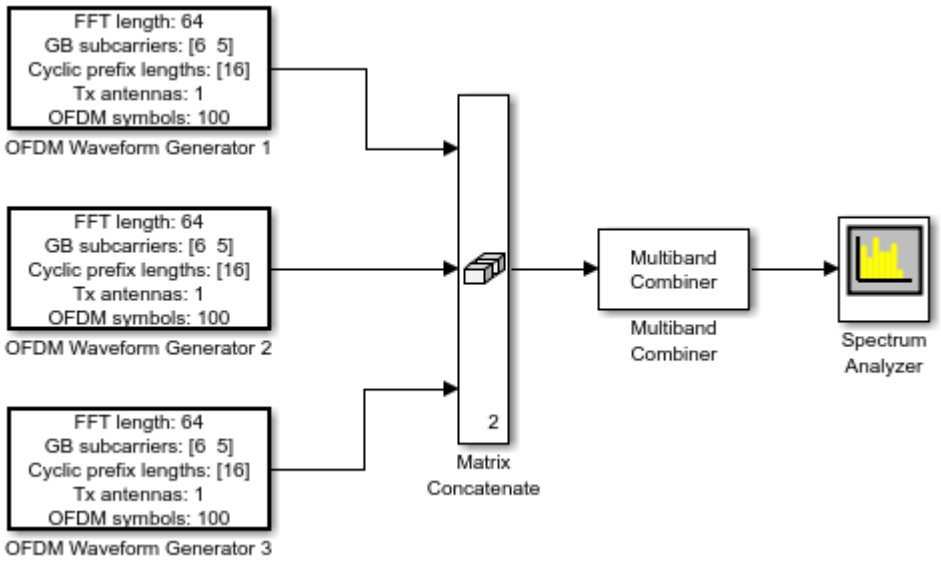


After demodulating the OFDM waveform by using the OFDM Demodulator block, the Constellation Diagram block displays the resulting QAM symbols.

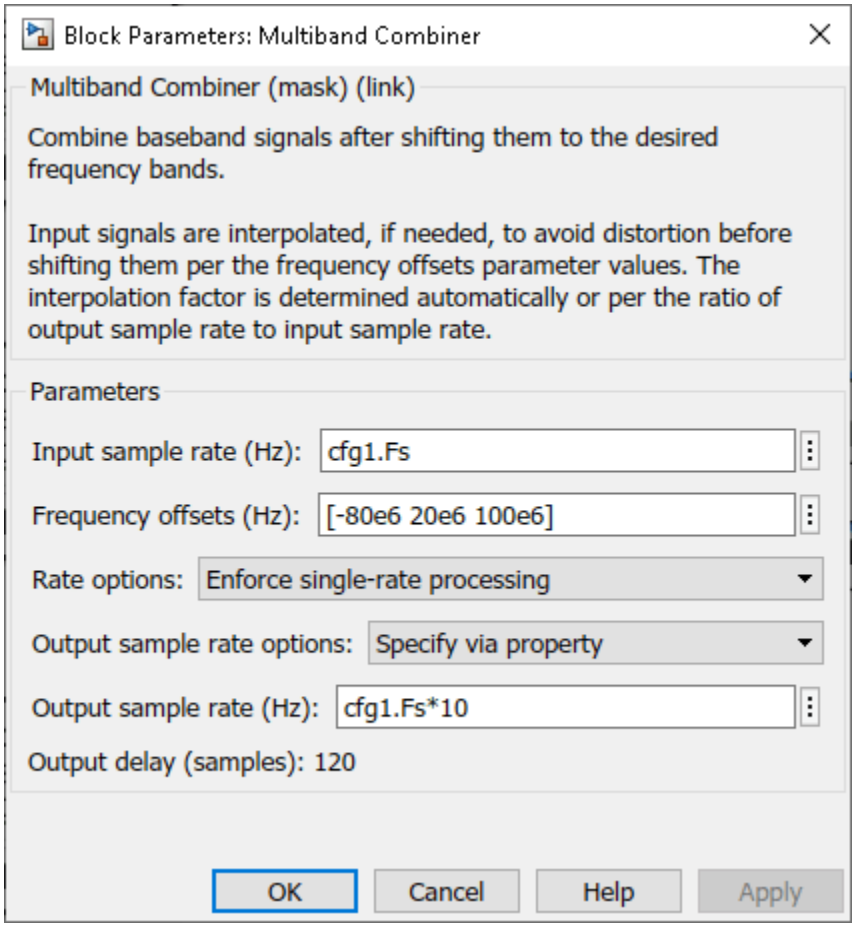
Generate Multicarrier Waveforms

For multicarrier generation, the sampling rates for all of the waveforms must be the same. To shift the waveforms to a carrier offset and aggregate them, you can use the Multiband Combiner block.

```
modelName = 'WWGExport2SimulinkMulticarrier';
open_system(modelName);
```

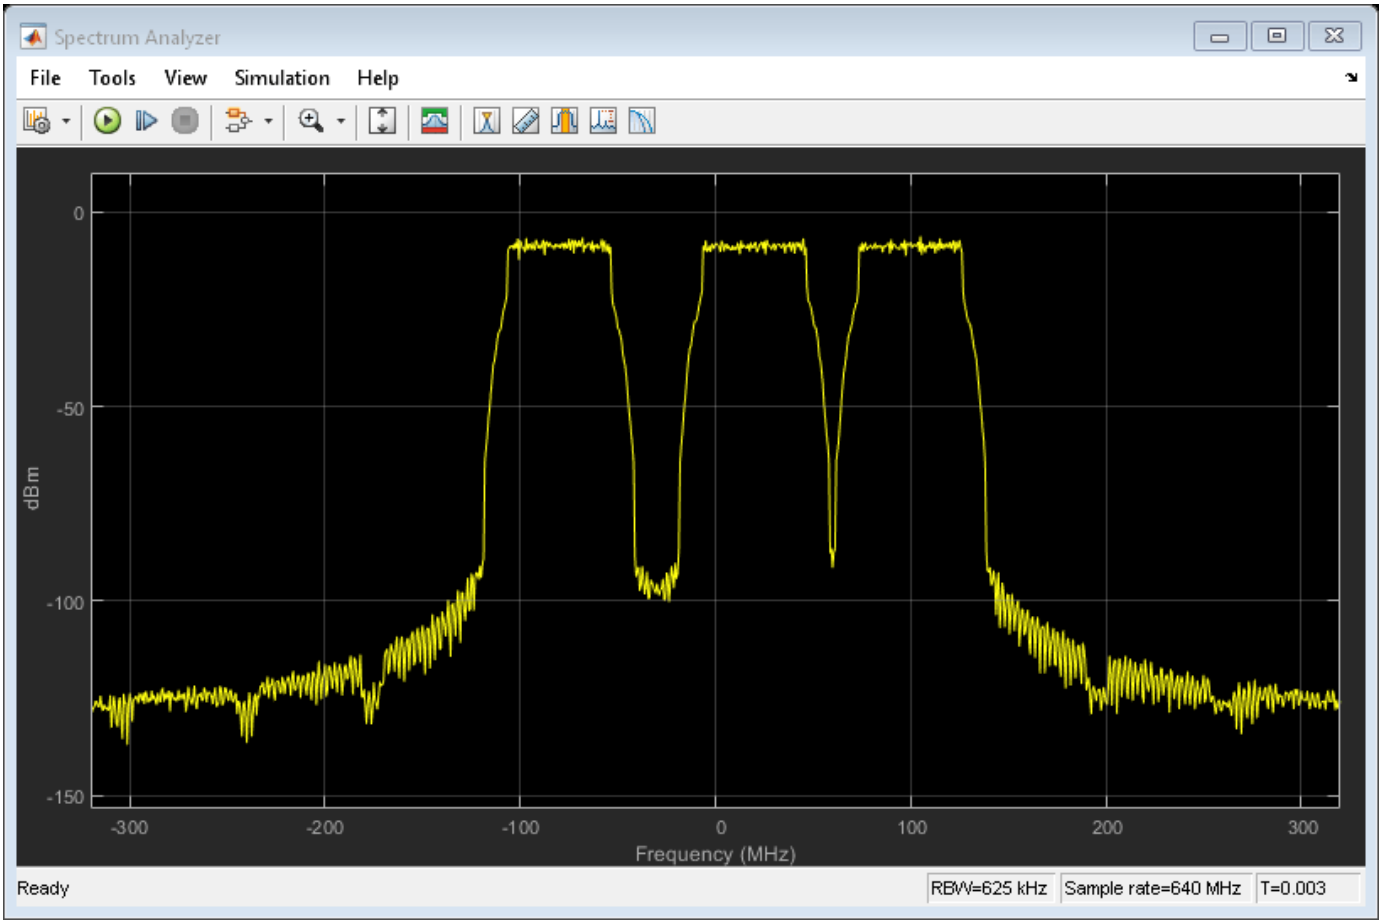


To shift the waveforms in frequency, you might have to increase the sampling rates. The Multiband Combiner block provides the option to oversample the input waveforms before shifting and combining them. This figure shows the parameters of the Multiband Combiner block.



Simulate the model to visualize the waveforms that are centered at -80, 20, and 100 MHz.

```
sim(modelName);
```



Transmit App-Generated Wireless Waveform Using Radio Transmitters

This example shows how to use the NI™ USRP™ N310, USRP N320, USRP N321, and USRP X310 radio transmitters available in the **Wireless Waveform Generator** app to transmit an app-generated waveform over the air (requires Wireless Testbench™). These radio transmitters enable you to transmit up to 2 GB of contiguous data over the air at full radio device rate.

Introduction

The Wireless Waveform Generator app is an interactive tool for creating, impairing, visualizing, and transmitting waveforms. Using the USRP N310, USRP N320, USRP N321, and USRP X310 radio transmitters available in the app, you can transmit your generated waveform repeatedly over the air. You can also export the waveform generation and transmission parameters to a runnable MATLAB® script. This example shows how to configure these radio transmitters.

Although this example shows how to transmit an OFDM waveform, the same process applies for all waveform types that you can generate with the app.

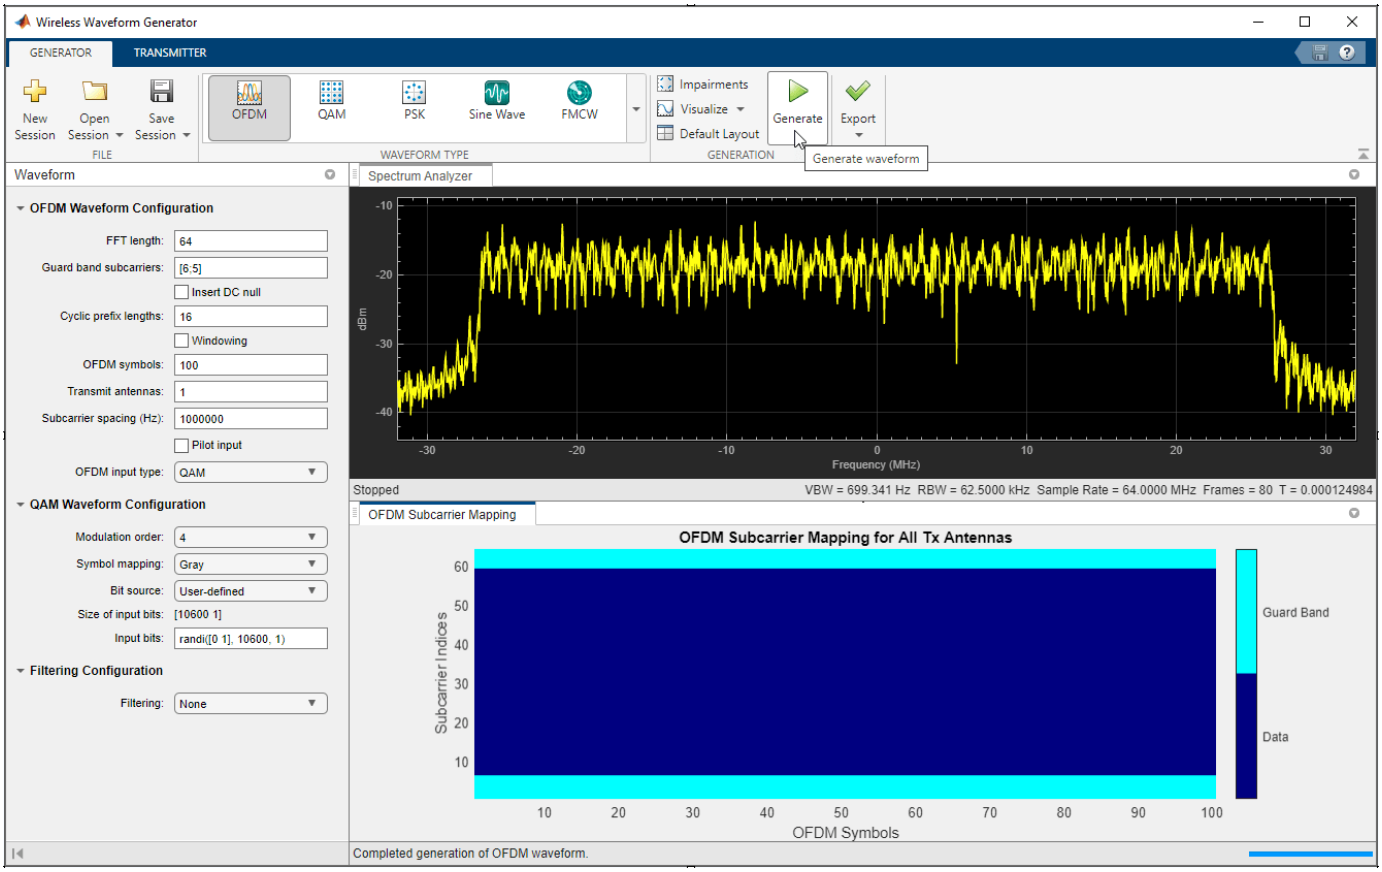
Set Up for Radio Transmission

To use the radio transmitters in the app, you need to install the Wireless Testbench Support Package for NI USRP Radios add-on and set up your radio outside the app. For more information, see “Connect and Set Up NI USRP Radios” (Wireless Testbench).

Generate Waveform for Transmission

Open the **Wireless Waveform Generator** app by clicking the app icon on the **Apps** tab, under **Signal Processing and Communications**. Alternatively, enter `wirelessWaveformGenerator` at the MATLAB command prompt.

In the **Waveform Type** section, select an OFDM waveform by clicking **OFDM**. In the leftmost pane of the app, adjust any configuration parameters for the selected waveform. Then generate the configuration by clicking **Generate** in the app toolstrip.



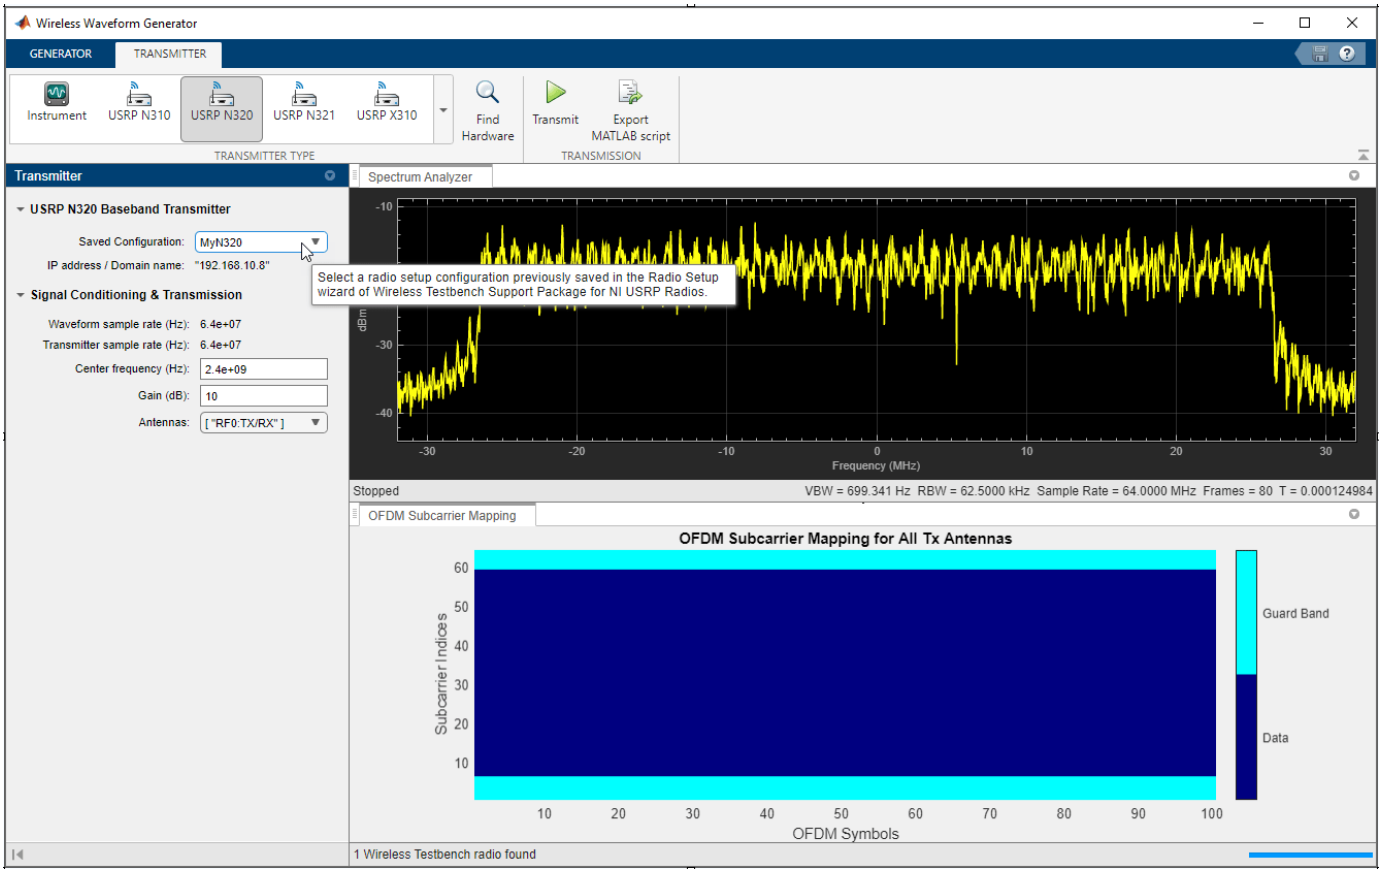
Configure Radio Transmitter

Select the **Transmitter** tab from the app toolstrip. In the transmitter gallery, select the USRP N310, USRP N320, USRP N321, or USRP X310 radio transmitter.

In the leftmost pane of the app, select the name of a radio setup configuration that you saved using the Radio Setup wizard. For more information, see “Connect and Set Up NI USRP Radios” (Wireless Testbench).

Set the center frequency, gain, and antennas configuration parameters. The app automatically sets the waveform sample rate based on the waveform that you generated earlier. The radio transmitter uses onboard data buffering to ensure contiguous data transmission at up to the full hardware sample rate. If necessary, to achieve the specified sample rate, the radio uses a Farrow rate converter. Use this list as a reference when setting the sample rate:

- **USRP N310** — 120,945 Hz to 76.8 MHz, or one of: 122.88 MHz, 125 MHz, or 153.6 MHz
- **USRP N320** — 196,851 Hz to 125 MHz, or one of: 200 MHz, 245.76 MHz or 250 MHz
- **USRP N321** — 196,851 Hz to 125 MHz, or one of: 200 MHz, 245.76 MHz or 250 MHz
- **USRP X310** — 181,418 Hz to 100 MHz, or one of: 184.32 MHz or 200 MHz



Transmit Waveform

To transmit the waveform continuously, click **Transmit**. To end the continuous transmission, click **Stop transmission**. To export the waveform generation and transmission parameters to a runnable MATLAB script, click **Export MATLAB script**.

Functions

algdeintrlv

Restore ordering of symbols using algebraically derived permutation table

Syntax

```
deintrlvd = algdeintrlv(data,num,'takeshita-costello',k,h)
deintrlvd = algdeintrlv(data,num,'welch-costas',alph)
```

Description

`deintrlvd = algdeintrlv(data,num,'takeshita-costello',k,h)` restores the original ordering of the elements in `data` using a permutation table that is algebraically derived using the Takeshita-Costello method. `num` is the number of elements in `data` if `data` is a vector, or the number of rows of `data` if `data` is a matrix with multiple columns. In the Takeshita-Costello method, `num` must be a power of 2. The multiplicative factor, `k`, must be an odd integer less than `num`, and the cyclic shift, `h`, must be a nonnegative integer less than `num`. If `data` is a matrix with multiple rows and columns, the function processes the columns independently.

`deintrlvd = algdeintrlv(data,num,'welch-costas',alph)` uses the Welch-Costas method. In the Welch-Costas method, `num+1` must be a prime number. `alph` is an integer between 1 and `num` that represents a primitive element of the finite field GF(`num+1`).

To use this function as an inverse of the `algintrlv` function, use the same inputs in both functions, except for the `data` input. In that case, the two functions are inverses in the sense that applying `algintrlv` followed by `algdeintrlv` leaves data unchanged.

Examples

Interleave and Deinterleave Symbols

This example uses the Takeshita-Costello method of `algintrlv` and `algdeintrlv`.

Generate random data symbols to interleave. The number of rows of input data, `num`, must be a power of two.

```
num = 16;
ncols = 3;
data = rand(num,ncols)
```

```
data = 16×3

    0.8147    0.4218    0.2769
    0.9058    0.9157    0.0462
    0.1270    0.7922    0.0971
    0.9134    0.9595    0.8235
    0.6324    0.6557    0.6948
    0.0975    0.0357    0.3171
    0.2785    0.8491    0.9502
    0.5469    0.9340    0.0344
    0.9575    0.6787    0.4387
```

```
    0.9649    0.7577    0.3816
      ⋮
```

Interleave the symbols using the Takeshita-Costello method. Set the multiplicative factor, `k`, to an odd integer less than `num`, and the cyclic shift, `h`, to a nonnegative integer less than `num`.

```
k = 3;
h = 4;
intdata = algintrlv(data,num,'takeshita-costello',k,h)
```

```
intdata = 16×3

    0.9572    0.6555    0.1869
    0.2785    0.8491    0.9502

`algintrlv`

Topics

“Interleaving”

algintrlv

Reorder symbols using algebraically derived permutation table

Syntax

```
intrlvd = algintrlv(data,num,'takeshita-costello',k,h)
intrlvd = algintrlv(data,num,'welch-costas',alph)
```

Description

`intrlvd = algintrlv(data,num,'takeshita-costello',k,h)` rearranges the elements in `data` using a permutation table that is algebraically derived using the Takeshita-Costello method. `num` is the number of elements in `data` if `data` is a vector, or the number of rows of `data` if `data` is a matrix with multiple columns. In the Takeshita-Costello method, `num` must be a power of 2. The multiplicative factor, `k`, must be an odd integer less than `num`, and the cyclic shift, `h`, must be a nonnegative integer less than `num`. If `data` is a matrix with multiple rows and columns, the function processes the columns independently.

`intrlvd = algintrlv(data,num,'welch-costas',alph)` uses the Welch-Costas method. In the Welch-Costas method, `num+1` must be a prime number. `alph` is an integer between 1 and `num` that represents a primitive element of the finite field GF(`num+1`). This means that every nonzero element of GF(`num+1`) can be expressed as `alph` raised to some integer power.

Examples

Reorder Symbols Using Algebraically Derived Permutation Table

This example illustrates how to use the Welch-Costas method of algebraic interleaving.

Define `num` such that `num+1` is prime. Create data to interleave.

```
num = 10;
ncols = 3; % Number of columns of data to interleave
data = randi([0 num-1],num,ncols); % Random data to interleave
```

Find primitive polynomials of the finite field GF(num+1). The `gfprimfd` function represents each primitive polynomial as a row containing the coefficients in order of ascending powers.

```
pr = gfprimfd(1,'all',num+1)
```

```
pr = 4×2

     3     1
     4     1
     5     1
     9     1
```

Notice from the output that `pr` has two columns and that the second column consists solely of 1s. In other words, each primitive polynomial is a monic degree-one polynomial. This is because `num+1` is

prime. As a result, to find the primitive element that is a root of each primitive polynomial, find a root of the polynomial by subtracting the first column of pr from `num+1` .

```
primel = (num+1)-pr(:,1) % Primitive elements of GF(num+1)
```

```
primel = 4×1

     8
     7
     6
     2
```

Now define `alph` as one of the elements of `primel` and use `algintrlv` to interleave.

```
alph = primel(1);
intrlvd = algintrlv(data,num,'Welch-Costas',alph);
```

Algorithms

- A Takeshita-Costello interleaver uses a length-`num` cycle vector whose `n`th element is `mod(k*(n-1)*n/2, num)` for integers `n` between 1 and `num`. The function creates a permutation vector by listing, for each element of the cycle vector in ascending order, one plus the element's successor. The interleaver's actual permutation table is the result of shifting the elements of the permutation vector left by `h`. (The function performs all computations on numbers and indices modulo `num`.)
- A Welch-Costas interleaver uses a permutation that maps an integer `K` to $\mathtt{mod}(A^K,\mathtt{num+1})-1$.

amdemod

Amplitude demodulation

Syntax

```
z = amdemod(y,Fc,Fs)
z = amdemod(y,Fc,Fs,ini_phase)
z = amdemod(y,Fc,Fs,ini_phase,carramp)
z = amdemod(y,Fc,Fs,ini_phase,carramp,num,den)
```

Description

`z = amdemod(y,Fc,Fs)` returns a demodulated signal `z`, given the input amplitude modulated (AM) signal `y`, where the carrier signal has frequency `Fc`. The carrier signal and `y` have sampling frequency `Fs`. The modulated signal `y` has zero initial phase and zero carrier amplitude, resulting from a suppressed-carrier modulation.

Note The value of `Fs` must satisfy $Fs \geq 2Fc$.

`z = amdemod(y,Fc,Fs,ini_phase)` specifies the initial phase of the modulated signal in radians.

`z = amdemod(y,Fc,Fs,ini_phase,carramp)` demodulates a signal created through transmitted-carrier modulation instead of suppressed-carrier modulation, where `carramp` is the carrier amplitude of the modulated signal.

`z = amdemod(y,Fc,Fs,ini_phase,carramp,num,den)` specifies the numerator and denominator of the lowpass Butterworth filter used in the demodulation. The numerator and denominator are generated by `[num,den] = butter(n,Fc*2/Fs)`, where `n` is the order of the lowpass filter.

Examples

Demodulate AM Signal

Set the carrier frequency to 10 kHz and sampling frequency to 80 kHz. Generate a time vector having a duration of 0.01 s.

```
fc = 10e3;
fs = 80e3;
t = (0:1/fs:0.01)';
```

Create a two-tone sinusoidal signal with frequencies 300 and 600 Hz.

```
s = sin(2*pi*300*t)+2*sin(2*pi*600*t);
```

Create a lowpass filter.

```
[num,den] = butter(10,fc*2/fs);
```

Amplitude modulate the signal `s`.

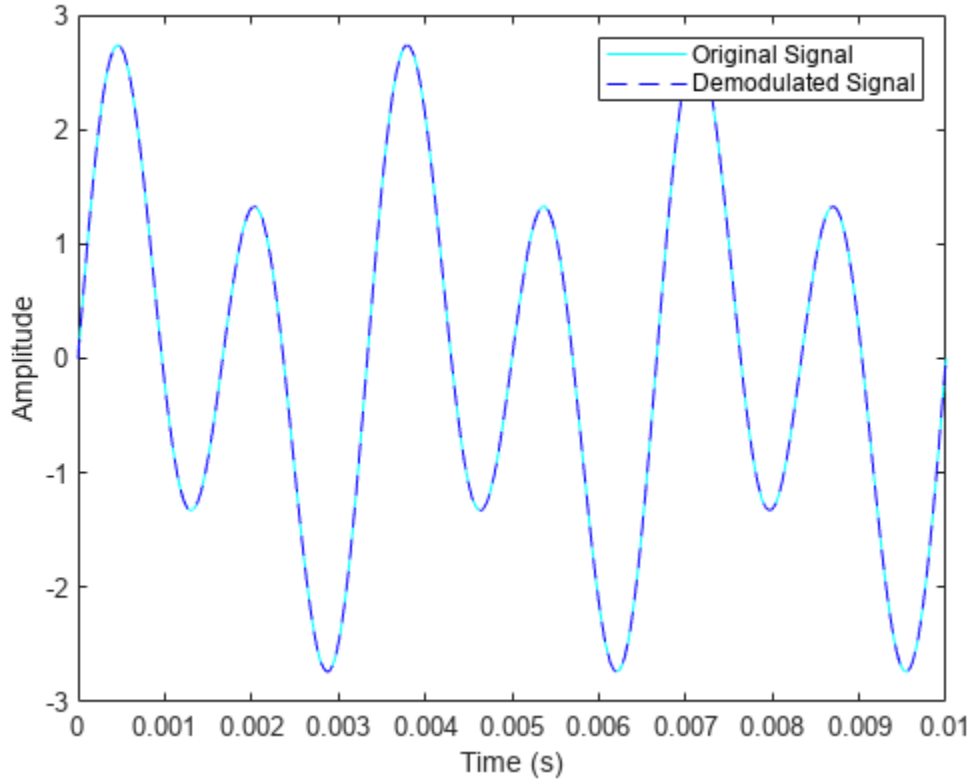
```
y = ammod(s,fc,fs);
```

Demodulate the received signal.

```
z = amdemod(y,fc,fs,0,0,num,den);
```

Plot the original and demodulated signals.

```
plot(t,s,'c',t,z,'b--')
legend('Original Signal','Demodulated Signal')
xlabel('Time (s)')
ylabel('Amplitude')
```



The demodulated signal is nearly identical to the original signal.

Input Arguments

y — Amplitude modulated input signal

scalar | vector | matrix | 3-D array

Amplitude modulated input signal, specified as a scalar, vector, matrix, or 3-D array. Each element of `y` must be real.

Data Types: `double` | `single`

Fc — Carrier signal frequency
positive scalar

Carrier signal frequency in hertz (Hz), specified as a positive scalar.

Data Types: `double`

Fs — Sampling frequency
positive scalar

Sampling frequency of the carrier signal and input message signal in hertz (Hz), specified as a positive scalar. To avoid aliasing, the value of `Fs` must satisfy `Fs > 2(Fc + BW)`, where `BW` is the bandwidth of the original modulated signal.

Data Types: `double`

ini_phase — Initial phase
scalar

Initial phase of the modulated signal in radians, specified as a scalar.

Data Types: `double`

carramp — Carrier amplitude
scalar

Carrier amplitude of the modulated signal, specified as a scalar.

Data Types: `double`

num — Lowpass Butterworth filter numerator
scalar

Lowpass Butterworth filter numerator, specified as a scalar.

Data Types: `double`

den — Lowpass Butterworth filter denominator
scalar

Lowpass Butterworth filter denominator, specified as a scalar.

Data Types: `double`

Output Arguments

z — Amplitude demodulated output signal
scalar | vector | matrix | 3-D array

Amplitude demodulated output signal, returned as a scalar, vector, matrix, or 3-D array.

Topics

“Analog Passband Modulation”

ammod

Amplitude modulation

Syntax

```
y = ammod(x,Fc,Fs)
y = ammod(x,Fc,Fs,ini_phase)
y = ammod(x,Fc,Fs,ini_phase,carramp)
```

Description

`y = ammod(x,Fc,Fs)` returns an amplitude modulated (AM) signal `y`, given the input message signal `x`, where the carrier signal has frequency `Fc`. The carrier signal and `x` have a sampling frequency `Fs`. The modulated signal has zero initial phase and zero carrier amplitude, so the result is suppressed-carrier modulation.

Note The value of `Fs` must satisfy $Fs \geq 2Fc$.

`y = ammod(x,Fc,Fs,ini_phase)` specifies the initial phase in the modulated signal `y` in radians.

`y = ammod(x,Fc,Fs,ini_phase,carramp)` performs transmitted-carrier modulation instead of suppressed-carrier modulation where `carramp` is the carrier amplitude of the modulated signal.

Examples

Compare Double-Sideband and Single-Sideband Amplitude Modulation

Set the sample rate to 100 Hz. Create a time vector 100 seconds long.

```
fs = 100;
t = (0:1/fs:100)';
```

Set the carrier frequency to 10 Hz. Generate a sinusoidal signal.

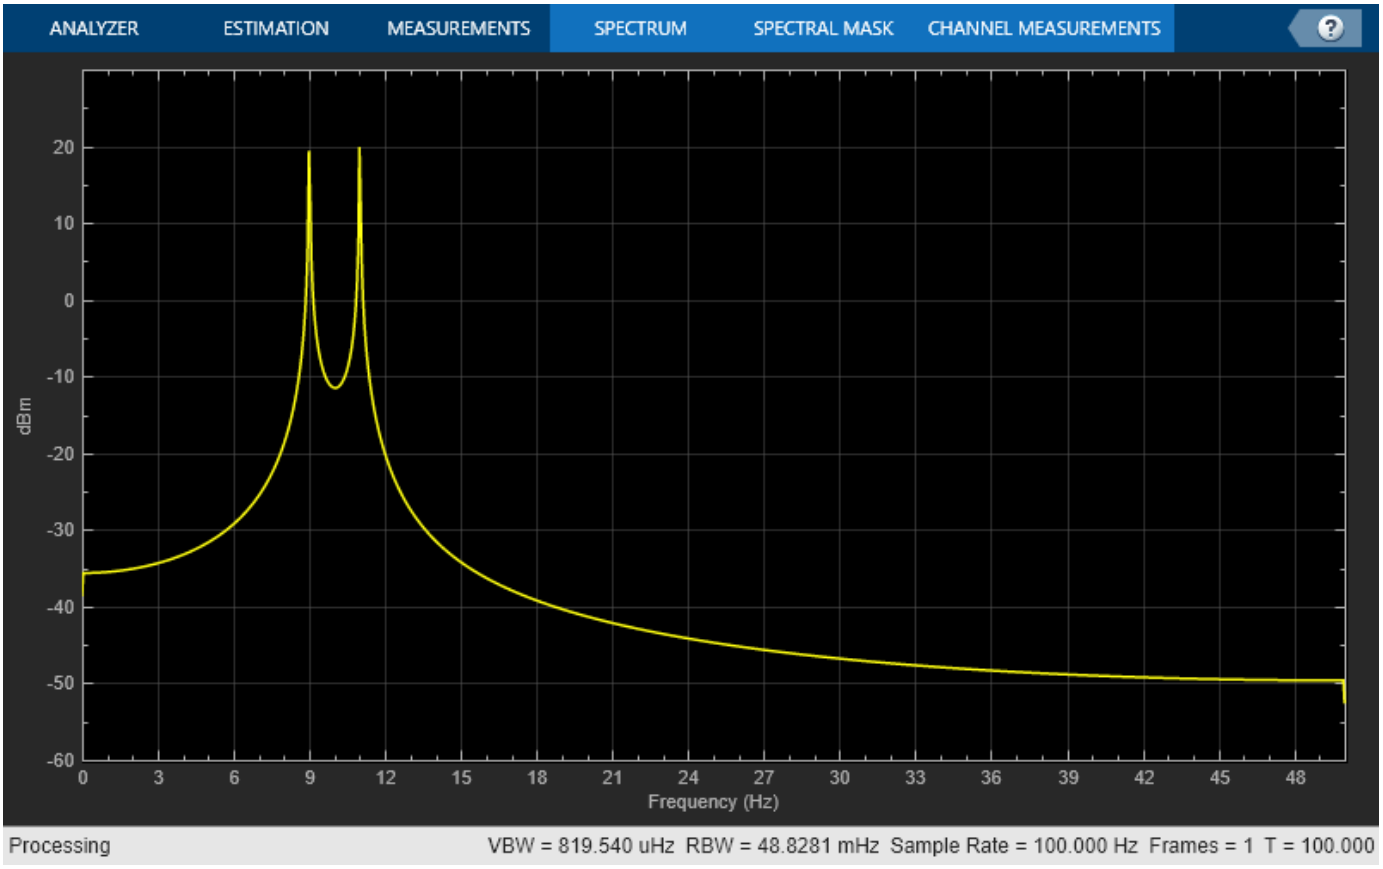
```
fc = 10;
x = sin(2*pi*t);
```

Modulate `x` using single- and double-sideband AM.

```
ydouble = ammod(x,fc,fs);
ysingle = ssbmod(x,fc,fs);
```

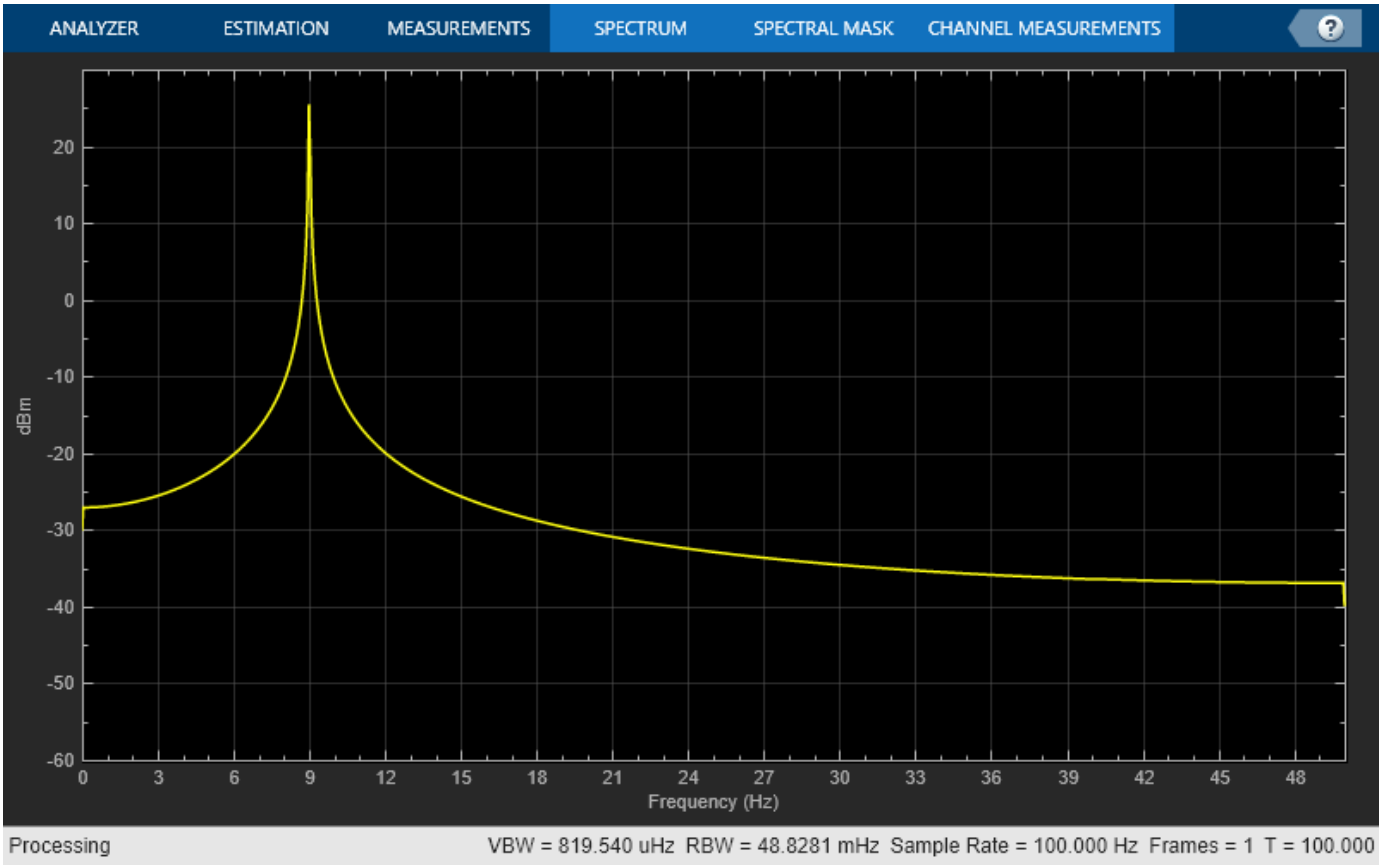
Create a spectrum analyzer object to plot the spectrum of the double-sideband signal.

```
sadsb = spectrumAnalyzer( ...
    SampleRate=fs, ...
    PlotAsTwoSidedSpectrum=false, ...
    YLimits=[-60 30]);
sadsb(ydouble)
```



Create a separate spectrum analyzer object to plot the single-sideband spectrum. A separate spectrum analyzer object is used to isolate each spectrum analyzer's signal buffers for the two signals.

```
sassb = spectrumAnalyzer( ...
    SampleRate=fs, ...
    PlotAsTwoSidedSpectrum=false, ...
    YLimits=[-60 30]);
sassb(ysingle)
```



Input Arguments

x — Input message signal

scalar | vector | matrix | 3-D array

Input message signal, specified as a scalar, vector, matrix, or a 3-D array. Each element of `x` must be real.

Data Types: `single` | `double`

Fc — Carrier signal frequency

positive real scalar

Carrier signal frequency in hertz (Hz), specified as a positive real scalar.

Data Types: `single` | `double`

Fs — Sampling frequency

positive real scalar

Sampling frequency of carrier signal and input message signal in hertz (Hz), specified as a positive real scalar. To avoid aliasing, the value of `Fs` must satisfy `Fs > 2(Fc + BW)`, where `BW` is the bandwidth of `x`.

Data Types: `single` | `double`

`ini_phase` — Initial phase
real scalar

Initial phase of the modulated signal in radians, specified as a real scalar.

Data Types: `single` | `double`

`carramp` — Carrier amplitude
real scalar

Carrier amplitude of the modulated signal, specified as a real scalar.

Data Types: `single` | `double`

Output Arguments

`y` — Amplitude modulated output signal
scalar | vector | matrix | 3-D array

Amplitude modulated signal, returned as a scalar, vector, matrix, or 3-D array.

Version History

Introduced before R2006a

“Analog Passband Modulation”

apskdemod

Amplitude phase shift keying (APSK) demodulation

Syntax

```
z = apskdemod(y,M,radii)
z = apskdemod(y,M,radii,phaseoffset)
z = apskdemod(___,Name,Value)
```

Description

`z = apskdemod(y,M,radii)` performs APSK demodulation of the input signal `y`, based on the specified number of constellation points per PSK ring, `M`, and the radius of each PSK ring, `radii`. For a description of APSK demodulation, see “APSK Hard Demodulation” on page 2-23 and “APSK Soft Demodulation” on page 2-24.

Note apskdemod specifically applies to multiple ring PSK constellations. For a single ring PSK constellation, use `pskdemod`.

`z = apskdemod(y,M,radii,phaseoffset)` specifies an initial phase offset for each PSK ring of the APSK modulated signal.

`z = apskdemod(___,Name,Value)` specifies options using one or more name-value pair arguments using any of the previous syntaxes. For example, `'OutputDataType','double'` specifies the desired output data type as double. Specify name-value pair arguments after all other input arguments.

Examples

Demodulate 16-APSK Signal

Demodulate a 16-APSK signal that has an unequal number of constellation points on each circle. Plot the received constellation.

Define vectors for modulation order and PSK ring radii. Generate random 16-ary data symbols.

```
M = [4 12];
radii = [1 2];
modOrder = sum(M);

x = randi([0 modOrder-1],1000,1);
```

Apply APSK modulation to the data.

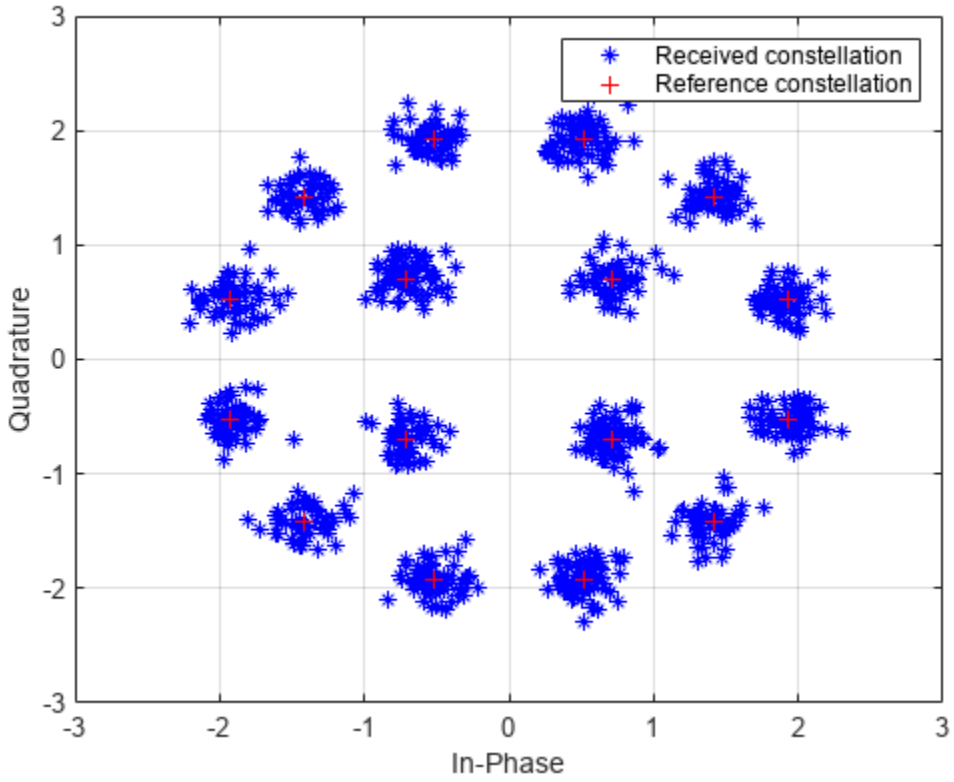
```
txSig = apskmod(x,M,radii);
```

Pass the modulated signal through a noisy channel.

```
snr = 20; % dB
rxSig = awgn(txSig,snr,'measured');
```

Plot the transmitted (reference) signal points and the noisy received signal points.

```
plot(rxSig,'b*')
hold on
grid
plot(txSig,'r+')
xlim([-3 3])
ylim([-3 3])
xlabel('In-Phase')
ylabel('Quadrature')
legend('Received constellation','Reference constellation')
```



Demodulate the received signal and compare to the input data.

```
z = apskdemod(rxSig,M,radii);
isequal(x,z)
```

```
ans = logical
   1
```

Demodulate 64-APSK Custom Symbol Mapped Signal

Demodulate a 64-APSK signal with custom symbol mapping. Compute hard decision bit output and verify that the input matches the output.

Define vectors for modulation order and PSK ring radii. Generate 100 symbols of random bit input.

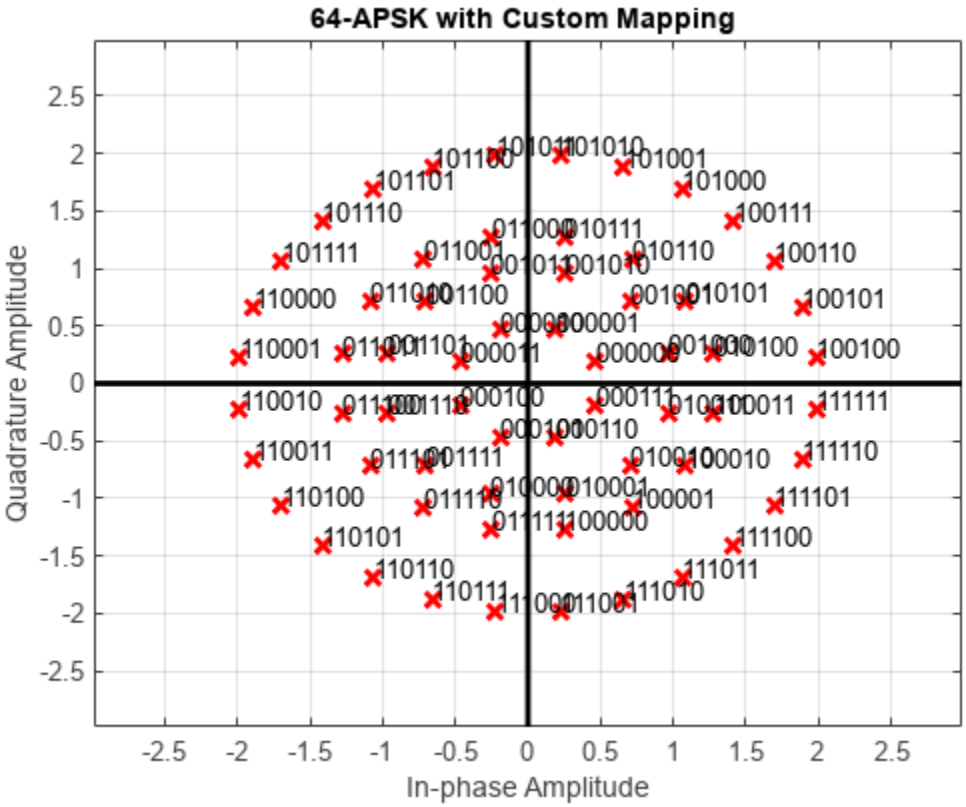
```
M = [8 12 16 28]; % 4-PSK circles
modOrder = sum(M);
radii = [0.5 1 1.3 2];
x = randi([0 1],100*log2(modOrder),1);
```

Create a custom symbol mapping vector of binary mapping.

```
cmap = 0:63;
```

Modulate the data and plot the constellation.

```
y = apskmod(x,M,radii,'SymbolMapping',cmap,'inputType','bit', ...
    'PlotConstellation',true);
```



Demodulate the received signal.

```
z = apskdemod(y,M,radii,'SymbolMapping',cmap,'OutputType','bit');
```

Verify that the demodulated signal is equal to the original data.

```
isequal(x,z)
```

```
ans = logical
   1
```

Soft Bit Demodulate 32-APSK Signal

Demodulate a 32-APSK signal and calculate soft bits.

Define vectors for modulation order and PSK ring radii. Generate 10000 symbols of random bit data.

```
M = [16 16];
modOrder = sum(M);
radii = [0.6 1.2];
numSym = 10000;
x = randi([0 1], numSym*log2(modOrder),1);
```

Generate a reference constellation. Create a constellation diagram object.

```
refAPSK = apskmod(0:modOrder-1,M,radii);
constDiagAPSK = comm.ConstellationDiagram('ReferenceConstellation',refAPSK, ...
  'Title','Received Symbols','XLimits',[-2 2],'YLimits',[-2 2]);
```

Modulate the data.

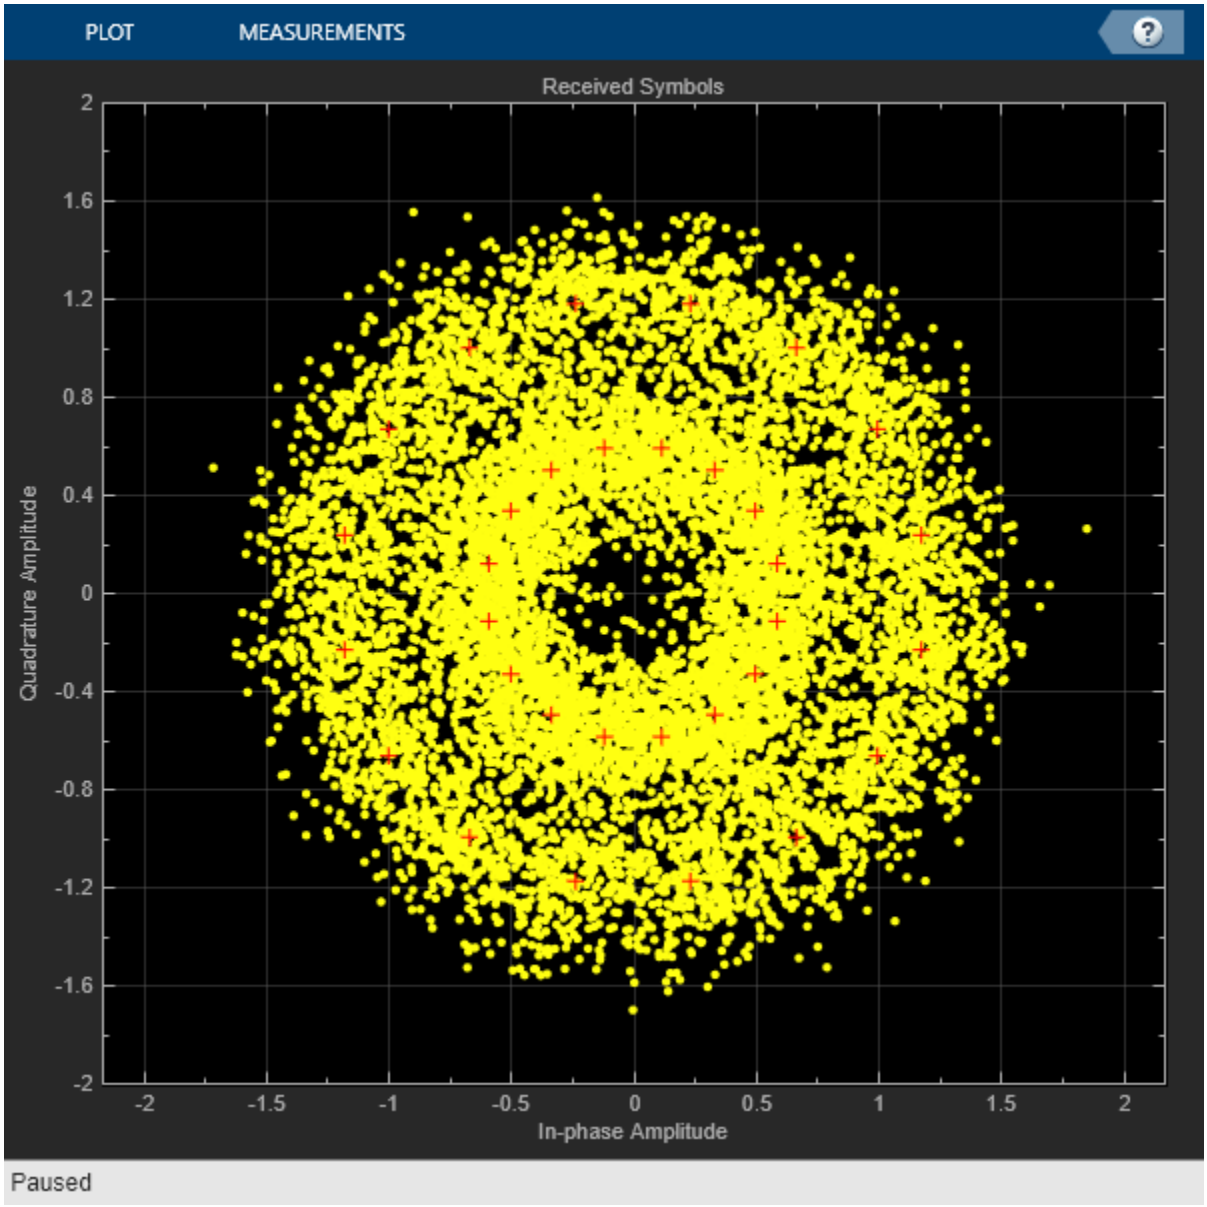
```
txSig = apskmod(x,M,radii,'InputType','bit');
sigPow = var(txSig);
```

Pass the signal through a noisy channel.

```
snr = 15;
rxSig = awgn(txSig,snr,sigPow,'linear');
```

Plot the reference and received constellation symbols.

```
constDiagAPSK(rxSig)
```



Demodulate the signal and compute soft bits.

```
z = apskdemod(rxSig,M,radii,'OutputType','approxllr', ...
    'NoiseVariance',sigPow/snr);
```

Input Arguments

y — APSK modulated signal

scalar | vector | matrix

APSK modulated signal, specified as a complex scalar, vector, or matrix. Each column is treated as an independent channel.

Data Types: `double` | `single`

Complex Number Support: Yes

`M` — Constellation points per PSK ring

vector

Constellation points per PSK ring, specified as a vector with more than one element. Vector elements indicate the number of constellation points in each PSK ring. The first element corresponds to the innermost circle, and so on, until the last element, that corresponds to the outermost circle. Element values must be multiples of four and `sum(M)` must be a power of two. The modulation order is the total number of points in the signal constellation and equals the sum of the vector elements, `sum(M)`.

Example: `[4 12 16]` specifies a three PSK ring constellation with a modulation order of `sum(M) = 32`.

Data Types: `double`

`radii` — PSK ring radii

vector

PSK ring radii, specified as a vector with the same length as `M`. The first element corresponds to the innermost circle, and so on, until the last element, that corresponds to the outermost circle. The elements must be positive and arranged in increasing order.

Example: `[0.5 1 2]` defines constellation PSK ring radii. The inner ring has a radius of 0.5, the second ring has a radius of 1.0, and the outer ring has a radius of 2.0.

Data Types: `double`

`phaseoffset` — PSK ring phase offsets

`[pi/M(1) pi/M(2) … pi/M(end)]` (default) | scalar | vector

Phase offset of each PSK ring in radians, specified as a scalar or vector with the same length as `M`. The first element corresponds to the innermost circle, and so on, until the last element, that corresponds to the outermost circle. The `phaseoffset` can be a scalar only if all the elements of `M` are the same value.

Example: `[pi/4 pi/12 pi/16]` defines three constellation PSK ring phase offsets. The inner ring has a phase offset of pi/4, the second ring has a phase offset of pi/12, and the outer ring has a phase offset of pi/16.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `y = apskdemod(x,M,radii,'OutputType','bit','OutputDataType','single');`

`SymbolMapping` — Symbol mapping

`'gray'` | `'contourwise-gray'` | integer vector

Symbol mapping, specified as the comma-separated pair consisting of `SymbolMapping` and one of the following:

- `'contourwise-gray'` — Uses Gray mapping along the contour in phase dimension.
- `'gray'` — Uses Gray mapping along the contour in both the amplitude and phase dimensions. For Gray symbol mapping, all the values for `M` must be equal and all the values for `phaseoffset` must be equal. For a description of the Gray mapping used, see [2].
- integer vector — Use custom symbol mapping. Vector must consist of `sum(M)` unique elements with values from 0 to (`sum(M)-1`). The first element corresponds to the constellation point in the first quadrant of the innermost circle, with subsequent elements positioned counterclockwise around the PSK rings.

The default symbol mapping depends on `M` and `phaseOffset`. When all the elements of `M` and `phaseOffset` are equal, the default is `'gray'`. For all other cases, the default is `'contourwise-gray'`.

Data Types: `double` | `char` | `string`

`OutputType` — Output type
`'integer'` (default) | `'bit'` | `'llr'` | `'approxllr'`

Output type, specified as the comma-separated pair consisting of `'OutputType'` and `'integer'`, `'bit'`, `'llr'`, or `'approxllr'`. For a description of the returned output, see `z`.

Data Types: `char` | `string`

`OutputDataType` — Output data type
`'double'` (default) | `...`

Output data type, specified as the comma-separated pair consisting of `OutputDataType` and one of the indicated data types. Acceptable values for `OutputDataType` depend on the `OutputType` value.

`OutputType` Value	Acceptable `OutputDataType` Values
`'integer'`	`'double'`, `'single'`, `'int8'`, `'int16'`, `'int32'`, `'uint8'`, `'uint16'`, or `'uint32'`
`'bit'`	`'double'`, `'single'`, `'int8'`, `'int16'`, `'int32'`, `'uint8'`, `'uint16'`, `'uint32'`, or `'logical'`

Dependencies

This name-value pair argument applies only when `OutputType` is set to `'integer'` or `'bit'`.

Data Types: `char` | `string`

`NoiseVariance` — Noise variance
1 (default) | positive scalar | vector of positive values

Noise variance, specified as the comma-separated pair consisting of `NoiseVariance` and a positive scalar or vector of positive values.

- When specified as a scalar, the same noise variance value is used on all input elements.
- When specified as a vector, the vector length must be equal to the number of columns in the input signal.

When the noise variance or signal power result in computations involving extreme positive or negative magnitudes, see “APSK Soft Demodulation” on page 2-24 for algorithm selection considerations.

Dependencies

This name-value pair argument applies only when `OutputType` is set to `'llr'` or `'approxllr'`.

Data Types: `double`

`PlotConstellation` — Option to plot constellation

`false` (default) | `true`

Option to plot constellation, specified as the comma-separated pair consisting of `'PlotConstellation'` and a logical scalar. To plot the constellation, set `PlotConstellation` to `true`.

Data Types: `logical`

Output Arguments

`z` — Demodulated signal

scalar | vector | matrix

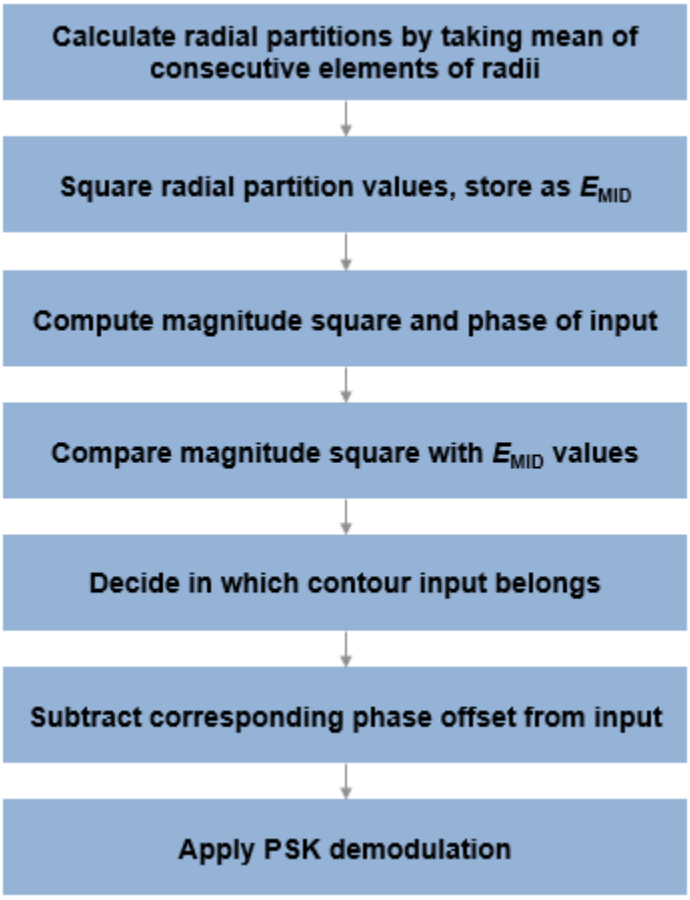
Demodulated signal, returned as a scalar, vector, or matrix. The dimensions of `z` depend on the specified `OutputType` value.

`OutputType` Value	Return Value of `apskdemod`	Dimensions of `z`
`'integer'`	Demodulated integer values from 0 to (sum(`M`) – 1)	`z` has the same dimensions as input `y`.
`'bit'`	Demodulated bits	The number of rows in `z` is $\log_2$(sum(`M`)) times the number of rows in `y`. Each demodulated symbol is mapped to a group of $\log_2$(sum(`M`)) elements in a column, where the first element represents the MSB and the last element represents the LSB.
`'llr'`	Log-likelihood ratio value for each bit	
`'approxllr'`	Approximate log-likelihood ratio value for each bit	

More About

APSK Hard Demodulation

The hard demodulation algorithm applies amplitude phase decoding as described in [1].



APSK Soft Demodulation

For soft demodulation, two soft-decision log-likelihood ratio (LLR) algorithms are available: exact LLR and approximate LLR. The exact LLR algorithm is more accurate but has slower execution speed than the approximate LLR algorithm. For further description of these algorithms, see the “Hard- vs. Soft-Decision Demodulation” topic.

Note The exact LLR algorithm computes exponentials using finite precision arithmetic. For computations involving very large positive or negative magnitudes, the exact LLR algorithm yields:

- `Inf` or `-Inf` if the noise variance is a very large value
- `NaN` if the noise variance and signal power are both very small values

The approximate LLR algorithm does not compute exponentials. You can avoid `Inf`, `-Inf`, and `NaN` results by using the approximate LLR algorithm.

Topics

“Hard- vs. Soft-Decision Demodulation”

apskmod

Amplitude phase shift keying (APSK) modulation

Syntax

```
y = apskmod(x,M,radii)
y = apskmod(x,M,radii,phaseoffset)
y = apskmod( ___ ,Name,Value)
```

Description

`y = apskmod(x,M,radii)` performs APSK modulation on the input data, `x`, based on the specified number of constellation points per PSK ring, `M`, and the radius of each PSK ring, `radii`. For a description of APSK modulation, see “Algorithms” on page 2-34.

Note apskmod specifically applies to multiple ring PSK constellations. For a single ring PSK constellation, use `pskmod`.

`y = apskmod(x,M,radii,phaseoffset)` specifies an initial phase offset for each PSK ring of the APSK modulated signal.

`y = apskmod( ___ ,Name,Value)` specifies options using one or more name-value pair arguments using any of the previous syntaxes. For example, `'OutputDataType','double'` specifies the desired output data type as double. Specify name-value pair arguments after all other input arguments.

Examples

Apply APSK Modulation

Modulate data using APSK with an unequal number of constellation points on each circle.

Define vectors for modulation order and PSK ring radii. Generate data for constellation points.

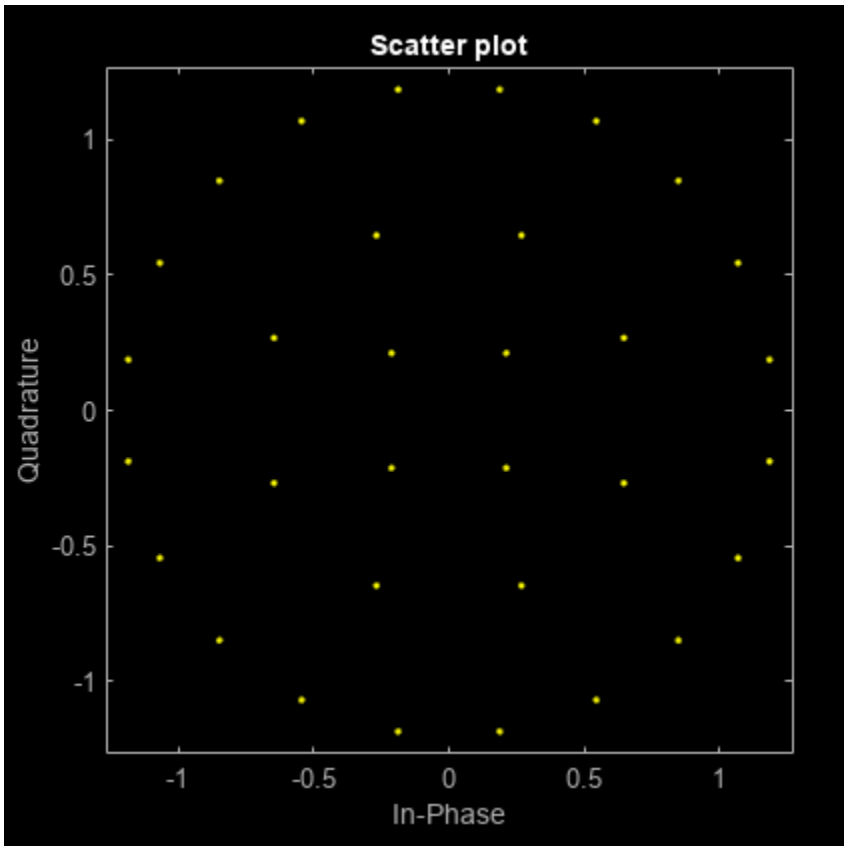
```
M = [4 8 20];
radii = [0.3 0.7 1.2];
modOrder = sum(M);
x = 0:modOrder-1;
```

Apply APSK modulation to the data.

```
y = apskmod(x,M,radii);
```

Plot the resulting constellation using a scatter plot.

```
scatterplot(y)
```



Apply APSK Modulation with Phase Offset

Modulate a random data sequence using APSK with zero phase offset for the inner circle and pi/6 phase offset for the outer circle.

Define vectors for modulation order, PSK ring radii, and PSK ring phase offset. Generate random data.

```
M = [8 8];
modOrder = sum(M);
radii = [0.5 1];
phOff = [0 pi/6];

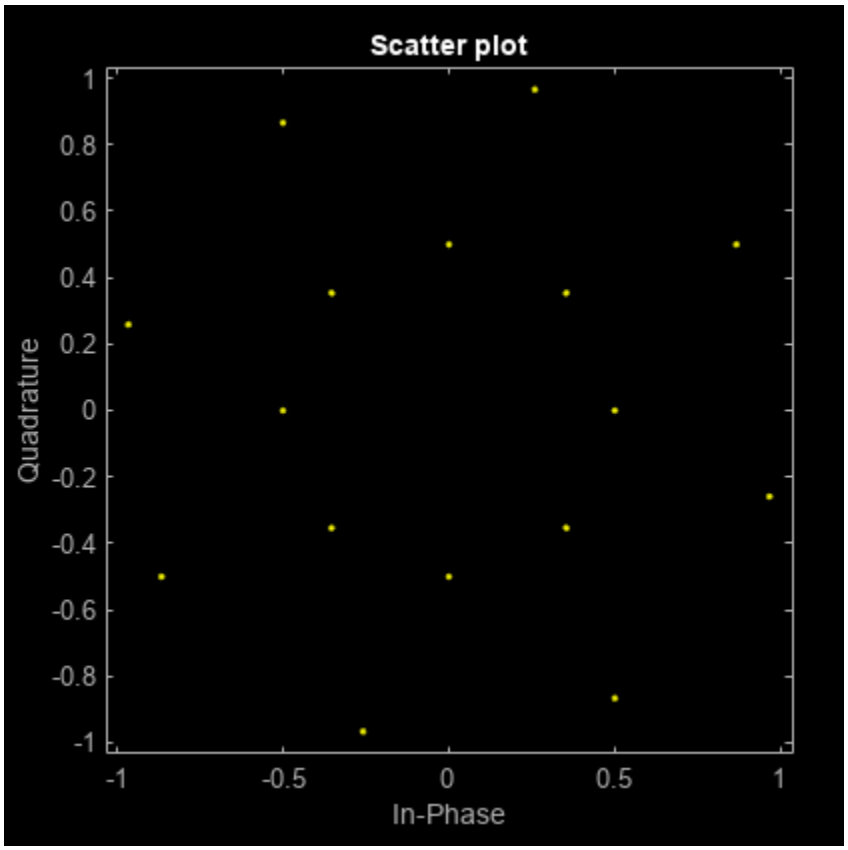
x = randi([0 modOrder-1],100,1);
```

Apply APSK modulation to the data.

```
y = apskmod(x,M,radii,phOff);
```

Plot the resulting constellation using a scatter plot and observe the phase offset between the constellation circles.

```
scatterplot(y)
```



Apply APSK Modulation Modifying Symbol Ordering

Plot APSK constellations for Gray-coded and custom-coded symbol mappings.

Define vectors for modulation order and PSK ring radii. Generate bit data for constellation points.

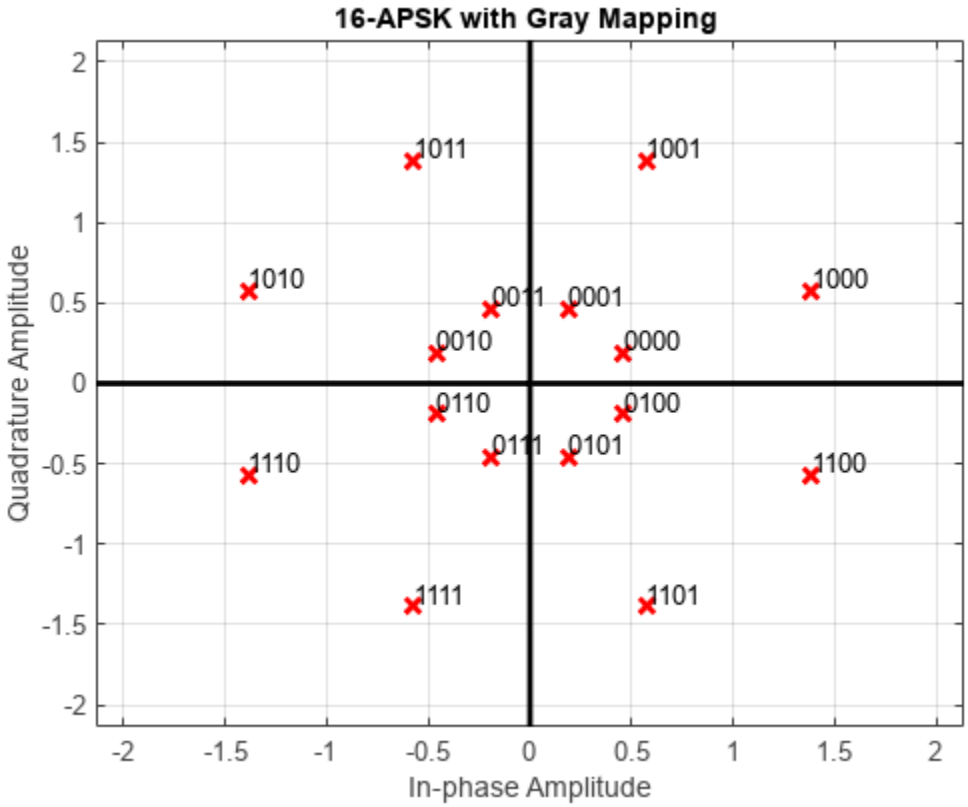
```
M = [8 8];
modOrder = sum(M);
radii = [0.5 1.5];
x = 0:modOrder-1;
```

The `apskmod` function assumes the single channel binary input is left-MSB aligned and specified column-wise. Use the `int2bit` function to express the integer input symbols as a single column binary vector.

```
xBit = int2bit(x,log2(modOrder));
```

Apply APSK modulation to the data using the default phase offset. Since element values for `M` are equal and element values for phase offset are equal, the symbol mapping defaults to `'gray'`. Plot the constellation using binary input to highlight the Gray-coded nature of the constellation mapping.

```
y = apskmod(xBit,M,radii,PlotConstellation=true,InputType='bit');
```

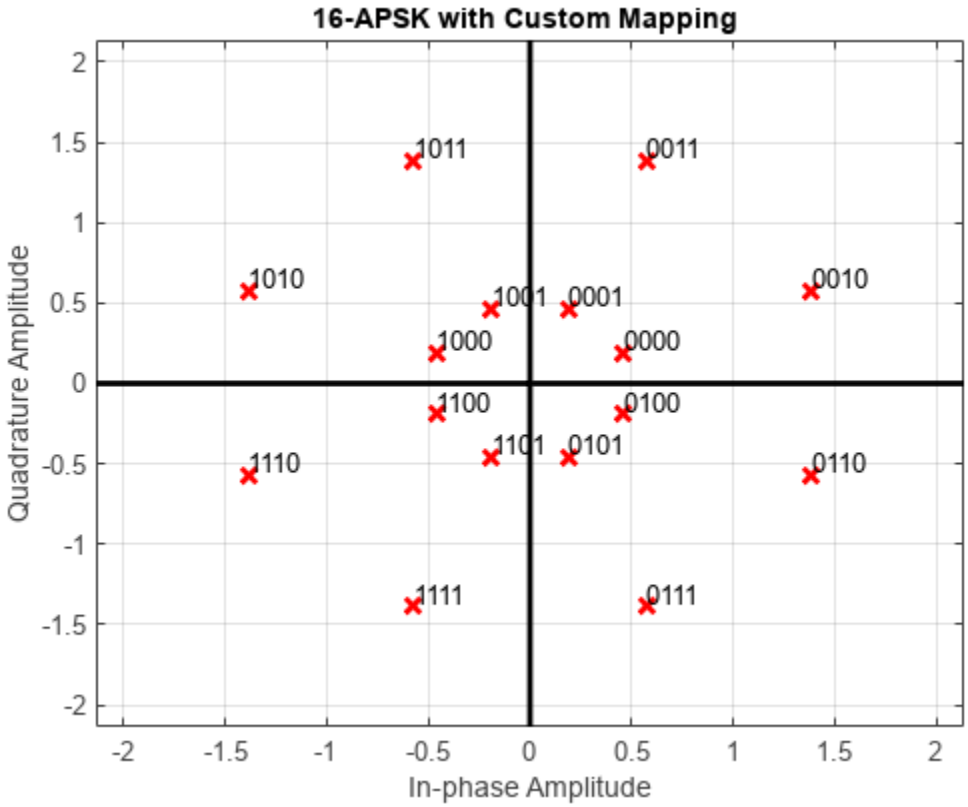


Create a custom-coded symbol mapping vector. This custom mapping happens to be another Gray-coded mapping.

```
cmap = [0;1;9;8;12;13;5;4;2;3;11;10;14;15;7;6];
```

Apply APSK modulation with a custom-coded symbol mapping. Plot the constellation using binary input to highlight that the custom mapping defines different Gray-coded symbol mapping.

```
z = apskmod(xBit,M,radii, ...
    SymbolMapping=cmap, ...
    PlotConstellation=true, ...
    InputType='bit');
```



Apply APSK Modulation to Input Bits

Modulate a random bit sequence using APSK and output data type `single`. Pass the signal through a noisy channel and display the constellation diagram.

Define vectors for modulation order and PSK ring radii. Generate random binary data.

```
M = [8 12 20 24];
radii = [0.8 1.2 2 2.5];
bitsPerSym = log2(sum(M));

x = randi([0 1],2000*bitsPerSym,1);
```

Apply APSK modulation to the data and use a name-value pair to output as data type `single`.

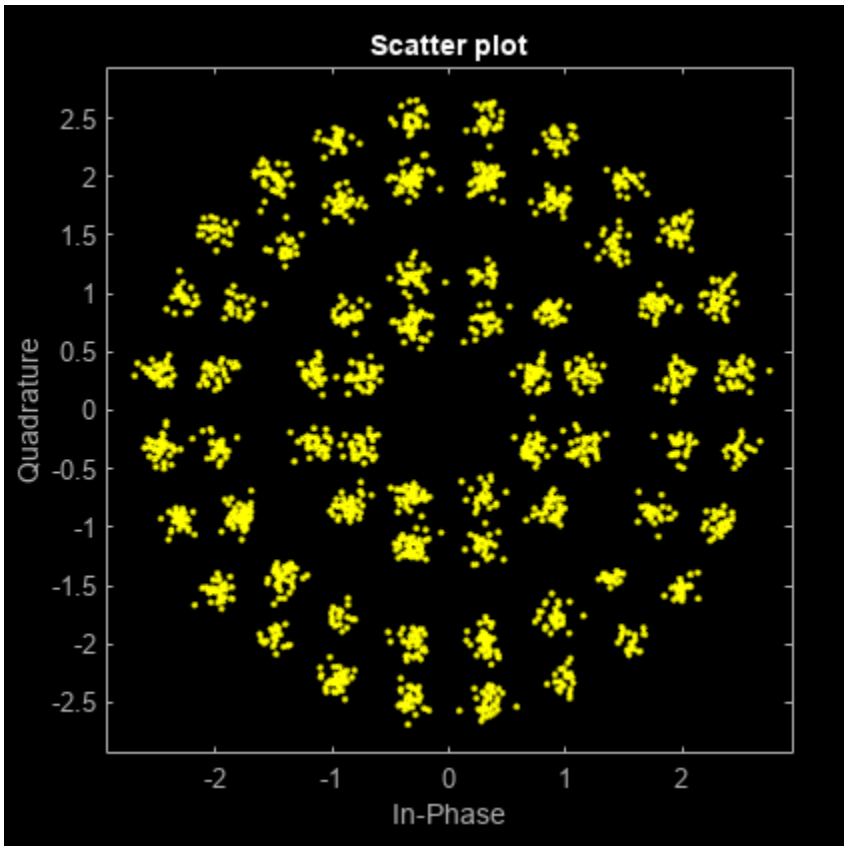
```
y = apskmod(x,M,radii,'InputType','bit','OutputDataType','single');
```

Pass through an AWGN channel with a 25 dB SNR.

```
yrec = awgn(y,25,'measured');
```

Plot the received constellation as a scatter plot.

```
scatterplot(yrec)
```



Input Arguments

x — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix. The elements of x must be binary values or integers in the range [0, (`sum(M)-1`)].

Note To process the input signal as binary elements, set the '`InputType`' name-value pair to `'bit'`. For binary inputs, the number of rows must be an integer multiple of $\log_2(\text{sum}(M))$. Groups of $\log_2(\text{sum}(M))$ bits in a column are mapped onto a symbol, with the first bit representing the MSB and the last bit representing the LSB.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

M — Constellation points per PSK ring

vector

Constellation points per PSK ring, specified as a vector with more than one element. Each vector element indicates the number of constellation points in its corresponding PSK ring. The first element corresponds to the innermost circle, and so on, until the last element, which corresponds to the outermost circle. Element values must be multiples of four and `sum(M)` must be a power of two. The

modulation order is the total number of points in the signal constellation and equals the sum of the vector elements, `sum(M)`.

Example: `[4 12 16]` specifies a three PSK ring constellation with a modulation order of `sum(M) = 32`.

Data Types: `double`

`radii` — Radius per PSK ring

vector

Radius per PSK ring, specified as a vector with the same length as `M`. The first element corresponds to the innermost circle, and so on, until the last element, which corresponds to the outermost circle. The elements must be positive and arranged in increasing order.

Example: `[0.5 1 2]` defines radii for three constellation PSK rings. The inner ring has a radius of 0.5, the second ring has a radius of 1.0, and the outer ring has a radius of 2.0.

Data Types: `double`

`phaseoffset` — Phase offset per PSK ring

`[pi/M(1) pi/M(2) … pi/M(end)]` (default) | scalar | vector

Phase offset per PSK ring in radians, specified as a scalar or vector with the same length as `M`. The first element corresponds to the innermost circle, and so on, until the last element, which corresponds to the outermost circle. The `phaseoffset` can be a scalar only if all the elements of `M` are the same value.

Example: `[pi/4 pi/12 pi/16]` defines three constellation PSK ring phase offsets. The inner ring has a phase offset of pi/4, the second ring has a phase offset of pi/12, and the outer ring has a phase offset of pi/16.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `y = apskmod(x,M,radii,'InputType','bit','OutputDataType','single');`

`SymbolMapping` — Symbol mapping

`'gray'` | `'contourwise-gray'` | integer vector

Symbol mapping, specified as the comma-separated pair consisting of `'SymbolMapping'` and one of the following:

- `'contourwise-gray'` — Uses Gray mapping along the contour in the phase dimension for each PSK ring.
- `'gray'` — Uses Gray mapping along the contour in both the amplitude and phase dimensions. For Gray symbol mapping, all the values for `M` must be equal and all the values for `phaseoffset` must be equal. For a description of the Gray mapping used, see [2].
- integer vector — Use custom symbol mapping. Vector must consist of `sum(M)` unique elements with values in the range [0, (`sum(M)-1`]. The first element corresponds to the constellation point

in the first quadrant of the innermost circle, with subsequent elements positioned counterclockwise around the PSK rings.

The default symbol mapping depends on `M` and `phaseOffset`. When all the elements of `M` are equal and all the elements of `phaseOffset` are equal, the default is `'gray'`. For all other cases, the default is `'contourwise-gray'`.

Data Types: `double` | `char` | `string`

`InputType` — Input type
`'integer'` (default) | `'bit'`

Input type, specified as the comma-separated pair consisting of `'InputType'` and either of these options:

- `'integer'` –– The input signal must consist of integers in the range [0, (`sum(M)` – 1)].
- `'bit'` –– The input signal must contain binary values, and the number of rows must be an integer multiple of $\log_2(\text{sum}(M))$. Binary input signals are assumed to be left-MSB aligned and specified column-wise. Groups of $\log_2(\text{sum}(M))$ bits in a column are mapped onto a symbol, with the first bit representing the MSB and the last bit representing the LSB.

Data Types: `char` | `string`

`OutputDataType` — Output data type
`'double'` (default) | `'single'`

Output data type, specified as the comma-separated pair consisting of `'OutputDataType'` and either `'double'` or `'single'`.

Data Types: `char` | `string`

`PlotConstellation` — Plot reference constellation
`false` (default) | `true`

Plot reference constellation, specified as the comma-separated pair consisting of `'PlotConstellation'` and a logical scalar. To plot the reference constellation, set `PlotConstellation` to `true`.

Data Types: `logical`

Output Arguments

`y` — APSK modulated signal
scalar | vector | matrix

APSK modulated signal, returned as a complex scalar, vector, or matrix. The dimensions of `y` depend on the specified `'InputType'` value.

`InputType`	Dimensions of `y`
`'integer'`	`y` has the same dimensions as input `x`.
`'bit'`	The number of rows in `y` equals the number of rows in `x` divided by $\log_2(\text{sum}(M))$.

Algorithms

The function implements a pure APSK constellation.

A pure M-APSK constellation is composed of N_C concentric rings or contours, each with uniformly spaced PSK points. The M-APSK constellation set is

$$\chi = \begin{cases} R_1 \exp\left(j\left(\frac{2\pi}{M_1} i + \phi_1\right)\right), & i = 0, \ldots, M_1 - 1, \\ R_2 \exp\left(j\left(\frac{2\pi}{M_2} i + \phi_2\right)\right), & i = 0, \ldots, M_2 - 1, \\ \vdots & \vdots \\ R_{N_C} \exp\left(j\left(\frac{2\pi}{M_{N_C}} i + \phi_{\mathrm{Nc}}\right)\right), & i = 0, \ldots, M_{N_C} - 1, \end{cases}$$

where:

- The modulation order is equal to the sum of all M_l for $l = 1, 2, \ldots, N_C$.
- N_C is the number of concentric rings. $N_C \geq 2$.
- M_l is the number of constellation points in the lth ring.
- R_l is the radius of the lth ring.
- ϕ_l is the phase offset of the lth ring.
- $j = \sqrt{-1}$

arithdeco

Decode binary code by arithmetic decoding

Syntax

```
dseq = arithdeco(code,counts,len)
```

Description

`dseq = arithdeco(code,counts,len)` decodes the binary arithmetic code in `code` to recover the corresponding sequence of `len` symbols. The input `counts`specifies the statistics of the source by listing the number of times each symbol of the source alphabet occurs in a test data set. `code` must be an output of the `arithenco` function.

Examples

Decode Sequence Using Arithmetic Code

Using a source with a two-symbol alphabet, produce a test data set in which 99% of the symbols are 1s. Encode 1000 symbols from this source to produce a code vector with less than 1000 elements. The actual number of elements in the encoded sequence varies depending on the particular random sequence.

Specify for symbol 1 from the source alphabet to occur 99 times in the test data set.

```
counts = [99 1];
```

Generate a random sequence of length 1000.

```
len = 1000;
seq = randsrc(1,len,[1 2; .99 .01]);
```

Encode the random sequence. Then, decode the encoded sequence.

```
code = arithenco(seq,counts);
dseq = arithdeco(code,counts,length(seq));
```

Verify that the decoded sequence matches the original random sequence.

```
isequal(seq,dseq)
```

```
ans = logical
   1
```

Input Arguments

code — Binary arithmetic code

nonnegative binary row vector

Binary arithmetic code, specified as a nonnegative binary row vector. This value must be a binary arithmetic code produced by the `arithenco` function.

Data Types: `double`

`counts` — Statistics of symbols
positive numeric vector

Statistics of symbols, specified as a positive numeric vector. This input specifies the number of times each symbol of the source alphabet occurs in a test data set.

Data Types: `double`

`len` — Length of sequence
positive scalar

Length of the sequence to decode, specified as a positive scalar.

Data Types: `double`

Output Arguments

`dseq` — Decoded arithmetic code
positive numeric row vector

Decoded arithmetic code with a sequence of `len` source symbols, specified as a positive numeric row vector.

Algorithms

The `arithdeco` function uses the algorithm described in [1] .

Version History

Introduced before R2006a

References

arithenco

Encode sequence of symbols by arithmetic encoding

Syntax

```
code = arithenco(seq,counts)
```

Description

`code = arithenco(seq,counts)` generates the binary arithmetic code corresponding to the sequence of symbols specified in `seq`. The input `counts` specifies the statistics of the source by listing the number of times each symbol of the source alphabet occurs in a test data set.

Examples

Encode Data Sequence with Arithmetic Code

Using a source with a two-symbol alphabet, produce a test data set in which 99% of the symbols are 1s. Encode 1000 symbols from this source to produce a code vector with less than 1000 elements. The actual number of elements in the encoded sequence varies depending on the particular random sequence.

Specify for symbol 1 from the source alphabet to occur 99 times in the test data set.

```
counts = [99 1]
```

```
counts = 1×2

    99     1
```

Generate a random sequence of length 1000.

```
len = 1000;
seq = randsrc(1,len,[1 2; .99 .01]);
```

Encode the random sequence and display the encoded length.

```
code = arithenco(seq,counts);
s = size(code)
```

```
s = 1×2

     1    57
```

Input Arguments

seq — Sequence of symbols

positive numeric row vector

Sequence of symbols, specified as a positive numeric row vector. This input specifies the random sequence for the function to encode.

Data Types: `double`

`counts` — Statistics of symbols
positive numeric row vector

Statistics of symbols, specified as a positive numeric row vector. This input specifies the number of times each symbol of the source alphabet occurs in a test data set.

Data Types: `double`

Output Arguments

`code` — Generated binary arithmetic code
nonnegative binary row vector

Generated binary arithmetic code corresponding to the sequence of source symbols, returned as a nonnegative binary row vector.

Algorithms

The `arithenco` function uses the algorithm described in [1].

Version History

Introduced before R2006a

awgn

Add white Gaussian noise to signal

Syntax

```
y = awgn(x,snr)
y = awgn(x,snr,signalpower)

y = awgn(x,snr,signalpower,randobject)
y = awgn(x,snr,signalpower,seed)
y = awgn( ___ ,powertype)

[y,var] = awgn( ___ )
```

Description

`y = awgn(x,snr)` adds white Gaussian noise to the vector signal `x`. This syntax assumes that the power of `x` is 0 dBW. For more information about additive white Gaussian noise, see “What is AWGN?” on page 2-45

`y = awgn(x,snr,signalpower)` accepts an input signal power value in dBW. To measure the power of `x` before adding noise, specify `signalpower` as `'measured'`. The `'measured'` option does not generate the requested average SNR for repeated `awgn` function calls in a loop if the input signal power varies over time due to fading and the coherence time of the channel is larger than the input duration.

`y = awgn(x,snr,signalpower,randobject)` additionally accepts a random number stream object to generate normal random noise samples. For information about producing repeatable noise samples, see “Tips” on page 2-45.

`y = awgn(x,snr,signalpower,seed)` specifies a seed value for initializing the normal random number generator that is used to add white Gaussian noise to the input signal.

`y = awgn( ___ ,powertype)` specifies the signal and noise power type as `'dB'` or `'linear'` in addition to the input arguments in any of the previous syntaxes. For information on the relationships between SNR and other measures of the relative power of the noise, such as E_s/N_0, and E_b/N_0, see “AWGN Channel Noise Level”.

`[y,var] = awgn( ___ )` also returns the total noise variance used to produce random noise samples.

Examples

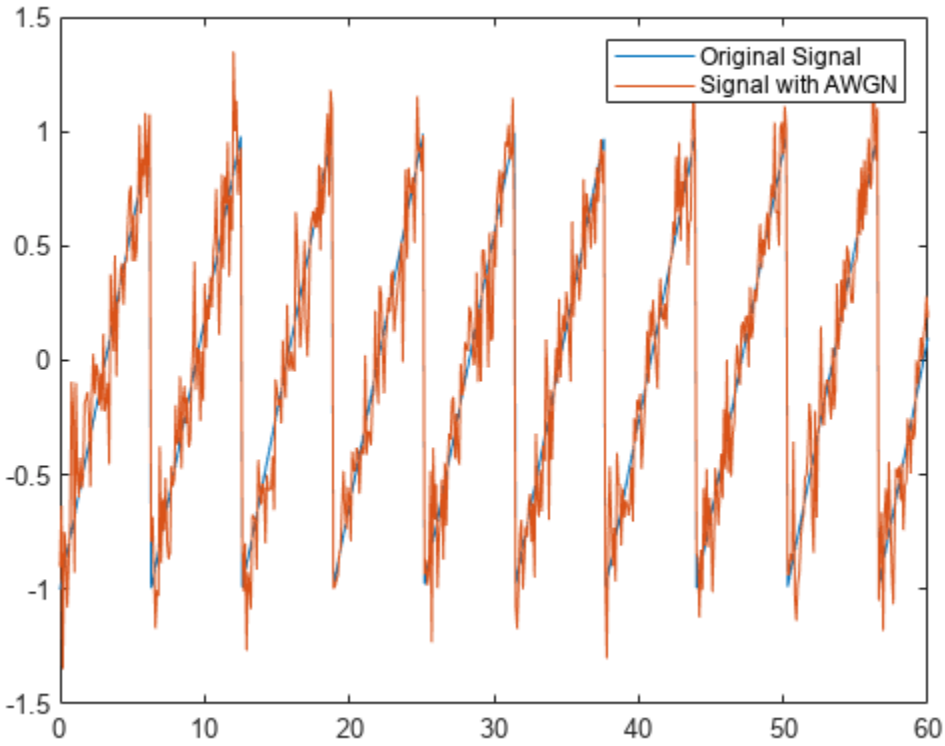
Add AWGN to Sawtooth Signal

Create a sawtooth wave.

```
t = (0:0.1:60)';
x = sawtooth(t);
```

Add white Gaussian noise and plot the results.

```
y = awgn(x,10,'measured');
plot(t,[x y])
legend('Original Signal','Signal with AWGN')
```



Estimate Symbol Rate for General QAM Modulation in AWGN Channel

Transmit and receive data using a nonrectangular 16-ary constellation in the presence of Gaussian noise. Show the scatter plot of the noisy constellation and estimate the symbol error rate (SER) for two different SNRs.

Create a 16-QAM constellation based on the V.29 standard for telephone-line modems.

```
c = [-5 -5i 5 5i -3 -3-3i -3i 3-3i 3 3+3i 3i -3+3i -1 -1i 1 1i];
sigpower = pow2db(mean(abs(c).^2));
M = length(c);
```

Generate random symbols.

```
data = randi([0 M-1],2000,1);
```

Modulate the data by using the `genqammod` function. General QAM modulation is necessary because the custom constellation is not rectangular.

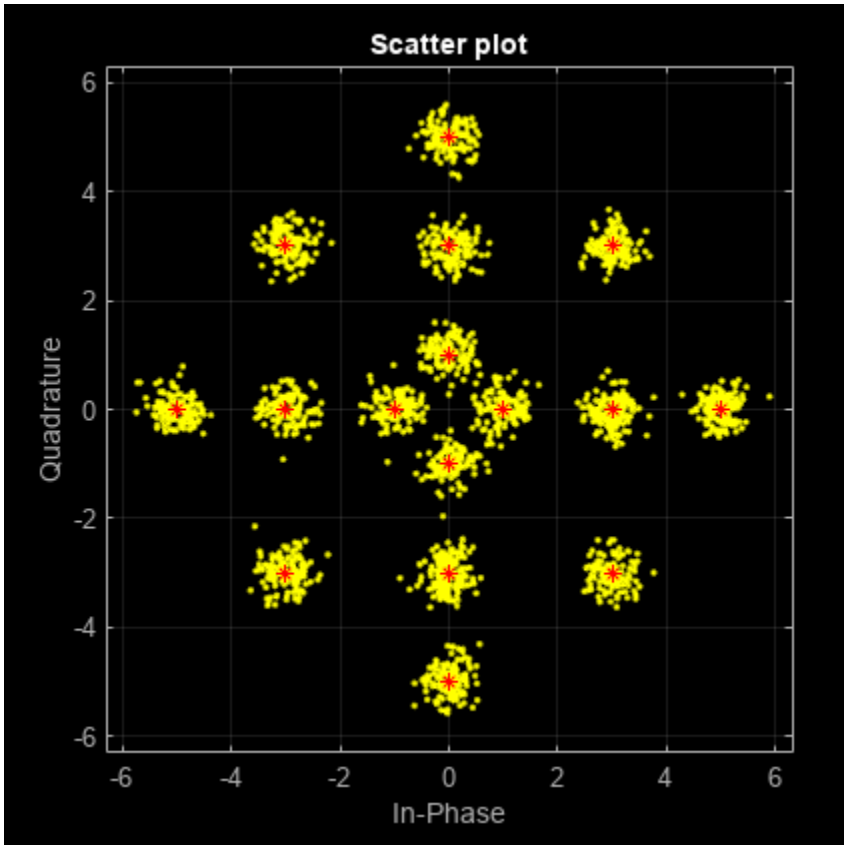
```
modData = genqammod(data,c);
```

Pass the signal through an AWGN channel with a 20 dB SNR.

```
rxSig = awgn(modData,20,sigpower);
```

Display a scatter plot of the received signal and the reference constellation `c`.

```
h = scatterplot(rxSig);
hold on
scatterplot(c,[],[],'r*',h)
grid
hold off
```



Demodulate the received signal by using the `genqamdemod` function. Determine the number of symbol errors and the SER.

```
demodData = genqamdemod(rxSig,c);
[numErrors,ser] = symerr(data,demodData)
```

```
numErrors = 1

ser = 5.0000e-04
```

Repeat the transmission and demodulation process with an AWGN channel with a 10 dB SNR. Determine the SER for the reduced SNR. As expected, the performance degrades when the SNR is decreased.

```
rxSig = awgn(modData,10,sigpower);
demodData = genqamdemod(rxSig,c);
[numErrors,ser] = symerr(data,demodData)

numErrors = 461

ser = 0.2305
```

Repeatable AWGN Simulation

Generate random data symbols and the 4-PSK modulated signal.

```
M = 4;
k = log2(M);
snr = 3;
data = randi([0 M-1],2000,1);
x = pskmod(data,M);
```

Set the random number generator seed.

```
seed = 12345;
```

Generate repeatable random noise using the `rng` function before calling the `awgn` function.

```
rng(seed);
y = awgn(x,snr);
```

Compute the bit errors.

```
dataHat = pskdemod(y,M);
numErr1 = biterr(data,dataHat,k)

numErr1 = 321
```

Reset the random number generator seed.

```
rng(seed);
```

Demodulate the PSK signal and compute the bit errors.

```
y = awgn(x,snr);
dataHat = pskdemod(y,M);
numErr2 = biterr(data,dataHat,k)

numErr2 = 321
```

Compare `numErr1` to `numErr2`. The errors are equal even after you reset the random number generator seed.

```
isequal(numErr1, numErr2)

ans = logical
   1
```

Repeatable AWGN with RandStream

Generate white Gaussian noise addition results using a `RandStream` object and the `reset` object function.

Specify the power of X as `0` dBW, add noise to produce an SNR of `10` dB, and use a local random stream.

```
S = RandStream('mt19937ar','Seed',5489);
sigin = sqrt(2)*sin(0:pi/8:6*pi);
sigout1 = awgn(sigin,10,0,S);
```

Add white Gaussian noise to `sigin`. Use `isequal` to compare `sigout1` to `sigout2`. The outputs are not equal when you do not reset the random stream.

```
sigout2 = awgn(sigin,10,0,S);
isequal(sigout1,sigout2)
```

```
ans = logical
   0
```

Reset the random stream object, returning the object to its state prior to adding AWGN to `sigout1`. Add AWGN to `sigin` and compare `sigout1` to `sigout3`. The outputs are equal when you reset the random stream.

```
reset(S);
sigout3 = awgn(sigin,10,0,S);
isequal(sigout1,sigout3)
```

```
ans = logical
   1
```

Input Arguments

x — Input signal

scalar | vector | array

Input signal, specified as a scalar, vector, or array. The power of the input signal is assumed to be 0 dBW.

Data Types: `double`
Complex Number Support: Yes

`snr` — Signal-to-noise ratio

scalar

Signal-to-noise ratio in dB, specified as a scalar. The function applies the same `snr` value to each channel. The columns of the input signal represent the different channels of a multichannel signal.

Data Types: `double`

`signalpower` — Signal power

scalar | `'measured'`

Signal power in dBW, specified as a scalar or `'measured'`.

- Scalar — The value is used as the signal level of `in` to determine the appropriate noise level based on the value of `snr`.
- `'measured'` — The signal level of `in` is computed to determine the appropriate noise level based on the value of `snr`.

If the input signal is a multichannel signal, the function calculates the `signalpower` value across all channels as a single value. It then uses the value to calculate the noise level for all the channels.

Data Types: `double`

`randobject` — Random number stream object
`RandStream` object

Random number stream object, specified as a `RandStream` object. The state of the random stream object determines the sequence of numbers produced by the `randn` function. Configure the random stream object using the `reset (RandStream)` function and its properties.

For information about producing repeatable noise samples, see “Tips” on page 2-45.

`seed` — Random number generator seed
scalar

Random number generator seed value, specified as a scalar.

Data Types: `double`

`powertype` — Signal power unit
`'dB'` (default) | `'linear'`

Signal power unit, specified as `'dB'` or `'linear'`.

- When `powertype` is `'dB'`, `snr` is measured in dB and `signalpower` is measured in dBW.
- When `powertype` is `'linear'`, the `snr` is measured as a ratio and `signalpower` is measured in watts assuming a reference load of 1 ohms.

To set the `powertype` argument, you must also set `snr` and `signalpower`.

Output Arguments

`y` — Output signal
scalar | vector | array

Output signal, returned as a scalar, vector, or array. The returned output signal is the input signal with added white Gaussian noise.

`var` — Noise variance
scalar

Total noise variance, returned as a positive scalar. The function uses the noise variance to generate random noise samples.

More About

What is AWGN?

Additive white Gaussian noise (AWGN) is a simple noise model that represents electron motion in the RF front end of a receiver. As the name implies, the noise gets added to the signal. The noise is called “white” because it is spectrally flat across the entire sampling bandwidth. Analogously, the color white contains equal spectral power levels at all frequencies of the visible light spectrum. The noise is Gaussian because its amplitude can be modeled with a normal probability distribution.

The AWGN channel is often used to model a satellite communications channel, since that channel typically does not suffer from common terrestrial impairments like fading, multipath, and interference. An AGWN channel serves as a good starting point for the analysis of terrestrial wireless links because it establishes a best-case bound on the bit error rate performance of a terrestrial link.

Tips

- For information on the relationships between SNR and other measures of the relative power of the noise, such as E_s/N_0, and E_b/N_0, see “AWGN Channel Noise Level”.
- To generate repeatable white Gaussian noise samples, do one of the following:
  - Use `rng(seed)` before calling the `awgn` function to generate repeatable random noise.
  - Provide a static `seed` value as an input to `awgn`.
  - Use the `reset (RandStream)` function on the `randobject` before passing it as an input to `awgn`.
  - Provide `randobject` in a known state as an input to `awgn`. For more information, see `RandStream`.

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

Code generation supported, except for syntaxes that include a `RandStream` object.

bchdec

BCH decoder

Syntax

```
decoded = bchdec(code,N,K)
decoded = bchdec(code,N,K,paritypos)
[decoded,cnumerr] = bchdec( ___ )
[decoded,cnumerr,ccode] = bchdec( ___ )
```

Description

`decoded = bchdec(code,N,K)` attempts to decode the received signal in `code` using an (`N`,`K`) BCH decoder with the narrow-sense generator polynomial. Parity symbols are at the end and the leftmost symbol is the most significant symbol.

In the `decoded` Galois field array, each row represents the attempt at decoding the corresponding row in `code`.

`decoded = bchdec(code,N,K,paritypos)` specifies in `paritypos` whether the parity symbols in `code` were appended or prepended to the message in the coding operation.

`[decoded,cnumerr] = bchdec( ___ )` returns a column vector, `cnumerr`, where each element is the number of corrected errors in the corresponding row of `code`. You can return `cnumerr` with either of the preceding syntaxes.

`[decoded,cnumerr,ccode] = bchdec( ___ )` returns `ccode`, the corrected version of `code`.

Examples

Results of Error Correction

BCH-decode an input that has more errors per codeword than the error correcting capability of the BCH decoder. Decode a BCH coded message with two errors per codeword using a single-error correcting BCH decoder. View the effects of the error mismatch on the output codeword.

Check the number of errors per codeword a [63,57] BCH decoder is capable of correcting.

```
n = 63;
k = 57;
t = bchnumerr(n,k)
```

```
t = 1
```

The [63,57] BCH decoder is capable of correcting one error per codeword.

Create a random stream and use it to generate a GF array. Encode the message.

```
s = RandStream('swb2712','Seed',9973);
msg = gf(randi(s,[0 1],1,k));
code = bchenc(msg,n,k);
```

Add two errors per codeword and decode the errored code.

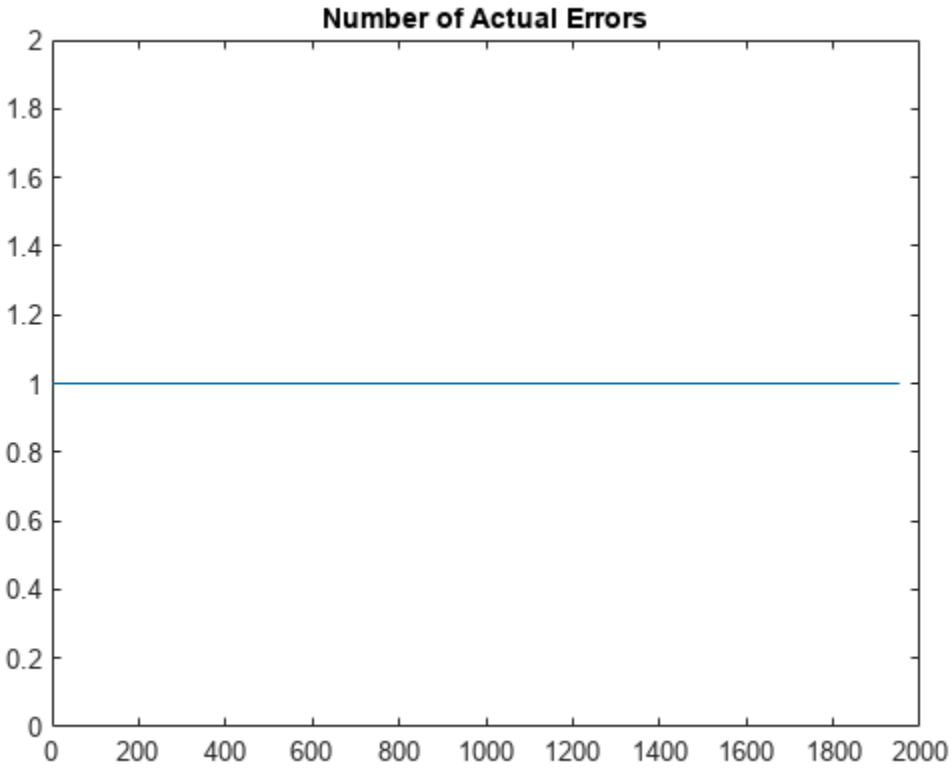
```
cnumerr2 = zeros(nchoosek(n,2),1);
nErrs = zeros(nchoosek(n,2),1);
cnumerrIdx = 1;
for idx1 = 1 : n-1
    %sprintf('idx1 for 2 errors = %d', idx1)
    for idx2 = idx1+1 : n
        errors = zeros(1,n);
        errors(idx1) = 1;
        errors(idx2) = 1;
        erroredCode = code + gf(errors);
        [decoded2, cnumerr2(cnumerrIdx)] ...
          = bchdec(erroredCode,n,k);
```

Encode the decoded message. Check that the re-encoded message differs from the errored message in only one bit.

```
        if cnumerr2(cnumerrIdx) == 1
            code2 = bchenc(decoded2,n,k);
            nErrs(cnumerrIdx) = biterr(double(erroredCode.x), ...
              double(code2.x));
        end
        cnumerrIdx = cnumerrIdx + 1;
    end
end
```

Plot the computed number of errors, based on the difference between the doubly-errored code and the re-encoded version of the initial decoding.

```
plot(nErrs)
title('Number of Actual Errors')
```



All inputs with two errors were decoded to a codeword that differs in exactly one bit from the re-encoded version.

Decode Received BCH Codeword in Noisy Channel

Set the BCH parameters for a Galois array of GF(2).

```
M = 4;
n = 2^M-1;   % Codeword length
k = 5;       % Message length
nwords = 10; % Number of words to encode
```

Create a message.

```
msgTx = gf(randi([0 1],nwords,k));
```

Find the error-correction capability.

```
t = bchnumerr(n,k)
```

```
t = 3
```

Encode the message.

```
enc = bchenc(msgTx,n,k);
```

Corrupt up to `t` bits in each codeword.

```
noisycode = enc + randerr(nwords,n,1:t);
```

Decode the noisy code.

```
msgRx = bchdec(noisycode,n,k);
```

Validate that the message was properly decoded.

```
isequal(msgTx,msgRx)
```

```
ans = logical
   1
```

Increase the number of possible errors, and generate another noisy codeword.

```
t2 = t + 1;
noisycode2 = enc + randerr(nwords,n,1:t2);
```

Decode the new received codeword.

```
[msgRx2,numerr] = bchdec(noisycode2,n,k);
```

Determine if the message was properly decoded by examining the number of corrected errors, `numerr`. Entries of `-1` correspond to decoding failures, which occur when the codeword has more errors than can be corrected for the specified `[n,k]` pair.

```
numerr
```

```
numerr = 10×1

     1
     2
    -1
     2
     3
     1
    -1
     4
     2
     3
```

Two of the ten transmitted codewords were not correctly received.

Input Arguments

code — Encoded message

Galois field array

Encoded message, specified as a Galois field array of symbols over GF(2). Each `N`-element row of `code` represents a corrupted systematic codeword.

For more information, see “Creating a Galois field array”.

N — Codeword length

integer

Codeword length, specified as an integer of the form $N = 2^M–1$, where M is an integer from 3 to 16. See “Tips” on page 2-52 for information about valid N values, valid (N,K) pairs, and error correcting capabilities for a given BCH code.

Example: 15 for M=4

K — Message length

integer

Message length, specified as an integer. N and K must produce a narrow-sense BCH code.

Example: 5 specifies a Galois field array with five elements.

paritypos — Parity position

'end' (default) | 'beginning'

Parity position, specified as 'end' or 'beginning'. Parity symbols are at the end or beginning of each word in the output Galois field array. If paritypos is 'beginning', then a decoding failure causes bchdec to remove N-K symbols from the beginning rather than the end of the row.

Output Arguments

decoded — Decoded message

Galois field array of symbols over GF(2)

Decoded message, returned as a Galois field array of symbols over GF(2). Each row represents the attempt at decoding the corresponding row in code. A decoding failure occurs if bchdec detects more than T errors in a row of code, where T is the number of errors per codeword that the decoder is capable of correcting. When a decoding failure occurs, bchdec forms the corresponding row of decoded by removing N-K symbols from the end of the row of code. For more information, see “Error Correcting Capability” on page 2-51.

cnumerr — Number of corrected errors

column vector

Number of corrected errors in the corresponding row of code, returned as a column vector. A value of –1 in cnumerr indicates a decoding failure in that row in code.

ccode — Corrected version of code

Galois field array

Corrected version of code, returned as a Galois field array. ccode has the same format as the input code. If a decoding failure occurs in a certain row of code, the corresponding row in ccode contains that row unchanged.

More About

Error Correcting Capability

BCH decoders correct up to a specified number of errors per codeword based on the (N,K) pair used to BCH encode that message. The error correcting capability, T, of a given (N,K) pair is returned by

`bchnumerr`. See “Tips” on page 2-52 for information about valid `N` values, valid (`N`,`K`) pairs, and error correcting capabilities for a given BCH code.

If the coded message contains more errors per codeword than the decoder is capable of correcting, the decoder is unlikely to decode to the correct codeword. For example, when a single-error-correcting BCH decoder (T=1) is given an input with two errors per codeword, it decodes it to a valid codeword but not the correct codeword. When a double-error-correcting BCH decoder (T=2) is given an input with three errors per codeword, the decoder sometimes decodes to an invalid codeword. The `cnumerr` and `ccode` output provide feedback to analyze the correctness of the decoded message.

Tips

- To generate the list of valid (`N`,`K`) pairs along with the corresponding values of the error-correction capability, run `bchnumerr(N)`.
- Valid values for `N` = 2^M–1, where M is an integer from 3 through 16. The maximum allowable value of `N` is 65,535.

Algorithms

`bchdec` uses the Berlekamp-Massey decoding algorithm. For information about this algorithm, see the works listed in “References” on page 2-52.

bchenc

BCH encoder

Syntax

```
code = bchenc(msg,N,K)
code = bchenc(msg,N,K,paritypos)
```

Description

`code = bchenc(msg,N,K)` encodes the input message using an (`N`,`K`) BCH encoder that uses a narrow-sense generator polynomial. For a description of Bose–Chaudhuri–Hocquenghem (BCH) coding, see [1].

`code = bchenc(msg,N,K,paritypos)` appends or prepends the parity symbols to the encoded input message to form the output.

Examples

Decode Received BCH Codeword in Noisy Channel

Set the BCH parameters for a Galois array of GF(2).

```
M = 4;
n = 2^M-1;   % Codeword length
k = 5;       % Message length
nwords = 10; % Number of words to encode
```

Create a message.

```
msgTx = gf(randi([0 1],nwords,k));
```

Find the error-correction capability.

```
t = bchnumerr(n,k)
```

```
t = 3
```

Encode the message.

```
enc = bchenc(msgTx,n,k);
```

Corrupt up to `t` bits in each codeword.

```
noisycode = enc + randerr(nwords,n,1:t);
```

Decode the noisy code.

```
msgRx = bchdec(noisycode,n,k);
```

Validate that the message was properly decoded.

```
isequal(msgTx,msgRx)
```

```
ans = logical
   1
```

Increase the number of possible errors, and generate another noisy codeword.

```
t2 = t + 1;
noisycode2 = enc + randerr(nwords,n,1:t2);
```

Decode the new received codeword.

```
[msgRx2,numerr] = bchdec(noisycode2,n,k);
```

Determine if the message was properly decoded by examining the number of corrected errors, `numerr`. Entries of `-1` correspond to decoding failures, which occur when the codeword has more errors than can be corrected for the specified `[n,k]` pair.

```
numerr
```

```
numerr = 10×1

     1
     2
    -1
     2
     3
     1
    -1
     4
     2
     3
```

Two of the ten transmitted codewords were not correctly received.

Input Arguments

`msg` — Message to encode

Galois field array of symbols over GF(2)

Message to encode, specified as a Galois field array of symbols over GF(2). Each K-element row of `msg` represents a message word, where the leftmost symbol is the most significant symbol.

For more information, see “Creating a Galois field array”.

Example: `msgTx = gf(randi([0 1],10,5))`, where `msgTx` is a 10-by-5 `gf array`.

`N` — Codeword length

integer

Codeword length, specified as an integer of the form `N` = 2^M–1, where M is an integer from 3 through 16. For more information, see “Tips” on page 2-55.

Example: 15 for M=4

K — Message length
integer

Message length, specified as an integer. `N` and `K` must produce a narrow-sense BCH code.

Example: 5 specifies a Galois array with five elements

paritypos — Parity position
`'end'` (default) | `'beginning'`

Parity position, specified as `'end'` or `'beginning'`. Parity symbols are at the end or beginning of each word in the output Galois array.

Output Arguments

code — Encoded message
Galois field array

Encoded message, returned as a Galois field array. Parity symbols are at the end or beginning of each word in the output Galois array. To specify the position of the parity symbols, use the `paritypos` argument.

Tips

- To generate the list of valid (`N`,`K`) pairs along with the corresponding values of the error-correction capability, run `bchnumerr(N)`.
- Valid values for `N` = 2^M–1, where M is an integer from 3 through 16. The maximum allowable value of `N` is 65,535.

bchgenpoly

Generator polynomial of BCH code

Syntax

```
genpoly = bchgenpoly(n,k)
genpoly = bchgenpoly(n,k,prim_poly)
genpoly = bchgenpoly(n,k,prim_poly,outputFormat)
[genpoly,t] = bchgenpoly(...)
```

Description

`genpoly = bchgenpoly(n,k)` returns the narrow-sense generator polynomial of a BCH code with codeword length `n` and message length `k`. The codeword length `n` must have the form 2^m-1 for some integer m between 3 and 16. The output `genpoly` is a Galois row vector that represents the coefficients of the generator polynomial in order of descending powers. The narrow-sense generator polynomial is LCM[m_1(x), m_2(x), ..., m_2t(x)], where:

- LCM represents the least common multiple,
- m_i(x) represents the minimum polynomial corresponding to α^i, α is a root of the default primitive polynomial for the field GF(`n+1`),
- and t represents the error-correcting capability of the code.

Note Although the `bchgenpoly` function performs intermediate computations in GF(`n+1`), the final polynomial has binary coefficients. The output from `bchgenpoly` is a Galois vector in GF(2) rather than in GF(`n+1`).

`genpoly = bchgenpoly(n,k,prim_poly)` is the same as the syntax above, except that `prim_poly` specifies the primitive polynomial for GF(`n+1`) that has Alpha as a root. `prim_poly` is either a polynomial character vector or an integer whose binary representation indicates the coefficients of the primitive polynomial in order of descending powers. To use the default primitive polynomial for GF(`n+1`), set `prim_poly` to `[]`.

`genpoly = bchgenpoly(n,k,prim_poly,outputFormat)` is the same as the previous syntax, except that `outputFormat` specifies output data type. The value of `outputFormat` can be '`gf`' or '`double`' corresponding to Galois field and double data types respectively. The default value of `outputFormat` is '`gf`'.

`[genpoly,t] = bchgenpoly(...)` returns `t`, the error-correction capability of the code.

Examples

Create a BCH Generator Polynomial

Create two BCH generator polynomials based on different primitive polynomials.

Set the codeword and message lengths, `n` and `k`.

```
n = 15;
k = 11;
```

Create the generator polynomial and return the error correction capability, `t`.

```
[genpoly,t] = bchgenpoly(15,11)
```

```
genpoly = GF(2) array.

Array elements =

   1   0   0   1   1

t = 1
```

Create a generator polynomial for a (15,11) BCH code using a different primitive polynomial expressed as a character vector. Note that `genpoly2` differs from `genpoly`, which uses the default primitive.

```
genpoly2 = bchgenpoly(15,11,'D^4 + D^3 + 1')
```

```
genpoly2 = GF(2) array.

Array elements =

   1   1   0   0   1
```

Limitations

The maximum allowable value of `n` is 65535.

Version History

Introduced before R2006a

bchnumerr

Number of correctable errors for BCH code

Syntax

```
T = bchnumerr(N)
T = bchnumerr(N, K)
```

Description

`T = bchnumerr(N)` returns all the possible combinations of message length, `K`, and number of correctable errors, `T`, for a BCH code of codeword length, `N`.

`T = bchnumerr(N, K)` returns the number of correctable errors, `T`, for an `(N, K)` BCH code.

Examples

Determine Message Length Combinations for BCH Code

Calculate the possible message length combinations for a BCH code word length of `15`.

```
T = bchnumerr(15)
```

```
T = 3×3

    15    11     1
    15     7     2
    15     5     3
```

Compute the Correctable Errors for BCH Code

Calculate the number of correctable errors for BCH code `15,11`

```
T = bchnumerr(15,11)
```

```
T = 1
```

Input Arguments

`N` — Codeword length

integer scalar

Codeword length, specified as an integer scalar. `N` must have the form 2^m-1 for some integer, m, between 3 and 16.

Example: 15

Data Types: `double`

K — Message length
integer scalar

Message length, specified as an integer scalar. `N` and `K` must produce a narrow-sense BCH code.

Example: 11

Data Types: `double`

Output Arguments

T — Number of correctable errors
scalar or matrix

Number of correctable errors, returned as a scalar or matrix value.

`bchnumerr(N)` returns a matrix with three columns. The first column lists `N`, the second column lists `K`, and the third column lists `T`.

`bchnumerr(N,K)` returns a scalar, which represents the number of correctable errors for the BCH code.

berawgn

BER and SER for uncoded data over AWGN channels

Syntax

```
ber = berawgn(EbNo,modtype,M)

ber = berawgn(EbNo,'psk',M,dataenc)
ber = berawgn(EbNo,'oqpsk',dataenc)

ber = berawgn(EbNo,'fsk',M,coherence)
ber = berawgn(EbNo,'fsk',M,coherence,rho)

ber = berawgn(EbNo,'msk',precoding)
ber = berawgn(EbNo,'msk',precoding,coherence)

ber = berawgn(EbNo,'cpfsk',M,modindex,kmin)

[ber,ser] = berawgn( ___ )
```

Description

The `berawgn` function returns the bit error rate (BER) and symbol error rate (SER) in an additive white Gaussian noise (AWGN) channel for uncoded data using various modulation schemes. The first input argument, `EbNo`, is the ratio of bit energy to noise power spectral density in dB (E_b/N_0). Values in the output `ber` and `ser` vectors correspond to the theoretical error rate at the specified E_b/N_0 levels for a Gray-coded signal constellation. For more information, see “Analytical Expressions Used in berawgn Function and Bit Error Rate Analysis App”.

`ber = berawgn(EbNo,modtype,M)` returns the BER of uncoded data over an AWGN channel at the specified E_b/N_0 levels for the modulation type and modulation order specified by `modtype` and `M`, respectively.

`ber = berawgn(EbNo,'psk',M,dataenc)` specifies the data encoding type as differential or nondifferential for PSK modulation.

`ber = berawgn(EbNo,'oqpsk',dataenc)` specifies the data encoding type as differential or nondifferential for OQPSK modulation.

`ber = berawgn(EbNo,'fsk',M,coherence)` specifies the receiver technique as coherent or noncoherent for FSK modulation.

`ber = berawgn(EbNo,'fsk',M,coherence,rho)` additionally specifies the complex correlation coefficient of the FSK-modulated signal.

`ber = berawgn(EbNo,'msk',precoding)` specifies whether precoding is applied for MSK modulation.

`ber = berawgn(EbNo,'msk',precoding,coherence)` additionally specifies the receiver technique as coherent or noncoherent for MSK modulation.

`ber = berawgn(EbNo,'cpfsk',M,modindex,kmin)` specifies the modulation index, `modindex`, and the number of paths having the minimum distance, `kmin`, for CPFSK modulation.

`[ber,ser] = berawgn( ___ )` returns the BER and symbol error rate (SER) using any input argument combination from previous syntaxes.

Examples

Return Theoretical BER Data for AWGN Channels

Return theoretical bit error rate data for several modulation schemes in an AWGN channel.

Create a vector of E_b/N_0 values and specify the modulation order.

```
EbNo = (0:10)';
M = 4; % Modulation order
```

Return theoretical BER data for QPSK modulation.

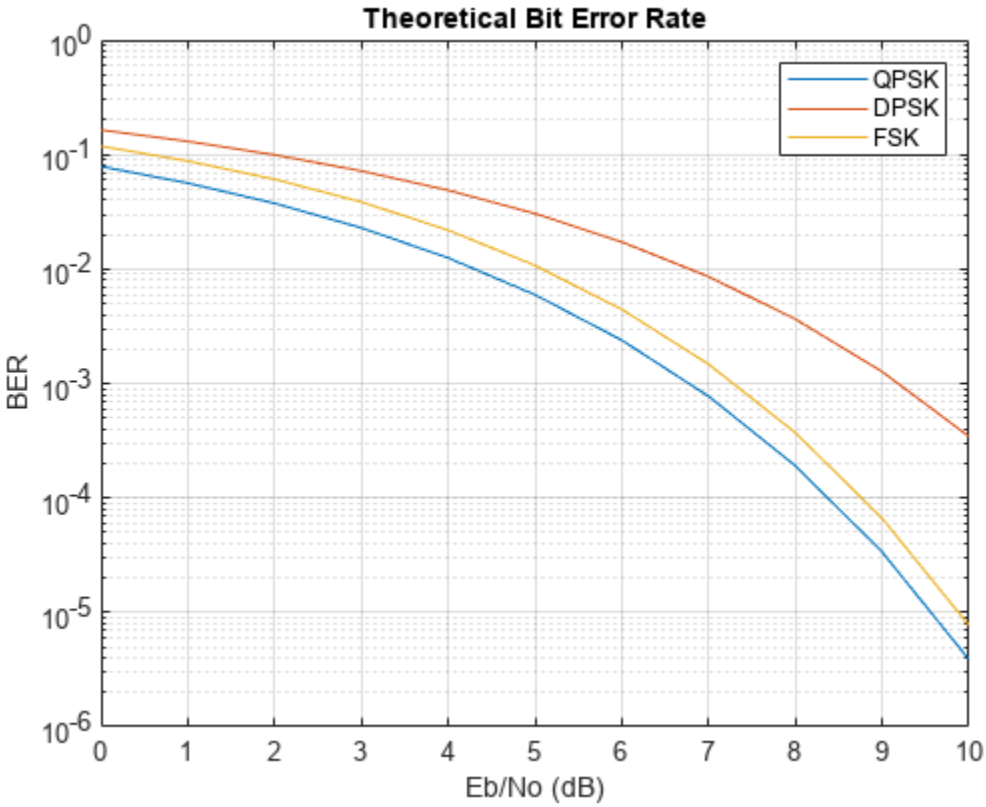
```
berQ = berawgn(EbNo,'psk',M,'nondiff');
```

Return equivalent data for DPSK and FSK modulations.

```
berD = berawgn(EbNo,'dpsk',M);
berF = berawgn(EbNo,'fsk',M,'coherent');
```

Plot the results.

```
semilogy(EbNo,[berQ berD berF])
xlabel('Eb/No (dB)')
ylabel('BER')
legend('QPSK','DPSK','FSK')
title("Theoretical Bit Error Rate")
grid
```



Input Arguments

EbNo — Energy per bit to noise power spectral density ratio

scalar | vector

Energy per bit to noise power spectral density ratio in dB, specified as a scalar or vector.

Data Types: `single` | `double`

modtype — Modulation type

`'psk'` | `'oqpsk'` | `'dpsk'` | ...

Modulation type, specified as one of these options.

modtype Value	Modulation Scheme	Dependencies
`'psk'`	Phase shift keying (PSK)	When you set the input `dataenc` to `'diff'`, modulation order `M` must be 2 or 4.
`'oqpsk'`	Offset quadrature phase shift keying (OQPSK)	None
`'dpsk'`	Differential phase shift keying (DPSK)	None

modtype Value	Modulation Scheme	Dependencies
'pam'	Pulse amplitude modulation (PAM)	None
'qam'	Quadrature amplitude modulation (QAM)	The modulation order M must be at least 4. • When $k = log_2$M is odd, the symbols lie in a rectangular constellation of size M = $I \times J$, where$I = 2^{\frac{k-1}{2}}$ and $J = 2^{\frac{k+1}{2}}$. • When k is even, the symbols lie in a square constellation of size$2^{\frac{k}{2}} \times 2^{\frac{k}{2}}$
'fsk'	Frequency-shift keying (FSK)	When you set the input coherence to 'noncoherent', modulation order M must be in the range [2, 64].
'msk'	Minimum-shift keying (MSK)	None
'cpfsk'	Continuous-phase frequency-shift keying (CPFSK)	None

Data Types: char | string

M — Modulation order

2^k

Modulation order, specified as an integer equal to 2^k, where k is a positive integer.

Example: 4 or 2^2

Data Types: single | double

dataenc — Data encoding type

'diff' | 'nondiff'

Data encoding type, specified as one of these values.

- 'diff' — For differential data encoding
- 'nondiff' — For nondifferential data encoding

Dependencies

To enable this argument, set the modtype argument to 'psk' or 'oqpsk'.

Data Types: char | string

coherence — Coherent detection type

'conherent' | 'noncoherent'

Coherent detection type, specified as one of these values.

- `'conherent'` — For coherent detection
- `'noncoherent'` — For noncoherent detection

Dependencies

To enable this argument, set the `modtype` argument to `'fsk'` or `'msk'`.

Data Types: `char` | `string`

`rho` — Complex correlation coefficient

complex scalar

Complex correlation coefficient, specified as a complex scalar. For more information about the complex correlation coefficient and how to compute it for nonorthogonal binary frequency-shift keying (BFSK) modulation, see “Nonorthogonal 2-FSK with Coherent Detection”.

Dependencies

To enable this argument, set the `modtype` argument to `'fsk'` and the `M` argument to `2`.

Data Types: `single` | `double`
Complex Number Support: Yes

`precoding` — Enable precoding

`'off'` | `'on'`

Enable precoding, specified as one of these values.

- `'off'` — For conventional MSK
- `'on'` — For precoded MSK

Dependencies

To enable this argument, set the `modtype` argument to `'msk'`.

Data Types: `char` | `string`

`modindex` — Modulation index

positive integer

Modulation index, specified as a positive integer.

Dependencies

To enable this argument, set the `modtype` argument to `'cpfsk'`.

Data Types: `single` | `double`

`kmin` — Number of paths having minimum distance

positive integer

Number of paths having the minimum distance, specified as a positive integer. If the number of paths is unknown, specify a value of 1.

Dependencies

To enable this argument, set the `modtype` argument to `'cpfsk'`.

Data Types: `single` | `double`

Output Arguments

`ber` — Bit error rate

scalar | vector

Bit error rate (BER) for uncoded data over an AWGN channel, returned as a scalar or vector. The BER is computed for each E_b/N_0 setting specified by input `EbNo` according to the modulation type specified by input `modtype` and related dependencies.

Data Types: `double`

`ser` — Symbol error rate

scalar | vector

Symbol error rate (SER) for uncoded data over an AWGN channel, returned as a scalar or vector. The SER is computed for each E_b/N_0 setting specified by input `EbNo` according to the modulation type specified by input `modtype` and related dependencies.

Data Types: `double`

Limitations

The numerical accuracy of the output returned by this function is limited by approximations related to the numerical implementation of the expressions to roughly two significant digits.

Alternatives

You can configure the **Theoretical** tab in the **Bit Error Rate Analysis** app to compute theoretical BER values instead of using the `berawgn` function.

bercoding

BER for coded AWGN channels

Syntax

```
ber = bercoding(EbNo,'conv',decision,coderate,dspec)

ber = bercoding(EbNo,'block',decision,N,K,dmin)
ber = bercoding(EbNo,'Golay','hard',24)

ber = bercoding(EbNo,'Hamming','hard',N)
ber = bercoding(EbNo,'RS','hard',N,K)
ber = bercoding(EbNo,coding,___,modulation)
```

Description

The `bercoding` function returns an upper bound or approximation of the bit error rate (BER) for coherent BPSK or QPSK modulation over an additive white Gaussian noise (AWGN) channel for a specified coding type, decoding decision, code rate, and distance spectrum of the code. The results for binary PSK and quadrature PSK modulation are the same. This function computes only modulation order 2 or 4 for *M*-ary PSK modulation. For more information, see “Analytical Expressions Used in bercoding Function and Bit Error Rate Analysis App”.

`ber = bercoding(EbNo,'conv',decision,coderate,dspec)` returns an upper bound or approximation of the BER for the convolutionally coded signal with the specified decoding decision, code rate, and distance spectrum of the code.

`ber = bercoding(EbNo,'block',decision,N,K,dmin)` returns the upper bound of the BER for an [`N`,`K`] binary block code for the specified decoding decision type and minimum distance of the code.

`ber = bercoding(EbNo,'Golay','hard',24)` returns the upper bound of the BER for an the extended (24, 12) Golay code using hard-decision decoding and coherent BPSK modulation. In accordance with [3], the Golay coding upper bound assumes only the correction of 3-error patterns. Even though correcting approximately 19% of 4-error patterns is theoretically possible in practice, most decoders do not have this capability.

`ber = bercoding(EbNo,'Hamming','hard',N)` returns an approximation of the BER for a Hamming code using hard-decision decoding and coherent BPSK modulation.

`ber = bercoding(EbNo,'RS','hard',N,K)` returns an approximation of the BER for an (`N`,`K`) Reed-Solomon code using hard-decision decoding and coherent BPSK modulation.

`ber = bercoding(EbNo,coding,___,modulation)` specifies a modulation type in addition to any of the previous input argument combinations. This syntax returns an approximation of the BER for coded AWGN channels.

Examples

Find Upper Bound of Theoretical BER for Block Code

Find the upper bound of the theoretical BER for a (23,12) block code.

Set the codeword length, message length, minimum distance, and E_b/N_0 range in dB.

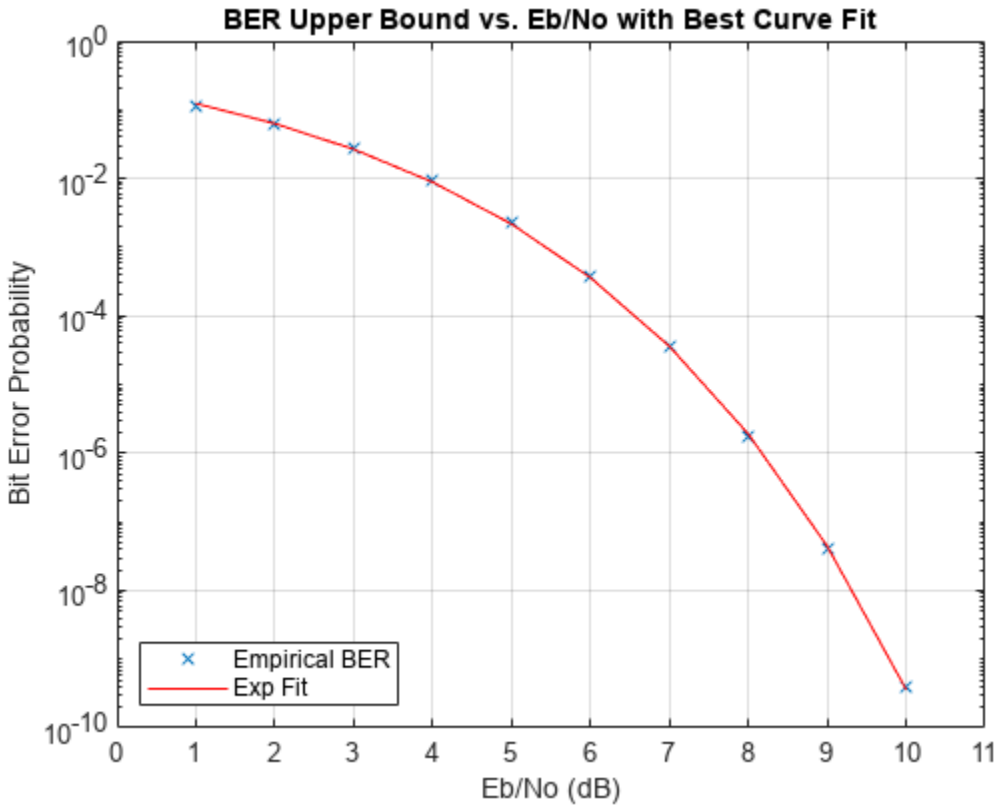
```
n = 23;              % Codeword length
k = 12;              % Message length
dmin = 7;            % Minimum distance
EbNo = 1:10;         % Eb/No range (dB)
```

Estimate the BER.

```
berBlk = bercoding(EbNo,'block','hard',n,k,dmin);
```

Plot the estimated BER.

```
berfit(EbNo,berBlk)
ylabel('Bit Error Probability')
title('BER Upper Bound vs. Eb/No with Best Curve Fit')
```



Estimate Coded BER Performance for 16-QAM in AWGN

Estimate the BER performance in an AWGN channel for a 16-QAM signal when encoded with a (15,11) Reed-Solomon code using hard-decision decoding.

Set the input Eb/No range and find the uncoded BER for 16-QAM.

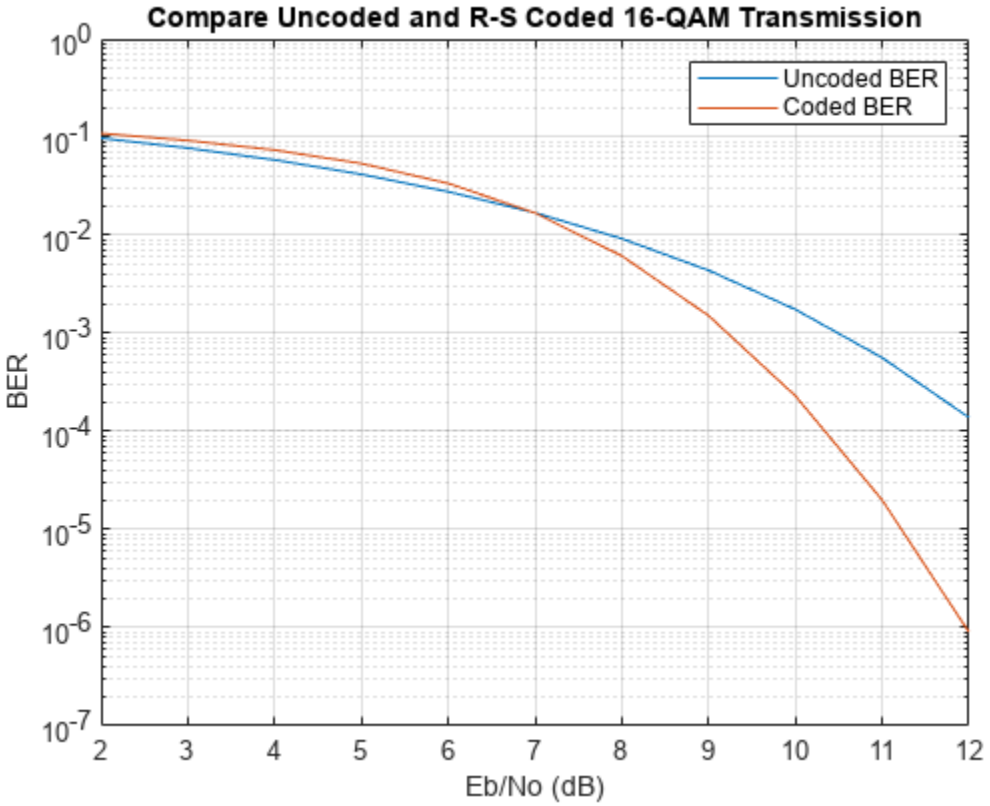
```
ebno = (2:12)';
uncodedBER = berawgn(ebno,'qam',16);
```

Estimate the coded BER for a 16-QAM signal with a (15,11) Reed-Solomon code using hard-decision decoding.

```
codedBER = bercoding(ebno,'RS','hard',15,11,'qam',16);
```

Plot the estimated BER curves.

```
semilogy(ebno,[uncodedBER codedBER])
grid
title('Compare Uncoded and R-S Coded 16-QAM Transmission')
legend('Uncoded BER','Coded BER')
xlabel('Eb/No (dB)')
ylabel('BER')
```



Input Arguments

EbNo — Energy per bit to noise power spectral density ratio

scalar | vector

Energy per bit to noise power spectral density ratio in dB, specified as a scalar or vector.

Data Types: `single` | `double`

`coding` — Source coding type

`'conv'` | `'block'` | `'Hamming'` | `'Golay'` | `'RS'`

Source coding type, specified as one of these options.

- `'conv'` — The returned BER is an upper bound of the BER for binary convolutional codes with coherent BPSK or QPSK modulation.
- `'block'` — The returned BER is an upper bound of the BER for (`N`, `K`) linear binary block codes with coherent BPSK or QPSK modulation.
- `'Hamming'` — The returned BER is an approximation of the BER for a Hamming code using hard-decision decoding and coherent BPSK or QPSK modulation.
- `'Golay'` — The returned BER is an upper bound of the BER for an extended (24,12) Golay code using hard-decision decoding and coherent BPSK or QPSK modulation. In accordance with [3], the Golay coding upper bound assumes the correction of 3-error patterns only. Even though correcting approximately 19% of 4-error patterns is theoretically possible, in practice, most decoders do not have this capability.
- `'RS'` — The returned BER is an approximation of the BER for an (`N`,`K`) Reed-Solomon code using hard-decision decoding and coherent BPSK modulation.

Data Types: `char` | `string`

`decision` — Decoding decision type

`'hard'` | `'soft'`

Decoding decision type, specified as one of these options.

- `'hard'` — Use this option for hard-decision decoding.
- `'soft'` — Use this option for unquantized soft-decision decoding. This option applies only when `coding` is set to `'conv'` or `'block'`.

Data Types: `char` | `string`

`coderate` — Code rate of convolutional code

positive scalar

Code rate of the convolutional code, specified as a positive scalar.

Dependencies

To enable this argument, set the `coding` argument to `'conv'`.

Data Types: `double` | `single`

`dspec` — Distance spectrum of code

structure

Distance spectrum of the code, specified as structure containing these fields. To find distance spectra for sample codes, use the `distspec` function or see [5] and [3].

`dfree` — Minimum free distance of code

positive scalar

Minimum free distance of the code, specified as a positive scalar.

Data Types: `double` | `single`

`weight` — Weight spectrum of code
positive scalar

Weight spectrum of the code, specified as a positive scalar.

Data Types: `double` | `single`

Dependencies

To enable this argument, set the `coding` argument to `'conv'`.

Data Types: `struct`

`N` — Codeword length
integer

Codeword length, specified as an integer of the form 2^M–1, where M is an integer in the range [3, 16]. For more information, see “N-K Pairs for Source Coding” on page 2-73.

Example: `15` or `2^4-1`

Dependencies

To enable this argument, set the `coding` argument to `'block'`, `'Hamming'`, `'Golay'`, or `'RS'`.

`K` — Message length
positive integer

Message length, specified as a positive integer. For more information, see “N-K Pairs for Source Coding” on page 2-73.

Example: `5` specifies a Galois field array with five elements.

Dependencies

To enable this argument, set the `coding` argument to `'block'` or `'RS'`.

`dmin` — Minimum distance of code
positive scalar

Minimum distance of the code, specified as a positive scalar smaller than or equal to (`N - K + 1`).

.

Dependencies

To enable this argument, set the `coding` argument to `'block'`.

Data Types: `double` | `single`

`modulation` — Modulation type
`'psk'` (default) | `'oqpsk'` | `'dpsk'` | `'pam'` | `'qam'` | `'fsk'` | `'msk'`

Modulation decision type, specified as `'psk'`, `'oqpsk'`, `'dpsk'`, `'pam'`, `'qam'`, `'fsk'`, or `'msk'`. The default modulation scheme is PSK modulation with a modulation order of 2 (specifically, nondifferential BPSK modulation).

Data Types: `char` | `string`

Output Arguments

`ber` — BER
scalar | vector

BER upper bound or approximation, returned as a scalar or vector. If the `EbNo` input is a vector, `ber` is a vector of the same size, and its elements correspond to the elements of the E_b/N_0 vector.

Limitations

In general, the numerical accuracy for the output BER is limited to approximately two significant digits. The numerical accuracy output by this function is limited by these restrictions.

- Approximations in the analysis leading to the closed-form expressions used by the function
- Approximations related to the numerical implementation of the expressions

More About

N-K Pairs for Source Coding

For block codes the codeword length (`N`) and message length (`K`) pairs must comply with these guidelines.

- `N` and `K` must produce a narrow-sense BCH code.
- To generate the list of valid (`N`,`K`) pairs and their corresponding values of error-correction capability, run the command `bchnumerr(N)`.
- Valid values for `N` have the form 2^M–1, where M is an integer in the range [3, 16]. The value of `N` cannot exceed 65,535.

For Hamming codes, `K` is computed directly from `N`.

For Reed-Solomon codes, `N` and `K` must differ by an even integer. Valid values for `N` have the form 2^M–1, where M is an integer in the range [3, 16]. The value of `N` cannot exceed 65,535.

Alternatives

You can configure the **Theoretical** tab in the **Bit Error Rate Analysis** app to compute theoretical BER values instead of using the `bercoding` function.

berconfint

Error probability estimate and confidence interval of Monte Carlo simulation

Syntax

```
[errprobest,interval] = berconfint(nerrs,ntrials)
[errprobest,interval] = berconfint(nerrs,ntrials,level)
```

Description

`[errprobest,interval] = berconfint(nerrs,ntrials)` returns the error probability estimate and 95% confidence interval for a Monte Carlo simulation of `ntrials` trials with `nerrs` errors.

`[errprobest,interval] = berconfint(nerrs,ntrials,level)` specifies the confidence level.

Examples

Compute BER Confidence Interval for Simulation Results

Compute the confidence interval for the simulation of a communication system that has 100 bit errors in 106 trials. The bit error rate (BER) for that simulation is 10^{-4}.

Compute the 90% confidence interval for the BER of the system. The output shows that, with 90% confidence level, the BER for the system is between 0.0000841 and 0.0001181.

```
nerrs = 100;    % Number of bit errors in simulation
ntrials = 10^6; % Number of trials in simulation
level = 0.90;   % Confidence level
[ber,interval] = berconfint(nerrs,ntrials,level)
```

```
ber = 1.0000e-04

interval = 1×2
10^-3 ×

    0.0841    0.1181
```

For an example that uses the output of the `berconfint` function to plot error bars on a BER plot, see “Use Curve Fitting on Error Rate Plot”.

Input Arguments

`nerrs` — Number of errors

scalar

Number of errors from Monte Carlo simulation results, specified as a scalar.

Data Types: `single` | `double`

`ntrials` — Number of trials
scalar

Number of trials from Monte Carlo simulation results, specified as a scalar.

Data Types: `single` | `double`

`level` — Confidence level
scalar in the range [0, 1]

Confidence level for a Monte Carlo simulation, specified as a scalar in the range [0, 1].

Data Types: `single` | `double`

Output Arguments

`errprobest` — Error probability estimate
scalar

Error probability estimate for a Monte Carlo simulation, returned as a scalar.

- If the errors and trials are measured in bits, the error probability is the bit error rate (BER).
- If the errors and trials are measured in symbols, the error probability is the symbol error rate (SER).

`interval` — Confidence interval
two-element column vector

Confidence interval for a Monte Carlo simulation, returned as a two-element column vector that lists the endpoints of the confidence interval for the confidence level specified by the input `level`.

`berfit`

berfading

BER and SER for uncoded data over Rayleigh and Rician fading channels

Syntax

```
ber = berfading(EbNo,modtype,M,divorder)

ber = berfading(EbNo,'psk',M,divorder)
ber = berfading(EbNo,'depsk',2,divorder)

ber = berfading(EbNo,'oqpsk',divorder)
ber = berfading(EbNo,'dpsk',divorder)

ber = berfading(EbNo,'fsk',M,divorder,coherence)
ber = berfading(EbNo,'fsk',2,divorder,coherence,rho)
ber = berfading( ___ ,K)

ber = berfading(EbNo,'psk',2,1,K,phaserr)

[ber,ser] = berfading( ___ )
```

Description

The `berfading` function returns the bit error rate (BER) and symbol error rate (SER) over a Rayleigh or Rician fading channel for uncoded data using a specified modulation scheme. The first input argument, `EbNo`, is the energy per bit to noise power spectral density ratio (E_b/N_0) in dB. Values in the `ber` and `ser` output vectors correspond to the theoretical error rates at the specified E_b/N_0 levels for a Gray-coded signal constellation. For more information, see “Analytical Expressions Used in berfading Function and Bit Error Rate Analysis App”.

`ber = berfading(EbNo,modtype,M,divorder)` returns the BER for PAM or QAM data over an uncoded Rayleigh fading channel with coherent demodulation at the specified E_b/N_0 levels for the modulation type, modulation order, and diversity order (specified by `modtype`, `M`, and `divorder`, respectively).

`ber = berfading(EbNo,'psk',M,divorder)` returns the BER for coherently detected PSK data over an uncoded Rayleigh fading channel.

`ber = berfading(EbNo,'depsk',2,divorder)` specifies coherently detected PSK data with differential data encoding over an uncoded Rayleigh fading channel. In this case, the modulation order is 2.

`ber = berfading(EbNo,'oqpsk',divorder)` specifies coherently detected OQPSK data over an uncoded Rayleigh fading channel.

`ber = berfading(EbNo,'dpsk',divorder)` specifies DPSK data over an uncoded Rayleigh fading channel. For DPSK modulation, the resulting BER assumes slow fading (such that any two consecutive symbols are affected by the same fading coefficient).

`ber = berfading(EbNo,'fsk',M,divorder,coherence)` returns the BER for orthogonal FSK data over an uncoded Rayleigh fading channel. `coherence` specifies the coherent detection type.

`ber = berfading(EbNo,'fsk',2,divorder,coherence,rho)` specifies binary nonorthogonal FSK data over an uncoded Rayleigh fading channel. `rho` specifies the complex correlation coefficient. The modulation order is 2. For the definition of the complex correlation coefficient and how to compute it for nonorthogonal BFSK modulation, see “Nonorthogonal 2-FSK with Coherent Detection”.

`ber = berfading( ___ ,K)` returns the BER over an uncoded Rician fading channel using any input argument combination from previous syntaxes. `K` is the ratio of specular to diffuse energy in linear scale. If you use the modulation type `'fsk'`, `rho` is required and must be specified before `K`.

`ber = berfading(EbNo,'psk',2,1,K,phaserr)` returns the BER of BPSK data over an uncoded Rician fading channel. `phaserr` specifies the imperfect phase synchronization, which is the standard deviation of the reference carrier phase error.

`[ber,ser] = berfading( ___ )` returns the BER and SER using any input argument combination from previous syntaxes.

Examples

Estimate BER Performance of 16-QAM in Rayleigh Fading Channel

Generate a vector of E_b/N_0 values to evaluate.

```
EbNo = 8:2:20;
```

Initialize a BER results vector.

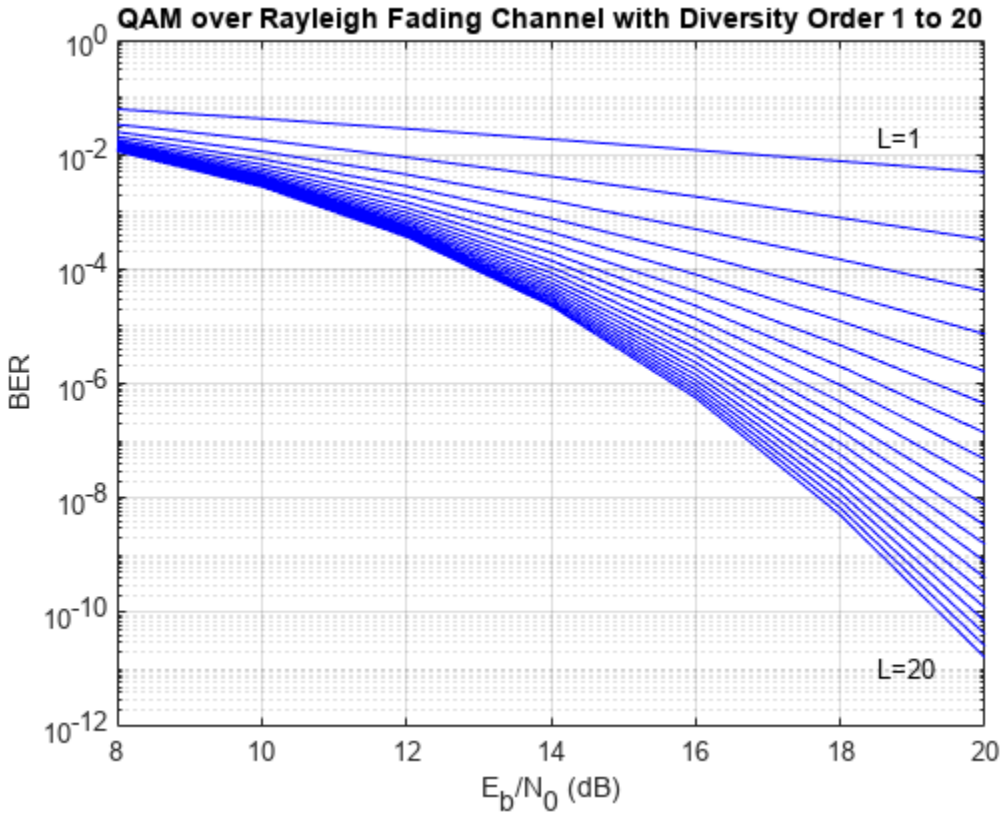
```
ber = zeros(length(EbNo),20);
```

Generate BER versus E_b/N_0 curves for 16-QAM in a Rayleigh fading channel. Vary the diversity order from 1 to 20.

```
for L = 1:20
    ber(:,L) = berfading(EbNo,'qam',16,L);
end
```

Plot the results.

```
semilogy(EbNo,ber,'b')
text(18.5, 0.02, sprintf('L=%d',1))
text(18.5, 1e-11, sprintf('L=%d',20))
title('QAM over Rayleigh Fading Channel with Diversity Order 1 to 20')
xlabel('E_b/N_0 (dB)')
ylabel('BER')
grid on
```



Input Arguments

EbNo — Energy per bit to noise power spectral density ratio

scalar | vector

Energy per bit to noise power spectral density ratio in dB, specified as a scalar or vector.

For cases where diversity is used, the E_b/N_0 on each diversity branch is `EbNo/divorder`.

Data Types: `single` | `double`

modtype — Modulation type

`'pam'` | `'qam'` | `'psk'` | `'oqpsk'` | `'dpsk'` | `'fsk'` | ...

Modulation type, specified as one of these options.

modtype Value	Modulation Scheme	Dependencies
`'pam'`	Pulse amplitude modulation (PAM)	None

modtype Value	Modulation Scheme	Dependencies
'qam'	Quadrature amplitude modulation (QAM)	The modulation order M must be at least 4. • When $k = log_2$M is odd, the symbols lie in a rectangular constellation of size M = $I \times J$, where $I = 2^{\frac{k-1}{2}}$ and $J = 2^{\frac{k+1}{2}}$. • When k is even, the symbols lie in a square constellation of size $2^{\frac{k}{2}} \times 2^{\frac{k}{2}}$.
'psk'	Phase shift keying (PSK)	None
'oqpsk'	Offset quadrature phase shift keying (OQPSK)	None
'dpsk'	Differential phase shift keying (DPSK)	None
'fsk'	Frequency-shift keying (FSK)	When you set the input coherence to 'noncoherent', modulation order M must be in the range [2, 64].

Data Types: char | string

M — Modulation order
2^k

Modulation order, specified as an integer equal to 2^k, where k is a positive integer.

Example: 4 or 2^2

Data Types: single | double

divorder — Diversity order
0 | nonnegative integer

Diversity order, specified as a nonnegative integer that represents the number of diversity branches.

When you specify a divorder value greater than 0, the error rate is computed using diversity. For cases where diversity is used, the E_b/N_0 on each diversity branch is EbNo/divorder.

Data Types: single | double

coherence — Coherent detection type
'coherent' | 'noncoherent'

Coherent detection type, specified as one of these options.

• 'coherent' — For coherent detection

- `'noncoherent'` — For noncoherent detection

Dependencies

To enable this argument, set the `modtype` argument to `'fsk'`.

Data Types: `char` | `string`

`rho` — Complex correlation coefficient
complex scalar

Complex correlation coefficient, specified as a complex scalar. For more information about the complex correlation coefficient and how to compute it for nonorthogonal binary FSK (BFSK) modulation, see “Nonorthogonal 2-FSK with Coherent Detection”.

Dependencies

To enable this argument, set the `modtype` argument to `'fsk'` and the `M` argument to `2`.

Data Types: `single` | `double`
Complex Number Support: Yes

`K` — Ratio of specular to diffuse energy
nonnegative scalar

Ratio of specular to diffuse energy in linear scale, specified as a nonnegative scalar.

Data Types: `single` | `double`

`phaserr` — Standard deviation of reference carrier phase error
nonnegative scalar

Standard deviation of the reference carrier phase error in radians, specified as a nonnegative scalar.

Data Types: `single` | `double`

Output Arguments

`ber` — BER
scalar | vector

BER for uncoded data over a Rayleigh or Rician channel, returned as a scalar or vector. The BER is computed for each E_b/N_0 setting specified by input `EbNo` according to the modulation type specified by input `modtype` and related dependencies.

Data Types: `double`

`ser` — SER
scalar | vector

SER for uncoded data over a Rayleigh or Rician channel, returned as a scalar or vector. The SER is computed for each E_b/N_0 setting specified by input `EbNo` according to the modulation type specified by input `modtype` and related dependencies.

Data Types: `double`

Limitations

The numerical accuracy of the output returned by this function is limited by approximations related to the numerical implementation of the expressions to roughly two significant digits.

Alternatives

You can configure the **Theoretical** tab in the **Bit Error Rate Analysis** app to compute theoretical BER values instead of using the `berfading` function.

berfit

Fit curve to nonsmooth empirical BER data

Syntax

```
fitber = berfit(empEbNo,empber)

fitber = berfit(empEbNo,empber,fitEbNo)
fitber = berfit(empEbNo,empber,fitEbNo,options)
fitber = berfit(empEbNo,empber,fitEbNo,options,fittype)

[fitber,fitprops] = berfit( ___ )
berfit( ___ )

berfit(empEbNo,empber,fitEbNo,options,'all')
```

Description

`fitber = berfit(empEbNo,empber)` fits a curve to the empirical BER data, `empber`, and returns a vector of fitted BER points. The values in `empber` and `fitber` correspond to the empirical energy per bit to noise power spectral density ratio (E_b/N_0) values given by `empEbNo`. For a general description of unconstrained nonlinear optimization, see [1].

Note The `berfit` function is intended for curve fitting or interpolation (not extrapolation). Extrapolating BER data beyond an order of magnitude below the smallest empirical BER value is inherently unreliable.

`fitber = berfit(empEbNo,empber,fitEbNo)` specifies a vector of E_b/N_0 values to use when fitting a curve to the empirical BER data in `empber` that correspond to the empirical E_b/N_0 values in `empEbNo`.

`fitber = berfit(empEbNo,empber,fitEbNo,options)` specifies a structure to override the default options used for optimization.

`fitber = berfit(empEbNo,empber,fitEbNo,options,fittype)` specifies the closed-form function used to fit the empirical data. If you do not want to override the default options for optimization, specify `options` as [ ].

`[fitber,fitprops] = berfit( ___ )` returns the `fitprops` structure with fields that describe the properties of the curve fit. Use any input argument combination from previous syntaxes.

`berfit( ___ )` plots the empirical and fitted BER data.

`berfit(empEbNo,empber,fitEbNo,options,'all')` plots the empirical and fitted BER data from all possible settings of `fittype` that are valid. If you do not want to override the default options for optimization, specify `options` as [ ].

Note To be valid a fit must conform to these criteria, otherwise it is rejected.

- real-valued
- monotonically decreasing
- greater than or equal to 0 and less than or equal to 1

Examples

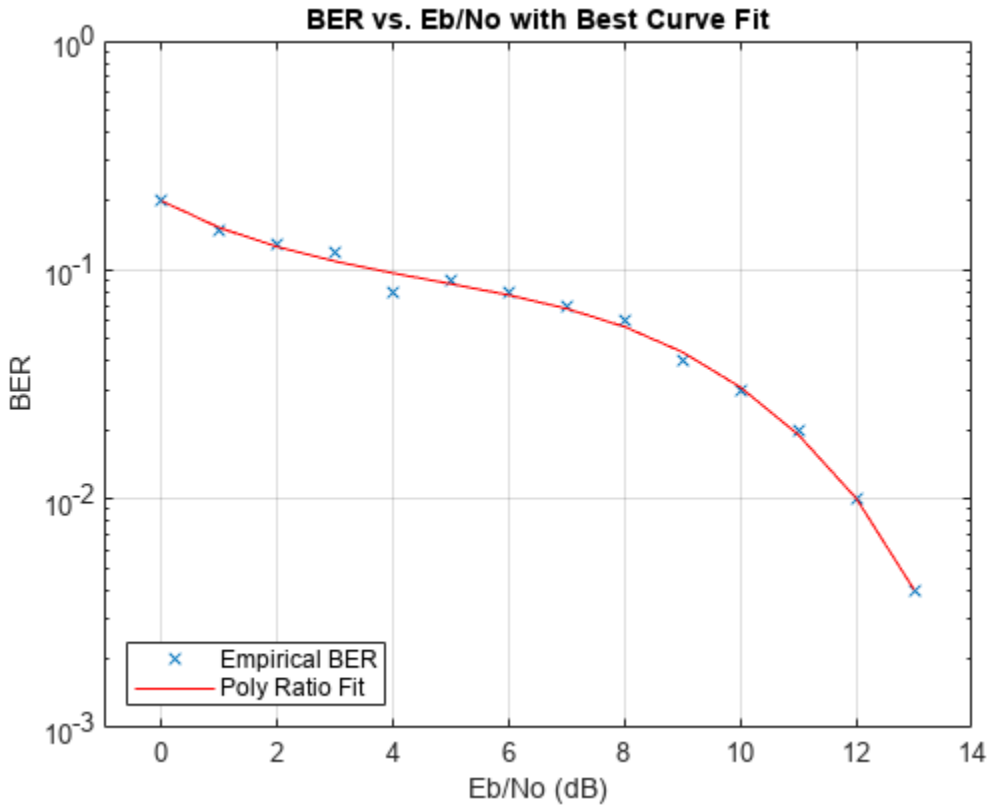
Fit Curve to BER Points

This example shows the use of the `berfit` function using hard-coded or theoretical BER points for simplicity. For an example that uses empirical BER data from a simulation, see “Use Curve Fitting on Error Rate Plot”.

Best Fit for Set of Sample Data

Define a range of E_b/N_0 values and BER points. Use this data as inputs for the `berfit` function.

```
EbN0 = 0:13;
berdata = [.2 .15 .13 .12 .08 .09 .08 .07 .06 .04 .03 .02 .01 .004];
berfit(EbN0,berdata);
```

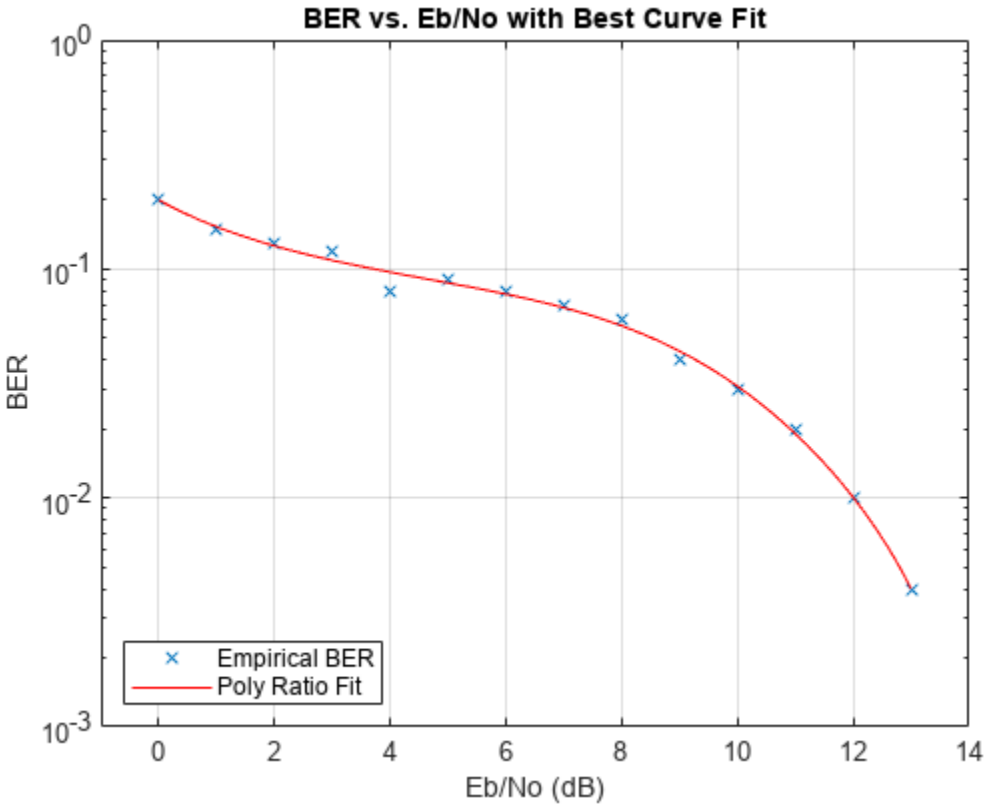


Plot Best Fit

The curve connects the points created by evaluating the fit expression at the specified E_b/N_0 values. To make the curve look smoother, provide an input vector of E_b/N_0 values for curve fitting in

ascending order. This vector provides more points for plotting the curve and does not change the fit expression.

```
fitEbNo = 0:0.2:13;
berfit(EbN0,berdata,fitEbNo)
```

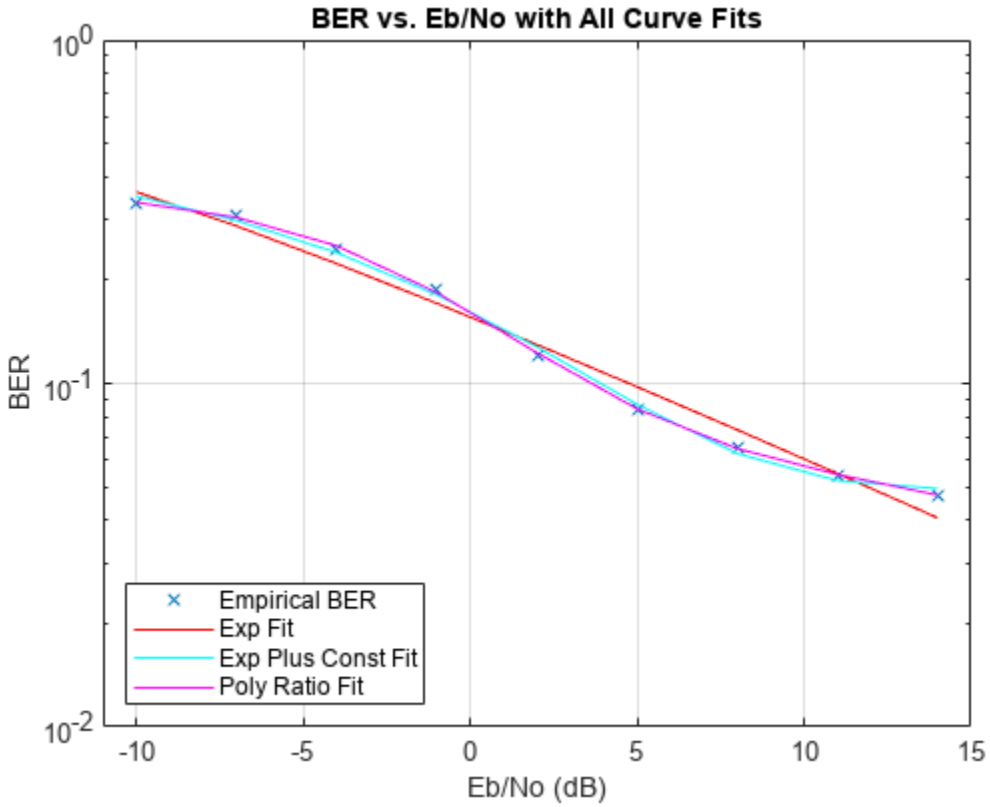


Fit for BER Curve with Error Floor

Run the `berfit` function using the `'all'` option on empirical BER results for a simulation of BPSK data transmitted over a channel with a null (`ch = [0.5 0.47]`) and recovered by using a linear MMSE equalizer at the receiver for the E_b/N_0 range [-10, 15]. Comparing the results of curve fitting methods

- `'doubleExp+const'` fit type does not provide a valid fit
- `'exp'` fit type does not work well for this data
- `'exp+const'` and `'polyRatio'` fit types closely match the simulated data

```
EbN0 = -10:3:15;
empBER = [0.3361 0.3076 0.2470 0.1878 0.1212 0.0845 0.0650 0.0540 0.0474];
figure;
berfit(EbN0,empBER,[],[],'all');
```



Use of `options` Input Structure and `fitprops` Output Structure

The `'notify'` value for the display level causes the function to produce output when one of the attempted fits does not converge. The `exitState` field of the output structure indicates which fit type converges.

Generate theoretical BER results for 8-PSK data with a diversity order of 2 transmitted over a Rayleigh fading channel for the E_b/N_0 range [3, 10] dB.

```
M = 8; EbN0 = 3:10;
berdata = berfading(EbN0,'psk',M,2); % Compute the theoretical BER
noisydata = berdata.*[.93 .92 1 .59 .08 .15 .01 .01];
```

Create the `options` structure by using the `optimset` function to configure display and notification of fit type results. Run exponential and polynomial ratio fit types.

```
options = optimset('display','notify');
disp('*** Trying exponential fit.') % Poor fit
```

```
*** Trying exponential fit.
```

```
[fitber1,fitprops1] = berfit(EbN0,noisydata,EbN0,...
   options,'exp')
```

```
Exiting: Maximum number of function evaluations has been exceeded
         - increase MaxFunEvals option.
         Current function value: 2.749919
```

```
fitber1 = 1×8

    0.1247    0.0727    0.0376    0.0168    0.0064    0.0020    0.0005    0.0001

fitprops1 = struct with fields:
       fitType: 'exp'
        coeffs: [4x1 double]
      sumSqErr: 2.7499
     exitState: 'The maximum number of function evaluations has been exceeded'
     funcCount: 10001
    iterations: 6193

disp('*** Trying polynomial ratio fit.') % Good fit

*** Trying polynomial ratio fit.

[fitber2,fitprops2] = berfit(EbN0,noisydata,EbN0,...
   options,'polyRatio')

fitber2 = 1×8

    0.1701    0.0874    0.0407    0.0169    0.0060    0.0016    0.0003    0.0001

fitprops2 = struct with fields:
       fitType: 'polyRatio'
        coeffs: [6x1 double]
      sumSqErr: 2.3880
     exitState: 'The curve fit converged to a solution'
     funcCount: 554
    iterations: 331
```

Input Arguments

empEbNo — Empirical E_b/N_0 values

vector

Empirical E_b/N_0 values in dB, specified as a vector with at least four elements. The element values in the vector must be in ascending order.

Data Types: `single` | `double`

empber — Empirical BER data

vector

Empirical BER data, specified as a vector with the same number of elements as input `empEbNo`. The values in `empber` correspond to the E_b/N_0 values given by `empEbNo`.

Data Types: `single` | `double`

fitEbNo — E_b/N_0 values for curve fitting

vector

E_b/N_0 values in dB for curve fitting, specified as a vector with element values in ascending order. The length of `fitEbNo` must equal or exceed that of input `empEbNo`.

Data Types: `single` | `double`

`options` — Override default options used for optimization

[ ] | structure

Override default options used for optimization, specified as a structure. The fields specified in the `options` structure are used by the `fminsearch` function. You can create the `options` structure by using the `optimset` function. This table describes the fields that are most relevant when using the `berfit` function. To use default options, you can specify this input as [ ].

Field	Description
`options.Display`	Level of display. • `'off'` (default) -- displays no output • `'iter'` -- displays output at each iteration • `'final'` -- displays only the final output • `'notify'` -- displays output only if the function does not converge
`options.MaxFunEvals`	The maximum number of function evaluations before optimization ceases. The default is 10^4.
`options.MaxIter`	The maximum number of iterations before optimization ceases. The default is 10^4.
`options.TolFun`	The termination tolerance for the closed-form function used to generate the fit. The default is 10^{-4}.
`options.TolX`	The termination tolerance for the coefficient values of the closed-form function used to generate the fit. The default is 10^{-4}.

Data Types: `struct`

`fittype` — Closed-form function used to fit empirical data

`'exp'` | `'exp+const'` | `'polyRatio'` | `'doubleExp+const'`

Closed-form function used to fit the empirical data, specified as `'exp'`, `'exp+const'`, `'polyRatio'`, or `'doubleExp+const'`. For more information, see “Algorithms” on page 2-90.

Data Types: `char` | `string`

Output Arguments

`fitber` — Fitted BER points

vector

Fitted BER points, returned as a vector. The BER is computed for each E_b/N_0 setting specified by the input `empEbNo` vector.

Data Types: `double`

`fitprops` — Fit properties

structure

Fit properties, returned as a structure with these fields to describe the properties of the curve fit.

Field	Description
`fitprops.fitType`	The closed-form function type used to generate the fit. Valid values include: `'exp'`, `'exp +const'`, `'polyRatio'`, or `'doubleExp +const'`.
`fitprops.coeffs`	The coefficients used to generate the fit. If the function cannot find a valid fit, `fitprops.coeffs` is an empty vector.
`fitprops.sumSqErr`	The sum squared error between the log of the fitted BER points and the log of the empirical BER points.
`fitprops.exitState`	The exit condition of `berfit`. Valid values include: • `'The curve fit converged to a solution.'` • `'The maximum number of function evaluations was exceeded.'` • `'No desirable fit was found.'`
`fitprops.funcCount`	The number of function evaluations used in minimizing the sum squared error function.
`fitprops.iterations`	The number of iterations taken in minimizing the sum squared error function. This value is not necessarily equal to the number of function evaluations.

Data Types: `struct`

Algorithms

The `berfit` function fits the BER data using unconstrained nonlinear optimization via the `fminsearch` function. This table lists the closed-form functions that `berfit` considers based on the value of the `fittype` input argument. These functions were empirically found to provide close fits in a wide variety of situations, including exponentially decaying BERs, linearly varying BERs, and BER curves with error rate floors. In the functional expressions, x is a linear E_b/N_0 value (not a dB value), and $f(x)$ is the estimated BER.

fittype Value	Functional Expression
`'exp'`	$f(x) = a_1 \exp\left[\frac{-(x-a_2)^{a3}}{a_4}\right]$
`'exp+const'`	$f(x) = a_1 \exp\left[\frac{-(x-a_2)^{a3}}{a_4}\right] + a_5$

fittype Value	Functional Expression
'polyRatio'	$f(x) = \frac{a_1x^2 + a_2x + a_3}{x^3 + a_4x^2 + a_5x + a_6}$
'doubleExp+const'	$a_1\exp\left[\frac{-(x - a_2)^{a3}}{a_4}\right] + a_5\exp\left[\frac{-(x - a_6)^{a7}}{a_8}\right] + a_9$

The sum squared error function that `fminsearch` attempts to minimize is

$$F = \sum[\log(\text{empirical BER}) - \log(\text{fitted BER})]^2$$

The fitted BER points are the values in the output `fitber`, and the sum is over the E_b/N_0 points given in the input `empEbNo`. To avoid high-BER regions dominating the objective function, the sum squared equation uses the log of the BER values rather than the BER values themselves.

Functions
`fminsearch` | `optimset`

bersync

BER for imperfect synchronization

Syntax

```
ber = bersync(EbNo,timerr,'timing')
ber = bersync(EbNo,phaserr,'carrier')
```

Description

The `bersync` function returns the bit error rate (BER) for uncoded coherent BPSK over an additive white Gaussian noise (AWGN) channel for imperfect synchronization. For more information, see "Analytical Expressions Used in bersync Function and Bit Error Rate Analysis App".

`ber = bersync(EbNo,timerr,'timing')` returns the BER from uncoded coherent binary phase shift keying (BPSK) modulation over an additive white Gaussian noise (AWGN) channel at the specified E_b/N_0 with imperfect timing specified by `timerr`. The normalized timing error is assumed to have a Gaussian distribution.

`ber = bersync(EbNo,phaserr,'carrier')` returns the bit error rate (BER) from uncoded BPSK modulation over an AWGN channel at the specified E_b/N_0 with a noisy phase reference specified by `phaserr`. The phase error is assumed to have a Gaussian distribution. `phaserr` is the standard deviation of the phase error of the reference carrier phase.

Examples

Calculate BER for Imperfect Synchronization

Compute the BER for coherent BPSK modulation over an AWGN channel with imperfect timing. Vary the ratio of bit energy to noise power spectral density (E_b/N_0) and the standard deviation of the timing error. When `timerr` assumes the final value of `0`, the `bersync` function produces the same result as `berawgn(EbNo,'psk',2)`.

```
EbNo = [4 8 12];
timerr = [0.2 0.07 0];
ber = zeros(length(timerr),length(EbNo));
for ii = 1:length(timerr)
    ber(ii,:) = bersync(EbNo,timerr(ii),'timerr');
end
```

Display the result using scientific notation.

```
format short e; ber
```

```
ber = 3×3

   5.2073e-02   2.0536e-02   1.1160e-02
   1.8948e-02   7.9757e-04   4.9008e-06
   1.2501e-02   1.9091e-04   9.0060e-09
```

Switch back to default notation format.

```
format;
```

Input Arguments

`EbNo` — Ratio of bit energy to noise power spectral density

scalar | vector

Ratio of bit energy to noise power spectral density (E_b/N_0) in dB, specified as a scalar or vector.

Data Types: `single` | `double`

`timerr` — Standard deviation of timing error

scalar in the range [0, 0.5]

Standard deviation of the timing error, specified as a scalar in the range [0, 0.5]. Provide the timing error normalized to the symbol interval. The normalized timing error is assumed to have a Gaussian distribution.

Data Types: `double` | `single`

`phaserr` — Standard deviation of phase error

scalar

Standard deviation of the phase error for the reference carrier phase in radians, specified as a scalar. The phase error is assumed to have a Gaussian distribution.

Data Types: `double` | `single`

Output Arguments

`ber` — BER

scalar | vector

BER for uncoded coherent BPSK modulation over an AWGN channel returned as a scalar or vector with

- imperfect timing if you specified the `timerr` input
- a noisy phase reference if you specified the `phaserr` input

The BER is computed for each E_b/N_0 setting specified by the input argument `EbNo`.

If `EbNo` is a vector, the output `ber` is a vector of the same size as input `EbNo` and its elements correspond to the different elements of the `EbNo` vector.

Data Types: `double`

Limitations

In general, the numerical accuracy for the output BER is limited to approximately two significant digits. The numerical accuracy output by this function is limited by:

- Approximations in the analysis leading to the closed-form expressions used by the function

- Approximations related to the numerical implementation of the expressions

Inherent limitations in numerical precision force the function to assume perfect synchronization if the value of `timerr` or `phaserr` is less than the positive distance from the absolute value of the error value to the next larger in magnitude floating point number as determined by the `eps` function. This table indicates how the function behaves under these conditions.

Condition	Behavior of bersync Function
`timerr < eps`	`bersync(EbNo,timerr,'timing')` is equivalent to `berawgn(EbNo,'psk',2)` with a timing error less than `eps`.
`phaserr < eps`	`bersync(EbNo,phaserr,'carrier')` is equivalent to `berawgn(EbNo,'psk',2)` with a phase error less than `eps`.

Algorithms

This function uses formulas from [3].

When the last input is `'timing'`, the function computes

$$\frac{1}{4\pi\sigma}\int_{-\infty}^{\infty}\exp(-\frac{\xi^2}{2\sigma^2})\int_{\sqrt{2R}(1-2|\xi|)}^{\infty}\exp(-\frac{x^2}{2})dxd\xi+\frac{1}{2\sqrt{2\pi}}\int_{\sqrt{2R}}^{\infty}\exp(-\frac{x^2}{2})dx$$

σ is the `timerr` input, and R is the value of the `EbNo` input converted from dB to a linear scale.

When the last input is `'carrier'`, the function computes

$$\frac{1}{\pi\sigma}\int_{0}^{\infty}\exp(-\frac{\phi^2}{2\sigma^2})\int_{\sqrt{2R}\cos\phi}^{\infty}\exp(-\frac{y^2}{2})dyd\phi$$

σ is the `phaserr` input, and R is the value of the `EbNo` input converted from dB to a linear scale.

Alternatives

You can configure the **Theoretical** tab in the **Bit Error Rate Analysis** app to compute theoretical BER values instead of using the `bersync` function.

bi2de

(Not recommended) Convert Binary to Base-P

Note is not recommended. Instead, use the `bit2int` function. For more information, see "Compatibility Considerations".

Syntax

```
d = bi2de(b)
d = bi2de(b,flg)
d = bi2de(b,p)
d = bi2de(b,p,flg)
```

Description

`d = bi2de(b)` converts a binary row vector `b` to a decimal integer.

`d = bi2de(b,flg)` converts a binary row vector to a decimal integer, where `flg` determines the position of the most significant digit.

`d = bi2de(b,p)` converts a base-`p` row vector `b` to a decimal integer.

`d = bi2de(b,p,flg)` converts a base-`p` row vector to a decimal integer, where `flg` determines the position of the most significant digit.

Examples

Convert Binary to Base-10

This example shows how to convert binary numbers to decimal integers. It highlights the difference between right- and left- most significant digit positioning.

```
b1 = [0 1 0 1 1];
b2 = [1 1 1 0];
```

Convert the two binary arrays to decimal by using the `bi2de` function. Assign the most significant digit is the leftmost element. The output of converting `b1` corresponds to $0(2^4) + 1(2^3) + 0(2^2) + 1(2^1) + 1(2^0) = 11$, and `b2` corresponds to $1(2^3) + 1(2^2) + 1(2^1) + 0(2^0) = 14$.

```
d1 = bi2de(b1,'left-msb')
```

```
d1 = 11
```

```
d2 = bi2de(b2,'left-msb')
```

```
d2 = 14
```

Assign the most significant digit is the rightmost element. The output of converting `b1` corresponds to $0(2^0) + 1(2^1) + 0(2^2) + 1(2^3) + 1(2^4) = 26$, and `b2` corresponds to $1(2^0) + 1(2^1) + 1(2^2) + 0(2^3) = 7$.

```
d1 = bi2de(b1,'right-msb')
```

```
d1 = 26
```

```
d2 = bi2de(b2,'right-msb')
```

```
d2 = 7
```

Input Arguments

b — Binary input

row vector | matrix

Binary input, specified as a row vector or matrix of positive integer or logical values.

Note b must represent an integer less than or equal to 2^{52}.

Data Types: `double` | `single` | `logical` | `integer` | `fi`

flg — MSB flag

`'right-msb'` (default) | `'left-msb'`

MSB flag, specified as `'right-msb'` or `'left-msb'`.

- `'right-msb'` –– Indicates the right (or last) column of the binary input, b, as the most significant bit (or highest-order digit).
- `'left-msb'` –– Indicates the left (or first) column of the binary input, b, as the most significant bit (or highest-order digit).

Data Types: `char` | `string`

p — Base

2 (default) | positive integer scalar

Base of the input b, specified as an integer greater than or equal to 2.

Data Types: `double` | `single`

Output Arguments

d — Decimal output

nonnegative integer | vector

Decimal output, returned as an nonnegative integer or row vector. If b is a matrix, each row represents a base-p number. In this case, the output d is a column vector in which each element is the decimal representation of the corresponding row of b.

If the input data type is

- An integer data type and the value of d can be contained in the same integer data type as the input, the output data type uses the same data type as the input. Otherwise, the output data type is chosen to be big enough to contain the decimal output.

- double or logical data type, the output data type is double.
- single data type, the output data type is single.

Version History

Introduced before R2006a

`bi2de` is not recommended. Use `bit2int` instead.

Not recommended starting in R2021b

Use `bit2int` instead of `bi2de`. If converting numbers from a nonbase-2 representation to decimal, use `base2dec`.

The code in this table shows binary-to-decimal conversion for various inputs using the recommended function.

Discouraged Feature	Recommended Replacement

`% Default (left MSB)`

bin2gray

(To be removed) Convert positive integers into corresponding Gray-encoded integers

Note will be removed in a future release. Instead, use the appropriate modulation object or function to remap constellation points. For more information, see “Compatibility Considerations”.

Syntax

```
y = bin2gray(x,modulation,M)
[y,map] = bin2gray(x,modulation,M)
```

Description

`y = bin2gray(x,modulation,M)` generates a Gray-encoded vector or matrix output `y` with the same dimensions as its input parameter `x`. `x` can be a scalar, vector, matrix, or 3-D array. `modulation` is the modulation type and must be `'qam'`, `'pam'`, `'fsk'`, `'dpsk'`, or `'psk'`. `M` is the modulation order and must be an integer power of 2.

Note If you are converting binary-coded data to Gray-coded data and modulating the result immediately afterwards, you should use the appropriate modulation object or function with the `'Gray'` option, instead of `bin2gray`.

`[y,map] = bin2gray(x,modulation,M)` generates a Gray-encoded output `y` with its respective Gray-encoded constellation map, `map`.

You can use map output to label a Gray-encoded constellation. The map output gives the Gray-encoded labels for the corresponding modulation.

Examples

Binary to Gray Symbol Mapping

This example shows how to use the bin2gray and gray2bin functions to map integer inputs from a natural binary order symbol mapping to a Gray-coded signal constellation and vice versa, assuming 16-QAM modulation. In addition, a visual representation of the difference between Gray-coded and binary-coded symbol mappings is shown.

Create a complete vector of 16-QAM integers. Convert the input vector from a natural binary order to a Gray-encoded vector using `bin2gray`. Convert Gray to Binary Convert the Gray-encoded symbols, `y`, back to a binary ordering using `gray2bin`. Verify that the original data, `x`, and the final output vector, `z`, are identical.

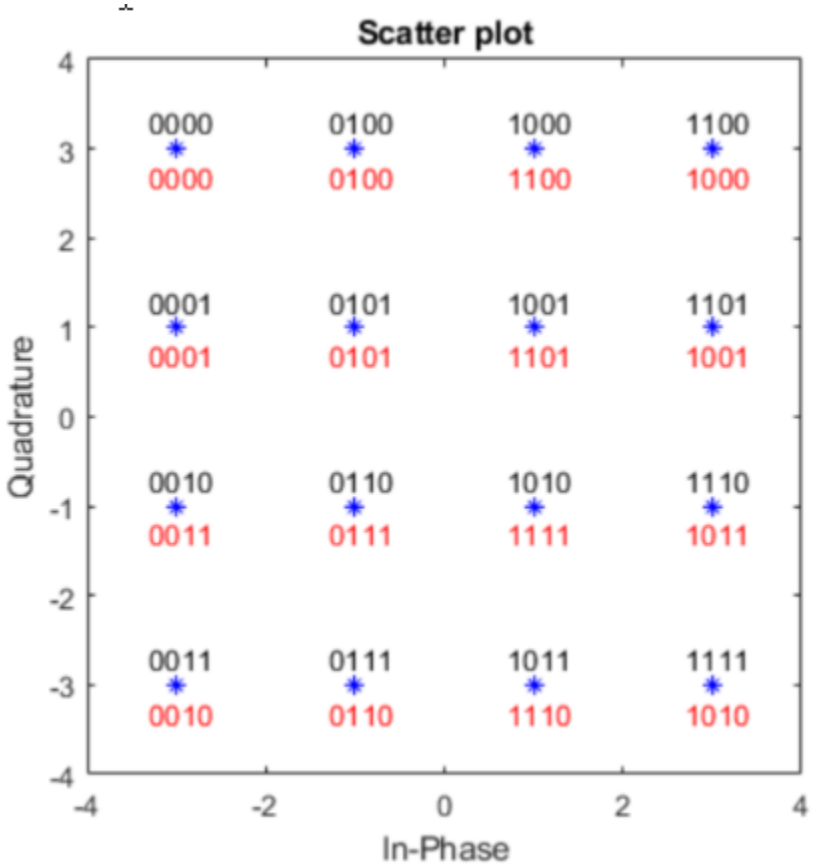
```
M = 16;
x = (0:M-1);
[y,mapy] = bin2gray(x,'qam',M);
```

```
z = gray2bin(y,'qam',M);
isequal(x,z)
```

```
ans = logical
   1
```

Show symbol mappings. To create a constellation plot showing the different symbol mappings, use the `qammod` function to find the complex symbol values. Plot the constellation symbols and label them using the Gray (`y`) and binary (`z`) output vectors. The binary representation of the Gray-coded symbols is shown in black and the binary representation of the naturally ordered symbols is shown in red. Set the axes scaling so that all points are displayed.

```
sym = qammod(x,M);
scatterplot(sym,1,0,'b*');
for k = 1:16
    text(real(sym(k))-0.3,imag(sym(k))+0.3,...
        dec2base(mapy(k),2,4));
    text(real(sym(k))-0.3,imag(sym(k))-0.3,...
        dec2base(z(k),2,4),'Color',[1 0 0]);
end
axis([-4 4 -4 4])
```



Input Arguments

x — Binary-encoded data

vector | matrix

Input binary-encoded data, specified as a vector or matrix.

Data Types: `double`

`modulation` — Modulation type
`'qam'` | `'pam'` | `'fsk'` | `'dpsk'` | `'psk'`

Modulation type, specified as, `'qam'`, `'pam'`, `'fsk'`, `'dpsk'`, or `'psk'`

`M` — Modulation order
scalar

Modulation order, specified as an integer power of 2.

Data Types: `double`

Output Arguments

`y` — Gray-encoded data
vector | matrix

Gray-encoded data with the same size and dimensions input `x`.

`map` — Map of labels
vector

Map output to label a Gray-encoded constellation, specified as a vector with a length the size of the modulation order, `M`. The map gives the Gray-encoded labels for the corresponding modulation.

Version History

Introduced before R2006a

`bin2gray` will be removed
Warns starting in R2021b

The `bin2gray` function will be removed in a future release. Instead, use the appropriate modulation object or function to remap constellation points. This table shows the remapping based on modulation type.

When you use the workflow that is discouraged, the `bin2gray` and `gray2bin` functions convert a binary representation to a natural binary or Gray encoding. After the conversion, you must specify `'bin'` for the symbol order when you call the modulation and demodulation functions.

When you use the workflow that is recommended, for any given of modulation scheme, you provide decimal values when you call the modulation and demodulation functions. When you call the modulation and demodulation functions, specify the symbol order as `'bin'` for natural binary encoding or `'gray'` for Gray encoding.

If your workflow uses `bin2gray` or `gray2bin` with any of the modulations schemes in this table, follow the appropriate example.

Modulation	Discouraged Usage	Recommended Replacement

QAM (qammod and qamdemod)	`x = randi([0 63],1,100);`
	`y = bin2gray(x,'qam',64);`
	`z = qammod(y,64,'bin');`
	
	`x = 2*(randn(100,1)+1j*randn(100,1));`
	`y = qamdemod(x,64,'bin');`
	`z = gray2bin(y,'qam',64);`
		`x = randi([0 63],1,100);`
		`z = qammod(x,64,'gray');`
		
		`x = 2*(randn(100,1)+1j*randn(100,1));`
		`z = qamdemod(x,64,'gray')`

PAM (pammod and pamdemod)	`x = randi([0 63],1,100);`
	`y = gray2bin(x,'pam',64);`
	`z = pammod(y,64,pi/4,'bin');`
	
	`x = 2*(randn(100,1)+1j*randn(100,1));`
	`y = pamdemod(x,64,pi/4,'bin');`
	`z = bin2gray(y,'pam',64);`

Topics

Gray Encoding a Modulated Signal

bit2int

Convert bits to integers

Syntax

```
Y = bit2int(X,n)
Y = bit2int(X,n,msbfirst)
```

Description

`Y = bit2int(X,n)` converts `n` column-wise bit elements in `X` to integer values, with the first bit as the most significant bit (MSB).

`Y = bit2int(X,n,msbfirst)` indicates whether the first bit in each set of `n` column-wise bits from `X` is the MSB or the least significant bit (LSB).

Examples

Convert Vector of Bits to Integers

Specify a column vector of bits.

```
X = [1 0 1 0 1 0 1 0]';
```

Specify for four column-wise bit elements of the input vector to be converted to integer values. Then, convert the bits to integers.

```
n = 4;
Y = bit2int(X,n)
```

```
Y = 2×1

    10
    10
```

Convert Matrix of Bits to Integers

Specify a matrix of bits.

```
X = int8([1 1 0; 0 1 1]')
```

```
X = 3x2 int8 matrix

   1   0
   1   1
   0   1
```

Specify that the first bit in each set of three column-wise bit elements is the LSB. Then, convert the bits to integers.

```
n = 3;
msbfirst = false;
Y = bit2int(X,n,msbfirst)
```

```
Y = 1x2 int8 row vector

   3   6
```

Convert Array of Bits to Integers

Specify an array of bits.

```
X = randi([0,1],8,2,2,'uint8')
```

```
X = 8x2x2 uint8 array
X(:,:,1) =

   1   1
   1   1
   0   0
   1   1
   1   1
   0   0
   0   1
   1   0

X(:,:,2) =

   0   1
   1   1
   1   1
   1   0
   1   1
   0   0
   1   1
   1   0
```

Specify that the first bit in each set of four column-wise bit elements is the MSB. Then, convert the bits to integers.

```
n = 4;
msbfirst = true;
Y = bit2int(X,n,msbfirst)
```

```
Y = 2x2x2 uint8 array
Y(:,:,1) =

   13   13
    9   10
```

```
Y(:,:,2) =

    7   14
   11   10
```

Input Arguments

X — Bits

column vector | matrix | 3-D array

Bits, specified as a column vector, matrix, or 3-D array of numeric or logical `0`s and `1`s.

Example: `[1 0 1 0 1 0 1 0]'` specifies an input column vector of size 8-by-1.

Note The number of rows in `X` must be a multiple of input `n`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

n — Number of bits to be converted

positive integer

Number of bits to be converted to integers, specified as a positive integer.

Data Types: `double`

msbfirst — Specification of MSB first

`true` or `1` | `false` or `0`

Specification of MSB first, specified as a numeric or logical `1` (`true`) or `0` (`false`).

- `true` –– For each set of `n` column-wise bits in `X`, the first bit is the MSB.
- `false` –– For each set of `n` column-wise bits in `X`, the first bit is the LSB.

Data Types: `logical`

Output Arguments

Y — Integer representation of input bits

scalar | column vector | matrix | 3-D array

Integer representation of input bits, returned as a scalar, column vector, matrix, or 3-D array. The function returns the integer-equivalent value for each set of `n` column-wise bits in `X`. Output `Y` has same dimensions as input `X` except that the number of rows in `Y` is `n` times less than the number of rows in `X`.

The data type of `Y` depends on the data type of `X`.

- If `X` is of data type `double` or `logical`, then `Y` is of data type `double`.
- If `X` is of data type `single`, then `Y` is of data type `single`.

- If X is an integer data type and the value of Y can be contained in the same integer data type, then Y is of the same data type and signedness as X. If the value of Y cannot be contained in the same integer data type as X, then the function sets the data type of Y to an integer data type that is big enough to contain its value.

Version History

Introduced in R2021b

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- For code generation, when input X is an integer data type, the input n must be compile-time constant. For example, use `coder.Constant(n)`.

Blocks

Bit to Integer Converter

biterr

Number of bit errors and bit error rate (BER)

Syntax

```
[number,ratio] = biterr(x,y)
[number,ratio] = biterr(x,y,k)
[number,ratio] = biterr(x,y,k,flag)
[number,ratio,individual] = biterr( ___ )
```

Description

`[number,ratio] = biterr(x,y)` compares the unsigned binary representation of elements in `x` to those in `y`. The function returns `number`, the number of bits that differ in the comparison, and `ratio`, the ratio of `number` to the total number of bits. The function determines the order in which it compares `x` and `y` based on their sizes. For more information, see the Algorithms on page 2-111 section.

`[number,ratio] = biterr(x,y,k)` also specifies `k`, the maximum number of bits for each element in `x` and `y`. If the unsigned binary representation of any element in `x` or `y` is more than `k` digits, the function errors.

`[number,ratio] = biterr(x,y,k,flag)` specifies a `flag` to override default settings for how the function compares the elements and computes the outputs. For more information, see the Algorithms on page 2-112 section.

`[number,ratio,individual] = biterr( ___ )` returns the binary comparison result of `x` and `y` as matrix `individual`. You can specify any of the input argument combination from the previous syntaxes.

Examples

Bit Error Rate Computation

Create two binary matrices.

```
x = [0 0; 0 0; 0 0; 0 0]
```

```
x = 4×2

     0     0
     0     0
     0     0
     0     0
```

```
y = [0 0; 0 0; 0 0; 1 1]
```

```
y = 4×2
```

```
     0     0
     0     0
     0     0
     1     1
```

Determine the number of bit errors.

```
numerrs = biterr(x,y)
```

```
numerrs = 2
```

Compute the number of column-wise errors.

```
numerrs = biterr(x,y,[],'column-wise')
```

```
numerrs = 1×2

     1     1
```

Compute the number of row-wise errors.

```
numerrs = biterr(x,y,[],'row-wise')
```

```
numerrs = 4×1

     0
     0
     0
     2
```

Compute the number of overall errors. Behavior is the same as the default behavior.

```
numerrs = biterr(x,y,[],'overall')
```

```
numerrs = 2
```

Estimate Bit Error Rate for 64-QAM in AWGN

Demodulate a noisy 64-QAM signal and estimate the bit error rate (BER) for a range of Eb/No values. Compare the BER estimate to theoretical values.

Set the simulation parameters.

```
M = 64;                 % Modulation order
k = log2(M);            % Bits per symbol
EbNoVec = (5:15)';      % Eb/No values (dB)
numSymPerFrame = 100;   % Number of QAM symbols per frame
```

Initialize the results vector.

```
berEst = zeros(size(EbNoVec));
```

The main processing loop executes these steps.

- Generate binary data and convert to 64-ary symbols.
- QAM-modulate the data symbols.
- Pass the modulated signal through an AWGN channel.
- Demodulate the received signal.
- Convert the demodulated symbols into binary data.
- Calculate the number of bit errors.

The `while` loop continues to process data until either 200 errors are encountered or 1e7 bits are transmitted.

```
for n = 1:length(EbNoVec)
    % Convert Eb/No to SNR
    snrdB = EbNoVec(n) + 10*log10(k);
    % Reset the error and bit counters
    numErrs = 0;
    numBits = 0;

    while numErrs < 200 && numBits < 1e7
        % Generate binary data and convert to symbols
        dataIn = randi([0 1],numSymPerFrame,k);
        dataSym = bi2de(dataIn);

        % QAM modulate using 'Gray' symbol mapping
        txSig = qammod(dataSym,M);

        % Pass through AWGN channel
        rxSig = awgn(txSig,snrdB,'measured');

        % Demodulate the noisy signal
        rxSym = qamdemod(rxSig,M);
        % Convert received symbols to bits
        dataOut = de2bi(rxSym,k);

        % Calculate the number of bit errors
        nErrors = biterr(dataIn,dataOut);

        % Increment the error and bit counters
        numErrs = numErrs + nErrors;
        numBits = numBits + numSymPerFrame*k;
    end

    % Estimate the BER
    berEst(n) = numErrs/numBits;
end
```

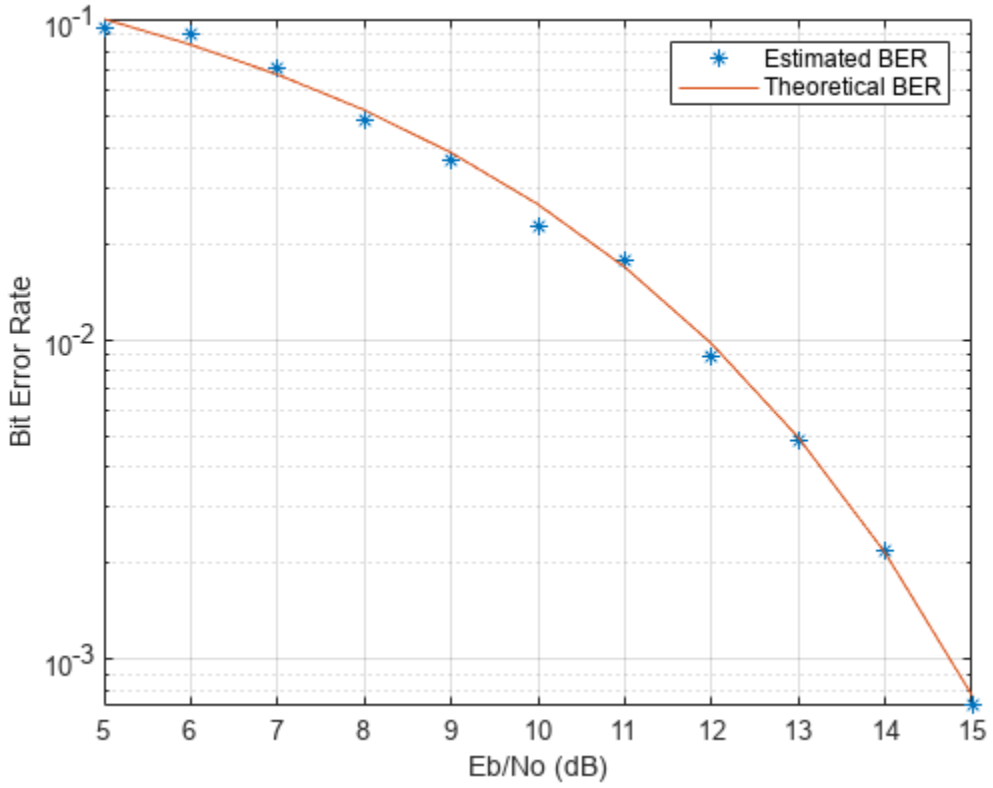
Determine the theoretical BER curve by using the `berawgn` function.

```
berTheory = berawgn(EbNoVec,'qam',M);
```

Plot the estimated and theoretical BER data. The estimated BER data points are well aligned with the theoretical curve.

```
semilogy(EbNoVec,berEst,'*')
hold on
semilogy(EbNoVec,berTheory)
grid
```

```
legend('Estimated BER','Theoretical BER')
xlabel('Eb/No (dB)')
ylabel('Bit Error Rate')
```



Input Arguments

x,y — Inputs to be compared (as separate arguments)

vector | matrix

Inputs to be compared, specified as separate arguments, as a vector or matrix of nonnegative integer elements. The function converts each element of x and y to its unsigned binary representation for comparison.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

k — Maximum number of bits for input elements

positive integer

Maximum number of bits for input elements of x and y, specified as a positive integer. If the number of bits required for binary representation of any element in x or y is greater than k, the function errors.

If you do not set k, the function sets it as the number of bits in the binary representation of the largest element in x and y.

Data Types: `single` | `double`

`flag` — Flag to override default settings
`'overall'` | `'row-wise'` | `'column-wise'`

Flag to override default settings of the function, specified as `'overall'`, `'row-wise'`, or `'column-wise'`. Flag specifies how the function compares elements in inputs `x,y` and computes the output. For more information, see the Algorithms on page 2-112 section.

Data Types: `string` | `char`

Output Arguments

`number` — Number of bit errors
nonnegative integer | integer vector

Number of bit errors, returned as a nonnegative integer or integer vector.

Data Types: `single` | `double`

`ratio` — Bit error rate
scalar

Bit error rate, returned as a scalar. `ratio` is the number of bit errors, `number`, to the total number of bits used in the binary representation. The total number of bits is `k` times the number of entries in the smaller of the inputs `x,y`.

`individual` — Results of each individual binary comparison
matrix

Results of each individual binary comparison, returned as a matrix whose dimensions are those of the larger of inputs `x` and `y`. Each element specifies the number of bits by which the elements in the pair differ. For more information, see the Algorithms on page 2-112 section.

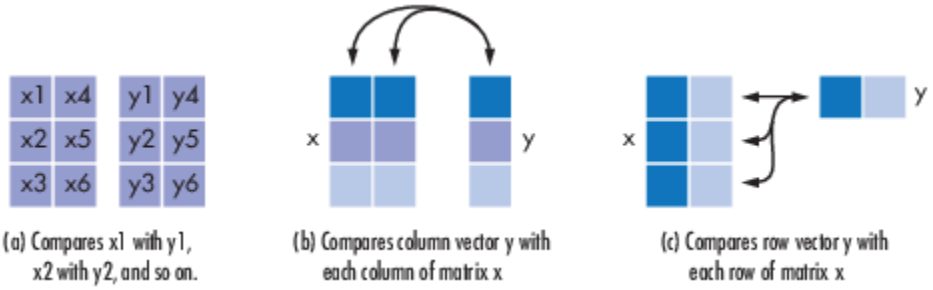
Data Types: `single` | `double`

Algorithms

Comparing Inputs Based on Sizes

The function uses the sizes of `x` and `y` to determine the order in which it compares their elements.

- If inputs are matrices of the same dimensions, then the function compares the inputs element by element. `number` is a nonnegative integer in this case. For example, see case (a) in the figure.
- If one input is a matrix and the other input is a column vector, then the function compares each column of the matrix element by element with the column vector. The number of rows in the matrix must be equal to the length of the column vector. In other words, if the matrix has dimensions *m*-by-*n*, then the column vector must have dimensions *m*-by-1. For example, see case (b) in the figure.
- If one input is a matrix and the other input is a row vector, then the function compares each row of the matrix element by element with the row vector. The number of columns in the matrix must be equal to the length of the row vector. In other words, if the matrix has dimensions *m*-by-*n*, then the row vector must have dimensions 1-by-*n*. For example, see case (c) in the figure.



Comparing Inputs Based on Flag

This table describes how the output is computed based on the different values of `flag`. `x` is considered as a matrix in this table and the size of `y` is varied.

Size of y	flag Value	Type of Comparison	number Value	Total Number of Bits
Matrix	`'overall'` (default)	Element by element	Total number of bit errors	k times the number of elements in y
	`'row-wise'`	*m*th row of x to *m*th row of y	Column vector whose elements represent the bit errors in each row	k times the number of elements in y
	`'column-wise'`	*m*th column of x to *m*th column of y	Row vector whose elements represent the bit errors in each column	k times the number of elements in y
Row vector	`'overall'`	y to each row of x	Total number of bit errors	k times the number of elements of x
	`'row-wise'`(default)	y to each row of x	Column vector whose elements represent the bit errors in each row of x	k times the size of y
Column vector	`'overall'`	y to each column of x	Total number of bit errors	k times the number of elements of x
	`'column-wise'` (default)	y to each column of x	Row vector whose elements represent bit errors in each column of x	k times the size of y

bsc

Binary symmetric channel

Syntax

```
ndata = bsc(data,probability)
ndata = bsc(data,probability,streamhandle)
ndata = bsc(data,probability,seed)
[ndata,err] = bsc( ___ )
```

Description

`ndata = bsc(data,probability)` passes the binary input signal `data` through a binary symmetric channel having the specified error probability. The channel introduces a bit error and processes each element of the input `data` independently. `data` must be an array of binary numbers or a Galois array in GF(2). `probability` must be a scalar from 0 to 1.

`ndata = bsc(data,probability,streamhandle)` accepts a random stream handle to generate uniform noise samples by using `rand`. Providing a random stream handle or using the `reset(RandStream)` function on the default random stream object enables you to generate repeatable noise samples. For more information, see `RandStream`.

`ndata = bsc(data,probability,seed)` accepts a seed value, for initializing the uniform random number generator, `rand`. If you want to generate repeatable noise samples, then either reset the random stream input before calling `bsc` or use the same seed input.

`[ndata,err] = bsc( ___ )` returns an array containing the channel errors, using any of the preceding syntaxes.

Examples

Add Bit Errors to Bit Stream

Using the `bsc` function, introduce bit errors in the bits in a random matrix with probability 0.15.

```
z = randi([0 1],100,100); % Random matrix
nz = bsc(z,.15); % Binary symmetric channel
[numerrs, pcterrs] = biterr(z,nz) % Number and percentage of errors
```

```
numerrs = 1509

pcterrs = 0.1509
```

The output below is typical. For relatively small sets of data, the percentage of bit errors is not exactly 15% in most trials. If the size of the matrix `z` is large, the bit error percentage will be closer to the exact probability you specify.

Check for Errors After Decoding

Using the `bsc` function, introduce bit errors in the bits in a random matrix with probability 0.01. Use Viterbi decoder to decode message data.

Define trellis for Viterbi decoder. Generate and encode message data.

```
trel = poly2trellis([4 3],[4 5 17;7 4 2]);
msg = ones(10000,1);
```

Create objects for convolutional encoder, Viterbi decoder, and error rate calculator.

```
hEnc = comm.ConvolutionalEncoder(trel);
hVitDec = comm.ViterbiDecoder(trel, 'InputFormat','hard', 'TracebackDepth',...
    2, 'TerminationMethod', 'Truncated');
hErrorCalc = comm.ErrorRate;
```

Encode the message data. Introduce bit errors. Display the total number of errors.

```
code = hEnc(msg);
[ncode,err] = bsc(code,.01);
numchanerrs = sum(sum(err))
```

```
numchanerrs = 158
```

Decode the data and check the number of errors after decoding.

```
dcode = hVitDec(ncode);
berVec = hErrorCalc(msg, dcode);
ber = berVec(1)
```

```
ber = 0.0049
```

```
numsyserrs = berVec(2)
```

```
numsyserrs = 49
```

cdma2000ForwardReferenceChannels

Define cdma2000 forward reference channel

Syntax

```
cfg = cdma2000ForwardReferenceChannels(wv)
cfg = cdma2000ForwardReferenceChannels(wv,numchips)
cfg = cdma2000ForwardReferenceChannels(BSTM-RC,numchips,P,M)
cfg = cdma2000ForwardReferenceChannels(traffic,numchips,F-SCH-SPEC)
```

Description

`cfg = cdma2000ForwardReferenceChannels(wv)` returns a structure, `cfg`, that defines the cdma2000® forward link parameters given the input waveform identifier, `wv`. To generate a forward link reference channel waveform, pass this structure to the `cdma2000ForwardWaveformGenerator` function.

For all syntaxes, `cdma2000ForwardReferenceChannels` creates a configuration structure that is compliant with the cdma2000 physical layer specification [1].

`cfg = cdma2000ForwardReferenceChannels(wv,numchips)` specifies the number of chips to generate.

`cfg = cdma2000ForwardReferenceChannels(BSTM-RC,numchips,P,M)` returns the data structure for the `BSTM-RC` waveform identifiers, given the total traffic channel power, `P`, and the number of traffic channels, `M`. For more information on base station testing, see Table 6.5.2-1 of [2].

`cfg = cdma2000ForwardReferenceChannels(traffic,numchips,F-SCH-SPEC)` returns the data structure for the specified traffic channel, `traffic`, and the forward supplemental channel (F-SCH) and frame length combination, `F-SCH-SPEC`. If omitted, `F-SCH-SPEC` has a default value of the lowest F-SCH data rate allowable for a 20 ms frame length, given the radio configuration specified by `traffic`.

Examples

Generate Waveform for RC2 Forward Traffic Channels

Create a parameter structure, `config`, for all forward traffic channels (F-FCH and F-SCCH) that are supported by radio configuration 2.

```
config = cdma2000ForwardReferenceChannels('ALL-RC2')
```

```
config = struct with fields:
          SpreadingRate: 'SR1'
              Diversity: 'NTD'
                    QOF: 'QOF1'
               PNOffset: 0
          LongCodeState: 0
     PowerNormalization: 'Off'
```

```
      OversamplingRatio: 4
             FilterType: 'cdma2000Long'
                InvertQ: 'Off'
       EnableModulation: 'Off'
    ModulationFrequency: 0
              NumChips: 1000
                 FPICH: [1x1 struct]
                FAPICH: [1x1 struct]
               FTDPICH: [1x1 struct]
              FATDPICH: [1x1 struct]
                  FPCH: [1x1 struct]
                 FSYNC: [1x1 struct]
                 FBCCH: [1x1 struct]
                 FCACH: [1x1 struct]
                 FCCCH: [1x1 struct]
                FCPCCH: [1x1 struct]
                 FQPCH: [1x1 struct]
                  FFCH: [1x1 struct]
                 FOCNS: [1x1 struct]
                 FSCCH: [1x1 struct]
```

Examine the fields for the Forward Fundamental Channel (F-FCH). The data rate is 14,400 bps and the frame length is 20 ms.

```
config.FFCH
```

```
ans = struct with fields:
                 Enable: 'On'
                  Power: 0
    RadioConfiguration: 'RC2'
              DataRate: 14400
           FrameLength: 20
          LongCodeMask: 0
          EnableCoding: 'On'
            DataSource: {'PN9'  [1]}
             WalshCode: 7
             EnableQOF: 'Off'
    PowerControlEnable: 'Off'
```

Generate the complex waveform using the corresponding waveform generator function.

```
waveform = cdma2000ForwardWaveformGenerator(config);
```

A waveform composed of the channels specified by each substructure of `config` is generated by `cdma2000ForwardWaveformGenerator`.

Generate CDMA200 Waveform Containing Sync Channel Message

Create a reference channel, specify the sync channel message as the data source, add the `SyncMessage` structure to the `FSYNC` substructure. Generate the waveform using this reference channel configuration.

Create a reference channel for testing a base station using radio configuration 3.

```
config = cdma2000ForwardReferenceChannels('BSTM-RC3');
```

Adjust the Forward Sync Channel (F-SYNC) settings. Set a relative channel power of 0.0 dB and specify the sync channel message as the data source.

```
config.FSYNC.Power = 0.0;
config.FSYNC.DataSource = 'SyncMessage';
```

Define the sync channel message structure (for P_REV = 6 (IS-2000-0)) and add it to the `config.FSYNC` substructure. Display the `FSYNC` structure.

```
sm = struct();
sm.P_REV = 6;                           % Protocol revision field
sm.MIN_P_REV = 6;                       % Minimum protocol revision field
sm.SID = hex2dec('14B');                % System identifier field
sm.NID = 1;                             % Network identification field
sm.PILOT_PN = 0;                        % Pilot PN offset field
sm.LC_STATE = hex2dec('20000000000');   % Long code state field
sm.SYS_TIME = hex2dec('36AE0924C');     % System time field
sm.LP_SEC = 0;                          % Leap second field
sm.LTM_OFF = 0;                         % Local time offset field
sm.DAYLT = 0;                           % Daylight saving time indicator field
sm.PRAT = 0;                            % Paging channel data rate field
sm.CDMA_FREQ = hex2dec('2F6');          % CDMA frequency field
sm.EXT_CDMA_FREQ = hex2dec('2F6');      % Extended CDMA frequency field

config.FSYNC.SyncMessage = sm;

config.FSYNC
```

```
ans = struct with fields:
          Enable: 'On'
           Power: 0
    EnableCoding: 'On'
      DataSource: 'SyncMessage'
     SyncMessage: [1x1 struct]
```

Generate the forward link waveform.

```
waveform = cdma2000ForwardWaveformGenerator(config);
```

Generate F-CCCH Waveform

Create a structure for a 2000-chip forward common control channel (F-CCCH). Specify a 38,400 bps data rate, a 5 ms frame length, and an accompanying broadcast control channel (F-BCCH) with a 9600 bps data rate.

```
config   = cdma2000ForwardReferenceChannels('CONTROL-38400-5-9600',2000)
```

```
config = struct with fields:
          SpreadingRate: 'SR1'
              Diversity: 'NTD'
                    QOF: 'QOF1'
               PNOffset: 0
          LongCodeState: 0
```

```
     PowerNormalization: 'Off'
      OversamplingRatio: 4
             FilterType: 'cdma2000Long'
                InvertQ: 'Off'
       EnableModulation: 'Off'
    ModulationFrequency: 0
              NumChips: 2000
                 FPICH: [1x1 struct]
                  FPCH: [1x1 struct]
                 FCCCH: [1x1 struct]
                 FBCCH: [1x1 struct]
```

Verify that the F-CCCH and F-BCCH data rates are 38,400 bps and 9600 bps, respectively.

```
config.FCCCH.DataRate
```

```
ans = 38400
```

```
config.FBCCH.DataRate
```

```
ans = 9600
```

Generate the forward link waveform.

```
waveform = cdma2000ForwardWaveformGenerator(config);
```

Generate Waveform for Base Station Testing

Create a reference channel for testing a base station using radio configuration 3. Specify the number of chips, the total power allocated to the individual channels, and the number of traffic channels. The FFCH substructure is a structure array whose dimensions are set by the number of traffic channels.

```
config = cdma2000ForwardReferenceChannels('BSTM-RC3',1000,-3,4)
```

```
config = struct with fields:
          SpreadingRate: 'SR1'
              Diversity: 'NTD'
                    QOF: 'QOF1'
               PNOffset: 0
          LongCodeState: 0
     PowerNormalization: 'Off'
      OversamplingRatio: 4
             FilterType: 'cdma2000Long'
                InvertQ: 'Off'
       EnableModulation: 'Off'
    ModulationFrequency: 0
              NumChips: 1000
                 FPICH: [1x1 struct]
                 FSYNC: [1x1 struct]
                  FPCH: [1x1 struct]
                  FFCH: [1x4 struct]
```

Verify that the length of the FFCH substructure corresponds to the number of specified traffic channels, 4.

```
length(config.FFCH)
```

```
ans = 4
```

Generate the forward link waveform.

```
waveform = cdma2000ForwardWaveformGenerator(config);
```

Generate F-SCH Waveform

Create a traffic channel using radio configuration 7 composed of a 614,400 bps forward supplemental channel (F-SCH) having a 20 ms frame length. Set the number of chips to 5000.

```
config = cdma2000ForwardReferenceChannels('TRAFFIC-RC7-4800', ...
    5000,'F-SCH-614400-20')
```

```
config = struct with fields:
          SpreadingRate: 'SR3'
              Diversity: 'NTD'
                    QOF: 'QOF1'
               PNOffset: 0
          LongCodeState: 0
     PowerNormalization: 'Off'
      OversamplingRatio: 4
             FilterType: 'cdma2000Long'
                InvertQ: 'Off'
       EnableModulation: 'Off'
    ModulationFrequency: 0
                NumChips: 5000
                   FPICH: [1x1 struct]
                    FFCH: [1x1 struct]
                    FSCH: [1x1 struct]
```

This channel uses spreading rate 3, `'SR3'`, which has a 3.75 MHz bandwidth.

Generate the forward link waveform.

```
waveform = cdma2000ForwardWaveformGenerator(config);
```

Input Arguments

`wv` — Waveform identification

character vector

Waveform identification of the reference channel, specified as a character vector. The input typically identifies the channel type, radio configuration, data rate, and frame length. To specify `wv`, connect the substrings with hyphens, for example, `'CONTROL-19200-10-4800'`.

Parameter Field	Values				Description
	Substring 1	Substring 2	Substring 3	Substring 4	
wv	'FPICH-ONLY'				Generates a waveform containing a pilot channel only.
	'CONTROL'	9600	20	4800 | 9600 | 19200	Character vector representing the forward common control channel (F-CCCH) data rate in bps, the frame length in ms, and the forward broadcast control channel (F-BCCH) data rate in bps. Specify 'CONTROL-9600-20-9600' to create a structure variable, wv, with a 9600 bps F-CCCH data rate, a 20 ms frame length, and a 9600 bps F-BCCH data rate.
		19200	10 | 20		
		38400	5 | 10 | 20		
	'TRAFFIC'	RC1	1200 | 2400 | 4800 | 9600	N/A	Character vector representing the radio configuration and the forward fundamental channel (F-FCH) data rate in bps. Specify 'TRAFFIC-RC9-14400' to create a channel with radio
		RC2 | RC5 | RC8 | RC9	1800 | 3600 | 7200 | 14400		

Parameter Field	Values				Description
	Substring 1	Substring 2	Substring 3	Substring 4	
		RC3 | RC4 | RC6 | RC7	1500 | 2700 | 4800 | 9600		configuration 9 having a 14400 bps F-FCH data rate.
	'BSTM'	RC1 | RC2 | RC3 | RC4 | RC5 | RC6 | RC7 | RC8 | RC9	N/A	N/A	Models for testing the base station transmitter. Specify 'BSTM-RC1' to create a structure for base station testing with radio configuration 1.
	'ALL'	RC1 | RC2 | RC3 | RC4 | RC5 | RC6 | RC7 | RC8 | RC9	N/A	N/A	Returns all channels that are supported for the specified radio configuration. Specify 'ALL-RC4' to create a structure containing all traffic channels for radio configuration 4.

Example: 'CONTROL-9600-20-9600'

Example: 'TRAFFIC-RC9-7200'

Example: 'ALL-RC5'

Data Types: char

numchips — Number of chips
1000 (default) | positive integer scalar

Number of chips, specified as a positive integer.

Example: 1024

Data Types: double

BSTM-RC — BSTM reference channel type
'BSTM-RC1' | 'BSTM-RC2' | 'BSTM-RC3' | 'BSTM-RC4' | 'BSTM-RC5' | 'BSTM-RC6' | 'BSTM-RC7' | 'BSTM-RC8' | 'BSTM-RC9'

BSTM reference channel type, specified as a character vector. For more information, see Table 6.5.2-1 of [2].

Example: `'BSTM-RC8'`

Data Types: `char`

`P` — Power budget allocated to traffic channels
`0` (default) | real scalar

Power budget allocated to all traffic channels, specified in decibels as a real scalar.

Example: `5`

Data Types: `double`

`M` — Number of traffic channels
`6` (default) | positive integer scalar

Number of traffic channels, specified as a positive integer.

Example: `8`

Data Types: `double`

`traffic` — Traffic configuration
character vector

Traffic channel configuration, specified as a character vector. The table shows the supported traffic channel configurations.

Radio Configuration	Traffic Channel Configuration			
1	'TRAFFIC-RC1-1200'	'TRAFFIC-RC1-2400'	'TRAFFIC-RC1-4800'	'TRAFFIC-RC1-9600'
2	'TRAFFIC-RC2-1800'	'TRAFFIC-RC2-3600'	'TRAFFIC-RC2-7200'	'TRAFFIC-RC2-14400'
3	'TRAFFIC-RC3-1500'	'TRAFFIC-RC3-2700'	'TRAFFIC-RC3-4800'	'TRAFFIC-RC3-9600'
4	'TRAFFIC-RC4-1500'	'TRAFFIC-RC4-2700'	'TRAFFIC-RC4-4800'	'TRAFFIC-RC4-9600'
5	'TRAFFIC-RC5-1800'	'TRAFFIC-RC5-3600'	'TRAFFIC-RC5-7200'	'TRAFFIC-RC5-14400'
6	'TRAFFIC-RC6-1500'	'TRAFFIC-RC6-2700'	'TRAFFIC-RC6-4800'	'TRAFFIC-RC6-9600'
7	'TRAFFIC-RC7-1500'	'TRAFFIC-RC7-2700'	'TRAFFIC-RC7-4800'	'TRAFFIC-RC7-9600'
8	'TRAFFIC-RC8-1800'	'TRAFFIC-RC8-3600'	'TRAFFIC-RC8-7200'	'TRAFFIC-RC8-14400'
9	'TRAFFIC-RC9-1800'	'TRAFFIC-RC9-3600'	'TRAFFIC-RC9-7200'	'TRAFFIC-RC9-14400'

Example: `'TRAFFIC-RC6-4800'` is a traffic channel that uses radio configuration 6 with a 4800 bps data rate.

Data Types: `char`

`F-SCH-SPEC` — Forward supplemental channel data rate and frame length
character vector

Forward supplemental channel data rate and frame length, specified as a character vector. The supported data rate and frame length combinations are summarized in the table.

Radio Configuration	Frame Length		
	20 ms	**40 ms**	**80 ms**
3 | **4** | **6** | **7**	`'F-SCH-1500-20'` | `'F-SCH-2700-20'` | `'F-SCH-4800-20'` | `'F-SCH-9600-20'` | `'F-SCH-19200-20'` | `'F-SCH-38400-20'` | `'F-SCH-76800-20'` | `'F-SCH-153600-20'`	`'F-SCH-1350-40'` | `'F-SCH-2400-40'` | `'F-SCH-4800-40'` | `'F-SCH-9600-40'` | `'F-SCH-19200-40'` | `'F-SCH-38400-40'` | `'F-SCH-76800-40'`	`'F-SCH-1200-80'` | `'F-SCH-2400-80'` | `'F-SCH-4800-80'` | `'F-SCH-9600-80'` | `'F-SCH-19200-80'` | `'F-SCH-38400-80'`

For more data rate information for the cdma2000 forward links, see tables 3.1.3.1.3-2 and 3.1.3.1.3-4 of [1].

Example: `'F-SCH-460800-20'` is a supplemental channel with a 460,800 bps data rate and a 20 ms frame length.

Data Types: `char`

Output Arguments

`cfg` — Configuration of the parameters and channels used by the waveform generator
structure

Configuration of the parameters and channels used by the waveform generator. The configuration structure is defined in these tables.

Top-Level Parameters and Substructures

Parameter Field	Values	Description
`SpreadingRate`	`'SR1'` | `'SR3'`	Spreading rate of the waveform. `SR1` corresponds to a 1.2288 Mcps carrier. `SR3` corresponds to a 3.6864 Mcps carrier. SR3 supports direct sequence spreading only.
`Diversity`	`'NTD'` | `'OTD'` | `'STS'`	Transmit diversity type (applicable only for `SR1`), where `NTD` is no transmit diversity, `OTD` is orthogonal transmit diversity, and `STS` is space time spreading
`QOF`	`'QOF1'` | `'QOF2'` | `'QOF3'`	Quasi-orthogonal function type
`PNOffset`	Nonnegative scalar integer	PN offset of the base station
`LongCodeState`	Positive scalar integer	Initial long code state
`PowerNormalization`	`'Off'` | `'NormalizeTo0dB'` | `'NoiseFillTo0dB'`	Power normalization of the waveform
`NumChips`	Positive scalar integer	Number of chips in the waveform
`FilterType`	`'cdma2000Long'` | `'cdma2000Short'` | `'Off'` | `'Custom'`	Type of output filtering
`CustomFilterCoefficients`	Real vector	Custom filter coefficients, used only when the `FilterType` field is set to `'Custom'`
`OversamplingRatio`	Positive scalar integer	Oversampling ratio at output
`InvertQ`	`'Off'` | `'On'`	Negate the quadrature output
`EnableModulation`	`'Off'` | `'On'`	Enable carrier modulation
`ModulationFrequency`	Nonnegative scalar integer	Carrier modulation frequency (applies when `EnableModulation` is `'On'`)
`FPICH`	Structure	See **`FPICH` Substructure**. Optional.
`FAPICH`	Structure	See **`FAPICH` Substructure**. Optional.
`FTDPICH`	Structure	See **`FTDPICH` Substructure**. Optional.
`FATDPICH`	Structure	See **`FATDPICH` Substructure**. Optional.
`FSYNC`	Structure	See **`FSYNC` Substructure**. Optional.
`FPCH`	Structure	See **`FPCH` Substructure**. Optional.
`FCCCH`	Structure	See **`FCCCH` Substructure**. Optional.
`FCACH`	Structure	See **`FCACH` Substructure**. Optional.
`FQPCH`	Structure	See **`FQPCH` Substructure**. Optional.
`FCPCCH`	Structure	See **`FCPCCH` Substructure**. Optional.
`FBCCH`	Structure	See **`FBCCH` Substructure**. Optional.
`FFCH`	Structure	See **`FFCH` Substructure**. Optional.
`FDCCH`	Structure	See **`FDCCH` Substructure**. Optional.
`FSCCH`	Structure	See **`FSCCH` Substructure**. Optional.

Parameter Field	Values	Description
FSCH	Structure	See **FSCH Substructure**. Optional.
FOCNS	Structure	See **FOCNS Substructure**. Optional.

FPICH Substructure

Include the FPICH substructure in the cfg structure to configure the forward pilot channel (F-PICH). The FPICH substructure contains these fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)

FAPICH Substructure

Include the FAPICH substructure in the cfg structure to configure the forward auxiliary pilot channel (F-APICH). The FAPICH substructure contains these fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
WalshLength	64 | 128 | 256 | 512	Walsh code length
WalshCode	Nonnegative integer scalar, such that 0 ≤ WalshCode ≤ WalshLength – 1	Walsh code number
LongCodeMask	Positive scalar integer	Long code identifier

FTDPICH Substructure

Include the FTDPICH substructure in the cfg structure to configure the forward transmit diversity pilot Channel (F-TDPICH). The FTDPICH substructure contains these fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)

FATDPICH

Include the FATDPICH substructure in the cfg structure to configure the forward auxiliary transmit diversity pilot channel (F-ATDPICH). The FATDPICH substructure contains these fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
WalshLength	64 | 128 | 256, 512	Walsh code length

Parameter Field	Values	Description
`WalshCode`	Nonnegative integer scalar, such that 0 ≤ `WalshCode` ≤ `WalshLength` – 1	Walsh code number
`LongCodeMask`	Positive scalar integer	Long code identifier

FSYNC Substructure

Include the `FSYNC` substructure in the `cfg` structure to configure the forward sync channel (F-SYNC). The `FSYNC` substructure contains these fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array: `{'PN Type', RN Seed}`, binary vector, or `'SyncMessage'`. Standard PN types are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed, a binary vector, or a `'SyncMessage'` character vector.
`SyncMessage`	Structure	See **`SyncMessage` Substructure**. Optional.

SyncMessage Substructure

If the `DataSource` field of the `FSYNC` substructure is set to `'SyncMessage'`, add the `SyncMessage` substructure to the `cfg.FSYNC` substructure to configure the sync channel message. The `SyncMessage` substructure contains these fields.

Parameter Field	Typical Value	Description
P_REV	`6`	Protocol revision
MIN_P_REV	`6`	Minimum protocol revision
SID	`hex2dec('14B')`	System identifier
NID	`1`	Network identification
PILOT_PN	`0`	Pilot PN offset
LC_STATE	`hex2dec('20000000000')`	Long code state
SYS_TIME	`hex2dec('36AE0924C')`	System time
LP_SEC	`0`	Leap second
LTM_OFF	`0`	Local time offset
DAYLT	`0`	Daylight saving time indicator
PRAT	`0`	Paging channel data rate
CDMA_FREQ	`hex2dec('2F6')`	CDMA frequency
EXT_CDMA_FREQ	`hex2dec('2F6')`	Extended CDMA frequency

FPCH Substructure

Include the `FPCH` substructure in the `cfg` substructure to configure the forward paging channel (F-PCH). The `FPCH` substructure contains these fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`DataRate`	`4800` | `9600`	Data rate (bps)
`LongCodeMask`	Positive scalar integer	Long code identifier
`WalshCode`	Nonnegative integer scalar, such that 0 ≤ `WalshCode` ≤ 7	Walsh code number
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array: `{'PN Type', RN Seed}`, binary vector, or a paging message character vector. Standard PN types are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`. Paging message options include `'PagingMessage1'`, `'PagingMessage2'`, and `'PagingMessage3'`.	Data source. Specify a standard PN sequence with a random number seed, a binary vector, or one of three paging messages. For a description of paging message contents see footnote 1.

1 When the `DataSource` enumeration specifies one of the paging message options, simulated paging message data is used as input to the F-PCH physical channel:

- `'PagingMessage1'` — Streams a 7680 bit sequence (800 ms at fullrate) of paging message contents onto the channel that includes the General Page Message, the CDMA Channel List Message, the Extended System Parameter Message, the Extended Neighbor List Message, the System Parameter Message, and the Access Parameter Message. The paging message repeats these messages in a nonsequential pattern.
- `'PagingMessage2'` — Streams a 2304 bit sequence (240 ms at fullrate) of paging message contents onto the channel that includes a truncated version of the full `'PagingMessage1'` content.
- `'PagingMessage3'` — Streams an 864 bit sequence (90 ms at fullrate) of paging message contents onto the channel that includes the Neighbor List Message, the CDMA Channel List Message, the General Page Message, the System Parameter Message, and the Access Parameter Message. The paging message repeats these messages in a sequential pattern.

For more information on the F-PCH contents, refer to 3GPP2 C.S0004, Table 3.1.2.3.1.1.2–1.

FCCCH Substructure

Include the `FCCCH` substructure in the `cfg` structure to configure the forward common control channel (F-CCCH). The `FCCCH` substructure contains these fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`DataRate`	`9600` | `19200` | `38400`	Data rate (bps)
`FrameLength`	`5` | `10` | `20`	Frame length (ms)
`CodingType`	`'conv'` | `'turbo'`	Type of error correction coding
`WalshCode`	Nonnegative integer scalar such that 0 ≤ `WalshCode` ≤ 255	Walsh code number
`LongCodeMask`	Positive scalar integer	Long code identifier
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array: `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

FCACH Substructure

Include the `FCACH` substructure in the `cfg` structure to configure the forward common assignment channel (F-CACH). The `FCACH` substructure contains these fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`CodingType`	`'conv'` | `'turbo'`	Type of error correction coding
`WalshCode`	Nonnegative integer scalar such that 0 ≤ `WalshCode` ≤ 255	Walsh code number
`LongCodeMask`	Positive scalar integer	Long code identifier
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array: `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

FQPCH Substructure

Include the `FQPCH` substructure in the `cfg` structure to configure the forward quick paging channel (F-QPCH). The `FQPCH` substructure contains these fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`DataRate`	`2400` | `4800`	Data rate (bps)
`WalshCode`	Nonnegative integer scalar such that 0 ≤ `WalshCode` ≤ 255	Walsh code number
`LongCodeMask`	Positive scalar integer	Long code identifier
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array: `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

FCPCCH Substructure

Include the `FCPCCH` substructure in the `cfg` structure to configure the forward common power control channel (F-CPCCH). The `FCPCCH` substructure contains these fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`WalshCode`	Nonnegative integer scalar such that 0 ≤ `WalshCode` ≤ 63	Walsh code number
`LongCodeMask`	Positive scalar integer	Long code identifier
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array: `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

FBCCH Substructure

Include the `FBCCH` substructure in the `cfg` structure to configure the forward broadcast control channel (F-BCCH). The `FBCCH` substructure contains these fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)

Parameter Field	Values	Description
`DataRate`	`4800` | `9600` | `19200`	Data rate (bps)
`CodingType`	`'conv'` | `'turbo'`	Type of error correction coding
`WalshCode`	Nonnegative integer scalar such that 0 ≤ `WalshCode` ≤ 127	Walsh code number
`LongCodeMask`	Positive scalar integer	Long code identifier
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array: `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

FFCH Substructure

Include the `FFCH` substructure in the `cfg` structure to configure the forward fundamental traffic channel (F-FCH). The `FFCH` substructure contains these fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`RadioConfiguration`	`'RC1'` through `'RC9'`	Radio configuration channel
`DataRate`	`1200` | `1500` | `1800` | `2400` | `2700` | `3600` | `4800` | `7200` | `9600` | `14400`	Data rate (bps)
`FrameLength`	`5` | `10` | `20`	Frame length (ms)
`WalshCode`	Nonnegative integer scalar such that 0 ≤ `WalshCode` ≤ 255	Walsh code number
`LongCodeMask`	Positive scalar integer	Long code identifier
`EnableQOF`	`'On'` | `'Off'`	Enable QOF spreading
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array: `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.
`PowerControlEnable`	`'On'` | `'Off'`	Enable or disable power control subchannel

Parameter Field	Values	Description
`PowerControlPower`	Real scalar	Power control subchannel power (relative to F-FCH)
`PowerControlDataSource`	Cell array: `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Power control subchannel data source

FDCCH Substructure

Include the `FDCCH` substructure in the `cfg` structure to configure the forward dedicated control channel (F-DCCH). The `FDCCH` substructure contains these fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`RadioConfiguration`	`'RC3'` through `'RC9'`	Radio configuration channel
`DataRate`	`9600` | `14400`	Data rate (bps)
`FrameLength`	`5` | `20`	Frame length (ms)
`WalshCode`	Nonnegative integer scalar such that $0 \le$ `WalshCode` ≤ 255	Walsh code number
`LongCodeMask`	Positive scalar integer	Long code identifier
`EnableQOF`	`'On'` | `'Off'`	Enable QOF spreading
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array: `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

FSCCH Substructure

Include the `FSCCH` substructure in the `cfg` structure to configure the forward supplemental code channel (F-SCCH). The `FSCCH` substructure contains these fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`RadioConfiguration`	`'RC1'` | `'RC2'`	Radio configuration channel

Parameter Field	Values	Description
`WalshCode`	Nonnegative integer scalar such that 0 ≤ `WalshCode` ≤ 255	Walsh code number
`LongCodeMask`	Positive scalar integer	Long code identifier
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array: `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

FSCH Substructure

Include the `FSCH` substructure in the `cfg` structure to configure the forward supplemental channel (F-SCH). The `FSCH` substructure contains these fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`RadioConfiguration`	`'RC3'` | `'RC4'` | `'RC5'` | `'RC6'` | `'RC7'` | `'RC8'` | `'RC9'`	Radio configuration channel
`DataRate`	`1200` | `1350` | `1500` | `1800` | `2400` | `2700` | `3600` | `4800` | `7200` | `9600` | `14400` | `19200` | `28800` | `38400` | `57600` | `76800` | `115200` | `153600` | `230400` | `307200`	Data rate (bps)
`FrameLength`	`20` | `40` | `80`	Frame length (ms)
`CodingType`	`'Conv'` | `'Turbo'`	Channel coding type, convolutional or turbo
`WalshCode`	Nonnegative integer scalar such that 0 ≤ `WalshCode` ≤ 255	Walsh code number
`LongCodeMask`	Positive scalar integer	Long code identifier
`EnableQOF`	`'On'` | `'Off'`	Enable QOF spreading
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array: `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

FOCNS Substructure

Include the `FOCNS` substructure in the `cfg` structure to configure orthogonal channel noise source information. The `FOCNS` substructure contains these fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`WalshLength`	`64` | `128` | `256`	Walsh code length
`WalshCode`	Nonnegative integer scalar such that 0 ≤ `WalshCode` ≤ `WalshLength` – 1	Walsh code number

cdma2000ForwardWaveformGenerator

Generate cdma2000 forward link waveform

Syntax

```
[waveform1,waveform2] = cdma2000ForwardWaveformGenerator(cfg)
```

Description

`[waveform1,waveform2] = cdma2000ForwardWaveformGenerator(cfg)` returns the cdma2000 forward link baseband primary waveform, `waveform1`, and the forward link diversity waveform, `waveform2`, as defined by the parameter definition structure, `cfg`.

The top-level parameters and lower-level substructures of `cfg` specify the waveform and channel properties the function uses to generate a cdma2000 waveform. You can generate `cfg` by using the `cdma2000ForwardReferenceChannels` function. The top-level parameters of `cfg` are `SpreadingRate`, `Diversity`, `QOF`, `PNOffset`, `LongCodeState`, `PowerNormalization`, `CustomFilterCoefficients`, `OversamplingRatio`, `FilterType`, `InvertQ`, `EnableModulation`, `ModulationFrequency`, and `NumChips`. To enable specific channels, add their associated substructures, for example, the forward paging channel, `FPCH`.

Note The tables herein list the allowable values for the top-level parameters and substructure fields. However, not all combinations of spreading rate, radio configuration, frame length, and data rate are supported. To ensure that the input argument is valid, use the `cdma2000ForwardReferenceChannels` function. If you input the structure fields manually, consult [1] to ensure that the input parameter combinations are permitted.

Examples

Generate Waveform for RC2 Forward Traffic Channels

Create a parameter structure, `config`, for all forward traffic channels (F-FCH and F-SCCH) that are supported by radio configuration 2.

```
config = cdma2000ForwardReferenceChannels('ALL-RC2')
```

```
config = struct with fields:
          SpreadingRate: 'SR1'
              Diversity: 'NTD'
                    QOF: 'QOF1'
               PNOffset: 0
          LongCodeState: 0
     PowerNormalization: 'Off'
      OversamplingRatio: 4
             FilterType: 'cdma2000Long'
                InvertQ: 'Off'
       EnableModulation: 'Off'
    ModulationFrequency: 0
```

```
                NumChips: 1000
                   FPICH: [1x1 struct]
                  FAPICH: [1x1 struct]
                 FTDPICH: [1x1 struct]
                FATDPICH: [1x1 struct]
                    FPCH: [1x1 struct]
                   FSYNC: [1x1 struct]
                   FBCCH: [1x1 struct]
                   FCACH: [1x1 struct]
                   FCCCH: [1x1 struct]
                  FCPCCH: [1x1 struct]
                   FQPCH: [1x1 struct]
                    FFCH: [1x1 struct]
                   FOCNS: [1x1 struct]
                   FSCCH: [1x1 struct]
```

Examine the fields for the Forward Fundamental Channel (F-FCH). The data rate is 14,400 bps and the frame length is 20 ms.

```
config.FFCH
```

```
ans = struct with fields:
                 Enable: 'On'
                  Power: 0
    RadioConfiguration: 'RC2'
              DataRate: 14400
           FrameLength: 20
          LongCodeMask: 0
          EnableCoding: 'On'
            DataSource: {'PN9'  [1]}
             WalshCode: 7
             EnableQOF: 'Off'
    PowerControlEnable: 'Off'
```

Generate the complex waveform using the corresponding waveform generator function.

```
waveform = cdma2000ForwardWaveformGenerator(config);
```

A waveform composed of the channels specified by each substructure of `config` is generated by `cdma2000ForwardWaveformGenerator`.

Generate Forward Traffic Channel for RC4

Configure a cdma2000 forward link supporting a 307.2 kbps forward supplemental channel (F-SCH) using radio configuration 4.

```
config = cdma2000ForwardReferenceChannels( ...
    "TRAFFIC-RC4-4800", ...
    20000, ...
    "F-SCH-307200-20")
```

```
config = struct with fields:
          SpreadingRate: 'SR1'
              Diversity: 'NTD'
```

```
                  QOF: 'QOF1'
              PNOffset: 0
         LongCodeState: 0
     PowerNormalization: 'Off'
      OversamplingRatio: 4
             FilterType: 'cdma2000Long'
                InvertQ: 'Off'
       EnableModulation: 'Off'
    ModulationFrequency: 0
              NumChips: 20000
                 FPICH: [1x1 struct]
                  FFCH: [1x1 struct]
                  FSCH: [1x1 struct]
```

Generate the waveform and plot its spectrum. The sample rate is equal to the product of the chip rate and the oversampling ratio. RC4 uses spreading rate 1, which is equivalent to a 1.2288 Mcps chip rate.

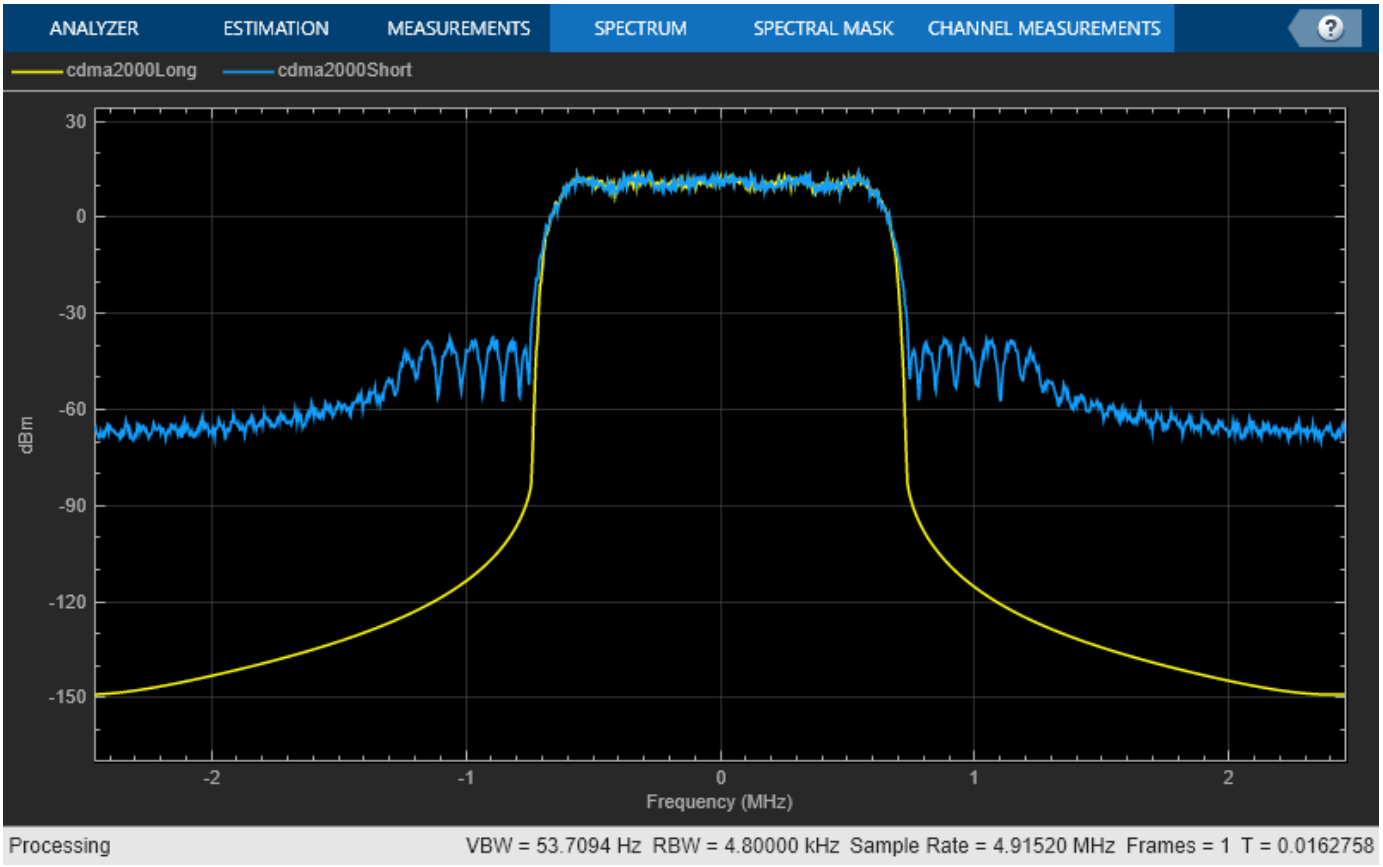
```
wv = cdma2000ForwardWaveformGenerator(config);
fs = 1.2288e6 * config.OversamplingRatio;
```

Change the filter type to `"cdma2000Short"`.

```
config.FilterType = "cdma2000Short";
wvShortFilt = cdma2000ForwardWaveformGenerator(config);
```

Use the `spectrumAnalyzer` object with `Method="welch"` to plot the spectrum for both waveforms. The `'cdma2000Short'` filter does not provide as much out-of-band attenuation as does the `'cdma2000Long'` filter.

```
sa = spectrumAnalyzer( ...
    SampleRate=fs, ...
    Method="welch", ...
    ChannelNames=["cdma2000Long","cdma2000Short"]);
sa(wv,wvShortFilt)
```



Generate cdma2000 Waveform with Two Forward Supplemental Channels

Create a parameter structure that specifies a forward traffic channel. Use it to generate a forward channel waveform.

Create a parameter structure specifying a traffic channel consisting of a 4800 bps fundamental channel, 5000 chips, and a 614.4 kbps supplemental channel (F-SCH) having a 20 ms frame duration.

```
cfg = cdma2000ForwardReferenceChannels('TRAFFIC-RC7-4800', ...
    5000,'F-SCH-614400-20');
```

Based on the first F-SCH, create a second F-SCH.

```
cfg(2).FSCH = cfg.FSCH;
```

Set the data rate of the second F-SCH to 38.4 kbps. Set the frame duration to 40 ms.

```
cfg(2).FSCH.DataRate = 38400;
cfg(2).FSCH.FrameLength = 40;
cfg.FSCH
```

```
ans = struct with fields:
                Enable: 'On'
                 Power: 0
```

```
    RadioConfiguration: 'RC7'
              DataRate: 614400
           FrameLength: 20
          LongCodeMask: 0
          EnableCoding: 'On'
            DataSource: {'PN9'  [1]}
             WalshCode: 2
             EnableQOF: 'Off'
            CodingType: 'conv'

ans = struct with fields:
                Enable: 'On'
                 Power: 0
    RadioConfiguration: 'RC7'
              DataRate: 38400
           FrameLength: 40
          LongCodeMask: 0
          EnableCoding: 'On'
            DataSource: {'PN9'  [1]}
             WalshCode: 2
             EnableQOF: 'Off'
            CodingType: 'conv'
```

Set the Walsh code of the second F-SCH so that it is not identical to the Walsh code of the first F-SCH.

```
cfg(2).FSCH.WalshCode = 3;
```

Generate the forward link waveform.

```
wv = cdma2000ForwardWaveformGenerator(cfg);
```

Input Arguments

`cfg` — Configuration of the parameters and channels used by the waveform generator

structure

Configuration of the parameters and channels used by the waveform generator. The configuration structure is defined in these tables.

Top-Level Parameters and Substructures

Parameter Field	Values	Description
`SpreadingRate`	`'SR1'` | `'SR3'`	Spreading rate of the waveform. `SR1` corresponds to a 1.2288 Mcps carrier. `SR3` corresponds to a 3.6864 Mcps carrier. SR3 supports direct sequence spreading only.
`Diversity`	`'NTD'` | `'OTD'` | `'STS'`	Transmit diversity type (applicable only for `SR1`), where `NTD` is no transmit diversity, `OTD` is orthogonal transmit diversity, and `STS` is space time spreading
`QOF`	`'QOF1'` | `'QOF2'` | `'QOF3'`	Quasi-orthogonal function type

Parameter Field	Values	Description
`PNOffset`	Nonnegative scalar integer	PN offset of the base station
`LongCodeState`	Positive scalar integer	Initial long code state
`PowerNormalization`	`'Off'` | `'NormalizeTo0dB'` | `'NoiseFillTo0dB'`	Power normalization of the waveform
`NumChips`	Positive scalar integer	Number of chips in the waveform
`FilterType`	`'cdma2000Long'` | `'cdma2000Short'` | `'Off'` | `'Custom'`	Type of output filtering
`CustomFilterCoefficients`	Real vector	Custom filter coefficients, used only when the `FilterType` field is set to `'Custom'`
`OversamplingRatio`	Positive scalar integer	Oversampling ratio at output
`InvertQ`	`'Off'` | `'On'`	Negate the quadrature output
`EnableModulation`	`'Off'` | `'On'`	Enable carrier modulation
`ModulationFrequency`	Nonnegative scalar integer	Carrier modulation frequency (applies when `EnableModulation` is `'On'`)
`FPICH`	Structure	See **`FPICH` Substructure**. Optional.
`FAPICH`	Structure	See **`FAPICH` Substructure**. Optional.
`FTDPICH`	Structure	See **`FTDPICH` Substructure**. Optional.
`FATDPICH`	Structure	See **`FATDPICH` Substructure**. Optional.
`FSYNC`	Structure	See **`FSYNC` Substructure**. Optional.
`FPCH`	Structure	See **`FPCH` Substructure**. Optional.
`FCCCH`	Structure	See **`FCCCH` Substructure**. Optional.
`FCACH`	Structure	See **`FCACH` Substructure**. Optional.
`FQPCH`	Structure	See **`FQPCH` Substructure**. Optional.
`FCPCCH`	Structure	See **`FCPCCH` Substructure**. Optional.
`FBCCH`	Structure	See **`FBCCH` Substructure**. Optional.
`FFCH`	Structure	See **`FFCH` Substructure**. Optional.
`FDCCH`	Structure	See **`FDCCH` Substructure**. Optional.
`FSCCH`	Structure	See **`FSCCH` Substructure**. Optional.
`FSCH`	Structure	See **`FSCH` Substructure**. Optional.
`FOCNS`	Structure	See **`FOCNS` Substructure**. Optional.

`FPICH` Substructure

Include the `FPICH` substructure in the `cfg` structure to configure the forward pilot channel (F-PICH). The `FPICH` substructure contains these fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)

FAPICH Substructure

Include the `FAPICH` substructure in the `cfg` structure to configure the forward auxiliary pilot channel (F-APICH). The `FAPICH` substructure contains these fields.

Parameter Field	Values	Description
`Enable`	`'On' | 'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`WalshLength`	`64 | 128 | 256 | 512`	Walsh code length
`WalshCode`	Nonnegative integer scalar, such that $0 \le$ `WalshCode` $\le$ `WalshLength` – 1	Walsh code number
`LongCodeMask`	Positive scalar integer	Long code identifier

FTDPICH Substructure

Include the `FTDPICH` substructure in the `cfg` structure to configure the forward transmit diversity pilot Channel (F-TDPICH). The `FTDPICH` substructure contains these fields.

Parameter Field	Values	Description
`Enable`	`'On' | 'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)

FATDPICH

Include the `FATDPICH` substructure in the `cfg` structure to configure the forward auxiliary transmit diversity pilot channel (F-ATDPICH). The `FATDPICH` substructure contains these fields.

Parameter Field	Values	Description
`Enable`	`'On' | 'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`WalshLength`	`64 | 128 | 256, 512`	Walsh code length
`WalshCode`	Nonnegative integer scalar, such that $0 \le$ `WalshCode` $\le$ `WalshLength` – 1	Walsh code number
`LongCodeMask`	Positive scalar integer	Long code identifier

FSYNC Substructure

Include the `FSYNC` substructure in the `cfg` structure to configure the forward sync channel (F-SYNC). The `FSYNC` substructure contains these fields.

Parameter Field	Values	Description
`Enable`	`'On' | 'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`EnableCoding`	`'On' | 'Off'`	Enable or disable channel coding

Parameter Field	Values	Description
`DataSource`	Cell array: `{'PN Type', RN Seed}`, binary vector, or `'SyncMessage'`. Standard PN types are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed, a binary vector, or a `'SyncMessage'` character vector.
`SyncMessage`	Structure	See **SyncMessage Substructure**. Optional.

SyncMessage Substructure

If the `DataSource` field of the `FSYNC` substructure is set to `'SyncMessage'`, add the `SyncMessage` substructure to the `cfg.FSYNC` substructure to configure the sync channel message. The `SyncMessage` substructure contains these fields.

Parameter Field	Typical Value	Description
P_REV	`6`	Protocol revision
MIN_P_REV	`6`	Minimum protocol revision
SID	`hex2dec('14B')`	System identifier
NID	`1`	Network identification
PILOT_PN	`0`	Pilot PN offset
LC_STATE	`hex2dec('20000000000')`	Long code state
SYS_TIME	`hex2dec('36AE0924C')`	System time
LP_SEC	`0`	Leap second
LTM_OFF	`0`	Local time offset
DAYLT	`0`	Daylight saving time indicator
PRAT	`0`	Paging channel data rate
CDMA_FREQ	`hex2dec('2F6')`	CDMA frequency
EXT_CDMA_FREQ	`hex2dec('2F6')`	Extended CDMA frequency

FPCH Substructure

Include the `FPCH` substructure in the `cfg` substructure to configure the forward paging channel (F-PCH). The `FPCH` substructure contains these fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`DataRate`	`4800` | `9600`	Data rate (bps)
`LongCodeMask`	Positive scalar integer	Long code identifier
`WalshCode`	Nonnegative integer scalar, such that $0 \le$ `WalshCode` ≤ 7	Walsh code number

Parameter Field	Values	Description
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array: `{'PN Type', RN Seed}`, binary vector, or a paging message character vector. Standard PN types are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`. Paging message options include `'PagingMessage1'`, `'PagingMessage2'`, and `'PagingMessage3'`.	Data source. Specify a standard PN sequence with a random number seed, a binary vector, or one of three paging messages. For a description of paging message contents see footnote 1.

1 When the `DataSource` enumeration specifies one of the paging message options, simulated paging message data is used as input to the F-PCH physical channel:

- `'PagingMessage1'` — Streams a 7680 bit sequence (800 ms at fullrate) of paging message contents onto the channel that includes the General Page Message, the CDMA Channel List Message, the Extended System Parameter Message, the Extended Neighbor List Message, the System Parameter Message, and the Access Parameter Message. The paging message repeats these messages in a nonsequential pattern.
- `'PagingMessage2'` — Streams a 2304 bit sequence (240 ms at fullrate) of paging message contents onto the channel that includes a truncated version of the full `'PagingMessage1'` content.
- `'PagingMessage3'` — Streams an 864 bit sequence (90 ms at fullrate) of paging message contents onto the channel that includes the Neighbor List Message, the CDMA Channel List Message, the General Page Message, the System Parameter Message, and the Access Parameter Message. The paging message repeats these messages in a sequential pattern.

For more information on the F-PCH contents, refer to 3GPP2 C.S0004, Table 3.1.2.3.1.1.2–1.

FCCCH Substructure

Include the `FCCCH` substructure in the `cfg` structure to configure the forward common control channel (F-CCCH). The `FCCCH` substructure contains these fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`DataRate`	`9600` | `19200` | `38400`	Data rate (bps)
`FrameLength`	`5` | `10` | `20`	Frame length (ms)
`CodingType`	`'conv'` | `'turbo'`	Type of error correction coding
`WalshCode`	Nonnegative integer scalar such that 0 ≤ `WalshCode` ≤ 255	Walsh code number
`LongCodeMask`	Positive scalar integer	Long code identifier

Parameter Field	Values	Description
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array: `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

FCACH Substructure

Include the `FCACH` substructure in the `cfg` structure to configure the forward common assignment channel (F-CACH). The `FCACH` substructure contains these fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`CodingType`	`'conv'` | `'turbo'`	Type of error correction coding
`WalshCode`	Nonnegative integer scalar such that 0 ≤ `WalshCode` ≤ 255	Walsh code number
`LongCodeMask`	Positive scalar integer	Long code identifier
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array: `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

FQPCH Substructure

Include the `FQPCH` substructure in the `cfg` structure to configure the forward quick paging channel (F-QPCH). The `FQPCH` substructure contains these fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`DataRate`	`2400` | `4800`	Data rate (bps)
`WalshCode`	Nonnegative integer scalar such that 0 ≤ `WalshCode` ≤ 255	Walsh code number
`LongCodeMask`	Positive scalar integer	Long code identifier
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding

Parameter Field	Values	Description
`DataSource`	Cell array: `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

FCPCCH Substructure

Include the `FCPCCH` substructure in the `cfg` structure to configure the forward common power control channel (F-CPCCH). The `FCPCCH` substructure contains these fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`WalshCode`	Nonnegative integer scalar such that $0 \le$ `WalshCode` ≤ 63	Walsh code number
`LongCodeMask`	Positive scalar integer	Long code identifier
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array: `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

FBCCH Substructure

Include the `FBCCH` substructure in the `cfg` structure to configure the forward broadcast control channel (F-BCCH). The `FBCCH` substructure contains these fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`DataRate`	`4800` | `9600` | `19200`	Data rate (bps)
`CodingType`	`'conv'` | `'turbo'`	Type of error correction coding
`WalshCode`	Nonnegative integer scalar such that $0 \le$ `WalshCode` ≤ 127	Walsh code number
`LongCodeMask`	Positive scalar integer	Long code identifier
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding

Parameter Field	Values	Description
`DataSource`	Cell array: `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

FFCH Substructure

Include the `FFCH` substructure in the `cfg` structure to configure the forward fundamental traffic channel (F-FCH). The `FFCH` substructure contains these fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`RadioConfiguration`	`'RC1'` through `'RC9'`	Radio configuration channel
`DataRate`	`1200` | `1500` | `1800` | `2400` | `2700` | `3600` | `4800` | `7200` | `9600` | `14400`	Data rate (bps)
`FrameLength`	`5` | `10` | `20`	Frame length (ms)
`WalshCode`	Nonnegative integer scalar such that 0 ≤ `WalshCode` ≤ 255	Walsh code number
`LongCodeMask`	Positive scalar integer	Long code identifier
`EnableQOF`	`'On'` | `'Off'`	Enable QOF spreading
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array: `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.
`PowerControlEnable`	`'On'` | `'Off'`	Enable or disable power control subchannel
`PowerControlPower`	Real scalar	Power control subchannel power (relative to F-FCH)
`PowerControlDataSource`	Cell array: `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Power control subchannel data source

FDCCH Substructure

Include the `FDCCH` substructure in the `cfg` structure to configure the forward dedicated control channel (F-DCCH). The `FDCCH` substructure contains these fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`RadioConfiguration`	`'RC3'` through `'RC9'`	Radio configuration channel
`DataRate`	`9600` | `14400`	Data rate (bps)
`FrameLength`	`5` | `20`	Frame length (ms)
`WalshCode`	Nonnegative integer scalar such that 0 ≤ `WalshCode` ≤ 255	Walsh code number
`LongCodeMask`	Positive scalar integer	Long code identifier
`EnableQOF`	`'On'` | `'Off'`	Enable QOF spreading
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array: `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

FSCCH Substructure

Include the `FSCCH` substructure in the `cfg` structure to configure the forward supplemental code channel (F-SCCH). The `FSCCH` substructure contains these fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`RadioConfiguration`	`'RC1'` | `'RC2'`	Radio configuration channel
`WalshCode`	Nonnegative integer scalar such that 0 ≤ `WalshCode` ≤ 255	Walsh code number
`LongCodeMask`	Positive scalar integer	Long code identifier
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding

Parameter Field	Values	Description
`DataSource`	Cell array: `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

FSCH Substructure

Include the `FSCH` substructure in the `cfg` structure to configure the forward supplemental channel (F-SCH). The `FSCH` substructure contains these fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`RadioConfiguration`	`'RC3'` | `'RC4'` | `'RC5'` | `'RC6'` | `'RC7'` | `'RC8'` | `'RC9'`	Radio configuration channel
`DataRate`	`1200` | `1350` | `1500` | `1800` | `2400` | `2700` | `3600` | `4800` | `7200` | `9600` | `14400` | `19200` | `28800` | `38400` | `57600` | `76800` | `115200` | `153600` | `230400` | `307200`	Data rate (bps)
`FrameLength`	`20` | `40` | `80`	Frame length (ms)
`CodingType`	`'Conv'` | `'Turbo'`	Channel coding type, convolutional or turbo
`WalshCode`	Nonnegative integer scalar such that $0 \le$ `WalshCode` ≤ 255	Walsh code number
`LongCodeMask`	Positive scalar integer	Long code identifier
`EnableQOF`	`'On'` | `'Off'`	Enable QOF spreading
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array: `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

FOCNS Substructure

Include the `FOCNS` substructure in the `cfg` structure to configure orthogonal channel noise source information. The `FOCNS` substructure contains these fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`WalshLength`	`64` | `128` | `256`	Walsh code length
`WalshCode`	Nonnegative integer scalar such that 0 ≤ `WalshCode` ≤ `WalshLength` – 1	Walsh code number

Output Arguments

`waveform1` — Modulated baseband waveform comprising the primary physical channels
complex vector array

Modulated baseband waveform comprising the primary cdma2000 physical channels, returned as a complex vector array.

`waveform2` — Modulated baseband waveform comprising the diversity physical channels
complex vector array

Modulated baseband waveform comprising the diversity cdma2000 physical channels, returned as a complex vector array.

Version History

Introduced in R2015b

`cdma2000ForwardReferenceChannels` | `cdma2000ReverseWaveformGenerator`

cdma2000ReverseReferenceChannels

Define cdma2000 reverse reference channel

Syntax

```
cfg = cdma2000ReverseReferenceChannels(wv)
cfg = cdma2000ReverseReferenceChannels(wv,numchips)
cfg = cdma2000ReverseReferenceChannels(traffic,numchips,R-SCH-SPEC)
```

Description

`cfg = cdma2000ReverseReferenceChannels(wv)` returns a structure, `cfg`, that defines the cdma2000 reverse link parameters given the input waveform identifier, `wv`. Pass the structure to the `cdma2000ReverseWaveformGenerator` function to generate a reverse link reference channel waveform.

For all syntaxes, `cdma2000ReverseReferenceChannels` creates a configuration structure that is compliant with the physical layer specification for cdma2000 systems described in [1].

`cfg = cdma2000ReverseReferenceChannels(wv,numchips)` specifies the number of chips to generate.

`cfg = cdma2000ReverseReferenceChannels(traffic,numchips,R-SCH-SPEC)` returns `cfg` for the specified traffic channel, `traffic`, and the reverse supplemental channel (R-SCH) and frame length combination, `R-SCH-SPEC`.

Examples

Generate Reverse Common Control Channel Waveform

Generate the structure corresponding to the reverse common control channel (R-CCCH) having a 19,200 bps data rate and 10 ms frames.

```
config = cdma2000ReverseReferenceChannels('R-CCCH-19200-10');
```

Verify that the R-CCCH substructure is configured for the correct data rate and frame duration.

```
config.RCCCH
```

```
ans = struct with fields:
          Enable: 'On'
           Power: 0
    LongCodeMask: 0
    EnableCoding: 'On'
      DataSource: {'PN9'  [1]}
        DataRate: 19200
     FrameLength: 10
       WalshCode: 1
```

Generate the reverse channel waveform using the corresponding waveform generator function, `cdma2000ReverseWaveformGenerator`.

```
wv = cdma2000ReverseWaveformGenerator(config);
```

Generate Reverse Channels for RC1 and RC6

Create a configuration structure to generate all possible channels associated with radio configuration 1 in which the number of chips is specified as 2500.

```
config = cdma2000ReverseReferenceChannels('ALL-RC1',2500)
```

```
config = struct with fields:
     RadioConfiguration: 'RC1'
     PowerNormalization: 'Off'
      OversamplingRatio: 4
             FilterType: 'cdma2000Long'
                InvertQ: 'Off'
       EnableModulation: 'Off'
    ModulationFrequency: 0
              NumChips: 2500
                  RFCH: [1x1 struct]
                  RACH: [1x1 struct]
                 RSCCH: [1x1 struct]
```

The structure contains substructures corresponding to the R-FCH, R-ACH, and R-SCCH channels.

Call the function again using radio configuration 6.

```
config = cdma2000ReverseReferenceChannels('ALL-RC6',2500)
```

```
config = struct with fields:
     RadioConfiguration: 'RC6'
     PowerNormalization: 'Off'
      OversamplingRatio: 4
             FilterType: 'cdma2000Long'
                InvertQ: 'Off'
       EnableModulation: 'Off'
    ModulationFrequency: 0
              NumChips: 2500
                  RFCH: [1x1 struct]
                 RPICH: [1x1 struct]
                 REACH: [1x1 struct]
                 RCCCH: [1x1 struct]
                 RDCCH: [1x1 struct]
                 RSCH1: [1x1 struct]
                 RSCH2: [1x1 struct]
```

The channels supported by RC6 differ from those supported by RC1. They include R-FCH, R-PICH, R-EACH, R-CCCH, R-DCCH, R-SCH1, and R-SCH2.

Create the waveform corresponding to the set of RC6 channels.

```
wv = cdma2000ReverseWaveformGenerator(config);
```

Generate Reverse Supplemental Channel

Create a configuration structure using radio configuration 3 with a reverse fundamental channel (R-FCH). Specify a 2700 bps data rate and a reverse supplemental channel (R-SCH) having a 76,800 bps data rate and an 80 ms frame length.

```
config = cdma2000ReverseReferenceChannels('TRAFFIC-RC3-2700',2000, ...
    'R-SCH-76800-80');
```

Verify that the R-FCH data rate is 2700 bps and the first R-SCH data rate is 76,800 bps with an 80 ms frame length.

```
config.RFCH.DataRate
```

```
ans = 2700
```

```
config.RSCH1.DataRate
```

```
ans = 76800
```

```
config.RSCH1.FrameLength
```

```
ans = 80
```

Generate the corresponding waveform.

```
wv = cdma2000ReverseWaveformGenerator(config);
```

Input Arguments

`wv` — Waveform identification

character vector

Waveform identification of the reference channel, specified as a character vector. The input typically identifies the channel type, radio configuration, data rate, and frame length. To specify `wv`, connect the substrings with hyphens, for example, `'TRAFFIC-RC2-3600'`.

Parameter Field	Values			Description
	Substring 1	Substring 2	Substring 3	
wv	`'R-PICH-ONLY'`			Generates a waveform containing a pilot channel only.
	`'R-CCCH'`	`9600`	`20`	Character vector representing the Reverse Common Control Channel (R-CCCH) data rate in bps and the frame length in
		`19200`	`10 | 20`	

Parameter Field	Values			Description
	Substring 1	Substring 2	Substring 3	
		38400	5 | 10 | 20	ms. Specify 'R-CCCH-9600-20' to create a structure variable, wv, with a 9600 bps R-CCCH data rate and a 20 ms frame length.
	'TRAFFIC'	RC1	1200 | 2400 | 4800 | 9600	Character vector representing the radio configuration and the Reverse Fundamental Channel (R-FCH) data rate in bps. Specify 'TRAFFIC-RC6-14400', corresponds to radio configuration 6 with a 14400 bps R-FCH data rate.
		RC2 | RC4 | RC6	1800 | 3600 | 7200 | 14400	
		RC3 | RC5 | RC6	1500 | 2700 | 4800 | 9600	
	'R-EACH'	9600	20	Reverse Enhanced Access Channel waveforms. Specify 'R-EACH-38400-5' to create a structure corresponding to an R-EACH channel with a 38400 bps data rate and a 5 ms frame length.
		19200	10 | 20	
		38400	5 | 10 | 20	
	'R-PICH-R-FCH'			Specify tests for the mobile transmitter in accordance with [2].

Parameter Field	Values			Description
	Substring 1	Substring 2	Substring 3	
	'ALL'	RC1 | RC2 | RC3 | RC4 | RC5 | RC6	N/A	Returns all channels that are supported for the specified radio configuration. Specify 'ALL-RC4' to create a structure containing all traffic channels for radio configuration 4.

Example: 'R-CCCH-9600-20' is a R-CCH channel having a 9600 bps data rate and a 20 ms frame length.

Example: 'R-EACH-38400-5' is a R-EACH channel having a 38,400 bps data rate and a 5 ms frame length.

Data Types: char

numchips — Number of chips
1000 (default) | positive integer scalar

Number of chips, specified as a positive integer.

Example: 2048

Data Types: double

traffic — Traffic configuration
character vector

Traffic channel configuration, specified as a character vector. The table shows the valid configurations.

Radio Configuration	Traffic Channel Configuration			
1	'TRAFFIC-RC1-1200'	'TRAFFIC-RC1-2400'	'TRAFFIC-RC1-4800'	'TRAFFIC-RC1-9600'
2	'TRAFFIC-RC2-1800'	'TRAFFIC-RC2-3600'	'TRAFFIC-RC2-7200'	'TRAFFIC-RC2-14400'
3	'TRAFFIC-RC3-1500'	'TRAFFIC-RC3-2700'	'TRAFFIC-RC3-4800'	'TRAFFIC-RC3-9600'
4	'TRAFFIC-RC4-1800'	'TRAFFIC-RC4-3600'	'TRAFFIC-RC4-7200'	'TRAFFIC-RC4-14400'
5	'TRAFFIC-RC5-1500'	'TRAFFIC-RC5-2700'	'TRAFFIC-RC5-4800'	'TRAFFIC-RC5-9600'

Radio Configuration	Traffic Channel Configuration			
6	'TRAFFIC-RC6-1800'	'TRAFFIC-RC6-3600'	'TRAFFIC-RC6-7200'	'TRAFFIC-RC6-14400'

Example: `'TRAFFIC-RC4-1800'` is a traffic channel using radio configuration 4 and having an R-FCH with an 1800 bps data rate .

Data Types: `char`

`R-SCH-SPEC` — Reverse Supplemental Channel data rate and frame length
character vector

Specify the R-SCH data rate and frame length as a character vector. If omitted, `R-SCH-SPEC` defaults to the lowest R-SCH data rate allowable for a 20 ms frame length given the radio configuration specified by `traffic`. The table summarizes the supported data rate and frame length combinations.

Radio Configuration	Frame Length		
	20 ms	40 ms	80 ms
3 | **5**	'R-SCH-1500-20' | 'R-SCH-2700-20' | 'R-SCH-4800-20' | 'R-SCH-9600-20' | 'R-SCH-19200-20' | 'R-SCH-38400-20' | 'R-SCH-76800-20' | 'R-SCH-153600-20' | 'R-SCH-307200-20'	'R-SCH-1350-40' | 'R-SCH-2400-40' | 'R-SCH-4800-40' | 'R-SCH-9600-40' | 'R-SCH-19200-40' | 'R-SCH-38400-40' | 'R-SCH-76800-40'| 'R-SCH-153600-40'	'R-SCH-1350-80' | 'R-SCH-2400-80' | 'R-SCH-4800-80' | 'R-SCH-9600-80' | 'R-SCH-19200-80' | 'R-SCH-38400-80' | 'R-SCH-76800-80'
5	'R-SCH-614400-20'	'R-SCH-307200-40'	'R-SCH-153600-80'
4 | **6**	'R-SCH-1800-20' | 'R-SCH-3600-20' | 'R-SCH-7200-20' | 'R-SCH-14400-20' | 'R-SCH-28800-20' | 'R-SCH-57600-20' | 'R-SCH-115200-20' | 'R-SCH-230400-20'	'R-SCH-1800-40' | 'R-SCH-3600-40' | 'R-SCH-7200-40' | 'R-SCH-14400-40' | 'R-SCH-28800-40' | 'R-SCH-57600-40' | 'R-SCH-115200-40'	'R-SCH-1800-80' | 'R-SCH-3600-80' | 'R-SCH-7200-80' | 'R-SCH-14400-80' | 'R-SCH-28800-80' | 'R-SCH-57600-80'
6	'R-SCH-460800-20' | 'R-SCH-1036800-20'	'R-SCH-230400-40' | 'R-SCH-518400-40'	'R-SCH-115200-80' | 'R-SCH-259200-80'

Additional data rate information for the cdma2000 reverse links is given in Tables 2.1.3.1.3-1 and 2.1.3.1.3-2 of [1].

Example: `'R-SCH-153600-20'` is an R-SCH having a 153,600 bps data rate and a 20 ms frame length.

Data Types: `char`

Output Arguments

`cfg` — Configuration of the parameters and channels used by the waveform generator
structure

Configuration of the parameters and channels used by the waveform generator. The configuration structure is defined in these tables.

Top-Level Parameters and Substructures

Parameter Field	Values	Description
`RadioConfiguration`	`'RC1'` | `'RC2'` | `'RC3'` | `'RC4'` | `'RC5'` | `'RC6'`	Radio configuration of the reverse channel. The spreading rate of the waveform is derived from the radio configuration. Spreading rate 1, SR1, corresponds to a 1.2288 Mcps carrier and is associated with RC1 through RC4. Spreading rate 3, SR3, corresponds to a 3.6864 Mcps carrier and is associated with RC5 and RC6.
`PowerNormalization`	`'Off'` | `'NormalizeTo0dB'`	Power normalization of the waveform
`NumChips`	Positive scalar integer	Number of chips in the waveform
`OversamplingRatio`	Positive scalar integer	Oversampling ratio at output
`FilterType`	`'cdma2000Long'` | `'cdma2000Short'` | `'Off'` | `'Custom'`	Type of output filtering
`CustomFilterCoefficients`	Real vector	Custom filter coefficients used only when the `FilterType` field is set to `'Custom'`
`InvertQ`	`'Off'` | `'On'`	Negate the quadrature output
`EnableModulation`	`'Off'` | `'On'`	Enable carrier modulation
`ModulationFrequency`	Nonnegative scalar integer	Carrier modulation frequency (applies when `EnableModulation` is `'On'`)
`RPICH`	Structure	See **`RPICH` Substructure**. Optional.
`RACH`	Structure	See **`RACH` Substructure**. Optional.
`REACH`	Structure	See **`REACH` Substructure**. Optional.
`RCCCH`	Structure	See **`RCCCH` Substructure**. Optional.
`RDCCH`	Structure	See **`RDCCH` Substructure**. Optional.
`RFCH`	Structure	See **`RFCH` Substructure**. Optional.
`RSCCH`	Structure	See **`RSCCH` Substructure**. Optional.
`RSCH1`	Structure	See **`RSCH1` Substructure**. Optional.
`RSCH2`	Structure	See **`RSCH2` Substructure**. Optional.

RPICH Substructure

Include the `RPICH` substructure in the `cfg` structure to configure the Reverse Pilot Channel (R-PICH). The `RPICH` substructure contains the following fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`LongCodeMask`	42-bit binary number	Long code identifier

Parameter Field	Values	Description
`PowerControlEnable`	`'On'` | `'Off'`	Enable or disable power control subchannel
`PowerControlPower`	Real scalar	Power control subchannel power (relative to R-PICH)
`PowerControlDataSource`	Cell array, `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Power control subchannel data source

RACH Substructure

Include the `RACH` substructure in the `cfg` structure to configure the Reverse Access Channel (R-ACH). The `RACH` substructure contains the following fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`LongCodeMask`	42-bit binary number	Long code identifier
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array: `{'PN Type', RN Seed}` or a binary vector. Standard PN types are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a binary vector.

REACH Substructure

Include the `REACH` substructure in the `cfg` structure to configure the Reverse Enhanced Access Channel (R-EACH). The `REACH` substructure contains the following fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`DataRate`	`9600` | `19200` | `38400`	Data rate (bps)
`FrameLength`	`5` | `10` | `20`	Frame length (ms)
`WalshCode`	Nonnegative integer scalar such that $0 \le$ `WalshCode` ≤ 7	Walsh code number
`LongCodeMask`	42-bit binary number	Long code identifier
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding

Parameter Field	Values	Description
`DataSource`	Cell array: `{'PN Type', RN Seed}` or a binary vector. Standard PN types are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a binary vector.

RCCCH Substructure

Include the `RCCCH` substructure in the `cfg` structure to configure the Reverse Common Control Channel (R-CCCH). The `RCCCH` substructure contains the following fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`DataRate`	`9600` | `19200` | `38400`	Data rate (bps)
`FrameLength`	`5` | `10` | `20`	Frame length (ms)
`CodingType`	`'conv'` | `'turbo'`	Type of error control coding
`WalshCode`	Nonnegative integer scalar such that $0 \le$ `WalshCode` ≤ 7	Walsh code number
`LongCodeMask`	42-bit binary number	Long code identifier
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array: `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

RDCCH Substructure

Include the `RDCCH` substructure in the `cfg` structure to configure the Reverse Dedicated Control Channel (R-DCCH). The `RDCCH` substructure contains the following fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`FrameLength`	`5` | `20`	Frame length (ms)
`WalshCode`	Nonnegative integer scalar such that $0 \le$ `WalshCode` ≤ 15	Walsh code number
`LongCodeMask`	42-bit binary number	Long code identifier
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding

Parameter Field	Values	Description
`DataSource`	Cell array, `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

RFCH Substructure

Include the `RFCH` substructure in the `cfg` structure to configure the Reverse Fundamental Traffic Channel (R-FCH). The `RFCH` substructure contains the following fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`DataRate`	`1200` | `1500` | `1800` | `2400` | `2700` | `3600` | `4800` | `7200` | `9600` | `14400`	Data rate (bps)
`FrameLength`	`5` | `10` | `20`	Frame length (ms)
`WalshCode`	Nonnegative integer scalar such that 0 ≤ `WalshCode` ≤ 15	Walsh code number
`LongCodeMask`	42-bit binary number	Long code identifier
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array, `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

RSCCH Substructure

Include the `RSCCH` substructure in the `cfg` structure to configure the Reverse Supplemental Code Channel (R-SCCH). The `RSCCH` substructure contains the following fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`LongCodeMask`	42-bit binary number	Long code identifier
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding

Parameter Field	Values	Description
`DataSource`	Cell array, `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

RSCH1 Substructure

Include the `RSCH1` substructure in the `cfg` structure to configure the Reverse Supplemental Channel 1 (R-SCH 1). The `RSCH1` substructure contains the following fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`DataRate`	`1200` | `1350` | `1500` | `1800` | `2400` | `2700` | `3600` | `4800` | `7200` | `9600` | `14400` | `19200` | `28800` | `38400` | `57600` | `76800` | `115200` | `153600` | `230400` | `259200` | `307200` | `460800` | `518400` | `614400` | `1036800`	Data rate (bps)
`FrameLength`	`20` | `40` | `80`	Frame length (ms)
`WalshLength`	`2` | `4`	Walsh code length
`WalshCode`	Nonnegative integer scalar such that $0 \le$ `WalshCode` $\le$ `WalshLength` – 1	Walsh code number
`LongCodeMask`	42-bit binary number	Long code identifier
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array, `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

RSCH2 Substructure

Include the `RSCH2` substructure in the `cfg` structure to configure the Reverse Supplemental Channel 2 (R-SCH 2). The `RSCH2` substructure contains the following fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)

Parameter Field	Values	Description
`DataRate`	`1200` | `1350` | `1500` | `1800` | `2400` | `2700` | `3600` | `4800` | `7200` | `9600` | `14400` | `19200` | `28800` | `38400` | `57600` | `76800` | `115200` | `153600` | `230400` | `259200` | `307200` | `460800` | `518400` | `614400` | `1036800`	Data rate (bps)
`FrameLength`	`20` | `40` | `80`	Frame length (ms)
`WalshLength`	`4` | `8`	Walsh code length
`WalshCode`	Nonnegative integer scalar such that 0 ≤ `WalshCode` ≤ `WalshLength` – 1	Walsh code number
`LongCodeMask`	42-bit binary number	Long code identifier
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array, `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

Data Types: `struct`

cdma2000ReverseWaveformGenerator

Generate cdma2000 reverse link waveform

Syntax

```
waveform = cdma2000ReverseWaveformGenerator(cfg)
```

Description

`waveform = cdma2000ReverseWaveformGenerator(cfg)` returns the cdma2000 reverse link baseband waveform, `waveform` as defined by the parameter configuration structure, `cfg`.

The top-level parameters and lower-level substructures of `cfg` specify the waveform and channel properties used by the function to generate a cdma2000 waveform. You can generate the input argument by using the `cdma2000ReverseReferenceChannels` function. The top-level parameters of `cfg` are `RadioConfiguration`, `LongCodeState`, `PowerNormalization`, `OversamplingRatio`, `FilterType`, `InvertQ`, `EnableModulation`, `ModulationFrequency`, and `NumChips`. To enable specific channels, add their associated substructures, for example, the reverse dedicated control channel, `RDCCH`.

Note The tables herein list the allowable values for the top-level parameters and substructure fields. However, not all combinations of spreading rate, radio configuration, frame length, and data rate are supported. To ensure that the input argument is valid, use the `cdma2000ReverseReferenceChannels` function. If you input the structure fields manually, consult [1] to ensure that the input parameter combinations are permitted.

Examples

Generate Reverse Common Control Channel Waveform

Generate the structure corresponding to the reverse common control channel (R-CCCH) having a 19,200 bps data rate and 10 ms frames.

```
config = cdma2000ReverseReferenceChannels('R-CCCH-19200-10');
```

Verify that the R-CCCH substructure is configured for the correct data rate and frame duration.

```
config.RCCCH
```

```
ans = struct with fields:
          Enable: 'On'
           Power: 0
    LongCodeMask: 0
    EnableCoding: 'On'
      DataSource: {'PN9'  [1]}
        DataRate: 19200
     FrameLength: 10
       WalshCode: 1
```

Generate the reverse channel waveform using the corresponding waveform generator function, `cdma2000ReverseWaveformGenerator`.

```
wv = cdma2000ReverseWaveformGenerator(config);
```

Generate R-SCH Channels for RC5

Create a configuration structure for a reverse channel having an R-FCH with a 4800 bps data rate and two R-SCHs. Specify that each R-SCH have a 153,600 bps data rate using RC5.

```
config = cdma2000ReverseReferenceChannels( ...
    "TRAFFIC-RC5-4800", ...
    5000, ...
    "R-SCH-153600-40");
```

Determine the sample rate. Because RC5 corresponds to SR3, the chip rate is 3.6864 Mcps. Multiply by the oversampling ratio to obtain the sample rate.

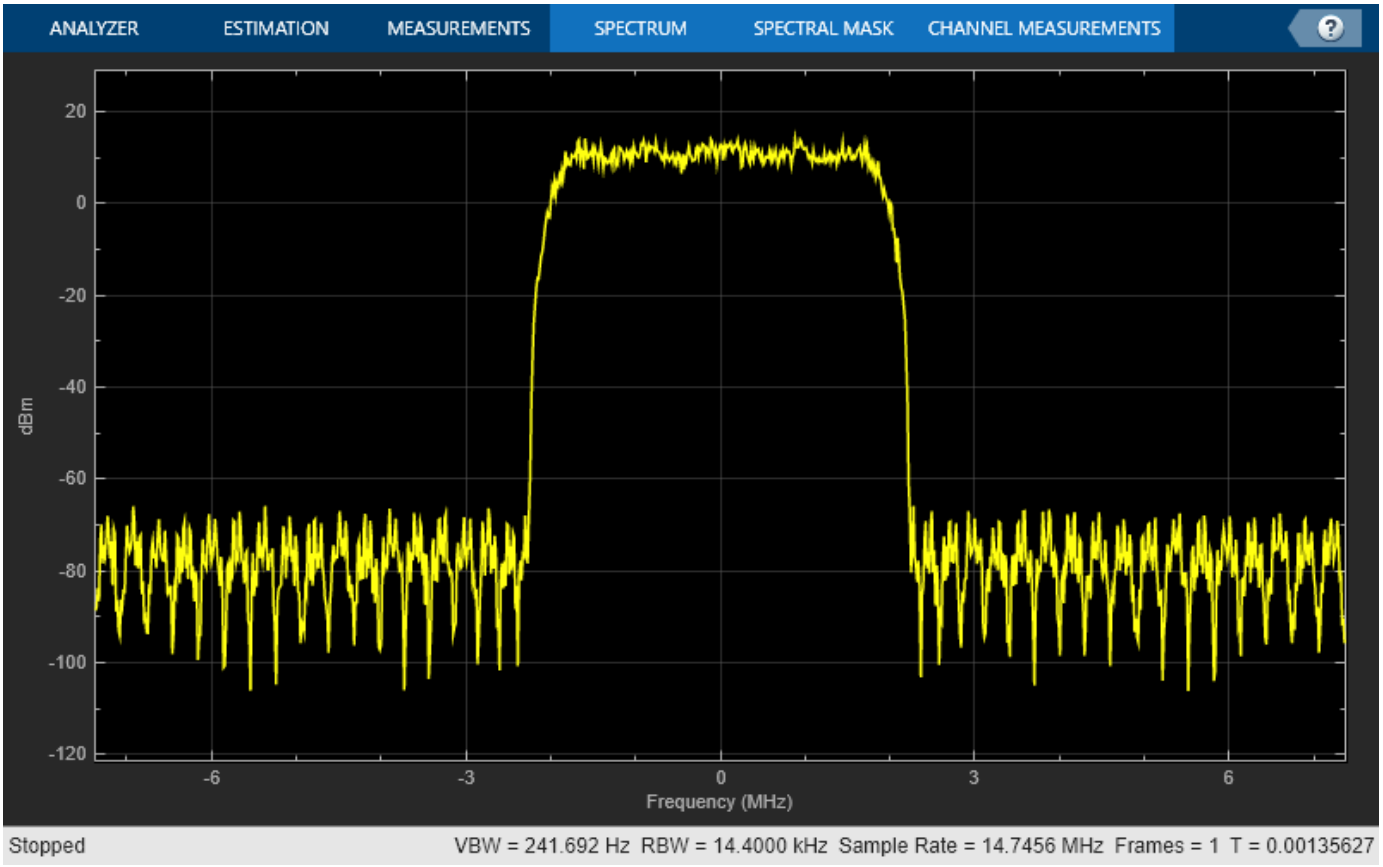
```
fs = 3.6864e6*config.OversamplingRatio;
```

Generate the reverse link waveform.

```
wv = cdma2000ReverseWaveformGenerator(config);
```

Plot the spectrum of the resultant waveform.

```
sa = spectrumAnalyzer(SampleRate=fs);
sa(wv)
release(sa)
```



Generate cdma2000 Waveform with Two Reverse Supplemental Channels

Create a parameter structure specifying a reverse traffic channel containing a pair of supplemental channels and generate the corresponding waveform.

Create a parameter structure specifying a traffic channel consisting of a 14,400 bps fundamental channel, 2000 chips, and a 57,600 bps supplemental channel (R-SCH) pair having a 40 ms frame duration.

```
cfg = cdma2000ReverseReferenceChannels( ...
    "TRAFFIC-RC4-14400", ...
    2000, ...
    "F-SCH-57600-40");
```

Create a second R-SCH pair by copying the R-SCH fields from the existing pair.

```
cfg(2).RSCH1 = cfg.RSCH1;
cfg(2).RSCH2 = cfg.RSCH2;
```

Set the data rate of the second R-SCH pair to 28,800 bps.

```
cfg(2).RSCH1.DataRate = 28800;
cfg(2).RSCH2.DataRate = 28800;
```

Set the Walsh codes of the second pair so that they differ from the first pair.

```
cfg(2).RSCH1.WalshCode = 4;
cfg(2).RSCH2.WalshCode = 5;
```

Verify that the data rates are set correctly and that no two supplemental channels share the same Walsh code.

```
cfg.RSCH1
```

```
ans = struct with fields:
          Enable: 'On'
           Power: 0
    LongCodeMask: 0
    EnableCoding: 'On'
      DataSource: {'PN9'  [1]}
        DataRate: 57600
     FrameLength: 40
     WalshLength: 2
       WalshCode: 0

ans = struct with fields:
          Enable: 'On'
           Power: 0
    LongCodeMask: 0
    EnableCoding: 'On'
      DataSource: {'PN9'  [1]}
        DataRate: 28800
     FrameLength: 40
     WalshLength: 2
       WalshCode: 4
```

```
cfg.RSCH2
```

```
ans = struct with fields:
          Enable: 'On'
           Power: 0
    LongCodeMask: 0

```

Generate the reverse link waveform.

```
wv = cdma2000ReverseWaveformGenerator(cfg);
```

Input Arguments

`cfg` — Configuration of the parameters and channels used by the waveform generator

structure

Configuration of the parameters and channels used by the waveform generator. The configuration structure is defined in these tables.

Top-Level Parameters and Substructures

Parameter Field	Values	Description
`RadioConfiguration`	`'RC1'` | `'RC2'` | `'RC3'` | `'RC4'` | `'RC5'` | `'RC6'`	Radio configuration of the reverse channel. The spreading rate of the waveform is derived from the radio configuration. Spreading rate 1, SR1, corresponds to a 1.2288 Mcps carrier and is associated with RC1 through RC4. Spreading rate 3, SR3, corresponds to a 3.6864 Mcps carrier and is associated with RC5 and RC6.
`PowerNormalization`	`'Off'` | `'NormalizeTo0dB'`	Power normalization of the waveform
`NumChips`	Positive scalar integer	Number of chips in the waveform
`OversamplingRatio`	Positive scalar integer	Oversampling ratio at output
`FilterType`	`'cdma2000Long'` | `'cdma2000Short'` | `'Off'` | `'Custom'`	Type of output filtering
`CustomFilterCoefficients`	Real vector	Custom filter coefficients used only when the `FilterType` field is set to `'Custom'`
`InvertQ`	`'Off'` | `'On'`	Negate the quadrature output
`EnableModulation`	`'Off'` | `'On'`	Enable carrier modulation
`ModulationFrequency`	Nonnegative scalar integer	Carrier modulation frequency (applies when `EnableModulation` is `'On'`)
`RPICH`	Structure	See **`RPICH` Substructure**. Optional.
`RACH`	Structure	See **`RACH` Substructure**. Optional.
`REACH`	Structure	See **`REACH` Substructure**. Optional.
`RCCCH`	Structure	See **`RCCCH` Substructure**. Optional.
`RDCCH`	Structure	See **`RDCCH` Substructure**. Optional.
`RFCH`	Structure	See **`RFCH` Substructure**. Optional.
`RSCCH`	Structure	See **`RSCCH` Substructure**. Optional.
`RSCH1`	Structure	See **`RSCH1` Substructure**. Optional.
`RSCH2`	Structure	See **`RSCH2` Substructure**. Optional.

RPICH Substructure

Include the `RPICH` substructure in the `cfg` structure to configure the Reverse Pilot Channel (R-PICH). The `RPICH` substructure contains the following fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`LongCodeMask`	42-bit binary number	Long code identifier
`PowerControlEnable`	`'On'` | `'Off'`	Enable or disable power control subchannel
`PowerControlPower`	Real scalar	Power control subchannel power (relative to R-PICH)
`PowerControlDataSource`	Cell array, `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Power control subchannel data source

RACH Substructure

Include the `RACH` substructure in the `cfg` structure to configure the Reverse Access Channel (R-ACH). The `RACH` substructure contains the following fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`LongCodeMask`	42-bit binary number	Long code identifier
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array: `{'PN Type', RN Seed}` or a binary vector. Standard PN types are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a binary vector.

REACH Substructure

Include the `REACH` substructure in the `cfg` structure to configure the Reverse Enhanced Access Channel (R-EACH). The `REACH` substructure contains the following fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`DataRate`	`9600` | `19200` | `38400`	Data rate (bps)

Parameter Field	Values	Description
`FrameLength`	`5` | `10` | `20`	Frame length (ms)
`WalshCode`	Nonnegative integer scalar such that 0 ≤ `WalshCode` ≤ 7	Walsh code number
`LongCodeMask`	42-bit binary number	Long code identifier
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array: `{'PN Type', RN Seed}` or a binary vector. Standard PN types are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a binary vector.

RCCCH Substructure

Include the `RCCCH` substructure in the `cfg` structure to configure the Reverse Common Control Channel (R-CCCH). The `RCCCH` substructure contains the following fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`DataRate`	`9600` | `19200` | `38400`	Data rate (bps)
`FrameLength`	`5` | `10` | `20`	Frame length (ms)
`CodingType`	`'conv'` | `'turbo'`	Type of error control coding
`WalshCode`	Nonnegative integer scalar such that 0 ≤ `WalshCode` ≤ 7	Walsh code number
`LongCodeMask`	42-bit binary number	Long code identifier
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array: `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

RDCCH Substructure

Include the `RDCCH` substructure in the `cfg` structure to configure the Reverse Dedicated Control Channel (R-DCCH). The `RDCCH` substructure contains the following fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)

Parameter Field	Values	Description
`FrameLength`	`5` | `20`	Frame length (ms)
`WalshCode`	Nonnegative integer scalar such that 0 ≤ `WalshCode` ≤ 15	Walsh code number
`LongCodeMask`	42-bit binary number	Long code identifier
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array, `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

RFCH Substructure

Include the `RFCH` substructure in the `cfg` structure to configure the Reverse Fundamental Traffic Channel (R-FCH). The `RFCH` substructure contains the following fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`DataRate`	`1200` | `1500` | `1800` | `2400` | `2700` | `3600` | `4800` | `7200` | `9600` | `14400`	Data rate (bps)
`FrameLength`	`5` | `10` | `20`	Frame length (ms)
`WalshCode`	Nonnegative integer scalar such that 0 ≤ `WalshCode` ≤ 15	Walsh code number
`LongCodeMask`	42-bit binary number	Long code identifier
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array, `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

RSCCH Substructure

Include the `RSCCH` substructure in the `cfg` structure to configure the Reverse Supplemental Code Channel (R-SCCH). The `RSCCH` substructure contains the following fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel

Parameter Field	Values	Description
`Power`	Real scalar	Relative channel power (dB)
`LongCodeMask`	42-bit binary number	Long code identifier
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array, `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

RSCH1 Substructure

Include the `RSCH1` substructure in the `cfg` structure to configure the Reverse Supplemental Channel 1 (R-SCH 1). The `RSCH1` substructure contains the following fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`DataRate`	`1200` | `1350` | `1500` | `1800` | `2400` | `2700` | `3600` | `4800` | `7200` | `9600` | `14400` | `19200` | `28800` | `38400` | `57600` | `76800` | `115200` | `153600` | `230400` | `259200` | `307200` | `460800` | `518400` | `614400` | `1036800`	Data rate (bps)
`FrameLength`	`20` | `40` | `80`	Frame length (ms)
`WalshLength`	`2` | `4`	Walsh code length
`WalshCode`	Nonnegative integer scalar such that 0 ≤ `WalshCode` ≤ `WalshLength` – 1	Walsh code number
`LongCodeMask`	42-bit binary number	Long code identifier
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array, `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

RSCH2 Substructure

Include the `RSCH2` substructure in the `cfg` structure to configure the Reverse Supplemental Channel 2 (R-SCH 2). The `RSCH2` substructure contains the following fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`DataRate`	`1200` | `1350` | `1500` | `1800` | `2400` | `2700` | `3600` | `4800` | `7200` | `9600` | `14400` | `19200` | `28800` | `38400` | `57600` | `76800` | `115200` | `153600` | `230400` | `259200` | `307200` | `460800` | `518400` | `614400` | `1036800`	Data rate (bps)
`FrameLength`	`20` | `40` | `80`	Frame length (ms)
`WalshLength`	`4` | `8`	Walsh code length
`WalshCode`	Nonnegative integer scalar such that 0 ≤ `WalshCode` ≤ `WalshLength` – 1	Walsh code number
`LongCodeMask`	42-bit binary number	Long code identifier
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array, `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

Output Arguments

`waveform` — Modulated baseband waveform comprising the physical channels
complex vector array

Modulated baseband waveform comprising the cdma2000 physical channels, returned as a complex vector array.

Version History

Introduced in R2015b

comm_links

Library link information for Communications Toolbox blocks

Syntax

```
comm_links
comm_links(sys)
comm_links(sys,color)
```

Description

`comm_links` returns a structure with two elements. Each element contains a cell array of strings containing names of library blocks in the current system. The blocks are grouped into two categories: obsolete and current. Blocks at all levels of the model are analyzed.

`comm_links(sys)` works as above on the named system `sys`, instead of the current system.

`comm_links(sys,color)` additionally colors all obsolete blocks according to the specified *`color`*. *`color`* is one of the following strings: 'blue', 'green', 'red', 'cyan', 'magenta', 'yellow', or 'black'.

Obsolete blocks are blocks that are no longer supported. They might or might not work properly.

Current blocks are supported and represent the latest block functionality.

Version History

Introduced before R2006a

`dsplib`

commscope

(To be removed) Package of communications scope classes

Note `commscope.eyediagram` will be removed in a future release. Use `comm.ConstellationDiagram` and `eyediagram` instead.

Syntax

```
h = commscope.<type>(...)
```

Description

`h = commscope.<type>(...)` returns a communications scope object `h` of type `type`.

Type `help commscope` to get a complete list of available types.

Each `type` of communications scope object is equipped with functions for simulation and visualization. Type `help commscope.<type>` to get the complete help on a specific communications scope object, for example `help commscope.eyediagram`.

Version History

Introduced in R2007b

`commscope` will be removed
Warns starting in R2017b

`commscope.eyediagram` will be removed in a future release. Use `comm.ConstellationDiagram` and `eyediagram` instead.

commsrc.combinedjitter

Construct combined jitter generator object

Syntax

```
combJitt = commsrc.combinedjitter
combJitt = commsrc.combinedjitter(Name,Value)
```

Description

`combJitt = commsrc.combinedjitter` constructs a default combined jitter generator object, `combJitt`, with all jitter components disabled.

Use the object to generate jitter samples that include any combination of random, periodic, and Dirac components.

`combJitt = commsrc.combinedjitter(Name,Value)` creates a combined jitter generator object with the specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

A combined jitter generator object includes these properties. You can edit all properties, except those explicitly noted.

Property	Description
`Type`	Type of object, `Combined Jitter Generator`. This property is not writable.
`SamplingFrequency`	Sampling frequency of the input signal in hertz. Default value 1e4.
`RandomJitter`	Variable to enable the random jitter generator. Specify as either `'off'` (default) or `'on'`.
`RandomStd`	Standard deviation of the random jitter generator in seconds. Applies when `RandomJitter` is `'on'`. Default value 1e-4.
`PeriodicJitter`	Variable to enable the periodic jitter generator. Specify as either `'off'` (default) or `'on'`.
`PeriodicNumber`	Number of sinusoidal components. The `PeriodicNumber` must be a finite positive scalar integer. Applies when `PeriodicJitter` is `'on'`. Default value 1.
`PeriodicAmplitude`	Amplitude of each sinusoidal component of the periodic jitter in seconds. Applies when `PeriodicJitter` is `'on'`. Default value 5e-4.

Property	Description
`PeriodicFrequencyHz`	Frequency of each sinusoidal component of the periodic jitter measured in Hz. Applies when `PeriodicJitter` is `'on'`. Default value is 200.
`PeriodicPhase`	Phase of each sinusoidal component of the periodic jitter in radians. Applies when `PeriodicJitter` is `'on'`. Default value 0.
`DiracJitter`	Variable to enable the Dirac jitter generator. Specify as either `'off'` (default) or `'on'`.
`DiracNumber`	Number of Dirac components. The `DiracNumber` must be a finite positive scalar integer. Applies when `DiracJitter` is `'on'`. Default value 2.
`DiracDelta`	Time delay of each Dirac component in seconds. Applies when `DiracJitter` is `'on'`. Default value [-5.e-4 5.e-4].
`DiracProbability`	Probability of each Dirac component represented as a vector of length `DiracNumber`. The sum of the probabilities must equal one. Applies when `DiracJitter` is `'on'`. Default value [0.5 0.5].

Object Functions

A combined jitter generator object has three object functions, as described in this section.

generate

This object function generates jitter samples based on the jitter generator object. It has one input argument, which is the number of samples in a frame. Its output is a single-column vector of length `N`. You can call this object function using this syntax:

```
x = generate(combJitt,N)
```

where `combJitt` is the generator object, `N` is the number of output samples, and `x` is a real single-column vector.

reset

This object function resets the internal states of the combined jitter generator. You can call this object function using this syntax:

```
reset(combJitt)
```

where `combJitt` is the generator object.

disp

Display the properties of the combined generator object, `combJitt`. You can call this object function using this syntax:

```
disp(combJitt)
```

where `combJitt` is the generator object.

Examples

Generate Combined Random and Periodic Jitter

Generate 500 jitter samples composed of random and periodic components.

Create a `commsrc.combinedjitter` object configured to apply a combination of random and periodic jitter components. Use name-value pairs to enable `RandomJitter` and `PeriodicJitter`, and to assign jitter settings. Set the standard deviation of the random jitter to `2e-4` seconds, the periodic jitter amplitude to `5e-4` seconds, and the periodic jitter frequency to 2 Hz.

```
numSamples = 500;
combJitt = commsrc.combinedjitter(...
    'RandomJitter','on', ...
    'RandomStd',2e-4, ...
    'PeriodicJitter','on', ...
    'PeriodicAmplitude',5e-4, ...
    'PeriodicFrequencyHz',200)
```

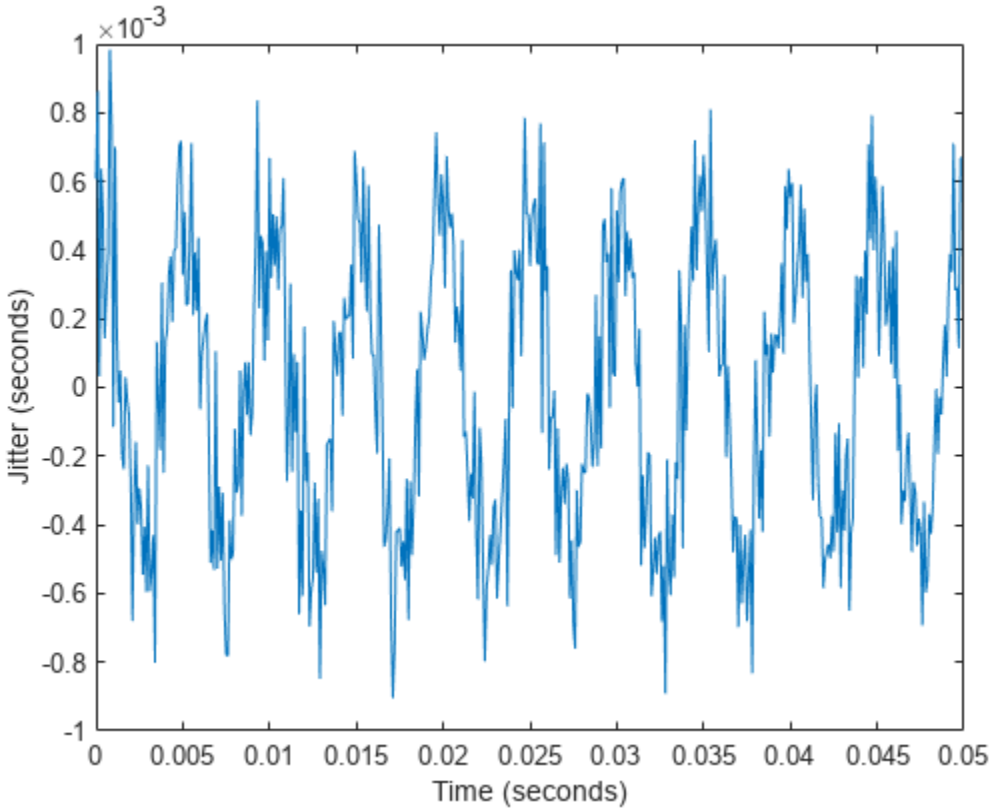
```
combJitt =
                  Type: 'Combined Jitter Generator'
      SamplingFrequency: 10000
           RandomJitter: 'on'
              RandomStd: 2.0000e-04
         PeriodicJitter: 'on'
         PeriodicNumber: 1
      PeriodicAmplitude: 5.0000e-04
    PeriodicFrequencyHz: 200
          PeriodicPhase: 0
            DiracJitter: 'off'
```

Use the `generate` method to create the combined jitter samples.

```
y = generate(combJitt,numSamples);
x = [0:numSamples-1];
```

Plot the jitter samples. You can see the Gaussian and periodic nature of the combined jitter.

```
plot(x/combJitt.SamplingFrequency,y)
xlabel('Time (seconds)')
ylabel('Jitter (seconds)')
```



Display commsrc.combinedjitter Object Settings

Create a `commsrc.combinedjitter` object. Display the default object property values.

```
combJitt = commsrc.combinedjitter;
disp(combJitt)
```

```
                Type: 'Combined Jitter Generator'
    SamplingFrequency: 10000
         RandomJitter: 'off'
      PeriodicJitter: 'off'
         DiracJitter: 'off'
```

Create a `commsrc.combinedjitter` object with random, periodic, and Dirac jitters enabled. Display the object property values.

```
combJitt = commsrc.combinedjitter('RandomJitter','on', ...
    'PeriodicJitter','on','DiracJitter','on');
disp(combJitt)
```

```
                  Type: 'Combined Jitter Generator'
      SamplingFrequency: 10000
           RandomJitter: 'on'
              RandomStd: 1.0000e-04
         PeriodicJitter: 'on'
```

```
         PeriodicNumber: 1
      PeriodicAmplitude: 5.0000e-04
    PeriodicFrequencyHz: 200
          PeriodicPhase: 0
            DiracJitter: 'on'
            DiracNumber: 2
             DiracDelta: [-5.0000e-04 5.0000e-04]
       DiracProbability: [0.5000 0.5000]
```

Generate Non-Return-to-Zero Pattern Signal

Generate a binary non-return-to-zero (NRZ) signal utilizing the pattern generator object. View the NRZ signal with and without jitter applied to the signal.

Initialize system parameters.

```
Fs = 10000; % Sample rate
Rs = 50; % Symbol rate
sps = Fs/Rs; % Number of samples per symbol
Trise = 1/(5*Rs); % Rise time of the NRZ signal
Tfall = 1/(5*Rs); % Fall time of the NRZ signal
frameLen = 100; % Number of symbols in a frame
spt = 200; % Number of samples per trace on eye diagram
```

Create a pattern generator object with no jitter component assigned.

```
src = commsrc.pattern('SamplingFrequency',Fs, ...
'SamplesPerSymbol',sps,'RiseTime',Trise,'FallTime',Tfall)
```

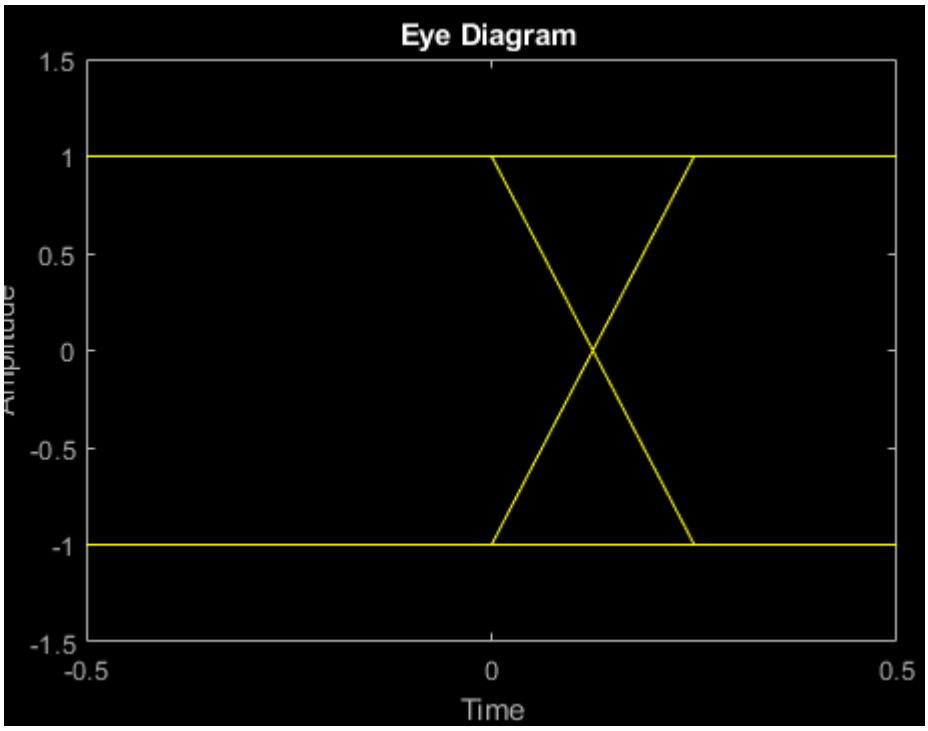
```
src =
                Type: 'Pattern Generator'
    SamplingFrequency: 10000
     SamplesPerSymbol: 200
           SymbolRate: 50
            PulseType: 'NRZ'
         OutputLevels: [-1 1]
             RiseTime: 0.0040
             FallTime: 0.0040
          DataPattern: 'PRBS7'
               Jitter: [1x1 commsrc.combinedjitter]
```

```
src.Jitter
```

```
ans =
                Type: 'Combined Jitter Generator'
    SamplingFrequency: 10000
         RandomJitter: 'off'
       PeriodicJitter: 'off'
          DiracJitter: 'off'
```

Generate an NRZ signal and view the eye diagram of the signal.

```
message = generate(src,frameLen);
eyediagram(message,spt)
```



Add inter-symbol-interference (ISI) to an NRZ signal. ISI is modeled by two equal amplitude Dirac functions. Create a combined jitter object with Dirac jitter and assign it to the pattern generator object.

```
jitterSrc = commsrc.combinedjitter('DiracJitter','on', ...
    'DiracDelta',0.05/Rs*[-1 1]);
src.Jitter = jitterSrc
```

```
src =
                Type: 'Pattern Generator'
    SamplingFrequency: 10000
     SamplesPerSymbol: 200
           SymbolRate: 50
            PulseType: 'NRZ'
         OutputLevels: [-1 1]
             RiseTime: 0.0040
             FallTime: 0.0040
          DataPattern: 'PRBS7'
               Jitter: [1x1 commsrc.combinedjitter]
```

Generate an NRZ signal that has jitter added to it and view the eye diagram of the signal.

```
reset(src);
message = generate(src,frameLen);
eyediagram(message,spt)
```

Topics

“Eye Diagram Analysis”

commsrc.pattern

Construct pattern generator object

Syntax

```
h = commsrc.pattern
h = commsrc.pattern(Name,Value)
```

Description

`h = commsrc.pattern` constructs a pattern generator object, `h`.

The pattern generator object produces modulated data patterns. The object can be used to inject jitter into modulated signals.

`h = commsrc.pattern(Name,Value)` creates a pattern generator object with the specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

A pattern generator object includes these properties. You can edit all properties, except those explicitly noted.

Property	Description
`Type`	Type of pattern generator object (`'Pattern Generator'`). This property is not writable.
`SamplingFrequency`	Sampling frequency of the input signal in hertz.
`SymbolRate`	The symbol rate of the input signal. This property depends upon the `SamplingFequency` and `SamplesPerSymbol` properties. This property is not writable.
`SamplesPerSymbol`	The number of samples representing a symbol. `SamplesPerSymbol` must be an integer. This property affects `SymbolRate`.
`PulseType`	The type of pulse the object generates. Pulse types available: return-to-zero (`'RZ'`) and non-return-to-zero (`'NRZ'`). The initial condition for an `'NRZ'` pulse is `0`.
`OutputLevels`	Amplitude levels that correspond to the symbol indices. For an `'NRZ'` pulse, specify as a 1-by-2 vector. The first element of the 1-by-2 vector corresponds to the 0th symbol (data bit value 0). The second element corresponds to the 1st symbol (data bit value 1). For an `'RZ'` pulse, specify as a scalar and the value corresponds to the data bit value `1`.

Property	Description
`DutyCycle`	The duty cycle of the pulse the object generates. Displays calculated duty cycle based on pulse parameters. This property is not writable.
`RiseTime`	Specifies 10% to 90% rise time of the pulse in seconds.
`PulseDuration`	Pulse duration in seconds defined by IEEE STD 181 standard. See the Return-to-Zero (RZ) Signal Conversion: Ideal Pulse to STD–181 figure in the “Object Functions” on page 2-184. Applies when `PulseType` is `'RZ'`.
`FallTime`	Fall time of the pulse in seconds, specified as a percentage from 10 to 90.
`DataPattern`	The bit sequence the object uses, specified as `'PRBS5'`, `'PRBS6'`, ..., `'PRBS15'`, `'PRBS23'`, `'PRBS31'`, and `'User Defined'`.
`UserDataPattern`	User-defined bit pattern consisting of a vector of ones and zeroes. Applies when `DataPattern` is `'User Defined'`.
`Jitter`	Jitter characteristics, specified as a `commsrc.combinedjitter` object. Use this property to configure Random, Periodic and Dual Dirac Jitter.

Object Functions

A pattern generator object has five object functions, as described in this section.

generate

This object function outputs a frame worth of modulated and interpolated symbols. It has one input argument, which is the number of symbols in a frame. Its output is a column vector. You can call the object function using this syntax:

```
x = generate(h, N)
```

where `h` is the handle to the object, `N` is the number of output symbols, and `x` is a column vector whose length is `N` multiplied by `h.SamplesPerSymbol`.

reset

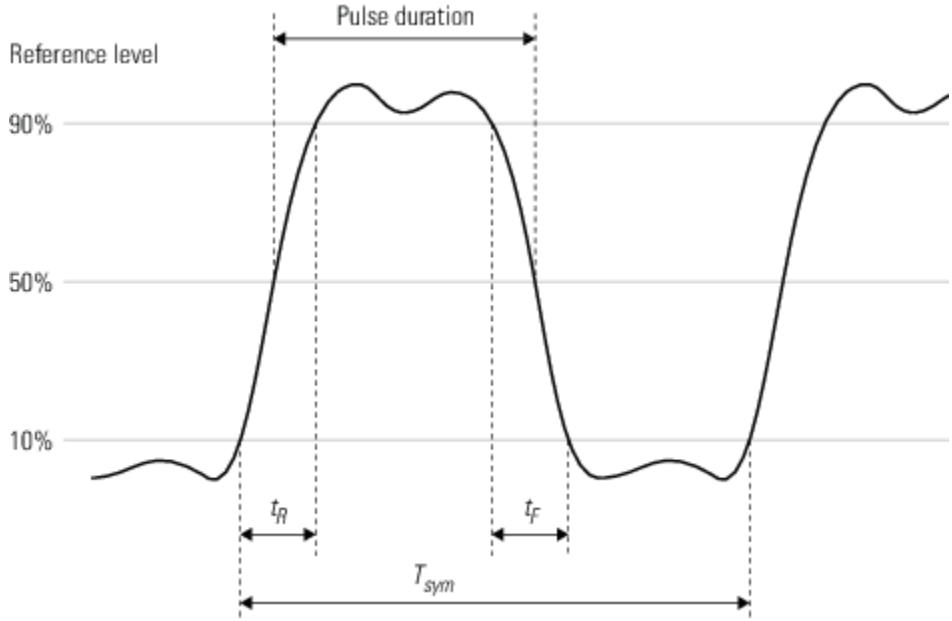
This object function resets the pattern generator to its default state. The property values do not reset unless they relate to the state of the object. This object function has no input arguments.

idealtostd181

This object function converts the ideal pulse specifications to IEEE STD-181 specifications. The ideal 0% to 100% span rise time (`tr`) and fall time (`tf`) are converted to 10% to 90% spans with a 50% pulse width duration (`pw`). Call the `idealtostd181` object function using this syntax:

```
h = idealtostd181(tr,tf,pw)
```

The object function sets the appropriate properties. The IEEE STD-181 Return-to-Zero (RZ) signal parameters are shown in this figure.

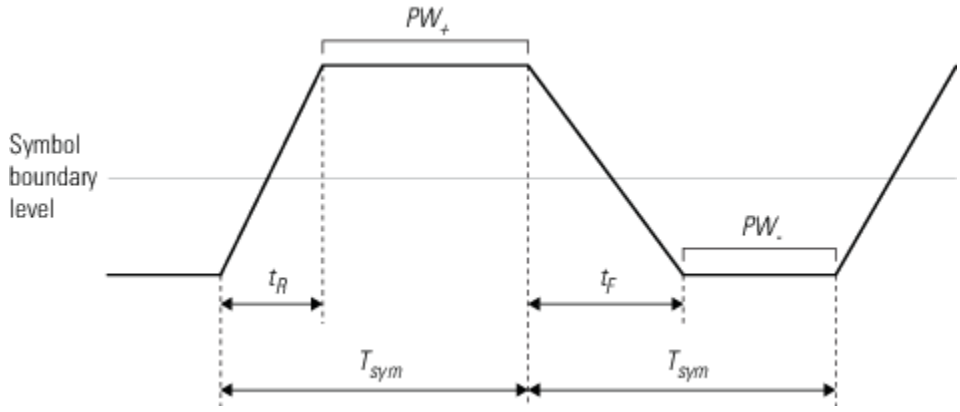


std181toideal

The `std181toideal` object function converts the IEEE STD-181 pulse specifications, stored in the pattern generator, to ideal pulse specifications. The function converts the rise and fall times from 10% – 90% span to 0% – 100% span, and converts the 50% pulse duration to pulse width. Call the `std181toideal` object function using this syntax:

```
[tr tf pw] = std181toideal(h)
```

where `h` is the pattern generator object handle, `tr` is the ideal 0% – 100% rise time, `tf` is the ideal 0% – 100% fall time, and `pw` is the ideal pulse width. The ideal pulse non-return-to-zero (NRZ) signal parameters are shown in this figure.



Use the property values for IEEE STD-181 specifications.

computedcd

The `computedcd` object function computes the duty cycle distortion, *DCD*, of the pulse defined by the pattern generator object *h*.

DCD represents the ratio of the pulse on duration to the pulse off duration. For an NRZ pulse, on duration is the duration the pulse spends above the symbol boundary level. Off duration is the duration the pulse spends below zero. Call the `computedcd` object function using this syntax:

```
dcd = computedcd(h)
```

The software calculates *DCD* given t_R, t_F, T_{sym}. This formula assumes that the symbol boundary level is zero.

$$T_h = (A_h\text{-}A_l) * \frac{t_R}{A_l} + (A_h\text{-}A_l) * \frac{t_F}{A_l} + PW_+$$

$$T_l = (A_h\text{-}A_l) * \frac{t_R}{A_l} + (A_h\text{-}A_l) * \frac{t_F}{A_l} + PW_-$$

$$DCD = \frac{T_h}{T_l}$$

Where T_h is the duration of the high signal, T_l is the duration of the low signal, and *DCD* represents the ratio of the duration of the high signal to the low signal.

Examples

Display commsrc.pattern Object Settings

Create a `commsrc.pattern` object. Display the default object property values.

```
h = commsrc.pattern;
disp(h)
```

```
                Type: 'Pattern Generator'
    SamplingFrequency: 10000
     SamplesPerSymbol: 100
           SymbolRate: 100
            PulseType: 'NRZ'
         OutputLevels: [-1 1]
             RiseTime: 0
             FallTime: 0
          DataPattern: 'PRBS7'
               Jitter: [1x1 commsrc.combinedjitter]
```

Generate Non-Return-to-Zero Pattern Signal

Generate a binary non-return-to-zero (NRZ) signal utilizing the pattern generator object. View the NRZ signal with and without jitter applied to the signal.

Initialize system parameters.

```
Fs = 10000; % Sample rate
Rs = 50; % Symbol rate
sps = Fs/Rs; % Number of samples per symbol
Trise = 1/(5*Rs); % Rise time of the NRZ signal
```

```
Tfall = 1/(5*Rs); % Fall time of the NRZ signal
frameLen = 100; % Number of symbols in a frame
spt = 200; % Number of samples per trace on eye diagram
```

Create a pattern generator object with no jitter component assigned.

```
src = commsrc.pattern('SamplingFrequency',Fs, ...
'SamplesPerSymbol',sps,'RiseTime',Trise,'FallTime',Tfall)
```

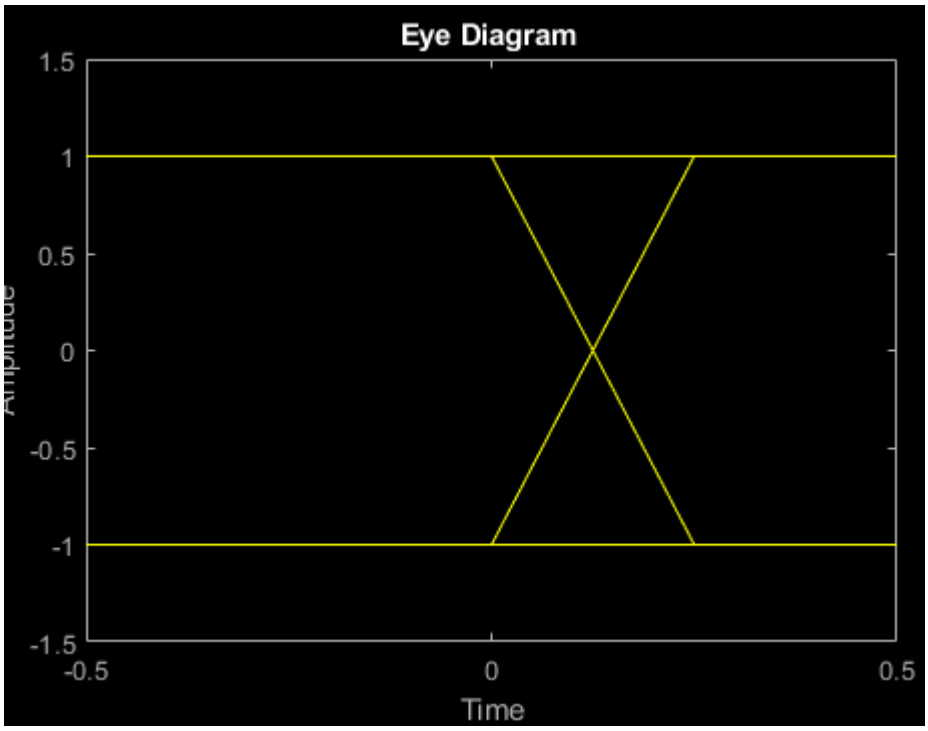
```
src =
                Type: 'Pattern Generator'
    SamplingFrequency: 10000
     SamplesPerSymbol: 200
           SymbolRate: 50
            PulseType: 'NRZ'
         OutputLevels: [-1 1]
             RiseTime: 0.0040
             FallTime: 0.0040
          DataPattern: 'PRBS7'
               Jitter: [1x1 commsrc.combinedjitter]
```

```
src.Jitter
```

```
ans =
                Type: 'Combined Jitter Generator'
    SamplingFrequency: 10000
         RandomJitter: 'off'
       PeriodicJitter: 'off'
          DiracJitter: 'off'
```

Generate an NRZ signal and view the eye diagram of the signal.

```
message = generate(src,frameLen);
eyediagram(message,spt)
```



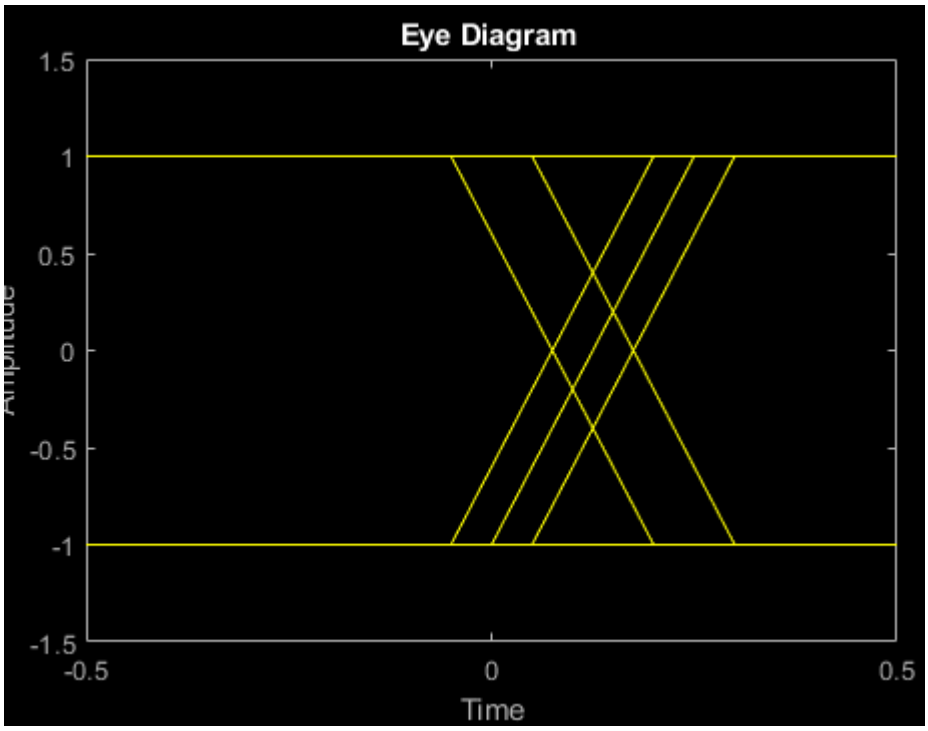
Add inter-symbol-interference (ISI) to an NRZ signal. ISI is modeled by two equal amplitude Dirac functions. Create a combined jitter object with Dirac jitter and assign it to the pattern generator object.

```
jitterSrc = commsrc.combinedjitter('DiracJitter','on', ...
    'DiracDelta',0.05/Rs*[-1 1]);
src.Jitter = jitterSrc
```

```
src =
                Type: 'Pattern Generator'
    SamplingFrequency: 10000
     SamplesPerSymbol: 200
           SymbolRate: 50
            PulseType: 'NRZ'
         OutputLevels: [-1 1]
             RiseTime: 0.0040
             FallTime: 0.0040
          DataPattern: 'PRBS7'
               Jitter: [1x1 commsrc.combinedjitter]
```

Generate an NRZ signal that has jitter added to it and view the eye diagram of the signal.

```
reset(src);
message = generate(src,frameLen);
eyediagram(message,spt)
```



Generate Custom Pattern Signal

Generate a custom binary pattern by using the `commsrc.pattern` function and the `generate` object function.

Define configuration variables and construct a pattern generator object.

```
fs = 80e9; % Sampling frequency in Hz
sps = 16;  % Samples per symbol
N = 32;    % Number of output symbols

patternGen = commsrc.pattern( ...
    'SamplingFrequency',fs, ...
    'SamplesPerSymbol',sps, ...
    'DataPattern','User Defined');
```

Define a binary pattern consisting of a vector to repeat.

```
binPattern = [0,1,0,0,0,0,0,1];
```

Assign the pattern to the pattern generator object and generate the custom pattern signal. Display the generated signal.

```
patternGen.UserDataPattern = binPattern;
myCustomData = generate(patternGen,N);
plot(myCustomData,'*-')
```

“Eye Diagram Analysis”

commsrc.pn

(To be removed) Create PN sequence generator object

Compatibility

`commsrc.pn` will be removed in a future release. Instead, to generate a pseudo-noise (PN) sequence, use the `comm.PNSequence` System object. For more details on the recommended workflow, see “Compatibility Considerations” on page 2-196.

Syntax

```
h = commsrc.pn
h = commsrc.pn(property1,value1,...)
```

Description

`h = commsrc.pn` creates a default PN sequence generator object *h*, and is equivalent to the following:

```
H = commsrc.pn('GenPoly',       [1 0 0 0 0 1 1], ...
               'InitialStates', [0 0 0 0 0 1],   ...
               'CurrentStates', [0 0 0 0 0 1],   ...
               'Mask',          [0 0 0 0 0 1],   ...
               'NumBitsOut',    1)
```

or

```
H = commsrc.pn('GenPoly',       [1 0 0 0 0 1 1], ...
               'InitialStates', [0 0 0 0 0 1],   ...
               'CurrentStates', [0 0 0 0 0 1],   ...
               'Shift',         0,               ...
               'NumBitsOut',    1)
```

`h = commsrc.pn(property1,value1,...)` creates a PN sequence generator object, *h*, with properties you specify as property/value pairs.

Properties

A PN sequence generator has the properties shown on the following table. All properties are writable except for the ones explicitly noted otherwise.

Property	Description
GenPoly	Generator polynomial vector array of bits; must be descending order
InitialStates	Vector array (with length of the generator polynomial order) of initial shift register values (in bits)

Property	Description
CurrentStates	Vector array (with length of the generator polynomial order) of present shift register values (in bits)
NumBitsOut	Number of bits to output at each `generate` method invocation
`Mask` or `Shift`	A mask vector of binary 0 and 1 values is used to specify which shift register state bits are XORed to produce the resulting output bit value. Alternatively, a scalar shift value may be used to specify an equivalent shift (either a delay or advance) in the output sequence.

The `'GenPoly'` property values specify the shift register connections. Enter these values as either a binary vector or a vector of exponents of the nonzero terms of the generator polynomial in descending order of powers. For the binary vector representation, the first and last elements of the vector must be 1. For the descending-ordered polynomial representation, the last element of the vector must be 0. For more information and examples, see the LFSR SSRG Details section of this page.

Methods

A PN sequence generator is equipped with the following methods.

generate

Generate [NumBitsOut x 1] PN sequence generator values

reset

Set the `CurrentStates` values to the `InitialStates` values

getshift

Get the actual or equivalent `Shift` property value

getmask

Get the actual or equivalent `Mask` property value

copy

Make an independent copy of a `commsrc.pn` object

disp

Display PN sequence generator object properties

Side Effects of Setting Certain Properties

Setting the GenPoly Property

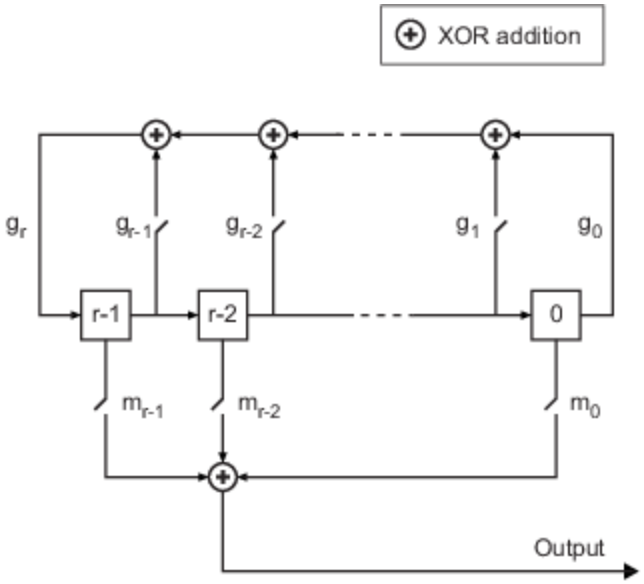
Every time this property is set, it will reset the entire object. In addition to changing the polynomial values, `'CurrentStates'`, `'InitialStates'`, and `'Mask'` will be set to their default values (`'NumBitsOut'` will remain the same), and no warnings will be issued.

Setting the InitialStates Property

Every time this property is set, it will also set `'CurrentStates'` to the new `'InitialStates'` setting.

LFSR SSRG Details

The `generate` method produces a pseudorandom noise (PN) sequence using a linear feedback shift register (LFSR). The LFSR is implemented using a simple shift register generator (SSRG, or Fibonacci) configuration, as shown below.



All *r* registers in the generator update their values at each time step according to the value of the incoming arrow to the shift register. The adders perform addition modulo 2. The shift register is described by the `'GenPoly'` property (generator polynomial), which is a primitive binary polynomial in *z*, $g_r z^r+g_{r-1}z^{r-1}+g_{r-2}z^{r-2}+\ldots+g_0$. The coefficient g_k is 1 if there is a connection from the kth register, as labeled in the preceding diagram, to the adder. The leading term g_r and the constant term g_0 of the `'GenPoly'` property must be 1 because the polynomial must be primitive.

You can specify the **Generator polynomial** parameter using either of these formats:

- A vector that lists the coefficients of the polynomial in descending order of powers. The first and last entries must be 1. Note that the length of this vector is one more than the degree of the generator polynomial.
- A vector containing the exponents of *z* for the nonzero terms of the polynomial in descending order of powers. The last entry must be `0`.

For example, `[1 0 0 0 0 0 1 0 1]` and `[8 2 0]` represent the same polynomial, $p(z) = z^8 + z^2 + 1$.

The **Initial states** parameter is a vector specifying the initial values of the registers. The **Initial states** parameter must satisfy these criteria:

- All elements of the **Initial states** vector must be binary numbers.
- The length of the **Initial states** vector must equal the degree of the generator polynomial.

Note At least one element of the **Initial states** vector must be nonzero in order for the block to generate a nonzero sequence. That is, the initial state of at least one of the registers must be nonzero.

For example, the following table indicates two sets of parameter values that correspond to a generator polynomial of $p(z) = z^8 + z^2 + 1$.

Quantity	Example 1	Example 2
Generator polynomial	`g1 = [1 0 0 0 0 0 1 0 1]`	`g2 = [8 2 0]`
Degree of generator polynomial	8, which is `length(g1)-1`	8
Initial states	`[1 0 0 0 0 0 1 0]`	`[1 0 0 0 0 0 1 0]`

Output mask vector (or scalar shift value) shifts the starting point of the output sequence. With the default setting for this parameter, the only connection is along the arrow labeled m_0, which corresponds to a shift of 0. The parameter is described in greater detail below.

You can shift the starting point of the PN sequence with **Output mask vector (or scalar shift value)**. You can specify the parameter in either of two ways:

- An integer representing the length of the shift
- A binary vector, called the *mask vector*, whose length is equal to the degree of the generator polynomial

The difference between the block's output when you set **Output mask vector (or scalar shift value)** to 0, versus a positive integer d, is shown in the following table.

	T = 0	T = 1	T = 2	...	T = d	T = d+1
Shift = 0	x_0	x_1	x_2	...	x_d	x_{d+1}
Shift = d	x_d	x_{d+1}	x_{d+2}	...	x_{2d}	x_{2d+1}

Alternatively, you can set **Output mask vector (or scalar shift value)** to a binary vector, corresponding to a polynomial in z, $m_{r-1}z^{r-1} + m_{r-2}z^{r-2} + ... + m_1z + m_0$, of degree at most r-1. The mask vector corresponding to a shift of d is the vector that represents $m(z) = z^d$ modulo $g(z)$, where $g(z)$ is the generator polynomial. For example, if the degree of the generator polynomial is 4, then the mask vector corresponding to d = 2 is `[0 1 0 0]`, which represents the polynomial $m(z) = z^2$. The preceding schematic diagram shows how **Output mask vector (or scalar shift value)** is implemented when you specify it as a mask vector. The default setting for **Output mask vector (or scalar shift value)** is `0`. You can calculate the mask vector using the Communications Toolbox function `shift2mask`.

Sequences of Maximum Length

If you want to generate a sequence of the maximum possible length for a fixed degree, *r*, of the generator polynomial, you can set **Generator polynomial** to a value from the following table. See Proakis, John G., *Digital Communications*, Third edition, New York, McGraw Hill, 1995 for more information about the shift-register configurations that these polynomials represent.

r	Generator Polynomial	r	Generator Polynomial
2	`[2 1 0]`	21	`[21 19 0]`

Examples

Typically `commsrc.pn` is used to output pseudorandom data streams.

Construct a PN object.

```
h = commsrc.pn('Shift',0);
```

Output 10 PN bits.

```
set(h,'NumBitsOut',10);
generate(h)
```

```
ans = 10×1

     1
     0
     0
     0
     0
     0
     1
     0
     0
     0
```

Output 10 more PN bits.

```
generate(h)
```

```
ans = 10×1

     0
     1
     1
     0
     0
     0
     1
     0
     1
     0
```

Reset the object to the initial shift register state values.

```
reset(h);
```

Output 4 PN bits.

```
set(h,'NumBitsOut',4);
generate(h)
```

```
ans = 4×1

     1
     0
     0
     0
```

Version History

Introduced in R2009a

`commsrc.pn` will be removed in a future release.
Warns starting in R2021b

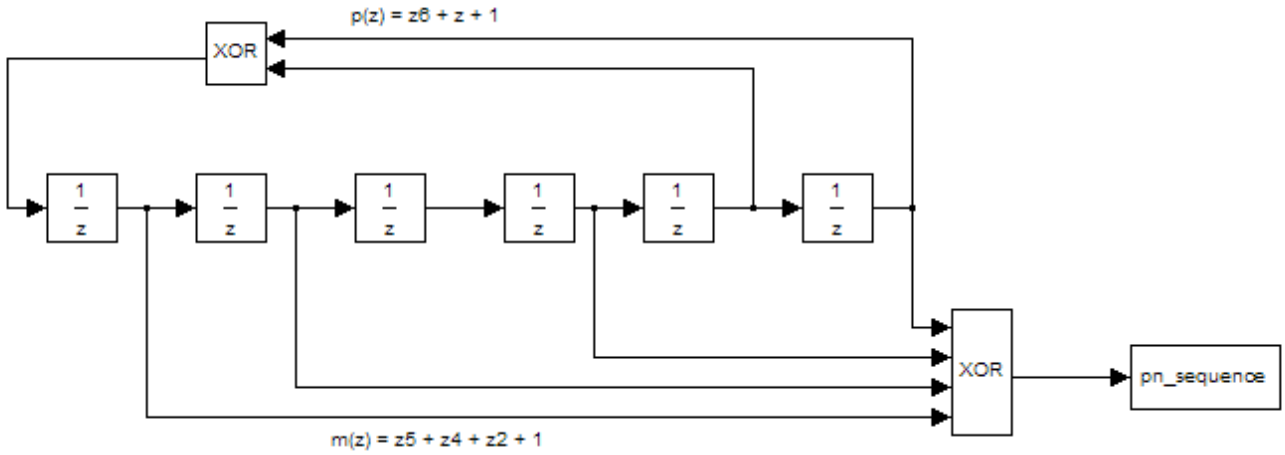
`commsrc.pn` will be removed in a future release. Instead, to generate a pseudo-noise (PN) sequence, use the `comm.PNSequence` System object™.

Replace instances of the `commsrc.pn` object with a `comm.PNSequence` System object. This table shows the mapping between `commsrc.pn` properties and `comm.PNSequence` properties.

`commsrc.pn` Object Properties	`comm.PNSequence` System Object Properties
`GenPoly`	`Polynomial`
`InitialStates`	`InitialConditions`
`Mask`	`Mask`
`NumBitsOut`	`SamplesPerFrame`
`CurrentStates`	Not applicable

Set up a PN sequence generator. Define the polynomial in binary vector format or exponential vector format.

For example, consider this PN sequence generator with a generator polynomial $p(z) = z^6 + z + 1$.



This table shows some typical usages of `commsrc.pn` and how to update your code to use `comm.PNSequence` instead.

Discouraged Usage	Recommended Replacement

Define the PN sequence generator.
 	
`h1 = commsrc.pn('GenPoly',[1 0 0 0 0 1 1], 'Mask',[1 1 0 1 0 1]);`
`h2 = commsrc.pn('GenPoly',[1 0 0 0 0 1 1], 'Shift',22);`
`mask2shift([1 0 0 0 0 1 1],[1 1 0 1 0 1])`
 	
`ans = 22`
 	
Alternatively, input `GenPoly` as the exponents of z for the nonzero terms of the polynomial in descending order of powers.
 	
`h = commsrc.pn('GenPoly',[6 1 0], 'Mask',[1 1 0 1 0 1])`
 	
`h =`
`GenPoly: [1 0 0 0 0 1 1]`
`InitialStates: [0 0 0 0 0 1]`
`CurrentStates: [0 0 0 0 0 1]`
`Mask: [1 1 0 1 0 1]`
`NumBitsOut: 1`
	Define the PN sequence generator.
	
	`h1 = comm.PNSequence('Polynomial',[1 0 0 0 0 1 1], ... 'InitialConditions', ... ...[1 1 0 1 0 1]);`
	`h2 = comm.PNSequence('Polynomial',[1 0 0 0 0 1 1], ... 'Mask',22);`
	`mask2shift([1 0 0 0 0 1 1],[1 1 0 1 0 1])`
	
	`ans = 22`
	
	Alternatively, input the polynomial exponents of z for the nonzero terms of the polynomial in descending order of powers.
	
	`h = comm.PNSequence('Polynomial',[6 1 0],... 'InitialConditions',[1 1 0 1 0 1])`
	
	`h =`
	`comm.PNSequence with properties:`
	
	`Polynomial: [6 1 0]`
	`InitialConditionsSource: 'Property'`
	`InitialConditions: [1 1 0 1 0 1]`
	`MaskSource: 'Property'`
	`Mask: 0`
	`VariableSizeOutput: false`
	`SamplesPerFrame: 1`
	`ResetInputPort: false`
	`BitPackedOutput: false`
	`OutputDataType: 'double'`

compand

Source coding mu-law or A-law compressor or expander

Syntax

```
out = compand(in,param,v)
out = compand(in,param,v,method)
```

Description

`out = compand(in,param,v)` performs mu-law compression on the input data sequence. The `param` input specifies the mu-law compression value and must be set to a mu value for mu-law compressor computation (a mu-law value of 255 is used in practice). `v` specifies the peak magnitude of the input data sequence.

`out = compand(in,param,v,method)` performs mu-law or A-law compression or expansion on the input data sequence. `param` specifies the mu-law compander or A-law compander value (a mu-law value of 255 and an A-law value of 87.6 are used in practice). `method` specifies the type of compressor or expander computation for the function to perform on the input data sequence.

Examples

Compress and Expand Data Sequence Using Mu-Law

Generate a data sequence.

```
data = 2:2:12
```

```
data = 1×6

     2     4     6     8    10    12
```

Compress the data sequence by using a mu-law compressor. Set the value for mu to 255. The compressed data sequence now ranges between 8.1 and 12.

```
compressed = compand(data,255,max(data),'mu/compressor')
```

```
compressed = 1×6

    8.1644    9.6394   10.5084   11.1268   11.6071   12.0000
```

Expand the compressed data sequence by using a mu-law expander. The expanded data sequence is nearly identical to the original data sequence.

```
expanded = compand(compressed,255,max(data),'mu/expander')
```

```
expanded = 1×6
```

```
    2.0000    4.0000    6.0000    8.0000   10.0000   12.0000
```

Calculate the difference between the original data sequence and the expanded sequence.

```
diffvalue = expanded - data
```

```
diffvalue = 1×6
10^-14 ×

   -0.0444    0.1776    0.0888    0.1776    0.1776   -0.3553
```

Compress and Expand Data Sequence Using A-Law

Generate a data sequence.

```
data = 1:5;
```

Compress the data sequence by using an A-law compressor. Set the value for A to 87.6. The compressed data sequence now ranges between 3.5 and 5.

```
compressed = compand(data,87.6,max(data),'A/compressor')
```

```
compressed = 1×5

    3.5296    4.1629    4.5333    4.7961    5.0000
```

Expand the compressed data sequence by using an A-law expander. The expanded data sequence is nearly identical to the original data sequence.

```
expanded = compand(compressed,87.6,max(data),'A/expander')
```

```
expanded = 1×5

    1.0000    2.0000    3.0000    4.0000    5.0000
```

Calculate the difference between the original data sequence and the expanded sequence.

```
diffvalue = expanded - data
```

```
diffvalue = 1×5
10^-14 ×

         0         0    0.1332    0.0888    0.0888
```

Quantize and Compand an Exponential Signal

When transmitting signals with a high dynamic range, quantization using equal length intervals can result in loss of precision and signal distortion. Companding is a operation that applies a logarithmic

computation to compress the signal before quantization on the transmit side and applies an inverse operation to expand the signal to restore it to full scale on the receive side. Companding avoids signal distortion without the need to specify many quantization levels. Compare distortion when using 6-bit quantization on an exponential signal with and without companding. Plot the original exponential signal, the quantized signal and the expanded signal.

Create an exponential signal and calculate its maximum value.

```
sig = exp(-4:0.1:4);
V = max(sig);
```

Quantize the signal by using equal-length intervals. Set partition and codebook values, assuming 6-bit quantization. Calculate the mean square distortion.

```
partition = 0:2^6 - 1;
codebook = 0:2^6;
[~,qsig,distortion] = quantiz(sig,partition,codebook);
```

Compress the signal by using the `compand` function configured to apply the mu-law method. Apply quantization and expand the quantized signal. Calculate the mean square distortion of the companded signal.

```
mu = 255; % mu-law parameter
csig_compressed = compand(sig,mu,V,'mu/compressor');
[~,quants] = quantiz(csig_compressed,partition,codebook);
csig_expanded = compand(quants,mu,max(quants),'mu/expander');
distortion2 = sum((csig_expanded - sig).^2)/length(sig);
```

Compare the mean square distortion for quantization versus combined companding and quantization. The distortion for the companded and quantized signal is an order of magnitude lower than the distortion of the quantized signal. Equal-length intervals are well suited to the logarithm of an exponential signal but not well suited to an exponential signal itself.

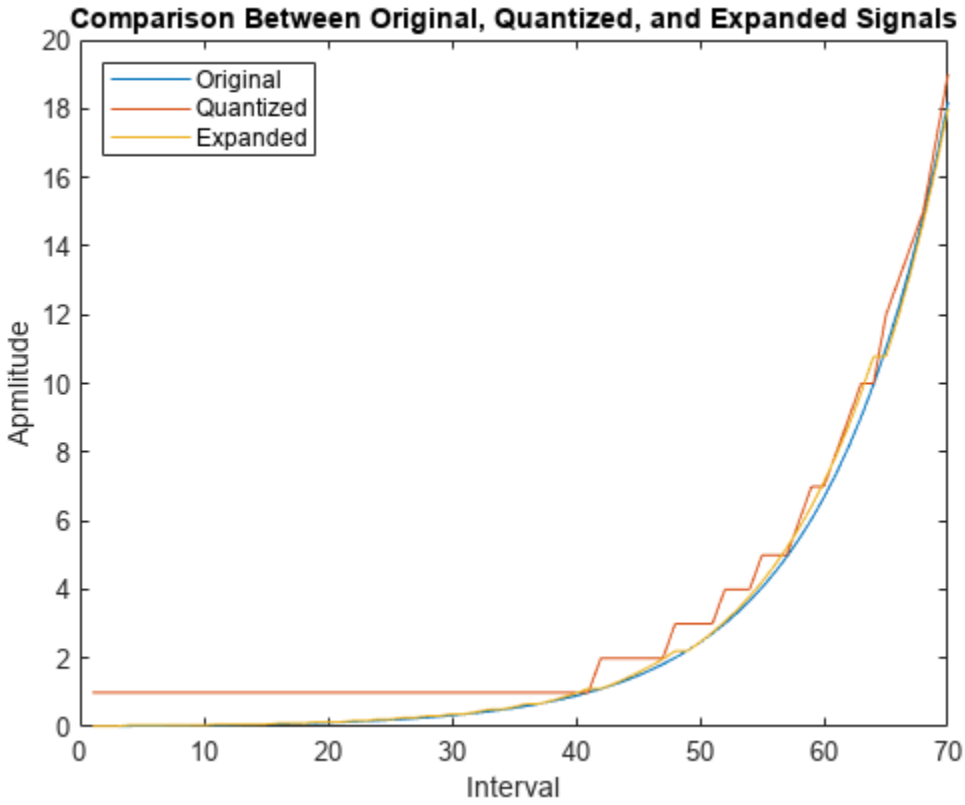
```
[distortion, distortion2]
```

```
ans = 1×2

    0.5348    0.0397
```

Plot the original exponential signal, the quantized signal, and the expanded signal. Zoom in on axis to highlight the quantized signal error at lower signal levels.

```
plot([sig' qsig' csig_expanded']);
title('Comparison Between Original, Quantized, and Expanded Signals');
xlabel('Interval');
ylabel('Apmlitude');
legend('Original','Quantized','Expanded','location','nw');
axis([0 70 0 20])
```



Input Arguments

`in` — Input data sequence

row vector

Input data sequence, specified as a row vector. This input specifies the data sequence for the function to perform compression or expansion.

Data Types: `double`

`param` — mu or A value of compander

positive scalar | 255 | 87.6

mu or A value of the compander, specified as a positive scalar. The prevailing values used in practice are μ = 255 and A = 87.6.

Data Types: `double`

`method` — Type of compressor or expander computation

`mu/compressorr` | `mu/expander` | `A/compressor` | `A/expander`

Type of compressor or expander computation for the function to perform on the input data sequence, specified as one of these values.

- `mu/compressor`

- `mu/expander`
- `A/compressor`
- `A/expander`

Data Types: `char` | `string`

v — Peak magnitude of input data sequence
positive scalar

Peak magnitude of the input data sequence, specified as a positive scalar.

Data Types: `double`

Output Arguments

`out` — Compressed or expanded signal
positive row vector

Compressed or expanded signal, returned as a positive row vector. The size of `out` matches that of input argument `in`.

Algorithms

In certain applications, such as speech processing, using a logarithmic computation (called a compressor) before quantizing the input data is common. The inverse operation of a compressor is called an *expander*. The combination of a compressor and expander is called a *compander*.

For a given signal, x, the output of the (μ-law) compressor is

$$y = \frac{\log(1+\mu|x|)}{\log(1+\mu)}\mathrm{sgn}(x)\,.$$

μ is the μ-law parameter of the compander, `log` is the natural logarithm, and `sgn` is the signum function (`sign` in MATLAB).

μ-law expansion for input signal x is given by the inverse function y^{-1},

$$y^{-1} = \mathrm{sgn}(y)\left(\frac{1}{\mu}\right)\left((1+\mu)^{|y|}-1\right) \qquad \text{for } -1 \le y \le 1$$

For a given signal, x, the output of the (A-law) compressor is

$$y = \begin{cases} \dfrac{A|x|}{1+\log A}\mathrm{sgn}(x) & \text{for } 0 \le |x| \le \dfrac{1}{A} \\ \dfrac{(1+\log(A|x|))}{1+\log A}\mathrm{sgn}(x) & \text{for } \dfrac{1}{A} < |x| \le 1 \end{cases}$$

A is the A-law parameter of the compander, `log` is the natural logarithm, and `sgn` is the signum function (`sign` in MATLAB).

A-law expansion for input signal x is given by the inverse function y^{-1},

$$y^{-1} = \mathrm{sgn}(y)\begin{cases} \dfrac{|y|(1+\log(A))}{A} & \text{for } 0 \le |y| < \dfrac{1}{1+\log(A)} \\ \dfrac{\exp(|y|(1+\log(A))-1)}{A} & \text{for } \dfrac{1}{1+\log(A)} \le |y| < 1 \end{cases}$$

convdeintrlv

Restore ordering of symbols using shift registers

Syntax

```
deintrlved = convdeintrlv(data,nrows,slope)
[deintrlved,state] = convdeintrlv(data,nrows,slope)
[deintrlved,state] = convdeintrlv(data,nrows,slope,init_state)
```

Description

`deintrlved = convdeintrlv(data,nrows,slope)` restores the ordering of elements in `data` by using a set of `nrows` internal shift registers. `slope` is the register length step. For information about delays, see “Delays of Convolutional Interleaving and Deinterleaving” on page 2-205.

`[deintrlved,state] = convdeintrlv(data,nrows,slope)` returns a structure that holds the final state of the shift registers. `state.value` stores any unshifted symbols. `state.index` is the index of the next register to be shifted.

`[deintrlved,state] = convdeintrlv(data,nrows,slope,init_state)` initializes the shift registers with the symbols contained in `init_state.value` and directs the first input symbol to the shift register referenced by `init_state.index`. The structure `init_state` is typically the `state` output from a previous call to this same function, and is unrelated to the corresponding interleaver.

Using an Interleaver-Deinterleaver Pair

To use this function as an inverse of the `convintrlv` function, use the same `nrows` and `slope` inputs in both functions. In that case, the two functions are inverses in the sense that applying `convintrlv` followed by `convdeintrlv` leaves data unchanged, after you take their combined delay of `nrows*(nrows-1)*slope` into account. For information about delays, see “Delays of Convolutional Interleaving and Deinterleaving” on page 2-205.

Examples

The example in “Effect of Delays on Recovery of Convolutionally Interleaved Data Using MATLAB” uses `convdeintrlv` and illustrates how you can handle the delay of the interleaver/deinterleaver pair when recovering data.

The example on the reference page for `muxdeintrlv` illustrates how to use the `state` output and `init_state` input with that function; the process is analogous for this function.

More About

Delays of Convolutional Interleaving and Deinterleaving

The total delay due to a convolutional interleaver and deinterleaver pair is $N \times slope \times (N - 1)$.

- N is the number of registers and equals the value of the `nrows` argument

- *slope* is the register length step and equals the value of the `slope` argument

This diagram shows the structure of a general convolutional interleaver comprised of a set of shift registers, each having a specified delay shown as D(1), D(2),..., D(*N*), and a commutator to switch input and output symbols through registers. The *k*th shift register holds D(*k*) symbols, where $k = 1, 2, 3, \ldots N$. The *k*th shift register has a delay value of $((k–1) \times slope)$. With each new input symbol, the commutator switches to a new register and shifts in the new symbol while shifting out the oldest symbol in that register. When the commutator reaches the *N*th register, upon the next new input, the commutator returns to the first register.

convenc

Convolutionally encode binary message

Syntax

```
codedout = convenc(msg,trellis)
codedout = convenc(msg,trellis,puncpat)
codedout = convenc( ___ ,istate)
[codedout,fstate] = convenc( ___ )
```

Description

`codedout = convenc(msg,trellis)` encodes the input binary message by using a convolutional encoder represented by a trellis structure. For details about trellis structures in MATLAB, see “Trellis Description of a Convolutional Code”. The input message contains one or more symbols, each of which consists of log2(`trellis.numInputSymbols`) bits. The coded output, `codedout`, contains one or more symbols, each of which consists of log2(`trellis.numOutputSymbols`) bits.

`codedout = convenc(msg,trellis,puncpat)` specifies a puncture pattern, `puncpat`, to enable higher rate encoding than unpunctured coding.

For some commonly used puncture patterns for specific rates and polynomials, see the last three references.

`codedout = convenc( ___ ,istate)` enables the encoder registers to start at a state specified by `istate`. Specify `istate` as the last input parameter preceded by any of the input argument combinations in the previous syntaxes.

`[codedout,fstate] = convenc( ___ )` also returns the final state of the encoder. When calling `convenc` iteratively, `fstate` is typically used to set `istate` for subsequent calls to the `convenc` function.

Examples

Create Convolutional Codes

Create convolutional codes by using a trellis structure. You can define the trellis by using the `poly2trellis` function or by manually specifying the trellis structure. The example shows both methods.

Define trellis by using `poly2trellis` function

Define the trellis structure to be used to configure the encoder by using the `poly2trellis` function.

```
trellis_a = poly2trellis([5 4],[23 35 0; 0 5 13])
```

```
trellis_a = struct with fields:
     numInputSymbols: 4
    numOutputSymbols: 8
```

```
          numStates: 128
         nextStates: [128x4 double]
            outputs: [128x4 double]
```

Use the trellis structure to configure the `convenc` function. Encode five two-bit symbols for a K/N rate 2/3 convolutional code by using the `convenc` function.

```
K = log2(trellis_a.numInputSymbols) % Number of input bit streams
```

```
K = 2
```

```
N = log2(trellis_a.numOutputSymbols) % Number of output bit streams
```

```
N = 3
```

```
numReg = log2(trellis_a.numStates) % Number of coder registers
```

```
numReg = 7
```

```
numSymPerFrame = 5; % Number of symbols per frame
data = randi([0 1],K*numSymPerFrame,1);
[code_a,fstate_a] = convenc(data,trellis_a);
```

Verify that the encoded output is 15 bits, which is 3/2 (N/K) times the length of the input sequence, `data`.

```
code_a'
```

```
ans = 1×15

     1     1     1     0     0     1     1     1     1     1     0     1     0     1     0
```

```
length(data)
```

```
ans = 10
```

```
length(code_a)
```

```
ans = 15
```

Define trellis manually

Manually define a trellis structure for a K/N rate 1/2 convolutional code.

```
trellis_b = struct('numInputSymbols',2,'numOutputSymbols',4, ...
'numStates',4,'nextStates',[0 2;0 2;1 3;1 3], ...
'outputs',[0 3;1 2;3 0;2 1])
```

```
trellis_b = struct with fields:
     numInputSymbols: 2
    numOutputSymbols: 4
           numStates: 4
          nextStates: [4x2 double]
             outputs: [4x2 double]
```

Use the trellis structure to configure the `convenc` function when encoding 10 one-bit symbols.

```
K = log2(trellis_b.numInputSymbols) % Number of input bit streams
```

```
K = 1
```

```
N = log2(trellis_b.numOutputSymbols) % Number of output bit streams
```

```
N = 2
```

```
numReg = log2(trellis_b.numStates) % Number of coder registers
```

```
numReg = 2
```

```
numSymPerFrame = 10; % Number of symbols per frame
data = randi([0 1],K*numSymPerFrame,1);
code_b = convenc(data,trellis_b);
```

Verify that the encoded output is 20 bits, which is 2/1 (N/K) times the length of the input sequence, `data`.

```
code_b'
```

```
ans = 1×20

     0     0     1     1     0     0     1     0     1     0     1     1     0     1     1     1
```

```
length(data)
```

```
ans = 10
```

```
length(code_b)
```

```
ans = 20
```

Adjust Convolutional Encoding Code Rate by Using Puncturing

Use puncturing to adjust the K/N code rate of the convolutional encoder from 1/2 to 3/4.

Initialize parameters for the encoding operation.

```
trellis = poly2trellis(7,[171 133])
```

```
trellis = struct with fields:
     numInputSymbols: 2
    numOutputSymbols: 4
           numStates: 64
          nextStates: [64x2 double]
             outputs: [64x2 double]
```

```
puncpat = [1;1;0];
```

Calculate the unpunctured and punctured code rates.

```
K = log2(trellis.numInputSymbols); % Number of input streams
N = log2(trellis.numOutputSymbols); % Number of output streams
unpunc_coderate = K/N; % Unpunctured code rate
punc_coderate = (K/N)*length(puncpat)/sum(puncpat); % Punctured code rate
fprintf('K is %d and N is %d. The unpunctured code rate is %3.2f and the punctured code rate is %
```

```
K is 1 and N is 2. The unpunctured code rate is 0.50 and the punctured code rate is 0.75.
```

Convolutionally encode an all 1s three-bit message without puncturing applied to the coded output. Then, convolutionally encode the same message with puncturing.

```
msg = ones(length(puncpat),1);
unpuncturedcode = convenc(msg,trellis);
puncturedcode = convenc(msg,trellis,puncpat);
```

Show the message, the unpunctured code, the punctured code, and the puncture pattern.

```
msg'
```

```
ans = 1×3

     1     1     1
```

```
unpuncturedcode'
```

```
ans = 1×6

     1     1     0     1     1     0
```

```
puncpat'
```

```
ans = 1×3

     1     1     0
```

```
puncturedcode'
```

```
ans = 1×4

     1     1     1     1
```

Without puncturing, the configured convolutional encoding inputs three message bits and outputs six coded bits. Confirm the resulting code rate matches the expected code rate of 1/2.

```
length(msg)/length(unpuncturedcode)
```

```
ans = 0.5000
```

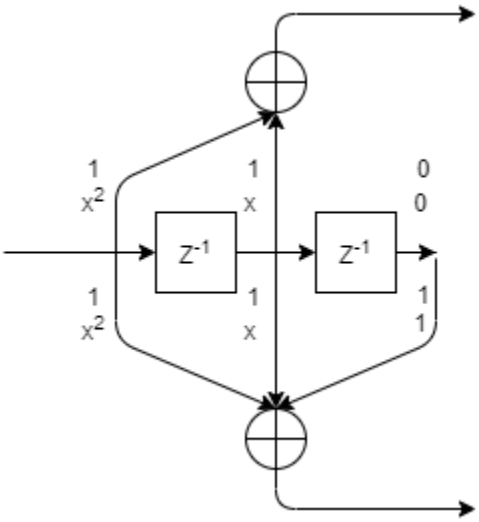
With puncturing, bits in positions 1 and 2 of the input message are transmitted, while the bit in position 3 is removed. For every three bits of input, the punctured code generates four bits of output. Confirm the resulting code rate matches the expected code rate of 3/4.

```
length(msg)/length(puncturedcode)
```

```
ans = 0.7500
```

Use Trellis Structure for Rate 1/2 Feedforward Convolutional Encoder

Use a trellis structure to configure the rate 1/2 feedforward convolutional code in this diagram.



Create a trellis structure, setting the constraint length to 3 and specifying the code generator as a vector of octal values. The diagram indicates the binary values and polynomial form, indicating the left-most bit is the most-significant-bit (MSB). The binary vector [1 1 0] represents octal 6 and corresponds to the upper row of binary digits in the diagram. The binary vector [1 1 1] represents octal 7 and corresponds to the lower row of binary digits in the diagram. These binary digits indicate connections from the outputs of the registers to the two adders in the diagram.

```
trellis = poly2trellis(3,[6 7])
```

```
trellis = struct with fields:
     numInputSymbols: 2
    numOutputSymbols: 4
           numStates: 4
          nextStates: [4x2 double]
             outputs: [4x2 double]
```

Generate random binary data. Convolutionally encode the data, by using the specified trellis structure. Decode the coded data by using the Viterbi algorithm with the specified trellis structure, 34 for its traceback depth, truncated operation mode, and hard decisions.

```
data = randi([0 1],70,1);
codedData = convenc(data,trellis);
tbdepth = 34;
decodedData = vitdec(codedData,trellis,tbdepth,'trunc','hard');
```

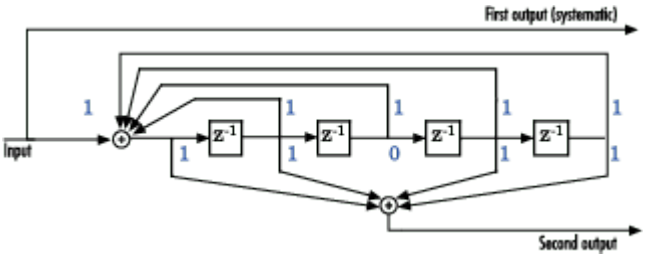
Verify the decoded data has zero bit errors.

```
biterr(data,decodedData)
```

```
ans = 0
```

Use Trellis Structure for Rate 1/2 Feedback Convolutional Encoder

Create a trellis structure to represent the rate 1/2 systematic convolutional encoder with feedback shown in this diagram.



This encoder has 5 for its constraint length, [37 33] as its generator polynomial matrix, and 37 for its feedback connection polynomial.

The first generator polynomial is octal 37. The second generator polynomial is octal 33. The feedback polynomial is octal 37. The first generator polynomial matches the feedback connection polynomial because the first output corresponds to the systematic bits.

The binary vector [1 1 1 1 1] represents octal 37 and corresponds to the upper row of binary digits in the diagram. The binary vector [1 1 0 1 1] represents octal 33 and corresponds to the lower row of binary digits in the diagram. These binary digits indicate connections from the outputs of the registers to the two adders in the diagram. The initial 1 corresponds to the input bit.

Convert the polynomial to a trellis structure by using the `poly2trellis` function. When used with a feedback polynomial, `poly2trellis` makes a feedback connection to the input of the trellis.

```
trellis = poly2trellis(5,[37 33],37)
```

```
trellis = struct with fields:
     numInputSymbols: 2
    numOutputSymbols: 4
           numStates: 16
          nextStates: [16x2 double]
             outputs: [16x2 double]
```

Generate random binary data. Convolutionally encode the data by using the specified trellis structure. Decode the coded data by using the Viterbi algorithm with the specified trellis structure, 34 for its traceback depth, truncated operation mode, and hard decisions.

```
data = randi([0 1],70,1);
codedData = convenc(data,trellis);
tbdepth = 34; % Traceback depth for Viterbi decoder
decodedData = vitdec(codedData,trellis,tbdepth,'trunc','hard');
```

Verify the decoded data has zero bit errors.

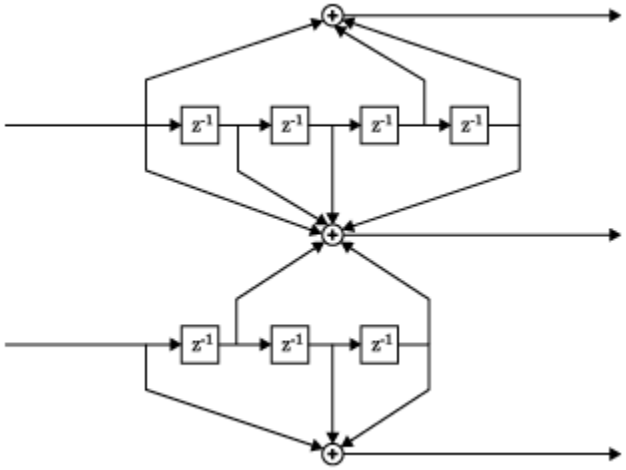
```
biterr(data,decodedData)
```

```
ans = 0
```

Compare Full Message to Piecewise Message Convolutional Encoding

Compare the convolutional encoding of a full message to the convolutional encoding of a message in two segments.

This diagram shows a rate 2/3 encoder with two input streams, three output streams, and seven shift registers.



Define the trellis structure in the diagram by using the `poly2trellis` function. Set the constraint length of the upper path to 5 and the constraint length of the lower path to 4. The octal representation of the code generator matrix corresponds to the taps from the upper and lower shift registers.

```
trellis = poly2trellis([5 4],[23 35 0; 0 5 13]);
```

Inspect the coder configuration.

```
K = log2(trellis.numInputSymbols) % Number of input bit streams
```

```
K = 2
```

```
N = log2(trellis.numOutputSymbols) % Number of output bit streams
```

```
N = 3
```

```
coderate = K/N
```

```
coderate = 0.6667
```

```
numReg = log2(trellis.numStates) % Number of coder registers
```

```
numReg = 7
```

Define a message with five two-bit input symbols.

```
numSymPerFrame = 5; % Number of symbols per frame
msg = randi([0 1],K*numSymPerFrame,1);
```

Encode the full message by using the trellis to configure the `convenc` function.

```
[code_a,fstate_a] = convenc(msg,trellis);
```

Apply piecewise message encoding by using the same trellis structure. Use the final and initial state arguments when using the `convenc` function. For piecewise message encoding, message segments must be a multiple of the number of bits in an input symbol.

Encode part of the message, recording the final state for later use.

```
[code_a1,fstate_a1] = convenc(msg(1:6),trellis);
```

Encode the rest of the message, using the final state, `fstate_a1`, as the initial state input argument.

```
[code_a2,fstate_a2] = convenc(msg(7:end),trellis,fstate_a1);
```

Verify that the full coded message, `code_a`, matches the concatenated piecewise coded message, `[code_a1; code_a2]`.

```
isequal(code_a,[code_a1; code_a2])
```

```
ans = logical
   1
```

Verify that the final state, `fstate_a`, of the encoder after the full message encoding matches the final state, `fstate_a2`, of the encoder after piecewise message encoding.

```
isequal(fstate_a,fstate_a2)
```

```
ans = logical
   1
```

Input Arguments

`msg` — Binary message

vector of binary values

Binary message, specified as a vector of binary values. `msg` must contain one or more symbols. Each symbol must consist of log2(`trellis.numInputSymbols`) bits.

Example: `[1 1 0 1 0 0 1 1]` specifies the message as a binary row vector with eight elements.

Data Types: `double` | `logical`

`trellis` — Trellis description

structure

Trellis description, specified as a MATLAB structure that contains the trellis description for a rate *K*/*N* code. *K* represents the number of input bit streams, and *N* represents the number of output bit streams.

The trellis structure contains these fields. You can either use the `poly2trellis` function to create the trellis structure or create it manually. For more about this structure, see “Trellis Description of a Convolutional Code” and the `istrellis` function.

`numInputSymbols` — Number of symbols input to encoder

2^K

Number of symbols input to the encoder, specified as an integer equal to 2^K, where K is the number of input bit streams.

Data Types: `double`

`numOutputSymbols` — Number of symbols output from encoder
2^N

Number of symbols output from the encoder, specified as an integer equal to 2^N, where N is the number of output bit streams.

Data Types: `double`

`numStates` — Number of states in encoder
power of 2

Number of states in the encoder, specified as a power of 2.

Data Types: `double`

`nextStates` — Next states
matrix of integers

Next states for all combinations of current states and current inputs, specified as a matrix of integers. The matrix size must be `numStates` by 2^K.

Data Types: `double`

`outputs` — Outputs
matrix of octal numbers

Outputs for all combinations of current states and current inputs, specified as a matrix of octal numbers. The matrix size must be `numStates` by 2^K.

Data Types: `double`

Data Types: `struct`

`puncpat` — Puncture pattern
vector of binary values

Puncture pattern, specified as a vector of binary values. Indicate punctured bits with `0`s and unpunctured bits with `1`s. The length of the `puncpat` vector must be an integer divisor of the input message vector length, `length(msg)`.

Data Types: `double`

`istate` — Initial state
integer scalar

Initial state used for the encoder registers, specified as an integer scalar in the range [0, (`trellis.numStates` – 1)].

Data Types: `double`

Output Arguments

`codedout` — Convolutionally encoded message

vector of binary values

Convolutionally encoded message, returned as a vector of binary values. This output vector has the same data type and orientation as input `msg`. Each symbol in `codedout` consists of log2(`trellis.numOutputSymbols`) bits.

Data Types: `double` | `logical`

`fstate` — Final state

integer scalar

Final state of the encoder registers, returned as an integer scalar. When calling `convenc` iteratively, such as in a loop, `fstate` is typically used to set `istate` for subsequent calls to the `convenc` function.

Data Types: `double`

More About

Convolutional Coding

Convolutional coding is an error-control coding that has memory. Specifically, the computations and coded output depend on the current set of input symbols and on a number of previous input symbols that varies depending on the trellis configuration. A convolutional encoder outputs *N* bits for every *K* input bits. The input can have varying multiples of *K* bits over a simulation.

Using a MATLAB trellis structure that defines a set of generator polynomials, you can model nonsystematic, systematic feedforward, or systematic feedback convolutional codes. For more information and examples that demonstrate various convolutional code architectures, see the “Convolutional Codes” topic.

To decode the convolutionally coded output, you can use:

- The `vitdec` function or `comm.ViterbiDecoder` System object — Uses the Viterbi algorithm with hard-decision and soft-decision decoding
- The `comm.APPDecoder` System object — Uses an *a posteriori* probability decoder for the soft output decoding of convolutional codes

convertSNR

Convert SNR values

Syntax

```
y = convertSNR(x,inputmode)
y = convertSNR(x,inputmode,outputmode)
y = convertSNR(x,inputmode,Name=Value)
```

Description

`y = convertSNR(x,inputmode)` converts the input signal-to-noise ratio value `x` to an SNR.

`y = convertSNR(x,inputmode,outputmode)` converts the input signal-to-noise ratio value `x` to `outputmode`.

`y = convertSNR(x,inputmode,Name=Value)` specifies additional name-value arguments.

Examples

Add Noise to 8-PSK Modulated Signal for Eb/No Value

Generate random data symbols and the 8-PSK modulated signal.

```
d = randi([0 7],100,1);
M = 8;                  % 8-PSK
k = log2(M);            % bits per symbol
psk = pskmod(d,M);
```

Add the noise equivalent of a 6 dB Eb/No value to the modulated signal. To do so, first convert the Eb/No value to an SNR.

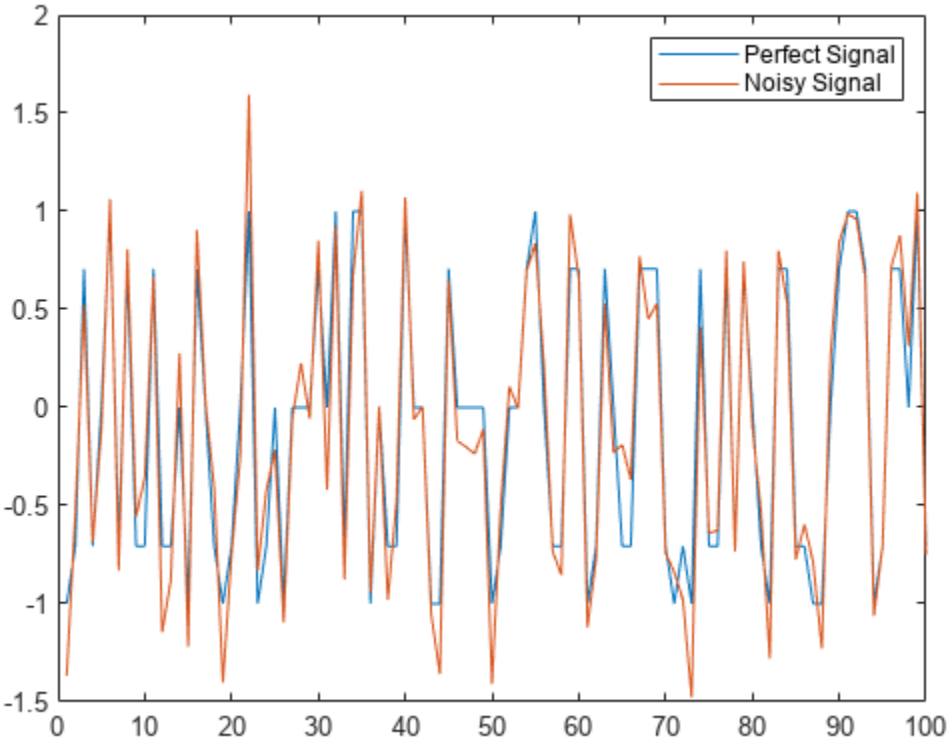
```
EbNo = 6;
SNR = convertSNR(EbNo,'ebno',BitsPerSymbol=k)
```

```
SNR = 10.7712
```

```
y = awgn(psk,SNR);
```

Plot the signal with and without the noise component.

```
figure
plot(real(psk));
hold on
plot(real(y))
legend("Perfect Signal","Noisy Signal")
```



Convert Eb/No Value to SNR Value

Set the simulation parameters

```
M = 16;         % Modulation order
k = log2(M);    % bits per symbol
nSamp = 4;      % Number of samples
```

Create the raised cosine transmit and receive filters

```
txfilter = comm.RaisedCosineTransmitFilter('OutputSamplesPerSymbol',nSamp);
rxfilter = comm.RaisedCosineReceiveFilter('InputSamplesPerSymbol',nSamp, ...
                                          'DecimationFactor',nSamp);
```

Generate random data symbols and the filtered 16-QAM modulated signal.

```
d = randi([0 1],1000,1);
sig1 = qammod(d,M,InputType="bit");
qam = txfilter(sig1);
```

Convert the Eb/No value of 10 dB to an SNR value and add the noise equivalent to the filtered modulated signal.

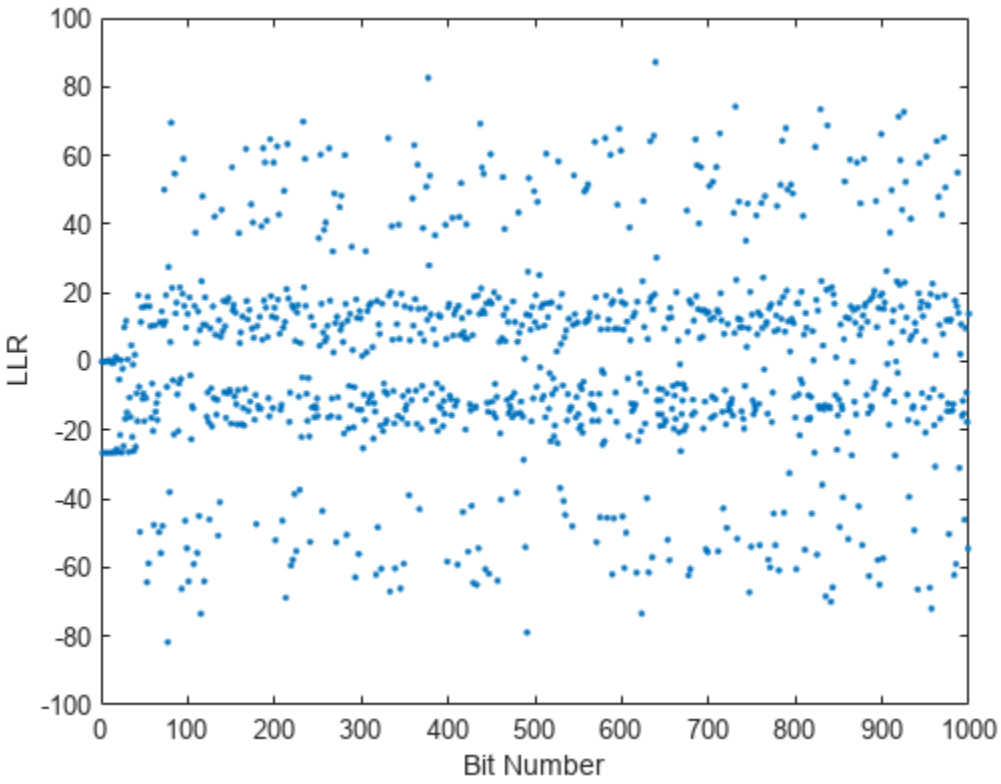
```
EbNo = 10;
SNR = convertSNR(EbNo,"ebno",BitsPerSymbol=k, ...
                 SamplesPerSymbol=nSamp,CodingRate=1/3)
```

```
SNR = 5.2288

[sig2,var] = awgn(qam,SNR);
y = rxfilter(sig2);
outsignal = qamdemod(y,M,OutputType="llr",NoiseVariance=var);
```

Plot the demodulated QAM signal.

```
figure
plot(outsignal,'.')
xlabel('Bit Number')
ylabel('LLR')
```



Input Arguments

x — Input value

numeric row vector

Input value, specified as a numeric row vector.

Data Types: `double`

inputmode — Input mode

`"ebno"` | `"esno"` | `"snr"`

Input mode, specified as `"ebno"`, `"esno"`, or `"snr"`.

- `"ebno"` — `x` is the energy per bit to noise power spectral density ratio (Eb/No).
- `"esno"` — `x` is the energy per symbol to noise power spectral density ratio (Es/No).
- `"snr"` — `x` is the SNR.

`outputmode` — Output mode
`"ebno"` | `"esno"` | `"snr"`

Output mode for `y`, specified as `"ebno"`, `"esno"`, or `"snr"`.

- `"ebno"` — `y` is the energy per bit to noise power spectral density ratio (Eb/No).
- `"esno"` — `y` is the energy per symbol to noise power spectral density ratio (Es/No).
- `"snr"` — `y` is the SNR.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `y = convertSNR(x,inputmode,outputmode,SamplesPerSymbol=2)`

`samplespersymbol` — Samples per symbol
1 (default) | positive integer

Samples per symbol, specified as a positive integer. The function ignores `samplespersymbol` value if you set:

- `inputmode` to `"ebno"` and `outputmode` to `"esno"`.
- `inputmode` to `"esno"` and `outputmode` to `"ebno"`.

For more information, see “Input mode to output mode conversion” on page 2-222.

Data Types: `double`

`bitspersymbol` — Bits per symbol
1 (default) | positive integer

Bits per symbol, specified as a positive integer. The function ignores `bitspersymbol` value if you set:

- `inputmode` to `"esno"` and `outputmode` to `"snr"`.
- `inputmode` to `"snr"` and `outputmode` to `"esno"`.

For more information, see “Input mode to output mode conversion” on page 2-222.

Data Types: `double`

`codingrate` — Coding rate
1 (default) | scalar in the range (0, 1]

Coding rate, specified as a scalar in the range (0, 1]. The function ignores `codingrate` value if you set:

- `inputmode` to `"esno"` and `outputmode` to `"snr"`.
- `inputmode` to `"snr"` and `outputmode` to `"esno"`.

For more information, see “Input mode to output mode conversion” on page 2-222.

Data Types: `double`

Output Arguments

y — Output value

row vector of numeric values

Output value, returned as a row vector of numeric values.

More About

Input mode to output mode conversion

The following table shows the parameters used in conversion based on the choice of `inputmode` and `outputmode`. The default value for all the parameters is `1`.

`inputmode` to `outputmode` Conversion	Parameters used
`ebno` to `snr`, `snr` to `ebno`	`bitspersymbol`, `codingrate`, `samplespersymbol`
`ebno` to `esno`, `esno` to `ebno`	`bitspersymbol`, `codingrate`
`esno` to `snr`, `snr` to `esno`	`samplespersymbol`

`awgn`

convintrlv

Permute symbols using shift registers

Syntax

```
intrlved = convintrlv(data,nrows,slope)
[intrlved,state] = convintrlv(data,nrows,slope)
[intrlved,state] = convintrlv(data,nrows,slope,init_state)
```

Description

`intrlved = convintrlv(data,nrows,slope)` permutes the elements in `data` by using a set of `nrows` internal shift registers. Before the function begins to process data, it initializes all shift registers with zeros. If `data` is a matrix with multiple rows and columns, the function processes the columns independently. For information about delays, see “Delays of Convolutional Interleaving and Deinterleaving” on page 2-224.

`[intrlved,state] = convintrlv(data,nrows,slope)` returns a structure that holds the final state of the shift registers. `state.value` stores any unshifted symbols. `state.index` is the index of the next register to be shifted.

`[intrlved,state] = convintrlv(data,nrows,slope,init_state)` initializes the shift registers with the symbols contained in `init_state.value` and directs the first input symbol to the shift register referenced by `init_state.index`. The structure `init_state` is typically the `state` output from a previous call to this same function, and is unrelated to the corresponding deinterleaver.

Examples

The example below shows that `convintrlv` is a special case of the more general function `muxintrlv`. Both functions yield the same numerical results.

```
x = randi([0 1],100,1); % Original data
nrows = 5; % Use 5 shift registers
slope = 3; % Delays are 0, 3, 6, 9, and 12.
y = convintrlv(x,nrows,slope); % Interleaving using convintrlv.
delay = [0:3:12]; % Another way to express set of delays
y1 = muxintrlv(x,delay); % Interleave using muxintrlv.
isequal(y,y1)
```

The output below shows that `y`, obtained using `convintrlv`, and `y1`, obtained using `muxintrlv`, are the same.

```
ans =

     1
```

Another example using this function is in “Effect of Delays on Recovery of Convolutionally Interleaved Data Using MATLAB”.

The example on the `muxdeintrlv` reference page illustrates how to use the `state` output and `init_state` input with that function; the process is analogous for this function.

More About

Delays of Convolutional Interleaving and Deinterleaving

The total delay due to a convolutional interleaver and deinterleaver pair is $N \times slope \times (N - 1)$.

- N is the number of registers and equals the value of the `nrows` argument
- *slope* is the register length step and equals the value of the `slope` argument

This diagram shows the structure of a general convolutional interleaver comprised of a set of shift registers, each having a specified delay shown as D(1), D(2),..., D(N), and a commutator to switch input and output symbols through registers. The kth shift register holds D(k) symbols, where k = 1, 2, 3, ... N. The kth shift register has a delay value of ((k–1) × *slope*). With each new input symbol, the commutator switches to a new register and shifts in the new symbol while shifting out the oldest symbol in that register. When the commutator reaches the Nth register, upon the next new input, the commutator returns to the first register.

convmtx

Convolution matrix of Galois field vector

Syntax

```
A = convmtx(c,n)
```

Description

A *convolution matrix* is a matrix, formed from a vector, whose inner product with another vector is the convolution of the two vectors.

`A = convmtx(c,n)` returns a convolution matrix for the Galois vector `c`. The output `A` is a Galois array that represents convolution with `c` in the sense that `conv(c,x)` equals

- `A*x`, if `c` is a column vector and `x` is any Galois column vector of length `n`. In this case, `A` has `n` columns and `m+n-1` rows.
- `x*A`, if `c` is a row vector and `x` is any Galois row vector of length `n`. In this case, `A` has `n` rows and `m+n-1` columns.

Examples

The code below illustrates the equivalence between using the `conv` function and multiplying by the output of `convmtx`.

```
m = 4;
c = gf([1; 9; 3],m); % Column vector
n = 6;
x = gf(randi([0 2^m-1],n,1),m);
ck1 = isequal(conv(c,x), convmtx(c,n)*x) % True
ck2 = isequal(conv(c',x'),x'*convmtx(c',n)) % True
```

The output is

```
ck1 =

     1

ck2 =

     1
```

cosets

Produce cyclotomic cosets for Galois field

Syntax

```
cst = cosets(m)
```

Description

`cst = cosets(m)` produces cyclotomic cosets mod `2^m-1`. Each element of the cell array `cst` is a Galois array that represents one cyclotomic coset.

A cyclotomic coset is a set of elements that share the same minimal polynomial. Together, the cyclotomic cosets mod `2^m-1` form a partition of the group of nonzero elements of GF(`2^m`). For more details on cyclotomic cosets, see the works listed in “References” on page 2-229.

Examples

The commands below find and display the cyclotomic cosets for GF(8). As an example of interpreting the results, `c{2}` indicates that A, A^2, and A^2 + A share the same minimal polynomial, where A is a primitive element for GF(8).

```
c = cosets(3);
c{1}'
c{2}'
c{3}'
```

The output is below.

```
ans = GF(2^3) array. Primitive polynomial = D^3+D+1 (11 decimal)

Array elements =

     1

ans = GF(2^3) array. Primitive polynomial = D^3+D+1 (11 decimal)

Array elements =

     2     4     6

ans = GF(2^3) array. Primitive polynomial = D^3+D+1 (11 decimal)

Array elements =

     3     5     7
```

crc.detector

(To be removed) Construct CRC detector object

Note will be removed in a future release. To detect errors in input data using cyclic redundancy check (CRC), use the `comm.CRCDetector` System object instead. For more details on the recommended workflow, see “Compatibility Considerations”.

Syntax

```
h= crc.detector(polynomial)

h= crc.detector(generatorObj)

h= crc.detector(‘Polynomial’, polynomial, ‘param1’, val1, etc.)

h= crc.detector
```

Description

`h= crc.detector(polynomial)` constructs a CRC detector object H defined by the generator polynomial POLYNOMIAL

`h= crc.detector(generatorObj)` constructs a CRC detector object H defined by the parameters found in the CRC generator object GENERATOROBJ

`h= crc.detector('property1', val1, ...)` constructs a CRC detector object H with properties as specified by PROPERTY/VALUE pairs.

`h= crc.detector` constructs a CRC detector object H with default properties. It constructs a CRC-CCITT detector, and is equivalent to:

```
h=
crc.detector('Polynomial','0x1021','InitialState','0xFFFF','ReflectInput',fal
se,'ReflectRemainder',false,'FinalXOR','0x0000')
```

Properties

The following table describes the properties of a CRC detector object. All properties are writable, except `Type`.

Property	Description
Type	Specifies the object as a 'CRC Detector'.

Property	Description
`Polynomial`	The generator polynomial that defines connections for a linear feedback shift register. This property can be specified as a binary vector representing descending powers of the polynomial. In this case, the leading '1' of the polynomial must be included. It can also be specified as a string, prefaced by '0x', that is a hexadecimal representation of the descending powers of the polynomial. In this case, the leading '1' of the polynomial is omitted.
`InitialState`	The initial contents of the shift register. This property can be specified as a binary scalar, a binary vector, or as a string, prefaced by '0x', that is a hexadecimal representation of the binary vector. As a binary vector, its length must be one less than the length of the binary vector representation of the Polynomial.
`ReflectInput`	A Boolean quantity that specifies whether the input data should be flipped on a bytewise basis prior to entering the shift register.
`ReflectRemainder`	A Boolean quantity that specifies whether the binary output CRC checksum should be flipped around its center after the input data is completely through the shift register.
`FinalXOR`	The value with which the CRC checksum is to be XORed just prior to detecting the input data. This property can be specified as a binary scalar, a binary vector or as a string, prefaced by '0x', that is a hexadecimal representation of the binary vector. As a binary vector, its length must be one less than the length of the binary vector representation of the Polynomial.

A detect method is used with the object to detect errors in digital transmission.

CRC Generation Algorithm

For information pertaining to the CRC generation algorithm, see “Cyclic Redundancy Check Codes”.

Detector Method

`[OUTDATA ERROR] = DETECT(H, INDATA)` detects transmission errors in the encoded input message `INDATA` by regenerating a CRC checksum using the CRC detector object H. The detector then compares the regenerated checksum with the checksum appended to INDATA. The binary-valued INDATA can be either a column vector or a matrix. If it is a matrix, each column is considered to be a separate channel. OUTDATA is identical to the input message INDATA, except that it has the CRC checksum stripped off. ERROR is a 1xC logical vector indicating if the encoded message INDATA has errors, where C is the number of channels in INDATA. An ERROR value of 0 indicates no errors, and a value of 1 indicates errors.

Examples

Create a CRC-16 CRC generator, then use it to generate a checksum for the binary vector represented by the ASCII sequence '123456789'. Introduce an error, then detect it using a CRC-16 CRC detector.

```
gen = crc.generator('Polynomial', '0x8005', 'ReflectInput', ...
true, 'ReflectRemainder', true);
det = crc.detector('Polynomial', '0x8005', 'ReflectInput', ...
true, 'ReflectRemainder', true);
% The message below is an ASCII representation
% of the digits 1-9
msg = int2bit((49:57)',8);
encoded = generate(gen, msg);
encoded(1) = ~encoded(1);                % Introduce an error
[outdata error] = detect(det, encoded);  % Detect the error
noErrors = isequal(msg, outdata)         % Should be 0
error                                    % Should be 1
```

This example generates the following output:

```
noErrors = 0 error = 1
```

Version History

Introduced in R2008a

`crc.detector` will be removed in a future release.

Warns starting in R2020b

crc.detector will be removed in a future release. To detect errors in input data using cyclic redundancy check (CRC), use the `comm.CRCDetector` System object instead.

Replace instances of crc.detector with a `comm.CRCDetector` System object. Note the mapping between crc.detector properties and `comm.CRCDetector` properties:

crc.detector	comm.CRCDetector
Polynomial	Polynomial
InitialState	InitialConditions
ReflectInput	ReflectInputBytes
ReflectRemainder	ReflectChecksums
FinalXOR	FinalXOR

See the following table for examples of migrating the old workflow to the recommended workflow.

Previous Workflow	Recommended Workflow

```
oldO = crc.generator;
oldOdet = crc.detector

crc.generator

(To be removed) Construct CRC generator object

Note will be removed in a future release. To generate cyclic redundancy check (CRC) code bits, use the `comm.CRCGenerator` System object instead. For more details on the recommended workflow, see “Compatibility Considerations”.

Syntax

```
h = crc.generator(polynomial)

h = crc.generator(detectorObj)

h = crc.generator(‘Polynomial’, polynomial, ‘param1’, val1, etc.)

h = crc.generator
```

Description

`h = crc.generator(polynomial)` constructs a CRC generator object H defined by the generator polynomial POLYNOMIAL.

`h = crc.generator(detectorObj)` constructs a CRC generator object H defined by the parameters found in the CRC detector object DETECTOROBJ.

`h = crc.generator(‘property1', val1, ...)` constructs a CRC generator object H with properties as specified by the PROPERTY/VALUE pairs.

`h = crc.generator` constructs a CRC generator object H with default properties. It constructs a CRC-CCITT generator, and is equivalent to: h = crc.generator('Polynomial', '0x1021', 'InitialState', '0xFFFF', ...

'ReflectInput', false, 'ReflectRemainder', false, 'FinalXOR', '0x0000').

Properties

The following table describes the properties of a CRC generator object. All properties are writable, except `Polynomial`.

Property	Description
`Polynomial`	The generator polynomial that defines connections for a linear feedback shift register. This property can be specified as a binary vector representing descending powers of the polynomial. In this case, the leading '1' of the polynomial must be included. It can also be specified as a string, prefaced by '0x', that is a hexadecimal representation of the descending powers of the polynomial. In this case, the leading '1' of the polynomial is omitted.
`InitialState`	The initial contents of the shift register. This property can be specified as a binary scalar, a binary vector, or as a string, prefaced by '0x', that is a hexadecimal representation of the binary vector. As a binary vector, its length must be one less than the length of the binary vector representation of the Polynomial.
`ReflectInput`	A Boolean quantity that specifies whether the input data should be flipped on a bytewise basis prior to entering the shift register.
`ReflectRemainder`	A Boolean quantity that specifies whether the binary output CRC checksum should be flipped around its center after the input data is completely through the shift register.
`FinalXOR`	The value with which the CRC checksum is to be XORed just prior to being appended to the input data. This property can be specified as a binary scalar, a binary vector, or as a string, prefaced by '0x', that is a hexadecimal representation of the binary vector. As a binary vector, its length must be one less than the length of the binary vector representation of the Polynomial.

CRC Generation Algorithm

For information pertaining to the CRC generation algorithm, refer to the “CRC Non-Direct Algorithm” section of the Communications Toolbox User's Guide.

Generator Method

encoded = generate(h, msg) generates a CRC checksum for an input message using the CRC generator object H. It appends the checksum to the end of MSG. The binary-valued MSG can be either a column vector or a matrix. If it is a matrix, then each column is considered to be a separate channel.

Examples

Create a CRC-16 CRC generator, then use it to generate a checksum for the binary vector represented by the ASCII sequence '123456789'.

```
gen = crc.generator('Polynomial', '0x8005', ...
'ReflectInput', true, 'ReflectRemainder', true);
```

The message below is an ASCII representation of the digits 1-9.

```
msg = int2bit((49:57)',8);
encoded = generate(gen, msg);
```

```
h =

                Type: CRC Generator
          Polynomial: 0xF
        InitialState: 0xF
        ReflectInput: true
    ReflectRemainder: false
             FinalXOR: 0x0
```

Version History

Introduced in R2008a

`crc.generator` will be removed in a future release.
Warns starting in R2020b

crc.generator will be removed in a future release. To generate cyclic redundancy check (CRC) code, use the `comm.CRCGenerator` System object instead.

Replace instances of crc.generator with a `comm.CRCGenerator` System object. Note the mapping between crc.generator properties and `comm.CRCGenerator` properties:

crc.generator	comm.CRCGenerator

cyclgen

Produce parity-check and generator matrices for cyclic code

Syntax

```
h = cyclgen(n,pol)
h = cyclgen(n,pol,opt)
[h,g] = cyclgen(...)
[h,g,k] = cyclgen(...)
```

Description

For all syntaxes, the codeword length is `n` and the message length is `k`. A polynomial can generate a cyclic code with codeword length `n` and message length `k` if and only if the polynomial is a degree-(`n`-`k`) divisor of x^`n`-1. (Over the binary field GF(2), x^`n`-1 is the same as x^`n`+1.) This implies that `k` equals `n` minus the degree of the generator polynomial.

`h = cyclgen(n,pol)` produces an (`n`-`k`)-by-`n` parity-check matrix for a systematic binary cyclic code having codeword length `n`. The row vector `pol` gives the binary coefficients, in order of ascending powers, of the degree-(`n`-`k`) generator polynomial. Alternatively, you can specify `pol` as a polynomial character vector. For more information, see “Representation of Polynomials in Communications Toolbox”.

`h = cyclgen(n,pol,opt)` is the same as the syntax above, except that the argument *`opt`* determines whether the matrix should be associated with a systematic or nonsystematic code. The values for *`opt`* are `'system'` and `'nonsys'`.

`[h,g] = cyclgen(...)` is the same as `h = cyclgen(...)`, except that it also produces the `k`-by-`n` generator matrix `g` that corresponds to the parity-check matrix `h`.

`[h,g,k] = cyclgen(...)` is the same as `[h,g] = cyclgen(...)`, except that it also returns the message length `k`.

Examples

Parity Check and Generator Matrices for Binary Cyclic Codes

Create parity check and generator matrices for a binary cyclic code having codeword length 7 and message length 4.

Create the generator polynomial using `cyclpoly`.

```
pol = cyclpoly(7,4);
```

Create the parity check and generator matrices. The parity check matrix `parmat` has a 3-by-3 identity matrix embedded in its leftmost columns.

```
[parmat,genmat,k] = cyclgen(7,pol)
```

```
parmat = 3×7

     1     0     0     1     1     1     0
     0     1     0     0     1     1     1
     0     0     1     1     1     0     1

genmat = 4×7

     1     0     1     1     0     0     0
     1     1     1     0     1     0     0
     1     1     0     0     0     1     0
     0     1     1     0     0     0     1

k = 4
```

Create a parity check matrix in which the code is not systematic. The matrix `parmatn` does not have an embedded 3-by-3 identity matrix.

```
parmatn = cyclgen(7,pol,'nonsys')
```

```
parmatn = 3×7

     1     1     1     0     1     0     0
     0     1     1     1     0     1     0
     0     0     1     1     1     0     1
```

Create the parity check and generator matrices for a (7,3) binary cyclic code. As this is a systematic code, there is a 4-by-4 identity matrix in the leftmost columns of `parmat2`.

```
parmat2 = cyclgen(7,'1 + x^2 + x^3 + x^4')
```

```
parmat2 = 4×7

     1     0     0     0     1     1     0
     0     1     0     0     0     1     1
     0     0     1     0     1     1     1
     0     0     0     1     1     0     1
```

Topics

“Block Codes”

cyclpoly

Produce generator polynomials for cyclic code

Syntax

```
pol = cyclpoly(n,k)
pol = cyclpoly(n,k,opt)
```

Description

For all syntaxes, a polynomial is represented as a row containing the coefficients in order of ascending powers.

`pol = cyclpoly(n,k)` returns the row vector representing one nontrivial generator polynomial for a cyclic code having codeword length `n` and message length `k`.

`pol = cyclpoly(n,k,opt)` searches for one or more nontrivial generator polynomials for cyclic codes having codeword length `n` and message length `k`. The output `pol` depends on the argument `opt` as shown in the table below.

opt	Significance of pol	Format of pol
`'min'`	One generator polynomial having the smallest possible weight	Row vector representing the polynomial
`'max'`	One generator polynomial having the greatest possible weight	Row vector representing the polynomial
`'all'`	All generator polynomials	Matrix, each row of which represents one such polynomial
a positive integer, *L*	All generator polynomials having weight *L*	Matrix, each row of which represents one such polynomial

The weight of a binary polynomial is the number of nonzero terms it has. If no generator polynomial satisfies the given conditions, the output `pol` is empty and a warning message is displayed.

Examples

Cyclic Code Generator Polynomials

Create [15,4] cyclic code generator polynomials.

Use the input `'all'` to show all possible generator polynomials for a [15,4] cyclic code. Use the input `'max'` to show that $1 + x + x^2 + x^3 + x^5 + x^7 + x^8 + x^{11}$ is one such polynomial that has the largest number of nonzero terms.

```
c1 = cyclpoly(15,4,'all')
```

```
c1 = 3×12
```

```
     1     1     0     0     0     1     1     0     0     0     1     1
     1     0     0     1     1     0     1     0     1     1     1     1
     1     1     1     1     0     1     0     1     1     0     0     1
```

```
c2 = cyclpoly(15,4,'max')
```

```
c2 = 1×12

     1     1     1     1     0     1     0     1     1     0     0     1
```

This command shows that no generator polynomial for a [15,4] cyclic code has exactly three nonzero terms.

```
c3 = cyclpoly(15,4,3)
```

```
Warning: No cyclic generator polynomial satisfies the given constraints.

c3 =

     []
```

Algorithms

If *opt* is `'min'`, `'max'`, or omitted, polynomials are constructed by converting decimal integers to base `p`. Based on the decimal ordering, `gfprimfd` returns the first polynomial it finds that satisfies the appropriate conditions. This algorithm is similar to the one used in `gfprimfd`.

“Block Codes”

de2bi

(Not recommended) Convert Decimal to Base-P

Note is not recommended. Instead, use the `int2bit` function. For more information, see "Compatibility Considerations".

Syntax

```
b = de2bi(d)
b = de2bi(d,n)
b = de2bi(d,n,p)
b = de2bi(d,[],p)
b = de2bi(d,___,flg)
```

Description

`b = de2bi(d)` converts a nonnegative decimal integer `d` to a binary row vector. If `d` is a vector, the output `b` is a matrix in which each row is the binary form of the corresponding element in `d`.

`b = de2bi(d,n)` has an output with `n` columns.

`b = de2bi(d,n,p)` converts a nonnegative decimal integer `d` to a base-`p` row vector.

`b = de2bi(d,[],p)` specifies the base, `p` .

`b = de2bi(d,___,flg)` uses `flg` to determine whether the first column of `b` contains the lowest-order or highest-order digits.

Examples

Convert Decimal to Base-2

This example shows how to convert decimals to binary numbers in their base-2 equivalents.

```
d_array = [1 2 3 4];
```

Convert the decimal array to binary by using the `de2bi` function. Specify that the most significant digit is the leftmost element and set the number of desired columns to 5. The output becomes a 4-by-5 matrix where each row corresponds to a decimal value from the input. Because the largest decimal value in `d_array` can be expressed in 3 columns, the `de2bi` pads the matrix with two extra zero columns at the specified most-significant bit side. If you specify too few columns, the conversion will fail.

```
b_array = de2bi(d_array,5,'left-msb')
```

```
b_array = 4×5

     0     0     0     0     1
```

```
     0     0     0     1     0
     0     0     0     1     1
     0     0     1     0     0
```

```
b_array = de2bi(d_array,5,'right-msb')
```

```
b_array = 4×5

     1     0     0     0     0
     0     1     0     0     0
     1     1     0     0     0
     0     0     1     0     0
```

If you do not specify a number of columns, the number of columns is exactly what is needed to express the largest decimal of the input.

```
b_array = de2bi(d_array,'left-msb')
```

```
b_array = 4×3

     0     0     1
     0     1     0
     0     1     1
     1     0     0
```

The output rows for specifying a leftmost-significant bit correspond to:

$1 = 0(2^2) + 0(2^1) + 1(2^0)$

$2 = 0(2^2) + 1(2^1) + 0(2^0)$

$3 = 0(2^2) + 1(2^1) + 1(2^0)$

$4 = 1(2^2) + 0(2^1) + 0(2^0)$

```
b_array = de2bi(d_array,'right-msb')
```

```
b_array = 4×3

     1     0     0
     0     1     0
     1     1     0
     0     0     1
```

The output rows for specifying a rightmost-significant bit correspond to:

$1 = 1(2^0) + 0(2^1) + 0(2^2)$

$2 = 0(2^0) + 1(2^1) + 0(2^2)$

$3 = 1(2^0) + 1(2^1) + 0(2^2)$

$4 = 0(2^0) + 0(2^1) + 1(2^2)$

Input Arguments

d — Decimal input

nonnegative integer | vector | matrix

Decimal input, specified as a nonnegative integer, vector, or matrix. If `d` is a matrix, it is treated like the column vector `d(:)`.

Note To ensure an accurate conversion, `d` must be less than or equal to 2^{52}.

Data Types: `double` | `single` | `integer` | `fi`

n — Number of output columns

positive integer scalar

The number of output columns specified as a positive scalar. If necessary, the binary representation of `d` is padded with extra zeros.

Data Types: `double` | `single`

p — Base

2 (default) | positive integer scalar

Base of the output `b`, specified as an integer greater than or equal to 2.

- If `d` is a vector, the output `b` is a matrix in which each row is the base-`p` form of the corresponding element in `d`.
- If `d` is a matrix, `de2bi` treats it like the vector `d(:)`.

Data Types: `double` | `single`

flg — MSB flag

`'right-msb'` (default) | `'left-msb'`

MSB flag, specified as `'right-msb'` or `'left-msb'`.

- `'right-msb'` –– Indicates the right (or last) column of the binary output, `b`, as the most significant bit (or highest-order digit).
- `'left-msb'` –– Indicates the left (or first) column of the binary output, `b`, as the most significant bit (or highest-order digit).

Data Types: `char` | `string`

Output Arguments

b — Binary output

vector | matrix

Binary representation of `d`, returned as a row vector or matrix. The output is of the same data type as the input.

Version History

Introduced before R2006a

`de2bi` is not recommended. Use `int2bit` instead.

Not recommended starting in R2021b

Use `int2bit` instead of `de2bi`. If converting the representation of numbers from decimal to a base other than 2, use `dec2base`.

The code in this table shows decimal-to-binary conversion for various inputs using the recommended function.

decode

Block decoder

Syntax

```
msg = decode(code,n,k,'hamming/fmt',prim_poly)
msg = decode(code,n,k,'linear/fmt',genmat,trt)
msg = decode(code,n,k,'cyclic/fmt',genpoly,trt)
msg = decode(code,n,k)
[msg,err] = decode(...)
[msg,err,ccode] = decode(...)
[msg,err,ccode,cerr] = decode(...)
```

Optional Inputs

Input	Default Value
fmt	`binary`
`prim_poly`	`gfprimdf(m)` where `n = 2^m-1`
`genpoly`	`cyclpoly(n,k)`
`trt`	Uses `syndtable` to create the syndrome decoding table associated with the method's parity-check matrix

Description

For All Syntaxes

The `decode` function aims to recover messages that were encoded using an error-correction coding technique. The technique and the defining parameters must match those that were used to encode the original signal.

The `encode` reference page explains the meanings of `n` and `k`, the possible values of *`fmt`*, and the possible formats for `code` and `msg`. You should be familiar with the conventions described there before reading the rest of this section. Using the `decode` function with an input argument `code` that was *not* created by the `encode` function might cause errors.

For Specific Syntaxes

`msg = decode(code,n,k,'hamming/fmt',prim_poly)` decodes `code` using the Hamming method. For this syntax, `n` must have the form 2^m-1 for some integer m greater than or equal to 3, and `k` must equal n-m. `prim_poly` is a polynomial character vector or a row vector that gives the binary coefficients, in order of ascending powers, of the primitive polynomial for GF(2^m) that is used in the encoding process. The default value of `prim_poly` is `gfprimdf`(m). The decoding table that the function uses to correct a single error in each codeword is `syndtable`(`hammgen`(m)).

`msg = decode(code,n,k,'linear/fmt',genmat,trt)` decodes `code`, which is a linear block code determined by the `k`-by-`n` generator matrix `genmat`. `genmat` is required as input. `decode` tries to correct errors using the decoding table `trt`, where `trt` is a `2^(n-k)`-by-`n` matrix.

`msg = decode(code,n,k,'cyclic/fmt',genpoly,trt)` decodes the cyclic code `code` and tries to correct errors using the decoding table `trt`, where `trt` is a `2^(n-k)`-by-`n` matrix. `genpoly` is a polynomial character vector or a row vector that gives the coefficients, in order of ascending powers, of the binary generator polynomial of the code. The default value of `genpoly` is `cyclpoly(n,k)`. By definition, the generator polynomial for an [`n`, `k`] cyclic code must have degree `n-k` and must divide x^n-1.

`msg = decode(code,n,k)` is the same as `msg = decode(code,n,k,'hamming/binary')`.

`[msg,err] = decode(...)` returns a column vector `err` that gives information about error correction. If the code is a convolutional code, `err` contains the metric calculations used in the decoding decision process. For other types of codes, a nonnegative integer in the rth row of `err` indicates the number of errors corrected in the rth *message* word; a negative integer indicates that there are more errors in the rth word than can be corrected.

`[msg,err,ccode] = decode(...)` returns the corrected code in `ccode`.

`[msg,err,ccode,cerr] = decode(...)` returns a column vector `cerr` whose meaning depends on the format of `code`:

- If `code` is a binary vector, a nonnegative integer in the rth row of `vec2matcerr` indicates the number of errors corrected in the rth *codeword*; a negative integer indicates that there are more errors in the rth codeword than can be corrected.
- If `code` is not a binary vector, `cerr = err`.

Examples

Encode and Decode Message with Hamming Code

Set the values of the codeword length and message length.

```
n = 15; % Codeword length
k = 11; % Message length
```

Create a random binary message with length equal to the message length.

```
data = randi([0 1],k,1);
```

Encode the message.

```
encData = encode(data,n,k,'hamming/binary');
```

Corrupt the encoded message sequence by introducing an error in the fourth bit.

```
encData(4) = ~encData(4);
```

Decode the corrupted sequence. Observe that the decoder has correctly recovered the message.

```
decData = decode(encData,n,k,'hamming/binary');
numerr = biterr(data,decData)
```

```
numerr = 0
```

Algorithms

Depending on the decoding method, `decode` relies on such lower-level functions as `hammgen`, `syndtable`, and `cyclgen`.

Topics

“Block Codes”

deintrlv

Restore ordering of symbols

Syntax

```
deintrlved = deintrlv(data,elements)
```

Description

`deintrlved = deintrlv(data,elements)` restores the original ordering of the elements of `data` by acting as an inverse of `intrlv`.

Examples

Apply Interleaving to Reorder and Deinterleaving to Restore Vector Data Order

Use the `intrlv` function to rearrange the elements of a vector to a random permutation determined by the `randperm` function. Use the `deintrlv` function to restore the element order of the initial vector by reusing the same random permutation. This illustrates the inverse relationship between the `intrlv` and `deintrlv` functions.

Generate an input signal, `data`, and a permutation vector, `elements`.

```
data = 10:10:100
```

```
data = 1×10

    10    20    30    40    50    60    70    80    90   100
```

```
elements = randperm(10) % Permutation vector
```

```
elements = 1×10

     6     3     7     8     5     1     2     4     9    10
```

Permute the input signal according to the permutation vector by using the `intrlv` function and the restore the input signal order by using the `deintrlv` function.

```
a = intrlv(data,elements)
```

```
a = 1×10

    60    30    70    80    50    10    20    40    90   100
```

```
b = deintrlv(a,elements)
```

```
b = 1×10
```

```
    10    20    30    40    50    60    70    80    90   100
```

Apply Interleaving to Reorder and Deinterleaving to Restore Matrix Data Order

Use the `intrlv` function to rearrange the elements in the columns of a matrix to a random permutation vector determined by the `randperm` function. Use the de`intrlv` function to restore the element order of the initial matrix by reusing the same random permutation. This illustrates the inverse relationship between the `intrlv` and `deintrlv` functions.

Generate an input signal, `data`, and a permutation vector, `elements`.

```
data(:,1) = 10:10:100
```

```
data = 10×1

    10
    20
    30
    40
    50
    60
    70
    80
    90
   100
```

```
data(:,2) = 0.1:0.1:1
```

```
data = 10×2

```

Input Arguments

`data` — Input signal

vector | matrix

Input signal, specified as a vector or matrix. If `data` is a matrix with multiple rows and columns, the function processes the columns independently.

If `data` is a length-N vector or an N-row matrix, `elements` is a length-N vector that permutes the integers from 1 to N. To use this function as an inverse of the `intrlv` function, use the same `elements` input in both functions. In that case, the two functions are inverses in the sense that applying `intrlv` followed by `deintrlv` leaves data unchanged.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `fi`
Complex Number Support: Yes

`elements` — Permutation vector

integer vector

Permutation vector, specified as an integer vector. The permutation vector specifies the mapping used to restore the input signal. The permutation vector length must equal the input signal length and contain for each integer k in the range [1 `length`(x,1)]. If `data` is a length-N vector or an N-row matrix, `elements` must be a length-N vector and contain each integer in the range [1 `length`(x,1)]. The sequence in `elements` is the sequence in which elements from `data` or its columns appear in `deintrlved`.

Data Types: `double`

Output Arguments

`deintrlved` — Deinterleaved data

vector | matrix

Deinterleaved data, returned as a vector or matrix with the same dimension and datatype as the input signal, `data`. The output contains elements from the input signal mapped as `deintrlved`(`elements`(k),n) = `data`(k,n), for each integer *k* in the range [1 `length`(`data`,1)].

Version History

Introduced before R2006a

Topics

“Interleaving”

dftmtx

Discrete Fourier transform matrix in Galois field

Syntax

```
dm = dftmtx(alph)
```

Description

`dm = dftmtx(alph)` returns a Galois array that represents the discrete Fourier transform operation on a Galois vector, with respect to the Galois scalar `alph`. The element `alph` is a primitive nth root of unity in the Galois field GF(2^m) = GF(n+1); that is, n must be the smallest positive value of `k` for which `alph^k` equals 1. The discrete Fourier transform has size n and `dm` is an n-by-n array. The array `dm` represents the transform in the sense that `dm` times any length-n Galois column vector yields the transform of that vector.

Note The inverse discrete Fourier transform matrix is `dftmtx(1/alph)`.

Examples

The example below illustrates the discrete Fourier transform and its inverse, with respect to the element `gf(3,4)`. The example examines the first n powers of that element to make sure that only the nth power equals one. Afterward, the example transforms a random Galois vector, undoes the transform, and checks the result.

```
m = 4;
n = 2^m-1;
a = 3;
alph = gf(a,m);
mp = minpol(alph);
if (mp(1)==1 && isprimitive(mp)) % Check that alph has order n.
    disp('alph is a primitive nth root of unity.')
    dm = dftmtx(alph);
    idm = dftmtx(1/alph);
    x = gf(randi([0 2^m-1],n,1),m);
    y = dm*x; % Transform x.
    z = idm*y; % Recover x.
    ck = isequal(x,z)
end
```

The output is

```
alph is a primitive nth root of unity.

ck =

     1
```

Limitations

The Galois field over which this function works must have 256 or fewer elements. In other words, `alph` must be a primitive nth root of unity in the Galois field GF(2^m), where m is an integer between 1 and 8.

Algorithms

The element `dm(a,b)` equals `alph^((a-1)*(b-1))`.

distspec

Compute distance spectrum of convolutional code

Syntax

```
spect = distspec(trellis,numcomp)
```

Description

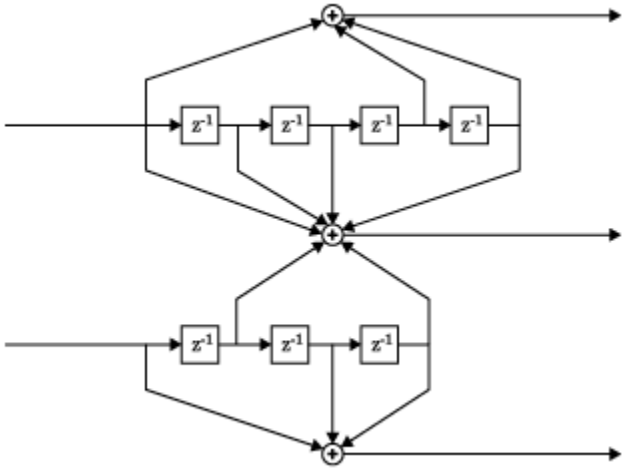
`spect = distspec(trellis,numcomp)` computes the free distance and the requested number of components of the weight and distance spectra of a linear convolutional code. Because convolutional codes do not have block boundaries, the weight spectrum and distance spectrum are semi-infinite and well approximated by the first few components.

Examples

Distance Spectrum for Rate 2/3 Convolutional Code

Use the `distspec` function to compute the distance spectrum for a rate 2/3 convolutional code. Use the output distance spectrum as an input to the `bercoding` function, to find a theoretical upper bound on the bit error rate for a system that uses this code with coherent BPSK modulation. Plot the upper bound using the `berfit` function.

The diagram shows a rate 2/3 encoder with two input streams, three output streams, and two shift registers.



Create a trellis structure to represent the encoder. Set the constraint length of the upper path to 5 and the constraint length of the lower path to 4. The octal representation of the code generator matrix corresponds to the taps from the upper and lower shift registers. The trellis structure serves as an input to the `distspec` function to represent the rate 2/3 convolutional code.

```
trellis = poly2trellis([5 4],[23 35 0; 0 5 13])
```

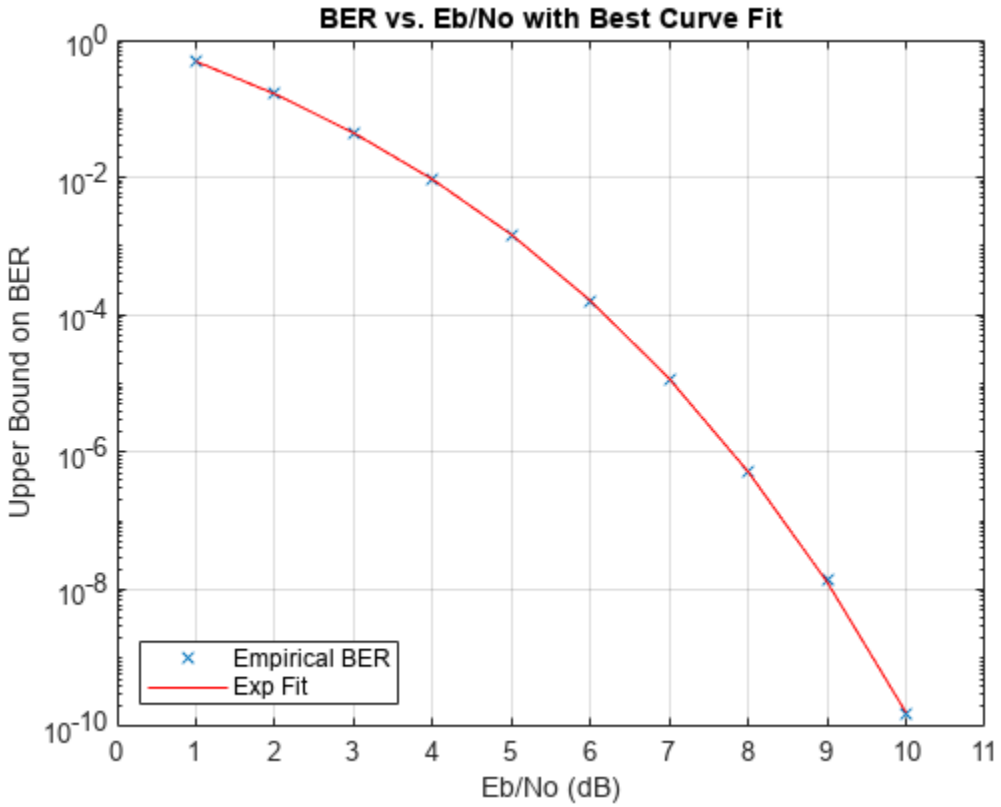
```
trellis = struct with fields:
     numInputSymbols: 4
    numOutputSymbols: 8
           numStates: 128
          nextStates: [128x4 double]
             outputs: [128x4 double]
```

```
spect = distspec(trellis,4)
```

```
spect = struct with fields:
     dfree: 5
    weight: [1 6 28 142]
     event: [1 2 8 25]
```

Use the `bercoding` function and the distance spectrum structure to find a theoretical upper bound on the bit error rate for a system that uses this code with coherent BPSK modulation. Plot the upper bound using the `berfit` function.

```
berub = bercoding(1:10,'conv','hard',2/3,spect);  % BER upper bound
berfit(1:10,berub); ylabel('Upper Bound on BER'); % Plot
```



Input Arguments

`trellis` — Trellis description

structure

Trellis description, specified as a MATLAB structure that contains the trellis description for a rate K/N code. K represents the number of input bit streams, and N represents the number of output bit streams.

The trellis structure contains these fields. You can either use the `poly2trellis` function to create the trellis structure or create it manually. For more about this structure, see "Trellis Description of a Convolutional Code" and the `istrellis` function.

`numInputSymbols` — Number of symbols input to encoder

2^K

Number of symbols input to the encoder, specified as an integer equal to 2^K, where K is the number of input bit streams.

Data Types: `double`

`numOutputSymbols` — Number of symbols output from encoder

2^N

Number of symbols output from the encoder, specified as an integer equal to 2^N, where N is the number of output bit streams.

Data Types: `double`

`numStates` — Number of states in encoder

power of 2

Number of states in the encoder, specified as a power of 2.

Data Types: `double`

`nextStates` — Next states

matrix of integers

Next states for all combinations of current states and current inputs, specified as a matrix of integers. The matrix size must be `numStates` by 2^K.

Data Types: `double`

`outputs` — Outputs

matrix of octal numbers

Outputs for all combinations of current states and current inputs, specified as a matrix of octal numbers. The matrix size must be `numStates` by 2^K.

Data Types: `double`

Data Types: `struct`

`numcomp` — Requested number of components

1 (default) | positive integer

Requested number of components of the weight and distance spectra of a linear convolutional code to compute, specified as a positive integer

Data Types: `double`

Output Arguments

`spect` — Distance spectrum

structure

Distance spectrum, returned as a structure containing these fields:

Field	Meaning
`spect.dfree`	Free distance of the code. This is the minimum number of errors in the encoded sequence required to create an error event.
`spect.weight`	A length-`n` vector that lists the total number of information bit errors in the error events enumerated in `spect.event`.
`spect.event`	A length-`n` vector that lists the number of error events for each distance between `spect.dfree` and `spect.dfree+n-1`. The vector represents the first `n` components of the distance spectrum.

Algorithms

The function uses a tree search algorithm implemented with a stack, as described in [2].

doppler

Construct Doppler spectrum structure

Syntax

```
s = doppler(specType)
s = doppler(specType, fieldValue)
s = doppler('BiGaussian', Name,Value)
```

Description

`s = doppler(specType)` constructs a Doppler spectrum structure of type `specType` for use with a fading channel System object. The returned structure, `s`, has default values for its dependent fields.

`s = doppler(specType, fieldValue)` constructs a Doppler spectrum structure of type `specType` for use with a fading channel System object. The returned structure, `s`, has its dependent field specified to `fieldValue`.

`s = doppler('BiGaussian', Name,Value)` constructs a BiGaussian Doppler spectrum structure for use with a fading channel System object. The returned structure, `s`, has dependent fields specified by `Name,Value` pair arguments.

Examples

Construct a Flat Doppler Spectrum Structure

Construct a flat Doppler structure variable for use with channel objects such as `comm.RayleighChannel`.

Invoke the `doppler` function to create a flat Doppler structure variable.

```
s = doppler('Flat')
```

```
s = struct with fields:
    SpectrumType: 'Flat'
```

Create a Bell Doppler Structure Variable

Use the `doppler` function to create a Doppler structure variable having the Bell spectrum.

```
s = doppler('Bell')
```

```
s = struct with fields:
    SpectrumType: 'Bell'
     Coefficient: 9
```

Construct a Rounded Doppler Spectrum Structure with Specified Polynomial

Specify the coefficients of the Doppler spectrum structure variable.

Construct a Rounded Doppler spectrum structure with coefficients `a0`, `a2`, and `a4` set to `2`, `6`, and `1`, respectively.

```
s = doppler('Rounded', [2, 6, 1])
```

```
s = struct with fields:
    SpectrumType: 'Rounded'
      Polynomial: [2 6 1]
```

Construct a BiGaussian Doppler Spectrum Structure with Specified Field Values

Use the `doppler` function to create a Doppler spectrum structure with the parameters specified for a BiGaussian spectrum.

```
s = doppler('BiGaussian','NormalizedCenterFrequencies', ...
    [.1 .85],'PowerGains',[1 2])
```

```
s = struct with fields:
                    SpectrumType: 'BiGaussian'
    NormalizedStandardDeviations: [0.7071 0.7071]
     NormalizedCenterFrequencies: [0.1000 0.8500]
                     PowerGains: [1 2]
```

The `NormalizedStandardDeviations` field is set to the default value. The `NormalizedCenterFrequencies`, and `PowerGains` fields are set to the values specified from the input arguments.

Input Arguments

specType — Spectrum type of Doppler spectrum structure for use with fading channel System object

`'Jakes'` | `'Flat'` | `'Rounded'` | `'Bell'` | `'Asymmetric Jakes'` | `'Restricted Jakes'` | `'Gaussian'` | `'BiGaussian'`

The spectrum type of a Doppler spectrum structure for use with a fading channel System object. Specify this value as a character vector.

The analytical expression for each Doppler spectrum type is described in the “Algorithms” on page 2-265 section.

Data Types: `char`

fieldValue — Value of dependent field of Doppler spectrum structure

scalar | vector

The value of the dependent field of the Doppler spectrum structure, specified as a scalar or vector of built-in data type. If you do not specify `fieldValue` , the dependent fields of the spectrum type use the default values.

Spectrum Type	Dependent Field	Description	Default Value
“Jakes” on page 2-265	—	—	—
“Flat” on page 2-265	—	—	—
“Rounded” on page 2-265	`Polynomial`	1-by-3 vector of real finite values, representing the polynomial coefficients, `a0, a2` and `a4`	`[1 -1.72 0.785]`
“Bell” on page 2-265	`Coefficient`	Nonnegative, finite, real scalar representing the Bell spectrum coefficient	`9`
“Asymmetric Jakes” on page 2-265	`NormalizedFrequencyInterval`	1-by-2 vector of real values between –1 and 1, inclusive, representing the minimum and maximum normalized Doppler shifts	`[0 1]`
“Restricted Jakes” on page 2-266	`NormalizedFrequencyInterval`	1-by-2 vector of real values between 0 and 1, inclusive, representing the minimum and maximum normalized Doppler shifts	`[0 1]`
“Gaussian” on page 2-266	`NormalizedStandardDeviation`	Normalized standard deviation of the Gaussian Doppler spectrum, specified as a positive, finite, real scalar	`0.7071`
“BiGaussian” on page 2-266	`NormalizedStandardDeviations`	Normalized standard deviations of the BiGaussian Doppler spectrum, specified as a positive, finite, real 1-by-2 vector	`[0.7071 0.7071]`
	`NormalizedCenterFreqencies`	Normalized center frequencies of the BiGaussian Doppler spectrum specified as a real 1-by-2 vector whose elements fall between –1 and 1	`[0 0]`

Spectrum Type	Dependent Field	Description	Default Value
	`PowerGains`	Linear power gains of the BiGaussian Doppler spectrum specified as a real nonnegative 1-by-2 vector	`[0.5 0.5]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `s=doppler('BiGaussian', 'NormalizedStandardDeviations', [.8 .75], 'NormalizedCenterFrequencies', [-.8 0], 'PowerGains', [.6 .6])`

`NormalizedStandardDeviations` — Normalized standard deviations of first and second Gaussian functions

`[1/sqrt(2) 1/sqrt(2)]` (default) | 1-by-2 positive numeric vector

The normalized standard deviation of the first and second Gaussian functions. You can specify this value as a 1-by-2 positive numeric vector, of built-in data types.

When you do not specify this dependent field, the default value is `[1/sqrt(2) 1/sqrt(2)]`.

Data Types: `double`

`NormalizedCenterFrequencies` — Normalized center frequencies of first and second Gaussian functions

`[0 0]` (default) | 1-by-2 numeric vector

The normalized center frequencies of the first and second Gaussian functions. You can specify this value as a 1-by-2 numeric vector of real values between –1 and 1, of built-in data types.

When you do not specify this dependent field, the default value is `[0 0]`.

Data Types: `double`

`PowerGains` — Power gains of first and second Gaussian functions

`[0.5 0.5]` (default) | 1-by-2 numeric vector

The power gains of the first and second Gaussian functions. You can specify this value as a 1-by-2 nonnegative numeric vector of built-in data types.

When you do not specify this dependent field, the default value is `[0.5 0.5]`.

Data Types: `double`

Algorithms

The following algorithms represent the analytical expressions for each Doppler spectrum type. In each case, f_d denotes the maximum Doppler shift (`MaximumDopplerShift` property) of the associated fading channel System object.

Jakes

The theoretical `Jakes` Doppler spectrum, *S(f)* has the analytic formula

$$S(f) = \frac{1}{\pi f_d \sqrt{1 - (f/f_d)^2}}, \ |f| \le f_d$$

Flat

The theoretical `Flat` Doppler spectrum, *S(f)* has the analytic formula

$$S(f) = \frac{1}{2f_d}, |f| \le f_d$$

Rounded

The theoretical `Rounded` Doppler spectrum, *S(f)* has the analytic formula

$$S(f) = C_r\left[a_0 + a_2\left(\frac{f}{f_d}\right)^2 + a_4\left(\frac{f}{f_d}\right)^4\right], |f| \le f_d$$

where

$$C_r = \frac{1}{2f_d\left[a_0 + \frac{a_2}{3} + \frac{a_4}{5}\right]}$$

and you can specify $[a_0, \ a_2, \ a_4]$ in the dependent field, `polynomial`.

Bell

The theoretical `Bell` Doppler spectrum, *S(f)* has the analytic formula

$$S(f) = \frac{C_b}{1 + A\left(\frac{f}{f_d}\right)^2}$$

$$|f| \le f_d$$

where

$$C_b = \frac{\sqrt{A}}{\pi f_d}$$

You can specify A in the dependent field, `coefficient`.

Asymmetric Jakes

The theoretical `Asymmetric Jakes` Doppler spectrum, *S(f)* has the analytic formula

$$S(f) = \frac{A_a}{\pi f_d \sqrt{1-(f/f_d)^2}}, \quad -f_d \le f_{\min} \le f \le f_{\max} \le f_d$$

$$A_a = \frac{1}{\frac{1}{\pi}\left[\sin^{-1}\left(\frac{f_{\max}}{f_d}\right) - \sin^{-1}\left(\frac{f_{\min}}{f_d}\right)\right]}$$

where you can specify $f_{\min}/f_d$ and $f_{\max}/f_d$ in the dependent field, `NormalizedFrequencyInterval`.

Restricted Jakes

The theoretical `Restricted Jakes` Doppler spectrum, *S(f)* has the analytic formula

$$S(f) = \frac{A_r}{\pi f_d \sqrt{1-(f/f_d)^2}}, \ 0 \le f_{\min} \le |f| \le f_{\max} \le f_d$$

where

$$A_r = \frac{1}{\frac{2}{\pi}\left[\sin^{-1}\left(\frac{f_{\max}}{f_d}\right) - \sin^{-1}\left(\frac{f_{\min}}{f_d}\right)\right]}$$

where you can specify $f_{\min}/f_d$ and $f_{\max}/f_d$ in the dependent field, `NormalizedFrequencyInterval`.

Gaussian

The theoretical `Gaussian` Doppler spectrum, *S(f)* has the analytic formula

$$S_G(f) = \frac{1}{\sqrt{2\pi\sigma_G^2}} \exp\left(-\frac{f^2}{2\sigma_G^2}\right)$$

You can specify σ_G/f_d in the dependent field, `NormalizedStandardDeviation`.

BiGaussian

The theoretical `BiGaussian` Doppler spectrum, *S(f)* has the analytic formula

$$S_G(f) = A_G\left[\frac{C_{G1}}{\sqrt{2\pi\sigma_{G1}^2}} \exp\left(-\frac{(f-f_{G1})^2}{2\sigma_{G1}^2}\right) + \frac{C_{G2}}{\sqrt{2\pi\sigma_{G2}^2}} \exp\left(-\frac{(f-f_{G2})^2}{2\sigma_{G2}^2}\right)\right]$$

where $A_G = \frac{1}{C_{G1} + C_{G2}}$ is a normalization coefficient.

You can specify σ_{G1}/f_d and σ_{G2}/f_d in the `NormalizedStandardDeviations` dependent field.

You can specify f_{G1}/f_d and f_{G2}/f_d in the `NormalizedCenterFrequencies` dependent field.

C_{G1} and C_{G2} are power gains that you can specify in the `PowerGains` dependent field.

dpcmdeco

Decode using differential pulse code modulation

Syntax

```
sig = dpcmdeco(indx,codebook,predictor)
[sig,quanterror] = dpcmdeco(indx,codebook,predictor)
```

Description

`sig = dpcmdeco(indx,codebook,predictor)` implements differential pulse code demodulation to decode the vector `indx`. The vector `codebook` represents the predictive-error quantization codebook. The vector `predictor` specifies the predictive transfer function. If the transfer function has predictive order M, `predictor` has length M+1 and an initial entry of 0. To decode correctly, use the same codebook and predictor in `dpcmenco` and `dpcmdeco`.

See “Represent Partitions”, “Represent Codebooks”, or the `quantiz` reference page, for a description of the formats of `partition` and `codebook`.

`[sig,quanterror] = dpcmdeco(indx,codebook,predictor)` is the same as the syntax above, except that the vector `quanterror` is the quantization of the predictive error based on the quantization parameters. `quanterror` is the same size as `sig`.

Note You can estimate the input parameters `codebook`, `partition`, and `predictor` using the function `dpcmopt`.

Examples

See “Example: DPCM Encoding and Decoding” and “Example: Comparing Optimized and Nonoptimized DPCM Parameters” for examples that use `dpcmdeco`.

Version History

Introduced before R2006a

Topics

“Differential Pulse Code Modulation”

dpcmenco

Encode using differential pulse code modulation

Syntax

```
indx = dpcmenco(sig,codebook,partition,predictor)
[indx,quants] = dpcmenco(sig,codebook,partition,predictor)
```

Description

`indx = dpcmenco(sig,codebook,partition,predictor)` implements differential pulse code modulation to encode the vector `sig`. `partition` is a vector whose entries give the endpoints of the partition intervals. `codebook`, a vector whose length exceeds the length of `partition` by one, prescribes a value for each partition in the quantization. `predictor` specifies the predictive transfer function. If the transfer function has predictive order M, `predictor` has length M+1 and an initial entry of 0. The output vector `indx` is the quantization index.

See “Differential Pulse Code Modulation” for more about the format of `predictor`. See “Represent Partitions”, “Represent Partitions”, or the reference page for `quantiz` in this chapter, for a description of the formats of `partition` and `codebook`.

`[indx,quants] = dpcmenco(sig,codebook,partition,predictor)` is the same as the syntax above, except that `quants` contains the quantization of `sig` based on the quantization parameters. `quants` is a vector of the same size as `sig`.

Note If `predictor` is an order-one transfer function, the modulation is called a *delta modulation*.

Examples

See “Example: DPCM Encoding and Decoding” and “Example: Comparing Optimized and Nonoptimized DPCM Parameters” for examples that use `dpcmenco`.

Version History

Introduced before R2006a

References

`quantiz` | `dpcmopt` | `dpcmdeco`

Topics

“Differential Pulse Code Modulation”

dpcmopt

Optimize differential pulse code modulation parameters

Syntax

```
predictor = dpcmopt(training_set,ord)
[predictor,codebook,partition] = dpcmopt(training_set,ord,len)
[predictor,codebook,partition] = dpcmopt(training_set,ord,ini_cb)
```

Description

`predictor = dpcmopt(training_set,ord)` returns a vector representing a predictive transfer function of order `ord` that is appropriate for the training data in the vector `training_set`. `predictor` is a row vector of length `ord`+1. See “Represent Predictors” for more about its format.

Note `dpcmopt` optimizes for the data in `training_set`. For best results, `training_set` should be similar to the data that you plan to quantize.

`[predictor,codebook,partition] = dpcmopt(training_set,ord,len)` is the same as the syntax above, except that it also returns corresponding optimized codebook and partition vectors `codebook` and `partition`. `len` is an integer that prescribes the length of `codebook`. `partition` is a vector of length `len`-1. See “Represent Partitions”, “Represent Codebooks”, or the reference page for `quantiz` in this chapter, for a description of the formats of `partition` and `codebook`.

`[predictor,codebook,partition] = dpcmopt(training_set,ord,ini_cb)` is the same as the first syntax, except that it also returns corresponding optimized codebook and partition vectors `codebook` and `partition`. `ini_cb`, a vector of length at least 2, is the initial guess of the codebook values. The output `codebook` is a vector of the same length as `ini_cb`. The output `partition` is a vector whose length is one less than the length of `codebook`.

Examples

See “Example: Comparing Optimized and Nonoptimized DPCM Parameters” for an example that uses `dpcmopt`.

“Differential Pulse Code Modulation”

dpskdemod

Differential phase shift keying demodulation

Syntax

```
z = dpskdemod(y,M)
z = dpskdemod(y,M,phaserot)
z = dpskdemod(y,M,phaserot,symorder)
```

Description

`z = dpskdemod(y,M)` demodulates the complex envelope, `y`, of a DPSK-modulated signal having modulation order `M`.

`z = dpskdemod(y,M,phaserot)` specifies the phase rotation of the DPSK modulation.

`z = dpskdemod(y,M,phaserot,symorder)` also specifies the symbol order.

Examples

DPSK Demodulation

Demodulate DPSK data in a communication channel in which a phase shift is introduced.

Generate a 4-ary data vector and modulate it using DPSK.

```
M = 4;                          % Alphabet size
dataIn = randi([0 M-1],1000,1); % Random message
txSig = dpskmod(dataIn,M);      % Modulate
```

Apply the random phase shift resulting from the transmission process.

```
rxSig = txSig*exp(2i*pi*rand());
```

Demodulate the received signal.

```
dataOut = dpskdemod(rxSig,M);
```

The modulator and demodulator have the same initial condition. However, only the received signal experiences a phase shift. As a result, the first demodulated symbol is likely to be in error. Therefore, you should always discard the first symbol when using DPSK.

Find the number of symbol errors.

```
errs = symerr(dataIn,dataOut)
```

```
errs = 1
```

One symbol is in error. Repeat the error calculation after discarding the first symbol.

```
errs = symerr(dataIn(2:end),dataIn(2:end))
```

```
errs = 0
```

Input Arguments

y — DPSK-modulated input signal

vector | matrix

DPSK-modulated input signal, specified as a real or complex vector or matrix. If `y` is a matrix, the function processes the columns independently.

Data Types: `double`
Complex Number Support: Yes

M — Modulation order

integer power of two

Modulation order, specified as an integer power of two.

Example: 2 | 4 | 16

Data Types: `double`

phaserot — Phase rotation

0 (default) | scalar | `[]`

Phase rotation of the DPSK modulation, specified in radians as a real scalar. The total phase shift per symbol is the sum of `phaserot` and the phase generated by the differential modulation.

If you specify `phaserot` as empty, then `dspkdemod` uses a phase rotation of 0 degrees.

Example: `pi/4`

Data Types: `double`

symorder — Symbol order

`'bin'` (default) | `'gray'`

Symbol order, specified as `'bin'` or `'gray'`. This argument specifies how the function assigns binary vectors to corresponding integers.

- If `symorder` is `'bin'`, the function uses a natural binary-coded ordering.
- If `symorder` is `'gray'`, the function uses a Gray-coded ordering.

Data Types: `char`

Output Arguments

z — DPSK-demodulated output signal

vector | matrix

DPSK-demodulated output signal, returned as a vector or matrix having the same number of columns as input signal `y`.

Note The differential algorithm used in this function compares two successive elements of a modulated signal. To determine the first element of vector `z`, or the first row of matrix `z`, the function uses an initial phase rotation of `0`.

Version History

Topics

“Phase Modulation”

dpskmod

Differential phase shift keying modulation

Syntax

```
y = dpskmod(x,M)
y = dpskmod(x,M,phaserot)
y = dpskmod(x,M,phaserot,symorder)
```

Description

`y = dpskmod(x,M)` modulates the input signal using differential phase shift keying (DPSK) with modulation order `M`.

`y = dpskmod(x,M,phaserot)` specifies the phase rotation of the DPSK modulation.

`y = dpskmod(x,M,phaserot,symorder)` also specifies the symbol order.

Examples

View Signal Trajectory of DPSK-Modulated Signal

Plot the output of the `dspkmod` function to view the possible transitions between DPSK symbols.

Set the modulation order to 4 to model DQPSK modulation.

```
M = 4;
```

Generate a sequence of 4-ary random symbols.

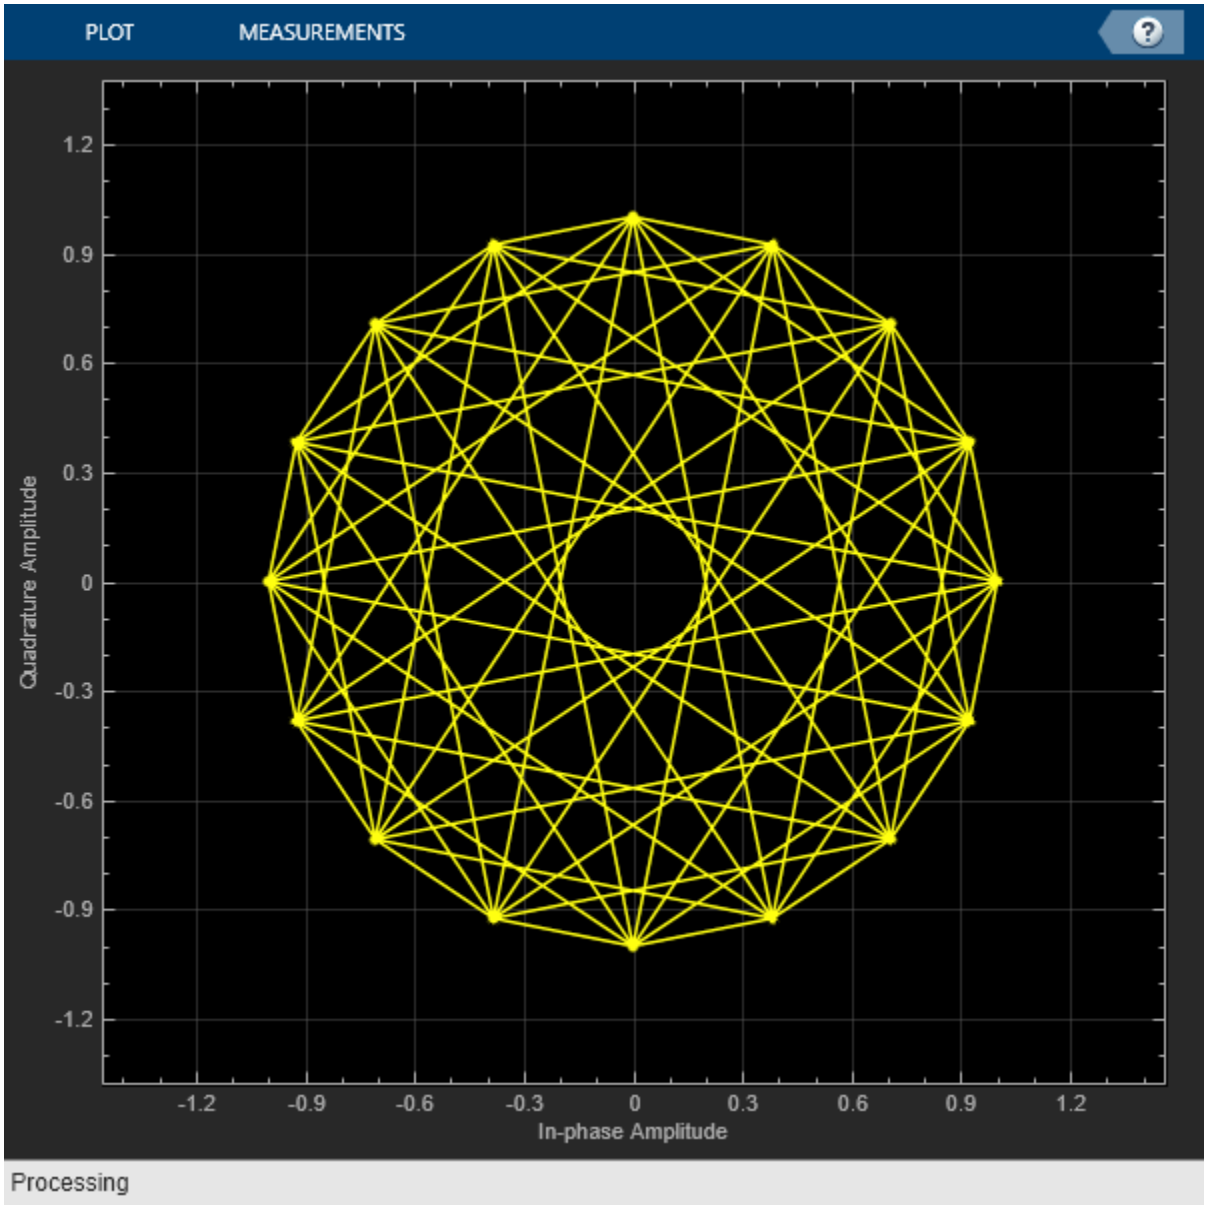
```
x = randi([0 M-1],500,1);
```

Apply DQPSK modulation to the input symbols.

```
y = dpskmod(x,M,pi/8);
```

Specify a constellation diagram object to display a signal trajectory diagram and without displaying the corresponding reference constellation. Display the trajectory.

```
cd = comm.ConstellationDiagram('ShowTrajectory',true,'ShowReferenceConstellation',false);
cd(y)
```



Input Arguments

x — Input signal

vector | matrix

Input signal, specified as a vector or matrix of positive integers. The elements of `x` must have values in the range of [0, `M` – 1].

Data Types: `double`

M — Modulation order

integer power of two

Modulation order, specified as an integer power of two.

Example: 2 | 4 | 16

Data Types: double

phaserot — Phase rotation
0 (default) | scalar | [ ]

Phase rotation of the DPSK modulation, specified in radians as a real scalar. The total phase shift per symbol is the sum of phaserot and the phase generated by the differential modulation.

If you specify phaserot as empty, then dpskmod uses a phase rotation of 0 degrees.

Example: pi/4

Data Types: double

symorder — Symbol order
'bin' (default) | 'gray'

Symbol order, specified as 'bin' or 'gray'. This argument specifies how the function assigns binary vectors to corresponding integers.

- If symorder is 'bin', the function uses a natural binary-coded ordering.
- If symorder is 'gray', the function uses a Gray-coded ordering.

Data Types: char

Output Arguments

y — DPSK-modulated output signal
vector | matrix

Complex baseband representation of a DPSK-modulated output signal, returned as vector or matrix of complex values. The columns represent independent channels.

Note An initial phase rotation of 0 is used in determining the first element of the output y (or the first row of y if it is a matrix with multiple rows), because two successive elements are required for a differential algorithm.

dvbs2ldpc

Low-density parity-check (LDPC) codes from DVB-S.2 standard

Syntax

```
H = dvbs2ldpc(r)
H = dvbs2ldpc(r,outputFormat)
```

Description

`H = dvbs2ldpc(r)` returns the parity-check matrix `H` of the LDPC code with code rate `r` from the Digital Video Broadcasting standard DVB-S.2. The block length of the code is 64,800.

`H = dvbs2ldpc(r,outputFormat)` specifies the format for the output parity-check matrix.

Examples

Create LDPC Code Parity-Check Matrix from DVB-S.2 Standard

Create an LDPC parity check matrix for a code rate of 3/5 from the DVB-S.2 standard.

```
p = dvbs2ldpc(3/5);
```

Create an LDPC encoder configuration object from the parity-check matrix `p`. The parity-check matrix has dimensions of (*N*-*K*)-by-*N*. In the configuration object, the `BlockLength` property is *N*, and the `NumInformationBits` property is *K*. Show the properties of the object. Encode a message with one column of information bits.

```
cfg = ldpcEncoderConfig(p)
```

```
cfg =
  ldpcEncoderConfig with properties:

     ParityCheckMatrix: [25920x64800 logical]

   Read-only properties:
           BlockLength: 64800
    NumInformationBits: 38880
    NumParityCheckBits: 25920
              CodeRate: 0.6000
```

```
infobits = randi([0 1],cfg.NumInformationBits,1);
enc = ldpcEncode(infobits,cfg);
```

Input Arguments

`r` — Code rate

`1/4` | `1/3` | `2/5` | `1/2` | ...

Code rate, specified as `1/4`, `1/3`, `2/5`, `1/2`, `3/5`, `2/3`, `3/4`, `4/5`, `5/6`, `8/9`, or `9/10`.

Data Types: `double`

`outputFormat` — Output format
`'sparse'` | `'indices'`

Output format for parity-check matrix `H`, specified as `'sparse'` or `'indices'`.

If you set this value to `'sparse'`, `H` is a sparse logical matrix. If you set this value to `'indices'`, `H` is a two-column matrix that defines the row and column indices of the 1s in `H`.

Data Types: `char` | `string`

Output Arguments

`H` — Parity-check matrix
matrix

Parity-check matrix, returned as a matrix.

The default parity-check matrix of size 32,400-by-64,800 corresponds to an irregular LDPC code with the structure shown in this table.

Row	Number of 1s per Row
1	6
2 to 32400	7

Column	Number of 1s per Column
1 to 12960	8
12961–32400	3

Columns from 32,401 to 64,800 form a lower triangular matrix. Only the elements on the main diagonal of the matrix and the subdiagonal immediately below the main diagonal are 1s. This LDPC code is used in conjunction with a BCH code in the DVB-S.2 standard to achieve a packet error rate below 10^{-7} at about 0.7 dB to 1 dB from the Shannon limit.

Version History

Introduced in R2007a

dvbsapskdemod

DVB-S2/S2X/SH standard-specific amplitude phase shift keying (APSK) demodulation

Syntax

```
z = dvbsapskdemod(y,M,stdSuffix)
z = dvbsapskdemod(y,M,stdSuffix,codeIDF)
z = dvbsapskdemod(y,M,stdSuffix,codeIDF,frameLength)
z = dvbsapskdemod( ___ ,Name,Value)
```

Description

`z = dvbsapskdemod(y,M,stdSuffix)` demodulates an APSK input signal, `y`, that was modulated in accordance with the digital video broadcast (DVB) standard identified by `stdSuffix` and the modulation order, `M`. For a description of DVB-compliant APSK demodulation, see “DVB Compliant APSK Hard Demodulation” on page 2-287 and “DVB Compliant APSK Soft Demodulation” on page 2-287.

`z = dvbsapskdemod(y,M,stdSuffix,codeIDF)` specifies code identifier `codeIDF`, to use when selecting the demodulation parameters.

`z = dvbsapskdemod(y,M,stdSuffix,codeIDF,frameLength)` specifies `codeIDF` and `frameLength` to use when selecting the demodulation parameters.

`z = dvbsapskdemod( ___ ,Name,Value)` specifies options using one or more name-value pair arguments using any of the previous syntaxes. For example, `'OutputDataType','double'` specifies the desired output data type. Specify name-value pair arguments after all other input arguments.

Examples

Demodulate DVB-S2X Specific 64-APSK Signal

Demodulate a 64-APSK signal that was modulated as specified in DVB-S2X. Compute hard decision integer output and verify that the output matches the input.

Set the modulation order and standard suffix. Generate random data.

```
M = 64;
std = 's2x';
x = randi([0 M-1],1000,1);
```

Modulate the data.

```
y = dvbsapskmod(x,M,std);
```

Demodulate the received signal. Compare the demodulated data to the original data.

```
z = dvbsapskdemod(y,M,std);
isequal(z,x)
```

```
ans = logical
   1
```

Demodulate DVB-S2 Specific 32-APSK Signal

Demodulate a 32-APSK signal that was modulated as specified in DVB-S2. Compute hard decision bit output and verify that the output matches the input.

Set the modulation order, standard suffix, and code identifier. Generate random bit data.

```
M = 32;
std = 's2';
codeIDF = '4/5';
numBitsPerSym = log2(M);
x = randi([0 1],100*numBitsPerSym,1,'uint32');
```

Modulate the data. Use a name-value pair to specify bit input data.

```
y = dvbsapskmod(x,M,std,codeIDF,'InputType','bit');
```

Demodulate the received signal. Compare the demodulated data to the original data.

```
z = dvbsapskdemod(y,M,std,'4/5','OutputType','bit', ...
    'OutputDataType','uint32');
isequal(z,x)
```

```
ans = logical
   1
```

Soft Bit Demodulate DVB-SH Specific 16-APSK Signal

Demodulate a DVB-SH compliant 16-APSK signal and calculate soft bits.

Set the modulation order and generate a random bit sequence.

```
M = 16;
std = 'sh';
numSym = 20000;
numBitsPerSym = log2(M);
x = randi([0 1],numSym*numBitsPerSym,1);
```

Modulate the data. Use a name-value pair to specify bit input data.

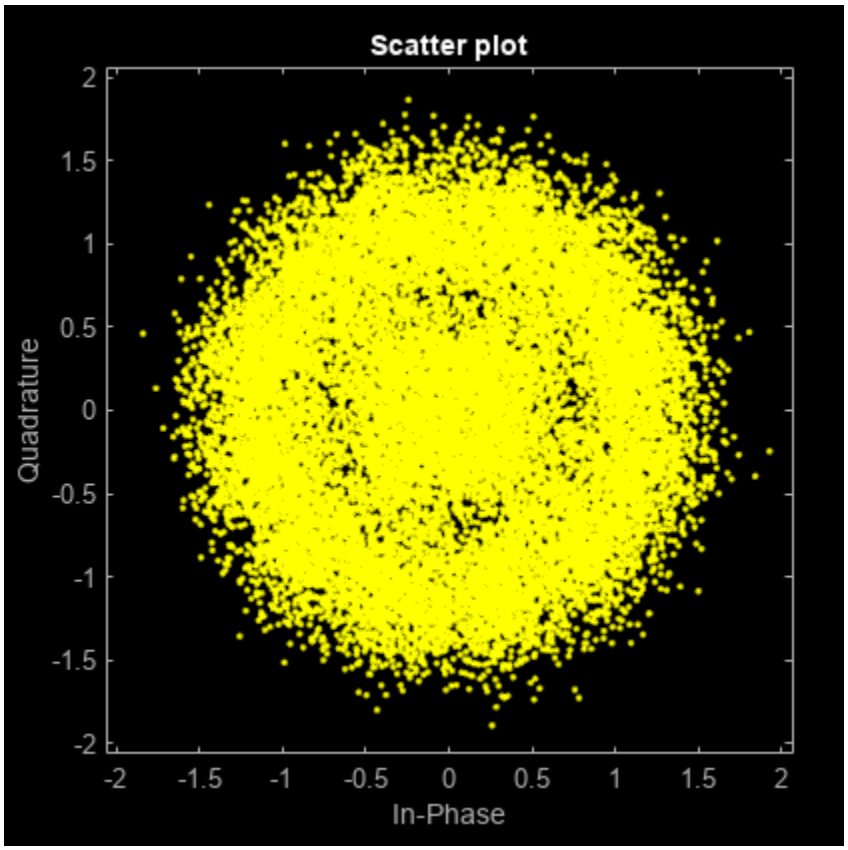
```
txSig = dvbsapskmod(x,M,std,'InputType','bit');
```

Pass the modulated signal through a noisy channel.

```
rxSig = awgn(txSig,10,'measured');
```

View the constellation of the received signal using a scatter plot.

```
scatterplot(rxSig)
```



DVB-SH compliant constellations have unit average power. Demodulate the signal, computing soft bits using the approximate LLR algorithm.

```
z = dvbsapskdemod(rxSig,M,std,'OutputType','approxllr', ...
     'NoiseVariance',0.1);
```

Input Arguments

y — APSK modulated signal

scalar | vector | matrix

APSK modulated signal, specified as a complex scalar, vector, or matrix. When `y` is a matrix, each column is treated as an independent channel.

`y` must be modulated in accordance with Digital Video Broadcasting (DVB) - Satellite Communications standard DVB-S2, DVB-S2X or DVB-SH. For more information, see [1], [2], and [3].

Data Types: `single` | `double`
Complex Number Support: Yes

M — Modulation order

integer

Modulation order, specified as a power of two. The modulation order specifies the total number of points in the signal constellation.

Data Types: `double`

`stdSuffix` — Standard suffix

`'s2'` | `'s2x'` | `'s2h'`

Standard suffix for DVBS modulation variant, specified as `'s2'`, `'s2x'`, or `'s2h'`.

Data Types: `char` | `string`

`codeIDF` — Code identifier

char | string

Code identifier, specified as a character vector or string. This table lists the acceptable `codeIDF` values.

Constellation Order (`M`)	Applicable Standard (`stdSuffix`)	Acceptable Code Identifier (`CodeIDF`) Values
16	`'s2'` or `'s2x'`	`'2/3'`, `'3/4'`, `'4/5'`, `'5/6'`, `'8/9'`, `'9/10'`
16	`'s2x'`	`'26/45'`, `'3/5'`, `'28/45'`, `'23/36'`, `'25/36'`, `'13/18'`, `'7/9'`, `'77/90'`, `'100/180'`, `'96/180'`, `'90/180'`, `'18/30'`, `'20/30'`
32	`'s2'` or `'s2x'`	`'3/4'`, `'4/5'`, `'5/6'`, `'8/9'`, `'9/10'`
32	`'s2x'`	`'32/45'`, `'11/15'`, `'7/9'`, `'2/3'`
64	`'s2x'`	`'11/15'`, `'7/9'`, `'4/5'`, `'5/6'`, `'128/180'`
128	`'s2x'`	`'3/4'`, `'7/9'`
256	`'s2x'`	`'32/45'`, `'3/4'`, `'116/180'`, `'20/30'`, `'124/180'`, `'22/30'`

For more information, refer to Tables 9 and 10 in the DVB-S2 standard [1] and Table 17a in the DVB-S2X standard [2].

Dependencies

This input argument applies only when `stdSuffix` is set to `'s2'` or `'s2x'`.

Data Types: `char` | `string`

`frameLength` — Frame length

`'normal'` (default) | `'short'`

Frame length, specified as `'normal'` or `'short'`. The function uses`frameLength` and `codeIDF` to select the modulation parameters.

Dependencies

This input argument applies only when `stdSuffix` is set to `'s2'` or `'s2x'`.

Data Types: `char` | `string`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `y = dvbsapskdemod(x,M,stdSuffix,'InputType','bit','OutputDataType','single');`

`OutputType` — Output type

`'integer'` (default) | `'bit'` | `'llr'` | `'approxllr'`

Output type, specified as the comma-separated pair consisting of `OutputType` and `'integer'`, `'bit'`, `'llr'`, or `'approxllr'`. For a description of returned output, see `z`.

Data Types: `char` | `string`

`OutputDataType` — Output data type

`'double'` (default) | `...`

Output data type, specified as the comma-separated pair consisting of `OutputDataType` and one of the indicated data types. Acceptable values for `OutputDataType` depend on the `OutputType` value.

`OutputType` Value	Acceptable `OutputDataType` Values
`'integer'`	`'double'`, `'single'`, `'int8'`, `'int16'`, `'int32'`, `'uint8'`, `'uint16'`, or `'uint32'`
`'bit'`	`'double'`, `'single'`, `'int8'`, `'int16'`, `'int32'`, `'uint8'`, `'uint16'`, `'uint32'`, or `'logical'`

Dependencies

This name-value pair argument applies only when `OutputType` is set to `'integer'` or `'bit'`.

Data Types: `char` | `string`

`UnitAveragePower` — Unit average power flag

`false` (default) | `true`

Unit average power flag, specified as the comma-separated pair consisting of `UnitAveragePower` and a logical scalar. When this flag is `true`, the function scales the constellation to an average power of 1 watt referenced to 1 ohm. When this flag is `false`, the function scales the constellation based on specifications in the relevant standard, as described in [1] and [2].

Note When `stdSuffix` is set to `'sh'`, the constellation always has unit average power.

Dependencies

This name-value pair argument applies only when `stdSuffix` is set to `'s2'` or `'s2x'`.

Data Types: `logical`

`NoiseVariance` — Noise variance

1 (default) | positive scalar | vector of positive values

Noise variance, specified as the comma-separated pair consisting of `NoiseVariance` and a positive scalar or vector of positive values.

- When specified as a scalar, the same noise variance value is used on all input elements.
- When specified as a vector, the vector length must be equal to the number of columns in the input signal.

When the noise variance or signal power result in computations involving extreme positive or negative magnitudes, see “DVB Compliant APSK Soft Demodulation” on page 2-287 for algorithm selection considerations.

Dependencies

This name-value pair argument applies only when `OutputType` is set to `'llr'` or `'approxllr'`.

Data Types: `double`

`PlotConstellation` — Option to plot constellation
`false` (default) | `true`

Option to plot constellation, specified as the comma-separated pair consisting of `'PlotConstellation'` and a logical scalar. To plot the constellation, set `PlotConstellation` to `true`.

Data Types: `logical`

Output Arguments

`z` — Demodulated signal
scalar | vector | matrix

Demodulated signal, returned as a scalar, vector, or matrix. The dimensions of the output vary depending on the specified `OutputType` value.

`OutputType` Value	Return Value of `dvbsapskdemod`	Dimensions of `z`
`'integer'`	Demodulated integer values from 0 to (`M` – 1)	`z` has the same dimensions as input `y`.
`'bit'`	Demodulated bits	The number of rows in `z` is $\log_2$(sum(`M`)) times the number of rows in `y`. Each demodulated symbol is mapped to a group of $\log_2$(sum(`M`)) elements in a column, where the first element represents the MSB and the last element represents the LSB.
`'llr'`	Log-likelihood ratio value for each bit	
`'approxllr'`	Approximate log-likelihood ratio value for each bit	

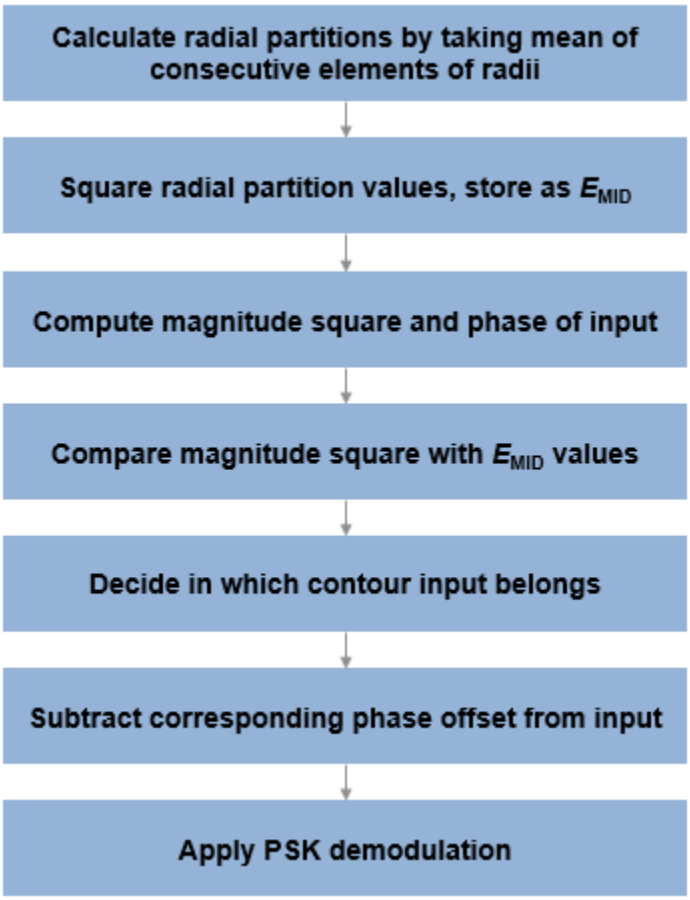
More About

DVB-S2/S2X/SH

Digital video broadcasting (DVB) standards specify S2, S2X, and SH standard-specific amplitude phase shift keying (APSK) modulation. For further information on the DVB-S2/S2X/SH standards, see specified in [1], [2], and [3], respectively.

DVB Compliant APSK Hard Demodulation

The hard demodulation algorithm applies amplitude phase decoding as described in [4].



DVB Compliant APSK Soft Demodulation

For soft demodulation, two soft-decision log-likelihood ratio (LLR) algorithms are available: exact LLR and approximate LLR. The exact LLR algorithm is more accurate but has slower execution speed than the approximate LLR algorithm. For further description of these algorithms, see the “Hard- vs. Soft-Decision Demodulation” topic.

Note The exact LLR algorithm computes exponentials using finite precision arithmetic. For computations involving very large positive or negative magnitudes, the exact LLR algorithm yields:

- `Inf` or `-Inf` if the noise variance is a very large value
- `NaN` if the noise variance and signal power are both very small values

The approximate LLR algorithm does not compute exponentials. You can avoid `Inf`, `-Inf`, and `NaN` results by using the approximate LLR algorithm.

dvbsapskmod

DVB-S2/S2X/SH standard-specific amplitude phase shift keying (APSK) modulation

Syntax

```
y = dvbsapskmod(x,M,stdSuffix)
y = dvbsapskmod(x,M,stdSuffix,codeIDF)
y = dvbsapskmod(x,M,stdSuffix,codeIDF,frameLength)
y = dvbsapskmod( ___ ,Name,Value)
```

Description

`y = dvbsapskmod(x,M,stdSuffix)` performs APSK modulation on the input signal, `x`, in accordance with the digital video broadcast (DVB) standard identified by `stdSuffix` and the modulation order, `M`.

`y = dvbsapskmod(x,M,stdSuffix,codeIDF)` specifies the code identifier, `codeIDF`, to use when selecting the modulation parameters.

`y = dvbsapskmod(x,M,stdSuffix,codeIDF,frameLength)` specifies `codeIDF` and `frameLength` to use when selecting the modulation parameters.

`y = dvbsapskmod( ___ ,Name,Value)` specifies options using one or more name-value pair arguments using any of the previous syntaxes. For example, `'OutputDataType','double'` specifies the desired output data type as double. Specify name-value pair arguments after all other input arguments.

Examples

Apply DVB-S2X 32-APSK Modulation to Data

Modulate data using the DVB-S2X standard specified 32-APSK modulation scheme. Display the result in a scatter plot.

Set the modulation order and the suffix identifying the DVB-S2X standard. Create a data vector with all possible symbols.

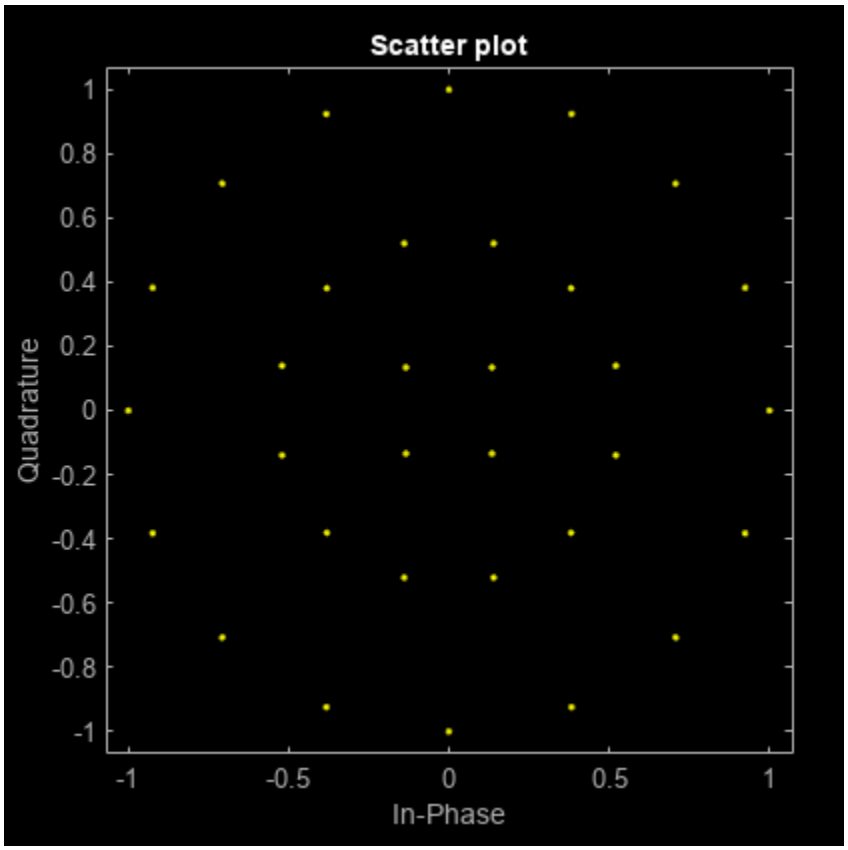
```
M = 32;
stdSuffix = 's2x';
x = (0:M-1);
```

Modulate the data.

```
y = dvbsapskmod(x,M,stdSuffix);
```

Display the constellation using a scatter plot.

```
scatterplot(y)
```



Apply DVB-S2X 64-APSK Modulation Specifying Code Identifier

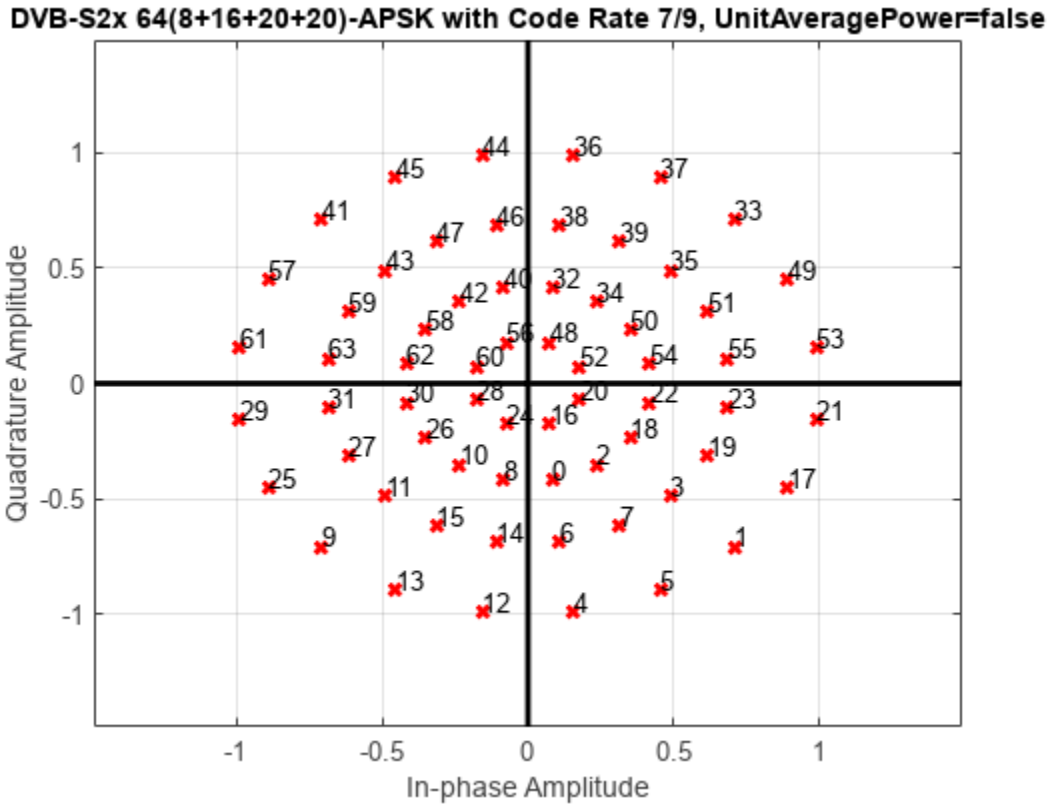
Modulate data using 64-APSK as specified in DVB-S2X standard. Plot constellation for different code identifiers.

Set the modulation order and standard suffix. Generate 1000 symbols of random data in one channel.

```
M = 64;
std = 's2x';
x = randi([0 M-1],1000,1);
```

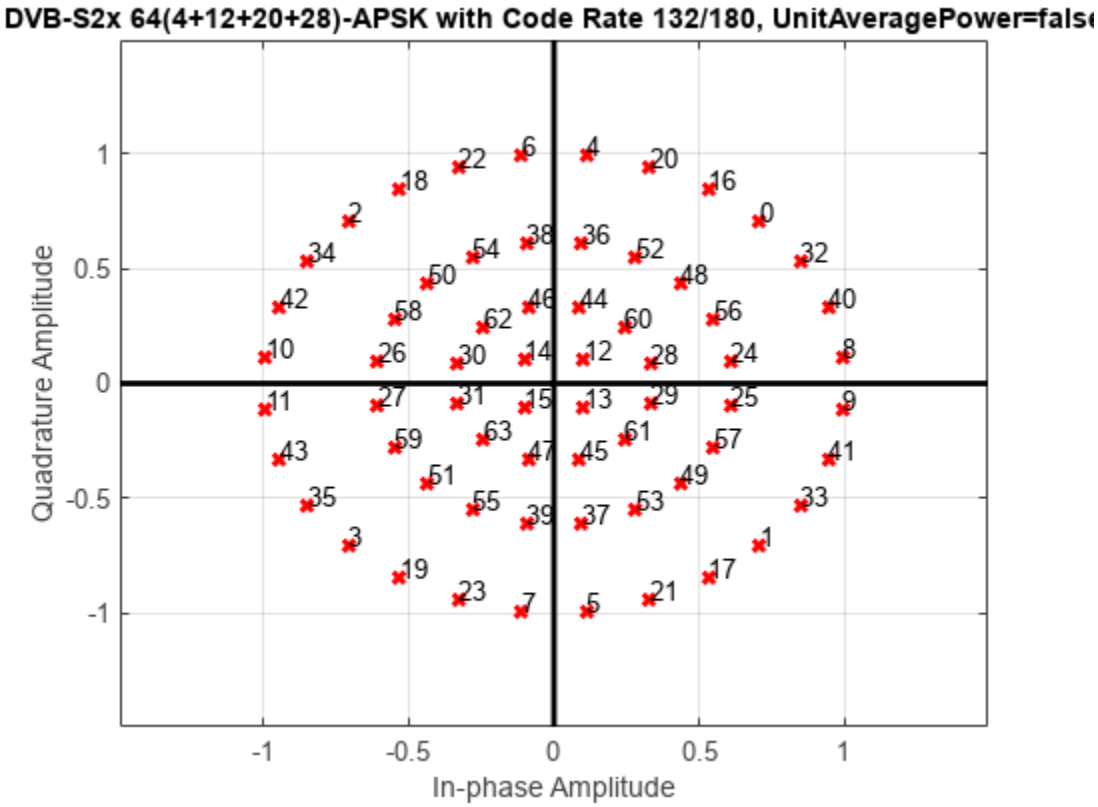
Modulate the data according to the 64-APSK constellation for the code identifier 7/9 and plot the reference constellation.

```
y1 = dvbsapskmod(x,M,std,'7/9','PlotConstellation',true);
```



Modulate setting the code identifier to 132/180 and observe the constellation structure differences.

```
y2 = dvbsapskmod(x,M,std,'132/180','PlotConstellation',true);
```



Apply DVB-S2 16-APSK Modulation Change Frame Length

Modulate data using 16-APSK as specified in DVB-S2 standard for normal and short frame lengths. Compute the output signal power.

Set the modulation order and the standard suffix. Generate random bit data for 1000 symbols in one channel.

```
M = 16;
std = 's2';
x = randi([0 1],1000*log2(M),1);
```

Set the input type to bit and modulate the data according to the 16-APSK constellation for code identifier 2/3. Use the default normal frame length.

```
y1 = dvbsapskmod(x,M,std,'2/3','InputType','bit');
```

Modulate the data using different settings, set the code-identifier to 8/9 and use a short frame length.

```
y2 = dvbsapskmod(x,M,std,'8/9','short','InputType','bit');
```

The average power of the modulated signal changes based on the code identifier. Compute the average power of the modulated signals.

```
y1avgPow = mean(abs(y1).^2)
```

```
y1avgPow = 0.7590

y2avgPow = mean(abs(y2).^2)

y2avgPow = 0.7716
```

Normalize 16-APSK Modulated DVB Signals by Average Power

Modulate data applying 16-APSK as specified in the DVB-SH and DVB-S2 standards. Normalize the modulator output so that it has an average signal power of 1 W.

Set the modulation order and generate all possible symbols.

```
M = 16;
x =  0:M-1;
```

Modulate the data applying 16-APSK as specified in DVB-SH. Use a name-value pair to specify single data type output.

```
y1 = dvbsapskmod(x,M,'sh','OutputDataType','single');
```

Modulate the data applying 16-APSK as specified in DVB-S2. Use a name-value pair to specify single data type output.

```
y2 = dvbsapskmod(x,M,'s2','OutputDataType','single');
```

Modulate the data applying 16-APSK as specified in DVB-S2. Use name-value pairs to set unit average power to true and to specify single data type output.

```
y3 = dvbsapskmod(x,M,'s2','UnitAveragePower',true,'OutputDataType','single');
```

Check which signals have unit average power.

```
y1avgPow = mean(abs(y1).^2)

y1avgPow = single
    1

y2avgPow = mean(abs(y2).^2)

y2avgPow = single
    0.7752

y3avgPow = mean(abs(y3).^2)

y3avgPow = single
    1.0000
```

Input Arguments

x — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix. The elements of x must be binary values or integers that range from 0 to (`M` – 1), where `M` is the modulation order.

Note To process the input signal as binary elements, set `'InputType'` value to `'bit'`. For binary inputs, the number of rows must be an integer multiple of $\log_2(M)$. A group of $\log_2(M)$ bits in a column are mapped onto a symbol, with the first bit representing the MSB and the last bit representing the LSB.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

`M` — Modulation order
integer

Modulation order, specified as a power of two. The modulation order specifies the total number of points in the signal constellation.

Data Types: `double`

`stdSuffix` — Standard suffix
`'s2'` | `'s2x'` | `'sh'`

Standard suffix for DVBS modulation variant, specified as `'s2'`, `'s2x'`, or `'sh'`.

Data Types: `char` | `string`

`codeIDF` — Code identifier
char | string

Code identifier, specified as a character vector or string. This table lists the acceptable `codeIDF` values.

Constellation Order (`M`)	Applicable Standard (`stdSuffix`)	Acceptable Code Identifier (`CodeIDF`) Values
16	`'s2'` or `'s2x'`	`'2/3'`, `'3/4'`, `'4/5'`, `'5/6'`, `'8/9'`, `'9/10'`
16	`'s2x'`	`'26/45'`, `'3/5'`, `'28/45'`, `'23/36'`, `'25/36'`, `'13/18'`, `'7/9'`, `'77/90'`, `'100/180'`, `'96/180'`, `'90/180'`, `'18/30'`, `'20/30'`
32	`'s2'` or `'s2x'`	`'3/4'`, `'4/5'`, `'5/6'`, `'8/9'`, `'9/10'`
32	`'s2x'`	`'32/45'`, `'11/15'`, `'7/9'`, `'2/3'`
64	`'s2x'`	`'11/15'`, `'7/9'`, `'4/5'`, `'5/6'`, `'128/180'`
128	`'s2x'`	`'3/4'`, `'7/9'`
256	`'s2x'`	`'32/45'`, `'3/4'`, `'116/180'`, `'20/30'`, `'124/180'`, `'22/30'`

For more information, refer to Tables 9 and 10 in the DVB-S2 standard, [1], and Table 17a in the DVB-S2X standard, [2].

Dependencies

This input argument applies only when `stdSuffix` is set to `'s2'` or `'s2x'`.

Data Types: `char` | `string`

`frameLength` — Frame length

`'normal'` (default) | `'short'`

Frame length, specified as `'normal'` or `'short'`. `frameLength` and `codeIDF` are used to determine the modulation parameters.

Dependencies

This input argument applies only when `stdSuffix` is set to `'s2'` or `'s2x'`.

Data Types: `char` | `string`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `y = dvbsapskmod(x,M,std,'InputType','bit','OutputDataType','single');`

`InputType` — Input type

`'integer'` (default) | `'bit'`

Input type, specified as the comma-separated pair consisting of `'InputType'` and either `'integer'` or `'bit'`. To use `'integer'`, the input signal must consist of integer values from `0` to (`M` – 1). To use `'bit'`, the input signal must contain binary values and the number of rows must be an integer multiple of $\log_2(M)$.

Data Types: `char` | `string`

`UnitAveragePower` — Unit average power flag

`false` (default) | `true`

Unit average power flag, specified as the comma-separated pair consisting of `'UnitAveragePower'` and a logical scalar. When this flag is `true`, the function scales the constellation to an average power of 1 watt referenced to 1 ohm. When this flag is `false`, the function scales the constellation based on specifications in the relevant standard, as described in [1] and [2].

Note When `stdSuffix` is set to `'sh'`, the constellation always has unit average power.

Dependencies

This name-value pair argument applies only when `stdSuffix` is set to `'s2'` or `'s2x'`.

Data Types: `logical`

`OutputDataType` — Output data type
`'double'` (default) | `'single'`

Output data type, specified as the comma-separated pair consisting of `'OutputDataType'` and either `'double'` or `'single'`.

Data Types: `char` | `string`

`PlotConstellation` — Option to plot constellation
`false` (default) | `true`

Option to plot constellation, specified as the comma-separated pair consisting of `'PlotConstellation'` and a logical scalar. To plot the constellation, set `PlotConstellation` to `true`.

Data Types: `logical`

Output Arguments

`y` — Modulated signal
scalar | vector | matrix

Modulated signal, returned as a complex scalar, vector, or matrix. The dimensions of `y` depend on the specified `'InputType'` value.

`'InputType'` Value	Dimensions of `y`
`'integer'`	`y` has the same dimensions as input `x`.
`'bit'`	The number of rows in `y` equals the number of rows in `x` divided by $\log_2(M)$.

Data Types: `double` | `single`

More About

DVB-S2/S2X/SH

Digital video broadcasting (DVB) standards specify S2, S2X, and SH standard-specific amplitude phase shift keying (APSK) modulation. For further information on the DVB-S2/S2X/SH standards, see specified in [1], [2], and [3], respectively.

Version History

Introduced in R2018a

encode

Block encoder

Syntax

```
code = encode(msg,n,k)
code = encode(msg,n,k,codingMethod,prim_poly)
code = encode(msg,n,k,codingMethod,genmat)
code = encode(msg,n,k,codingMethod,genpoly)
[code,added] = encode( ___ )
```

Description

`code = encode(msg,n,k)` encodes message, `msg`, using the Hamming encoding method with codeword length, `n`, and message length, `k`. The value of `n` must be calculated for an integer, *m*, such that $m \geq 2$. The values of `n` and `k` are calculated as $2^m–1$ and `n`–*m*, respectively.

`code = encode(msg,n,k,codingMethod,prim_poly)` encodes `msg` using `codingMethod` as the Hamming encoding method, and `prim_poly` as the primitive polynomial. The value of `n` must be calculated for an integer, `m`≥2.

`code = encode(msg,n,k,codingMethod,genmat)` encodes `msg` using `codingMethod` as the linear block encoding method and `genmat` as the generator matrix. The value of `n` must be calculated for an integer, `m`≥2.

`code = encode(msg,n,k,codingMethod,genpoly)` encodes `msg` using `codingMethod` as the systematic cyclic code and `genpoly`, as the generator polynomial. The value of `n` must be calculated for an integer, `m`≥2.

`[code,added] = encode( ___ )` returns the additional variable `added`. `added` denotes the number of zeros appended at the end of the message matrix before encoding. You can specify any of the input argument combinations from the previous syntaxes.

Examples

Encode and Decode Message with Hamming Code

Set the values of the codeword length and message length.

```
n = 15; % Codeword length
k = 11; % Message length
```

Create a random binary message with length equal to the message length.

```
data = randi([0 1],k,1);
```

Encode the message.

```
encData = encode(data,n,k,'hamming/binary');
```

Corrupt the encoded message sequence by introducing an error in the fourth bit.

```
encData(4) = ~encData(4);
```

Decode the corrupted sequence. Observe that the decoder has correctly recovered the message.

```
decData = decode(encData,n,k,'hamming/binary');
numerr = biterr(data,decData)
```

```
numerr = 0
```

Encode and Decode Message with Linear Block Code

Set the values of codeword length and message length.

```
n = 7; % Codeword length
k = 3; % Message length
```

Create a random binary message with length equal to the message length.

```
data = randi([0 1],k,1);
```

Create a cyclic generator polynomial. Then, create a parity-check matrix and convert it into a generator matrix.

```
pol = cyclpoly(n,k);
parmat = cyclgen(n,pol);
genmat = gen2par(parmat);
```

Encode the message sequence by using the generator matrix.

```
encData = encode(data,n,k,'linear/binary',genmat);
```

Corrupt the encoded message sequence by introducing an error in the third bit.

```
encData(3) = ~encData(3);
```

Decode the corrupted sequence. Observe that the decoder has correctly recovered the message.

```
decData = decode(encData,n,k,'linear/binary',genmat);
```

```
Single-error patterns loaded in decoding table.  8 rows remaining.
2-error patterns loaded.  1 rows remaining.
3-error patterns loaded.  0 rows remaining.
```

```
numerr = biterr(data,decData)
```

```
numerr = 0
```

Encode and Decode Message with Cyclic Block Code

Set the values of the codeword length and message length.

```
n = 15; % Codeword length
k = 5; % Message length
```

Create a random binary message with length equal to the message length.

```
data = randi([0 1],k,1);
```

Create a generator polynomial for a cyclic code. Create a parity-check matrix by using the generator polynomial.

```
genpoly = cyclpoly(n,k);
parmat = cyclgen(n,genpoly);
```

Create a syndrome decoding table by using the parity-check matrix.

```
trt = syndtable(parmat);
```

```
Single-error patterns loaded in decoding table.  1008 rows remaining.
2-error patterns loaded.  918 rows remaining.
3-error patterns loaded.  648 rows remaining.
4-error patterns loaded.  243 rows remaining.
5-error patterns loaded.  0 rows remaining.
```

Encode the data by using the generator polynomial.

```
encData = encode(data,n,k,'cyclic/binary',genpoly);
```

Corrupt the encoded message sequence by introducing errors in the first, second, fourth and seventh bits.

```
encData(1) = ~encData(1);
encData(2) = ~encData(2);
encData(4) = ~encData(4);
```

Decode the corrupted sequence. Observe that the decoder has correctly recovered the message.

```
decData = decode(encData,n,k,'cyclic/binary',genpoly,trt);
numerr = biterr(data,decData)
```

```
numerr = 0
```

Input Arguments

`msg` — Input messages

binary column or row vector | binary matrix with `k` columns | column or row vector of integers in the range [0, 2^k–1]

Input messages, specified as one of these options:

- Binary column or row vector with `k` columns
- Binary matrix with `k` columns
- Column or row vector of `k` columns and having integers in the range [0, 2^k–1]

Example: `msg = [0 1 1 0, 0 1 0 1, 1 0 0 1]` specifies a binary row vector for `k=4`.

Example: `msg = [0 1 1 0; 0 1 0 1; 1 0 0 1]` specifies a binary matrix for `k=4`.

Example: `msg = [6, 10, 9]` specifies a row vector of integers for `k=4`.

Data Types: `double`

n — Codeword length

positive integer

Codeword length, specified as a positive integer. The function calculates this value as 2^*m*–1, where *m* must be greater than or equal to 2.

Data Types: `double`

k — Message length

positive integer

Message length, specified as a positive integer. The function calculates this value as n–*m*, where *m* must be greater than or equal to 2.

Data Types: `double`

codingMethod — Error coding method and format

`'hamming/binary'` (default) | `'hamming/decimal'` | `'linear/binary'` | `...`

Error coding method and format, specified as one of these:

- `'hamming/binary'`
- `'hamming/decimal'`
- `'linear/binary'`
- `'linear/decimal'`
- `'cyclic/binary'`
- `'cyclic/decimal'`

Data Types: `char` | `string`

prim_poly — Primitive polynomial

`gfprimdf(n-k)` (default) | binary row vector | character vector | string scalar | positive integer

Primitive polynomial, specified as one of these options:

- Binary row vector — This vector gives coefficients of `prim_poly` in the order of ascending powers.
- Character vector or a string scalar — This value defines `prim_poly` in textual representation. For more information, see polynomial character vector.
- Positive integer — This value defines `prim_poly` in the range $[2^m + 1, 2^{m+1} - 1]$.

For more information about default primitive polynomials, see “Default Primitive Polynomials” on page 2-367. For more information about the representation of primitive polynomials, see “Primitive Polynomials and Element Representations”.

Data Types: `double` | `char` | `string`

genmat — Generator matrix

k-by-n numeric matrix

Generator matrix, specified as a k-by-n numeric matrix.

Data Types: `double`

genpoly — Generator polynomial

`cyclpoly(n-k)` (default) | binary row vector | character vector | string scalar

Generator polynomial, specified as a polynomial character vector or a row vector that gives the coefficients in order of ascending powers of the binary generator polynomial. The value of `genpoly` for an [`n`, `k`] cyclic code must have degree `n`–`k` and divide x^n-1, where x is an identifier.

Data Types: `char` | `string`

Output Arguments

code — Output code

binary column or row vector | binary matrix with `n` columns | column or row vector of integers in the range [0, 2^n–1].

Output code, returned as one of the options in this table. The value and dimension of `code` depends on the value and dimension of the "msg" on page 2-0 and the input message format according to this table:

msg Value	Input Message Format	code Value
Binary column or row vector	binary	Binary column or row vector
Binary matrix with `k` columns	binary	Binary matrix with `n` columns
Column or row vector of integers in the range [0, 2^k–1]	decimal	Column or row vector of integers in the range [0, 2^n–1]

added — Additional variable

nonnegative integer

Additional variable, returned as the number of zeros that were appended at the end of the message matrix before encoding for the matrix to have the appropriate size. The size of the message matrix depends on the `n`, `k`, and `msg` and the encoding method.

Algorithms

Depending on the error-correction coding method, the `encode` function relies on lower-level functions such as `hammgen` and `cyclgen`.

Version History

Introduced before R2006a

evdoForwardReferenceChannels

Define 1xEV-DO forward reference channel

Syntax

```
cfg = evdoForwardReferenceChannels(wv)
cfg = evdoForwardReferenceChannels(wv,numpackets)
```

Description

`cfg = evdoForwardReferenceChannels(wv)` returns a structure, `cfg`, that defines 1xEV-DO forward link parameters given the input waveform identifier, `wv`. Pass this structure to the `evdoForwardWaveformGenerator` function to generate a forward link reference channel waveform.

For all syntaxes, `evdoForwardReferenceChannels` creates a configuration structure that is compliant with the cdma2000 high data rate packet specification, [1].

`cfg = evdoForwardReferenceChannels(wv,numpackets)` specifies the number of packets to be generated.

Examples

Generate 1xEV-DO Release 0 Forward Link Waveform

Create a configuration structure for a Release 0 channel having a 921.6 kbps data rate and transmitted over two slots.

```
config = evdoForwardReferenceChannels('Rel0-921600-2');
```

Display the number of slots and the data rate.

```
config.PacketSequence
```

```
ans = struct with fields:
    MACIndex: 0
    DataRate: 921600
    NumSlots: 2
```

Generate the complex waveform using the associated waveform generator function, `evdoForwardWaveformGenerator`.

```
wv = evdoForwardWaveformGenerator(config);
```

Generate 1xEV-DO Revision A Forward Link Waveform

Create a structure to transmit a Revision A 1xEV-DO channel consisting of three 1024-bit packets transmitted over 2 slots with a 64-bit preamble length.

```
config = evdoForwardReferenceChannels('RevA-1024-2-64',3);
```

Verify that the function created a 1-by-3 structure array. Each element in the structure array corresponds to a data packet.

```
config.PacketSequence
```

```
ans=1×3 struct array with fields:
    MACIndex
    PacketSize
    NumSlots
    PreambleLength
```

Examine the first structure element to verify the packet size, number of slots, and preamble length match what you specified in the function call.

```
config.PacketSequence(1)
```

```
ans = struct with fields:
          MACIndex: 0
        PacketSize: 1024
          NumSlots: 2
    PreambleLength: 64
```

Generate the waveform.

```
wv = evdoForwardWaveformGenerator(config);
```

Input Arguments

wv — Waveform identification

character vector

Waveform identification of the reference channel, specified as a character vector.

Parameter Field	Values	Description
wv	`'Rel0-38400-16'` | `'Rel0-76800-8'` | `'Rel0-153600-4'` | `'Rel0-307200-2'` | `'Rel0-307200-4'` | `'Rel0-614400-1'` | `'Rel0-614400-2'` | `'Rel0-921600-2'` | `'Rel0-1228800-1'` | `'Rel0-1228800-2'` | `'Rel0-1843200-1'` | `'Rel0-2457600-1'`	Character vector representing the 1xEV-DO Release 0 reference channel with data rate in bps and number of slots. For example, you can specify `'Rel0-153600-4'` to create a structure that represents a reference channel with a 153,600 bps data rate and uses four slots.

Parameter Field	Values	Description
	`'RevA-128-1-64'` | `'RevA-128-2-128'` | `'RevA-128-4-256'` | `'RevA-128-4-1024'` | `'RevA-128-8-512'` | `'RevA-256-1-64'` | `'RevA-256-2-128'` | `'RevA-256-4-256'` | `'RevA-256-4-1024'` | `'RevA-256-8-512'` | `'RevA-256-16-1024'` | `'RevA-512-1-64'` | `'RevA-512-2-64'` | `'RevA-512-2-128'` | `'RevA-512-4-128'` | `'RevA-512-4-256'` | `'RevA-512-4-1024'` | `'RevA-512-8-512'` | `'RevA-512-16-1024'` | `'RevA-1024-1-64'` | `'RevA-1024-2-64'` | `'RevA-1024-2-128'` | `'RevA-1024-4-128'` | `'RevA-1024-4-256'` | `'RevA-1024-8-512'` | `'RevA-1024-16-1024'` | `'RevA-2048-1-64'` | `'RevA-2048-2-64'` | `'RevA-2048-4-128'` | `'RevA-3072-1-64'` | `'RevA-3072-2-64'` `'RevA-4096-1-64'` | `'RevA-4096-2-64'` | `'RevA-5120-1-64'` | `'RevA-5120-2-64'`	Character vector representing the 1xEV-DO Revision A reference channel with the packet size in bits, the number of slots, and the preamble length in chips. For example, you can specify `'RevA-256-1-64'` to create a reference channel having a 256-bit packet, transmitted in one slot, with a 64-bit preamble length.

Example: `'Rel0-614400-2'`

Example: `'RevA-4096-2-64'`

Data Types: `char`

`numpackets` — Number of packets
1 (default) | positive integer scalar

Number of packets, specified as a positive integer.

Example: 4

Data Types: `double`

Output Arguments

`cfg` — Configuration of the parameters and channels used by the waveform generator
structure

Configuration of the parameters and channels used by the waveform generator. The configuration structure is defined in these tables.

Top-Level Parameters and Substructures

Parameter Field	Values	Description
Release	'Release0' | 'RevisionA'	1xEV-DO
PNOffset	Nonnegative scalar integer [0, 511]	PN offset of the base station
IdleSlotsWithControl	'Off' | 'On'	Include idle slots with control channels
EnableControl	'Off' | 'On'	Enable control signaling
NumChips	Positive scalar integer	Number of chips in the waveform
OversamplingRatio	Positive scalar integer [1, 8]	Oversampling ratio at output
FilterType	'cdma2000Long' | 'cdma2000short' | 'Custom' | 'Off'	Select filter type or disable filtering
CustomFilterCoefficients	Real vector	Custom filter coefficients (applies when the FilterType field is set to 'Custom')
InvertQ	'Off' | 'On'	Negate the quadrature output
EnableModulation	'Off' | 'On'	Enable carrier modulation
ModulationFrequency	Nonnegative scalar integer	Carrier modulation frequency (applies when EnableModulation is 'On')
PacketSequence	Structure	See **PacketSequence substructure**.
PacketDataSources	Structure	See **PacketDataSources substructure**.

PacketSequence Substructure

Include the PacketSequence substructure in the cfg structure to define a sequence of data packets for consecutive transmission. The PacketSequence substructure contains these fields.

Parameter Field	Values	Description
MACIndex	Positive scalar integer	MAC index associated with the packet
Release 0		
DataRate	38400 | 76800 | 153600 | 307200 | 614400 | 921600 | 1228800 | 1843200 | 2457600	Data rate (bps)
NumSlots	Positive scalar integer	Number of slots
Revision A		
PacketSize	128 | 256 | 512 | 1024 | 2048 | 3072 | 4096 | 5120	Packet size (bits)
NumSlots	1 | 2 | 4 | 8 | 16	Number of slots
PreambleLength	64 | 128 | 256 | 512 | 1024	Preamble length (chips)

PacketDataSources Substructure

Include a `PacketDataSources` substructure in the `cfg` structure to define a set of matching data sources for each MAC index. The `PacketDataSources` substructure contains these fields.

Parameter Field	Values	Description
`MACIndex`	Positive scalar integer	MAC index associated with the packet
`DataSource`	Cell array, `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.
`EnableCoding`	`'Off'` | `'On'`	Enable error correction coding

Version History

Introduced in R2015b

`evdoForwardWaveformGenerator` | `evdoReverseReferenceChannels`

evdoForwardWaveformGenerator

Generate 1xEV-DO forward link waveform

Syntax

```
waveform = evdoForwardWaveformGenerator(cfg)
```

Description

`waveform = evdoForwardWaveformGenerator(cfg)` returns the 1xEV-DO forward link `waveform` as defined by the parameter configuration structure, `cfg`.

The top-level parameters and lower-level substructures of `cfg` specify the waveform and channel properties the function uses to generate a 1xEV-DO waveform. You can generate `cfg` by using the `evdoForwardReferenceChannels` function.

Note The tables herein list the allowable values for the top-level parameters and substructure fields. However, not all parameter combinations are supported. To ensure that the input argument is valid, use the `evdoForwardReferenceChannels` function. If you input the structure fields manually, consult [1] to ensure that the input parameter combinations are permitted.

Examples

Generate 1xEV-DO Revision A Forward Link Waveform

Create a structure to transmit a Revision A 1xEV-DO channel consisting of three 1024-bit packets transmitted over 2 slots with a 64-bit preamble length.

```
config = evdoForwardReferenceChannels('RevA-1024-2-64',3);
```

Verify that the function created a 1-by-3 structure array. Each element in the structure array corresponds to a data packet.

```
config.PacketSequence
```

```
ans=1×3 struct array with fields:
    MACIndex
    PacketSize
    NumSlots
    PreambleLength
```

Examine the first structure element to verify the packet size, number of slots, and preamble length match what you specified in the function call.

```
config.PacketSequence(1)
```

```
ans = struct with fields:
          MACIndex: 0
```

```
        PacketSize: 1024
          NumSlots: 2
    PreambleLength: 64
```

Generate the waveform.

```
wv = evdoForwardWaveformGenerator(config);
```

Generate 1xEV-DO Forward Link Waveform with Custom Filter

Create a structure to generate two packets of a 1.8 Mbps Release 0 channel.

```
config = evdoForwardReferenceChannels("Rel0-1843200-1",2);
```

Calculate the sample rate of the waveform.

```
fs = 1.2288e6 * config.OversamplingRatio;
```

Disable the internal filter of the `evdoForwardWaveformGenerator` function. Generate the 1xEV-DO waveform.

```
config.FilterType = "off";
wv = evdoForwardWaveformGenerator(config);

sa = spectrumAnalyzer( ...
    SampleRate=fs, ...
    ChannelNames=["1xEv-DO","1xEV-DO filtered"]);
```

Create a lowpass FIR filter with a 500 kHz passband, a 750 kHz stopband, and a stopband attenuation of 60 dB.

```
d = designfilt("lowpassfir", ...
    PassbandFrequency=500e3, ...
    StopbandFrequency=750e3, ...
    StopbandAttenuation=60, ...
    SampleRate=fs);
```

Change the filter type to "`Custom`" and specify the coefficients from the digital filter, `d`.

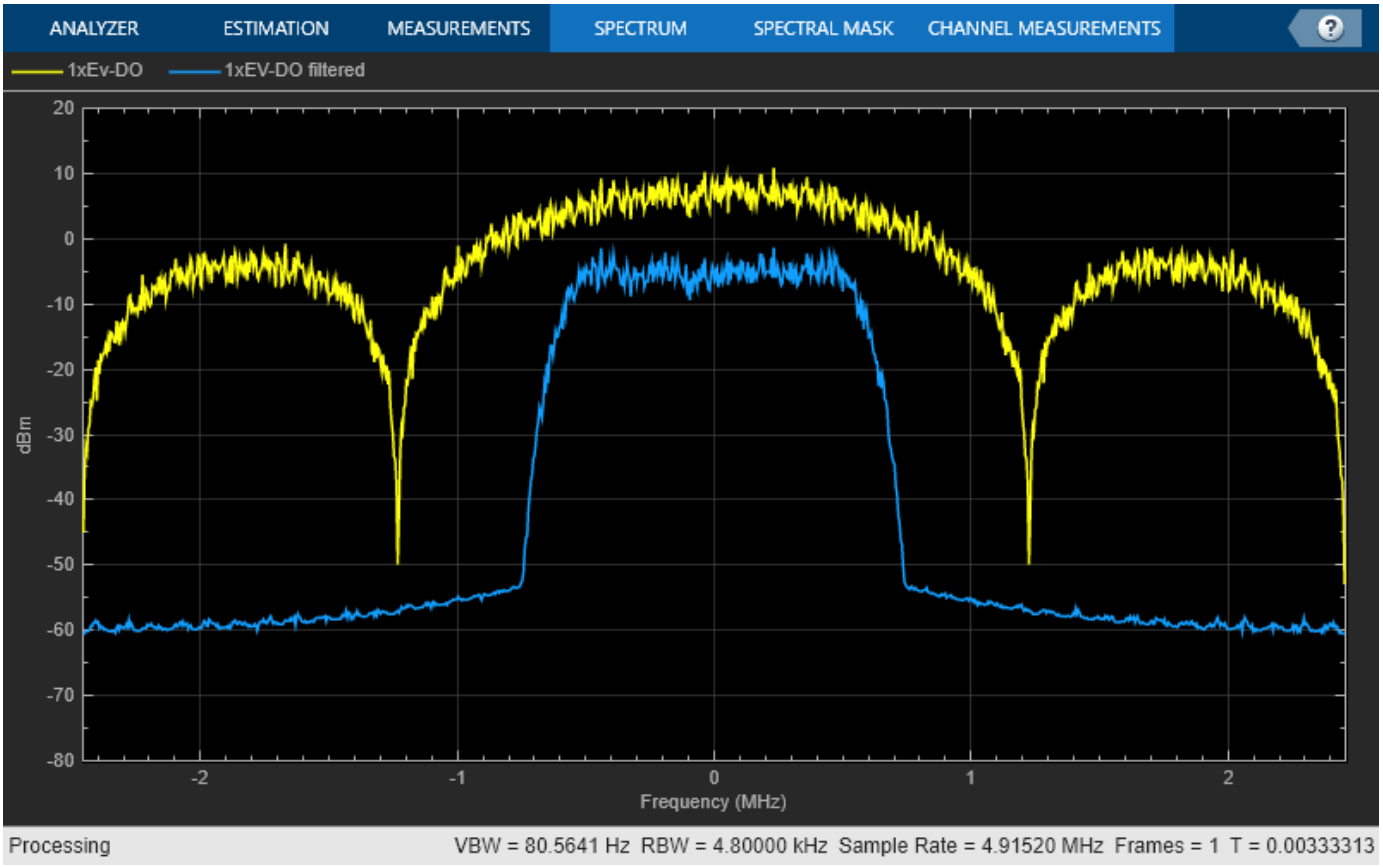
```
config.FilterType = "Custom";
config.CustomFilterCoefficients = d.Coefficients;
```

Generate the waveform using the custom filter coefficients.

```
wvfiltered = evdoForwardWaveformGenerator(config);
```

Plot the spectrum of the unfiltered and filtered 1xEV-DO waveform. The filter attenuates the waveform by 60 dB for frequencies outside of ± 750 kHz.

```
sa(wv,wvfiltered)
```



Input Arguments

`cfg` — Configuration of the parameters and channels used by the waveform generator

structure

Configuration of the parameters and channels used by the waveform generator. The configuration structure is defined in these tables.

Top-Level Parameters and Substructures

Parameter Field	Values	Description
`Release`	`'Release0'` | `'RevisionA'`	1xEV-DO
`PNOffset`	Nonnegative scalar integer [0, 511]	PN offset of the base station
`IdleSlotsWithControl`	`'Off'` | `'On'`	Include idle slots with control channels
`EnableControl`	`'Off'` | `'On'`	Enable control signaling
`NumChips`	Positive scalar integer	Number of chips in the waveform
`OversamplingRatio`	Positive scalar integer [1, 8]	Oversampling ratio at output

Parameter Field	Values	Description
FilterType	`'cdma2000Long'` | `'cdma2000short'` | `'Custom'` | `'Off'`	Select filter type or disable filtering
CustomFilterCoefficients	Real vector	Custom filter coefficients (applies when the `FilterType` field is set to `'Custom'`)
InvertQ	`'Off'` | `'On'`	Negate the quadrature output
EnableModulation	`'Off'` | `'On'`	Enable carrier modulation
ModulationFrequency	Nonnegative scalar integer	Carrier modulation frequency (applies when `EnableModulation` is `'On'`)
PacketSequence	Structure	See **PacketSequence substructure**.
PacketDataSources	Structure	See **PacketDataSources substructure**.

PacketSequence Substructure

Include the `PacketSequence` substructure in the `cfg` structure to define a sequence of data packets for consecutive transmission. The `PacketSequence` substructure contains these fields.

Parameter Field	Values	Description
MACIndex	Positive scalar integer	MAC index associated with the packet
Release 0		
DataRate	`38400` | `76800` | `153600` | `307200` | `614400` | `921600` | `1228800` | `1843200` | `2457600`	Data rate (bps)
NumSlots	Positive scalar integer	Number of slots
Revision A		
PacketSize	`128` | `256` | `512` | `1024` | `2048` | `3072` | `4096` | `5120`	Packet size (bits)
NumSlots	`1` | `2` | `4` | `8` | `16`	Number of slots
PreambleLength	`64` | `128` | `256` | `512` | `1024`	Preamble length (chips)

PacketDataSources Substructure

Include a `PacketDataSources` substructure in the `cfg` structure to define a set of matching data sources for each MAC index. The `PacketDataSources` substructure contains these fields.

Parameter Field	Values	Description
MACIndex	Positive scalar integer	MAC index associated with the packet
DataSource	Cell array, `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

Parameter Field	Values	Description
EnableCoding	'Off' | 'On'	Enable error correction coding

Output Arguments

waveform — Modulated baseband waveform comprising the primary physical channels
complex vector array

Modulated baseband waveform comprising the primary cdma2000 physical channels, returned as a complex vector array.

Version History

Introduced in R2015b

cdma2000ForwardReferenceChannels | cdma2000ReverseWaveformGenerator

evdoReverseReferenceChannels

Define 1xEV-DO reverse reference channel

Syntax

```
cfg = evdoReverseReferenceChannels(wv)
cfg = evdoReverseReferenceChannels(wv,numpackets)
```

Description

`cfg = evdoReverseReferenceChannels(wv)` returns a structure, `cfg`, that defines 1xEV-DO reverse link parameters given the input waveform identifier, `wv`. Pass this structure to the `evdoReverseWaveformGenerator` function to generate a reverse link reference channel waveform.

For all syntaxes, `evdoReverseReferenceChannels` creates a structure that is compliant with the cdma2000 high data rate packet specification,[1].

`cfg = evdoReverseReferenceChannels(wv,numpackets)` specifies the number of packets to be generated.

Examples

Generate 1xEV-DO Reverse Channel Waveform

Create a structure to generate a Release 0, 1xEV-DO waveform having a 19.2 kbps data rate.

```
config = evdoReverseReferenceChannels('Rel0-19200');
```

Verify that the packet has a data rate of 19.2 kbps.

```
config.PacketSequence.DataRate
```

```
ans = 19200
```

Generate the complex waveform.

```
wv = evdoReverseWaveformGenerator(config);
```

Generate 1xEV-DO Revision A Reverse Link Waveform

Create a structure for a Revision A 1xEV-DO channel having 2048-bit packets, transmitted in 12 slots. Specify that five packets are transmitted.

```
config = evdoReverseReferenceChannels('RevA-2048-12',5);
```

Verify that a 1-by-5 structure array is created. Each element in the structure array corresponds to a data packet.

```
config.PacketSequence
```

```
ans=1×5 struct array with fields:
    Power
    DataSource
    EnableCoding
    PayloadSize
    NumSlots
    DataRate
```

Examine the first structure element to verify the packet size and the number of slots are as specified in the function call.

```
config.PacketSequence(1)
```

```
ans = struct with fields:
           Power: 0
      DataSource: {'PN9'  [1]}
    EnableCoding: 'On'
     PayloadSize: 2048
        NumSlots: 12
        DataRate: 102400
```

Generate the waveform.

```
wv = evdoReverseWaveformGenerator(config);
```

Input Arguments

wv — Waveform identification

character vector

Waveform identification of the reference channel, specified as a character vector.

Parameter Field	Values	Description
wv	`'Rel0-9600'` | `'Rel0-19200'` | `'Rel0-38400'` | `'Rel0-76800'` | `'Rel0-153600'`	Character vector representing the 1xEV-DO Release 0 data rate in bps. For example, you can specify `'Rel0-153600'` to create a structure corresponding to a Release 0 reference channel having a 153,600 bps data rate.

Parameter Field	Values	Description
	'RevA-128-4' | 'RevA-128-8' | 'RevA-128-12' | 'RevA-128-16' | 'RevA-256-4' | 'RevA-256-8' | 'RevA-256-12' | 'RevA-256-16' | 'RevA-512-4' | 'RevA-512-8' | 'RevA-512-12' | 'RevA-512-16' | 'RevA-768-4' | 'RevA-768-8' | 'RevA-768-12' | 'RevA-768-16' | 'RevA-1024-4' | 'RevA-1024-8' | 'RevA-1024-12' | 'RevA-1024-16' | 'RevA-1536-4' | 'RevA-1536-8' | 'RevA-1536-12' | 'RevA-1536-16' | 'RevA-2048-4' | 'RevA-2048-8' | 'RevA-2048-12' | 'RevA-2048-16' | 'RevA-3072-4' | 'RevA-3072-8' | 'RevA-3072-12' | 'RevA-3072-16' | 'RevA-4096-4' | 'RevA-4096-8' | 'RevA-4096-12' | 'RevA-4096-16' | 'RevA-6144-4' | 'RevA-6144-8' | 'RevA-6144-12' | 'RevA-6144-16' | 'RevA-8192-4' | 'RevA-8192-8' | 'RevA-8192-12' | 'RevA-8192-16' | 'RevA-12288-4' | 'RevA-12288-8' | 'RevA-12288-12' | 'RevA-12288-16'	Character vector representing the 1xEV-DO Revision A packet size in bits and the number of slots. For example, you can specify 'RevA-256-4' to create a structure corresponding to a Revision A reference channel having 256-bit packets and transmitted in four slots.

Example: `'Rel0-38400'`

Example: `'RevA-3072-12'`

Data Types: `char`

`numpackets` — Number of packets
1 (default) | positive integer scalar

Number of packets, specified as a positive integer.

Example: 2

Data Types: `double`

Output Arguments

`cfg` — Configuration of the parameters and channels used by the waveform generator
structure

Configuration of the parameters and channels used by the waveform generator. The configuration structure is defined in these tables.

Top-Level Parameters and Substructures

Parameter Field	Values	Description
`Release`	`'Release0'` | `'RevisionA'`	1xEV-DO applicable standard
`LongCodeMaskI`	42-bit binary number	Long code identifier for in-phase channel
`LongCodeMaskQ`	42-bit binary number	Long code identifier for quadrature channel
`NumChips`	Positive scalar integer	Number of chips in the waveform
`OversamplingRatio`	Positive scalar integer	Oversampling ratio at output
`FilterType`	`'cdma2000Long'` | `'cdma2000Short'` | `'Custom'` | `'Off'`	Specify the filter type or disable filtering
`CustomFilterCoefficients`	Real vector	Custom filter coefficients (applies when `FilterType` is set to `'Custom'`)
`InvertQ`	`'Off'` | `'On'`	Negate the quadrature output
`EnableModulation`	`'Off'` | `'On'`	Enable carrier modulation
`ModulationFrequency`	Nonnegative scalar integer	Carrier modulation frequency (applies when `EnableModulation` is `'On'`)
`ACKChannel`	Structure	See **`ACKChannel` substructure**.
`PilotChannel`	Structure	See **`PilotChannel` substructure**.
`AuxPilotChannel`	Not present or structure	See **`AuxPilotChannel` substructure**.
`PacketSequence`	Structure	See **`PacketSequence` substructure**.

ACKChannel Substructure

Include the `ACKChannel` substructure in the `cfg` structure to specify the acknowledgment channel. The `ACKChannel` substructure contains these fields.

Parameter Fields	Values	Description
Enable	`'On'` | `'Off'`	Character vector to enable or disable the channel
Power	Real scalar	Channel power (dBW)
DataSource	Cell array, `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

PilotChannel Substructure

Include the `PilotChannel` substructure in the `cfg` structure to specify the pilot channel. The `PilotChannel` substructure contains these fields.

Parameter Fields	Values	Description
Enable	`'On'` | `'Off'`	Character vector to enable or disable the channel
Power	Real scalar	Channel power (dBW)
DataSource	Cell array, `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.
EnableCoding	`'On'` | `'Off'`	Enable channel coding

AuxPilotChannel Substructure

Include the `AuxPilotChannel` substructure in the `cfg` structure to specify the auxiliary pilot channel, which is available only for Revision A. The `AuxPilotChannel` substructure contains these fields.

Parameter Fields	Values	Description
Enable	`'On'` | `'Off'`	Character vector to enable or disable the channel
Power	Real scalar	Channel power (dBW)
DataSource	Cell array, `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.
EnableCoding	`'On'` | `'Off'`	Enable channel coding

PacketSequence Substructure

Include the `PacketSequence` substructure in the `cfg` structure to define a sequence of data packets for consecutive transmission. The `PacketSequence` substructure contains these fields.

Parameter Field	Values	Description
Power	Real scalar	MAC index associated with the packet
EnableCoding	`'Off'` | `'On'`	Enable error correction coding
DataSource	Cell array, `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.
Release 0		
DataRate	`9600` | `19200` | `38400` | `76800` | `153600`	Data rate (bps)
Revision A		
PacketSize	`128` | `256` | `512` | `768` | `1024` | `1536` | `2048` | `3072` | `4096` | `6144` | `8192` | `12288`	Packet size (bits)
NumSlots	`4` | `8` | `12` | `16`	Number of slots

Data Types: `struct`

Version History

Introduced in R2015b

`evdoReverseWaveformGenerator` | `evdoForwardReferenceChannels`

evdoReverseWaveformGenerator

Generate 1xEV-DO reverse link waveform

Syntax

```
waveform = evdoReverseWaveformGenerator(cfg)
```

Description

`waveform = evdoReverseWaveformGenerator(cfg)` returns the 1xEV-DO reverse link `waveform` as defined by the parameter configuration structure, `cfg`.

The top-level parameters and lower-level substructures of `cfg` specify the waveform and channel properties used by the function to generate a 1xEV-DO waveform. You can generate `cfg` by using the `evdoReverseReferenceChannels` function.

Note The tables herein list the allowable values for the top-level parameters and substructure fields. However, not all parameter combinations are supported. To ensure that the input argument is valid, use the `evdoReverseReferenceChannels` function. If you input the structure fields manually, consult [1] to ensure that the input parameter combinations are permitted.

Examples

Generate 1xEV-DO Reverse Channel Waveform

Create a structure to generate a Release 0, 1xEV-DO waveform having a 19.2 kbps data rate.

```
config = evdoReverseReferenceChannels('Rel0-19200');
```

Verify that the packet has a data rate of 19.2 kbps.

```
config.PacketSequence.DataRate
```

```
ans = 19200
```

Generate the complex waveform.

```
wv = evdoReverseWaveformGenerator(config);
```

Generate 1xEV-DO Reverse Link Waveform with Custom Filter

Create a structure to generate four packets of a Revision A channel having 768-bit packets transmitted over eight slots.

```
config = evdoReverseReferenceChannels("RevA-768-8",4);
```

Calculate the sample rate of the waveform.

```
fs = 1.2288e6 * config.OversamplingRatio;
```

Disable the internal filter of the `evdoReverseWaveformGenerator`. Generate the 1xEV-DO waveform.

```
config.FilterType = "off";
wv = evdoReverseWaveformGenerator(config);

sa = spectrumAnalyzer( ...
    SampleRate=fs, ...
    ChannelNames=["1xEV-DO","1xEV-DO filtered"]);
```

Create a lowpass FIR filter with a 500 kHz passband, a 750 kHz stopband, and a stopband attenuation of 60 dB.

```
d = designfilt("lowpassfir", ...
    PassbandFrequency=500e3, ...
    StopbandFrequency=750e3, ...
    StopbandAttenuation=60, ...
    SampleRate=fs);
```

Change the filter type to "`Custom`" and specify the coefficients from the digital filter, `d`.

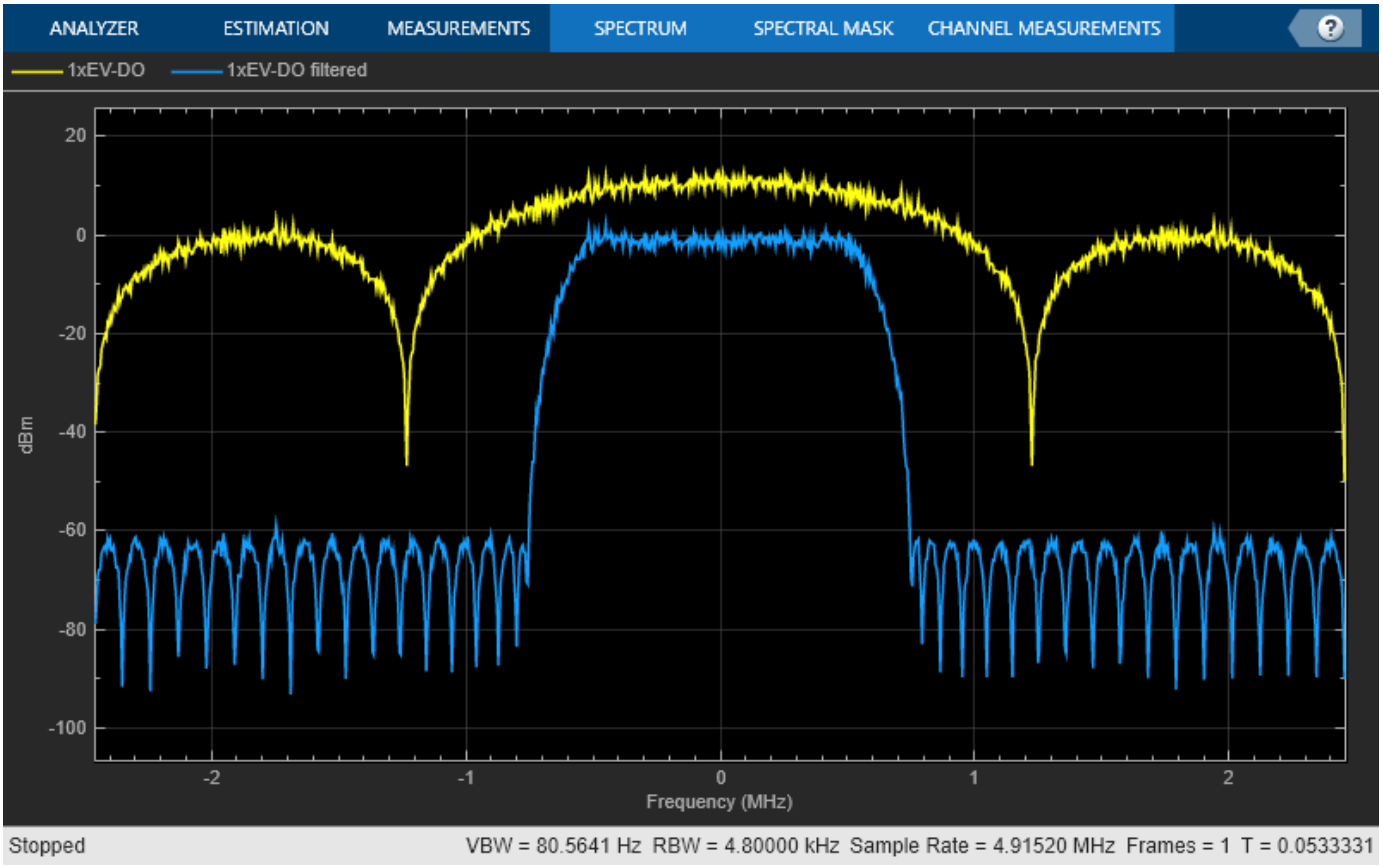
```
config.FilterType = "Custom";
config.CustomFilterCoefficients = d.Coefficients;
```

Generate the waveform using the custom filter coefficients.

```
filtwv = evdoReverseWaveformGenerator(config);
```

Plot the spectrum of the unfiltered and filtered 1xEV-DO waveform. The filter attenuates the waveform by 60 dB for frequencies outside of ± 750 kHz.

```
sa(wv,filtwv)
release(sa)
```



Input Arguments

`cfg` — Configuration of the parameters and channels used by the waveform generator

structure

Configuration of the parameters and channels used by the waveform generator. The configuration structure is defined in these tables.

Top-Level Parameters and Substructures

Parameter Field	Values	Description
`Release`	`'Release0'` | `'RevisionA'`	1xEV-DO applicable standard
`LongCodeMaskI`	42-bit binary number	Long code identifier for in-phase channel
`LongCodeMaskQ`	42-bit binary number	Long code identifier for quadrature channel
`NumChips`	Positive scalar integer	Number of chips in the waveform
`OversamplingRatio`	Positive scalar integer	Oversampling ratio at output
`FilterType`	`'cdma2000Long'` | `'cdma2000Short'` | `'Custom'` | `'Off'`	Specify the filter type or disable filtering

Parameter Field	Values	Description
CustomFilterCoefficients	Real vector	Custom filter coefficients (applies when `FilterType` is set to `'Custom'`)
InvertQ	`'Off'` | `'On'`	Negate the quadrature output
EnableModulation	`'Off'` | `'On'`	Enable carrier modulation
ModulationFrequency	Nonnegative scalar integer	Carrier modulation frequency (applies when `EnableModulation` is `'On'`)
ACKChannel	Structure	See **ACKChannel substructure**.
PilotChannel	Structure	See **PilotChannel substructure**.
AuxPilotChannel	Not present or structure	See **AuxPilotChannel substructure**.
PacketSequence	Structure	See **PacketSequence substructure**.

ACKChannel Substructure

Include the `ACKChannel` substructure in the `cfg` structure to specify the acknowledgment channel. The `ACKChannel` substructure contains these fields.

Parameter Fields	Values	Description
Enable	`'On'` | `'Off'`	Character vector to enable or disable the channel
Power	Real scalar	Channel power (dBW)
DataSource	Cell array, `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

PilotChannel Substructure

Include the `PilotChannel` substructure in the `cfg` structure to specify the pilot channel. The `PilotChannel` substructure contains these fields.

Parameter Fields	Values	Description
Enable	`'On'` | `'Off'`	Character vector to enable or disable the channel
Power	Real scalar	Channel power (dBW)
DataSource	Cell array, `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.
EnableCoding	`'On'` | `'Off'`	Enable channel coding

AuxPilotChannel Substructure

Include the `AuxPilotChannel` substructure in the `cfg` structure to specify the auxiliary pilot channel, which is available only for Revision A. The `AuxPilotChannel` substructure contains these fields.

Parameter Fields	Values	Description
`Enable`	`'On'` | `'Off'`	Character vector to enable or disable the channel
`Power`	Real scalar	Channel power (dBW)
`DataSource`	Cell array, `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.
`EnableCoding`	`'On'` | `'Off'`	Enable channel coding

PacketSequence Substructure

Include the `PacketSequence` substructure in the `cfg` structure to define a sequence of data packets for consecutive transmission. The `PacketSequence` substructure contains these fields.

Parameter Field	Values	Description
`Power`	Real scalar	MAC index associated with the packet
`EnableCoding`	`'Off'` | `'On'`	Enable error correction coding
`DataSource`	Cell array, `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.
Release 0		
`DataRate`	`9600` | `19200` | `38400` | `76800` | `153600`	Data rate (bps)
Revision A		
`PacketSize`	`128` | `256` | `512` | `768` | `1024` | `1536` | `2048` | `3072` | `4096` | `6144` | `8192` | `12288`	Packet size (bits)
`NumSlots`	`4` | `8` | `12` | `16`	Number of slots

Output Arguments

`waveform` — Modulated baseband waveform comprising the physical channels

complex vector array

Modulated baseband waveform comprising the 1xEV-DO physical channels, returned as a complex vector array.

Version History

Introduced in R2015b

References

See Also

`evdoReverseReferenceChannels` | `evdoForwardWaveformGenerator`

eyediagram

Generate eye diagram

Syntax

```
eyediagram(x,n)
eyediagram(x,n,period)
eyediagram(x,n,period,offset)
eyediagram(x,n,period,offset,plotstring)
eyediagram(x,n,period,offset,plotstring,h)
h = eyediagram( ___ )
```

Description

`eyediagram(x,n)` generates an eye diagram for signal `x`, plotting `n` samples in each trace. The labels on the horizontal axis of the diagram range between –1/2 and 1/2. The function assumes that the first value of the signal and every `n`th value thereafter, occur at integer times.

`eyediagram(x,n,period)` sets the labels on the horizontal axis to the range between –`period`/2 to `period`/2.

`eyediagram(x,n,period,offset)` specifies the offset for the eye diagram. The function assumes that the (`offset` + 1)th value of the signal and every `n`th value thereafter, occur at times that are integer multiples of `period`.

`eyediagram(x,n,period,offset,plotstring)` specifies plot attributes for the eye diagram.

`eyediagram(x,n,period,offset,plotstring,h)` generates the eye diagram in an existing figure whose handle is `h`.

Note Use of `hold on` to plot multiple signals in the same figure is not supported.

`h = eyediagram( ___ )` returns the handle to the figure that contains the eye diagram. You can specify any of the input argument combinations from the previous syntaxes.

Examples

Generate Eye Diagram of Filtered QPSK Signal

Generate an eyediagram of a filtered QPSK signal.

Generate random symbols. Apply QPSK modulation to get a modulated signal.

```
data = randi([0 3],1000,1);
modSig = pskmod(data,4,pi/4);
```

Specify the number of output samples per symbol parameter. Create a transmit filter object, `txfilter`.

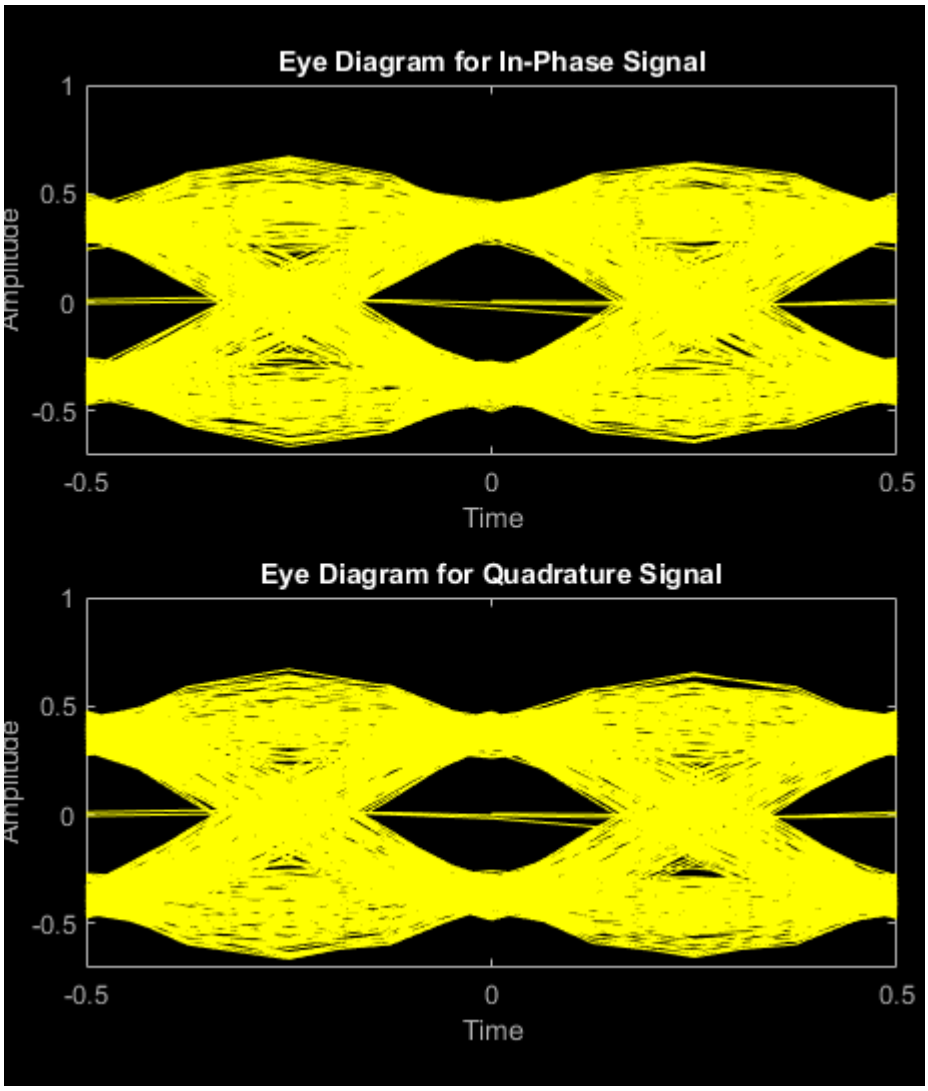
```
sps=4;
txfilter = comm.RaisedCosineTransmitFilter('OutputSamplesPerSymbol',sps);
```

Filter the modulated signal `modSig`.

```
txSig = txfilter(modSig);
```

Display the eye diagram.

```
eyediagram(txSig,2*sps)
```



Input Arguments

x — Input signal

vector | matrix

Input signal, specified as a vector or matrix.

The interpretation of `x` and the number of plots depend on the shape and complexity of `x`.

- If `x` is a real-valued two-column matrix, the function interprets the first column as in-phase components and the second column as quadrature components. The two components appear in different subplots of a single figure window.
- If `x` is a complex-valued vector, the function interprets the real part as in-phase components and the imaginary part as quadrature components. The two components appear in different subplots of a single figure window.
- If `x` is a real-valued vector, the function interprets the vector as a real signal. The figure window contains a single plot.

Data Types: `double`
Complex Number Support: Yes

`n` — Number of samples per trace
integer greater than 1

Number of samples per trace, specified as a integer greater than 1.

Data Types: `double`

`period` — Trace period
`1` (default) | positive scalar

Trace period, specified as a positive scalar. The labels on the horizontal axis of the eye diagram range between –`period`/2 to `period`/2.

Data Types: `double`

`offset` — Offset value
`0` (default) | integer in the range from 0 to (n–1)

Offset value, specified as an integer in the range 0 to (`n`–1). The function assumes that the (`offset` + 1)th value of the signal and every `n`th value thereafter, occur at times that are integer multiples of the input `period`.

Data Types: `double`

`plotstring` — Plot attributes
`'b-'` (default) | character vector | string scalar

Plot attributes, specified as a character vector or string scalar containing symbols.

This argument sets the plotting symbol, line type, and color for the eye diagram. The format and meaning of the symbols are the same as in the `plot` function. For example, the default value `'b-'` produces a solid blue line.

Data Types: `char` | `string`

`h` — Figure handle
`Figure` object

Figure handle to an existing figure that contains an eye diagram, specified as a `Figure` object. `h` must be a handle to a figure that the `eyediagram` function previously generated.

Output Arguments

h — Figure handle
`Figure` object

Figure handle, returned as a `Figure` object. To modify properties of this object, see Figure Properties.

Version History

Introduced before R2006a

fft

Discrete Fourier transform of Galois array

Syntax

```
fft(x)
```

Description

`fft(x)` is the discrete Fourier transform (DFT) of the Galois vector `x`. If `x` is in the Galois field GF(2^m), the length of `x` must be 2^m-1.

Examples

Discrete Fourier Transform of Galois Vector

Set the order of the Galois field. Because `x` is in the Galois field (2^4), the length of `x` must be $2^m - 1$.

```
m = 4;
n = 2^m-1;
```

Generate a random GF vector.

```
x = gf(randi([0 2^m-1],n,1),m);
```

Perform the Fourier transform.

```
y = fft(x);
```

Invert the transform.

```
z = ifft(y);
```

Confirm that the inverse transform `z = x`.

```
isequal(z,x)
```

```
ans = logical
   1
```

Limitations

The Galois field over which this function works must have 256 or fewer elements. In other words, `x` must be in the Galois field GF(2^m), where m is an integer between 1 and 8.

Algorithms

If `x` is a column vector, `fft` applies `dftmtx` to the primitive element of the Galois field and multiplies the resulting matrix by `x`.

Version History

Introduced before R2006a

Topics

“Signal Processing Operations in Galois Fields”

filter (Galois field)

1-D digital filter over Galois field

Syntax

```
y = filter(b,a,x)
[y,zf] = filter(b,a,x)
```

Description

`y = filter(b,a,x)` filters the data in the vector `x` with the filter described by numerator coefficient vector `b` and denominator coefficient vector `a`. The vectors `b`, `a`, and `x` must be Galois vectors in the same field. If `a(1)` is not equal to `1`, then `filter` normalizes the filter coefficients by `a(1)`. As a result, `a(1)` must be nonzero.

The filter is a *Direct Form II Transposed* implementation of the standard difference equation shown here:

```
a(1)*y(n) = b(1)*x(n) + b(2)*x(n-1) + ... + b(nb+1)*x(n-nb) ...
                      - a(2)*y(n-1) - ... - a(na+1)*y(n-na)
```

`[y,zf] = filter(b,a,x)` returns the final conditions of the filter delays in the Galois vector `zf`. The length of the vector `zf` is `max(size(a),size(b))-1`.

Examples

Filter a Galois Field

When using the Galois 1-D digital filter function, the data is normalized by the first element of the denominator coefficient vector.

```
a = gf([2 3 5 7],3);
b = gf([1 3],3);
x = gf(randi([0,7],10,1),3);
filt_x = filter(b,a,x)
```

```
filt_x = GF(2^3) array. Primitive polynomial = D^3+D+1 (11 decimal)

Array elements =

   6
   6
   3
   4
   7
   4
   2
   2
   0
   5
```

The first coefficient of the denominator coefficient vector, a(1) = 2. To confirm the function normalizes the data, manually normalize the filtered data. Use `isequal` to compare the outputs. We see they are equal.

```
filt_x2 = a(1) * filter(b/a(1),a,x)
```

```
filt_x2 = GF(2^3) array. Primitive polynomial = D^3+D+1 (11 decimal)

Array elements =

   6
   6
   3
   4
   7
   4
   2
   2
   0
   5
```

```
isequal(filt_x,filt_x2)
```

```
ans = logical
   1
```

fmdemod

Frequency demodulation

Syntax

```
z = fmdemod(y,Fc,Fs,freqdev)
z = fmdemod(y,Fc,Fs,freqdev,ini_phase)
```

Description

`z = fmdemod(y,Fc,Fs,freqdev)` returns a demodulated signal `z`, given the input frequency modulated (FM) signal `y`, where the carrier signal has frequency `Fc` and sampling rate `Fs`. `freqdev` is the frequency deviation of the modulated signal.

Note

- The value of `Fs` must satisfy $Fs \geq 2Fc$.
- The value of `freqdev` must satisfy $freqdev < Fc$.

`z = fmdemod(y,Fc,Fs,freqdev,ini_phase)` specifies the initial phase of the modulated signal in radians.

Examples

FM Modulate and Demodulate Sinusoidal Signal

Set the sampling frequency to 1kHz and carrier frequency to 200 Hz. Generate a time vector having a duration of 0.2 s.

```
fs = 1000;
fc = 200;
t = (0:1/fs:0.2)';
```

Create two-tone sinusoidal signal with frequencies 30 and 60 Hz.

```
x = sin(2*pi*30*t)+2*sin(2*pi*60*t);
```

Set the frequency deviation to 50 Hz.

```
fDev = 50;
```

Frequency modulate `x`.

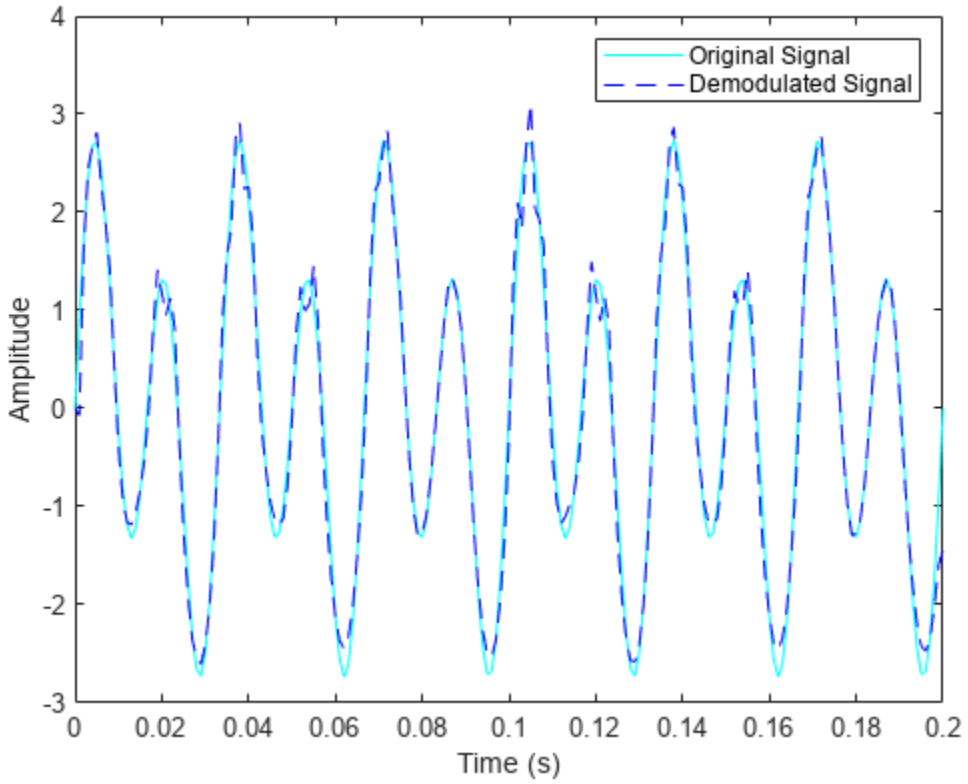
```
y = fmmod(x,fc,fs,fDev);
```

Demodulate z.

```
z = fmdemod(y,fc,fs,fDev);
```

Plot the original and demodulated signals.

```
plot(t,x,'c',t,z,'b--');
xlabel('Time (s)')
ylabel('Amplitude')
legend('Original Signal','Demodulated Signal')
```



The demodulated signal closely approximates the original.

Input Arguments

y — Frequency modulated input signal

scalar | vector | matrix | 3-D array

Frequency modulated input signal, specified as a scalar, vector, matrix, or 3-D array. Each element of y must be real.

Data Types: `double` | `single`

Fc — Carrier frequency

positive real scalar

Carrier frequency in hertz (Hz), specified as a positive real scalar.

Data Types: `double`

`Fs` — Sampling rate
positive scalar

Sampling rate in hertz (Hz), specified as a positive scalar.

Data Types: `double`

`freqdev` — Frequency deviation
positive scalar

Frequency deviation of the modulated signal in hertz (Hz), specified as a positive scalar.

Data Types: `double`

`ini_phase` — Initial phase
scalar

Initial phase of the modulated signal in radians, specified as a scalar.

Data Types: `double`

Output Arguments

`z` — Frequency demodulated output signal
scalar | vector | matrix | 3-D array

Frequency demodulated signal, returned as a scalar, vector, matrix, or 3-D array.

fmmod

Frequency modulation

Syntax

```
y = fmmod(x,Fc,Fs,freqdev)
y = fmmod(x,Fc,Fs,freqdev,ini_phase)
```

Description

`y = fmmod(x,Fc,Fs,freqdev)` returns a frequency modulated (FM) signal `y`, given the input message signal `x`, where the carrier signal has frequency `Fc` and sampling rate `Fs`. `freqdev` is the frequency deviation of the modulated signal.

Note

- The value of `Fs` must satisfy `Fs` ≥ 2`Fc`.
- The value of `freqdev` must satisfy `freqdev` < `Fc`.

`y = fmmod(x,Fc,Fs,freqdev,ini_phase)` specifies the initial phase of the modulated signal.

Examples

FM Modulate a Sinusoidal Signal

Set the sampling frequency to 1kHz and carrier frequency to 200 Hz. Generate a time vector having a duration of 0.2 s.

```
fs = 1000;
fc = 200;
t = (0:1/fs:0.2)';
```

Create two tone sinusoidal signal with frequencies 30 and 60 Hz.

```
x = sin(2*pi*30*t)+2*sin(2*pi*60*t);
```

Set the frequency deviation to 50 Hz.

```
fDev = 50;
```

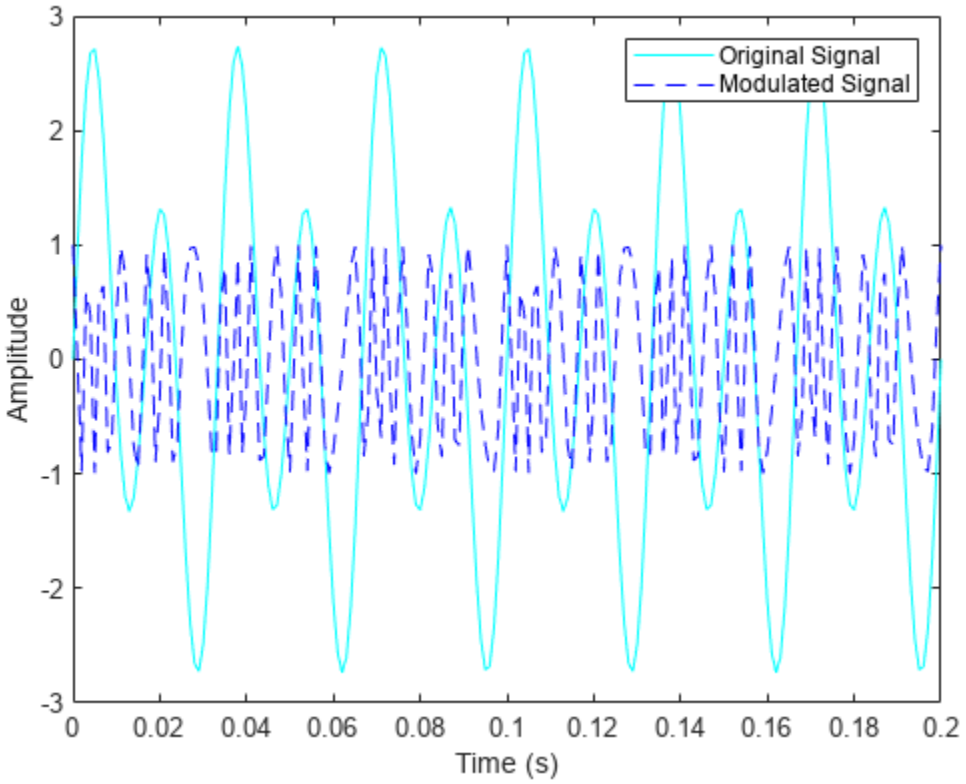
Frequency modulate `x`.

```
y = fmmod(x,fc,fs,fDev);
```

Plot the original and modulated signals.

```
plot(t,x,'c',t,y,'b--')
xlabel('Time (s)')
```

```
ylabel('Amplitude')
legend('Original Signal','Modulated Signal')
```



Input Arguments

x — Input message signal

scalar | vector | matrix | 3-D array

Input message signal, specified as a scalar, vector, matrix, or a 3-D array. Each element of `x` must be real.

Data Types: `single` | `double`

Fc — Carrier frequency

positive real scalar

Carrier frequency in hertz (Hz), specified as a positive real scalar.

Data Types: `single` | `double`

Fs — Sampling rate

positive real scalar

Sampling rate in hertz (Hz), specified as a positive real scalar.

Data Types: `single` | `double`

`freqdev` — Frequency deviation
positive real scalar

Frequency deviation of the modulated signal in hertz (Hz), specified as a positive real scalar.

Data Types: `single` | `double`

`ini_phase` — Initial phase
real scalar

Initial phase of the modulated signal in radians, specified as a real scalar.

Data Types: `single` | `double`

Output Arguments

`y` — Frequency modulated output signal
scalar | vector | matrix | 3-D array

Frequency modulated signal, returned as a scalar, vector, matrix, or 3-D array.

frequencyOffset

Apply frequency offset to input signal

Syntax

```
y = frequencyOffset(x,samplerate,offset)
```

Description

`y = frequencyOffset(x,samplerate,offset)` applies the specified frequency offset to the input signal `x`.

Examples

Apply Frequency Offset to Rectangular 16-QAM Signal

Generate a rectangular 16-point quadrature amplitude modulated (16-QAM) signal by modulating a vector of input data.

```
M = 16;
data = (0:M-1)';
x = qammod(data,M);
```

Specify the signal sample rate and the frequency offset to apply.

```
samplerate = 1;
offset = 100e3;
```

Apply the frequency offset to the input signal.

```
y = frequencyOffset(x,samplerate,offset);
```

Apply Frequency Offset to Sine Wave

Define parameters to configure the signal and spectrum analyzer.

```
fc = 1e6;         % Carrier frequency (Hz)
fs = 4e6;         % Sample rate (Hz)
Nspf = 100e3;     % Number of samples per frame
freqSpan = 400e3; % Frequency span for spectrum computation (Hz)
```

Create sine wave and spectrum analyzer objects with the specified parameter values.

```
sinewave = dsp.SineWave(Amplitude=1, ...
    Frequency=fc, ...
    SampleRate=fs, ...
    SamplesPerFrame=Nspf, ...
    ComplexOutput=true);
```

```
sascope = spectrumAnalyzer( ...
    SampleRate=fs, ...
    FrequencySpan="Span and center frequency", ...
    CenterFrequency=fc, ...
    Span=freqSpan, ...
    SpectrumType="Power density", ...
    SpectralAverages=10, ...
    SpectrumUnits="dBW/Hz", ...
    ShowLegend=true, ...
    ChannelNames=["Input sine wave","Frequency-offset sine wave"], ...
    YLimits=[-50 10]);
```

Generate a sine wave signal.

```
x = sinewave();
```

Apply a frequency offset of 100 kHz to the signal.

```
offset = 100e3;
y = frequencyOffset(x,fs,offset);
```

Display the input and frequency-shifted signals by using the spectrum analyzer.

```
sascope(x,y)
```

Input Arguments

x — Input signal

column vector | matrix

Input signal, specified as a column vector or matrix.

Data Types: `double` | `single`
Complex Number Support: Yes

`samplerate` — Sampling rate

positive scalar

Sampling rate of the input signal in Hz, specified as a positive scalar.

Data Types: `double`

`offset` — Frequency offset

scalar | row vector

Frequency offset in Hz, specified as a scalar or row vector.

- If `offset` is a scalar, the function applies the same frequency offset to each channel.
- If `offset` is a vector, then each element specifies the frequency offset that the function applies to the corresponding column (channel) of the input signal. The number of elements in `offset` must equal the number of columns in `x`.

Data Types: `double`

Output Arguments

y — Output signal

column vector | matrix

Output signal, returned as a vector or matrix with the same dimensions and data type as `x`. The number of columns in `y` corresponds to the number of channels.

Data Types: `double` | `single`
Complex Number Support: Yes

Phase/Frequency Offset

fskdemod

Frequency shift keying demodulation

Syntax

```
z = fskdemod(y,M,freq_sep,nsamp)
z = fskdemod(y,M,freq_sep,nsamp,Fs)
z = fskdemod(y,M,freq_sep,nsamp,Fs,symorder)
```

Description

`z = fskdemod(y,M,freq_sep,nsamp)` noncoherently demodulates the complex envelope `y` of a signal using the frequency shift key method.

`z = fskdemod(y,M,freq_sep,nsamp,Fs)` specifies the sampling frequency in Hz.

`z = fskdemod(y,M,freq_sep,nsamp,Fs,symorder)` specifies how the function assigns binary words to corresponding integers.

Examples

Modulation and Demodulation of an FSK Signal in AWGN

Pass an FSK signal through an AWGN channel and estimate the resulting bit error rate (BER). Compare the estimated BER to the theoretical value.

Set the simulation parameters.

```
M = 2;          % Modulation order
k = log2(M);    % Bits per symbol
EbNo = 5;       % Eb/No (dB)
Fs = 16;        % Sample rate (Hz)
nsamp = 8;      % Number of samples per symbol
freqsep = 10;   % Frequency separation (Hz)
```

Generate random data symbols.

```
data = randi([0 M-1],5000,1);
```

Apply FSK modulation.

```
txsig = fskmod(data,M,freqsep,nsamp,Fs);
```

Pass the signal through an AWGN channel

```
rxSig  = awgn(txsig,EbNo+10*log10(k)-10*log10(nsamp),...
    'measured',[],'dB');
```

Demodulate the received signal.

```
dataOut = fskdemod(rxSig,M,freqsep,nsamp,Fs);
```

Calculate the bit error rate.

```
[num,BER] = biterr(data,dataOut);
```

Determine the theoretical BER and compare it to the estimated BER. Your BER value might vary because the example uses random numbers.

```
BER_theory = berawgn(EbNo,'fsk',M,'noncoherent');
[BER BER_theory]
```

```
ans = 1×2

    0.0958    0.1029
```

Input Arguments

y — FSK-modulated output signal

vector | matrix

Complex baseband representation of a FSK-modulated signal, specified as vector or matrix of complex values. If `y` is a matrix with multiple rows and columns, fskdemod processes the columns independently.

Data Types: `double` | `single`

M — Modulation order

integer power of two

Modulation order, specified as an integer power of two.

Example: 2 | 4 | 16

Data Types: `double`

symorder — Symbol order

`'bin'` (default) | `'gray'`

Symbol order, specified as `'bin'` or `'gray'`. This argument specifies how the function assigns binary vectors to corresponding integers.

- If `symorder` is `'bin'`, the function uses a binary-coded ordering.
- If `symorder` is `'gray'`, the function uses a Gray-coded ordering.

Data Types: `char`

freq_sep — Desired separation between frequencies

positive scalar

Desired separation between frequencies, specified in Hz. By the Nyquist sampling theorem, `freq_sep` and `M` must satisfy (`M`-1)*`freq_sep` <= 1.

Data Types: `double`

nsamp — Number of samples per output symbol

positive scalar greater than 1

Number of samples per output symbol, specified as a positive scalar greater than 1.

Data Types: `double`

Fs — Sample rate
1 Hz (default) | positive scalar

Sample rate, specified as a positive scalar.

Data Types: `double`

Output Arguments

z — Output signal
vector | matrix

Output signal, returned as a vector or matrix of positive integers. The elements of `z` have values in the range of [0, `M` – 1].

Example: `randi([0 3],100,1)`

Data Types: `double`

fskmod

Frequency shift keying modulation

Syntax

```
y = fskmod(x,M,freq_sep,nsamp)
y = fskmod(x,M,freq_sep,nsamp,Fs)
y = fskmod(x,M,freq_sep,nsamp,Fs,phase_cont)
y = fskmod(x,M,freq_sep,nsamp,Fs,phase_cont,symorder)
```

Description

`y = fskmod(x,M,freq_sep,nsamp)` outputs the complex envelope `y` of the modulation of the message signal `x` using frequency shift keying modulation.

`y = fskmod(x,M,freq_sep,nsamp,Fs)` specifies the sampling rate of `y`.

`y = fskmod(x,M,freq_sep,nsamp,Fs,phase_cont)` specifies the phase continuity.

`y = fskmod(x,M,freq_sep,nsamp,Fs,phase_cont,symorder)` specifies how the function assigns binary words to corresponding integers.

Examples

Plot FSK Signal Spectrum

Generate an FSK modulated signal and display its spectral characteristics.

Set the function parameters.

```
M = 4;       % Modulation order
freqsep = 8; % Frequency separation (Hz)
nsamp = 8;   % Number of samples per symbol
Fs = 32;     % Sample rate (Hz)
```

Generate random M-ary symbols.

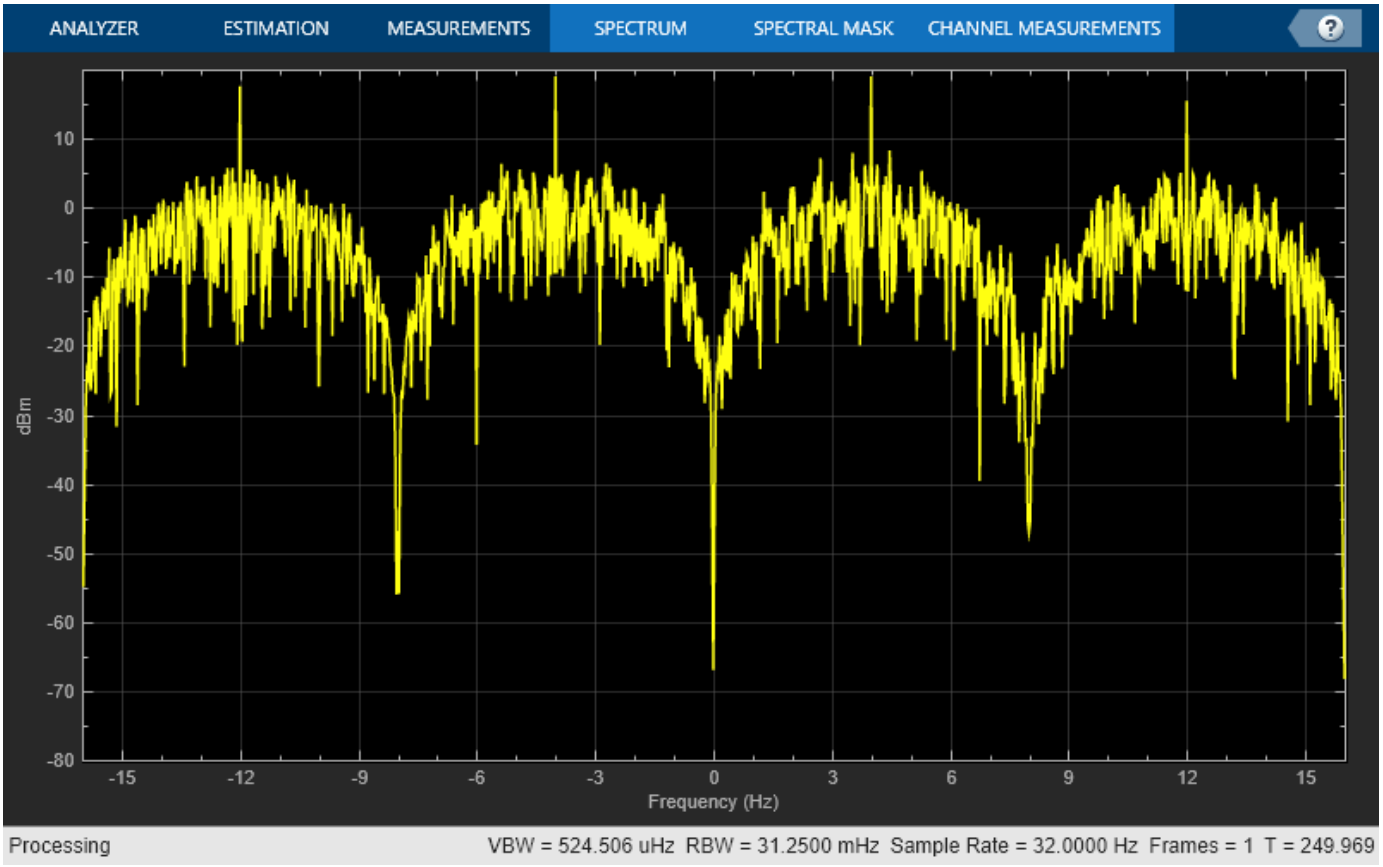
```
x = randi([0 M-1],1000,1);
```

Apply FSK modulation.

```
y = fskmod(x,M,freqsep,nsamp,Fs);
```

Create a spectrum analyzer System object™ and call it to display a plot of the signal spectrum.

```
specAnal = spectrumAnalyzer(SampleRate=Fs);
specAnal(y)
```



Input Arguments

`x` — Input signal

vector | matrix

Input signal, specified as a vector or matrix of positive integers. The elements of `x` must have values in the range of [0, `M` – 1]. If `x` is a matrix, `fskmod` processes the columns independently.

Example: `randi([0 3],100,1)`

Data Types: `double`

`M` — Modulation order

integer power of two

Modulation order, specified as an integer power of two.

Example: 2 | 4 | 16

Data Types: `double`

`symorder` — Symbol order

`'bin'` (default) | `'gray'`

Symbol order, specified as `'bin'` or `'gray'`. This argument specifies how the function assigns binary vectors to corresponding integers.

- If `symorder` is `'bin'`, the function uses a natural binary-coded ordering.
- If `symorder` is `'gray'`, the function uses a Gray-coded ordering.

Data Types: `char`

`freq_sep` — Desired separation between frequencies
positive scalar

Desired separation between frequencies, specified in Hz. By the Nyquist sampling theorem, `freq_sep` and `M` must satisfy (`M`-1)*`freq_sep` <= 1.

Data Types: `double`

`nsamp` — Number of samples per output symbol
positive scalar greater than 1

Number of samples per output symbol, specified as a positive scalar greater than 1.

Data Types: `double`

`Fs` — Sample rate
1 Hz (default) | positive scalar

Sample rate, specified as a positive scalar.

Data Types: `double`

`phase_cont` — Phase continuity
`'cont'` (default) | `'discont'`

Phase continuity, specified as either `'cont'` or `'discont'`. Set `phase_cont` to `'cont'` to force phase continuity across symbol boundaries in `y`, or `'discont'` to avoid forcing phase continuity.

Data Types: `char`

Output Arguments

`y` — FSK-modulated output signal
vector | matrix

Complex baseband representation of a FSK-modulated signal, returned as vector or matrix of complex values. The columns of `y` represent independent channels.

Data Types: `double` | `single`

Version History

Introduced before R2006a

gen2par

Convert between parity-check and generator matrices

Syntax

```
parmat = gen2par(genmat)
genmat = gen2par(parmat)
```

Description

`parmat = gen2par(genmat)` converts the standard-form binary generator matrix `genmat` into the corresponding parity-check matrix `parmat`.

`genmat = gen2par(parmat)` converts the standard-form binary parity-check matrix `parmat` into the corresponding generator matrix `genmat`.

The standard forms of the generator and parity-check matrices for an [n,k] binary linear block code are shown in the table below

Type of Matrix	Standard Form	Dimensions
Generator	[I_k P] or [P I_k]	k-by-n
Parity-check	[-P' I_{n-k}] or [I_{n-k} -P']	(n-k)-by-n

.

where I_k is the identity matrix of size k and the ' symbol indicates matrix transpose. Two standard forms are listed for each type, because different authors use different conventions. For *binary* codes, the minus signs in the parity-check form listed above are irrelevant; that is, -1 = 1 in the binary field.

Examples

Convert Parity-Check Matrix for a Hamming Code to Generator Matrix

Convert the parity-check matrix for a Hamming code into the corresponding generator matrix and back again.

Create the parity-check matrix.

```
parmat = hammgen(3)
```

```
parmat = 3×7

     1     0     0     1     0     1     1
     0     1     0     1     1     1     0
     0     0     1     0     1     1     1
```

Convert the parity-check matrix into the corresponding generator matrix.

```
genmat = gen2par(parmat)
```

```
genmat = 4×7

     1     1     0     1     0     0     0
     0     1     1     0     1     0     0
     1     1     1     0     0     1     0
     1     0     1     0     0     0     1
```

Convert the generator matrix back again. The output, `parmat2`, should be the same as the original matrix, `parmat`.

```
parmat2 = gen2par(genmat)
```

```
parmat2 = 3×7

     1     0     0     1     0     1     1
     0     1     0     1     1     1     0
     0     0     1     0     1     1     1
```

genqamdemod

General quadrature amplitude demodulation

Syntax

```
z = genqamdemod(y,const)
```

Description

`z = genqamdemod(y,const)` demodulates the complex envelope, `y`, of a quadrature amplitude modulated signal using the signal mapping specified in `const`.

Examples

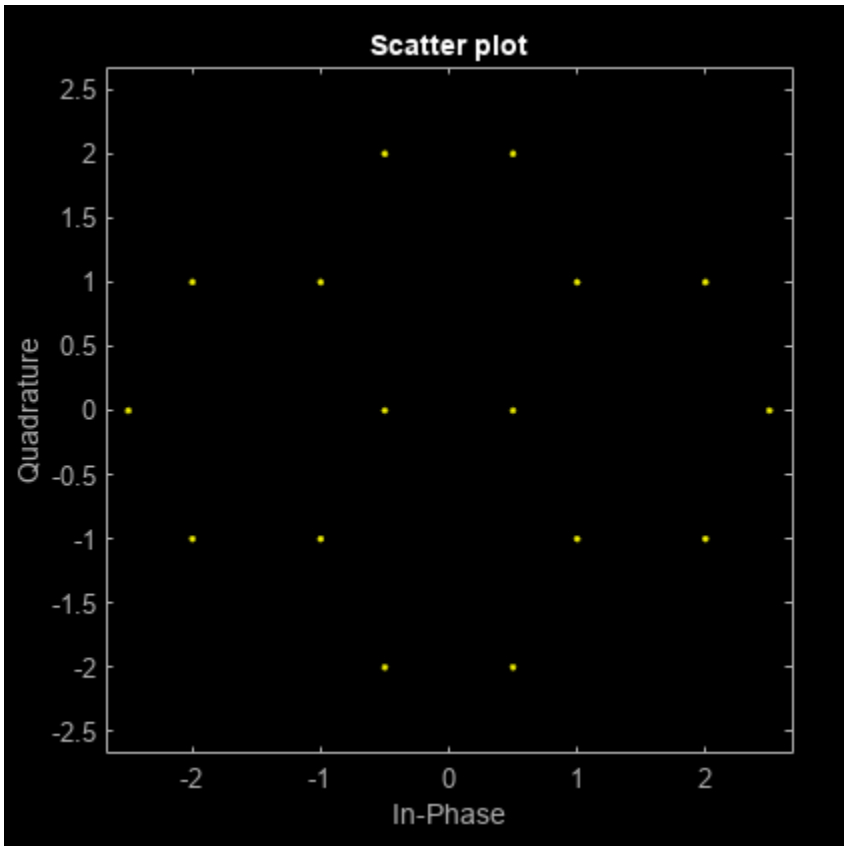
General QAM Modulation and Demodulation

Create the points that describe a hexagonal constellation.

```
inphase = [1/2 1 1 1/2 1/2 2 2 5/2];
quadr = [0 1 -1 2 -2 1 -1 0];
inphase = [inphase;-inphase]; inphase = inphase(:);
quadr = [quadr;quadr]; quadr = quadr(:);
const = inphase + 1i*quadr;
```

Plot the constellation.

```
h = scatterplot(const);
```



Generate input data symbols. Modulate the symbols using this constellation.

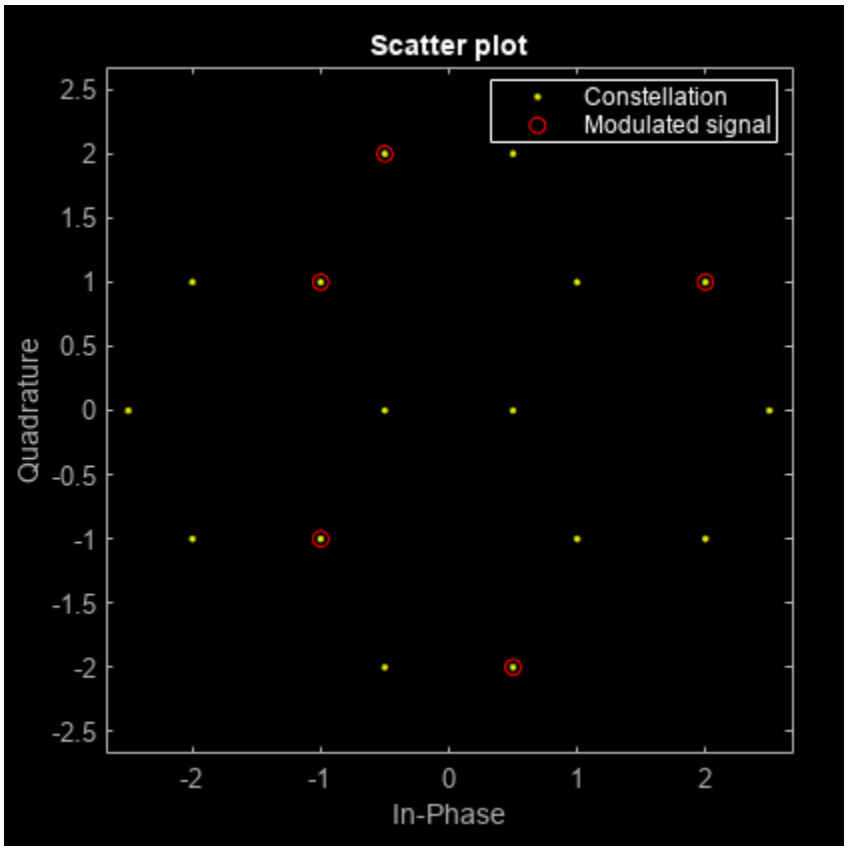
```
x = [3 8 5 10 7];
y = genqammod(x,const);
```

Demodulate the modulated signal, `y`.

```
z = genqamdemod(y,const);
```

Plot the modulated signal in same figure.

```
hold on;
scatterplot(y,1,0,'ro',h);
legend('Constellation','Modulated signal');
```



Determine the number of symbol errors between the demodulated data to the original sequence.

```
numErrs = symerr(x,z)
```

```
numErrs = 0
```

Input Arguments

y — Complex envelope

scalar | vector | matrix | 3-D array

Complex envelope, specified as a scalar, vector, matrix, or 3-D array of numeric values. If `y` is a matrix with multiple rows, the function processes the rows independently.

const — Signal mapping

complex vector

Signal mapping, specified as a complex vector.

Data Types: `double` | `single`

Output Arguments

z — Message signal

scalar | vector | matrix | 3-D array

Message signal, returned as a scalar, vector, matrix, or 3-D array of numeric values. The message signal consists of integers between 0 and `length(const)`–1. The datatype of `z` is the same as the data type of input `x`.

Data Types: `double` | `single`

Version History

Introduced before R2006a

Topics

“Digital Baseband Modulation”

genqammod

General quadrature amplitude modulation (QAM)

Syntax

```
y = genqammod(x,const)
```

Description

`y = genqammod(x,const)` returns the complex envelop of the QAM for message signal `x`. Input `const` specifies the signal mapping for the modulation.

Examples

Estimate Symbol Rate for General QAM Modulation in AWGN Channel

Transmit and receive data using a nonrectangular 16-ary constellation in the presence of Gaussian noise. Show the scatter plot of the noisy constellation and estimate the symbol error rate (SER) for two different SNRs.

Create a 16-QAM constellation based on the V.29 standard for telephone-line modems.

```
c = [-5 -5i 5 5i -3 -3-3i -3i 3-3i 3 3+3i 3i -3+3i -1 -1i 1 1i];
sigpower = pow2db(mean(abs(c).^2));
M = length(c);
```

Generate random symbols.

```
data = randi([0 M-1],2000,1);
```

Modulate the data by using the `genqammod` function. General QAM modulation is necessary because the custom constellation is not rectangular.

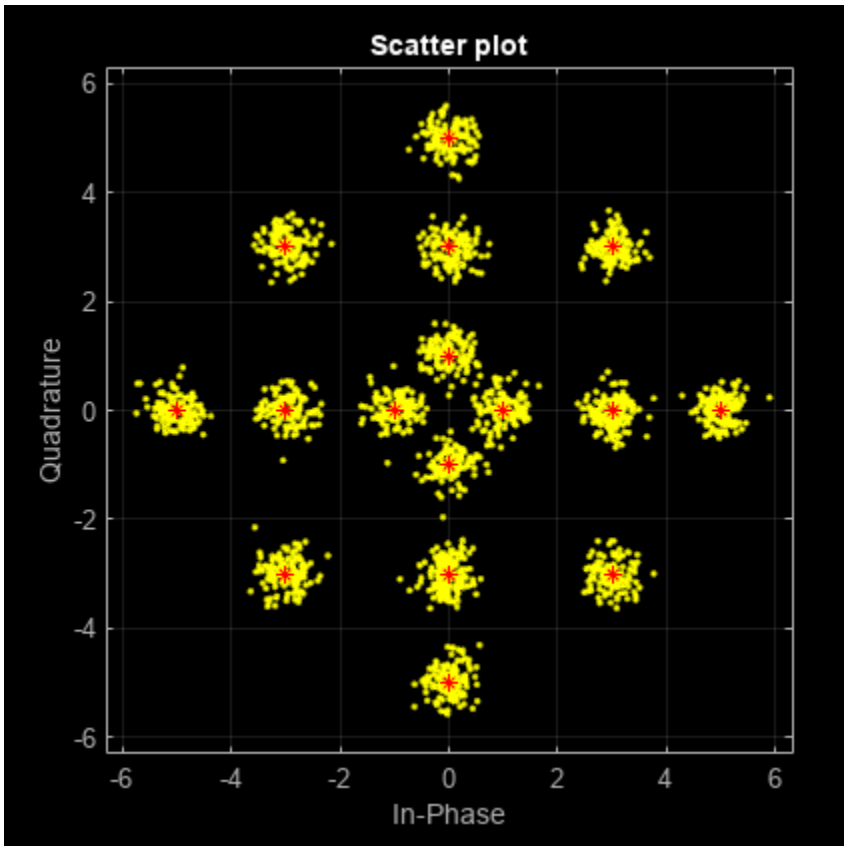
```
modData = genqammod(data,c);
```

Pass the signal through an AWGN channel with a 20 dB SNR.

```
rxSig = awgn(modData,20,sigpower);
```

Display a scatter plot of the received signal and the reference constellation `c`.

```
h = scatterplot(rxSig);
hold on
scatterplot(c,[],[],'r*',h)
grid
hold off
```



Demodulate the received signal by using the `genqamdemod` function. Determine the number of symbol errors and the SER.

```
demodData = genqamdemod(rxSig,c);
[numErrors,ser] = symerr(data,demodData)
```

```
numErrors = 1

ser = 5.0000e-04
```

Repeat the transmission and demodulation process with an AWGN channel with a 10 dB SNR. Determine the SER for the reduced SNR. As expected, the performance degrades when the SNR is decreased.

```
rxSig = awgn(modData,10,sigpower);
demodData = genqamdemod(rxSig,c);
[numErrors,ser] = symerr(data,demodData)
```

```
numErrors = 461

ser = 0.2305
```

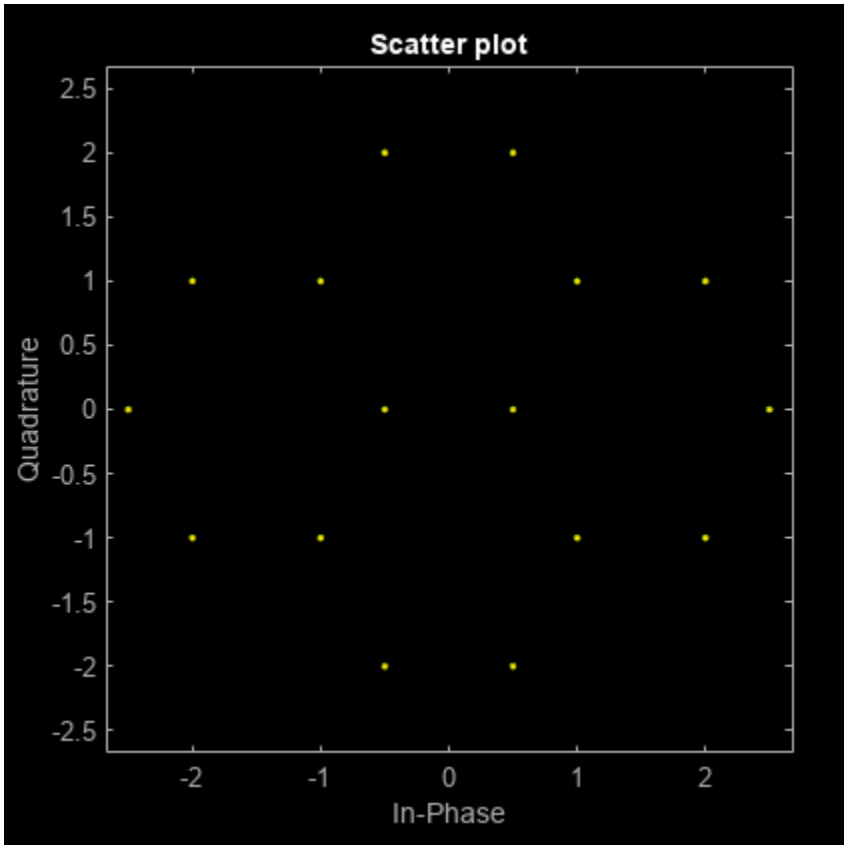
General QAM Modulation and Demodulation

Create the points that describe a hexagonal constellation.

```
inphase = [1/2 1 1 1/2 1/2 2 2 5/2];
quadr = [0 1 -1 2 -2 1 -1 0];
inphase = [inphase;-inphase]; inphase = inphase(:);
quadr = [quadr;quadr]; quadr = quadr(:);
const = inphase + 1i*quadr;
```

Plot the constellation.

```
h = scatterplot(const);
```



Generate input data symbols. Modulate the symbols using this constellation.

```
x = [3 8 5 10 7];
y = genqammod(x,const);
```

Demodulate the modulated signal, `y`.

```
z = genqamdemod(y,const);
```

Plot the modulated signal in same figure.

```
hold on;
scatterplot(y,1,0,'ro',h);
legend('Constellation','Modulated signal');
```

Determine the number of symbol errors between the demodulated data to the original sequence.

```
numErrs = symerr(x,z)
```

```
numErrs = 0
```

Input Arguments

x — Message signal

scalar | vector | matrix | 3-D array

Message signal, specified as a scalar, vector, matrix, or 3-D array of numeric values. The message signal must consist of integers from 0 and `length(const)`–1. If `x` is a matrix with multiple rows, the function processes the columns independently.

Data Types: `double` | `single` | `fi` | `int8` | `int16` | `uint8` | `uint16`

const — Signal mapping

complex vector

Signal mapping, specified as a complex vector.

Data Types: `double` | `single` | `fi` | `int8` | `int16` | `uint8` | `uint16`

Output Arguments

y — Complex envelope
scalar | vector | matrix | 3-D array

Complex envelope, returned as a scalar, vector, matrix, or 3-D array of numeric values. The length of `y` is the same as the length of input `x`.

Data Types: `double` | `single` | `fi` | `int8` | `int16` | `uint8` | `uint16`

Version History

Introduced before R2006a

getTurboIOIndices

Compute output indices for turbo coding

Syntax

```
indices=getTurboIOIndices(blklen,N,mlen)
indices=getTurboIOIndices(blklen,N,mlen,'LTE')
```

Description

Use getTurboIOIndices to generate the output indices for the `comm.TurboEncoder` and input indices for the `comm.TurboDecoder` and System objects.

`indices=getTurboIOIndices(blklen,N,mlen)` computes the indices for a given input block length, `blklen`, number of output streams, `N`, and the memory length, `mlen`, relative to the fully encoded output. In this mode, the second interleaved, systematic bit-stream is punctured. `N` and `mlen` correspond to the constituent coder configuration for the `comm.TurboEncoder` and `comm.TurboDecoder` System objects.

`indices=getTurboIOIndices(blklen,N,mlen,'LTE')` computes LTE-like output indices as specified by TS 36.212. For LTE, the second systematic bit-stream is punctured and the tail bits are reordered.

Examples

Create Output Indices for Turbo Encoder

Create output indices for use with a turbo encoder System object™.

Initialize input parameters for a constituent turbo encoder configuration having 2 streams, 3 registers and a block length of 64. Create the output indices vector. Display the number of tail bits and the values of the tail bits.

```
blklen = 64; % Block length
N = 2;       % Number of streams
mlen = 3;    % Number of registers
firsttailbit = blklen * (2*N - 1) + 1;
outindices = getTurboIOIndices(blklen,N,mlen);
numtailbits = length(outindices(firsttailbit:end)')
```

```
numtailbits = 9
```

```
tailbits = outindices(firsttailbit:end)'
```

```
tailbits = 1×9

   257   258   260   261   262   264   265   266   268
```

For comparison, keep the same input settings for the block length, number of streams, and number of registers, but create a set of LTE-like output indices vector by adding `'LTE'` as the fourth input argument.

```
outindices = getTurboIOIndices(blklen,N,mlen,'LTE');
```

Display the number of tail bits and the values of the tail bits. The LTE-like output indices have ordering as specified in TS 36.212 and include tail bits for all output streams.

```
numtailbitsLTE = length(outindices(firsttailbit:end)')
```

```
numtailbitsLTE = 12
```

```
tailbitsLTE = outindices(firsttailbit:end)'
```

```
tailbitsLTE = 1×12

   257   258   261   262   265   266   259   260   263   264   267   268
```

Input Arguments

`blklen` — Block length

64 (default) | nonnegative integer

Block length, specified as a nonnegative integer.

Data Types: `double`

`N` — Number of output streams

2 (default) | integer greater than 1

Number of output streams, specified as an integer greater than 1.

Data Types: `double`

`mlen` — Number of registers

2 (default) | integer

Number of registers, specified as a positive integer.

Data Types: `double`

Output Arguments

`indices` — Output indices

column vector

Output indices, returned as column vector of positive integers.

Version History

Introduced in R2021a

gf

Galois field array

Syntax

```
x_gf = gf(x)
x_gf = gf(x,m)
x_gf = gf(x,m,prim_poly)
```

Description

`x_gf = gf(x)` creates a Galois field (GF) array, GF(2), from matrix `x`.

`x_gf = gf(x,m)` creates a Galois field array from matrix `x`. The Galois field has 2^m elements, where `m` is an integer from 1 through 16.

`x_gf = gf(x,m,prim_poly)` creates a Galois field array from matrix `x` by using the primitive polynomial `prim_poly`.

Examples

Create GF(2) Array from Specified Matrix

Specify a matrix of `0`s and `1`s.

```
x = [0 1 1; 0 1 0; 1 1 1];
```

Create a GF(2) array from `x`.

```
x_gf = gf(x)
```

```
x_gf = GF(2) array.

Array elements =

   0   1   1
   0   1   0
   1   1   1
```

Create Sequence of GF(16) Elements

Set the order of the Galois field to 16, where the order equals 2^m. Specify a matrix of elements that range from 0 to $2^m - 1$. Create the Galois field array.

```
m = 4;
x = [3 2 9; 1 2 1];
y = gf(x,m)
```

```
y = GF(2^4) array. Primitive polynomial = D^4+D+1 (19 decimal)

Array elements =

   3   2   9
   1   2   1
```

Create GF Sequence with Specified Primitive Polynomial

Create a sequence of integers. Create a Galois field array in GF(2^5).

```
x = [17 8 11 27];
y = gf(x,5)
```

```
y = GF(2^5) array. Primitive polynomial = D^5+D^2+1 (37 decimal)

Array elements =

   17    8   11   27
```

Determine all possible primitive polynomials for GF(2^5).

```
pp = primpoly(5,'all')
```

```
Primitive polynomial(s) =

D^5+D^2+1
D^5+D^3+1
D^5+D^3+D^2+D^1+1
D^5+D^4+D^2+D^1+1
D^5+D^4+D^3+D^1+1
D^5+D^4+D^3+D^2+1

pp = 6×1

    37
    41
    47
    55
    59
    61
```

Create a Galois field array using the primitive polynomial that has a decimal equivalent of 59.

```
z = gf(x,5,'D5+D4+D3+D+1')
```

```
z = GF(2^5) array. Primitive polynomial = D^5+D^4+D^3+D+1 (59 decimal)

Array elements =

   17    8   11   27
```

Check Galois Generator Polynomial Validity

Use the `genpoly2b` function to return the corresponding Galois field array value and the generator polynomial validity indication.

Create a valid Galois field array object.

```
genpoly = gf([1 1 6],3)

genpoly = GF(2^3) array. Primitive polynomial = D^3+D+1 (11 decimal)

Array elements =

   1   1   6

[b,ecode] = genpoly2b(genpoly,3,11)

b = 1

ecode = 1
```

Input Arguments

`x` — Input matrix

matrix with all values greater than or equal to zero

Input matrix, specified as a matrix with values greater than or equal to zero. The function uses this value to create a GF array.

- If you do not specify the `prim_poly` input argument, each element of `x` must be an integer in the range [0, 2^m–1].
- If you specify `prim_poly` input argument, each element of `x` must be `0` or `1`.

Data Types: `double`

`m` — Order of primitive polynomial

positive integer

Order of primitive polynomial, specified as a positive integer from 1 through 16. The function uses this value to calculate the distinct number of elements in the GF.

Data Types: `double`

`prim_poly` — Primitive polynomial

primitive polynomial in GF(2^m) (default) | binary row vector | character vector | string scalar | positive integer

Primitive polynomial, specified as one of these options:

- Binary row vector — This vector specifies coefficients of `prim_poly` in the order of ascending powers.

- Character vector or a string scalar — This value defines `prim_poly` in a textual representation. For more details, refer to polynomial character vector.
- Positive integer — This value defines `prim_poly` in the range $[(2^m + 1), (2^{m+1} - 1)]$.

If `prim_poly` is not specified, see “Default Primitive Polynomials” on page 2-367 for the list of default primitive polynomial used for each Galois field array GF(2^m).

Data Types: `double` | `char` | `string`

Output Arguments

x_gf — Galois field array

variable that MATLAB recognizes as a Galois field array

Galois field array, returned as a variable that MATLAB recognizes as a Galois field array, rather than an array of integers. As a result, when you manipulate the variable, MATLAB works within the Galois field the variable specifies. For example, if you apply the `log` function to a Galois array, MATLAB computes the logarithm in the Galois field for that Galois array and not in the field of real or complex numbers.

More About

Default Primitive Polynomials

This table lists the default primitive polynomial used for each Galois field array GF(2^m). To use a different primitive polynomial, specify `prim_poly` as an input argument. `prim_poly` must be in the range $[(2^m + 1), (2^{m+1} - 1)]$ and must indicate an irreducible polynomial. For more information, see “Primitive Polynomials and Element Representations”.

Value of m	Default Primitive Polynomial	Integer Representation
1	$D + 1$	3
2	$D^2 + D + 1$	7
3	$D^3 + D + 1$	11
4	$D^4 + D + 1$	19
5	$D^5 + D^2 + 1$	37
6	$D^6 + D + 1$	67
7	$D^7 + D^3 + 1$	137
8	$D^8 + D^4 + D^3 + D^2 + 1$	285
9	$D^9 + D^4 + 1$	529
10	$D^{10} + D^3 + 1$	1033
11	$D^{11} + D^2 + 1$	2053
12	$D^{12} + D^6 + D^4 + D + 1$	4179
13	$D^{13} + D^4 + D^3 + D + 1$	8219
14	$D^{14} + D^{10} + D^6 + D + 1$	17475
15	$D^{15} + D + 1$	32771

Value of m	Default Primitive Polynomial	Integer Representation
16	$D^{16} + D^{12} + D^3 + D + 1$	69643

Galois Computations

This table lists the operations supported for Galois field arrays.

Operation	Description
+ -	Addition and subtraction of Galois arrays
* / \	Matrix multiplication and division of Galois arrays
.* ./ .\	Elementwise multiplication and division of Galois arrays
^	Matrix exponentiation of Galois array
.^	Elementwise exponentiation of Galois array
' .'	Transpose of Galois array
==, ~=	Relational operators for Galois arrays
all	True if all elements of a Galois vector are nonzero
any	True if any element of a Galois vector is nonzero
conv	Convolution of Galois vectors
`convmtx`	Convolution matrix of Galois field vector
deconv	Deconvolution and polynomial division
det	Determinant of square Galois matrix
`dftmtx`	Discrete Fourier transform matrix in a Galois field
diag	Diagonal Galois matrices and diagonals of a Galois matrix
`fft`	Discrete Fourier transform
`filter (gf)`	One-dimensional digital filter over a Galois field
`ifft`	Inverse discrete Fourier transform
inv	Inverse of Galois matrix
length	Length of Galois vector
`log`	Logarithm in a Galois field
lu	Lower-Upper triangular factorization of Galois array
`minpol`	Find the minimal polynomial for a Galois element
`mldivide`	Matrix left division \ of Galois arrays
polyval	Evaluate polynomial in Galois field
rank	Rank of a Galois array
reshape	Reshape Galois array
roots	Find polynomial roots across a Galois field
size	Size of Galois array

Operation	Description
tril	Extract lower triangular part of Galois array
triu	Extract upper triangular part of Galois array

gfadd

Add polynomials over Galois field

Syntax

```
c = gfadd(a,b)
c = gfadd(a,b,p)
c = gfadd(a,b,p,len)
c = gfadd(a,b,field)
```

Description

Note This function performs computations in GF(p^m) where p is prime. To work in GF(2^m), apply the + operator to Galois arrays of equal size. For details, see “Example: Addition and Subtraction”.

`c = gfadd(a,b)` adds two GF(2) polynomials, `a` and `b`, which can be either polynomial character vectors or numeric vectors. If `a` and `b` are vectors of the same orientation but different lengths, then the shorter vector is zero-padded. If `a` and `b` are matrices they must be of the same size.

`c = gfadd(a,b,p)` adds two GF(`p`) polynomials, where `p` is a prime number. `a`, `b`, and `c` are row vectors that give the coefficients of the corresponding polynomials in order of ascending powers. Each coefficient is between 0 and `p`-1. If `a` and `b` are matrices of the same size, the function treats each row independently.

`c = gfadd(a,b,p,len)` adds row vectors `a` and `b` as in the previous syntax, except that it returns a row vector of length `len`. The output `c` is a truncated or extended representation of the sum. If the row vector corresponding to the sum has fewer than `len` entries (including zeros), extra zeros are added at the end; if it has more than `len` entries, entries from the end are removed.

`c = gfadd(a,b,field)` adds two GF(p^m) elements, where m is a positive integer. `a` and `b` are the exponential format of the two elements, relative to some primitive element of GF(p^m). `field` is the matrix listing all elements of GF(p^m), arranged relative to the same primitive element. `c` is the exponential format of the sum, relative to the same primitive element. See “Representing Elements of Galois Fields” for an explanation of these formats. If `a` and `b` are matrices of the same size, the function treats each element independently.

Examples

Add Two GF Arrays

Sum $2 + 3x + x^2$ and $4 + 2x + 3x^2$ over GF(5).

```
x = gfadd([2 3 1],[4 2 3],5)
```

```
x = 1×3

     1     0     4
```

Add the two polynomials and display the first two elements.

```
y = gfadd([2 3 1],[4 2 3],5,2)
```

```
y = 1×2

     1     0
```

For prime number `p` and exponent `m`, create a matrix listing all elements of GF(p^m) given primitive polynomial $2 + 2x + x^2$.

```
p = 3;
m = 2;
primpoly = [2 2 1];
field = gftuple((-1:p^m-2)',primpoly,p);
```

Sum A^2 and A^4. The result is A.

```
g = gfadd(2,4,field)
```

```
g = 1
```

Version History

Introduced before R2006a

Topics

“Arithmetic in Galois Fields”

gfconv

Multiply polynomials over Galois field

Syntax

```
c = gfconv(a,b)
c = gfconv(a,b,p)
c = gfconv(a,b,field)

c = gfconv(polys)
c = gfconv(polys,p)
c = gfconv(polys,field)
```

Description

`c = gfconv(a,b)` returns a row vector that specifies the GF(2) polynomial coefficients in order of ascending powers. The returned vector results from the multiplication of GF(2) polynomials `a` and `b`. The polynomial degree of the resulting GF(2) polynomial `c` equals the degree of `a` plus the degree of `b`.

For additional information, see “Tips” on page 2-376.

`c = gfconv(a,b,p)` multiplies two GF(`p`) polynomials, where `p` is a prime number. `a`, `b`, and `c` are in the same Galois field. `a`, `b`, and `c` are polynomials with coefficients in order of ascending powers. Each coefficient is in the range [0, `p`–1].

`c = gfconv(a,b,field)` multiplies two GF(p^m) polynomials, where `field` is a matrix containing the m-tuple of all elements in GF(p^m). p is a prime number, and m is a positive integer. `a`, `b`, and `c` are in the same Galois field.

In this syntax, each coefficient is specified in exponential format, specifically [-Inf, 0, 1, 2, ...]. The elements in exponential format represent the `field` elements [0, 1, α, α^2, ...] relative to some primitive element α of GF(p^m).

`c = gfconv(polys)` returns a row vector that specifies the GF(2) polynomial coefficients in order of ascending powers. The returned vector results from the multiplication of the GF(2) polynomials specified in `polys`. The polynomial degree of the resulting GF(2) polynomial `c` equals the sum of the degrees of the polynomials contained in `polys`. Use this syntax when `polys` specifies polynomials as a cell array of character vectors or as a string array.

`c = gfconv(polys,p)` multiplies the GF(`p`) polynomials specified in `polys`, where `p` is a prime number. `polys` and `c` are polynomials with coefficients in order of ascending powers. Each coefficient is in the range [0, `p`–1]. `a`, `b`, and `c` are in the same Galois field.

`c = gfconv(polys,field)` multiplies the GF(p^m) polynomials in `polys`, where `field` is a matrix containing the m-tuple of all elements in GF(p^m). p is a prime number, and m is a positive integer. `a`, `b`, and `c` are in the same Galois field.

In this syntax, each coefficient is specified in exponential format, specifically [-Inf, 0, 1, 2, ...]. The elements in exponential format represent the `field` elements [0, 1, α, α^2, ...] relative to some primitive element α of GF(p^m).

Examples

Multiply GF(2) Polynomials

Multiply $1 + 2x + 3x^2 + 4x^3$ and $1 + x$ three times. Represent the polynomials as row vectors, character vectors, and strings.

```
c_rv = gfconv([1 1 0 1],[1 1])
```

```
c_rv = 1×5

     1     0     1     1     1
```

```
c_cv = gfconv('1 + x + x^3','1 + x')
```

```
c_cv = 1×5

     1     0     1     1     1
```

```
c_s = gfconv("1 + x + x^3","1 + x")
```

```
c_s = 1×5

     1     0     1     1     1
```

The results corresponds to $1 + x^2 + x^3 + x^4$.

Multiply Polynomials Over GF(3)

Multiply $1 + x + x^4$ and $x + x^2$ over the Galois field GF(3).

```
gfc = gfconv([1 1 0 0 1],[0 1 1],3)
```

```
gfc = 1×7

     0     1     2     1     0     1     1
```

The result corresponds to $x + 2x^2 + x^3 + x^5 + x^6$.

Multiply Polynomials Over GF(2^4) Using Field Input

Multiply $1 + 2x + 3x^2 + 4x^3 + 5x^4$ and $1 + x$ in the Galois field GF(2^4).

```
field = gftuple([-1:2^4-2]',4,2);
c = gfconv('1 + 2x + 3x^2 + 4x^3 + 5x^4','1 + x',field)
```

```
c = 1×6
```

```
     2     6     7     8     9     6
```

Use the `gfpretty` function to display the result in polynomial form.

```
gfpretty(c)
```

```
                        2     3     4     5
2 + 6 X + 7 X  + 8 X  + 9 X  + 6 X
```

Multiply GF(2) Polynomials Specified As Cell Array

Create a cell array containing three polynomials that result in the DVB-S2 generator polynomial for $t = 3$ when multiplied together.

```
polyCell = {'1 + x + x3 + x5 + x14', ...
    '1 + x6 + x8 + x11 + x14','1 + x + x2 + x6 + x9 + x10 + x14'};
gp = gfconv(polyCell); % DVB-S2 for t=3
```

Use the `gfpretty` function to display the result in polynomial form.

```
gfpretty(gp)
```

```
     4    6    8    10    11    13    16    17    20    24    25    26    27
1 + X  + X  + X  + X   + X   + X   + X   + X   + X   + X   + X   + X   + X

              30    31    32    33    34    35    36    37    38    39    42
           + X   + X   + X   + X   + X   + X   + X   + X   + X   + X   + X
```

Multiply Polynomials Expressed As Strings in GF(2^4) Using Field Input

Multiply $1 + 2x + 3x^2 + 4x^3 + 5x^4$, $1 + x$, and $1 + x^3$ in the Galois field GF(2^4).

```
field = gftuple((-1:2^4-2)', 4, 2);
c = gfconv(["1 + 2x + 3x^2 + 4x^3 + 5x^4","1 + x","1 + x3"],field)
```

```
c = 1×9
```

```
     4    13    14     9     2     1     7     8     8
```

Use the `gfpretty` function to display the result in polynomial form.

```
gfpretty(c)
```

```
                      2     3     4    5     6     7     8
4 + 13 X + 14 X  + 9 X  + 2 X  + X  + 7 X  + 8 X  + 8 X
```

Input Arguments

a — Galois field polynomial

row vector | character vector | string

Galois field polynomial, specified as a row vector, character vector, or string. `a` can be either a "Representation of Polynomials in Communications Toolbox" or numeric vector.

`a` and `b` must both be GF(p) polynomials or GF(p^m) polynomials, where p is prime. The value of p is as specified when included, `2` when omitted, or implied when `field` is specified.

Example: `[1 2 3 4]` is the polynomial $1+2x+3x^2+4x^3$ in GF(5) expressed as a row vector.

Data Types: `double` | `char` | `string`

b — Galois field polynomial

row vector | character vector | string

Galois field polynomial, specified as a row vector, character vector, or string. `b` can be either a "Representation of Polynomials in Communications Toolbox" or numeric vector.

`a` and `b` must both be GF(p) polynomials or GF(p^m) polynomials, where p is prime. The value of p is as specified when included, `2` when omitted, or implied when `field` is specified.

Example: `'1 + x'` is a polynomial in GF(2^4) expressed as a character vector.

Data Types: `double` | `char` | `string`

p — Prime number

2 (default) | prime number

Prime number, specified as a prime number.

Data Types: `double`

field — *m*-tuple of all elements in GF(p^m)

matrix

m-tuple of all elements in GF(p^m), specified as a matrix. `field` is the matrix listing all elements of GF(p^m), arranged relative to the same primitive element. To generate the m-tuple of all elements in GF(p^m), use

```
field =gftuple([-1:p^m-2]',m,p)
```

The coefficients, specified in exponential format, represent the field elements in GF(p^m). For an explanation of these formats, see "Representing Elements of Galois Fields".

Data Types: `double`

polys — Galois field polynomial list

cell array of character vectors | string array

Galois field polynomial list, specified as a cell array of character vectors or a string array.

Example: `["1+x+x3+x5+x14","1+x6+x8+x11+x14"]` is a string array of polynomials.

Data Types: `cell` | `string`

Output Arguments

c — Galois field polynomial

row vector

Galois field polynomial, returned as a row vector of the polynomial coefficients in order of ascending powers. The polynomial degree of the resulting GF(p^m) polynomial `c` equals the sum of the degrees of the input polynomials. `c` is in the same Galois field as the input polynomials.

Tips

- The gfconv function performs computations in GF(p^m), where p is prime, and m is a positive integer. It multiplies polynomials over a Galois field. To work in GF(2^m), you can also use the `conv` function of the `gf` object with Galois arrays. For details, see “Multiplication and Division of Polynomials”.
- To multiply elements of a Galois field, use `gfmul` instead of `gfconv`. Algebraically, multiplying polynomials over a Galois field is equivalent to convolving vectors containing the coefficients of the polynomials. This convolution operation uses arithmetic over the same Galois field.

Version History

Introduced before R2006a

gfcosets

Produce cyclotomic cosets for Galois field

Syntax

```
c = gfcosets(m)
c = gfcosets(m,p)
```

Description

Note This function performs computations in GF(p^m), where p is prime. To work in GF(2^m), use the `cosets` function.

`c = gfcosets(m)` produces cyclotomic cosets mod(2^m - 1). Each row of the output GFCS contains one cyclotomic coset.

`c = gfcosets(m,p)` produces the cyclotomic cosets for GF(`p^m`), where `m` is a positive integer and `p` is a prime number.

The output matrix `c` is structured so that each row represents one coset. The row represents the coset by giving the exponential format of the elements of the coset, relative to the default primitive polynomial for the field. For a description of exponential formats, see “Representing Elements of Galois Fields”.

The first column contains the coset leaders. Because the lengths of cosets might vary, entries of `NaN` are used to fill the extra spaces when necessary to make `c` rectangular.

A cyclotomic coset is a set of elements that all satisfy the same minimal polynomial. For more details on cyclotomic cosets, see the works listed in “References” on page 2-378.

Examples

The command below finds the cyclotomic cosets for GF(9).

```
c = gfcosets(2,3)
```

The output is

```
c =

     0   NaN
     1     3
     2     6
     4   NaN
     5     7
```

The `gfminpol` function can check that the elements of, for example, the third row of `c` indeed belong in the same coset.

```
m = [gfminpol(2,2,3); gfminpol(6,2,3)] % Rows are identical.
```

The output is

```
m =

     1     0     1
     1     0     1
```

gfdeconv

Divide polynomials over Galois field

Syntax

```
[q,r] = gfdeconv(b,a)
[q,r] = gfdeconv(b,a,p)
[q,r] = gfdeconv(b,a,field)
```

Description

`[q,r] = gfdeconv(b,a)` returns the quotient `q` and remainder `r` as row vectors that specify GF(2) polynomial coefficients in order of ascending powers. The returned vectors result from the division `b` by `a`. `a`, `b`, and `q` are in GF(2).

For additional information, see “Tips” on page 2-382.

`[q,r] = gfdeconv(b,a,p)` divides two GF(`p`) polynomials, where `p` is a prime number. `b`, `a`, and `q` are in the same Galois field. `b`, `a`, `q`, and `r` are polynomials with coefficients in order of ascending powers. Each coefficient is in the range [0, `p`–1].

`[q,r] = gfdeconv(b,a,field)` divides two GF(p^m) polynomials, where `field` is a matrix containing the m-tuple of all elements in GF(p^m). p is a prime number, and m is a positive integer. `b`, `a`, and `q` are in the same Galois field.

In this syntax, each coefficient is specified in exponential format, specifically [-Inf, 0, 1, 2, ...]. The elements in exponential format represent the `field` elements [0, 1, α, α^2, ...] relative to some primitive element α of GF(p^m).

Examples

Divide Polynomials in GF(3)

Divide $x + x^3 + x^4$ by $1 + x$ in the Galois field GF(3) three times. Represent the polynomials as row vectors, character vectors, and strings.

```
p = 3;
```

Represent the polynomials using row vectors and divide them in GF(3).

```
b = [0 1 0 1 1];
a = [1 1];
[q_rv,r_rv] = gfdeconv(b,a,p)
```

```
q_rv = 1×4

     1     0     0     1

r_rv = 2
```

To confirm the output, compare the original Galois field polynomials to the result of adding the remainder to the product of the quotient and the divisor.

```
bnew = gfadd(gfconv(q_rv,a,p),r_rv,p);
isequal(b,bnew)
```

```
ans = logical
   1
```

Represent the polynomials using character vectors and divide them in GF(3).

```
b = 'x + x^3 + x^4';
a = '1 + x';
[q_cv,r_cv] = gfdeconv(b,a,p)
```

```
q_cv = 1×4

     1     0     0     1

r_cv = 2
```

Represent the polynomials using strings and divide them in GF(3) .

```
b = "x + x^3 + x^4";
a = "1 + x";
[q_s,r_s] = gfdeconv(b,a,p)
```

```
q_s = 1×4

     1     0     0     1

r_s = 2
```

Use the `gfpretty` function to display the result without the remainder in polynomial form.

```
gfpretty(q_s)
```

```
          3
1 + X
```

Check for Irreducibility and Primitiveness over GF(3^k)

In the Galois field GF(3), output polynomials of the form $x^k - 1$ for k in the range [2, 8] that are evenly divisible by $1 + x^2$. An irreducible polynomial over GF(p) of degree at least 2 is primitive if and only if it does not divide $-1 + x^k$ evenly for any positive integer k less than $p^m - 1$. For more information, see the `gfprimck` function.

The irreducibility of $1 + x^2$ over GF(3), along with the polynomials that are output, indicates that $1 + x^2$ is not primitive for GF(3^2).

```
p = 3; m = 2;
a = [1 0 1]; % 1+x^2
```

```
for ii = 2:p^m-1
   b = gfrepcov(ii); % x^ii
   b(1) = p-1; % -1+x^ii
   [quot,remd] = gfdeconv(b,a,p);
   % Display -1+x^ii if a divides it evenly.
   if remd==0
      multiple{ii}=b;
      gfpretty(b)
   end
end
```

```
     4
2 + X

     8
2 + X
```

Input Arguments

b — Galois field polynomial

row vector | character vector | string

Galois field polynomial, specified as a row vector, character vector, or string. `b` can be either a "Representation of Polynomials in Communications Toolbox" or numeric vector.

`a` and `b` must both be GF(p) polynomials or GF(p^m) polynomials, where p is prime. The value of p is as specified when included, `2` when omitted, or implied when `field` is specified.

Example: `'1 + x'` is a polynomial in GF(2^4) expressed as a character vector.

Data Types: `double` | `char` | `string`

a — Galois field polynomial

row vector | character vector | string

Galois field polynomial, specified as a row vector, character vector, or string. `a` can be either a "Representation of Polynomials in Communications Toolbox" or numeric vector.

`a` and `b` must both be GF(p) polynomials or GF(p^m) polynomials, where p is prime. The value of p is as specified when included, `2` when omitted, or implied when `field` is specified.

Example: `[1 2 3 4]` is the polynomial $1+2x+3x^2+4x^3$ in GF(5) expressed as a row vector.

Data Types: `double` | `char` | `string`

p — Prime number

2 (default) | prime number

Prime number, specified as a prime number.

Data Types: `double`

field — *m*-tuple of all elements in GF(p^m)

matrix

m-tuple of all elements in GF(p^m), specified as a matrix. `field` is the matrix listing all elements of GF(p^m), arranged relative to the same primitive element. To generate the *m*-tuple of all elements in GF(p^m), use

```
field =gftuple([-1:p^m-2]',m,p)
```

The coefficients, specified in exponential format, represent the field elements in GF(p^m). For an explanation of these formats, see “Representing Elements of Galois Fields”.

Data Types: `double`

Output Arguments

`q` — Galois field polynomial

row vector

Galois field polynomial, returned as a row vector of the polynomial coefficients in order of ascending powers. `q` is the quotient from the division of `b` by `a` and is in the same Galois field as the input polynomials.

`r` — Division remainder

scalar | row vector

Division remainder, returned as a scalar or a row vector of the polynomial coefficients in order of ascending powers. `r` is the remainder resulting from the division of `b` by `a`.

Tips

- The gfdeconv function performs computations in GF(p^m), where *p* is prime, and *m* is a positive integer. It divides polynomials over a Galois field. To work in GF(2^m), use the `deconv` function of the `gf` object with Galois arrays. For details, see “Multiplication and Division of Polynomials”.
- To divide elements of a Galois field, you can also use `gfdiv` instead of `gfdeconv`. Algebraically, dividing polynomials over a Galois field is equivalent to deconvolving vectors containing the coefficients of the polynomials. This deconvolution operation uses arithmetic over the same Galois field.

Version History

Introduced before R2006a

gfdiv

Divide elements of Galois field

Syntax

```
quot = gfdiv(b,a)
quot = gfdiv(b,a,p)
quot = gfdiv(b,a,field)
```

Description

Note This function performs computations in GF(p^m), where p is prime. To work in GF(2^m), apply the `./` operator to Galois arrays. For details, see "Example: Division".

The `gfdiv` function divides elements of a Galois field. (To divide polynomials over a Galois field, use `gfdeconv` instead.)

`quot = gfdiv(b,a)` divides `b` by `a` in GF(2) element-by-element. `a` and `b` are scalars, vectors or matrices of the same size. Each entry in `a` and `b` represents an element of GF(2). The entries of `a` and `b` are either 0 or 1.

`quot = gfdiv(b,a,p)` divides b by a in GF(`p`) and returns the quotient. `p` is a prime number. If `a` and `b` are matrices of the same size, the function treats each element independently. All entries of `b`, `a`, and `quot` are between 0 and `p`-1.

`quot = gfdiv(b,a,field)` divides `b` by `a` in GF(p^m) and returns the quotient. p is a prime number and m is a positive integer. If `a` and `b` are matrices of the same size, then the function treats each element independently. All entries of `b`, `a`, and `quot` are the exponential formats of elements of GF(p^m) relative to some primitive element of GF(p^m). `field` is the matrix listing all elements of GF(p^m), arranged relative to the same primitive element. See "Representing Elements of Galois Fields" for an explanation of these formats.

In all cases, an attempt to divide by the zero element of the field results in a "quotient" of `NaN`.

Examples

The code below displays lists of multiplicative inverses in GF(5) and GF(25). It uses column vectors as inputs to `gfdiv`.

```
% Find inverses of nonzero elements of GF(5).
p = 5;
b = ones(p-1,1);
a = [1:p-1]';
quot1 = gfdiv(b,a,p);
disp('Inverses in GF(5):')
disp('element  inverse')
disp([a, quot1])

% Find inverses of nonzero elements of GF(25).
```

```
m = 2;
field = gftuple([-1:p^m-2]',m,p);
b = zeros(p^m-1,1); % Numerator is zero since 1 = alpha^0.
a = [0:p^m-2]';
quot2 = gfdiv(b,a,field);
disp('Inverses in GF(25), expressed in EXPONENTIAL FORMAT with')
disp('respect to a root of the default primitive polynomial:')
disp('element  inverse')
disp([a, quot2])
```

gffilter (prime Galois field)

Filter data using polynomials over prime Galois field

Syntax

```
y = gffilter(b,a,x)
y = gffilter(b,a,x,p)
```

Description

Note This function performs computations in GF(p^m), where p is prime. To work in GF(2^m), use the `filter` function with Galois arrays. For details, see “Filtering”.

`y = gffilter(b,a,x)` filters the data in vector `x` with the filter described by vectors `b` and `a`. The vectors `b`, `a` and `x` must be in GF(2), that is, be binary and `y` is also in GF(2).

`y = gffilter(b,a,x,p)` filters the data `x` using the filter described by vectors `a` and `b`. `y` is the filtered data in GF(`p`). `p` is a prime number, and all entries of `a` and `b` are between 0 and `p`-1.

By definition of the filter, `y` solves the difference equation

```
a(1)y(n) = b(1)x(n)+b(2)x(n-1)+b(3)x(n-2)+...+b(B+1)x(n-B)
                     -a(2)y(n-1)-a(3)y(n-2)-...-a(A+1)y(n-A)
```

where

- `A`+1 is the length of the vector `a`
- `B`+1 is the length of the vector `b`
- `n` varies between 1 and the length of the vector `x`.

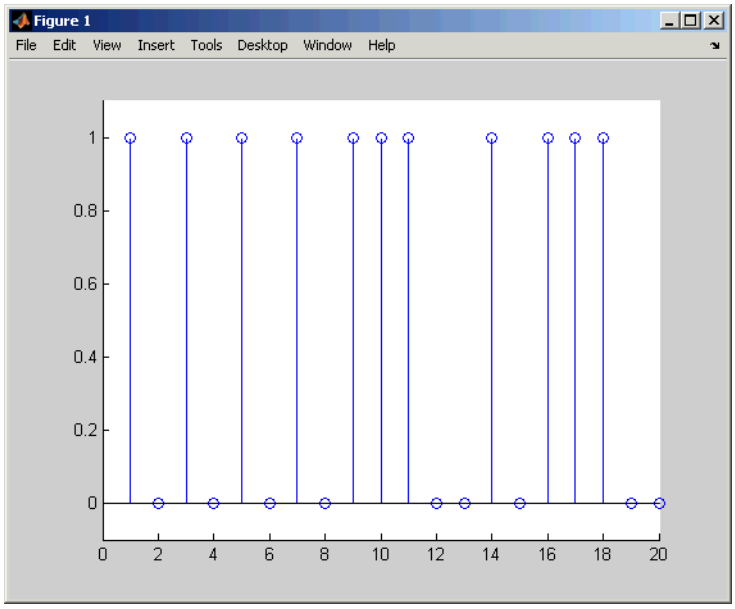
The vector `a` represents the degree-n_a polynomial

```
a(1)+a(2)x+a(3)x^2+...+a(A+1)x^A
```

Examples

The impulse response of a particular filter is given in the code and diagram below.

```
b = [1 0 0 1 0 1 0 1];
a = [1 0 1 1];
y = gffilter(b,a,[1,zeros(1,19)]);
stem(y);
axis([0 20 -.1 1.1])
```



Version History

Introduced before R2006a

`gfconv` | `gfadd`

gflineq

Find particular solution of `Ax = b` over prime Galois field

Syntax

```
x = gflineq(A,b)
x = gflineq(A,b,p)
[x,vld] = gflineq(...)
```

Description

Note This function performs computations in GF(p), where p is prime. To work in GF(2^m), apply the \ or / operator to Galois arrays. For details, see “Solving Linear Equations”.

`x = gflineq(A,b)` outputs a particular solution of the linear equation `A x = b` in GF(2). The elements in `a`, `b` and `x` are either 0 or 1. If the equation has no solution, then `x` is empty.

`x = gflineq(A,b,p)` returns a particular solution of the linear equation `A x = b` over GF(`p`), where `p` is a prime number. If `A` is a k-by-n matrix and `b` is a vector of length k, `x` is a vector of length n. Each entry of `A`, `x`, and `b` is an integer between 0 and `p-1`. If no solution exists, `x` is empty.

`[x,vld] = gflineq(...)` returns a flag `vld` that indicates the existence of a solution. If `vld` = 1, the solution `x` exists and is valid; if `vld` = 0, no solution exists.

Examples

The code below produces some valid solutions of a linear equation over GF(3).

```
A = [2 0 1;
     1 1 0;
     1 1 2];
% An example in which the solutions are valid
[x,vld] = gflineq(A,[1;0;0],3)
```

The output is below.

```
x =

     2
     1
     0

vld =

     1
```

By contrast, the command below finds that the linear equation has *no* solutions.

```
[x2,vld2] = gflineq(zeros(3,3),[2;0;0],3)
```

The output is below.

```
This linear equation has no solution.

x2 =

     []

vld2 =

     0
```

Algorithms

`gflineq` uses Gaussian elimination.

gfminpol

Find minimal polynomial of Galois field element

Syntax

```
pol = gfminpol(k,m)
pol = gfminpol(k,m,p)
pol = gfminpol(k,prim_poly,p)
```

Description

Note This function performs computations in GF(p^m), where p is prime. To work in GF(2^m), use the `minpol` function with Galois arrays. For details, see “Minimal Polynomials”.

`pol = gfminpol(k,m)` produces a minimal polynomial for each entry in `k`. `k` must be either a scalar or a column vector. Each entry in `k` represents an element of GF(2^m) in exponential format. That is, `k` represents alpha^`k`, where alpha is a primitive element in GF(2^m). The *i*th row of `pol` represents the minimal polynomial of `k`(*i*). The coefficients of the minimal polynomial are in the base field GF(2) and listed in order of ascending exponents.

`pol = gfminpol(k,m,p)` finds the minimal polynomial of A^k over GF(`p`), where `p` is a prime number, `m` is an integer greater than 1, and A is a root of the default primitive polynomial for GF(`p^m`). The format of the output is as follows:

- If `k` is a nonnegative integer, `pol` is a row vector that gives the coefficients of the minimal polynomial in order of ascending powers.
- If `k` is a vector of length *len* all of whose entries are nonnegative integers, `pol` is a matrix having *len* rows; the rth row of `pol` gives the coefficients of the minimal polynomial of $A^{k(r)}$ in order of ascending powers.

`pol = gfminpol(k,prim_poly,p)` is the same as the first syntax listed, except that A is a root of the primitive polynomial for GF(p^m) specified by `prim_poly`. `prim_poly` is a polynomial character vector or a row vector that gives the coefficients of the degree-m primitive polynomial in order of ascending powers.

Examples

The syntax `gfminpol(k,m,p)` is used in the sample code in “Characterization of Polynomials”.

`gfprimdf` | `gfcosets` | `gfroots`

gfmul

Multiply elements of Galois field

Syntax

```
c = gfmul(a,b,p)
c = gfmul(a,b,field)
```

Description

Note This function performs computations in GF(p^m) where p is prime. To work in GF(2^m), apply the `.*` operator to Galois arrays. For details, see "Example: Multiplication".

The `gfmul` function multiplies elements of a Galois field. (To multiply polynomials over a Galois field, use `gfconv` instead.)

`c = gfmul(a,b,p)` multiplies `a` and `b` in GF(`p`). Each entry of `a` and `b` is between 0 and `p`-1. `p` is a prime number. If `a` and `b` are matrices of the same size, the function treats each element independently.

`c = gfmul(a,b,field)` multiplies `a` and `b` in GF(p^m), where p is a prime number and m is a positive integer. `a` and `b` represent elements of GF(p^m) in exponential format relative to some primitive element of GF(p^m). `field` is the matrix listing all elements of GF(p^m), arranged relative to the same primitive element. `c` is the exponential format of the product, relative to the same primitive element. See "Representing Elements of Galois Fields" for an explanation of these formats. If `a` and `b` are matrices of the same size, the function treats each element independently.

Examples

"Arithmetic in Galois Fields" contains examples. Also, the code below shows that

$$A^2 \cdot A^4 = A^6$$

where A is a root of the primitive polynomial $2 + 2x + x^2$ for GF(9).

```
p = 3; m = 2;
prim_poly = [2 2 1];
field = gftuple([-1:p^m-2]',prim_poly,p);
a = gfmul(2,4,field)
```

The output is

```
a =

     6
```

Version History

Introduced before R2006a

gfpretty

Polynomial in traditional format

Syntax

```
gfpretty(a)
gfpretty(a,st)
gfpretty(a,st,n)
```

Description

`gfpretty(a)` displays a polynomial in a traditional format, using `X` as the variable and the entries of the row vector `a` as the coefficients in order of ascending powers. The polynomial is displayed in order of ascending powers. Terms having a zero coefficient are not displayed.

`gfpretty(a,st)` is the same as the first syntax listed, except that the content of `st` is used as the variable instead of `X`.

`gfpretty(a,st,n)` is the same as the first syntax listed, except that the content of `st` is used as the variable instead of `X`, and each line of the display has width `n` instead of the default value of 79.

Note For all syntaxes: If you do not use a fixed-width font, the spacing in the display might not look correct.

Examples

Display Polynomials in Traditional Format

Display statements about randomly selected elements of GF(81).

Use the `gfprimfd` function to find the primitive polynomials for GF(81).

```
p = 3;
m = 4;
primpolys = gfprimfd(m,'all',p);
[rows, cols] = size(primpolys);
```

Randomly select a primitive polynomial by selecting a row `jj` from `primpolys`, and then display the `jj`th primitive polynomial in the traditional format by using the `gfpretty` function.

```
jj = randi([1,rows]);
gfpretty(primpolys(jj,:))
```

```
                2      3    4
2 + X + X  + 2 X  + X
```

For the root `A` of the primitive polynomial `primpoly(jj,:)`, a randomly selected element `A^ii` from GF(81) can be displayed in traditional format by using the `gfpretty` function.

```
ii = randi([1,p^m-2]);
gfpretty([zeros(1,ii),1],'A')
```

```
 72
A
```

The element `A^ii` can be expressed as shown here by using the `gfpretty` and `gftuple` functions.

```
gfpretty(gftuple(ii,m,p),'A')
```

```
     2      3
1 + A  + 2 A
```

Version History

Introduced before R2006a

`gftuple` | `gfprimdf`

gfprimck

Check whether polynomial over Galois field is primitive

Syntax

```
ck = gfprimck(a)
ck = gfprimck(a,p)
```

Description

Note This function performs computations in GF(p^m), where p is prime. If you are working in GF(2^m), use the `isprimitive` function. For details, see *Finding Primitive Polynomials* in "Primitive Polynomials and Element Representations".

`ck = gfprimck(a)` checks whether the degree-m GF(2) polynomial `a` is a primitive polynomial for GF(2^m), where m = length(`a`) - 1. The output `ck` is as follows:

- -1 if `a` is not an irreducible polynomial
- 0 if `a` is irreducible but not a primitive polynomial for GF(p^m)
- 1 if `a` is a primitive polynomial for GF(p^m)

`ck = gfprimck(a,p)` checks whether the degree-m GF(P) polynomial `a` is a primitive polynomial for GF(p^m). p is a prime number.

`a` is either a polynomial character vector or a row vector representing the polynomial by listing its coefficients in ascending order. For example, in GF(5), `'4 + 3x + 2x^3'` and `[4 3 0 2]` are equivalent.

This function considers the zero polynomial to be "not irreducible" and considers all polynomials of degree zero or one to be primitive.

Examples

"Characterization of Polynomials" contains examples.

Algorithms

An irreducible polynomial over GF(p) of degree at least 2 is primitive if and only if it does not divide -1 + x^k for any positive integer k smaller than p^m-1.

Version History

Introduced before R2006a

gfprimdf

Provide default primitive polynomials for Galois field

Syntax

```
pol = gfprimdf(m)
pol = gfprimdf(m,p)
```

Description

Note This function performs computations in GF(p^m), where p is prime. To work in GF(2^m), use the `primpoly` function. For details, see *Finding Primitive Polynomials* in "Primitive Polynomials and Element Representations".

`pol = gfprimdf(m)` outputs the default primitive polynomial `pol` in GF(2^m).

`pol = gfprimdf(m,p)` returns the row vector that gives the coefficients, in order of ascending powers, of the default primitive polynomial for GF(p^m). `m` is a positive integer and `p` is a prime number.

Examples

Find Default Primitive Polynomial for GF(52)

Find the default primitive polynomial for GF(52) by using the `gfprimdf` function. Then use the `gfpretty` function to display it in polynomial format.

```
pol = gfprimdf(2,5)
```

```
pol = 1×3

     2     1     1
```

```
gfpretty(pol)
```

```
                  2
2 + X + X
```

Find Default Primitive Polynomials for Range of Galois Fields

Find the default primitive polynomials for a range of Galois fields by using the `gfprimdf` function.

Use the `gfpretty` function to display the default primitive polynomial for each of the fields GF(3*m*), where the range for *m* is [3, 5].

```
for m = 3:5
   gfpretty(gfprimdf(m,3))
end
```

```
                                  3
                1 + 2 X + X

                                4
                 2 + X + X

                                5
                1 + 2 X + X
```

gfprimfd

Find primitive polynomials for Galois field

Syntax

```
pol = gfprimfd(m,opt,p)
```

Description

Note This function performs computations in GF(p^m), where p is prime. To work in GF(2^m), use the `primpoly` function. For details, see *Finding Primitive Polynomials* in "Primitive Polynomials and Element Representations".

- If `m` = 1, `pol` = [1 1].
- A polynomial is represented as a row containing the coefficients in order of ascending powers.

`pol = gfprimfd(m,opt,p)` searches for one or more primitive polynomials for GF(`p^m`), where `p` is a prime number and `m` is a positive integer. If `m` = 1, `pol` = [1 1]. If `m` > 1, the output `pol` depends on the argument *`opt`* as shown in the table below. Each polynomial is represented in `pol` as a row containing the coefficients in order of ascending powers.

opt	Significance of pol	Format of pol
`'min'`	One primitive polynomial for GF(`p^m`) having the smallest possible number of nonzero terms	The row vector representing the polynomial
`'max'`	One primitive polynomial for GF(`p^m`) having the greatest possible number of nonzero terms	The row vector representing the polynomial
`'all'`	All primitive polynomials for GF(`p^m`)	A matrix, each row of which represents one such polynomial
A positive integer	All primitive polynomials for GF(`p^m`) that have *`opt`* nonzero terms	A matrix, each row of which represents one such polynomial

Examples

The code below seeks primitive polynomials for GF(81) having various other properties. Notice that `fourterms` is empty because no primitive polynomial for GF(81) has exactly four nonzero terms. Also notice that `fewterms` represents a *single* polynomial having three terms, while `threeterms` represents *all* of the three-term primitive polynomials for GF(81).

```
p = 3; m = 4; % Work in GF(81).
fewterms = gfprimfd(m,'min',p)
```

```
threeterms = gfprimfd(m,3,p)
fourterms = gfprimfd(m,4,p)
```

The output is below.

```
fewterms =

     2     1     0     0     1

threeterms =

     2     1     0     0     1
     2     2     0     0     1
     2     0     0     1     1
     2     0     0     2     1

No primitive polynomial satisfies the given constraints.

fourterms =

     []
```

Algorithms

`gfprimfd` tests for primitivity using `gfprimck`. If *`opt`* is `'min'`, `'max'`, or omitted, polynomials are constructed by converting decimal integers to base `p`. Based on the decimal ordering, `gfprimfd` returns the first polynomial it finds that satisfies the appropriate conditions.

gfrank

Compute rank of matrix over Galois field

Syntax

```
rk = gfrank(A,p)
```

Description

Note This function performs computations in GF(p) where p is prime. If you are working in GF(2^m), use the `rank` function with Galois arrays. For details, see “Computing Ranks”.

`rk = gfrank(A,p)` calculates the rank of the matrix `A` in GF(`p`), where `p` is a prime number.

Examples

In the code below, `gfrank` says that the matrix `A` has less than full rank. This conclusion makes sense because the determinant of `A` is zero mod `p`.

```
A = [1 0 1;
   2 1 0;
   0 1 1];
p = 3;
det_a = det(A); % Ordinary determinant of A
detmodp = rem(det(A),p); % Determinant mod p
rankp = gfrank(A,p);
disp(['Determinant = ',num2str(det_a)])
disp(['Determinant mod p is ',num2str(detmodp)])
disp(['Rank over GF(p) is ',num2str(rankp)])
```

The output is below.

```
Determinant = 3
Determinant mod p is 0
Rank over GF(p) is 2
```

Algorithms

`gfrank` uses an algorithm similar to Gaussian elimination.

Version History

Introduced before R2006a

gfrepcov

Convert one binary polynomial representation to another

Syntax

```
polystandard = gfrepcov(poly2)
```

Description

Two logical ways to represent polynomials over GF(2) are listed below.

1 `[A_0 A_1 A_2 ... A_(m-1)]` represents the polynomial

$$A\_0 + A\_1x + A\_2x^2 + \cdots + A\_(m\text{-}1)x^{m-1}$$

Each entry `A_k` is either one or zero.

2 [A_0 A_1 A_2 ... A_(m-1)] represents the polynomial

$$x^{A\_0} + x^{A\_1} + x^{A\_2} + \cdots + x^{A\_(m\text{-}1)}$$

Each entry `A_k` is a nonnegative integer. All entries must be distinct.

Format **1** is the standard form used by the Galois field functions in this toolbox, but there are some cases in which format **2** is more convenient.

`polystandard = gfrepcov(poly2)` converts from the second format to the first, for polynomials of degree *at least* 2. `poly2` and `polystandard` are row vectors. The entries of `poly2` are distinct integers, and at least one entry must exceed 1. Each entry of `polystandard` is either 0 or 1.

Examples

The command below converts the representation format of the polynomial $1 + x^2 + x^5$.

```
polystandard = gfrepcov([0 2 5])

polystandard =

     1     0     1     0     0     1
```

`gfpretty`

gfroots

Find roots of polynomial over prime Galois field

Syntax

```
rt = gfroots(f,m,p)
rt = gfroots(f,prim_poly,p)
[rt,rt_tuple] = gfroots(...)
[rt,rt_tuple,field] = gfroots(...)
```

Description

Note This function performs computations in GF(p^m), where p is prime. To work in GF(2^m), use the `roots` function with Galois arrays. For details, see “Roots of Polynomials”.

For all syntaxes, `f` is a polynomial character vector or a row vector that gives the coefficients, in order of ascending powers, of a degree-d polynomial.

Note `gfroots` lists each root exactly once, ignoring multiplicities of roots.

`rt = gfroots(f,m,p)` finds roots in GF(`p^m`) of the polynomial that `f` represents. `rt` is a column vector each of whose entries is the exponential format of a root. The exponential format is relative to a root of the default primitive polynomial for GF(`p^m`).

`rt = gfroots(f,prim_poly,p)` finds roots in GF(p^m) of the polynomial that `f` represents. `rt` is a column vector each of whose entries is the exponential format of a root. The exponential format is relative to a root of the degree-m primitive polynomial for GF(p^m) that `prim_poly` represents.

`[rt,rt_tuple] = gfroots(...)` returns an additional matrix `rt_tuple`, whose kth row is the polynomial format of the root `rt(k)`. The polynomial and exponential formats are both relative to the same primitive element.

`[rt,rt_tuple,field] = gfroots(...)` returns additional matrices `rt_tuple` and `field`. `rt_tuple` is described in the preceding paragraph. `field` gives the list of elements of the extension field. The list of elements, the polynomial format, and the exponential format are all relative to the same primitive element.

Note For a description of the various formats that `gfroots` uses, see “Representing Elements of Galois Fields”.

Examples

“Roots of Polynomials” contains a description and example of the use of `gfroots`.

The code below finds the polynomial format of the roots of the primitive polynomial $2 + x^3 + x^4$ for GF(81). It then displays the roots in traditional form as polynomials in `alph`. (The output is omitted

here.) Because `prim_poly` is both the primitive polynomial and the polynomial whose roots are sought, `alph` itself is a root.

```
p = 3; m = 4;
prim_poly = [2 0 0 1 1]; % A primitive polynomial for GF(81)
f = prim_poly; % Find roots of the primitive polynomial.
[rt,rt_tuple] = gfroots(f,prim_poly,p);
% Display roots as polynomials in alpha.
for ii = 1:length(rt_tuple)
  gfpretty(rt_tuple(ii,:),'alpha')
end
```

Version History

Introduced before R2006a

`gfprimdf`

gfsub

Subtract polynomials over Galois field

Syntax

```
c = gfsub(a,b,p)
c = gfsub(a,b,p,len)
c = gfsub(a,b,field)
```

Description

Note This function performs computations in GF(p^m), where p is prime. To work in GF(2^m), apply the - operator to Galois arrays of equal size. For details, see “Example: Addition and Subtraction”.

`c = gfsub(a,b,p)` calculates `a` minus `b`, where `a` and `b` represent polynomials over GF(`p`) and `p` is a prime number. `a`, `b`, and `c` are row vectors that give the coefficients of the corresponding polynomials in order of ascending powers. Each coefficient is between 0 and `p`-1. If `a` and `b` are matrices of the same size, the function treats each row independently. Alternatively, `a` and `b` can be represented as polynomial character vectors.

`c = gfsub(a,b,p,len)` subtracts row vectors as in the syntax above, except that it returns a row vector of length `len`. The output `c` is a truncated or extended representation of the answer. If the row vector corresponding to the answer has fewer than `len` entries (including zeros), extra zeros are added at the end; if it has more than `len` entries, entries from the end are removed.

`c = gfsub(a,b,field)` calculates `a` minus `b`, where `a` and `b` are the exponential format of two elements of GF(p^m), relative to some primitive element of GF(p^m). p is a prime number and m is a positive integer. `field` is the matrix listing all elements of GF(p^m), arranged relative to the same primitive element. `c` is the exponential format of the answer, relative to the same primitive element. See “Representing Elements of Galois Fields” for an explanation of these formats. If `a` and `b` are matrices of the same size, the function treats each element independently.

Examples

Subtract Two GF Arrays

Calculate $(2 + 3x + x^2) - (4 + 2x + 3x^2)$ over GF(5).

```
x = gfsub([2 3 1],[4 2 3],5)
```

```
x = 1×3

     3     1     3
```

Subtract the two polynomials and display the first two elements.

```
y = gfsub([2 3 1],[4 2 3],5,2)
```

```
y = 1×2

     3     1
```

For prime number `p` and exponent `m`, create a matrix listing all elements of GF(p^m) given primitive polynomial $2 + 2x + x^2$.

```
p = 3;
m = 2;
primpoly = [2 2 1];
field = gftuple((-1:p^m-2)',primpoly,p);
```

Subtract A^4 from A^2. The result is A^7.

```
g = gfsub(2,4,field)
```

```
g = 7
```

gftable

Generate file to accelerate Galois field computations

Syntax

```
gftable(m,prim_poly);
```

Description

`gftable(m,prim_poly)` generates a file that can help accelerate computations in the field GF(2^m) as described by the *nondefault* primitive polynomial `prim_poly`, which can be either a polynomial character vector or an integer. `prim_poly` represents a primitive polynomial for GF(2^m), where $1 < m < 16$, using the format described in "Primitive Polynomials and Element Representations". The function places the file, called `userGftable.mat`, in your current working folder. If necessary, the function overwrites any writable existing version of the file.

Note If `prim_poly` is the default primitive polynomial for GF(2^m) listed in the table on the `gf` reference page, this function has no effect. A MAT-file in your MATLAB installation already includes information that facilitates computations with respect to the default primitive polynomial.

Examples

In the example below, you expect `t3` to be similar to `t1` and to be significantly smaller than `t2`, assuming that you do not already have a `userGftable.mat` file that includes the (`m`, `prim_poly`) pair (`8`, `501`). Notice that before executing the `gftable` command, MATLAB displays a warning and that after executing `gftable`, there is no warning. By executing the `gftable` command you save the GF table for faster calculations.

```
% Sample code to check how much gftable improves speed.
tic; a = gf(repmat([0:2^8-1],1000,1),8); b = a.^100; t1 = toc;
tic; a = gf(repmat([0:2^8-1],1000,1),8,501); b = a.^100; t2 = toc;
gftable(8,501); % Include this primitive polynomial in the file.
tic; a = gf(repmat([0:2^8-1],1000,1),8,501); b = a.^100; t3 = toc;
```

Version History

Introduced before R2006a

gftrunc

Minimize length of polynomial representation

Syntax

```
c = gftrunc(a)
```

Description

`c = gftrunc(a)` truncates a row vector, `a`, that gives the coefficients of a GF(p) polynomial in order of ascending powers. If `a`(k) = 0 whenever k > d + 1, the polynomial has degree d. The row vector `c` omits these high-order zeros and thus has length d + 1.

Examples

Truncate Row-Vector Representation of Galois Field Polynomial

Use `gftrunc` to truncate the row-vector representation of $x^2 + 2x^3 + 3x^4 + 4x^7 + 5x^8$, removing nonsignificant zero-valued elements.

```
vec = [0 0 1 2 3 0 0 4 5 0 0]
```

```
vec = 1×11

     0     0     1     2     3     0     0     4     5     0     0
```

```
gfpretty([vec])
```

```
                        2      3      4      7      8
                       X  + 2 X  + 3 X  + 4 X  + 5 X
```

Zeros are removed from the end of the row-vector representation, but not from the beginning or middle of the row vector.

```
c = gftrunc([0 0 1 2 3 0 0 4 5 0 0])
```

```
c = 1×9

     0     0     1     2     3     0     0     4     5
```

```
gfpretty(c)
```

```
                        2      3      4      7      8
                       X  + 2 X  + 3 X  + 4 X  + 5 X
```

Version History

Introduced before R2006a

gftuple

Simplify or convert Galois field element formatting

Syntax

```
tp = gftuple(a,m)
tp = gftuple(a,prim_poly)
tp = gftuple(a,m,p)
tp = gftuple(a,prim_poly,p)
tp = gftuple(a,prim_poly,p,prim_ck)
[tp,expform] = gftuple(...)
```

Description

Note This function performs computations in GF(p^m), where p is prime. To perform equivalent computations in GF(2^m), apply the `.^` operator and the `log` function to Galois arrays. For more information, see “Example: Exponentiation” and “Example: Elementwise Logarithm”.

For All Syntaxes

`gftuple` serves to simplify the polynomial or exponential format of Galois field elements, or to convert from one format to another. For an explanation of the formats that `gftuple` uses, see “Representing Elements of Galois Fields”.

In this discussion, the format of an element of GF(p^m) is called “simplest” if all exponents of the primitive element are

- Between 0 and m-1 for the polynomial format
- Either `-Inf`, or between 0 and p^{m-2}, for the exponential format

For all syntaxes, `a` is a matrix, each row of which represents an element of a Galois field. The format of `a` determines how MATLAB interprets it:

- If `a` is a column of integers, MATLAB interprets each row as an *exponential* format of an element. Negative integers are equivalent to `-Inf` in that they all represent the zero element of the field.
- If `a` has more than one column, MATLAB interprets each row as a *polynomial* format of an element. (Each entry of `a` must be an integer between 0 and `p`-1.)

The exponential or polynomial formats mentioned above are all relative to a primitive element specified by the *second* input argument. The second argument is described below.

For Specific Syntaxes

`tp = gftuple(a,m)` returns the simplest polynomial format of the elements that `a` represents, where the kth row of `tp` corresponds to the kth row of `a`. The formats are relative to a root of the default primitive polynomial for GF(`2^m`), where `m` is a positive integer.

`tp = gftuple(a,prim_poly)` is the same as the syntax above, except that `prim_poly` is a polynomial character vector or a row vector that lists the coefficients of a degree `m` primitive polynomial for GF(2^m) in order of ascending exponents.

`tp = gftuple(a,m,p)` is the same as `tp = gftuple(a,m)` except that 2 is replaced by a prime number `p`.

`tp = gftuple(a,prim_poly,p)` is the same as `tp = gftuple(a,prim_poly)` except that 2 is replaced by a prime number `p`.

`tp = gftuple(a,prim_poly,p,prim_ck)` is the same as `tp = gftuple(a,prim_poly,p)` except that `gftuple` checks whether `prim_poly` represents a polynomial that is indeed primitive. If not, then `gftuple` generates an error and `tp` is not returned. The input argument `prim_ck` can be any number or character vector; only its existence matters.

`[tp,expform] = gftuple(...)` returns the additional matrix `expform`. The kth row of `expform` is the simplest exponential format of the element that the kth row of `a` represents. All other features are as described in earlier parts of this “Description” section, depending on the input arguments.

Examples

- “List of All Elements of a Galois Field” (end of section)
- “Converting to Simplest Polynomial Format”

As another example, the `gftuple` command below generates a list of elements of GF(`p^m`), arranged relative to a root of the default primitive polynomial. Some functions in this toolbox use such a list as an input argument.

```
p = 5; % Or any prime number
m = 4; % Or any positive integer
field = gftuple([-1:p^m-2]',m,p);
```

Finally, the two commands below illustrate the influence of the *shape* of the input matrix. In the first command, a column vector is treated as a sequence of elements expressed in exponential format. In the second command, a row vector is treated as a single element expressed in polynomial format.

```
tp1 = gftuple([0; 1],3,3)
tp2 = gftuple([0, 0, 0, 1],3,3)
```

The output is below.

```
tp1 =

     1     0     0
     0     1     0

tp2 =

     2     1     0
```

The outputs reflect that, according to the default primitive polynomial for GF(3^3), the relations below are true.

$\alpha^0 = 1 + 0\alpha + 0\alpha^2$

$\alpha^1 = 0 + 1\alpha + 0\alpha^2$

$0 + 0\alpha + 0\alpha^2 + \alpha^3 = 2 + \alpha + 0\alpha^2$

Algorithms

`gftuple` uses recursive callbacks to determine the exponential format.

gfweight

Calculate minimum distance of linear block code

Syntax

```
wt = gfweight(genmat)
wt = gfweight(genmat,'gen')
wt = gfweight(parmat,'par')
wt = gfweight(genpoly,n)
```

Description

The minimum distance, or minimum weight, of a linear block code is defined as the smallest positive number of nonzero entries in any n-tuple that is a codeword.

`wt = gfweight(genmat)` returns the minimum distance of the linear block code whose generator matrix is `genmat`.

`wt = gfweight(genmat,'gen')` returns the minimum distance of the linear block code whose generator matrix is `genmat`.

`wt = gfweight(parmat,'par')` returns the minimum distance of the linear block code whose parity-check matrix is `parmat`.

`wt = gfweight(genpoly,n)` returns the minimum distance of the *cyclic* code whose codeword length is `n` and whose generator polynomial is represented by `genpoly`. `genpoly` is a polynomial character vector or a row vector that gives the coefficients of the generator polynomial in order of ascending powers.

Examples

Calculate Minimum Distance of Linear Block Code

Calculate the minimum distance of a cyclic code using several methods.

Create the generate polynomial for a (7,4) cyclic code.

```
n = 7;
genpoly = cyclpoly(n,4);
```

Calculate the minimum distance for the cyclic code using:

1. Generator polynomial `genmat`
2. Parity check matrix `parmat`
3. Generator polynomial `genpoly`
4. Generator polynomial specified as a character vector

```
[parmat, genmat] = cyclgen(n,genpoly);
wts = [gfweight(genmat,'gen') gfweight(parmat,'par'),...
    gfweight(genpoly,n) gfweight('1+x2+x3',n)]
```

```
wts = 1×4

     3     3     3     3
```

“Block Codes”

gray2bin

(To be removed) Convert Gray-encoded positive integers to corresponding Gray-decoded integers

Note will be removed in a future release. Instead, use the appropriate modulation object or function to remap constellation points. For more information, see “Compatibility Considerations”.

Syntax

```
y = gray2bin(x,modulation,M)
[y,map] = gray2bin(x,modulation,M)
```

Description

`y = gray2bin(x,modulation,M)` generates a Gray-decoded output vector or matrix `y` with the same dimensions as its input parameter `x`. `x` can be a scalar, vector, matrix, or 3-D array. `modulation` is the modulation type and must be `'qam'`, `'pam'`, `'fsk'`, `'dpsk'`, or `'psk'`. `M` is the modulation order and must be an integer power of 2.

`[y,map] = gray2bin(x,modulation,M)` generates a Gray-decoded output `y` with its respective Gray-encoded constellation map, `map`.

You can use map output to label a Gray-encoded constellation. The map output gives the Gray-encoded labels for the corresponding modulation. See “Binary to Gray Symbol Mapping” on page 2-414 example.

Note If you are converting binary coded data to Gray-coded data and modulating the result immediately afterwards, you should use the appropriate modulation object or function with the `'Gray'` symbol ordering option, instead of `gray2bin`.

Examples

Binary to Gray Symbol Mapping

This example shows how to use the bin2gray and gray2bin functions to map integer inputs from a natural binary order symbol mapping to a Gray-coded signal constellation and vice versa, assuming 16-QAM modulation. In addition, a visual representation of the difference between Gray-coded and binary-coded symbol mappings is shown.

Create a complete vector of 16-QAM integers. Convert the input vector from a natural binary order to a Gray-encoded vector using `bin2gray`. Convert Gray to Binary Convert the Gray-encoded symbols, `y`, back to a binary ordering using `gray2bin`. Verify that the original data, `x`, and the final output vector, `z`, are identical.

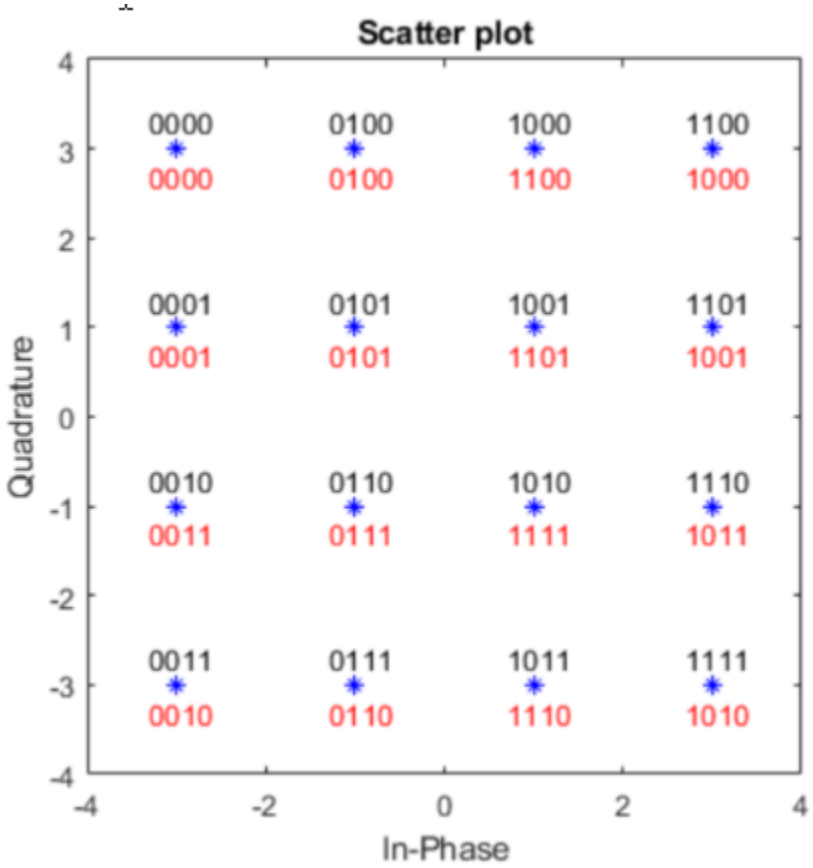
```
M = 16;
x = (0:M-1);
[y,mapy] = bin2gray(x,'qam',M);
```

```
z = gray2bin(y,'qam',M);
isequal(x,z)
```

```
ans = logical
   1
```

Show symbol mappings. To create a constellation plot showing the different symbol mappings, use the `qammod` function to find the complex symbol values. Plot the constellation symbols and label them using the Gray (`y`) and binary (`z`) output vectors. The binary representation of the Gray-coded symbols is shown in black and the binary representation of the naturally ordered symbols is shown in red. Set the axes scaling so that all points are displayed.

```
sym = qammod(x,M);
scatterplot(sym,1,0,'b*');
for k = 1:16
    text(real(sym(k))-0.3,imag(sym(k))+0.3,...
        dec2base(mapy(k),2,4));
    text(real(sym(k))-0.3,imag(sym(k))-0.3,...
        dec2base(z(k),2,4),'Color',[1 0 0]);
end
axis([-4 4 -4 4])
```



Input Arguments

x — Gray-encoded data

vector | matrix

Gray-encoded input data, specified as a vector or matrix.

Data Types: `double`

`modulation` — Modulation type
`'qam'` | `'pam'` | `'fsk'` | `'dpsk'` | `'psk'`

Modulation type, specified as, `'qam'`, `'pam'`, `'fsk'`, `'dpsk'`, or `'psk'`

`M` — Modulation order
scalar

Modulation order, specified as an integer power of 2.

Data Types: `double`

Output Arguments

`y` — Gray-decoded data
vector | matrix

Gray-decoded data with the same size and dimensions input `x`.

`map` — Map of labels
vector

Map output to label a Gray-encoded constellation, specified as a vector with a length the size of the modulation order, `M`. The map gives the Gray-encoded labels for the corresponding modulation.

Version History

`gray2bin` will be removed
Warns starting in R2021b

The `gray2bin` function will be removed in a future release. Instead, use the appropriate modulation object or function to remap constellation points. This table shows the remapping based on modulation type.

When you use the workflow that is discouraged, the `bin2gray` and `gray2bin` functions convert a binary representation to a natural binary or Gray encoding. After the conversion, you must specify `'bin'` for the symbol order when you call the modulation and demodulation functions.

When you use the workflow that is recommended, for any given of modulation scheme, you provide decimal values when you call the modulation and demodulation functions. When you call the modulation and demodulation functions, specify the symbol order as `'bin'` for natural binary encoding or `'gray'` for Gray encoding.

If your workflow uses `bin2gray` or `gray2bin` with any of the modulations schemes in this table, follow the appropriate example.

Modulation	Discouraged Usage	Recommended Replacement

QAM (qammod and qamdemod)	`x = randi([0 63],1,100);`
	`y = bin2gray(x,'qam',64);`
	`z = qammod(y,64,'bin');`
	
	`x = 2*(randn(100,1)+1j*randn(100,1));`
	`y = qamdemod(x,64,'bin');`
	`z = gray2bin(y,'qam',64);`
		`x = randi([0 63],1,100);`
		`z = qammod(x,64,'gray');`
		
		`x = 2*(randn(100,1)+1j*randn(100,1));`
		`z = qamdemod(x,64,'gray')`

PAM (pammod and pamdemod)	`x = randi([0 63],1,100);`
	`y = gray2bin(x,'pam',64);`
	`z = pammod(y,64,pi/4,'bin');`
	
	`x = 2*(randn(100,1)+1j*randn(100,1));`
	`y = pamdemod(x,64,pi/4,'bin');`
	`z = bin2gray(y,'pam',64);`
		`x = randi([0 63],1,100);`
		`z = pammod(x,64,pi/4,'gray');`
		
		`x = 2*(randn(100,1)+1j*randn(100,1));`
		`z = pamdemod(x,64,pi/4,'gray')`

FSK (fskmod and fskdemod)	`x = randi([0 63],1,100);`
	`y = gray2bin(x,'fsk',64);`
	`z = fskmod(y,64,1,256,256,'cont','bin')`
	
	`x = 2*(randn(512,1)+1j*randn(512,1));`
	`y = fskdemod(x,64,1,256,256,'bin');`
	`z = bin2gray(y,'fsk',64)`
		`x = randi([0 63],1,100);`
		`z = fskmod(x,64,1,256,256,'cont','gray')`
		`x = 2*(randn(512,1)+1j*randn(512,1));`
		`z = fskdemod(x,64,1,256,256,'gray');`

DPSK (dpskmod and dpskdemod)	`x = randi([0 63],1,100);`
	`y = gray2bin(x,'dpsk',64);`
	`z = dpskmod(y,64,pi/4,'bin');`
	
	`x = 2*(randn(100,1)+1j*randn(100,1));`
	`y = dpskdemod(x,64,pi/4,'bin');`
	`z = bin2gray(y,'dpsk',64);`
		`x = randi([0 63],1,100);`
		`z = dpskmod(x,64,pi/4,'gray');`
		
		`x = 2*(randn(100,1)+1j*randn(100,1));`
		`z = dpskdemod(x,64,pi/4,'gray');`

PSK (pskmod and pskdemod)	`x = randi([0 63],1,100);`
	`y = gray2bin(x,'psk',64);`
	`z = pskmod(y,64,0,'bin');`
	
	`x = 2*(randn(100,1)+1j*randn(100,1));`
	`y = pskdemod(x,64,0,'bin');`
	`z = bin2gray(y,'psk',64);`
		`x = randi([0 63],1,100);`
		`z = pskmod(x,64,0,'gray');`
		
		`x = 2*(randn(100,1)+1j*randn(100,1));`
		`z = pskdemod(x,64,0,'gray');`

Gray Encoding a Modulated Signal

gsmCheckTimeMask

Inspect GSM burst against time mask

Syntax

```
gsmCheckTimeMask(gsmCfg)
gsmCheckTimeMask(gsmCfg,tn)

pf = gsmCheckTimeMask(gsmCfg)
pf = gsmCheckTimeMask(gsmCfg,tn)
```

Description

`gsmCheckTimeMask(gsmCfg)` plots the burst for the first time slot and the upper and lower time masks for the input GSM configuration object. The `RiseTime`, `RiseDelay`, `FallTime`, and `FallDelay` properties of the configuration object define the power level versus time characteristics. For more information, see “Time Mask” on page 2-432.

`gsmCheckTimeMask(gsmCfg,tn)` plots the burst for the specified time slot, `tn`.

`pf = gsmCheckTimeMask(gsmCfg)` returns a pass or fail result for the specified configuration object indicating compliance of the burst in the first time slot with the time mask defined in the GSM standard. For more information, see “Time Mask” on page 2-432.

`pf = gsmCheckTimeMask(gsmCfg,tn)` returns a pass or fail result indicating compliance of the burst in the specified time slot, `tn`.

Examples

Check GSM Burst Against Time Mask

Create a GSM uplink TDMA frame configuration object with default settings. The GSM TDMA frame has eight time slots. Check the burst in the first time slot against the time mask specified by the GSM standard.

Create a GSM uplink TDMA frame configuration object with default settings.

```
cfggsmul = gsmUplinkConfig;
```

Use the `gsmCheckTimeMask` function to view the time mask and verify that the configured rise and fall characteristics of the burst comply with the time mask specified in the GSM standard. Plot the GSM burst and time mask. When no time slot number is provided, the `gsmCheckTimeMask` function shows the first time slot, `TN=0`.

```
pf = gsmCheckTimeMask(cfggsmul);
if pf
    disp('Time mask test passed.')
else
    disp('Time mask test failed.')
end
```

```
Time mask test passed.
```

```
gsmCheckTimeMask(cfggsmul);
```

Adjust the rise time of the GSM uplink TDMA frame configuration object, specifying a value that causes a time mask failure.

```
cfggsmul.RiseTime = 5
```

```
cfggsmul =
  gsmUplinkConfig with properties:

           BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
    SamplesPerSymbol: 16
                 TSC: [0 1 2 3 4 5 6 7]
         Attenuation: [0 0 0 0 0 0 0 0]
            RiseTime: 5
           RiseDelay: 0
            FallTime: 2
           FallDelay: 0
```

Use the `gsmCheckTimeMask` function to inspect the time mask of `cfggsmul`. The pass or fail result shows that the `cfggsmul` configuration now fails the time mask and the plot shows the upper time mask fails.

```
pf = gsmCheckTimeMask(cfggsmul);
if pf
```

```
    disp('Time mask test passed.')
else
    disp('Time mask test failed.')
end
```

```
Time mask test failed.
```

```
gsmCheckTimeMask(cfggsmul);
```

Check GSM Burst in Specified Time Slot Against Time Mask

Create a GSM uplink TDMA frame configuration object with default settings. The GSM TDMA frame has eight time slots. Check the burst in the specified time slot against the time mask specified by the GSM standard.

Create a GSM downlink TDMA frame configuration object with default settings.

```
cfggsmul = gsmDownlinkConfig;
```

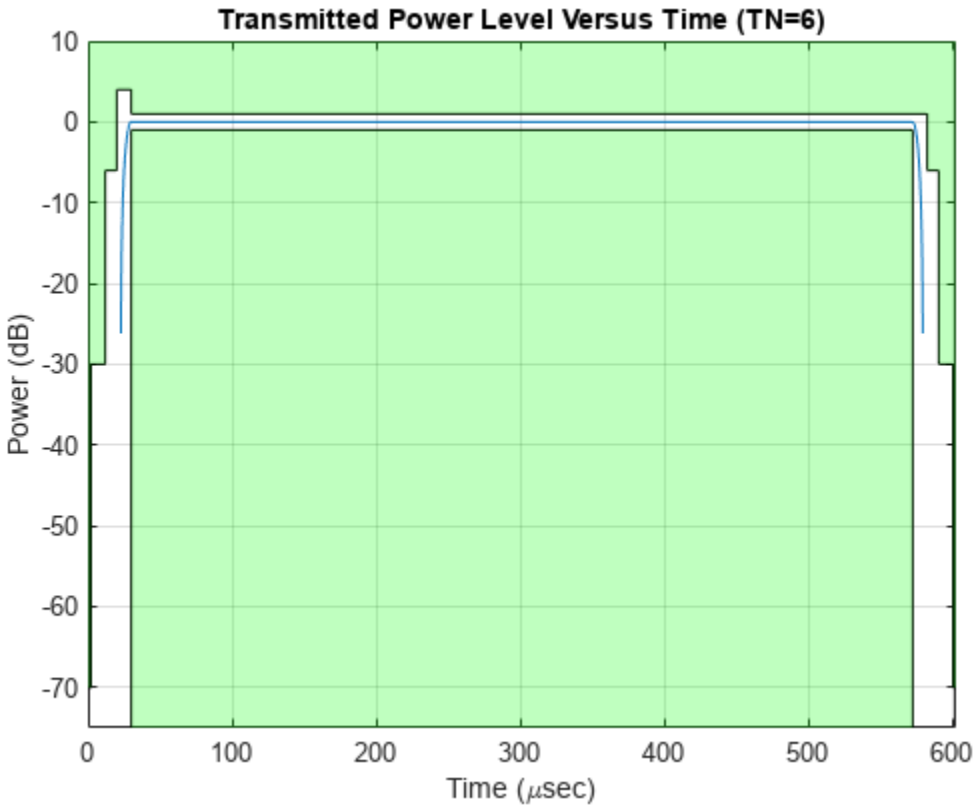
Use the `gsmCheckTimeMask` function to view the time mask and verify that the configured rise and fall characteristics of the burst in the specified time slot comply with the time mask specified by the GSM standard. Plot the GSM burst and time mask.

```
tn = 6; % Time slot number 6
pf = gsmCheckTimeMask(cfggsmul,tn);
```

```
if pf
    disp('Time mask test passed.')
else
    disp('Time mask test failed.')
end
```

```
Time mask test passed.
```

```
gsmCheckTimeMask(cfggsmul,tn);
```



Adjust the fall delay of the GSM downlink TDMA frame configuration object, specifying a value that causes a time mask failure.

```
cfggsmul.FallDelay = 4
```

```
cfggsmul =
  gsmDownlinkConfig with properties:

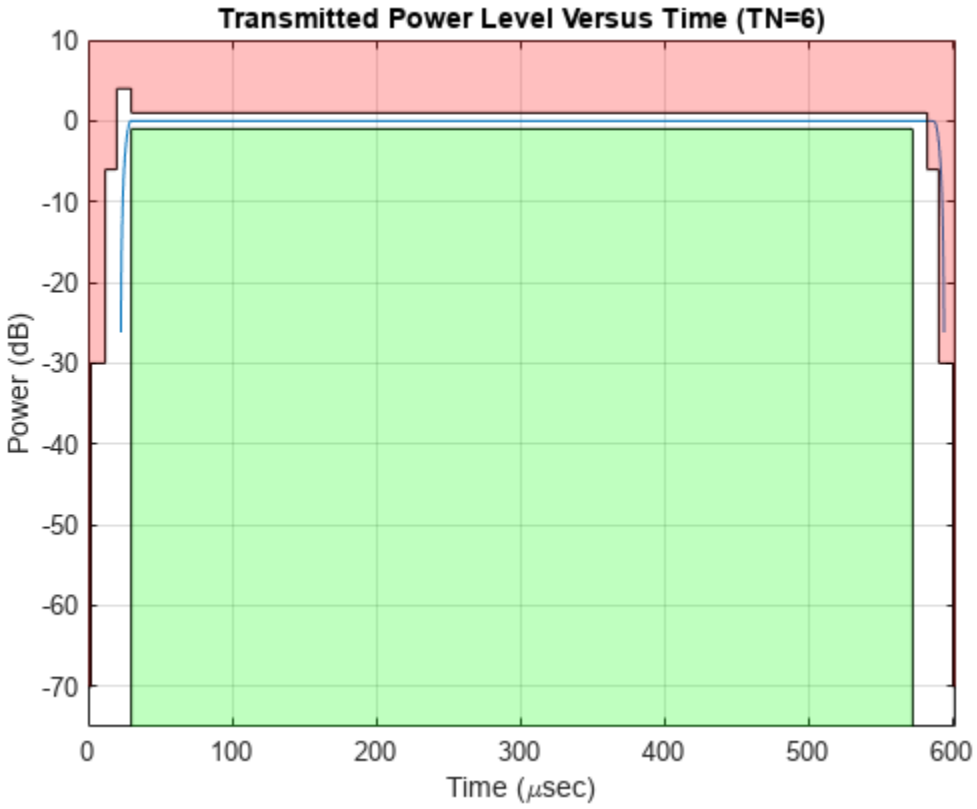
           BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
    SamplesPerSymbol: 16
                 TSC: [0 1 2 3 4 5 6 7]
        Attenuation: [0 0 0 0 0 0 0 0]
           RiseTime: 2
          RiseDelay: 0
           FallTime: 2
          FallDelay: 4
```

Use the `gsmCheckTimeMask` function to inspect the time mask of `cfggsmul`. The pass or fail result shows that the `cfggsmul` configuration now fails the time mask and the plot shows the upper time mask fails.

```
pf = gsmCheckTimeMask(cfggsmul,tn);
if pf
    disp('Time mask test passed.')
else
    disp('Time mask test failed.')
end
```

```
Time mask test failed.
```

```
gsmCheckTimeMask(cfggsmul,tn);
```



Check Time Mask for GSM Bursts

Create GSM downlink and uplink TDMA frame configuration objects that use the various burst types available.

- Normal bursts and bursts with no data are valid for downlink and uplink frames.
- Frequency correction, synchronization, and dummy bursts are valid in downlink frames only.
- Access bursts are valid in uplink frames only.

View time masks for the different burst types against the time mask specified by the GSM standard for the downlink and uplink frames.

Create a GSM downlink TDMA frame configuration object that configures the times slot bursts as [NB FB SB Dummy Off Off Off Off].

```
cfggsmdl = gsmDownlinkConfig('BurstType',["NB" "FB" "SB" "Dummy" "Off" "Off" "Off" "Off"])
```

```
cfggsmdl =
  gsmDownlinkConfig with properties:

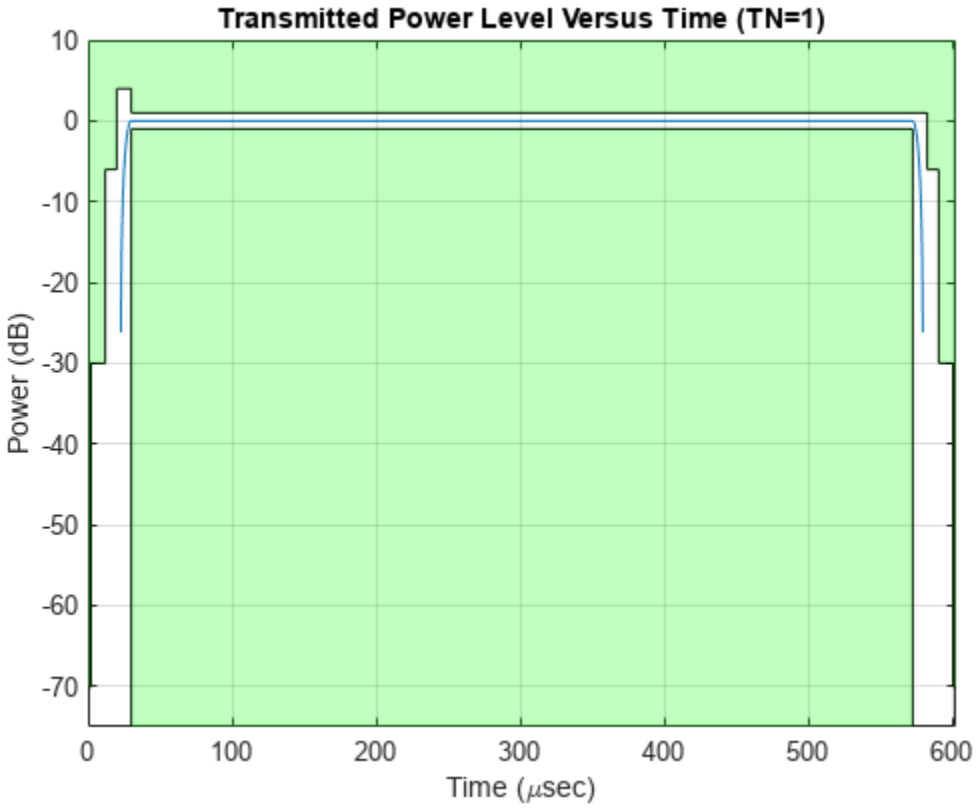
           BurstType: [NB    FB    SB    Dummy    Off    Off    Off    Off]
    SamplesPerSymbol: 16
                 TSC: [0 1 2 3 4 5 6 7]
         Attenuation: [0 0 0 0 0 0 0 0]
            RiseTime: 2
           RiseDelay: 0
            FallTime: 2
           FallDelay: 0
```

Use the `gsmCheckTimeMask` function to view the time mask for the different time slot burst types. For downlink GSM TDMA frames the same time mask limits applies for all burst types.

```
for tn = 0:4
    [dlbt,dlbtVal] = enumeration(cfggsmdl.BurstType);
    dlBurstInfo = ['Downlink (TN=',num2str(tn),'), BurstType: ',dlbtVal{tn+1}];
    disp(dlBurstInfo)
    gsmCheckTimeMask(cfggsmdl,tn);
end
```

```
Downlink (TN=0), BurstType: NB
```

```
Downlink (TN=1), BurstType: FB
```



```
Downlink (TN=2), BurstType: SB
```

```
Downlink (TN=3), BurstType: Dummy
```

```
Downlink (TN=4), BurstType: Off
```

Create a GSM uplink TDMA frame configuration object that configures the times slot bursts as [NB AB Off Off Off Off Off Off].

```
cfggsmul = gsmUplinkConfig('BurstType',["NB" "AB" "Off" "Off" "Off" "Off" "Off" "Off"])
```

```
cfggsmul =
  gsmUplinkConfig with properties:

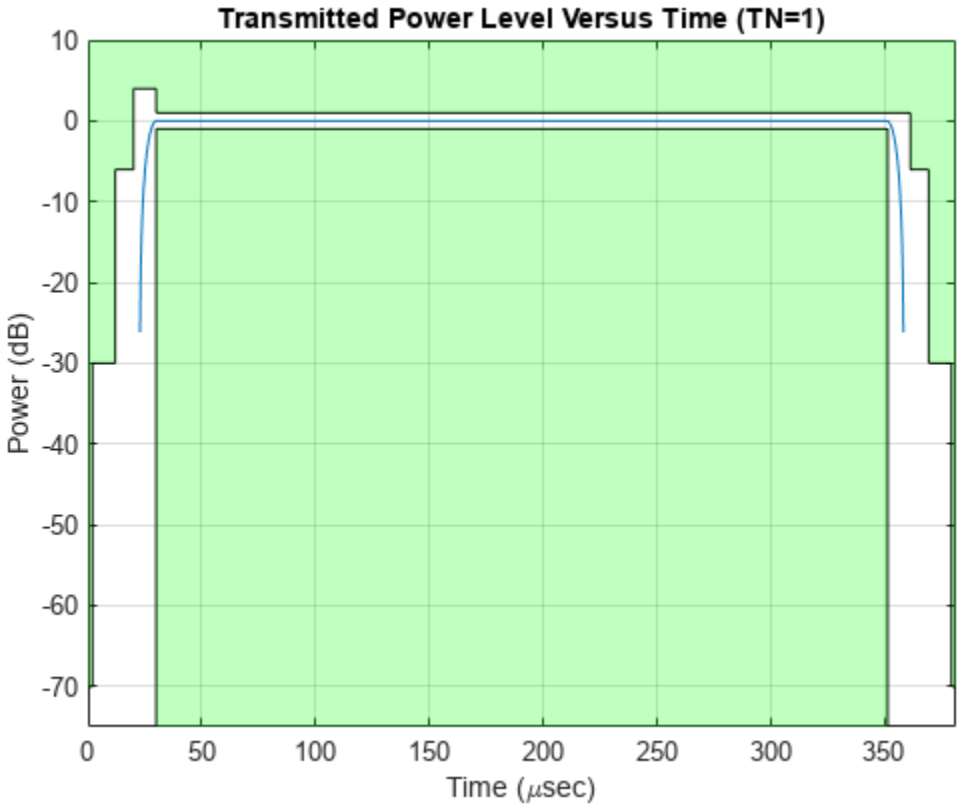
           BurstType: [NB    AB    Off    Off    Off    Off    Off    Off]
    SamplesPerSymbol: 16
                 TSC: [0 1 2 3 4 5 6 7]
        Attenuation: [0 0 0 0 0 0 0 0]
            RiseTime: 2
           RiseDelay: 0
            FallTime: 2
           FallDelay: 0
```

Use the `gsmCheckTimeMask` function to view the time masks for the different time slot burst types. For uplink GSM TDMA frames the access burst has a shorter time mask than the normal burst or no data burst.

```
for tn = 0:2
    [ulbt,ulbtVal] = enumeration(cfggsmul.BurstType);
    ulBurstInfo = ['Uplink (TN=',num2str(tn),'), BurstType: ',ulbtVal{tn+1}];
    disp(ulBurstInfo)
    gsmCheckTimeMask(cfggsmul,tn);
end
```

```
Uplink (TN=0), BurstType: NB
```

```
Uplink (TN=1), BurstType: AB
```



```
Uplink (TN=2), BurstType: Off
```

Input Arguments

`gsmCfg` — GSM configuration

`gsmUplinkConfig` object | `gsmDownlinkConfig` object

GSM configuration, specified as a `gsmUplinkConfig` or `gsmDownlinkConfig` object.

`tn` — Time slot number

`0` (default) | integer in the range [0, 7]

Time slot number, specified as an integer in the range [0, 7].

Data Types: `double`

Output Arguments

`pf` — Pass or fail result

`0` | `1`

Pass or fail result, returned as:

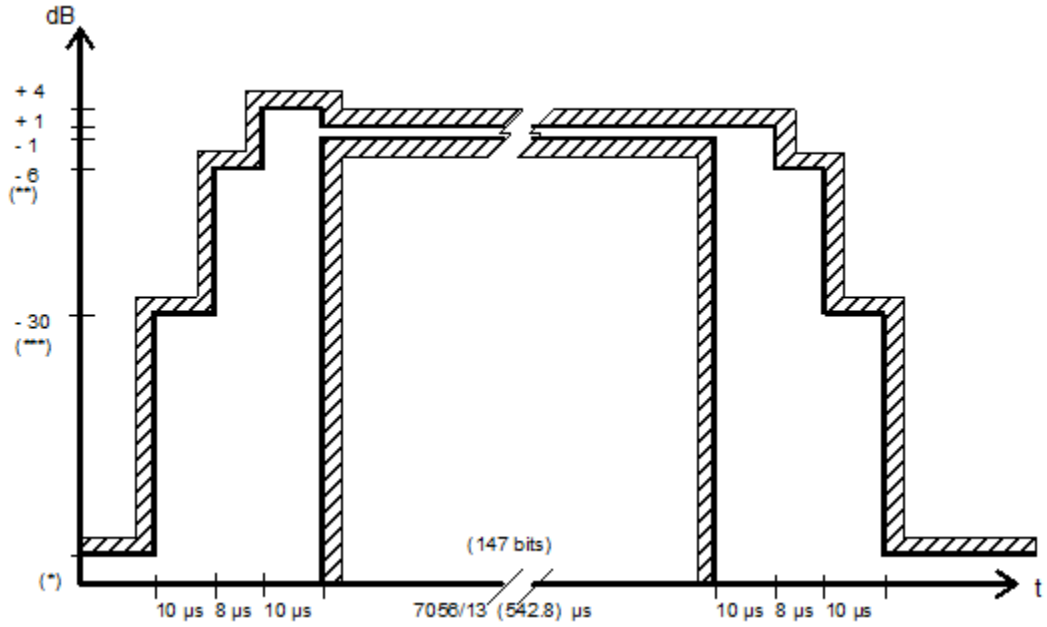
- `1` if the time mask passes
- `0` if the time mask fails

For more information, see “Time Mask” on page 2-432.

More About

Time Mask

The time mask defines the allowable transmitted power level versus time for time slot bursts in a GSM TDMA frame. This figure, from Annex B of TS 45.005, shows the upper and lower power limits for the time mask of a burst.



Version History

Introduced in R2019b

“GSM TDMA Frame Parameterization for Waveform Generation”

gsmFrame

Create GSM waveform

Syntax

```
gsmWaveform = gsmFrame(gsmCfg)
gsmWaveform = gsmFrame(gsmCfg,numFrames)
```

Description

`gsmWaveform = gsmFrame(gsmCfg)` creates a GSM waveform with one TDMA frame based on the input GSM configuration object. The encrypted bit field of the transmission data bursts is filled with random data. For more information, see “GSM Frames, Time Slots, and Bursts” on page 2-440.

`gsmWaveform = gsmFrame(gsmCfg,numFrames)` creates a GSM waveform, with `numFrames` identically configured TDMA frames. In each frame, the encrypted bit field of the transmission data bursts is filled with random data. For more information, see “GSM Frames, Time Slots, and Bursts” on page 2-440.

Examples

Create GSM Uplink Waveform

Create a GSM uplink TDMA frame configuration object with default settings, and then create a GSM waveform containing one TDMA frame. GSM TDMA frames have eight time slots, each separated by a guard period of 8.25 symbols or about 30.46x10e-3 ms. Plot the GSM waveform.

Create a GSM uplink TDMA frame configuration object with default settings.

```
cfggsmul = gsmUplinkConfig
```

```
cfggsmul =
  gsmUplinkConfig with properties:

           BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
    SamplesPerSymbol: 16
                 TSC: [0 1 2 3 4 5 6 7]
         Attenuation: [0 0 0 0 0 0 0 0]
            RiseTime: 2
           RiseDelay: 0
            FallTime: 2
           FallDelay: 0
```

Display information about the configured `gsmUplinkConfig` object by using the `gsmInfo` function. Assign the sample rate to a variable, `Rs`, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmul)
```

```
wfInfo = struct with fields:
              SymbolRate: 2.7083e+05
```

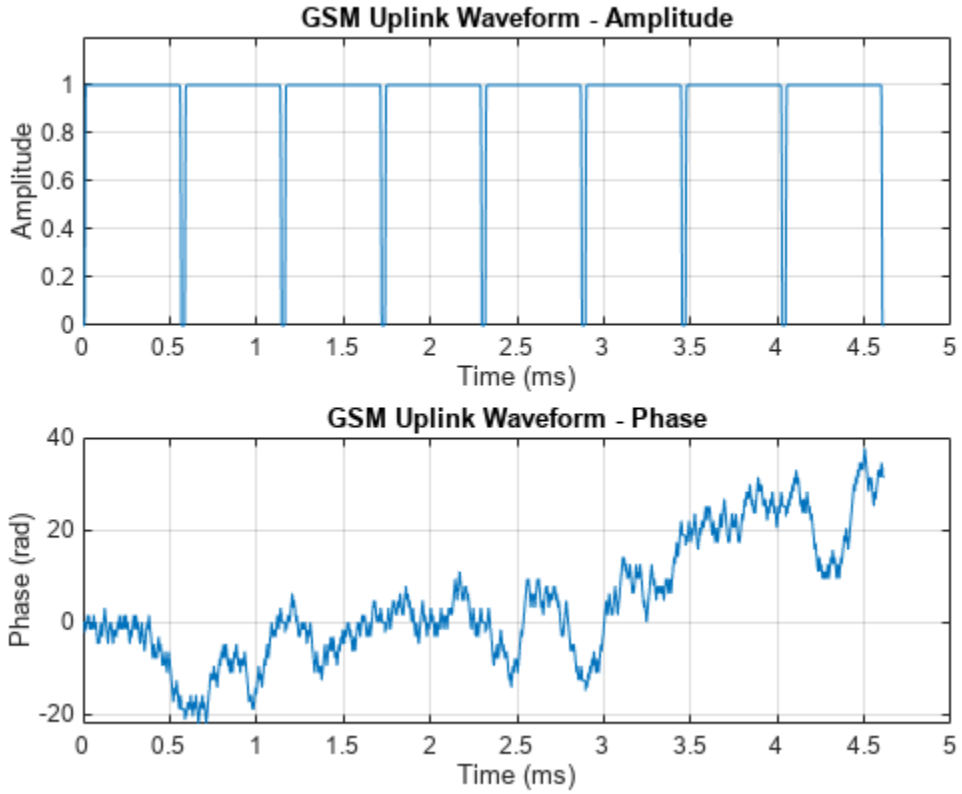
```
              SampleRate: 4.3333e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
       NumBurstsPerFrame: 8
    BurstLengthInSamples: 2500
    FrameLengthInSamples: 20000
```

```
Rs = wfInfo.SampleRate;
```

Create the GSM waveform by using the `gsmFrame` function, and then plot the GSM waveform.

```
waveform = gsmFrame(cfggsmul);

t = (0:length(waveform)-1)/Rs*1e3;
subplot(2,1,1)
plot(t,abs(waveform))
grid on
axis([0 5 0 1.2])
title('GSM Uplink Waveform - Amplitude')
xlabel('Time (ms)')
ylabel('Amplitude')
subplot(2,1,2)
plot(t,unwrap(angle(waveform)))
grid on
title('GSM Uplink Waveform - Phase')
xlabel('Time (ms)')
ylabel('Phase (rad)')
```



Create GSM Uplink Waveform Containing Five TDMA Frames

Create a GSM downlink TDMA frame configuration object with default settings, and then create a GSM waveform containing five TDMA frames. GSM TDMA frames have eight time slots, each separated by a guard period of 8.25 symbols or about 30.46x10e-3 ms. Plot the GSM waveform.

Create a GSM uplink TDMA frame configuration object, specifying 3 dB of attenuation in the last time slot to help identify the end of each frame.

```
cfggsmul = gsmUplinkConfig('Attenuation',[0 0 0 0 0 0 0 3])
```

```
cfggsmul =
  gsmUplinkConfig with properties:

           BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
    SamplesPerSymbol: 16
                 TSC: [0 1 2 3 4 5 6 7]
         Attenuation: [0 0 0 0 0 0 0 3]
            RiseTime: 2
           RiseDelay: 0
            FallTime: 2
           FallDelay: 0
```

Display information about the configured `gsmUplinkConfig` object by using the `gsmInfo` function. Assign the frame length in samples to a variable, `spf`, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmul)
```

```
wfInfo = struct with fields:
               SymbolRate: 2.7083e+05
               SampleRate: 4.3333e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
       NumBurstsPerFrame: 8
    BurstLengthInSamples: 2500
    FrameLengthInSamples: 20000
```

```
spf = wfInfo.FrameLengthInSamples;
```

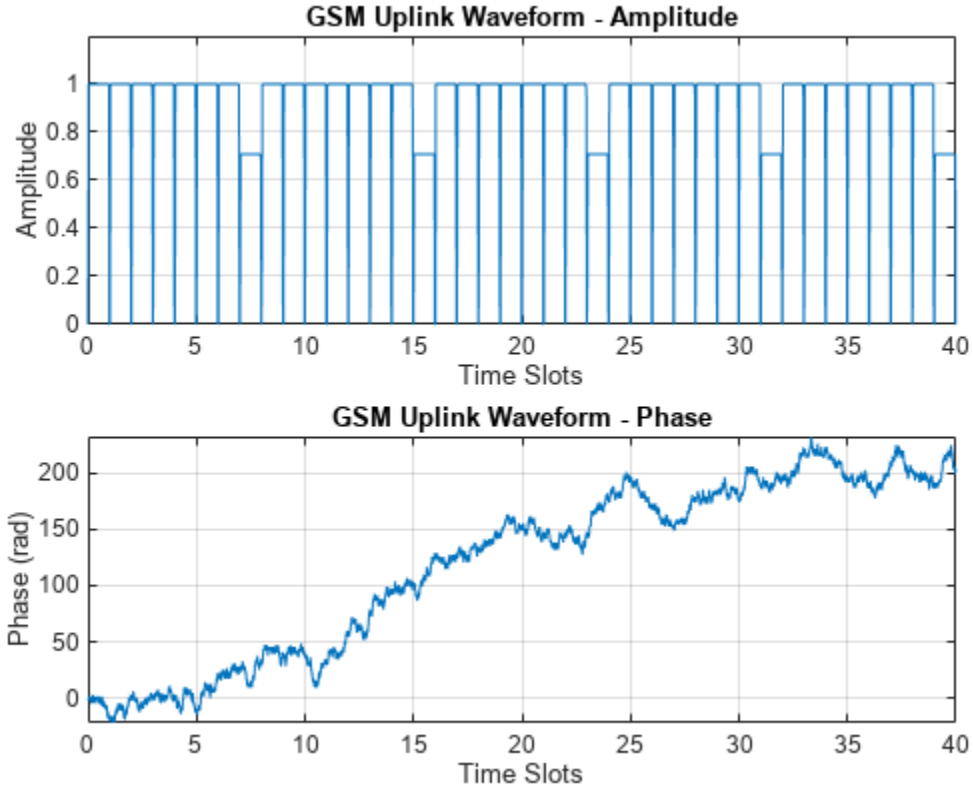
Create the GSM waveform by using the `gsmFrame` function, and then plot the GSM waveform. The last time slot of each frame is 3 dB less than the other time slots in that frame.

```
numFrames = 5;
waveform = gsmFrame(cfggsmul,numFrames);

t = 8*(0:length(waveform)-1)/spf;

numTS = 8*numFrames;
subplot(2,1,1)
plot(t,abs(waveform))
grid on
axis([0 numTS 0 1.2])
title('GSM Uplink Waveform - Amplitude')
```

```
xlabel('Time Slots')
ylabel('Amplitude')
subplot(2,1,2)
plot(t,unwrap(angle(waveform)))
grid on
title('GSM Uplink Waveform - Phase')
xlabel('Time Slots')
ylabel('Phase (rad)')
```



Create GSM Downlink Waveform

Create a GSM downlink TDMA frame configuration object with default settings, and then create a GSM waveform containing one TDMA frame. The GSM TDMA frame has eight time slots, each separated by a guard period of 8.25 symbols or about 30.46x10e-3 ms. Plot the GSM waveform.

Create a GSM downlink TDMA frame configuration object with default settings.

```
cfggsmdl = gsmDownlinkConfig
```

```
cfggsmdl =
  gsmDownlinkConfig with properties:

           BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
    SamplesPerSymbol: 16
                 TSC: [0 1 2 3 4 5 6 7]
```

```
          Attenuation: [0 0 0 0 0 0 0 0]
             RiseTime: 2
            RiseDelay: 0
             FallTime: 2
            FallDelay: 0
```

Display information about the configured `gsmDownlinkConfig` object by using the `gsmInfo` function. Assign the sample rate to a variable, `Rs`, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmdl)
```

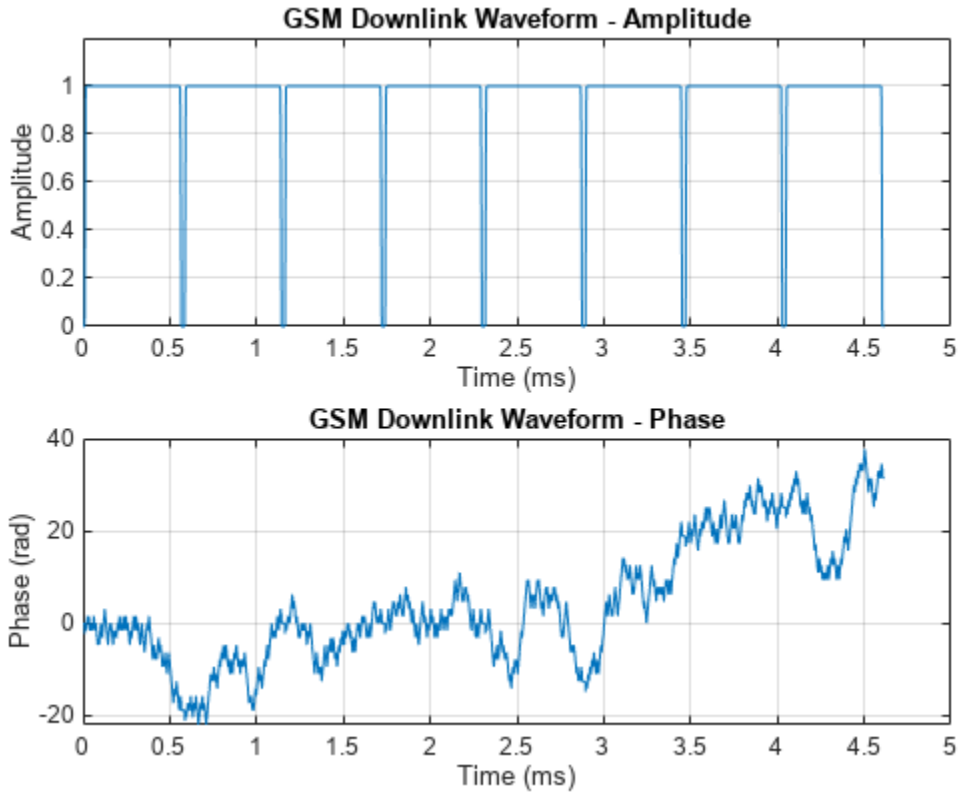
```
wfInfo = struct with fields:
              SymbolRate: 2.7083e+05
              SampleRate: 4.3333e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
       NumBurstsPerFrame: 8
    BurstLengthInSamples: 2500
    FrameLengthInSamples: 20000
```

```
Rs = wfInfo.SampleRate;
```

Create the GSM waveform by using the `gsmFrame` function, and then plot the GSM waveform.

```
waveform = gsmFrame(cfggsmdl);

t = (0:length(waveform)-1)/Rs*1e3;
subplot(2,1,1)
plot(t,abs(waveform))
grid on
axis([0 5 0 1.2])
title('GSM Downlink Waveform - Amplitude')
xlabel('Time (ms)')
ylabel('Amplitude')
subplot(2,1,2)
plot(t,unwrap(angle(waveform)))
grid on
title('GSM Downlink Waveform - Phase')
xlabel('Time (ms)')
ylabel('Phase (rad)')
```



Input Arguments

`gsmCfg` — GSM configuration

`gsmUplinkConfig` object | `gsmDownlinkConfig` object

GSM configuration, specified as a `gsmUplinkConfig` or `gsmDownlinkConfig` object.

`numFrames` — Number of TDMA frames

16 (default) | positive integer

Number of TDMA frames in the waveform, specified as a positive integer.

Data Types: `double`

Output Arguments

`gsmWaveform` — Output time-domain waveform

complex-valued column vector

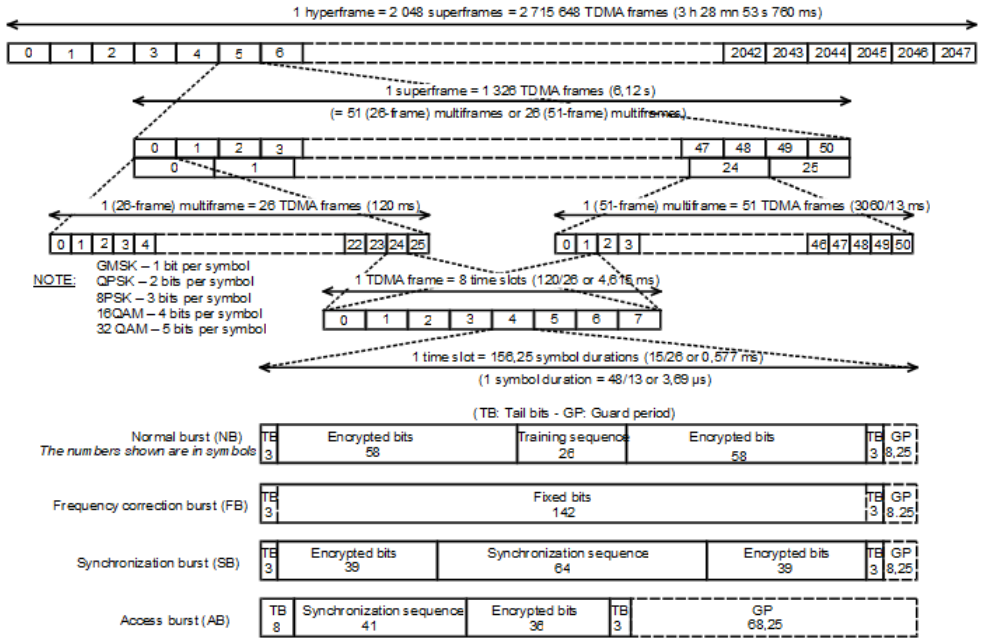
Output time-domain waveform, returned as a complex-valued column vector of length N_s, where N_s represents the number of time-domain samples. The function generates this waveform in the form of complex in-phase quadrature (IQ) samples.

More About

GSM Frames, Time Slots, and Bursts

In GSM, transmissions consist of TDMA frames. Each GSM TDMA frame consists of eight time slots. The transmission data content of a time slot is called a burst. As described in Section 5.2 of 3GPP TS 45.011, a GSM time slot has a 156.25-symbol duration when using the normal symbol period, which is a time interval of 15/26 ms or about 576.9 microseconds. A guard period of 8.25 symbols or about 30.46 microseconds separates each time slot. The GSM standards describes a symbol as one bit period. Since GSM uses GMSK modulation, there is one bit per bit period. The transmission timing of a burst within a time slot is defined in terms of the bit number (BN). The BN refers to a particular bit period within a time slot. The bit with the lowest BN is transmitted first. BN0 is the first bit period, and BN156 is the last quarter-bit period.

This image from 3GPP TS 45.011 shows the relationship between different frame types and the relationship between different burst types.

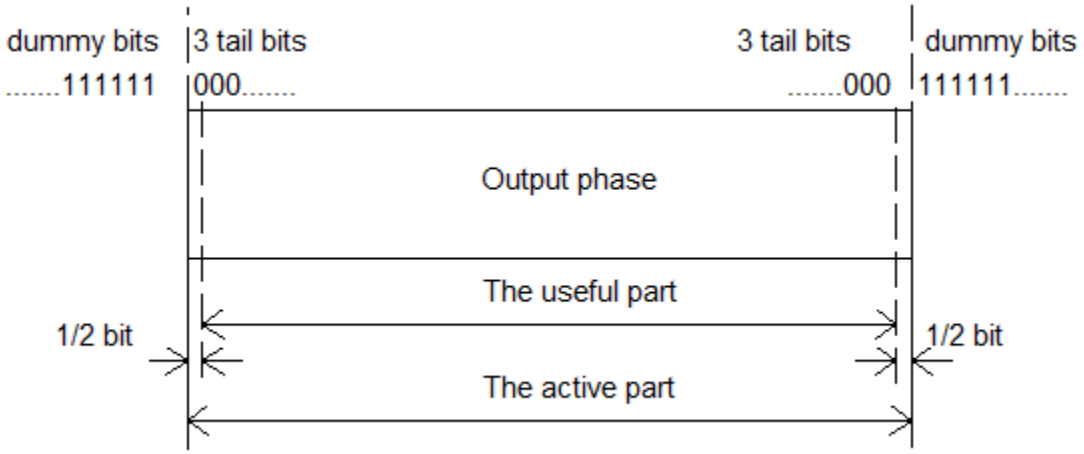


This table shows the supported burst types and their characteristics.

Burst Type	Description	Link Direction	Useful Duration
`NB`	Normal burst	Uplink/Downlink	147
`FB`	Frequency correction burst	Downlink	147
`SB`	Synchronization burst	Downlink	147
`Dummy`	Dummy burst	Downlink	147
`AB`	Access burst	Uplink	87
`Off`	No burst sent	Uplink/Downlink	0

Useful duration, described in Section 5.2.2 of 3GPP TS 45.002, is a characteristic of GSM bursts. The useful duration, or useful part, of a burst is defined as beginning halfway through BN0 and ending

half a bit period before the start of the guard period. The guard period is the period between bursts in successive time slots. This figure, from Section 2.2 of 3GPP TS 45.004, shows the leading and trailing ½ bit difference between the useful and active parts of the burst.



For more information, see “GSM TDMA Frame Parameterization for Waveform Generation”.

Training Sequence Code (TSC)

Normal bursts include a training sequence bits field assigned a bit pattern based on the specified TSC. For GSM, you can select one of these eight training sequences for normal burst type time slots.

Training Sequence Code (TSC)	Training Sequence Bits (BN61, BN62, ..., BN86)
0	(0,0,1,0,0,1,0,1,1,1,0,0,0,0,1,0,0,0,1,0,0,1,0,1,1,1)
1	(0,0,1,0,1,1,0,1,1,1,0,1,1,1,1,0,0,0,1,0,1,1,0,1,1,1)
2	(0,1,0,0,0,0,1,1,1,0,1,1,1,0,1,0,0,1,0,0,0,0,0,1,1,1,0)

Topics
“GSM TDMA Frame Parameterization for Waveform Generation”

gsmInfo

View GSM waveform information

Syntax

```
infostruct= gsmInfo(gsmCfg)
```

Description

`infostruct= gsmInfo(gsmCfg)` returns a structure containing characteristic waveform information for the input GSM configuration object.

Examples

View GSM Configuration Object Information

View information from downlink and uplink GSM configuration objects.

Create a GSM downlink configuration object with default settings and use `gsmInfo` to view the waveform information structure.

```
cfgDL = gsmDownlinkConfig;
infostructDL = gsmInfo(cfgDL)
```

```
infostructDL = struct with fields:
              SymbolRate: 2.7083e+05
              SampleRate: 4.3333e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
       NumBurstsPerFrame: 8
    BurstLengthInSamples: 2500
    FrameLengthInSamples: 20000
```

Create a GSM uplink configuration object with default settings and use `gsmInfo` to view the waveform information structure.

```
cfgUL = gsmUplinkConfig;
infostructUL = gsmInfo(cfgUL)
```

```
infostructUL = struct with fields:
              SymbolRate: 2.7083e+05
              SampleRate: 4.3333e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
       NumBurstsPerFrame: 8
    BurstLengthInSamples: 2500
    FrameLengthInSamples: 20000
```

Create GSM Uplink Waveform Containing Five TDMA Frames

Create a GSM downlink TDMA frame configuration object with default settings, and then create a GSM waveform containing five TDMA frames. GSM TDMA frames have eight time slots, each separated by a guard period of 8.25 symbols or about 30.46x10e-3 ms. Plot the GSM waveform.

Create a GSM uplink TDMA frame configuration object, specifying 3 dB of attenuation in the last time slot to help identify the end of each frame.

```
cfggsmul = gsmUplinkConfig('Attenuation',[0 0 0 0 0 0 0 3])
```

```
cfggsmul =
  gsmUplinkConfig with properties:

           BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
    SamplesPerSymbol: 16
                 TSC: [0 1 2 3 4 5 6 7]
         Attenuation: [0 0 0 0 0 0 0 3]
            RiseTime: 2
           RiseDelay: 0
            FallTime: 2
           FallDelay: 0
```

Display information about the configured `gsmUplinkConfig` object by using the `gsmInfo` function. Assign the frame length in samples to a variable, `spf`, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmul)
```

```
wfInfo = struct with fields:
               SymbolRate: 2.7083e+05
               SampleRate: 4.3333e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
       NumBurstsPerFrame: 8
    BurstLengthInSamples: 2500
    FrameLengthInSamples: 20000
```

```
spf = wfInfo.FrameLengthInSamples;
```

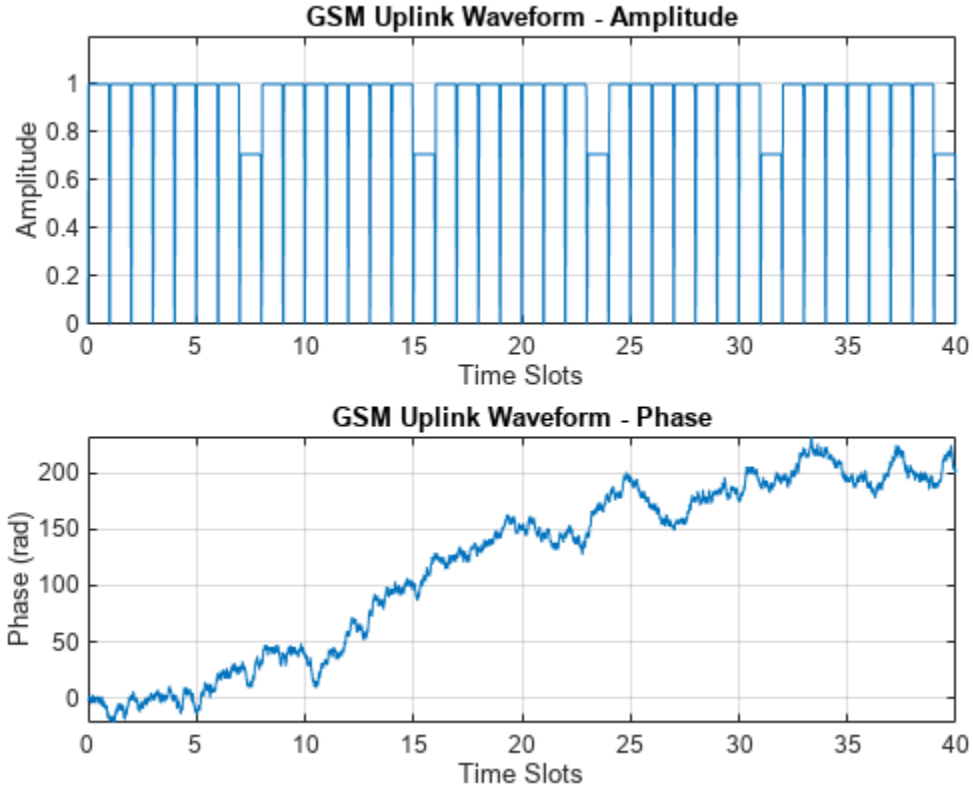
Create the GSM waveform by using the `gsmFrame` function, and then plot the GSM waveform. The last time slot of each frame is 3 dB less than the other time slots in that frame.

```
numFrames = 5;
waveform = gsmFrame(cfggsmul,numFrames);

t = 8*(0:length(waveform)-1)/spf;

numTS = 8*numFrames;
subplot(2,1,1)
plot(t,abs(waveform))
grid on
axis([0 numTS 0 1.2])
title('GSM Uplink Waveform - Amplitude')
xlabel('Time Slots')
ylabel('Amplitude')
subplot(2,1,2)
```

```
plot(t,unwrap(angle(waveform)))
grid on
title('GSM Uplink Waveform - Phase')
xlabel('Time Slots')
ylabel('Phase (rad)')
```



Input Arguments

`gsmCfg` — GSM configuration

`gsmUplinkConfig` object | `gsmDownlinkConfig` object

GSM configuration, specified as a `gsmUplinkConfig` or `gsmDownlinkConfig` object.

Output Arguments

`infostruct` — Structure containing object information

struct

Structure containing these fields with information about the characteristic GSM waveform based on the input configuration object.

`SymbolRate` — GSM symbol rate

positive integer

GSM symbol rate in symbols per second, returned as a positive integer.

`SampleRate` — GSM sample rate
positive integer

GSM sample rate in samples per second, returned as a positive integer.

`BandwidthTimeProduct` — Product of bandwidth and symbol time of Gaussian pulse
positive integer

Product of bandwidth and symbol time of Gaussian pulse for the GMSK modulator, returned as a positive integer.

`BurstLengthInSymbols` — GSM burst length
positive scalar

GSM burst length in symbols, returned as a positive scalar.

`NumBurstsPerFrame` — Number of bursts in GSM TDMA frame
positive integer

Number of bursts in a GSM TDMA frame, returned as a positive integer.

`BurstLengthInSamples` — GSM burst length
positive integer

GSM burst length in samples, returned as a positive integer.

`FrameLengthInSamples` — GSM frame length
positive integer

GSM frame length in samples, returned as a positive integer.

hammgen

Parity-check and generator matrices for Hamming code

Syntax

```
h = hammgen(m)
h = hammgen(m,poly)
[h,g] = hammgen(___)
[h,g,n,k] = hammgen(___)
```

Description

`h = hammgen(m)` returns an `m`-by-*n* parity-check matrix, `h`, for a Hamming code of codeword length $n = 2^m-1$. The message length of the Hamming code is $n - m$. The binary primitive polynomial that the function uses to create the Hamming code is the default primitive polynomial in GF(`2^m`). For more details of this default polynomial, see the `gfprimdf` function.

`h = hammgen(m,poly)` specifies `poly`, a binary primitive polynomial for GF(2^m). The function uses `poly` to create the Hamming code.

`[h,g] = hammgen(___)` additionally returns a *k*-by-*n* generator matrix, `g`, that corresponds to the parity-check matrix `h`. Specify any of the input argument combinations from the previous syntaxes.

`[h,g,n,k] = hammgen(___)` also returns `n`, the codeword length and `k`, the message length, for the Hamming code.

Examples

Generate Hamming Code Parity-Check Matrix Using Default Primitive Polynomial

Generate a parity-check matrix, `h`, for a Hamming code of codeword length 7. The function uses the default primitive polynomial in GF(8) to create the Hamming code.

```
h = hammgen(3)
```

```
h = 3×7

     1     0     0     1     0     1     1
     0     1     0     1     1     1     0
     0     0     1     0     1     1     1
```

Generate Hamming Code Parity-Check Matrix from Primitive Polynomials

Generate the parity-check matrices for the Hamming code of codeword length 15, specifying the primitive polynomials $1 + D + D^4$ and $1 + D^3 + D^4$ in GF(16).

```
h1 = hammgen(4,'1+D+D^4')
```

```
h1 = 4×15

     1     0     0     0     1     0     0     1     1     0     1     0     1     1     1
     0     1     0     0     1     1     0     1     0     1     1     1     1     0     0
     0     0     1     0     0     1     1     0     1     0     1     1     1     1     0
     0     0     0     1     0     0     1     1     0     1     0     1     1     1     1
```

```
h2 = hammgen(4,'1+D^3+D^4')
```

```
h2 = 4×15

     1     0     0     0     1     1     1     1     0     1     0     1     1     0     0
     0     1     0     0     0     1     1     1     1     0     1     0     1     1     0
     0     0     1     0     0     0     1     1     1     1     0     1     0     1     1
     0     0     0     1     1     1     1     0     1     0     1     1     0     0     1
```

Remove the embedded 4-by-4 identity matrices that is, the leftmost four columns in each parity-check matrix.

```
h1 = h1(:,5:end)
```

```
h1 = 4×11

     1     0     0     1     1     0     1     0     1     1     1
     1     1     0     1     0     1     1     1     1     0     0
     0     1     1     0     1     0     1     1     1     1     0
     0     0     1     1     0     1     0     1     1     1     1
```

```
h2 = h2(:,5:end)
```

```
h2 = 4×11

     1     1     1     1     0     1     0     1     1     0     0
     0     1     1     1     1     0     1     0     1     1     0
     0     0     1     1     1     1     0     1     0     1     1
     1     1     1     0     1     0     1     1     0     0     1
```

Verify that the two resulting matrices differ.

```
isequal(h1,h2)
```

```
ans = logical
   0
```

Generate Hamming Code Parity-Check and Generator Matrices

Generate the parity-check matrix, `h` and the generator matrix, `g` for the Hamming code of codeword length 7. Also return the codeword length, `n`, and the message length, `k` for the Hamming code. The function uses the default primitive polynomial in GF(8) to create the Hamming code.

```
[h,g,n,k] = hammgen(3)

h = 3×7

     1     0     0     1     0     1     1
     0     1     0     1     1     1     0
     0     0     1     0     1     1     1

g = 4×7

     1     1     0     1     0     0     0
     0     1     1     0     1     0     0
     1     1     1     0     0     1     0
     1     0     1     0     0     0     1

n = 7

k = 4
```

Input Arguments

`m` — Number of rows in parity-check matrix

integer greater than or equal to two

Number of rows in parity-check matrix, specified as an integer greater than or equal to two. The function uses this value to calculate the codeword length and the message length of the Hamming code.

Data Types: `double`

`poly` — Binary primitive polynomial in GF(2^m)

binary row vector | character vector | string scalar

Binary primitive polynomial in GF(2^m), specified as one of these values:

- Binary row vector of the polynomial coefficients in order of ascending powers
- Character vector
- String scalar

If `poly` is specified as a non-primitive polynomial, then the function `hammgen` displays an error.

Data Types: `double` | `char` | `string`

Output Arguments

`h` — Parity-check matrix for Hamming code

`m`-by-`n` matrix of binary values

Parity-check matrix for Hamming code, returned as an `m`-by-`n` matrix of binary values for the Hamming code.

Data Types: `single` | `double`

g — Generator matrix for Hamming code
k-by-n matrix of binary values

Generator matrix for Hamming code, returned as a k-by-n matrix of binary values corresponding to the parity-check matrix h.

Data Types: `single` | `double`

n — Codeword length of Hamming code
positive integer

Codeword length of Hamming code, returned as a positive integer. This value is calculated as $2^m–1$.

Data Types: `single` | `double`

k — Message length of Hamming code
positive integer

Message length of Hamming code, returned as a positive integer. This value is calculated as n–m.

Data Types: `single` | `double`

Algorithms

`hammgen` uses the function `gftuple` to create the parity-check matrix by converting each element in the Galois field (GF) to its polynomial representation. Unlike `gftuple`, which performs computations in GF(2^m) and processes one `m`-tuple at a time, the `hammgen` function generates the entire sequence from 0 to $2^m–1$. The computation algorithm uses all previously computed values to generate the computation result. If the value of `m` is less than 25 and the primitive polynomial is the default primitive polynomial for GF(2^m), the syntax `hammgen(m)` might be faster than the syntax `hammgen(m,poly)`.

hank2sys

(To be removed) Convert Hankel matrix to linear system model

Compatibility

hank2sys will be removed in a future release.

Syntax

```
[num,den] = hank2sys(h,ini,tol)
[num,den,sv] = hank2sys(h,ini,tol)
[a,b,c,d] = hank2sys(h,ini,tol)
[a,b,c,d,sv] = hank2sys(h,ini,tol)
```

Description

`[num,den] = hank2sys(h,ini,tol)` converts a Hankel matrix `h` to a linear system transfer function with numerator `num` and denominator `den`. The vectors `num` and `den` list the coefficients of their respective polynomials in ascending order of powers of z^{-1}. The argument `ini` is the system impulse at time zero. If `tol` > 1, `tol` is the order of the conversion. If `tol` < 1, `tol` is the tolerance in selecting the conversion order based on the singular values. If you omit `tol`, its default value is 0.01. This conversion uses the singular value decomposition method.

`[num,den,sv] = hank2sys(h,ini,tol)` returns a vector `sv` that lists the singular values of `h`.

`[a,b,c,d] = hank2sys(h,ini,tol)` converts a Hankel matrix `h` to a corresponding linear system state-space model. `a`, `b`, `c`, and `d` are matrices. The input parameters are the same as in the first syntax above.

`[a,b,c,d,sv] = hank2sys(h,ini,tol)` is the same as the syntax above, except that `sv` is a vector that lists the singular values of `h`.

Examples

```
h = hankel([1 0 1]);
[num,den,sv] = hank2sys(h,0,.01)
```

The output is

```
num =

         0    1.0000    0.0000    1.0000

den =

    1.0000    0.0000    0.0000    0.0000

sv =
```

```
1.6180
1.0000
0.6180
```

Version History

Introduced before R2006a

hank2sys will be removed in a future release.
Warns starting in R2021b

hank2sys will be removed in a future release.

`hankel`

heldeintrlv

Restore ordering of symbols permuted using `helintrlv`

Syntax

```
[deintrlved,state] = heldeintrlv(data,col,ngrp,stp)
[deintrlved,state] = heldeintrlv(data,col,ngrp,stp,init_state)
deintrlved = heldeintrlv(data,col,ngrp,stp,init_state)
```

Description

`[deintrlved,state] = heldeintrlv(data,col,ngrp,stp)` restores the ordering of symbols in `data` by placing them in an array row by row and then selecting groups in a helical fashion to place in the output, `deintrlved`. `data` must have `col*ngrp` elements. If `data` is a matrix with multiple rows and columns, it must have `col*ngrp` rows, and the function processes the columns independently. `state` is a structure that holds the final state of the array. `state.value` stores input symbols that remain in the `col` columns of the array and do not appear in the output.

The function uses the array internally for its computations. The array has unlimited rows indexed by 1, 2, 3,..., and `col` columns. The function initializes the top of the array with zeros. It then places `col*ngrp` symbols from the input into the next `ngrp` rows of the array. The function places symbols from the array in the output, `intrlved`, placing `ngrp` symbols at a time; the kth group of `ngrp` symbols comes from the kth column of the array, starting from row 1+(k-1)*`stp`. Some output symbols are default values of 0 rather than input symbols; similarly, some input symbols are left in the array and do not appear in the output.

`[deintrlved,state] = heldeintrlv(data,col,ngrp,stp,init_state)` initializes the array with the symbols contained in `init_state.value` instead of zeros. The structure `init_state` is typically the `state` output from a previous call to this same function, and is unrelated to the corresponding interleaver. In this syntax, some output symbols are default values of 0, some are input symbols from `data`, and some are initialization values from `init_state.value`.

`deintrlved = heldeintrlv(data,col,ngrp,stp,init_state)` is the same as the syntax above, except that it does not record the deinterleaver's final state. This syntax is appropriate for the last in a series of calls to this function. However, if you plan to call this function again to continue the deinterleaving process, the syntax above is more appropriate.

Using an Interleaver-Deinterleaver Pair

To use this function as an inverse of the `helintrlv` function, use the same `col`, `ngrp`, and `stp` inputs in both functions. In that case, the two functions are inverses in the sense that applying `helintrlv` followed by `heldeintrlv` leaves data unchanged, after you take their combined delay of `col*ngrp*ceil(stp*(col-1)/ngrp)` into account. To learn more about delays of convolutional interleavers, see “Delays of Convolutional Interleavers”.

Note Because the delay is an integer multiple of the number of symbols in `data`, you must use `heldeintrlv` at least *twice* (possibly more times, depending on the actual delay value) before the function returns results that represent more than just the delay.

Examples

Recover interleaved data, taking into account the delay of the interleaver-deinterleaver pair.

```
col = 4; ngrp = 3; stp = 2; % Helical interleaver parameters
% Compute the delay of interleaver-deinterleaver pair.
delayval = col * ngrp * ceil(stp * (col-1)/ngrp);

len = col*ngrp; % Process this many symbols at one time.
data = randi([0 9],len,1); % Random symbols
data_padded = [data; zeros(delayval,1)]; % Pad with zeros.

% Interleave zero-padded data.
[i1,istate] = helintrlv(data_padded(1:len),col,ngrp,stp);
[i2,istate] = helintrlv(data_padded(len+1:2*len),col,ngrp, ...
              stp,istate);
i3 = helintrlv(data_padded(2*len+1:end),col,ngrp,stp,istate);

% Deinterleave.
[d1,dstate] = heldeintrlv(i1,col,ngrp,stp);
[d2,dstate] = heldeintrlv(i2,col,ngrp,stp,dstate);
d3 = heldeintrlv(i3,col,ngrp,stp,dstate);

% Check the results.
d0 = [d1; d2; d3]; % All the deinterleaved data
d0_trunc = d0(delayval+1:end); % Remove the delay.
ser = symerr(data,d0_trunc)
```

The output below shows that no symbol errors occurred.

```
ser =

     0
```

“Interleaving”

helintrlv

Permute symbols using helical array

Syntax

```
intrlved = helintrlv(data,col,ngrp,stp)
[intrlved,state] = helintrlv(data,col,ngrp,stp)
[intrlved,state] = helintrlv(data,col,ngrp,stp,init_state)
```

Description

`intrlved = helintrlv(data,col,ngrp,stp)` permutes the symbols in `data` by placing them in an unlimited-row array in helical fashion and then placing rows of the array in the output, `intrlved`. `data` must have `col*ngrp` elements. If `data` is a matrix with multiple rows and columns, it must have `col*ngrp` rows, and the function processes the columns independently.

The function uses the array internally for its computations. The array has unlimited rows indexed by 1, 2, 3,..., and `col` columns. The function partitions `col*ngrp` symbols from the input into consecutive groups of `ngrp` symbols. The function places the kth group in the array along column k, starting from row 1+(k-1)*`stp`. Positions in the array that do not contain input symbols have default values of 0. The function places `col*ngrp` symbols from the array in the output, `intrlved`, by reading the first `ngrp` rows sequentially. Some output symbols are default values of 0 rather than input symbols; similarly, some input symbols are left in the array and do not appear in the output.

`[intrlved,state] = helintrlv(data,col,ngrp,stp)` returns a structure that holds the final state of the array. `state.value` stores input symbols that remain in the `col` columns of the array and do not appear in the output.

`[intrlved,state] = helintrlv(data,col,ngrp,stp,init_state)` initializes the array with the symbols contained in `init_state.value`. The structure `init_state` is typically the `state` output from a previous call to this same function, and is unrelated to the corresponding deinterleaver. In this syntax, some output symbols are default values of 0, some are input symbols from `data`, and some are initialization values from `init_state.value`.

Examples

The example below rearranges the integers from 1 to 24.

```
% Interleave some symbols. Record final state of array.
[i1,state] = helintrlv([1:12]',3,4,1);
% Interleave more symbols, remembering the symbols that
% were left in the array from the earlier command.
i2 = helintrlv([13:24]',3,4,1,state);

disp('Interleaved data:')
disp([i1,i2]')
disp('Values left in array after first interleaving operation:')
state.value{:}
```

During the successive calls to `helintrlv`, it internally creates the three-column arrays

```
[1  0  0;
 2  5  0;
 3  6  9;
 4  7 10;
 0  8 11;
 0  0 12]
```

and

```
[13  8 11;
 14 17 12;
 15 18 21;
 16 19 22;
  0 20 23;
  0  0 24]
```

In the second array shown above, the 8, 11, and 12 are values left in the array from the previous call to the function. Specifying the `init_state` input in the second call to the function causes it to use those values rather than the default values of 0.

The output from this example is below. (The matrix has been transposed for display purposes.) The interleaved data comes from the top four rows of the three-column arrays shown above. Notice that some of the symbols in the first half of the interleaved data are default values of 0, some of the symbols in the second half of the interleaved data were left in the array from the first call to `helintrlv`, and some of the input symbols (20, 23, and 24) do not appear in the interleaved data at all.

```
Interleaved data:
  Columns 1 through 10

     1     0     0     2     5     0     3     6     9     4
    13     8    11    14    17    12    15    18    21    16

  Columns 11 through 12

     7    10
    19    22

Values left in array after first interleaving operation:

ans =

     []

ans =

     8

ans =

    11    12
```

The example on the reference page for `heldeintrlv` also uses this function.

helscandeintrlv

Restore ordering of symbols in helical pattern

Syntax

```
deintrlvd = helscandeintrlv(data,Nrows,Ncols,hstep)
```

Description

`deintrlvd = helscandeintrlv(data,Nrows,Ncols,hstep)` rearranges the elements in `data` by filling a temporary matrix with the elements in a helical fashion and then sending the matrix contents to the output row by row. `Nrows` and `Ncols` are the dimensions of the temporary matrix. `hstep` is the slope of the diagonal, that is, the amount by which the row index increases as the column index increases by one. `hstep` must be a nonnegative integer less than `Nrows`.

Helical fashion means that the function places input elements along diagonals of the temporary matrix. The number of elements in each diagonal is exactly `Ncols`, after the function wraps past the edges of the matrix when necessary. The function traverses diagonals so that the row index and column index both increase. Each diagonal after the first one begins one row below the first element of the previous diagonal.

If `data` is a vector, it must have `Nrows*Ncols` elements. If `data` is a matrix with multiple rows and columns, `data` must have `Nrows*Ncols` rows and the function processes the columns independently.

To use this function as an inverse of the `helscanintrlv` function, use the same `Nrows`, `Ncols`, and `hstep` inputs in both functions. In that case, the two functions are inverses in the sense that applying `helscanintrlv` followed by `helscandeintrlv` leaves data unchanged.

Examples

Apply Helical Deinterleaving to Integer Row Vector

Apply helical scan deinterleaving to the vector [1:12], rearranging the vector using a 3-by-4 temporary matrix and diagonals of slope 1.

Internally, the `helscandeintrlv` function creates the 3-by-4 temporary matrix using length-four diagonals. As represented here.

```
[1 10  7  4;
 5  2 11  8;
 9  6  3 12]
```

```
ans = 3×4

     1    10     7     4
     5     2    11     8
     9     6     3    12
```

The function then sends the elements, row by row, to the output `d`.

```
d = helscandeintrlv(1:12,3,4,1)
```

```
d = 1×12

     1    10     7     4     5     2    11     8     9     6     3    12
```

helscanintrlv

Reorder symbols in helical pattern

Syntax

```
intrlvd = helscanintrlv(data,Nrows,Ncols,hstep)
```

Description

`intrlvd = helscanintrlv(data,Nrows,Ncols,hstep)` rearranges the elements in `data` by filling a temporary matrix with the elements row by row and then sending the matrix contents to the output in a helical fashion. `Nrows` and `Ncols` are the dimensions of the temporary matrix. `hstep` is the slope of the diagonal, that is, the amount by which the row index increases as the column index increases by one. `hstep` must be a nonnegative integer less than `Nrows`.

Helical fashion means that the function selects elements along diagonals of the temporary matrix. The number of elements in each diagonal is exactly `Ncols`, after the function wraps past the edges of the matrix when necessary. The function traverses diagonals so that the row index and column index both increase. Each diagonal after the first one begins one row below the first element of the previous diagonal.

If `data` is a vector, it must have `Nrows*Ncols` elements. If `data` is a matrix with multiple rows and columns, `data` must have `Nrows*Ncols` rows and the function processes the columns independently.

Examples

The command below rearranges a vector using diagonals of two different slopes.

```
i1 = helscanintrlv(1:12,3,4,1) % Slope of diagonal is 1.
i2 = helscanintrlv(1:12,3,4,2) % Slope of diagonal is 2.
```

The output is below.

```
i1 =

  Columns 1 through 10

     1     6    11     4     5    10     3     8     9     2

  Columns 11 through 12

     7    12

i2 =

  Columns 1 through 10

     1    10     7     4     5     2    11     8     9     6

  Columns 11 through 12
```

```
     3    12
```

In each case, the function internally creates the temporary 3-by-4 matrix

```
[1  2  3  4;
 5  6  7  8;
 9 10 11 12]
```

To form `i1`, the function forms each slope-one diagonal by moving one row down and one column to the right. The first diagonal contains `1`, `6`, `11`, and `4`, while the second diagonal starts with `5` because that is beneath `1` in the temporary matrix.

To form `i2`, the function forms each slope-two diagonal by moving two rows down and one column to the right. The first diagonal contains `1`, `10`, `7`, and `4`, while the second diagonal starts with `5` because that is beneath `1` in the temporary matrix.

hex2poly

Convert hexadecimal character vector to binary coefficients

Syntax

```
b = hex2poly(hex)
b = hex2poly(hex,ord)
```

Description

`b = hex2poly(hex)` converts a hexadecimal character vector, `hex`, to a vector of binary coefficients, `b`.

`b = hex2poly(hex,ord)` specifies the power order, `ord`, of the coefficients that comprise the output. If omitted, `ord` is `'descending'`.

Examples

Convert Hexadecimal Polynomial to Binary Vector

Convert the hexadecimal polynomial `'1AF'` to a vector of binary coefficients. The coefficients represent the polynomial $x^8 + x^7 + x^5 + x^3 + x^2 + x + 1$.

```
b = hex2poly('1AF')
```

```
b = 1×9

     1     1     0     1     0     1     1     1     1
```

Convert Hexadecimal into Ascending Order Binary Vector

Convert hexadecimal `'0x82608EDB'` to a vector of binary coefficients. Specify that the binary coefficients are in ascending order.

```
b = hex2poly('0x82608EDB','ascending')
```

```
b = 1×32

     1     1     0     1     1     0     1     1     0     1     1     1     0     0     0     1
```

The binary representation corresponds to a polynomial of $x^{31} + x^{25} + x^{22} + x^{21} + x^{15} + x^{11} + x^{10} + x^9 + x^7 + x^6 + x^4 + x^3 + x + 1$.

Input Arguments

hex — Hexadecimal number

character vector

Hexadecimal number, specified as a character vector.

Example: `'FF'`

Example: `'0x3FA'`

Data Types: `char`

ord — Power order

`'descending'` (default) | `'ascending'`

Power order of the vector of binary coefficients, specified as a character vector having a value of `'ascending'` or `'descending'`.

Data Types: `char`

Output Arguments

b — Binary coefficients

vector

Binary coefficients representing a polynomial, returned as a row vector having length equal to $p + 1$, where p is the order of hexadecimal input.

Version History

Introduced in R2015b

hilbiir

(Removed) Design Hilbert transform IIR filter

Compatibility

hilbiir has been removed. To design a Hilbert transform filter, use the `fdesign.hilbert` object.

Syntax

```
hilbiir
hilbiir(ts)
hilbiir(ts,dly)
hilbiir(ts,dly,bandwidth)
hilbiir(ts,dly,bandwidth,tol)
[num,den] = hilbiir(...)
[num,den,sv] = hilbiir(...)
[a,b,c,d] = hilbiir(...)
[a,b,c,d,sv] = hilbiir(...)
```

Description

The function `hilbiir` designs a Hilbert transform filter. The output is either

- A plot of the filter's impulse response, or
- A quantitative characterization of the filter, using either a transfer function model or a state-space model

Background Information

An ideal Hilbert transform filter has the transfer function `H(s) = -jsgn(s)`, where `sgn(.)` is the signum function (`sign` in MATLAB). The impulse response of the Hilbert transform filter is

$$h(t) = \frac{1}{\pi t}$$

Because the Hilbert transform filter is a noncausal filter, the `hilbiir` function introduces a group delay, `dly`. A Hilbert transform filter with this delay has the impulse response

$$h(t) = \frac{1}{\pi(t - \mathrm{dly})}$$

Choosing a Group Delay Parameter

The filter design is an approximation. If you provide the filter's group delay as an input argument, these two suggestions can help improve the accuracy of the results:

- Choose the sample time `ts` and the filter's group delay `dly` so that `dly` is at least a few times larger than `ts` and `rem(dly,ts) = ts/2`. For example, you can set `ts` to `2*dly/N`, where `N` is a positive integer.

- At the point t = `dly`, the impulse response of the Hilbert transform filter can be interpreted as `0`, `-Inf`, or `Inf`. If `hilbiir` encounters this point, it sets the impulse response there to zero. To improve accuracy, avoid the point t = `dly`.

Syntaxes for Plots

Each of these syntaxes produces a plot of the impulse response of the filter that the `hilbiir` function designs, as well as the impulse response of a corresponding ideal Hilbert transform filter.

`hilbiir` plots the impulse response of a fourth-order digital Hilbert transform filter with a one-second group delay. The sample time is 2/7 seconds. In this particular design, the tolerance index is 0.05. The plot also displays the impulse response of the ideal Hilbert transform filter with a one-second group delay.

`hilbiir(ts)` plots the impulse response of a fourth-order Hilbert transform filter with a sample time of `ts` seconds and a group delay of `ts*7/2` seconds. The tolerance index is 0.05. The plot also displays the impulse response of the ideal Hilbert transform filter having a sample time of `ts` seconds and a group delay of `ts*7/2` seconds.

`hilbiir(ts,dly)` is the same as the syntax above, except that the filter's group delay is `dly` for both the ideal filter and the filter that `hilbiir` designs. See “Choosing a Group Delay Parameter” on page 2-464 above for guidelines on choosing `dly`.

`hilbiir(ts,dly,bandwidth)` is the same as the syntax above, except that `bandwidth` specifies the assumed bandwidth of the input signal and that the filter design might use a compensator for the input signal. If `bandwidth` = 0 or `bandwidth` > 1/(2*`ts`), `hilbiir` does not use a compensator.

`hilbiir(ts,dly,bandwidth,tol)` is the same as the syntax above, except that `tol` is the tolerance index. If `tol` < 1, the order of the filter is determined by

$$\frac{\text{truncated-singular-value}}{\text{maximum-singular-value}} < \text{tol}$$

If `tol` > 1, the order of the filter is `tol`.

Syntaxes for Transfer Function and State-Space Quantities

Each of these syntaxes produces quantitative information about the filter that `hilbiir` designs, but does *not* produce a plot. The input arguments for these syntaxes (if you provide any) are the same as those described in “Syntaxes for Plots” on page 2-465.

`[num,den] = hilbiir(...)` outputs the numerator and denominator of the IIR filter's transfer function.

`[num,den,sv] = hilbiir(...)` outputs the numerator and denominator of the IIR filter's transfer function, and the singular values of the Hankel matrix that `hilbiir` uses in the computation.

`[a,b,c,d] = hilbiir(...)` outputs the discrete-time state-space model of the designed Hilbert transform filter. `a`, `b`, `c`, and `d` are matrices.

`[a,b,c,d,sv] = hilbiir(...)` outputs the discrete-time state-space model of the designed Hilbert transform filter, and the singular values of the Hankel matrix that `hilbiir` uses in the computation.

Examples

```
[num,den] = hilbiir
```

The output is

```
num =

   -0.3183   -0.3041   -0.5160   -1.8453    3.3105

den =

    1.0000   -0.4459   -0.1012   -0.0479   -0.0372
```

Algorithms

The `hilbiir` function calculates the impulse response of the ideal Hilbert transform filter response with a group delay. It fits the response curve using a singular-value decomposition method. See the book by Kailath [1].

Version History

Introduced before R2006a

Function has been removed
Errors starting in R2022b

The `hilbiir` has been removed. Use `fdesign.hilbert` object to design Hilbert transform IIR filter.

Function issues a warning
Warns starting in R2021b

The hilbiir function will be removed in a future release. To design Hilbert transform IIR filter, use the `fdesign.hilbert` object.

`grpdelay`

huffmandeco

Decode binary code by Huffman decoding

Syntax

```
sig = huffmandeco(code,dict)
```

Description

`sig = huffmandeco(code,dict)` decodes the numeric Huffman code vector, `code`, by using the Huffman codes described by input code dictionary `dict`. Input `dict` is an *N*-by-2 cell array, where *N* is the number of distinct possible symbols in the original signal that encodes `code`. The first column of `dict` represents the distinct symbols, and the second column represents the corresponding codewords. Each codeword is represented as a numeric row vector, and no codeword in `dict` can be the prefix of any other codeword in `dict`. You can generate `dict` by using the `huffmandict` function and `code` by using the `huffmanenco` function. If all symbols in `dict` are numeric, output `sig` is a vector. If any symbol in `dict` is alphabetic, `sig` is a one-dimensional cell array.

Examples

Huffman Encoding and Decoding

Create unique symbols, and assign probabilities of occurrence to them.

```
symbols = 1:6;
p = [.5 .125 .125 .125 .0625 .0625];
```

Create a Huffman dictionary based on the symbols and their probabilities.

```
dict = huffmandict(symbols,p);
```

Generate a vector of random symbols.

```
inputSig = randsrc(100,1,[symbols;p]);
```

Encode the random symbols.

```
code = huffmanenco(inputSig,dict);
```

Decode the data. Verify that the decoded symbols match the original symbols.

```
sig = huffmandeco(code,dict);
isequal(inputSig,sig)
```

```
ans = logical
   1
```

Convert the original signal to a binary, and determine the length of the binary symbols.

```
binarySig = de2bi(inputSig);
seqLen = numel(binarySig)
```

```
seqLen = 300
```

Convert the Huffman-encoded symbols to binary, and determine the length of the encoded binary symbols.

```
binaryComp = de2bi(code);
encodedLen = numel(binaryComp)
```

```
encodedLen = 224
```

Huffman Encoding and Decoding with Alphanumeric Signal

Define the alphanumeric symbols in cell array form.

```
inputSig = {'a2',44,'a3',55,'a1'}
```

```
inputSig=1×5 cell array
    {'a2'}    {[44]}    {'a3'}    {[55]}    {'a1'}
```

Define a Huffman dictionary. Codes for signal letters must be numeric.

```
dict = {'a1',0; 'a2',[1,0]; 'a3',[1,1,0]; 44,[1,1,1,0]; 55,[1,1,1,1]}
```

```
dict=5×2 cell array
    {'a1'}    {[      0]}
    {'a2'}    {[    1 0]}
    {'a3'}    {[  1 1 0]}
    {[44]}    {[1 1 1 0]}
    {[55]}    {[1 1 1 1]}
```

Encode the alphanumeric symbols.

```
enco = huffmanenco(inputSig,dict);
```

Decode the data. Verify that the decoded symbols match the original symbols.

```
sig = huffmandeco(enco,dict)
```

```
sig=1×5 cell array
    {'a2'}    {[44]}    {'a3'}    {[55]}    {'a1'}
```

```
isequal(inputSig,sig)
```

```
ans = logical
   1
```

Input Arguments

code — Huffman code

numeric vector

Huffman code, specified as a numeric vector. This value must be a Huffman code encoded using a code dictionary produced by the `huffmandict` function.

Data Types: `double`

`dict` — Huffman code dictionary
N-by-2 cell array

Huffman code dictionary, specified as an *N*-by-2 cell array. *N* is the number of distinct possible symbols for the function to encode. The first column of `dict` represents the distinct symbols, and the second column represents the corresponding codewords. Each codeword is represented as a numeric row vector, and no codeword in `dict` can be the prefix of any other codeword in `dict`. You can generate `dict` by using the `huffmandict` function.

Data Types: `double` | `cell`

Output Arguments

`sig` — Decoded signal
numeric vector | numeric cell array | alphanumeric cell array

Decoded signal, returned as a numeric vector, numeric cell array, or alphanumeric cell array.

- If all symbols in input code dictionary `dict` are numeric, `sig` is a vector.
- If any symbol in input code dictionary `dict` is alphabetic, `sig` is a one-dimensional cell array.

huffmandict

Generate Huffman code dictionary for source with known probability model

Syntax

```
[dict,avglen] = huffmandict(symbols,prob)
[dict,avglen] = huffmandict(symbols,prob,N)
[dict,avglen] = huffmandict(symbols,prob,N,variance)
```

Description

`[dict,avglen] = huffmandict(symbols,prob)` generates a binary Huffman code dictionary, `dict`, for the source symbols, `symbols`, by using the maximum variance algorithm. The input `prob` specifies the probability of occurrence for each of the input symbols. The length of `prob` must equal the length of `symbols`. The function also returns average codeword length `avglen` of the dictionary, weighted according to the probabilities in the input `prob`.

`[dict,avglen] = huffmandict(symbols,prob,N)` generates an `N`-ary Huffman code dictionary using maximum variance algorithm. `N` must not exceed the number of source symbols.

`[dict,avglen] = huffmandict(symbols,prob,N,variance)` generates an `N`-ary Huffman code dictionary with the specified variance.

Examples

Generate Huffman Code and View Results

Generate a binary Huffman code dictionary, additionally returning the average code length.

Specify a symbol alphabet vector and a symbol probability vector.

```
symbols = (1:5); % Alphabet vector
prob = [.3 .3 .2 .1 .1]; % Symbol probability vector
```

Generate a binary Huffman code, displaying the average code length and the cell array containing the codeword dictionary.

```
[dict,avglen] = huffmandict(symbols,prob)
```

```
dict=5×2 cell array
    {[1]}    {[  0 1]}
    {[2]}    {[  0 0]}
    {[3]}    {[  1 0]}
    {[4]}    {[1 1 1]}
    {[5]}    {[1 1 0]}

avglen = 2.2000
```

Display the fifth codeword from the dictionary.

```
samplecode = dict{5,2} % Codeword for fifth signal value
```

```
samplecode = 1×3

     1     1     0
```

Generate Ternary Huffman Codes

Use the code dictionary generator for Huffman coder function to generate binary and ternary Huffman codes.

Specify a symbol alphabet vector and a symbol probability vector.

```
symbols = (1:5); % Alphabet vector
prob = [.3 .3 .2 .1 .1]; % Symbol probability vector
```

Generate a binary Huffman code, displaying the cell array containing the codeword dictionary.

```
[dict,avglen] = huffmandict(symbols,prob);
dict(:,2) = cellfun(@num2str,dict(:,2),'UniformOutput',false)
```

```
dict=5×2 cell array
    {[1]}    {'0  1'   }
    {[2]}    {'0  0'   }
    {[3]}    {'1  0'   }
    {[4]}    {'1  1  1'}
    {[5]}    {'1  1  0'}
```

Generate a ternary Huffman code with minimum variance.

```
[dict,avglen] = huffmandict(symbols,prob,3,'min');
dict(:,2) = cellfun(@num2str,dict(:,2),'UniformOutput',false)
```

```
dict=5×2 cell array
    {[1]}    {'2'   }
    {[2]}    {'1'   }
    {[3]}    {'0  0'}
    {[4]}    {'0  2'}
    {[5]}    {'0  1'}
```

Input Arguments

`symbols` — Source symbols

vector | cell array | alphanumeric cell array

Source symbols, specified as a vector, cell array, or an alphanumeric cell array. `symbols` lists the distinct signal values that the source produces. If `symbols` is a cell array, it must be a 1-by-*S* or *S*-by-1 cell array, where *S* is the number of symbols.

Data Types: `double` | `cell`

`prob` — Probability of occurrence
vector in the range [0, 1]

Probability of occurrence for each symbol, specified as a vector in the range [0, 1]. The elements of this vector must sum to 1. The length this vector must equal the length of input `symbols`.

Data Types: `double`

`N` — N-ary Huffman code dictionary
scalar in the range [2, 10]

N-ary Huffman code dictionary, specified as a scalar in the range [2, 10]. This value must be less than or equal to the length of input `symbols`.

Data Types: `double`

`variance` — Variance for Huffman code
`'min'` | `'max'`

Variance for Huffman code, specified as one of these values.

- `'min'` — This function generates `N`-ary Huffman code dictionary with the minimum variance. If you do not specify the variance input argument, the function uses this case.
- `'max'` — This function generates `N`-ary Huffman code dictionary with the maximum variance.

Data Types: `char`

Output Arguments

`dict` — Huffman code dictionary
two-column cell array

Huffman code dictionary, returned as a two-column cell array. The first column lists the distinct signal values from input `symbols`. The second column corresponds to Huffman codewords, where each Huffman codeword is represented as a row vector. If you specify the input argument `N`, the function returns dict as an `N`-ary Huffman code dictionary.

Data Types: `double` | `cell`

`avglen` — Average codeword length
positive scalar

Average codeword length, weighted according to the probabilities in the input `prob`, returned as a positive scalar.

Data Types: `double`

“Huffman Coding”

huffmanenco

Encode sequence of symbols by Huffman encoding

Syntax

```
code = huffmanenco(sig,dict)
```

Description

`code = huffmanenco(sig,dict)` encodes input signal `sig` using the Huffman codes described by input code dictionary `dict`. `sig` can have the form of a vector, cell array, or alphanumeric cell array. If `sig` is a cell array, it must be either a row or a column. `dict` is an N-by-2 cell array, where *N* is the number of distinct possible symbols to encode. The first column of `dict` represents the distinct symbols and the second column represents the corresponding codewords. Each codeword is represented as a row vector, and no codeword in `dict` can be the prefix of any other codeword in `dict`. You can generate `dict` using the `huffmandict` function.

Examples

Huffman Encoding and Decoding

Create unique symbols, and assign probabilities of occurrence to them.

```
symbols = 1:6;
p = [.5 .125 .125 .125 .0625 .0625];
```

Create a Huffman dictionary based on the symbols and their probabilities.

```
dict = huffmandict(symbols,p);
```

Generate a vector of random symbols.

```
inputSig = randsrc(100,1,[symbols;p]);
```

Encode the random symbols.

```
code = huffmanenco(inputSig,dict);
```

Decode the data. Verify that the decoded symbols match the original symbols.

```
sig = huffmandeco(code,dict);
isequal(inputSig,sig)
```

```
ans = logical
   1
```

Convert the original signal to a binary, and determine the length of the binary symbols.

```
binarySig = de2bi(inputSig);
seqLen = numel(binarySig)
```

```
seqLen = 300
```

Convert the Huffman-encoded symbols to binary, and determine the length of the encoded binary symbols.

```
binaryComp = de2bi(code);
encodedLen = numel(binaryComp)
```

```
encodedLen = 224
```

Huffman Encoding and Decoding with Alphanumeric Signal

Define the alphanumeric symbols in cell array form.

```
inputSig = {'a2',44,'a3',55,'a1'}
```

```
inputSig=1×5 cell array
    {'a2'}    {[44]}    {'a3'}    {[55]}    {'a1'}
```

Define a Huffman dictionary. Codes for signal letters must be numeric.

```
dict = {'a1',0; 'a2',[1,0]; 'a3',[1,1,0]; 44,[1,1,1,0]; 55,[1,1,1,1]}
```

```
dict=5×2 cell array
    {'a1'}    {[      0]}
    {'a2'}    {[    1 0]}
    {'a3'}    {[  1 1 0]}
    {[44]}    {[1 1 1 0]}
    {[55]}    {[1 1 1 1]}
```

Encode the alphanumeric symbols.

```
enco = huffmanenco(inputSig,dict);
```

Decode the data. Verify that the decoded symbols match the original symbols.

```
sig = huffmandeco(enco,dict)
```

```
sig=1×5 cell array
    {'a2'}    {[44]}    {'a3'}    {[55]}    {'a1'}
```

```
isequal(inputSig,sig)
```

```
ans = logical
   1
```

Input Arguments

`sig` — Input signal

vector | cell array | alphanumeric cell array

Input signal for the compression, specified as a vector, cell array, or an alphanumeric cell array. `sig` can have the form of a vector, cell array, or alphanumeric cell array. If `sig` is a cell array, it must be a 1-by-*S* or *S*-by-1 cell array, where *S* is the number of symbols.

Data Types: `double` | `cell`

`dict` — Huffman code dictionary
N-by-2 cell array

Huffman code dictionary, specified as an *N*-by-2 cell array. *N* is the number of distinct possible symbols for the function to encode. The first column of dict represents the distinct symbols and the second column represents the corresponding codewords. Each codeword is represented as a row vector, and no codeword in dict can be the prefix of any other codeword in dict. You can generate dict by using the `huffmandict` function.

Data Types: `double` | `cell`

Output Arguments

`code` — Encoded signal
vector

Encoded signal for the input Huffman code dictionary `dict`, returned as a vector.

Version History

Introduced before R2006a

ifft

Inverse discrete Fourier transform of Galois array

Syntax

```
ifft(x)
```

Description

`ifft(x)` is the inverse discrete Fourier transform (DFT) of the Galois vector `x`. If `x` is in the Galois field GF(2^m), the length of `x` must be 2^m-1.

Examples

For an example using `ifft`, see the reference page for `fft`.

Limitations

The Galois field over which this function works must have 256 or fewer elements. In other words, `x` must be in the Galois field GF(2^m), where m is an integer between 1 and 8.

Algorithms

If `x` is a column vector, `ifft` applies `dftmtx` to the multiplicative inverse of the primitive element of the Galois field and multiplies the resulting matrix by `x`.

Version History

Introduced before R2006a

int2bit

Convert integers to bits

Syntax

```
Y = int2bit(X,n)
Y = int2bit(X,n,msbfirst)
```

Description

`Y = int2bit(X,n)` converts each integer element in `X` to `n` column-wise bits in `Y`, with the first bit as the most significant bit (MSB).

`Y = int2bit(X,n,msbfirst)` indicates whether the first bits in each set of `n` column-wise bits from `Y` is MSB or the least significant bit (LSB).

Examples

Convert Vector of Integers to Bits

Specify a row vector of integers.

```
X = [12 5]
```

```
X = 1×2

    12     5
```

Specify for four column-wise bit elements for the converted output. Then, convert the integers to bits.

```
n = 4;
Y = int2bit(X,n)
```

```
Y = 4×2

     1     0
     1     1
     0     0
     0     1
```

Convert Matrix of Integers to Bits

Specify a matrix of integers.

```
X = int8([10 6 14; 11 5 9])
```

```
X = 2x3 int8 matrix
```

```
   10    6   14
   11    5    9
```

Specify that the first bit in each set of four column-wise bit elements for the output is LSB. Then, convert the integers to bits.

```
n = 4;
msbfirst = false;
Y = int2bit(X,n,msbfirst)
```

```
Y = 8x3 int8 matrix

   0   0   0
   1   1   1
   0   1   1
   1   0   1
   1   1   1
   1   0   0
   0   1   0
   1   0   1
```

Convert Array of Integers to Bits

Specify an array of integers.

```
X = randi([0,9],4,3,2,'uint16')
```

```
X = 4x3x2 uint16 array
X(:,:,1) =

   8   6   9
   9   0   9
   1   2   1
   9   5   9

X(:,:,2) =

   9   4   6
   4   9   0
   8   7   8
   1   9   9
```

Specify for three column-wise bit elements for the converted output. Then, convert the integers to bits.

```
n = 3;
Y = int2bit(X,n)
```

```
Y = 12x3x2 uint8 array
Y(:,:,1) =

   0   1   0
```

```
   0   1   0
   0   0   1
   0   0   0
   0   0   0
   1   0   1
   0   0   0
   0   1   0
   1   0   1
   0   1   0
   0   0   0
   1   1   1

Y(:,:,2) =

   0   1   1
   0   0   1
   1   0   0
   1   0   0
   0   0   0
   0   1   0
   0   1   0
   0   1   0
   0   1   0
   0   0   0
   0   0   0
   1   1   1
```

Input Arguments

X — Integers

scalar | vector | matrix | 3-D array

Integers, specified as a scalar, vector, matrix, or 3-D array of nonnegative integer values.

Example: `[10 2]` specifies an input row vector of size 1-by-2.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

n — Number of bits for conversion

positive integer

The number of bits for conversion to bits, specified as a positive integer.

Data Types: `double`

msbfirst — Specification of MSB first

`true` or `1` | `false` or `0`

Specification of MSB first, specified as a numeric or logical `1` (`true`) or `0` (`false`).

- `true` -- For each set of `n` column-wise bits in `X`, the first bit is the MSB.
- `false` -- For each set of `n` column-wise bits in `X`, the first bit is the LSB.

Data Types: `logical`

Output Arguments

Y — Bit representation of input integers

column vector | matrix | 3-D array

Bit representation of input integers, returned as a column vector, matrix, or 3-D array. Y has the same dimensions as X except that the number of rows in Y is n times the number of rows in X. The output Y consists of n least significant bits in the specified orientation. If n is less than the number of required bits to represent the values in X, then the output Y consists of n least significant bits.

The data type of Y depends on the data type of X.

- If X is a floating-point data type, then Y is a floating-point data type.
- If X is a built-in unsigned integer data type, then Y is of data type `uint8`.
- If X is a built-in signed integer data type, then Y is of data type `int8`.
- If X is of data type `double`, then Y is of data type `double` with n no larger than 53.
- If X is of data type `single`, then Y is of data type `single` with n no larger than 24.

Version History

Introduced in R2021b

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Input values must be less than 2^{64} for code generation when the input data type is double.

Functions

`bit2int` | `dec2base`

Blocks

Integer to Bit Converter

intdump

Integrate and dump

Syntax

```
y = intdump(x,nsamp)
```

Description

`y = intdump(x,nsamp)` integrates the signal `x` for one symbol period, then outputs the averaged one value into `Y`. `nsamp` is the number of samples per symbol. For two-dimensional signals, the function treats each column as one channel.

Examples

To see this function in conjunction with modulation, see “Modulation with Pulse Shaping and Filtering Examples”.

Processes two independent channels, each of which contain three symbols of data made up of four samples.

```
s = rng;
rng(68521);
nsamp = 4; % Number of samples per symbol
ch1 = randi([0 1],3*nsamp,1); % Random binary channel
ch2 = rectpulse([1 2 3]',nsamp); % Rectangular pulses
x = [ch1 ch2]; % Two-channel signal
y = intdump(x,nsamp)
rng(s);
```

The output is below. Each column corresponds to one channel, and each row corresponds to one symbol.

```
y =

    0.5000    1.0000
    0.5000    2.0000
    1.0000    3.0000
```

Version History

`rectpulse`

intrlv

Reorder sequence of symbols

Syntax

```
intrlved = intrlv(data,elements)
```

Description

`intrlved = intrlv(data,elements)` rearranges the elements of `data` as specified by `elements`.

Examples

Apply Interleaving to Reorder and Deinterleaving to Restore Vector Data Order

Use the `intrlv` function to rearrange the elements of a vector to a random permutation determined by the `randperm` function. Use the `deintrlv` function to restore the element order of the initial vector by reusing the same random permutation. This illustrates the inverse relationship between the `intrlv` and `deintrlv` functions.

Generate an input signal, `data`, and a permutation vector, `elements`.

```
data = 10:10:100
```

```
data = 1×10

    10    20    30    40    50    60    70    80    90   100
```

```
elements = randperm(10) % Permutation vector
```

```
elements = 1×10

     6     3     7     8     5     1     2     4     9    10
```

Permute the input signal according to the permutation vector by using the `intrlv` function and the restore the input signal order by using the `deintrlv` function.

```
a = intrlv(data,elements)
```

```
a = 1×10

    60    30    70    80    50    10    20    40    90   100
```

```
b = deintrlv(a,elements)
```

```
b = 1×10
```

```
    10    20    30    40    50    60    70    80    90   100
```

Apply Interleaving to Reorder and Deinterleaving to Restore Matrix Data Order

Use the `intrlv` function to rearrange the elements in the columns of a matrix to a random permutation vector determined by the `randperm` function. Use the de`intrlv` function to restore the element order of the initial matrix by reusing the same random permutation. This illustrates the inverse relationship between the `intrlv` and `deintrlv` functions.

Generate an input signal, `data`, and a permutation vector, `elements`.

```
data(:,1) = 10:10:100
```

```
data = 10×1

    10
    20
    30
    40
    50
    60
    70
    80
    90
   100
```

```
data(:,2) = 0.1:0.1:1
```

```
data = 10×2

   10.0000    0.1000
   20.0000    0.2000
   30.0000    0.3000
   40.0000    0.4000
   50.0000    0.5000
   60.0000    0.6000
   70.0000    0.7000
   80.0000    0.8000
   90.0000    0.9000
  100.0000    1.0000
```

```
elements = randperm(10) % Permutation vector
```

```
elements = 1×10

     6     3     7     8     5     1     2     4     9    10
```

Permute the input signal according to the permutation vector by using the `intrlv` function, and then restore the input signal order by using the `deintrlv` function.

```
a = intrlv(data,elements)
```

```
a = 10×2

   60.0000    0.6000
   30.0000    0.3000
   70.0000    0.7000
   80.0000    0.8000
   50.0000    0.5000
   10.0000    0.1000
   20.0000    0.2000
   40.0000    0.4000
   90.0000    0.9000
  100.0000    1.0000
```

```
b = deintrlv(a,elements)
```

```
b = 10×2

   10.0000    0.1000
   20.0000    0.2000
   30.0000    0.3000
   40.0000    0.4000
   50.0000    0.5000
   60.0000    0.6000
   70.0000    0.7000
   80.0000    0.8000
   90.0000    0.9000
  100.0000    1.0000
```

Input Arguments

`data` — Input signal

vector | matrix

Input signal, specified as a vector or matrix. If `data` is a matrix with multiple rows and columns, the function processes the columns independently.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `fi`
Complex Number Support: Yes

`elements` — Permutation vector

integer vector

Permutation vector, specified as an integer vector. The permutation vector specifies the mapping used to permute the input signal, `data`. The permutation vector length must equal the input signal length and contain for each integer *k* in the range [1 `length`(`data`,1)]. If `data` is a length-*N* vector or an *N*-row matrix, `elements` must be a length-*N* vector and contain each integer in the range [1 `length`(`data`,1)]. The sequence in `elements` is the sequence in which elements from `data` or its columns appear in `intrlved`.

Data Types: `double`

Output Arguments

`intrlved` — Interleaved data

vector | matrix

Interleaved data, returned as a vector or matrix with the same dimension and datatype as the input signal. The output contains elements from the input signal mapped as `intrlved`(k,n) = `data`(`elements`(k),n), for each integer *k* in the range [1 `length`(`data`,1)].

iqcoef2imbal

Convert compensator coefficient to amplitude and phase imbalance

Syntax

```
[A,P] = iqcoef2imbal(C)
```

Description

`[A,P] = iqcoef2imbal(C)` converts compensator coefficient `C` to its equivalent amplitude and phase imbalance.

Examples

Estimate I/Q Imbalance from Compensator Coefficient

Use `iqcoef2imbal` to estimate the amplitude and phase imbalance for a given complex coefficient. The coefficients are an output from the `step` function of the `IQImbalanceCompensator`.

Create a raised cosine transmit filter to generate a 64-QAM signal.

```
M = 64;
txFilt = comm.RaisedCosineTransmitFilter;
```

Modulate and filter random 64-ary symbols.

```
data = randi([0 M-1],100000,1);
dataMod = qammod(data,M);
txSig = step(txFilt,dataMod);
```

Specify amplitude and phase imbalance.

```
ampImb = 2; % dB
phImb = 15; % degrees
```

Apply the specified I/Q imbalance.

```
gainI = 10.^(0.5*ampImb/20);
gainQ = 10.^(-0.5*ampImb/20);
imbI = real(txSig)*gainI*exp(-0.5i*phImb*pi/180);
imbQ = imag(txSig)*gainQ*exp(1i*(pi/2 + 0.5*phImb*pi/180));
rxSig = imbI + imbQ;
```

Normalize the power of the received signal

```
rxSig = rxSig/std(rxSig);
```

Remove the I/Q imbalance using the `comm.IQImbalanceCompensator` System object™. Set the compensator object such that the complex coefficients are made available as an output argument.

```
hIQComp = comm.IQImbalanceCompensator('CoefficientOutputPort',true);
[compSig,coef] = step(hIQComp,rxSig);
```

Estimate the imbalance from the last value of the compensator coefficient.

```
[ampImbEst,phImbEst] = iqcoef2imbal(coef(end));
```

Compare the estimated imbalance values with the specified ones. Notice that there is good agreement.

```
[ampImb phImb; ampImbEst phImbEst]
```

```
ans = 2×2

    2.0000   15.0000
    2.0178   14.5740
```

Input Arguments

`C` — Compensator coefficient

complex-valued scalar or vector

Coefficient used to compensate for an I/Q imbalance, specified as a complex-valued vector.

Example: `0.4+0.6i`

Example: `[0.1+0.2i; 0.3+0.5i]`

Data Types: `single` | `double`

Output Arguments

`A` — Amplitude imbalance

real-valued vector

Amplitude imbalance in dB, returned as a real-valued vector with the same dimensions as `C`.

`P` — Phase imbalance

real-valued vector

Phase imbalance in degrees, returned as a real-valued vector with the same dimensions as `C`.

More About

I/Q Imbalance Compensation

The function `iqcoef2imbal` is a supporting function for the `comm.IQImbalanceCompensator` System object.

Given a scaling and rotation factor, G, compensator coefficient, C, and received signal, x, the compensated signal, y, has the form

$$y = G[x + C\text{conj}(x)] \ .$$

In matrix form, this can be rewritten as

$$\mathbf{Y} = \mathbf{RX} \ ,$$

where **X** is a 2-by-1 vector representing the imbalanced signal $[X_I, X_Q]$ and **Y** is a 2-by-1 vector representing the compensator output $[Y_I, Y_Q]$.

The matrix **R** is expressed as

$$\mathbf{R} = \begin{bmatrix} 1 + \mathrm{Re}\{C\} & \mathrm{Im}\{C\} \\ \mathrm{Im}\{C\} & 1 - \mathrm{Re}\{C\} \end{bmatrix}$$

For the compensator to perfectly remove the I/Q imbalance, $\mathbf{R} = \mathbf{K}^{-1}$ because $\mathbf{X} = \mathbf{K}\,\mathbf{S}$, where **K** is a 2-by-2 matrix whose values are determined by the amplitude and phase imbalance and **S** is the ideal signal. Define a matrix **M** with the form

$$\mathbf{M} = \begin{bmatrix} 1 & -\alpha \\ \alpha & 1 \end{bmatrix}$$

Both **M** and $\mathbf{M}^{-1}$ can be thought of as scaling and rotation matrices that correspond to the factor G. Because $\mathbf{K} = \mathbf{R}^{-1}$, the product $\mathbf{M}^{-1}\,\mathbf{R}\,\mathbf{K}\,\mathbf{M}$ is the identity matrix, where $\mathbf{M}^{-1}\,\mathbf{R}$ represents the compensator output and **K M** represents the I/Q imbalance. The coefficient α is chosen such that

$$\mathbf{K}\mathbf{M} = L\begin{bmatrix} I_{gain}\cos(\theta_I) & Q_{gain}\cos(\theta_Q) \\ I_{gain}\sin(\theta_I) & Q_{gain}\sin(\theta_Q) \end{bmatrix}$$

where L is a constant. From this form, we can obtain I_{gain}, Q_{gain}, θ_I, and θ_Q. For a given phase imbalance, Φ_{Imb}, the in-phase and quadrature angles can be expressed as

$$\begin{aligned} \theta_I &= -(\pi/2)(\Phi_{Imb}/180) \\ \theta_Q &= \pi/2 + (\pi/2)(\Phi_{Imb}/180) \end{aligned}$$

Hence, $\cos(\theta_Q) = \sin(\theta_I)$ and $\sin(\theta_Q) = \cos(\theta_I)$ so that

$$L\begin{bmatrix} I_{gain}\cos(\theta_I) & Q_{gain}\cos(\theta_Q) \\ I_{gain}\sin(\theta_I) & Q_{gain}\sin(\theta_Q) \end{bmatrix} = L\begin{bmatrix} I_{gain}\cos(\theta_I) & Q_{gain}\sin(\theta_I) \\ I_{gain}\sin(\theta_I) & Q_{gain}\cos(\theta_I) \end{bmatrix}$$

The I/Q imbalance can be expressed as

$$\begin{aligned} \mathbf{K}\mathbf{M} &= \begin{bmatrix} K_{11} + \alpha K_{12} & -\alpha K_{11} + K_{12} \\ K_{21} + \alpha K_{22} & -\alpha K_{21} + K_{22} \end{bmatrix} \\ &= L\begin{bmatrix} I_{gain}\cos(\theta_I) & Q_{gain}\sin(\theta_I) \\ I_{gain}\sin(\theta_I) & Q_{gain}\cos(\theta_I) \end{bmatrix} \end{aligned}$$

Therefore,

$$(K_{21} + \alpha K_{22})/(K_{11} + \alpha K_{12}) = (-\alpha K_{11} + K_{12})/(-\alpha K_{21} + K_{22}) = \sin(\theta_I)/\cos(\theta_I)$$

The equation can be written as a quadratic equation to solve for the variable α, that is $D_1\alpha^2 + D_2\alpha + D_3 = 0$, where

$$\begin{aligned} D_1 &= -K_{11}K_{12} + K_{22}K_{21} \\ D_2 &= K_{12}^2 + K_{21}^2 - K_{11}^2 - K_{22}^2 \\ D_3 &= K_{11}K_{12} - K_{21}K_{22} \end{aligned}$$

When $|C| \le 1$, the quadratic equation has the following solution:

$$\alpha = \frac{-D_2 - \sqrt{D^2 - 4D_1D_3}}{2D_1}$$

Otherwise, when $|C| > 1$, the solution has the following form:

$$\alpha = \frac{-D_2 + \sqrt{D^2 - 4D_1D_3}}{2D_1}$$

Finally, the amplitude imbalance, A_{Imb}, and the phase imbalance, Φ_{Imb}, are obtained.

$$\mathbf{K}' = \mathbf{K}\begin{bmatrix} 1 & -\alpha \\ \alpha & 1 \end{bmatrix}$$

$$A_{Imb} = 20\log_{10}(K'_{11}/K'_{22})$$

$$\Phi_{Imb} = -2\tan^{-1}(K'_{21}/K'_{11})(180/\pi)$$

Note

- If C is real and $|C| \le 1$, the phase imbalance is 0 and the amplitude imbalance is $20\log_{10}((1–C)/(1+C))$
- If C is real and $|C| > 1$, the phase imbalance is 180° and the amplitude imbalance is $20\log_{10}((C+1)/(C-1))$.
- If C is imaginary, $A_{Imb} = 0$.

iqimbal2coef

Convert I/Q imbalance to compensator coefficient

Syntax

```
C = iqimbal2coef(A,P)
```

Description

`C = iqimbal2coef(A,P)` converts an I/Q amplitude and phase imbalance to its equivalent compensator coefficient.

Examples

Generate Coefficients for I/Q Imbalance Compensation

Generate coefficients for the I/Q imbalance compensator System object™ using `iqimbal2coef`. The compensator corrects for an I/Q imbalance using the generated coefficients.

Create a raised cosine transmit filter System object.

```
txRCosFilt = comm.RaisedCosineTransmitFilter;
```

Modulate and filter random 64-ary symbols.

```
M= 64;
data = randi([0 M-1],100000,1);
dataMod = qammod(data,M);
txSig = txRCosFilt(dataMod);
```

Specify amplitude and phase imbalance.

```
ampImb = 2; % dB
phImb = 15; % degrees
```

Apply the specified I/Q imbalance.

```
gainI = 10.^(0.5*ampImb/20);
gainQ = 10.^(-0.5*ampImb/20);
imbI = real(txSig)*gainI*exp(-0.5i*phImb*pi/180);
imbQ = imag(txSig)*gainQ*exp(1i*(pi/2 + 0.5*phImb*pi/180));
rxSig = imbI + imbQ;
```

Normalize the power of the received signal.

```
rxSig = rxSig/std(rxSig);
```

Remove the I/Q imbalance by creating and applying a `comm.IQImbalanceCompensator` object. Set the compensator such that the complex coefficients are made available as an output argument.

```
iqComp = comm.IQImbalanceCompensator('CoefficientOutputPort',true);
[compSig,coef] = iqComp(rxSig);
```

Compare the final compensator coefficient to the coefficient generated by the `iqimbal2coef` function. Observe that there is good agreement.

```
idealcoef = iqimbal2coef(ampImb,phImb);
[coef(end); idealcoef]
```

```
ans = 2×1 complex

  -0.1137 + 0.1296i
  -0.1126 + 0.1334i
```

Input Arguments

`A` — Amplitude imbalance

real-valued scalar or vector

Amplitude imbalance in dB, specified as a real-valued row or column vector.

Example: `3`

Example: `[0; 5]`

Data Types: `double`

`P` — Phase imbalance

real-valued scalar or vector

Phase imbalance in degrees, specified as a real-valued row or column vector.

Example: `10`

Example: `[15; 45]`

Data Types: `double`

Output Arguments

`C` — Compensator coefficient

complex-valued vector

Coefficient that perfectly compensates for the I/Q imbalance, returned as a complex-valued vector having the same dimensions as `A` and `P`.

More About

I/Q Imbalance Compensation

The function `iqimbal2coef` is a supporting function for the `comm.IQImbalanceCompensator` System object.

Define **S** and **X** as 2-by-1 vectors representing the I and Q components of the ideal and I/Q imbalanced signals, respectively.

$$\mathbf{X} = \mathbf{K} \cdot \mathbf{S}$$

where **K** is a 2-by-2 matrix whose values are determined by the amplitude imbalance, A, and phase imbalance, P. A is expressed in dB and P is expressed in degrees.

The imbalance can be expressed as:

$$I_{gain} = 10^{0.5A/20}$$
$$Q_{gain} = 10^{-0.5A/20}$$
$$\theta_i = -\left(\frac{P}{2}\right)\left(\frac{\pi}{180}\right)$$
$$\theta_q = \frac{\pi}{2} + \left(\frac{P}{2}\right)\left(\frac{\pi}{180}\right)$$

Then **K** has the form:

$$\mathbf{K} = \begin{bmatrix} I_{gain}\cos(\theta_i) & Q_{gain}\cos(\theta_q) \\ I_{gain}\sin(\theta_i) & Q_{gain}\sin(\theta_q) \end{bmatrix}$$

The vector **Y** is defined as the I/Q imbalance compensator output.

$$\mathbf{Y} = \mathbf{R} \cdot \mathbf{X}$$

For the compensator to perfectly remove the I/Q imbalance, **R** must be the matrix inversion of **K**, namely:

$$\mathbf{R} = \mathbf{K}^{-1}$$

Using complex notation, the vector **Y** can be rewritten as:

$$y = w_1 x + w_2 \text{conj}(x)$$
$$= w_1\left(x + \left({}^{w_2}\!/_{w_1}\right)\text{conj}(x)\right)$$

where,

$$\text{Re}\{w_1\} = (R_{11} + R_{22})/2$$
$$\text{Im}\{w_1\} = (R_{21} - R_{12})/2$$
$$\text{Re}\{w_2\} = (R_{11} - R_{22})/2$$
$$\text{Im}\{w_2\} = (R_{21} + R_{12})/2$$

The output of the function is w_2/w_1. To exactly obtain the original signal, the compensator output needs to be scaled and rotated by the complex number w_1.

Note There are cases for which the output of `iqimbal2coef` is unreliable.

- If the phase imbalance is ±90°, the in-phase and quadrature components will become co-linear; consequently, the I/Q imbalance cannot be compensated.
- If the amplitude imbalance is 0 dB and the phase imbalance is 180°, $w_1 = 0$ and $w_2 = 1$i; therefore, the compensator takes the form of $y = 1i$*conj(x).

Functions

`iqimbal` | `iqcoef2imbal`

Objects

`comm.IQImbalanceCompensator`

iqimbal

Apply I/Q imbalance to input signal

Syntax

```
y = iqimbal(x,A)
y = iqimbal(x,A,P)
```

Description

`y = iqimbal(x,A)` applies I/Q amplitude imbalance `A` to input signal `x`.

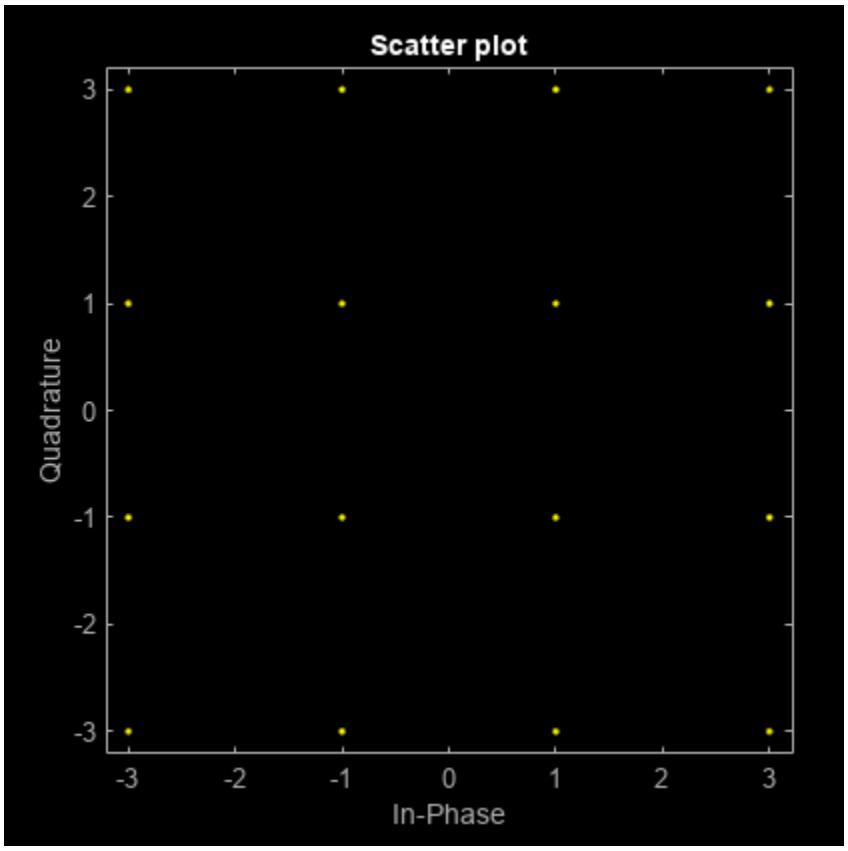
`y = iqimbal(x,A,P)` applies I/Q amplitude imbalance `A` and phase imbalance `P` to input signal `x`.

Examples

Apply Amplitude Imbalance to 16-QAM

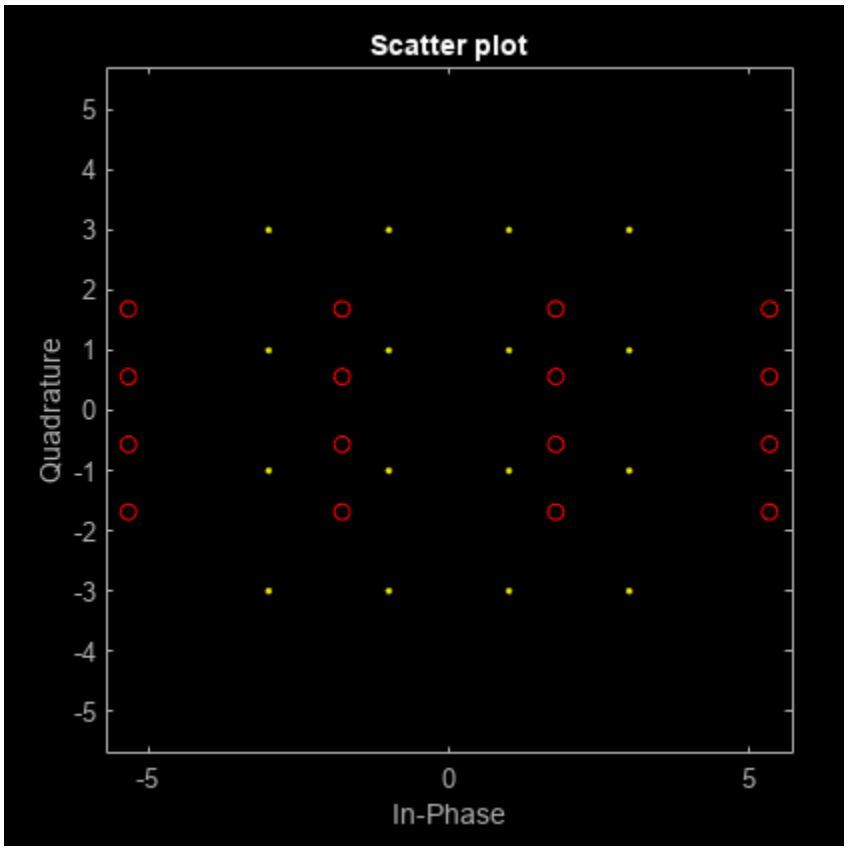
Generate a 16-QAM signal. Display the scatter plot.

```
x = qammod(randi([0 15],1000,1),16);
h = scatterplot(x);
hold on
```



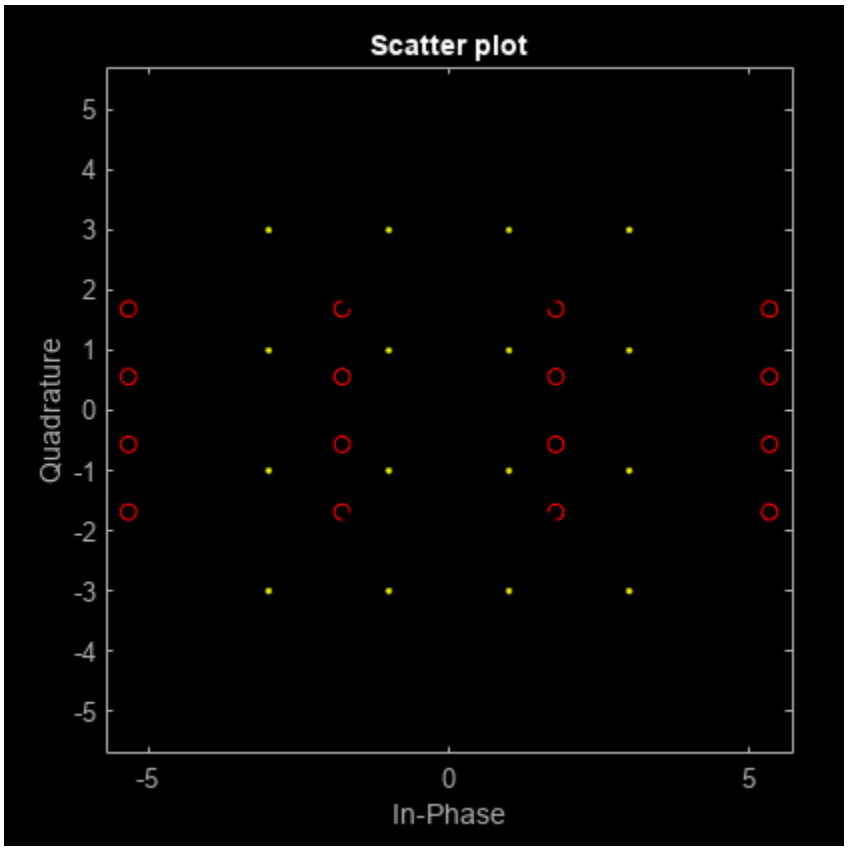
Apply a 10 dB amplitude imbalance. A positive amplitude imbalance causes horizontal stretching of the constellation.

```
y = iqimbal(x,10);
scatterplot(y,1,0,'ro',h)
```



Apply a -10 dB amplitude imbalance. A negative amplitude imbalance causes vertical stretching of the constellation.

```
z = iqimbal(x,-10);
scatterplot(z,1,0,'k*',h)
hold off
```



Apply Phase and Amplitude Imbalance to 16-QAM Signal

Generate a 16-QAM signal having two channels.

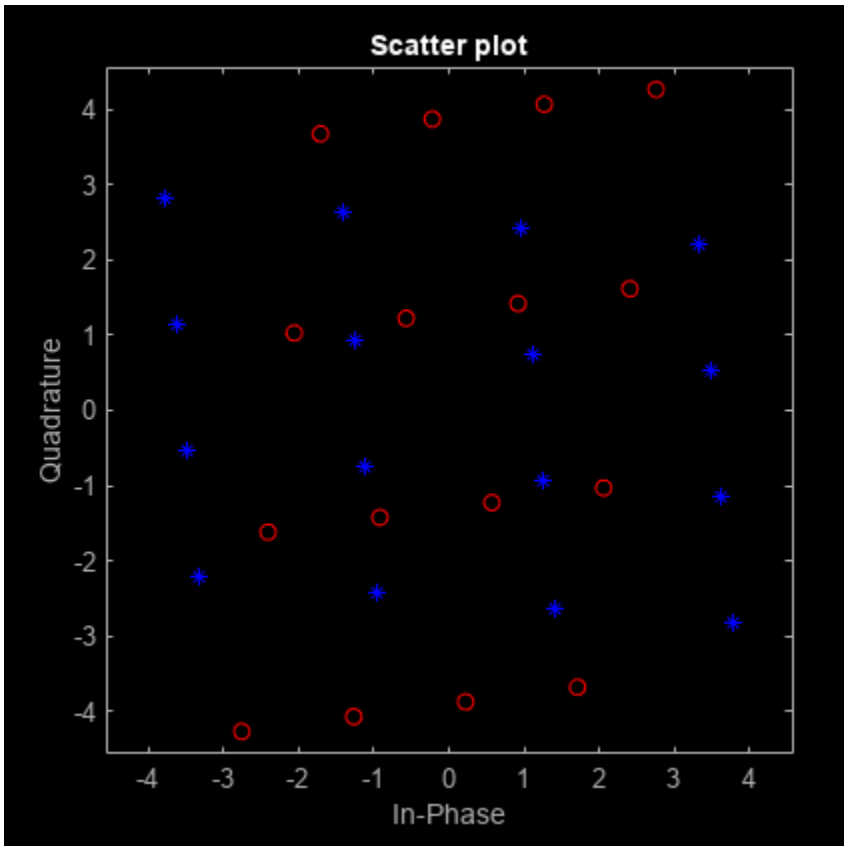
```
x = qammod(randi([0 15],1000,2),16);
```

Apply a 3 dB amplitude imbalance and a 10 degree phase imbalance to the first channel. Apply a –5 dB amplitude imbalance and a –15 degree phase imbalance to the second channel.

```
y = iqimbal(x,[3 -5],[10 -15]);
```

Plot the constellation diagram of both channels of the impaired signal.

```
h = scatterplot(y(:,1),1,0,'b*');
hold on
scatterplot(y(:,2),1,0,'ro',h)
hold off
```



The first channel is stretched horizontally, and the second channel is stretched vertically.

Apply I/Q Imbalance and DC Offset to QPSK

Apply a 1 dB, 5 degree I/Q imbalance to a QPSK signal. Then apply a DC offset. Visualize the offset using a spectrum analyzer.

Generate a QPSK sequence.

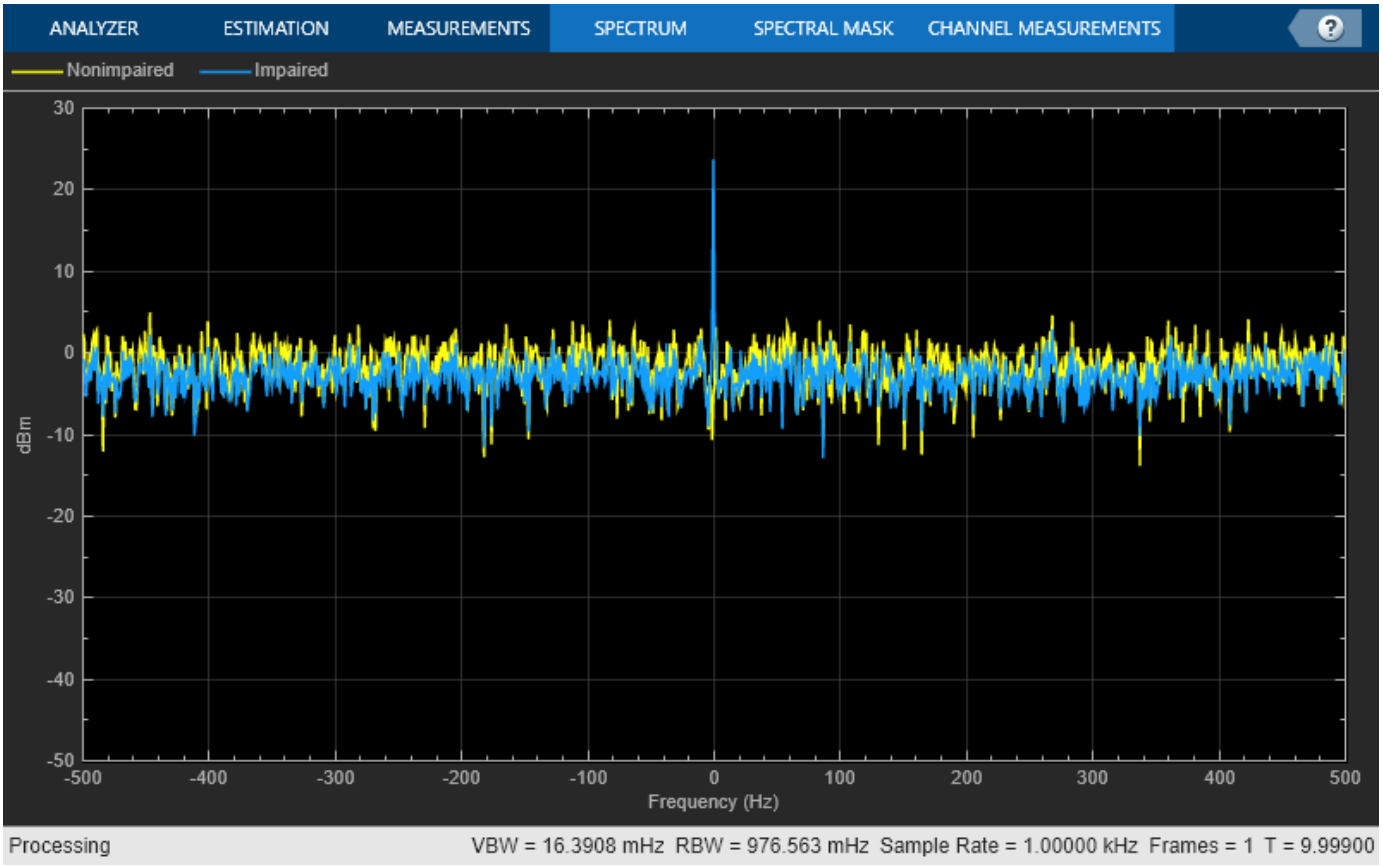
```
x = pskmod(randi([0 3],1e4,1),4,pi/4);
```

Apply a 1 dB amplitude imbalance and 5 degree phase imbalance to a QPSK signal. Apply a 0.5 + 0.3i DC offset.

```
y = iqimbal(x,1,5);
z = y + complex(0.5,0.3);
```

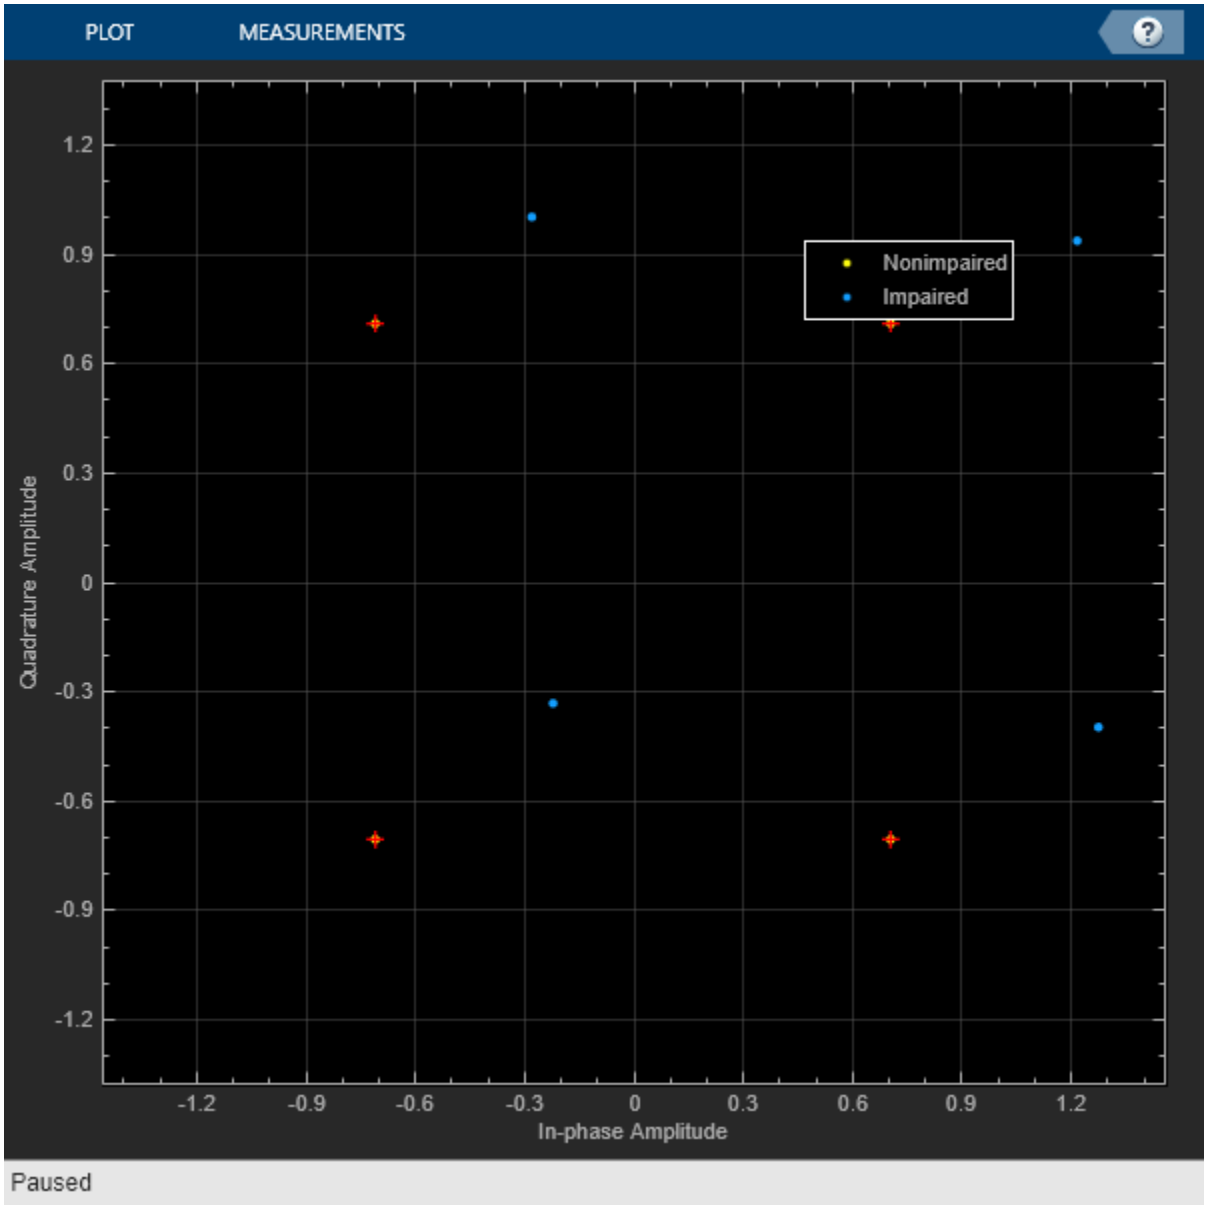
Plot the spectrum of the nonimpaired and impaired signals.

```
sa = spectrumAnalyzer( ...
    SampleRate=1000, ...
    ChannelNames=["Nonimpaired","Impaired"], ...
    YLimits=[-50 30]);
sa(x,z)
```



Display the corresponding scatter plot to see the effect of the I/Q imbalance and the DC offset.

```
cd = comm.ConstellationDiagram( ...
    NumInputPorts=2, ...
    ChannelNames=["Nonimpaired","Impaired"]);
cd(x,z)
```



Correct I/Q Imbalance on Noisy 8-PSK Signal

Generate random data and apply 8-PSK modulation.

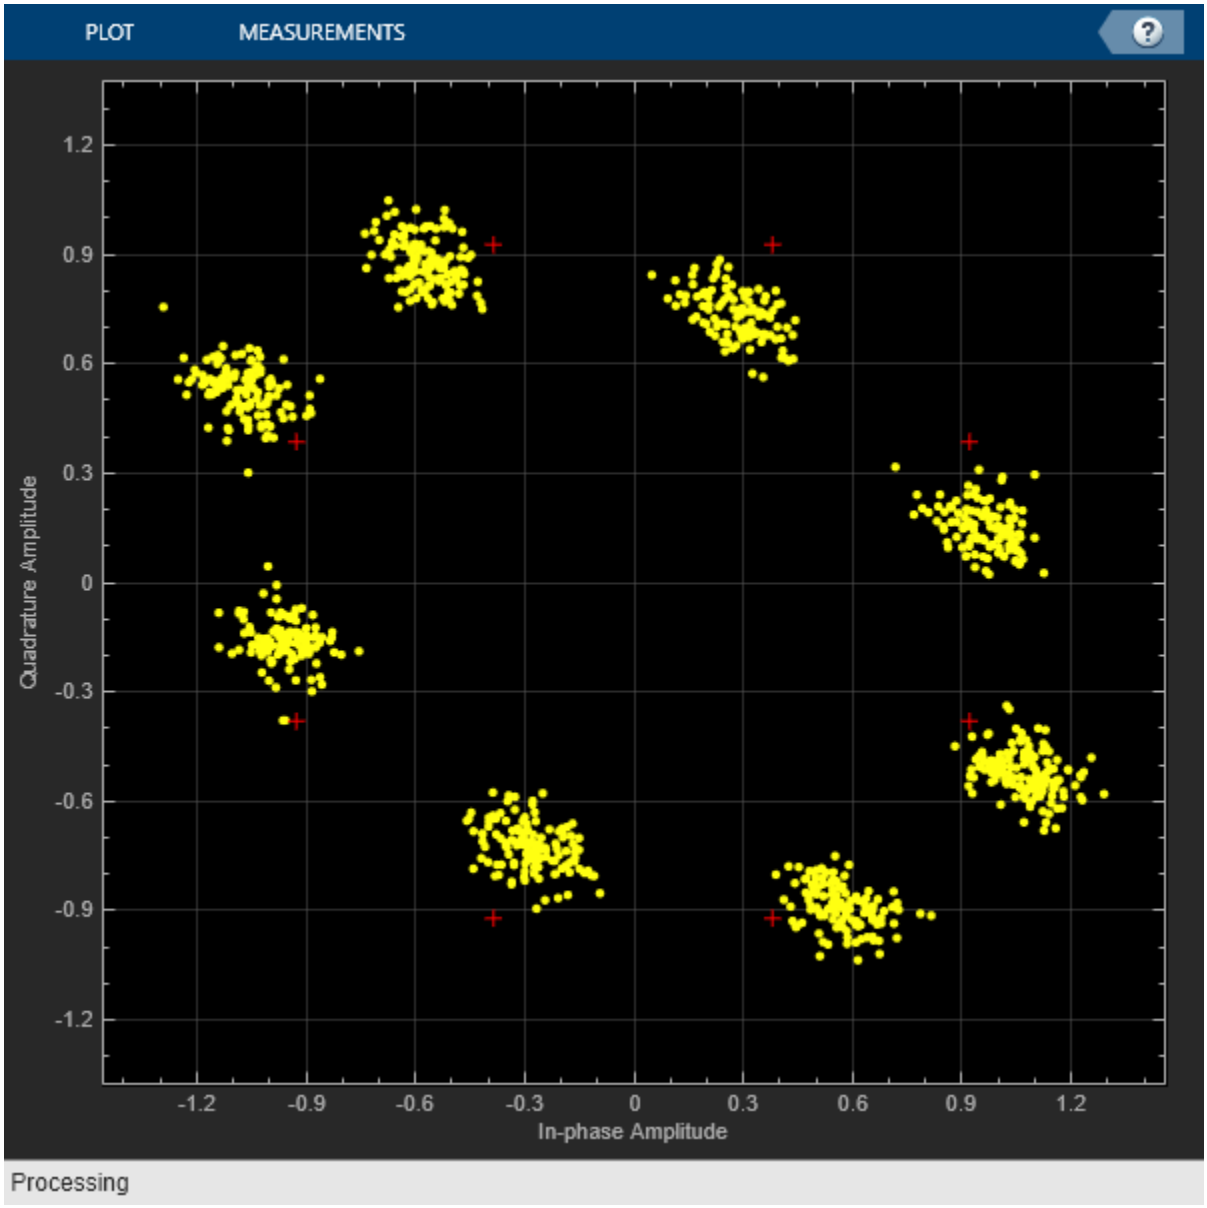
```
data = randi([0 7],2000,1);
txSig = pskmod(data,8,pi/8);
```

Pass the transmitted signal through an AWGN channel. Apply an I/Q imbalance.

```
noisySig = awgn(txSig,20);
rxSig = iqimbal(noisySig,2,20);
```

Create a constellation diagram object that displays only the last 1000 symbols. Plot the constellation diagram of the impaired signal.

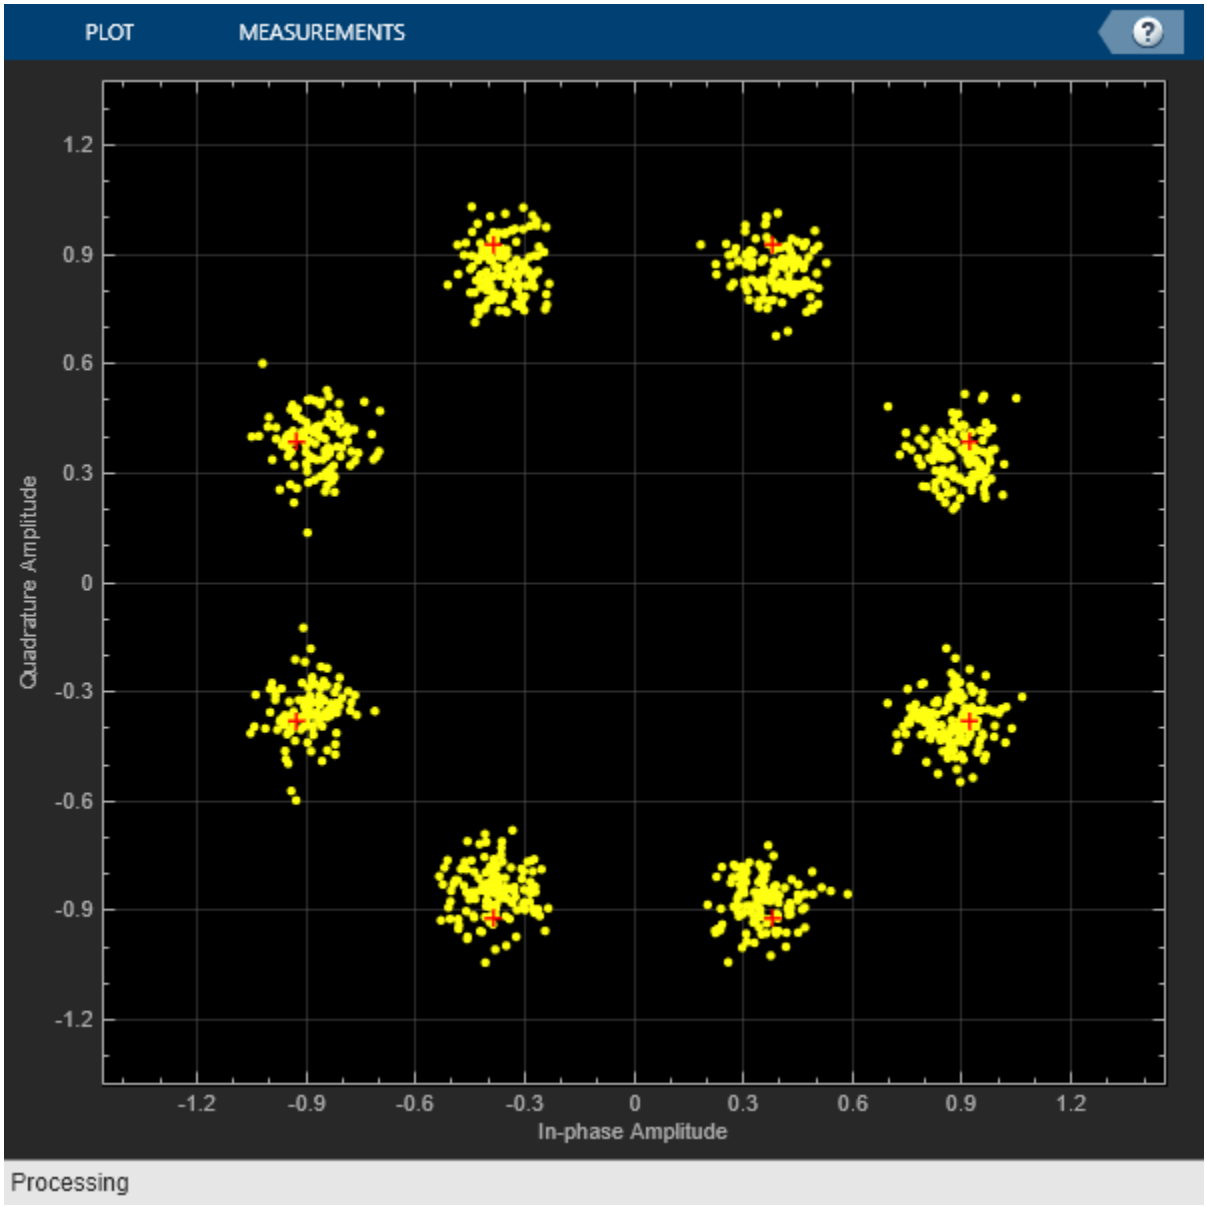
```
cd = comm.ConstellationDiagram('ReferenceConstellation',pskmod(0:7,8,pi/8), ...
    'SymbolsToDisplaySource','Property','SymbolsToDisplay',1000);
cd(rxSig)
```



Correct for the I/Q imbalance by using a `comm.IQImbalanceCompensator` object. Plot the constellation diagram of the signal after compensation.

```
iqComp = comm.IQImbalanceCompensator('StepSize',1e-3);
compSig = iqComp(rxSig);

cd(compSig)
```



The compensator removes the I/Q imbalance.

Input Arguments

x — Input signal

column vector | matrix

Input signal, specified as a column vector or matrix. The function supports multichannel operations, where the number of columns corresponds to the number of channels.

Example: `pskmod(randi([0 3],100,1),4,pi/4)`

Data Types: `single` | `double`

A — Amplitude imbalance

real scalar | row vector

Amplitude imbalance in dB, specified as a real scalar or row vector.

- If A is a scalar, the function applies the same amplitude imbalance to each channel.
- If A is a vector, then each element specifies the amplitude imbalance that is applied to the corresponding column (channel) of the input signal. The number of elements in A must equal the number of columns in x.

Example: 3

Example: [0 5]

Data Types: single | double

P — Phase imbalance

0 (default) | real scalar | row vector

Phase imbalance in degrees, specified as a real scalar or row vector.

- If P is omitted, a phase imbalance of zero degrees is used.
- If P is a scalar, the function applies the same phase imbalance to each channel.
- If P is a vector, then each element specifies the phase imbalance that is applied to the corresponding column (channel) of the input signal. The number of elements in P must equal the number of columns in x.

Example: 10

Example: [2.5 7]

Data Types: single | double

Output Arguments

y — Output signal

vector | matrix

Output signal, returned as a vector or matrix having the same dimensions as x. The number of columns in y corresponds to the number of channels.

Data Types: single | double

Algorithms

The iqimbal function applies an I/Q amplitude and phase imbalance to an input signal.

Given amplitude imbalance I_a in dB, the gain, g, resulting from the imbalance is defined as

$$g \triangleq g_r + ig_i = \left[10^{0.5\frac{I_a}{20}}\right] + i\left[10^{-0.5\frac{I_a}{20}}\right].$$

Applying the I/Q imbalance to input signal x results in output signal y such that

$$y = \mathrm{Re}(x) \cdot g_r e^{-i0.5I_p(\pi/180)} + i\mathrm{Im}(x) \cdot g_i e^{i0.5I_p(\pi/180)},$$

where g is the imbalance gain and I_p is the phase imbalance in degrees.

iscatastrophic

True for trellis corresponding to catastrophic convolutional code

Syntax

```
iscatastrophic(s)
```

Description

`iscatastrophic(s)` returns `true` if the trellis `s` corresponds to a convolutional code that causes catastrophic error propagation. Otherwise, it returns `false`.

Examples

Determine if a Convolutional Code is Catastrophic

Determine if a convolutional code causes catastrophic error propagation.

Create the trellis for the standard, rate 1/2, constraint length 7 convolutional code.

```
t = poly2trellis(7,[171 133]);
```

Verify that the code is not catastrophic.

```
iscatastrophic(t)
```

```
ans = logical
   0
```

Create a trellis for a different convolutional code using the `poly2trellis` function.

```
u = poly2trellis(7,[161 143]);
```

Verify that the code is catastrophic.

```
iscatastrophic(u)
```

```
ans = logical
   1
```

“Convolutional Codes”

isprimitive

True for primitive polynomial for Galois field

Syntax

```
isprimitive(a)
```

Description

`isprimitive(a)` returns `1` if the polynomial that `a` represents is primitive for the Galois field GF(2^m), and `0` otherwise. The input `a` can represent the polynomial using one of these formats:

- A nonnegative integer less than 2^{17}. The binary representation of this integer indicates the coefficients of the polynomial. In this case, m is `floor(log2(a))`.
- A Galois row vector in GF(2), listing the coefficients of the polynomial in order of descending powers. In this case, m is the order of the polynomial represented by `a`.

Examples

The example below finds all primitive polynomials for GF(8) and then checks using `isprimitive` whether specific polynomials are primitive.

```
a = primpoly(3,'all','nodisplay'); % All primitive polys for GF(8)

isp1 = isprimitive(13) % 13 represents a primitive polynomial.

isp2 = isprimitive(14) % 14 represents a nonprimitive polynomial.
```

The output is below. If you examine the vector `a`, notice that `isp1` is true because `13` is an element in `a`, while `isp2` is false because `14` is not an element in `a`.

```
isp1 =

     1

isp2 =

     0
```

istrellis

True for valid trellis structure

Syntax

```
[isok,status] = istrellis(s)
```

Description

`[isok,status] = istrellis(s)` checks if the input `s` is a valid trellis structure. If the input is a valid trellis structure, `isok` is 1 and `status` is an empty character vector. Otherwise, `isok` is 0 and `status` indicates why `s` is not a valid trellis structure.

A valid trellis structure is a MATLAB structure whose fields are as in the table below.

Fields of a Valid Trellis Structure for a Rate k/n Code

Field in Trellis Structure	Dimensions	Meaning
`numInputSymbols`	Scalar	Number of input symbols to the encoder: 2^k
`numOutputSymbols`	Scalar	Number of output symbols from the encoder: 2^n
`numStates`	Scalar	Number of states in the encoder
`nextStates`	`numStates`-by-2^k matrix	Next states for all combinations of current state and current input
`outputs`	`numStates`-by-2^k matrix	Outputs (in octal) for all combinations of current state and current input

In the `nextStates` matrix, each entry is an integer between 0 and `numStates`-1. The element in the sth row and uth column denotes the next state when the starting state is s-1 and the input bits have decimal representation u-1. To convert the input bits to a decimal value, use the first input bit as the most significant bit (MSB). For example, the second column of the `nextStates` matrix stores the next states when the current set of input values is {0,...,0,1}.

To convert the state to a decimal value, use this rule: If k exceeds 1, the shift register that receives the first input stream in the encoder provides the least significant bits in the state number, and the shift register that receives the last input stream in the encoder provides the most significant bits in the state number.

In the `outputs` matrix, the element in the sth row and uth column denotes the encoder's output when the starting state is s-1 and the input bits have decimal representation u-1. To convert to decimal value, use the first output bit as the MSB.

Examples

These commands assemble the fields into a very simple trellis structure, and then verify the validity of the trellis structure.

```
trellis.numInputSymbols = 2;
trellis.numOutputSymbols = 2;
trellis.numStates = 2;
trellis.nextStates = [0 1;0 1];
trellis.outputs = [0 0;1 1];
[isok,status] = istrellis(trellis)
```

The output is below.

```
isok =

     1

status =

     ''
```

Another example of a trellis is in “Trellis Description of a Convolutional Code”.

ldpcDecode

Decode binary LDPC code

Syntax

```
[y,actualnumiter,finalparitychecks] = ldpcDecode(llr,decodercfg,maxnumiter)
[y,actualnumiter,finalparitychecks] = ldpcDecode(llr,decodercfg,maxnumiter,
Name,Value)
```

Description

The `ldpcDecode` function decodes the input codeword using one of four algorithms. For more information, see “Algorithms” on page 2-516. LDPC codes are linear error control codes with sparse parity-check matrices and long block lengths that can attain performance near the Shannon limit.

`[y,actualnumiter,finalparitychecks] = ldpcDecode(llr,decodercfg,maxnumiter)` decodes the input log-likelihood ratio (LLR), `llr`, using the LDPC matrix specified by the input `ldpcDecoderConfig` configuration object, `decodercfg`. A positive LLR indicates that the corresponding bit is more likely a zero. Decoding terminates when all of the parity checks are satisfied, up to a maximum number of iterations specified by the input `maxnumiter`. LDPC codes are linear error control codes with sparse parity-check matrices and long block lengths that can attain performance near the Shannon limit.

`[y,actualnumiter,finalparitychecks] = ldpcDecode(llr,decodercfg,maxnumiter, Name,Value)` specifies options using one or more name-value arguments. For example, `DecisionType='soft'` specifies soft-decision decoding and outputs LLRs.

Examples

Decode Rate 3/4 LDPC Codewords

Initialize parameters for the prototype matrix and block size to configure a rate 3/4 LDPC code specified in IEEE® 802.11. Create the parity-check matrix by using the `ldpcQuasiCyclicMatrix` function.

```
P = [
    16 17 22 24  9  3 14 -1  4  2  7 -1 26 -1  2 -1 21 -1  1  0 -1 -1 -1 -1
    25 12 12  3  3 26  6 21 -1 15 22 -1 15 -1  4 -1 -1 16 -1  0  0 -1 -1 -1
    25 18 26 16 22 23  9 -1  0 -1  4 -1  4 -1  8 23 11 -1 -1 -1  0  0 -1 -1
     9  7  0  1 17 -1 -1  7  3 -1  3 23 -1 16 -1 -1 21 -1  0 -1 -1  0  0 -1
    24  5 26  7  1 -1 -1 15 24 15 -1  8 -1 13 -1 13 -1 11 -1 -1 -1 -1  0  0
     2  2 19 14 24  1 15 19 -1 21 -1  2 -1 24 -1  3 -1  2  1 -1 -1 -1 -1  0
    ];
blockSize = 27;
pcmatrix = ldpcQuasiCyclicMatrix(blockSize,P);
```

Create LDPC encoder and decoder configuration objects, displaying their properties.

```
cfgLDPCEnc = ldpcEncoderConfig(pcmatrix)
```

```
cfgLDPCEnc =
  ldpcEncoderConfig with properties:

     ParityCheckMatrix: [162x648 logical]

   Read-only properties:
           BlockLength: 648
    NumInformationBits: 486
    NumParityCheckBits: 162
              CodeRate: 0.7500
```

```
cfgLDPCDec = ldpcDecoderConfig(pcmatrix)
```

```
cfgLDPCDec =
  ldpcDecoderConfig with properties:

     ParityCheckMatrix: [162x648 logical]
             Algorithm: 'bp'

   Read-only properties:
           BlockLength: 648
    NumInformationBits: 486
    NumParityCheckBits: 162
              CodeRate: 0.7500
```

Transmit an LDPC-encoded, QPSK-modulated bit stream through an AWGN channel. Demodulate the signal, decode the received codewords, and then count bit errors. Use nested `for` loops to process multiple SNR settings and frames with and without LDPC forward error correction (FEC) coding of the transmitted data.

```
M = 4;
maxnumiter = 10;
snr = [3 6 20];
numframes = 10;
qpskmod = comm.PSKModulator(M,'BitInput',true);
qpskmod2 = comm.PSKModulator(M);

ber = comm.ErrorRate;
ber2 = comm.ErrorRate;

for ii = 1:length(snr)
    qpskdemod = comm.PSKDemodulator(M,'BitOutput',true, ...
        'DecisionMethod','Approximate log-likelihood ratio', ...
        'Variance',1/10^(snr(ii)/10));
    qpskdemod2 = comm.PSKDemodulator(M);
    for counter = 1:numframes
        data = randi([0 1],cfgLDPCEnc.NumInformationBits,1,'int8');
        % Transmit and receive with LDPC coding
        encodedData = ldpcEncode(data,cfgLDPCEnc);
        modSignal = qpskmod(encodedData);
        receivedSignal = awgn(modSignal,snr(ii));
        demodSignal = qpskdemod(receivedSignal);
        receivedBits = ldpcDecode(demodSignal,cfgLDPCDec,maxnumiter);
        errStats = ber(data,receivedBits);
        % Transmit and receive with no LDPC coding
        noCoding = qpskmod2(data);
```

```
        rxNoCoding = awgn(noCoding,snr(ii));
        rxBitsNoCoding = qpskdemod2(rxNoCoding);
        errStatsNoCoding = ber2(data,int8(rxBitsNoCoding));
    end
    fprintf(['SNR = %2d\n   Coded: Error rate = %1.2f, ' ...
        'Number of errors = %d\n'], ...
        snr(ii),errStats(1),errStats(2))
    fprintf(['Noncoded: Error rate = %1.2f, ' ...
        'Number of errors = %d\n'], ...
        errStatsNoCoding(1),errStatsNoCoding(2))
    reset(ber);
    reset(ber2);
end
```

```
SNR =  3
   Coded: Error rate = 0.07, Number of errors = 335

Noncoded: Error rate = 0.15, Number of errors = 714

SNR =  6
   Coded: Error rate = 0.00, Number of errors = 0

Noncoded: Error rate = 0.04, Number of errors = 196

SNR = 20
   Coded: Error rate = 0.00, Number of errors = 0

Noncoded: Error rate = 0.00, Number of errors = 0
```

Input Arguments

`llr` — Log-likelihood ratios

matrix

Log-likelihood ratios, specified as a matrix with the number of rows equal to the `BlockLength` property of the input `decodercfg`. Each column of `llr` corresponds to a codeword. The function decodes each column independently. A positive LLR indicates that the corresponding bit is more likely a zero.

Data Types: `single` | `double`

`decodercfg` — LDPC decoder configuration

`ldpcDecoderConfig` object

LDPC decoder configuration, specified as an `ldpcDecoderConfig` object.

`maxnumiter` — Maximum number of decoding iterations

positive scalar

Maximum number of decoding iterations, specified as a positive scalar.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `Termination='max'`

`OutputFormat` — Output format

`'info'` (default) | `'whole'`

Output format, specified as one of these values:

- `'info'` — Output only the decoded information bits. The number of rows that the function outputs equals the `NumInformationBits`property for the input `decodercfg`.
- `'whole'` — Output all of the decoded LDPC codeword bits, including information bits and parity-check bits. The number of rows that the function outputs equals the `BlockLength` property for the input `decodercfg`.

Data Types: `char` | `string`

`DecisionType` — Decision type

`'hard'` (default) | `'soft'`

Decision type for LDPC decoding, specified as one of these values:

- `'hard'` — Perform hard-decision decoding and output decoded bits as values of `int8` data type.
- `'soft'` — Perform soft-decision decoding and output LLRs with the same data type as the input.

Data Types: `char` | `string`

`MinSumScalingFactor` — Scaling factor for normalized min-sum decoding algorithm

`0.75` (default) | scalar in the range (0, 1]

Scaling factor for the normalized min-sum decoding algorithm, specified as a scalar in the range (0, 1]. For more information, see “Normalized Min-Sum Decoding” on page 2-518.

Dependencies

To enable this property, set the `Algorithm` property of the input `decodercfg` to `'norm-min-sum'`.

Data Types: `double`

`MinSumOffset` — Offset for min-sum decoding algorithm

`0.5` (default) | scalar

Offset for the min-sum decoding algorithm, specified as a scalar. For more information, see “Offset Min-Sum Decoding” on page 2-518.

Dependencies

To enable this property, set the `Algorithm` property of the input `decodercfg` to `'offset-min-sum'`.

Data Types: `double`

`Termination` — Decoding termination criteria

`'early'` (default) | `'max'`

Decoding termination criteria, specified as one of these values:

- `'early'` — Terminate decoding iterations when all of the parity checks are satisfied, up to a maximum number of iterations specified by input `maxnumiter`.
- `'max'` — Terminate decoding when the maximum number of iterations, `maxnumiter`, are complete.

Data Types: `char` | `string`

`Multithreaded` — Enable multithreaded execution
`true` or `1` (default) | `false` or `0`

Enable multithreaded execution, specified as a logical `1` (`true`) or `0` (`false`). When you run MATLAB in interpreted mode and set this argument to `true`, the function executes the decoding algorithm with multiple threads.

Tip

For large parity-check matrices, multithreaded execution significantly reduces the processing time for LDPC decoding.

Dependencies

To enable this property, run MATLAB in interpreted mode.

Output Arguments

`y` — Decoded codewords
matrix

Decoded codewords, returned as a matrix with *K* rows that represent the decoded bits for `llr`(1:*K*,:). *K* equals the `NumInformationBits` property of the input `decodercfg`. For the decoding operation, each column of `llr` corresponds to a codeword. The function decodes each column independently. The `'OutputFormat'` name-value argument specifies whether the output contains decoded information bits (default) or whole LDPC codeword bits. The `'DecisionType'` name-value argument specifies and determines the decoding decision type and the data type of this output.

For more information, see “Algorithms” on page 2-516.

Data Types: `int8` | `double` | `single`

`actualnumiter` — Actual number of decoding iterations
row vector

Actual number of decoding iterations, returned as a row vector. If all of the parity checks for a codeword are satisfied, decoding can stop before the maximum number of iterations, `maxnumiter`, is reached. This output is a row vector of the actual number of iterations that the function executes for the codewords.

Data Types: `double`

`finalparitychecks` — Final parity checks for each codeword
matrix

Final parity checks for each codeword, returned as a matrix with the number of rows equal to the `ParityCheckBits` property of input `decodercfg`. For the decoding operation, each column of this output is the final parity checks for the corresponding codeword.

Data Types: `double`

Algorithms

LDPC decoding using one of these message-passing algorithms.

Belief Propagation Decoding

The implementation of the belief propagation algorithm is based on the decoding algorithm presented by Gallager [2].

For transmitted LDPC-encoded codeword $c = c_0, c_1, \ldots, c_{n-1}$, the input to the LDPC decoder is the log-likelihood ratio (LLR) value $L(c_i) = \log\left(\frac{\Pr(c_i = 0 \,|\, \text{channel output for } c_i)}{\Pr(c_i = 1 \,|\, \text{channel output for } c_i)}\right)$.

In each iteration, the key components of the algorithm are updated based on these equations:

$$L(r_{ji}) = 2\,\mathrm{atanh}\left(\prod_{i' \in V_j \backslash i} \tanh\left(\frac{1}{2}L(q_{i'j})\right)\right),$$

$L(q_{ij}) = L(c_i) + \sum_{j' \in C_i \backslash j} L(r_{j'i})$, initialized as $L(q_{ij}) = L(c_i)$ before the first iteration, and

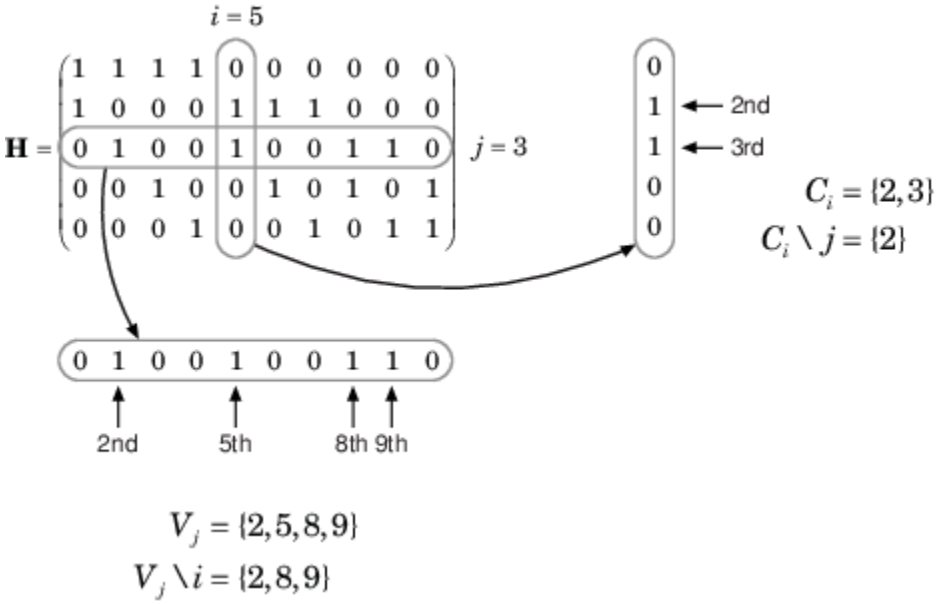
$$L(Q_i) = L(c_i) + \sum_{j' \in C_i} L(r_{j'i}).$$

At the end of each iteration, $L(Q_i)$ contains the updated estimate of the LLR value for transmitted bit c_i. The value $L(Q_i)$ is the soft-decision output for c_i. If $L(Q_i) < 0$, the hard-decision output for c_i is 1. Otherwise, the hard-decision output for c_i is 0.

If decoding is configured to stop when all of the parity checks are satisfied, the algorithm verifies the parity-check equation ($H\,c' = 0$) at the end of each iteration. When all of the parity checks are satisfied, or if the maximum number of iterations is reached, decoding stops.

Index sets $C_i\backslash j$ and $V_j\backslash i$ are based on the parity-check matrix (PCM). Index sets C_i and V_j correspond to all nonzero elements in column i and row j of the PCM, respectively.

This figure shows the computation of these index sets in a given PCM for $i = 5$ and $j = 3$.



To avoid infinite numbers in the algorithm equations, atanh(1) and atanh(–1) are set to 19.07 and –19.07, respectively. Due to finite precision, MATLAB returns 1 for tanh(19.07) and –1 for tanh(-19.07).

Layered Belief Propagation Decoding

The implementation of the layered belief propagation algorithm is based on the decoding algorithm presented in Hocevar [3], Section II.A. The decoding loop iterates over subsets of rows (layers) of the PCM. For each row, m, in a layer and each bit index, j, the implementation updates the key components of the algorithm based on these equations:

(1) $L(q_{mj}) = L(q_j) - R_{mj}$,

(2) $A_{mj} = \underset{n \in N(m),\ n \neq j}{\sum} \psi(L(q_{mn}))$,

(3) $s_{mj} = \underset{n \in N(m),\ n \neq j}{\prod} \text{sign}(L(q_{mn}))$,

(4) $R_{mj} = -s_{mj}\psi(A_{mj})$, and

(5) $L(q_j) = L(q_{mj}) + R_{mj}$.

For each layer, the decoding equation (5) works on the combined input obtained from the current LLR inputs $L(q_{mj})$ and the previous layer updates R_{mj}.

Because only a subset of the nodes is updated in a layer, the layered belief propagation algorithm is faster compared to the belief propagation algorithm. To achieve the same error rate as attained with belief propagation decoding, use half the number of decoding iterations when you use the layered belief propagation algorithm.

Normalized Min-Sum Decoding

The implementation of the normalized min-sum decoding algorithm follows the layered belief propagation algorithm with equation (2) replaced by

$$A_{mj} = \min_{\substack{n \in N(m) \\ n \neq j}} (|L(q_{mn})| \cdot \alpha),$$

where α is in the range (0, 1] and is the scaling factor specified by the `MinSumScalingFactor` input argument to the `ldpcDecode` function. This equation is an adaptation of equation (4) presented in Chen [4].

Offset Min-Sum Decoding

The implementation of the offset min-sum decoding algorithm follows the layered belief propagation algorithm with equation (2) replaced by

$$A_{mj} = \max\left(\min_{\substack{n \in N(m) \\ n \neq j}} (|L(q_{mn})| - \beta), 0\right),$$

where $\beta \geq 0$ and is the offset specified by the `MinSumOffset` input argument to the `ldpcDecode` function. This equation is an adaptation of equation (5) presented in Chen [4].

ldpcEncode

Encode binary LDPC code

Syntax

```
y = ldpcEncode(informationbits,encodercfg)
y = ldpcEncode(informationbits,encodercfg,OutputFormat=fmt)
```

Description

`y = ldpcEncode(informationbits,encodercfg)` encodes the input message, `informationbits`, using the LDPC matrix specified by the LDPC encoder configuration object, `encodercfg`. The output LPDC codeword contains the information bits followed by the parity-check bits. LDPC codes are linear error control codes with sparse parity-check matrices and long block lengths that can attain performance near the Shannon limit.

`y = ldpcEncode(informationbits,encodercfg,OutputFormat=fmt)` specifies the output format of the codeword.

Examples

Encode Information Bits Using Rate 3/4 LDPC Code

Initialize parameters for the prototype matrix and block size to configure a rate 3/4 LDPC code specified in IEEE® 802.11. Create the parity-check matrix by using the `ldpcQuasiCyclicMatrix` function.

```
P = [16 17 22 24  9  3 14 -1  4  2  7 -1 26 -1  2 -1 21 -1  1  0 -1 -1 -1 -1
     25 12 12  3  3 26  6 21 -1 15 22 -1 15 -1  4 -1 -1 16 -1  0  0 -1 -1 -1
     25 18 26 16 22 23  9 -1  0 -1  4 -1  4 -1  8 23 11 -1 -1 -1  0  0 -1 -1
      9  7  0  1 17 -1 -1  7  3 -1  3 23 -1 16 -1 -1 21 -1  0 -1 -1  0  0 -1
     24  5 26  7  1 -1 -1 15 24 15 -1  8 -1 13 -1 13 -1 11 -1 -1 -1 -1  0  0
      2  2 19 14 24  1 15 19 -1 21 -1  2 -1 24 -1  3 -1  2  1 -1 -1 -1 -1  0
    ];
blockSize = 27;
pcmatrix = ldpcQuasiCyclicMatrix(blockSize,P);
```

Create an LDPC encoder configuration object, displaying its properties. Generate random information bits by using the `NumInformationBits` property of the configuration object to specify the number of information bits in an LPDC codeword. Encode the information bits by the LDPC code specified by the LDPC encoder configuration object.

```
cfgLDPCEnc = ldpcEncoderConfig(pcmatrix)
```

```
cfgLDPCEnc =
  ldpcEncoderConfig with properties:

     ParityCheckMatrix: [162x648 logical]

   Read-only properties:
```

```
           BlockLength: 648
    NumInformationBits: 486
    NumParityCheckBits: 162
              CodeRate: 0.7500
```

```
infoBits = rand(cfgLDPCEnc.NumInformationBits,1) < 0.5;
codeword = ldpcEncode(infoBits, cfgLDPCEnc);
```

Input Arguments

`informationbits` — Information bits

matrix

Information bits, specified as a matrix. The number of rows in `informationbits` must equal the value of the `NumInformationBits` property of the input `encodercfg`.

Data Types: `single` | `double` | `int8` | `logical`

`encodercfg` — LDPC encoder configuration

`ldpcEncoderConfig` object

LDPC encoder configuration, specified as an `ldpcEncoderConfig` object.

`fmt` — Output format

`'whole'` (default) | `'parity'`

Output format, specified as one of these values:

- `'whole'` — Output the whole LDPC codeword, including information bits and parity-check bits. The number of rows that the function outputs equals the value of the`BlockLength` property for the input `encodercfg`.
- `'parity'` — Output only the parity-check bits. The number of rows that the function outputs equals the value of the `NumParityCheckBits` property for the input `encodercfg`.

Output Arguments

`y` — Encoded codeword

matrix

Encoded codeword, returned as a matrix. For the encoding operation, the function encodes each column of the input `informationbits` independently. The function treats nonzero values in `informationbits` as ones. The encoding computes a systematic codeword matrix populated with the original information bits in the [1:K,:] submatrix and the parity-check bits in the ((1:K + 1):end,:) submatrix. K equals the `NumInformationBits` property of the input `encodercfg`.

- When the output format is `'whole'`, the output contains the whole LDPC codeword, including the information bits and the parity-check bits. The number of rows output by the function equals the value of the `BlockLength` property for the input `encodercfg`.
- When the output format is `'parity'`, the output contains only the parity-check bits. The number of rows that the function outputs equals the `NumParityCheckBits` property for the input `encodercfg`.

For information about setting the output format, see the `OutputFormat` argument. The output has the same data type as the input `informationbits`.

ldpcQuasiCyclicMatrix

Parity-check matrix of quasi-cyclic LDPC code

Syntax

```
H = ldpcQuasiCyclicMatrix(blocksize,P)
```

Description

`H = ldpcQuasiCyclicMatrix(blocksize,P)` returns parity-check matrix `H` for a quasi-cyclic LDPC code based on the input block size, `blocksize`, and the prototype matrix, `P`.

Examples

Create Parity-Check Matrix of a Quasicyclic LDPC Code

Create a parity-check matrix of a quasicyclic LDPC code. Set the block size to `3` and the prototype matrix to `[0 -1 1 2; 2 1 -1 0]`.

```
blockSize = 3;
p = [0 -1 1 2; 2 1 -1 0];
pcmatrix = ldpcQuasiCyclicMatrix(blockSize,p)
```

```
pcmatrix = 6x12 sparse logical array
   (1,1)      1
   (5,1)      1
   (2,2)      1
   (6,2)      1
   (3,3)      1
   (4,3)      1
   (6,4)      1
   (4,5)      1
   (5,6)      1
   (3,7)      1
   (1,8)      1
   (2,9)      1
   (2,10)     1
   (4,10)     1
   (3,11)     1
   (5,11)     1
   (1,12)     1
   (6,12)     1
```

Confirm that the resulting parity-check matrix is a sparse and logical matrix.

```
issparse(pcmatrix) & islogical(pcmatrix)
```

```
ans = logical
   1
```

Parity-check matrices can be large, and displaying them as a full matrix is generally not advisable. Because the parity-check matrix in this example is only 6-by-12, display it as a full matrix.

```
full(pcmatrix)
```

```
ans = 6x12 logical array

   1   0   0   0   0   0   0   1   0   0   0   1
   0   1   0   0   0   0   0   0   1   1   0   0
   0   0   1   0   0   0   1   0   0   0   1   0
   0   0   1   0   1   0   0   0   0   1   0   0
   1   0   0   0   0   1   0   0   0   0   1   0
   0   1   0   1   0   0   0   0   0   0   0   1
```

Encode Information Bits Using Rate 3/4 LDPC Code

Initialize parameters for the prototype matrix and block size to configure a rate 3/4 LDPC code specified in IEEE® 802.11. Create the parity-check matrix by using the `ldpcQuasiCyclicMatrix` function.

```
P = [16 17 22 24  9  3 14 -1  4  2  7 -1 26 -1  2 -1 21 -1  1  0 -1 -1 -1 -1
     25 12 12  3  3 26  6 21 -1 15 22 -1 15 -1  4 -1 -1 16 -1  0  0 -1 -1 -1
     25 18 26 16 22 23  9 -1  0 -1  4 -1  4 -1  8 23 11 -1 -1 -1  0  0 -1 -1
      9  7  0  1 17 -1 -1  7  3 -1  3 23 -1 16 -1 -1 21 -1  0 -1 -1  0  0 -1
     24  5 26  7  1 -1 -1 15 24 15 -1  8 -1 13 -1 13 -1 11 -1 -1 -1 -1  0  0
      2  2 19 14 24  1 15 19 -1 21 -1  2 -1 24 -1  3 -1  2  1 -1 -1 -1 -1  0
    ];
blockSize = 27;
pcmatrix = ldpcQuasiCyclicMatrix(blockSize,P);
```

Create an LDPC encoder configuration object, displaying its properties. Generate random information bits by using the `NumInformationBits` property of the configuration object to specify the number of information bits in an LPDC codeword. Encode the information bits by the LDPC code specified by the LDPC encoder configuration object.

```
cfgLDPCEnc = ldpcEncoderConfig(pcmatrix)
```

```
cfgLDPCEnc =
  ldpcEncoderConfig with properties:

     ParityCheckMatrix: [162x648 logical]

   Read-only properties:
           BlockLength: 648
    NumInformationBits: 486
    NumParityCheckBits: 162
              CodeRate: 0.7500
```

```
infoBits = rand(cfgLDPCEnc.NumInformationBits,1) < 0.5;
codeword = ldpcEncode(infoBits, cfgLDPCEnc);
```

Decode Rate 3/4 LDPC Codewords

Initialize parameters for the prototype matrix and block size to configure a rate 3/4 LDPC code specified in IEEE® 802.11. Create the parity-check matrix by using the `ldpcQuasiCyclicMatrix` function.

```
P = [
    16 17 22 24  9  3 14 -1  4  2  7 -1 26 -1  2 -1 21 -1  1  0 -1 -1 -1 -1
    25 12 12  3  3 26  6 21 -1 15 22 -1 15 -1  4 -1 -1 16 -1  0  0 -1 -1 -1
    25 18 26 16 22 23  9 -1  0 -1  4 -1  4 -1  8 23 11 -1 -1 -1  0  0 -1 -1
     9  7  0  1 17 -1 -1  7  3 -1  3 23 -1 16 -1 -1 21 -1  0 -1 -1  0  0 -1
    24  5 26  7  1 -1 -1 15 24 15 -1  8 -1 13 -1 13 -1 11 -1 -1 -1 -1  0  0
     2  2 19 14 24  1 15 19 -1 21 -1  2 -1 24 -1  3 -1  2  1 -1 -1 -1 -1  0
    ];
blockSize = 27;
pcmatrix = ldpcQuasiCyclicMatrix(blockSize,P);
```

Create LDPC encoder and decoder configuration objects, displaying their properties.

```
cfgLDPCEnc = ldpcEncoderConfig(pcmatrix)
```

```
cfgLDPCEnc =
  ldpcEncoderConfig with properties:

     ParityCheckMatrix: [162x648 logical]

   Read-only properties:
           BlockLength: 648
    NumInformationBits: 486
    NumParityCheckBits: 162
              CodeRate: 0.7500
```

```
cfgLDPCDec = ldpcDecoderConfig(pcmatrix)
```

```
cfgLDPCDec =
  ldpcDecoderConfig with properties:

     ParityCheckMatrix: [162x648 logical]
             Algorithm: 'bp'

   Read-only properties:
           BlockLength: 648
    NumInformationBits: 486
    NumParityCheckBits: 162
              CodeRate: 0.7500
```

Transmit an LDPC-encoded, QPSK-modulated bit stream through an AWGN channel. Demodulate the signal, decode the received codewords, and then count bit errors. Use nested `for` loops to process multiple SNR settings and frames with and without LDPC forward error correction (FEC) coding of the transmitted data.

```
M = 4;
maxnumiter = 10;
snr = [3 6 20];
numframes = 10;
qpskmod = comm.PSKModulator(M,'BitInput',true);
```

```
qpskmod2 = comm.PSKModulator(M);

ber = comm.ErrorRate;
ber2 = comm.ErrorRate;

for ii = 1:length(snr)
    qpskdemod = comm.PSKDemodulator(M,'BitOutput',true, ...
        'DecisionMethod','Approximate log-likelihood ratio', ...
        'Variance',1/10^(snr(ii)/10));
    qpskdemod2 = comm.PSKDemodulator(M);
    for counter = 1:numframes
        data = randi([0 1],cfgLDPCEnc.NumInformationBits,1,'int8');
        % Transmit and receive with LDPC coding
        encodedData = ldpcEncode(data,cfgLDPCEnc);
        modSignal = qpskmod(encodedData);
        receivedSignal = awgn(modSignal,snr(ii));
        demodSignal = qpskdemod(receivedSignal);
        receivedBits = ldpcDecode(demodSignal,cfgLDPCDec,maxnumiter);
        errStats = ber(data,receivedBits);
        % Transmit and receive with no LDPC coding
        noCoding = qpskmod2(data);
        rxNoCoding = awgn(noCoding,snr(ii));
        rxBitsNoCoding = qpskdemod2(rxNoCoding);
        errStatsNoCoding = ber2(data,int8(rxBitsNoCoding));
    end
    fprintf(['SNR = %2d\n   Coded: Error rate = %1.2f, ' ...
        'Number of errors = %d\n'], ...
        snr(ii),errStats(1),errStats(2))
    fprintf(['Noncoded: Error rate = %1.2f, ' ...
        'Number of errors = %d\n'], ...
        errStatsNoCoding(1),errStatsNoCoding(2))
    reset(ber);
    reset(ber2);
end
```

```
SNR =  3
   Coded: Error rate = 0.07, Number of errors = 335

Noncoded: Error rate = 0.15, Number of errors = 714

SNR =  6
   Coded: Error rate = 0.00, Number of errors = 0

Noncoded: Error rate = 0.04, Number of errors = 196

SNR = 20
   Coded: Error rate = 0.00, Number of errors = 0

Noncoded: Error rate = 0.00, Number of errors = 0
```

Input Arguments

`blocksize` — Block size

positive scalar

Block size of the quasi-cyclic LDPC code, specified as a positive scalar.

Data Types: `double`

`P` — Prototype matrix
matrix

Prototype matrix, specified as a matrix. The number of columns in `P` must be greater than the number of rows in `P`. All values in `P` must be `-1`, `0`, or positive integers less than the input `blocksize`. A value of `-1` produces a zero-valued `blocksize`-by-`blocksize` submatrix. Other values indicate that the number of columns a `blocksize`-by-`blocksize` diagonal matrix must be cyclically shifted to the right. Each submatrix is either a zero matrix or a cyclically shifted version of a diagonal matrix.

Data Types: `double`

Output Arguments

`H` — Parity-check matrix
sparse logical matrix

Parity-check matrix, returned as a sparse logical matrix. The function expands each element of input `P` to a `blocksize`-by-`blocksize` submatrix in `H`.

Data Types: `logical`

lloyds

Optimize quantization parameters using Lloyd algorithm

Syntax

```
[partition,codebook] = lloyds(training_set,initcodebook)
[partition,codebook] = lloyds(training_set,len)
[partition,codebook] = lloyds(training_set,...,tol)
[partition,codebook,distor] = lloyds(...)
[partition,codebook,distor,reldistor] = lloyds(...)
```

Description

`[partition,codebook] = lloyds(training_set,initcodebook)` optimizes the scalar quantization parameters `partition` and `codebook` for the training data in the vector `training_set`. `initcodebook`, a vector of length at least 2, is the initial guess of the codebook values. The output `codebook` is a vector of the same length as `initcodebook`. The output `partition` is a vector whose length is one less than the length of `codebook`.

See “Represent Partitions”, “Represent Codebooks”, or the reference page for `quantiz` in this chapter, for a description of the formats of `partition` and `codebook`.

Note `lloyds` optimizes for the data in `training_set`. For best results, `training_set` should be similar to the data that you plan to quantize.

`[partition,codebook] = lloyds(training_set,len)` is the same as the first syntax, except that the scalar argument `len` indicates the size of the vector `codebook`. This syntax does not include an initial codebook guess.

`[partition,codebook] = lloyds(training_set,...,tol)` is the same as the two syntaxes above, except that `tol` replaces 10^{-7} in condition 1 of the algorithm description below.

`[partition,codebook,distor] = lloyds(...)` returns the final mean square distortion in the variable `distor`.

`[partition,codebook,distor,reldistor] = lloyds(...)` returns a value `reldistor` that is related to the algorithm's termination. In condition 1 of the algorithm below, `reldistor` is the relative change in distortion between the last two iterations. In condition 2, `reldistor` is the same as `distor`.

Examples

The code below optimizes the quantization parameters for a sinusoidal transmission via a three-bit channel. Because the typical data is sinusoidal, `training_set` is a sampled sine wave. Because the channel can transmit three bits at a time, `lloyds` prepares a codebook of length 2^3.

```
% Generate a complete period of a sinusoidal signal.
x = sin([0:1000]*pi/500);
[partition,codebook] = lloyds(x,2^3)
```

The output is below.

```
partition =

  Columns 1 through 6

   -0.8540   -0.5973   -0.3017    0.0031    0.3077    0.6023

  Column 7

Algorithms

`lloyds` uses an iterative process to try to minimize the mean square distortion. The optimization processing ends when either

- The relative change in distortion between iterations is less than 10^{-7}.
- The distortion is less than `eps*max(training_set)`, where `eps` is the MATLAB floating-point relative accuracy.

log

Logarithm in Galois field

Syntax

```
y = log(x)
```

Description

`y = log(x)` computes the logarithm of each element in the Galois array `x`. `y` is an integer array that solves the equation `A.^y = x`, where `A` is the primitive element used to represent elements in `x`. More explicitly, the base `A` of the logarithm is `gf(2,x.m)` or `gf(2,x.m,x.prim_poly)`. All elements in `x` must be nonzero because the logarithm of zero is undefined.

Examples

The code below illustrates how the logarithm operation inverts exponentiation.

```
m = 4; x = gf([8 1 6; 3 5 7; 4 9 2],m);
y = log(x);
primel = gf(2,m); % Primitive element in the field
z = primel .^ y; % This is now the same as x.
ck = isequal(x,z)
```

The output is

```
ck =

     1
```

The code below shows that the logarithm of `1` is `0` and that the logarithm of the base (`primel`) is `1`.

```
m = 4; primel = gf(2,m);
yy = log([1, primel])
```

The output is

```
yy =

     0     1
```

`gf`

mask2shift

Convert mask vector to shift for shift register configuration

Syntax

```
shift = mask2shift(prpoly,mask)
```

Description

`shift = mask2shift(prpoly,mask)` returns the shift that is equivalent to a mask, for a linear feedback shift register whose connections are specified by the primitive polynomial `prpoly`. The `prpoly` input can have one of these formats:

- A polynomial character vector
- A binary vector that lists the coefficients of the primitive polynomial in order of descending powers
- An integer scalar whose binary representation gives the coefficients of the primitive polynomial, where the least significant bit is the constant term

The `mask` input is a binary vector whose length is the degree of the primitive polynomial.

Note To save time, `mask2shift` does not check that `prpoly` is primitive. If it is not primitive, the output is not meaningful. To find primitive polynomials, use `primpoly` or see [2].

For more information about how masks and shifts are related to pseudonoise sequence generators, see `shift2mask`.

Definition of Equivalent Shift

If A is a root of the primitive polynomial and m(A) is the mask polynomial evaluated at A, the equivalent shift s solves the equation A^s = m(A). To interpret the vector `mask` as a polynomial, treat `mask` as a list of coefficients in order of descending powers.

Examples

Convert Mask to Shift

Convert masks into shifts for a linear feedback shift register.

Convert a mask of $x^3 + 1$ into an equivalent shift for the linear feedback shift register whose connections are specified by the primitive polynomial $x^4 + x^3 + 1$.

```
s1 = mask2shift([1 1 0 0 1],[1 0 0 1])
```

```
s1 = 4
```

Convert a mask of `1` to a shift. The mask is equivalent to a shift of `0`.

```
s2 = mask2shift([1 1 0 0 1],[0 0 0 1])
```

```
s2 = 0
```

Convert a mask of x^2 into an equivalent shift for the primitive polynomial $x^3 + x + 1$.

```
s3 = mask2shift('x3+x+1','x2')
```

```
s3 = 2
```

matdeintrlv

Restore ordering of symbols by filling matrix by columns and emptying it by rows

Syntax

```
deintrlvd = matdeintrlv(data,Nrows,Ncols)
```

Description

`deintrlvd = matdeintrlv(data,Nrows,Ncols)` rearranges the elements in `data` by filling a temporary matrix with the elements column by column and then sending the matrix contents, row by row, to the output. `Nrows` and `Ncols` are the dimensions of the temporary matrix. If `data` is a vector, it must have `Nrows*Ncols` elements. If `data` is a matrix with multiple rows and columns, `data` must have `Nrows*Ncols` rows and the function processes the columns independently.

To use this function as an inverse of the `matintrlv` function, use the same `Nrows` and `Ncols` inputs in both functions. In that case, the two functions are inverses in the sense that applying `matintrlv` followed by `matdeintrlv` leaves data unchanged.

Examples

The code below illustrates the inverse relationship between `matintrlv` and `matdeintrlv`.

```
Nrows = 2; Ncols = 3;
data = [1 2 3 4 5 6; 2 4 6 8 10 12]';
a = matintrlv(data,Nrows,Ncols); % Interleave.
b = matdeintrlv(a,Nrows,Ncols) % Deinterleave.
```

The output below shows that `b` is the same as `data`.

```
b =

     1     2
     2     4
     3     6
     4     8
     5    10
     6    12
```

matintrlv

Reorder symbols by filling matrix by rows and emptying it by columns

Syntax

```
intrlvd = matintrlv(data,Nrows,Ncols)
```

Description

`intrlvd = matintrlv(data,Nrows,Ncols)` rearranges the elements in `data` by filling a temporary matrix with the elements row by row and then sending the matrix contents, column by column, to the output. `Nrows` and `Ncols` are the dimensions of the temporary matrix. If `data` is a vector, it must have `Nrows*Ncols` elements. If `data` is a matrix with multiple rows and columns, `data` must have `Nrows*Ncols` rows and the function processes the columns independently.

Examples

Apply Matrix Interleaving to Reorder Input Matrix

Use the `matintrlv` function to reorder the elements filling matrix by rows and emptying it by columns.

To form the first column of the output, the function creates the temporary 2-by-3 matrix [1 2 3; 4 5 6]. Then the function reads down each column of the temporary matrix to get [1 4 2 5 3 6].

```
b = matintrlv([1 2 3 4 5 6; 2 4 6 8 10 12]',2,3)
```

```
b = 6×2

     1     2
     4     8
     2     4
     5    10
     3     6
     6    12
```

To form the first column of the output, the function creates the temporary 3-by-2 matrix [1 2; 3 4; 5 6]. Then the function reads down each column of the temporary matrix to get [1 3 5 2 4 6].

```
b = matintrlv([1 2 3 4 5 6; 2 4 6 8 10 12]',3,2)
```

```
b = 6×2

     1     2
     3     6
     5    10
     2     4
     4     8
     6    12
```

mil188qamdemod

MIL-STD-188-110 B/C standard-specific quadrature amplitude demodulation

Syntax

```
z = mil188qamdemod(y,M)
z = mil188qamdemod(y,M,Name,Value)
```

Description

`z = mil188qamdemod(y,M)` performs QAM demodulation on an input signal, `y`, that was modulated in accordance with MIL-STD-188-110 and the modulation order, `M`. For a description of MIL-STD-188-110 QAM demodulation, see “MIL-STD-188-110 QAM Hard Demodulation” on page 2-544 and “MIL-STD-188-110 QAM Soft Demodulation” on page 2-545.

`z = mil188qamdemod(y,M,Name,Value)` specifies options using one or more name-value pair arguments. For example, `'OutputDataType','double'` specifies the desired output data type as double. Specify name-value pair arguments after all other input arguments.

Examples

Demodulate MIL-STD-188-110B Specific 16-QAM Signal

Demodulate a 16-QAM signal that was modulated as specified in MIL-STD-188-110B. Plot the received constellation and verify that the output matches the input.

Set the modulation order and generate random data.

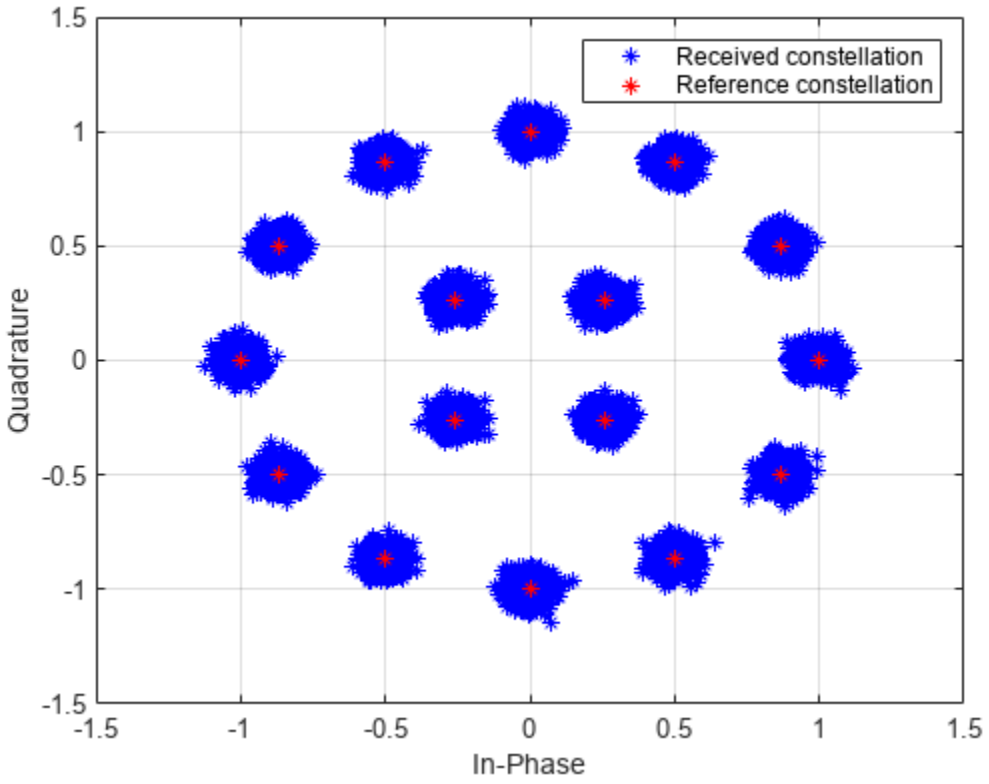
```
M = 16;
numSym = 20000;
x = randi([0 M-1],numSym,1);
```

Modulate the data and pass through a noisy channel.

```
txSig = mil188qammod(x,M);
rxSig = awgn(txSig,25,'measured');
```

Plot the transmitted and received signal.

```
plot(rxSig,'b*')
hold on; grid
plot(txSig,'r*')
xlim([-1.5 1.5]);
ylim([-1.5 1.5])
xlabel('In-Phase')
ylabel('Quadrature')
legend('Received constellation','Reference constellation')
```



Demodulate the received signal. Compare the demodulated data to the original data.

```
z = mil188qamdemod(rxSig,M);
isequal(x,z)
```

```
ans = logical
   1
```

Demodulate MIL-STD-188-110C Specific 64-QAM Signal

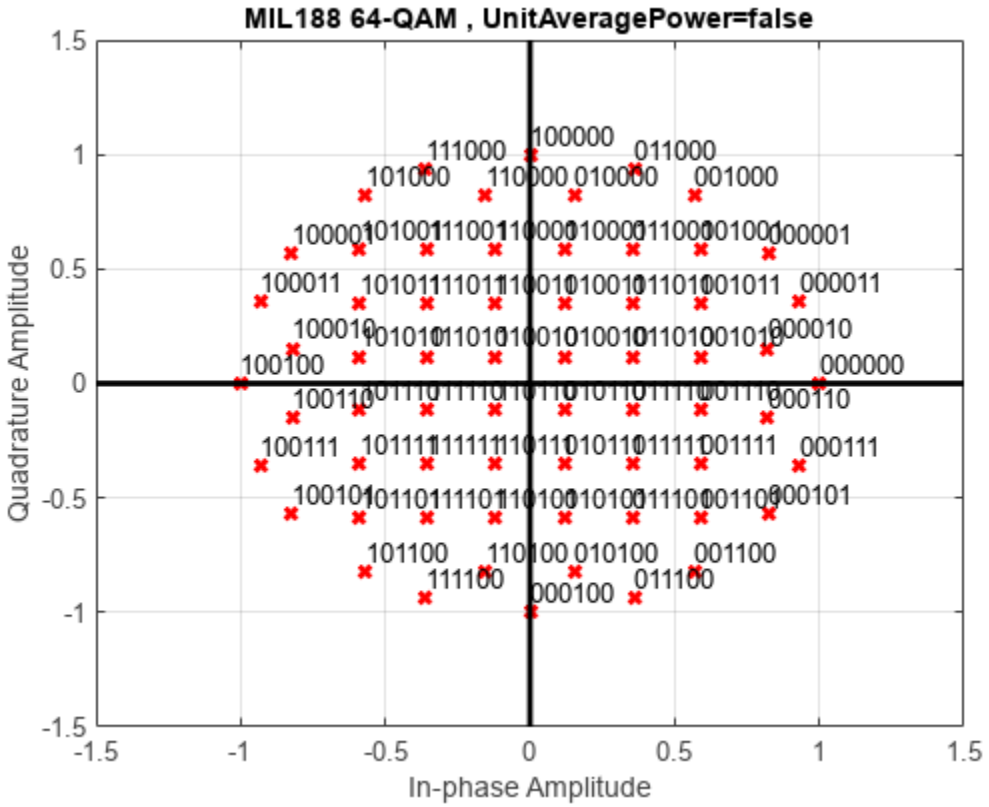
Demodulate a 64-QAM signal that was modulated as specified in MIL-STD-188-110C. Compute hard decision bit output and verify that the output matches the input.

Set the modulation order and generate random bit data.

```
M = 64;
numBitsPerSym = log2(M);
x = randi([0 1],1000*numBitsPerSym,1);
```

Modulate the data. Use name-value pairs to specify bit input data and to plot the constellation.

```
txSig = mil188qammod(x,M,'InputType','bit','PlotConstellation',true);
```



Demodulate the received signal. Compare the demodulated data to the original data.

```
z = mil188qamdemod(txSig,M,'OutputType','bit');
isequal(z,x)
```

```
ans = logical
   1
```

Soft Bit Demodulate MIL-STD-188-110 Specific 32-QAM Signal

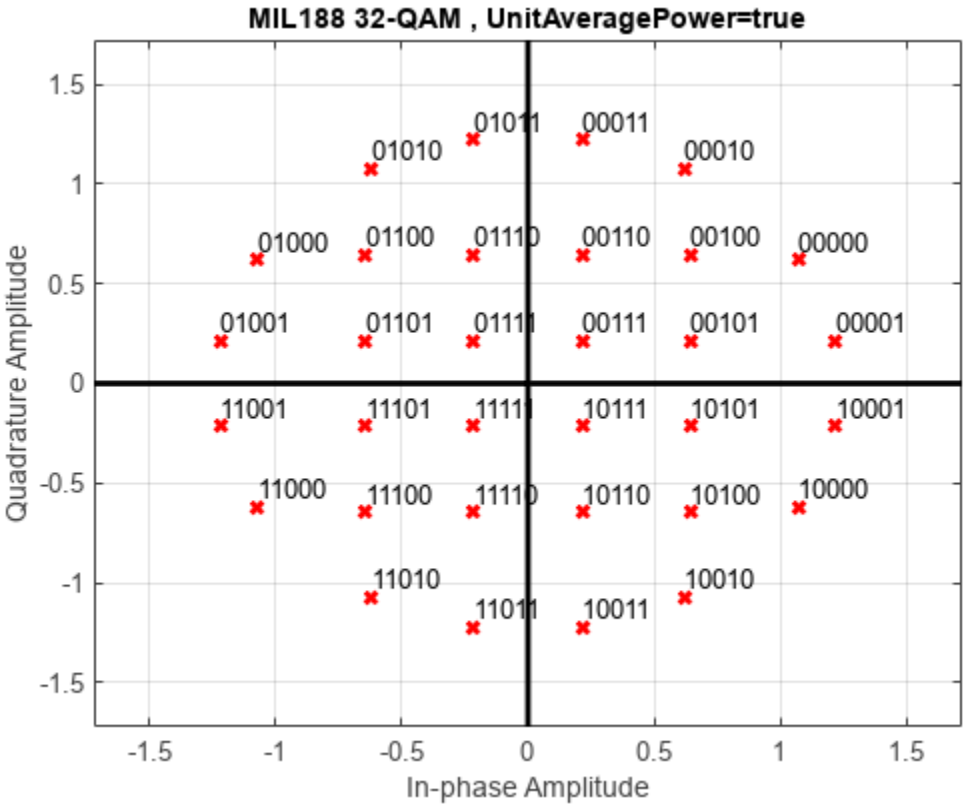
Demodulate a 32-QAM signal and calculate soft bits.

Set the modulation order and generate a random bit sequence.

```
M = 32;
numSym = 20000;
numBitsPerSym = log2(M);
x = randi([0 1], numSym*numBitsPerSym,1);
```

Modulate the data. Use name-value pairs to specify bit input data and unit average power, and to plot the constellation.

```
txSig = mil188qammod(x,M,'InputType','bit','UnitAveragePower',true, ...
    'PlotConstellation',true);
```

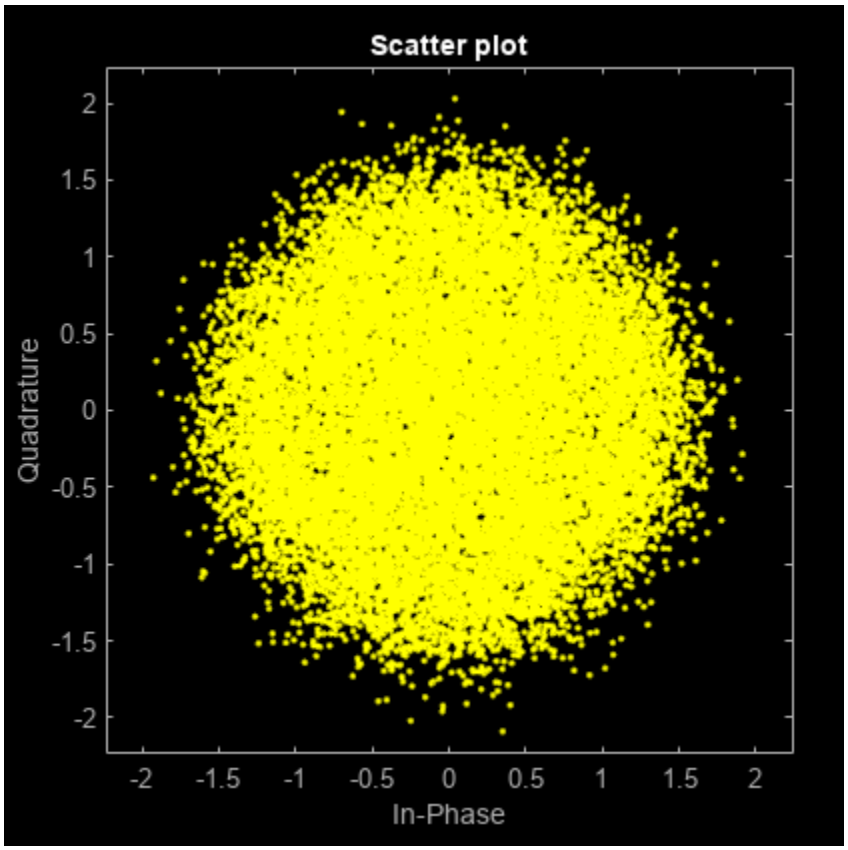


Pass the transmitted data through white Gaussian noise.

```
rxSig = awgn(txSig,10,'measured');
```

View the constellation using a scatter plot.

```
scatterplot(rxSig)
```



Demodulate the signal, computing soft bits using the approximate LLR algorithm.

```
z = mil188qamdemod(rxSig,M,'OutputType','approxllr', ...
     'NoiseVariance',10^(-1));
```

Input Arguments

y — Modulated signal

scalar | vector | matrix

Modulated signal, specified as a complex scalar, vector, or matrix. When `y` is a matrix, each column is treated as an independent channel.

`y` must be modulated in accordance with MIL-STD-188-110 [1].

Data Types: `single` | `double`
Complex Number Support: Yes

M — Modulation order

integer

Modulation order, specified as a power of two. The modulation order specifies the total number of points in the signal constellation.

Example: 16

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `y = mil188qamdemod(x,M,'OutputType','bit','OutputDataType','single');`

`OutputType` — Output type

`'integer'` (default) | `'bit'` | `'llr'` | `'approxllr'`

Output type, specified as the comma-separated pair consisting of `OutputType` and `'integer'`, `'bit'`, `'llr'`, or `'approxllr'`.

Data Types: `char` | `string`

`OutputDataType` — Output data type

`'double'` (default) | `...`

Output data type, specified as the comma-separated pair consisting of `OutputDataType` and one of the indicated data types. Acceptable values for `OutputDataType` depend on the `OutputType` value.

`OutputType` Value	Acceptable `OutputDataType` Values
`'integer'`	`'double'`, `'single'`, `'int8'`, `'int16'`, `'int32'`, `'uint8'`, `'uint16'`, or `'uint32'`
`'bit'`	`'double'`, `'single'`, `'int8'`, `'int16'`, `'int32'`, `'uint8'`, `'uint16'`, `'uint32'`, or `'logical'`

Dependencies

This name-value pair argument applies only when `OutputType` is set to `'integer'` or `'bit'`.

Data Types: `char` | `string`

`UnitAveragePower` — Unit average power flag

`false` (default) | `true`

Unit average power flag, specified as the comma-separated pair consisting of `UnitAveragePower` and a logical scalar. When this flag is `true`, the function scales the constellation to an average power of 1 watt referenced to 1 ohm. When this flag is `false`, the function scales the constellation based on specifications in the relevant standard, as described in [1].

Data Types: `logical`

`NoiseVariance` — Noise variance

1 (default) | positive scalar | vector of positive values

Noise variance, specified as the comma-separated pair consisting of `NoiseVariance` and a positive scalar or vector of positive values.

- When specified as a scalar, the same noise variance value is used on all input elements.

- When specified as a vector, the vector length must be equal to the number of columns in the input signal.

When the noise variance or signal power result in computations involving extreme positive or negative magnitudes, see “MIL-STD-188-110 QAM Soft Demodulation” on page 2-545 for algorithm selection considerations.

Dependencies

This name-value pair argument applies only when `OutputType` is set to `'llr'` or `'approxllr'`.

Data Types: `double`

`PlotConstellation` — Option to plot constellation

`false` (default) | `true`

Option to plot constellation, specified as the comma-separated pair consisting of `'PlotConstellation'` and a logical scalar. To plot the constellation, set `PlotConstellation` to `true`.

Data Types: `logical`

Output Arguments

`z` — Demodulated signal

scalar | vector | matrix

Demodulated signal, returned as a scalar, vector, or matrix. The dimensions of `z` depend on the specified `OutputType` value.

`OutputType` Value	Return Value of `mil188qamdemod`	Dimensions of `z`
`'integer'`	Demodulated integer values from 0 to (`M` – 1)	`z` has the same dimensions as input `y`.
`'bit'`	Demodulated bits	The number of rows in `z` is $\log_2$(sum(`M`)) times the number of rows in `y`. Each demodulated symbol is mapped to a group of $\log_2$(sum(`M`)) elements in a column, where the first element represents the MSB and the last element represents the LSB.
`'llr'`	Log-likelihood ratio value for each bit	
`'approxllr'`	Approximate log-likelihood ratio value for each bit	

More About

MIL-STD-188-110 QAM Hard Demodulation

The hard demodulation algorithm uses optimum decision region-based demodulation. Since all the constellation points are equally probable, maximum a posteriori probability (MAP) detection reduces to a maximum likelihood (ML) detection. The ML detection rule is equivalent to choosing the closest constellation point to the received symbol. The decision region for each constellation point is designed by drawing perpendicular bisectors between adjacent points. A received symbol is mapped to the proper constellation point based on which decision region it lies in.

Since all MIL-STD constellations are quadrant-based symmetric, for each symbol the optimum decision region-based demodulation:

- Maps the received symbol into the first quadrant
- Chooses the decision region for the symbol
- Maps the constellation point back to its original quadrant using the sign of real and imaginary parts of the received symbol

MIL-STD-188-110 QAM Soft Demodulation

For soft demodulation, two soft-decision log-likelihood ratio (LLR) algorithms are available: exact LLR and approximate LLR. The exact LLR algorithm is more accurate but has slower execution speed than the approximate LLR algorithm. For further description of these algorithms, see the “Hard- vs. Soft-Decision Demodulation” topic.

Note The exact LLR algorithm computes exponentials using finite precision arithmetic. For computations involving very large positive or negative magnitudes, the exact LLR algorithm yields:

- `Inf` or `-Inf` if the noise variance is a very large value
- `NaN` if the noise variance and signal power are both very small values

The approximate LLR algorithm does not compute exponentials. You can avoid `Inf`, `-Inf`, and `NaN` results by using the approximate LLR algorithm.

mil188qammod

MIL-STD-188-110 B/C standard-specific quadrature amplitude modulation (QAM)

Syntax

```
y = mil188qammod(x,M)
y = mil188qammod(x,M,Name,Value)
```

Description

`y = mil188qammod(x,M)` performs QAM modulation on the input signal, `x`, in accordance with MIL-STD-188-110 and the modulation order, `M`. For more information, see “MIL-STD-188-110” on page 2-551.

`y = mil188qammod(x,M,Name,Value)` specifies options using one or more name-value pair arguments. For example, `'OutputDataType','double'` specifies the desired output data type as double. Specify name-value pair arguments after all other input arguments.

Examples

Apply 32-QAM to Data per MIL-STD-188-110C

Modulate data using 32-QAM as specified in the MIL-188-110C standard. Display the result using a scatter plot.

Set M to 32 and create a data vector containing all possible symbols.

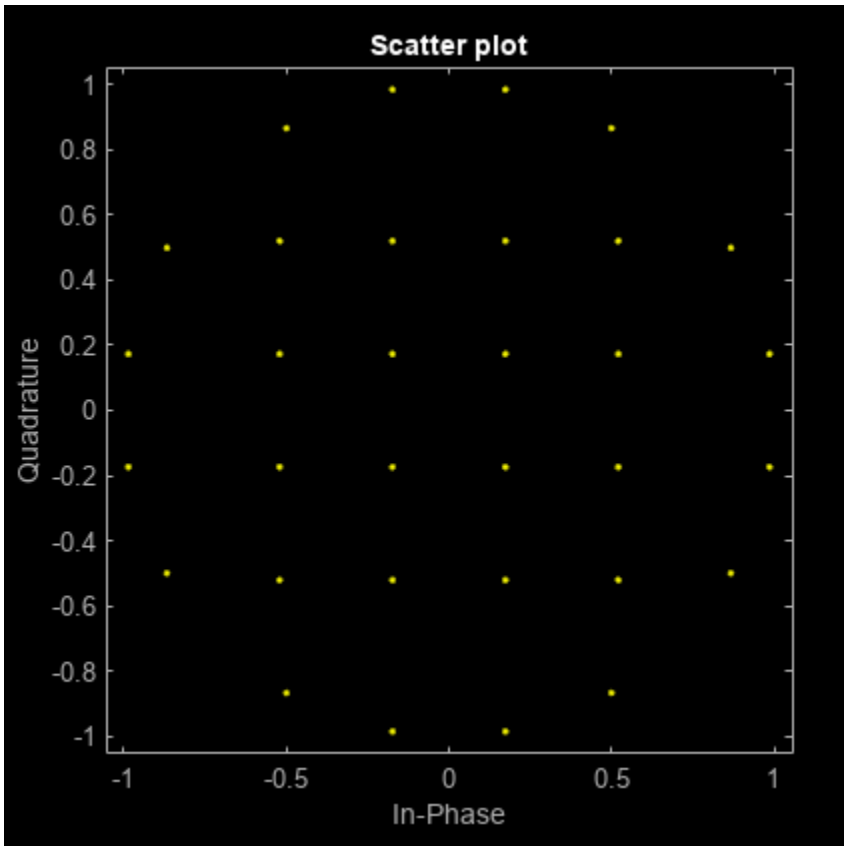
```
M = 32;
x = (0:M-1);
```

Modulate the data using QAM as specified in MIL-STD-188-110C.

```
y = mil188qammod(x,M);
```

Display the constellation as a scatter plot.

```
scatterplot(y)
```



Normalize 16-QAM Modulated MIL-STD-188-110B Signal by Average Power

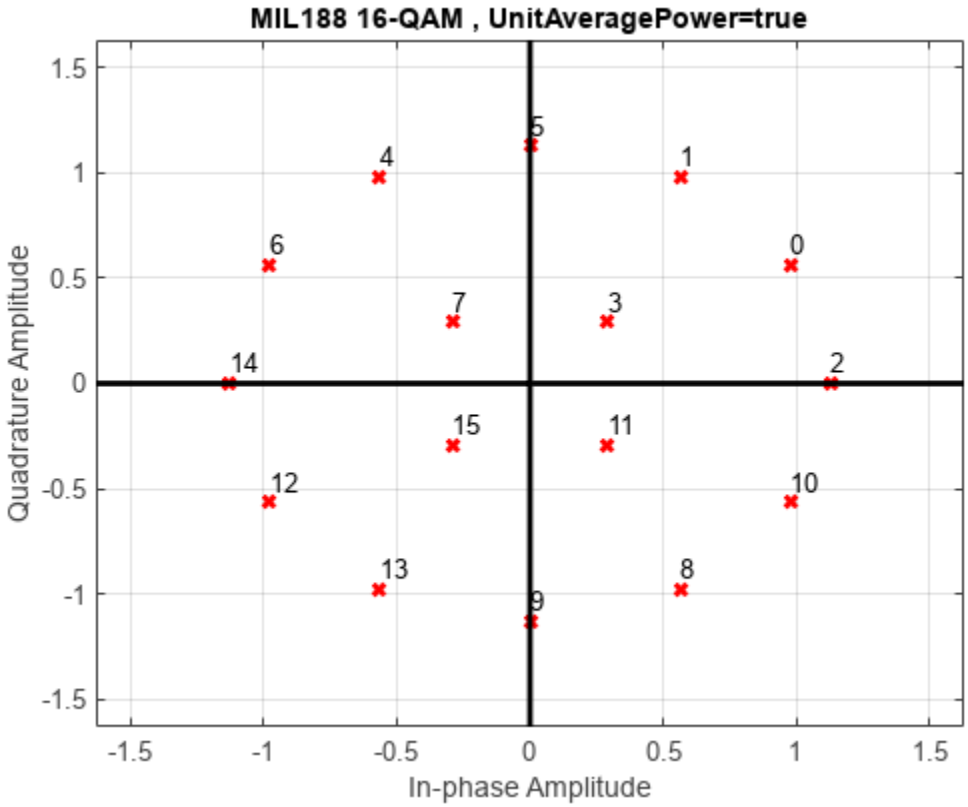
Modulate data using 16-QAM as specified in the MIL-STD-188-110B standard. Normalize the modulator output so that it has an average signal power of 1 W.

Set M and generate random data.

```
M = 16;
x = randi([0 M-1],1e5,1);
```

Modulate the data applying 16-QAM as specified in MIL-STD-188-110B. Using name-value pairs, set the unit average power to `true` and enable the constellation plot.

```
y = mil188qammod(x,M,'UnitAveragePower',true,'PlotConstellation',true);
```



Verify that the signal has approximately unit average power.

```
avgPow = mean(abs(y).^2)
```

```
avgPow = 1.0012
```

Apply 64-QAM MIL-STD-188-110B Modulation to Bit Data

Modulate a sequence of bits using 64-QAM as specified by MIL-STD188-110B. Display the constellation.

Set the modulation order and generate a sequence of random bits.

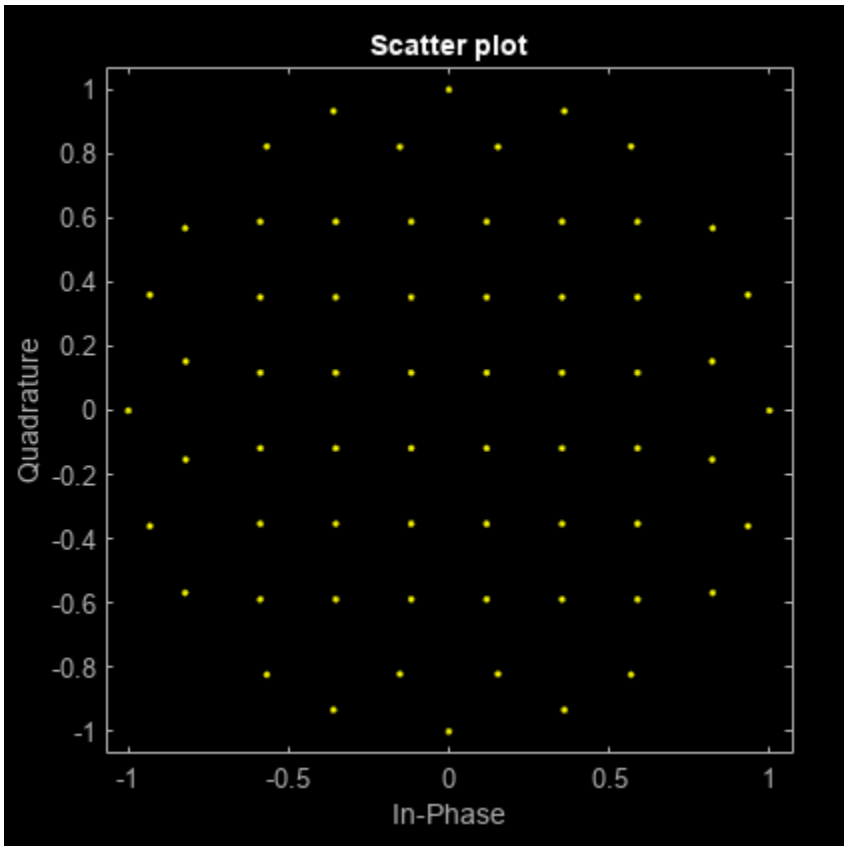
```
M = 64;
numBitsPerSym = log2(M);
data = randi([0 1],1000*numBitsPerSym,1);
```

Modulate the data applying 64-QAM as specified by MIL-STD-188-110B, and output constellation symbols of single data type.

```
y = mil188qammod(data,M,'InputType','bit','OutputDataType','single');
```

Plot the result constellation using a scatter plot.

```
scatterplot(y)
```



Input Arguments

x — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix. The elements of x must be binary values or integers that range from 0 to (`M` – 1), where `M` is the modulation order.

Note To process input signal as binary elements, set the `'InputType'` value to `'bit'`. For binary inputs, the number of rows must be an integer multiple of $\log_2(M)$. Groups of $\log_2(M)$ bits in a column are mapped onto a symbol, with the first bit representing the MSB and the last bit representing the LSB.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

M — Modulation order

integer

Modulation order, specified as a power of two. The modulation order specifies the total number of points in the signal constellation.

Example: 16

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: y = mil188qammod(data,M,'InputType','bit','OutputDataType','single');

`InputType` — Input type
`'integer'` (default) | `'bit'`

Input type, specified as the comma-separated pair consisting of `'InputType'` and either `'integer'` or `'bit'`. If you specify `'integer'`, the input signal must consist of integers from 0 to `M` – 1. If you specify `'bit'`, the input signal must contain binary values, and the number of rows must be an integer multiple of $\log_2(M)$.

Data Types: `char` | `string`

`OutputDataType` — Output data type
`'double'` (default) | `'single'`

Output data type, specified as the comma-separated pair consisting of `OutputDataType` and `'double'` or `'single'`.

Data Types: `char` | `string`

`UnitAveragePower` — Unit average power flag
`false` (default) | `true`

Unit average power flag, specified as the comma-separated pair consisting of `'UnitAveragePower'` and a logical scalar. When this flag is `true`, the function scales the constellation to an average power of 1 watt referenced to 1 ohm. When this flag is `false`, the function scales the constellation based on specifications in the relevant standard, as described in [1].

Data Types: `logical`

`PlotConstellation` — Option to plot constellation
`false` (default) | `true`

Option to plot constellation, specified as the comma-separated pair consisting of `'PlotConstellation'` and a logical scalar. To plot the constellation, set `PlotConstellation` to `true`.

Data Types: `logical`

Output Arguments

y — Modulated signal
scalar | vector | matrix

Modulated signal, returned as a complex scalar, vector, or matrix. The dimension of the output depends on the specified `InputType` value.

InputType	Dimensions of Output
`'integer'`	`y` has the same dimensions as input `x`.
`'bit'`	The number of rows in `y` equals the number of rows in `x` divided by $\log_2(M)$.

Data Types: `double` | `single`

More About

MIL-STD-188-110

MIL-STD-188-110 is a US Department of Defense standard for HF communications using serial PSK mode of both data and voice signals.

The standard specifies physical layer modulation schemes for tactical and long-haul communications. The modulation scheme specified by the standard is a mix of QAM and APSK. For a detailed description of the modulation scheme, see [1].

minpol

Find minimal polynomial of Galois field element

Syntax

```
pl = minpol(x)
```

Description

`pl = minpol(x)` finds the minimal polynomial of each element in the Galois column vector, `x`. The output `pl` is an array in GF(2). The kth row of `pl` lists the coefficients, in order of descending powers, of the minimal polynomial of the kth element of `x`.

Note The output is in GF(2) even if the input is in a different Galois field.

Examples

The code below uses `m = 4` and finds that the minimal polynomial of `gf(2,m)` is just the primitive polynomial used for the field GF(`2^m`). This is true for any value of `m`, not just the value used in the example.

```
m = 4;
A = gf(2,m)
pl = minpol(A)
```

The output is below. Notice that the row vector `[1 0 0 1 1]` represents the polynomial `D^4 + D + 1`.

```
A = GF(2^4) array. Primitive polynomial = D^4+D+1 (19 decimal)

Array elements =

     2

pl = GF(2) array.

Array elements =

     1     0     0     1     1
```

Another example is in “Minimal Polynomials”.

```

Description

`x = A\B` divides the Galois array `A` into `B` to produce a particular solution of the linear equation `A*x = B`. In the special case when `A` is a nonsingular square matrix, `x` is the unique solution, `inv(A)*B`, to the equation.

Examples

The code below shows that `A \ eye(size(A))` is the inverse of the nonsingular square matrix `A`.

```
m = 4; A = gf([8 1 6; 3 5 7; 4 9 2],m);
Id = gf(eye(size(A)),m);
X = A \ Id;
ck1 = isequal(X*A, Id)
ck2 = isequal(A*X, Id)
```

The output is below.

```
ck1 =

     1

ck2 =

     1
```

Other examples are in “Solving Linear Equations”.

Limitations

The matrix `A` must be one of these types:

- A nonsingular square matrix
- A matrix, in which there are more rows than columns, such that `A'*A` is nonsingular
- A matrix, in which there are more columns than rows, such that `A*A'` is nonsingular

Algorithms

If `A` is an M-by-N matrix where M > N, `A \ B` is the same as `(A'*A) \ (A'*B)`.

If `A` is an M-by-N matrix where M < N, `A \ B` is the same as `A' * ((A*A') \ B)`. This solution is not unique.

mlseeq

Equalize linearly modulated signal using MLSE

Syntax

```
y = mlseeq(x,chcffs,const,tblen,opmode)
y = mlseeq( ___ ,nsamp)

y = mlseeq( ___ ,nsamp,preamble,postamble)

y = mlseeq( ___ ,nsamp,init_metric,init_states,init_inputs)
[y,final_metric,final_states,final_inputs] = mlseeq( ___ )
```

Description

`y = mlseeq(x,chcffs,const,tblen,opmode)` equalizes the baseband signal vector `x` using the maximum likelihood sequence estimation (MLSE). `chcffs` provides estimated channel coefficients. `const` provides the ideal signal constellation points. `tblen` specifies the traceback depth. `opmode` specifies the operation mode of the equalizer. MLSE is implemented using the “Viterbi Algorithm” on page 2-563.

`y = mlseeq( ___ ,nsamp)` specifies the number of samples per symbol in `x`, in addition to arguments in the previous syntax.

`y = mlseeq( ___ ,nsamp,preamble,postamble)` specifies the number of samples per symbol in `x`, preamble, and postamble, in addition to arguments in the first syntax. This syntax applies when `opmode` is `'rst'` only. For more information, see “Preamble and Postamble in Reset Operation Mode” on page 2-563.

`y = mlseeq( ___ ,nsamp,init_metric,init_states,init_inputs)`specifies the number of samples per symbol in `x`, initial likelihood state metrics, initial traceback states, and initial traceback inputs for the equalizer, in addition to arguments in the first syntax. These three inputs are typically the `final_metric`, `final_states`, and `final_inputs` outputs from a previous call to this function. This syntax applies when `opmode` is `'cont'` only. For more information, see “Initialization in Continuous Operation Mode” on page 2-563.

`[y,final_metric,final_states,final_inputs] = mlseeq( ___ )` returns the normalized final likelihood state metrics, final traceback states, and final traceback inputs at the end of the traceback decoding process, using any of the previous input argument syntaxes. This syntax applies when `opmode` is `'cont'` only. For more information, see “Initialization in Continuous Operation Mode” on page 2-563.

Examples

Using MLSE Equalizer Reset Operating Mode

Use the reset operating mode of the `mlseeq` equalizer. Demodulate the signal and check the bit error rate.

Specify the modulation order, equalizer traceback depth, number of samples per symbol, and message length.

```
M = 2;
tblen =  10;
nsamp = 2;
msgLen = 1000;
```

Generate the reference constellation.

```
const = pammod([0:M-1],M);
```

Generate a message with random data. Modulate and upsample the signal.

```
msgData = randi([0 M-1],msgLen,1);
msgSym = pammod(msgData,M);
msgSymUp = upsample(msgSym,nsamp);
```

Filter the data through a distortion channel and add Gaussian noise to the signal.

```
chanest = [0.986; 0.845; 0.237; 0.12345+0.31i];
msgFilt = filter(chanest,1,msgSymUp);
msgRx = awgn(msgFilt,5,'measured');
```

Equalize and then demodulate the signal to recover the message. To initialize the equalizer, provide the channel estimate, reference constellation, equalizer traceback depth, number of samples per symbol, and set the operating mode to reset. Check the message bit error rate. Your results might vary because this example uses random numbers.

```
eqSym = mlseeq(msgRx,chanest,const,tblen,'rst',nsamp);
eqMsg = pamdemod(eqSym,M);

[nerrs ber] = biterr(msgData, eqMsg)

nerrs = 1

ber = 1.0000e-03
```

Recover Message Containing Preamble

Recover a message that includes a preamble, equalize the signal, and check the symbol error rate.

Specify the modulation order, equalizer traceback depth, number of samples per symbol, preamble, and message length.

```
M = 4;
tblen = 16;
nsamp = 1;
preamble = [3;1];
msgLen = 500;
```

Generate the reference constellation.

```
const = pskmod(0:3,4);
```

Generate a message by using random data and prepend the preamble to the message. Modulate the random data.

```
msgData = randi([0 M-1],msgLen,1);
msgData = [preamble; msgData];
msgSym = pskmod(msgData,M);
```

Filter the data through a distortion channel and add Gaussian noise to the signal.

```
chcoeffs = [0.623; 0.489+0.234i; 0.398i; 0.21];
chanest = chcoeffs;
msgFilt = filter(chcoeffs,1,msgSym);
msgRx = awgn(msgFilt,9,'measured');
```

Equalize the received signal. To configure the equalizer, provide the channel estimate, reference constellation, equalizer traceback depth, operating mode, number of samples per symbol, and preamble. The same preamble symbols appear at the beginning of the message vector and in the syntax for `mlseeq`. Because the system does not use a postamble, an empty vector is specified as the last input argument in this `mlseeq` syntax.

Check the symbol error rate of the equalized signal. Run-to-run results vary due to use of random numbers.

```
eqSym = mlseeq(msgRx,chanest,const,tblen,'rst',nsamp,preamble,[]);
[nsymerrs,ser] = symerr(msgSym,eqSym)
```

```
nsymerrs = 8

ser = 0.0159
```

Using MLSE Equalizer Continuous Operating Mode

Use the continuous operating mode of the `mlseeq` equalizer. Demodulate received signal packets and check the symbol error statistics.

Specify the modulation order, equalizer traceback depth, number of samples per symbol, message length, and number of packets to process.

```
M = 4;
tblen =  10;
nsamp = 1;
msgLen = 1000;
numPkts = 25;
```

Generate the reference constellation.

```
const = pskmod(0:M-1,M);
```

Set the initial input parameters for the metric, states, and inputs of the equalizer to empty vectors. These initial assignments represent the parameters for the first packet transmitted.

```
eq_metric = [];
eq_states = [];
eq_inputs = [];
```

Assign variables for symbol error statistics.

```
ttlSymbErrs = 0;
aggrPktSER = 0;
```

Send and receive multiple message packets in a simulation loop. Between the packet transmission and reception filter each packet through a distortion channel and add Gaussian noise.

```
for jj = 1:numPkts
```

Generate a message with random data. Modulate the signal.

```
    msgData = randi([0 M-1],msgLen,1);
    msgMod = pskmod(msgData,M);
```

Filter the data through a distortion channel and add Gaussian noise to the signal.

```
    chanest = [.986; .845; .237; .12345+.31i];
    msgFilt = filter(chanest,1,msgMod);
    msgRx = awgn(msgFilt,10,'measured');
```

Equalize the received symbols. To configure the equalizer, provide the channel estimate, reference constellation, equalizer traceback depth, operating mode, number of samples per symbol, and the equalizer initialization information. Continuous operating mode is specified for the equalizer. In continuous operating mode, the equalizer initialization information (metric, states, and inputs) are returned and used as inputs in the next iteration of the `for` loop.

```
    [eqSym,eq_metric,eq_states,eq_inputs] = ...
        mlseeq(msgRx,chanest,const,tblen,'cont',nsamp, ...
        eq_metric,eq_states,eq_inputs);
```

Save the symbol error statistics. Update the symbol error statistics with the aggregate results. Display the total number of errors. Your results might vary because this example uses random numbers.

```
    [nsymerrs,ser] = symerr(msgMod(1:end-tblen),eqSym(tblen+1:end));
    ttlSymbErrs = ttlSymbErrs + nsymerrs;
    aggrPktSER = aggrPktSER + ser;
end
printTtlErr = 'A total of %d symbol errors over the %d packets received.\n';
fprintf(printTtlErr,ttlSymbErrs,numPkts);
```

```
A total of 172 symbol errors over the 25 packets received.
```

Display the aggregate symbol error rate.

```
printAggrSER = 'The aggregate symbol error rate was %6.5d.\n';
fprintf(printAggrSER,aggrPktSER/numPkts);
```

```
The aggregate symbol error rate was 6.94949e-03.
```

Input Arguments

x — Input signal

vector

Input signal, specified as a vector of modulated symbols. The vector length of `x` must be an integer multiple of `nsamp`.

Data Types: `double`
Complex Number Support: Yes

`chcffs` — Channel coefficients

vector

Channel coefficients, specified as a vector. The channel coefficients provide an estimate of the channel response. When `nsamp` > 1, the `chcffs` input specifies the oversampled channel coefficients.

Data Types: `double`
Complex Number Support: Yes

`const` — Reference constellation

vector

Reference constellation, specified as a vector with *M* elements. *M* is the modulation order. `const` lists the ideal signal constellation points in the sequence used by the modulator.

Data Types: `double`
Complex Number Support: Yes

`tblen` — Traceback depth

positive integer

Traceback depth, specified as a positive integer. The equalizer traces back from the likelihood state with the maximum metric.

Data Types: `double`

`opmode` — Operation mode

`'rst'` | `'cont'`

Operation mode, specified as `'rst'` or `'cont'`.

Value	Usage
`'rst'`	Run equalizer using reset operating mode. Enables you to specify a `preamble` and `postamble` that accompany the input signal. The function processes the input signal, `x`, independently of the input signal from any other invocations of this function. This operating mode does not incur an output delay. For more information, see “Preamble and Postamble in Reset Operation Mode” on page 2-563.
`'cont'`	Run equalizer using continuous operating mode. Enables you to save the internal state information of the equalizer for use in a subsequent invocation of this function. Continuous operating mode is useful if the input signal is partitioned into a stream of packets processed within a loop. This operating mode incurs an output delay of `tblen` symbols. For more information, see “Initialization in Continuous Operation Mode” on page 2-563.

Data Types: `char`

`nsamp` — Number of samples per symbol

1 (default) | positive integer

Number of samples per symbol, specified as a positive integer. `nsamp` is the oversampling factor.

Dependencies

The input signal, `x`, must be an integer multiple of `nsamp`.

Data Types: `double`

`preamble` — Input signal preamble

vector of integers

Input signal preamble, specified as a vector of integers between 0 and M–1, where M is the modulation order. To omit a preamble, specify `[]`.

For more information, see “Preamble and Postamble in Reset Operation Mode” on page 2-563.

Dependencies

This input argument applies only when `opmode` is set to `'rst'`.

Data Types: `double`

`postamble` — Input signal postamble

vector of integers

Input signal postamble, specified as a vector of integers between 0 and M–1, where M is the modulation order. To omit a postamble, specify `[]`.

For more information, see “Preamble and Postamble in Reset Operation Mode” on page 2-563.

Dependencies

This input argument applies only when `opmode` is set to `'rst'`.

Data Types: `double`

`init_metric` — Initial state metrics

[ ] (default) | column vector

Initial state metrics, specified as a column vector with N_{states} elements. For the description of N_{states}, see “Number of Likelihood States” on page 2-564.

For more information, see “Initialization in Continuous Operation Mode” on page 2-563.

Dependencies

This input argument applies only when `opmode` is set to `'cont'`. If specifying `[]` for `init_metric`, you must also specify `[]` for `init_states` and `init_inputs`.

Data Types: `double`

`init_states` — Initial traceback states

[ ] (default) | matrix of integers

Initial traceback states, specified as an N_{states}-by-`tblen` matrix of integers with values between 0 and N_{states}–1. For the description of N_{states}, see “Number of Likelihood States” on page 2-564.

For more information, see “Initialization in Continuous Operation Mode” on page 2-563.

Dependencies

This input argument applies only when `opmode` is set to `'cont'`. If specifying `[]` for `init_states`, you must also specify `[]` for `init_metric` and `init_inputs`.

Data Types: `double`

`init_inputs` — Initial traceback inputs

`[]` (default) | matrix of integers

Initial traceback inputs, specified as an N_{states}-by-`tblen` matrix of integers with values between 0 and M–1. For the description of N_{states}, see “Number of Likelihood States” on page 2-564.

For more information, see “Initialization in Continuous Operation Mode” on page 2-563.

Dependencies

This input argument applies only when `opmode` is set to `'cont'`. If specifying `[]` for `init_inputs`, you must also specify `[]` for `init_metric` and `init_states`.

Data Types: `double`

Output Arguments

y — Output signal

vector

Output signal, returned as a vector of modulated symbols.

`final_metric` — Final normalized state metrics

vector

Final normalized state metrics, returned as a vector with N_{states} elements. `final_metric` corresponds to the final state metrics at the end of the traceback decoding process. For the description of N_{states}, see “Number of Likelihood States” on page 2-564.

For more information, see “Initialization in Continuous Operation Mode” on page 2-563.

`final_states` — Final traceback states

vector

Final traceback states, returned as a N_{states}-by-`tblen` matrix of integers with values between 0 and N_{states}–1. `final_states` corresponds to the final traceback states at the end of the traceback decoding process. For the description of N_{states}, see “Number of Likelihood States” on page 2-564.

For more information, see “Initialization in Continuous Operation Mode” on page 2-563.

`final_inputs` — Final traceback inputs

vector

Final traceback inputs, returned as an N_{states}-by-`tblen` matrix of integers with values between 0 and M–1. `final_inputs` corresponds to the final traceback inputs at the end of the traceback decoding process. M is the order of the modulation. For the description of N_{states}, see “Number of Likelihood States” on page 2-564.

For more information, see “Initialization in Continuous Operation Mode” on page 2-563.

More About

Viterbi Algorithm

The Viterbi algorithm is a sequential trellis search algorithm used to perform maximum likelihood sequence detection.

The MLSE equalizer uses the Viterbi algorithm to recursively search for the sequences that maximize the likelihood function. Using the Viterbi algorithm reduces the number of sequences in the trellis search by eliminating sequences as new data is received. The metric used to determine the maximum likelihood sequence is the correlation between the received signal and an estimated signal for each received symbol over the “Number of Likelihood States” on page 2-564.

For more information, see [1] and [2].

Preamble and Postamble in Reset Operation Mode

When operating the MLSE equalizer in reset mode, you can specify a preamble and postamble as input arguments. Specify `preamble` and `postamble` as vectors equal to the preamble and postamble that are prepended and appended, respectively, to the input signal. The `preamble` and `postamble` vectors consist of integers between 0 and *M*-1, where *M* is the number of elements in `const`. To omit the `preamble` or `postamble` input argument, specify `[]`.

When the function applies the Viterbi algorithm, it initializes state metrics in a way that depends on whether you specify a preamble, a postamble, or both:

- If `preamble` is nonempty, the function decodes the preamble and assigns a metric of 0 to the decoded state. If the preamble does not decode to a unique state (that is, if the length of the preamble is less than the channel memory), the decoder assigns a metric of 0 to all states that are represented by the preamble. The traceback path ends at one of the states represented by the preamble.
- If `preamble` is `[]`, the decoder initializes the metrics of all states to 0.
- If `postamble` is nonempty, the traceback path begins at the smallest of all possible decoded states that are represented by the postamble.
- If `postamble` is `[]`, the traceback path starts at the state with the smallest metric.

Initialization in Continuous Operation Mode

When operating the MLSE equalizer in continuous mode, you can initialize the equalization based on values returned in the previous call of the function.

At the end of the traceback decoding process, the function returns `final_metric`, `final_states`, and `final_inputs`. When `opmode` is `'cont'`, assign these outputs to `init_metric`, `init_states`, and `init_inputs`, respectively for the next call of the function. These assignments initialize the equalizer to start with the final state metrics, final traceback states, and final traceback inputs from the previous call of the function.

Each real number in `init_metric` represents the starting state metric of the corresponding state. `init_states` and `init_inputs` jointly specify the initial traceback memory of the equalizer.

Output Argument	Input Argument	Meaning	Matrix Size	Range of Values
`final_metric`	`init_metric`	State metrics	1-by-N_{states}	Real numbers
`final_states`	`init_states`	Traceback states	N_{states}-by-`tblen`	Integers between 0 and N_{states}–1
`fianl_inputs`	`init_inputs`	Traceback inputs	N_{states}-by-`tblen`	Integers between 0 and M–1

To use default values for `init_metric`, `init_states`, and `init_inputs`, specify each as `[]`. For the description of N_{states}, see “Number of Likelihood States” on page 2-564.

Number of Likelihood States

The number of likelihood states, N_{states}, is the number of correlative phase states in the trellis. N_{states} is equal to $M^{L\text{-}1}$, where M is the number of elements in `const` and L is the number of symbols in the nonoversampled impulse response of the channel.

modnorm

Scaling factor for normalizing modulation output

Syntax

```
normfactor = modnorm(refconst,type,power)
```

Description

`normfactor = modnorm(refconst,type,power)` returns a scale factor for normalizing a PAM or QAM modulator output using the specified reference constellation, normalization type, and output power.

Examples

Normalize Power of QAM Signal

Generate a 16-QAM reference constellation.

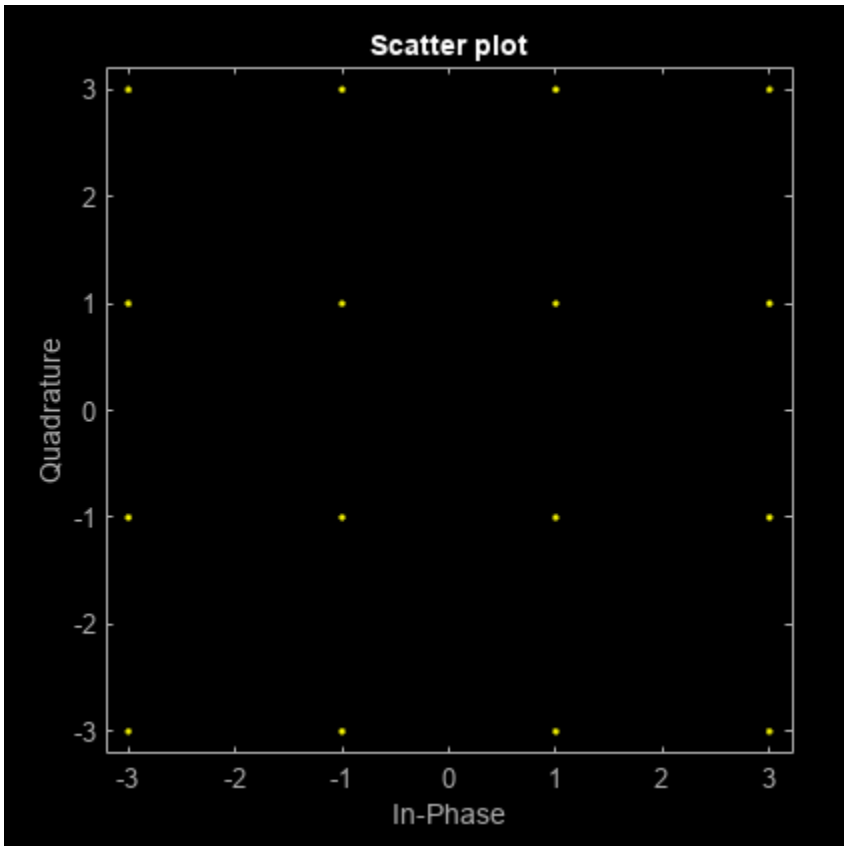
```
refconst = qammod(0:15,16);
```

Generate random symbols and apply 16-QAM modulation.

```
x = randi([0 15],1000,1);
y = qammod(x,16);
```

Plot the constellation.

```
h = scatterplot(y);
```



Compute the normalization factor so that the output signal has a peak power of 1 W.

```
nf = modnorm(refconst,'peakpow',1);
z = nf*y;
```

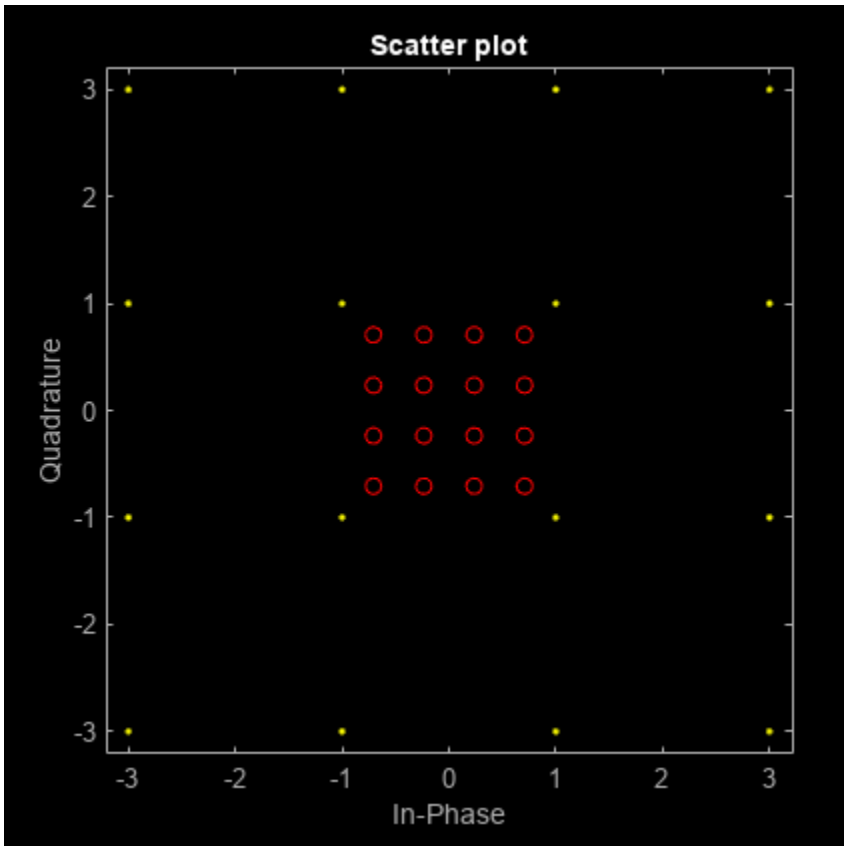
Confirm that no element of the normalized signal has a power greater than 1 W.

```
max(z.*conj(z))
```

```
ans = 1.0000
```

Add the normalized constellation to the scatter plot.

```
hold on
scatterplot(z,1,0,'ro',h)
hold off
```



Input Arguments

`refconst` — Reference constellation

vector

Reference constellation, specified as a vector of complex elements that comprise the reference constellation points.

Example: `qammod(0:15,16)`

Data Types: `double`
Complex Number Support: Yes

`type` — Normalization type

`'avpow'` | `'peakpow'`

Normalization type, specified as either `'avpow'` or `'peakpow'`.

- If `type` is `'avpow'`, the normalization factor is calculated based on average power.
- If `type` is `'peakpow'`, the normalization factor is calculated based on peak power.

Data Types: `char`

`power` — Target power

scalar

Target power, specified as a real scalar. The target power is the intended power of the modulated signal multiplied by `normfactor`.

Data Types: `double`

Output Arguments

`normfactor` — Normalization factor

scalar

Normalization factor, returned as a real scalar. When a modulated signal is multiplied by the normalization factor, its average or peak power matches the target power. The function assumes that the signal you want to normalize has a minimum distance of 2.

pammod | pamdemod | qammod | qamdemod

mskdemod

Minimum shift keying demodulation

Syntax

```
z = mskdemod(y,nsamp)
z = mskdemod(y,nsamp,dataenc)
z = mskdemod(y,nsamp,dataenc,ini_phase)
z = mskdemod(y,nsamp,dataenc,ini_phase,ini_state)
[z,phaseout] = mskdemod(...)
[z,phaseout,stateout] = mskdemod(...)
```

Description

`z = mskdemod(y,nsamp)` demodulates the complex envelope `y` of a signal using the differentially encoded minimum shift keying (MSK) method. `nsamp` denotes the number of samples per symbol and must be a positive integer. The initial phase of the demodulator is 0. If `y` is a matrix with multiple rows and columns, the function treats the columns as independent channels and processes them independently.

`z = mskdemod(y,nsamp,dataenc)` specifies the method of encoding data for MSK. *`dataenc`* can be either `'diff'` for differentially encoded MSK or `'nondiff'` for nondifferentially encoded MSK.

`z = mskdemod(y,nsamp,dataenc,ini_phase)` specifies the initial phase of the demodulator. `ini_phase` is a row vector whose length is the number of channels in `y` and whose values are integer multiples of `pi/2`. To avoid overriding the default value of *`dataenc`*, set *`dataenc`* to `[]`.

`z = mskdemod(y,nsamp,dataenc,ini_phase,ini_state)` specifies the initial state of the demodulator. `ini_state` contains the last half symbol of the previously received signal. `ini_state` is an `nsamp`-by-C matrix, where C is the number of channels in `y`.

`[z,phaseout] = mskdemod(...)` returns the final phase of `y`, which is important for demodulating a future signal. The output `phaseout` has the same dimensions as the `ini_phase` input, and assumes the values `0`, `pi/2`, `pi`, and `3*pi/2`.

`[z,phaseout,stateout] = mskdemod(...)` returns the final `nsamp` values of `y`, which is useful for demodulating the first symbol of a future signal. `stateout` has the same dimensions as the `ini_state` input.

Examples

MSK Demodulation

Modulate and demodulate a noisy MSK signal. Display the number of received errors.

Define the number of samples per symbol for the MSK signal.

```
nsamp = 16;
```

Initialize the simulation parameters.

```
numerrs = 0;
modPhase = zeros(1,2);
demodPhase = zeros(1,2);
demodState = complex(zeros(nsamp,2));
```

The main processing loop includes these steps:

- Generate binary data.
- MSK modulate the data.
- Pass the signal through an AWGN channel.
- Demodulate the MSK signal.
- Determine the number of bit errors.

```
for iRuns = 1:20
    txData = randi([0 1],100,2);
    [modSig,modPhase] = mskmod(txData,nsamp,[],modPhase);
    rxSig = awgn(modSig,20,'measured');
    [rxData,demodPhase,demodState] = mskdemod(rxSig,nsamp,[],demodPhase,demodState);
    numerrs = numerrs + biterr(txData,rxData);
end
```

Display the number of bit errors.

```
numerrs
```

```
numerrs = 0
```

Topics

“Digital Baseband Modulation”

mskmod

Minimum shift keying modulation

Syntax

```
y = mskmod(x,nsamp)
y = mskmod(x,nsamp,dataenc)
y = mskmod(x,nsamp,dataenc,ini_phase)
[y,phaseout] = mskmod(...)
```

Description

`y = mskmod(x,nsamp)` outputs the complex envelope `y` of the modulation of the message signal `x` using differentially encoded minimum shift keying (MSK) modulation. The elements of `x` must be 0 or 1. `nsamp` denotes the number of samples per symbol in `y` and must be a positive integer. The initial phase of the MSK modulator is 0. If `x` is a matrix with multiple rows and columns, the function treats the columns as independent channels and processes them independently.

`y = mskmod(x,nsamp,dataenc)` specifies the method of encoding data for MSK. *`dataenc`* can be either `'diff'` for differentially encoded MSK or `'nondiff'` for nondifferentially encoded MSK.

`y = mskmod(x,nsamp,dataenc,ini_phase)` specifies the initial phase of the MSK modulator. `ini_phase` is a row vector whose length is the number of channels in `y` and whose values are integer multiples of `pi/2`. To avoid overriding the default value of *`dataenc`*, set *`dataenc`* to `[]`.

`[y,phaseout] = mskmod(...)` returns the final phase of `y`. This is useful for maintaining phase continuity when you are modulating a future bit stream with differentially encoded MSK. `phaseout` has the same dimensions as the `ini_phase` input, and assumes the values `0`, `pi/2`, `pi`, and `3*pi/2`.

Examples

Eye Diagram of MSK Signal

Generate a random binary signal.

```
x = randi([0 1],100,1);
```

MSK modulate the data.

```
y = mskmod(x,8,[],pi/2);
```

Pass the signal through an AWGN channel. Display the eye diagram.

```
z = awgn(y,30,'measured');
eyediagram(z,16);
```

muxdeintrlv

Restore ordering of symbols using specified shift registers

Syntax

```
deintrlved = muxdeintrlv(data,delay)
[deintrlved,state] = muxdeintrlv(data,delay)
[deintrlved,state] = muxdeintrlv(data,delay,init_state)
```

Description

`deintrlved = muxdeintrlv(data,delay)` restores the ordering of elements in `data` by using a set of internal shift registers, each with its own delay value. `delay` is a vector whose entries indicate how many symbols each shift register can hold. The length of `delay` is the number of shift registers. Before the function begins to process data, it initializes all shift registers with zeros. If `data` is a matrix with multiple rows and columns, the function processes the columns independently.

`[deintrlved,state] = muxdeintrlv(data,delay)` returns a structure that holds the final state of the shift registers. `state.value` stores any unshifted symbols. `state.index` is the index of the next register to be shifted.

`[deintrlved,state] = muxdeintrlv(data,delay,init_state)` initializes the shift registers with the symbols contained in `init_state.value` and directs the first input symbol to the shift register referenced by `init_state.index`. The structure `init_state` is typically the `state` output from a previous call to this same function, and is unrelated to the corresponding interleaver.

Using an Interleaver-Deinterleaver Pair

To use this function as an inverse of the `muxintrlv` function, use the same `delay` input in both functions. In that case, the two functions are inverses in the sense that applying `muxintrlv` followed by `muxdeintrlv` leaves data unchanged, after you take their combined delay of `length(delay)*max(delay)` into account. To learn more about delays of convolutional interleavers, see “Delays of Convolutional Interleavers”.

Examples

The example below illustrates how to use the state input and output when invoking `muxdeintrlv` repeatedly. Notice that `[deintrlved1; deintrlved2]` is the same as `deintrlved`.

```
delay = [0 4 8 12]; % Delays in shift registers
symbols = 100; % Number of symbols to process
% Interleave random data.
intrlved = muxintrlv(randi([0 1],symbols,1),delay);

% Deinterleave some of the data, recording state for later use.
[deintrlved1,state] = muxdeintrlv(intrlved(1:symbols/2),delay);
% Deinterleave the rest of the data, using state as an input argument.
deintrlved2 = muxdeintrlv(intrlved(symbols/2+1:symbols),delay,state);

% Deinterleave all data in one step.
deintrlved = muxdeintrlv(intrlved,delay);

isequal(deintrlved,[deintrlved1; deintrlved2])
```

The output is below.

```
ans =

     1
```

Another example using this function is in “Convolutional Interleaving and Deinterleaving Using a Sequence of Consecutive Integers in MATLAB”.

muxintrlv

Permute symbols using shift registers with specified delays

Syntax

```
intrlved = muxintrlv(data,delay)
[intrlved,state] = muxintrlv(data,delay)
[intrlved,state] = muxintrlv(data,delay,init_state)
```

Description

`intrlved = muxintrlv(data,delay)` permutes the elements in `data` by using internal shift registers, each with its own delay value. `delay` is a vector whose entries indicate how many symbols each shift register can hold. The length of `delay` is the number of shift registers. Before the function begins to process data, it initializes all shift registers with zeros. If `data` is a matrix with multiple rows and columns, the function processes the columns independently.

`[intrlved,state] = muxintrlv(data,delay)` returns a structure that holds the final state of the shift registers. `state.value` stores any unshifted symbols. `state.index` is the index of the next register to be shifted.

`[intrlved,state] = muxintrlv(data,delay,init_state)` initializes the shift registers with the symbols contained in `init_state.value` and directs the first input symbol to the shift register referenced by `init_state.index`. The structure `init_state` is typically the `state` output from a previous call to this same function, and is unrelated to the corresponding deinterleaver.

Examples

The examples in “Convolutional Interleaving and Deinterleaving Using a Sequence of Consecutive Integers in MATLAB” and on the reference page for the `convintrlv` function use `muxintrlv`.

The example on the reference page for `muxdeintrlv` illustrates how to use the `state` output and `init_state` input with that function; the process is analogous for this function.

noisebw

Equivalent noise bandwidth of digital lowpass filter

Syntax

```
bw = noisebw(num,den,N,Fs)
```

Description

`bw = noisebw(num,den,N,Fs)` returns the two-sided equivalent noise bandwidth of a digital lowpass filter in Hz. Specify the filter coefficients in descending polynomial powers by numerator `num` and denominator `den`. Input `N` is the number of samples of the impulse response. `Fs` is the sampling rate for the filtered signal. For more information on the two-sided equivalent noise bandwidth computation, see “Algorithms” on page 2-578.

Examples

Obtain Noise Equivalent Bandwidth of Butterworth Filter

Set the sampling rate, Nyquist frequency, and carrier frequency.

```
fs = 16;
fNyq = fs/2;
fc = 0.5;
```

Generate a Butterworth filter.

```
[num,den] = butter(2,fc/fNyq);
```

Compute the equivalent noise bandwidth of the filter over 100 samples of the impulse response.

```
bw = noisebw(num,den,100,fs)
```

```
bw = 1.1049
```

Input Arguments

`num` — Numerator coefficients of filter

numeric row vector

Numerator coefficients of the filter in descending polynomial powers, specified as a numeric row vector.

Data Types: `double`

`den` — Denominator coefficients of filter

numeric row vector

Denominator coefficients of the filter in descending polynomial powers, specified as a numeric row vector.

Data Types: `double`

`N` — Number of samples of impulse response
positive integer

Number of samples of the impulse response to use when calculating the bandwidth, specified as a positive integer.

Data Types: `double`

`Fs` — Sampling rate for filtered signal
positive integer

Sampling rate for the filtered signal, specified as a positive integer. The function uses this input value as a scaling factor to convert a normalized unitless quantity into a bandwidth in Hz.

Data Types: `double`

Output Arguments

`bw` — Equivalent noise bandwidth
numeric scalar

Equivalent noise bandwidth in Hz, returned as a numeric scalar.

Algorithms

This formula specifies the two-sided equivalent noise bandwidth computation.

$$\frac{\mathrm{Fs}\sum_{i=1}^{N}|h(i)|^2}{\left|\sum_{i=1}^{N}h(i)\right|^2}$$

h is the impulse response of the filter and is specified by input arguments `num` and `den`.

oct2dec

Convert octal to decimal numbers

Syntax

```
d = oct2dec(c)
```

Description

`d = oct2dec(c)` converts an octal matrix `c` to a decimal matrix `d`, element by element. In both octal and decimal representations, the rightmost digit is the least significant.

Examples

Convert Octal Matrix to Decimal Equivalent

Convert a 2-by-2 octal matrix its decimal equivalent.

```
d = oct2dec([12 144;0 25])
```

```
d = 2×2

    10   100
     0    21
```

The octal number 144 is equivalent to 100 because $144 = 1(8^2) + 4(8^1) + 4(8^0) = 100$.

Version History

Introduced before R2006a

oct2poly

Convert octal number to binary coefficients

Syntax

```
b = oct2poly(oct)
b = oct2poly(oct,ord)
```

Description

`b = oct2poly(oct)` converts an octal number, `oct`, to a vector of binary coefficients, `b`.

`b = oct2poly(oct,ord)` specifies the power order, `ord`, of the coefficients that comprise the output. If omitted, `ord` is `'descending'`.

Examples

Convert Octal Number to Binary Vector

Convert the octal number `11` to a binary vector.

```
b = oct2poly(11)
```

```
b = 1×4

     1     0     0     1
```

The binary vector corresponds to the polynomial $x^3 + 1$.

Convert Octal Number to Ascending Order Binary Vector

Convert the octal number `65` to an ascending order binary vector.

```
b = oct2poly(65,'ascending')
```

```
b = 1×6

     1     0     1     0     1     1
```

Sixty-five octal is the generator polynomial of a (15,10) Hamming code in the Bluetooth® v4.0 standard. The binary representation of 65 octal is 110101 and the GF(2) polynomial is $1 + x^2 + x^4 + x^5$ or [1 0 1 0 1 1] in ascending powers.

Input Arguments

`oct` — Octal number

scalar

Octal number, specified as a positive integer scalar.

Example: `15`

Example: `3177`

Data Types: `double`

`ord` — Power order

`'descending'` (default) | `'ascending'`

Power order of the binary coefficients vector, specified as a character vector having a value of `'ascending'` or `'descending'`.

Data Types: `char`

Output Arguments

`b` — Binary coefficients

vector

Binary coefficients representing a polynomial, returned as a row vector having length equal to $p + 1$, where p is the order of octal input.

`hex2poly` | `oct2dec`

ofdmdemod

Demodulate time-domain signal using orthogonal frequency division multiplexing (OFDM)

Syntax

```
outSym = ofdmdemod(ofdmSig,nfft,cplen)
outSym = ofdmdemod(ofdmSig,nfft,cplen,symOffset)
outSym = ofdmdemod(ofdmSig,nfft,cplen,symOffset,nullidx)
[outSym,pilots] = ofdmdemod(ofdmSig,nfft,cplen,symOffset,nullidx,pilotidx)
outSym = ofdmdemod(ofdmSig,nfft,cplen,___,OvesamplingFactor=Value)
```

Description

`outSym = ofdmdemod(ofdmSig,nfft,cplen)` performs OFDM demodulation on the input time domain signal specified in `ofdmSig`, using an FFT size specified by `nfft` and cyclic prefix length specified by `cplen`. For information, see “OFDM Demodulation” on page 2-590.

`outSym = ofdmdemod(ofdmSig,nfft,cplen,symOffset)` applies the symbol sampling offset, `symOffset`, for each OFDM symbol before demodulation of the input.

`outSym = ofdmdemod(ofdmSig,nfft,cplen,symOffset,nullidx)` removes null subcarriers from the locations specified in `nullidx`. For this syntax, the symbol sampling offset is applied to each OFDM symbol and the number of rows in the output is `nfft` – `length(nullidx)`, which accounts for the removal of null subcarriers. Use null subcarriers to account for guard bands and DC subcarriers. For information, see “Subcarrier Allocation and Guard Bands” on page 2-591.

`[outSym,pilots] = ofdmdemod(ofdmSig,nfft,cplen,symOffset,nullidx,pilotidx)` returns pilot subcarriers for the pilot indices specified in `pilotidx`. For this syntax, the symbol sampling offset is applied to each OFDM symbol and number of rows in the output is `nfft` – `length(nullidx)` – `length(pilotidx)`, which accounts for the removal of null and pilot subcarriers. The function assumes that pilot subcarrier locations are the same across each OFDM symbol and transmit antenna.

`outSym = ofdmdemod(ofdmSig,nfft,cplen,___,OvesamplingFactor=Value)` specifies the optional oversampling factor name-value argument in addition to input arguments in previous syntaxes. The oversampling factor for an upsampled input signal must be specified as a positive scalar. Additionally, the products (`OversamplingFactor×nfft`) and (`OversamplingFactor×cplen`) must both result in integers. The default value for `OversamplingFactor` is `1`.

For example, `ofdmdemod(inSym,nfft,cplen,OversamplingFactor=2)` demodulates assuming the input signal was upsampled by a factor of two.

Examples

OFDM Demodulation with Different CP Lengths

OFDM-demodulate a signal with different CP lengths for different symbols.

Initialize input parameters defining locations for null and pilot subcarriers. Generate random data and perform OFDM modulation.

```
M = 16;
nfft = 64;
cplen = [16 32];
nSym = 2;
dataSym = randi([0 M-1],nfft,nSym);
qamSig = qammod(dataSym,M,UnitAveragePower=true);
y1 = ofdmmod(qamSig,nfft,cplen);
```

Demodulate the OFDM symbols. Compare the results to the original input data. The difference between the signals is negligible.

```
x1 = ofdmdemod(y1,nfft,cplen);
rxData = qamdemod(x1,M,UnitAveragePower=true);
isequal(rxData,dataSym)
```

```
ans = logical
   1
```

OFDM Mod-Demod SISO Link

Apply OFDM multiplexing to a 16-QAM signal filtered by a SISO link with Rayleigh fading.

Initialize simulation variables, and create Rayleigh fading channel and constellation diagram objects.

```
s1 = RandStream('mt19937ar',Seed=12345);
nFFT = 64;
cpLen = 16;
nullIdx = [1:6 33 64-4:64].';
numTones = nFFT-length(nullIdx);

k = 4; % bits per symbol
M = 2^k;
constSym = qammod((0:M-1),M, ...
    UnitAveragePower=true); % reference constellation symbols

maxDopp = 1;
pathDelays = [0 4e-3 8e-3];
pathGains = [0 -2 -3];
sRate = 1000;
sampIdx = round(pathDelays/(1/sRate)) + 1;

chan = comm.RayleighChannel(PathGainsOutputPort=true, ...
    MaximumDopplerShift=maxDopp, ...
    PathDelays=pathDelays, ...
    AveragePathGains=pathGains, ...
    SampleRate=sRate, ...
    RandomStream='mt19937ar with seed');

cdScope = comm.ConstellationDiagram( ...
    ShowReferenceConstellation=true, ...
    ReferenceConstellation=constSym);
```

Generate signal data and apply 16-QAM modulation.

```
data = randi(s1,[0 M-1],numTones,1);
modOut = qammod(data,M,UnitAveragePower=true);
```

Apply OFDM modulation and pass the signal through the channel.

```
y = ofdmmod(modOut,nFFT,cpLen,nullIdx);
[fadSig,pg] = chan(y);
```

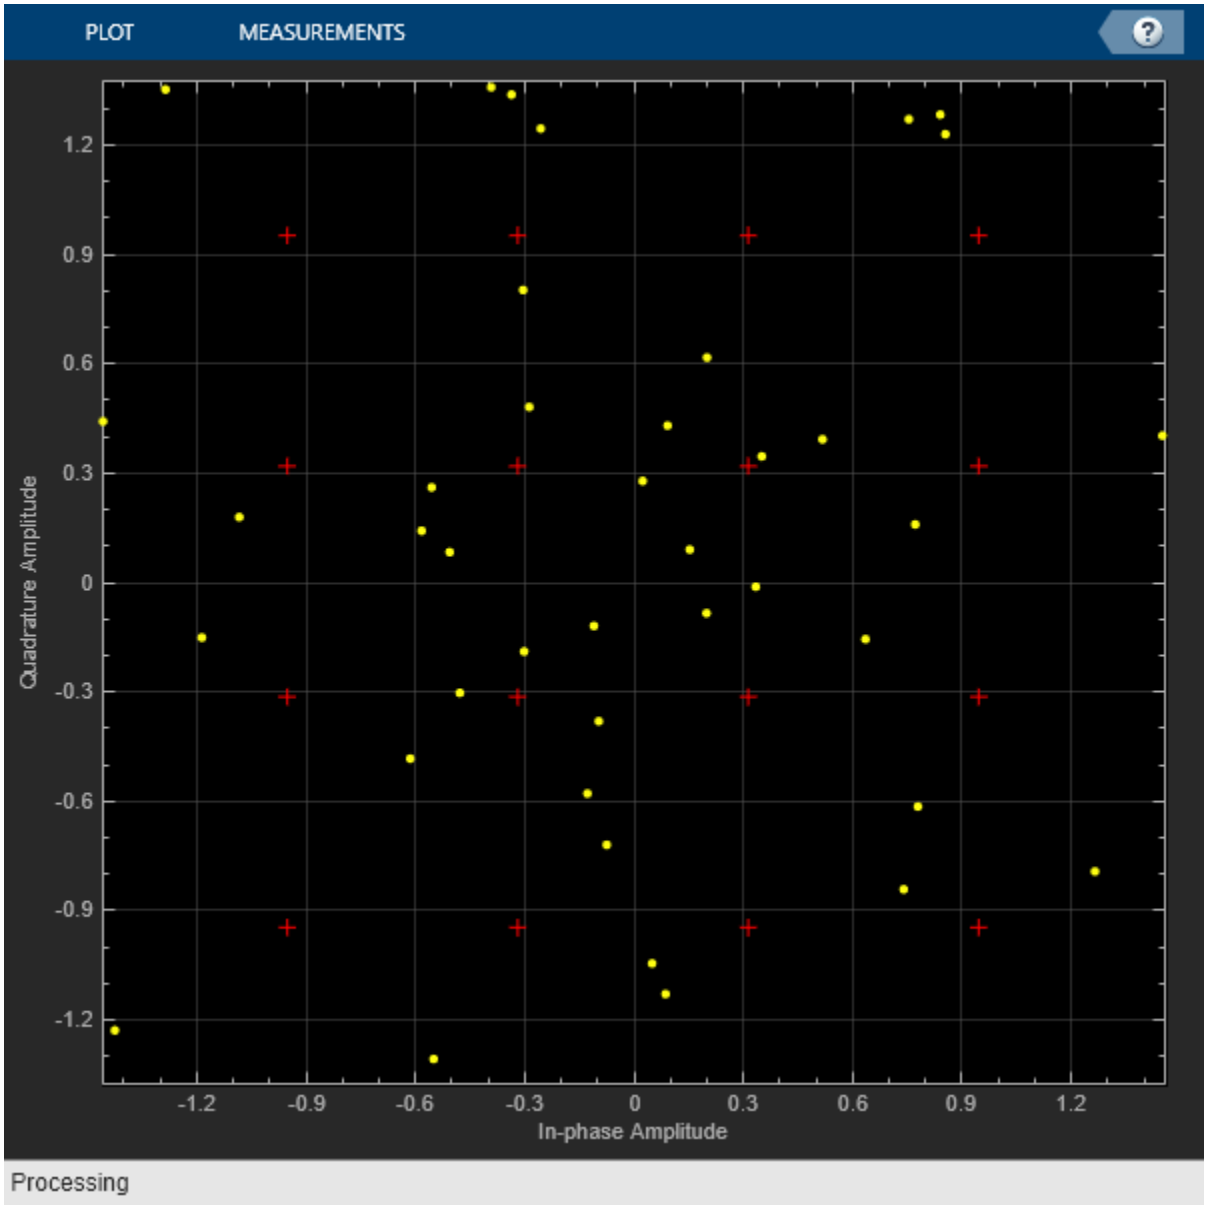
Determine symbol sampling offset.

```
symOffset = min(max(sampIdx),cpLen)
```

```
symOffset = 9
```

OFDM demodulate the received signal with a time shift. Display the constellation diagram before equalization.

```
x = ofdmdemod(fadSig,nFFT,cpLen,symOffset,nullIdx);
cdScope(x);
```

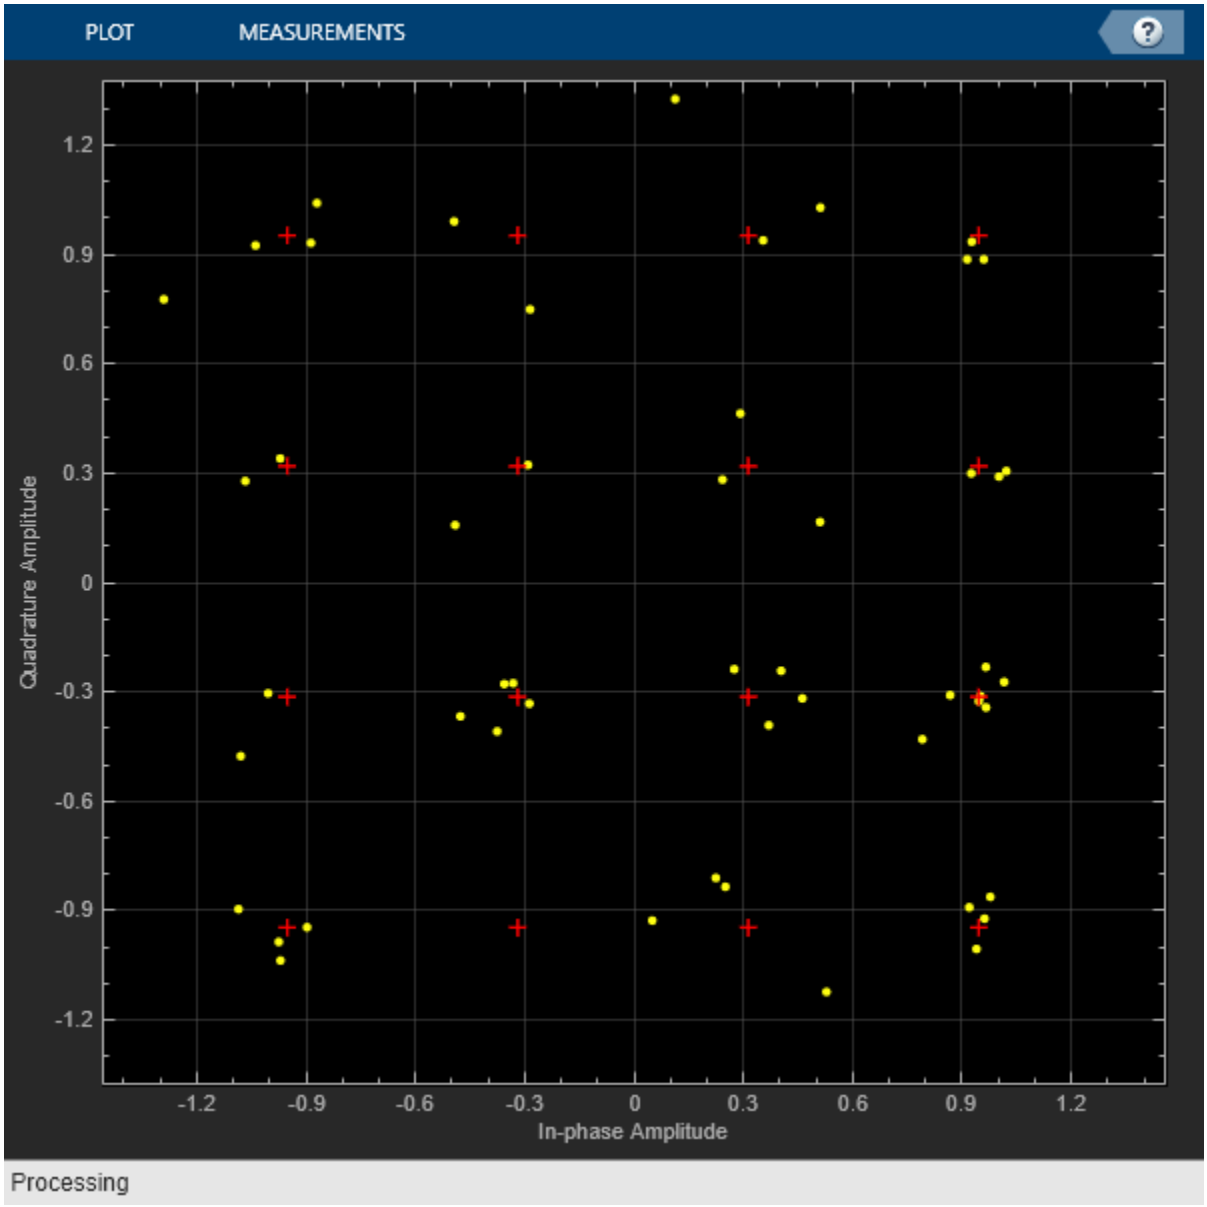


Convert the vector of path gains, `pg`, to scalar tap gains that correspond to data subcarriers, `h_datasubcarr`. Use the `h_datasubcarr` tap gains for equalization during signal recovery.

```
hImp = complex(zeros(nFFT,1));
hImp(sampIdx) = mean(pg,1);
hall = fftshift(fft(hImp));
dataIdx = setdiff((1:nFFT)',nullIdx);
h_datasubcarr = hall(dataIdx);
```

Equalize the signal. Display the constellation diagram after equalization.

```
eqSig = x ./ h_datasubcarr;
cdScope(eqSig);
```



Demodulate the 16-QAM symbols to recover the signal. Compute the symbol error rate.

```
rxSym = qamdemod(eqSig,M,UnitAveragePower=true);
numErr = symerr(data,rxSym);
disp(['Number of symbol errors: ' num2str(numErr) ...
    ' out of ' num2str(length(data)) ' symbols.'])
```

```
Number of symbol errors: 2 out of 52 symbols.
```

OFDM Demodulation with Null and Pilot Packing

OFDM-demodulate data input that includes null and pilot packing.

Initialize input parameters, defining locations for null and pilot subcarriers. Generate random data and perform OFDM modulation.

```
Mqam = 16;
Mpsk = 4;
nfft = 64;
cplen = 16;
nSym = 10;
nullIdx = [1:6 33 64-4:64]';
pilotIdx = [12 26 40 54]';
numDataCarrs = nfft-length(nullIdx)-length(pilotIdx);
dataSym = randi([0 Mqam-1],numDataCarrs,nSym);
qamSig = qammod(dataSym,Mqam,UnitAveragePower=true);
pilotSym = repmat((0:Mpsk-1).',1,nSym);
pilots = pskmod(pilotSym,Mpsk);
y2 = ofdmmod(qamSig,nfft,cplen,nullIdx,pilotIdx,pilots);
```

Demodulate the OFDM symbols. Compare the results to the original input data to show that the demodulated signal and the original data and pilot signals are equal.

```
symOffset = cplen;
[x2,rxPilots] = ofdmdemod(y2,nfft,cplen,symOffset,nullIdx,pilotIdx);
rxData = qamdemod(x2,Mqam,UnitAveragePower=true);
isequal(rxData,dataSym)
```

```
ans = logical
   1
```

```
rxPilotSym = pskdemod(rxPilots,Mpsk);
isequal(rxPilotSym,repmat((0:Mpsk-1).',1,nSym))
```

```
ans = logical
   1
```

Demodulate Oversampled OFDM Signal

Demodulate an oversampled OFDM modulation that has a sample offset. Insert nulls in the OFDM grid and oversample the output signal.

Initialize variables for the oversampling factor, FFT size, cyclic prefix length, and sample offset.

```
M = 64;
osf = 4/3;
nfft = 768;
cplen = 24;
sampOffset = 5;
symOffset = cplen - (sampOffset/osf);
```

Generate data symbols and OFDM-modulate the data.

```
dataSym = randi([0 M-1],nfft,1);
qamSig = qammod(dataSym,M,UnitAveragePower=true);
y3 = ofdmmod(qamSig,nfft,cplen,OversamplingFactor=osf);
```

Demodulate the signal and show the demodulated data symbols match the original input data symbols.

```
x3 = ofdmdemod(y3,nfft,cplen,symOffset,OversamplingFactor=osf);
rxSym = qamdemod(x3,M,UnitAveragePower=true);
isequal(rxSym,dataSym)
```

```
ans = logical
   1
```

Input Arguments

`ofdmSig` — Modulated OFDM symbols

2-D array of complex symbols

Modulated OFDM symbols, specified as a 2-D array of complex symbols.

- If `cplen` is a scalar, the array size is ((`nfft` + `cplen`) × N_{Sym})-by-N_R.
- If `cplen` is a row vector, the array size is ((`nfft` × N_{Sym}) + `sum`(`cplen`))-by-N_R.

  N_{Sym} is the number of symbols per antenna and N_R is the number of receive antennas.

Data Types: `double` | `single`
Complex Number Support: Yes

`nfft` — FFT length

integer greater than or equal to 8

FFT length, specified as an integer greater than or equal to 8. `nfft` is equivalent to the number of subcarriers used in the demodulation process.

Data Types: `double`

`cplen` — Cyclic prefix length

scalar | row vector of length N_{Sym}

Cyclic prefix length, specified as a scalar or as a row vector of length N_{Sym}.

- When you specify `cplen` as a scalar, the cyclic prefix length is the same for all symbols through all antennas.
- When you specify `cplen` as a row vector of length N_{Sym}, the cyclic prefix length can vary across symbols but remains the same length through all antennas.

Data Types: `double`

`symOffset` — Symbol sampling offset

`cplen` (default) | scalar | row vector

Symbol sampling offset, specified as values from 0 to `cplen`.

- If you do not specify `symOffset`, the default value is an offset equal to `cplen`.
- If you specify `symOffset` as a scalar, the same offset is used for all symbols.

- If you specify `symOffset` as a row vector, the offset value can be different for each symbol.

For information, see “Windowing and Symbol Offset” on page 2-592.

Data Types: `double`

`nullidx` — Indices of null subcarrier locations
column vector

Indices of null subcarrier locations, specified as a column vector with element values from 1 to `nfft`. If you specify `nullidx`, the number of rows in `outSym` is `(nfft-length(nullidx))`. For information, see “Subcarrier Allocation and Guard Bands” on page 2-591.

Data Types: `double`

`pilotidx` — Indices of pilot subcarrier locations
column vector

Indices of pilot subcarrier locations, specified as a column vector with element values from 1 to `nfft`. If you specify `pilotidx`, the number of rows in `outSym` is `(nfft-length(nullidx)-length(pilotidx))`.For information, see “Subcarrier Allocation and Guard Bands” on page 2-591.

Data Types: `double`

Output Arguments

`outSym` — Output demodulated symbols
3-D array

Output demodulated symbols, returned as an N_D-by-N_{Sym}-by-N_R array of symbols. N_D must equal `nfft` – `length(nullidx)` – `length(pilotidx)`. N_{Sym} is the number of OFDM symbols per antenna. N_R is the number of receive antennas. For information, see “OFDM Demodulation” on page 2-590.

`pilots` — Pilot subcarriers
3-D array

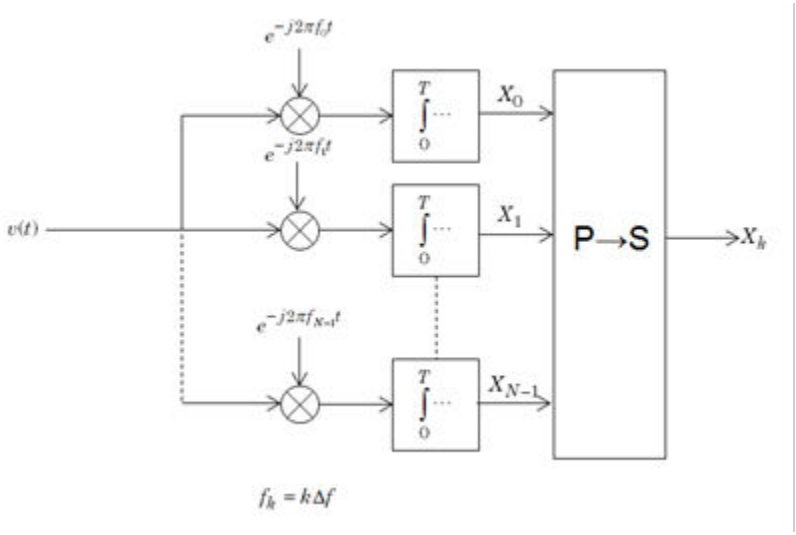
Pilot subcarriers, returned as an N_{Pilot}-by-N_{Sym}-by-N_R array of symbols. N_{Pilot} must equal the length of `pilotidx`. N_{Sym} is the number of OFDM symbols per antenna. N_R is the number of receive antennas. The function assumes that the pilot subcarrier locations are the same across each OFDM symbol and transmit antenna. Use the `comm.OFDMDemodulator` to vary pilot subcarrier locations across OFDM symbols or antennas.

More About

OFDM Demodulation

An OFDM demodulator demultiplexes a multi-subcarrier time-domain signal using orthogonal frequency division multiplexing.

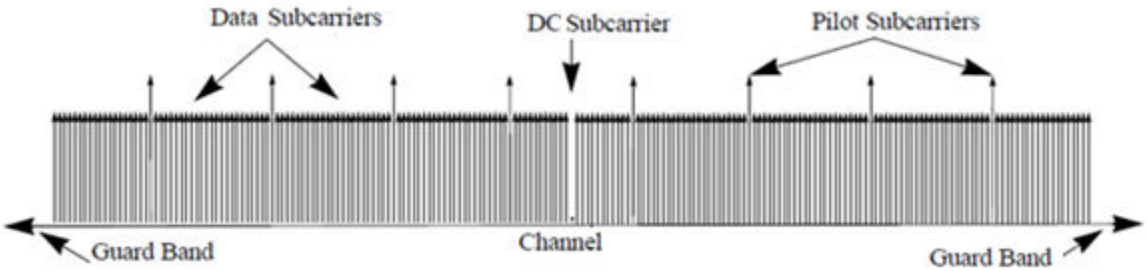
OFDM demodulation uses an FFT operation that results in N parallel data streams. An OFDM demodulator consists of a bank of N correlators, with one correlator assigned to each OFDM subcarrier, followed by a parallel-to-serial conversion.



Subcarrier Allocation and Guard Bands

Individual OFDM subcarriers are allocated as data, pilot, or null subcarriers.

As shown here, subcarriers are designated as data, DC, pilot, or guard band subcarriers.

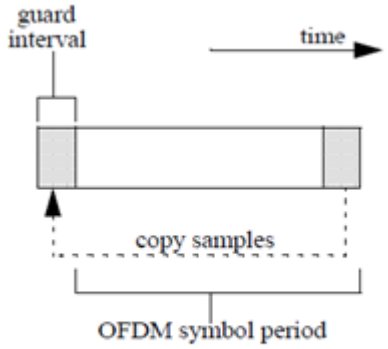


- Data subcarriers transmit user data.
- Pilot subcarriers are used for channel estimation.
- Null subcarriers transmit no data. Subcarriers with no data are used to provide a DC null and serve as buffers between OFDM resource blocks.
  - The null DC subcarrier is the center of the frequency band with an index value of (`nfft`/2 + 1) if `nfft` is even, or ((`nfft` + 1) / 2) if `nfft` is odd.
  - The guard bands provide buffers between adjacent signals in neighboring bands to reduce interference caused by spectral leakage.

Null subcarriers enable you to model guard bands and DC subcarrier locations for specific standards, such as the various 802.11 formats, LTE, WiMAX, or for custom allocations. You can allocate the location of nulls by assigning a vector of null subcarrier indices.

Similar to guard bands, guard intervals are used in OFDM to protect the integrity of transmitted signals by reducing intersymbol interference.

Assignment of guard intervals is analogous to the assignment of guard bands. You can model guard intervals to provide temporal separation between OFDM symbols. The guard intervals help preserve intersymbol orthogonality after the signal passes through time-dispersive channels. Guard intervals are created by using cyclic prefixes. Cyclic prefix insertion copies the last part of an OFDM symbol as the first part of the OFDM symbol.



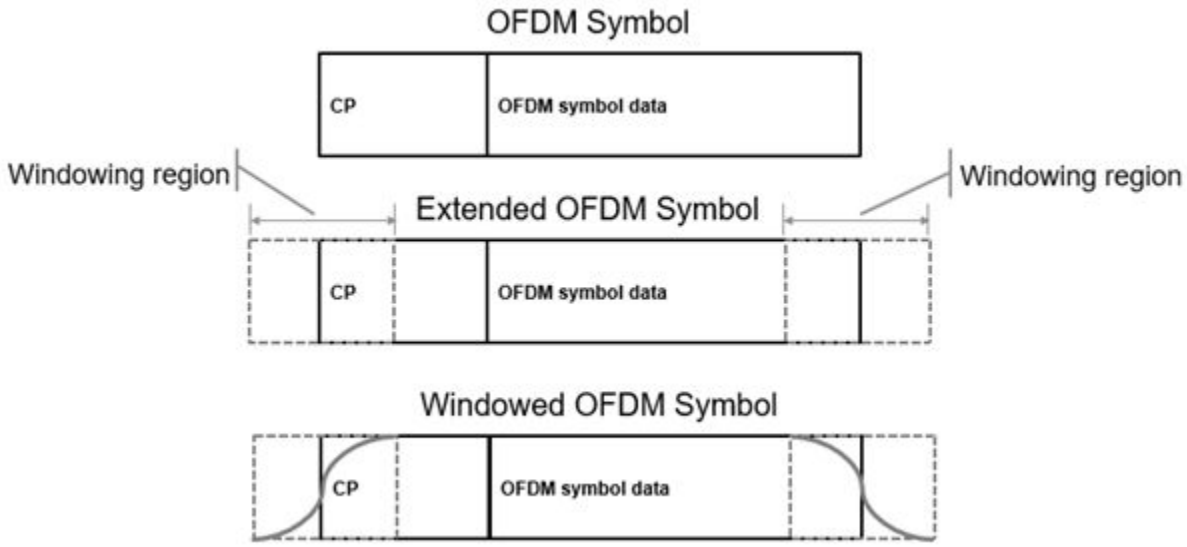
As long as the span of the time dispersion does not exceed the duration of the cyclic prefix, the benefit of cyclic prefix insertion is maintained.

Inserting a cyclic prefix results in a fractional reduction of user data throughput because the cyclic prefix occupies bandwidth that could be used for data transmission.

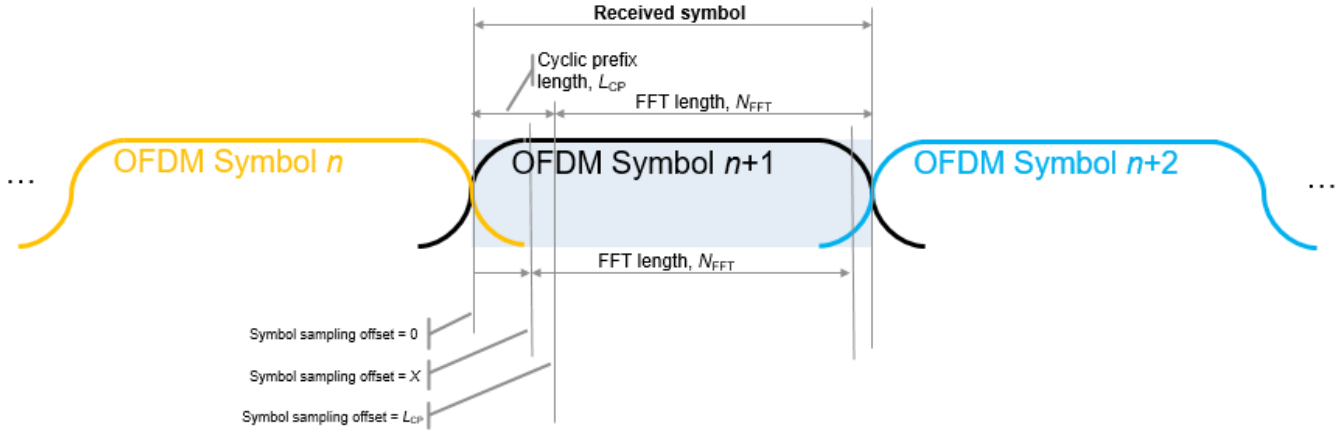
Windowing and Symbol Offset

To reduce intersymbol interference (ISI) introduced by signal windowing applied at the transmitter, the function applies a fractional symbol offset before demodulation of each OFDM symbol. Signal windowing is often applied to transmitted OFDM symbols to smooth the discontinuity between consecutive OFDM symbols. Windowing reduces intersymbol out-of-band emissions but increases ISI.

The windowed OFDM symbol consists of the cyclic prefix (CP), ODFM symbol data, plus windowing regions at the beginning and end of the symbol. The leading and trailing windowing shoulders have tails as shown in the figure.



To reduce ISI, you can align signal sample timing by specifying a symbol sampling offset that gets applied before OFDM symbol demodulation.



Specify the symbol sampling offset as a value from 0 to L_{CP}.

- When the symbol sampling offset is a scalar from 0 to L_{CP}, the FFT window begins at the X+1 sample of the CP length.
- When the symbol sampling offset is zero, no offset is applied and the FFT window starts at the first sample of the symbol.
- When the symbol sampling offset is the cyclic prefix length, L_{CP}, the FFT window begins after the last CP sample. This offset is the default setting if symbol sampling offset is not specified.

ofdmEqualize

Equalize OFDM signals

Syntax

```
[eqsym,csi]= ofdmEqualize(rxsym,hest,nvar)
[eqsym,csi]= ofdmEqualize(rxsym,hest)
[eqsym,csi]= ofdmEqualize( ___ ,Name=Value)
```

Description

`[eqsym,csi]= ofdmEqualize(rxsym,hest,nvar)` returns equalized symbols `eqsym` and soft channel state information `csi` after performing minimum mean squared error (MMSE) equalization on input OFDM symbols `rxsym`. `hest` specifies the estimated channel information. `nvar` specifies the estimated noise variance.

`[eqsym,csi]= ofdmEqualize(rxsym,hest)` performs MMSE equalization with the estimated noise variance equal to 0.

`[eqsym,csi]= ofdmEqualize( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to the input arguments in the previous syntaxes. For example, `ofdmEqualize(rxsym,hest,Algorithm="zf")` equalizes the input OFDM symbols using the zero-forcing algorithm.

Examples

OFDM Equalization for MIMO Channel

Equalize an OFDM signal filtered through a MIMO channel.

Define variables for a 2-by-4 MIMO system transmitting a 64-QAM signal that is OFDM modulated.

```
numTxAntenna = 2;
numRxAntenna = 4;
fftLen = 256;
cpLen = 16;
k = 6;              % Bits per symbol for each OFDM data subcarrier
modOrder = 2^k;     % 64-QAM for k = 6
numOFDMSymbols = 8;
SNRdB = 40;
```

Specify null indices for guard bands and a DC subcarrier.

```
ofdmNullIdx = [1:9 (fftLen/2+1) (fftLen-8+1:fftLen)]';
```

Apply QAM and OFDM modulation to random bit data.

```
numDataSubcarriers = fftLen-length(ofdmNullIdx);
srcBits = randi([0,1], ...
    [numDataSubcarriers*log2(modOrder) numOFDMSymbols numTxAntenna]);
```

```
ofdmData = qammod(srcBits,modOrder, ...
    InputType="bit", ...
    UnitAveragePower=true);
txSignal = ofdmmod(ofdmData,fftLen,cpLen,ofdmNullIdx);
```

Filter the OFDM signal through a MIMO channel and add AWGN.

```
mimoChannel = comm.MIMOChannel( ...
    SampleRate=1e6, ...
    PathDelays=[3e-6 5e-6 8e-6], ...
    AveragePathGains=[1.2 0.5 0.1], ...
    MaximumDopplerShift=1, ...
    SpatialCorrelationSpecification="None", ...
    NumTransmitAntennas=numTxAntenna, ...
    NumReceiveAntennas=numRxAntenna, ...
    PathGainsOutputPort=true);

```

Show Equivalence of 2-D and 3-D Data Format for OFDM Equalization

Initialize variables for simulation of a MIMO system and a 120-resource-element subset of the OFDM subcarrier-symbol grid.

```
Nre = 120;
Nt = 4;
Nr = 8;
nvar = 0.1;
```

Create random signals for a 2-D symbol array and a channel estimate.

```
rxsym2d = complex(randn(Nre,Nr),randn(Nre,Nr));
Hest = complex(randn(Nre,Nt,Nr),randn(Nre,Nt,Nr));
```

Apply OFDM equalization to the 2-D signal contained in an 120-by-8 symbol array.

```
[eqsym2d,csi2d] = ofdmEqualize(rxsym2d,Hest,nvar,DataFormat="2-D");
```

Reshape the 2-D signal to a 30-by-4-by-8 symbol array. Apply OFDM equalization to the 3-D signal. Compare the results of OFDM equalization for the 30-by-4-by-8 symbol array with OFDM equalization for the 120-by-8 symbol array. As the `isequal` function result shows, the equalized symbols and soft channel state information returned for the 30-by-4-by-8 and 120-by-8 symbol arrays are equal.

```
rxsym3d = reshape(rxsym2d,30,4,Nr);
[eqsym3d,csi3d] = ofdmEqualize(rxsym3d,Hest,nvar,DataFormat="3-D");
isequal(eqsym3d,reshape(eqsym2d,30,4,Nt))
```

```
ans = logical
   1
```

```
isequal(csi3d,csi2d)
```

```
ans = logical
   1
```

Reshape the 2-D signal to a 60-by-2-by-8 symbol array. Apply OFDM equalization to the 3-D signal. Compare the results of OFDM equalization for the 60-by-2-by-8 symbol array with OFDM equalization for the 120-by-8 symbol array. As the `isequal` function result shows, the equalized symbols and soft channel state information returned for the 60-by-2-by-8 and 120-by-8 symbol arrays are equal.

```
rxsym3d2 = reshape(rxsym2d,60,2,Nr);
[eqsym3d2,csi3d2] = ofdmEqualize(rxsym3d2,Hest,nvar,DataFormat="3-D");
isequal(eqsym3d2,reshape(eqsym2d,60,2,Nt))
```

```
ans = logical
   1
```

```
isequal(csi3d2,csi2d)
```

```
ans = logical
   1
```

Input Arguments

`rxsym` — Received symbols

3-D array | 2-D array

Received symbols, specified as a 3-D or 2-D array.

- If `DataFormat` is set to `"3-D"`, the function expects `rxsym` to be specified as an N_{SC}-by-$N_{Symbols}$-by-N_R array. N_{SC} represents the number of OFDM subcarriers, $N_{Symbols}$ represents the number of OFDM symbols, and N_R represents the number of receive antennas.

- If `DataFormat` is set to `"2-D"`, the function expects `rxsym` to be specified as an N_{RE}-by-N_R array. N_{RE} represents the number of resource elements in an irregular subset of the OFDM subcarrier symbol grid.

Data Types: `double` | `single`
Complex Number Support: Yes

`hest` — Channel estimate

3-D array

Channel estimate, specified as a 3-D array.

- If `DataFormat` is set to `"3-D"`, the function expects `hest` to be an N_{SC}-by-N_T-by-N_R or an (N_{SC}×$N_{Symbols}$)-by-N_T-by-N_R array.
  - If `hest` is an N_{SC}-by-N_T-by-N_R array, all OFDM symbols in `rxsym` are equalized by the same channel estimate. N_{SC} represents the number of OFDM subcarriers, N_T represents the number of transmit antennas, and N_R represents the number of receive antennas.
  - If `hest` is an (N_{SC}×$N_{Symbols}$)-by-N_T-by-N_R array, each OFDM symbol in `rxsym` is equalized by the corresponding entry in `hest`. $N_{Symbols}$ represents the number of OFDM symbols.
- If `DataFormat` is set to `"2-D"`, the function expects `hest` to be an N_{RE}-by-N_T-by-N_R array. Each OFDM symbol in `rxsym` is equalized by the corresponding entry in `hest`. N_{RE} represents the number of resource elements in an irregular subset of the OFDM subcarrier symbol grid.

Data Types: `double` | `single`
Complex Number Support: Yes

`nvar` — Noise variance

0 (default) | nonnegative scalar

Noise variance estimate for MMSE equalization, specified as a nonnegative scalar.

Dependencies

The noise variance setting is used only when you set `Algorithm` to `"mmse"`.

Data Types: `double` | `single`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `ofdmEqualize(rxsym,hest,DataFormat="2-D")` equalizes an N_{RE}-by-N_R input OFDM symbol array using the MMSE algorithm.

`Algorithm` — Equalization algorithm

`"mmse"` (default) | `"zf"`

Equalization algorithm, specified as `"mmse"` or `"zf"`.

- When this argument is set to `"mmse"`, the function equalizes using the MMSE algorithm.

- When this argument is set to `"zf"`, the function equalizes using the zero-forcing algorithm. When using the zero-forcing algorithm, the `nvar` argument value is ignored.

`DataFormat` — Format of signals
`"3-D"` (default) | `"2-D"`

Format of the signals, specified as `"3-D"` or `"2-D"`.

When this argument is set to `"3-D"`, OFDM subcarriers and OFDM symbols use two separate dimensions in the representation of `rxsym` and `eqsym`.

- The `rxsym` input must be an N_{SC}-by-$N_{Symbols}$-by-N_R array.
- The `eqsym` output is returned as an N_{SC}-by-$N_{Symbols}$-by-N_T array.

When this argument is set to `"2-D"`, OFDM subcarriers and OFDM symbols use one combined dimension in the representation of `rxsym` and `eqsym`.

- The `rxsym` input must be an N_{RE}-by-N_R array.
- The `eqsym` output is returned as an N_{RE}-by-N_T array.

N_{SC} represents the number of OFDM subcarriers. $N_{Symbols}$ represents the number of symbols. N_{RE} represents the number of resource elements in an irregular subset of the OFDM subcarrier symbol grid. N_T represents the number of transmit antennas. N_R represents the number of receive antennas.

Output Arguments

`eqsym` — Equalized symbols
3-D array | 2-D array

Equalized symbols, returned as a 3-D or 2-D array.

- If `DataFormat` is set to `"3-D"`, the function returns an N_{SC}-by-$N_{Symbols}$-by-N_T array. N_{SC} represents the number of OFDM subcarriers, $N_{Symbols}$ represents the number of OFDM symbols, and N_T represents the number of transmit antennas.
- If `DataFormat` is set to `"2-D"`, the function returns an N_{RE}-by-N_T array. N_{RE} represents the number of resource elements in an irregular subset of the OFDM subcarrier symbol grid.

`csi` — Soft channel state information
matrix

Soft channel state information, returned as a matrix with `size(csi,1) = size(hest,1)` and `size(csi,2) = ` N_T `= size(hest,2)`. N_T represents the number of transmit antennas.

OFDM Equalizer

ofdmmod

Modulate frequency-domain signal using orthogonal frequency division multiplexing (OFDM)

Syntax

```
ofdmSig = ofdmmod(inSym,nfft,cplen)
ofdmSig = ofdmmod(inSym,nfft,cplen,nullidx)
ofdmSig = ofdmmod(inSym,nfft,cplen,nullidx,pilotidx,pilots)
ofdmSig = ofdmmod(inSym,nfft,cplen,___,OvesamplingFactor=Value)
```

Description

`ofdmSig = ofdmmod(inSym,nfft,cplen)` performs OFDM modulation on the frequency-domain input data subcarriers, `inSym`, using an FFT size specified by `nfft` and cyclic prefix length specified by `cplen`. For information, see “OFDM Modulation” on page 2-606.

`ofdmSig = ofdmmod(inSym,nfft,cplen,nullidx)` inserts null subcarriers into the frequency domain input data signal prior to performing OFDM modulation. The null subcarriers are inserted at index locations from 1 to `nfft`, as specified by `nullidx`. For this syntax, the number of rows in the input `inSym` must be `nfft` – `length(nullidx)`. Use null carriers to account for guard bands and DC subcarriers. For information, see “Subcarrier Allocation, Guard Bands and Guard Intervals” on page 2-608.

`ofdmSig = ofdmmod(inSym,nfft,cplen,nullidx,pilotidx,pilots)` inserts null and pilot subcarriers into the frequency domain input data symbols prior to performing OFDM modulation. The null subcarriers are inserted at the index locations specified by `nullidx`. The pilot subcarriers, `pilots`, are inserted at the index locations specified by `pilotidx`. For this syntax, the number of rows in the input `inSym` must be `nfft` – `length(nullidx)` – `length(pilotidx)`. The function assumes pilot subcarrier locations are the same across each OFDM symbol and transmit antenna.

`ofdmSig = ofdmmod(inSym,nfft,cplen,___,OvesamplingFactor=Value)` specifies the optional oversampling factor name-value argument in addition to input arguments in previous syntaxes. The oversampling factor for an upsampled output signal must be specified as a positive scalar. Additionally, the products (`OversamplingFactor×nfft`) and (`OversamplingFactor×cplen`) must both result in integers. The default value for `OversamplingFactor` is `1`.

For example, `ofdmmod(inSym,nfft,cplen,OversamplingFactor=2)` upsamples the output signal by a factor of two.

Examples

OFDM Modulation over Two Antennas

OFDM-modulate a fully packed input over two transmit antennas.

Initialize input parameters, generate random data, and perform OFDM modulation.

```
M = 16;      % Modulation order for 16QAM
nfft  = 128; % Number of data carriers
```

```
cplen = 16;  % Cyclic prefix length
nSym  = 5;   % Number of symbols per RE
nt    = 2;   % Number of transmit antennas
dataIn = randi([0 M-1],nfft,nSym,nt);
qamSig = qammod(dataIn,M,'UnitAveragePower',true);
y1 = ofdmmod(qamSig,nfft,cplen);
```

Apply OFDM Assigning Null Subcarriers

Apply OFDM modulation assigning null subcarriers.

Initialize input parameters and generate random data.

```
M = 16;     % Modulation order for 16QAM
nfft  = 64; % FFT length
cplen = 16; % Cyclic prefix length
nSym  = 10; % Number of symbols per RE

nullIdx  = [1:6 33 64-4:64]';
numDataCarrs = nfft-length(nullIdx);
inSym = randi([0 M-1],numDataCarrs,nSym);
```

QAM modulate data. Perform OFDM modulation.

```
qamSig = qammod(inSym,M,'UnitAveragePower',true);
outSig = ofdmmod(qamSig,nfft,cplen,nullIdx);
```

Perform OFDM Modulation Varying Cyclic Prefix per Symbol

Perform OFDM modulation to input frequency domain data signal varying cyclic prefix length applied to each symbol.

Initialize input parameters and generate random data.

```
M = 16; % Modulation order for 16QAM
nfft  = 64;
cplen = [4 8 10 7 2 2 4 11 16 3];
nSym  = 10;
nullIdx  = [1:6 33 64-4:64]';
numDataCarrs = nfft-length(nullIdx);
inSym = randi([0 M-1],numDataCarrs,nSym);
```

QAM modulate the data symbols and perform OFDM modulation to the QAM signal.

```
qamSig = qammod(inSym,M,UnitAveragePower=true);
outSig = ofdmmod(qamSig,nfft,cplen,nullIdx);
```

Apply OFDM to QPSK Signal Spatially Multiplexed over Two Antennas

Apply OFDM modulation to a QPSK signal that is spatially multiplexed over two transmit antennas.

Initialize input parameters and generate random data for each antenna.

```
M = 4;      % Modulation order for QPSK
nfft  = 64;
cplen = 16;
nSym  = 5;
nt    = 2;
nullIdx  = [1:6 33 64-4:64]';
pilotIdx = [12 26 40 54]';
numDataCarrs = nfft-length(nullIdx)-length(pilotIdx);
pilots = repmat(pskmod((0:M-1).',M),1,nSym,2);

ant1 = randi([0 M-1],numDataCarrs,nSym);
ant2 = randi([0 M-1],numDataCarrs,nSym);
```

QPSK modulate data individually for each antenna. Perform OFDM modulation.

```
qpskSig(:,:,1) = pskmod(ant1,M);
qpskSig(:,:,2) = pskmod(ant2,M);
y1 = ofdmmod(qpskSig,nfft,cplen,nullIdx,pilotIdx,pilots);
```

OFDM Modulation with Null and Pilot Packing

OFDM-modulate data input, specifying null and pilot packing.

Initialize input parameters, defining locations for null and pilot subcarriers. Generate random data, apply 16-QAM to data, QSPK to pilots, and perform OFDM modulation.

```
M = 16;     % Modulation order
nfft = 64;  % FFT length
cplen = 16; % Cyclic prefix length
nSym  = 10; % Number of symbols per RE

nullIdx  = [1:6 33 64-4:64]';
pilotIdx = [12 26 40 54]';

numDataCarrs = nfft-length(nullIdx)-length(pilotIdx);
dataSym = randi([0 M-1],numDataCarrs,nSym);
qamSig = qammod(dataSym,M,UnitAveragePower=true);
pilots = repmat(pskmod((0:3).',4),1,nSym);

y2 = ofdmmod(qamSig,nfft,cplen,nullIdx,pilotIdx,pilots);
```

OFDM Modulate with Upsampling and Nulls

Apply OFDM modulation to symbols. Insert nulls in the OFDM grid and oversample the output signal.

Initialize variables for the modulation order, oversampling factor, FFT size, cyclic prefix length, and null indices.

```
M = 64;      % Modulation order
osf = 3;     % Oversampling factor
nfft = 256;  % FFT length
```

```
cplen = 16;  % Cyclic prefix length

nullidx  = [1:6 nfft/2+1 nfft-5:nfft]';
numDataCarrs = nfft-length(nullidx);
```

Generate data symbols, apply QAM, and OFDM-modulate the data.

```
x = randi([0 M-1],numDataCarrs,1);
qamSig = qammod(x,M,UnitAveragePower=true);
y = ofdmmod(qamSig,nfft,cplen,nullidx,OversamplingFactor=osf);
```

Input Arguments

`inSym` — Input data subcarriers

3-D array

Input data subcarriers, specified as an N_D-by-N_{Sym}-by-N_T array of symbols. The number of data subcarriers, N_D, must equal `nfft` – `length(nullidx)` – `length(pilotidx)`. N_{Sym} is the number of OFDM symbols per transmit antenna, N_T is the number of transmit antennas.

Input data symbols to an OFDM modulator are typically created with a baseband digital modulator, such as `qammod`.

Data Types: `double` | `single`
Complex Number Support: Yes

`nfft` — FFT length

integer greater than or equal to 8

FFT length, specified as an integer greater than or equal to 8. `nfft` is equivalent to the number of subcarriers used in the modulation process.

Data Types: `double`

`cplen` — Cyclic prefix length

scalar | row vector of length N_{Sym}

Cyclic prefix length, specified as a scalar or as a row vector of length N_{Sym}.

- When you specify `cplen` as a scalar, the cyclic prefix length is the same for all symbols through all antennas.
- When you specify `cplen` as a row vector of length N_{Sym}, the cyclic prefix length can vary across symbols but remains the same length through all antennas.

For more information, see “Subcarrier Allocation, Guard Bands and Guard Intervals” on page 2-608.

Data Types: `double`

`nullidx` — Indices of null subcarrier locations

column vector

Indices of null subcarrier locations, specified as a column vector with element values from 1 to `nfft`.

Data Types: `double`

`pilotidx` — Indices of pilot subcarrier locations

column vector

Indices of pilot subcarrier locations, specified as a column vector with element values from 1 to `nfft`.

Data Types: `double`

`pilots` — Pilot subcarriers

3-D array

Pilot subcarriers, specified as an N_{Pilot}-by-N_{Sym}-by-N_{T} array of symbols. N_{Pilot} must equal the length of `pilotidx`. N_{Sym} is the number of OFDM symbols per transmit antenna. N_{T} is the number of transmit antennas. The function assumes pilot subcarrier locations are the same across each OFDM symbol and transmit antenna. Use the `comm.OFDMModulator` to vary pilot subcarrier locations across OFDM symbols or antennas.

Data Types: `double` | `single`

Output Arguments

`ofdmSig` — Modulated OFDM symbols

2-D array of complex symbols

Modulated OFDM symbols, returned as a 2-D array of complex symbols.

- If `cplen` is a scalar, the array size is ((`nfft` + `cplen`) × N_{Sym})-by-N_{T}.
- If `cplen` is a row vector, the array size is ((`nfft` × N_{Sym}) + `sum`(`cplen`))-by-N_{T}.

  N_{Sym} is the number of symbols per transmit antenna and N_{T} is the number of transmit antennas.

Data Types: `double` | `single`

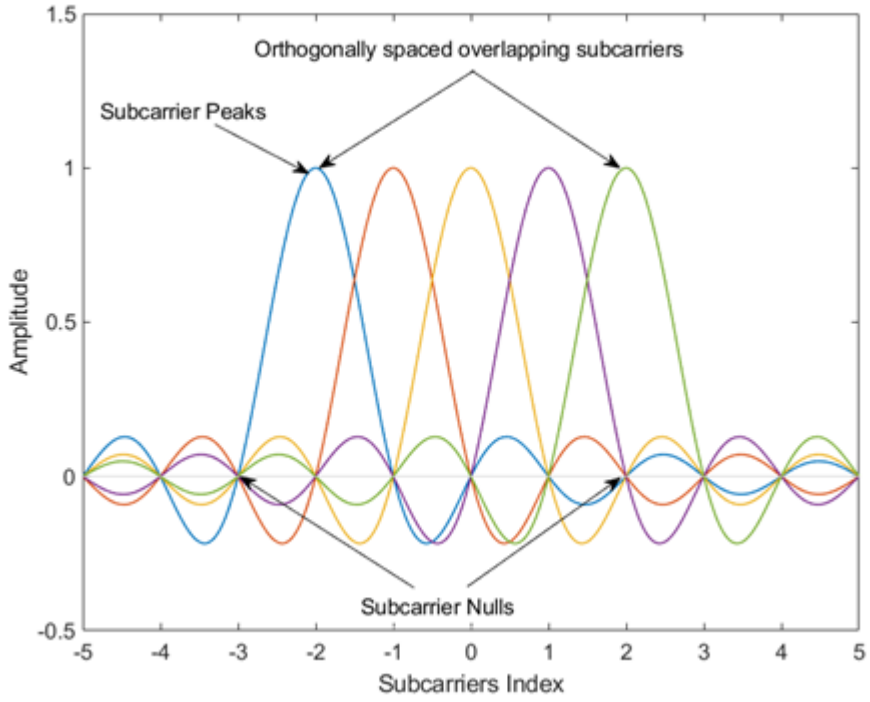
More About

OFDM Modulation

OFDM belongs to the class of multicarrier modulation schemes. Since the multiple data streams can be transmitted simultaneously with multiple carriers, OFDM is not influenced by noise to the same degree as single-carrier modulation.

OFDM operation divides a high-rate data stream into lower data rate substreams by decomposing the transmission frequency band into *N* contiguous individually modulated subcarriers. Multiple parallel and orthogonal subcarriers carry the samples with almost the same bandwidth as a wideband channel. By using narrow orthogonal subcarriers, the OFDM signal gains robustness over a frequency-selective fading channel and eliminates adjacent subcarrier interference. Intersymbol interference (ISI) is reduced because the lower data rate substreams have symbol durations larger than the channel delay spread.

This image shows a frequency domain representation of orthogonal subcarriers in an OFDM waveform.



The transmitter applies inverse fast Fourier transform (IFFT) to N symbols at a time. Typically, the output of the IFFT is the sum of the N orthogonal sinusoids:

$$x(t) = \sum_{k=0}^{N-1} X_k e^{j2\pi k\Delta f t}, \quad 0 \le t \le T,$$

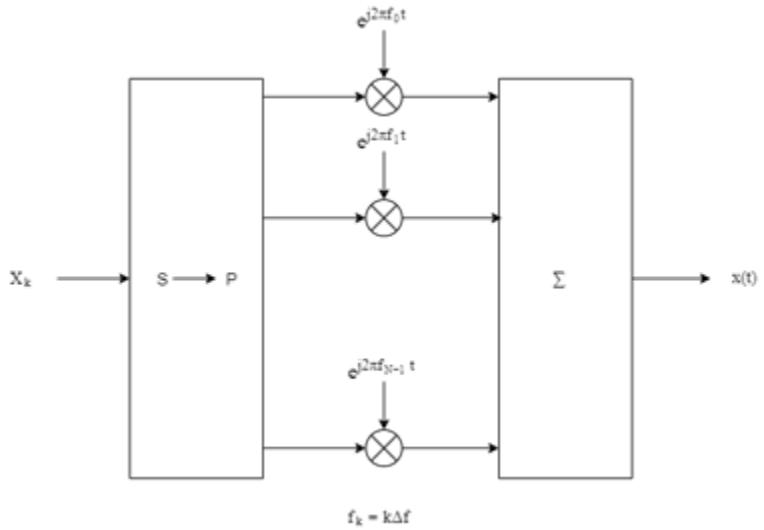
where $\{X_k\}$ are data symbols, and T is the OFDM symbol time. The data symbols X_k are typically complex and can be from any digital modulation alphabet (for example, QPSK, 16-QAM, 64-QAM, ...).

Note The MATLAB implementation of the discrete Fourier transform normalizes the output of the IFFT by $1/N$. For more information, see “Discrete Fourier Transform of Vector” on the `ifft` reference page.

The subcarrier spacing is $\Delta f = 1/T$, ensuring that the subcarriers are orthogonal over each symbol period, as shown below:

$$\frac{1}{T}\int_0^T \left(e^{j2\pi m\Delta f t}\right)^* \left(e^{j2\pi n\Delta f t}\right) dt = \frac{1}{T}\int_0^T e^{j2\pi (m-n)\Delta f t}\, dt = 0 \quad \text{for } m \ne n\,.$$

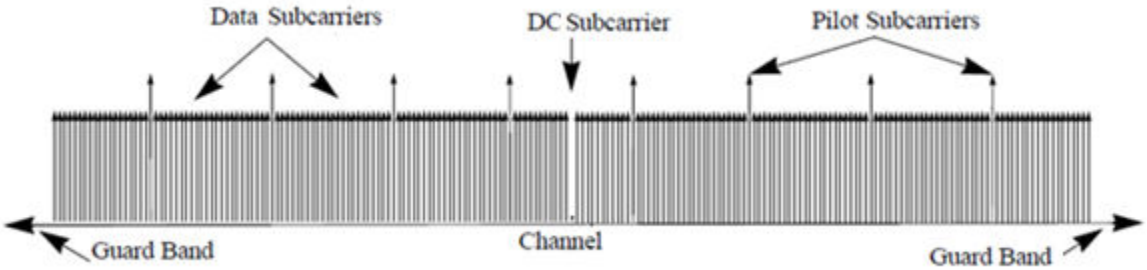
An OFDM modulator consists of a serial-to-parallel conversion followed by a bank of N complex modulators, individually corresponding to each OFDM subcarrier.



Subcarrier Allocation, Guard Bands and Guard Intervals

Individual OFDM subcarriers are allocated as data, pilot, or null subcarriers.

As shown here, subcarriers are designated as data, DC, pilot, or guard band subcarriers.

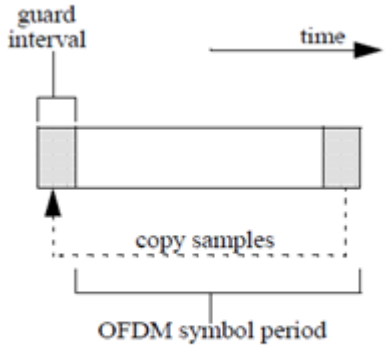


- Data subcarriers transmit user data.
- Pilot subcarriers are used for channel estimation.
- Null subcarriers transmit no data. Subcarriers with no data are used to provide a DC null and serve as buffers between OFDM resource blocks.
  - The null DC subcarrier is the center of the frequency band with an index value of (`nfft`/2 + 1) if `nfft` is even, or ((`nfft` + 1) / 2) if `nfft` is odd.
  - The guard bands provide buffers between adjacent signals in neighboring bands to reduce interference caused by spectral leakage.

Null subcarriers enable you to model guard bands and DC subcarrier locations for specific standards, such as the various 802.11 formats, LTE, WiMAX, or for custom allocations. You can allocate the location of nulls by assigning a vector of null subcarrier indices.

Similar to guard bands, guard intervals are used in OFDM to protect the integrity of transmitted signals by reducing intersymbol interference.

Assignment of guard intervals is analogous to the assignment of guard bands. You can model guard intervals to provide temporal separation between OFDM symbols. The guard intervals help preserve intersymbol orthogonality after the signal passes through time-dispersive channels. Guard intervals are created by using cyclic prefixes. Cyclic prefix insertion copies the last part of an OFDM symbol as the first part of the OFDM symbol.



As long as the span of the time dispersion does not exceed the duration of the cyclic prefix, the benefit of cyclic prefix insertion is maintained.

Inserting a cyclic prefix results in a fractional reduction of user data throughput because the cyclic prefix occupies bandwidth that could be used for data transmission.

Objects

`comm.OFDMModulator` | `comm.OFDMDemodulator`

pamdemod

Pulse amplitude demodulation

Syntax

```
z = pamdemod(y,M)
z = pamdemod(y,M,ini_phase)
z = pamdemod(y,M,ini_phase,symbol_order)
```

Description

`z = pamdemod(y,M)` demodulates the complex envelope `y` of a pulse amplitude modulated signal. `M` is the alphabet size. The ideal modulated signal should have a minimum Euclidean distance of 2.

`z = pamdemod(y,M,ini_phase)` specifies the initial phase of the modulated signal in radians.

`z = pamdemod(y,M,ini_phase,symbol_order)` specifies how the function assigns binary words to corresponding integers. If `symbol_order` is set to `'bin'` (default), the function uses a natural binary-coded ordering. If `symbol_order` is set to `'gray'`, it uses a Gray-coded ordering.

Examples

Demodulate PAM Signal

Modulate and demodulate random integers using pulse amplitude modulation. Verify that the output data matches the original data.

Set the modulation order and generate 100 M-ary data symbols.

```
M = 12;
dataIn = randi([0 M-1],100,1);
```

Perform modulation and demodulation operations.

```
modData = pammod(dataIn,M);
dataOut = pamdemod(modData,M);
```

Compare the first five symbols.

```
[dataIn(1:5) dataOut(1:5)]
```

```
ans = 5×2

     9     9
    10    10
     1     1
    10    10
     7     7
```

Verify that there are no symbol errors in the entire sequence.

```
symErrors = symerr(dataIn,dataOut)
```

```
symErrors = 0
```

Topics

“Digital Baseband Modulation”
“Compare Theoretical and Empirical Error Rates”

pammod

Pulse amplitude modulation (PAM)

Syntax

```
y = pammod(x,M)
y = pammod(x,M,initphase)
y = pammod(x,M,initphase,symorder)
```

Description

`y = pammod(x,M)` returns the complex envelope of the modulation of the input message signal, `x`, using PAM and the alphabet size, `M`.

`y = pammod(x,M,initphase)` specifies the initial phase of the modulated signal.

`y = pammod(x,M,initphase,symorder)` specifies natural binary-coded or Gray-coded binary vector mapping order for the modulation symbols.

Examples

Modulate Data Symbols with PAM

Generate random data symbols and apply pulse amplitude modulation.

Set the modulation order.

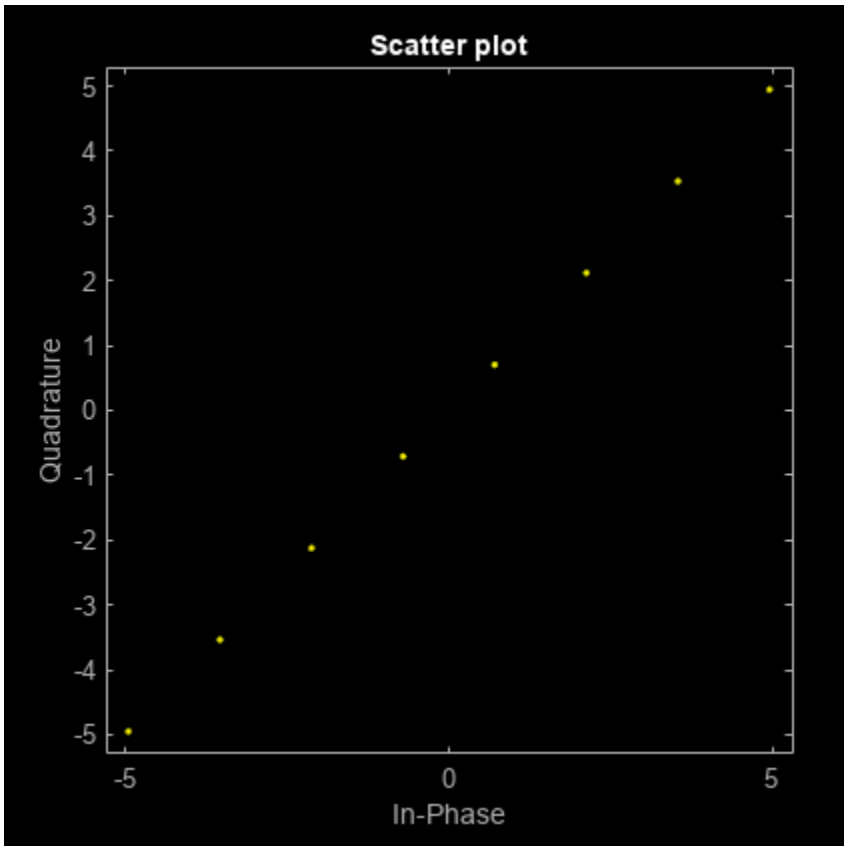
```
M = 8;
```

Generate random integers and apply PAM modulation having an initial phase of $\pi/4$.

```
data = randi([0 M-1],100,1);
modData = pammod(data,M,pi/4);
```

Display the PAM constellation diagram.

```
scatterplot(modData)
```



PAM Symbol Mapping

Plot PAM symbol mapping for Gray and natural binary encoded data.

Set the modulation order, and then create a data sequence containing a complete set of constellation points.

```
M = 8;
data = [0:M-1];
```

Modulate and demodulate Gray and natural binary encoded data.

```
symgray = pammod(data,M,0,'gray');
mapgray = pamdemod(symgray,M,0,'gray');

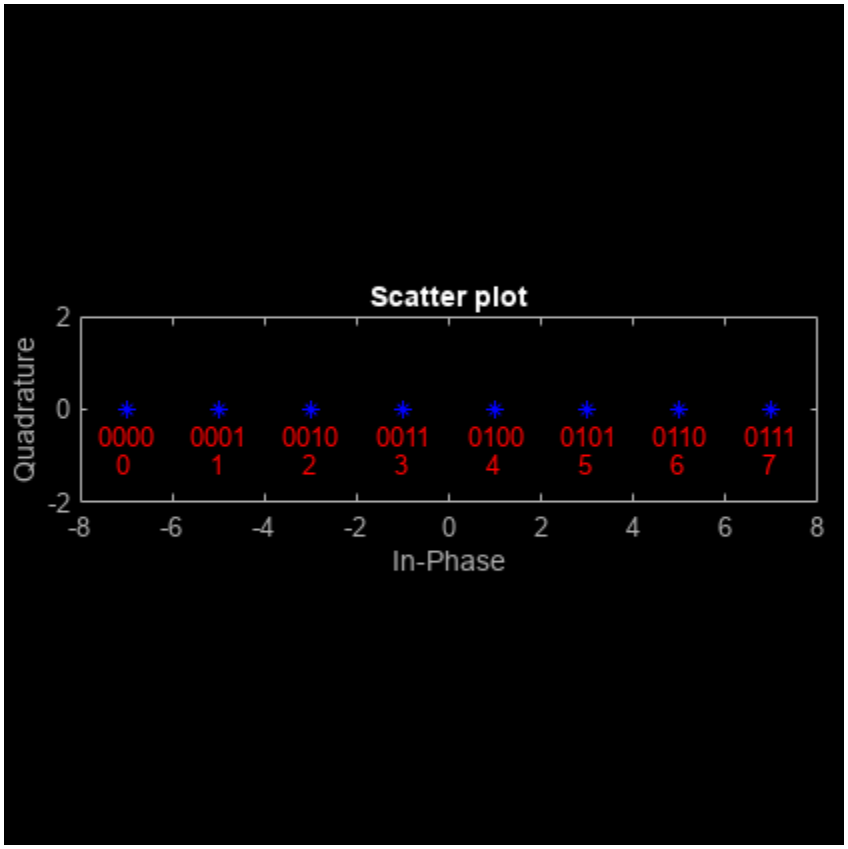
symbin = pammod(data,M,0,'bin');
mapbin = pamdemod(symbin,M,0,'bin');
```

Plot the constellation points using one of the symbol sets. For each constellation point, assign a label indicating the Gray and natural binary values for each symbol.

- For Gray binary symbol mapping, adjacent constellation points differ by a single binary bit and are not numerically sequential.
- For natural binary symbol mapping, adjacent constellation points follow the natural binary encoding and are sequential.

```
scatterplot(symgray,1,0,'b*');
for k = 1:M
    text(real(symgray(k))-0.6,imag(symgray(k))+0.6,...
        dec2base(mapgray(k),2,4));
    text(real(symgray(k))-0.2,imag(symgray(k))+1.2,...
        num2str(mapgray(k)));

    text(real(symbin(k))-0.6,imag(symbin(k))-0.6,...
        dec2base(mapbin(k),2,4),'Color',[1 0 0]);
    text(real(symbin(k))-0.2,imag(symbin(k))-1.2,...
        num2str(mapbin(k)),'Color',[1 0 0]);
end
axis([-M M -2 2])
```



Input Arguments

x — Input signal

vector | matrix

Input signal, specified as a vector or matrix of integers in the range of [0, `M` – 1].

Example: `randi([0 3],100,1)`

Data Types: `double`

M — Modulation order

power of two

Modulation order, specified as a power of two.

Example: 4

Data Types: double

initphase — Initial phase
0 (default) | real-valued scalar | []

Initial phase of the modulated signal (in radians), specified as a real scalar.

Example: pi/4

Data Types: double

symorder — Mapping order for modulation symbols
'bin' (default) | 'gray'

Mapping order for the modulation symbols, specified as 'bin' or 'gray'. This argument specifies how the function assigns binary vectors to corresponding integers.

- If symorder is 'bin', the function uses a natural binary-coded mapping order.
- If symorder is 'gray', the function uses a Gray-coded mapping order.

Data Types: char | string

Output Arguments

y — Complex baseband representation of PAM-modulated signal
vector | matrix

Complex baseband representation of a PAM-modulated signal, returned as vector or matrix of complex values. The modulated signal has a minimum Euclidean distance of 2. The columns of y represent independent channels.

Data Types: double | single

channelDelay

Channel timing delay

Syntax

```
[delay,mag] = channelDelay(pathGains,pathFilters)
```

Description

`[delay,mag] = channelDelay(pathGains,pathFilters)` computes the channel timing delay by finding the peak of the channel impulse response. The function reconstructs the impulse response from a channel path gains array and a path filter impulse response matrix. The function returns the channel timing delay in samples, and the channel impulse response magnitude. For more information, see “Channel Delay and Magnitude Computation” on page 2-619.

Examples

Compute Timing Delay for 2-by-2 MIMO Channel

Configure a 2-by-2 MIMO channel. Use the `info` object function to retrieve the path filters.

```
chan = comm.MIMOChannel('SampleRate',1000,'PathDelays',[0 1.5e-3], ...
    'AveragePathGains',[1 0.8],'RandomStream','mt19937ar with seed', ...
    'Seed',10,'PathGainsOutputPort',true);
chanInfo = info(chan);
pathFilters = chanInfo.ChannelFilterCoefficients;
```

Compute the path gains by passing an impulse through the channel.

```
[~,pathGains] = chan(ones(1,2));
```

Compute the channel timing delay, specifying the retrieved path filters and computed path gains.

```
delay = channelDelay(pathGains,pathFilters)
```

```
delay = 6
```

Show Relative Timing Delay For Rayleigh Channel

Compute and show the relative timing delay for a Rayleigh channel over time.

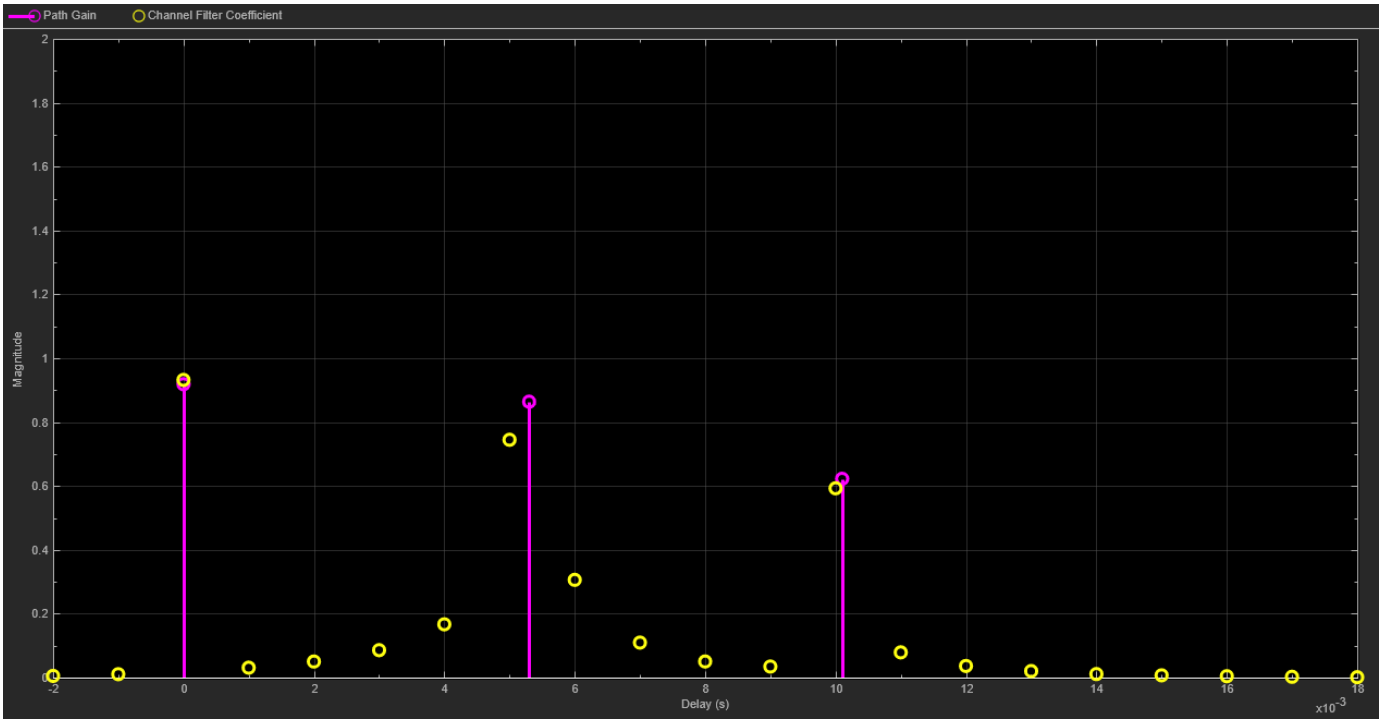
Create a `comm.RayleighChannel` System object™ configured with three paths and impulse response visualization enabled.

```
chan = comm.RayleighChannel;
chan.SampleRate = 1e3;
chan.PathDelays = [0 5.3e-3 10.1e-3];
chan.AveragePathGains = [0.1 1 0.5];
```

```
chan.PathGainsOutputPort = true;
chan.RandomStream = 'mt19937ar with seed';
chan.Seed = 1;
chan.Visualization = 'Impulse response';
chan.MaximumDopplerShift = 1;
```

Use the `info` object function to retrieve the Rayleigh channel path filters. In a loop, pass a static signal of all ones through the Rayleigh channel. The `channelDelay` function uses the channel path gains array from each pass through the channel and the path filter coefficients, `chanInfo.ChannelFilterCoefficients` (returned by the `info` function) to compute the relative channel timing delay. The impulse response varies for each iteration. The impulse response for the last iteration is shown here. The `delay` vector shows the relative channel timing delay computed for each iteration.

```
chanInfo = info(chan);
numIter = 12;
delay = zeros(1,numIter);
for p=1:numIter
    [~,pg] = chan(ones(1e3,1));
    delay(p) = channelDelay(pg,chanInfo.ChannelFilterCoefficients);
end
```



```
delay
```

```
delay = 1×12

    12     7    12     2    12     7    12     7     7     7     2     2
```

Input Arguments

`pathGains` — Channel path gains

4-D array

Channel path gains, specified as an N_{cs}-by-N_p-by-N_t-by-N_r array, where:

- N_{cs} is the number of channel snapshots.
- N_p is the number of paths.
- N_t is the number of transmit antennas.
- N_r is the number of receive antennas.

If any element in `pathGains` is `NaN`, the function assumes that no path exists between the transmitter and the receiver.

Data Types: `double` | `single`
Complex Number Support: Yes

`pathFilters` — Path filter impulse response

matrix

Path filter impulse response, specified as an N_p-by-N_h matrix. N_p is the number of paths, and N_h is the number of impulse response samples.

Data Types: `double` | `single`
Complex Number Support: Yes

Output Arguments

`delay` — Channel timing delay

integer

Channel timing delay in samples, returned as an integer. This value represents the number of samples of delay relative to the first sample of the channel impulse response reconstructed from the `pathGains` and `pathFilters` inputs. The function computes the channel timing delay by finding the peak of the composite channel impulse response. For more information, see “Channel Delay and Magnitude Computation” on page 2-619.

`mag` — Channel impulse response magnitude

matrix

Channel impulse response magnitude for each receive antenna, returned as an N_h-by-N_r matrix. N_h is the number of impulse response samples, and N_r is the number of receive antennas. For more information, see “Channel Delay and Magnitude Computation” on page 2-619.

More About

Channel Delay and Magnitude Computation

The computation of the channel delay and impulse response magnitudes uses the composite channel impulse response.

The composite channel impulse response results from averaging the impulse response across all channel snapshots as represented in the path gains array. The input path gains array must be of the format N_{cs}-by-N_p-by-N_t-by-N_r , where:

- N_{cs} is the number of channel snapshots.
- N_p is the number of paths.
- N_t is the number of transmit antennas.
- N_r is the number of receive antennas.

The channel timing delay, output as a single value, is relative to the first sample of the channel impulse response. The function computes this value by finding the peak of the composite channel impulse response. The composite channel impulse response is the summation of the impulse responses across all transmit and receive antennas.

The receive impulse response magnitudes are output as an N_h-by-N_r matrix. N_h is the number of impulse response samples, and N_r is the number of receive antennas. To compute the receive impulse response magnitudes,

1. Path gains are summed across all channel snapshots.
2. The contribution from each path is added to the channel impulse response across all transmit and receive antennas.
3. The transmit antenna paths are combined in the channel impulse response array, leaving a matrix of impulse response samples versus receive antennas.

plotPhaseNoiseFilter

Plot response of phase noise filter block

Syntax

```
plotPhaseNoiseFilter(blockname)
```

Description

`plotPhaseNoiseFilter(blockname)` plots the response of the phase noise filter associated with the Phase Noise block specified by the variable `blockname`.

Examples

View Filter Response of Phase Noise Block

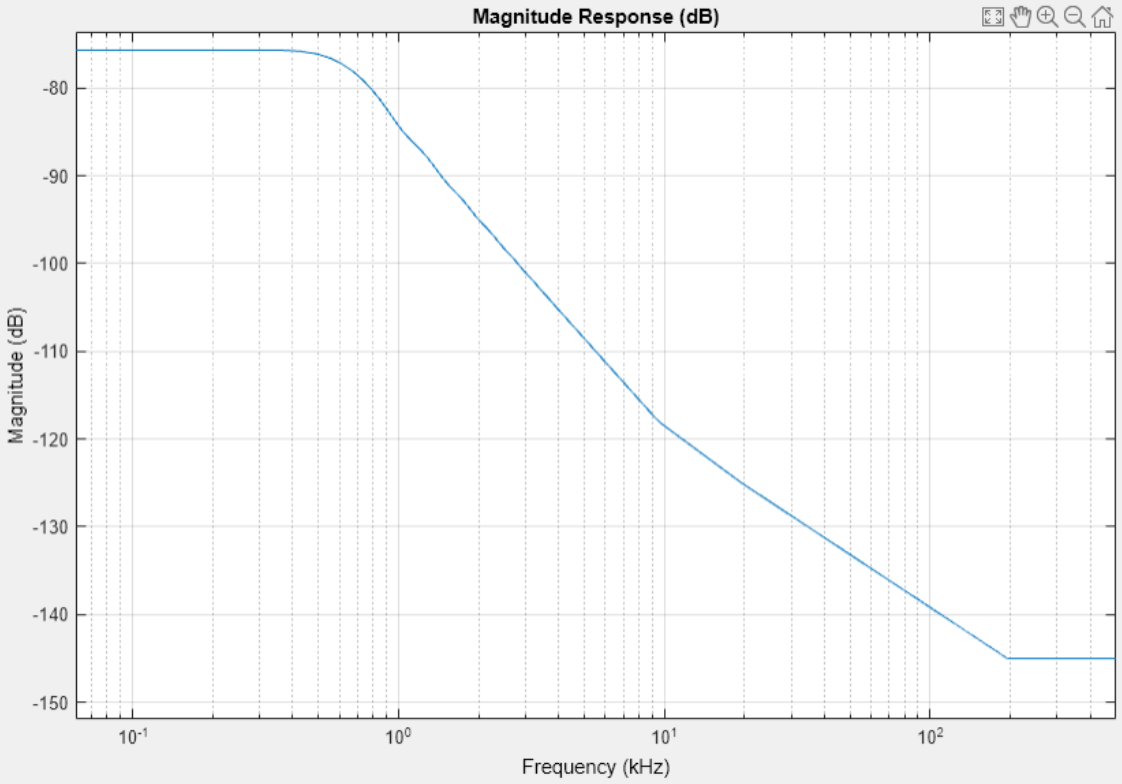
This example shows how to use the `plotPhaseNoiseFilter` function to view the filter response of a Phase Noise block in a Simulink® model.

Load a Simulink model that contains a Phase Noise block. The `load_system` (Simulink) command loads a model into memory without making its model window visible. The function will also work with models whose window is visible. The example, `slex_phasenoise`, contains a `Phase Noise` block.

```
load_system('slex_phasenoise')
```

Run the `plotPhaseNoiseFilter` function to view the filter response of the block Phase Noise.

```
plotPhaseNoiseFilter('slex_phasenoise/Phase Noise')
```



Input Arguments

`blockname` — Phase noise block name

character vector

The name of a Phase Noise block in a Simulink model

Example: `plotPhaseNoiseFilter('Model Name/Phase Noise')`

Data Types: `char`

Version History

Introduced in R2014b

Phase Noise

pmdemod

Phase demodulation

Syntax

```
z = pmdemod(y,Fc,Fs,phasedev)
z = pmdemod(y,Fc,Fs,phasedev,ini_phase)
```

Description

`z = pmdemod(y,Fc,Fs,phasedev)` demodulates the phase-modulated signal `y` at the carrier frequency `Fc` (hertz). `z` and the carrier signal have sampling rate `Fs` (hertz), where `Fs` must be at least `2*Fc`. The `phasedev` argument is the phase deviation of the modulated signal, in radians.

`z = pmdemod(y,Fc,Fs,phasedev,ini_phase)` specifies the initial phase of the modulated signal, in radians.

Examples

Recover Phase Modulated Signal from AWGN Channel

Set the sample rate. To plot the signals, create a time vector.

```
fs = 50;
t = (0:2*fs+1)'/fs;
```

Create a sinusoidal input signal.

```
x = sin(2*pi*t) + sin(4*pi*t);
```

Set the carrier frequency and phase deviation.

```
fc = 10;
phasedev = pi/2;
```

Modulate the input signal.

```
tx = pmmod(x,fc,fs,phasedev);
```

Pass the signal through an AWGN channel.

```
rx = awgn(tx,10,'measured');
```

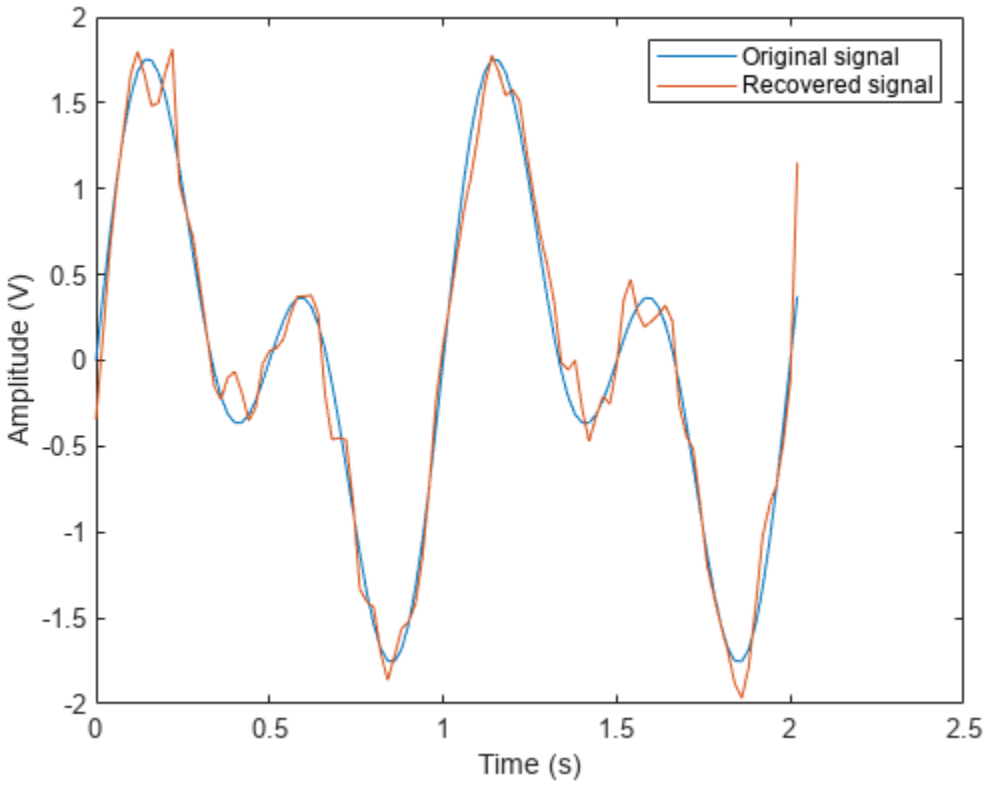
Demodulate the noisy signal.

```
y = pmdemod(rx,fc,fs,phasedev);
```

Plot the original and recovered signals.

```
figure; plot(t,[x y]);
legend('Original signal','Recovered signal');
```

```
xlabel('Time (s)')
ylabel('Amplitude (V)')
```



Version History

Introduced before R2006a

pmmod

Phase modulation

Syntax

```
y = pmmod(x,Fc,Fs,phasedev)
y = pmmod(x,Fc,Fs,phasedev,ini_phase)
```

Description

`y = pmmod(x,Fc,Fs,phasedev)` modulates the message signal `x` using phase modulation.

`y = pmmod(x,Fc,Fs,phasedev,ini_phase)` specifies the initial phase of the modulated signal in radians.

Examples

Recover Phase Modulated Signal from AWGN Channel

Set the sample rate. To plot the signals, create a time vector.

```
fs = 50;
t = (0:2*fs+1)'/fs;
```

Create a sinusoidal input signal.

```
x = sin(2*pi*t) + sin(4*pi*t);
```

Set the carrier frequency and phase deviation.

```
fc = 10;
phasedev = pi/2;
```

Modulate the input signal.

```
tx = pmmod(x,fc,fs,phasedev);
```

Pass the signal through an AWGN channel.

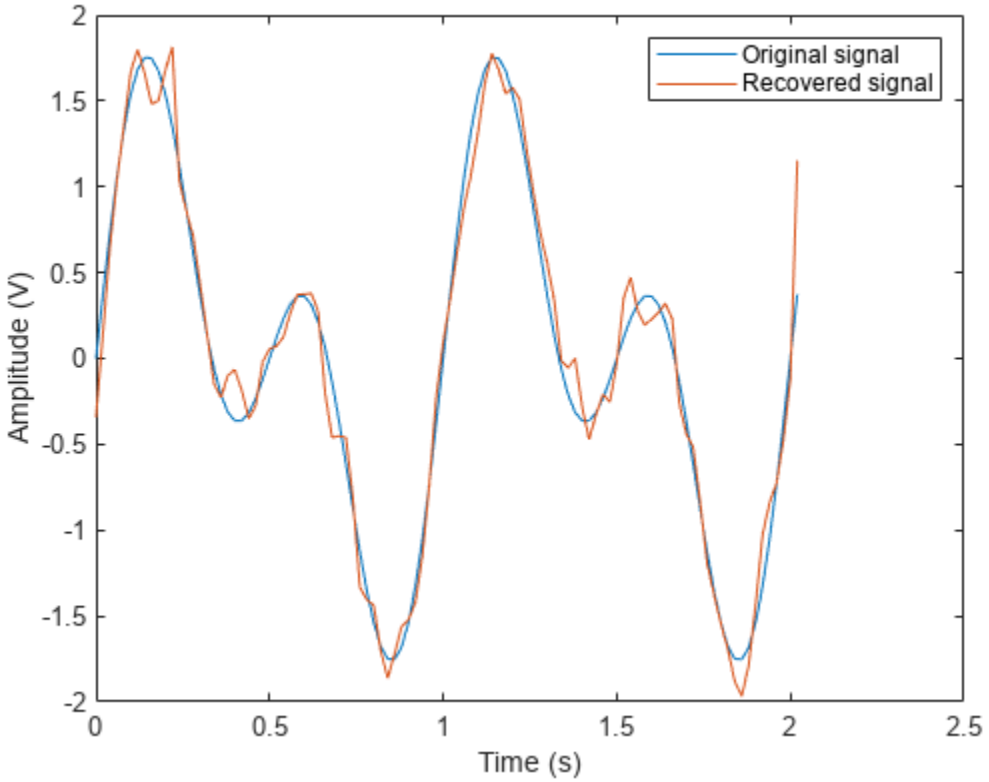
```
rx = awgn(tx,10,'measured');
```

Demodulate the noisy signal.

```
y = pmdemod(rx,fc,fs,phasedev);
```

Plot the original and recovered signals.

```
figure; plot(t,[x y]);
legend('Original signal','Recovered signal');
xlabel('Time (s)')
ylabel('Amplitude (V)')
```



Input Arguments

x — Input signal

vector | matrix

Input signal, specified as a vector or matrix of positive integers. If `x` is a matrix, `pmmod` processes the columns independently.

Example: `sin(2*pi*t) + sin(6*pi*t)`

Data Types: `double`

Fc — Carrier frequency

positive scalar

Carrier frequency, specified as a positive scalar.

Data Types: `double`

Fs — Sample rate

positive scalar

Sample rate, specified as a positive scalar. `Fs` must be at least 2*`Fc`.

Data Types: `double`

`ini_phase` — Initial phase
0 (default) | scalar | `[]`

Initial phase of the modulated signal (in radians), specified as a real scalar.

Example: `pi/4`

Data Types: `double`

`phasedev` — Phase deviation
positive scalar

Phase deviation, specified as a positive scalar in radians.

Data Types: `double`

Output Arguments

`y` — PM-modulated output signal
vector | matrix

Complex baseband representation of a PM-modulated signal, returned as vector or matrix of complex values. The columns of `y` represent independent channels.

Data Types: `double` | `single`

Version History

Introduced before R2006a

poly2trellis

Convert convolutional code polynomials to trellis description

Syntax

```
trellis = poly2trellis(ConstraintLength,CodeGenerator)
trellis = poly2trellis(ConstraintLength,CodeGenerator,FeedbackConnection)
```

Description

`trellis = poly2trellis(ConstraintLength,CodeGenerator)` returns the trellis structure description corresponding to the conversion for a rate *K* / *N* feedforward encoder. *K* is the number of input bit streams to the encoder, and *N* is the number of output connections. `ConstraintLength` specifies the delay for the input bit streams to the encoder. `CodeGenerator` specifies the output connections for the input bit streams to the encoder.

The poly2trellis function accepts a polynomial description of a convolutional encoder and returns the corresponding trellis structure description. This output can be used as an input to the `convenc` and `vitdec` functions. It can also be used as a mask parameter value for the Convolutional Encoder, Viterbi Decoder, and APP Decoder blocks.

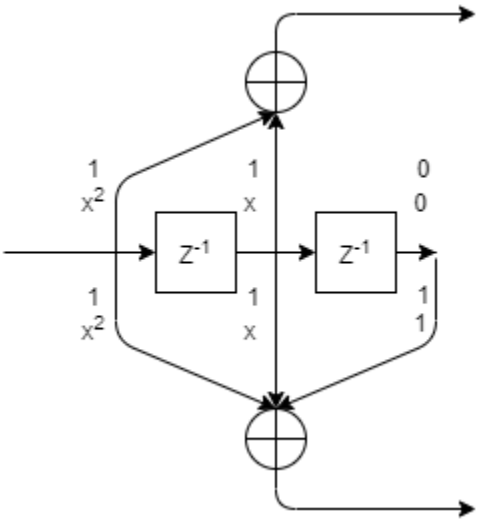
Note When used with a feedback polynomial, poly2trellis makes a feedback connection to the input of the trellis.

`trellis = poly2trellis(ConstraintLength,CodeGenerator,FeedbackConnection)` returns the trellis structure description corresponding to the conversion for a rate *K* / *N* feedback encoder. *K* is the number of input bit streams to the encoder, and *N* is the number of output connections. `ConstraintLength` specifies the delay for the input bit streams to the encoder. `CodeGenerator` specifies the output connections for the input bit streams to the encoder. `FeedbackConnection` specifies the feedback connection for each of the *K* input bit streams to the encoder.

Examples

Use Trellis Structure for Rate 1/2 Feedforward Convolutional Encoder

Use a trellis structure to configure the rate 1/2 feedforward convolutional code in this diagram.



Create a trellis structure, setting the constraint length to 3 and specifying the code generator as a vector of octal values. The diagram indicates the binary values and polynomial form, indicating the left-most bit is the most-significant-bit (MSB). The binary vector [1 1 0] represents octal 6 and corresponds to the upper row of binary digits in the diagram. The binary vector [1 1 1] represents octal 7 and corresponds to the lower row of binary digits in the diagram. These binary digits indicate connections from the outputs of the registers to the two adders in the diagram.

```
trellis = poly2trellis(3,[6 7])
```

```
trellis = struct with fields:
     numInputSymbols: 2
    numOutputSymbols: 4
           numStates: 4
          nextStates: [4x2 double]
             outputs: [4x2 double]
```

Generate random binary data. Convolutionally encode the data, by using the specified trellis structure. Decode the coded data by using the Viterbi algorithm with the specified trellis structure, 34 for its traceback depth, truncated operation mode, and hard decisions.

```
data = randi([0 1],70,1);
codedData = convenc(data,trellis);
tbdepth = 34;
decodedData = vitdec(codedData,trellis,tbdepth,'trunc','hard');
```

Verify the decoded data has zero bit errors.

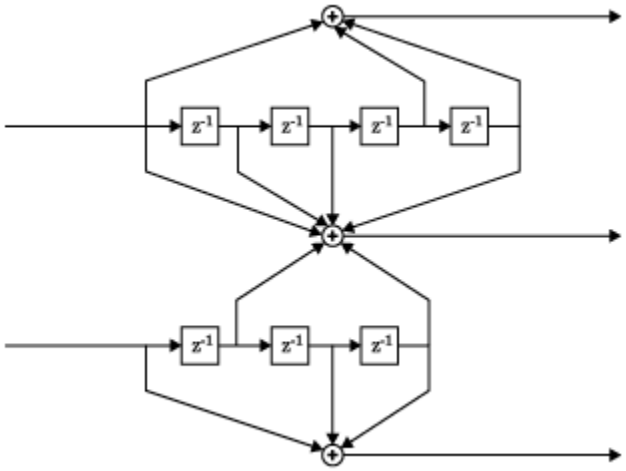
```
biterr(data,decodedData)
```

```
ans = 0
```

Trellis Structure for 2/3 Feedforward Convolutional Encoder

Create a trellis structure for a rate 2/3 feedforward convolutional code and display a portion of the next states of the trellis. See `convenc` for an example using this encoder.

The diagram shows a rate 2/3 encoder with two input streams, three output streams, and seven shift registers.



Create a trellis structure. Set the constraint length of the upper path to 5 and the constraint length of the lower path to 4. The octal representation of the code generator matrix corresponds to the taps from the upper and lower shift registers.

```
trellis = poly2trellis([5 4],[23 35 0; 0 5 13])
```

```
trellis = struct with fields:
     numInputSymbols: 4
    numOutputSymbols: 8
           numStates: 128
          nextStates: [128x4 double]
             outputs: [128x4 double]
```

The structure field `numInputSymbols` equals 4 because two bit streams can produce four different input symbols. The structure field `numOutputSymbols` equals 8 because three bit streams produce eight different output symbols. Because the encoder has seven total shift registers, the number of possible states is $2^7 = 128$, as shown by the `nextStates` field.

Display the first five rows of the 128-by-4 `trellis.nextStates` matrix.

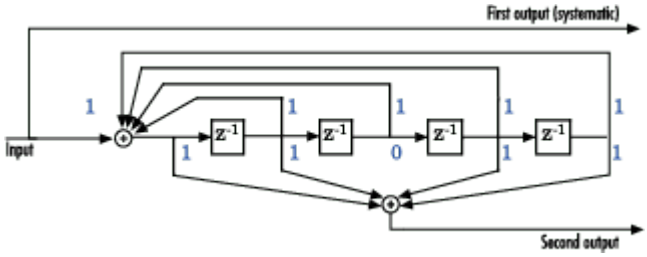
```
trellis.nextStates(1:5,:)
```

```
ans = 5×4

     0    64     8    72
     0    64     8    72
     1    65     9    73
     1    65     9    73
     2    66    10    74
```

Use Trellis Structure for Rate 1/2 Feedback Convolutional Encoder

Create a trellis structure to represent the rate 1/2 systematic convolutional encoder with feedback shown in this diagram.



This encoder has 5 for its constraint length, [37 33] as its generator polynomial matrix, and 37 for its feedback connection polynomial.

The first generator polynomial is octal 37. The second generator polynomial is octal 33. The feedback polynomial is octal 37. The first generator polynomial matches the feedback connection polynomial because the first output corresponds to the systematic bits.

The binary vector [1 1 1 1 1] represents octal 37 and corresponds to the upper row of binary digits in the diagram. The binary vector [1 1 0 1 1] represents octal 33 and corresponds to the lower row of binary digits in the diagram. These binary digits indicate connections from the outputs of the registers to the two adders in the diagram. The initial 1 corresponds to the input bit.

Convert the polynomial to a trellis structure by using the `poly2trellis` function. When used with a feedback polynomial, `poly2trellis` makes a feedback connection to the input of the trellis.

```
trellis = poly2trellis(5,[37 33],37)
```

```
trellis = struct with fields:
     numInputSymbols: 2
    numOutputSymbols: 4
           numStates: 16
          nextStates: [16x2 double]
             outputs: [16x2 double]
```

Generate random binary data. Convolutionally encode the data by using the specified trellis structure. Decode the coded data by using the Viterbi algorithm with the specified trellis structure, 34 for its traceback depth, truncated operation mode, and hard decisions.

```
data = randi([0 1],70,1);
codedData = convenc(data,trellis);
tbdepth = 34; % Traceback depth for Viterbi decoder
decodedData = vitdec(codedData,trellis,tbdepth,'trunc','hard');
```

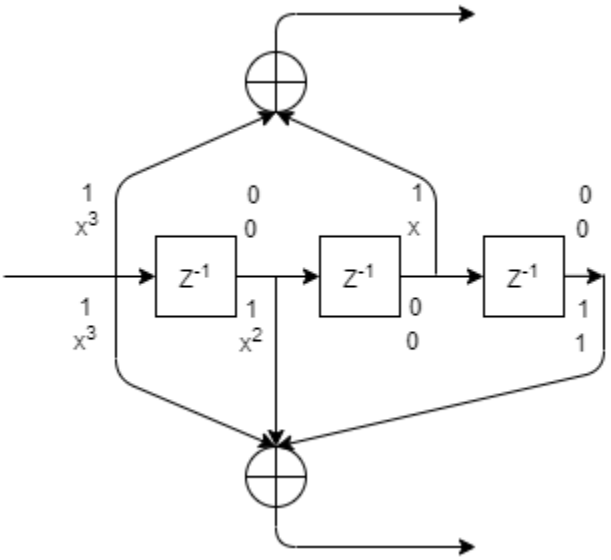
Verify the decoded data has zero bit errors.

```
biterr(data,decodedData)
```

```
ans = 0
```

Specifying Code Generators in Polynomial Form

Demonstrate alternative forms of specifying code generators for a trellis structure are equivalent.



Use a trellis structure to configure the rate 1/2 feedforward convolutional code in this diagram. The diagram indicates the binary values and polynomial form, indicating the left-most bit is the most-significant-bit (MSB).

Set the constraint length to 4. Use a cell array of polynomial character vectors to specify code generators. For more information, see “Representation of Polynomials in Communications Toolbox”. When using character representation to specify the code generator, you can specify the polynomial in ascending or descending order, but the `poly2trellis` function always assigns registers in descending order with the left-most register for the MSB.

```
trellis_poly = poly2trellis(4,{'x3 + x','x3 + x2 + 1'})
```

```
trellis_poly = struct with fields:
     numInputSymbols: 2
    numOutputSymbols: 4
           numStates: 8
          nextStates: [8x2 double]
             outputs: [8x2 double]
```

The binary vector [1 0 1 0] represents octal 12 and corresponds to the upper row of binary digits in the diagram. The binary vector [1 1 0 1] represents octal 15 and corresponds to the lower row of binary digits in the diagram. Use octal representation to specify the code generators for an equivalent trellis structure.

```
trellis = poly2trellis(4,[12 15])
```

```
trellis = struct with fields:
     numInputSymbols: 2
    numOutputSymbols: 4
           numStates: 8
          nextStates: [8x2 double]
```

```
              outputs: [8x2 double]
```

Use `isequal` to confirm the two trellises are equal.

```
isequal(trellis,trellis_poly)
```

```
ans = logical
   1
```

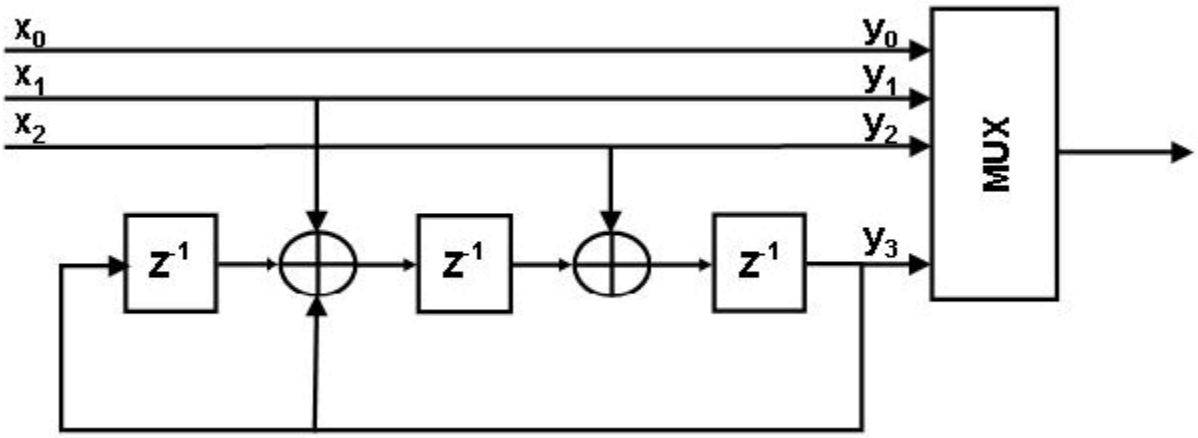
Create User Defined Trellis Structure

This example demonstrates creation of a nonstandard trellis structure for a convolutional encoder with uncoded bits and feedback. The encoder cannot be created using `poly2trellis` because the peculiar specifications for the encoder do not match the input requirements of `poly2trellis`.

You can manually create the trellis structure, and then use it as the input trellis structure for an encoder and decoder. The Convolutional Encoder and Viterbi Decoder blocks used in the "Convolutional Encoder with Uncoded Bits and Feedback" model load the trellis structure created here using a `PreLoadFcn` callback.

Convolutional Encoder

Create a rate 3/4 convolutional encoder with feedback connection whose MSB bit remains uncoded.



Declare variables according to the specifications.

```
K = 3;
N = 4;
constraintLength = 4;
```

Create trellis structure

A trellis is represented by a structure with the following fields:

- `numInputSymbols` – Number of input symbols

- `numOutputSymbols` – Number of output symbols
- `numStates` – Number of states
- `nextStates` – Next state matrix
- `outputs` – Output matrix

For more information about these structure fields, see `istrellis`.

Reset any previous occurrence of `myTrellis` structure.

```
clear myTrellis;
```

Define the trellis structure fields.

```
myTrellis.numInputSymbols = 2^K;
myTrellis.numOutputSymbols = 2^N;
myTrellis.numStates  = 2^(constraintLength-1);
```

Create nextStates Matrix

The `nextStates` matrix is a [`numStates` x `numInputSymbols`] matrix. The (*i*,*j*) element of the next state matrix is the resulting final state index that corresponds to a transition from the initial state *i* for an input equal to *j*.

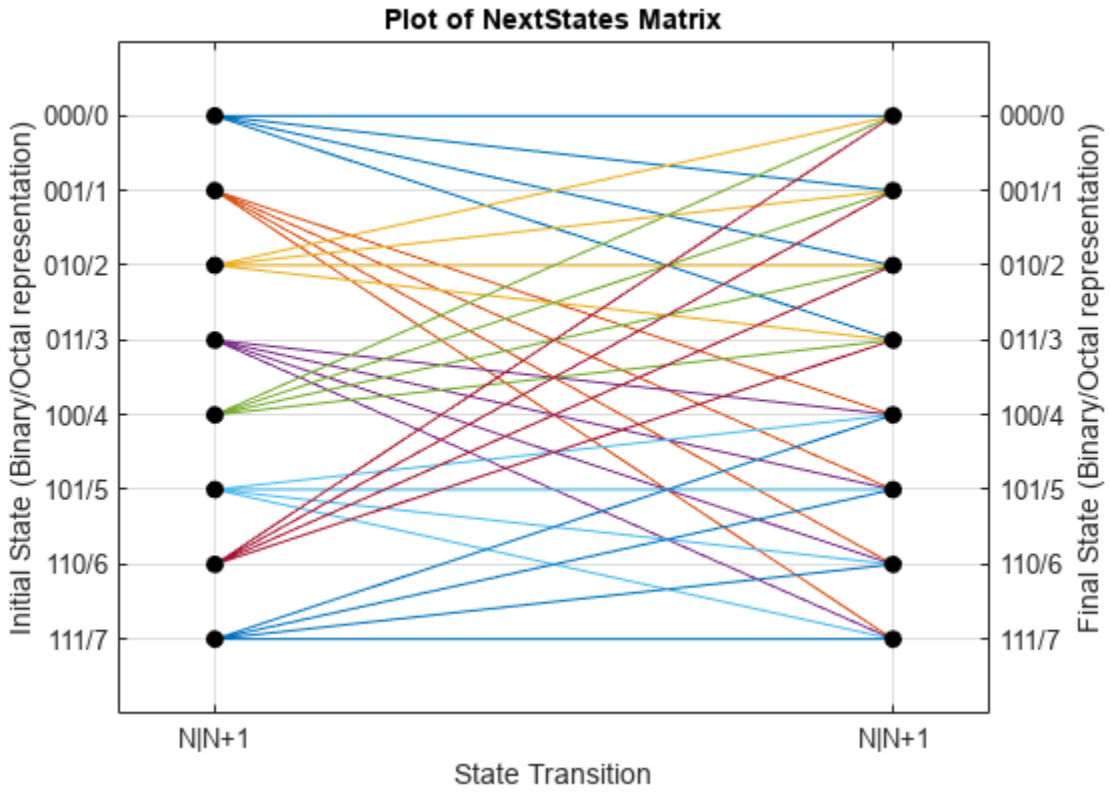
```
myTrellis.nextStates = [0  1  2  3  0  1  2  3; ...
                        6  7  4  5  6  7  4  5; ...
                        1  0  3  2  1  0  3  2; ...
                        7  6  5  4  7  6  5  4; ...
                        2  3  0  1  2  3  0  1; ...
                        4  5  6  7  4  5  6  7; ...
                        3  2  1  0  3  2  1  0; ...
                        5  4  7  6  5  4  7  6]
```

```
myTrellis = struct with fields:
     numInputSymbols: 8
    numOutputSymbols: 16
           numStates: 8
          nextStates: [8x8 double]
```

Plot nextStates Matrix

Use the `commcnv_plotnextstates` helper function to plot the `nextStates` matrix to illustrate the branch transitions between different states for a given input.

```
commcnv_plotnextstates(myTrellis.nextStates);
```



Create `outputs` Matrix

The `outputs` matrix is a [`numStates` x `numInputSymbols`] matrix. The (*i*,*j*) element of the output matrix is the output symbol in octal format given a current state *i* for an input equal to *j*.

```
outputs =  [0  2  4  6  10  12  14  16; ...
            1  3  5  7  11  13  15  17; ...
            0  2  4  6  10  12  14  16; ...
            1  3  5  7  11  13  15  17; ...
            0  2  4  6  10  12  14  16; ...
            1  3  5  7  11  13  15  17; ...
            0  2  4  6  10  12  14  16; ...
            1  3  5  7  11  13  15  17]
```

```
outputs = 8×8

     0     2     4     6    10    12    14    16
     1     3     5     7    11    13    15    17
     0     2     4     6    10    12    14    16
     1     3     5     7    11    13    15    17
     0     2     4     6    10    12    14    16
     1     3     5     7    11    13    15    17
     0     2     4     6    10    12    14    16
     1     3     5     7    11    13    15    17
```

Use `oct2dec` to display these values in decimal format.

```
outputs_dec = oct2dec(outputs)
```

```
outputs_dec = 8×8

     0     2     4     6     8    10    12    14
     1     3     5     7     9    11    13    15
     0     2     4     6     8    10    12    14
     1     3     5     7     9    11    13    15
     0     2     4     6     8    10    12    14
     1     3     5     7     9    11    13    15
     0     2     4     6     8    10    12    14
     1     3     5     7     9    11    13    15
```

Copy outputs matrix into the `myTrellis` structure.

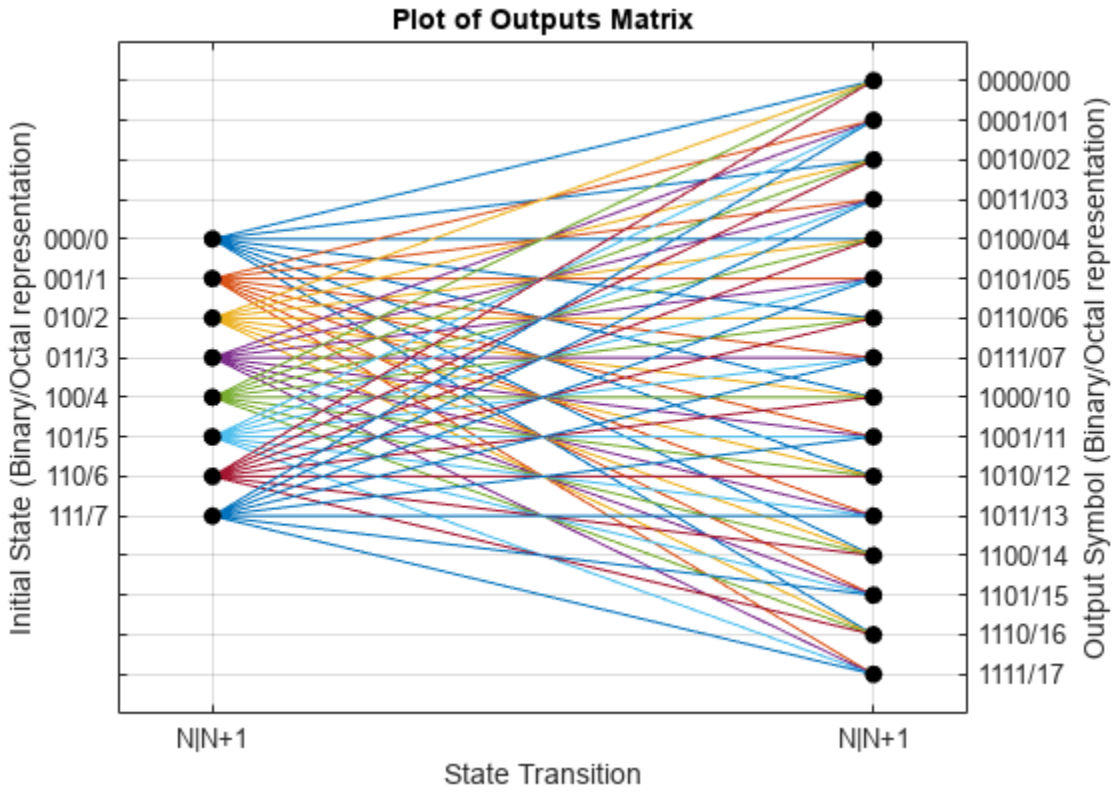
```
myTrellis.outputs = outputs
```

```
myTrellis = struct with fields:
     numInputSymbols: 8
    numOutputSymbols: 16
           numStates: 8
          nextStates: [8x8 double]
             outputs: [8x8 double]
```

Plot `outputs` Matrix

Use the `commcnv_plotoutputs` helper function to plot the `outputs` matrix to illustrate the possible output symbols for a given state depending on the input symbol.

```
commcnv_plotoutputs(myTrellis.outputs, myTrellis.numOutputSymbols);
```



Check Resulting Trellis Structure

```
istrellis(myTrellis)
```

```
ans = logical
   1
```

A return value of 1 confirms the trellis structure is valid.

Implement Soft-Decision Decoding

Decode with 3-bit soft decisions partitioned so that values near 0 map to 0, and values near 1 map to 7. If your application requires better decoding performance, refine the partition to obtain finer quantization.

The example decodes the code and computes the bit error rate. When comparing the decoded data with the original message, the example must take the decoding delay into account. The continuous operation mode of the Viterbi decoder causes a delay equal to the traceback length, so `msg(1)` corresponds to `decoded(tblen+1)` rather than to `decoded(1)`.

System Setup

Initialize runtime variables for the message data, trellis, bit error rate computations, and traceback length.

```
stream = RandStream.create('mt19937ar', 'seed',94384);
prevStream = RandStream.setGlobalStream(stream);
msg = randi([0 1],4000,1); % Random data

trellis = poly2trellis(7,[171 133]); % Define trellis

ber = zeros(3,1); % Store BER values
tblen = 48; % Traceback length
```

Create an AWGN channel System object™, a Viterbi decoder System object, and an error rate calculator System object. Account for the receive delay caused by the traceback length of the Viterbi decoder.

```
awgnChan = comm.AWGNChannel('NoiseMethod','Signal to noise ratio (SNR)','SNR',6);
vitDec = comm.ViterbiDecoder(trellis,'InputFormat','Soft', ...
    'SoftInputWordLength',3,'TracebackDepth',tblen,'TerminationMethod','Continuous');
errorCalc = comm.ErrorRate('ReceiveDelay', tblen);
```

Run Coding and Decoding

Convolutionally code the message, pass in through an AWGN filter, quantize the noisy message for soft-decision decoding. Perform Viterbi decoding using the trellis generated using `poly2trellis`.

```
code = convenc(msg,trellis);
awgnChan.SignalPower = (code'*code)/length(code);
ncode = awgnChan(code);
```

Use `quantiz` to map the noisy data values to appropriate decision-value integers between 0 and 7. The second argument in `quantiz` is a partition vector that determines which data values map to 0, 1, 2, etc.

```
qcode = quantiz(ncode,[0.001,0.1,0.3,0.5,0.7,0.9,0.999]);
decoded = vitDec(qcode);
```

Compute bit error rate.

```
ber = errorCalc(msg,decoded);
ratio = ber(1)
```

```
ratio = 0.0013
```

```
number = ber(2)
```

```
number = 5
```

```
RandStream.setGlobalStream(prevStream);
```

Input Arguments

`ConstraintLength` — Constraint length

row vector

Constraint length, specified as a 1-by-*K* row vector defining the delay for each of the *K* input bit streams to the encoder.

Data Types: `double`

`CodeGenerator` — Code generator

matrix | cell array of character vector | string array

Code generator, specified as a *K*-by-*N* matrix of octal numbers, a *K*-by-*N* cell array of polynomial character vectors, or a *K*-by-*N* string array. `CodeGenerator` specifies the *N* output connections for each of the *K* input bit streams to the encoder.

When using character representation to specify the code generator, you can specify the polynomial in ascending or descending order, but the `poly2trellis` function always assigns registers in descending order with the left-most register for the most-significant-bit (MSB). For more information, see “Specifying Code Generators in Polynomial Form” on page 2-631.

Data Types: `double` | `char` | `string`

`FeedbackConnection` — Feedback connection

row vector

Feedback connection, specified as a 1-by-*K* row vector of octal numbers defining the feedback connection for each of the *K* input bit streams to the encoder.

Data Types: `double`

Output Arguments

`trellis` — Trellis description

structure

Trellis description, returned as a structure with these fields. For more about this structure, see the `istrellis` function.

Trellis Structure Fields for Rate K/N Code

`numInputSymbols` — Number of input symbols

scalar

Number of input symbols, returned as a scalar with a value of 2^K. This value represents the number of input symbols to the encoder and *K* represents the number of input bit streams.

`numOutputSymbols` — Number of output symbols

scalar

Number of output symbols, returned as a scalar with a value of 2^N. This value represents the number of output symbols from the encoder and *N* represents the number of output bit streams.

`numStates` — Number of states

scalar

Number of states in the encoder, returned as a scalar.

`nextStates` — Next states

matrix

Next states for all combinations of current states and current inputs, returned as a `numStates`-by-2^K matrix, where *K* represents the number of input bit streams.

`outputs` — Outputs
matrix

Outputs for all combinations of current states and current inputs, returned as a `numStates`-by-2^K matrix, K represents the number of input bit streams. The elements of this matrix are octal numbers.

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Inputs must be constants, of which there can be at most 3 (`ConstraintLength`, `CodeGenerator`, `FeedbackConnection`).

Topics

“Convolutional Codes”
“Representation of Polynomials in Communications Toolbox”

primpoly

Find primitive polynomials for Galois field

Syntax

```
pr = primpoly(m)
pr = primpoly(m,opt)
pr = primpoly(m...,'nodisplay')
```

Description

`pr = primpoly(m)` returns the primitive polynomial for GF(2^m), where `m` is an integer between 2 and 16. The Command Window displays the polynomial using "D" as an indeterminate quantity. The output argument `pr` is an integer whose binary representation indicates the coefficients of the polynomial.

`pr = primpoly(m,opt)` returns one or more primitive polynomials for GF(2^m). The output `pol` depends on the argument *`opt`* as shown in the table below. Each element of the output argument `pr` is an integer whose binary representation indicates the coefficients of the corresponding polynomial. If no primitive polynomial satisfies the constraints, `pr` is empty.

opt	Meaning of pr
`'min'`	One primitive polynomial for GF(2^m) having the smallest possible number of nonzero terms
`'max'`	One primitive polynomial for GF(2^m) having the greatest possible number of nonzero terms
`'all'`	All primitive polynomials for GF(2^m)
Positive integer k	All primitive polynomials for GF(2^m) that have k nonzero terms

`pr = primpoly(m...,'nodisplay')` prevents the function from displaying the result as polynomials in "D" in the Command Window. The output argument `pr` is unaffected by the `'nodisplay'` option.

Examples

The first example below illustrates the formats that `primpoly` uses in the Command Window and in the output argument `pr`. The subsequent examples illustrate the display options and the use of the *`opt`* argument.

```
pr = primpoly(4)

pr1 = primpoly(5,'max','nodisplay')

pr2 = primpoly(5,'min')

pr3 = primpoly(5,2)

pr4 = primpoly(5,3);
```

The output is below.

```
Primitive polynomial(s) =

D^4+D^1+1

pr =

    19

pr1 =

    61

Primitive polynomial(s) =

D^5+D^2+1

pr2 =

    37

No primitive polynomial satisfies the given constraints.

pr3 =

     []

Primitive polynomial(s) =

D^5+D^2+1
D^5+D^3+1
```

pskdemod

Demodulate using M-ary PSK method

Syntax

```
z = pskdemod(y,M)
z = pskdemod(y,M,phaseoffset)
z = pskdemod(y,M,phaseoffset,symorder)
z = pskdemod(y,M,Name=Value)
```

Description

`z = pskdemod(y,M)` demodulates the input M-PSK signals `y`. `M` specifies the modulation order.

`z = pskdemod(y,M,phaseoffset)` specifies the phase offset of the M-PSK constellation.

`z = pskdemod(y,M,phaseoffset,symorder)` specifies the symbol order of the M-PSK constellation.

`z = pskdemod(y,M,Name=Value)` specifies options using name-value arguments.

Examples

Compare Phase Noise Effects on PSK and PAM Signals

Compare PSK and PAM modulation schemes to demonstrate that PSK is more sensitive to phase noise. PSK is more sensitive to phase noise because the PSK constellation is circular, while the PAM constellation is linear.

Specify the number of symbols and the modulation order parameters. Generate random data symbols.

```
len = 10000;
M = 16;
msg = randi([0 M-1],len,1);
```

Create a phase noise System object™ and show the configured settings.

```
phasenoise = comm.PhaseNoise(Level=[-70 -80])
```

```
phasenoise =
  comm.PhaseNoise with properties:

             Level: [-70 -80]
    FrequencyOffset: [2000 20000]
         SampleRate: 1000000
       RandomStream: 'Global stream'
```

Modulate `msg` using both PSK and PAM to compare the two methods.

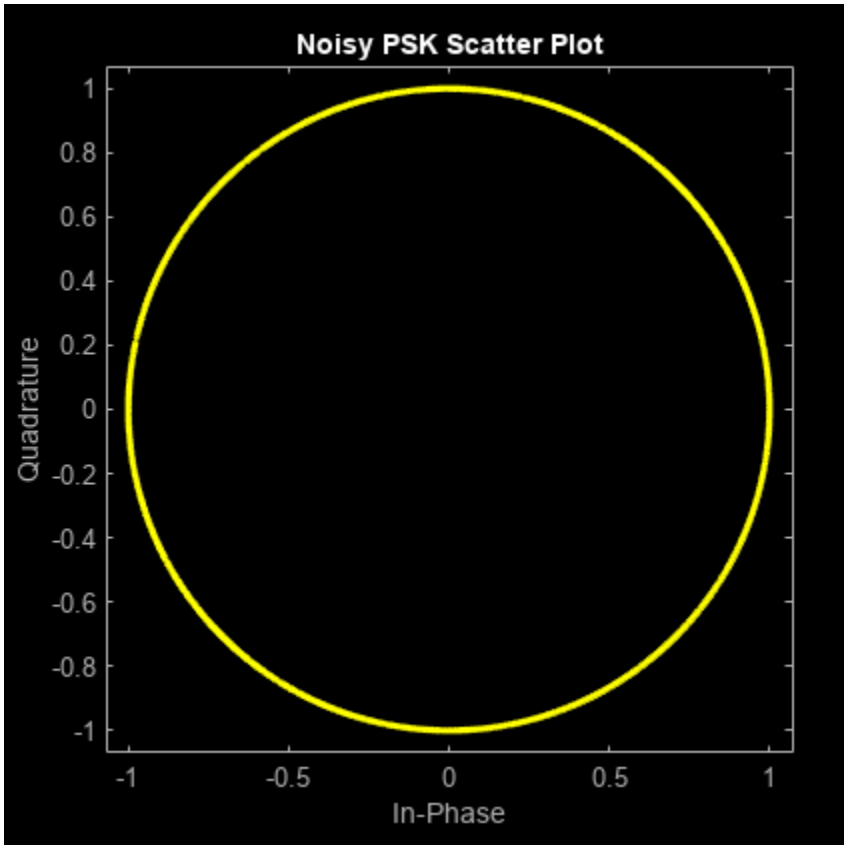
```
txpsk = pskmod(msg,M);
txpam = pammod(msg,M);
```

Perturb the phase of the modulated signals.

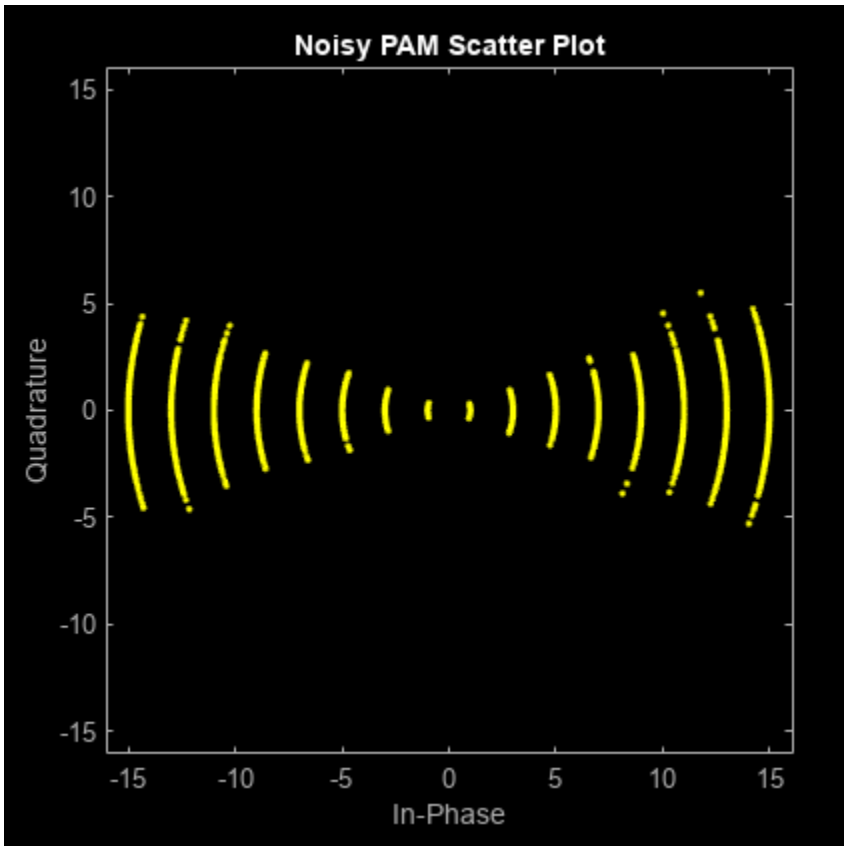
```
rxpsk = phasenoise(txpsk);
rxpam = phasenoise(txpam);
```

Create scatter plots of the received signals.

```
scatterplot(rxpsk);
title('Noisy PSK Scatter Plot')
```



```
scatterplot(rxpam);
title('Noisy PAM Scatter Plot')
```



Demodulate the received signals.

```
recovpsk = pskdemod(rxpsk,M);
recovpam = pamdemod(rxpam,M);
```

Compute the number of symbol errors for each modulation scheme. The PSK signal experiences a much greater number of symbol errors.

```
numerrs_psk = symerr(msg,recovpsk);
numerrs_pam = symerr(msg,recovpam);
[numerrs_psk numerrs_pam]
```

```
ans = 1×2

   286     1
```

Modulate and Demodulate QPSK Signal in AWGN

Generate random symbols.

```
dataIn = randi([0 3],1000,1);
```

QPSK modulate the data.

```
txSig = pskmod(dataIn,4,pi/4);
```

Pass the signal through an AWGN channel.

```
rxSig = awgn(txSig,10);
```

Demodulate the received signal and compute the number of symbol errors.

```
dataOut = pskdemod(rxSig,4,pi/4);
numErrs = symerr(dataIn,dataOut)
```

```
numErrs = 2
```

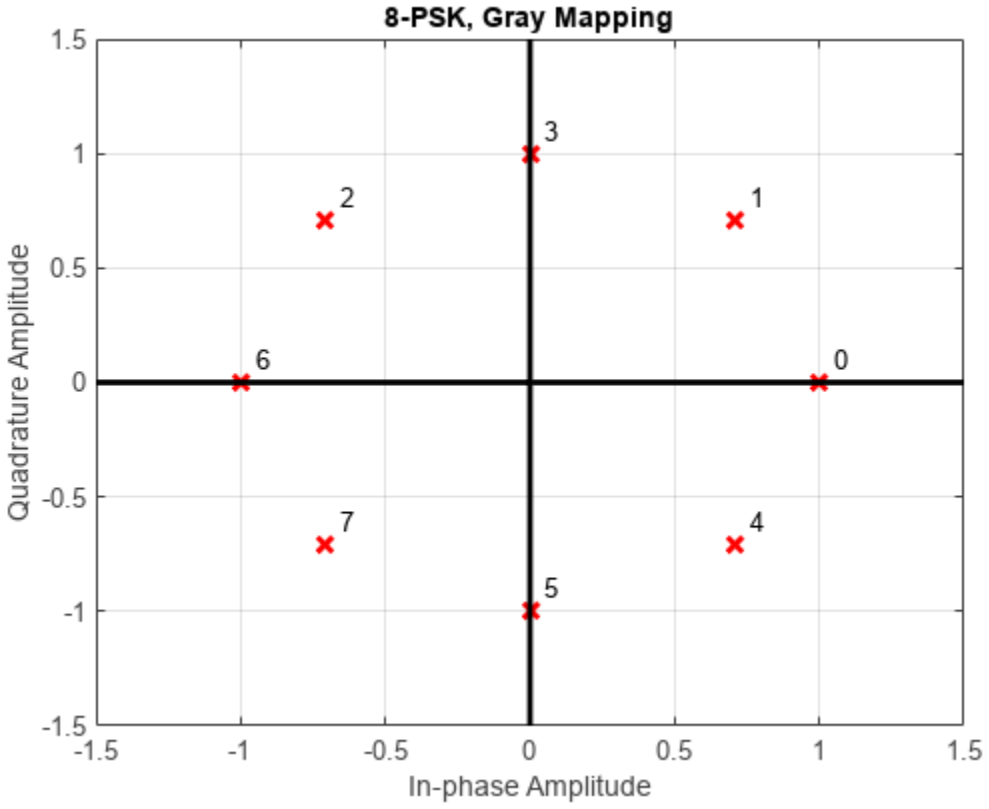
PSK Symbol Mapping

Set the modulation order, then create a data sequence containing a complete set of constellation points.

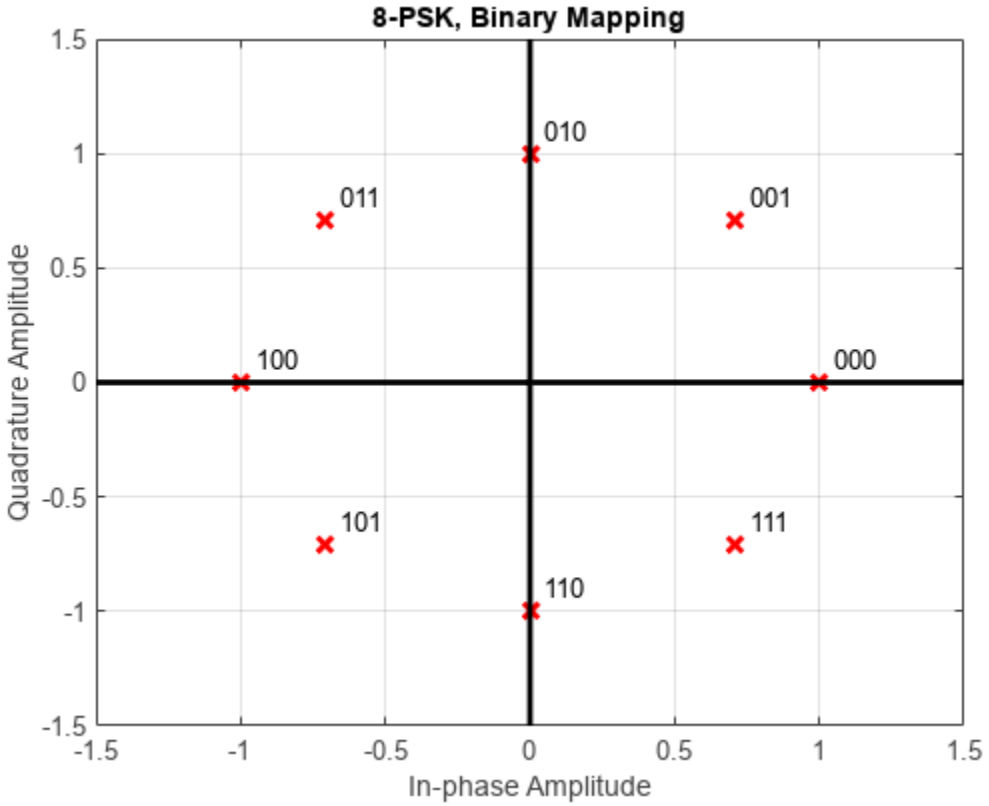
```
M = 8;
data = (0:M-1);
phaseoffset = 0;
```

Visualize the plot constellations of 8-PSK symbol mapping for modulated and demodulated gray and natural binary encoded data.

```
symgray = pskmod(data,M,phaseoffset,'gray',PlotConstellation=true, ...
          InputType='integer');
```



```
mapgray = pskdemod(symgray,M,phaseoffset,'gray',OutputType='integer');
symbin = pskmod(data,M,phaseoffset,'bin');
mapbin = pskdemod(symbin,M,phaseoffset,'bin',PlotConstellation=true, ...
         OutputType='bit');
```



Input Arguments

y — M-PSK modulated input signal

scalar | vector | matrix

M-PSK modulated input signal, specified as a scalar, vector, or matrix. If `y` is a matrix, the function processes the columns independently.

Data Types: `double` | `single`
Complex Number Support: Yes

M — Modulation order

integer value greater than 1

Modulation order, specified as an integer value greater than 1.

Data Types: `double`

phaseoffset — Phase offset

`0` (default) | scalar

Phase offset of the PSK constellation in radians, specified as a scalar.

Data Types: `double`

`symorder` — Symbol order

`'gray'` (default) | `'bin'` | vector

Symbol order, specified as `'gray'`, `'bin'` or a vector. This argument specifies how the function assigns binary vectors to corresponding integers.

- `'gray'` — Use a Gray-coded ordering.
- `'bin'` — Use a natural binary-coded ordering.
- vector –– Use custom symbol ordering. The vector is of length `M` containing unique values in the range [0, `M`– 1]. The first element correlates to the constellation point corresponding to angle `phaseoffset`, with subsequent elements running counter-clockwise.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `y = pskdemod(x,M,phaseoffset,symorder,OutputType='bit')`

`OutputType` — Type of output

`'integer'` (default) | `'bit'` | `'llr'` | `'approxllr'`

Type of output, specified as `'integer'`, `'bit'`, `'llr'`, or `'approxllr'`.

`OutputDataType` — Data type of the output

`'double'` | `'single'` | ...

Output data type, specified as one of the following:

`OutputType` Value	Acceptable `OutputDataType` Values
`'integer'`	`'double'`, `'single'`, `'int8'`, `'int16'`, `'int32'`, `'uint8'`, `'uint16'`, or `'uint32'`
`'bit'`	`'double'`, `'single'`, `'int8'`, `'int16'`, `'int32'`, `'uint8'`, `'uint16'`, `'uint32'`, or `'logical'`

The default value is the data type of input `y`.

Dependencies

To enable this argument, set the `OutputType` argument to either `'integer'` or `'bit'`. Otherwise, the output data type is same as the input data type `y`.

`NoiseVariance` — Noise variance

1 (default) | positive scalar | vector of positive values

Noise variance, specified as one of these options:

- Positive scalar — Use the same noise variance value on all input elements.
- Vector of positive values — Use noise variance for all the elements of the input along the corresponding last dimension, specified by each element of the vector. The vector length must be equal to the number of elements in the last dimension of the input signal.

Tip The exact LLR algorithm computes exponentials using finite precision arithmetic. For computations involving very large positive or negative magnitudes, the exact LLR algorithm yields:

- `Inf` or `-Inf` if the noise variance is a very large value
- `NaN` if the noise variance and signal power are both very small values

The approximate LLR algorithm does not compute exponentials. You can avoid `Inf`, `-Inf`, and `NaN` results by using the approximate LLR algorithm.

Dependencies

To enable this argument, set the `OutputType` argument to either `'llr'` or `'approxllr'`.

Data Types: `double`

`PlotConstellation` — Option to plot constellation

`false` or `0` (default) | `true` or `1`

Option to plot constellation, specified as logical `0` (`false`) or `1` (`true`). To plot the PSK constellation, set `'PlotConstellation'` to `true`.

Output Arguments

`z` — M-PSK demodulated output signal

scalar | vector | matrix

M-PSK demodulated output signal, returned as a scalar, vector or matrix with the same number of columns as the input signal `y`. The value and dimension of this output vary depending on the specified `'OutputType'` value, as shown in this table.

`'OutputType'`	`pskdemod` Output Value	Dimensions of Output
`'integer'`	Demodulated integer values in the range [0, `M` – 1]	`z` has the same dimensions as the input `y`.
`'bit'`	Demodulated bits	The number of rows in `z` is $\log_2(M)$ times the number of rows in `y`. The function maps each demodulated symbol to a group of $\log_2(M)$ bits, where the first bit represents the most significant bit (MSB) and the last bit represents the least significant bit (LSB).
`'llr'`	Log-likelihood ratio value for each bit calculated using the exact log-likelihood algorithm. For details, see “Exact LLR Algorithm”.	

'OutputType'	pskdemod Output Value	Dimensions of Output
'approxllr'	Approximate log-likelihood ratio value for each bit. The values are calculated using the approximate log-likelihood algorithm. For details, see "Approximate LLR Algorithm".	

Version History

Introduced before R2006a

New enhancements to the function

You can now:

- Specify a binary output using the `OutputType` argument.
- Specify custom symbol mapping using the `symorder` argument. The default now is `'gray'` symbol mapping.
- Perform soft-decision demodulation by using the bit-wise log-likelihood or approximate log-likelihood algorithm
- Specify all built-in numeric data types using the `OutputDataType` argument.
- Visualize the reference constellation using the `PlotConstellation` argument.

Topics

"Phase Modulation"
"Hard- vs. Soft-Decision Demodulation"

pskmod

Modulate signal using M-PSK method

Syntax

```
y = pskmod(x,M)
y = pskmod(x,M,phaseoffset)
y = pskmod(x,M,phaseoffset,symorder)
y = pskmod(x,M,Name=Value)
```

Description

`y = pskmod(x,M)` modulates the input signal `x` using the M-Ary phase shift keying (M-PSK) method. `M` specifies the modulation order.

`y = pskmod(x,M,phaseoffset)` specifies the phase offset of the M-PSK constellation.

`y = pskmod(x,M,phaseoffset,symorder)` specifies the symbol order of the M-PSK constellation.

`y = pskmod(x,M,Name=Value)` specifies options using name-value arguments.

Examples

Modulate PSK Signal

Modulate and plot the constellations of QPSK and 16-PSK signals.

QPSK

Set the modulation order to 4.

```
M = 4;
```

Generate random data symbols.

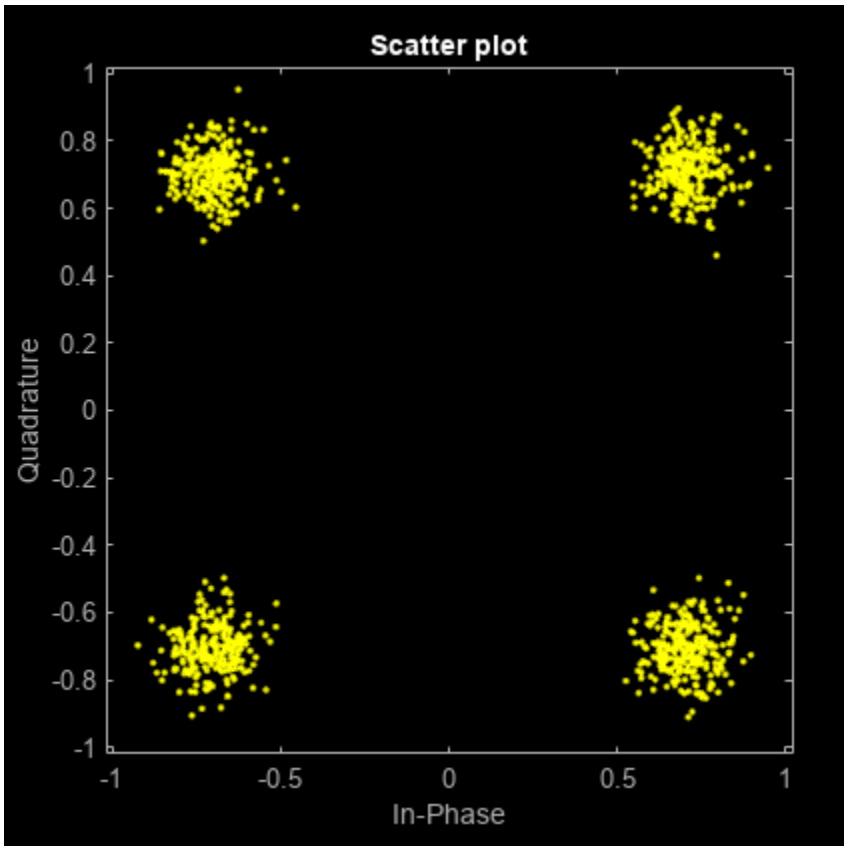
```
data = randi([0 M-1],1000,1);
```

Modulate the data symbols.

```
txSig = pskmod(data,M,pi/M);
```

Pass the signal through white noise and plot its constellation.

```
rxSig = awgn(txSig,20);
scatterplot(rxSig)
```



16-PSK

Change the modulation order from 4 to 16.

```
M = 16;
```

Generate random data symbols.

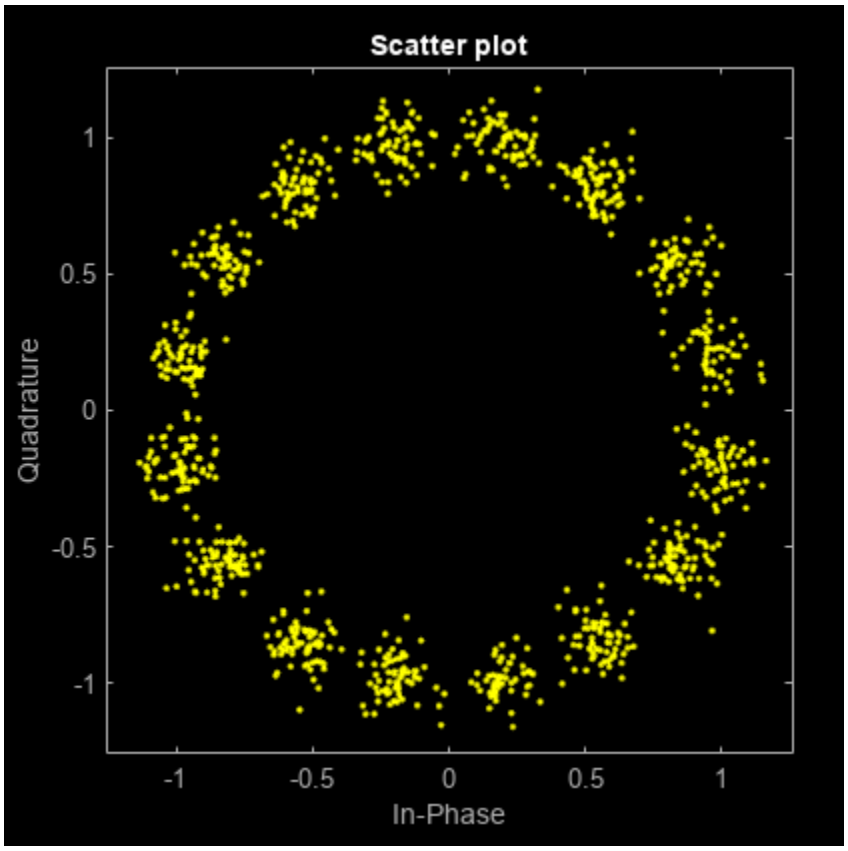
```
data = randi([0 M-1],1000,1);
```

Modulate the data symbols.

```
txSig = pskmod(data,M,pi/M);
```

Pass the signal through white noise and plot its constellation.

```
rxSig = awgn(txSig,20);
scatterplot(rxSig)
```



Modulate and Demodulate QPSK Signal in AWGN

Generate random symbols.

```
dataIn = randi([0 3],1000,1);
```

QPSK modulate the data.

```
txSig = pskmod(dataIn,4,pi/4);
```

Pass the signal through an AWGN channel.

```
rxSig = awgn(txSig,10);
```

Demodulate the received signal and compute the number of symbol errors.

```
dataOut = pskdemod(rxSig,4,pi/4);
numErrs = symerr(dataIn,dataOut)
```

```
numErrs = 2
```

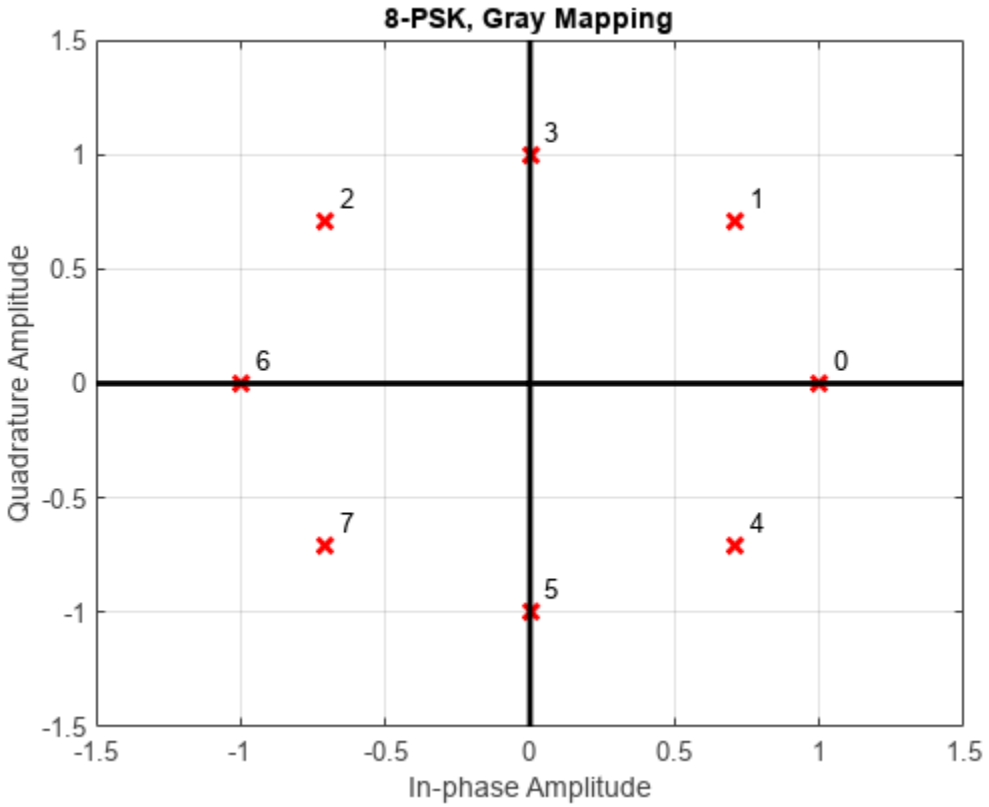
PSK Symbol Mapping

Set the modulation order, then create a data sequence containing a complete set of constellation points.

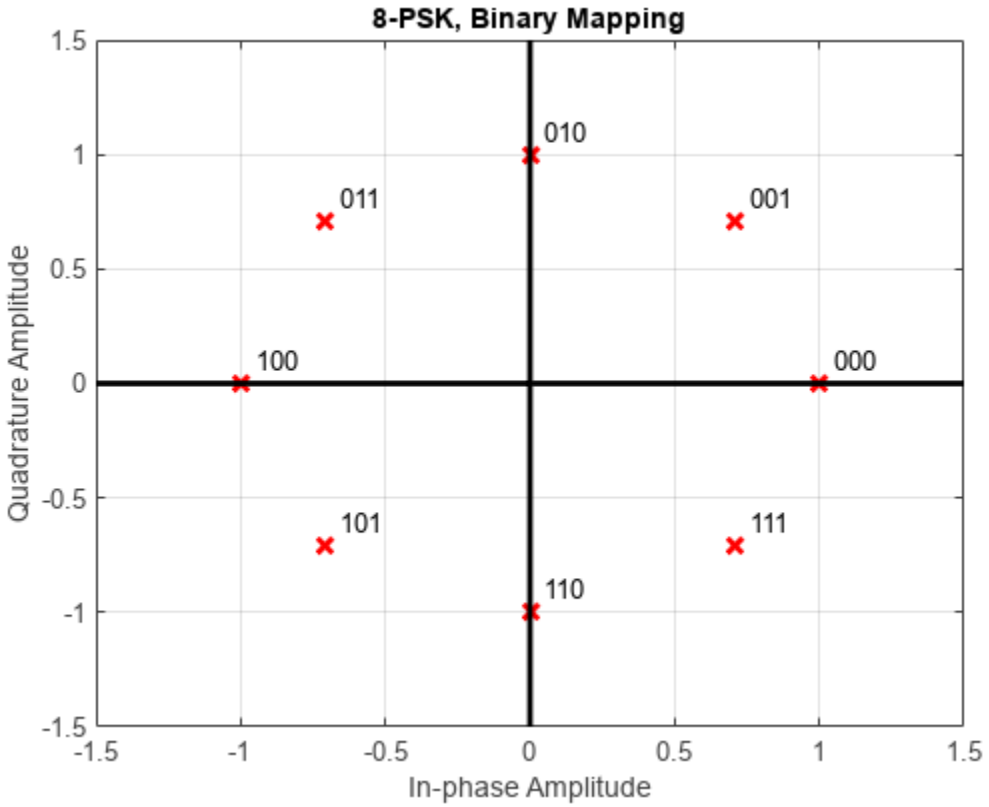
```
M = 8;
data = (0:M-1);
phaseoffset = 0;
```

Visualize the plot constellations of 8-PSK symbol mapping for modulated and demodulated gray and natural binary encoded data.

```
symgray = pskmod(data,M,phaseoffset,'gray',PlotConstellation=true, ...
          InputType='integer');
```



```
mapgray = pskdemod(symgray,M,phaseoffset,'gray',OutputType='integer');
symbin = pskmod(data,M,phaseoffset,'bin');
mapbin = pskdemod(symbin,M,phaseoffset,'bin',PlotConstellation=true, ...
         OutputType='bit');
```



Input Arguments

`x` — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix of positive integers. The elements of `x` must have binary or integer values in the range [0, `M`–1], where `M` is the modulation order.

Note To process an input signal as binary elements, set the `InputType` name-value argument to `'bit'`. For binary inputs, the number of rows must be an integer multiple of $\log_2(M)$. The function maps groups of $\log_2(M)$ bits are mapped onto a symbol, with the first bit representing the MSB and the last bit representing the LSB.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

`M` — Modulation order

integer value greater than 1

Modulation order, specified as an integer value greater than 1.

Data Types: `double`

`phaseoffset` — Phase offset

`0` (default) | scalar

Phase offset of the PSK constellation in radians, specified as a scalar.

Data Types: `double`

`symorder` — Symbol order
`'gray'` (default) | `'bin'` | vector

Symbol order, specified as `'gray'`, `'bin'`, or a vector. This argument specifies how the function assigns binary vectors to corresponding integers.

- `'gray'` — Use a Gray-coded ordering.
- `'bin'` — Use a natural binary-coded ordering.
- vector –– Use custom symbol ordering. The vector is of length `M` containing unique values in the range [0, `M`– 1]. The first element correlates to the constellation point corresponding to angle `phaseoffset`, with subsequent elements running counter-clockwise.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `y = pskmod(x,M,phaseoffset,symorder,InputType='bit')`

`InputType` — Input type
`'integer'` (default) | `'bit'`

Input type, specified as either `'integer'` or `'bit'`.

- `'integer'` –– Input signal consists of integers in the range [0, `M`–1].
- `'bit'` –– Input signal consists of binary values and the number of rows must be an integer multiple of $\log_2(M)$.

`OutputDataType` — Output data type
`'double'` (default) | `'single'`

Output data type, specified as either `'double'` or `'single'`.

`PlotConstellation` — Option to plot constellation
`false` or `0` (default) | `true` or `1`

Option to plot constellation, specified as logical `0` (`false`) or `1` (`true`). To plot the PSK constellation, set `'PlotConstellation'` to `true`.

Output Arguments

`y` — M-PSK modulated baseband signal
scalar | vector | matrix

M-PSK modulated baseband signal, returned as a scalar, vector or matrix of complex values. The columns of `y` represent independent channels. For integer inputs, the output `y` has the same dimensions as the input signal `x`. For bit inputs, the number of rows in `y` is the number of rows in `x` divided by $\log_2(M)$.

Version History

Introduced before R2006a

New enhancements to the function

You can now:

- Specify a binary input using the `InputType` argument.
- Specify custom symbol mapping using the `symorder` argument. The default now is `'gray'` symbol mapping.
- Perform soft-decision demodulation by using the bit-wise log-likelihood or approximate log-likelihood algorithm
- Specify all built-in numeric data types using the `OutputDataType` argument.
- Visualize the reference constellation using the `PlotConstellation` argument.

Topics

“Phase Modulation”

qamdemod

Quadrature amplitude demodulation

Syntax

```
z = qamdemod(y,M)
z = qamdemod(y,M,symOrder)
z = qamdemod( ___ ,Name,Value)
```

Description

`z = qamdemod(y,M)` returns a demodulated signal, `z`, given quadrature amplitude modulation (QAM) signal `y` of modulation order `M`.

`z = qamdemod(y,M,symOrder)` returns a demodulated signal, `z`, and specifies the symbol order for the demodulation.

`z = qamdemod( ___ ,Name,Value)` specifies options using one or more name-value pair arguments. For example, `'OutputType','bit'` sets the type of output signal to bits.

Examples

Demodulate 8-QAM Signal

Demodulate an 8-QAM signal and plot the points corresponding to symbols 0 and 3.

Generate random 8-ary data symbols.

```
data = randi([0 7],1000,1);
```

Modulate `data` by applying 8-QAM.

```
txSig = qammod(data,8);
```

Pass the modulated signal through an AWGN channel.

```
rxSig = awgn(txSig,18,'measured');
```

Demodulate the received signal using an initial phase of $\pi/8$.

```
rxData = qamdemod(rxSig.*exp(-1i*pi/8),8);
```

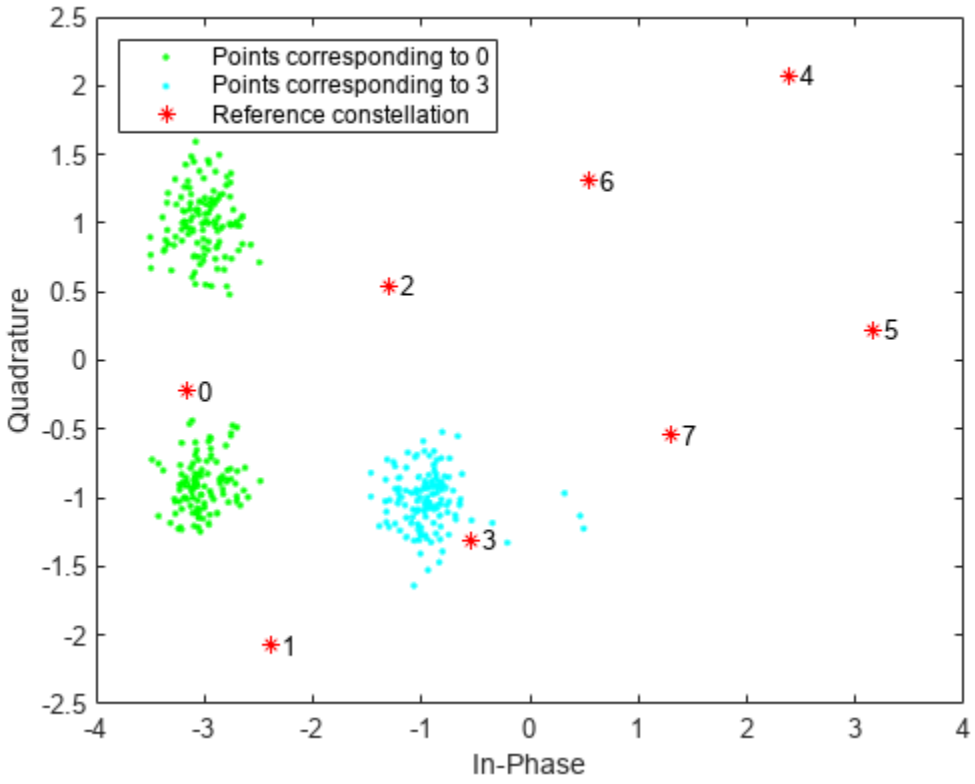
Generate the reference constellation points.

```
refpts = qammod((0:7)',8) .* exp(1i*pi/8);
```

Plot the received signal points corresponding to symbols 0 and 3 and overlay the reference constellation. The received data corresponding to those symbols is displayed.

```
plot(rxSig(rxData==0),'g.');
hold on
```

```
plot(rxSig(rxData==3),'c.');
plot(refpts,'r*')
text(real(refpts)+0.1,imag(refpts),num2str((0:7)'))
xlabel('In-Phase')
ylabel('Quadrature')
legend('Points corresponding to 0','Points corresponding to 3', ...
    'Reference constellation','location','nw');
```



QAM Demodulation with WLAN Symbol Mapping

Modulate and demodulate random data by using 16-QAM with WLAN symbol mapping. Verify that the input data symbols match the demodulated symbols.

Generate a 3-D array of random symbols.

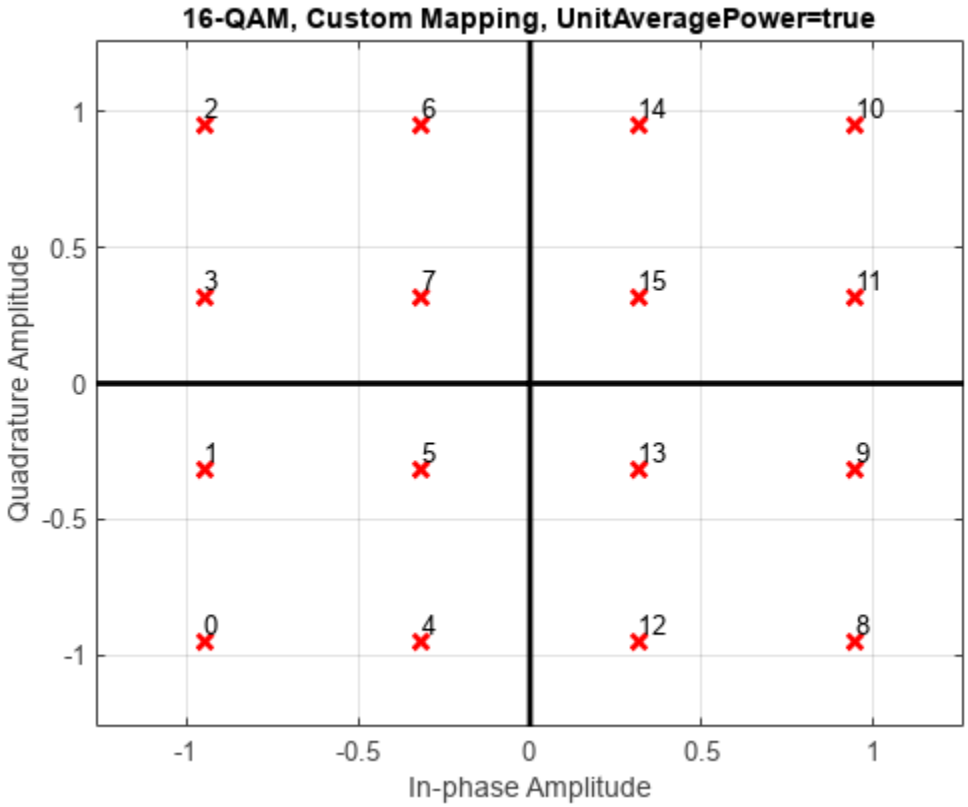
```
x = randi([0,15],20,4,2);
```

Create a custom symbol mapping for the 16-QAM constellation based on WLAN standards.

```
wlanSymMap = [2 3 1 0 6 7 5 4 14 15 13 12 10 11 9 8];
```

Modulate the data, and set the constellation to have unit average signal power. Plot the constellation.

```
y = qammod(x,16,wlanSymMap, ...
    UnitAveragePower=true, ...
    PlotConstellation=true);
```



Demodulate the received signal.

```
z = qamdemod(y,16,wlanSymMap, ...
    UnitAveragePower=true);
```

Verify that the demodulated signal is equal to the original data.

```
isequal(x,z)
```

```
ans = logical
   1
```

Demodulate QAM Fixed-Point Signal

Demodulate a fixed-point QAM signal and verify that the data is recovered correctly.

Set the modulation order as 64, and determine the number of bits per symbol.

```
M = 64;
bitsPerSym = log2(M);
```

Generate random bits. When operating in bit mode, the length of the input data must be an integer multiple of the number of bits per symbol.

```
x = randi([0 1],10*bitsPerSym,1);
```

Modulate the input data using a binary symbol mapping. Set the modulator to output fixed-point data. The numeric data type is signed with a 16-bit word length and a 10-bit fraction length.

```
y = qammod(x,M,'bin','InputType','bit','OutputDataType', ...
    numerictype(1,16,10));
```

Demodulate the 64-QAM signal. Verify that the demodulated data matches the input data.

```
z = qamdemod(y,M,'bin','OutputType','bit');
s = isequal(x,double(z))
```

```
s = logical
   1
```

Estimate BER for Hard and Soft Decision Viterbi Decoding

Estimate bit error rate (BER) performance for hard-decision and soft-decision Viterbi decoders in AWGN. Compare the performance to that of an uncoded 64-QAM link.

Set the simulation parameters.

```
rng default
M = 64;                 % Modulation order
k = log2(M);            % Bits per symbol
EbNoVec = (4:10)';      % Eb/No values (dB)
numSymPerFrame = 1000; % Number of QAM symbols per frame
```

Initialize the BER results vectors.

```
berEstSoft = zeros(size(EbNoVec));
berEstHard = zeros(size(EbNoVec));
```

Set the trellis structure and traceback depth for a rate `1/2`, constraint length `7`, convolutional code.

```
trellis = poly2trellis(7,[171 133]);
tbl = 32;
rate = 1/2;
```

The main processing loops perform these steps:

- Generate binary data
- Convolutionally encode the data
- Apply QAM modulation to the data symbols. Specify unit average power for the transmitted signal
- Pass the modulated signal through an AWGN channel
- Demodulate the received signal using hard decision and approximate LLR methods. Specify unit average power for the received signal
- Viterbi decode the signals using hard and unquantized methods
- Calculate the number of bit errors

The `while` loop continues to process data until either 100 errors are encountered or 10^7 bits are transmitted.

```
for n = 1:length(EbNoVec)
    % Convert Eb/No to SNR
    snrdB = EbNoVec(n) + 10*log10(k*rate);
    % Noise variance calculation for unity average signal power
    noiseVar = 10.^(-snrdB/10);
    % Reset the error and bit counters
    [numErrsSoft,numErrsHard,numBits] = deal(0);

    while numErrsSoft < 100 && numBits < 1e7
        % Generate binary data and convert to symbols
        dataIn = randi([0 1],numSymPerFrame*k,1);

        % Convolutionally encode the data
        dataEnc = convenc(dataIn,trellis);

        % QAM modulate
        txSig = qammod(dataEnc,M, ...
            InputType='bit', ...
            UnitAveragePower=true);

        % Pass through AWGN channel
        rxSig = awgn(txSig,snrdB,'measured');

        % Demodulate the noisy signal using hard decision (bit) and
        % soft decision (approximate LLR) approaches.
        rxDataHard = qamdemod(rxSig,M, ...
            OutputType='bit', ...
            UnitAveragePower=true);
        rxDataSoft = qamdemod(rxSig,M, ...
            OutputType='approxllr', ...
            UnitAveragePower=true, ...
            NoiseVariance=noiseVar);

        % Viterbi decode the demodulated data
        dataHard = vitdec(rxDataHard,trellis,tbl,'cont','hard');
        dataSoft = vitdec(rxDataSoft,trellis,tbl,'cont','unquant');

        % Calculate the number of bit errors in the frame.
        % Adjust for the decoding delay, which is equal to
        % the traceback depth.
        numErrsInFrameHard = ...
            biterr(dataIn(1:end-tbl),dataHard(tbl+1:end));
        numErrsInFrameSoft = ...
            biterr(dataIn(1:end-tbl),dataSoft(tbl+1:end));

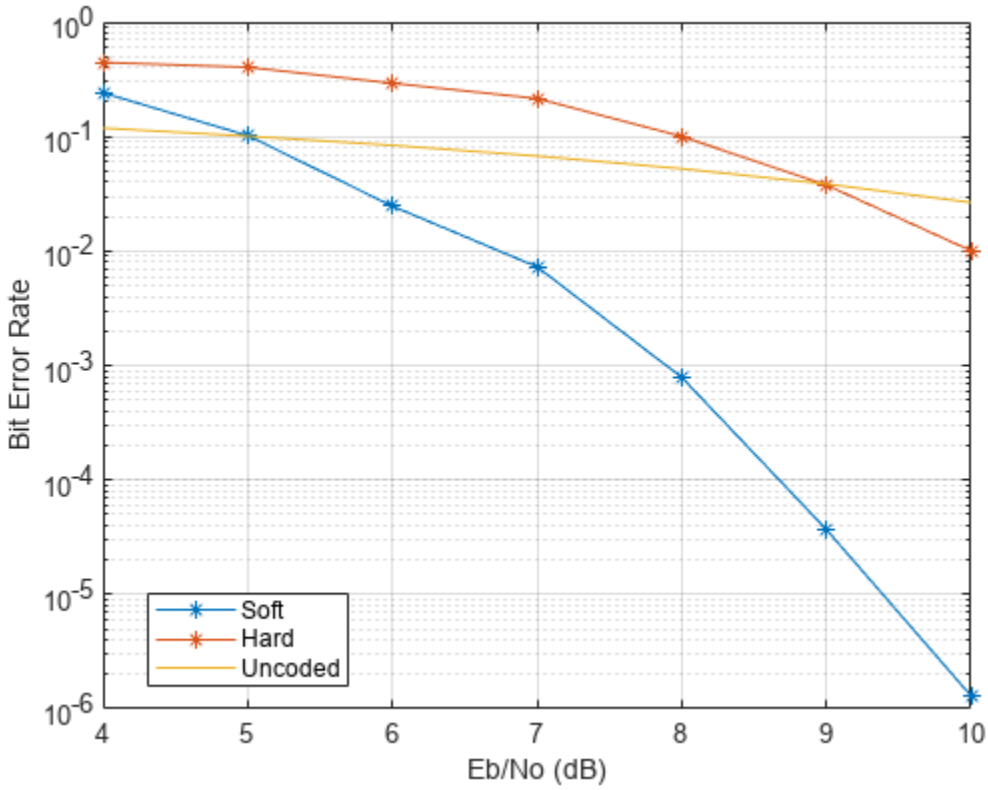
        % Increment the error and bit counters
        numErrsHard = numErrsHard + numErrsInFrameHard;
        numErrsSoft = numErrsSoft + numErrsInFrameSoft;
        numBits = numBits + numSymPerFrame*k;

    end

    % Estimate the BER for both methods
    berEstSoft(n) = numErrsSoft/numBits;
    berEstHard(n) = numErrsHard/numBits;
end
```

Plot the estimated hard and soft BER data. Plot the theoretical performance for an uncoded 64-QAM channel.

```
semilogy(EbNoVec,[berEstSoft berEstHard],'-*')
hold on
semilogy(EbNoVec,berawgn(EbNoVec,'qam',M))
legend('Soft','Hard','Uncoded','location','best')
grid
xlabel('Eb/No (dB)')
ylabel('Bit Error Rate')
```



As expected, the soft decision decoding produces the best results.

Soft-Decision OQPSK Modulation-Demodulation

Use the `qamdemod` function to simulate soft decision output for OQPSK-modulated signals.

Generate an OQPSK modulated signal.

```
sps = 4;
msg = randi([0 1],1000,1);
oqpskMod = comm.OQPSKModulator('SamplesPerSymbol',sps,'BitInput',true);
oqpskSig = oqpskMod(msg);
```

Add noise to the generated signal.

```
impairedSig = awgn(oqpskSig,15);
```

Perform Soft-Decision Demodulation

Create QPSK equivalent signal to align in-phase and quadrature.

```
impairedQPSK = complex( ...
    real(impairedSig(1+sps/2:end-sps/2)), ...
    imag(impairedSig(sps+1:end)));
```

Apply matched filtering to the received OQPSK signal.

```
halfSinePulse = sin(0:pi/sps:(sps)*pi/sps);
matchedFilter = dsp.FIRDecimator(sps,halfSinePulse, ...
    'DecimationOffset',sps/2);
filteredQPSK = matchedFilter(impairedQPSK);
```

To perform soft demodulation of the filtered OQPSK signal use the `qamdemod` function. Align symbol mapping of `qamdemod` with the symbol mapping used by the `comm.OQPSKModulator`, then demodulate the signal.

```
oqpskModSymbolMapping = [1 3 0 2];
demodulated = qamdemod(filteredQPSK,4,oqpskModSymbolMapping, ...
    'OutputType','llr');
```

Input Arguments

y — Input signal

scalar | vector | matrix | 3-D array

Input signal that resulted QAM, specified as a scalar, vector, matrix, or 3-D array of complex values. Each column in the matrix and 3-D array is considered as an independent channel.

Data Types: `single` | `double` | `fi`
Complex Number Support: Yes

M — Modulation order

scalar integer

Modulation order, specified as a power-of-two scalar integer. The modulation order specifies the number of points in the signal constellation.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

symOrder — Symbol order

`'gray'` (default) | `'bin'` | vector

Symbol order, specified as one of these options:

- `'gray'` — Use “Gray Code” on page 2-666 ordering.
- `'bin'` — Use natural binary-coded ordering.
- Vector — Use custom symbol ordering. The vector must be of length `M`. Vectors must use unique elements whose values range from 0 to `M` – 1. The first element corresponds to the upper left point of the constellation, with subsequent elements running down column-wise from left to right.

Data Types: `char` | `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `z = qamdemod(y,M,symOrder,'OutputType','bit')`

`UnitAveragePower` — Unit average power flag

`false` or `0` (default) | `true` or `1`

Unit average power flag, specified as the comma-separated pair consisting of `'UnitAveragePower'` and a numeric or logical `0` (`false`) or `1` (`true`). When this flag is `1` (`true`), the function scales the constellation to the average power of one watt referenced to 1 ohm. When this flag is `0` (`false`), the function scales the constellation so that the QAM constellation points are separated by a minimum distance of two.

`OutputType` — Type of output

`'integer'` (default) | `'bit'` | `'llr'` | `'approxllr'`

Type of output, specified as the comma-separated pair consisting of `'OutputType'` and `'integer'`, `'bit'`, `'llr'`, or `'approxllr'`.

Data Types: `char`

`NoiseVariance` — Noise variance

1 (default) | positive scalar | vector of positive values

Noise variance, specified as the comma-separated pair consisting of `'NoiseVariance'` and one of these options:

- Positive scalar — The same noise variance value is used on all input elements.
- Vector of positive values — The vector length must be equal to the number of elements in the last dimension of the input signal. Each element of the vector specifies the noise variance for all the elements of the input along the corresponding last dimension.

Tip Because the Log-Likelihood algorithm computes exponentials using finite precision arithmetic, the computation of exponentials with large or small numbers can yield positive or negative infinity. The approximate LLR algorithm does not compute exponentials. For more details, see “Hard- vs. Soft-Decision Demodulation”.

When `'OutputType'` is ‘`llr`’, any `Inf` or `-Inf` values returned by the demodulation computation output are likely due to the specified noise variance values being smaller than the signal-to-noise ratio (SNR).

To avoid returning output values of `Inf` or `-Inf`, set `'OutputType'` to ‘`approxllr`’ instead of `'llr'`.

Dependencies

To enable this name-value pair argument, set `'OutputType'` is `'llr'` or `'approxllr'`.

Data Types: `double`

`PlotConstellation` — Option to plot constellation
`false` or `0` (default) | `true` or `1`

Option to plot constellation, specified as the comma-separated pair consisting of `'PlotConstellation'` and a numeric or logical `0` (`false`) or `1` (`true`) To plot the QAM constellation, set `'PlotConstellation'` to `true`.

Output Arguments

`z` — Demodulated output signal
scalar | vector | matrix | 3-D array

Demodulated output signal, returned as a scalar, vector, matrix, or 3-D array. The data type is the same as that of the input signal, `y`. The value and dimension of this output vary depending on the specified `'OutputType'` value, as shown in this table.

`'OutputType'`	Return Value of `qamdemod`	Dimensions of Output
`'integer'`	Demodulated integer values from 0 to (`M` – 1)	`z` has the same dimensions as input `y`.
`'bit'`	Demodulated bits	The number of rows in `z` is $\log_2(M)$ times the number of rows in `y`. Each demodulated symbol is mapped to a group of $\log_2(M)$ bits, where the first bit represents the most significant bit (MSB) and the last bit represents the least significant bit (LSB).
`'llr'`	Log-likelihood ratio value for each bit calculated using the Exact Log Likelihood algorithm. For more details, see “Exact LLR Algorithm”.	
`'approxllr'`	Approximate log-likelihood ratio value for each bit. The values are calculated using the Approximate Log Likelihood algorithm. For more details, see “Approximate LLR Algorithm”.	

More About

Gray Code

A Gray code, also known as a reflected binary code, is a system where the bit patterns in adjacent constellation points differ by only one bit.

Version History

Introduced before R2006a

Initial Phase Input Removed
Errors starting in R2018b

Starting in R2018b, you can no longer offset the initial phase for the QAM constellation using the `qamdemod` function.

Instead, use the genqamdemod function to offset the initial phase of the QAM signal being demodulated. Alternatively, you can multiply the modulated input of qamdemod by the desired initial phase, as shown in this code

```
z = qamdemod(y.*exp(-1i*initPhase,M))
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Topics

“Compute Symbol Error Rate”
“Hard- vs. Soft-Decision Demodulation”

qammod

Quadrature amplitude modulation (QAM)

Syntax

```
y = qammod(x,M)
y = qammod(x,M,symOrder)
y = qammod( ___ ,Name,Value)
```

Description

`y = qammod(x,M)` modulates input signal `x` by using QAM with the specified modulation order `M`. Output `y` is the modulated signal.

`y = qammod(x,M,symOrder)` specifies the symbol order.

`y = qammod( ___ ,Name,Value)` specifies options using name-value pair arguments in addition to any of the input argument combinations from previous syntaxes.

Examples

Modulate Data Using QAM

Modulate data using QAM and display the result in a scatter plot.

Set the modulation order to 16 and create a data vector containing each of the possible symbols.

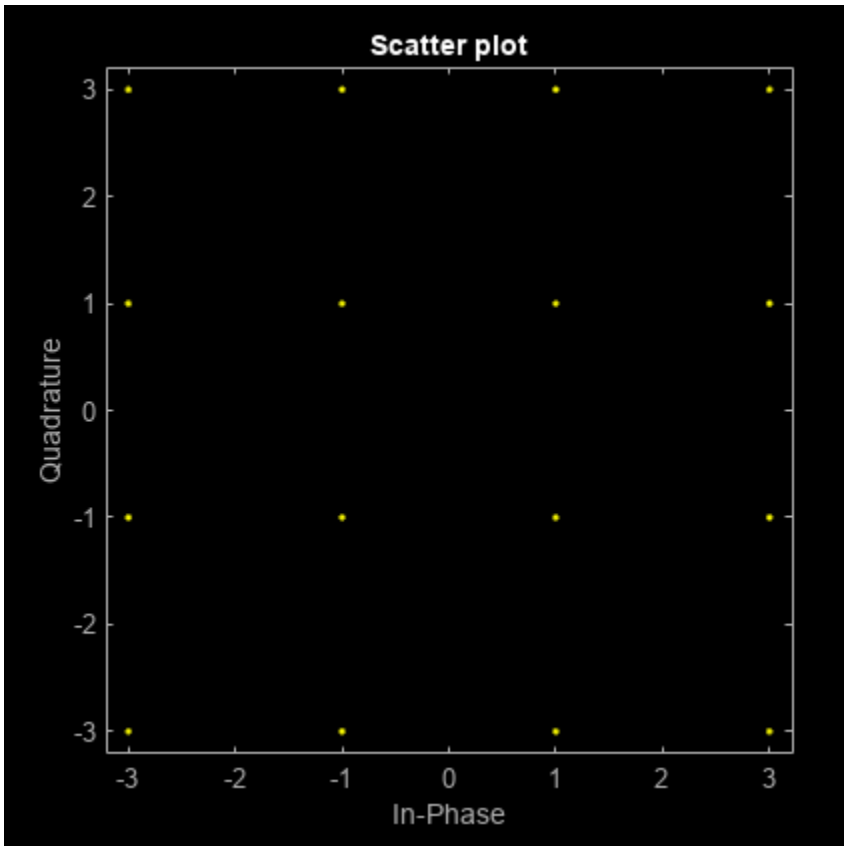
```
M = 16;
x = (0:M-1)';
```

Modulate the data using the `qammod` function.

```
y = qammod(x,M);
```

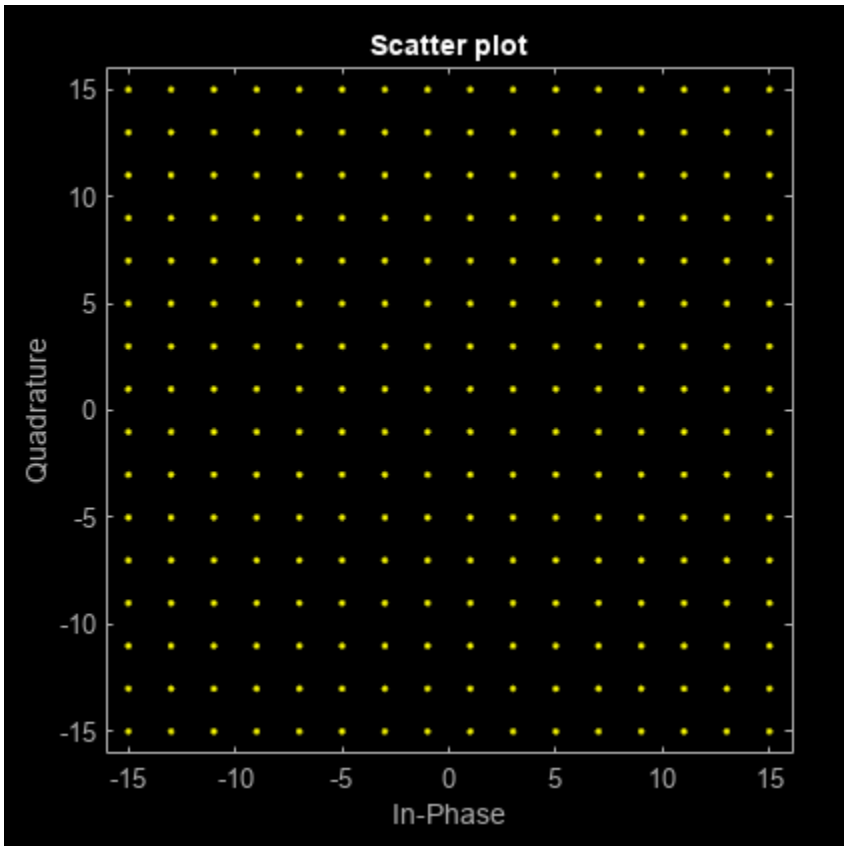
Display the modulated signal constellation using the `scatterplot` function.

```
scatterplot(y)
```



Set the modulation order to 256, and display the scatter plot of the modulated signal.

```
M = 256;
x = (0:M-1)';
y = qammod(x,M);
scatterplot(y)
```



Normalize QAM Signal by Average Power

Modulate random data symbols using QAM. Normalize the modulator output so that it has an average signal power of 1 W.

Set the modulation order and generate random data.

```
M = 64;
x = randi([0 M-1],1000,1);
```

Modulate the data. Use the `'UnitAveragePower'` name-value pair to set the output signal to have an average power of 1 W.

```
y = qammod(x,M,'UnitAveragePower',true);
```

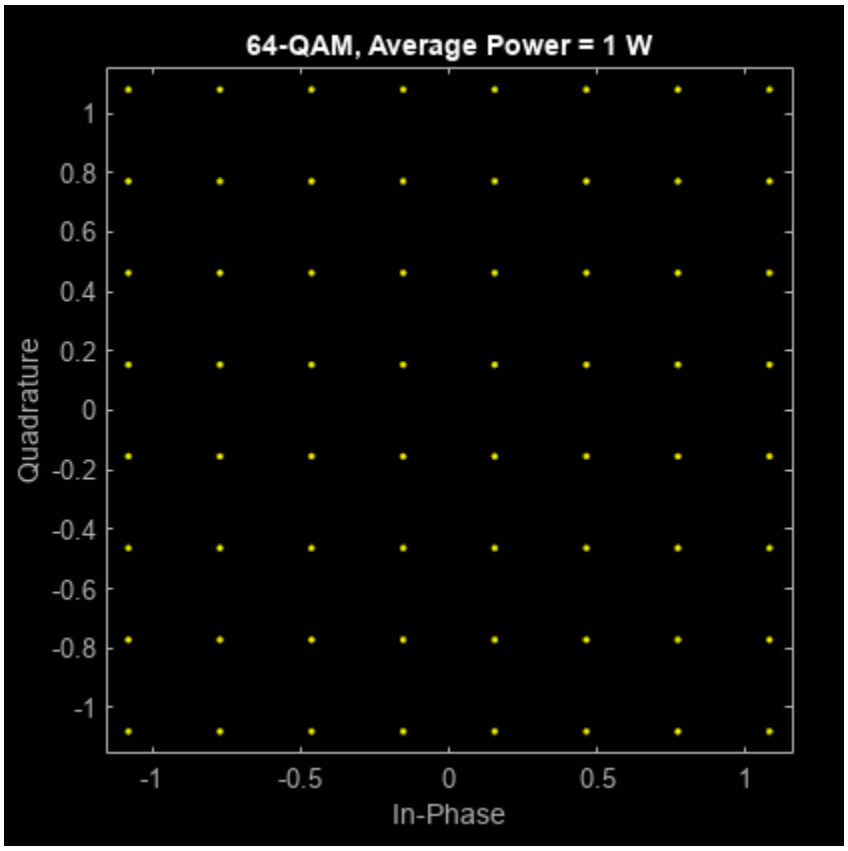
Confirm that the signal has unit average power.

```
avgPower = mean(abs(y).^2)
```

```
avgPower = 1.0070
```

Plot the resulting constellation.

```
scatterplot(y)
title('64-QAM, Average Power = 1 W')
```



QAM Symbol Ordering

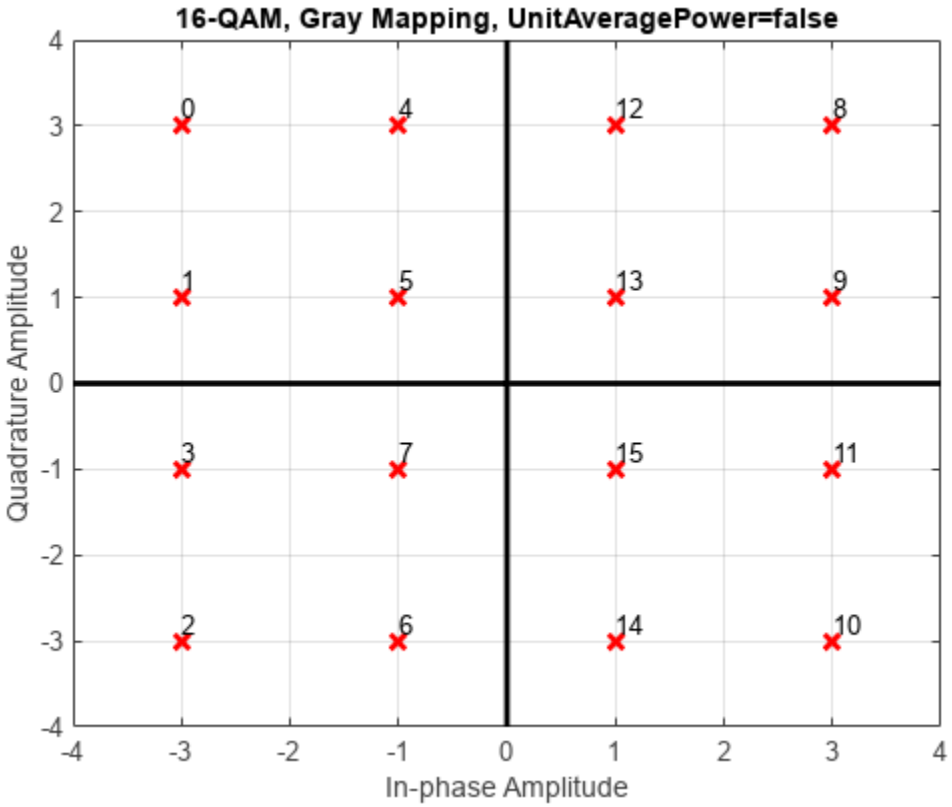
Plot QAM constellations for Gray, binary, and custom symbol mappings.

Set the modulation order, and create a data sequence that includes a complete set of symbols for the modulation scheme.

```
M = 16;
d = [0:M-1];
```

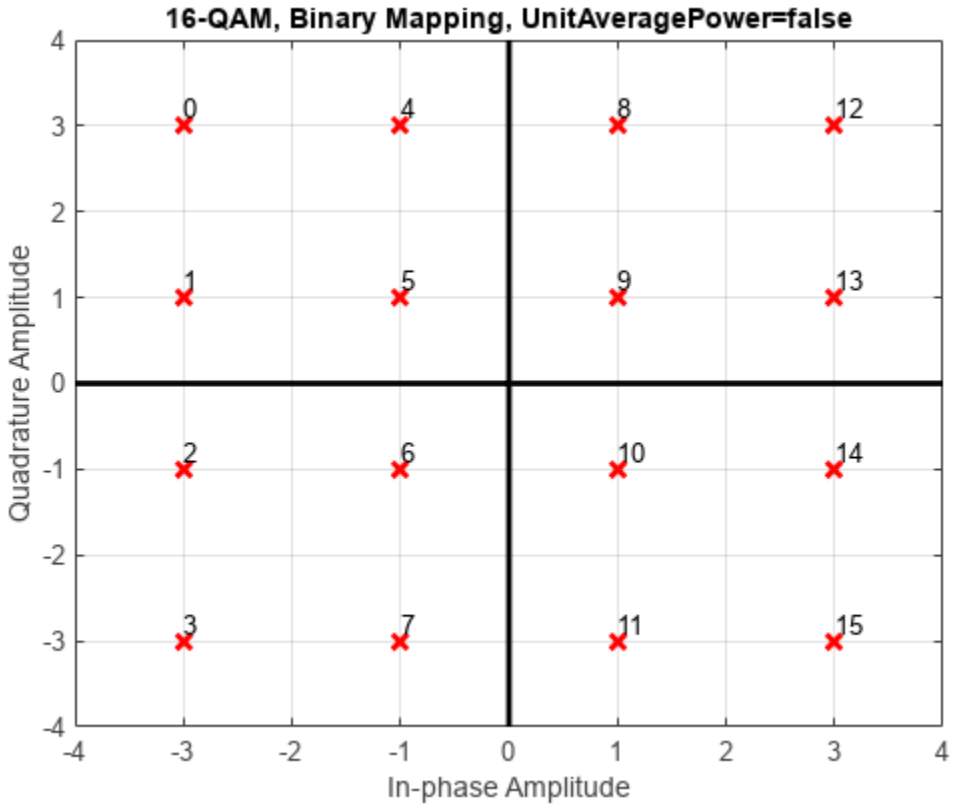
Modulate the data, and plot its constellation. The default symbol mapping uses Gray ordering. The ordering of the points is not sequential.

```
y = qammod(d,M,'PlotConstellation',true);
```



Repeat the modulation process with binary symbol mapping. The symbol mapping follows a natural binary order and is sequential.

```
z = qammod(d,M,'bin','PlotConstellation',true);
```

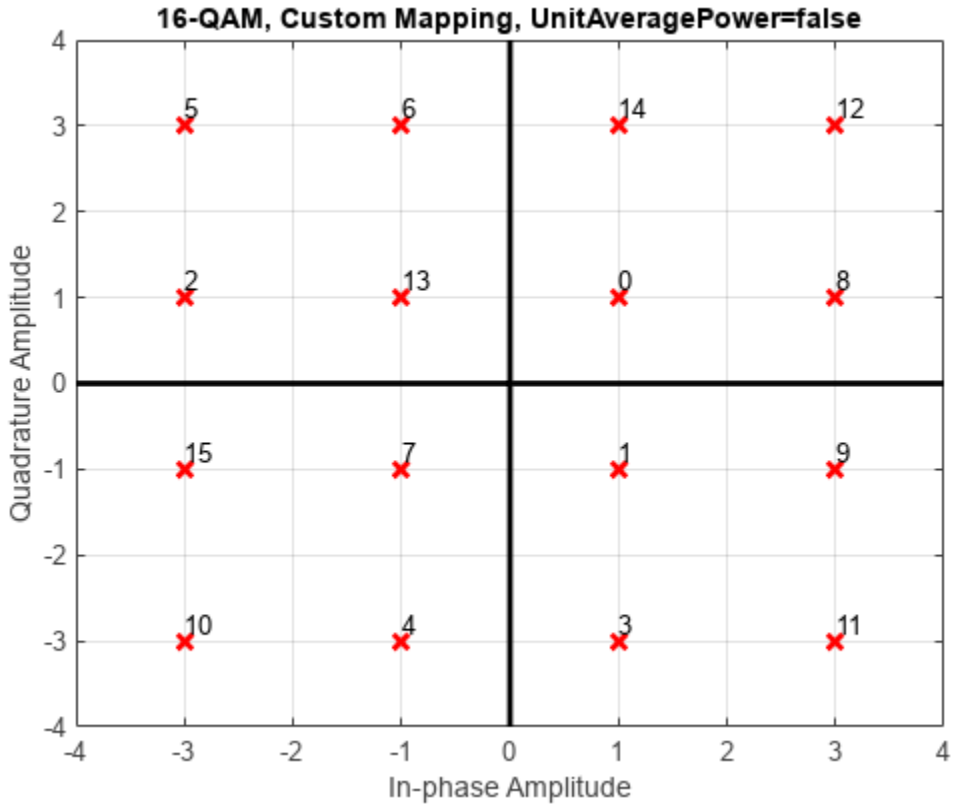


Create a custom symbol mapping.

```
smap = randperm(M)-1;
```

Modulate and plot the constellation.

```
w = qammod(d,M,smap,'PlotConstellation',true);
```



Quadrature Amplitude Modulation with Bit Inputs

Modulate a sequence of bits using 64-QAM. Pass the signal through a noisy channel. Display the resultant constellation diagram.

Set the modulation order, and determine the number of bits per symbol.

```
M = 64;
k = log2(M);
```

Create a binary data sequence. When using binary inputs, the number of rows in the input must be an integer multiple of the number of bits per symbol.

```
data = randi([0 1],1000*k,1);
```

Modulate the signal using bit inputs, and set it to have unit average power.

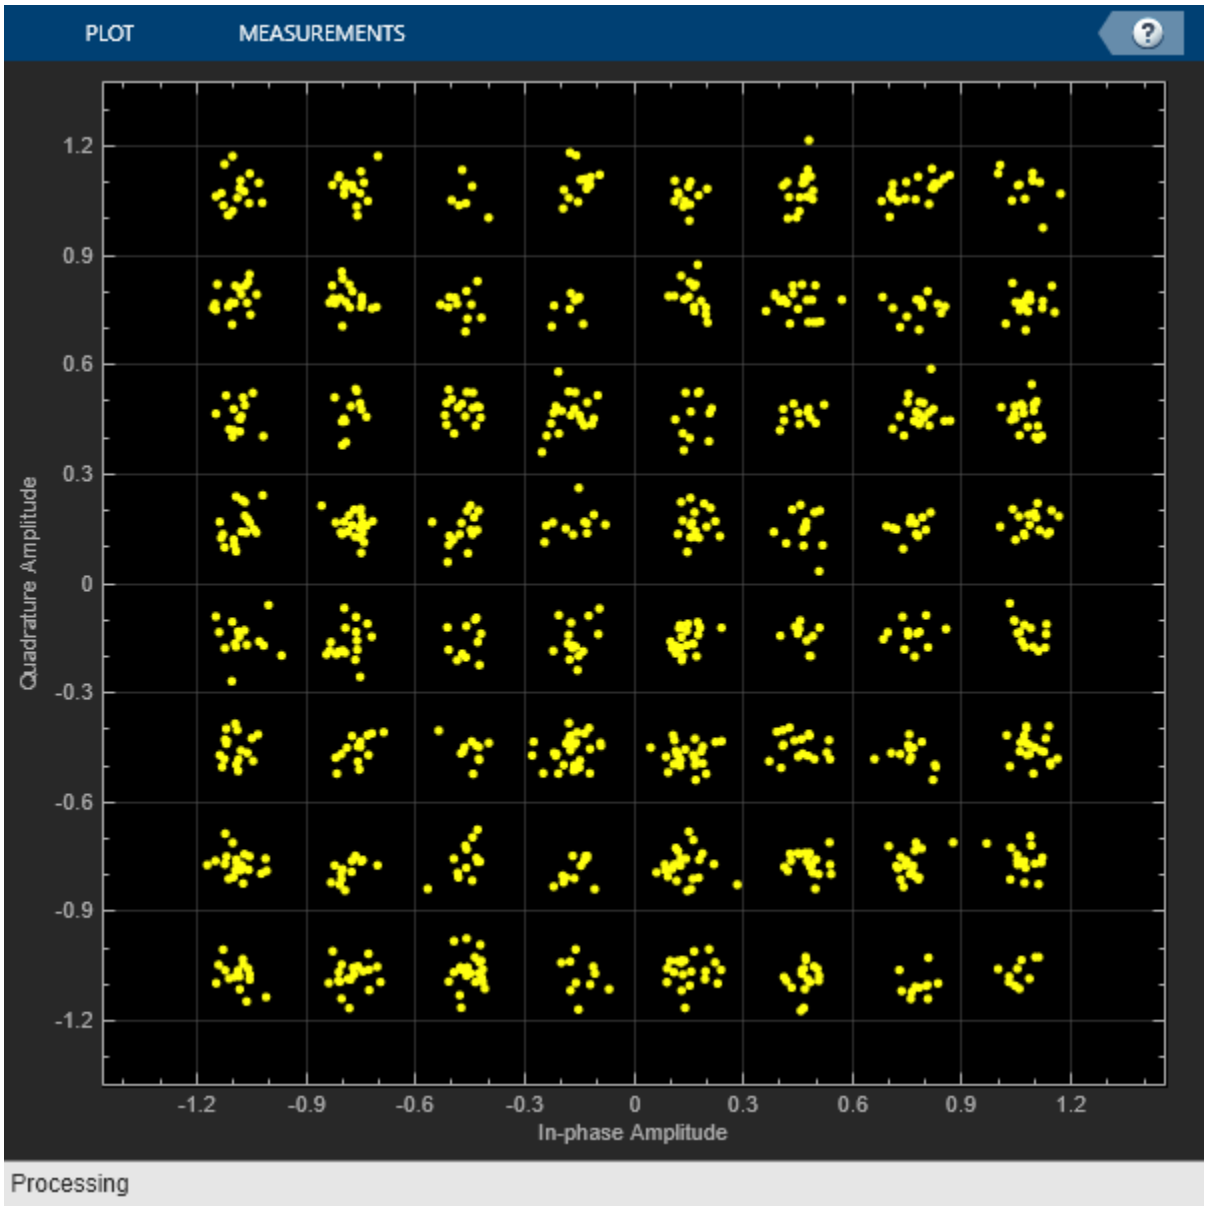
```
txSig = qammod(data,M,'InputType','bit','UnitAveragePower',true);
```

Pass the signal through a noisy channel.

```
rxSig = awgn(txSig,25);
```

Plot the constellation diagram.

```
cd = comm.ConstellationDiagram('ShowReferenceConstellation',false);
cd(rxSig)
```



Demodulate QAM Fixed-Point Signal

Demodulate a fixed-point QAM signal and verify that the data is recovered correctly.

Set the modulation order as 64, and determine the number of bits per symbol.

```
M = 64;
bitsPerSym = log2(M);
```

Generate random bits. When operating in bit mode, the length of the input data must be an integer multiple of the number of bits per symbol.

```
x = randi([0 1],10*bitsPerSym,1);
```

Modulate the input data using a binary symbol mapping. Set the modulator to output fixed-point data. The numeric data type is signed with a 16-bit word length and a 10-bit fraction length.

```
y = qammod(x,M,'bin','InputType','bit','OutputDataType', ...
    numerictype(1,16,10));
```

Demodulate the 64-QAM signal. Verify that the demodulated data matches the input data.

```
z = qamdemod(y,M,'bin','OutputType','bit');
s = isequal(x,double(z))
```

```
s = logical
   1
```

Input Arguments

x — Input signal

scalar | vector | matrix | 3-D array

Input signal, specified as a scalar, vector, matrix, or 3-D array. The elements of x must be binary values or integers that range from 0 to (`M` – 1), where `M` is the modulation order.

Note To process input signal as binary elements, set the `'InputType'` name-value pair to `'bit'`. For binary inputs, the number of rows must be an integer multiple of $\log_2(M)$. Groups of $\log_2(M)$ bits are mapped onto a symbol, with the first bit representing the MSB and the last bit representing the LSB.

Data Types: `double` | `single` | `fi` | `int8` | `int16` | `uint8` | `uint16`

M — Modulation order

scalar integer

Modulation order, specified as a power-of-two scalar integer. The modulation order specifies the number of points in the signal constellation.

Example: 16

Data Types: `double`

symOrder — Symbol order

`'gray'` (default) | `'bin'` | vector

Symbol order, specified as `'gray'`, `'bin'`, or a vector.

- `'gray'` — Use “Gray Code” on page 2-678 ordering
- `'bin'` — Use natural binary-coded ordering
- Vector — Use custom symbol ordering

Vectors must use unique elements whose values range from 0 to `M` – 1. The first element corresponds to the upper-left point of the constellation, with subsequent elements running down column-wise from left to right.

Example: [0 3 1 2]

Data Types: `char` | `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `y = qammod(x,M,symOrder,'InputType','bit')`

`InputType` — Input type

`'integer'` (default) | `'bit'`

Input type, specified as the comma-separated pair consisting of `'InputType'` and either `'integer'` or `'bit'`. If you specify `'integer'`, the input signal must consist of integers from 0 to `M` – 1. If you specify `'bit'`, the input signal must contain binary values, and the number of rows must be an integer multiple of $\log_2(M)$.

Data Types: `char`

`UnitAveragePower` — Unit average power flag

`false` or `0` (default) | `true` or `1`

Unit average power flag, specified as the comma-separated pair consisting of `'UnitAveragePower'` and a numeric or logical `0` (`false`) or `1` (`true`). When this flag is `1` (`true`), the function scales the constellation to the average power of one watt referenced to 1 ohm. When this flag is `0` (`false`), the function scales the constellation so that the QAM constellation points are separated by a minimum distance of two.

`OutputDataType` — Output data type

`numerictype` object

Output data type, specified as the comma-separated pair consisting of `'OutputDataType'` and a `numerictype` object.

For more information on constructing these objects, see `numerictype`. If you do not specify `'OutputDataType'`, data type is `double` if the input is of data type `double` or built-in integer and `single` if the input is of data type `single`.

`PlotConstellation` — Option to plot constellation

`false` or `0` (default) | `true` or `1`

Option to plot constellation, specified as the comma-separated pair consisting of `'PlotConstellation'` and a numeric or logical `0` (`false`) or `1` (`true`) To plot the QAM constellation, set `'PlotConstellation'` to `true`.

Output Arguments

y — Modulated signal

scalar | vector | matrix | 3-D array

Modulated signal, returned as a complex scalar, vector, matrix, or 3-D array of numeric values. For integer inputs, output `y` has the same dimensions as input signal `x`. For bit inputs, the number of rows in `y` is the number of rows in `x` divided by $\log_2(M)$.

Data Types: `double` | `single`

“Digital Baseband Modulation”

qfunc

Q function

Syntax

```
y = qfunc(x)
```

Description

`y = qfunc(x)` returns the output of the Q function for each element of the real-valued input. The Q function is (1 – *f*), where *f* is the result of the cumulative distribution function of the standardized normal random variable. For more information, see “Algorithms” on page 2-681.

Examples

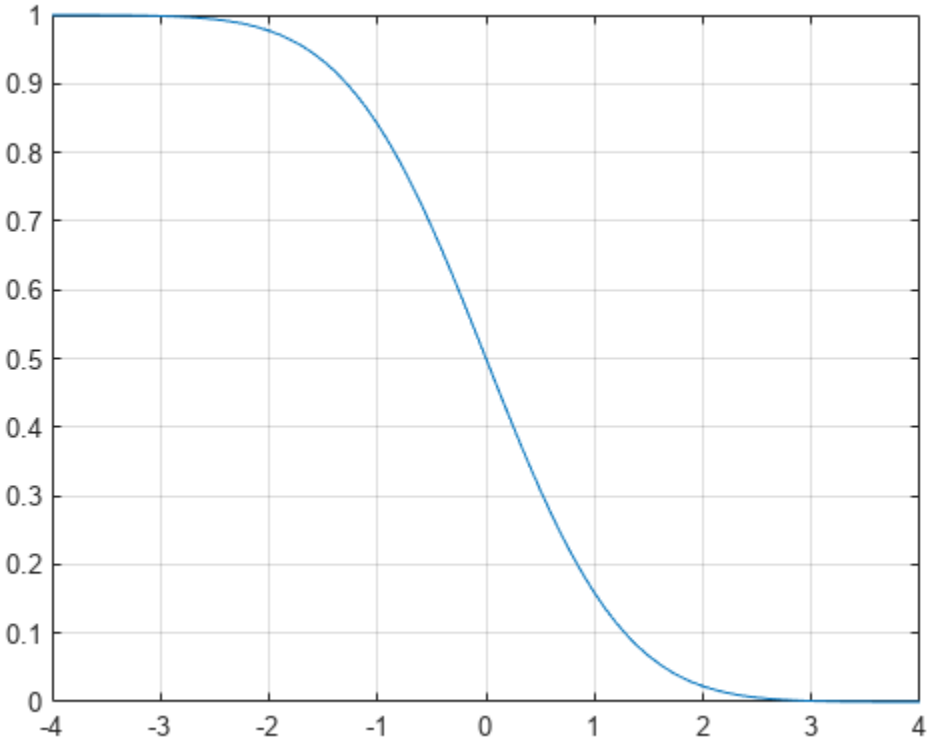
Calculate Q Function Value and Plot Results

Calculate the Q function values for a real-valued input vector.

```
x = -4:0.1:4;
y = qfunc(x);
```

Plot the results.

```
plot(x,y)
grid
```



Calculate QPSK Error Probability Using Q Function

Calculate the QPSK error probability at an E_b/N_0 setting of 7 dB by using the Q function.

Convert the E_b/N_0 in dB to its linear equivalent.

```
ebnodB = 7;
ebno = 10^(ebnodB/10);
```

Using the Q function, calculate the QPSK error probability, $P_b = Q\left(\sqrt{2\frac{E_b}{N_0}}\right)$.

```
Pb = qfunc(sqrt(2*ebno))
```

```
Pb = 7.7267e-04
```

Input Arguments

x — Input

scalar | vector | matrix | array

Input, specified as a real-valued scalar, matrix, or array.

Data Types: `double`

Output Arguments

y — Q function output

scalar | vector | matrix | array

Q function output, returned as a scalar, matrix, or array. `y` has the same dimensions as input `x`. Output values are in the range [0, 1].

Algorithms

For a scalar x, the Q function is (1 – f), where f is the result of the cumulative distribution function of the standardized normal random variable. The Q function is defined as

$$Q(x) = \frac{1}{\sqrt{2\pi}} \int_x^\infty \exp(-t^2/2) dt$$

The Q function is related to the complementary error function, erfc, according to

$$Q(x) = \frac{1}{2} \mathrm{erfc}\left(\frac{x}{\sqrt{2}}\right)$$

qfuncinv

Inverse Q function

Syntax

```
z = qfuncinv(y)
```

Description

`z = qfuncinv(y)` returns the input argument of the Q function for which the output value of the Q function is `y`. For more information, see “Algorithms” on page 2-683.

Examples

Recover Argument of Q Function

Recover the Q function input argument by using the inverse Q function. Show the inverse relationship between Q function and its inverse.

Calculate the Q function values for a real-valued input.

```
x1 = [0 1 2; 3 4 5];
y1 = qfunc(x1)
```

```
y1 = 2×3

    0.5000    0.1587    0.0228
    0.0013    0.0000    0.0000
```

Recover the Q function input argument by calculating the inverse Q function values for `y1`.

```
x1_recovered = qfuncinv(y1)
```

```
x1_recovered = 2×3

     0     1     2
     3     4     5
```

Confirm the original and recovered Q functions arguments are the same.

```
isequal (x1,x1_recovered)
```

```
ans = logical
   1
```

Calculate the inverse of values representing Q function output values.

```
y2 = 0:0.2:1;
x2 = qfuncinv(y2)
```

```
x2 = 1×6

       Inf    0.8416    0.2533   -0.2533   -0.8416      -Inf
```

Recover the Q function output argument by calculating the Q function values for `x2`.

```
y2_recovered = qfunc(x2)
```

```
y2_recovered = 1×6

         0    0.2000    0.4000    0.6000    0.8000    1.0000
```

Confirm the original values and recovered inverse Q functions arguments are the same.

```
isequal (y2,y2_recovered)
```

```
ans = logical
   1
```

Input Arguments

y — Q function output

scalar | vector | matrix | array

Q function output, specified as a scalar, matrix, or array. Input values must be in the range [0, 1].

Data Types: `double`

Output Arguments

z — Q function input argument

scalar | vector | matrix | N-D array

Q function input argument, returned as a real-valued scalar, matrix, or array. `z` has the same dimensions as input `y`.

Algorithms

For a scalar x, the Q function is (1 – f), where f is the result of the cumulative distribution function of the standardized normal random variable. The Q function is defined as

$$Q(x) = \frac{1}{\sqrt{2\pi}} \int_x^\infty \exp(-t^2/2) dt$$

The Q function is related to the complementary error function, erfc, according to

$$Q(x) = \frac{1}{2}\mathrm{erfc}\left(\frac{x}{\sqrt{2}}\right)$$

Version History

Introduced before R2006a

quantiz

Produce quantization index and quantized output value

Syntax

```
index = quantiz(sig,partition)
[index,quants] = quantiz(sig,partition,codebook)
[index,quants,distor] = quantiz(sig,partition,codebook)
```

Description

`index = quantiz(sig,partition)` returns the quantization levels of input signal `sig` by using the scalar quantization partition specified in input `partition`.

`[index,quants] = quantiz(sig,partition,codebook)` specifies `codebook`, which prescribes a value for each partition in the scalar quantization. `codebook` is a vector whose length must exceed the length of `partition` by one. The function also returns `quants`, which contains the scalar quantization of `sig` and depends on the quantization levels and prescribed values in the codebook.

`[index,quants,distor] = quantiz(sig,partition,codebook)` returns an estimate of the mean square distortion of the quantization data.

Examples

Produce Quantization Index and Quantized Output Value

Generate sample data.

```
samp = [-2.4, -1, -0.2, 0, 0.2, 1, 1.2, 2, 2.9, 3, 3.5, 5]
```

```
samp = 1×12

   -2.4000   -1.0000   -0.2000         0    0.2000    1.0000    1.2000    2.0000    2.9000    3.0
```

Create the quantization partition. To specify a partition, list the distinct endpoints of the different ranges of values.

```
partition = [0, 1, 3];
```

Specify the codebook values.

```
codebook = [-1, 0.5, 2, 3]; % Codebook length must be equal to the number of partition intervals
```

Perform quantization on the sampled data. Display the quantization index and the corresponding quantized output value of the input data.

```
[index,quantized] = quantiz(samp,partition,codebook)
```

```
index = 1×12
```

```
     0     0     0     0     1     1     2     2     2     2     3     3

quantized = 1×12

   -1.0000   -1.0000   -1.0000   -1.0000    0.5000    0.5000    2.0000    2.0000    2.0000    2.0
```

Quantize Sampled Sine Wave

Generate a sampled sine wave.

```
t = [0:.1:2*pi];
sig = sin(t);
```

Create the quantization partition. To specify a partition, list the distinct endpoints of the different ranges of values.

```
partition = [-1:.2:1];
```

Specify the codebook values.

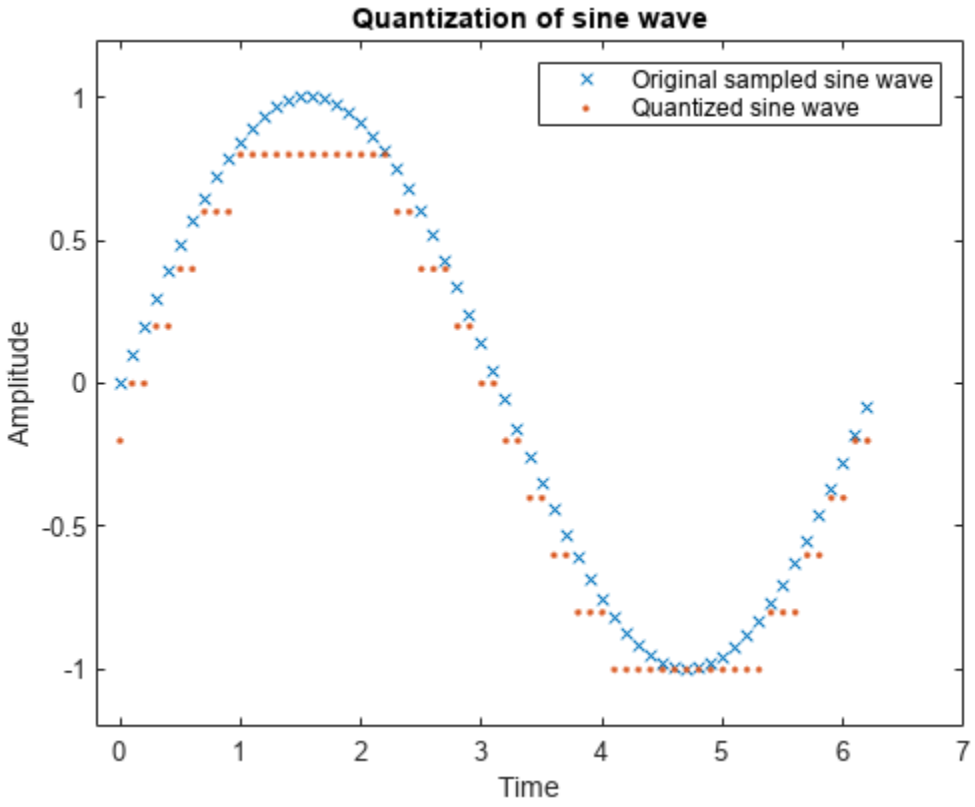
```
codebook = [-1.2:.2:1]; % Codebook length must be equal to the number of partition intervals
```

Perform quantization on the sampled sine wave.

```
[index,quants] = quantiz(sig,partition,codebook);
```

Plot the quantized sine wave and the sampled sine wave.

```
plot(t,sig,'x',t,quants,'.')
title('Quantization of sine wave')
xlabel('Time')
ylabel('Amplitude')
legend('Original sampled sine wave','Quantized sine wave');
axis([-.2 7 -1.2 1.2])
```



Input Arguments

`sig` — Input signal

vector

Input signal, specified as a vector. This input specifies the sampled signal for this function to perform quantization.

Data Types: `double`

`partition` — Distinct endpoints of different ranges

row vector

Distinct endpoints of different ranges, specified as a row vector. This input defines several contiguous, nonoverlapping ranges of values within the set of real numbers. The values present in this input must be strictly in ascending order. The length of this vector must be one less than the number of partition intervals.

Example: `[0, 1, 3]` partitions the input row vector into the four sets $\{X: X \le 0\}$, $\{X: 0 < X \le 1\}$, $\{X: 1 < X \le 3\}$, and $\{X: 3 < X\}$.

Data Types: `double`

`codebook` — Quantization value for each partition

row vector

Quantization value for each partition, specified as a row vector. This input prescribes a common value for each partition in the scalar quantization. The length of this vector must equal the number of partition intervals, that is, the length of this vector must exceed the length of the `partition` input by one.

Data Types: `double`

Output Arguments

`index` — Quantization index

nonnegative row vector

Quantization index of the input signal, returned as a nonnegative row vector. This output determines on which partition interval, each input value is mapped. Each element in `index` is one of the N integers in the range [0, N–1].

If the `partition` input has length N, `index` is a vector whose Kth entry is:

- `0` if `sig`(K) ≤ `partition`(1)
- M if `partition`(M) < `sig`(K) ≤ `partition`($M+1$)
- N if `partition`(N) ≤ `sig`(K)

`quants` — Output of quantizer

row vector

Output of the quantizer, which contains the quantization values of the input signal, returned as a row vector. The size of `quants` matches that of input argument `sig`. When `codebook` is not specified as an input argument, you can define the codebook values as a vector whose length must exceed the length of the `partition` by one.

`quants` is calculated based on the `codebook` and `index` inputs and is given by `quants`(i) = `codebook`(`index`(i) + 1), where i is an integer between 1 and the length of `sig`.

`distor` — Mean square distortion

positive scalar

Mean square distortion of the quantized signal, returned as a positive scalar. You can reduce this distortion by choosing appropriate partition and codebook values. For more information on optimizing partition and codebook values, see the `lloyds` function.

randdeintrlv

Restore ordering of symbols using random permutation

Syntax

```
deintrlvd = randdeintrlv(data,state)
```

Description

`deintrlvd = randdeintrlv(data,state)` restores the original ordering of the elements in `data` by inverting a random permutation. The `state` parameter initializes the random number generator that the function uses to determine the permutation. `state` is either a scalar or a 35x1 vector, and is described in the `rand` function, which is used in `randintrlv`. The function is predictable for a given state, but different states produce different permutations. If `data` is a matrix with multiple rows and columns, the function processes the columns independently.

To use this function as an inverse of the `randintrlv` function, use the same `state` input in both functions. In that case, the two functions are inverses in the sense that applying `randintrlv` followed by `randdeintrlv` leaves data unchanged.

This function uses, by default, the Mersenne Twister algorithm by Nishimura and Matsumoto.

Note Using the `state` parameter causes this function to switch random generators to use the `'state'` algorithm of the `rand` function.

See `rand` for details on the generator algorithm.

Examples

For an example using random interleaving and deinterleaving, see “Improve Error Rate Using Block Interleaving in MATLAB”.

randerr

Generate bit error patterns

Syntax

```
out = randerr(m)
out = randerr(m,n)
out = randerr(m,n,errors)
out = randerr(m,n,errors,seed)
out = randerr(m,n,errors,randstream)
```

Description

Use the `randerr` function to generate bit error patterns. For all syntaxes, `randerr` treats each row of the output independently.

`out = randerr(m)` generates an `m`-by-`m` binary matrix, where each row has exactly one nonzero entry in a random position. Each permutation has an equal probability.

`out = randerr(m,n)` generates an `m`-by-`n` binary matrix, where each row has exactly one nonzero entry in a random position. Each permutation has an equal probability.

`out = randerr(m,n,errors)` uses the `errors` input to determine the number of nonzero entries in each row of the output `m`-by-`n` binary matrix.

`out = randerr(m,n,errors,seed)` specifies a seed value for initializing the uniform random number generator of the `rand` function.

`out = randerr(m,n,errors,randstream)` specifies a random stream object to generate uniform random noise samples by using the `rand` function. Providing a random stream object or using the `reset (RandStream)` function on the default random stream object enables you to generate repeatable noise samples.

Note To generate repeatable noise samples, use the same seed input value for each call of `randerr` or reset the random stream input before calling `randerr`. For more information on resetting the random stream, see the `RandStream` object.

Examples

Generate Random Error Matrix

Generate an 8-by-7 binary matrix in which each row is equally likely to have either zero or two nonzero elements.

```
out = randerr(8,7,[0 2])
```

```
out = 8×7
```

```
     0     1     0     0     0     1     0
     0     1     0     0     0     1     0
     0     0     0     0     0     0     0
     0     0     0     0     0     1     1
     0     0     0     0     0     0     0
     0     0     0     0     0     0     0
     0     0     1     0     0     0     1
     0     0     1     0     1     0     0
```

Generate a matrix in which each row is three times more likely to have two nonzero elements rather than zero nonzero elements.

```
out = randerr(8,7,[0 2; 0.25 0.75])
```

```
out = 8×7
```

```
     0     0     0     0     1     0     1
     0     1     0     0     0     0     1
     0     0     1     0     0     1     0
     0     1     0     0     1     0     0
     1     0     0     0     1     0     0
     0     0     0     0     0     0     0
     0     0     0     0     0     0     0
     0     0     0     0     0     0     0
```

Generate Repeatable Random Error Matrix

Demonstrate generation of a random error matrix without a seed input value for a nonrepeatable output and with the seed input value for a repeatable output.

Specify input parameters for the output matrix dimensions, the number of errors, and a seed value.

```
m = 2;
n = 8;
errors = 2;
seed = 1234;
```

Use the `randerr` function to generate a random error binary matrix twice with the same command. The output binary matrix values are the same for each execution of the `randerr` function.

```
out = randerr(m,n,errors,seed)
```

```
out = 2×8
```

```
     0     0     1     1     0     0     0     0
     0     1     0     1     0     0     0     0
```

```
out = randerr(m,n,errors,seed)
```

```
out = 2×8
```

```
     0     0     1     1     0     0     0     0
```

```
     0     1     0     1     0     0     0     0
```

Change the seed value and call the `randerr` function twice. The binary matrix output values are the same for each execution of the `randerr` function, but they differ from the binary matrix values output using the previous seed value.

```
seed = 345;
out = randerr(m,n,errors,seed)
```

```
out = 2×8

     0     0     0     0     1     0     1     0
     1     0     0     0     1     0     0     0
```

```
out = randerr(m,n,errors,seed)
```

```
out = 2×8

     0     0     0     0     1     0     1     0
     1     0     0     0     1     0     0     0
```

Use the `randerr` function to generate a random error binary matrix twice with the same command, not specifying a seed input value. The output matrix values change for each execution of the `randerr` function.

```
out = randerr(m,n,errors)
```

```
out = 2×8

     0     1     0     0     0     1     0     0
     0     1     0     0     0     0     0     1
```

```
out = randerr(m,n,errors)
```

```
out = 2×8

     0     1     0     0     0     0     0     1
     0     0     0     1     0     1     0     0
```

Input Arguments

`m` — Size of random binary matrix

positive integer

Size of the random binary matrix, specified as a positive integer.

- When you specify only the input `m`, the random binary matrix output is of size `m`-by-`m`.
- When you specify the inputs `m` and `n`, the random binary matrix output is of size `m`-by-`n`.

Data Types: `double`

`n` — Column size of random binary matrix

1 (default) | positive integer

Column size of the random binary matrix, specified as a positive integer.

Data Types: `double`

`errors` — Number of nonzero entries

1 (default) | nonnegative integer | nonnegative integer row vector | nonnegative two-row matrix

Number of nonzero entries, specified as one of these forms.

- If specified as a integer, `errors` defines the number of 1s in each row.
- If specified as a integer row vector, `errors` defines the number of 1s possible in each row. Every number of 1s included in this vector occurs with equal probability.
- If specified as a two-row matrix, the first row of `errors` defines the integer number of 1s possible in any given row of the output matrix. The second row specifies the probabilities of each corresponding number of ones. The elements in the second row of `errors` must sum to 1.

Data Types: `double`

`seed` — Seed value

nonnegative integer value less than 2^{32}

Seed value for initializing the uniform random number generator used in the `rand` function, specified as nonnegative integer value less than 2^{32}.

Data Types: `double`

`randstream` — Random stream object

`RandStream` object

Random stream object to generate uniform random noise samples by using the `rand` function, specified as a `RandStream` object. Providing a random stream object or using the `reset(RandStream)` function on the default random stream object enables you to generate repeatable noise samples.

Output Arguments

`out` — Random binary matrix output

matrix

Random binary matrix output, returned as a matrix of binary values.

- When you specify only the input `m`, this output is of size `m`-by-`m`.
- When you specify the inputs `m` and `n`, this output is of size `m`-by-`n`.

Data Types: `double`

randintrlv

Reorder symbols using random permutation

Syntax

```
intrlvd = randintrlv(data,state)
```

Description

`intrlvd = randintrlv(data,state)` rearranges the elements in `data` using a random permutation. The `state` parameter initializes the random number generator that the function uses to determine the permutation. `state` is either a scalar or a 35x1 vector, and is described in the `rand` function, which is used in `randintrlv`. The function is predictable and invertible for a given state, but different states produce different permutations. If `data` is a matrix with multiple rows and columns, the function processes the columns independently.

This function uses, by default, the Mersenne Twister algorithm by Nishimura and Matsumoto.

Note Using the `state` parameter causes this function to switch random generators to use the `'state'` algorithm of the `rand` function.

See `rand` for details on the generator algorithm.

Examples

For an example using random interleaving and deinterleaving, see “Improve Error Rate Using Block Interleaving in MATLAB”.

randsrc

Generate random matrix using prescribed alphabet

Syntax

```
out = randsrc
out = randsrc(m)
out = randsrc(m,n)
out = randsrc(m,n,alphabet)
out = randsrc(m,n,[alphabet; prob])
out = randsrc(m,n,___,seed)
out = randsrc(m,n,___,streamhandle)
```

Description

`out = randsrc` generates a random scalar that is either `-1` or `1`, with equal probability.

`out = randsrc(m)` generates an `m`-by-`m` random bipolar matrix. Each entry independently takes the value `-1` or `1` with equal probability.

`out = randsrc(m,n)` generates an `m`-by-`n` random bipolar matrix. Each entry independently takes the value `-1` or `1` with equal probability.

`out = randsrc(m,n,alphabet)` generates an `m`-by-`n` matrix, with each entry independently chosen from the entries in the row vector `alphabet`. Each entry in `alphabet` occurs in `out` with equal probability. Duplicate values in `alphabet` are ignored.

`out = randsrc(m,n,[alphabet; prob])` generates an `m`-by-`n` matrix, with each entry independently chosen from the entries in the row vector `alphabet`. Duplicate values in `alphabet` are ignored. The row vector `prob` lists corresponding probabilities, so that the symbol `alphabet(k)` occurs with probability `prob(k)`, where `k` is any integer between one and the number of columns of `alphabet`. The elements of `prob` must add up to 1.

`out = randsrc(m,n,___,seed)` accepts input combinations from prior syntaxes and a seed value, for initializing the uniform random number generator, `rand`.

`out = randsrc(m,n,___,streamhandle)` accepts input combinations from prior syntaxes and a random stream handle to generate uniform random noise samples by using `rand`. Providing a random stream handle or using the `reset (RandStream)` function on the default random stream object enables you to generate repeatable noise samples. If you want to generate repeatable noise samples, then either reset the random stream input before calling `randsrc` or use the same seed input. For more information, see `RandStream`.

Examples

Generate Random Matrix from Prescribed Alphabet

Generate a 10-by-10 matrix from the set of {-3,-1,1,3}.

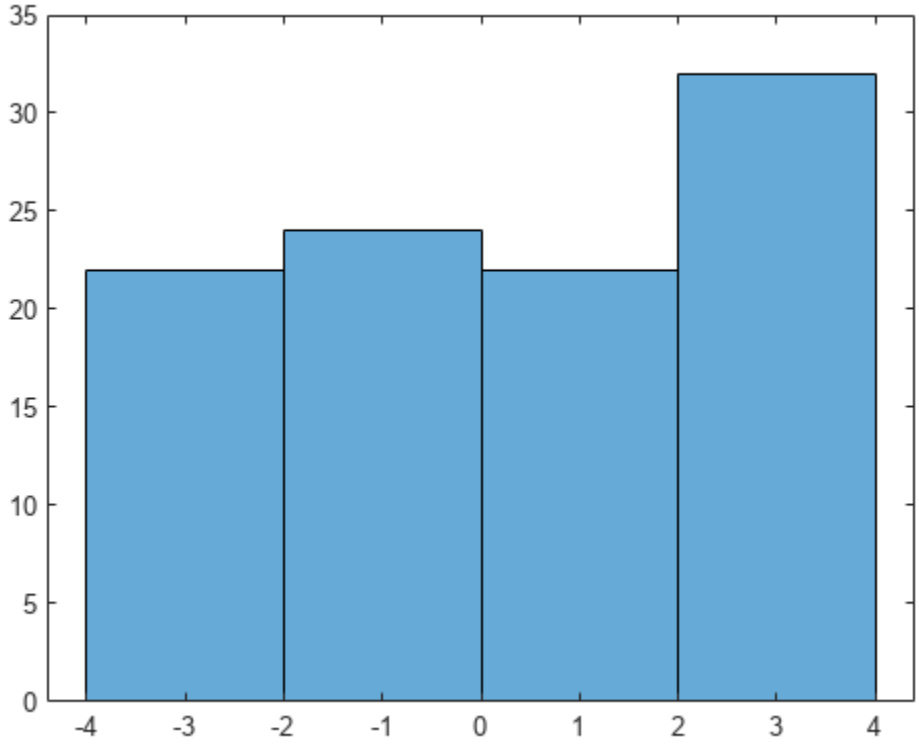
```
out = randsrc(10,10,[-3 -1 1 3])
```

```
out = 10×10

     3    -3     1     1    -1    -1     3     3    -1    -3
     3     3    -3    -3    -1     1    -1    -1     3    -3
    -3     3     3    -1     3     1     1     3     1     1
     3    -1     3    -3     3    -3     1    -3     1     3
     1     3     1    -3    -3    -3     3     3     3     3
    -3    -3     3     3    -1    -1     3    -1    -1    -3
    -1    -1     1     1    -1     3     1    -3     3     1
     1     3    -1    -1     1    -1    -3    -1     3    -1
     3     3     1     3     1     1    -3     1    -1    -3
     3     3    -3    -3     3    -3    -1    -1     1    -1
```

Plot the histogram. Each of the four possible element values occur with equal probability. Your values might differ.

```
histogram(out,[-4 -2 0 2 4])
```



Generate a matrix in which the likelihood of a -1 or 1 is four times higher than the likelihood of a -3 or 3.

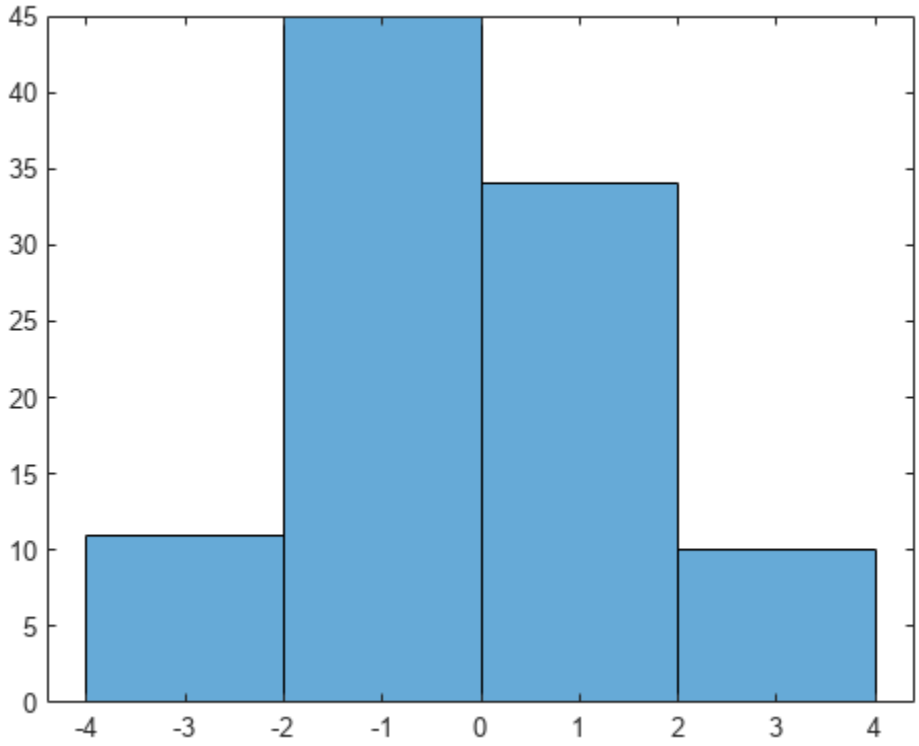
```
out = randsrc(10,10,[-3 -1 1 3; 0.1 0.4 0.4 0.1])
```

```
out = 10×10
```

```
    -1    -1    -1    -1     1    -1     1    -1     1     3
     1    -3     3     3     1    -3    -1    -1    -1     1
    -1    -1    -3    -1    -1     3    -1     1     1    -1
     1     3     1    -1     1     3    -1    -3    -1    -1
    -1    -1     1    -1    -1    -1    -3    -3     1    -1
     1     1     1    -1    -3    -1    -1    -1    -1    -1
    -1     1    -3     1    -1    -1     3     1    -1     1
     1     3    -1     1    -1     3     3     1     1     1
     1    -3    -1     1    -1    -1     1     1     1     1
     1    -1     1    -1    -1    -1    -3    -1    -3     1
```

Plot the histogram. Values of -1 and 1 are more likely.

```
histogram(out,[-4 -2 0 2 4])
```



Input Arguments

`m` — Bipolar matrix size

1 (default) | scalar

Size of random bipolar matrix, specified as a scalar. If `n` is specified, then `m` is the row size of the random bipolar matrix.

Data Types: `double`

`n` — Bipolar matrix column size
`1` (default) | scalar

Column size of random binary matrix, specified as a scalar.

Data Types: `double`

`alphabet` — Possible element values
`[-1 1]` (default) | vector | matrix

Possible elements of output vector or matrix. If `alphabet` is a row vector, the contents of `alphabet` define which possible elements `randsrc` output. If `alphabet` is a two-row matrix, then the first row is defines the possible elements, and the second row defines the probabilities for each corresponding element in the first row. The elements of the second row must sum to one. If all entries of alphabet are distinct, then the probability distribution is uniform.

Data Types: `double`

`prob` — Element probabilities
`[0.5 0.5]` (default) | vector

Row vector of probabilities that correspond to elements of the corresponding `alphabet` vector.

Data Types: `double`

`seed` — Seed value
scalar

Seed value for initializing the uniform random number generator, `rand`.

Data Types: `double`

`streamhandle` — Random stream handle
`RandStream` Object

Random stream handle to generate uniform random noise samples by using `rand`. Providing a random stream handle or using the `reset (RandStream)` function on the default random stream object enables you to generate repeatable noise samples. If you want to generate repeatable noise samples, then either reset the random stream input before calling `randsrc` or use the same seed input. For more information, see `RandStream`.

Data Types: `double`

Output Arguments

`out` — Random matrix output
scalar | vector | matrix

Random output, returned as a scalar, vector, or matrix. The dimensions of the output are specified by arguments `m` and `n`, otherwise it is a 1-by-1 scalar. The possible elements of the output and their probabilities are specified by `alphabet`, `prob` respectively, otherwise the elements of the output are `-1` and `1`, with equal distribution.

Data Types: `double`

`rand` | `randi` | `randerr` | `RandStream`

rectpulse

Rectangular pulse shaping

Syntax

```
y = rectpulse(x,nsamp)
```

Description

`y = rectpulse(x,nsamp)` applies rectangular pulse shaping to `x` to produce an output signal having `nsamp` samples per symbol. Rectangular pulse shaping means that each symbol from `x` is repeated `nsamp` times to form the output `y`. If `x` is a matrix with multiple rows, the function treats each column as a channel and processes the columns independently.

Note To insert zeros between successive samples of `x` instead of repeating the samples of `x`, use the `upsample` function instead.

Examples

To see this function in conjunction with modulation, see “Modulation with Pulse Shaping and Filtering Examples”.

The code below processes two independent channels, each containing three symbols of data. In the pulse-shaped matrix `y`, each symbol contains four samples.

```
nsamp = 4; % Number of samples per symbol
nsymb = 3; % Number of symbols
s = RandStream('mt19937ar', 'Seed', 0);
ch1 = randi(s, [0 1], nsymb, 1); % Random binary channel
ch2 = [1:nsymb]';
x = [ch1 ch2] % Two-channel signal
y = rectpulse(x,nsamp)
```

The output is below. In `y`, each column corresponds to one channel and each row corresponds to one sample. Also, the first four rows of `y` correspond to the first symbol, the next four rows of `y` correspond to the second symbol, and the last four rows of `y` correspond to the last symbol.

```
x =

     1     1
     1     2
     0     3

y =

     1     1
     1     1
     1     1
     1     1
```

```
1     2
1     2
1     2
1     2
0     3
0     3
0     3
0     3
```

`intdump` | `upsample`

rsdec

Reed-Solomon decoder

Syntax

```
decoded = rsdec(code,n,k)
decoded = rsdec(code,n,k,genpoly)
decoded = rsdec(...,paritypos)
[decoded,cnumerr] = rsdec(...)
[decoded,cnumerr,ccode] = rsdec(...)
```

Description

`decoded = rsdec(code,n,k)` attempts to decode the received signal in `code` using an [`n`,`k`] Reed-Solomon decoding process with the narrow-sense generator polynomial. `code` is a Galois array of symbols having m bits each. Each `n`-element row of `code` represents a corrupted systematic codeword, where the parity symbols are at the end and the leftmost symbol is the most significant symbol. `n` is at most 2^m-1. If `n` is not exactly 2^m-1, `rsdec` assumes that `code` is a corrupted version of a shortened code.

In the Galois array `decoded`, each row represents the attempt at decoding the corresponding row in `code`. A *decoding failure* occurs if `rsdec` detects more than `(n-k)/2` errors in a row of `code`. In this case, `rsdec` forms the corresponding row of `decoded` by merely removing `n-k` symbols from the end of the row of `code`.

`decoded = rsdec(code,n,k,genpoly)` is the same as the syntax above, except that a nonempty value of `genpoly` specifies the generator polynomial for the code. In this case, `genpoly` is a Galois row vector that lists the coefficients, in order of descending powers, of the generator polynomial. The generator polynomial must have degree `n-k`. To use the default narrow-sense generator polynomial, set `genpoly` to `[]`.

`decoded = rsdec(...,paritypos)` specifies whether the parity symbols in `code` were appended or prepended to the message in the coding operation. *`paritypos`* can be either `'end'` or `'beginning'`. The default is `'end'`. If *`paritypos`* is `'beginning'`, a decoding failure causes `rsdec` to remove `n-k` symbols from the beginning rather than the end of the row.

`[decoded,cnumerr] = rsdec(...)` returns a column vector `cnumerr`, each element of which is the number of corrected errors in the corresponding row of `code`. A value of `-1` in `cnumerr` indicates a decoding failure in that row in `code`.

`[decoded,cnumerr,ccode] = rsdec(...)` returns `ccode`, the corrected version of `code`. The Galois array `ccode` has the same format as `code`. If a decoding failure occurs in a certain row of `code`, the corresponding row in `ccode` contains that row unchanged.

Examples

Reed-Solomon Decoding

Set the RS code parameters.

```
m = 3;                    % Number of bits per symbol
n = 2^m-1;                % Codeword length
k = 3;                    % Message length
```

Generate three codewords composed of 3-bit symbols. Encode the message with a (7,3) RS code.

```
msg = gf([2 7 3; 4 0 6; 5 1 1],m);
code = rsenc(msg,n,k);
```

Introduce one error on the first codeword, two errors on the second codeword, and three errors on the third codeword.

```
errors = gf([2 0 0 0 0 0 0; 3 4 0 0 0 0 0; 5 6 7 0 0 0 0],m);
noisycode = code + errors;
```

Decode the corrupted codeword.

```
[rxcode,cnumerr] = rsdec(noisycode,n,k);
```

Observe that the number of corrected errors matches the introduced errors for the first two rows. In row three, the number of corrected errors is `-1` because a (7,3) RS code cannot correct more than two errors.

```
cnumerr
```

```
cnumerr = 3×1

     1
     2
    -1
```

Limitations

`n` and `k` must differ by an even integer. `n` must be between 3 and 65535.

Algorithms

`rsdec` uses the Berlekamp-Massey decoding algorithm. For information about this algorithm, see the works listed in “References” on page 2-704 below.

Version History

“Block Codes”

rsenc

Reed-Solomon encoder

Syntax

```
code = rsenc(msg,n,k)
code = rsenc(msg,n,k,genpoly)
code = rsenc(...,paritypos)
```

Description

`code = rsenc(msg,n,k)` encodes the message in `msg` using an [n,k] Reed-Solomon code with the narrow-sense generator polynomial. `msg` is a Galois array of symbols having m bits each. Each k-element row of `msg` represents a message word, where the leftmost symbol is the most significant symbol. `n` is at most 2^m-1. If `n` is not exactly 2^m-1, `rsenc` uses a shortened Reed-Solomon code. Parity symbols are at the end of each word in the output Galois array `code`.

`code = rsenc(msg,n,k,genpoly)` is the same as the syntax above, except that a nonempty value of `genpoly` specifies the generator polynomial for the code. In this case, `genpoly` is a Galois row vector that lists the coefficients, in order of descending powers, of the generator polynomial. The generator polynomial must have degree `n-k`. To use the default narrow-sense generator polynomial, set `genpoly` to `[]`.

`code = rsenc(...,paritypos)` specifies whether `rsenc` appends or prepends the parity symbols to the input message to form `code`. *`paritypos`* can be either `'end'` or `'beginning'`. The default is `'end'`.

Examples

Reed-Solomon Code Generation

Set the code parameters.

```
m = 3;           % Number of bits per symbol
n = 2^m - 1;     % Codeword length
k = 3;           % Message length
```

Create two messages based on GF(8).

```
msg = gf([2 7 3; 4 0 6],m)
```

```
msg = GF(2^3) array. Primitive polynomial = D^3+D+1 (11 decimal)

Array elements =

   2   7   3
   4   0   6
```

Generate RS (7,3) codewords.

```
code = rsenc(msg,n,k)

code = GF(2^3) array. Primitive polynomial = D^3+D+1 (11 decimal)

Array elements =

   2   7   3   3   6   7   6
   4   0   6   4   2   2   0
```

The codes are systematic so the first three symbols of each row match the rows of `msg`.

Limitations

`n` and `k` must differ by an integer. `n` between 7 and 65535.

rsgenpoly

Generator polynomial of Reed-Solomon code

Syntax

```
genpoly = rsgenpoly(N,K)
genpoly = rsgenpoly(N,K,prim_poly)
genpoly = rsgenpoly(N,K,prim_poly,B)
genpoly = rsgenpoly(N,K,prim_poly,B,outputFormat)
[genpoly,T] = rsgenpoly( ___ )
```

Description

`genpoly = rsgenpoly(N,K)` returns the narrow-sense generator polynomial of an `[N,K]` Reed-Solomon code. The output `genpoly` is a Galois field array that represents the coefficients of the generator polynomial in order of descending powers. A narrow-sense BCH code is a BCH code with `B = 1`. Here, the narrow-sense generator polynomial is $(X - \alpha^1)(X - \alpha^2)...(X - \alpha^{N-K})$, where α is a root of the default primitive polynomial for the field GF(`N+1`). For additional information, see Narrow-Sense BCH Codes and “Reed-Solomon Codes”.

`genpoly = rsgenpoly(N,K,prim_poly)` also specifies the primitive polynomial, `prim_poly`, for GF(`N+1`) that has α as a root.

`genpoly = rsgenpoly(N,K,prim_poly,B)` returns the generator polynomial, $(X - \alpha^B)(X - \alpha^{B+1})...(X - \alpha^{B+N-K-1})$, where `B` is an integer.

`genpoly = rsgenpoly(N,K,prim_poly,B,outputFormat)` specifies the output format of `genpoly` as a Galois field array or double-precision array.

`[genpoly,T] = rsgenpoly( ___ )` also returns the error-correction capability of the `[N,K]` Reed-Solomon code, `T`, using any of the preceding input argument syntaxes.

Examples

Create Narrow-Sense Generator Polynomial

Specify the codeword length, `n`, and message length, `k`.

```
n = 7;
k = 3;
```

Create the narrow-sense generator polynomial for the [n,k] Reed-Solomon code. `genpoly` is a Galois field array, by default, that represents the coefficients of this generator polynomial in order of descending powers.

```
genpoly = rsgenpoly(n,k)
```

```
genpoly = GF(2^3) array. Primitive polynomial = D^3+D+1 (11 decimal)
```

```
Array elements =

   1   3   1   2   3
```

Create Narrow-Sense Generator Polynomial Specifying Primitive Polynomial

Create the narrow-sense generator polynomial of a Reed-Solomon code with respect to the primitive polynomial $D^3 + D^2 + 1$.

Specify the codeword length, `n`, message length, `k`, and primitive polynomial $D^3 + D^2 + 1$ represented in decimal form.

```
n = 7;
k = 3;
prim_poly = 13;
```

Create the narrow-sense generator polynomial for the [`n`,`k`] Reed-Solomon code with respect to primitive polynomial $D^3 + D^2 + 1$ for GF(8). `genpoly` is a Galois field array, by default, that represents the coefficients of this generator polynomial in order of descending powers.

```
genpoly = rsgenpoly(n,k,prim_poly)
```

```
genpoly = GF(2^3) array. Primitive polynomial = D^3+D^2+1 (13 decimal)

Array elements =

   1   4   5   1   5
```

Create Generator Polynomial for Specified B

Create the generator polynomial of a Reed-Solomon code with respect to the default primitive polynomial.

Specify the codeword length, `n`, message length, `k`, and exponent of α, `b`.

```
n = 7;
k = 3;
b = 4;
```

Create the generator polynomial $\left(X - \alpha^4\right)\left(X - \alpha^5\right)\left(X - \alpha^6\right)\left(X - \alpha^7\right)$, with respect to the default primitive polynomial. `genpoly` is a Galois field array that represents the coefficients of this generator polynomial in order of descending powers. Display the error-correcting capability of the code.

```
[genpoly,t] = rsgenpoly(n,k,[],b)
```

```
genpoly = GF(2^3) array. Primitive polynomial = D^3+D+1 (11 decimal)

Array elements =
```

```
   1   5   5   3   2

t = 2
```

Create Generator Polynomial for DVB-S and WiMAX

Create the generator polynomial of a Reed-Solomon code with respect to the primitive polynomial $D^8 + D^4 + D^3 + D^2 + 1$.

Specify the codeword length, `n`, message length, `k`, the primitive polynomial represented in decimal form, and the exponent of α, `b`.

```
n = 255;
k = 239;
prim_poly = 285;
b = 0;
```

Create the generator polynomial for the [n,k] Reed-Solomon code. `genpoly` is a Galois field array that represents a generator polynomial and is compliant with DVB-S and WiMAX.

```
genpoly = rsgenpoly(n,k,prim_poly,b)
```

```
genpoly = GF(2^8) array. Primitive polynomial = D^8+D^4+D^3+D^2+1 (285 decimal)

Array elements =

  Columns 1 through 13

     1    59    13   104   189    68   209    30     8   163    65    41   229

  Columns 14 through 17

    98    50    36    59
```

Create Narrow-Sense Generator Polynomial with Output Format Double

Create the narrow-sense generator polynomial of a Reed-Solomon code. Specify the output data type as a double-precision array.

Specify the codeword length, `n`, and message length, `k`.

```
n = 7;
k = 3;
```

Create the narrow-sense generator polynomial for the [n,k] Reed-Solomon code. `genpoly` is a double-precision array, that represents the coefficients of this generator polynomial in order of descending powers. Specify defaults values for the primitive polynomial and exponent of α inputs by assigning [ ] for them.

```
genpoly = rsgenpoly(n,k,[],[],'double')
```

```
genpoly = 1×5

     1     3     1     2     3
```

Determine Corresponding Galois Field Array Value

Use the `genpoly2b` function to determine the corresponding Galois field array value.

Use `rsgenpoly` with codeword length of 7 and message word length of 3 to create a valid Galois field array.

```
n = 7;
k = 3;

genpoly = rsgenpoly(n,k)
```

```
genpoly = GF(2^3) array. Primitive polynomial = D^3+D+1 (11 decimal)

Array elements =

   1   3   1   2   3
```

Use `genpoly2b` to determine the corresponding Galois field array value for the polynomial input.

```
b = genpoly2b(genpoly)
```

```
b = 1
```

Input Arguments

`N` — Codeword length

positive odd integer

Codeword length, specified as an integer of the form `N` = 2^M – 1, where M is in the range [3,16]. For more information, see “Limitations” on page 2-712.

Example: Set `N` to 15 for M=4.

`K` — Message length

positive integer

Message length, specified as a positive integer. For more information, see “Limitations” on page 2-712.

`prim_poly` — Primitive polynomial

GF(N+1) (default) | positive integer

Primitive polynomial, specified as a positive integer. `prim_poly` is an integer whose binary representation indicates the coefficients of the primitive polynomial. To use the default primitive polynomial GF(`N+1`), set `prim_poly` to `[]`. For more information, see “Default Primitive Polynomials” on page 2-712.

Example: 19 specifies the primitive polynomial D^4+D+1 because its binary representation is 10011.

B — Exponent of α
1 (default) | positive integer

Exponent of α, specified as a positive integer. α is a root of `prim_poly`.

`outputFormat` — Output format
`'gf'` (default) | `'double'`

Output format of `genpoly`, specified as:

- `'gf'` — to output a Galois field array.
- `'double'` — to output a double-precision array of the Galois field values.

For more information, see “Working with Galois Fields”.

Output Arguments

`genpoly` — Generator polynomial coefficients
Galois field array | double-precision array

Generator polynomial coefficients in descending order, returned as a Galois field array or double-precision array. `genpoly` is a row vector that represents the coefficients of the narrow-sense generator polynomial of an [N,K] Reed-Solomon code in order of descending powers.

T — Error-correction capability
positive integer

Error-correction capability of the code, returned as a positive integer equal to $\lfloor(N - K)/2\rfloor$.

Limitations

- Valid values for $N = 2^M - 1$, where M is an integer in the range [3,16]. The maximum allowable value of $N = 2^{16} - 1 = 65{,}535$.
- Valid values for $K = [1, N - 1]$.

More About

Default Primitive Polynomials

This table lists the default primitive polynomial used for each Galois field array GF(2^m). To use a different primitive polynomial, specify `prim_poly` as an input argument. `prim_poly` must be in the range $[(2^m + 1), (2^{m+1} - 1)]$ and must indicate an irreducible polynomial. For more information, see “Primitive Polynomials and Element Representations”.

Value of m	Default Primitive Polynomial	Integer Representation
1	$D + 1$	3
2	$D^2 + D + 1$	7
3	$D^3 + D + 1$	11

Value of m	Default Primitive Polynomial	Integer Representation
4	$D^4 + D + 1$	19
5	$D^5 + D^2 + 1$	37
6	$D^6 + D + 1$	67
7	$D^7 + D^3 + 1$	137
8	$D^8 + D^4 + D^3 + D^2 + 1$	285
9	$D^9 + D^4 + 1$	529
10	$D^{10} + D^3 + 1$	1033
11	$D^{11} + D^2 + 1$	2053
12	$D^{12} + D^6 + D^4 + D + 1$	4179
13	$D^{13} + D^4 + D^3 + D + 1$	8219
14	$D^{14} + D^{10} + D^6 + D + 1$	17475
15	$D^{15} + D + 1$	32771
16	$D^{16} + D^{12} + D^3 + D + 1$	69643

rsgenpolycoeffs

Generator polynomial coefficients of Reed-Solomon code

Syntax

```
x = rsgenpolycoeffs(...)
[x,t] = rsgenpolycoeffs(...)
```

Description

`x = rsgenpolycoeffs(...)` returns the coefficients for the generator polynomial of the Reed-Solomon code. The output is identical to genpoly = rsgenpoly(...); x = genpoly.x.

`[x,t] = rsgenpolycoeffs(...)` returns *t*, the error-correction capability of the code.

Examples

Generate Polynomial Coefficients for a Reed-Solomon Code

This example shows how to generate polynomial coefficients for a (15,11) Reed-Solomon code.

Generate the coefficients using `rsgenpolycoeffs`.

```
genpoly = rsgenpolycoeffs(15,11)
```

```
genpoly = 1x5 uint32 row vector

    1   13   12    8    7
```

Version History

Introduced in R2010b

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

For C/C++ code generation, these usage notes and limitations apply:

All inputs must be constants. Expressions or variables are allowed if their values do not change.

scatterplot

Display input signal in IQ-plane

Syntax

```
scatterplot(x)
scatterplot(x,n)
scatterplot(x,n,offset)
scatterplot(x,n,offset,plotstring)
scatterplot(x,n,offset,plotstring,scatfig)
scatfig = scatterplot( ___ )
```

Description

`scatterplot(x)` creates a scatter plot to display the input signal `x` in the IQ-plane. Specifically, the IQ-plane displays the in-phase and quadrature components of a modulated signal on the real and imaginary axis of an xy-plot.

`scatterplot(x,n)` specifies decimation factor `n`. The function plots every `n`th value of `x`, starting from its first value.

`scatterplot(x,n,offset)` specifies the offset value. The function plots every `n`th value of `x`, starting from its (`offset` + 1)th value.

`scatterplot(x,n,offset,plotstring)` specifies plot attributes for the scatter plot.

`scatterplot(x,n,offset,plotstring,scatfig)` generates the scatter plot in the existing `Figure` object, `scatfig`. To plot multiple signals in the same figure, use `hold on`.

`scatfig = scatterplot( ___ )` returns the `Figure` object of the scatter plot. Use `scatfig` to query or modify properties of the figure after it is created. You can specify any of the input argument combinations from the previous syntaxes.

Examples

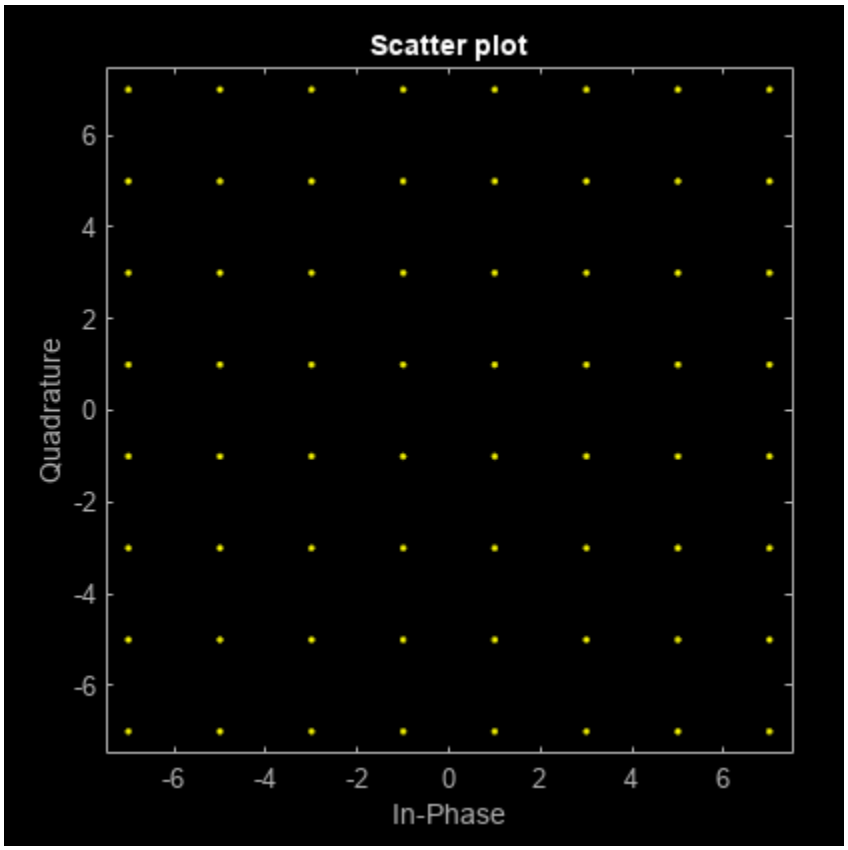
Generate Scatter Plot of 64-QAM Signal

Create a 64-QAM signal in which each constellation point is used.

```
d = (0:63)';
s = qammod(d,64);
```

Display the scatter plot of the constellation.

```
scatterplot(s)
```



Input Arguments

x — Input signal

vector | matrix

Input signal, specified as a vector or matrix.

The interpretation of x depends on its shape and complexity.

- If x is a real-valued two-column matrix, the function interprets the first column as in-phase components and the second column as quadrature components.
- If x is a complex-valued vector, the function interprets the real part as in-phase components and the imaginary part as quadrature components.
- If x is a real-valued vector, the function interprets it as a real signal.

Data Types: `double` | `single`
Complex Number Support: Yes

n — Decimation factor

1 (default) | positive integer

Decimation factor, specified as a positive integer. The function plots every nth value of input signal x, starting from its first value.

Data Types: `double`

`offset` — Offset value
`0` (default) | nonnegative integer

Offset value, specified as a nonnegative integer. This offset value specifies the number of samples at the beginning of input `x` that the function skips before generating the scatter plot.

Data Types: `double`

`plotstring` — Plot attributes
`'b.'` (default) | character vector | string scalar

Plot attributes, specified as a character vector or string scalar containing symbols.

This argument sets the plotting symbol, line type, and color for the scatter plot. The format and meaning of the symbols are the same as in the `plot` function. For example, the default value `'b.'` produces blue dots.

Data Types: `char` | `string`

`scatfig` — Target scatterplot
`Figure` object

Target scatterplot, specified as a `Figure` object for a previously generated `scatterplot`.

Output Arguments

`scatfig` — Target scatterplot
`Figure` object

Target scatterplot, returned as a `Figure` object. To modify properties of this object, see Figure Properties.

semianalytic

BER using semianalytic technique

Syntax

```
ber = semianalytic(txsig,rxsig,modtype,M,Nsamp)
ber = semianalytic(txsig,rxsig,modtype,M,Nsamp,num,den)
ber = semianalytic( ___ ,EbNo)
[ber,avgampl,avgpower] = semianalytic( ___ )
```

Description

The `semianalytic` function computes the bit error rate (BER) of a communication system for the specified energy per bit to noise power spectral density ratio (E_b/N_0) levels by using the semianalytic technique. The system transmits complex baseband signal `txsig` and receives noiseless complex baseband signal `rxsig`. The function filters the received signal `rxsig` and determines the symbol error probability of each received IQ symbol by analytically applying a Gaussian noise distribution to each complex value. The function averages the error probabilities over the entire received signal to determine the overall error probability. For each symbol error probability, the function returns a BER, assuming a Gray-coded constellation. For more information, see “When to Use Semianalytic Technique” on page 2-723.

`ber = semianalytic(txsig,rxsig,modtype,M,Nsamp)` returns the BER of the system for the transmitted signal `txsig`, received noiseless signal `rxsig`, modulation type `modtype`, and modulation order `M`. The function uses an ideal integrator to filter `rxsig`. Input `Nsamp` is the number of samples per symbol for each signal. The returned BER values correspond to the default E_b/N_0 levels in the range [0, 20] in dB.

`ber = semianalytic(txsig,rxsig,modtype,M,Nsamp,num,den)` specifies the filter coefficients of the receiver filter in descending polynomial powers by numerator `num` and denominator `den`. The function uses the specified receiver filter instead of an ideal integrator to filter `rxsig`.

`ber = semianalytic( ___ ,EbNo)` specifies the E_b/N_0 levels in addition to any of the input argument combinations in the previous syntaxes. The returned BER values correspond to the specified E_b/N_0 levels.

`[ber,avgampl,avgpower] = semianalytic( ___ )` returns the mean signal amplitude and the mean power of the received signal after filtering and sampling the signal at the symbol rate.

Examples

Analyze BER Using Semianalytic Technique

Use the semianalytic technique for BER analysis using a 16-QAM modulated signal. Compare the error rates obtained from the semianalytic technique with the theoretical error rates obtained from published formulas and computed using the `berawgn` function.

Generate a message signal. To obtain accurate results, the signal must be at least M^L long. M is the modulation order of the signal, and L is the length of the channel impulse response.

```
M = 16;          % Alphabet size of modulation
L = 1;           % Length of impulse response of channel
msg = [0:M-1 0]; % M-ary message sequence of length greater than M^L
```

Modulate the message signal using baseband modulation.

```
modsig = qammod(msg',M);          % Modulate data
Nsamp = 16;
modsig = rectpulse(modsig,Nsamp); % Rectangular pulse shaping
```

Apply a transmitter filter.

```
txsig = modsig;  % No filter in this example
```

Pass `txsig` through a noiseless channel, applying a static phase offset of 1 degree.

```
rxsig = txsig*exp(1i*pi/180);
```

Specify the receiver filter as a pair of input arguments. In this case, `num` and `den` represent an ideal integrator.

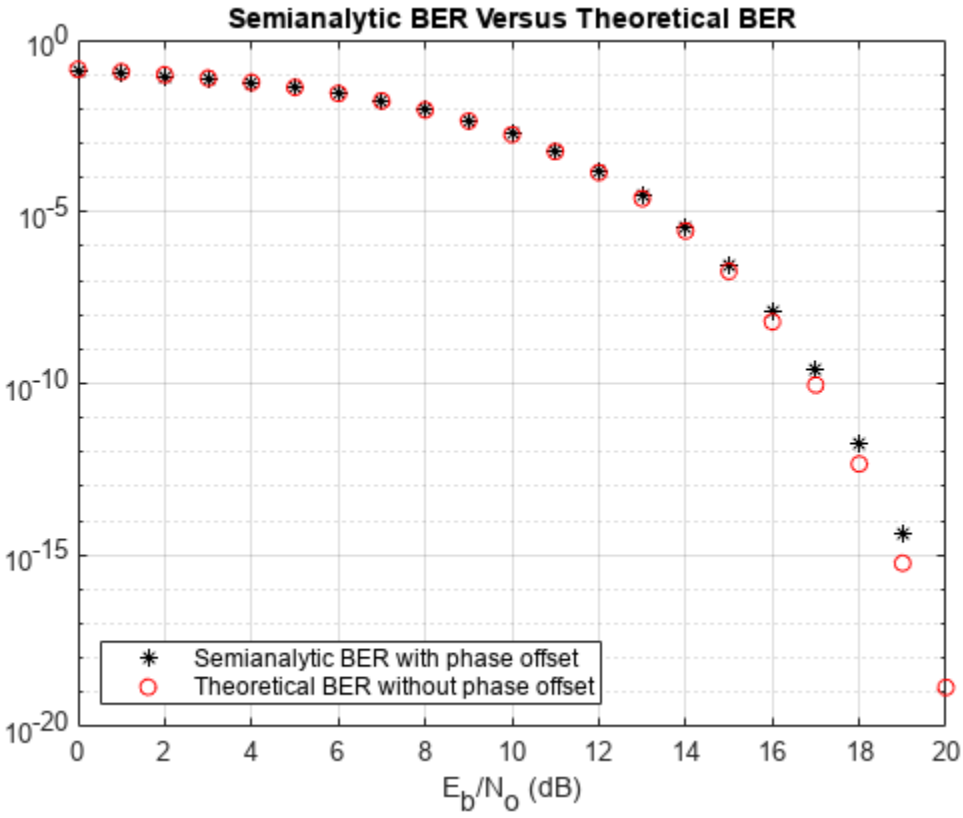
```
num = ones(Nsamp,1)/Nsamp;
den = 1;
EbNo = 0:20;
ber = semianalytic(txsig,rxsig,'qam',M,Nsamp,num,den,EbNo);
```

For comparison, calculate theoretical BER.

```
bertheory = berawgn(EbNo,'qam',M);
```

Plot the computed BER and theoretical BER. The differences between the theoretical and semianalytic error rates are due to the phase offset added to the 16-QAM signal.

```
semilogy(EbNo,ber,'k*');
hold on; semilogy(EbNo,bertheory,'ro');
title('Semianalytic BER Versus Theoretical BER');
xlabel('E_b/N_o (dB)');
legend('Semianalytic BER with phase offset',...
    'Theoretical BER without phase offset','Location','SouthWest');
hold off;
grid on;
```



Input Arguments

`txsig` — Transmitted baseband signal

complex vector

Transmitted baseband signal, specified as a complex vector. `txsig` must contain at least M^L symbols. `M` is the modulation order of the signal and L is the length of the channel impulse response in symbols. For more information on how to generate a transmitted baseband signal to use in this function, see “Procedure for Using Semianalytic Technique” on page 2-723.

Data Types: `double`
Complex Number Support: Yes

`rxsig` — Received noiseless baseband signal

complex vector

Received noiseless baseband signal, specified as a complex vector.

Data Types: `double`
Complex Number Support: Yes

`modtype` — Modulation type

`'dpsk'` | `'msk/diff'` | `'msk/nondiff'` | `'psk/diff'` | `'psk/nondiff'` | `'oqpsk'` | `'qam'` | ...

Modulation type, specified as one of these options in this table.

modtype Value	Modulation Scheme	Valid Values of Input M
'dpsk'	Differential phase shift keying (DPSK)	2 or 4
'msk/diff'	Minimum shift keying (MSK) with differential encoding, which is equivalent to conventional MSK	2
'msk/nondiff'	Minimum shift keying (MSK) with nondifferential encoding, which is equivalent to precoded MSK	2
'psk/diff'	Phase shift keying (PSK) with differential encoding	2 or 4
'psk/nondiff'	Phase shift keying (PSK) with nondifferential encoding	2, 4, 8, 16, 32, or 64
'oqpsk'	Offset quadrature phase shift keying (OQPSK)	4
'qam'	Quadrature amplitude modulation (QAM)	4, 8, 16, 32, 64, 128, 256, 512, or 1024

Data Types: char | string

M — Modulation order
power of two

Modulation order, specified as a power of two. Valid modulation order values depend on the specified modulation type, as described in the modtype input.

Data Types: single | double

Nsamp — Number of samples per symbol of received and transmitted signals
positive integer

Number of samples per symbol of received and transmitted signals, specified as a positive integer.

Data Types: double

num — Numerator coefficients of receiver filter
numeric row vector

Numerator coefficients of the receiver filter in descending polynomial powers, specified as a numeric row vector. If you do not specify this input, the function sets num to a default value to model an ideal integrator. The function bases the default value on the modtype input, as this table shows.

modtype Value	Default num Value
'dpsk', 'psk/diff', 'psk/nondiff', or 'qam'	ones(Nsamp,1)/Nsamp
'oqpsk', 'msk/diff', or 'msk/nondiff'	ones(2*Nsamp,1)/(2*Nsamp)

Data Types: double

den — Denominator coefficients of receiver filter
`1` (default) | numeric row vector

Denominator coefficients of the receiver filter in descending polynomial powers, specified as a numeric row vector. The default value corresponds to an ideal integrator.

Data Types: `double`

EbNo — E_b/N_0 levels
`[0:20]` (default) | numeric scalar | numeric vector

E_b/N_0 levels in dB, specified as a numeric scalar or numeric vector.

Data Types: `single` | `double`

Output Arguments

ber — BER
numeric scalar | numeric vector

BER, returned as a numeric scalar or numeric vector. The function computes the BER for the E_b/N_0 levels that you specify for the `EbNo` input. If `EbNo` is a vector, then the output `ber` is a vector of the size of `EbNo` and consists of elements corresponding to the different E_b/N_0 levels.

Note The output `ber` is an upper bound on the BER for these modulation schemes.

- DQPSK (that is, if you set input `modtype` to `'dpsk'` and input `M` to 4)
- Cross QAM (that is, if you set input `modtype` to `'qam'` and input `M` to a value that is not a perfect square). In this case, the upper bound is slightly tighter than the upper bound used for the cross QAM case of the `berawgn` function.

Data Types: `double`

avgampl — Mean signal amplitude of received signal
complex number

Mean signal amplitude of the I and Q components of the received signal after filtering and decimating the signal to the symbol rate, returned as a complex number.

Data Types: `double`
Complex Number Support: Yes

avgpower — Mean power of received signal
numeric scalar.

Mean power of the received signal after filtering and sampling the signal at the symbol rate, returned as a numeric scalar.

Data Types: `double`

Limitations

The `semianalytic` function makes several assumptions about the communication system. To find out whether your communication system is suitable for the semianalytic technique and the `semianalytic` function, see “When to Use Semianalytic Technique” on page 2-723.

More About

When to Use Semianalytic Technique

The Monte-Carlo simulation described in the “Performance Results via Simulation” section effectively calculates the BER for a variety of communication systems but can be prohibitively time-consuming for small error rates (for example, error rates of 10^{-6} or less). The semianalytic technique is an alternative way to compute error rates. This technique can produce results faster than a nonanalytic method that uses only simulated data.

To apply the semianalytic technique, the communication system must satisfy these characteristics.

- Any effects of multipath fading, quantization, and amplifier nonlinearities must precede the effects of noise in the modeled channel.
- The receiver is perfectly synchronized with the carrier, and timing jitter is negligible. Because phase noise and timing jitter can be slow processes, they can reduce the applicability of the semianalytic technique to a communication system.
- The noiseless simulation has no errors in the received signal constellation. Distortions from sources other than noise must be mild enough to keep each signal point in its correct decision region. For instance, if the modeled system has a phase rotation that places the received signal points outside of their proper decision regions, then the semianalytic technique is not suitable to predict system performance.

If the communication system does not satisfy these characteristics, the calculated BER can be lower than expected. The `semianalytic` function assumes that the noise in the modeled channel is Gaussian. For details on how to adapt the semianalytic technique for non-Gaussian noise, see the discussion of generalized exponential distributions in [1].

Procedure for Using Semianalytic Technique

These steps describe how to implement the semianalytic technique by using the `semianalytic` function.

1. Generate a message signal containing at least M^L symbols. `M` is the modulation order, and L is the length of the impulse response of the channel in symbols. Start with an augmented binary pseudonoise (PN) sequence of length $(\log_2 M)M^L$. An augmented PN sequence is a PN sequence with an extra zero appended to it, which makes the distribution of ones and zeros equal.
2. Modulate a carrier with the message signal by using one of the baseband modulation types that `semianalytic` supports. For an overview, see the `modtype` input. Shape the resultant signal with rectangular pulse shaping, using an oversampling factor that you use later for filtering the modulated signal. Use the result of this step as `txsig` when you call the `semianalytic` function.
3. Filter the modulated signal with a transmit filter. This filter is often a square-root raised cosine filter, but you can also use a Butterworth, Bessel, Chebyshev type 1 or 2, elliptic, or more general FIR or IIR filter. If you use a square-root raised cosine filter, use the filter on the nonoversampled

modulated signal, and specify the oversampling factor in the filtering function. You can apply the other filters to the rectangularly pulse shaped signal.

4. Pass the filtered signal through a noiseless channel. This channel can include multipath fading effects, phase shifts, amplifier nonlinearities, quantization, and additional filtering, but it must not include noise. Use the result of this step as the `rxsig` input when you call the `semianalytic` function.
5. Call the `semianalytic` function, specifying the transmitted and received signals, `txsig` and `rxsig`, obtained in the previous steps. Optionally, you can specify a custom receiver filter by using the `num` and `den` inputs or custom E_b/N_0 levels by using the `EbNo` input.

shift2mask

Convert shift to mask vector for shift register configuration

Syntax

```
mask = shift2mask(prpoly,shift)
```

Description

`mask = shift2mask(prpoly,shift)` returns the mask that is equivalent to the shift (or offset) specified by `shift`, for a linear feedback shift register whose connections are specified by the primitive polynomial `prpoly`. The `prpoly` input can have one of these formats:

- A polynomial character vector
- A binary vector that lists the coefficients of the primitive polynomial in order of descending powers
- An integer scalar whose binary representation gives the coefficients of the primitive polynomial, where the least significant bit is the constant term

The `shift` input is an integer scalar.

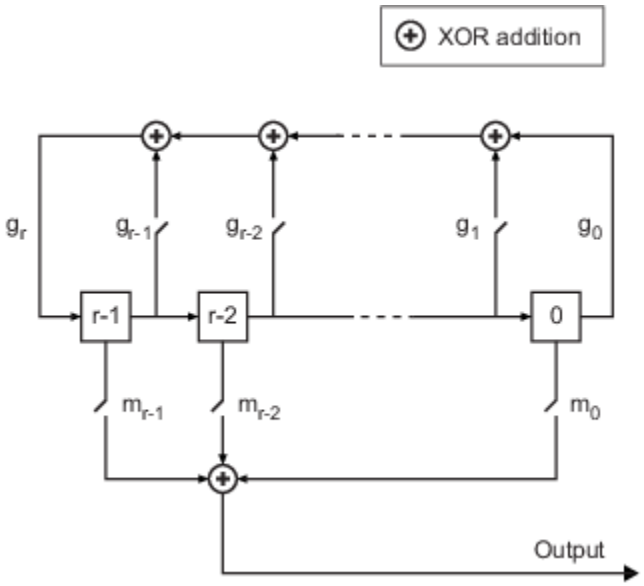
Note To save time, `shift2mask` does not check that `prpoly` is primitive. If it is not primitive, the output is not meaningful. To find primitive polynomials, use `primpoly` or see [2].

Definition of Equivalent Mask

The equivalent mask for the shift s is the remainder after dividing the polynomial x^s by the primitive polynomial. The vector `mask` represents the remainder polynomial by listing the coefficients in order of descending powers.

Shifts, Masks, and Pseudonoise Sequence Generators

Linear feedback shift registers are part of an implementation of a pseudonoise sequence generator. Below is a schematic diagram of a pseudonoise sequence generator. All adders perform addition modulo 2.



The primitive polynomial determines the state of each switch labeled g_k, and the mask determines the state of each switch labeled m_k. The lower half of the diagram shows the implementation of the shift, which delays the starting point of the output sequence. If the shift is zero, the m_0 switch is closed while all other m_k switches are open. The table below indicates how the shift affects the shift register's output.

	T = 0	T = 1	T = 2	...	T = s	T = s+1
Shift = 0	x_0	x_1	x_2	...	x_s	x_{s+1}
Shift = s > 0	x_s	x_{s+1}	x_{s+2}	...	x_{2s}	x_{2s+1}

If you have Communications Toolbox software and want to generate a pseudonoise sequence in a Simulink model, see the PN Sequence Generator block reference page.

Examples

Convert Shift to Mask

Convert a shift in a linear feedback shift register into an equivalent mask.

Convert a shift of 5 into the equivalent mask $x^3 + x + 1$ for the linear feedback shift register whose connections are specified by the primitive polynomial $x^4 + x^3 + 1$. The length of the mask is equal to the degree of the primitive polynomial, 4.

```
mk = shift2mask([1 1 0 0 1],5)
```

```
mk = 1×4

     1     0     1     1
```

Convert a shift of 7 to a mask of $x^4 + x^2$ for the primitive polynomial $x^5 + x^2 + 1$.

```
mk2 = shift2mask('x5+x2+1',7)
```

```
mk2 = 1×5

     1     0     1     0     0
```

showcommblockdatatypetable

Communications Toolbox block characteristics

Syntax

```
showcommblockdatatypetable
```

Description

`showcommblockdatatypetable` shows a table of characteristics for the Communications Toolbox blocks. The table lists capabilities and limitations about code generation, variable size, and supported data types for each block. If a cell includes an "X", the corresponding block supports the capability indicated by the column heading. Descriptions for numbered footnotes, "(#)", follow the table.

Examples

Show Communications Toolbox Block Characteristics

To show a table of Communications Toolbox block characteristics, enter `showcommblockdatatypetable` at the MATLAB command line. The table opens in a separate window.

srmdelay

Compute delay introduced by Sample-Rate Match block

Syntax

```
delay = srmdelay(inputrates,inputlengths,outputrate,outputlength)
delay = srmdelay(inputrates,inputlengths,outputrate,outputlength,mode)
```

Description

`delay = srmdelay(inputrates,inputlengths,outputrate,outputlength)` returns delay in number of samples for the specified inputs. Use this function to compute the delay that will be introduced by the Sample-Rate Match block.

`delay = srmdelay(inputrates,inputlengths,outputrate,outputlength,mode)` returns delay in number of samples for the specified inputs. Use this function to compute the delay that will be introduced by the Sample-Rate Match block.

Examples

Determine Delay for Rate Matched 5G and LTE Signals

Resample a 5G signal at 7.68 MHz and an LTE signal at 3.84 MHz to a higher rate of 15.36 MHz.

```
inpRates = [7.68 3.84]*1e6;
inpLengths = [1e3 1e3];
outRate = 15.36e6;
outLength = 1e3;
```

Determine delay incurred for a model configured for multitasking mode.

```
d = srmdelay(inpRates,inpLengths,outRate,outLength)
```

```
d = 2×1

        1024
        1048
```

Determine Delay for Rate Matched WLAN and 5G Signals

Resample a WLAN signal at 20 MHz and a 5g signal at 15.36 MHz to a higher rate of 30.72 MHz.

```
inpRates = [20 15.36]*1e6;
inpLengths = [2 1]*10;
outRate = 30.72e6;
outLength = 50;
```

Determine delay incurred for a model configured for single-tasking mode.

```
d = srmdelay(inpRates,inpLengths,outRate,outLength,"singletasking")
```

```
d = 2×1

   145
   174
```

Input Arguments

`inputrates` — Input sample rates

2-element vector

Input sample rates in Hz, specified as a 2-element vector of positive values.

Data Types: `double`

`inputlengths` — Input lengths

2-element vector

Input lengths in samples, specified as a 2-element vector of positive integer values.

Data Types: `double`

`outputrate` — Output sample rate

positive scalar

Output sample rate in Hz, specified as a positive scalar.

Data Types: `double`

`outputlength` — Output length

positive integer

Output length in samples, specified as a positive integer.

Data Types: `double`

`mode` — Tasking mode

`"multitasking"` (default) | `"singletasking"`

Tasking mode of the model, specified as either `"multitasking"` or `"singletasking"`. The **Treat each discrete rate as a separate task** parameter of the **Solver** controls the mode of the model. For more information on the **Treat each discrete rate as a separate task** and **Solver** parameters, see “Solver Pane” (Simulink).

Output Arguments

`delay` — Sample rate match delay

column vector

Sample rate match delay in samples, returned as a 2-element column vector. The first element corresponds to the delay introduced in the first input and the second element corresponds to the delay introduced in the second input.

ssbdemod

Single sideband amplitude demodulation

Syntax

```
z = ssbdemod(y,Fc,Fs)
z = ssbdemod(y,Fc,Fs,ini_phase)
z = ssbdemod(y,Fc,Fs,ini_phase,num,den)
```

Description

For All Syntaxes

`z = ssbdemod(y,Fc,Fs)` demodulates the single sideband amplitude modulated signal `y` from the carrier signal having frequency `Fc` (Hz). The carrier signal and `y` have sampling rate `Fs` (Hz). The modulated signal has zero initial phase, and can be an upper- or lower-sideband signal. The demodulation process uses the lowpass filter specified by `[num,den] = butter(5,Fc*2/Fs)`.

Note The `Fc` and `Fs` arguments must satisfy `Fs` > 2(`Fc` + `BW`), where `BW` is the bandwidth of the original signal that was modulated.

`z = ssbdemod(y,Fc,Fs,ini_phase)` specifies the initial phase of the modulated signal in radians.

`z = ssbdemod(y,Fc,Fs,ini_phase,num,den)` specifies the numerator and denominator of the lowpass filter used in the demodulation.

Examples

Demodulate Sideband Signal

Define the sampling frequency and original signal.

```
fs = 270000;
t = (0:1/fs:0.01)';
signal = sin(2*pi*300.*t)+2*sin(2*pi*600.*t);
```

Convert the original signal to upper-sideband and lower-sideband modulated signals using `ssbmod`. Use a cutoff frequency of `12000` and an initial phase of `0`.

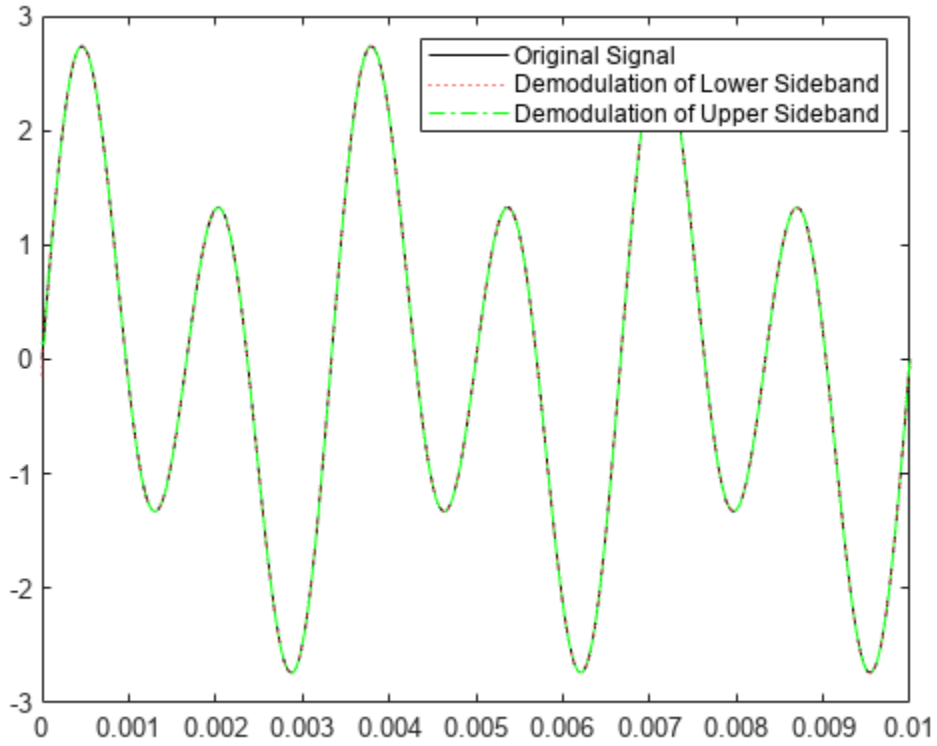
```
fc = 12000;
initialPhase = 0;
lowerSidebandSignal = ssbmod(signal,fc,fs,initialPhase);
upperSidebandSignal = ssbmod(signal,fc,fs,initialPhase,'upper');
```

Demodulate the lower and upper sideband signals.

```
s1 = ssbdemod(lowerSidebandSignal,fc,fs);
s2 = ssbdemod(upperSidebandSignal,fc,fs);
```

Compare processed signals with original and verify reconstruction.

```
plot(t,signal,'k',t,s1,'r:',t,s2,'g-.');
legend('Original Signal','Demodulation of Lower Sideband','Demodulation of Upper Sideband');
```



Version History

Introduced before R2006a

ssbmod

Single sideband amplitude modulation

Syntax

```
y = ssbmod(x,Fc,Fs)
y = ssbmod(x,Fc,Fs,ini_phase)
y = ssbmod(x,fc,fs,ini_phase,'upper')
```

Description

`y = ssbmod(x,Fc,Fs)` uses the message signal `x` to modulate a carrier signal with frequency `Fc` (Hz) using single sideband amplitude modulation in which the lower sideband is the desired sideband. The generated output `y` is a single side band signal with a suppressed carrier. The carrier signal and `x` have sample frequency `Fs` (Hz). The modulated signal has zero initial phase.

`y = ssbmod(x,Fc,Fs,ini_phase)` specifies the initial phase of the modulated signal in radians.

`y = ssbmod(x,fc,fs,ini_phase,'upper')` uses the upper sideband as the desired sideband.

Examples

Compare Double-Sideband and Single-Sideband Amplitude Modulation

Set the sample rate to 100 Hz. Create a time vector 100 seconds long.

```
fs = 100;
t = (0:1/fs:100)';
```

Set the carrier frequency to 10 Hz. Generate a sinusoidal signal.

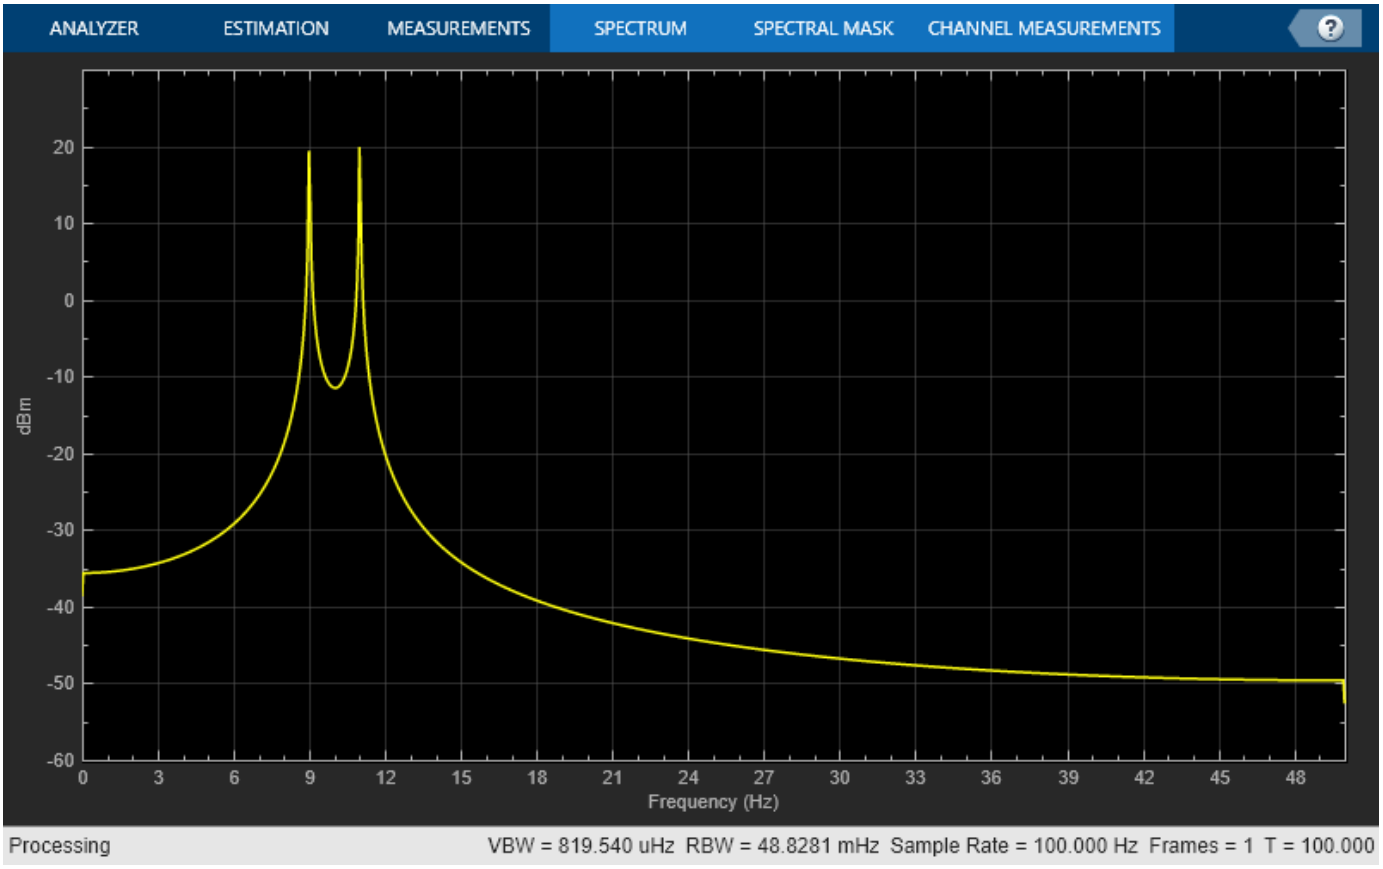
```
fc = 10;
x = sin(2*pi*t);
```

Modulate `x` using single- and double-sideband AM.

```
ydouble = ammod(x,fc,fs);
ysingle = ssbmod(x,fc,fs);
```

Create a spectrum analyzer object to plot the spectrum of the double-sideband signal.

```
sadsb = spectrumAnalyzer( ...
    SampleRate=fs, ...
    PlotAsTwoSidedSpectrum=false, ...
    YLimits=[-60 30]);
sadsb(ydouble)
```



Create a separate spectrum analyzer object to plot the single-sideband spectrum. A separate spectrum analyzer object is used to isolate each spectrum analyzer's signal buffers for the two signals.

```
sassb = spectrumAnalyzer( ...
    SampleRate=fs, ...
    PlotAsTwoSidedSpectrum=false, ...
    YLimits=[-60 30]);
sassb(ysingle)
```

stdchan

Construct channel System object from set of standardized channel models

Syntax

```
chan = stdchan(chantype,rs,fd)
```

Description

`chan = stdchan(chantype,rs,fd)` constructs a fading channel object `chan` according to the specified `chantype`. `chantype` is chosen from the channel models listed in “Supported Standards” on page 2-739. `rs` is the sampling rate of the input signal and `fd` is the maximum Doppler shift.

Examples

Filter Signal Through CDMA Channel

Set the sample rate and the maximum Doppler shift.

```
rs = 20e6;
fd = 3;
```

Create a CDMA Typical Urban channel model (TUx) channel object and turn on frequency response visualization.

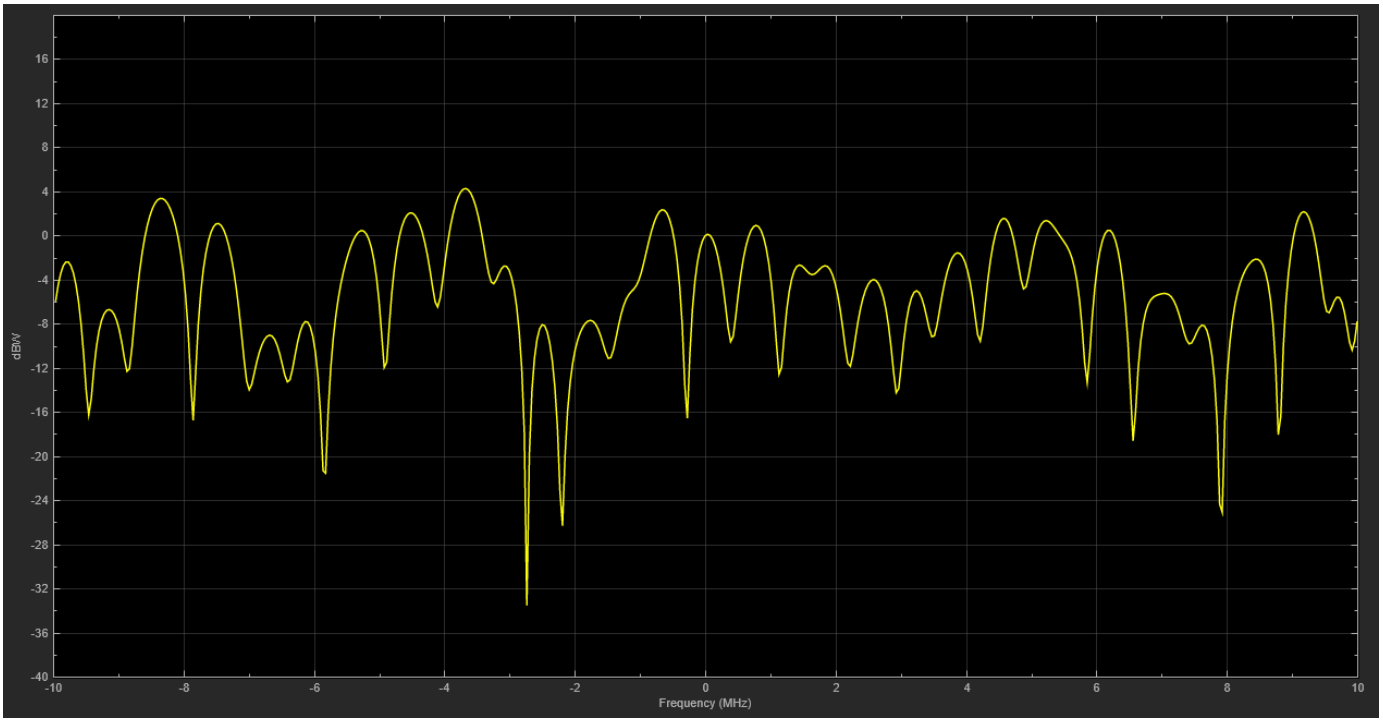
```
chan = stdchan('cdmaTUx',rs,fd);
chan.Visualization = 'Frequency response';
```

Generate random data and apply QPSK modulation.

```
data = randi([0 3],10000,1);
txSig = pskmod(data,4,pi/4);
```

Filter the QPSK signal through the CDMA channel.

```
y = chan(txSig);
```



Input Arguments

`chantype` — Channel type

string | character vector

Channel type, specified as a string or character vector. Valid options are listed in “Supported Standards” on page 2-739.

Example: `stdchan('gsmRAx6c1',rs,fd)`, configures a channel model for the GSM typical case for rural area (RAx), 6 taps, case 1, with a sample rate `rs`, and maximum Doppler shift `fd`

Data Types: `char` | `string`

`rs` — Sample rate

scalar

Sample rate in Hertz, specified as a scalar.

Data Types: `double`

`fd` — Maximum Doppler shift

scalar

Maximum Doppler shift in Hertz, specified as a scalar.

Data Types: `double`

Output Arguments

chan — Channel object

System object

Channel object, returned as a `comm.RayleighChannel` or `comm.RicianChannel` System object.

More About

Supported Standards

For GSM, CDMA, and ITU-R HF standards, call `stdchan` to return a `comm.RayleighChannel` or `comm.RicianChannel` System object modeling one of these profiles.

GSM/EDGE channel models (3GPP TS 45.005 V7.9.0 (2007-2), 3GPP TS 05.05 V8.20.0 (2005-11)):

Channel model	Profile
`gsmRAx6c1`	Typical case for rural area (RAx), 6 taps, case 1
`gsmRAx4c2`	Typical case for rural area (RAx), 4 taps, case 2
`gsmHTx12c1`	Typical case for hilly terrain (HTx), 12 taps, case 1
`gsmHTx12c2`	Typical case for hilly terrain (HTx), 12 taps, case 2
`gsmHTx6c1`	Typical case for hilly terrain (HTx), 6 taps, case 1
`gsmHTx6c2`	Typical case for hilly terrain (HTx), 6 taps, case 2
`gsmTUx12c1`	Typical case for urban area (TUx), 12 taps, case 1
`gsmTUx12c1`	Typical case for urban area (TUx), 12 taps, case 2
`gsmTUx6c1`	Typical case for urban area (TUx), 6 taps, case 1
`gsmTUx6c2`	Typical case for urban area (TUx), 6 taps, case 2
`gsmEQx6`	Profile for equalization test (EQx), 6 taps
`gsmTIx2`	Typical case for very small cells (TIx), 2 taps

CDMA channel models for deployment evaluation (3GPP TR 25.943 V6.0.0 (2004-12)):

Channel model	Profile
`cdmaTUx`	Typical Urban channel model (TUx)
`cdmaRAx`	Rural Area channel model (RAx)
`cdmaHTx`	Hilly Terrain channel model (HTx)

ITU-R HF channel models (ITU-R F.1487 (2000)) (FD must be 1 to obtain the correct frequency spreads for these models.):

Channel model	Profile
`iturHFLQ`	Low latitudes, Quiet conditions
`iturHFLM`	Low latitudes, Moderate conditions

Channel model	Profile
`iturHFLD`	Low latitudes, Disturbed conditions
`iturHFMQ`	Medium latitudes, Quiet conditions
`iturHFMM`	Medium latitudes, Moderate conditions
`iturHFMD`	Medium latitudes, Disturbed conditions
`iturHFMDV`	Medium latitudes, Disturbed conditions near vertical incidence
`iturHFHQ`	High latitudes, Quiet conditions
`iturHFHM`	High latitudes, Moderate conditions
`iturHFHD`	High latitudes, Disturbed conditions

Version History

Introduced in R2007b

`stdchan(ts,fd,channType)` syntax has been removed

stdchan`(ts,fd,chanType)` syntax has been removed.

Compatibility considerations for the `stdchan` function includes addition of a function syntax, removal of a function syntax, and removal of configuration support for several channel models.

- The syntax `chan = stdchan(ts,fd,chantype)` has been removed. A System object is returned using the new syntax.
- `stdchan` has removed support for configuration of several channel models by supported standards and associated syntax, compatibility considerations are indicated here:

Standard	Previous Syntax	New Syntax to Return System Object	Notes
3GPP, CDMA	`stdchan(ts,fd,'3gppXXX')`	`stdchan('cdmaXXX',rs,fd)`	Prefix changed from '`3gpp`' to '`cdma`'. `ts` and `rs` are reciprocal values.
GSM	`stdchan(ts,fd,'gsmXXX')`	`stdchan('gsmXXX',rs,fd)`	`ts` and `rs` are reciprocal values.
ITU-R HF	`stdchan(ts,fd,'iturHFXXX')`	`stdchan('iturHFXXX',rs,fd)`	`ts` and `rs` are reciprocal values.
COST207	`stdchan(ts,fd,'cost207XXX')`	N/A	In the future `stdchan` will not configure these channels. Use `comm.RayleighChannel` or `comm.RicianChannel` to configure the
ITU-R 3G	`stdchan(ts,fd,'itur3GXXX')`	N/A	
JTC	`stdchan(ts,fd,'jtcXXX')`	N/A	

HIPERLAN/2	`stdchan(ts,fd,'hiperlan2XXX')`	N/A	channel models for COST207, ITU-R 3G, JTC, HIPERLAN/2, and 802.11a/b/g standards. For guidance mapping parameters, see “Rayleigh Channel Compatibility Considerations” and “Rician Channel Compatibility Considerations”.

symerr

Compute number of symbol errors and symbol error rate

Syntax

```
[number,ratio] = symerr(x,y)
[number,ratio] = symerr(x,y,flg)
[number,ratio,individual] = symerr(...)
```

Description

`[number,ratio] = symerr(x,y)` compares the elements in `x` and `y`. The sizes of `x` and `y` determine which elements are compared. The output `number` is a scalar or vector that indicates the number of elements that differ. The output `ratio` equals `number` divided by the total number of elements in the *smaller* input.

`[number,ratio] = symerr(x,y,flg)` compares the elements in `x` and `y`. Optional input *`flg`* and the size of x, and y, determine the size of `number`.

`[number,ratio,individual] = symerr(...)` returns a binary matrix `individual` that indicates which elements of `x` and `y` differ. An element of `individual` is zero if the corresponding comparison yields no discrepancy, and one otherwise.

Examples

Compare Elements of Matrix

Compare Elements of Matrix with Another Matrix

```
x = [1,1,3,1;3,2,2,2;3,3,8,3]
```

```
x = 3×4

     1     1     3     1
     3     2     2     2
     3     3     8     3
```

```
aMatrix = [1,1,1,1;2,2,2,2;3,3,3,3]
```

```
aMatrix = 3×4

     1     1     1     1
     2     2     2     2
     3     3     3     3
```

```
[number1,ratio1] = symerr(x,aMatrix)
```

```
number1 = 3
```

```
ratio1 = 0.2500
```

Compare Elements of Matrix with Row Vector

```
x = [1,1,3,1;3,2,2,2;3,3,8,3]
```

```
x = 3×4

     1     1     3     1
     3     2     2     2
     3     3     8     3
```

```
aRowVector = [1,2,3,1]
```

```
aRowVector = 1×4

     1     2     3     1
```

```
[number2,ratio2] = symerr(x,aRowVector)
```

```
number2 = 3×1

     1
     3
     4
```

```
ratio2 = 3×1

    0.2500
    0.7500
    1.0000
```

Compare Elements of Matrix with Column Vector

```
x = [1,1,3,1;3,2,2,2;3,3,8,3]
```

```
x = 3×4

     1     1     3     1
     3     2     2     2
     3     3     8     3
```

```
aColumnVector = [1;2;3]
```

```
aColumnVector = 3×1

     1
     2
     3
```

```
[number3,ratio3] = symerr(x,aColumnVector)
```

```
number3 = 1×4

     1     0     2     0

ratio3 = 1×4

    0.3333         0    0.6667         0
```

Use Alternative Type of Comparison

You can specify alternative comparison methods used by `symerr`. In this example, you use a flag to override the default row-by-row comparison. Notice that number and ratio are scalars.

```
format rat;
[number,ratio,loc] = symerr([1 2; 3 4],[1 3],'overall')
```

```
number =
       3

ratio =
       3/4

loc = 2x2 logical array

   0   1
   1   1
```

Input Arguments

x — First input to compare

scalar | vector | matrix

First input to compare, specified as a vector, or a matrix.

Data Types: `double`

y — Second input to compare

scalar | vector | matrix

Second input to compare, specified as a vector, or a matrix.

Data Types: `double`

flg — Element comparison type

`'overall'` | `'column-wise'` | `'row-wise'`

Optional argument to override the defaults that govern which elements `symerr` compares and how `symerr` computes the outputs.

- `'overall'` –– `x` and `y` are compared element by element.

- `'column-wise'` –– m^{th} row of `x` vs. m^{th} row of `y`.
- `'row-wise'` –– m^{th} column of `x` vs. m^{th} column of `y`.

For more information, see the “Specifying Element Comparison” on page 2-746 section.

Output Arguments

`number` — Number of differing elements

scalar | vector

Number of elements that differ between `x` and `y`, returned as a scalar or vector. The size of `number` is determined by the optional input *`flg`* and by the dimensions of `x` and `y`. For more information, see the “Default Element Comparison” on page 2-745 and “Specifying Element Comparison” on page 2-746 sections.

`ratio` — Ratio of differing elements

scalar

The ratio of the number of differing elements, `number`, and the total number of elements of the *smaller* input, returned as a scalar.

`individual` — Results of each individual symbol comparison

matrix

Results of each individual symbol comparison, returned as a matrix of same size and dimensions as inputs `x` and `y`. The output matrix contains zeros for all locations corresponding to the elements of `x` and `y` that are equal, and ones where the two elements differ.

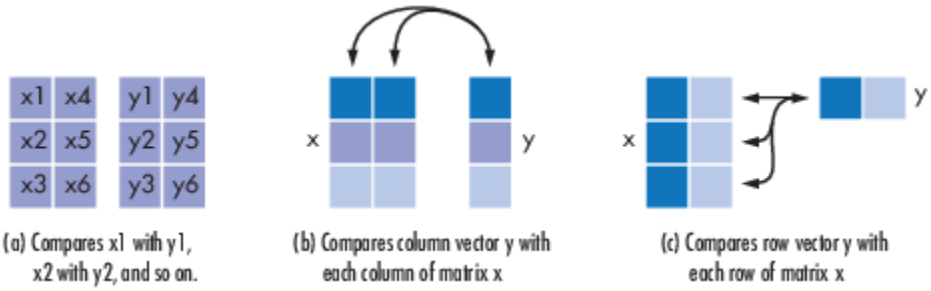
Data Types: `logical`

More About

Default Element Comparison

The `symerr` function compares binary representations of elements in `x` with those in `y`. When optional argument *`flg`* is not specified, `symerr` uses the shape of the inputs `x` and `y` to determine the element comparison method.

The schematics below illustrate how the shapes of `x` and `y` determine which elements `symerr` compares:



- If `x` and `y` are matrices of the same dimensions, then `symerr` compares `x` and `y` element by element. `number` is a scalar. See schematic (a) in the figure.

- If one is a row (respectively, column) vector and the other is a two-dimensional matrix, then `symerr` compares the vector element by element with *each row (resp., column)* of the matrix. The length of the vector must equal the number of columns (resp., rows) in the matrix. `number` is a column (resp., row) vector whose mth entry indicates the number of elements that differ when comparing the vector with the mth row (resp., column) of the matrix. See schematics (b) and (c) in the figure.

Specifying Element Comparison

Use *`flg`* to override the defaults that govern which elements `symerr` compares and how `symerr` computes the outputs. The values of *`flg`* are `'overall'`, `'column-wise'`, and `'row-wise'`. The table below describes the differences that result from various combinations of inputs. In all cases, `ratio` is `number` divided by the total number of elements in `y`.

Comparing a Two-Dimensional Matrix x with Another Input y

Shape of y	*flg*	Type of Comparison	number
Two-dim. matrix	`'overall'` (default)	Element by element	Total number of symbol errors
	`'column-wise'`	m^{th} column of `x` vs. m^{th} column of `y`	Row vector whose entries count symbol errors in each column
	`'row-wise'`	m^{th} row of `x` vs. m^{th} row of `y`	Column vector whose entries count symbol errors in each row
Column vector	`'overall'`	`y` vs. each column of `x`	Total number of symbol errors
	`'column-wise'` (default)	`y` vs. each column of `x`	Row vector whose entries count symbol errors in each column of `x`
Row vector	`'overall'`	`y` vs. each row of `x`	Total number of symbol errors
	`'row-wise'` (default)	`y` vs. each row of `x`	Column vector whose entries count symbol errors in each row of `x`

syndtable

Produce syndrome decoding table

Syntax

```
t = syndtable(h)
```

Description

`t = syndtable(h)` returns a decoding table for an error-correcting binary code having codeword length n and message length k. `h` is an (n-k)-by-n parity-check matrix for the code. `t` is a 2^{n-k}-by-n binary matrix. The rth row of `t` is an error pattern for a received binary codeword whose syndrome has decimal integer value r-1. (The syndrome of a received codeword is its product with the transpose of the parity-check matrix.) In other words, the rows of `t` represent the coset leaders from the code's standard array.

When converting between binary and decimal values, the leftmost column is interpreted as the *most* significant digit.

Examples

An example is in “Use Decoding Table in MATLAB”.

Topics

“Block Codes”

tpcdec

Turbo product code (TPC) decoder

Syntax

```
decoded = tpcdec(llr,N,K)
decoded = tpcdec(llr,N,K,S)
decoded = tpcdec(llr,N,K,S,maxnumiter)
decoded = tpcdec(llr,N,K,S,maxnumiter,earlyterm)
[decoded,actualnumiter] = tpcdec( ___ )
```

Description

`decoded = tpcdec(llr,N,K)` performs 2-D TPC decoding on input log likelihood ratios, `llr`, using two linear block codes specified by codeword length `N` and message length `K`. For a description of 2-D TPC decoding, see “Turbo Product Code Decoding” on page 2-753.

`decoded = tpcdec(llr,N,K,S)` performs 2-D TPC decoding on the shortened `llr` using a 2-D TPC decoder specified by codeword length (`N`–`K`+`S`) and message length `S`.

`decoded = tpcdec(llr,N,K,S,maxnumiter)` performs 2-D TPC decoding for `maxnumiter` iterations. To use `maxnumiter` with full-length messages, specify `S` as empty, [ ].

`decoded = tpcdec(llr,N,K,S,maxnumiter,earlyterm)` performs 2-D TPC decoding and terminates early if the calculated syndrome or parity-check of the component code evaluates to zero before `maxnumiter` decoding iterations. To use `maxnumiter` and `earlyterm` with full-length messages, specify `S` as empty, [ ].

`[decoded,actualnumiter] = tpcdec( ___ )` also returns the actual number of decoding iterations after performing 2-D TPC decoding using any of the prior syntaxes.

Examples

Decode Using Full-Length TPC Codes

Decode an approximate log-likelihood ratio output signal from 16-QAM demodulation.

Begin by encoding a random bit vector using 2-D turbo product coding (TPC) with extended Hamming codes and extended BCH codes.

Specify the (N,K) code pairs to use for TPC encoding.

```
N = [32;16];
K = [21;11];
```

Generate a column vector of random message bits and TPC-encode the message. Specify the message bits as a vector with length equal to the product of the elements in `K`.

```
msg = randi([0 1],prod(K),1);
code = tpcenc(msg,N,K);
```

Apply 16-QAM modulation. Add AWGN to the signal. Demodulate the signal, outputting approximate LLRs.

```
M = 16;
snr = 10;

txsig = qammod(code,M,'InputType','bit', ...
    'UnitAveragePower',true);

rxsig = awgn(txsig,snr,'measured');

llr = qamdemod(rxsig,M,'OutputType','approxllr', ...
    'UnitAveragePower',true,'NoiseVariance',10.^(-snr/10));
```

Perform TPC decoding using three iterations. Because the demodulator output is negative bipolar mapped and TPC decoder expects positive bipolar mapped input, the demodulated signal output must be negated at the decoder input. Check the number of bit errors in the decoded signal.

```
iterations = 3;
decoded = tpcdec(-llr,N,K,[],iterations);

numerr = biterr(msg,decoded)
```

```
numerr = 0
```

Decode Using Shortened TPC Codes

Decode a shortened TPC code. Apply QPSK modulation and output the approximate log-likelihood ratio signal obtained from QPSK demodulation.

Begin by encoding a random bit vector using 2-D turbo product coding (TPC) with extended Hamming codes and extended BCH codes.

Specify (N,K) code pairs and S for TPC encoding.

```
N = [32;32];
K = [21;26];
S = [19;24];
```

Generate a column vector of random message bits and TPC-encode the message. Specify the shortened message bits as a vector with length equal to the product of the elements in `S`.

```
msg = randi([0 1],prod(S),1);
code = tpcenc(msg,N,K,S);
```

Apply QPSK modulation. Add AWGN to the signal. Demodulate the signal and output approximate LLRs.

```
M = 4;
snr = 3;

txsig = qammod(code,M,'InputType','bit', ...
    'UnitAveragePower',true);

rxsig = awgn(txsig,snr,'measured');
```

```
llr = qamdemod(rxsig,M,'OutputType','approxllr', ...
    'UnitAveragePower',true,'NoiseVariance',10.^(-snr/10));
```

Perform TPC decoding using two iterations. Because the demodulator output is negative bipolar mapped and TPC decoder expects positive bipolar mapped input, the demodulated signal output must be negated at the decoder input. Check the bit error rate of the decoded signal.

```
iterations = 2;
decoded = tpcdec(-llr,N,K,S,iterations);

[~,ber] = biterr(msg,decoded)
```

```
ber = 0.0066
```

TPC Decoding with Shortening and Early Termination

Decode a shortened TPC code and specify early termination of decoding. Apply QPSK modulation and output the approximate log-likelihood ratio signal obtained from QPSK demodulation.

Begin by encoding a random bit vector using 2-D turbo product coding (TPC) with extended Hamming codes and extended BCH codes. Specify (N,K) code pairs and S for TPC encoding, and a maximum of 10 decoding iterations. Perform QPSK modulation on the signal.

```
n = [64; 32];
k = [51; 26];
s = [49; 24];
maxnumiter = 10;
M = 4;

msg = randi([0 1],prod(s),1);  % Random bits
code = tpcenc(msg,n,k,s);

txsig = qammod(code,M,'InputType','bit', ...
    'UnitAveragePower',true);
```

Add noise to the transmitted signal.

```
snr = 5;
rxsig = awgn(txsig,snr,'measured');
```

Demodulate the received signal using approximate LLR demapping.

```
llr = qamdemod(rxsig,M,'OutputType', ...
    'approxllr','UnitAveragePower',true, ...
    'NoiseVariance',10.^(-snr/10));
```

Specify the maximum number of TPC decoding iterations and return the actual number of iterations performed. Early termination of the TPC decoding is on by default. Display the number of errors and the number of iterations performed.

```
[decoded,actualNumIter] = tpcdec(-llr,n,k,s,maxnumiter);
numErr = biterr(msg,decoded);
disp(['Terminated after ' num2str(actualNumIter) ' iterations.' ...
    ' Number of errors = ' num2str(numErr) '.']);
```

```
Terminated after 4 iterations. Number of errors = 0.
```

Input Arguments

`llr` — Log likelihood ratios

column vector

Log likelihood ratios, specified as a column vector.

- For full-length codes, the length of the input column vector is the product of the elements in `N`.
- For shortened codes, the length of the input column vector is the product of the elements in (`N`–`K` +`S`).

Data Types: `double` | `single`

`N` — Codeword length

two-element integer vector

Codeword length, specified as a two-element integer vector, [N_R; N_C]. N_R represents the number of rows in the product code matrix. N_C represents the number of columns in the product code matrix. For more information about N_R and N_C, see "Turbo Product Code Decoding" on page 2-753. For a list of valid ($N(i)$, $K(i)$) code pairs, see "More About" on page 2-752.

Data Types: `double`

`K` — Message length

two-element integer vector

Message length, specified as a two-element integer vector, [K_R; K_C]. For a full-length message, the input column vector containing the input LLRs is arranged into a K_R-by-K_C matrix. K_R represents the number of rows in the message matrix. K_C represents the number of columns in the message matrix. For more information about K_R and K_C, see "Turbo Product Code Decoding" on page 2-753. For a list of valid ($N(i)$, $K(i)$) code pairs, see "More About" on page 2-752.

Data Types: `double`

`S` — Shortened message length

two-element integer vector

Shortened message length, specified as a two-element integer vector, [S_R; S_C]. For a shortened message, the input column vector containing the input LLRs is arranged into an S_R-by-S_C matrix. S_R represents the number of rows in the matrix. S_C represents the number of columns in the matrix. For more information about S_R and S_C, see "Turbo Product Code Decoding" on page 2-753.

When you specify this parameter, specify N and K vectors for the full-length TPC codes that are shortened to ($N(i) - K(i) + S(i)$, $S(i)$) codes.

Data Types: `double`

`maxnumiter` — Maximum number of decoding iterations

4 (default) | positive integer

Maximum number of decoding iterations, specified as a positive integer.

Data Types: `double`

`earlyterm` — Enable early termination

`true` (default) | `false`

Enable early termination of decoding, specified as a logical. When `earlyterm` is `true` the decoding terminates early if the calculated syndrome or parity-check of the component code evaluates to zero before `maxnumiter` decoding iterations.

Data Types: `double`

Output Arguments

`decoded` — TPC decoded message

column vector

TPC decoded message, returned as a column vector.

- For full-length codes, the length of the returned column vector is the product of the elements in K.
- For shortened codes, the length of the returned column vector is the product of the elements in S.

Data Types: `logical`

`actualnumiter` — Actual number of decoding iterations

positive integer

Actual number of decoding iterations performed, returned as a positive integer.

Data Types: `double`

More About

Component Codes

This table lists the supported component code pairs for the row (N_R,K_R) and column (N_C,K_C) parameters.

- N_R and K_R represent the number of rows in the product code matrix and message matrix, respectively.
- N_C and K_C represent the number of columns in the product code matrix and message matrix, respectively.

Within each code type, any two component code pairs can form a 2-D TPC code. The table also includes the error-correction capability for each code pair.

Code type	**Component Code Pairs**(N_R,K_R) and (N_C,K_C)	**Error-Correction Capability (*T*)**

Turbo Product Code Decoding

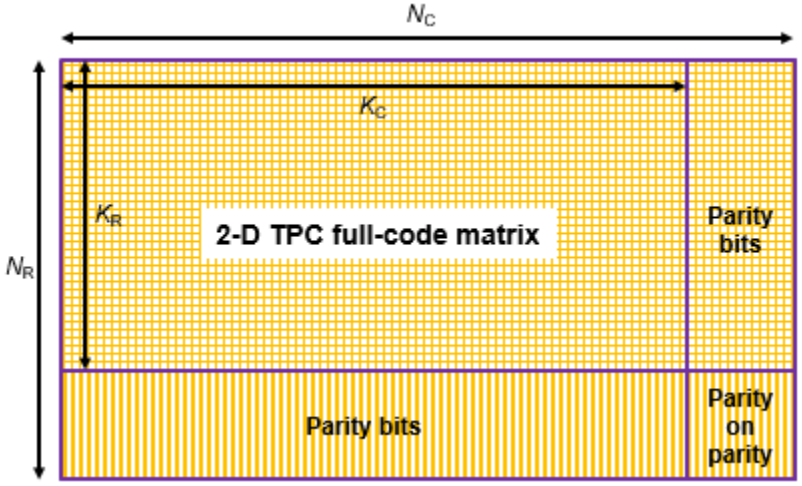
Turbo product codes (TPC) are a form of concatenated codes used as forward error correcting (FEC) codes. Two or more component block codes, such as systematic linear block codes, are used to construct TPCs. The TPC decoder achieves near-optimum decoding of product codes using Chase decoding and the Pyndiah algorithm to perform iterative soft input, soft output decoding. For a detailed description, see [1] and [2]. This decoder implements an iterative soft input, soft output 2-D product code decoding, as described in [2], using two “Linear Block Codes”. The decoder expects the soft bit log likelihood ratios (LLRs) obtained from digital demodulation as the input signal.

Note The TPC decoder expects a positive bipolar mapped input, specifically –1 mapped to 0 and +1 mapped to 1. The output from demodulators in the Communications Toolbox is negative bipolar mapping, specifically +1 mapped to 0 and –1 mapped to +1. Therefore, the LLR output from demodulators must be negated to provide the positive bipolar mapped input expected by the TPC decoder.

The TPC decoder decodes either full-length or shortened codes.

TPC Decoding Full-Length Messages

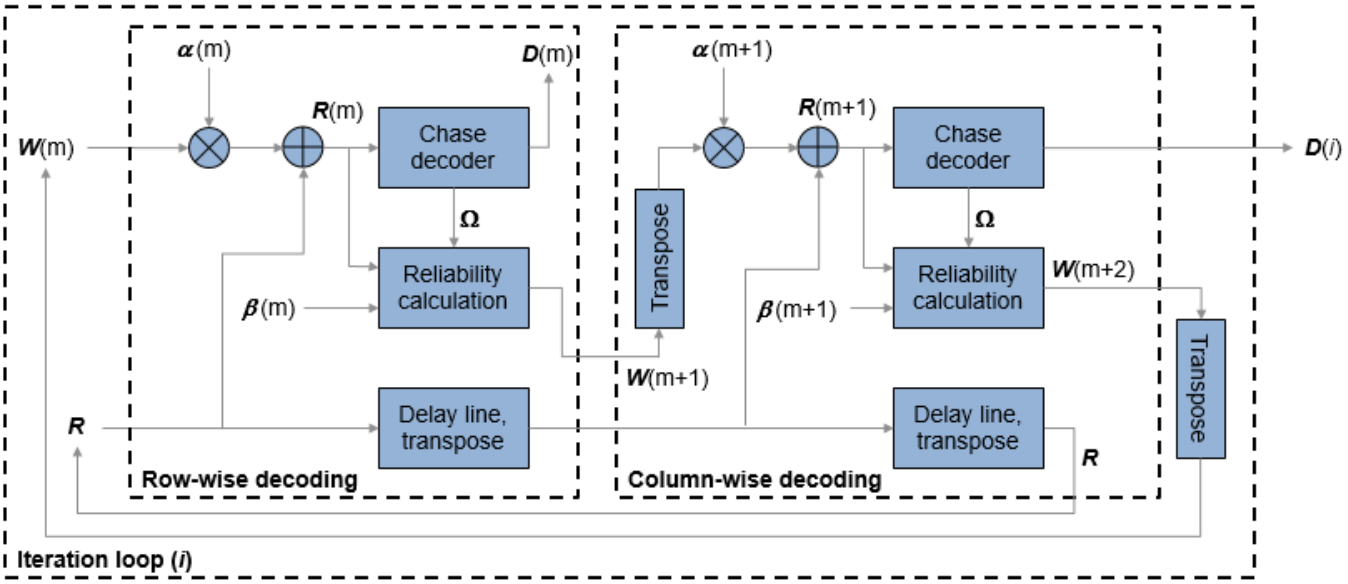
TPC encoded full-length input messages are decoded using specified 2-D TPC code pairs. Row-wise decoding uses the (N_C,K_C) code pair and column-wise decoding uses the (N_R,K_R) code pair. The input vector length must be $N_R \times N_C$. To perform the 2-D TPC decoding, the column vector of the input LLRs, composed of the message and parity bits, is arranged into an N_R-by-N_C matrix.



The TPC decoder achieves near-optimum decoding of product codes using Chase decoding and the Pyndiah algorithm to perform iterative soft input, soft output decoding. Chase decoding forms a set of possible codewords for each row or column. The Pyndiah algorithm calculates soft information required for the next decoding step.

Iterative Soft Input, Soft Output Decoder

The iterative soft input, soft output decoding, as shown in the block diagram, carries out two decoding steps for each iteration.



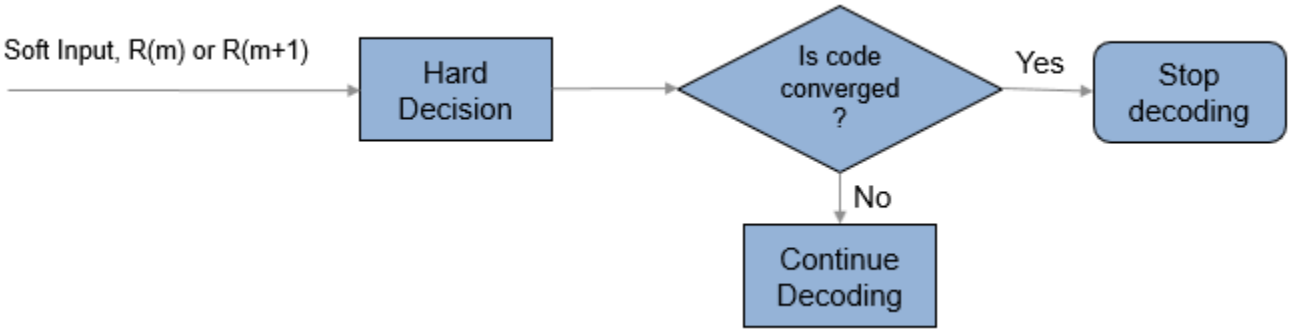
The soft inputs for decoding are $\boldsymbol{R}(m) = \boldsymbol{R} + \alpha(m)\boldsymbol{W}(m)$.

- Iteration loop counter i increments from $i = 1$ to the specified number of iterations.
- $m = 2i - 1$ is the decoding step index.
- $\boldsymbol{R}$ is the received LLR matrix.
- $\boldsymbol{R}(m)$ is the soft input for the mth decoding step.
- $\boldsymbol{W}(m)$ is the input extrinsic information for the mth decoding step.
- $\alpha(m)$ = [0,0.2,0.3,0.5,0.7,0.9,1,1, ...], where α is a weighting factor applied based on the decoding step index. For higher decoding steps, $\alpha = 1$.
- $\beta(m)$ = [0.2,0.4,0.6,0.8,1,1, ...], where β is a reliability factor applied based on the decoding step index. For higher decoding steps, $\beta = 1$.
- $\boldsymbol{D}$ contains the decoded message bits. The output message bits are formed from $\boldsymbol{D}$ by mapping –1 to 0 and +1 to 1, then reshaping the message block into a column vector.

The output message bits are formed after iterating through the specified number of iterations, or, if early termination is enabled, after code convergence.

Early Termination of TPC Decoding

If early termination is enabled, a code convergence check is performed on the hard decision of the soft input in each row-wise and column-wise decoding step. Early termination can be triggered after either the row-wise decoding or column-wise decoding converges.



The code is converged if, for all rows or all columns,

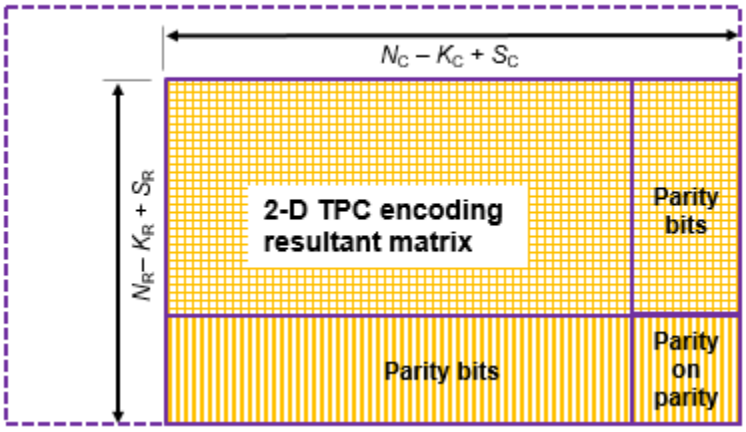
- The syndrome evaluates to zero in the codes (Hamming codes, Extended Hamming codes, BCH codes, or Extended BCH codes).
- The parity check is evaluated to zero in parity check codes.

The reported number of iterations evaluates to the iteration value that is currently in progress. For example, if the code convergence check is satisfied after row-wise decoding in the third iteration (after 2.5 decoding steps), then the number of iteration returned is 3.

TPC Decoding Shortened Messages

TPC encoded shortened input messages are decoded using specified 2-D TPC code pairs. Row-wise decoding uses the ($N_C - K_C + S_C$, S_C) code pair and column-wise decoding uses the ($N_R - K_R + S_R$, S_R) code pair. The input vector length must be ($N_R - K_R + S_R$) × ($N_C - K_C + S_C$). To perform the 2-D TPC

decoding of shortened messages, the column vector of the input LLRs, composed of the shortened message and parity bits, is arranged into an (N_R – K_R + S_R)-by-(N_C – K_C + S_C) matrix.



The TPC decoder processes the received shortened message LLRs similar to full length codes, with these exceptions:

- The shortened bit positions in the received codeword are set to –1.
- The Chase algorithm does not consider the shortened bit positions while choosing the least reliable bits.

Blocks
TPC Decoder

tpcenc

Turbo product code (TPC) encoder

Syntax

```
code = tpcenc(msg,N,K)
code = tpcenc(msg,N,K,S)
```

Description

`code = tpcenc(msg,N,K)` performs 2-D TPC encoding of the input message, `msg`, using two linear block codes specified by codeword length `N` and message length `K`. For a description of 2-D TPC encoding, see “Turbo Product Code Construction” on page 2-761.

`code = tpcenc(msg,N,K,S)` performs 2-D TPC encoding on the shortened input message of length `S`, using a 2-D TPC encoder specified by codeword length (`N`–`K`+`S`) and message length `S`.

Examples

Encode Using Full-Length TPC Codes

Encode a random bit vector using 2-D turbo product coding (TPC) with extended Hamming codes and extended BCH codes.

Specify (N,K) code pairs for TPC encoding.

```
N = [32;64];
K = [21;57];
```

Generate a column vector of random message bits. The desired length for the message bits is the product of elements in `K`.

```
msg = randi([0 1],prod(K),1);
```

TPC-encode the message.

```
code = tpcenc(msg,N,K);
```

Verify that the length of the encoded codeword is the product of elements in `N`.

```
size(code)
```

```
ans = 1×2

        2048           1
```

```
prod(N)
```

```
ans = 2048
```

Encode Shortened Message Using Turbo Product Coding

Encode a random bit vector using 2-D turbo product coding (TPC), applying message shortening.

Specify (N,K) code pairs and S for TPC encoding.

```
N = [32;64];
K = [21;57];
S = [19;24];
```

Generate a column vector of random message bits. The desired length for the shortened message bits is the product of the elements in `S`.

```
msg = randi([0 1],prod(S),1);
```

TPC-encode the shortened message.

```
code = tpcenc(msg,N,K,S);
```

Verify that the length of the encoded codeword is the product of elements in (`N-K+S`).

```
size(code)
```

```
ans = 1×2

   930     1
```

```
prod(N-K+S)
```

```
ans = 930
```

Input Arguments

`msg` — Input message bits to encode

column vector

Input message bits to encode, specified as a column vector.

- For a full-length input messages, the length of the column vector must be the product of the elements in `K`.
- For a shortened input messages, the length of the column vector must be the product of the elements in `S`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

`N` — Codeword length

two-element integer vector

Codeword length, specified as a two-element integer vector, [N_R; N_C]. N_R represents the number of rows in the product code matrix. N_C represents the number of columns in the product code matrix. For more information about N_R and N_C, see “Turbo Product Code Construction” on page 2-761. For a list of valid ($N(i)$,$K(i)$) code pairs, see “Component Codes” on page 2-760.

Data Types: `double`

K — Message length

two-element integer vector

Message length, specified as a two-element integer vector, [K_R; K_C]. For a full-length message, the input column vector containing the message bits to encode is arranged into a K_R-by-K_C matrix. K_R represents the number of rows in the message matrix. K_C represents the number of columns in the message matrix. For more information about K_R and K_C, see "Turbo Product Code Construction" on page 2-761. For a list of valid ($N(i)$,$K(i)$) code pairs, see "Component Codes" on page 2-760.

Data Types: `double`

S — Shortened message length

two-element integer vector

Shortened message length, specified as a two-element integer vector, [S_R; S_C]. For a shortened message, the input column vector containing the message bits to encode is arranged into an S_R-by-S_C matrix. S_R represents the number of rows in the matrix. S_C represents the number of columns in the matrix. For more information about S_R and S_C, see "Turbo Product Code Construction" on page 2-761.

When you specify this parameter, specify N and K vectors for the full-length TPC codes that are shortened to ($N(i)$–$K(i)$+$S(i)$, $S(i)$) codes.

Data Types: `double`

Output Arguments

code — TPC-encoded message

column vector

TPC-encoded message, returned as a column vector with the same data type as the input message bits.

- For full-length input messages, the length of the returned column vector is the product of the elements in `N`.
- For shortened input messages, the length of the returned column vector is the product of the elements in (`N`–`K`+`S`).

More About

Component Codes

This table lists the supported component code pairs for the row (N_R,K_R) and column (N_C,K_C) parameters.

- N_R and K_R represent the number of rows in the product code matrix and message matrix, respectively.
- N_C and K_C represent the number of columns in the product code matrix and message matrix, respectively.

Within each code type, any two component code pairs can form a 2-D TPC code. The table also includes the error-correction capability for each code pair.

Code type	**Component Code Pairs**(N_R,K_R) and (N_C,K_C)	**Error-Correction Capability (*T*)**

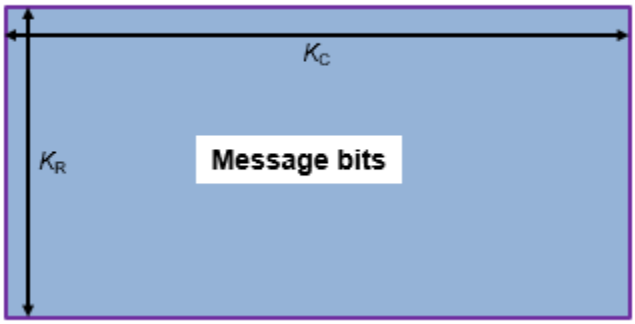
Turbo Product Code Construction

Turbo product codes (TPC) are a form of concatenated codes used as forward error-correcting (FEC) codes. Two or more component block codes, such as systematic linear block codes, are used to construct TPCs. This encoder implements 2-D product code encoding, as described in [1], using two “Linear Block Codes”.

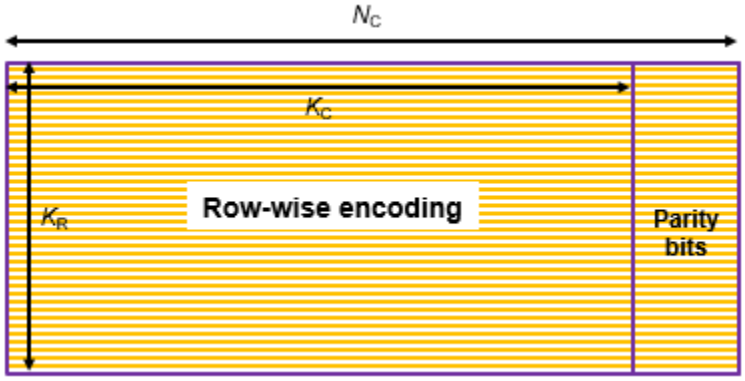
The TPC encoder accepts either full-length or shortened messages.

Construction of Full-Length Message Product Codes

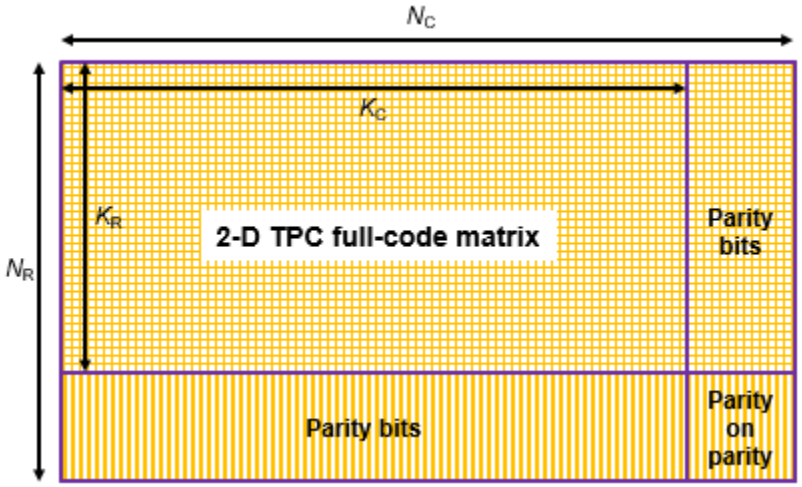
Full-length input messages are encoded using specified 2-D TPC code pairs. Row-wise encoding uses the (N_C,K_C) code pair and column-wise encoding uses the (N_R,K_R) code pair. The input vector length must be $K_R \cdot K_C$. The input message bits vector is arranged into a K_R-by-K_C matrix.



Row-wise encoding uses an (N_C,K_C) systematic linear block encoder with K_C bits per row. The row-wise encoding results in a K_R-by-N_C matrix that includes parity bits added to each row.



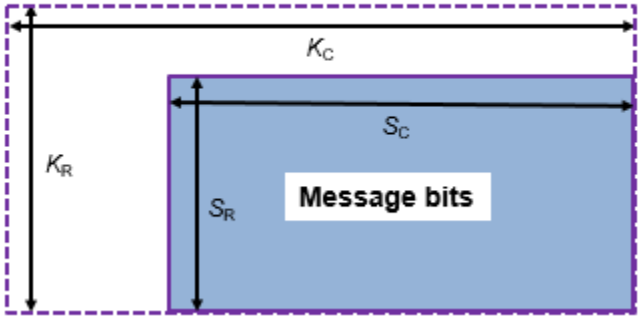
Next, column-wise encoding uses an (N_R,K_R) systematic linear block encoder on each of the N_C columns. Applying this 2-D TPC encoding to the initial K_R-by-K_C matrix results in an N_R-by-N_C matrix that includes parity bits added to each row and column.



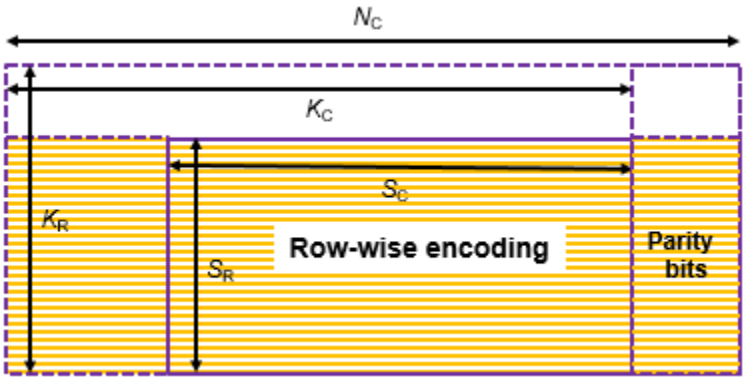
The 2-D TPC full-code matrix is reshaped into a column vector of length $N_R \cdot N_C$ and returned as the TPC-encoded output.

Construction of Shortened Message Product Codes

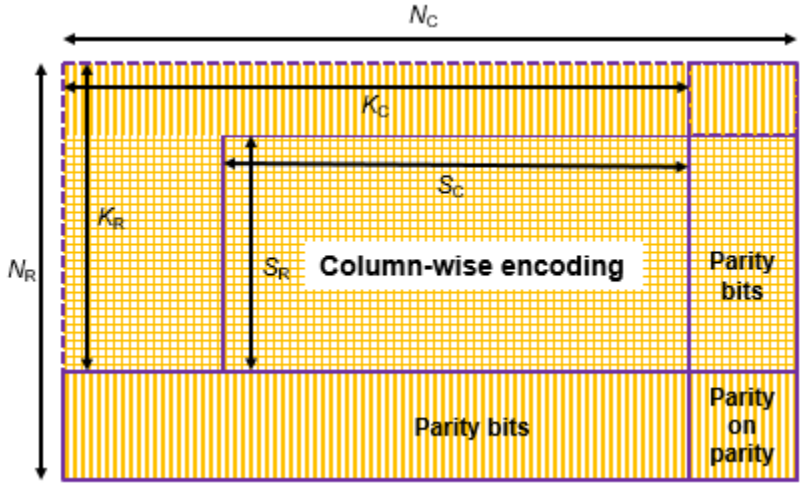
Shortened input messages are encoded using specified 2-D TPC code pairs. Row-wise encoding uses the (N_C,K_C) code pair and column-wise encoding uses an (N_R,K_R) code pair. The input vector length must be $S_R \cdot S_C$. The input shortened message bits vector is arranged into an S_R-by-S_C matrix. The shortened message matrix prepends two dimensions by padding the beginning of the message matrix with zeros. The resulting matrix is a K_R-by-K_C matrix.



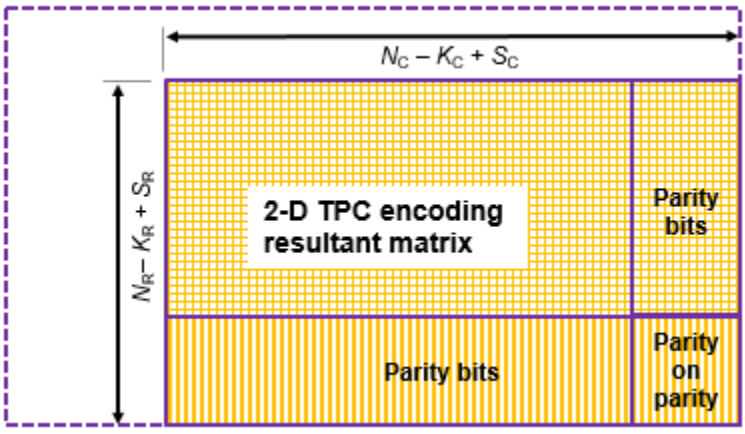
Row-wise encoding uses an (N_C,K_C) systematic linear block encoder with K_C bits per row. The row-wise encoding results in a K_R-by-N_C matrix that includes parity bits added to each row.



Next, the column-wise encoding uses an (N_R,K_R) systematic linear block encoder on each of the N_C columns.



Applying this 2-D TPC encoding to the initial K_R-by-K_C matrix and excluding the zero-padded bits from the output results in an (N_R–K_R+S_R)-by-(N_C–K_C+S_C) matrix. This matrix includes parity bits added to each row and column.



The 2-D TPC shortened-code matrix is reshaped into a column vector of length $(N_R–K_R+S_R) \cdot (N_C–K_C+S_C)$ and returned as the TPC-encoded output.

Version History

Introduced in R2018a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- TPC parameters `N`, `K`, and `S` must be constant values. If the value used for each of these parameters does not change, then you can assign them by expression or variable.

Blocks

TPC Encoder

vec2mat

(Not recommended) Change dimension

Note is not recommended. Use `reshape` instead. For more information, see “Compatibility Considerations”.

Syntax

```
mat = vec2mat(vec,matcol)
mat = vec2mat(vec,matcol,padding)
[mat,padded] = vec2mat( ___ )
```

Description

`mat = vec2mat(vec,matcol)` converts vector `vec` to matrix `mat` with `matcol` columns. The function creates the matrix one row at a time, filling the rows with elements from `vec` in order. If the length of `vec` is not a multiple of `matcol`, then the function pads the last row of `mat` with zeros until the row contains `matcol` elements.

`mat = vec2mat(vec,matcol,padding)` specifies values for the function to use to pad the last row of `mat`. The function uses the value from `padding` in order.

`[mat,padded] = vec2mat( ___ )` also returns `padded`, the number of padded elements in the last row of `mat`. You can specify any of the input argument combinations from previous syntaxes.

Examples

Change Dimensions and Add Padding

This example uses shows you how to add padding, as needed, when converting a vector to matrix.

Create a vector that will be converted to a matrix and a vector to provide padding values.

```
vec = [10;20;30;40;50];
padding = [1,2;3,4;5,6];
n = 4;
```

When using `vec2mat` to convert the vector to a matrix, the function determines needed padding.

```
[mat4,numPadded4] = vec2mat(vec,n,padding)
```

```
mat4 =
    10    20    30    40
    50     1     3     5
numPadded4 =
     3
```

When using `reshape` to convert the vector to a matrix, the needed padding must be computed and appended to the vector before converting the vector to a matrix.

```
numPadded = mod(numel(vec),n);
if numPadded > 0
    numPadded = n - numPadded
    mat = reshape([vec.' padding(1:numPadded)], n, []).'
else
    numPadded % No padding required
    mat = reshape(vec.', n, []).'
end
```

```
numPadded =
     3
mat =
    10    20    30    40
    50     1     3     5
```

Input Arguments

`vec` — Input array

vector

Input array, specified as a vector.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`
Complex Number Support: Yes

`matcol` — Number of columns

positive integer

Number of columns for the output matrix `mat`, specified as a positive integer. If the length of `vec` is not a multiple of `matcol`, then the function pads the last row of `mat` with zeros until the row contains `matcol` elements.

Data Types: `double`

`padding` — Padding values

vector | matrix

Padding values for the last row of `mat`, specified as a vector or matrix. The `padding` input inherits the data type of the `vec` input. The function uses the values from `padding` in order. If `padding` has fewer elements than what the function needs to complete the last row of `mat`, then the function repeats the last element of `padding` until `mat` is full.

Output Arguments

`mat` — Output array

matrix

Output array, returned as a matrix with elements from `vec` and having `matcol` columns. The output inherits the data type of the input. The number of rows is equal to `ceil(length(vec)/matcol)`.

`padded` — Number of padded elements

positive integer

Number of padded elements in the last row of `mat`, returned as a positive integer.

Version History

Introduced before R2006a

`vec2mat` is not recommended

Not recommended starting in R2020a

- vec2mat is not recommended. Use `reshape` instead.
- Given a vector input, `reshape` creates its corresponding matrix one column at a time (instead of one row at a time).
- `reshape` requires its input and output arrays to have the same number of elements, whereas `vec2mat` pads its output matrix if necessary.
- For an example comparing use of `reshape` to `vec2mat`, see “Change Dimensions and Add Padding” on page 2-766.

`reshape`

vitdec

Convolutionally decode binary data by using Viterbi algorithm

Syntax

```
decodedout = vitdec(codedin,trellis,tbdepth,opmode,dectype)
decodedout = vitdec(codedin,trellis,tbdepth,opmode,'soft',nsdec)
decodedout = vitdec(codedin,trellis,tbdepth,opmode,dectype,puncpat)
decodedout = vitdec(codedin,trellis,tbdepth,opmode,dectype,puncpat,eraspat)
decodedout = vitdec(codedin,trellis,tbdepth,'cont',dectype,___,imetric,
istate,iinput)
[decodedout,fmetric,fstate,finput] = vitdec(codedin,trellis,tbdepth,'cont',
___)
```

Description

`decodedout = vitdec(codedin,trellis,tbdepth,opmode,dectype)` decodes each symbol of the `codedin` input by using the Viterbi algorithm. All other inputs specify the convolutional coding trellis, traceback depth, operating mode, and decision type, respectively and collectively configure the Viterbi algorithm at runtime.

`decodedout = vitdec(codedin,trellis,tbdepth,opmode,'soft',nsdec)` configures the Viterbi algorithm for soft-decision decoding for `dectype` and with `nsdec` bits of quantization.

`decodedout = vitdec(codedin,trellis,tbdepth,opmode,dectype,puncpat)` decodes each symbol of the punctured `codedin` input, where `puncpat` is the puncture pattern.

`decodedout = vitdec(codedin,trellis,tbdepth,opmode,dectype,puncpat,eraspat)` specifies an erasure pattern, `eraspat`. To not use puncturing, specify `puncpat` as `[]`.

`decodedout = vitdec(codedin,trellis,tbdepth,'cont',dectype,___,imetric,
istate,iinput)` specifies a continuous operation mode for `opmode` for any of the preceding syntaxes. The decoder starts with its initial state metrics, traceback states, and traceback inputs specified by `imetric`, `istate`, and `iinput`, respectively.

Continuous operation mode enables you to save the internal state information of the decoder for use in subsequent calls to this function. Repeated calls to this function can be useful if your data is partitioned into a series of vectors that you process within a loop. For workflows that require repeated calls to the Viterbi decoding algorithm, see “Tips” on page 2-778.

`[decodedout,fmetric,fstate,finput] = vitdec(codedin,trellis,tbdepth,'cont',
___)` also returns the final state metrics, traceback states, and traceback inputs at the end of the decoding process when using a continuous operation mode for any of the preceding syntaxes. Use `fmetric`, `fstate`, and `finput` as the initial settings of `imetric`, `istate`, and `iinput`, respectively, in subsequent calls to this function. For workflows that require repeated calls to the Viterbi decoding algorithm, see “Tips” on page 2-778.

Examples

Decode Convolutional Code by Using Viterbi Decoder

Convolutionally encode a vector of 1s by using the `convenc` function, and decode it by using the `vitdec` function.

Define a trellis structure, by using the `poly2trellis` function. Use the trellis structure to configure the `convenc` function when encoding a vector of ones.

```
trellis = poly2trellis([4 3],[4 5 17;7 4 2]);
x = ones(100,1);
code = convenc(x,trellis);
```

When decoding the encoded message, configure the Viterbi decoder to use the trellis structure defined previously, a traceback depth of 2, the truncated operating mode, and hard decisions.

```
tb = 2;
decoded = vitdec(code,trellis,tb,'trunc','hard');
```

Verify that the decoded message is a vector of 100 1s.

```
isequal(decoded,ones(100,1))
```

```
ans = logical
   1
```

Decode Punctured Signal Using Viterbi Algorithm

Apply Viterbi decoding to a punctured signal. The puncturing changes the code rate from 1/2 to 3/4.

Initialize parameters for the encoding and decoding operations.

```
trellis = poly2trellis(7,[171 133])
```

```
trellis = struct with fields:
     numInputSymbols: 2
    numOutputSymbols: 4
           numStates: 64
          nextStates: [64x2 double]
             outputs: [64x2 double]
```

```
tbdepth = 96;
opmode = 'trunc';
dectype = 'hard';
puncpat = [1;1;0;1;1;0];
```

Calculate the unpunctured and punctured code rates.

```
K = log2(trellis.numInputSymbols);  % Number of input streams
N = log2(trellis.numOutputSymbols); % Number of output streams
unpunc_coderate = K/N
```

```
unpunc_coderate = 0.5000
```

```
punc_coderate = (K/N)*(length(puncpat)/sum(puncpat))
```

```
punc_coderate = 0.7500
```

Convolutionally encode an all 1s bit message with puncturing applied to the coded output.

```
msg = ones(100*length(puncpat),1);
puncturedcode = convenc(msg,trellis,puncpat);
```

Show the lengths of the message, the punctured code, and the puncture pattern.

```
length(msg)
```

```
ans = 600
```

```
length(puncturedcode)
```

```
ans = 800
```

```
length(puncpat)
```

```
ans = 6
```

Apply Viterbi decoding to the punctured coded message. Compare the decoded output to the original message. Even with puncturing applied to the coded message, the Viterbi decoding recovered the message with zero error.

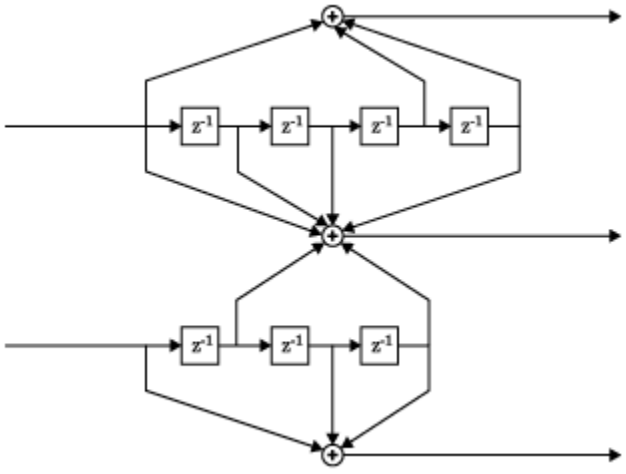
```
codedin = puncturedcode;
decodedout = vitdec(codedin,trellis,tbdepth,opmode,dectype,puncpat);
```

```
isequal(msg,decodedout)
```

```
ans = logical
   1
```

Estimate BER for Rate 2/3 Convolutional Code

Estimate the bit error rate (BER) simulation for a link that uses a rate 2/3 convolutional code, applies 16-QAM modulation, and transmits data through an AWGN channel. This diagram shows a rate 2/3 encoder with two input streams, three output streams, and seven shift registers.



Define the convolutional coding trellis represented by the diagram.

```
trellis = poly2trellis([5 4],[23 35 0; 0 5 13])
```

```
trellis = struct with fields:
     numInputSymbols: 4
    numOutputSymbols: 8
           numStates: 128
          nextStates: [128x4 double]
             outputs: [128x4 double]
```

```
K = log2(trellis.numInputSymbols); % Number of input bit streams
N = log2(trellis.numOutputSymbols); % Number of output bit streams
coderate = K/N;

fprintf('K is %d and N is %d. The code rate is %3.2f.\n', ...
    K,N,coderate)
```

```
K is 2 and N is 3. The code rate is 0.67.
```

Set the modulation order, and compute the number of bits per modulation symbol. Generate random binary data. The input bit stream must be a multiple of number of the input bit streams (`K`) for the coding operation and must be a multiple of the number of bits per modulation symbol (`bps`) for the modulation operation.

```
M = 16; % Modulation order
bps = log2(M); % Bits per modulation symbol
numSymPerFrame = 5000;
dataIn = randi([0 1],K*bps*numSymPerFrame,1);
```

Convolutionally encode the input data.

```
codedout = convenc(dataIn,trellis);
```

Apply 16-QAM modulation to the encoded symbols.

```
txSig = qammod(codedout,M,'InputType','bit');
```

Using the number of bits per symbol (bps) and the code rate (`coderate`), convert the ratio of energy per bit to noise power spectral density (`EbNo`) to an signal-to-noise (`snr`) value for use by the `awgn` function. Convert a 10 dB Eb/No to an equivalent SNR ratio. Pass the signal through an AWGN channel.

```
EbNo = 9;
snr = EbNo + 10*log10(bps*coderate);
rxSig = awgn(txSig,snr,'measured');
```

Demodulate the received signal.

```
demodSig = qamdemod(rxSig,M,'OutputType','bit');
```

Specify the traceback depth of the Viterbi decoder.

```
tbdepth = 16;
```

Decode the binary demodulated signal by using a Viterbi decoder operating in a continuous termination mode.

```
dataOut = vitdec(demodSig,trellis,tbdepth,'cont','hard');
```

Calculate the delay through the decoder, and account for the decoding delay when computing the BER. Compare the coded BER with the theoretical uncoded BER to see the improved BER for the coded data.

```
decDelay = K*tbdepth;
berCoded = biterr( ...
    dataIn(1:end-decDelay),dataOut(decDelay+1:end)) / ...
     length(dataOut(decDelay+1:end));
berUncoded = berawgn(EbNo,'qam',M);
fprintf('The coded BER is %6.5f.\nThe uncoded BER is %6.5f.\n', ...
    berCoded,berUncoded)
```

```
The coded BER is 0.00060.
The uncoded BER is 0.00439.
```

Input Arguments

`codedin` — Convolutionally encoded message

vector of binary values | vector of numeric values

Convolutionally encoded message, specified as a vector of binary or numeric values. Each symbol in `codedin` consists of log2(`trellis.numOutputSymbols`) bits.

When you set `dectype` to `'unquant'`, input values outside of the range [–10^{12}, 10^{12}] are clipped to –10^{12} and 10^{12}, respectively.

Data Types: `double` | `logical`

`trellis` — Trellis description

structure

Trellis description, specified as a MATLAB structure that contains the trellis description for a rate K/N code. K represents the number of input bit streams, and N represents the number of output bit streams.

The trellis structure contains these fields. You can either use the `poly2trellis` function to create the trellis structure or create it manually. For more about this structure, see “Trellis Description of a Convolutional Code” and the `istrellis` function.

`numInputSymbols` — Number of symbols input to encoder

2^K

Number of symbols input to the encoder, specified as an integer equal to 2^K, where K is the number of input bit streams.

Data Types: `double`

`numOutputSymbols` — Number of symbols output from encoder

2^N

Number of symbols output from the encoder, specified as an integer equal to 2^N, where N is the number of output bit streams.

Data Types: `double`

numStates — Number of states in encoder
power of 2

Number of states in the encoder, specified as a power of 2.

Data Types: `double`

nextStates — Next states
matrix of integers

Next states for all combinations of current states and current inputs, specified as a matrix of integers. The matrix size must be `numStates` by 2^K.

Data Types: `double`

outputs — Outputs
matrix of octal numbers

Outputs for all combinations of current states and current inputs, specified as a matrix of octal numbers. The matrix size must be `numStates` by 2^K.

Data Types: `double`

Data Types: `struct`

tbdepth — Traceback depth
positive integer

Traceback depth, specified as a positive integer. For more information, see “Traceback Depth Estimates” on page 2-778.

Data Types: `double`

opmode — Operating mode
`'cont'` | `'term'` | `'trunc'`

Operating mode, specified as `'cont'`, `'term'`, or `'trunc'`. This input indicates the operating mode of the decoder and these assumptions made about the operation of the corresponding encoder.

- `'cont'` — Specifies continuous operating mode. In continuous operating mode, the encoder is assumed to have started at the all-zeros state. The decoder traces back from the state with the best metric. A delay equal to input `tbdepth` symbols elapses before the first decoded symbol appears in the output. This mode is appropriate when you call this function repeatedly and want to preserve continuity between successive calls. For workflows that require repeated calls to the Viterbi decoding algorithm, see “Tips” on page 2-778.
- `'term'` — Specifies terminated operating mode. In terminated operating mode, the encoder is assumed to have started and ended at the all-zeros state, which is true for the default syntax of the `convenc` function. The decoder traces back from the all-zeros state. This mode incurs zero delay.

  This mode is appropriate when the message input to the `convenc` function has enough zeros at its end to fill all memory registers of the encoder. The zero-valued tail bits flush all message data bits out of the encoder. Using the polynomial description of the encoder, for an encoder with K input bits and the constraint length vector `ConstraintLength`, the number of zeros required to flush the encoder is $K \times \max(\texttt{ConstraintLength} - 1)$. The constraint length vector is the first input argument to the `poly2trellis` function.

- `'trunc'` — Specifies truncated operating mode. In truncated operating mode, the encoder is assumed to have started at the all-zeros state. The decoder traces back from the state with the best metric. This mode incurs zero delay. This mode is appropriate when you cannot assume the encoder ended at the all-zeros state and when you do not want to preserve continuity between successive calls to this function.

For the `'term'` and `'trunc'` modes, the traceback depth, `tbdepth`, must be a positive integer, less than or equal to the number of input symbols in input `codedin`.

For more information, see “Traceback and Decoding Delay” on page 2-778 and “Traceback Depth Estimates” on page 2-778.

Data Types: `char` | `string`

`dectype` — Decoding type

`'unquant'` | `'hard'` | `'soft'`

Decoding type, specified as `'unquant'`, `'hard'`, or `'soft'`. This parameter indicates the type of decoding decision that the decoder makes and influences the type of data the decoder expects as input in `codedin`.

- `'unquant'` — The decoder expects signed numeric input values, where positive values map to a logical `0` and negative values map to a logical `1`.
- `'hard'` — The decoder expects binary input values of `0` or `1`.
- `'soft'` — The decoder expects integer input values in the range [0, (2^{nsdec} – 1)]. The Viterbi algorithm decision criteria regards 0 as the most confident 0 and 2^{nsdec} – 1 as the most confident 1.

Data Types: `char` | `string`

`nsdec` — Number of soft decision quantization bits

integer in the range [1, 13]

Number of soft decision quantization bits, specified as a integer in the range [1, 13]. For reference, soft decision decoding with 3 bits of quantization improves error decoding recovery by approximately 2 dB as compared to hard decision decoding.

Dependencies

To enable this input argument set the `dectype` input argument to `'soft'`.

Data Types: `double`

`puncpat` — Puncture pattern

vector of binary values

Puncture pattern, specified as a vector of binary values. Indicate punctured bits with `0`s and unpunctured bits with `1`s. The input code length divided by the number of 1s in the puncture pattern times the length of the puncture pattern must be an integer multiple of the number of bits in an input symbol.

Data Types: `double`

`eraspat` — Erasure pattern

vector of binary values

Erasure pattern, specified as a vector of binary values. Indicate erased bits with `1`s and nonerased bits with `0`s. The length of the erasures pattern must be the same as the input code length.

Data Types: `double`

`imetric` — Decoder state metrics

integer | vector of integer values

Decoder state metrics, specified as an integer or a vector of integer values. Each value in `imetric` represents the starting state metric of the corresponding decoder state. When you set `imetric` to a vector, the length must be `trellis.numStates`. To use the default decoder state metrics, specify `imetric` as `[]`.

Dependencies

To enable this input argument set the `opmode` input argument to `'cont'`.

Data Types: `double`

`istate` — Decoder initial traceback states

matrix of integer values

Decoder initial traceback states, specified as a `trellis.numStates`-by-`tbdepth` matrix of integer values in the range [0, (`trellis.numStates` – 1)]. To use the default decoder initial traceback states, specify `istate` as `[]`.

Inputs `istate` and `iinput` jointly specify the initial traceback memory of the decoder. If the encoder schematic has more than one input stream, the shift register that receives the first input stream provides the least significant bits in `istate`, and the shift register that receives the last input stream provides the most significant bits in `istate`.

Dependencies

To enable this input argument set the `opmode` input argument to `'cont'`.

Data Types: `double`

`iinput` — Decoder initial traceback inputs

matrix of integer values

Decoder initial traceback inputs, specified as a `trellis.numStates`-by-`tbdepth` matrix of integer values in the range [0, (`trellis.numStates` – 1)]. To use the default decoder initial traceback inputs, specify `iinput` as `[]`.

Inputs `istate` and `iinput` jointly specify the initial traceback memory of the decoder.

Dependencies

To enable this input argument set the `opmode` input argument to `'cont'`.

Data Types: `double`

Output Arguments

`decodedout` — Decoded message

vector of binary values

Decoded message, returned as a vector of binary values. Each symbol in the vector `decodedout` consists of log2(`trellis.numInputSymbols`) bits.

`fmetric` — Decoder final state metrics

vector of integer values

Decoder final state metrics, returned as an vector of integer values with `trellis.numStates` elements. Each value in `fmetric` represents the final state metric of the corresponding decoder state.

When calling `vitdec` in continuous mode, `fmetric` is typically used to set `imetric` for subsequent calls to the `vitdec` function.

Dependencies

This output applies when the `opmode` parameter is set to `'cont'`.

Data Types: `double`

`fstate` — Decoder final traceback states

matrix of integer values

Decoder final traceback states, returned as a `trellis.numStates`-by-`tbdepth` matrix of integer values in the range [0, (`trellis.numStates` – 1)].

Outputs `fstate` and `finput` jointly describe the final traceback memory of the decoder. If the encoder schematic has more than one input stream, the shift register that receives the first input stream provides the least significant bits in `fstate`, and the shift register that receives the last input stream provides the most significant bits in `fstate`.

When calling `vitdec` in continuous mode, `fstate` is typically used to set `istate` for subsequent calls to the `vitdec` function.

Dependencies

This output applies when the `opmode` parameter is set to `'cont'`.

Data Types: `double`

`finput` — Decoder final traceback inputs

matrix of integer values

Decoder final traceback inputs, returned as a `trellis.numStates`-by-`tbdepth` matrix of integer values in the range [0, (`trellis.numStates` – 1)].

Outputs `fstate` and `finput` jointly specify the final traceback memory of the decoder.

When calling `vitdec` in continuous mode, `finput` is typically used to set `iinput` for subsequent calls to the `vitdec` function.

Dependencies

This output applies when the `opmode` parameter is set to `'cont'`.

Data Types: `double`

More About

Traceback and Decoding Delay

The traceback depth influences the decoding delay. The decoding delay is the number of zero symbols that precede the first decoded symbol in the output.

- For the continuous operating mode, the decoding delay is equal to the number of traceback depth symbols.
- For the truncated or terminated operating mode, the decoding delay is zero. In this case, the traceback depth must be less than or equal to the number of symbols in each input.

Traceback Depth Estimates

As a general estimate, a typical traceback depth value is approximately two to three times (*ConstraintLength* – 1) / (1 – *coderate*). The constraint length of the code, *ConstraintLength*, is equal to (log2(`trellis.numStates`) + 1). The *coderate* is equal to (*K* / *N*) × (length(*PuncturePattern*) / sum(*PuncturePattern*).

K is the number of input symbols, *N* is the number of output symbols, and *PuncturePattern* is the puncture pattern vector.

For example, applying this general estimate, results in these approximate traceback depths.

- A rate 1/2 code has a traceback depth of 5(*ConstraintLength* – 1).
- A rate 2/3 code has a traceback depth of 7.5(*ConstraintLength* – 1).
- A rate 3/4 code has a traceback depth of 10(*ConstraintLength* – 1).
- A rate 5/6 code has a traceback depth of 15(*ConstraintLength* – 1).

For more information, see [7].

Tips

- Consider using the `comm.ViterbiDecoder` System object when successive calls to the Viterbi algorithm are needed. The System object simplifies the required state retention operation by inherently retaining state metrics, traceback states, and inputs between calls.

Version History

Introduced before R2006a

Version History

Behavior changed in R2022b

When you set `dectype` to `'unquant'`, input values outside of the range [-10^{12}, 10^{12}] are clipped to -10^{12} and 10^{12}, respectively.

wgn

Generate white Gaussian noise samples

Syntax

```
noise = wgn(m,n,power)
noise = wgn(m,n,power,imp)
noise = wgn(m,n,power,imp,randobject)
noise = wgn(m,n,power,imp,seed)

noise = wgn( ___ ,powertype)
noise = wgn( ___ ,outputtype)
```

Description

`noise = wgn(m,n,power)` generates an `m`-by-`n` matrix of white Gaussian noise samples in volts. `power` specifies the power of `noise` in dBW.

`noise = wgn(m,n,power,imp)` specifies the load impedance in ohms.

`noise = wgn(m,n,power,imp,randobject)` specifies a random number stream object to use when generating the matrix of white Gaussian noise samples. For information about producing repeatable noise samples, see “Tips” on page 2-782.

`noise = wgn(m,n,power,imp,seed)` specifies a seed value for initializing the normal random number generator that is used when generating the matrix of white Gaussian noise samples. For information about producing repeatable noise samples, see “Tips” on page 2-782.

`noise = wgn( ___ ,powertype)` specifies the units of `power` as `'dBW'`, `'dBm'`, or `'linear'` in addition to the input arguments in any of the previous syntaxes.

`noise = wgn( ___ ,outputtype)` specifies the output type as `'real'` or `'complex'` in addition to the input arguments in any of the previous syntaxes.

Examples

Generate White Gaussian Noise

Generate real and complex white Gaussian noise (WGN) samples. Check the power of output WGN matrices.

Generate a 1000-element column vector of real WGN samples and confirm that the power is approximately 1 watt, which is 0 dBW.

```
y1 = wgn(1000,1,0);
var(y1)
```

```
ans = 0.9979
```

Generate a 1000-element column vector of complex WGN samples and confirm that the power is approximately 0.25 watts, which is –6 dBW.

```
y2 = wgn(1000,1,-6,'complex');
var(y2)
```

```
ans = 0.2521
```

Input Arguments

`m` — Number of white Gaussian noise samples

positive integer

Number of white Gaussian noise samples desired per channel, specified as a positive integer.

Data Types: `double`

`n` — Number of channels

positive integer

Number of channels of white Gaussian noise samples desired, specified as a positive integer.

Data Types: `double`

`power` — Power of noise samples

scalar

Power of noise samples, specified as a scalar. The default units for power is dBW. Use `powertype` to change the units of `power`.

Data Types: `double`

`imp` — Load impedance

1 (default) | scalar

Load impedance in ohms, specified as a scalar.

Data Types: `double`

`randobject` — Random number stream object

`RandStream` object

Random number stream object, specified as a `RandStream` object. The state of the random stream object determines the sequence of numbers produced by the `randn` function. Configure the random stream object using the `reset (RandStream)` function and its properties.

`wgn` generates normal random noise samples using `randn`. The `randn` function uses one or more uniform values from the `RandStream` object to generate each normal value.

For information about producing repeatable noise samples, see “Tips” on page 2-782.

`seed` — Random number generator seed

nonnegative integer

Random number generator seed, specified as a nonnegative integer. For more information on the random number generator, see `randn`.

powertype — Signal power unit
`'dBW'` (default) | `'dBm'` | `'linear'`

Signal power unit, specified as `'dBW'`, `'dBm'`, or `'linear'`. Linear power is in watts.

outputtype — Output type
`'real'` (default) | `'complex'`

Output type, specified as `'real'` or `'complex'`. If `outputtype` is `'complex'`, then the real and imaginary parts of `noise` each have a noise power of (`power` / 2).

Output Arguments

noise — Output white Gaussian noise samples
scalar | vector | array

Output white Gaussian noise samples in volts, returned as an `m`-by-`n` matrix.

Note Unless the default impedance for `imp` is changed, a load of 1 ohm is used for power calculations.

Tips

- To generate repeatable white Gaussian noise samples, use one of these tips:
  - Provide a static `seed` value as an input to `wgn`.
  - Use the `reset (RandStream)` function on the `randobject` before passing it as an input to `wgn`.
  - Provide `randobject` in a known state as an input to `wgn`. For more information, see `RandStream`.

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

Code generation supported, except for syntaxes that include a `RandStream` object.

Topics
“Sources and Sinks”

winner2.AntennaArray

Create antenna array

Syntax

```
antArray = winner2.AntennaArray
antArray = winner2.AntennaArray(Name,Value)
```

Description

Download Required: To use winner2.AntennaArray, first download the WINNER II Channel Model for Communications Toolbox add-on.

`antArray = winner2.AntennaArray` returns a structure representing an antenna array with one isotropic antenna element. Both the antenna array and the single element have no rotation and are located at the origin, [0;0;0].

`antArray = winner2.AntennaArray(Name,Value)` returns a structure representing an antenna array defined using one or more `Name,Value` pair arguments.

For more information, see “Antenna Array Model” on page 2-788.

Examples

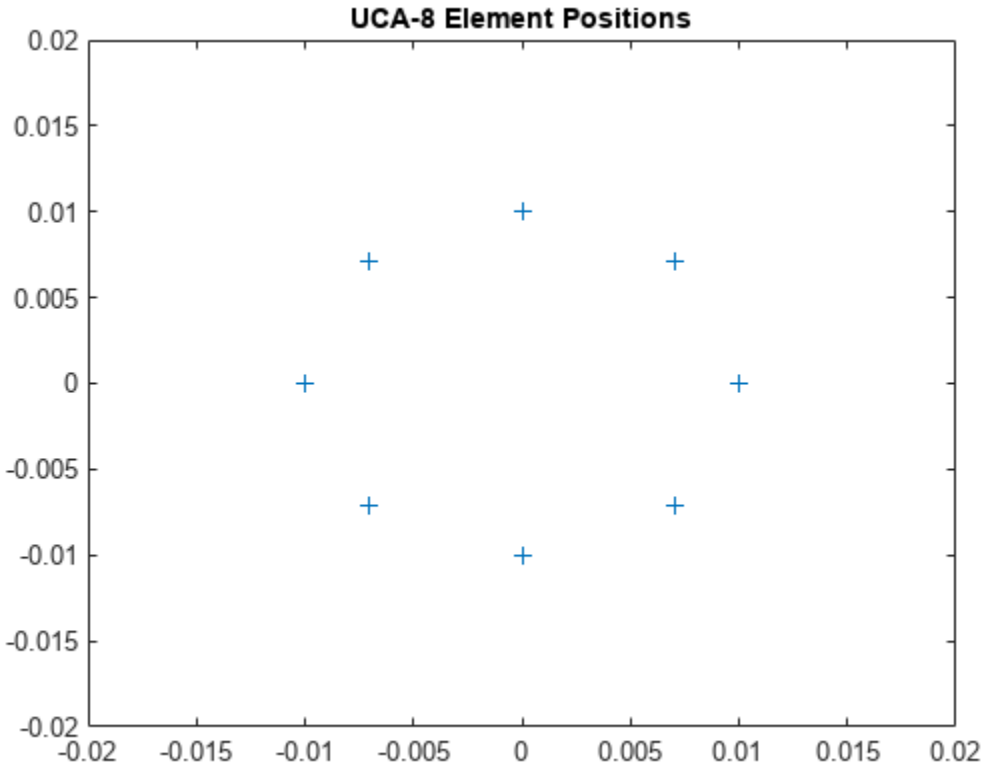
Create WINNER II Eight Element Uniform Circular Array

Use the `winner2.AntennaArray` function to create an eight element uniform circular array (UCA-8) with a 1 cm radius.

```
UCA8 = winner2.AntennaArray('UCA',8,0.01);
```

Plot element positions.

```
pos = {UCA8.Element(:).Pos};
plot(cellfun(@(x) x(1),pos),cellfun(@(x) x(2),pos),'+');
xlim([-0.02 0.02]);
ylim([-0.02 0.02]);
title('UCA-8 Element Positions');
```



Create WINNER II Two Element Uniform Linear Array

Use the `winner2.AntennaArray` function to create a two element uniform linear array (ULA-2) with 50 cm spacing and the dipole elements slanted at +45 and -45 degrees.

```
az = -180:179; % 1-degree spacing
pattern = cat(1,shiftdim(winner2.dipole(az,45),-1), ...
    shiftdim(winner2.dipole(az,-45),-1));
ULA2 = winner2.AntennaArray('ULA',2,0.5, ...
    'FP-ECS',pattern,'Azimuth',az);
```

Input Arguments

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `'Pos',[1 0 0; 0 1 0],'Rot',[0 0 0; 0 pi() 0]` indicates the coordinates and rotation angles for two antenna elements.

Pos — Position of each antenna element
`0` (default) | column vector | matrix

Position of each antenna element, specified as the comma-separated pair consisting of `'Pos'` and a column vector or an N_E-by-3 matrix. The three columns represent the x-, y-, and z-coordinates in meters from the origin. N_E indicates the number of elements in the antenna array. The elements have no rotation. When there is more than one element, the `'Element'` field of `antArray` is a row vector of structures representing all the elements.

Example: `'Pos',[63.1 10.2 11.5; 62 11 12]` indicates the coordinates for two antenna elements.

Data Types: `double`

Rot — Rotation angle of each antenna element
`0` (default) | column vector | matrix | optional

Rotation angle of each antenna element, specified as the comma-separated pair consisting of `'Rot'` and a column vector or an N_E-by-3 matrix. The three columns represent the Rot_X, Rot_Y, and Rot_Z rotation angles of each antenna element in radians. N_E indicates the number of elements in the antenna array. `Rot` only applies when `Pos` is specified. If not specified with `Pos`, the rotation angle is `0`.

Example: `'Rot',[2 1.5 0; 0 pi() 0]` indicates the rotation angles for two antenna elements.

Data Types: `double`

UCA — Uniform circular antenna array
`N,1` (default) | `N,Rad`

Uniform circular antenna array, specified as the comma-separated pair consisting of `'UCA'` and `N,Rad`. In this argument, `N` indicates the number of elements (N_E) and `Rad` indicates the radius in meters. If `Rad` is not specified, the default radius is 1 meter.

Example: `'UCA',8,0.5` indicates an eight element uniform circular array with 0.5 meter radius.

Data Types: `double`

ULA — Uniform linear antenna array
`N,1/N` (default) | `N,Spacing`

Uniform linear antenna array, specified as the comma-separated pair consisting of `'ULA'` and `N,Spacing`. In this argument, `N` indicates the number of elements (N_E) and `Spacing` indicates the separation between adjacent elements in meters. If `Spacing` is not specified, the default separation is 1/`N` meters.

ULA elements are placed along *x-axis* with the center of the array at [0;0;0]. For an even number of elements, there is no antenna element at [0;0;0].

Example: `'ULA',3,0.25` indicates a three element uniform linear array with 0.25 meter spacing between adjacent elements.

Data Types: `double`

FP-ECS — Field pattern of element coordinate system
4-D array

Field pattern of element coordinate system, specified as the comma-separated pair consisting of `'FP-ECS'` and a *P*-by-2-by1-by-N_{AZ} array.

- The first dimension, *P*, can be either 1 or any number greater than or equal to the number of elements in the antenna array (N_E). When $P = 1$, the same pattern applies to all elements. When $P > N_E$, the first N_E rows apply.
- The second dimension, 2, indicates that two polarizations characterize the field pattern. The first dimension in the field pattern stores vertical polarization, and the second one stores horizontal polarization.
- The third dimension, 1, indicates that one elevation angle characterizes the field pattern.
- The fourth dimension, N_{AZ}, is the number of field pattern samples taken between –180 and 180 degrees. N_{AZ} equals the number of elements specified in `Azimuth` or when `Azimuth` is not present it equals the number of equidistant field pattern samples taken over azimuth angle.

Data Types: `double`

FP-ACS — Field pattern array coordinate system

4-D array

Field pattern array coordinate system, specified as the comma-separated pair consisting of `'FP-ACS'` and a *P*-by-2-by1-by-N_{AZ} array. Array format is the same as the `FP-ECS` syntax, except that the field pattern is specified in the array-coordinate-system (ACS).

- The first dimension, *P*, can be either 1 or any number greater than or equal to the number of elements in the antenna array (N_E). When $P = 1$, the same pattern applies to all elements. When $P > N_E$, the first N_E rows apply.
- The second dimension, 2, indicates that two polarizations characterize the field pattern. The first dimension in the field pattern stores vertical polarization, and the second one stores horizontal polarization. Missing polarization dimensions of the field pattern are substituted with zeros.
- The third dimension, 1, indicates that one elevation angle characterizes the field pattern.
- The fourth dimension, N_{AZ}, is the number of field pattern samples taken between –180 and 180 degrees. N_{AZ} equals the number of elements specified in `Azimuth` or when `Azimuth` is not present it equals the number of equidistant field pattern samples taken over azimuth angle.

Data Types: `double`

Azimuth — Azimuth angles for 'FP-ACS' or 'FP-ECS' field patterns

row vector

Azimuth angles for `FP-ACS` or `FP-ECS` field patterns in degrees , specified as the comma-separated pair consisting of `'Azimuth'` and an 1-by-N_{AZ} row vector. The values in the row vector indicate azimuth angles for elements in the field patterns.

Note `Azimuth` applies only when `FP-ACS` or `FP-ECS` are defined. If `Azimuth` is not specified, uniform spacing is used for elements in the field pattern.

Example: `'Azimuth',[0 10 20 90 180 270 340 350]`

Data Types: `double`

Output Arguments

`antArray` — Antenna array definition
structure

Antenna array definition, returned as a structure containing these fields.

`Name` — Antenna array name
character vector

Antenna array name, returned as a character vector.

`Pos` — Antenna array position
vector

Antenna array position, returned as a 3-by-1 vector, representing the x-, y-, and z-coordinates in meters from the origin.

`Rot` — Antenna array rotation
vector

Antenna array rotation, returned as a 3-by-1 vector, representing the Rot_X, Rot_Y, and Rot_Z rotation angles of each antenna element in radians.

`Element` — Element definition
row vector of structures

Element definition, returned as a row vector of structures, with each structure representing one element and containing these fields.

`Pos` — Antenna array position
vector

Antenna array position, returned as a 3-by-1 vector, representing the x-, y-, and z-coordinates in meters from the origin.

`Rot` — Antenna array rotation
vector

Antenna array rotation, returned as a 3-by-1 vector, representing the Rot_X, Rot_Y, and Rot_Z rotation angles of each antenna element in radians.

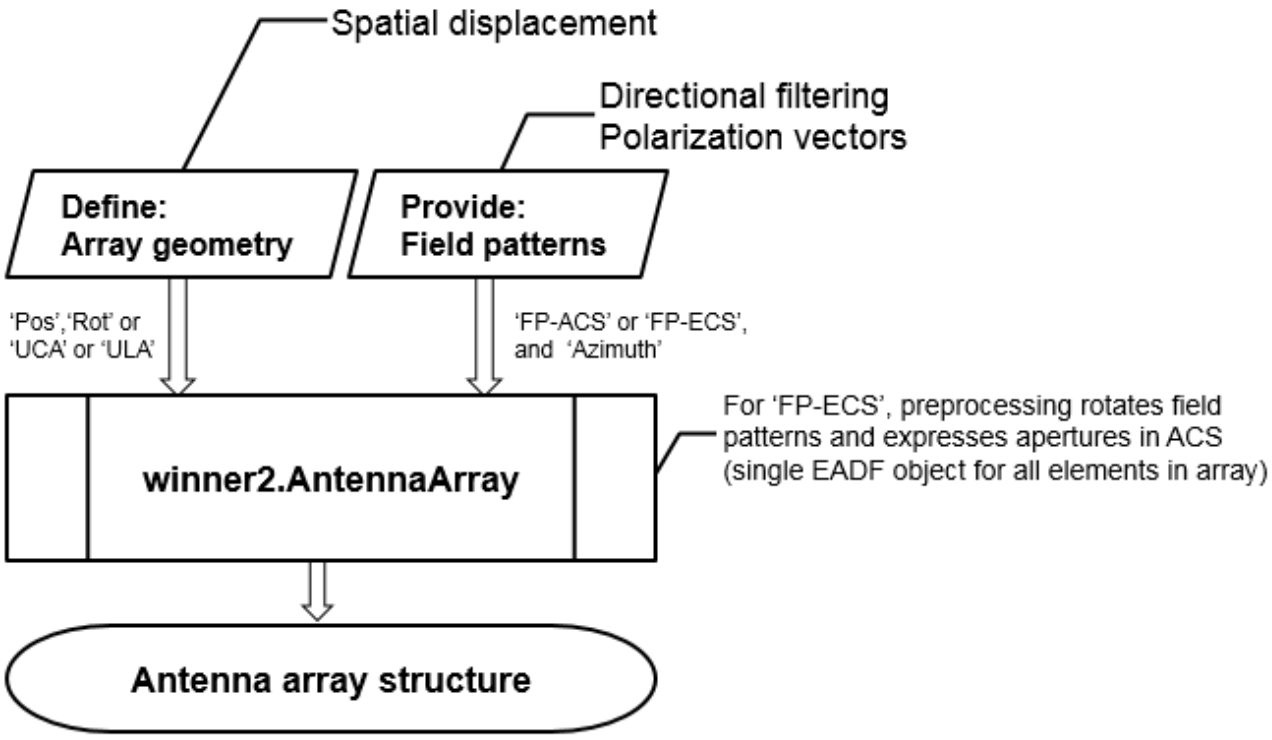
`Aperture` — Aperture definition
structure

Aperture definition, returned as a structure representing the antenna aperture.

More About

Antenna Array Model

To create an antenna array model, you must define the geometry of array elements (positions and rotation) and the element field patterns. The arguments provided to `winner2.AntennaArray` are always processed such that the array geometry is created first, and then the field patterns are assigned.



For a detailed description of the antenna array specification for the WINNER channel model, see WINNER II Channel Models [1], Section 4.1.

Version History

Introduced in R2017a

See Also

`winner2.dipole` | `winner2.layoutparset`

winner2.dipole

Calculate field pattern of half-wavelength dipole

Syntax

```
pat = winner2.dipole(az)
pat = winner2.dipole(az,slant)
```

Description

Download Required: To use winner2.dipole, first download the WINNER II Channel Model for Communications Toolbox add-on.

`pat = winner2.dipole(az)` returns the azimuth field pattern of a 0-degree slanted dipole at the azimuth angles specified in `az`.

`pat = winner2.dipole(az,slant)` returns the azimuth field pattern of a slanted dipole at the azimuth angles specified in `az`.

Examples

Create 45 and 90 Degree Slanted Dipoles

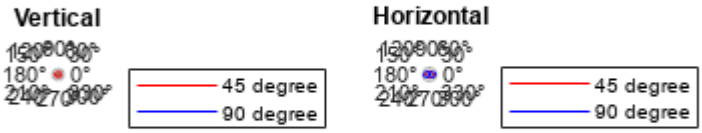
Create 45 and 90 degree slanted dipoles by using the `winner2.dipole` function.

```
az = -180:179; % 1 degree spacing
pattern45 = squeeze(winner2.dipole(az,45));
pattern90 = squeeze(winner2.dipole(az,90));
```

Display the antenna pattern by using the `polarplot` function.

```
fh = figure;
set(fh, 'Position', [100 100 1000 500]);
fh.Name = 'Dipole Pattern Plots';
subplot(1,2,1);
polarplot(az/180*pi,pattern45(1,:),'r');
hold on;
polarplot(az/180*pi,pattern90(1,:),'b');
rlim([0 1.5]);
legend('45 degree','90 degree');
title('Vertical');

subplot(1,2,2);
polarplot(az/180*pi,pattern45(2,:),'r');
hold on;
polarplot(az/180*pi,pattern90(2,:),'b');
rlim([0 1.5]);
legend('45 degree','90 degree');
title('Horizontal');
```



Input Arguments

`az` — Azimuth angles

vector

Azimuth angles, specified as a vector indicating the azimuth angles to compute the field pattern gain. Units are in degrees.

Data Types: `double`

`slant` — Slant angle

scalar

Slant angle, specified as a scalar representing the counterclockwise angle seen from the front of the dipole. Units are in degrees.

Data Types: `double`

Output Arguments

`pat` — Field pattern

3-D array

Field pattern, returned as a 2-by-1-by-N_{AZ} array representing the vertical and horizontal field pattern, where N_{AZ} is the number of elements in the `az` input vector.

Version History

Introduced in R2017a

`winner2.AntennaArray` | `winner2.layoutparset`

winner2.layoutparset

WINNER II layout parameter configuration

Syntax

```
cfgLayout = winner2.layoutparset(msIdx,bsIdx,K,arrays)
cfgLayout = winner2.layoutparset(msIdx,bsIdx,K,arrays,rmax)
cfgLayout = winner2.layoutparset(msIdx,bsIdx,K,arrays,rmax,seed)
```

Description

Download Required: To use winner2.layoutparset, first download the WINNER II Channel Model for Communications Toolbox add-on.

`cfgLayout = winner2.layoutparset(msIdx,bsIdx,K,arrays)` returns a structure of randomly generated WINNER II network layout parameters given mobile station (MS) indices, base station (BS) indices, BS to MS links, and antenna array configurations.

`cfgLayout = winner2.layoutparset(msIdx,bsIdx,K,arrays,rmax)` additionally specifies the maximum layout range used when generating MS and BS positions.

`cfgLayout = winner2.layoutparset(msIdx,bsIdx,K,arrays,rmax,seed)` additionally specifies a seed value for repeatability. To assign `seed` when not assigning `rmax`, specify `rmax` as [ ].

Examples

Create Two MS to One BS WINNER II System Layout

Create a WINNER II system layout with two mobile stations (MS) connecting to the same base station (BS).

Define antenna arrays for one BS and two MS.

```
BSAA  = winner2.AntennaArray('UCA', 8, 0.02);  % UCA-8 array for BS
MSAA1 = winner2.AntennaArray('ULA', 2, 0.01);  % ULA-2 array for MS
MSAA2 = winner2.AntennaArray('ULA', 4, 0.005); % ULA-4 array for MS
```

Create system layout by using the `winner2.layoutparset` function.

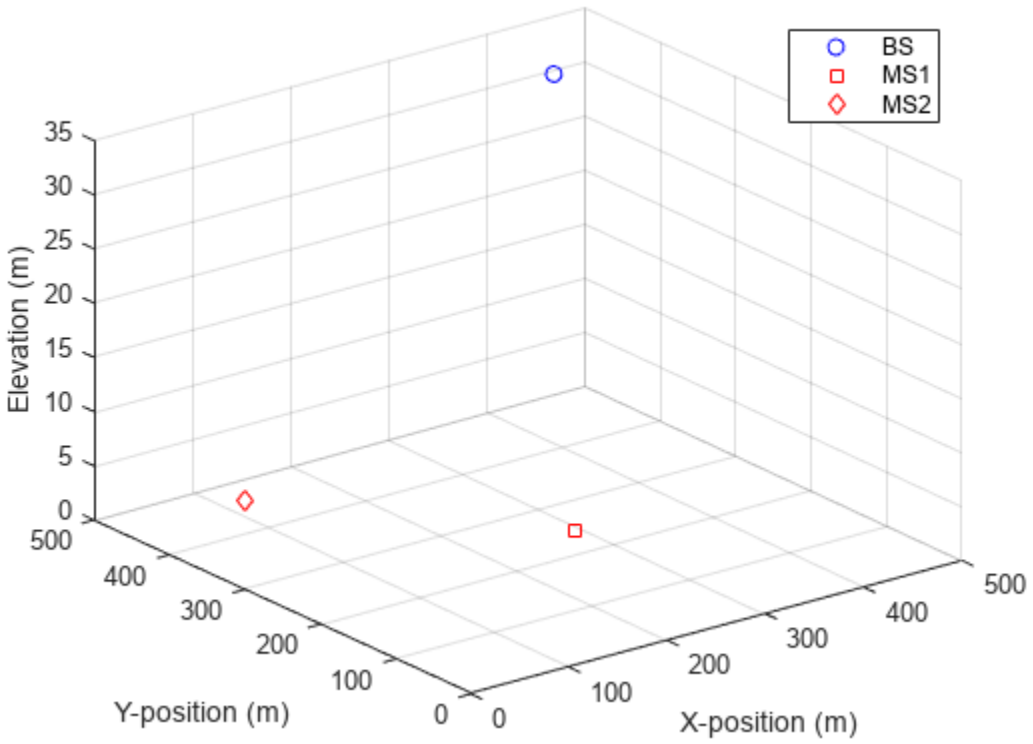
```
MSIdx = [2 3];
BSIdx = {1};
K = 2;
rndSeed = 5;
cfgLayout = winner2.layoutparset(MSIdx,BSIdx, ...
    K,[BSAA,MSAA1,MSAA2],[],rndSeed);
```

Visualize BS and MS positions.

```
BSPos  = cfgLayout.Stations(cfgLayout.Pairing(1,1)).Pos;
MS1Pos = cfgLayout.Stations(cfgLayout.Pairing(2,1)).Pos;
```

```
MS2Pos = cfgLayout.Stations(cfgLayout.Pairing(2,2)).Pos;

plot3(BSPos(1),BSPos(2),BSPos(3),'bo', ...
    MS1Pos(1),MS1Pos(2),MS1Pos(3),'rs', ...
    MS2Pos(1),MS2Pos(2),MS2Pos(3),'rd');
grid on;
xlim([0 500]);
ylim([0 500]);
zlim([0 35]);
xlabel('X-position (m)');
ylabel('Y-position (m)');
zlabel('Elevation (m)');
legend('BS','MS1','MS2','Location','northeast');
```



Input Arguments

`msIdx` — Mobile station index

row vector

Mobile station index, specified as a row vector indicating the indices in `arrays` to serve as mobile stations.

Data Types: `double`

`bsIdx` — Base station index

column cell array

Base station index, specified as a column cell array, with each element representing one base station. Each cell element is an integer-valued row vector to indicate the indices in `arrays` to serve as different sectors of that base station.

Data Types: `double`

K — Number of links
scalar

Number of links, specified as a scalar representing the number of BS-MS links to be formulated.

Data Types: `double`

`arrays` — Antenna array configurations
vector of structures

Antenna array configurations, specified as a vector of structures defining all available arrays. All MS and BS sectors are chosen from this vector. The array of elements is typically created using the `winner2.AntennaArray` function.

Data Types: `double`

`rmax` — Maximum layout range
`500` (default) | scalar

Maximum layout range, specified as a scalar representing the maximum layout range in meters used to randomly generate the MS and BS positions.

Data Types: `double`

`seed` — Seed value
integer

Seed value used to provide repeatability, specified as an integer. When `seed` is not specified, the global random number generator is used. To assign `seed` when not assigning `rmax`, specify `rmax` as `[]`.

Data Types: `double`

Output Arguments

`cfgLayout` — Configuration layout
structure

Configuration layout, returned as a structure containing these fields, which represent the location and orientation parameters for all simulated stations.

`Stations` — Active stations
row vector of structures

Active stations, returned as a row vector of structures describing the antenna arrays for active stations. `Stations` is created from the `arrays` input and adds an additional `Velocity` field. The row ordering specifies base station (BS) sectors first, followed by the mobile stations (MS). The BS sector and MS positions are randomly assigned. The BS sectors have no velocity. Each MS has a velocity of about 1.42 m/s with a randomly assigned direction.

`NofSect` — Number of sectors
vector

Number of sectors, returned as a vector indicating the number of sectors in each BS.

`Pairing` — BS to MS pairing
matrix

BS to MS pairing, returned as a 2-by-N_L matrix, where N_L specifies the number of links to be modeled. See `Stations` for BS and MS row ordering.

`ScenarioVector` — Spatial scenario

`1` (default) | vector

Spatial scenario, returned as a 1-by-N_L vector of scenario numbers. The default is `1`, which specifies scenario A1.

The scenarios numbers map as {`1`=A1, `2`=A2, `3`=B1, `4`=B2, `5`=B3, `6`=B4, `10`=C1, `11`=C2, `12`=C3, `13`=C4, `14`=D1, `15`=D2a}.

For more information, see WINNER II Channel Models [1], Section 2.3.

`PropagConditionVector` — Propagation condition
`1` (default) | vector

Propagation condition, returned as a 1-by-N_L vector of propagation conditions (LOS = 1 and NLOS = 0) for each link. The default is `1`.

`StreetWidth` — Street width
`20` (default) | vector

Street width, returned as a 1-by-N_L vector of identical values that specify the average width (in meters) of the streets. `StreetWidth` is used for the path loss model of the B1 and B2 scenarios. See `ScenarioVector` for the scenario number mapping. All elements must have the same value. `StreetWidth` applies only when the `PathLossModelUsed` field from `winner2.wimparset` is set to `'yes'`.

`Dist1` — Distances from BS to the last LOS point
`NaN` (default) | vector

Distances from BS to the last LOS point, returned as a 1-by-N_L vector. `Dist1` is used for the path loss model of the B1 and B2 scenarios. The default value of `NaN` indicates that the distance is randomly determined in path loss function. See `ScenarioVector` for the scenario number mapping. `Dist1` applies only when the `PathLossModelUsed` field from `winner2.wimparset` is set to `'yes'`.

For more information, see WINNER II Channel Models [1], Figure 4-3.

`NumFloors` — Floor numbers
`1` (default) | vector

Floor numbers, returned as a 1-by-N_L vector indicating the floor number where the indoor BS or MS is located. The `NumFloors` property is used for the path loss model of the A2 and B4 scenarios only. See `ScenarioVector` for the scenario number mapping. `NumFloors` applies only when the `PathLossModelUsed` field from `winner2.wimparset` is set to `'yes'`.

`NumPenetratedFloors` — Number of floors penetrated
`0` (default) | vector

Number of floors penetrated, returned as a 1-by-N_L vector indicating the number of penetrated floors between BS and MS. The `NumPenetratedFloors` property is used for the NLOS path loss model of the A1 scenario. See `ScenarioVector` for the scenario number mapping. `NumPenetratedFloors` applies only when the `PathLossModelUsed` field from `winner2.wimparset` is set to `'yes'`.

For more information, see WINNER II Channel Models [1], Table 4-4.

Version History

Introduced in R2017a

Objects
`comm.WINNER2Channel`

Functions
`winner2.wim` | `winner2.wimparset` | `winner2.AntennaArray`

winner2.wim

Generate channel coefficients using WINNER II channel model

Syntax

```
chanCoef = winner2.wim(cfgWim,cfgLayout)
[chanCoef,pathDelays] = winner2.wim(cfgWim,cfgLayout)
[chanCoef,pathDelays,finalCond] = winner2.wim(cfgWim,cfgLayout)
[chanCoef,pathDelays,finalCond] = winner2.wim(cfgWim,cfgLayout,initCond)
```

Description

Download Required: To use winner2.wim, first download the WINNER II Channel Model for Communications Toolbox add-on.

`chanCoef = winner2.wim(cfgWim,cfgLayout)` returns channel coefficients based on the WINNER II model parameters for all links defined in the WINNER II network layout.

`[chanCoef,pathDelays] = winner2.wim(cfgWim,cfgLayout)` also returns the path delays for all links.

`[chanCoef,pathDelays,finalCond] = winner2.wim(cfgWim,cfgLayout)` also returns the final condition of the system after generating the channel coefficients.

`[chanCoef,pathDelays,finalCond] = winner2.wim(cfgWim,cfgLayout,initCond)` generates the channel coefficients by using the initial system conditions rather than of performing random initialization. `initCond` is of the same form as `finalCond` and is typically the `finalCond` output from the prior call of this function. Use this syntax to repeatedly generate channel coefficients for continuous time samples.

Examples

Continuously Generate WINNER II Channel Coefficients

Continuously generate channel coefficients for each link in a two-link system layout.

Configure model parameters.

```
cfgWim = winner2.wimparset;
cfgWim.SampleDensity = 20;
cfgWim.RandomSeed = 10; % For repeatability
```

Configure layout parameters.

```
BSAA  = winner2.AntennaArray('UCA',8,0.02);  % UCA-8 array for BS
MSAA1 = winner2.AntennaArray('ULA',2,0.01);  % ULA-2 array for MS1
MSAA2 = winner2.AntennaArray('ULA',4,0.005); % ULA-4 array for MS2
MSIdx = [2,3];
BSIdx = {1};
```

```
NL = 2;
rndSeed = 5;
cfgLayout = winner2.layoutparset(MSIdx,BSIdx,NL,[BSAA,MSAA1,MSAA2],[],rndSeed);
```

Generate channel coefficients for the first time.

```
[H1,~,finalCond] = winner2.wim(cfgWim,cfgLayout);
```

Generate a second set of channel coefficients.

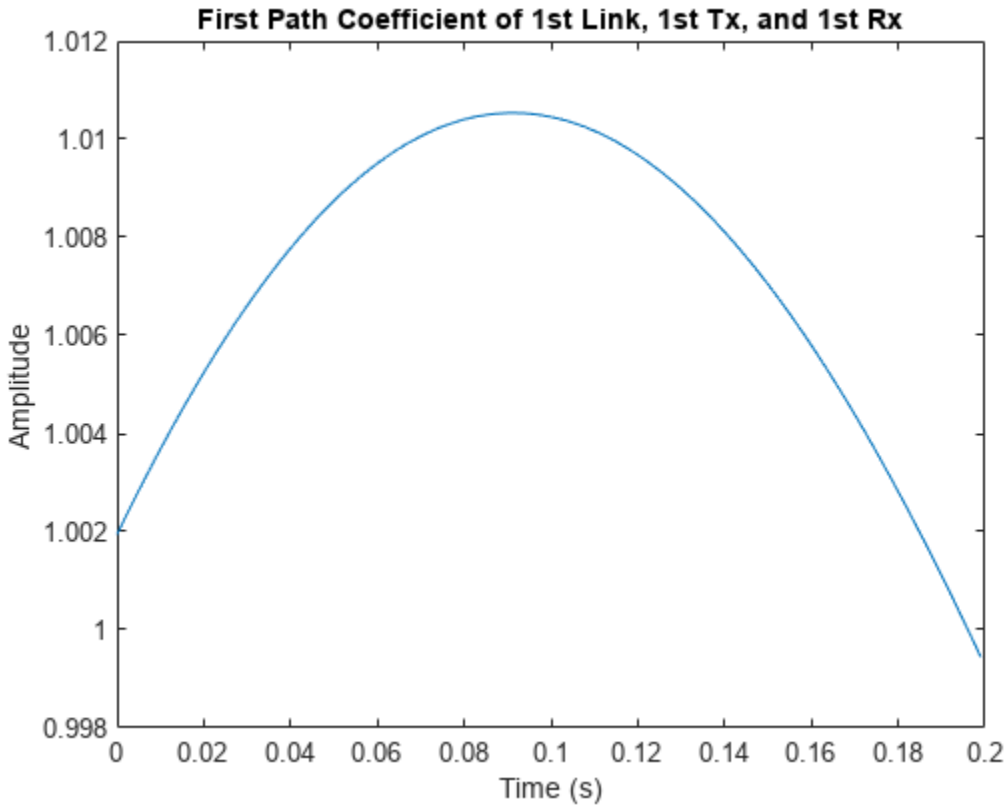
```
[H2,~,finalCond] = winner2.wim(cfgWim,cfgLayout,finalCond);
```

Concatenate H1 and H2 in time domain.

```
H = cellfun(@(x,y) cat(4,x,y),H1,H2,'UniformOutput',false);
```

Plot H for the first link, 1st Tx, 1st Rx, and 1st path. The plot shows the channel continuity over the two outputs from the `winner2.wim` function.

```
figure;
Ts = finalCond.delta_t(1);  % Sample time for the 1st link
plot(Ts*(0:2*cfgWim.NumTimeSamples-1)', ...
    abs(squeeze(H{1}(1,1,1,:))));
xlabel('Time (s)');
ylabel('Amplitude');
title('First Path Coefficient of 1st Link, 1st Tx, and 1st Rx');
```



Input Arguments

`cfgWim` — Configuration layout
structure

Configuration model, specified as a structure containing these fields. `cfgWim` is typically created using the `winner2.wimparset` function.

`NumTimeSamples` — Number of time samples
`100` (default) | scalar

Number of time samples, specified as a scalar.

`FixedPdpUsed` — Use predefined path delays and powers for specific scenarios
`'no'` (default) | `'yes'`

Use predefined path delays and powers for specific scenarios, specified as `'no'` or `'yes'`.

`FixedAnglesUsed` — Use predefined path angles of departure (AoDs) and angles of arrival (AoAs) for specific scenarios
`'no'` (default) | `'yes'`

Use predefined path angles of departure (AoDs) and angles of arrival (AoAs) for specific scenarios, specified as `'yes'` or `'no'`.

`IntraClusterDsUsed` — Divide each of the two strongest clusters into three subclusters per link
`'yes'` (default) | `'no'`

Divide each of the two strongest clusters into three subclusters per link, specified as `'yes'` or `'no'`.

`PolarisedArrays` — Use dual-polarized arrays
`'yes'` (default) | `'no'`

Use dual-polarized arrays, specified as `'yes'` or `'no'`.

`UseManualPropCondition` — Use manually defined propagation conditions
`'yes'` (default) | `'no'`

Use manually defined propagation conditions, specified as `'yes'` or `'no'`. Set to `'yes'` to enforce the use of manually defined propagation conditions (LOS/NLOS) in the `PropagConditionVector` structure field returned by `winner2.layoutparset`. Set to `'no'` to draw propagation conditions from pre-defined LOS probabilities.

`CenterFrequency` — Carrier frequency
`5.25e9` (default) | scalar

Carrier frequency in Hz, specified as a scalar.

`UniformTimeSampling` — Enforce uniform time sampling
`'no'` (default) | `'yes'`

Enforce all links to be sampled at the same time instants, specified as `'no'` or `'yes'`.

`SampleDensity` — Number of time samples per half wavelength
`2e6` (default) | scalar

Number of time samples per half wavelength, specified as a scalar.

`DelaySamplingInterval` — Sampling interval
`5e-9` (default) | scalar

Sampling interval, specified as an scalar indicating the input signal sample time in seconds. `DelaySamplingInterval` defines the sampling grid to which the path delays are rounded. A value of `0` seconds indicates no rounding on path delays.

`ShadowingModelUsed` — Use shadow fading
`'no'` (default) | `'yes'`

Use shadow fading, specified as `'no'` or `'yes'`.

`PathLossModelUsed` — Use path loss model
`'no'` (default) | `'yes'`

Use path loss model, specified as `'no'` or `'yes'`.

`PathLossModel` — Path loss model
`'pathloss'` (default) | character vector

Path loss model, specified as a character vector representing a valid function name. `PathLossModel` applies only when `PathLossModelUsed` is set to `'yes'`.

`PathLossOption` — Wall material
`'CR_light'` (default) | `'CR_heavy'` | `'RR_light'` | `'RR_heavy'`

Wall material, specified as `'CR_light'`, `'CR_heavy'`, `'RR_light'`, or `'RR_heavy'`, indicating the wall material for the *A1* scenario NLOS path loss calculation. `PathLossOption` applies only when `PathLossModelUsed` is set to `'yes'`.

`RandomSeed` — Seed for random number generators
`[]` (default) | scalar

Seed for random number generators, specified as a scalar or empty brackets. Empty brackets, `[]`, indicate that the global random stream is used.

`cfgLayout` — Configuration layout
structure

Configuration layout, specified as a structure containing these fields, which represent the location and orientation parameters for all simulated stations. `cfgLayout` is typically created using the `winner2.layoutparset` function.

`Stations` — Active stations
row vector of structures

Active stations, specified as a row vector of structures describing the antenna arrays for active stations. `Stations` is created from the `arrays` input of `winner2.layoutparset` and adds an additional `Velocity` field. The row ordering specifies base station (BS) sectors first, followed by the mobile stations (MS). The BS sector and MS positions are randomly assigned. The BS sectors have no velocity. Each MS has a velocity of about 1.42 m/s with a randomly assigned direction.

`NofSect` — Number of sectors
vector

Number of sectors, specified as a vector indicating the number of sectors in each BS.

`Pairing` — BS to MS pairing
matrix

BS to MS pairing, specified as a 2-by-N_L matrix, where N_L specifies the number of links to be modeled. See `Stations` for BS and MS row ordering.

`ScenarioVector` — Spatial scenario

`1` (default) | vector

Spatial scenario, specified as a 1-by-N_L vector of scenario numbers. The default is `1`, which specifies scenario A1.

The scenarios numbers map as {`1`=A1, `2`=A2, `3`=B1, `4`=B2, `5`=B3, `6`=B4, `10`=C1, `11`=C2, `12`=C3, `13`=C4, `14`=D1, `15`=D2a}.

For more information, see WINNER II Channel Models [1], Section 2.3.

`PropagConditionVector` — Propagation condition
`1` (default) | vector

Propagation condition, specified as a 1-by-N_L vector of propagation conditions (LOS = 1 and NLOS = 0) for each link.

`StreetWidth` — Street width
`20` (default) | vector

Street width, specified as a 1-by-N_L vector of identical values that specify the average width (in meters) of the streets. `StreetWidth` is used for the path loss model of the B1 and B2 scenarios. See `ScenarioVector` for the scenario number mapping. All elements must have the same value. `StreetWidth` applies only when `cfgWim.PathLossModelUsed` is set to `'yes'`.

`Dist1` — Distances from BS to the last LOS point
`NaN` (default) | vector

Distances from BS to the last LOS point, specified as a 1-by-N_L vector. `Dist1` is used for the path loss model of the B1 and B2 scenarios. The default value of `NaN` indicates that the distance is randomly determined in path loss function. See `ScenarioVector` for the scenario number mapping. `Dist1` applies only when `cfgWim.PathLossModelUsed` is set to `'yes'`.

For more information, see WINNER II Channel Models [1], Figure 4-3.

`NumFloors` — Floor numbers
`1` (default) | vector

Floor numbers, specified as a 1-by-N_L vector indicating the floor number where the indoor BS or MS is located. The default value is `1`. The `NumFloors` field is used for the path loss model of the A2 and B4 scenarios only. See `ScenarioVector` for the scenario number mapping. `NumFloors` applies only when `cfgWim.PathLossModelUsed` is set to `'yes'`.

`NumPenetratedFloors` — Number of floors penetrated
0 (default) | vector

Number of floors penetrated, specified as a 1-by-N_L vector indicating the number of penetrated floors between BS and MS. The default value is `0`. The `NumPenetratedFloors` is used for the NLOS path loss model of the A1 scenario. See `ScenarioVector` for the scenario number mapping. `NumPenetratedFloors` field applies only when `cfgWim.PathLossModelUsed` is set to `'yes'`.

For more information, see WINNER II Channel Models [1], Table 4-4.

`initCond` — Initial system condition

structure | optional

Initial system condition, specified as a structure. `initCond` is of the same form as `finalCond` and is typically the `finalCond` output from the prior call of `winner2.wim`.

Data Types: `struct`

Output Arguments

`chanCoef` — Channel coefficients

cell array containing 4-D arrays of complex values

Channel coefficients, returned as an N_L-by-1 cell array. N_L is the number of links in the system. The ith element of `chanCoef` is an $N_R(i)$-by-$N_T(i)$-by-$N_P(i)$-by-N_S array. N_R, N_T, and N_P are link specific. N_S is the same for all the links.

- $N_R(i)$ is the number of receive antenna elements at MS for the ith link.
- $N_T(i)$ is the number of transmit antenna elements at BS for the ith link.
- $N_P(i)$ is the number of paths for the ith link.
- N_S is the number of time samples given by `cfgWim.NumTimeSamples`.

For more information , see “Channel Power” on page 2-804.

Data Types: `cell`

`pathDelays` — Path delays

matrix

Path delays, returned as an N_L-by-$maxN_P$ matrix. N_L is the number of links in the system and $maxN_P$ is the maximum number of paths among all links. Each row of the matrix applies to each link. When a link has fewer than $maxN_P$ paths, the corresponding row in `pathDelays` is `NaN` padded.

Data Types: `double`

`finalCond` — Final system condition

structure

Final system condition, returned as a structure. When generating channel coefficients for continuous time samples, use `finalCond` as the `initCond` input for the next call to `winner2.wim`.

For more information, see WINNER II Channel Models [1], Section 5.2.

Data Types: `struct`

More About

Channel Power

When path loss and shadowing are off, path gains of the computed WINNER channel are normalized. Specifically, path gains are normalized when the `ShadowingModelUsed` and `PathLossModelUsed` parameters are set to `'no'`.

Version History

Introduced in R2017a

Functions

`winner2.wimparset` | `winner2.AntennaArray` | `winner2.layoutparset`

winner2.wimparset

WINNER II model parameter configuration

Syntax

```
cfgWim = winner2.wimparset
```

Description

Download Required: To use winner2.wimparset, first download the WINNER II Channel Model for Communications Toolbox add-on.

`cfgWim = winner2.wimparset` returns a structure of WINNER II model parameters with their default values.

Examples

Create a WINNER II model parameter set

Use the `winner2.wimparset` function to create a WINNER II model parameter set.

```
cfgwim = winner2.wimparset;
```

Adjust default settings.

```
cfgwim.RandomSeed = 31; % Set the rng seed for repeatability
cfgwim.NumTimeSamples = 250;
cfgwim.CenterFrequency = 4e9;
```

Display the WINNER II model parameter settings.

```
cfgwim
```

```
cfgwim = struct with fields:
            NumTimeSamples: 250
              FixedPdpUsed: 'no'
           FixedAnglesUsed: 'no'
        IntraClusterDsUsed: 'yes'
           PolarisedArrays: 'yes'
    UseManualPropCondition: 'yes'
           CenterFrequency: 4.0000e+09
       UniformTimeSampling: 'no'
             SampleDensity: 2000000
     DelaySamplingInterval: 5.0000e-09
        ShadowingModelUsed: 'no'
         PathLossModelUsed: 'no'
             PathLossModel: 'pathloss'
            PathLossOption: 'CR_light'
                RandomSeed: 31
```

Output Arguments

`cfgWim` — Configuration layout
structure

Configuration model, returned as a structure containing these fields.

`NumTimeSamples` — Number of time samples
`100` (default) | scalar

Number of time samples, specified as a scalar.

`FixedPdpUsed` — Use predefined path delays and powers for specific scenarios
`'no'` (default) | `'yes'`

Use predefined path delays and powers for specific scenarios, specified as `'no'` or `'yes'`.

`FixedAnglesUsed` — Use predefined path angles of departure (AoDs) and angles of arrival (AoAs) for specific scenarios
`'no'` (default) | `'yes'`

Use predefined path angles of departure (AoDs) and angles of arrival (AoAs) for specific scenarios, specified as `'yes'` or `'no'`.

`IntraClusterDsUsed` — Divide each of the two strongest clusters into three subclusters per link
`'yes'` (default) | `'no'`

Divide each of the two strongest clusters into three subclusters per link, specified as `'yes'` or `'no'`.

`PolarisedArrays` — Use dual-polarized arrays
`'yes'` (default) | `'no'`

Use dual-polarized arrays, specified as `'yes'` or `'no'`.

`UseManualPropCondition` — Use manually defined propagation conditions
`'yes'` (default) | `'no'`

Use manually defined propagation conditions, specified as `'yes'` or `'no'`. Set to `'yes'` to enforce the use of manually defined propagation conditions (LOS/NLOS) in the `PropagConditionVector` structure field returned by `winner2.layoutparset`. Set to `'no'` to draw propagation conditions from pre-defined LOS probabilities.

`CenterFrequency` — Carrier frequency
`5.25e9` (default) | scalar

Carrier frequency in Hz, specified as a scalar.

`UniformTimeSampling` — Enforce uniform time sampling
`'no'` (default) | `'yes'`

Enforce all links to be sampled at the same time instants, specified as `'no'` or `'yes'`.

`SampleDensity` — Number of time samples per half wavelength
`2e6` (default) | scalar

Number of time samples per half wavelength, specified as a scalar.

`DelaySamplingInterval` — Sampling interval
`5e-9` (default) | scalar

Sampling interval, specified as an scalar indicating the input signal sample time in seconds. `DelaySamplingInterval` defines the sampling grid to which the path delays are rounded. A value of `0` seconds indicates no rounding on path delays.

`ShadowingModelUsed` — Use shadow fading
`'no'` (default) | `'yes'`

Use shadow fading, specified as `'no'` or `'yes'`.

`PathLossModelUsed` — Use path loss model
`'no'` (default) | `'yes'`

Use path loss model, specified as `'no'` or `'yes'`.

`PathLossModel` — Path loss model
`'pathloss'` (default) | character vector

Path loss model, specified as a character vector representing a valid function name. `PathLossModel` applies only when `PathLossModelUsed` is set to `'yes'`.

`PathLossOption` — Wall material
`'CR_light'` (default) | `'CR_heavy'` | `'RR_light'` | `'RR_heavy'`

Wall material, specified as `'CR_light'`, `'CR_heavy'`, `'RR_light'`, or `'RR_heavy'`, indicating the wall material for the *A1* scenario NLOS path loss calculation. `PathLossOption` applies only when `PathLossModelUsed` is set to `'yes'`.

`RandomSeed` — Seed for random number generators
`[]` (default) | scalar

Seed for random number generators, specified as a scalar or empty brackets. Empty brackets, `[]`, indicate that the global random stream is used.

Functions
winner2.wim | winner2.layoutparset

zadoffChuSeq

Generate root Zadoff-Chu sequence

Syntax

```
seq = zadoffChuSeq(R,N)
```

Description

`seq = zadoffChuSeq(R,N)` generates the `R`th root Zadoff-Chu sequence with length `N`, as defined in 3GPP TS 36.211.

The function generates the sequence using the algorithm given by

$seq(m+1) = exp(-j \cdot \pi \cdot R \cdot m \cdot (m+1)/N)$, for $m = 0, \ldots, N-1$.

The function uses a negative polarity on the argument of the exponent, that is, a clockwise sequence of phases.

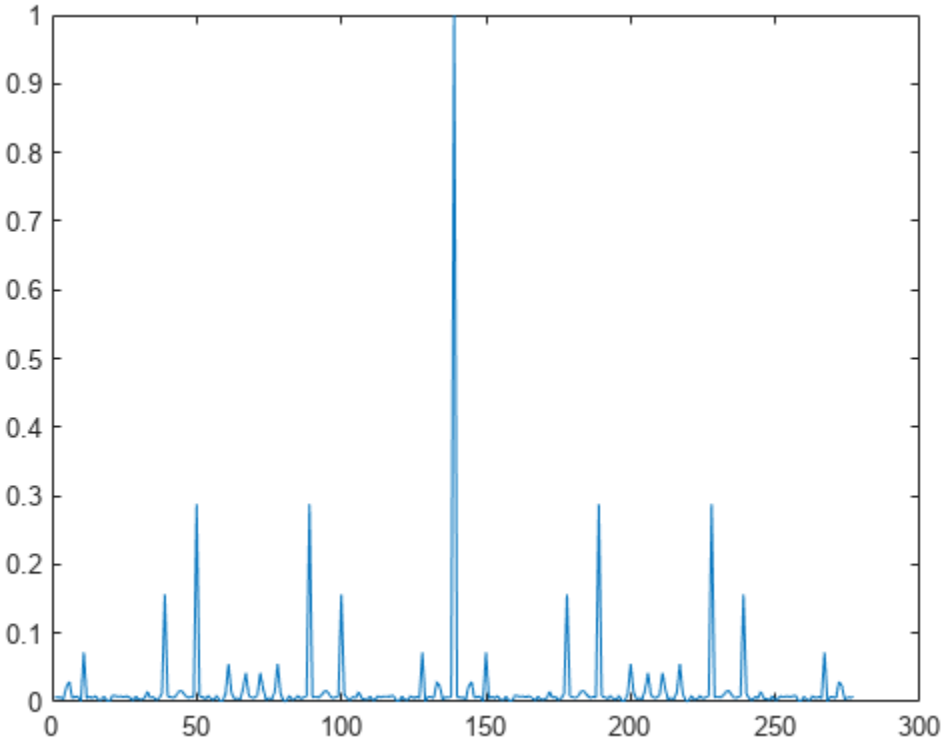
Examples

Examine Correlation Properties of Root Zadoff-Chu Sequence

Generate the 25th root Zadoff-Chu sequence with a length of 139.

Plot the absolute values of the output sequence.

```
seq = zadoffChuSeq(25,139);
plot(abs(xcorr(seq)./length(seq)))
```



Input Arguments

R — Root of Zadoff-Chu sequence
positive integer

Root of the Zadoff-Chu sequence, specified as a positive integer.

Example: 25

Data Types: `double`

N — Length of Zadoff-Chu sequence
odd positive integer

Length of the Zadoff-Chu sequence, specified as an odd positive integer.

Example: 139

Data Types: `double`

Output Arguments

seq — Rth root Zadoff-Chu sequence
column vector of complex values

Rth root Zadoff-Chu sequence, returned as an `N`-by-1 vector of complex values.

Version History

Introduced in R2012b

`lteZadoffChuSeq` was renamed to `zadoffChuSeq`

In release R2019a, the `lteZadoffChuSeq` function was renamed to `zadoffChuSeq`.

addCustomBasemap

Add custom basemap

Syntax

```
addCustomBasemap(basemapName,URL)
addCustomBasemap( ___ ,Name,Value)
```

Description

`addCustomBasemap(basemapName,URL)` adds the custom basemap specified by `URL` to the list of basemaps available for use with mapping functions. `basemapName` is the name you choose to call the custom basemap. Added basemaps remain available for use in future MATLAB sessions.

`addCustomBasemap( ___ ,Name,Value)` specifies name-value arguments that set additional parameters of the basemap.

Examples

Add and Remove a Custom Basemap

Add a custom basemap to view locations on an OpenTopoMap® basemap, then remove the custom basemap from `siteviewer`.

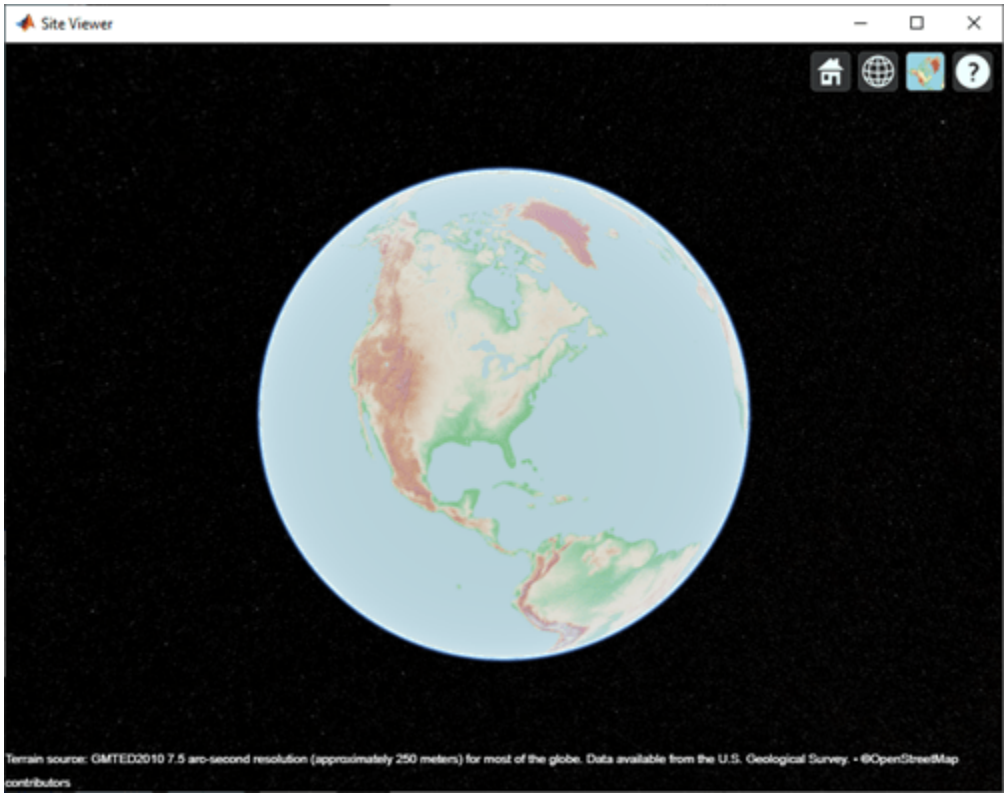
Initialize simulation variables to:

- Define the name that you will use to specify your custom basemap.
- Specify the website that provides the map data. The first character of the URL indicates which server to use to get the data. For load balancing, the provider has three servers that you can use: a, b, or c.
- Create an attribution to display on the map that gives credit to the provider of the map data. Web map providers might define specific requirements for the attribution.
- Define a display name for the custom map.

```
name = 'opentopomap';
url = 'a.tile.opentopomap.org';
copyright = char(uint8(169));
attribution = copyright + "OpenStreetMap contributors";
displayName = 'Open Topo Map';
```

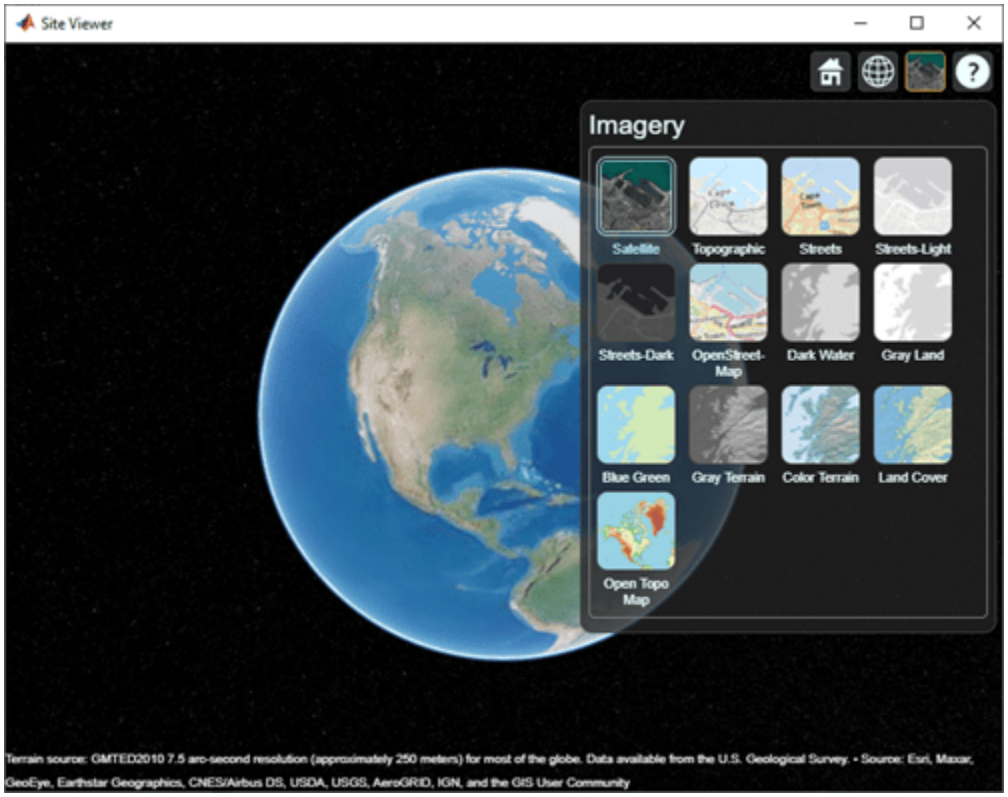
Use `addCustomBasemap` to load the custom basemap, and then create a `siteviewer` object that loads the custom basemap.

```
addCustomBasemap(name,url,'Attribution',attribution','DisplayName',displayName)
viewer = siteviewer('Basemap',name);
```



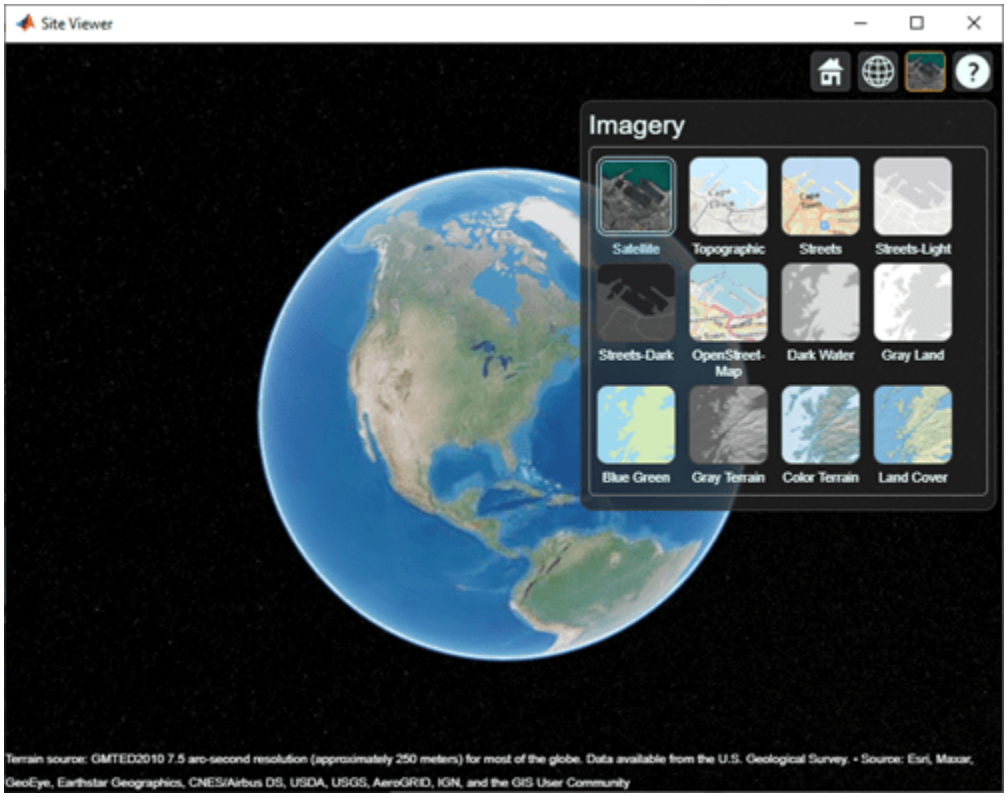
After a custom basemap is added to `siteviewer`, the custom map is available for future calls to `siteviewer`. Note the `'Open Topo Map'` icon in the `Imagery` tab.

```
siteviewer;
```



Use `removeCustomBasemap` to remove the custom basemap from future calls to `siteviewer`. Note the `'Open Topo Map'` icon is no longer available in the `Imagery` tab.

```
removeCustomBasemap(name)
siteviewer;
```



Input Arguments

basemapName — Name used to identify basemap programmatically

string scalar | character vector

Name used to identify basemap programmatically, specified as a string scalar or character vector.

Example: `'openstreetmap'`

Data Types: `string` | `char`

URL — Parameterized map URL

string scalar | character vector

Parameterized map URL, specified as a string scalar or character vector. A parameterized URL is an index of the map tiles, formatted as `${z}/${x}/${y}.png` or `{z}/{x}/{y}.png`, where:

- `${z}` or `{z}` is the tile zoom level.
- `${x}` or `{x}` is the tile column index.
- `${y}` or `{y}` is the tile row index.

Example: `'https://hostname/${z}/${x}/${y}.png'`

Data Types: `string` | `char`

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `addCustomBasemap(basemapName,URL,"Attribution",attribution)`

`Attribution` — Attribution of custom basemap
string scalar | string array | character vector | cell array of character vectors

Attribution of the custom basemap, specified as a string scalar, string array, character vector, or cell array of character vectors. To create a multiline attribution, specify a string array or nonscalar cell array of character vectors.

When you create a custom basemap from a URL, the default attribution is `'Tiles courtesy of` *`DOMAIN_NAME_OF_URL`*`'`, where *`DOMAIN_NAME_OF_URL`* is the domain name from the `URL` input argument. If the host is `'localhost'`, or if `URL` contains only IP numbers, specify the attribution as an empty string (`""`).

Example: `"Credit: U.S. Geological Survey"`

Data Types: `string` | `char` | `cell`

`DisplayName` — Display name of custom basemap
string scalar | character vector

Display name of the custom basemap, specified as a string scalar or character vector.

Example: `"OpenStreetMap"`

Data Types: `string` | `char`

`MaxZoomLevel` — Maximum zoom level of basemap
`18` (default) | integer in range [0, 25]

Maximum zoom level of the basemap, specified as an integer in the range [0, 25].

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`IsDeployable` — Map is deployable using MATLAB Compiler™
`false` or `0` (default) | `true` or `1`

Map is deployable using MATLAB Compiler, specified as a numeric or logical `0` (`false`) or `1` (`true`).

Data Types: `logical`

Limitations

The `addCustomBasemap` function does not support adding custom basemaps from vector map tiles.

Tips

- You can find tiled web maps from various vendors, such as OpenStreetMap®, the USGS National Map, Mapbox, DigitalGlobe, Esri® ArcGIS Online, the Geospatial Information Authority of Japan

(GSI), and HERE Technologies. Abide by the map vendors terms-of-service agreement and include accurate attribution with the maps you use.

- If you have Mapping Toolbox™, you can create custom basemaps from MBTiles files. For more information, see `addCustomBasemap`.
- To access a list of available basemaps, press **Tab** before specifying the basemap in your plotting function. This image shows a sample list of available basemaps, including several custom basemaps from the USGS National Map.

Topics

“Use Basemaps in Offline Environments” (Mapping Toolbox)

removeCustomBasemap

Remove custom basemap

Syntax

```
removeCustomBasemap(basemapName)
```

Description

`removeCustomBasemap(basemapName)` removes the custom basemap specified by `basemapName` from the list of available basemaps.

Examples

Add and Remove a Custom Basemap

Add a custom basemap to view locations on an OpenTopoMap® basemap, then remove the custom basemap from `siteviewer`.

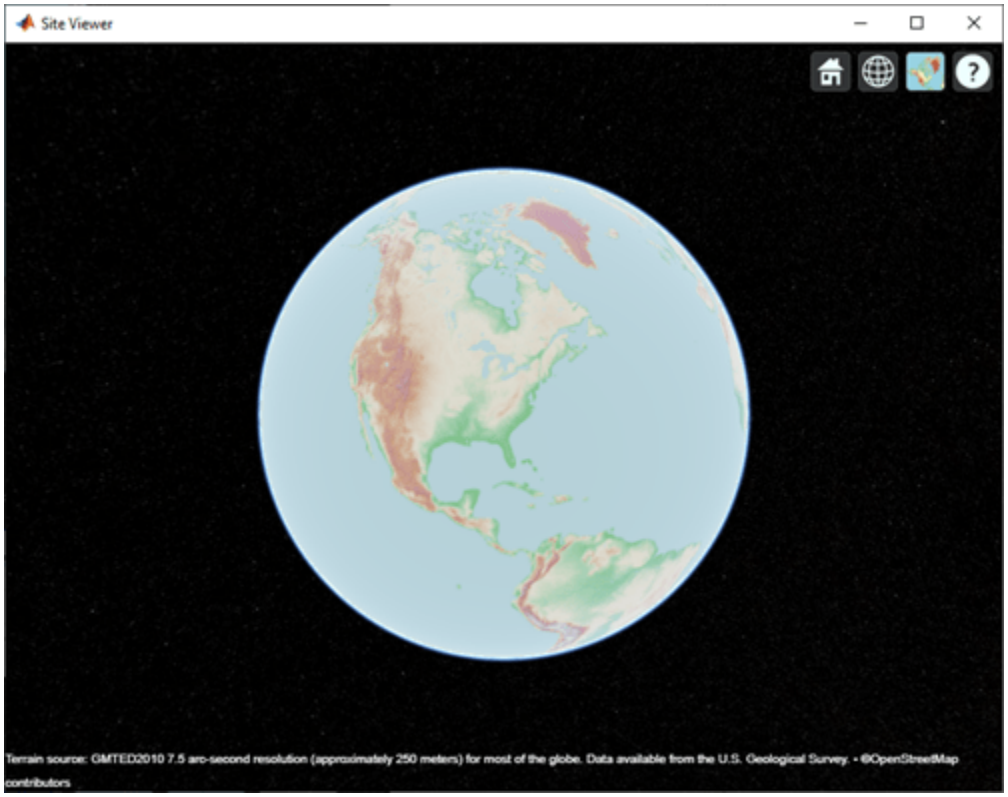
Initialize simulation variables to:

- Define the name that you will use to specify your custom basemap.
- Specify the website that provides the map data. The first character of the URL indicates which server to use to get the data. For load balancing, the provider has three servers that you can use: a, b, or c.
- Create an attribution to display on the map that gives credit to the provider of the map data. Web map providers might define specific requirements for the attribution.
- Define a display name for the custom map.

```
name = 'opentopomap';
url = 'a.tile.opentopomap.org';
copyright = char(uint8(169));
attribution = copyright + "OpenStreetMap contributors";
displayName = 'Open Topo Map';
```

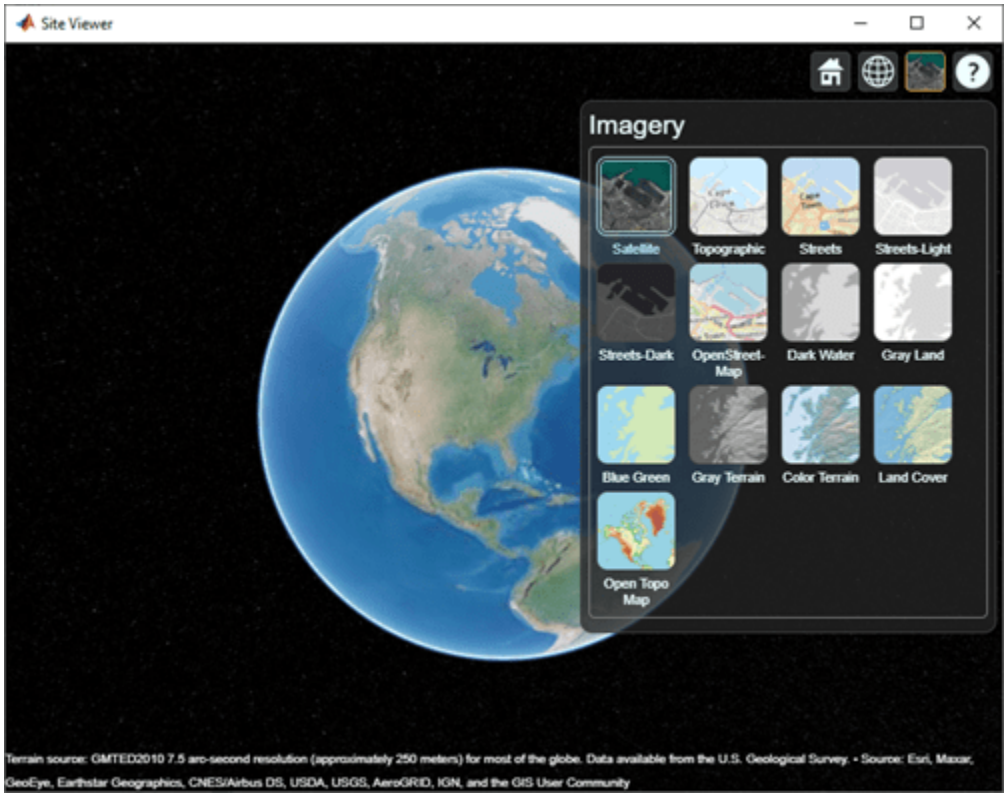
Use `addCustomBasemap` to load the custom basemap, and then create a `siteviewer` object that loads the custom basemap.

```
addCustomBasemap(name,url,'Attribution',attribution','DisplayName',displayName)
viewer = siteviewer('Basemap',name);
```



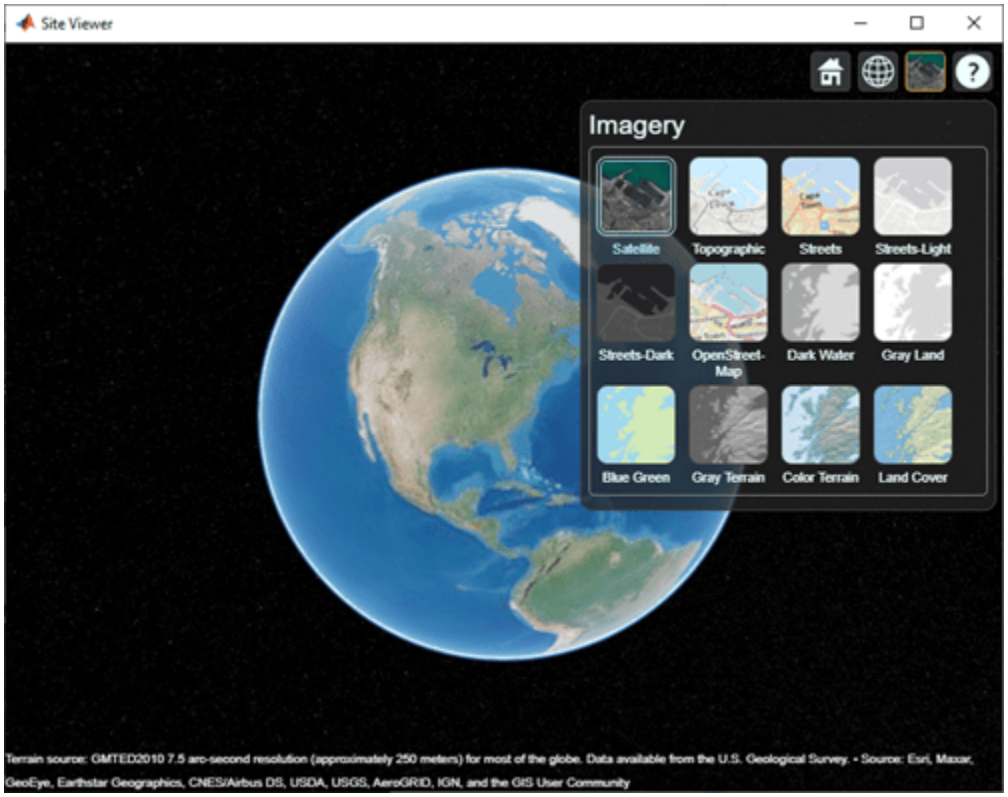
After a custom basemap is added to `siteviewer`, the custom map is available for future calls to `siteviewer`. Note the `'Open Topo Map'` icon in the `Imagery` tab.

```
siteviewer;
```



Use `removeCustomBasemap` to remove the custom basemap from future calls to `siteviewer`. Note the `'Open Topo Map'` icon is no longer available in the `Imagery` tab.

```
removeCustomBasemap(name)
siteviewer;
```



Input Arguments

`basemapName` — Name of custom basemap

string scalar | character vector

Name of the custom basemap to remove, specified as a string scalar or character vector. You define the basemap name when you add the basemap using the `addCustomBasemap` function.

Data Types: `string` | `char`

See Also

`geoaxes` | `geobasemap` | `geobubble` | `geodensityplot` | `geoplot` | `geoscatter` | `addCustomBasemap`

buildingMaterialPermittivity

Permittivity and conductivity of building materials

Syntax

```
[epsilon,sigma,complexepsilon] = buildingMaterialPermittivity(material,fc)
```

Description

`[epsilon,sigma,complexepsilon] = buildingMaterialPermittivity(material,fc)` calculates the relative permittivity, conductivity, and complex relative permittivity for the specified material at the specified frequency. The methods and equations modeled in the `buildingMaterialPermittivity` function are presented in Recommendation ITU-R P.2040 [1].

Examples

Calculate Permittivity of Various Building Materials

Calculate relative permittivity and conductivity at 9 GHz for various building materials as defined by textual classifications in ITU-R P.2040, Table 3.

```
material = ["vacuum";"concrete";"brick";"plasterboard";"wood"; ...
    "glass";"ceiling-board";"chipboard";"floorboard";"metal"];
fc = repmat(9e9,size(material)); % Frequency in Hz
[permittivity,conductivity] = ...
    arrayfun(@(x,y)buildingMaterialPermittivity(x,y),material,fc);
```

Display the results in a table.

```
varNames = ["Material";"Permittivity";"Conductivity"];
table(material,permittivity,conductivity,'VariableNames',varNames)
```

```
ans=10×3 table
       Material        Permittivity    Conductivity
    _______________    ____________    ____________

    "vacuum"                  1               0
    "concrete"             5.31           0.19305
    "brick"                3.75             0.038
    "plasterboard"         2.94          0.054914
    "wood"                 1.99          0.049528
    "glass"                6.27          0.059075
    "ceiling-board"         1.5         0.0064437
    "chipboard"            2.58           0.12044
    "floorboard"           3.66          0.085726
    "metal"                   1             1e+07
```

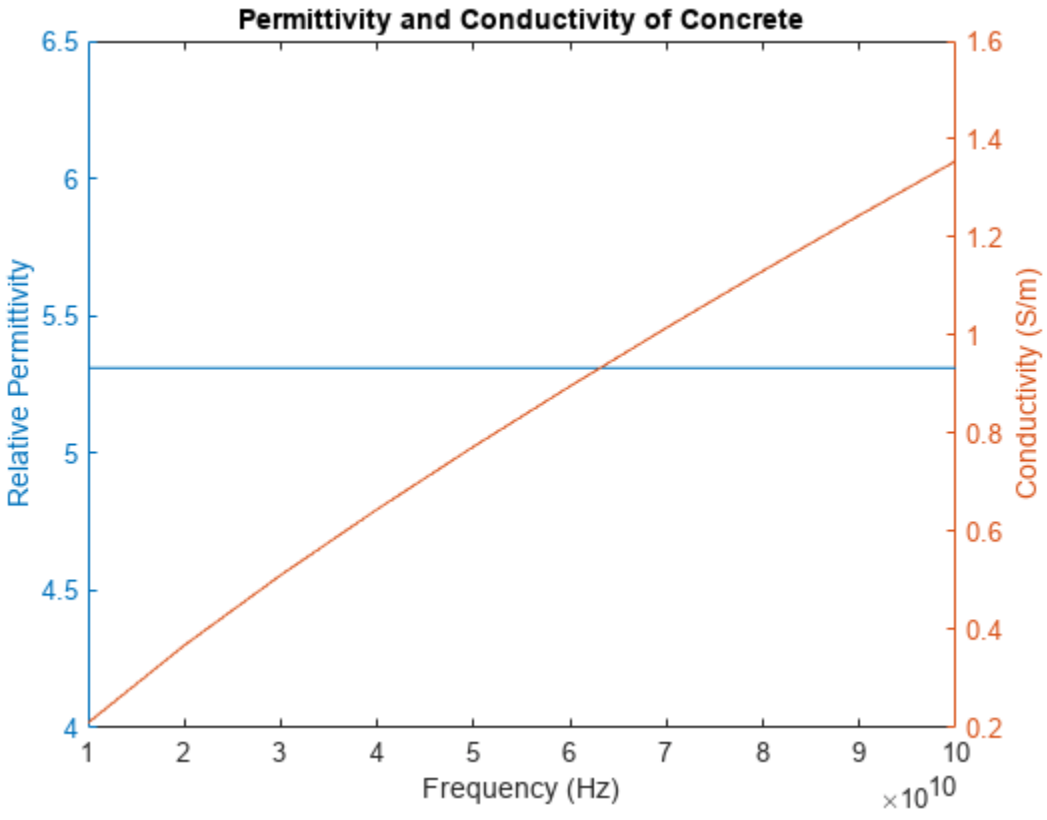
Plot Permittivity and Conductivity of Concrete at Various Frequencies

Calculate the relative permittivity and conductivity for concrete at frequencies specified.

```
fc = ((1:1:10)*10e9); % Frequency in Hz
[permittivity,conductivity] = ...
    arrayfun(@(y)buildingMaterialPermittivity("concrete",y),fc);
```

Plot the relative permittivity and conductivity of concrete across the range of frequencies.

```
figure
yyaxis left
plot(fc,permittivity)
ylabel('Relative Permittivity')
yyaxis right
plot(fc,conductivity)
ylabel('Conductivity (S/m)')
xlabel('Frequency (Hz)')
title('Permittivity and Conductivity of Concrete')
```



Input Arguments

`material` — Building material

`"vacuum"` | `"concrete"` | `"brick"` | `"plasterboard"` | ...

Building material, specified as vector of strings, or an equivalent character vector or cell array of character vectors including one or more of these options:

`"vacuum"`	`"glass"`	`"very-dry-ground"`
`"concrete"`	`"ceiling-board"`	`"medium-dry-ground"`
`"brick"`	`"floorboard"`	`"wet-ground"`
`"plasterboard"`	`"chipboard"`	
`"wood"`	`"metal"`	

Example: `["vacuum" "brick"]`

Data Types: `char` | `string`

`fc` — Carrier frequency
positive scalar

Carrier frequency in Hz, specified as a positive scalar.

Note `fc` must be in the range [1e6, 10e6] when the `material` is `"very-dry-ground"`, `"medium-dry-ground"` or `"wet-ground"`.

Data Types: `double`

Output Arguments

`epsilon` — Relative permittivity
nonnegative scalar | nonnegative row vector

Relative permittivity of the building material, returned as a nonnegative scalar or row vector. The output dimension of `epsilon` matches that of the input argument `material`. For more information about the computation for the relative permittivity, see “ITU Building Materials” on page 2-825.

`sigma` — Conductivity
nonnegative scalar | nonnegative row vector

Conductivity, in Siemens/m, of the building material, returned as a nonnegative scalar or row vector. The output dimension of `sigma` matches that of the input argument `material`. For more information about the computation for the conductivity, see “ITU Building Materials” on page 2-825.

`complexepsilon` — Complex relative permittivity
complex scalar | row vector of complex values

Complex relative permittivity of the building material, returned as a complex scalar or row vector of complex values.

The output dimension of `complexepsilon` matches that of the input argument `material`. For more information about the computation for the complex relative permittivity, see “ITU Building Materials” on page 2-825.

More About

ITU Building Materials

Section 3 of ITU-R P.2040-1 [1] presents methods, equations, and values used to calculate real relative permittivity, conductivity, and complex relative permittivity at carrier frequencies up to 100 GHz for common building materials.

The `buildingMaterialPermittivity` function uses equations from ITU-R P.2040-1 to compute these values.

- The real part of the relative permittivity is calculated as `epsilon` = af^b.
  The computation of `epsilon` is based on equation (58). f is the frequency in GHz. Values for a and b are specified in Table 3 from ITU-R P.2040-1.
- The conductivity in Siemens/m is calculated as `sigma` = cf^d.
  The computation of `sigma` is based on equation (59). f is the frequency in GHz. Values for c and d are specified in Table 3 from ITU-R P.2040-1.
- The complex permittivity is calculated as `complexepsilon` = `epsilon` – 1i `sigma` / ($2\pi fc\varepsilon_0$).
  The computation of `complexepsilon` is based on Equations (59) and (9b). f is the frequency in GHz. c is the velocity of light in free space. ε_0 = 8.854187817e-12 Farads/m, where ε_0 is the electric constant for the permittivity of free space.

For cases where the value of b or d is zero, the corresponding value of `epsilon` or `sigma` is a or c, respectively and independent of frequency.

The contents of Table 3 from ITU-R P.2040-1 are repeated in this table. The values a, b, c, and d are used to calculate relative permittivity and conductivity. Except as noted for the three ground types, the frequency ranges given in the table are not hard limits but are indicative of the measurements used to derive the models. The `buildingMaterialPermittivity` function interpolates or extrapolates relative permittivity and conductivity values for frequencies that fall outside of the noted limits. To compute relative permittivity and conductivity for different types of ground as a function carrier frequencies up to 1000 GHz, see the `earthSurfacePermittivity` function.

Material Class	Real Part of Relative Permittivity		Conductivity (S/m)		Frequency Range (GHz)
	a	***b***	***c***	***d***	
Vacuum (~ air)	1	0	0	0	[0.001, 100]
Concrete	5.31	0	0.0326	0.8095	[1, 100]
Brick	3.75	0	0.038	0	[1, 10]
Plasterboard	2.94	0	0.0116	0.7076	[1, 100]
Wood	1.99	0	0.0047	1.0718	[0.001, 100]
Glass	6.27	0	0.0043	1.1925	[0.1, 100]
Ceiling board	1.50	0	0.0005	1.1634	[1, 100]
Chipboard	2.58	0	0.0217	0.78	[1, 100]
Floorboard	3.66	0	0.0044	1.3515	[50, 100]

Material Class	Real Part of Relative Permittivity		Conductivity (S/m)		Frequency Range (GHz)
	a	*b*	*c*	*d*	
Metal	1	0	10^7	0	[1, 100]
Very dry ground	3	0	0.00015	2.52	[1, 10] only(a)
Medium dry ground	15	– 0.1	0.035	1.63	[1, 10] only(a)
Wet ground	30	– 0.4	0.15	1.30	[1, 10] only(a)
Note (a): For the three ground types (very dry, medium dry, and wet), the noted frequency limits cannot be exceeded.

earthSurfacePermittivity

Permittivity and conductivity of earth surface materials

Syntax

```
[epsilon,sigma,complexepsilon] = earthSurfacePermittivity('pure-water',fc,
temp)
[epsilon,sigma,complexepsilon] = earthSurfacePermittivity('dry-ice',fc,temp)
[epsilon,sigma,complexepsilon] = earthSurfacePermittivity('sea-water',fc,
temp,salinity)
[epsilon,sigma,complexepsilon] = earthSurfacePermittivity('wet-ice',fc,
liqfrac)

[epsilon,sigma,complexepsilon] = earthSurfacePermittivity('soil',fc,temp,
sandpercent,claypercent,specificgravity,vwc)
[epsilon,sigma,complexepsilon] = earthSurfacePermittivity('soil',___,
bulkdensity)

[epsilon,sigma,complexepsilon] = earthSurfacePermittivity('vegetation',fc,
temp,gwc)
```

Description

The `earthSurfacePermittivity` function computes electrical characteristics (relative permittivity, conductivity, and complex relative permittivity) of earth surface materials based on the methods and equations presented in ITU-R P.527 [1]. The `earthSurfacePermittivity` function provides various syntaxes to account for characteristics germane to the specified surface material.

`[epsilon,sigma,complexepsilon] = earthSurfacePermittivity('pure-water',fc, temp)` calculates the electrical characteristics for pure water at the specified frequency and temperature. For pure-water, the temperature setting must be greater than 0 ℃.

`[epsilon,sigma,complexepsilon] = earthSurfacePermittivity('dry-ice',fc,temp)` calculates the electrical characteristics for dry-ice at the specified frequency and temperature. For dry-ice, the temperature must be less than or equal to 0 ℃.

`[epsilon,sigma,complexepsilon] = earthSurfacePermittivity('sea-water',fc, temp,salinity)` calculates the electrical characteristics for sea water at the specified frequency, temperature, and salinity. For sea-water, the temperature must be greater than –2 ℃.

`[epsilon,sigma,complexepsilon] = earthSurfacePermittivity('wet-ice',fc, liqfrac)` calculates the electrical characteristics for wet ice at the specified frequency, and liquid water volume fraction. For wet-ice, the temperature is 0 ℃.

`[epsilon,sigma,complexepsilon] = earthSurfacePermittivity('soil',fc,temp, sandpercent,claypercent,specificgravity,vwc)` calculates the electrical characteristics for soil at the specified frequency, temperature, sand percentage, clay percentage, specific gravity, and volumetric water content.

`[epsilon,sigma,complexepsilon] = earthSurfacePermittivity('soil',___, bulkdensity)` sets the soil bulk density in addition to input arguments from the previous syntax.

`[epsilon,sigma,complexepsilon] = earthSurfacePermittivity('vegetation',fc, temp,gwc)` calculates the electrical characteristics for vegetation at the specified frequency, temperature, and gravimetric water content. For vegetation, the temperature must be greater than or equal to –20 ℃.

Examples

Compare Permittivity and Conductivity of Salt-free Sea Water to Pure Water

Compare the relative permittivity and conductivity for salt-free (zero-salinity) sea water to pure water.

Specify a carrier frequency of 9 GHz, temperature of 30℃, and salinity of zero.

```
fc = 9e9; % Carrier frequency in Hz.
temp = 30;
salinity = 0;
```

Compute the relative permittivity and conductivity.

```
[epsilon_pure_water,sigma_pure_water] = earthSurfacePermittivity('pure-water',fc,temp);
[epsilon_sea_water,sigma_sea_water] = earthSurfacePermittivity('sea-water',fc,temp,salinity);
```

Confirm that salt-free sea water and pure water have equal relative permittivity and conductivity.

```
isequal(epsilon_pure_water,epsilon_sea_water)
```

```
ans = logical
   1
```

```
isequal(sigma_pure_water,sigma_sea_water)
```

```
ans = logical
   1
```

Compare Permittivity and Conductivity of Wet Ice to Dry Ice

Compare the relative permittivity and conductivity for wet ice with no liquid water to dry ice at 0℃. Confirm the results differ by a negligible amount.

Specify a carrier frequency of 12 GHz.

```
fc = 12e9; % Carrier frequency in Hz.
```

Calculate the relative permittivity and conductivity for wet ice with zero liquid water by volume.

```
liqfrac = 0;
[epsilon_wet_ice_0,sigma_wet_ice_0] = earthSurfacePermittivity('wet-ice',fc,liqfrac); % Set liqu
```

Calculate the relative permittivity and conductivity for dry ice at 0 ℃.

```
temp = 0;
[epsilon_dry_ice_0,sigma_dry_ice_0] = earthSurfacePermittivity('dry-ice',fc,temp); % Set tempera
```

Compare the relative permittivity and conductivity for wet ice with no liquid to dry ice at 0°C. Confirm that wet ice with no liquid and dry ice at 0°C have essentially equal relative permittivity and conductivity.

```
epsilon_wet_ice_0-epsilon_dry_ice_0
```

```
ans = 8.8818e-16
```

```
sigma_wet_ice_0-sigma_dry_ice_0
```

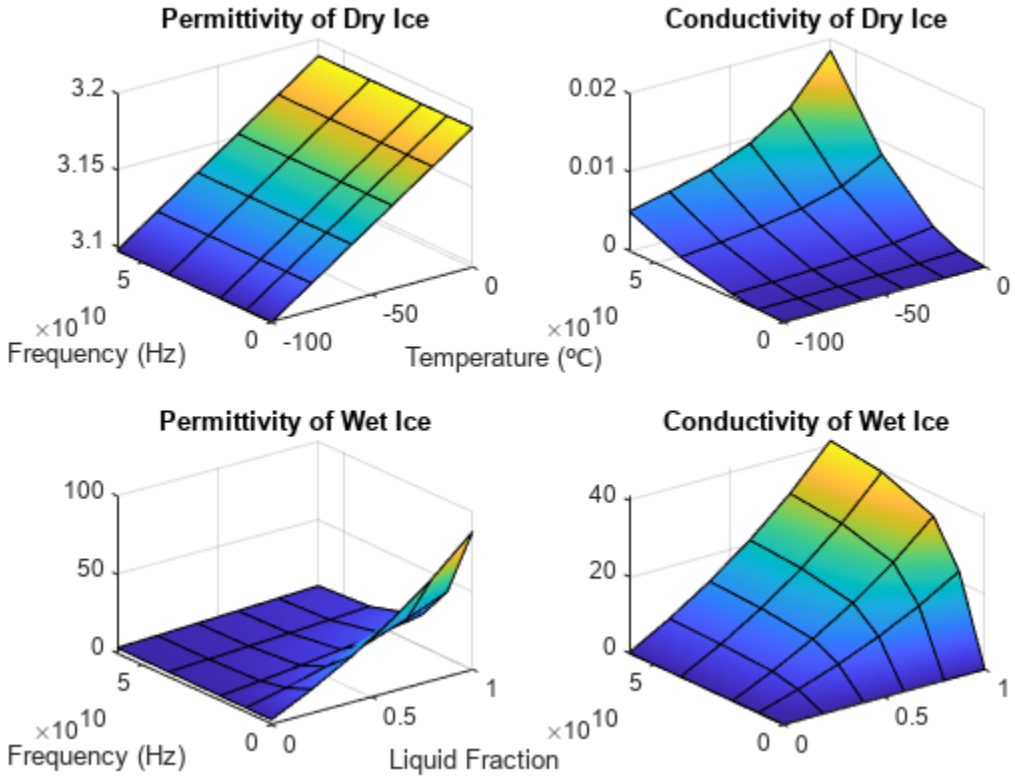
```
ans = -9.2179e-16
```

Plot permittivity and conductivity versus frequency for dry ice and for wet ice. For dry ice, vary the temperature. For wet ice, vary the liquid water volume fraction. Calculate the permittivity and conductivity values by using `arrayfun` to apply the `earthSurfacePermittivity` function to the elements of the arrayed inputs.

```
freq = repmat([0.1,10,20,40,60]*1e9,6,1);
temp = repmat((-100:20:0)',1,5);
liqfrac = repmat((0:0.2:1)',1,5);
[epsilon_dry_ice, sigma_dry_ice] = arrayfun(@(x,y)earthSurfacePermittivity('dry-ice',x,y),freq,te
[epsilon_wet_ice, sigma_wet_ice] = arrayfun(@(x,y)earthSurfacePermittivity('wet-ice',x,y),freq,li
```

Display tiled surface plots across specified ranges.

```
figure
tiledlayout(2,2)
nexttile
surf(temp,freq,epsilon_dry_ice,'FaceColor','interp')
title('Permittivity of Dry Ice')
xlabel('Temperature (°C)')
ylabel('Frequency (Hz)')
nexttile
surf(temp,freq,sigma_dry_ice,'FaceColor','interp')
title('Conductivity of Dry Ice')
nexttile
surf(liqfrac,freq,epsilon_wet_ice,'FaceColor','interp')
title('Permittivity of Wet Ice')
xlabel('Liquid Fraction')
ylabel('Frequency (Hz)')
nexttile
surf(liqfrac,freq,sigma_wet_ice,'FaceColor','interp')
title('Conductivity of Wet Ice')
```



Calculate Permittivity and Conductivity of Various Soil Mixtures

Calculate relative permittivity and conductivity for various soil mixtures as defined by textual classifications in ITU-R P.527, Table 1.

Initialize computation variables for constant values and arrayed values.

```
fc = 28e9; % Frequency in Hz
temp = 23; % Temperature in °C
vwc = 0.5; % Volumetric water content
pSand = [51.52; 41.96; 30.63; 5.02]; % Sand percentage
pClay = [13.42; 8.53; 13.48; 47.38]; % Clay percentage
sg = [2.66; 2.70; 2.59; 2.56]; % Specific gravity
bd = [1.6006; 1.5781; 1.5750; 1.4758]; % Bulk density (g/cm^3)
```

Calculate the relative permittivity and conductivity for these textual classifications: sandy loam, loam, silty loam, and silty clay. Use `arrayfun` to apply the `earthSurfacePermittivity` function to the elements of the arrayed inputs. Tabulate the results.

```
[Permittivity,Conductivity] = arrayfun(@(w,x,y,z)earthSurfacePermittivity( ...
    'soil',fc,temp,w,x,y,vwc,z),pSand,pClay,sg,bd);

pSilt = 100 - (pSand + pClay); % Silt percentage
soilType = ["Sandy Loam";"Loam";"Silty Loam";"Silty Clay"];
```

```
varNames1 = ["Soil Textual Classification";"Sand";"Clay";"Silt";"Specific Gravity";"Bulk Density"
varNames2 = ["Soil Textual Classification";"Permittivity";"Conductivity"];
```

ITU-R P.527, Table 1 specifies the sand percentage, clay percentage, specific gravity, and bulk density for soil mixtures with these soil textual classifications.

```
table(soilType,pSand,pClay,pSilt,sg,bd,'VariableNames',varNames1)
```

Calculate Permittivity and Conductivity of Vegetation

Calculate relative permittivity and conductivity versus frequency for vegetation, varying gravimetric water content and temperature.

Calculate relative permittivity and conductivity for vegetation at specified settings.

```
fc = 10e9; % Frequency in Hz
temp  = 23; % Temperature in °C
gwc = 0.68; % Gravimetric water content
[epsilon_veg,sigma_veg] = ...
    earthSurfacePermittivity('vegetation',fc,temp,gwc)
```

```
epsilon_veg = 20.5757
```

```
sigma_veg = 4.9320
```

Calculate values necessary to plot permittivity and conductivity by using `arrayfun` to apply the `earthSurfacePermittivity` function to the elements of the arrayed inputs.

For a range of temperatures, calculate values to plot permittivity and conductivity versus frequency for vegetation at a 0.68 gravimetric water content.

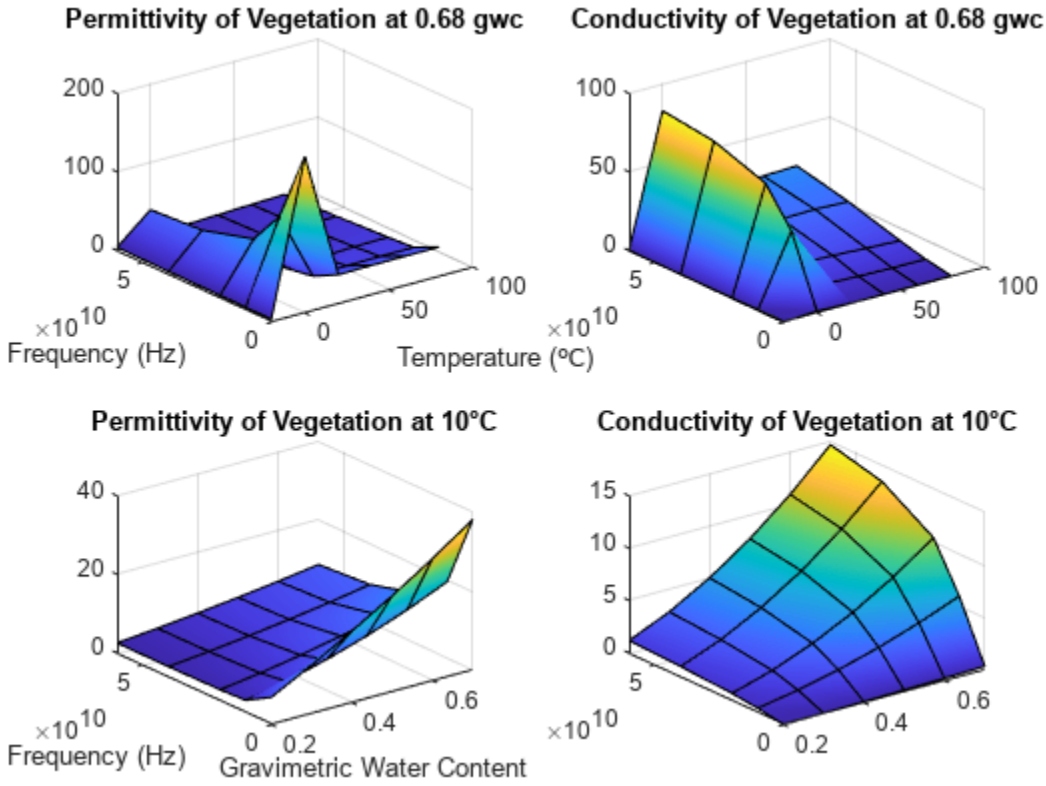
```
fc = repmat([0.1,10,20,40,60]*1e9,6,1);
gwc1 = 0.68;
temp1 = repmat((-20:20:80)',1,5);
[epsilon_veg_gwc,sigma_veg_gwc] = ...
    arrayfun(@(x,y)earthSurfacePermittivity('vegetation',x,y,gwc1),fc,temp1);
```

For a range of gravimetric water contents, calculate values to plot permittivity and conductivity versus frequency for vegetation at 10°C.

```
temp2 = 10;
gwc2 = repmat((0.2:0.1:0.7)',1,5);
[epsilon_veg_tmp, sigma_veg_tmp] = ...
    arrayfun(@(x,z)earthSurfacePermittivity('vegetation',x,temp2,z),fc,gwc2);
```

Display tiled surface plots across specified ranges.

```
figure
tiledlayout(2,2)
nexttile
surf(temp1,fc,epsilon_veg_gwc,'FaceColor','interp')
title('Permittivity of Vegetation at 0.68 gwc')
xlabel('Temperature (℃)')
ylabel('Frequency (Hz)')
nexttile
surf(temp1,fc,sigma_veg_gwc,'FaceColor','interp')
title('Conductivity of Vegetation at 0.68 gwc')
nexttile
surf(gwc2,fc,epsilon_veg_tmp,'FaceColor','interp')
title('Permittivity of Vegetation at 10°C')
xlabel('Gravimetric Water Content')
ylabel('Frequency (Hz)')
nexttile
surf(gwc2,fc,sigma_veg_tmp,'FaceColor','interp')
title('Conductivity of Vegetation at 10°C')
```



Input Arguments

`fc` — Carrier frequency

scalar in the range (0, 1e12]

Carrier frequency in Hz, specified as a scalar in the range (0, 1e12].

Data Types: `double`

`temp` — Temperature

numeric scalar

Temperature in °C, specified as a numeric scalar. Valid surfaces and associated temperature limits are indicated in this table.

Surface	Valid Temperature (°C)
pure-water	greater than 0
dry-ice	less than or equal to 0
sea-water	greater than or equal to –2
soil	any numeric
vegetation	≥ –20

Note When the surface is wet-ice, the temperature is 0 ℃.

Data Types: `double`

`salinity` — Salinity of sea water
nonnegative scalar

Salinity of the sea water in g/Kg, specified as a nonnegative scalar.

Data Types: `double`

`liqfrac` — Liquid water volume fraction of wet ice
numeric scalar in the range [0, 1]

Liquid water volume fraction of the wet ice, specified as a numeric scalar in the range [0, 1].

Data Types: `double`

`sandpercent` — Sand percentage of soil
numeric scalar in the range [0, 100]

Sand percentage of the soil, specified as a numeric scalar in the range [0, 100]. The sum of `sandpercent` and `claypercent` must be less than or equal to 100.

Data Types: `double`

`claypercent` — Clay percentage of soil
numeric scalar in the range [0, 100]

Clay percentage of the soil, specified as a numeric scalar in the range [0, 100]. The sum of `sandpercent` and `claypercent` must be less than or equal to 100.

Data Types: `double`

`specificgravity` — Specific gravity of soil
nonnegative scalar

Specific gravity of the soil, specified as a nonnegative scalar. The specific gravity is the mass density of the soil sample divided by the mass density of the amount of water in the soil sample.

Data Types: `double`

`vwc` — Volumetric water content of soil
numeric scalar in the range [0, 1]

Volumetric water content of the soil, specified as a numeric scalar in the range [0, 1]. For more information, see “Soil Water Content” on page 2-836.

Data Types: `double`

`bulkdensity` — Bulk density of soil
nonnegative scalar

Bulk density, in g/cm^3, of the soil, specified as a nonnegative scalar. For more information, see “Soil Water Content” on page 2-836.

Data Types: `double`

`gwc` — Gravimetric water content of vegetation
numeric scalar in the range [0, 0.7]

Gravimetric water content of the vegetation, specified as a numeric scalar in the range [0, 0.7]. For more information, see “Soil Water Content” on page 2-836.

Data Types: `double`

Output Arguments

`epsilon` — Relative permittivity
nonnegative scalar

Relative permittivity of the earth surface, returned as a nonnegative scalar.

`sigma` — Conductivity
nonnegative scalar

Conductivity of the earth surface in Siemens per meter (S/m), returned as a nonnegative scalar.

`complexepsilon` — Complex relative permittivity
complex scalar

Complex relative permittivity of the earth surface, returned as a complex scalar calculated as `complexepsilon` = `epsilon` – 1*i* `sigma` / ($2\pi fc\varepsilon_0$).
The computation of `complexepsilon` is based on Equations (59) and (9b) in ITU-R P.527 [1]. *f* is the frequency in GHz. *c* is the velocity of light in free space. ε_0 = 8.854187817e-12 Farads/m, where ε_0 is the electric constant for the permittivity of free space.

More About

ITU Terrain Materials

ITU-R P.527 [1] presents methods and equations to calculate complex relative permittivity at carrier frequencies up to 1,000 GHz for these common earth surface materials.

- Water
- Sea Water
- Dry or Wet Ice
- Dry or Wet Soil (combination of sand, clay, and silt)
- Vegetation (above and below freezing)

As described in ITU-R P.527, specific textural classification applies to these mixtures of sand, clay, and silt in soil with associated specific gravities and bulk densities.

Soil Designation Textural Class	Sandy Loam	Loam	Silty Loam	Silty Clay
% Sand	51.52	41.96	30.63	5.02
% Clay	13.42	8.53	13.48	47.38
% Silt	35.06	49.51	55.89	47.60

Soil Designation Textural Class	Sandy Loam	Loam	Silty Loam	Silty Clay
Specific gravity (ρ_s)	2.66	2.70	2.59	2.56
Bulk Density (ρ_b) in g/cm^3	1.6006	1.5781	1.5750	1.4758

Soil Water Content

Soil water content is expressed on a gravimetric or volumetric basis. Gravimetric water content, `gwc`, is the mass of water per mass of dry soil. Volumetric water content, `vwc`, is the volume of liquid water per volume of soil. The bulk density, `bulkdensity`, is the ratio of the dry soil weight to the volume of the soil sample. The relationship between `gwc` and `vwc` is `vwc = gwc  bulkdensity`. When bulk density is not specified, the value of `bulkdensity` is computed by using ITU-R P.527, Equation 36:

`bulkdensity` = 1.07256 + 0.078886 ln(*pSand*) + 0.038753 ln(*pClay*) + 0.032732 ln(*pSilt*),

where

- *pSand* = `sandpercent`
- *pClay* = `claypercent`
- *pSilt* = 100 – (`sandpercent` + `claypercent`)

Version History

Introduced in R2020a

Objects

`comm.Ray`

raypl

Path loss and phase change for RF propagation ray

Syntax

```
[pl,phase] = raypl(ray)
[pl,phase] = raypl(ray,Name,Value)
```

Description

`[pl,phase] = raypl(ray)` returns the path loss `pl` in dB and phase shift `phase` in radians for the RF propagation ray `ray`. The function calculates the path loss and phase shift using free space loss and reflection loss derived from the propagation path, reflection materials, and antenna polarizations.

By default, `raypl` assumes the antennas are unpolarized. You can polarize the antennas by specifying the `TransmitterPolarization` and `ReceiverPolarization` name-value arguments.

For more information about the path loss computations, see “Path Loss Computation” on page 2-845.

`[pl,phase] = raypl(ray,Name,Value)` specifies options using name-value arguments. For example, `"ReflectionMaterials","brick"` specifies the reflection material as brick.

Examples

Reevaluate Path Loss Changing Reflection Materials and Frequency

Change the reflection materials and frequency for a ray and reevaluate the path loss and phase shift.

Launch Site Viewer with buildings in Hong Kong. For more information about the osm file, see [1] on page 2-841. Specify transmitter and receiver sites.

```
viewer = siteviewer("Buildings","hongkong.osm");

tx = txsite("Latitude",22.2789,"Longitude",114.1625, ...
    "AntennaHeight",10,"TransmitterPower",5, ...
    "TransmitterFrequency",28e9);
rx = rxsite("Latitude",22.2799,"Longitude",114.1617, ...
    "AntennaHeight",1);
```

Perform ray tracing between the sites.

```
pm = propagationModel("raytracing", ...
    "Method","image", ...
    "MaxNumReflections",2);
rays = raytrace(tx,rx,pm);
```

Find the first ray with 2-order reflections from the result. Display the ray characteristics. Plot the ray to see the ray reflect off two buildings.

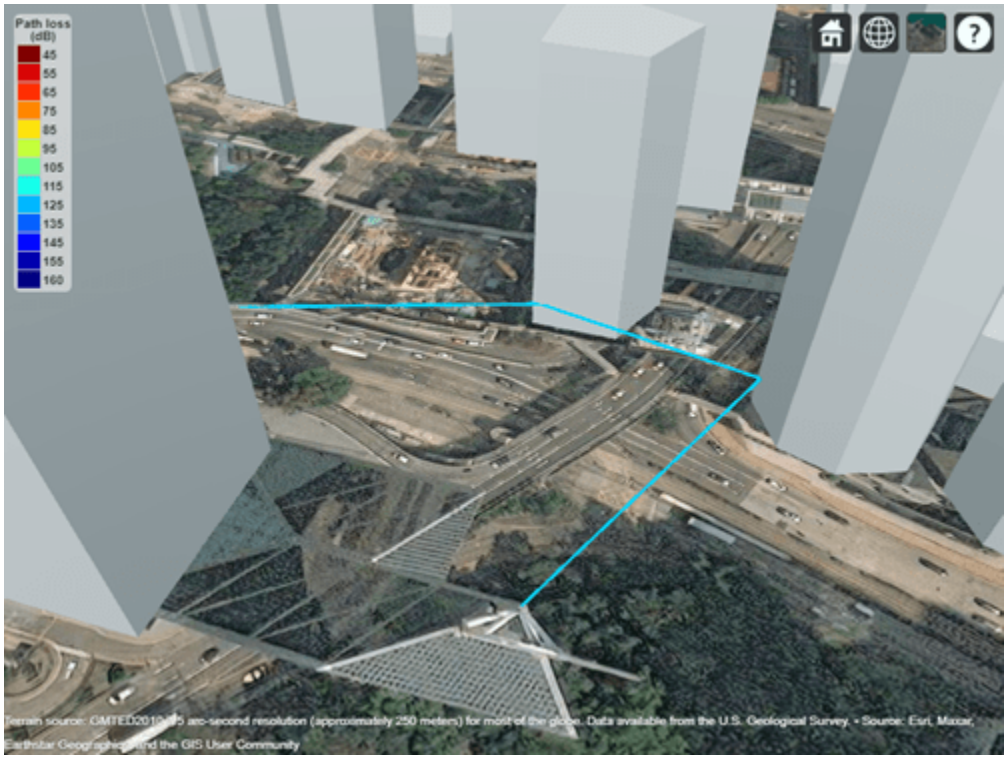
```
ray = rays{1}(find([rays{1}.NumInteractions] == 2,1))
```

```
ray =
  Ray with properties:

      PathSpecification: 'Locations'
       CoordinateSystem: 'Geographic'
    TransmitterLocation: [3×1 double]
       ReceiverLocation: [3×1 double]
            LineOfSight: 0
           Interactions: [1×2 struct]
              Frequency: 2.8000e+10
         PathLossSource: 'Custom'
               PathLoss: 121.8178
             PhaseShift: 4.5601

   Read-only properties:
       PropagationDelay: 8.3060e-07
    PropagationDistance: 249.0068
       AngleOfDeparture: [2×1 double]
         AngleOfArrival: [2×1 double]
          NumInteractions: 2
```

```
plot(ray)
```



By default, all buildings have concrete building material electrical characteristics. Change the material to metal for the second reflection and re-evaluate path loss. Use the `raypl` function to reevaluate the pathloss for the ray. Display the ray path to compare the change in path loss. Replot to show the slight change in color due to the path loss change of the ray.

```
[ray.PathLoss,ray.PhaseShift] = raypl(ray, ...
    "ReflectionMaterials",["concrete","metal"])
```

```
ray =
  Ray with properties:

      PathSpecification: 'Locations'
       CoordinateSystem: 'Geographic'

         AngleOfArrival: [2×1 double]
        NumInteractions: 2
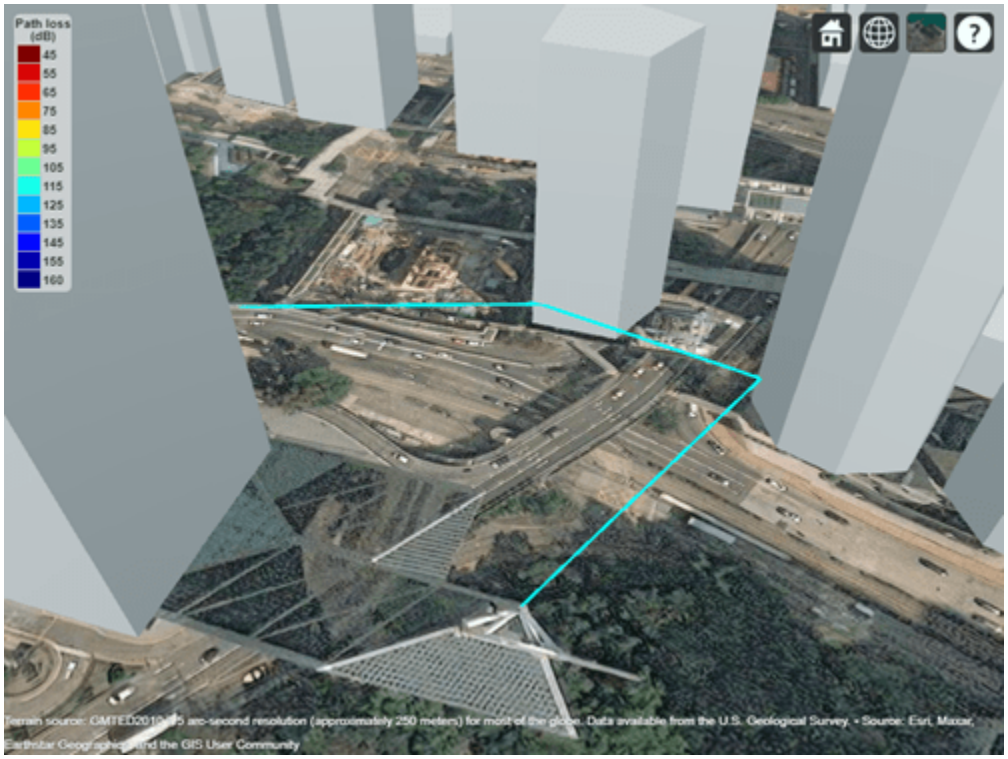
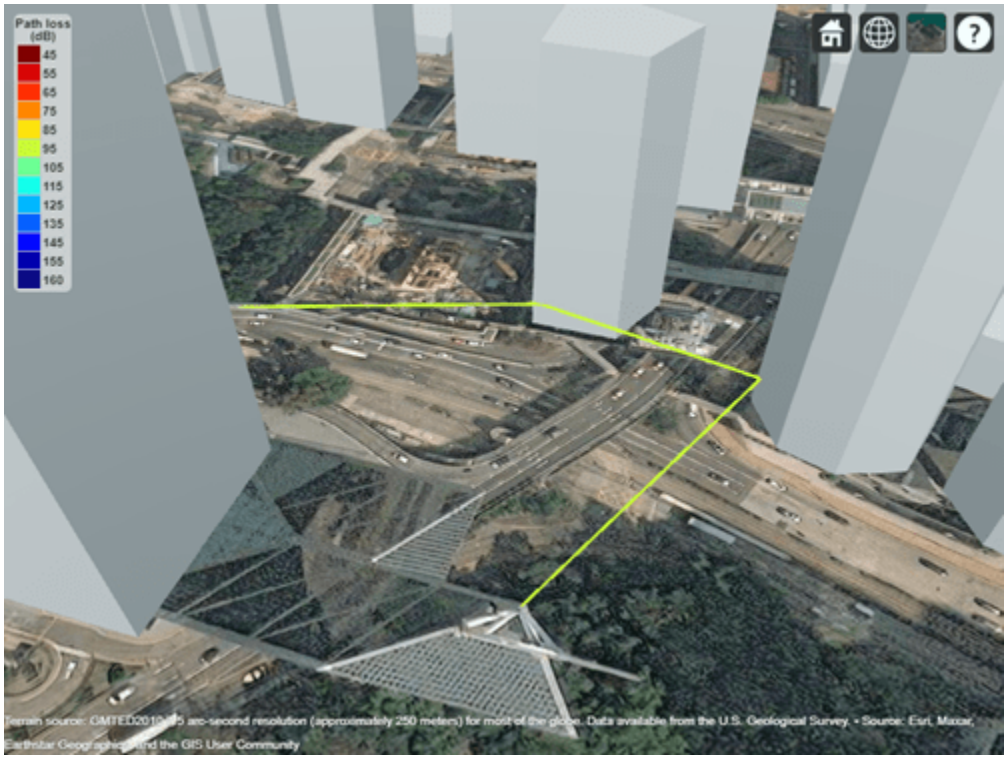
```

```
plot(ray)
```



Change the frequency and reevaluate the path loss and phase shift. Plot the ray again and observe the obvious color change.

```
ray.Frequency = 2e9;
[ray.PathLoss,ray.PhaseShift] = raypl(ray, ...
    "ReflectionMaterials",["concrete","metal"]);
plot(ray)
```



Appendix

[1] The osm file is downloaded from https://www.openstreetmap.org, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), https://opendatacommons.org/licenses/odbl/.

Input Arguments

`ray` — RF propagation ray

`comm.Ray` object

RF propagation ray, specified as one `comm.Ray` object. The `PathSpecification` property of the object must be `"Locations"`.

Data Types: `comm.Ray`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `raypl(ray,"TransmitterPolarization","H","ReceiverPolarization","H")`, specifies the horizontal polarizations for the transmit and receive antennas for `ray`.

`ReflectionMaterials` — Reflection materials
`"concrete"` (default) | string scalar | 1-by-*NR* string vector | character vector | 1-by-*NR* cell array of character vectors | 2-by-1 numeric vector | 2-by-*NR* numeric matrix

Reflection materials for a non-line-of-sight (NLOS) ray, specified as a string scalar, a 1-by-*NR* string vector, a character vector, a 1-by-*NR* cell array of character vectors, a 2-by-1 numeric vector, or a 2-by-*NR* numeric matrix. *NR* is the number of reflections stored in the `NumReflections` property of `ray`.

When you specify one reflection material, the reflection material applies to all the reflections. When you specify multiple reflection materials, each material applies to the associated reflection point in `ray`.

- To use predefined reflection materials, specify `ReflectionMaterials` as a string scalar, a character vector, a string vector, or a cell array of character vectors. Specify each reflection material as one of these options: `"concrete"`, `"brick"`, `"wood"`, `"glass"`, `"plasterboard"`, `"ceiling-board"`, `"chipboard"`, `"floorboard"`, `"metal"`, `"water"`, `"vegetation"`, `"loam"`, or `"perfect-reflector"`.
- To use custom reflection materials, specify a 2-by-1 numeric vector or a 2-by-*NR* numeric matrix. Each column is of the form `[rp; cv]`, where `rp` is the relative permittivity and `cv` is the conductivity.

For more information, see “ITU Permittivity and Conductivity Values for Common Materials” on page 2-844.

Example: `"ReflectionMaterials",["concrete","water"]`, specifies that a ray with two reflections uses the electrical characteristics of concrete at the first reflection point and water at the second reflection point.

Data Types: `string` | `char` | `double`

`TransmitterPolarization` — Transmit antenna polarization type
`"none"` (default) | `"V"` | `"H"` | `"LHCP"` | `"RHCP"` | normalized 2-by-1 Jones vector

Transmit antenna polarization type, specified as one of these values:

- `"none"` — Unpolarized
- `"V"` — Linearly polarized in the vertical (θ) direction
- `"H"` — Linearly polarized in the horizontal (φ) direction
- `"LHCP"` — Left-hand circular polarized
- `"RHCP"` — Right-hand circular polarized
- A normalized 2-by-1 Jones vector (also called a polarization matrix) of the form `[H;V]`, where `H` is the horizontal component and `V` is the vertical component.

For more information about polarization types and Jones vectors, see “Jones Vector Notation” on page 2-847.

Example: `"TransmitterPolarization","RHCP"` specifies right-hand circular polarization for the transmit antenna.

Data Types: `double` | `char` | `string`

`ReceiverPolarization` — Receive antenna polarization type
`"none"` (default) | `"V"` | `"H"` | `"LHCP"` | `"RHCP"` | normalized 2-by-1 Jones vector

Receive antenna polarization type, specified as one of these values:

- `"none"` — Unpolarized
- `"V"` — Linearly polarized in the vertical (θ) direction
- `"H"` — Linearly polarized in the horizontal (φ) direction
- `"LHCP"` — Left-hand circular polarized
- `"RHCP"` — Right-hand circular polarized
- A normalized 2-by-1 Jones vector (also called a polarization matrix) of the form `[H;V]`, where `H` is the horizontal component and `V` is the vertical component.

For more information about polarization types and Jones vectors, see “Jones Vector Notation” on page 2-847.

Example: `"ReceiverPolarization",[1;0]` specifies horizontal polarization for the receive antenna by using Jones vector notation.

Data Types: `double` | `char` | `string`

`TransmitterAxes` — Orientation of transmit antenna axes

3-by-3 identity matrix (default) | 3-by-3 unitary matrix

Orientation of the transmit antenna axes, specified as a 3-by-3 unitary matrix indicating the rotation from the transmitter local coordinate system (LCS) into the global coordinate system (GCS). When the `CoordinateSystem` property of the `comm.Ray` is set to `"Geographic"`, the GCS orientation is the local East-North-Up (ENU) coordinate system at transmitter. For more information, see “Coordinate System Orientation” on page 2-844.

Example: `"TransmitterAxes",eye(3)`, specifies that the local coordinate system for the transmitter axes is aligned with the global coordinate system. This is the default orientation.

Data Types: `double`

`ReceiverAxes` — Orientation of receive antenna axes

3-by-3 identity matrix (default) | 3-by-3 unitary matrix

Orientation of the receive antenna axes, specified as a 3-by-3 unitary matrix indicating the rotation from the receiver local coordinate system (LCS) into the global coordinate system (GCS). The GCS orientation is the local East-North-Up (ENU) coordinate system at receiver when the .`CoordinateSystem` property of the `comm.Ray` is set to `"Geographic"`. For more information, see “Coordinate System Orientation” on page 2-844.

Example: `"ReceiverAxes",[0 -1 0; 1 0 0; 0 0 1]`, specifies a 90° rotation around the z-axis of the local receiver coordinate system with respect to the global coordinate system.

Data Types: `double`

Output Arguments

`pl` — Path loss

nonnegative scalar

Path loss in dB, returned as a nonnegative scalar.

Data Types: `double`

phase — Phase shift
scalar

Phase shift in radians, returned as a scalar in the range [–π, π] radians. The argument uses the $e^{-i\omega t}$ time convention.

Data Types: `double`

More About

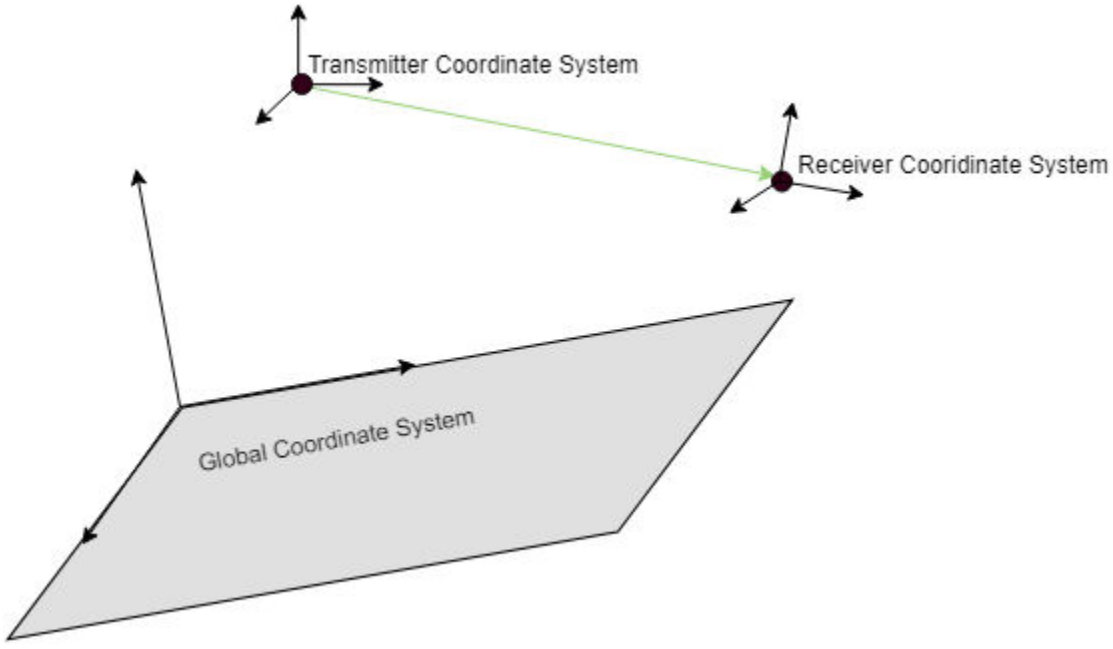
ITU Permittivity and Conductivity Values for Common Materials

ITU-R P.2040-1 [2] and ITU-R P.527-5 [3] present methods, equations, and values used to calculate real relative permittivity, conductivity, and complex relative permittivity for the common materials.

- For information about the values computed for building materials specified in ITU-R P.2040-1, see `buildingMaterialPermittivity`.
- For information about the values computed for terrain materials specified in ITU-R P.527-5, see `earthSurfacePermittivity`.

Coordinate System Orientation

This image shows the orientation of the electromagnetic fields in the global coordinate system (GCS) and the local coordinate systems of the transmitter and receiver.

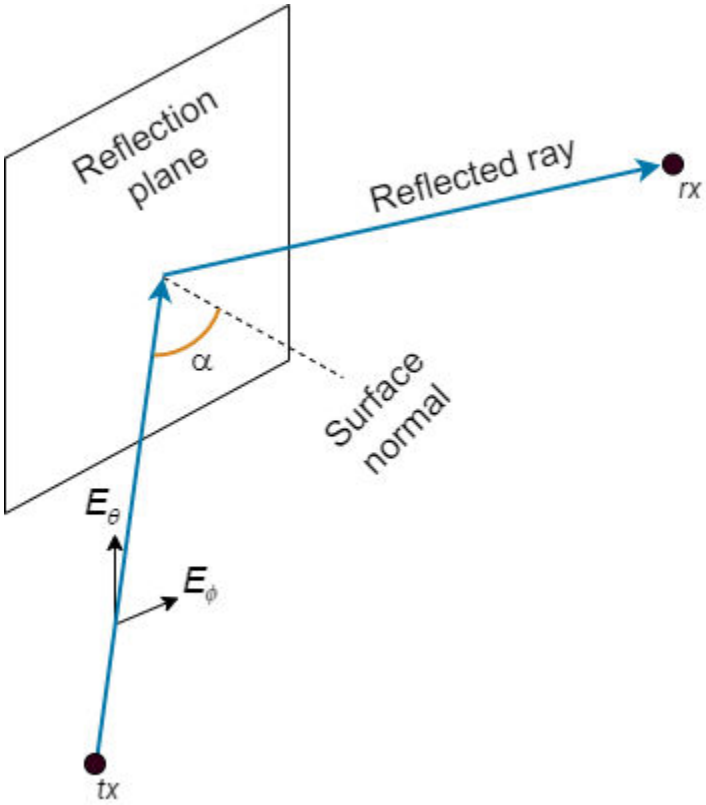


When the `CoordinateSystem` property of the `comm.Ray` is set to `"Geographic"`, the GCS orientation is the local East-North-Up (ENU) coordinate system at observer. The path loss computation accounts for the round-earth differences between ENU coordinates at the transmitter and receiver.

Path Loss Computation

The ray tracing model used by the `raypl` function calculates reflection losses by tracking the horizontal and vertical polarizations of signals through the propagation path. Total power loss is the sum of free space loss and reflection loss.

This image shows a reflection path from a transmitter site *tx* to a receiver site *rx*.



The model determines polarization and reflection loss using these steps.

1 Track the propagation of the ray in 3-D space by calculating the propagation matrix P. The matrix is a repeating product, where i is the number of reflection points.

$$P = \prod_i P_i$$

For each reflection, calculate P_i by transforming the global coordinates of the incident electromagnetic field into the local coordinates of the reflection plane, multiplying the result by a reflection coefficient matrix, and transforming the coordinates back into the original global coordinate system [1]. The equations for P_i and P_0 are:

$$P_i = \left[s_{out}\ p_{out}\ k_{out}\right]_i \begin{bmatrix} R_V(\alpha) & 0 & 0 \\ 0 & R_H(\alpha) & 0 \\ 0 & 0 & 1 \end{bmatrix}_i \left[s_{in}\ p_{in}\ k_{in}\right]_i^{-1}$$

$$P_0 = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

where:

- s, p, and k form a basis for the plane of incidence (the plane created by the incident ray and the surface normal of the reflection plane). s and p are perpendicular and parallel, respectively, to the plane of incidence.
- k_{in} and k_{out} are the directions (in global coordinates) of the incident and exiting rays, respectively.
- s_{in} and s_{out} are the directions (in global coordinates) of the horizontal polarizations for the incident and exiting rays, respectively.
- p_{in} and p_{out} are the directions (in global coordinates) of the vertical polarizations for the incident and exiting rays, respectively.
- R_H and R_V are the Fresnel reflection coefficients for the horizontal and vertical polarizations, respectively. α is the incident angle of the ray and ε_r is the complex relative permittivity of the material.

$$R_H(\alpha) = \frac{\cos(\alpha) - \sqrt{(\varepsilon_r - \sin^2(\alpha))/\varepsilon_r{}^2}}{\cos(\alpha) + \sqrt{(\varepsilon_r - \sin^2(\alpha))/\varepsilon_r{}^2}}$$

$$R_V(\alpha) = \frac{\cos(\alpha) - \sqrt{\varepsilon_r - \sin^2(\alpha)}}{\cos(\alpha) + \sqrt{\varepsilon_r - \sin^2(\alpha)}}$$

2 Project the propagation matrix P into a 2-by-2 polarization matrix R. The model rotates the coordinate systems for the transmitter and receiver so that they are in global coordinates.

$$R = \begin{bmatrix} H_{in} \cdot H_{rx} & V_{in} \cdot H_{rx} \\ H_{in} \cdot V_{rx} & V_{in} \cdot V_{rx} \end{bmatrix}$$

$$H_{in} = P(V_{tx} \times k_{tx})$$

$$V_{in} = PV_{tx}$$

where:

- H_{rx} and V_{rx} are the directions (in global coordinates) of the horizontal (E_θ) and vertical (E_ϕ) polarizations, respectively, for the receiver.
- H_{in} and V_{in} are the directions (in global coordinates) of the propagated horizontal and vertical polarizations, respectively.
- V_{tx} is the direction (in global coordinates) of the nominal vertical polarization for the ray departing the transmitter.
- k_{tx} is the direction (in global coordinates) of the ray departing the transmitter.

3 Specify the normalized horizontal and vertical polarizations of the electric field at the transmitter and receiver by using the 2-by-1 Jones polarization vectors J_{tx} and J_{rx}, respectively. If either the transmitter or receiver are unpolarized, then the model assumes $J_{tx} = J_{rx} = \frac{\sqrt{2}}{2}\begin{bmatrix} 1 \\ 1 \end{bmatrix}$.

4 Calculate the polarization and reflection loss IL by combining R, J_{tx}, and J_{rx}.

$$IL = -20\log_{10}\left|J_{rx}^{-1}RJ_{tx}\right|$$

Jones Vector Notation

For Jones vector notation, the raypl function describes signal polarization using Jones calculus.

The orthogonal components of Jones vectors are defined for E_θ and E_φ. This table shows the Jones vector corresponding to various antenna polarizations.

Antenna Polarization Type	Corresponding Jones Vector
Linear polarized in the θ direction	$\begin{pmatrix} H \\ V \end{pmatrix} = \begin{pmatrix} 0 \\ 1 \end{pmatrix}$
Linear polarized in the φ direction	$\begin{pmatrix} H \\ V \end{pmatrix} = \begin{pmatrix} 1 \\ 0 \end{pmatrix}$
Left-hand circular polarized (LHCP)	$\begin{pmatrix} H \\ V \end{pmatrix} = \frac{1}{\sqrt{2}}\begin{pmatrix} j \\ 1 \end{pmatrix}$
Right-hand circular polarized (RHCP)	$\begin{pmatrix} H \\ V \end{pmatrix} = \frac{1}{\sqrt{2}}\begin{pmatrix} -j \\ 1 \end{pmatrix}$

Version History

Introduced in R2020a

Ray tracing models using SBR method find paths with exact geometric accuracy

Behavior changed in R2022b

When you find propagation paths using the `raytrace` function and a ray tracing model that uses the shooting and bouncing rays (SBR) method, MATLAB corrects the results so that the geometric accuracy of each path is exact, using single-precision floating-point computations. In previous releases, the paths have approximate geometric accuracy.

As a result, when you use rays returned by the `raytrace` function as input to the `raypl` function, the `raypl` function can return different results than in previous releases.

blkdiagbfweights

MIMO channel block diagonalized weights

Syntax

```
[wp,wc] = blkdiagbfweights(chanmat,ns)
[wp,wc] = blkdiagbfweights(chanmat,ns,pt)
```

Description

`[wp,wc] = blkdiagbfweights(chanmat,ns)` returns precoding weights, `wp`, and combining weights, `wc`, derived from the channel response matrices contained in a MATLAB cell array `chanmat`.

- You can specify multiple user channels by putting each channel in a `chanmat` cell. `chanmat{k}` represents the k^{th}channel from the transmitter to the user.
- • For a single frequency, specify the channel cell as a matrix.
  - For multiple frequencies, specify the channel cell as a three-dimensional array where the rows represent different subcarriers.
- Specify multiple subchannels per channel using the `ns` argument. Subchannels represent different data streams. `ns` specifies the number of subchannels for each user channel. Multiply the data streams by the precoding weights, `wp`.

The precoding and combining weights diagonalize the channel into independent subchannels so that for the k^{th}user, the matrix `wp*chanmat{k}*wc{k}` is diagonal for each subcarrier.

`[wp,wc] = blkdiagbfweights(chanmat,ns,pt)` also specifies the total transmitted power, `pt`, per subcarrier.

Examples

Spatial Multiplexing with Block Diagonal Weights

Start with a base station consisting of a uniform linear array (ULA) with 16 antennas, and two users having receiver ULA arrays with 8 and 4 antennas, respectively. Show that using block diagonalization-based precoding and combining weights achieves spatial multiplexing, where the received signal at each user can be decoded without interference from the other user. Specify two data streams for each user.

Specify the transmitter location in `txpos` and two user receiver locations in `rxpos1` and `rxpos2`. Array elements are spaced one-half wavelength apart.

```
txpos = (0:15)*0.5;
rxpos1 = (0:7)*0.5;
rxpos2 = (0:3)*0.5;
```

Create the channel matrix cell array using `scatteringchanmtx` and then compute the beamforming weights `wp` and `wc`. Each channel corresponds to a user. Assume that the channels have 10 scatterers. Each channel has two subchannels specified by the vector `ns`.

```
chanmat = {scatteringchanmtx(txpos,rxpos1,10), ...
    scatteringchanmtx(txpos,rxpos2,10)};
ns = [2 2];
[wp,wc] = blkdiagbfweights(chanmat,ns);
```

The weights diagonalize the channel matrices for each user.

For channel 1:

```
disp(wp*chanmat{1}*wc{1})
```

```
   8.2269 - 0.0000i   0.0000 - 0.0000i
   0.0000 + 0.0000i   6.1371 - 0.0000i
   0.0000 - 0.0000i  -0.0000 + 0.0000i
   0.0000 - 0.0000i   0.0000 + 0.0000i
```

For channel 2:

```
disp(wp*chanmat{2}*wc{2})
```

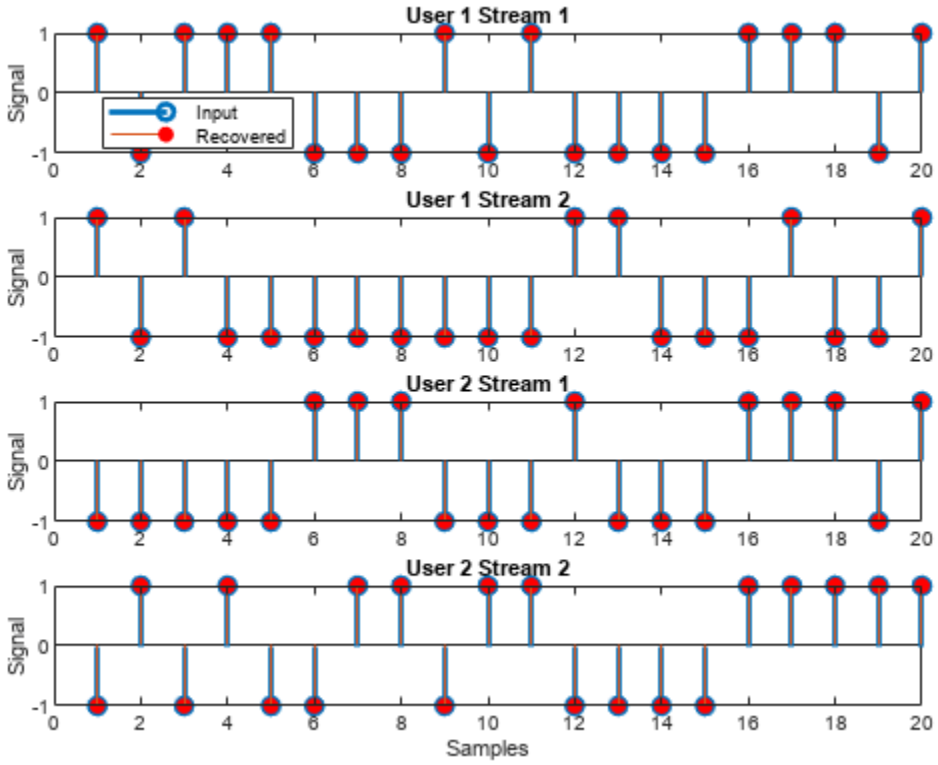
```
  -0.0000 + 0.0000i  -0.0000 + 0.0000i
  -0.0000 + 0.0000i  -0.0000 + 0.0000i
   8.7543 - 0.0000i   0.0000 - 0.0000i
   0.0000 + 0.0000i   4.4372 + 0.0000i
```

First create four subchannels to carry the data streams: two subchannels per channel. Each data stream contains 20 samples of ±1. Precode the input streams and combine the streams to produce the recovered signals.

```
x = 2*round(rand([20,4])) - 1;
xp = x*wp;
y1 = xp*chanmat{1} + 0.1*randn(20,8);
y2 = xp*chanmat{2} + 0.1*randn(20,4);
y = [y1*wc{1},y2*wc{2}];
```

Overlay stem plots of the input and recovered signals to show that the received user signals are the same as the transmitted signals.

```
for m = 1:4
    subplot(4,1,m)
    s = stem([x(:,m) 2*((real(y(:,m)) > 0) - 0.5)]);
    s(1).LineWidth = 2;
    s(2).MarkerEdgeColor = 'none';
    s(2).MarkerFaceColor = 'r';
    ylabel('Signal')
    title(sprintf('User %d Stream %d',ceil(m/2),rem(m-1,2) + 1))
    if m==1
        legend('Input','Recovered','Location','best')
    end
end
xlabel('Samples')
```



Spatial Multiplexing with Specified Power

Start with a base station consisting of a uniform linear array (ULA) with 16 antennas, and two users having receiver ULA arrays with 8 and 5 antennas, respectively. Show how to use three-dimensional arrays of channel matrices to handle two subcarriers. Then, the channel matrix for the first user takes the form 2-by-16-by-8 and the channel matrix for the second user takes the form 2-by-16-by-5. Also assume that there are two data streams for each user.

Specify the transmitter location in `txpos` and two user receiver locations in `rxpos1` and `rxpos2`. Array elements are spaced one-half wavelength apart.

```
nr1 = 8;
nr2 = 5;
txpos = (0:15)*0.5;
rxpos1 = (0:(nr1-1))*0.5;
rxpos2 = (0:(nr2-1))*0.5;
```

Create the channel matrices using `scatteringchanmtx` and put them in a cell array. To create a second subchannel for each receiver, duplicate each channel matrix. Assume 10 point scatterers in computing the channel matrix.

```
smtmp1 = scatteringchanmtx(txpos,rxpos1,10);
smtmp2 = scatteringchanmtx(txpos,rxpos2,10);
sm1 = zeros(2,16,8);
```

```
sm2 = zeros(2,16,5);
sm1(1,:,:) = smtmp1;
sm1(2,:,:) = smtmp1;
sm2(1,:,:) = smtmp2;
sm2(2,:,:) = smtmp2;
chanmat = {sm1,sm2};
```

Specify that there are two data streams for each user.

```
ns = [2 2];
```

Specify the transmitted powers for each subcarrier.

```
pt = [1.0 1.5];
```

Compute the beamforming weights.

```
[wp,wc] = blkdiagbfweights(chanmat,ns,pt);
```

Show that the channels are diagonalized for the first subcarrier.

```
ksubcr = 1;
wpx = squeeze(wp(ksubcr,:,:));
chanmat1 = squeeze(chanmat{1}(ksubcr,:,:));
chanmat2 = squeeze(chanmat{2}(ksubcr,:,:));
wc1 = squeeze(wc{1}(ksubcr,:,:));
wc2 = squeeze(wc{2}(ksubcr,:,:));
wpx*chanmat1*wc1
```

```
ans = 4×2 complex

   8.2104 + 0.0000i  -0.0000 - 0.0000i
   0.0000 - 0.0000i   5.9732 - 0.0000i

```

Propagate the signals to each user and then decode. Generate four streams of random data containing -1's and +1's and having two columns for each user. Each stream is a subchannel.

```
x = 2*(round(rand([20 4]))) - 1;
```

Precode the data streams.

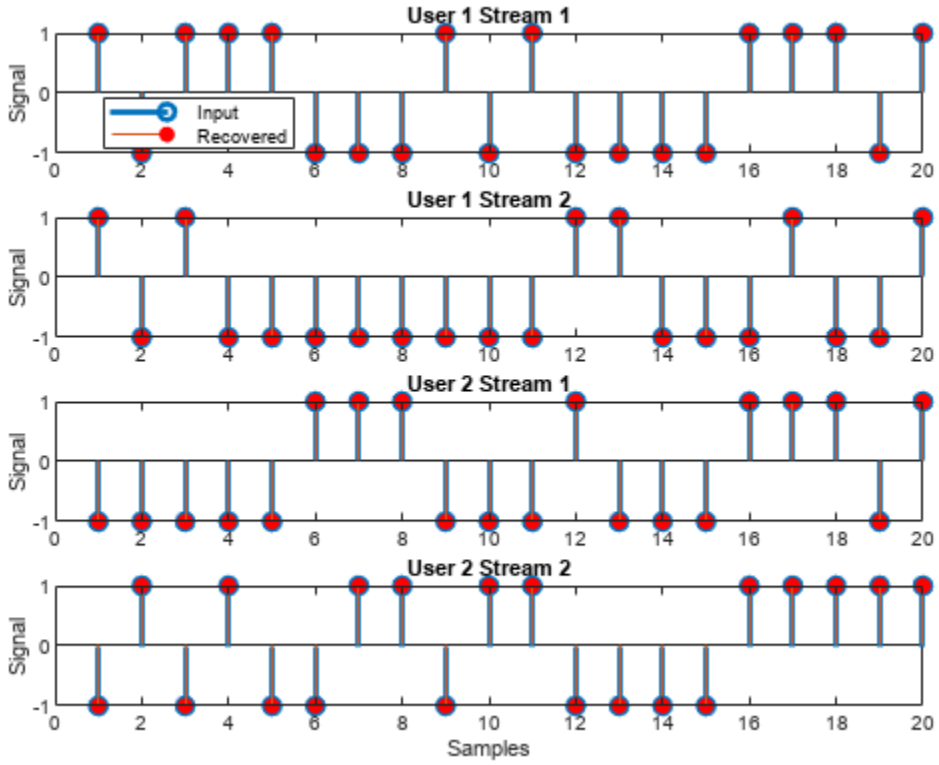
```
xp = x*wpx;
y1 = xp*chanmat1 + 0.1*randn(20,8);
y2 = xp*chanmat2 + 0.1*randn(20,5);
```

Decode the data streams.

```
y = [y1*wc1,y2*wc2];
```

Overlay stem plots of the input and recovered signals to show that the received user signals are the same as the transmitted signals.

```
for m = 1:4
    subplot(4,1,m)
    s = stem([x(:,m) 2*((real(y(:,m)) > 0) - 0.5)]);
    s(1).LineWidth = 2;
    s(2).MarkerEdgeColor = 'none';
    s(2).MarkerFaceColor = 'r';
    ylabel('Signal')
    title(sprintf('User %d Stream %d',ceil(m/2),rem(m-1,2) + 1))
    if m==1
        legend('Input','Recovered','Location','best')
    end
end
xlabel('Samples')
```



Input Arguments

`chanmat` — Channel response matrices

N_u-element cell array

Channel response matrices, specified as an N_u-element cell array. N_u is the number of receive arrays. Each cell corresponds to a different channel and contains a channel response matrix or a three

dimensional MATLAB array. The cell array must contain either all matrices or all arrays. For matrices, the number of rows for all matrices must be the same. For three-dimensional arrays, the number of rows and columns must be the same.

- If the k^{th} cell is a matrix, the matrix has the size N_t-by-$N_r(k)$. N_t is the number of elements in the transmitting array and $N_r(k)$ is the number of elements in the k^{th} receiving array.
- If the k^{th} cell is an array, the array has the size L-by-N_t-by-$N_r(k)$. L is the number of subcarriers. N_t is the number of elements in the transmit array and $N_r(k)$ is the number of elements in the k^{th} receive array.

Data Types: `double`
Complex Number Support: Yes

`ns` — Number of data streams per receive array

N_u-element row vector of positive integers

Number of data streams per receive array, specified as an N_u-element row vector of positive integers. N_u is the number of receive arrays.

Data Types: `double`

`pt` — Total transmitted power per subcarrier

1 (default) | positive scalar | L-element vector of positive values

Total transmitted power per subcarrier, specified as a positive scalar or an L-element vector of positive values. L is the number of subcarriers. If `pt` is a scalar, all subcarriers have the same transmitted power. If `pt` is a vector, each vector element specifies the transmitted power for the corresponding subcarrier. Power is in linear units.

Data Types: `double`

Output Arguments

`wp` — Precoding weights

complex-valued N_{st}-by-N_t matrix | complex-valued L-by-N_{st}-by-N_t MATLAB array

Precoding weights, returned as a complex-valued N_{st}-by-N_t matrix or a complex-valued L-by-N_{st}-by-N_t MATLAB array.

- If `chanmat` contains matrices, `wp` is a complex-valued N_{st}-by-N_t matrix where N_{st} is the total number of data channels (`sum(ns)`).
- If `chanmat` contains three-dimensional MATLAB arrays, `wp` is a complex-valued L-by-N_{st}-by-N_t MATLAB array where N_{st} is the total number of data channels (`sum(ns)`).

Units are dimensionless.

Data Types: `double`

`wc` — Combining weights

N_u-element cell array

Combining weights, returned as an N_u-element cell array. Units are dimensionless.

- If `chanmat` contains matrices, the k^{th} cell in `wc` contains a complex valued $N_r(k)$-by-$N_s(k)$ matrix. $N_s(k)$ is the value of the argument `ns` for the k^{th} receive array.

- If `chanmat` contains three-dimensional MATLAB arrays, the k^{th} cell of `wc` contains a complex-valued L-by-$N_r(k)$-by-$N_s(k)$ MATLAB array. $N_s(k)$ is the value of the k^{th} entry of the `ns` vector.

Data Types: `double`

`comm.MIMOChannel`

cart2sphvec

Convert vector from Cartesian components to spherical representation

Syntax

```
vs = cart2sphvec(vr,az,el)
```

Description

`vs = cart2sphvec(vr,az,el)` converts the components of a vector or set of vectors, `vr`, from their representation in a local Cartesian coordinate system to a spherical basis representation contained in `vs`. A spherical basis representation is the set of components of a vector projected into a basis given by ($\widehat{\mathbf{e}}_{az}$, $\widehat{\mathbf{e}}_{el}$, $\widehat{\mathbf{e}}_{R}$). The orientation of a spherical basis depends upon its location on the sphere as determined by azimuth, `az`, and elevation, `el`.

Examples

Spherical Representation of Unit Z-Vector

Start with a vector in Cartesian coordinates pointing along the *z*-direction and located at 45° azimuth, 45° elevation. Compute its components with respect to the spherical basis at that point.

```
vr = [0;0;1];
vs = cart2sphvec(vr,45,45)
```

```
vs = 3×1

         0
    0.7071
    0.7071
```

Input Arguments

vr — Vector in Cartesian basis representation

3-by-1 column vector | 3-by-N matrix

Vector in Cartesian basis representation specified as a 3-by-1 column vector or 3-by-N matrix. Each column of `vr` contains the three components of a vector in the right-handed Cartesian basis *x*,*y*,*x*.

Example: `[4.0; -3.5; 6.3]`

Data Types: `double`
Complex Number Support: Yes

az — Azimuth angle

scalar in range [–180,180]

Azimuth angle specified as a scalar in the closed range [–180,180]. Angle units are in degrees. To define the azimuth angle of a point on a sphere, construct a vector from the origin to the point. The

azimuth angle is the angle in the *xy*-plane from the positive *x*-axis to the vector's orthogonal projection into the *xy*-plane. As examples, zero azimuth angle and zero elevation angle specify a point on the *x*-axis while an azimuth angle of 90° and an elevation angle of zero specify a point on the *y*-axis.

Example: `45`

Data Types: `double`

`el` — Elevation angle
scalar in range [–90,90]

Elevation angle specified as a scalar in the closed range [–90,90]. Angle units are in degrees. To define the elevation of a point on the sphere, construct a vector from the origin to the point. The elevation angle is the angle from its orthogonal projection into the *xy*-plane to the vector itself. As examples, zero elevation angle defines the equator of the sphere and ±90° elevation define the north and south poles, respectively.

Example: `30`

Data Types: `double`

Output Arguments

`vs` — Vector in spherical basis
3-by-1 column vector | 3-by-N matrix

Spherical representation of a vector returned as a 3-by-1 column vector or 3-by-N matrix having the same dimensions as `vs`. Each column of `vs` contains the three components of the vector in the right-handed ($\widehat{\mathbf{e}}_{az}$, $\widehat{\mathbf{e}}_{el}$, $\widehat{\mathbf{e}}_{R}$) basis.

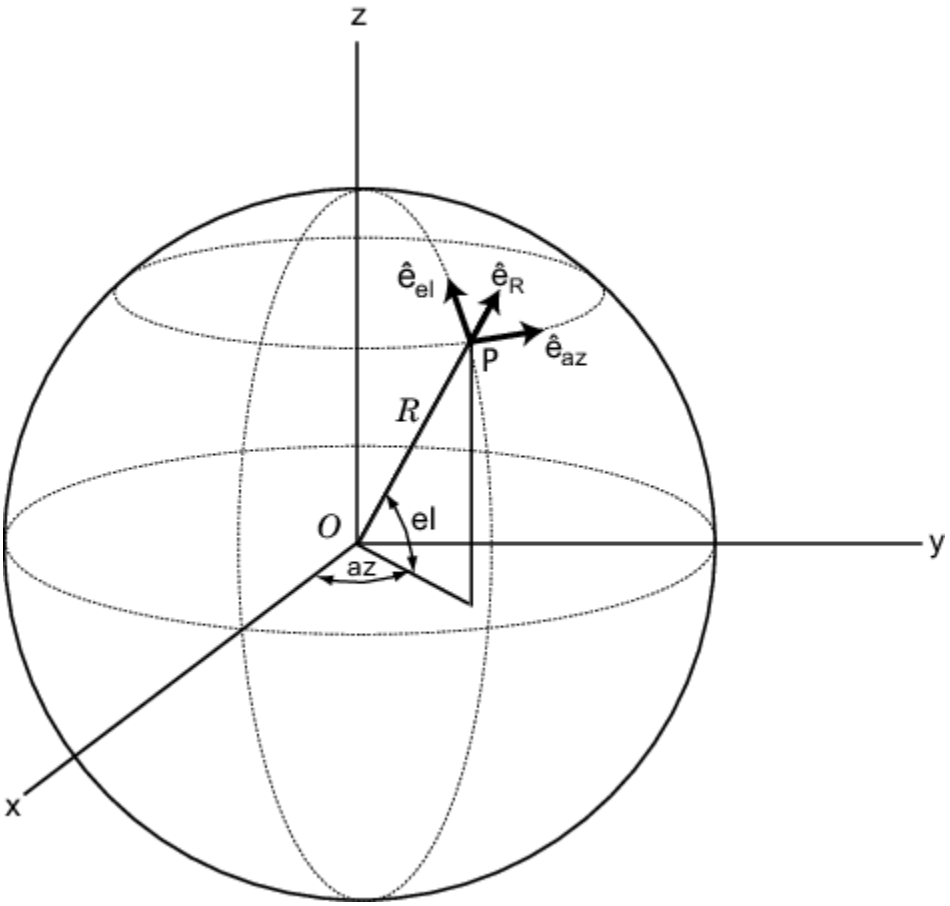
More About

Spherical basis representation of vectors

Spherical basis vectors are a local set of basis vectors which point along the radial and angular directions at any point in space.

The spherical basis is a set of three mutually orthogonal unit vectors ($\widehat{\mathbf{e}}_{az}$, $\widehat{\mathbf{e}}_{el}$, $\widehat{\mathbf{e}}_{R}$) defined at a point on the sphere. The first unit vector points along lines of azimuth at constant radius and elevation. The second points along the lines of elevation at constant azimuth and radius. Both are tangent to the surface of the sphere. The third unit vector points radially outward.

The orientation of the basis changes from point to point on the sphere but is independent of R so as you move out along the radius, the basis orientation stays the same. The following figure illustrates the orientation of the spherical basis vectors as a function of azimuth and elevation:



For any point on the sphere specified by *az* and *el*, the basis vectors are given by:

$$\widehat{\mathbf{e}}_{\mathbf{az}} = -\sin(az)\widehat{\mathbf{i}} + \cos(az)\widehat{\mathbf{j}}$$

$$\widehat{\mathbf{e}}_{\mathbf{el}} = -\sin(el)\cos(az)\widehat{\mathbf{i}} - \sin(el)\sin(az)\widehat{\mathbf{j}} + \cos(el)\widehat{\mathbf{k}}$$

$$\widehat{\mathbf{e}}_{\mathbf{R}} = \cos(el)\cos(az)\widehat{\mathbf{i}} + \cos(el)\sin(az)\widehat{\mathbf{j}} + \sin(el)\widehat{\mathbf{k}} \quad .$$

Any vector can be written in terms of components in this basis as $\mathbf{v} = v_{az}\widehat{\mathbf{e}}_{\mathbf{az}} + v_{el}\widehat{\mathbf{e}}_{\mathbf{el}} + v_R\widehat{\mathbf{e}}_{\mathbf{R}}$. The transformations between spherical basis components and Cartesian components take the form

$$\begin{bmatrix} v_x \\ v_y \\ v_z \end{bmatrix} = \begin{bmatrix} -\sin(az) & -\sin(el)\cos(az) & \cos(el)\cos(az) \\ \cos(az) & -\sin(el)\sin(az) & \cos(el)\sin(az) \\ 0 & \cos(el) & \sin(el) \end{bmatrix} \begin{bmatrix} v_{az} \\ v_{el} \\ v_R \end{bmatrix}$$

.

and

$$\begin{bmatrix} v_{az} \\ v_{el} \\ v_R \end{bmatrix} = \begin{bmatrix} -\sin(az) & \cos(az) & 0 \\ -\sin(el)\cos(az) & -\sin(el)\sin(az) & \cos(el) \\ \cos(el)\cos(az) & \cos(el)\sin(az) & \sin(el) \end{bmatrix} \begin{bmatrix} v_x \\ v_y \\ v_z \end{bmatrix}.$$

cranerainpl

RF signal attenuation due to rainfall using Crane model

Syntax

```
L = cranerainpl(range,freq,rainrate)
L = cranerainpl(range,freq,rainrate,elev)
L = cranerainpl(range,freq,rainrate,elev,tau)
```

Description

`L = cranerainpl(range,freq,rainrate)` returns the signal attenuation, `L`, due to rain based on the Crane rain model [1]. Signal attenuation is a function of the signal path length, `range`, the signal frequency, `freq`, and the rain rate, `rainrate`. The rain rate is defined as the long-term statistical rain rate. The attenuation model applies only for frequencies from 1 GHz to 1000 GHz and is valid for ranges up to 22.5 km. The Crane model accounts for the cellular nature of rainstorms.

`L = cranerainpl(range,freq,rainrate,elev)` also specifies the elevation angle, `elev`, of the signal path.

`L = cranerainpl(range,freq,rainrate,elev,tau)` also specifies the polarization tilt angle, `tau`, of the signal.

Examples

Compare Attenuation for Two Rain Rates Using Crane Model

Use the Crane rain model to compute the signal attenuation caused by rain for a 20 GHz signal sent over a distance of 10 km. Use rain rates of 10.0 and 100.0 mm/hr.

First, set the rain rate to 10 mm/hr.

```
rr = 10.0;
L = cranerainpl(10e3,20.0e9,rr)
```

```
L = 12.5988
```

Repeat the computation using a rain rate of 100.0 mm/hr.

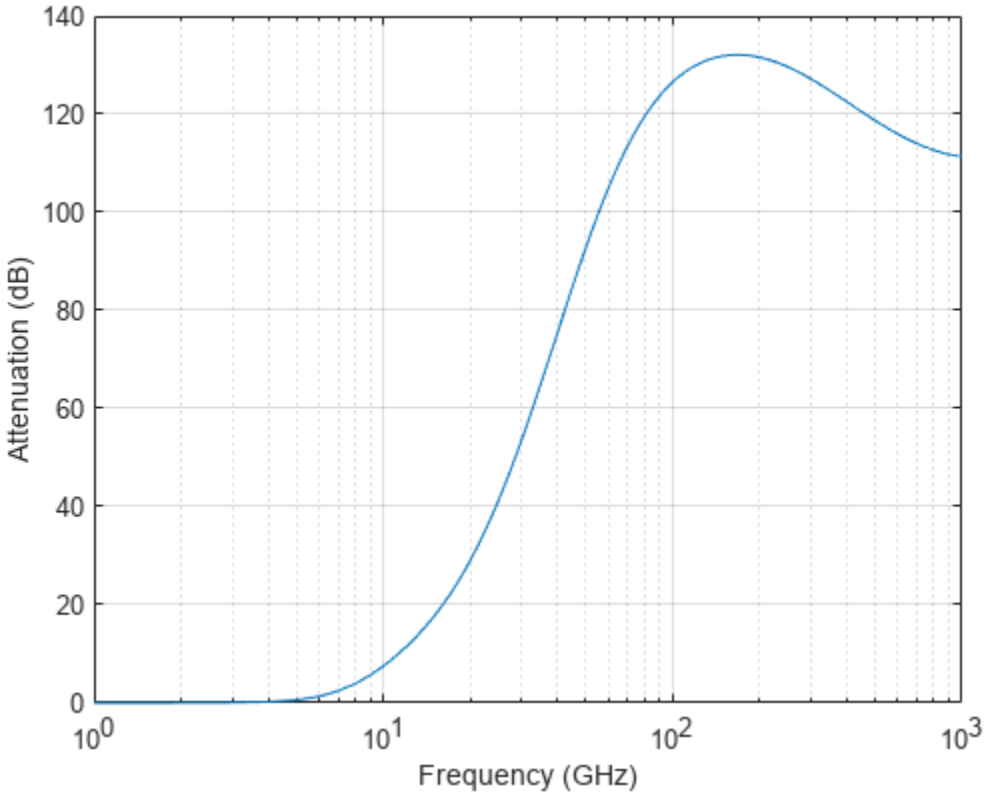
```
rr = 100.0;
L = cranerainpl(10e3,20.0e9,rr)
```

```
L = 73.1912
```

Rain Attenuation as a Function of Frequency Using Crane Model

Plot the signal attenuation due to rain for signals in the frequency range from 1 to 1000 GHz. Use the Crane model to compute the attenuation for a rain rate of 30.0 mm/hr and a signal path distance of 10 km.

```
rr = 30.0;
freq = [1:1000]*1e9;
L = cranerainpl(10e3,freq,rr);
semilogx(freq/1e9,L)
grid
xlabel('Frequency (GHz)')
ylabel('Attenuation (dB)')
```



Rain Attenuation as a Function of Elevation Using Crane Model

Plot the signal attenuation due to rain as a function of elevation angle. Elevation angles vary from 0 to 90 degrees. Assume a path distance of 10 km and a signal frequency of 10 GHz. The rain rate is 100 mm/hr.

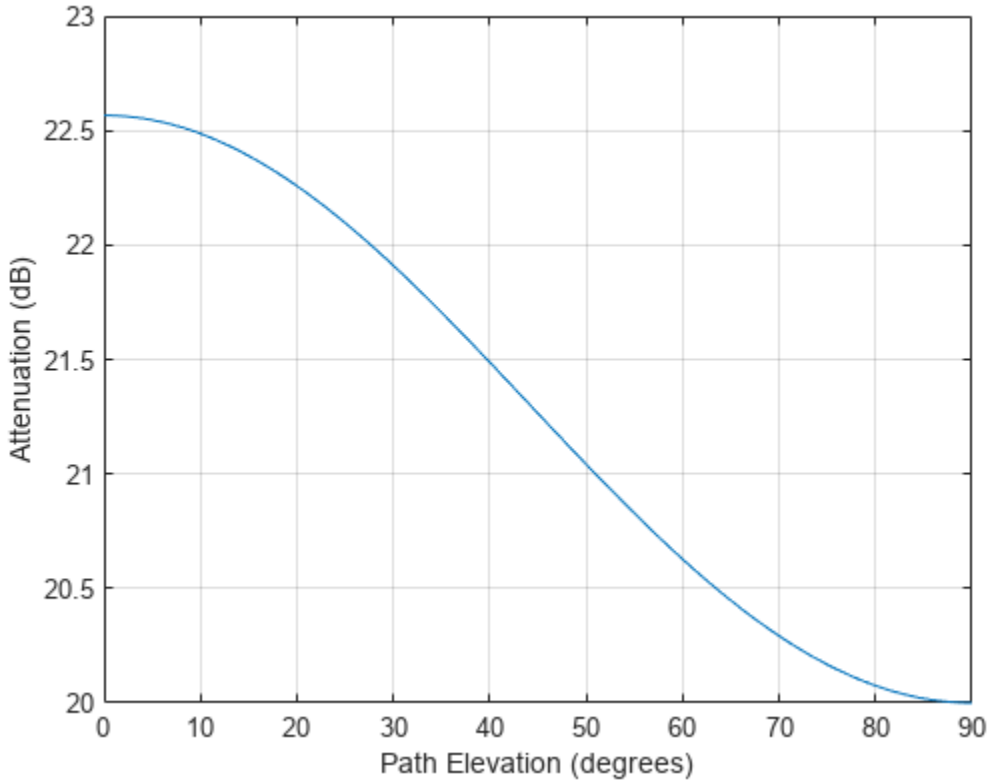
```
rr = 100.0;
```

Set the elevation angles, frequency, and path length.

```
elev = [0:1:90];
freq = 10.0e9;
rng = 10e3*ones(size(elev));
```

Compute and plot the loss.

```
L = cranerainpl(rng,freq,rr,elev);
plot(elev,L)
grid
xlabel('Path Elevation (degrees)')
ylabel('Attenuation (dB)')
```



Rain Attenuation as a Function of Polarization Using Crane Model

Plot the signal attenuation due to rainfall as a function of the polarization tilt angle. Assume a path distance of 10 km, a signal frequency of 10 GHz, and a path elevation angle of 0 degrees. Set the rainfall rate to 70 mm/hour. Plot the signal attenuation against polarization tilt angle.

Set the polarization tilt angle to vary from -90 to 90 degrees.

```
tau = -90:90;
```

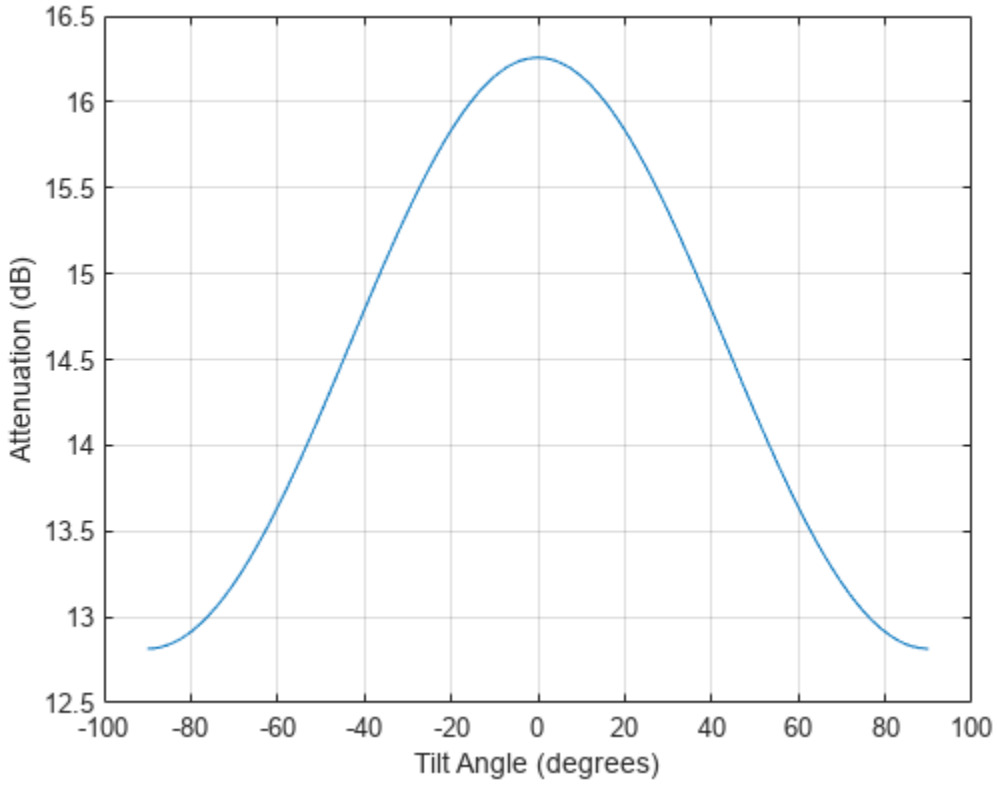
Set the elevation angle, frequency, path distance, and rain rate.

```
elev = 0;
freq = 10.0e9;
```

```
rng = 10e3*ones(size(tau));
rr = 70.0;
```

Compute and plot the attenuation.

```
L = cranerainpl(rng,freq,rr,elev,tau);
plot(tau,L)
grid
xlabel('Tilt Angle (degrees)')
ylabel('Attenuation (dB)')
```



Input Arguments

`range` — Signal path length

positive scalar | real-valued 1-by-*M* vector of positive values | real-valued *M*-by-1 vector of positive values

Signal path length, specified as a positive scalar, a real-valued 1-by-*M* vector of positive values, or real-valued *M*-by-1 vector of positive values. Units are in meters.

Example: `[13000.0,14000.0]`

`freq` — Signal frequency

positive scalar | real-valued 1-by-*N* vector of positive values | real-valued *N*-by-1 vector of positive values

Signal frequency, specified as a positive scalar, a real-valued 1-by-*N* vector of positive values, or a real-valued *N*-by-1 vector of positive values. Units are in Hz. Frequencies must lie in the range 1–1000 GHz.

Example: `[2.0:2:10.0]*1e9]`

`rainrate` — Rain rate

nonnegative scalar

Rain rate, specified as a nonnegative scalar. Rain rate represents the long-term statistical rainfall rate provided by Crane (see [1]). Units are in mm/hr.

Example: `100.5`

`elev` — Signal path elevation angle

0.0 (default) | scalar | real-valued 1-by-*M* vector | real-valued *M*-by-1 vector

Signal path elevation angle, specified as a real-valued scalar, or real-valued *M*-by-1 or real-valued 1-by-*M* vector. Units are in degrees between –90° and 90°.

- If `elev` is a scalar, all propagation paths have the same elevation angle.
- If `elev` is a vector, its length must match the length of `range` and each element in `elev` corresponds to a propagation range.

Example: `[0,45]`

`tau` — Tilt angle of signal polarization ellipse

0.0 (default) | scalar | real-valued 1-by-*M* vector | real-valued *M*-by-1 vector

Tilt angle of the signal polarization ellipse, specified as a scalar, a real-valued 1-by-*M* vector, or a real-valued *M*-by-1 vector. Tilt angle values are in the range –90° and 90°, inclusive. Units are in degrees.

- If `tau` is a scalar, all signals have the same tilt angle.
- If `tau` is a vector, its length must match the length of `range`. In that case, each element in `tau` corresponds to a propagation path in `range`.

The tilt angle is defined as the angle between the semimajor axis of the polarization ellipse and the *x*-axis. Because the ellipse is symmetrical, a tilt angle of 10° corresponds to the same polarization state as a tilt angle of -80°. Thus, the tilt angle need only be specified between ±90°.

Example: `[45,30]`

Output Arguments

`L` — Signal attenuation

real-valued *M*-by-*N* matrix

Signal attenuation, returned as a real-valued *M*-by-*N* matrix. Each matrix row represents a different path where *M* is the number of paths. Each column represents a different frequency where *N* is the number of frequencies. Units are in dB.

More About

Crane Rainfall Attenuation Model

The Crane model calculates the attenuation of signals that propagate through regions of rainfall. The model was developed for use on Earth–space or terrestrial propagation paths and is a commonly-used method for the calculation of rain attenuation. The model is based on observations of rain rate, rain structure, and the vertical variation of temperature in the atmosphere. The Crane model (see *Electromagnetic Wave Propagation through Rain*) is primarily applicable to North America. The Crane model generally predicts losses greater than those of the ITU rain attenuation model used in the `rainpl` function. However, the uncertainty of both models and the short-term variation of fade can be large.

The ITU and Crane models are very similar but have some differences. The ITU and Crane rain attenuation models both require statistical annual rainfall rates and utilize an effective path length reduction factor to account for the cellular nature of storms. The 0.01% rainfall rate tables provided by Crane and the ITU are different. The Crane rainfall zones are similar to the ITU zones but more zones are defined in the US than in the ITU model. The ITU rainfall zones are discussed in *ITU-R P.838-3: Specific attenuation model for rain for use in prediction methods*. The Crane model is more complex consisting of a piecewise combination of path profiles composed of exponential functions.

The Crane model utilizes two exponential functions to span the distance from 0 to 22.5 km.

- For $\delta < D < 22.5$,

  $$L = \gamma\left(\frac{e^{y\delta} - 1}{y} - \frac{b^{\alpha}e^{z\delta}}{z} + \frac{b^{\alpha}e^{zD}}{z}\right)$$

- For $0 < D < \delta$,

  $$L = \gamma\left(\frac{e^{yD} - 1}{y}\right)$$

where

- L = path attenuation (dB)
- □□= propagation distance (km)
- R = statistical 0.01% rain rate (mm/hr)
- γ = specific attenuation identical to that calculated in `rainpl`.

  $$\gamma_R = kR^{\alpha},$$

  The parameters k and α depend on the frequency, the polarization state, and the elevation angle of the signal path. These coefficients, given by both Crane *Electromagnetic Wave Propagation through Rain* and the *ITU-R P.838-3: Specific attenuation model for rain for use in prediction methods*, are identical and are valid from 1 GHz to 1000 GHz. The specific attenuation model is valid for frequencies from 1–1000 GHz. Rainfall specific attenuation is computed according to the ITU rainfall model in *ITU-R P.838-3: Specific attenuation model for rain for use in prediction methods*.

The remaining parameters are empirical constants defined as:

- $b = 2.3R^{-0.17}$

- $c = 0.026 - 0.03\ln R$
- $\delta = 3.8 - 0.6 \ln R$
- $u = \ln (be^{c\delta})/\delta$
- $y = \alpha u$
- $z = \alpha c$

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the propagation distance.

You can also apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

`fspl` | `gaspl` | `fogpl` | `rainpl`

fogpl

RF signal attenuation due to fog and clouds

Syntax

```
L = fogpl(R,freq,T,den)
```

Description

`L = fogpl(R,freq,T,den)` returns attenuation, `L`, when signals propagate in fog or clouds. `R` represents the signal path length. `freq` represents the signal carrier frequency, `T` is the ambient temperature, and `den` specifies the liquid water density in the fog or cloud.

The `fogpl` function applies the International Telecommunication Union (ITU) cloud and fog attenuation model to calculate path loss of signals propagating through clouds and fog. See [1] (Phased Array System Toolbox). Fog and clouds are the same atmospheric phenomenon, differing only by height above ground. Both environments are parametrized by their liquid water density. Other model parameters include signal frequency and temperature. This function applies to cases when the signal path is contained entirely in a uniform fog or cloud environment. The liquid water density does not vary along the signal path. The attenuation model applies only for frequencies at 10–1000 GHz.

Examples

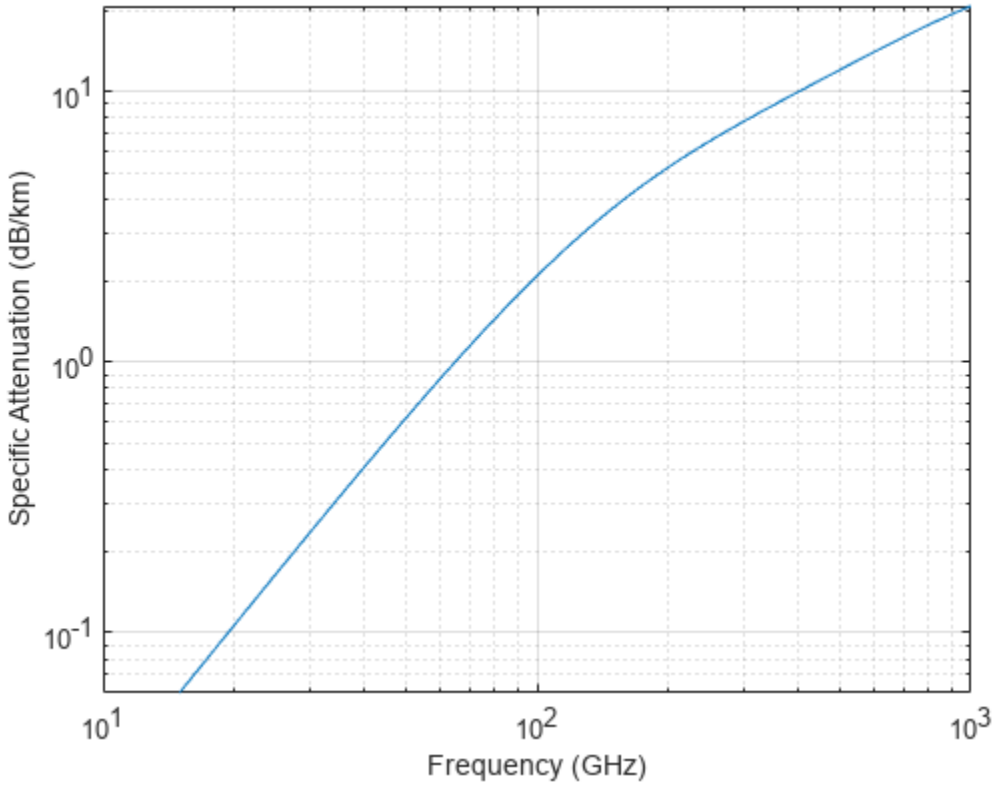
Attenuation in Cumulus Clouds

Compute the attenuation of signals propagating through a cloud that is 1 km long at 1000 meters altitude. Compute the attenuation for frequencies from 15 to 1000 GHz. A typical value for the cloud liquid water density is 0.5 g/m^3. Assume the atmospheric temperature at 1000 meters is 20˚C.

```
R = 1000.0;
freq = [15:5:1000]*1e9;
T = 20.0;
lwd = 0.5;
L = fogpl(R,freq,T,lwd);
```

Plot the specific attenuation as a function of frequency. Specific attenuation is the attenuation or loss per kilometer.

```
loglog(freq/1e9,L)
grid
xlabel('Frequency (GHz)')
ylabel('Specific Attenuation (dB/km)')
```



Input Arguments

R — Signal path length

positive real-valued scalar | *M*-by-1 nonnegative real-valued vector | 1-by-*M* nonnegative real-valued vector

Signal path length, specified as a scalar or as an *M*-by-1 or 1-by-*M* vector of nonnegative real-values. Total attenuation is the specific attenuation multiplied by the path length. Units are meters.

Example: `[1300.0,1400.0]`

freq — Signal frequency

positive real-valued scalar | *N*-by-1 nonnegative real-valued column vector | 1-by-*N* nonnegative real-valued row vector

Signal frequency, specified as a positive real-valued scalar or as an *N*-by-1 nonnegative real-valued vector or 1-by-*N* nonnegative real-valued vector. Frequencies must lie in the range 10–1000 GHz. Units are in Hz.

Example: `[14.0e9,15.0e9]`

T — Ambient temperature

real-valued scalar

Ambient temperature in fog or cloud, specified as a real-valued scalar. Units are in degrees Celsius.

Example: `-10.0`

den — Liquid water density
nonnegative real-valued scalar

Liquid water density, specified as a nonnegative real-valued scalar. Units are g/m^3. Typical values for liquid water density in fog range from approximately 0.05 g/m^3 for medium fog to approximately 0.5 g/m^3 for thick fog. For medium fog, visibility is about 300 meters. For heavy fog, visibility is about 50 meters. Cumulus cloud liquid water density is typically 0.5 g/m^3.

Example: `0.01`

Output Arguments

L — Signal attenuation
real-valued *M*-by-*N* matrix

Signal attenuation, returned as a real-valued *M*-by-*N* matrix. Each matrix row represents a different path where *M* is the number of paths. Each column represents a different frequency where *N* is the number of frequencies. Units are in dB.

More About

Fog and Cloud Attenuation Model

This model calculates the attenuation of signals that propagate through fog or clouds.

Fog and cloud attenuation are the same atmospheric phenomenon. The ITU model, *Recommendation ITU-R P.840-6: Attenuation due to clouds and fog* is used. The model computes the specific attenuation (attenuation per kilometer), of a signal as a function of liquid water density, signal frequency, and temperature. The model applies to polarized and nonpolarized fields. The formula for specific attenuation at each frequency is

$$\gamma_c = K_l(f)M,$$

where M is the liquid water density in gm/m^3. The quantity $K_l(f)$ is the specific attenuation coefficient and depends on frequency. The cloud and fog attenuation model is valid for frequencies 10–1000 GHz. Units for the specific attenuation coefficient are (dB/km)/(g/m^3).

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length R. Total attenuation is $L_c = R\gamma_c$.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply narrowband attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

`fspl` | `rainpl` | `gaspl`

fspl

Free space path loss

Syntax

```
L = fspl(R,lambda)
```

Description

`L = fspl(R,lambda)` returns the free space path loss in decibels for a waveform with wavelength `lambda` propagated over a distance of `R` meters. The minimum value of `L` is zero, indicating no path loss.

Examples

Calculate Free-Space Path Loss

Calculate the free-space path loss (in dB) of a 10 GHz radar signal over a distance of 10 km.

```
fc = 10.0e9;
lambda = physconst('LightSpeed')/fc;
R = 10e3;
L = fspl(R,lambda)
```

```
L = 132.4478
```

Input Arguments

`R` — Propagation distance of signal

real-valued 1-by-*M* or *M*-by-1 vector

Units are in meters.

`lambda` — Speed of propagation divided by the signal frequency

real-valued 1-by-*N* or *N*-by-1 vector

Wavelength units are meters.

Output Arguments

`L` — Path loss in decibels

M-by-*N* non-negative matrix. A value of zero signifies no path loss.

When `lambda` is a scalar, `L` has the same dimensions as `R`.

More About

Free Space Path Loss

The free-space path loss, L, in decibels is:

$$L = 20\log_{10}(\frac{4\pi R}{\lambda})$$

This formula assumes that the target is in the far-field of the transmitting element or array. In the near-field, the free-space path loss formula is not valid and can result in a loss smaller than 0 dB, equivalent to a signal gain. For this reason, the loss is set to 0 dB for range values $R \le \lambda/4\pi$.

gaspl

RF signal attenuation due to atmospheric gases

Syntax

```
L = gaspl(range,freq,T,P,den)
```

Description

`L = gaspl(range,freq,T,P,den)` returns the attenuation, `L`, of signals propagating through the atmosphere.

- `range` represents the signal path length.
- `freq` represents the signal carrier frequency.
- `T` represents the ambient temperature.
- `P` represents the atmospheric pressure.
- `den` represents the atmospheric water vapor density.

The `gaspl` function applies the International Telecommunication Union (ITU) atmospheric gas attenuation model [1] to calculate path loss for signals primarily due to oxygen and water vapor. The model computes attenuation as a function of ambient temperature, pressure, water vapor density, and signal frequency.

The function requires that the signal path is contained entirely in a homogeneous environment – temperature `T`, atmospheric pressure `P`, and water vapor density `den` do not vary along the signal path. You can account for the variation of atmospheric parameters with height using the `tropopl` and `atmositu` functions in the Radar Toolbox.

The attenuation model applies only for frequencies at 1–1000 GHz.

Examples

Atmospheric Gas Attenuation Spectrum

Compute the attenuation spectrum from 1 to 1000 GHz for an atmospheric pressure of 101.300 kPa and a temperature of 15˚C. Plot the spectrum for a water vapor density of 7.5 g/m^3 and then plot the spectrum for dry air (zero water vapor density).

Set the attenuation frequencies.

```
freq = [1:1000]*1e9;
```

Assume a 1 km path distance.

```
R = 1000.0;
```

Compute the attenuation for air containing water vapor.

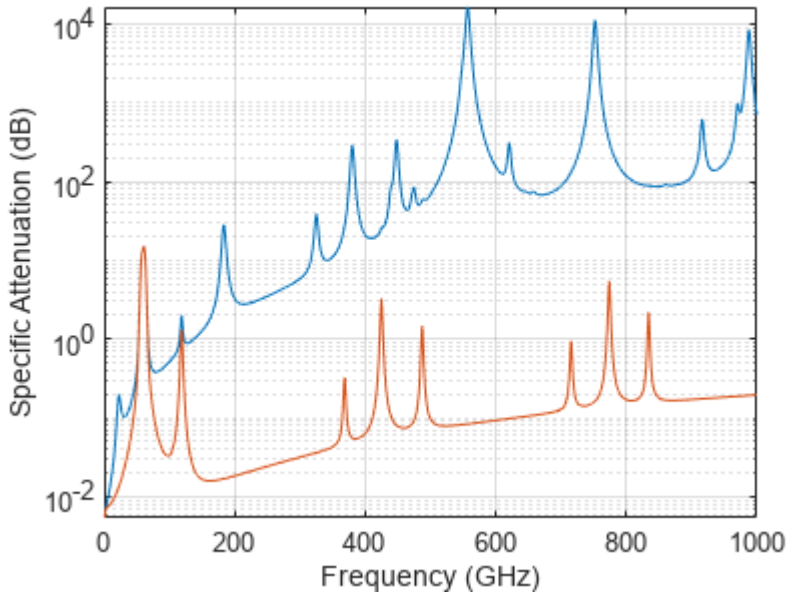
```
T = 15;
P = 101300.0;
W = 7.5;
L = gaspl(R,freq,T,P,W);
```

Compute the attenuation for dry air.

```
L0 = gaspl(R,freq,T,P,0.0);
```

Plot the attenuations.

```
semilogy(freq/1e9,L)
hold on
semilogy(freq/1e9,L0)
grid
xlabel('Frequency (GHz)')
ylabel('Specific Attenuation (dB)')
hold off
```



Plot Attenuation Due to Atmospheric Gases and Free Space

First, plot the specific attenuation of atmospheric gases for frequencies from 1 GHz to 1000 GHz. Assume a sea-level dry air pressure of 101.325e5 kPa and a water vapor density of 7.5 g/m^3. The air temperature is 20˚C. Specific attenuation is defined as dB loss per kilometer. Then, plot the actual attenuation at 10 GHz for a span of ranges.

Plot Specific Atmospheric Gas Attenuation

Set the atmosphere temperature, pressure, water vapor density.

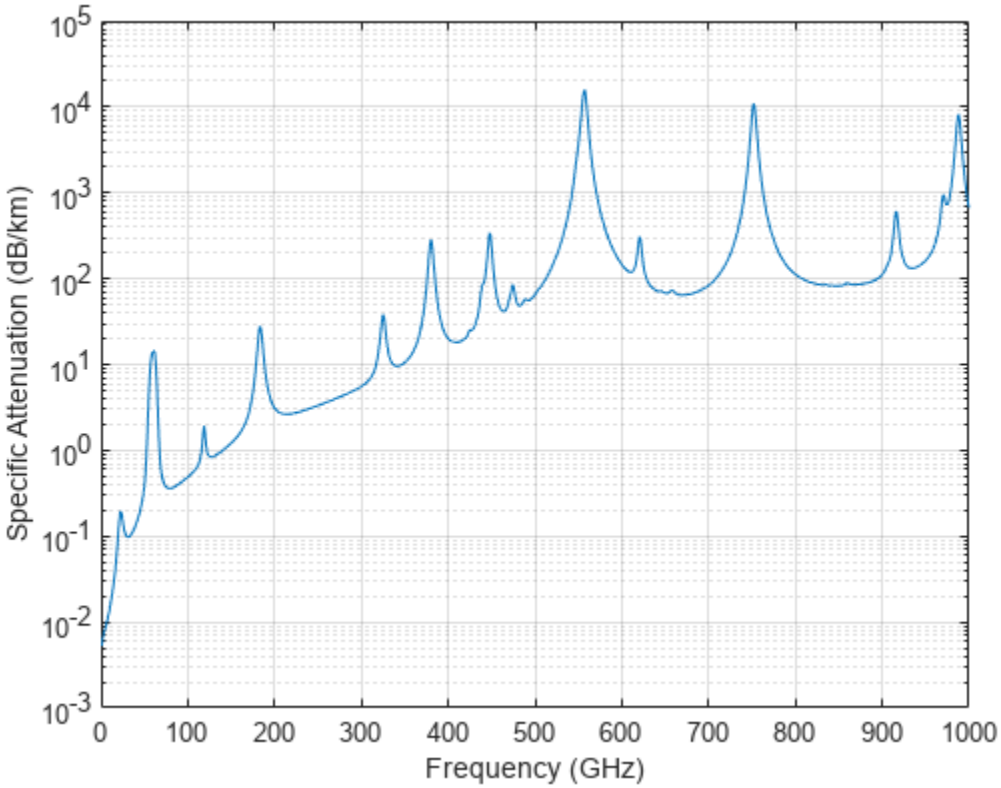
```
T = 20.0;
Patm = 101.325e3;
rho_wv = 7.5;
```

Set the propagation distance, speed of light, and frequencies.

```
km = 1000.0;
c = physconst('LightSpeed');
freqs = [1:1000]*1e9;
```

Compute and plot the atmospheric gas loss.

```
loss = gaspl(km,freqs,T,Patm,rho_wv);
semilogy(freqs/1e9,loss)
grid on
xlabel('Frequency (GHz)')
ylabel('Specific Attenuation (dB/km)')
```

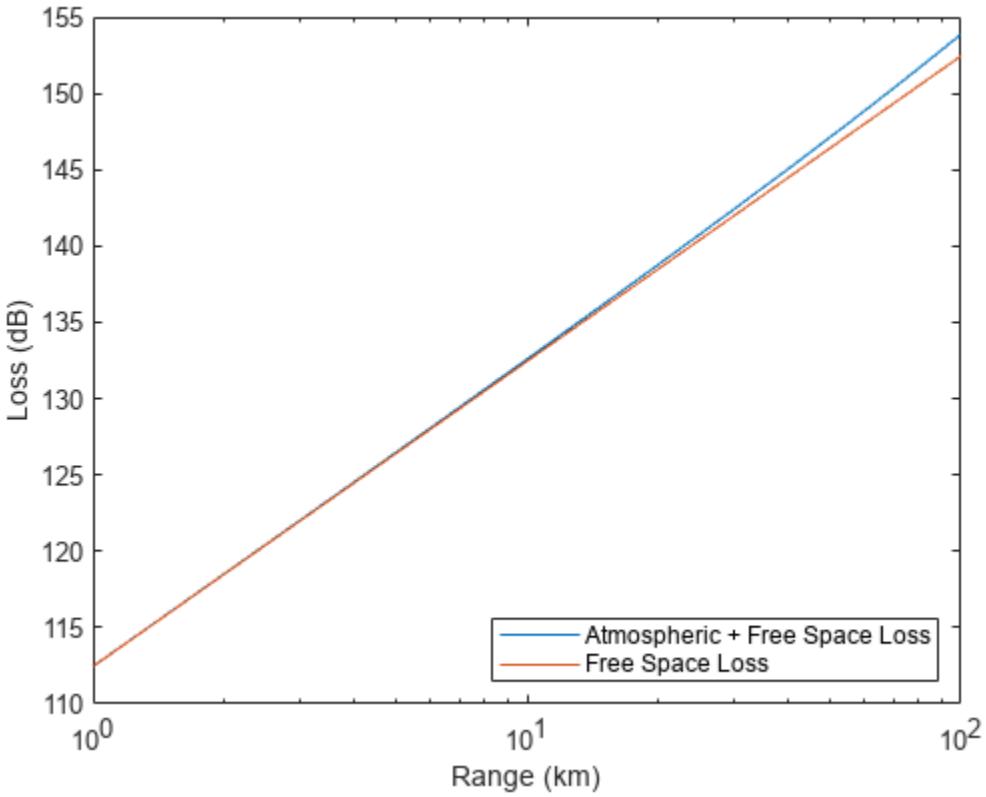


Plot Actual Atmospheric and Free Space Attenuation

Compute both free space loss and atmospheric gas loss at 10 GHz for ranges from 1 to 100 km. The frequency corresponds to an *X*-band radar. Then, plot the free space loss and the total (atmospheric + free space) loss.

```
ranges = [1:100]*1000;
freq_xband = 10e9;
loss_gas = gaspl(ranges,freq_xband,T,Patm,rho_wv);
lambda = c/freq_xband;
```

```
loss_fsp = fspl(ranges,lambda);
semilogx(ranges/1000,loss_gas + loss_fsp.',ranges/1000,loss_fsp)
legend('Atmospheric + Free Space Loss','Free Space Loss','Location','SouthEast')
xlabel('Range (km)')
ylabel('Loss (dB)')
```



Input Arguments

`range` — Signal path length

nonnegative real-valued scalar | *M*-by-1 nonnegative real-valued column vector | 1-by-*M* nonnegative real-valued row vector

Signal path length used to compute attenuation, specified as a nonnegative real-valued scalar or vector. You can specify multiple path lengths simultaneously. Units are in meters.

Example: `[13000.0,14000.0]`

`freq` — Signal frequency

positive real-valued scalar | *N*-by-1 nonnegative real-valued column vector | 1-by-*N* nonnegative real-valued row vector

Signal frequency, specified as a positive real-valued scalar, or as an *N*-by-1 nonnegative real-valued vector or 1-by-*N* nonnegative real-valued vector. You can specify multiple frequencies simultaneously. Frequencies must lie in the range 1–1000 GHz. Units are in hertz.

Example: `[1.4e9,2.0e9]`

T — Ambient temperature
real-valued scalar

Ambient temperature, specified as a real-valued scalar. Units are in degrees Celsius.

Example: `-10.0`

P — Dry air pressure
positive real-valued scalar

Dry air pressure, specified as a positive real-valued scalar. Units are in Pa. One standard atmosphere at sea level is 101325 Pa.

Example: `101300.0`

den — Water vapor density
nonnegative real-valued scalar

Water vapor density or absolute humidity, specified as a nonnegative real-valued scalar. Units are g/m^3. The maximum water vapor density of air at 30° C is approximately 30.0 g/m^3. The maximum water vapor density of air at 0°C is approximately 5.0 g/m^3.

Example: `4.0`

Output Arguments

L — Signal attenuation
real-valued *M*-by-*N* matrix

Signal attenuation, returned as a real-valued *M*-by-*N* matrix. Each matrix row represents a different path where *M* is the number of paths. Each column represents a different frequency where *N* is the number of frequencies. Units are in dB.

More About

Atmospheric Gas Attenuation Model

This model calculates the attenuation of signals that propagate through atmospheric gases.

Electromagnetic signals attenuate when they propagate through the atmosphere. This effect is due primarily to the absorption resonance lines of oxygen and water vapor, with smaller contributions coming from nitrogen gas. The model also includes a continuous absorption spectrum below 10 GHz. The ITU model *Recommendation ITU-R P.676-10: Attenuation by atmospheric gases* is used. The model computes the specific attenuation (attenuation per kilometer) as a function of temperature, pressure, water vapor density, and signal frequency. The atmospheric gas model is valid for frequencies from 1–1000 GHz and applies to polarized and nonpolarized fields.

The formula for specific attenuation at each frequency is

$$\gamma = \gamma_o(f) + \gamma_w(f) = 0.1820 f N''(f)\,.$$

The quantity $N''()$ is the imaginary part of the complex atmospheric refractivity and consists of a spectral line component and a continuous component:

$$N''(f) = \sum_i S_i F_i + N''_D(f)$$

The spectral component consists of a sum of discrete spectrum terms composed of a localized frequency bandwidth function, $F(f)_i$, multiplied by a spectral line strength, S_i. For atmospheric oxygen, each spectral line strength is

$$S_i = a_1 \times 10^{-7}\left(\frac{300}{T}\right)^3 \exp\left[a_2(1-\left(\frac{300}{T}\right)\right]P\,.$$

For atmospheric water vapor, each spectral line strength is

$$S_i = b_1 \times 10^{-1}\left(\frac{300}{T}\right)^{3.5} \exp\left[b_2(1-\left(\frac{300}{T}\right)\right]W\,.$$

P is the dry air pressure, W is the water vapor partial pressure, and T is the ambient temperature. Pressure units are in hectoPascals (hPa) and temperature is in degrees Kelvin. The water vapor partial pressure, W, is related to the water vapor density, ρ, by

$$W = \frac{\rho T}{216.7}\,.$$

The total atmospheric pressure is $P + W$.

For each oxygen line, S_i depends on two parameters, a_1 and a_2. Similarly, each water vapor line depends on two parameters, b_1 and b_2. The ITU documentation cited at the end of this section contains tabulations of these parameters as functions of frequency.

The localized frequency bandwidth functions $F_i(f)$ are complicated functions of frequency described in the ITU references cited below. The functions depend on empirical model parameters that are also tabulated in the reference.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length, R. Then, the total attenuation is $L_g = R(\gamma_o + \gamma_w)$.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

global2localcoord

Convert global to local coordinates

Syntax

```
lclCoord = global2localcoord(gCoord)
lclCoord = global2localcoord(gCoord,option)
lclCoord = global2localcoord( ___ ,localOrigin)
lclCoord = global2localcoord( ___ ,localAxes)
```

Description

`lclCoord = global2localcoord(gCoord)` converts the global rectangular coordinates `gCoord` to the local rectangular coordinates `lclCoord`. In this syntax, the global coordinate origin is located at (0, 0, 0) and the coordinate axes are the unit vectors in the *x*, *y*, and *z* directions.

`lclCoord = global2localcoord(gCoord,option)` converts global coordinates to local coordinates using the coordinate transformation type `option`.

`lclCoord = global2localcoord( ___ ,localOrigin)` specifies the origin of the local coordinate system `localOrigin`. Use this syntax with any of the input arguments in previous syntaxes.

`lclCoord = global2localcoord( ___ ,localAxes)` specifies the axes of the local coordinate system `localAxes`. Use this syntax with any of the input arguments in previous syntaxes.

Examples

Convert Global Coordinates to Local Coordinates

Convert the global rectangular coordinates, (0, 1, 0), to local rectangular coordinates. The local coordinate origin is (1, 1, 1).

```
lclCoord = global2localcoord([0;1;0],"rr",[1;1;1])
```

```
lclCoord = 3×1

    -1
     0
    -1
```

Convert global spherical coordinates to local rectangular coordinates.

```
lclCoord = global2localcoord([45;45;50],"sr",[50;50;50])
```

```
lclCoord = 3×1

  -25.0000
  -25.0000
```

```
   -14.6447
```

Convert Two Vectors Between Local and Global Coordinates

Convert two vectors from global to local coordinates using the `global2localcoord` function. Then convert them back from local to global coordinates using the `local2globalcoord` function.

Start with two vectors in global coordinates, (0, 1, 0) and (1, 1, 1). The local coordinate origins are (1, 5, 2) and (-4, 5, 7), respectively.

```
gCoord = [0 1;1 1;0 1]
```

```
gCoord = 3×2

     0     1
     1     1
     0     1
```

```
lclOrig = [1 -4;5 5;2 7];
```

Construct two rotation matrices using the rotation functions.

```
lclAxes(:,:,1) = rotz(45)*roty(-15);
lclAxes(:,:,2) = roty(45)*rotx(35);
```

Convert the vectors from global coordinates to local coordinates.

```
lclCoord = global2localcoord(gCoord,"rr",lclOrig,lclAxes)
```

```
lclCoord = 3×2

   -3.9327    7.7782
   -2.1213   -3.6822
   -1.0168    1.7151
```

Convert the vectors from local coordinates back to global coordinates.

```
gCoord1 = local2globalcoord(lclCoord,"rr",lclOrig,lclAxes)
```

```
gCoord1 = 3×2

   -0.0000    1.0000
    1.0000    1.0000
         0    1.0000
```

Input Arguments

gCoord — Global coordinates in rectangular or spherical coordinate form

3-by-*N* matrix

Global coordinates in rectangular or spherical coordinate form, specified as a 3-by-*N* matrix. Each column represents one set of global coordinates.

If the coordinates are in rectangular form, each column contains the (*x*,*y*,*z*) components. Units are in meters.

If the coordinates are in spherical form, each column contains (*az*,*el*,*r*) components. *az* is the azimuth angle on page 2-883 in degrees, *el* is the elevation angle on page 2-883 in degrees, and *r* is the radius in meters.

The origin of the global coordinate system is assumed to be (0, 0, 0). The global system axes are the standard unit basis vectors in three-dimensional space, (1, 0, 0), (0, 1, 0), and (0, 0, 1).

Data Types: `double`

`option` — Type of coordinate transformation

`"rr"` (default) | string scalar | character vector

Type of coordinate transformation, specified as a string scalar or character vector. Specify one of the following values.

Value	Transformation
`"rr"` or `'rr'`	Global rectangular to local rectangular
`"rs"` or `'rs'`	Global rectangular to local spherical
`"sr"` or `'sr'`	Global spherical to local rectangular
`"ss"` or `'ss'`	Global spherical to local spherical

Data Types: `string` | `char`

`localOrigin` — Origin of local coordinate system

`[0;0;0]` (default) | 3-by-*N* matrix

Origin of the local coordinate system, specified as a 3-by-*N* matrix containing the rectangular coordinates of the local coordinate system origin with respect to the global coordinate system. *N* must match the number of columns of `gCoord`. Each column represents a separate origin. Alternatively, you can specify `localOrigin` as a 3-by-1 vector. If you do so, `localOrigin` expands to a 3-by-*N* matrix with identical columns.

Data Types: `double`

`localAxes` — Axes of local coordinate system

`[1 0 0;0 1 0;0 0 1]` (default) | 3-by-3-by-*N* array

Axes of the local coordinate system, specified as a 3-by-3-by-*N* array. Each page contains a 3-by-3 matrix representing axes for a different local coordinate system. The columns of the 3-by-3 matrices specify the local *x*, *y*, and *z* axes in rectangular form with respect to the global coordinate system. Alternatively, you can specify `localAxes` as a single 3-by-3 matrix. If you do so, `localAxes` expands to a 3-by-3-by-*N* array with identical 3-by-3 matrices. The default value is the identity matrix.

Data Types: `double`

Output Arguments

`lclCoord` — Local coordinates in rectangular or spherical coordinate form

3-by-*N* matrix

Local coordinates in rectangular or spherical coordinate form, returned as a 3-by-*N* matrix. The dimensions of `lclCoord` match the dimensions of `gCoord`.

Data Types: `double`

More About

Azimuth and Elevation Angles

The azimuth angle of a vector is the angle between the *x*-axis and the orthogonal projection of the vector onto the *xy*-plane. The angle is positive from the *x*-axis toward the *y*-axis. Azimuth angles lie between –180 and 180 degrees. The elevation angle is the angle between the vector and its orthogonal projection onto the *xy*-plane. The angle is positive toward the positive *z*-axis from the *xy*-plane. By default, the boresight direction of an element or array is aligned with the positive *x*-axis. The boresight direction is the direction of the main lobe of an element or array.

Note The elevation angle is sometimes defined as the angle a vector makes with the positive *z*-axis. The MATLAB and Communications Toolbox products do not use this definition.

This figure illustrates the azimuth and elevation angles of a direction vector.

rainpl

RF signal attenuation due to rainfall

Syntax

```
L = rainpl(range,freq,rainrate)
L = rainpl(range,freq,rainrate,elev)
L = rainpl(range,freq,rainrate,elev,tau)
L = rainpl(range,freq,rainrate,elev,tau,pct)
```

Description

`L = rainpl(range,freq,rainrate)` returns the signal attenuation, `L`, due to rainfall. In this syntax, attenuation is a function of signal path length, `range`, signal frequency, `freq`, and rain rate, `rainrate`. The path elevation angle and polarization tilt angles are assumed to zero.

The `rainpl` function applies the International Telecommunication Union (ITU) rainfall attenuation model to calculate path loss of signals propagating in a region of rainfall [1]. The function applies when the signal path is contained entirely in a uniform rainfall environment. Rain rate does not vary along the signal path. The attenuation model applies only for frequencies at 1–1000 GHz.

`L = rainpl(range,freq,rainrate,elev)` also specifies the elevation angle, `elev`, of the propagation path.

`L = rainpl(range,freq,rainrate,elev,tau)` also specifies the polarization tilt angle, `tau`, of the signal.

`L = rainpl(range,freq,rainrate,elev,tau,pct)` also specifies the specified percentage of time, `pct`. `pct` is a scalar in the range of 0.001–1, inclusive. The attenuation, `L`, is computed from a power law using the long-term statistical 0.01% rain rate (in mm/h).

Examples

Signal Attenuation Due to Rainfall

Compute the signal attenuation due to rainfall for a 20 GHz signal over a distance of 10 km in light and heavy rain.

Propagate the signal in a light rainfall of 1 mm/hr.

```
rr = 1.0;
L = rainpl(10000,20.0e9,rr)
```

```
L = 1.3009
```

Propagate the signal in a heavy rainfall of 10 mm/hr.

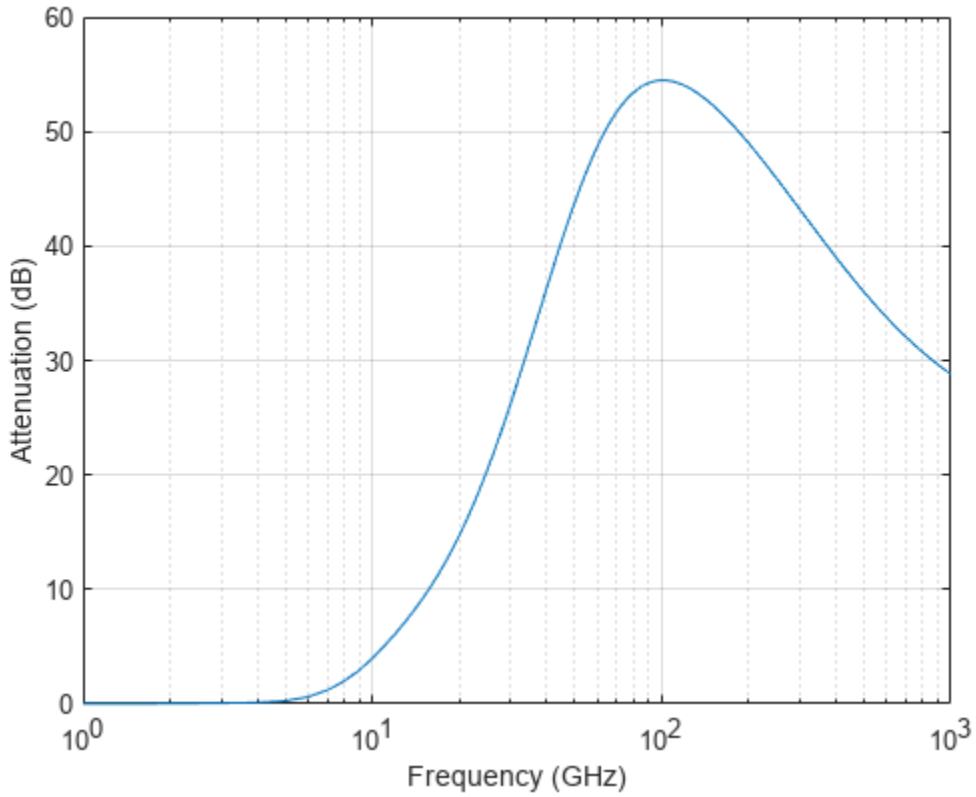
```
rr = 10.0;
L = rainpl(10000,20.0e9,rr)
```

```
L = 8.1584
```

Signal Attenuation Due to Rainfall as Function of Frequency

Plot the signal attenuation due to a 20 mm/hr statistical rainfall for signals in the frequency range from 1 to 1000 GHz. The path distance is 10 km.

```
rr = 20.0;
freq = [1:1000]*1e9;
L = rainpl(10000,freq,rr);
semilogx(freq/1e9,L)
grid
xlabel('Frequency (GHz)')
ylabel('Attenuation (dB)')
```



Signal Attenuation Due to Rainfall as Function of Elevation Angle

Compute the signal attenuation due to heavy rain as a function of elevation angle. Elevation angles vary from 0 to 90 degrees. Assume a path distance of 100 km and a signal frequency of 100 GHz.

Set the rain rate to 10 mm/hr.

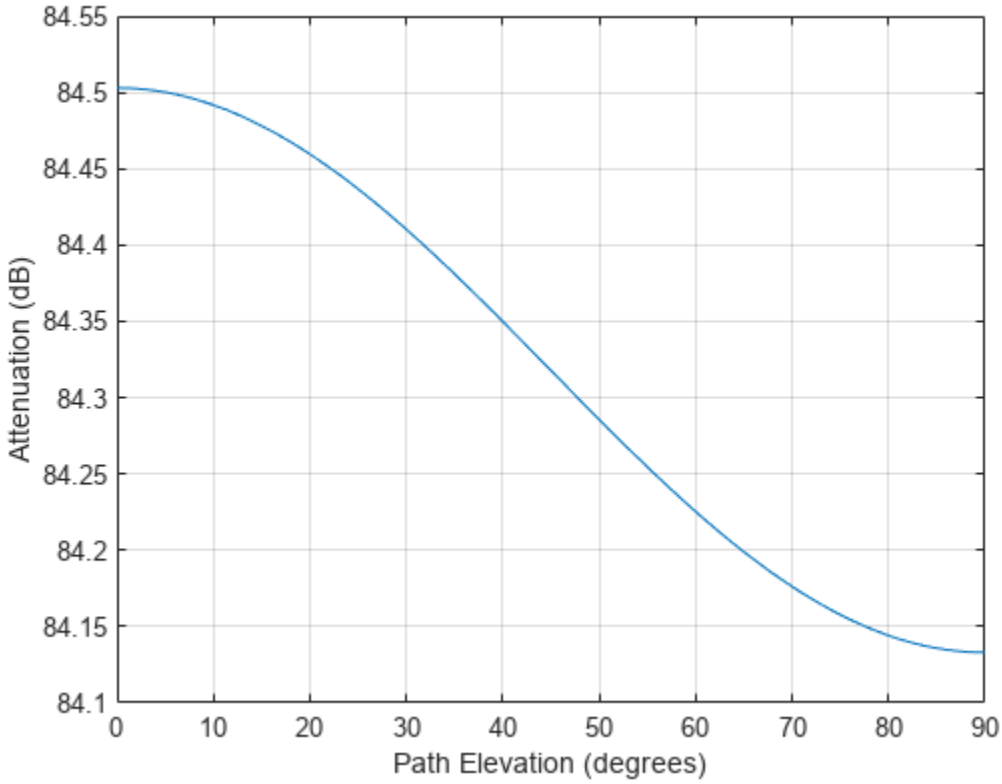
```
rr = 10.0;
```

Set the elevation angles, frequency, range.

```
elev = [0:1:90];
freq = 100.0e9;
rng = 100000.0*ones(size(elev));
```

Compute and plot the loss.

```
L = rainpl(rng,freq,rr,elev);
plot(elev,L)
grid
xlabel('Path Elevation (degrees)')
ylabel('Attenuation (dB)')
```



Signal Attenuation Due to Rainfall as Function of Polarization

Compute the signal attenuation due to heavy rainfall as a function of the polarization tilt angle. Assume a path distance of 100 km, a signal frequency of 100 GHz, and a path elevation angle of 0 degrees. Set the rainfall rate to 10 mm/hour. Plot the signal attenuation versus polarization tilt angle.

Set the polarization tilt angle to vary from -90 to 90 degrees.

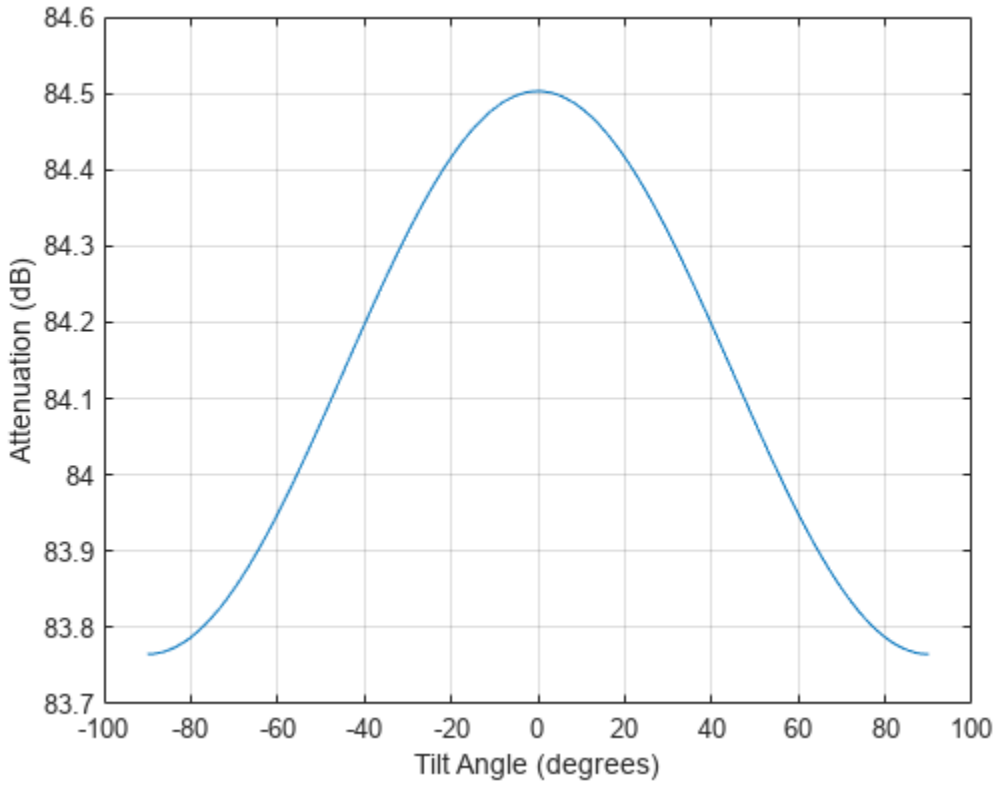
```
tau = -90:90;
```

Set the elevation angle, frequency, path distance, and rain rate.

```
elev = 0;
freq = 100.0e9;
rng = 100e3*ones(size(tau));
rr = 10.0;
```

Compute and plot the attenuation.

```
L = rainpl(rng,freq,rr,elev,tau);
plot(tau,L)
grid
xlabel('Tilt Angle (degrees)')
ylabel('Attenuation (dB)')
```



Input Arguments

`range` — Signal path length

nonnegative real-valued scalar | nonnegative real-valued *M*-by-1 column vector | nonnegative real-valued 1-by-*M* row vector

Signal path length, specified as a nonnegative real-valued scalar, or as a *M*-by-1 or 1-by-*M* vector. Units are in meters.

Example: `[13000.0,14000.0]`

`freq` — Signal frequency

positive real-valued scalar | nonnegative real-valued *N*-by-1 column vector | nonnegative real-valued 1-by-*N* row vector

Signal frequency, specified as a positive real-valued scalar, or as a nonnegative *N*-by-1 or 1-by-*N* vector. Frequencies must lie in the range 1–1000 GHz.

Example: `[1400.0e6,2.0e9]`

`rainrate` — Long-term statistical rain rate

nonnegative real-valued scalar

Long-term statistical rain rate, specified as a nonnegative real-valued scalar. The long-term statistical rain rate is the rain rate that is exceeded 0.01% of the time. You can adjust the percent of time using the `pct` argument. Units are in mm/hr.

Example: `1.5`

`elev` — Signal path elevation angle

0.0 (default) | real-valued scalar | real-valued *M*-by-1 column vector | real-valued 1-by-*M* row vector

Signal path elevation angle, specified as a real-valued scalar, or as an *M*-by-1 or 1-by- *M* vector. Units are in degrees between –90° and 90°. If `elev` is a scalar, all propagation paths have the same elevation angle. If `elev` is a vector, its length must match the dimension of `range` and each element in `elev` corresponds to a propagation range in `range`.

Example: `[0,45]`

`tau` — Tilt angle of polarization ellipse

0.0 (default) | real-valued scalar | real-valued *M*-by-1 column vector | real-valued 1-by-*M* row vector

Tilt angle of the signal polarization ellipse, specified as a real-valued scalar, or as an *M*-by-1 or 1-by-*M* vector. Units are in degrees between –90° and 90°. If `tau` is a scalar, all signals have the same tilt angle. If `tau` is a vector, its length must match the dimension of `range`. In that case, each element in `tau` corresponds to a propagation path in `range`.

The tilt angle is defined as the angle between the semi-major axis of the polarization ellipse and the *x*-axis. Because the ellipse is symmetrical, a tilt angle of 100° corresponds to the same polarization state as a tilt angle of -80°. Thus, the tilt angle need only be specified between ±90°.

Example: `[45,30]`

`pct` — Exceedance percentage of rainfall

`0.01` (default) | positive scalar between 0.001 and 1

Exceedance percentage of rainfall, specified as a positive scalar between 0.001 and 1. The long-term statistical rain rate is the rain rate that is exceeded `pct` of the time. Units are dimensionless.

Data Types: `double`

Output Arguments

`L` — Signal attenuation

real-valued *M*-by-*N* matrix

Signal attenuation, returned as a real-valued *M*-by-*N* matrix. Each matrix row represents a different path where *M* is the number of paths. Each column represents a different frequency where *N* is the number of frequencies. Units are in dB.

More About

Rainfall Attenuation Model

This model calculates the attenuation of signals that propagate through regions of rainfall. Rain attenuation is a dominant fading mechanism and can vary from location-to-location and from year-to-year.

Electromagnetic signals are attenuated when propagating through a region of rainfall. Rainfall attenuation is computed according to the ITU rainfall model *Recommendation ITU-R P.838-3: Specific attenuation model for rain for use in prediction methods*. The model computes the specific attenuation (attenuation per kilometer) of a signal as a function of rainfall rate, signal frequency, polarization, and path elevation angle. The specific attenuation, γ_R, is modeled as a power law with respect to rain rate

$$\gamma_R = kR^{\alpha},$$

where R is rain rate. Units are in mm/hr. The parameter k and exponent α depend on the frequency, the polarization state, and the elevation angle of the signal path. The specific attenuation model is valid for frequencies from 1–1000 GHz.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the an effective propagation distance, d_{eff}. Then, the total attenuation is $L = d_{\text{eff}}\gamma_R$.

The effective distance is the geometric distance, d, multiplied by a scale factor

$$r = \frac{1}{0.477d^{0.633}R_{0.01}^{0.073\alpha}f^{0.123} - 10.579(1 - \exp(-0.024d))}$$

where f is the frequency. The article *Recommendation ITU-R P.530-17 (12/2017): Propagation data and prediction methods required for the design of terrestrial line-of-sight systems* presents a complete discussion for computing attenuation.

The rain rate, R, used in these computations is the long-term statistical rain rate, $R_{0.01}$. This is the rain rate that is exceeded 0.01% of the time. The calculation of the statistical rain rate is discussed in *Recommendation ITU-R P.837-7 (06/2017): Characteristics of precipitation for propagation modelling*. This article also explains how to compute the attenuation for other percentages from the 0.01% value.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

rangeangle

Range and angle calculation

Syntax

```
[rng,ang] = rangeangle(pos)
[rng,ang] = rangeangle(pos,refpos)
[rng,ang] = rangeangle(pos,refpos,refaxes)
[rng,ang] = rangeangle( ___ ,model)
```

Description

The function `rangeangle` determines the propagation path length and path direction of a signal from a source point or set of source points to a reference point. The function supports two propagation models – the *free space* model and the *two-ray* model. The *free space* model is a single line-of-sight path from a source point to a reference point. The *two-ray* multipath model generates two paths. The first path follows the free-space path. The second path is a reflected path off a boundary plane at $z = 0$. Path directions are defined with respect to either the global coordinate system at the reference point or a local coordinate system at the reference point. Distances and angles at the reference point do not depend upon which direction the signal is travelling along the path.

`[rng,ang] = rangeangle(pos)` returns the propagation path length, `rng`, and direction angles, `ang`, of a signal path from a source point or set of source points, `pos`, to the origin of the global coordinate system. The direction angles are the azimuth and elevation with respect to the global coordinate axes at the origin. Signals follow a line-of-sight path from the source point to the origin. The line-of-sight path corresponds to the geometric straight line between the points.

`[rng,ang] = rangeangle(pos,refpos)` also specifies a reference point or set of reference points, `refpos`. `rng` now contains the propagation path length from the source points to the reference points. The direction angles are the azimuth and elevation with respect to the global coordinate axes at the reference points. You can specify multiple points and multiple reference points.

`[rng,ang] = rangeangle(pos,refpos,refaxes)` also specifies local coordinate system axes, `refaxes`, at the reference points. Direction angles are the azimuth and elevation with respect to the local coordinate axes centered at `refpos`.

`[rng,ang] = rangeangle( ___ ,model)`, also specifies a propagation model. When `model` is set to `"freespace"`, the signal propagates along a line-of-sight path from source point to reception point. When `model` is set to `"two-ray"`, the signal propagates along two paths from source point to reception point. The first path is the line-of-sight path. The second path is the reflecting path. In this case, the function returns the distances and angles for two paths for each source point and corresponding reference point.

Examples

Range and Angle Computation

Compute the range and angle of a target located at *(1000,2000,50)* meters from the origin.

```
TargetLoc = [1000;2000;50];
[tgtrng,tgtang] = rangeangle(TargetLoc)

tgtrng = 2.2366e+03

tgtang = 2×1

   63.4349
    1.2810
```

Range and Angle With Respect to Local Origin

Compute the range and angle of a target located at *(1000,2000,50)* meters with respect to a local origin at *(100,100,10)* meters.

```
TargetLoc = [1000;2000;50];
Origin = [100;100;10];
[tgtrng,tgtang] = rangeangle(TargetLoc,Origin)

tgtrng = 2.1028e+03

tgtang = 2×1

   64.6538
    1.0900
```

Range and Angle With Respect to Local Coordinates

Compute the range and angle of a target located at *(1000,2000,50)* meters but with respect to a local coordinate system origin at *(100,100,10)* meters. Choose a local coordinate reference frame that is rotated about the z-axis by 45° from the global coordinate axes.

```
targetpos = [1000;2000;50];
origin = [100;100;10];
refaxes = [1/sqrt(2) -1/sqrt(2) 0; 1/sqrt(2) 1/sqrt(2) 0; 0 0 1];
[tgtrng,tgtang] = rangeangle(targetpos,origin,refaxes)

tgtrng = 2.1028e+03

tgtang = 2×1

   19.6538
    1.0900
```

Input Arguments

pos — Source point position

real-valued 3-by-1 vector | real-valued 3-by-*N* matrix

Source point position in meters, specified as a real-valued 3-by-1 vector or a real-valued 3-by-*N* matrix. A matrix represents multiple source points. The columns contain the Cartesian coordinates of *N* points in the form `[x;y;z]`.

When `pos` is a 3-by-*N* matrix, you must specify `refpos` as a 3-by-*N* matrix for *N* reference positions. If all the reference points are identical, you can specify `refpos` by a single 3-by-1 vector.

Example: `[1000;2000;50]`

Data Types: `double`

`refpos` — Reference point position
`[0;0;0]` (default) | real-valued 3-by-1 vector | real-valued 3-by-*N* matrix

Reference point position in meters, specified as a real-valued 3-by-1 vector or a real-valued 3-by-*N* matrix. A matrix represents multiple reference points. The columns contain the Cartesian coordinates of *N* points ins the form `[x;y;z]`.

When `refpos` is a 3-by-*N* matrix, you must specify `pos` as a 3-by-*N* matrix for *N* source positions. If all the source points are identical, you can specify `pos` by a single 3-by-1 vector.

Position units are meters.

Example: `[100;100;10]`

Data Types: `double`

`refaxes` — Local coordinate system axes
`[1 0 0;0 1 0;0 0 1]` (default) | real-valued 3-by-3 matrix | real-valued 3-by-3-by-*N* array

Local coordinate system axes, specified as a real-valued 3-by-3 matrix or a 3-by-3-by-*N* array. For an array, each page corresponds to a local coordinate axes at each reference point. The columns in `refaxes` specify the direction of the coordinate axes for the local coordinate system in Cartesian coordinates. *N* must match the number of columns in `pos` or `refpos` when these dimensions are greater than one.

Example: `rotz(45)`

Data Types: `double`

`model` — Propagation model
`"freespace"` (default) | `"two-ray"`

Propagation model, specified as `"freespace"` or `"two-ray"`. Choosing `"freespace"` invokes the free space propagation model. Choosing `"two-ray"` invokes the two-ray propagation model.

Data Types: `char` | `string`

Output Arguments

`rng` — Propagation range
real-valued 1-by-*N* vector | real-valued 1-by-2*N* vector

Propagation range in meters, returned as a real-valued 1-by-*N* vector or real-valued 1-by-2*N* vector.

- When `model` is set to `"freespace"`, the size of `rng` is 1-by-*N*. The propagation range is the length of the direct path from the position defined in `pos` to the corresponding reference position defined in `refpos`.

- When `model` is set to `"two-ray"`, `rng` contains the ranges for the direct path and the reflected path. Alternate columns of `rng` refer to the line-of-sight path and reflected path, respectively for the same source-reference point pair.

ang — Azimuth and elevation angles
real-valued 2-by-*N* matrix | real-valued 2-by-2*N* matrix

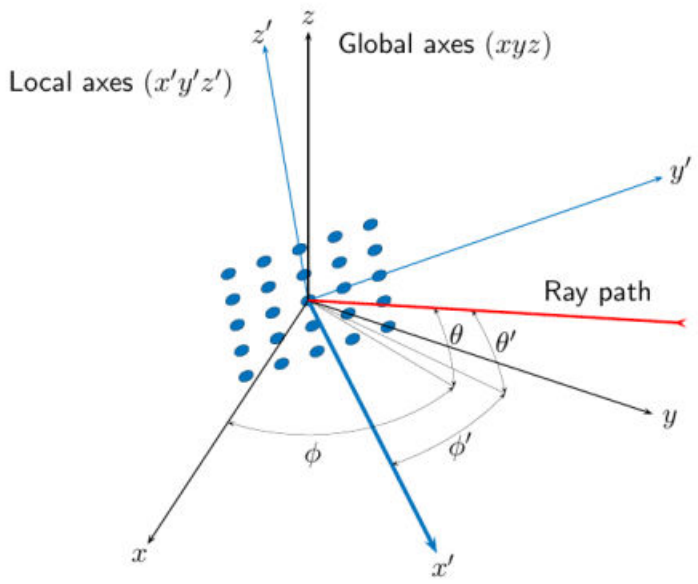
Azimuth and elevation angles in degrees, returned as a 2-by-*N* matrix or 2-by-2*N* matrix. Each column represents a direction angle in the form `[azimuth;elevation]`.

- When `model` is set to `"freespace"`, `ang` is a 2-by-*N* matrix and represents the angle of the path from a source point to a reference point.
- When `model` is set to `"two-ray"`, `ang` is a 2-by-2*N* matrix. Alternate columns of `ang` refer to the line-of-sight path and reflected path, respectively.

More About

Angles in Local and Global Coordinate Systems

The `rangeangle` function returns the path distance and path angles in either the global or local coordinate systems. By default, the `rangeangle` function determines the angle a signal path makes with respect to global coordinates. If you add the `refaxes` argument, you can compute the angles with respect to local coordinates. As an illustration, this figure shows a 5-by-5 uniform rectangular array (URA) rotated from the global coordinates (*xyz*) using `refaxes`. The *x*' axis of the local coordinate system (*x*'*y*'*z*') is aligned with the main axis of the array and moves as the array moves. The path length is independent of orientation. The global coordinate system defines the azimuth and elevation angles (Φ,θ) and the local coordinate system defines the azimuth and elevations angles (Φ',θ').



Local and Global Coordinate Axes

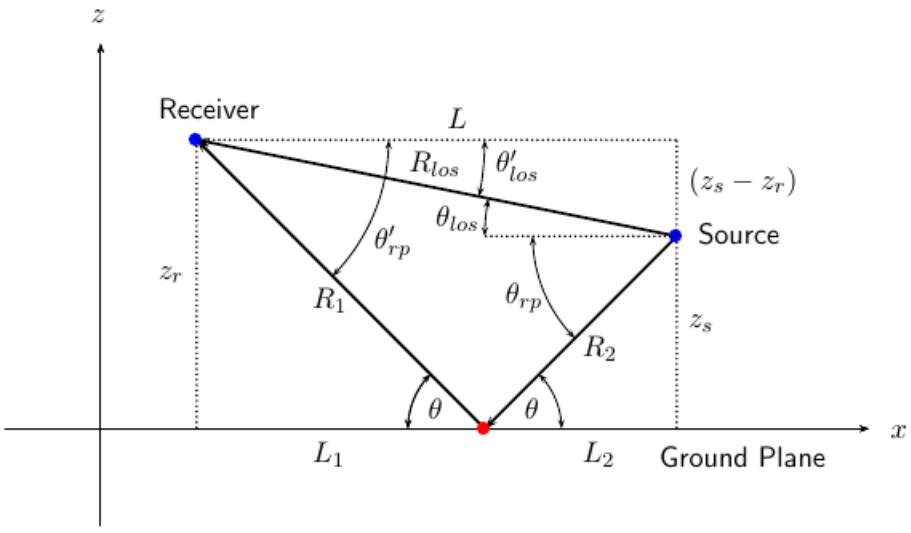
Free Space Propagation Model

The free-space signal propagation model states that a signal propagating from one point to another in a homogeneous, isotropic medium travels in a straight line, called the line-of-sight or direct path. The straight line is defined by the geometric vector from the radiation source to the destination.

Two-Ray Propagation Model

A two-ray propagation channel is the next step up in complexity from a free-space channel and is the simplest case of a multipath propagation environment. The free-space channel models a straight-line *line-of-sight* path from point 1 to point 2. In a two-ray channel, the medium is specified as a homogeneous, isotropic medium with a reflecting planar boundary. The boundary is always set at $z = 0$. There are at most two rays propagating from point 1 to point 2. The first ray path propagates along the same line-of-sight path as in the free-space channel. The line-of-sight path is often called the *direct path*. The second ray reflects off the boundary before propagating to point 2. According to the Law of Reflection , the angle of reflection equals the angle of incidence. In short-range simulations such as cellular communications systems and automotive radars, you can assume that the reflecting surface, the ground or ocean surface, is flat.

The figure illustrates two propagation paths. From the source position, s_s, and the receiver position, s_r, you can compute the arrival angles of both paths, θ'_{los} and θ'_{rp}. The arrival angles are the elevation and azimuth angles of the arriving radiation with respect to a local coordinate system. In this case, the local coordinate system coincides with the global coordinate system. You can also compute the transmitting angles, θ_{los} and θ_{rp}. In the global coordinates, the angle of reflection at the boundary is the same as the angles θ_{rp} and θ'_{rp}. The reflection angle is important to know when you use angle-dependent reflection-loss data. You can determine the reflection angle by using the `rangeangle` function and setting the reference axes to the global coordinate system. The total path length for the line-of-sight path is shown in the figure by R_{los} which is equal to the geometric distance between source and receiver. The total path length for the reflected path is $R_{rp} = R_1 + R_2$. The quantity L is the ground range between source and receiver.



You can easily derive exact formulas for path lengths and angles in terms of the ground range and object heights in the global coordinate system.

$$\vec{R} = \vec{x}_s - \vec{x}_r$$

$$R_{los} = \left|\vec{R}\right| = \sqrt{(z_r - z_s)^2 + L^2}$$

$$R_1 = \frac{z_r}{z_r + z_z}\sqrt{(z_r + z_s)^2 + L^2}$$

$$R_2 = \frac{z_s}{z_s + z_r}\sqrt{(z_r + z_s)^2 + L^2}$$

$$R_{rp} = R_1 + R_2 = \sqrt{(z_r + z_s)^2 + L^2}$$

$$\tan\theta_{los} = \frac{(z_s - z_r)}{L}$$

$$\tan\theta_{rp} = -\frac{(z_s + z_r)}{L}$$

$$\theta'_{los} = -\theta_{los}$$

$$\theta'_{rp} = \theta_{rp}$$

sph2cartvec

Convert vector from spherical basis components to Cartesian components

Syntax

```
vr = sph2cartvec(vs,az,el)
```

Description

`vr = sph2cartvec(vs,az,el)` converts the components of a vector or set of vectors, `vs`, from their spherical basis representation to their representation in a local Cartesian coordinate system. A spherical basis representation is the set of components of a vector projected into the right-handed spherical basis given by ($\hat{\mathbf{e}}_{az}$, $\hat{\mathbf{e}}_{el}$, $\hat{\mathbf{e}}_{R}$). The orientation of a spherical basis depends upon its location on the sphere as determined by azimuth, `az`, and elevation, `el`.

Examples

Cartesian Representation of Azimuthal Vector

Start with a vector in a spherical basis located at 45° azimuth, 45° elevation. The vector points along the azimuth direction. Compute the vector components with respect to Cartesian coordinates.

```
vs = [1;0;0];
vr = sph2cartvec(vs,45,45)
```

```
vr = 3×1

   -0.7071
    0.7071
         0
```

Input Arguments

vs — Vector in spherical basis representation

3-by-1 column vector | 3-by-*N* matrix

Vector in spherical basis representation specified as a 3-by-1 column vector or 3-by-*N* matrix. Each column of `vs` contains the three components of a vector in the right-handed spherical basis ($\hat{\mathbf{e}}_{az}$, $\hat{\mathbf{e}}_{el}$, $\hat{\mathbf{e}}_{R}$).

Example: `[4.0; -3.5; 6.3]`

Data Types: `double`
Complex Number Support: Yes

az — Azimuth angle

scalar in range [–180,180]

Azimuth angle specified as a scalar in the closed range [–180,180]. Angle units are in degrees. To define the azimuth angle of a point on a sphere, construct a vector from the origin to the point. The azimuth angle is the angle in the *xy*-plane from the positive *x*-axis to the vector's orthogonal projection into the *xy*-plane. As examples, zero azimuth angle and zero elevation angle specify a point on the *x*-axis while an azimuth angle of 90° and an elevation angle of zero specify a point on the *y*-axis.

Example: `45`

Data Types: `double`

`el` — Elevation angle
scalar in range [–90,90]

Elevation angle specified as a scalar in the closed range [–90,90]. Angle units are in degrees. To define the elevation of a point on the sphere, construct a vector from the origin to the point. The elevation angle is the angle from its orthogonal projection into the *xy*-plane to the vector itself. As examples, zero elevation angle defines the equator of the sphere and ±90° elevation define the north and south poles, respectively.

Example: `30`

Data Types: `double`

Output Arguments

`vr` — Vector in Cartesian representation
3-by-1 column vector | 3-by-*N* matrix

Cartesian vector returned as a 3-by-1 column vector or 3-by-*N* matrix having the same dimensions as `vs`. Each column of `vr` contains the three components of the vector in the right-handed *x*,*y*,*z* basis.

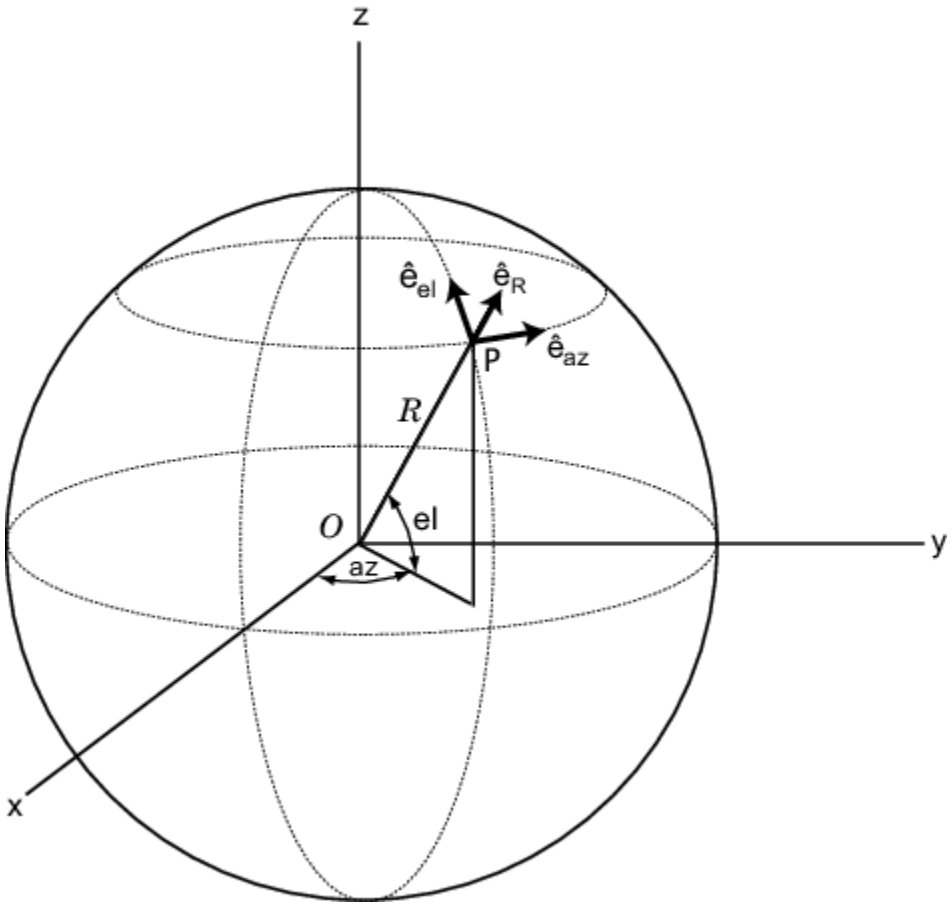
More About

Spherical basis representation of vectors

Spherical basis vectors are a local set of basis vectors which point along the radial and angular directions at any point in space.

The spherical basis is a set of three mutually orthogonal unit vectors ($\hat{\mathbf{e}}_{az}$, $\hat{\mathbf{e}}_{el}$, $\hat{\mathbf{e}}_{R}$) defined at a point on the sphere. The first unit vector points along lines of azimuth at constant radius and elevation. The second points along the lines of elevation at constant azimuth and radius. Both are tangent to the surface of the sphere. The third unit vector points radially outward.

The orientation of the basis changes from point to point on the sphere but is independent of *R* so as you move out along the radius, the basis orientation stays the same. The following figure illustrates the orientation of the spherical basis vectors as a function of azimuth and elevation:



For any point on the sphere specified by *az* and *el*, the basis vectors are given by:

$$\widehat{\mathbf{e}}_{\mathbf{az}} = -\sin(az)\widehat{\mathbf{i}} + \cos(az)\widehat{\mathbf{j}}$$

$$\widehat{\mathbf{e}}_{\mathbf{el}} = -\sin(el)\cos(az)\widehat{\mathbf{i}} - \sin(el)\sin(az)\widehat{\mathbf{j}} + \cos(el)\widehat{\mathbf{k}}$$

$$\widehat{\mathbf{e}}_{\mathbf{R}} = \cos(el)\cos(az)\widehat{\mathbf{i}} + \cos(el)\sin(az)\widehat{\mathbf{j}} + \sin(el)\widehat{\mathbf{k}} \quad .$$

Any vector can be written in terms of components in this basis as $\mathbf{v} = v_{az}\widehat{\mathbf{e}}_{\mathbf{az}} + v_{el}\widehat{\mathbf{e}}_{\mathbf{el}} + v_R\widehat{\mathbf{e}}_{\mathbf{R}}$. The transformations between spherical basis components and Cartesian components take the form

$$\begin{bmatrix} v_x \\ v_y \\ v_z \end{bmatrix} = \begin{bmatrix} -\sin(az) & -\sin(el)\cos(az) & \cos(el)\cos(az) \\ \cos(az) & -\sin(el)\sin(az) & \cos(el)\sin(az) \\ 0 & \cos(el) & \sin(el) \end{bmatrix} \begin{bmatrix} v_{az} \\ v_{el} \\ v_R \end{bmatrix}$$

.

and

$$\begin{bmatrix} v_{az} \\ v_{el} \\ v_R \end{bmatrix} = \begin{bmatrix} -\sin(az) & \cos(az) & 0 \\ -\sin(el)\cos(az) & -\sin(el)\sin(az) & \cos(el) \\ \cos(el)\cos(az) & \cos(el)\sin(az) & \sin(el) \end{bmatrix} \begin{bmatrix} v_x \\ v_y \\ v_z \end{bmatrix}.$$

tdmsinfo

Information about TDMS-file

Syntax

```
info = tdmsinfo(tdmsfile)
```

Description

`info = tdmsinfo(tdmsfile)` returns a `TdmsInfo` object with properties containing general information about the TDMS-file, such as file name, location, description, author, version, and list of channels.

Examples

Get Information on a TDMSFile

Get information on a TDMS-file and its channels.

```
info = tdmsinfo("Turbine_003.tdms")
```

```
info =

  TdmsInfo with properties:

          Path: "C:\data\tdms\Turbine_003.tdms"
          Name: "Turbine_003"
    Description: "Test the Acceleration, Force and Torque of Turbine"
         Title: "Turbine Tests"
        Author: "xyz"
       Version: "2.0"
   ChannelList: [6×8 table]
```

View the channel information in the file.

```
>> info.ChannelList
```

```
ans =

  6×8 table

    ChannelGroupNumber    ChannelGroupName    ChannelGroupDescription      ChannelName      ChannelDescription      Unit      DataType

           1               "Acceleration"        "CGAcceleration"        "Acceleration1"     "from Clipboard"     "m/s^2"    "Double"
           1               "Acceleration"        "CGAcceleration"        "Acceleration2"     "from Clipboard"     "m/s^2"    "Double"
           2               "Force"               "CGForce"               "Force1"            "from Clipboard"     "N"        "Double"
           2               "Force"               "CGForce"               "Force2"            "from Clipboard"     "N"        "Double"
           3               "Torque"              "CGTorque"              "Torque1"           "from Clipboard"     "Nm"       "Double"
           3               "Torque"              "CGTorque"              "Torque2"           "from Clipboard"     "Nm"       "Double"
```

Input Arguments

`tdmsfile` — TDMS file name

string

TDMS file name, specified as a string.

For local files, use a full or relative path that contains a file name and extension. You also can specify a file on the MATLAB path.

For Internet files, specify the URL. For example, to read a remote file from the Amazon S3 cloud:

```
data = tdmsread("s3://bucketname/path_to_file/data.tdms");
```

Example: `"airlinesmall.tdms"`

Data Types: `char` | `string`

Output Arguments

`info` — TDMS-file information

`TdmsInfo` object

TDMS-file information, returned as a `TdmsInfo` object with the following properties:

Property	Type	Description
`Path`	string	Full path to file
`Name`	string	TDMS-file name attribute
`Description`	string	TDMS-file description attribute
`Title`	string	TDMS-file title attribute
`Author`	string	TDMS-file author attribute
`Version`	string	TDMS-file version attribute
`ChannelList`	table	TDMS channel and channel group attributes

The `ChannelList` property value is a table with the following variables:

Table Variable	Type	Notes
`ChannelGroupNumber`	double	Internally created representational index of channel group
`ChannelGroupName`	string	
`ChannelGroupDescription`	string	
`ChannelName`	string	
`ChannelDescription`	string	
`Unit`	string	Unit of channel data
`DataType`	string	TDMS datatype in file
`NumSamples`	uint64	Number of samples in channel

Limitations

- TDMS functions are supported on Windows® platforms only.

Functions

`tdmsread` | `tdmsreadprop`

tdmsread

Read data from TDMS-file

Syntax

```
data = tdmsread(tdmsfile)
data = tdmsread(tdmsfile,Name=Value)
```

Description

`data = tdmsread(tdmsfile)` retrieves data from the specified TDMS-file and returns a cell array of tables. Each element of the cell array is a table corresponding to a channel group.

`data = tdmsread(tdmsfile,Name=Value)` uses name-value pairs to filter the data reading and specify output format.

Examples

Read TDMS File Data

Read data from a specified TDMS-file. You can determine which channels are read, and what format the result has.

Read all data from a TDMS-file into a table.

```
data = tdmsread("airlinesmall.tdms");
```

Read a subset of the variables in a TDMS-file into MATLAB as a timetable. Use the variable `ArrTime` in the TDMS-file as the time vector of the output timetable.

```
data = tdmsread("airlinesmall.tdms", ...
           ChannelGroupName = "Airline", ...
           ChannelNames = ["ArrTime" "FlightNum" "ArrDelay"], ...
           RowTimes = "ArrTime");
```

Read the channel data into a timetable with a specified start time and step duration.

```
data = tdmsread("airlinesmall.tdms", ...
           ChannelGroupName = "Airline", ...
           ChannelNames = ["ArrTime" "FlightNum" "ArrDelay"], ...
           TimeStep = seconds(0.01), StartTime = seconds(30));
```

Input Arguments

`tdmsfile` — TDMS file name

string

TDMS file name, specified as a string.

For local files, use a full or relative path that contains a file name and extension. You also can specify a file on the MATLAB path.

For Internet files, specify the URL. For example, to read a remote file from the Amazon S3 cloud:

```
data = tdmsread("s3://bucketname/path_to_file/data.tdms");
```

Example: `"airlinesmall.tdms"`

Data Types: `char` | `string`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `ChannelGroupName="Torque",ChannelNames="Torque1"`

Supported name-value pairs are:

`ChannelGroupName` — Channel group containing the channels to read from

string | char

Channel group containing the channels to read from, specified as a string or character vector.

Example: `"Torque"`

Data Types: `string` | `char`

`ChannelNames` — Names of channels to read

char | string | cell

Names of channels to read, specified as a string, string array, character vector, or cell array of character vectors. The channels must be in the channel group specified by `ChannelGroupName`.

Example: `["Torque1" "Torque2"]`

Data Types: `char` | `string` | `cell`

`RowTimes` — Times associated with rows of table

datetime | duration | channel name

Times associated with rows of the table, specified as a selected time channel name, a datetime vector, or a duration vector. Specifying this option causes the function to output a cell array of timetables. Each time element labels a row in the output timetable.

Example: `duration(seconds([1:1000]/1000))`

Data Types: `datetime` | `duration` | `string`

`StartTime` — Start time of output timetable

datetime | duration

Start time of the output timetable, specified as a scalar datetime or duration indicating the time of the first data record in the timetable.

Example: `StartTime=seconds(60)`

Data Types: `datetime` | `duration`

`SampleRate` — Sample rate of output timetable
double

Sample rate of the output timetable, specified as a positive scalar double indicating samples per second.

Example: `SampleRate=1000`

Data Types: `double`

`TimeStep` — Step time of output timetable
duration | calendarDuration

Time step of the output timetable, specified as a scalar duration or calendarDuration indicating the time span between data records.

Example: `TimeStep=seconds(0.01)`

Data Types: `duration` | `calendarDuration`

Output Arguments

`data` — Output data
cell array of tables

Output data, returned as a cell array of tables or timetables with data records from the TDMS-file. Each element of the cell array is a table or timetable for a channel group. The cell array index corresponds to the channel group number.

When the start time for the first sample is 0 and the sample times are relative to that (duration), the sample times returned to the timetable are based on seconds since the epoch in the local time zone equivalent to 01/01/1904 00:00:00.00 UTC (using the Gregorian calendar and ignoring leap seconds). For more information, see TDMS File Format Internal Structure.

Limitations

- TDMS functions are supported on Windows platforms only.

Functions
`tdmsinfo` | `tdmsreadprop`

tdmsreadprop

Read properties as single row table from TDMS-file

Syntax

```
props = tdmsreadprop(tdmsfile)
props = tdmsreadprop(tdmsfile,Name=Value)
```

Description

`props = tdmsreadprop(tdmsfile)` returns a table of properties from the specified TDMS-file.

`props = tdmsreadprop(tdmsfile,Name=Value)` uses name-value pairs to filter the information to get specific properties.

Examples

Read Properties from TDMS-File

Read the high level properties of a TDMS-file.

```
props = tdmsreadprop("Turbine_003.tdms")
```

```
props =

  1×7 table

       name             title         author                        description
    ____________    _____________    ______    ____________________________________________

    "Turbine_003"    "Turbine Tests"    "xyz"     "Test the Acceleration, Force and Torque of Tu
```

Read the properties of one channel group.

```
props = tdmsreadprop("Turbine_003.tdms",ChannelGroupName="Torque")
```

```
props =

  1×2 table

      name       description
    ________    ___________

    "Torque"    "CGTorque"
```

Narrow the scope to a single channel.

```
props = tdmsreadprop("Turbine_003.tdms",ChannelGroupName="Torque",ChannelName="Torque2")
```

```
props =

  1×19 table
```

```
      name         datatype      ...
    _________    ____________    ...

    "Torque2"    "DT_DOUBLE"    ...
```

Filter on specific properties.

```
props = tdmsreadprop("Turbine_003.tdms",PropertyNames=["title" "datetime" "datestring"])
```

```
props =

  1×3 table

        title                   datetime                 datestring
    _______________    ____________________________    ____________

    "Turbine Tests"    2021-10-18 01:57:17.000000000    "10/18/2021"
```

Input Arguments

`tdmsfile` — TDMS file name

string

TDMS file name, specified as a string.

For local files, use a full or relative path that contains a file name and extension. You also can specify a file on the MATLAB path.

For Internet files, specify the URL. For example, to read a remote file from the Amazon S3 cloud:

```
data = tdmsread("s3://bucketname/path_to_file/data.tdms");
```

Example: `"airlinesmall.tdms"`

Data Types: `char` | `string`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `ChannelGroupName="Torque",ChannelName="Torque2"`

Supported name-value pairs are:

`ChannelGroupName` — Channel group containing the channels to read from

string | char

Channel group containing the channels to read from, specified as a string or character vector.

Example: `"Torque"`

Data Types: `string` | `char`

`ChannelName` — Name of channel to read

char | string

Name of channel to read, specified as a string or character vector. The channel must be in the channel group specified by `ChannelGroupName`.

Example: `"Torque2"`

Data Types: `char` | `string`

`PropertyNames` — Property names to read
string | char | cell

Property names to read, specified as a string, string array, character vector, or cell array of character vectors.

Example: `["Torque1" "Torque2"]`

Data Types: `char` | `string` | `cell`

Output Arguments

`props` — Table of properties from TDMS-file
table

Properties in the TDMS-file, returned as a table.

Limitations

- TDMS functions are supported on Windows platforms only.

Functions
`tdmsread` | `tdmsinfo`

tdmswrite

Write data to TDMS-file

Syntax

```
tdmswrite(tdmsfile,tdmsdata)
tdmswrite(tdmsfile,tdmsdata,ChannelGroupNames=chGrpName)
tdmswrite( ___ ,TimeChannel=timeChan)
```

Description

With the `tdmswrite` function you can write table or timetable data to a new or existing TDMS-file.

`tdmswrite(tdmsfile,tdmsdata)` writes data to the specified TDMS-file from a table, timetable, or cell array of tables or timetables. Each table is written to the file as a new channel group, automatically incrementing the channel group name with each write.

`tdmswrite(tdmsfile,tdmsdata,ChannelGroupNames=chGrpName)` specifies an existing channel group to write the data to. When specifying data as a cell array, use a cell array of strings to identify the corresponding channel group names, sequentially mapped by elements.

`tdmswrite( ___ ,TimeChannel=timeChan)` specifies how measurement time is included in the file when writing data from a timetable. A `TimeChannel` value of `"none"` adds the start time and step time to the channel properties. A value of `"single"` adds a single channel with a timestamp for every measurement. If you are writing data from a regular table, the `TimeChannel` setting is ignored.

Examples

Read TDMS File Data

Write data to a specified TDMS-file. You can use default channel groups or specify channel group names.

Write a table or timetable of data, `T`, to a new channel group in the TDMS-file named `sinewave.tdms`.

```
tdmswrite("sinewave.tdms",T)
```

Write table or timetable of data, `T`, to a specific channel group in a TDMS-file. If the channel group does not exist, it is added to the file.

```
tdmswrite("sinewave.tdms", T, ChannelGroupNames="MeasuredData")
```

Write two tables of data to multiple channel groups in a TDMS-file.

```
tdmswrite("sinewave.tdms", {T1,T2}, ChannelGroupNames=["Measurement1" "Measurement2"])
```

Input Arguments

`tdmsfile` — TDMS file name

string

TDMS file name, specified as a string.

For local files, use a full or relative path that contains a file name and extension. You also can specify a file on the MATLAB path.

Example: `"sample332.tdms"`

Data Types: `char` | `string`

`tdmsdata` — TDMS data

table | timetable | cell array of tables and timetables

TDMS data, specified as table, timetable, or cell array of tables and timetables. Alternatively, you can specify several tables or timetables as a series of arguments, such as `T1,T2,T3`.

For a duration timetable, the written start time is 0. When reading this file with `tdmsread`, the start time is the epoch in the local time zone equivalent to 01/01/1904 00:00:00.00 UTC (using the Gregorian calendar and ignoring leap seconds). For more information, see TDMS File Format Internal Structure.

Data Types: `table` | `timetable` | `cell`

`chGrpName` — Channel group name

string | char

Channel group name, specified as a string or character vector. Use an array of channel group names when writing multiple tables.

- If the channel group does not exist in the TDMS-file, a new channel group is created.
- If the channel group exists, data is appended to channels with names matching the table variables. New channels are added to the channel group for table variables not already represented by existing channel names.

Example: `"ChannelGroup1"`

Data Types: `char` | `string` | `cell`

`timeChan` — Time channel format

`"single"` (default) | `"none"`

Time channel format layout, specified as a string or character vector with value `"single"` or `"none"`:

- A value of `"single"` (default) adds a single channel with a timestamp for every measurement. This is appropriate for timetables with irregular timing, when each measurement has a unique datetime or duration, shared across the channels in the channel group. This `Time` channel is derived from the `Time` variable of the input timetable.

- A value of `"none"` adds only the start time and step time to the channel properties `wf_start_time` and `wf_increment`, respectively. Appropriate for regular timetables with fixed sample rates, this option can reduce the size of the TDMS-file.

Example: `"none"`

Data Types: `char` | `string`

Limitations

- TDMS functions are supported on Windows platforms only.

TDMS Fragmentation: Why Your TDMS Files Use Too Much Memory

tdmswriteprop

Write properties to TDMS-file

Syntax

```
tdmswriteprop(tdmsfile,propname,propvalue)
tdmswriteprop(tdmsfile,propname,propvalue,ChannelGroupName=chGrpName)
tdmswriteprop(tdmsfile,propname,propvalue,ChannelGroupName=
chGrpName,ChannelName=chName)
```

Description

With the `tdmswriteprop` function you can write file properties, channel properties and channel group properties to a TDMS-file.

`tdmswriteprop(tdmsfile,propname,propvalue)` writes file property names and corresponding values to the specified TDMS-file. You can set a single property or multiple properties. To set multiple properties, use arrays to specify property names and values. With `tdmswriteprop` you can specify and modify existing properties, or add new properties.

`tdmswriteprop(tdmsfile,propname,propvalue,ChannelGroupName=chGrpName)` and `tdmswriteprop(tdmsfile,propname,propvalue,ChannelGroupName=chGrpName,ChannelName=chName)` specify the existing channel group or channel that the property is assigned to. You can set the properties of only one channel or channel group at a time.

Examples

Write Properties to TDMS-File

Write the `title` file property of a TDMS-file.

```
tdmswriteprop("sinewave.tdms","title","Measurement Data")
```

Write a channel group description property of a TDMS-file.

```
tdmswriteprop("sinewave.tdms","description","Amplitude and Phase Sweep",...
    ChannelGroupName="ChannelGroup1")
```

Write a channel property of a TDMS-file.

```
tdmswriteprop("sinewave.tdms","max_value", max(data), ...
    ChannelGroupName="ChannelGroup1", ChannelName="Amplitude Sweep")
```

Write two properties of a channel.

```
tdmswriteprop("sinewave.tdms",["max_value" "min_value"],[max(data),min(data)] ...
    ChannelGroupName="ChannelGroup1", ChannelName="Amplitude Sweep")
```

Input Arguments

`tdmsfile` — TDMS file name

string | char

TDMS file name, specified as a string or character vector.

For local files, use a full or relative path that contains a file name and extension. You also can specify a file on the MATLAB path.

Example: `"sinewave.tdms"`

Data Types: `char` | `string`

`propname` — Property name
string | char

Property name, specified as a string or character vector. When writing multiple properties, use an array of strings to identify them. To create custom properties, specify a name that does not already exist.

Example: `"title"`

Data Types: `char` | `string`

`propvalue` — Property value
property-dependent

Property value, specified as a supported type for its property. To set multiple properties, use an array of values. If the values are different types, for example numeric and string, use a cell array.

Example: `{"Input Channel",2.0,"mV"}`

`chGrpName` — Channel group name
string | char

Channel group name, specified as a string or character vector.

Example: `"ChannelGroup1"`

Data Types: `char` | `string`

`chName` — Channel name
string | char

Channel name, specified as a string or character vector.

Example: `"Amplitude sweep"`

Data Types: `char` | `string`

Limitations

- TDMS functions are supported on Windows platforms only.

System Objects

comm.ACPR

Package: comm

Measure adjacent channel power ratio (ACPR)

Description

The comm.ACPR System object measures the ACPR of an input signal.

To measure the ACPR of an input signal:

1. Create the comm.ACPR object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
acpr = comm.ACPR
acpr = comm.ACPR(Name,Value)
```

Description

acpr = comm.ACPR creates an ACPR measurement System object.

acpr = comm.ACPR(Name,Value) sets properties on page 3-2 using one or more name-value arguments. For example, comm.ACPR('NormalizedFrequency',true) creates an ACPR measurement object with normalized frequency values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

NormalizedFrequency — Normalized frequency values
0 or false (default) | 1 or true

Normalized frequency values, specified as one of these logical values.

- 0 (false) — Frequency values are measured in Hz.

- `1` (`true`) — Frequency values are normalized in the range [-1, 1].

Data Types: `logical` | `double`

`SampleRate` — Sample rate of input signal
`1000000` (default) | positive scalar

Sample rate of input signal in Hz, specified as a positive scalar.

Dependencies

To enable this property, set the `NormalizedFrequency` property to `false`.

Data Types: `double`

`MainChannelFrequency` — Main channel center frequency
`0` (default) | numeric scalar

Main channel center frequency, specified as a numeric scalar.

- If you set the `NormalizedFrequency` property to `true`, specify the center frequency as a normalized value in the range [−1, 1].
- If you set the `NormalizedFrequency` property to `false`, specify the center frequency in Hz.

This property specifies where the object measures the main channel power in the bandwidth specified by the `MainMeasurementBandwidth` property. For more details on how to set these two properties, see “Algorithms” on page 3-10.

Data Types: `double`

`MainMeasurementBandwidth` — Main channel measurement bandwidth
`50000` (default) | positive scalar

Main channel measurement bandwidth, specified as a positive scalar.

- If you set the `NormalizedFrequency` property to `true`, specify the measurement bandwidth as a normalized value in the range [0, 1].
- If you set the `NormalizedFrequency` property to `false`, specify the measurement bandwidth in Hz.

This property specifies the bandwidth in which the object measures the main channel power. The measurement is taken at the center of the frequency, specified by the `MainChannelFrequency` property. For more details on how to set these two properties, see “Algorithms” on page 3-10.

Data Types: `double`

`AdjacentChannelOffset` — Adjacent channel frequency offsets
`[-100000 100000]` (default) | numeric scalar | numeric row vector

Adjacent channel frequency offsets, specified as a numeric scalar or row vector comprising frequencies that define the location of adjacent channels of interest.

- If you set the `NormalizedFrequency` property to `true`, specify the adjacent channel frequency offsets as normalized values in the range [−1, 1].
- If you set the `NormalizedFrequency` property to `false`, specify the adjacent channel frequency offsets in Hz.

The offset values indicate the distance between the main channel center frequency and adjacent channel center frequencies. Positive offsets indicate adjacent channels to the right of the main channel center frequency. Negative offsets indicate adjacent channels to the left of the main channel center frequency. For more details on how to set properties of the adjacent channels, see “Algorithms” on page 3-10.

Data Types: `double`

`AdjacentMeasurementBandwidth` — Measurement bandwidth for each adjacent channel
`50000` (default) | numeric scalar or row vector

Measurement bandwidth for each adjacent channel, specified as one of these options.

- Numeric scalar — The object obtains all adjacent channel power measurements within equal measurement bandwidths.
- Numeric row vector of length equal to the number of offsets specified in the `AdjacentChannelOffset` property — The object obtains each adjacent channel power measurement based on its specific bandwidth that is centered at the frequency defined by the corresponding frequency offset. The `AdjacentChannelOffset` property defines this frequency offset.

Set the values of this property with respect to the `NormalizedFrequency` property.

- If you set the `NormalizedFrequency` property to `true`, specify the measurement bandwidth values as normalized values in the range [0, 1].
- If you set the `NormalizedFrequency` property to `false`, specify the measurement bandwidth values in Hz.

For more details on how to set properties of the adjacent channels, see “Algorithms” on page 3-10.

Data Types: `double`

`MeasurementFilterSource` — Source of measurement filter
`'None'` (default) | `'Property'`

Source of the measurement filter, specified as one of these values.

- `'None'` — The object does not apply filtering to obtain ACPR measurements.
- `'Property'` — The object applies a measurement filter to the main channel before measuring the average power. Specify the measurement filter coefficients by using the `MeasurementFilter` property. Each of the adjacent channel bands also receives a measurement filter.

Data Types: `char` | `string`

`MeasurementFilter` — Measurement filter coefficients
`1` (default) | numeric row vector

Measurement filter coefficients, specified as a numeric row vector containing the coefficients of an FIR filter in descending polynomial powers. Center the response of the filter at DC. The object automatically shifts and applies the filter response at each of the main and adjacent channel center frequencies before obtaining the average power measurements. The internal filter states persist between calls to the object. To clear the states, call the `reset` object function.

The default value specifies an all-pass filter that has no effect on the measurements.

Dependencies

To enable this property, set the `MeasurementFilterSource` property to `'Property'`.

Data Types: `double`

`SpectralEstimation` — Spectral estimation control

`'Auto'` (default) | `'Specify frequency resolution'` | `'Specify window parameters'`

Spectral estimation control, specified as one of these values.

- `'Auto'` — The object obtains power measurements with a Welch spectral estimator with zero-percent overlap, a Hamming window, and a segment length equal to the length of the input data vector. The spectral estimator set can achieve the maximum frequency resolution that is attainable with the input data length.
- `'Specify frequency resolution'` — The object uses the value specified by the `FrequencyResolution` property to automatically compute the size of the spectral estimator data window.
- `'Specify window parameters'` — The object obtains power measurements with a Welch spectral estimator determined by the `SegmentLength`, `OverlapPercentage`, `Window`, and `SidelobeAttenuation` properties. In this setting, the `FrequencyResolution` property does not apply, but you can use these properties to control also the resolution.

Data Types: `char` | `string`

`SegmentLength` — Segment length for spectral estimator

`64` (default) | positive integer

Segment length for the spectral estimator in samples, specified as a positive integer. The segment length enables you to make tradeoffs between frequency resolution and variance in the spectral estimates. A long segment length results in better resolution. A short segment length results in more averaging and a decrease in variance.

Dependencies

To enable this property, set the `SpectralEstimation` property to `'Specify window parameters'`.

Data Types: `double`

`OverlapPercentage` — Overlap percentage between segments

`0` (default) | numeric scalar in the range [0, 100]

Overlap percentage between segments in the spectral estimator, specified as a numeric scalar in the range [0, 100].

Dependencies

To enable this property, set the `SpectralEstimation` property to `'Specify window parameters'`.

Data Types: `double`

`Window` — Window function for spectral estimator

`'Hamming'` (default) | `'Bartlett'` | `'Bartlett-Hanning'` | `'Blackman'` | `'Blackman-Harris'` | `'Bohman'` | `'Chebyshev'` | `'Flat Top'` | `'Hann'` | `'Nuttall'` | `'Parzen'` | `'Rectangular'` | `'Triangular'`

Window function for the spectral estimator, specified as `'Hamming'`, `'Bartlett'`, `'Bartlett-Hanning'`, `'Blackman'`, `'Blackman-Harris'`, `'Bohman'`, `'Chebyshev'`, `'Flat Top'`, `'Hann'`, `'Nuttall'`, `'Parzen'`, `'Rectangular'`, or `'Triangular'`.

The default Hamming window has a sidelobe attenuation of 42.5 dB. This attenuation can mask spectral content below this value, relative to the peak spectral content. Choosing different windows enables you to make tradeoffs between resolution and sidelobe attenuation.

Dependencies

To enable this property, set the `SpectralEstimation` property to `'Specify window parameters'`.

Data Types: `char` | `string`

`SidelobeAttenuation` — Sidelobe attenuation for Chebyshev window

`100` (default) | nonnegative scalar

Sidelobe attenuation for the Chebyshev window function in dB, specified as a nonnegative scalar.

Dependencies

To enable this property, set the `SpectralEstimation` property to `'Specify window parameters'` and the `Window` property to `'Chebyshev'`.

Data Types: `double`

`FrequencyResolution` — Frequency resolution of spectral estimator

`10625` (default) | numeric scalar

Frequency resolution of the spectral estimator, specified as a numeric scalar.

- If you set the `NormalizedFrequency` property to `true`, specify the frequency resolution as a normalized value in the range [0, 1].
- If you set the `NormalizedFrequency` property to `false`, specify the frequency resolution in Hz.

Dependencies

To enable this property, set the `SpectralEstimation` property to `'Specify frequency resolution'`.

Data Types: `double`

FFTLength — Number of FFT points

`'Next power of 2'` (default) | `'Same as segment length'` | `'Custom'`

Number of fast Fourier transform (FFT) points that the spectral estimator uses, specified as one of these values.

- `'Next power of 2'` — The object sets the number of FFT points to the next power of 2 that is greater than `max(SegmentLength,256)`.
- `'Same as segment length'` — The object sets the number of FFT points to the value of the `SegmentLength` property.
- `'Custom'` — The object sets the number of FFT points to the value of the `CustomFFTLength` property.

Data Types: `char` | `string`

CustomFFTLength — Custom number of FFT points

`256` (default) | positive integer

Custom number of FFT points, specified as a positive integer.

Dependencies

To enable this property, set the `FFTLength` property to `'Custom'`.

Data Types: `double`

MaxHold — Maximum-hold setting control

`0` or `false` (default) | `1` or `true`

Maximum-hold setting control, specified as one of these logical values.

- `0` (`false`) — The object obtains power measurements by using instantaneous power spectral density estimates.
- `1` (`true`) — The object obtains power measurements by comparing two vectors. One vector is the current estimated power spectral density vector (obtained with the current input data frame). The object checks this vector against the previous maximum-hold accumulated power spectral density vector (obtained at the previous call of the object). The object stores the maximum values at each frequency bin and uses these values to compute average power measurements. To clear the maximum-hold spectrum, use the `reset` object function.

Tunable: Yes

Data Types: `logical` | `double`

PowerUnits — Power measurement units

`'dBm'` (default) | `'dBW'` | `'Watts'`

Power measurement units, specified as one of these values.

- `'dBm'` or `'dBW'` — The object returns ACPR measurements in a dBc scale (the adjacent channel power referenced to the main channel power).

- `'Watts'` — The object returns ACPR measurements in a linear scale.

Data Types: `char` | `string`

`MainChannelPowerOutputPort` — Option to enable main channel power measurement output
`0` or `false` (default) | `1` or `true`

Option to enable main channel power measurement output, specified as a logical `0` (`false`) or `1` (`true`). When you set this property to `true`, the object returns the main channel power measurement. The main channel power is the power of the input signal measured in the band specified by the `MainChannelFrequency` and `MainMeasurementBandwidth` properties. The object returns the power measurements in the unit specified by the `PowerUnits` property.

Data Types: `logical` | `double`

`AdjacentChannelPowerOutputPort` — Option to enable adjacent channel power measurements output
`0` or `false` (default) | `1` or `true`

Option to enable adjacent channel power measurements output, specified as a logical `0` (`false`) or `1` (`true`). When you set this property to `true`, the object returns a vector containing adjacent channel power measurements. The adjacent channel powers correspond to the power of the input measured in the bands specified by the `AdjacentChannelOffset` and `AdjacentMeasurementBandwidth` properties. The object returns the power measurements in the unit specified by the `PowerUnits` property.

Data Types: `logical` | `double`

Usage

Syntax

```
adjChPowRatio = acpr(signal)
[adjChPowRatio,mainChPow] = acpr(signal)
[adjChPowRatio,adjChPow] = acpr(signal)
[adjChPowRatio,mainChPow,adjChPow] = acpr(signal)
```

Description

`adjChPowRatio = acpr(signal)` measures the ACPR in input data `signal`. The measurements are at the frequency bands specified by the `MainChannelFrequency`, `MainMeasurementBandwidth`, `AdjacentChannelOffset`, and `AdjacentMeasurementBandwidth` properties.

`[adjChPowRatio,mainChPow] = acpr(signal)` measures the main channel power, `mainChPow`. To use this syntax, set the `MainChannelPowerOutputPort` property to `true`. The main channel power is measured within the main channel frequency band specified by the `MainChannelFrequency` and `MainMeasurementBandwidth` properties.

`[adjChPowRatio,adjChPow] = acpr(signal)` measures the adjacent channel powers, `adjChPow`. To use this syntax, set the `AdjacentChannelPowerOutputPort` property to `true`. The

adjacent channel powers are measured at the adjacent frequency bands specified by the `AdjacentChannelOffset` and `AdjacentMeasurementBandwidth` properties.

`[adjChPowRatio,mainChPow,adjChPow] = acpr(signal)` measures the ACPR, the main channel power, and adjacent channel powers. To use this syntax, set the `MainChannelPowerOutputPort` and `AdjacentChannelPowerOutputPort` properties to `true`.

Input Arguments

`signal` — Input signal
column vector of complex numbers

Input signal, specified as a column vector of complex numbers.

Data Types: `double`
Complex Number Support: Yes

Output Arguments

`adjChPowRatio` — ACPR measurements
numeric row vector

ACPR measurements, returned as a numeric row vector. The length of the vector equals the number of adjacent channels specified by the `AdjacentChannelOffset` property.

Data Types: `double`

`mainChPow` — Main channel power measurements
numeric scalar

Main channel power measurements, returned as a numeric scalar. The `PowerUnits` property specifies the units used for the returned value.

Data Types: `double`

`adjChPow` — Adjacent channel power measurements
numeric row vector

Adjacent channel power measurements, returned as a numeric row vector. The length of the vector equals the number of adjacent channels specified by the `AdjacentChannelOffset` property. The `PowerUnits` property specifies the units used for the returned value.

Data Types: `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics

reset Reset internal states of System object

Examples

Measure ACPR of 16-QAM Signal

Generate data with an alphabet size of 16, and then modulate the data.

```
x = randi([0 15],5000,1);
y = qammod(x,16);
```

Upsample the data by using a rectangular pulse shape.

```
L = 8;
yPulse = rectpulse(y,L);
```

Create an ACPR measurement object.

```
acpr = comm.ACPR(...
    'SampleRate',3.84e6*8, ...
    'MainChannelFrequency',0, ...
    'MainMeasurementBandwidth',3.84e6, ...
    'AdjacentChannelOffset',[-5e6 5e6], ...
    'AdjacentMeasurementBandwidth',3.84e6, ...
    'MainChannelPowerOutputPort',true, ...
    'AdjacentChannelPowerOutputPort',true);
```

Measure the ACPR, main channel power, and adjacent channel powers of the modulated signal.

```
[adjChPowRatio,mainChPow,adjChPow] = acpr(yPulse)
```

```
adjChPowRatio = 1×2

  -14.3659  -14.3681

mainChPow = 38.8668

adjChPow = 1×2

   24.5010   24.4988
```

Algorithms

To comply with the Nyquist sampling theorem, these conditions must be satisfied when you set the frequencies and measurement bandwidths of the main and adjacent channels.

$$\left|\text{MainChannelFrequency} \pm \frac{\text{MainMeasurementBandwidth}}{2}\right| < F_{\max}$$

$$\left|(\text{MainChannelFrequency} + \text{AdjacentChannelOffset}) \pm \frac{\text{AdjacentMeasurementBandwidth}}{2}\right| < F_{\max}$$

If you set the `NormalizedFrequency` property to `false`, $F_{\max} = F_s/2$, where F_s is the sampling frequency specified by the `SampleRate` property.

If you set the `NormalizedFrequency` property to `true`, $F_{max} = 1$.

comm.AGC

Package: comm

Adaptively adjust gain for constant signal level output

Description

The comm.AGC System object creates an automatic gain controller (AGC) that adaptively adjusts its gain to achieve a constant signal level at the output. For more information, see “Logarithmic-Loop AGC” on page 3-27. This object is designed for streaming applications. For more information, see “Tips” on page 3-29.

To adaptively adjust gain for a constant signal level at the output:

1. Create the comm.AGC object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
agc = comm.AGC
agc = comm.AGC(Name,Value)
```

Description

agc = comm.AGC creates an AGC System object that adaptively adjusts its gain to achieve a constant signal level at the output.

agc = comm.AGC(Name,Value) set properties using one or more name-value pairs. Enclose each name in quotes. For example, 'AdaptationStepSize',0.05 sets the step size for gain updates to 0.05.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

AdaptationStepSize — Step size for gain updates
0.01 (default) | positive scalar

Step size for gain updates, specified as a positive scalar. Increasing the step size enables the AGC to respond more quickly to changes in the input signal level but increases variation in the output signal level after reaching steady-state operation. For more information, see “AGC Performance Criteria” on page 3-29, and the “Vary AGC Step Size” on page 3-19, and “Plot Effect of Step Size on AGC Performance” on page 3-22 examples.

Tunable: Yes

Data Types: `double`

`DesiredOutputPower` — Target output power level
`1` W (default) | positive scalar

Target output power level, specified as a positive scalar. The power is measured in Watts referenced to 1 ohm. For more information, see the “Adaptively Adjust Received Signal Amplitude Using AGC” on page 3-21 example.

Data Types: `double`

`AveragingLength` — Length of averaging window
`100` samples (default) | positive integer

Length of the averaging window in samples, specified as a positive integer. For more information on how the averaging length influences the variance of the AGC output signal in steady-state operation and the execution speed, see “Tips” on page 3-29 and the “Vary AGC Averaging Length” on page 3-14 example.

Data Types: `double`

`MaxPowerGain` — Maximum power gain
`60` dB (default) | positive scalar

Maximum power gain in decibels, specified as a positive scalar. Large gain adjustments can cause clipping when a small input signal power suddenly increases. Use this property to avoid large gain adjustments by limiting the gain that the AGC applies to the input signal. For more information, see the “Vary AGC Maximum Gain” on page 3-16 and “Demonstrate Effect of Maximum AGC Gain on Packet Data” on page 3-25 examples.

Data Types: `double`

Usage

Syntax

```
y = agc(x)
[y,powerlevel] = agc(x)
```

Description

`y = agc(x)` adaptively adjusts the gain to the input signal to achieve a reference signal level at the output. The AGC System object uses a square law detector to determine the output signal level. For more information, see “AGC Detector” on page 3-28.

`[y,powerlevel] = agc(x)` returns `powerlevel`, the power level estimate of the input signal. You can use `powerlevel` as an energy detector output.

Input Arguments

x — Input signal
column vector

Input signal, specified as a column vector.

Data Types: `single` | `double`

Output Arguments

y — Output signal
column vector

Output signal, returned as a column vector. The output signal is the same data type as the input signal, `x`.

`powerlevel` — Power level estimate
N_S-element column vector

Power level estimate, returned as an N_S-element column vector. N_S is the length of the input signal, `x`. You can use `powerlevel` as an energy detector output.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Vary AGC Averaging Length

Apply different AGC averaging lengths to QAM-modulated signals. Compare the variance and plot of the signals after AGC is applied.

Create three AGC System objects with their average window lengths set to 10, 100, and 1000 samples, respectively.

```
agc1 = comm.AGC('AveragingLength',10);
agc2 = comm.AGC('AveragingLength',100);
agc3 = comm.AGC('AveragingLength',1000);
```

Generate 16-QAM modulated and raised cosine pulse shaped packetized data.

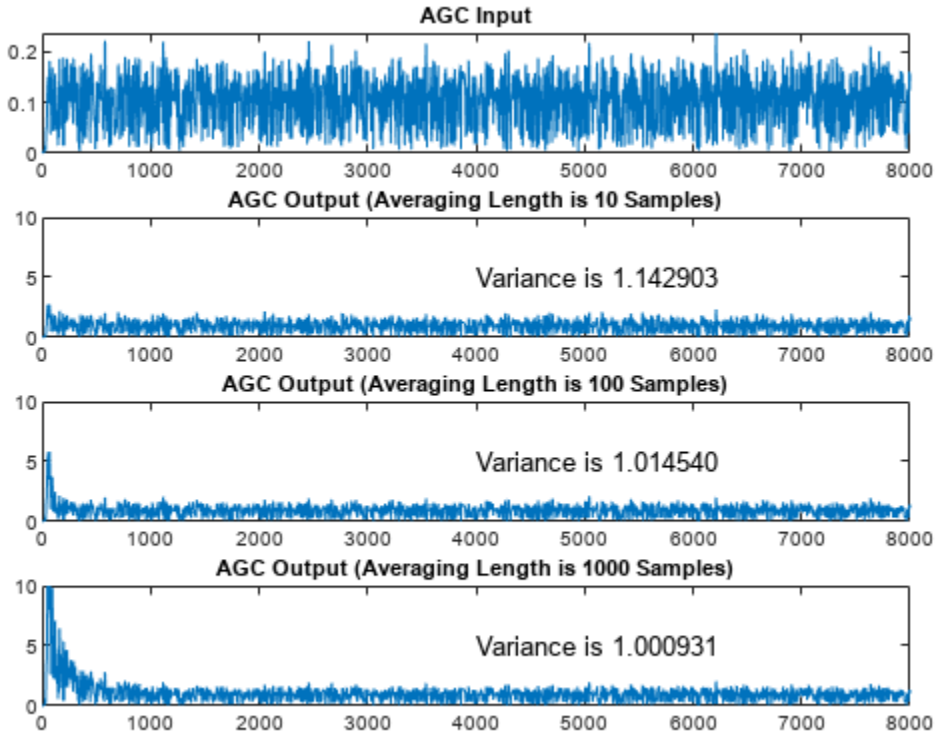
```
M = 16;
d = randi([0 M-1],1000,1);
s = qammod(d,M);
x = 0.1*s;
pulseShaper = comm.RaisedCosineTransmitFilter;
y = awgn(pulseShaper(x),inf);
```

Apply AGC to the data capturing separate outputs for each AGC object.

```
r1 = agc1(y);
r2 = agc2(y);
r3 = agc3(y);
```

Plot and compare the signals. As the averaging length increases, the variance at the output of AGC decreases.

```
figure(1)
subplot(4,1,1)
plot(abs(y))
title('AGC Input')
subplot(4,1,2)
plot(abs(r1))
axis([0 8000 0 10])
title('AGC Output (Averaging Length is 10 Samples)')
text(4000,5,sprintf('Variance is %f',var(r1(3000:end))))
subplot(4,1,3)
plot(abs(r2))
axis([0 8000 0 10])
title('AGC Output (Averaging Length is 100 Samples)')
text(4000,5,sprintf('Variance is %f',var(r2(3000:end))))
subplot(4,1,4)
plot(abs(r3))
axis([0 8000 0 10])
title('AGC Output (Averaging Length is 1000 Samples)')
text(4000,5,sprintf('Variance is %f',var(r3(3000:end))))
```



Vary AGC Maximum Gain

Apply different AGC maximum gain levels to QPSK-modulated signals. Compare the plot of the signals after AGC is applied.

Create three AGC System objects with their maximum gain values set to 10, 20, and 30 dB, respectively.

```
agc1 = comm.AGC('MaxPowerGain',10);
agc2 = comm.AGC('MaxPowerGain',20);
agc3 = comm.AGC('MaxPowerGain',30);
```

Generate QPSK-modulated data. Pass the data through raised cosine pulse shaped filtering and an AWGN channel.

```
M = 4;
pktLen = 10000;
d = randi([0 M-1],pktLen,1);
s = pskmod(d,M,pi/4);
x = repmat([zeros(pktLen,1); 0.3*s],3,1);
pulseShaper = comm.RaisedCosineTransmitFilter;
y = awgn(pulseShaper(x),50);
```

Apply AGC to the data capturing separate outputs for each AGC object.

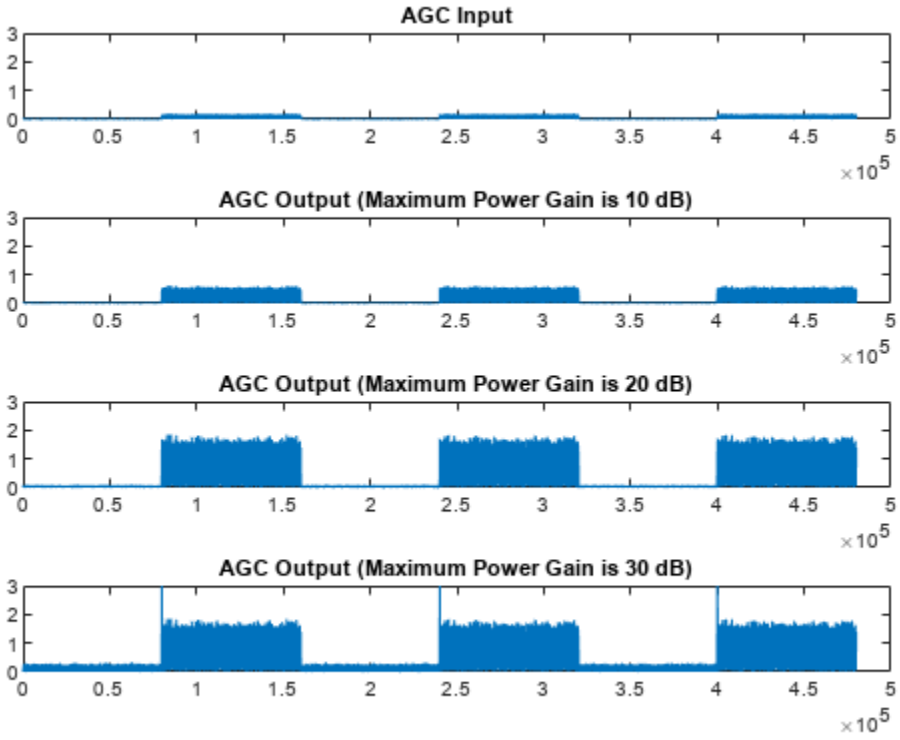
```
r1 = agc1(y);
r2 = agc2(y);
r3 = agc3(y);
```

Plot the input signal and the AGC-adjusted signal with various maximum gain levels. Compare the results for the conditions in this example.

- A maximum gain setting of 10 dB is too small, and the AGC output does not reach the desired output signal level risking data loss due to decreased signal dynamic range.
- A maximum gain setting of 20 dB is optimal, and the AGC output reaches the desired level without signal loss due to saturation.
- A maximum gain setting of 30 dB is too large, and the AGC output overshoots the desired signal level risking signal saturation and data loss at the start of received packets.
- Between packets the input signal contains only noise.

As shown in the plots, the packet transmissions have extended periods when no data is received. The extended periods with no data received results in AGC increasing to the maximum gain setting. If a packet arrives when the AGC gain is too high, the output power overshoots the desired signal level until the AGC can respond to the change in the input power level and reduce its gain.

```
limits = [0 3];
figure(1)
subplot(4,1,1)
plot(abs(y))
ylim(limits)
title('AGC Input')
subplot(4,1,2)
plot(abs(r1))
ylim(limits)
title('AGC Output (Maximum Power Gain is 10 dB)')
subplot(4,1,3)
plot(abs(r2))
ylim(limits)
title('AGC Output (Maximum Power Gain is 20 dB)')
subplot(4,1,4)
plot(abs(r3))
ylim(limits)
title('AGC Output (Maximum Power Gain is 30 dB)')
```



Show Power Level Estimate Output from AGC

Plot a signal and the power level estimate. Compare the results. The power level estimate can serve as a power detector, indicating exactly when the received packet has arrived.

Create an AGC System object with its maximum gain value set to 20 dB.

```
agc20 = comm.AGC('MaxPowerGain',20);
```

Generate QPSK-modulated data. Pass the data through raised cosine pulse shaped filtering and an AWGN channel.

```
modOrd = 4; % Modulation order
pktLen = 10000; % Packet length
d = randi([0 modOrd-1],pktLen,1);
s = pskmod(d,modOrd,pi/4);
x = repmat([zeros(pktLen,1); 0.3*s],3,1);
pulseShaper = comm.RaisedCosineTransmitFilter;
y = awgn(pulseShaper(x),50);
```

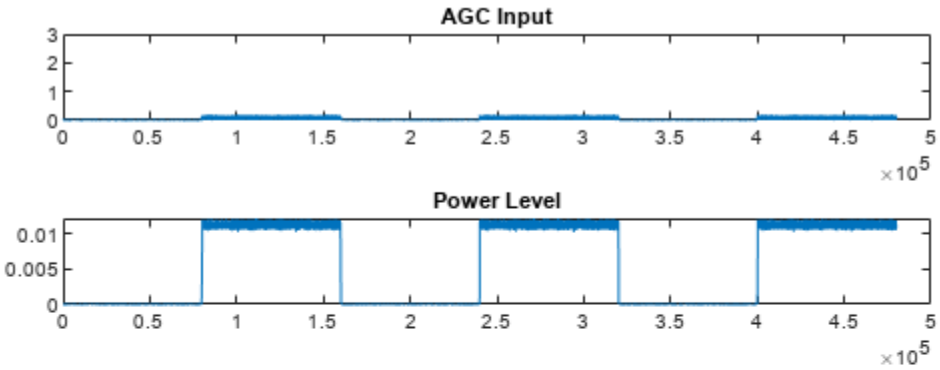
Apply AGC to the data capturing separate outputs for each AGC object.

```
[r2,p2] = agc20(y);
```

Plot the input signal and the received signal power level estimate. Compare the results. Reception of packetized data with extended periods when no data is received results in the detected power level

estimate decreasing to nearly zero. While an input signal is detected, the output power level estimate, p2, serves as a power detector, indicating exactly when the received packet has arrived.

```
limits = [0 3];
figure(1)
subplot(4,1,1)
plot(abs(y))
ylim(limits)
title('AGC Input')
subplot(4,1,2)
plot(abs(p2))
title('Power Level')
```



Vary AGC Step Size

Apply different AGC step sizes to QPSK-modulated signals. Compare the signals after applying AGC.

Create three AGC System objects with their step sizes set to 1e-1, 1e-3, and 1e-4, respectively.

```
agc1 = comm.AGC('AdaptationStepSize',1e-1);
agc2 = comm.AGC('AdaptationStepSize',1e-3);
agc3 = comm.AGC('AdaptationStepSize',1e-4);
```

Generate QPSK-modulated data with raised cosine pulse shaping.

```
d = randi([0 3],500,1);
s = pskmod(d,4,pi/4);
x = 0.1*s;
pulseShaper = comm.RaisedCosineTransmitFilter;
y = pulseShaper(x);
```

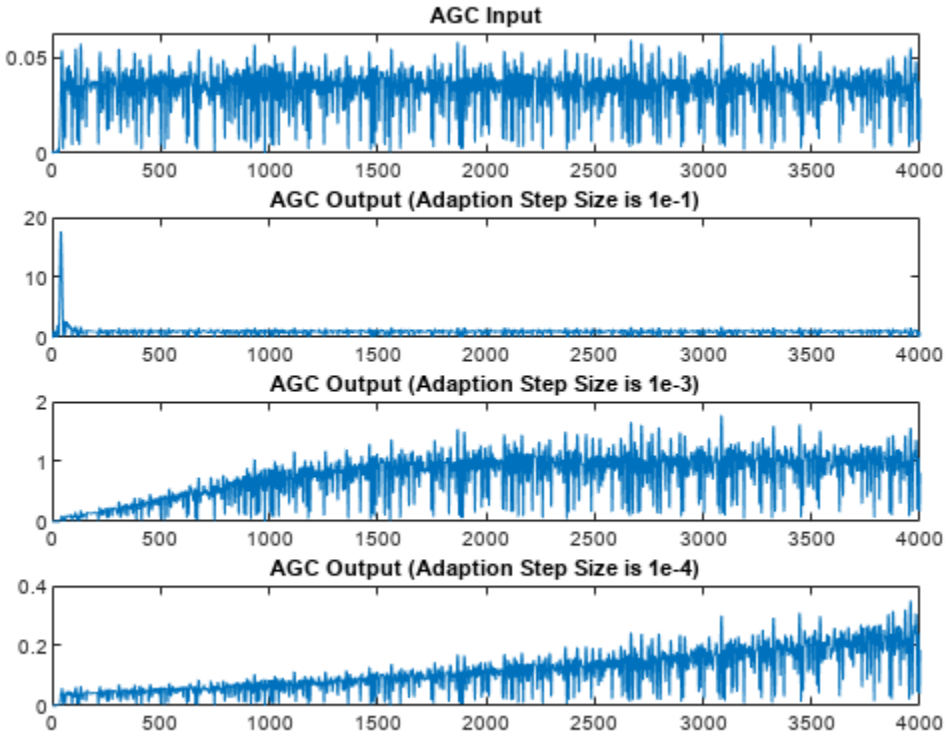
Apply AGC to the data capturing separate outputs for each AGC object.

```
r1 = agc1(y);
r2 = agc2(y);
r3 = agc3(y);
```

Plot the input and output signal after the various AGC step sizes.

- With the step size set to 1e-1, the AGC output signal overshoot is evident. The output signal converges very quickly.
- With the step size set to 1e-3, the AGC output signal overshoot disappears. The output signal gradually converges.
- With the step size set to 1e-4, the AGC output signal takes 2 to 3 times longer to converge than a step size of 1e-3.

```
figure
subplot(4,1,1)
plot(abs(y))
title('AGC Input')
subplot(4,1,2)
plot(abs(r1))
title('AGC Output (Adaption Step Size is 1e-1)')
subplot(4,1,3)
plot(abs(r2))
title('AGC Output (Adaption Step Size is 1e-3)')
subplot(4,1,4)
plot(abs(r3))
title('AGC Output (Adaption Step Size is 1e-4)')
```



Adaptively Adjust Received Signal Amplitude Using AGC

Modulate and amplify a QPSK signal. Set the received signal amplitude to approximately 1 volt by using an AGC. Plot the output.

Create a QPSK-modulated signal by using the QPSK System object.

```
data = randi([0 3],1000,1);
qpsk = comm.QPSKModulator;
modData = qpsk(data);
```

Attenuate the modulated signal.

```
txSig = 0.1*modData;
```

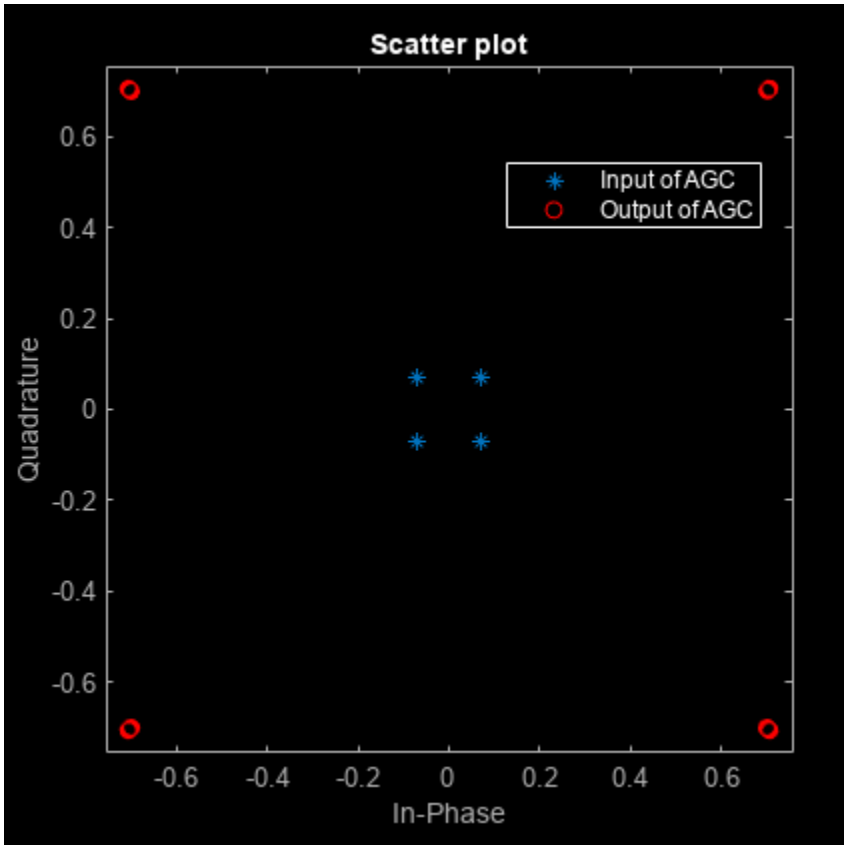
Create an AGC System object and pass the transmitted signal through it. The AGC adjusts the received signal power to approximately 1 W.

```
agc = comm.AGC;
rxSig = agc(txSig);
```

Plot the signal constellations of the transmit and received signals after the AGC reaches steady-state.

```
h = scatterplot(txSig(200:end),1,0,'*');
hold on
```

```
scatterplot(rxSig(200:end),1,0,'or',h);
legend('Input of AGC','Output of AGC')
```



Measure and compare the power of the transmitted and received signals after the AGC reaches a steady state. The power of the transmitted signal is 100 times smaller than the power of the received signal.

```
txPower = var(txSig(200:end));
rxPower = var(rxSig(200:end));
[txPower rxPower]
```

```
ans = 1×2

    0.0100    0.9970
```

Plot Effect of Step Size on AGC Performance

Create two AGC System objects™ to adjust the level of the received signal using two different step sizes with identical update periods.

Generate an 8-PSK signal such that its power is 10 W.

```
data = randi([0 7],200,1);
modData = sqrt(10)*pskmod(data,8,pi/8,'gray');
```

Create a pair of raised cosine matched filters with their `Gain` property set so that they have unity output power.

```
txfilter = comm.RaisedCosineTransmitFilter('Gain',sqrt(8));
rxfilter = comm.RaisedCosineReceiveFilter('Gain',sqrt(1/8));
```

Filter the modulated signal through the raised cosine transmit filter.

```
txSig = txfilter(modData);
```

Create two AGC System objects to adjust the received signal level. Set a step size of 0.01 and 0.1, respectively.

```
agc1 = comm.AGC('AdaptationStepSize',0.01);
agc2 = comm.AGC('AdaptationStepSize',0.1);
```

Apply AGC to the modulated signal capturing separate outputs for each AGC object.

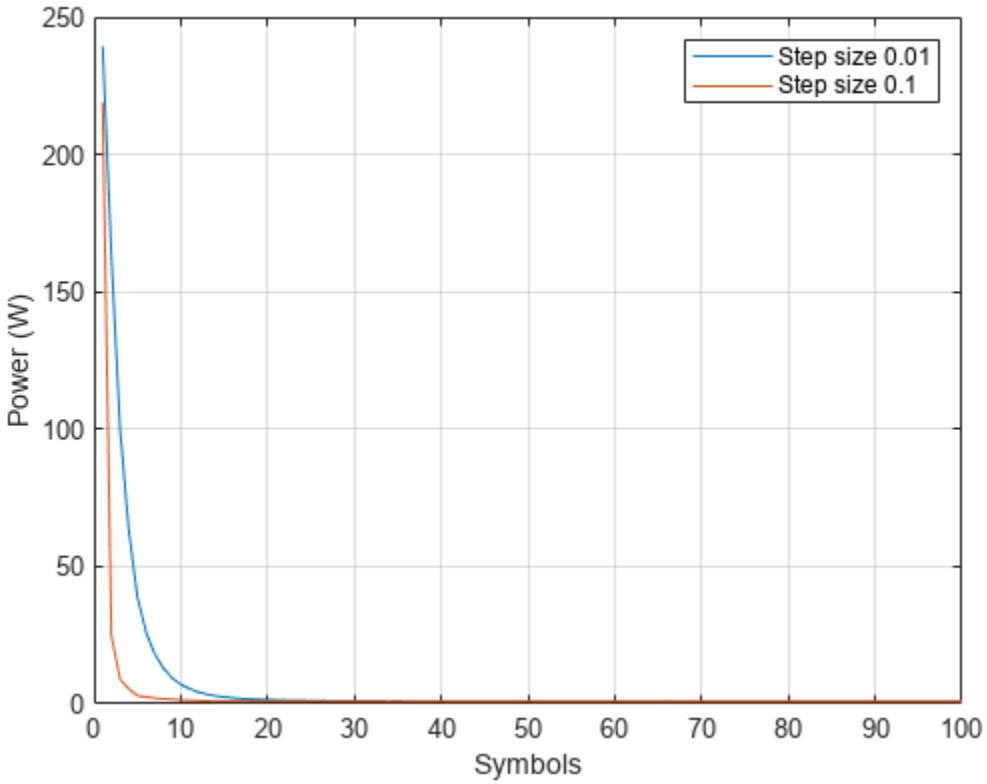
```
agcOut1 = agc1(txSig);
agcOut2 = agc2(txSig);
```

Filter the AGC output signals by using the raised cosine receive filter.

```
rxSig1 = rxfilter(agcOut1);
rxSig2 = rxfilter(agcOut2);
```

Plot the power of the filtered AGC responses while accounting for the 10 symbol delay through the transmit-receive filter pair.

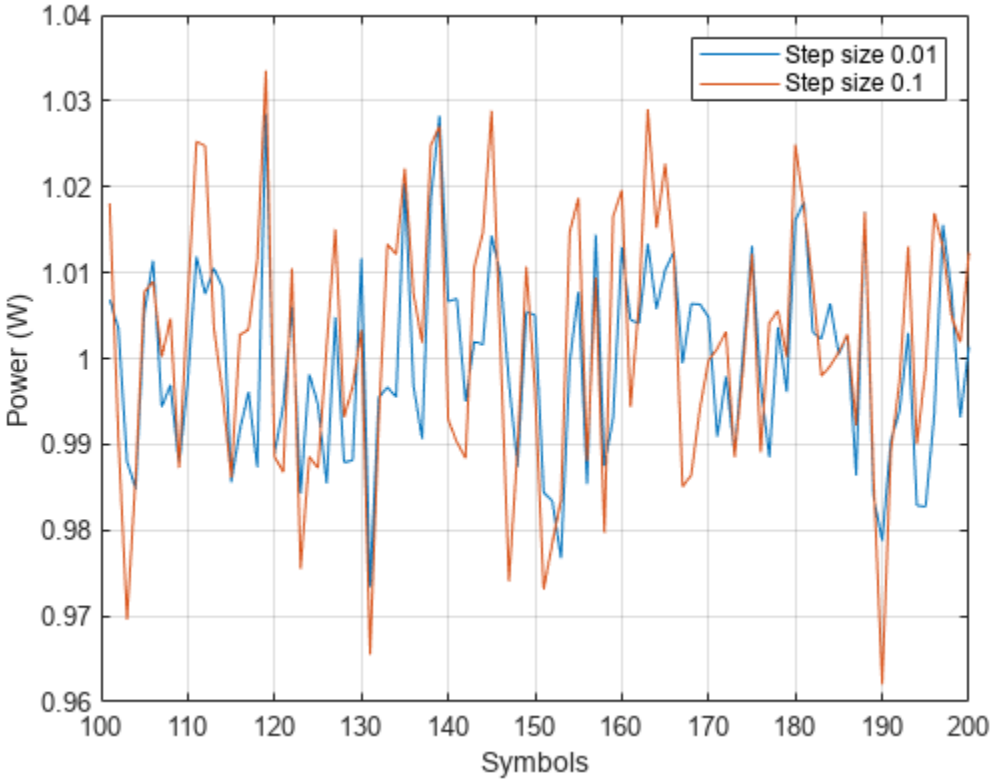
```
plot([abs(rxSig1(11:110)).^2 abs(rxSig2(11:110)).^2])
grid on
xlabel('Symbols')
ylabel('Power (W)')
legend('Step size 0.01','Step size 0.1')
```



The signal with the larger step size converges faster to the AGC target power level of 1 W.

Plot the power of the steady-state filtered AGC signals by including only the last 100 symbols. The larger AGC step size results in less accurate gain correction. Larger AGC step size values result in faster convergence at the expense of less accurate gain control.

```
plot((101:200),[abs(rxSig1(101:200)).^2 abs(rxSig2(101:200)).^2])
grid on
xlabel('Symbols')
ylabel('Power (W)')
legend('Step size 0.01','Step size 0.1')
```



Demonstrate Effect of Maximum AGC Gain on Packet Data

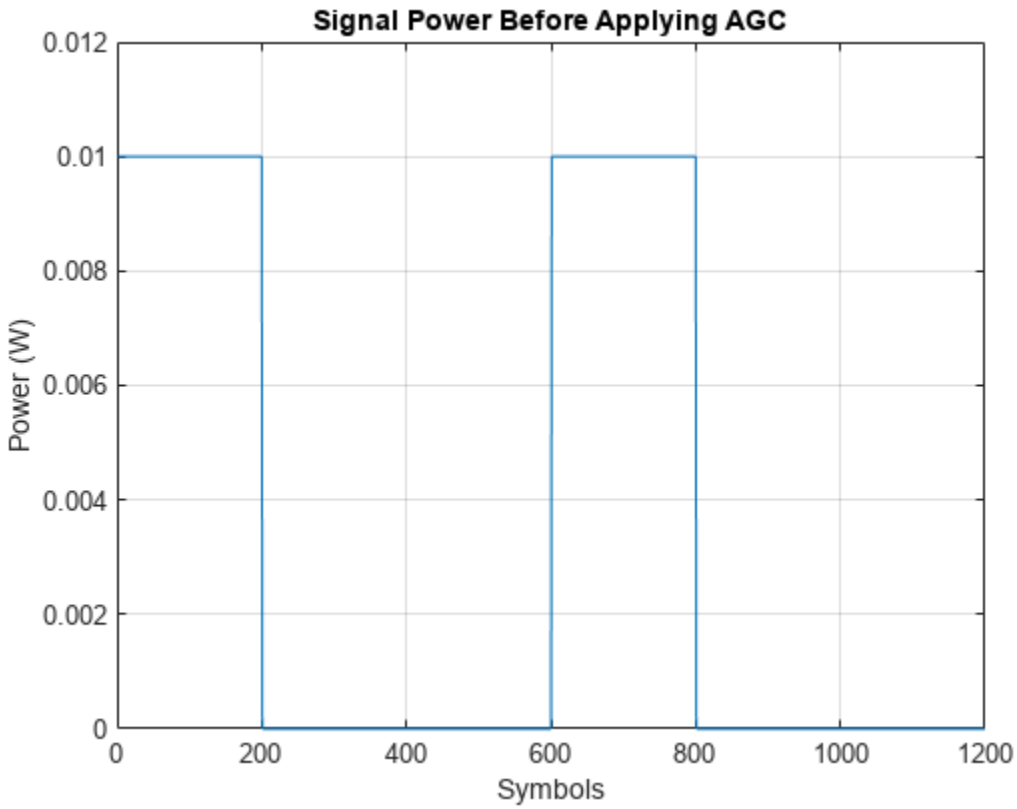
Pass attenuated QPSK packet data to two AGCs with different maximum gains. Plot the results.

Create two, 200-symbol QSPK data packets. Transmit the packets over a 1200-symbol frame.

```
modData1 = pskmod(randi([0 3],200,1),4,pi/4);
modData2 = pskmod(randi([0 3],200,1),4,pi/4);
txSig = [modData1; zeros(400,1); modData2; zeros(400,1)];
```

Attenuate the transmitted burst signal by 20 dB and plot its power.

```
rxSig = 0.1*txSig;
rxSigPwr = abs(rxSig).^2;
plot(rxSigPwr)
grid
xlabel('Symbols')
ylabel('Power (W)')
title('Signal Power Before Applying AGC')
```



Create two AGCs with maximum power gains of 30 dB and 24 dB, respectively.

```
agc1 = comm.AGC('MaxPowerGain',30,'AdaptationStepSize',0.02);

agc2 = comm.AGC('MaxPowerGain',24,'AdaptationStepSize',0.02);
```

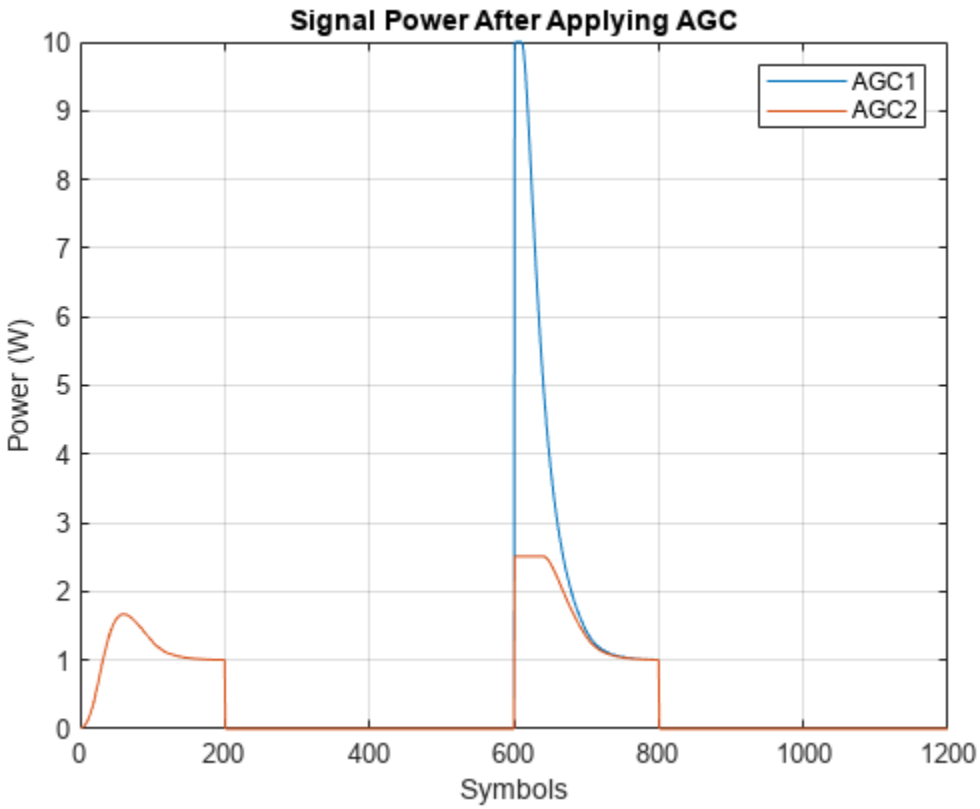
Apply AGC to the attenuated signal capturing separate outputs for each AGC object. Calculate the output power for each case.

```
rxAGC1 = agc1(rxSig);
rxAGC2 = agc2(rxSig);

pwrAGC1 = abs(rxAGC1).^2;
pwrAGC2 = abs(rxAGC2).^2;
```

Plot the output powers. Initially, for the second packet, the `agc1` output signal power is too high because the AGC applied its maximum gain during the period when no data was transmitted. The corresponding `agc2` output signal power (2.5 W) overshoots the target power level of 1 W by significantly less than the `agc1` output signal power (10 W). The convergence time for `agc2` is shorter than the convergence time for `agc1`, because the signal input to `agc2` applies a smaller maximum gain than `agc1`.

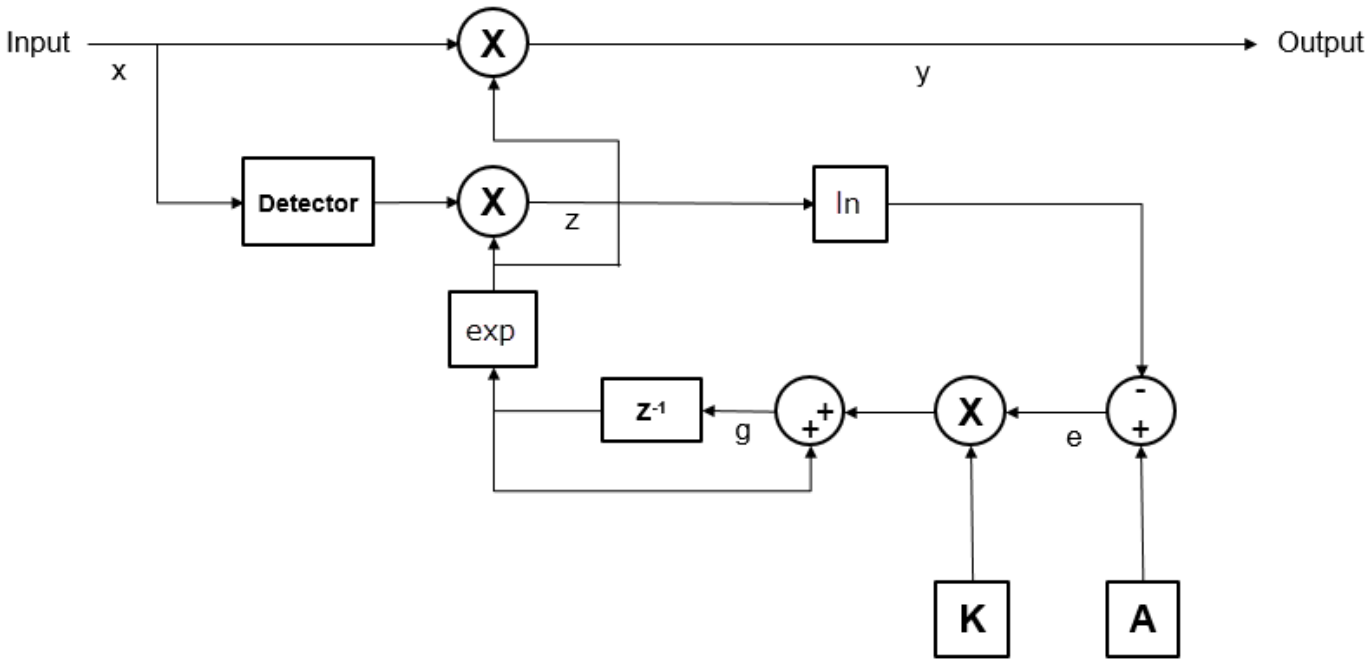
```
plot([pwrAGC1 pwrAGC2])
legend('AGC1','AGC2')
grid
xlabel('Symbols')
ylabel('Power (W)')
title('Signal Power After Applying AGC')
```



More About

Logarithmic-Loop AGC

The AGC implementation uses a logarithmic feedback loop. As this figure of the logarithmic-loop AGC algorithm shows, the output signal is the product of the input signal and the exponential of the loop gain. The error signal is the difference between the reference level and the product of the logarithm of the detector output and the exponential of the loop gain. After multiplying by the step size, the AGC passes the error signal to an integrator.



The logarithmic-loop AGC performs well for a variety of signal types, including amplitude modulation. The "AGC Detector" on page 3-28 is applied to the input signal, which improves convergence times, but increases signal power variation at the detector input. Large signal variation at the detector input is acceptable for floating-point systems.

Mathematically, the algorithm is summarized as

$$y(n) = x(n) \cdot \exp(g(n-1)),$$
$$z(n) = D(x(n)) \cdot \exp(2g(n-1)),$$
$$e(n) = A - \ln(z(n)), \text{ and}$$
$$g(n) = g(n-1) + K \cdot e(n),$$

where:

- x is the input signal.
- y is the output signal.
- g is the loop gain.
- $D(\bullet)$ is the detector function.
- z is the detector output.
- A is the reference value.
- e is the error signal.
- K is the step size.

AGC Detector

The AGC detector output, z, computes a square law detector given by

$$z(m) = \frac{1}{N}\sum_{n=mN}^{(m+1)N-1} |y(n)|^2,$$

where N is the update period. The square law detector produces an output proportional to the square of the input signal y.

AGC Performance Criteria

Increasing the step size decreases the attack time and decay times, but it also increases gain pumping.

- Attack time — The duration taken for the AGC to respond to an increase in the input amplitude
- Decay time — The duration taken for the AGC to respond to a decrease in the input amplitude
- Gain pumping — The variation in the gain value during steady-state operation

Tips

- This System object is designed for streaming applications.
- If the signal amplitude does not change within the frame, you can simulate an ideal AGC by calculating the average gain desired for a frame of samples. Then, apply the gain to each sample in the frame.
- If you use the AGC with higher order QAM signals, you might need to reduce the variation in the gain during steady-state operation. Inspect the constellation diagram at the output of the AGC during steady-state operation. You can increase the averaging length to avoid frequent gain adjustments. An increase in averaging length reduces execution speed.

AGC

comm.APPDecoder

Package: comm

Decode convolutional code by using APP method

Description

The APPDecoder System object performs a posteriori probability (APP) decoding of a convolutional code.

To decode convolutional code by using APP method:

1. Create the comm.APPDecoder object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
appDec = comm.APPDecoder
appDec = comm.APPDecoder(Name,Value)
appDec = comm.APPDecoder(trellis,Name,Value)
```

Description

appDec = comm.APPDecoder creates an APP decoder System object, appDec, that decodes a convolutional code using the APP method.

appDec = comm.APPDecoder(Name,Value) sets properties using one or more name-value pairs. For example, comm.APPDecoder('Algorithm','True APP') configures the System object, appDec, to implement true a posteriori probability decoding. Enclose each property name in quotes.

appDec = comm.APPDecoder(trellis,Name,Value) creates an APP decoder object, appDec, with the TrellisStructure property set to trellis.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

TrellisStructure — Trellis description of constituent convolutional code
poly2trellis(7,[171 133],171) (default) | structure

Trellis description, specified as a MATLAB structure that contains the trellis description for a rate K/N code. K represents the number of input bit streams, and N represents the number of output bit streams.

You can either use the `poly2trellis` function to create the trellis structure or create it manually. For more about this structure, see “Trellis Description of a Convolutional Code” and the `istrellis` function.

The trellis structure contains these fields.

`numInputSymbols` — Number of symbols input to encoder
2^K

Number of symbols input to the encoder, specified as an integer equal to 2^K, where K is the number of input bit streams.

Data Types: `double`

`numOutputSymbols` — Number of symbols output from encoder
2^N

Number of symbols output from the encoder, specified as an integer equal to 2^N, where N is the number of output bit streams.

Data Types: `double`

`numStates` — Number of states in encoder
power of 2

Number of states in the encoder, specified as a power of 2.

Data Types: `double`

`nextStates` — Next states
matrix of integers

Next states for all combinations of current states and current inputs, specified as a matrix of integers. The matrix size must be `numStates` by 2^K.

Data Types: `double`

`outputs` — Outputs
matrix of octal numbers

Outputs for all combinations of current states and current inputs, specified as a matrix of octal numbers. The matrix size must be `numStates` by 2^K.

Data Types: `double`

Data Types: `struct`

`TerminationMethod` — Termination method of encoded frame
`'Truncated'` (default) | `'Terminated'`

Termination method of encoded frame, specified as `'Truncated'` or `'Terminated'`. When you set this property to `'Truncated'`, this System object assumes that the encoder stops after encoding the last symbol in the input frame. When you set this property to `'Terminated'`, this System object assumes that the encoder forces the trellis to end each frame in the all-zeros state by encoding additional symbols. If you use the `comm.ConvolutionalEncoder` System object to generate the encoded frame, this property value must match the property value of the convolutional encoder and this System object.

Data Types: `char` | `string`

`Algorithm` — Decoding algorithm
`'Max*'` (default) | `'True APP'` | `'Max'`

Decoding algorithm, specified as `'Max*'`, `'True APP'`, or `'Max'`. When you set this property to `'True APP'`, this System object implements true APP decoding. When you set this property to any other value, this System object uses approximations to increase the speed of the computations. For more information, see “Algorithms” on page 3-39.

Data Types: `char` | `string`

`NumScalingBits` — Number of scaling bits
3 (default) | integer in the range [0, 8]

Number of scaling bits, specified as an integer in the range [0, 8]. This property specifies the number of bits the decoder uses to scale the input data to avoid losing precision during the computations.

Dependencies

To enable this property, set the “Algorithm” on page 3-0 property to `'Max*'`.

Data Types: `double`

`CodedBitLLROutputPort` — Option to enable coded-bit log-likelihood ratio output
`true or 1` (default) | `false or 0`

Option to enable coded-bit log-likelihood ratio (LLR) output, specified as a numeric or logical `1` (`true`) or `0` (`false`). To disable the second output when you call this System object, set this property to `0` (`false`).

Data Types: `logical`

Usage

Syntax

```
[LUD,LCD] = appDec(LU,LC)
LUD = appDec(LU,LC)
```

Description

`[LUD,LCD] = appDec(LU,LC)` performs APP decoding on the sequence of LLRs of encoder input bits, `LU`, and the sequence of LLRs of encoded bits, `LC`. The System object returns `LUD` and `LCD`.

These output values are the updated versions of `LU` and `LC`, respectively, and are obtained based on the encoder information.

`LUD = appDec(LU,LC)` performs APP decoding with the `LCD` output disabled. To disable the `LCD` output, set the "CodedBitLLROutputPort" on page 3-0 property to `0` (`false`).

Input Arguments

`LU` — Sequence of LLRs of encoder input data

real-valued column vector

Sequence of LLRs of encoder input data, specified as a real-valued column vector. A positive soft input is interpreted as a logical `1`, and a negative soft input is interpreted as a logical `0`.

Data Types: `single` | `double`

`LC` — Sequence of LLRs of encoded data

real-valued column vector

Sequence of LLRs of encoded data, specified as a real-valued column vector of. A positive soft input is interpreted as a logical `1`, and a negative soft input is interpreted as a logical `0`.

Data Types: `single` | `double`

Output Arguments

`LUD` — Updated value of `LU`

real-valued column vector

Updated value of LU, returned as a real-valued column vector.

Data Types: `single` | `double`

`LCD` — Updated value of `LC`

real-valued column vector

Updated value of LC, returned as a real-valued column vector.

Data Types: `single` | `double`

Note If the convolutional code uses an alphabet of 2^n possible symbols, where n is the number of bits per input symbol, then the `LC` and `LCD` vector lengths are $L \times n$ for some positive integer L. Similarly, if the decoded data uses an alphabet of 2^k output symbols, where k is the number of bits per output symbol, then the `LU` and `LUD` vector lengths are $L \times k$.

This System object accepts a column vector input signal with any positive integer value for L. For variable-sized inputs, L can vary during multiple calls.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Decode Convolutional Code Using the APP Decoder

Specify noise variance and the frame length in bits. Create convolutional encoder, PSK modulator, and AWGN channel System objects.

```
noiseVar = 2e-1;
frameLength = 300;
convEncoder = comm.ConvolutionalEncoder( ...
    'TerminationMethod','Truncated');
pskMod = comm.PSKModulator('BitInput',true,'PhaseOffset',0);
awgnChan = comm.AWGNChannel('NoiseMethod','Variance', ...
    'Variance',noiseVar);
```

Create convolutional APP decoder, PSK demodulator, and error rate System objects.

```
appDecoder = comm.APPDecoder(...
    'TrellisStructure',poly2trellis(7,[171 133]), ...
    'Algorithm','True APP', ...
    'CodedBitLLROutputPort',false);
pskDemod = comm.PSKDemodulator( ...
    'BitOutput',true, ...
    'PhaseOffset',0, ...
    'DecisionMethod','Approximate log-likelihood ratio', ...
    'Variance',noiseVar);
errRate = comm.ErrorRate;
```

Transmit a convolutionally encoded 8-PSK-modulated bit stream through an AWGN channel. Demodulate the received signal using soft-decision. Decode the demodulated signal using the APP decoder.

```
for counter = 1:5
     data = randi([0 1],frameLength,1);
     encodedData = convEncoder(data);
     modSignal = pskMod(encodedData);
     receivedSignal = awgnChan(modSignal);
     demodSignal = pskDemod(receivedSignal);
     % The APP decoder assumes a polarization of the soft
     % inputs that is inverse to that of the demodulator
     % soft outputs. Change the sign of demodulated signal.
     receivedSoftBits = appDecoder( ...
         zeros(frameLength,1),-demodSignal);
     % Convert from soft-decision to hard-decision.
     receivedBits = double(receivedSoftBits > 0);
     % Count errors
     errorStats = errRate(data,receivedBits);
end
```

Display the error rate information.

```
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
     errorStats(1), errorStats(2))
```

```
Error rate = 0.000000
Number of errors = 0
```

High Rate Convolutional Codes for Turbo Coding

Concatenated convolutional codes offer high reliability and have gained in prominence and usage as turbo codes. The `comm.TurboEncoder` and `comm.TurboDecoder` System objects support rate 1/n convolutional codes only. This example shows the parallel concatenation of two rate 2/3 convolutional codes to achieve an effective rate 1/3 turbo code by using `comm.ConvolutionalEncoder` and `comm.APPDecoder` System objects.

System Parameters

```
blkLength = 1024;   % Block length
EbNo = 0:5;         % Eb/No values to loop over
numIter = 3;        % Number of decoding iterations
maxNumBlks = 1e2;   % Maximum number of blocks per Eb/No value
```

Convolutional Encoder/Decoder Parameters

```
trellis = poly2trellis([5 4],[23 35 0; 0 5 13]);
k = log2(trellis.numInputSymbols);      % number of input bits
n = log2(trellis.numOutputSymbols);     % number of output bits
intrIndices = randperm(blkLength/k)';   % Random interleaving
decAlg = 'True App';                    % Decoding algorithm
modOrder = 2;                           % PSK-modulation order
```

Initialize System Objects

Initialize Systems object™ for convolutional encoding, APP Decoding, BPSK modulation and demodulation, AGWN channel, and error rate computation. The demodulation output soft bits using a log-likelihood ratio method.

```
cEnc1 = comm.ConvolutionalEncoder( ...
    'TrellisStructure',trellis, ...
    'TerminationMethod','Truncated');
cEnc2 = comm.ConvolutionalEncoder( ...
    'TrellisStructure',trellis, ...
    'TerminationMethod','Truncated');
cAPPDec1 = comm.APPDecoder( ...
    'TrellisStructure',trellis, ...
    'TerminationMethod','Truncated', ...
    'Algorithm',decAlg);
cAPPDec2 = comm.APPDecoder( ...
    'TrellisStructure',trellis, ...
    'TerminationMethod','Truncated', ...
    'Algorithm',decAlg);

bpskMod = comm.BPSKModulator;
bpskDemod = comm.BPSKDemodulator( ...
    'DecisionMethod','Log-likelihood ratio', ...
    'VarianceSource','Input port');
```

```
awgnChan = comm.AWGNChannel( ...
    'NoiseMethod','Variance', ...
    'VarianceSource','Input port');

bitError = comm.ErrorRate; % BER measurement
```

Frame Processing Loop

Loop through a range of E_b/N_0 values to generate results for BER performance. The `helperTurboEnc` and `helperTurboDec` helper functions on page 3-37 perform the turbo encoding and decoding.

```
ber = zeros(length(EbNo),1);
bitsPerSymbol = log2(modOrder);
turboEncRate = k/(2*n);

for ebNoIdx = 1:length(EbNo)
    % Calculate the noise variance from EbNo
    EsNo = EbNo(ebNoIdx) + 10*log10(bitsPerSymbol);
    SNRdB = EsNo + 10*log10(turboEncRate); % Account for code rate
    noiseVar = 10^(-SNRdB/10);

    for  numBlks = 1:maxNumBlks
        % Generate binary data
        data = randi([0 1],blkLength,1);

        % Turbo encode the data
        [encodedData,outIndices] = helperTurboEnc( ...
            data,cEnc1,cEnc2, ...
            trellis,blkLength,intrIndices);

        % Modulate the encoded data
        modSignal = bpskMod(encodedData);

        % Pass the modulated signal through an AWGN channel
        receivedSignal = awgnChan(modSignal,noiseVar);

        % Demodulate the noisy signal using LLR to output soft bits
        demodSignal = bpskDemod(receivedSignal,noiseVar);

        % Turbo decode the demodulated data
        receivedBits = helperTurboDec( ...
            -demodSignal,cAPPDec1,cAPPDec2, ...
            trellis,blkLength,intrIndices,outIndices,numIter);

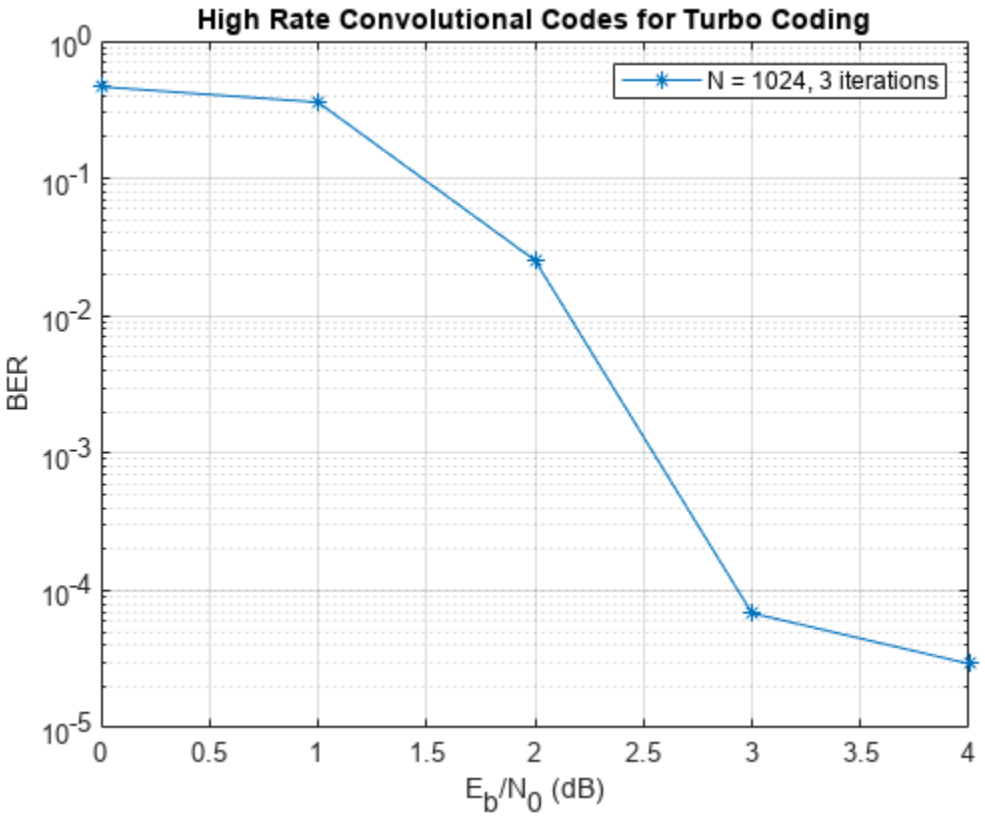
        % Calculate the error statistics
        errorStats = bitError(data,receivedBits);
    end

    ber(ebNoIdx) = errorStats(1);
    reset(bitError);
end
```

Display Results

While the practical wireless systems, such as LTE and CCSDS, specify base rate-1/n convolutional codes for turbo codes, the results show use of higher rate convolutional codes as turbo codes is viable.

```
figure;
semilogy(EbNo, ber, '*-');
grid on;
xlabel('E_b/N_0 (dB)');
ylabel('BER');
title('High Rate Convolutional Codes for Turbo Coding');
legend(['N = ' num2str(blkLength) ', ' num2str(numIter) ' iterations']);
```



Helper Functions

```
function [yEnc,outIndices] = helperTurboEnc( ...
    data,hCEnc1,hCEnc2,trellis,blkLength,intrIndices)
% Turbo encoding using two parallel convolutional encoders.
% No tail bits handling and assumes no output stream puncturing.

    % Trellis parameters
    k = log2(trellis.numInputSymbols);
    n = log2(trellis.numOutputSymbols);
    cLen = blkLength*n/k;

    punctrVec = [0;0;0;0;0;0];      % assumes all streams are output
    N = length(find(punctrVec==0));
```

```
    % Encode random data bits
    y1 = hCEnc1(data);
    y2 = hCEnc2( ...
        reshape(intrlv(reshape(data,k,[])',intrIndices)',[],1));
    y1D = reshape(y1(1:cLen),n,[]);
    y2D = reshape(y2(1:cLen),n,[]);
    yDTemp = [y1D; y2D];
    y = yDTemp(:);

    % Generate output indices vector using puncturing vector
    idx = 0 : 2*n : (blkLength - 1)*2*(n/k);
    punctrVecIdx = find(punctrVec==0);
    dIdx = repmat(idx, N, 1) + punctrVecIdx;
    outIndices = dIdx(:);
    yEnc = y(outIndices);
end

function yDec = helperTurboDec( ...
    yEnc,cAPPDec1,cAPPDec2,trellis, ...
    blkLength,intrIndices,inIndices,numIter)
% Turbo decoding using two a-posteriori probability (APP) decoders

    % Trellis parameters
    k = log2(trellis.numInputSymbols);
    n = log2(trellis.numOutputSymbols);
    rCodLen = 2*(n/k)*blkLength;
    typeyEnc = class(yEnc);

    % Re-order encoded bits according to outIndices
    x = zeros(rCodLen,1);
    x(inIndices) = yEnc;

    % Generate output of first encoder
    yD = reshape(x(1:rCodLen),2*n,[]);
    lc1D = yD(1:n, :);
    Lc1_in = lc1D(:);

    % Generate output of second encoder
    lc2D   = yD(n+1:2*n, :);
    Lc2_in = lc2D(:);

    % Initialize unencoded data input
    Lu1_in = zeros(blkLength,1,typeyEnc);

    % Turbo Decode
    out1 = zeros(blkLength/k,k,typeyEnc);
    for iterIdx = 1 : numIter
        [Lu1_out, ~] = cAPPDec1(Lu1_in,Lc1_in);
        tmp = Lu1_out(1:blkLength);
        Lu2_in = reshape(tmp,k,[])';
        [Lu2_out, ~] = cAPPDec2( ...
            reshape(Lu2_in(intrIndices, :)',[],1),Lc2_in);
        out1(intrIndices, :) = reshape(Lu2_out(1:blkLength),k,[])';
        Lu1_in = reshape(out1',[],1);
    end
    % Calculate llr and decoded bits for the final iteration
    llr = reshape(out1', [], 1) + Lu1_out(1:blkLength);
```

```
    yDec = cast((llr>=0), typeyEnc);
end
```

Algorithms

This System object implements the soft-input-soft-output APP decoding algorithm according to [1] and [2].

The `'True APP'` option of the `Algorithm` property implements APP decoding as per equations 20–23 in section V of [1]. To gain speed, the `'Max*'` and `'Max'` values of the `Algorithm` property approximate expressions like $\log\sum_i \exp(a_i)$ by other quantities. The `'Max'` option uses $\max(a_i)$ as the approximation. The `'Max*'` option uses $\max(a_i)$ plus a correction term given by the expression $\ln(1 + \exp(-|a_{i-1} - a_i|))$.

Setting the `Algorithm` property to `'Max*'` enables the `NumScalingBits` property of this System object. This property denotes the number of bits by which this System object scales the data it processes (multiplies the input by $2^{\texttt{NumScalingBits}}$ and divides the pre-output by the same factor). Use this property to avoid losing precision during computations.

Version History

Introduced in R2012a

arrayConfig

Create phased array configuration

Description

The `arrayConfig` object sets phased array configuration properties. Use an `arrayConfig` object to configure a uniform rectangular array (URA) with isotropic antenna elements, a uniform linear array (ULA) with isotropic antenna elements, or a single isotropic antenna element.

Creation

Syntax

```
cfgArray = arrayConfig
cfgArray = arrayConfig(Name,Value)
```

Description

`cfgArray = arrayConfig` creates a configuration object with default property values. The *x*-axis is normal to the plane on which the elements are placed. The default array is a 2-by-2 URA with an element spacing of 0.5 meter.

`cfgArray = arrayConfig(Name,Value)` sets properties using one or more name-value pair arguments. Enclose each property name in quotes. For example, `arrayConfig('Size',[8 1],'ElementSpacing',0.1)` specifies an eight-element ULA along the *z*-axis with an element spacing of 0.1 meter.

Properties

`Element` — Array element

`'isotropic'` (default)

This property is read-only.

Array element, returned as `'isotropic'`. Array elements are isotropic radiators.

Data Types: `char` | `string`

`Size` — Antenna array size

`[2 2]` (default) | two-element row vector of positive integers

Antenna array size, specified as a two-element row vector of positive integers. The first element specifies the number of rows of the antenna array and the second element specifies the number of columns of the antenna array. The rows of the array are along the *z*-axis. The columns of the array are along the *y*-axis.

- When both elements of this vector are greater than 1, the array is a URA.

- When one element of this vector is 1, the array is a ULA.
- When both elements of this vector are 1, the array is a single isotropic element.

Array elements are indexed from top to bottom along a column, continuing to the next column from left to right. For more information, see “Array Alignment” on page 3-43.

Data Types: `double`

`ElementSpacing` — Antenna array element spacing

`0.5` (default) | positive scalar | two-element row vector

Antenna array element spacing in meters, specified as one of these values.

- A positive scalar — This value specifies the spacing between rows and the spacing between columns of the antenna array.
- A two-element vector of positive values — The first element of the vector specifies the spacing between rows of the antenna array. The second element specifies the spacing between columns of the antenna array.

The rows of the array are along the *z*-axis, and the columns of the array are along the *y*-axis. For more information, see “Array Alignment” on page 3-43.

Dependencies

To enable this property, set at least one element in the `Size` property vector to a value greater than `1`.

Data Types: `double`

Examples

Configure 4-by-4 URA

Configure a 4-by-4 URA with an element spacing of 0.1 meter along rows and 0.2 meter along columns.

```
cfgArray = arrayConfig("Size",[4 4],"ElementSpacing",[0.1 0.2])
```

```
cfgArray =
  arrayConfig with properties:

              Size: [4 4]
    ElementSpacing: [0.1000 0.2000]

   Constant properties:
           Element: 'isotropic'
```

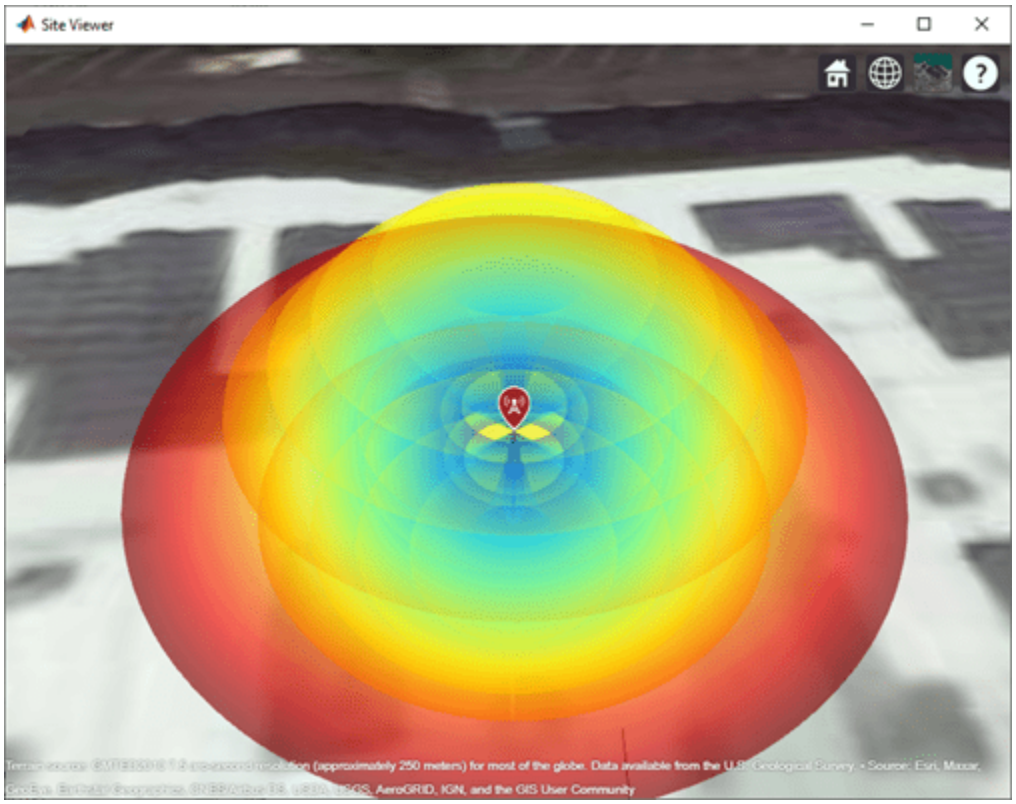
Configure Eight-Element ULA for Transmitter Site

Configure an eight-element ULA along the *z*-axis with an element spacing of 0.1 meter.

```
cfgArray = arrayConfig("Size",[8 1],"ElementSpacing",0.1);
```

Assign the array to a transmitter site and display the antenna pattern.

```
tx = txsite("Antenna",cfgArray);
pattern(tx,'Size',6);
```



More About

Array Alignment

Array elements are indexed from top to bottom along a column, continuing to the next column from left to right. The spacing between columns is the distance between adjacent elements in the same row. The spacing between rows is the distance between elements in the same column.

This illustration shows orientation and spacing between rows and columns for a URA of size 3-by-2. The array has three rows and two columns.

comm.AWGNChannel

Package: `comm`

Add white Gaussian noise to input signal

Description

comm.AWGNChannel adds white Gaussian noise to the input signal.

When applicable, if inputs to the object have a variable number of channels, the EbNo, EsNo, SNR, BitsPerSymbol, SignalPower, SamplesPerSymbol, and Variance properties must be scalars.

To add white Gaussian noise to an input signal:

1. Create the `comm.AWGNChannel` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
awgnchan = comm.AWGNChannel
awgnchan = comm.AWGNChannel(Name,Value)
```

Description

`awgnchan = comm.AWGNChannel` creates an additive white Gaussian noise (AWGN) channel System object, `awgnchan`. This object then adds white Gaussian noise to a real or complex input signal.

`awgnchan = comm.AWGNChannel(Name,Value)` creates a AWGN channel object, `awgnchan`, with the specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`NoiseMethod` — Noise level method

`'Signal to noise ratio (Eb/No)'` (default) | `'Signal to noise ratio (Es/No)'` | `'Signal to noise ratio (SNR)'` | `'Variance'`

Noise level method, specified as `'Signal to noise ratio (Eb/No)'`, `'Signal to noise ratio (Es/No)'`, `'Signal to noise ratio (SNR)'`, or `'Variance'`. For more information, see “Relationship Between Eb/No, Es/No, and SNR Modes” on page 3-63 and “Specifying Variance Directly or Indirectly” on page 3-64.

Data Types: `char`

EbNo — Ratio of energy per bit to noise power spectral density

`10` (default) | scalar | row vector

Ratio of energy per bit to noise power spectral density (Eb/No) in decibels, specified as a scalar or 1-by-N_C vector. N_C is the number of channels.

Tunable: Yes

Dependencies

This property applies when NoiseMethod is set to `'Signal to noise ratio (Eb/No)'`.

Data Types: `double`

EsNo — Ratio of energy per symbol to noise power spectral density

`10` (default) | scalar | row vector

Ratio of energy per symbol to noise power spectral density (Es/No) in decibels, specified as a scalar or 1-by-N_C vector. N_C is the number of channels.

Tunable: Yes

Dependencies

This property applies when NoiseMethod is set to `'Signal to noise ratio (Es/No)'`.

Data Types: `double`

SNR — Ratio of signal power to noise power

`10` (default) | scalar | row vector

Ratio of signal power to noise power in decibels, specified as a scalar or 1-by-N_C vector. N_C is the number of channels.

Tunable: Yes

Dependencies

This property applies when NoiseMethod is set to `'Signal to noise ratio (SNR)'`.

Data Types: `double`

BitsPerSymbol — Number of bits per symbol

`1` (default) | positive integer

Number of bits per symbol, specified as a positive integer.

Dependencies

This property applies when NoiseMethod is set to `'Signal to noise ratio (Eb/No)'`.

Data Types: `double`

`SignalPower` — Input signal power

1 (default) | positive scalar | row vector

Input signal power in watts, specified as a positive scalar or 1-by-N_C vector. N_C is the number of channels. The object assumes a nominal impedance of 1 Ω.

Tunable: Yes

Dependencies

This property applies when NoiseMethod is set to `'Signal to noise ratio (Eb/No)'`, `'Signal to noise ratio (Es/No)'`, or `'Signal to noise ratio (SNR)'`.

Data Types: `double`

`SamplesPerSymbol` — Number of samples per symbol

1 (default) | positive integer | row vector

Number of samples per symbol, specified as a positive integer or 1-by-N_C vector. N_C is the number of channels.

Dependencies

This property applies when NoiseMethod is set to `'Signal to noise ratio (Eb/No)'` or `'Signal to noise ratio (Es/No)'`.

Data Types: `double`

`VarianceSource` — Source of noise variance

`'Property'` (default) | `'Input port'`

Source of noise variance, specified as `'Property'` or `'Input port'`.

- Set `VarianceSource` to `'Property'` to specify the noise variance value using the Variance property.
- Set `VarianceSource` to `'Input port'` to specify the noise variance value using an input to the object, when you call it as a function.

For more information, see “Specifying Variance Directly or Indirectly” on page 3-64.

Dependencies

This property applies when NoiseMethod is `'Variance'`.

Data Types: `char`

`Variance` — White Gaussian noise variance

1 (default) | positive scalar | row vector

White Gaussian noise variance, specified as a positive scalar or 1-by-N_C vector. N_C is the number of channels.

Tunable: Yes

Dependencies

This property applies when NoiseMethod is set to `'Variance'` and VarianceSource is set to `'Property'`.

Data Types: `double`

`RandomStream` — Source of random number stream
`'Global stream'` (default) | `'mt19937ar with seed'`

Source of random number stream, specified as `'Global stream'` or `'mt19937ar with seed'`.

- When you set `RandomStream` to `'Global stream'`, the object uses the MATLAB default random stream to generate random numbers. To generate reproducible numbers using this object, you can reset the MATLAB default random stream. For example `reset(RandStream.getGlobalStream)`. For more information, see `RandStream`.
- When you set `RandomStream` to `'mt19937ar with seed'`, the object uses the mt19937ar algorithm for normally distributed random number generation. In this scenario, when you call the `reset` function, the object reinitializes the random number stream to the value of the `Seed` property. You can generate reproducible numbers by resetting the object.

For a complex input signal, the object creates the random data as follows:

`noise = randn(`N_S`,`N_C`)+1i(randn(`N_S`,`N_C`))`

N_S is the number of samples and N_C is the number of channels.

Dependencies

This property applies when NoiseMethod is set to `'Variance'`.

Data Types: `char`

`Seed` — Initial seed
67 (default) | nonnegative integer

Initial seed of the mt19937ar random number stream, specified as a nonnegative integer. For each call to the `reset` function, the object reinitializes the mt19937ar random number stream to the `Seed` value.

Dependencies

This property applies when RandomStream is set to `'mt19937ar with seed'`.

Data Types: `double`

Usage

Syntax

```
outsignal = awgnchan(insignal)
outsignal = awgnchan(insignal,var)
```

Description

`outsignal = awgnchan(insignal)` adds white Gaussian noise, as specified by `awgnchan`, to the input signal. The result is returned in `outsignal`.

`outsignal = awgnchan(insignal,var)` specifies the variance of the white Gaussian noise. This syntax applies when you set the NoiseMethod to `'Variance'` and VarianceSource to `'Input port'`.

For example:

```
awgnchan = comm.AWGNChannel('NoiseMethod','Variance', ...
     'VarianceSource','Input port');
var = 12;
...
outsignal = awgnchan(insignal,var);
```

Input Arguments

`insignal` — Input signal
scalar | vector | matrix

Input signal, specified as a scalar, an N_S-element vector, or an N_S-by-N_C matrix. N_S is the number of samples and N_C is the number of channels.

Data Types: `double`
Complex Number Support: Yes

`var` — Variance of additive white Gaussian noise
positive scalar | row vector

Variance of additive white Gaussian noise, specified as a positive scalar or 1-by-N_C vector. N_C is the number of channels, as determined by the number of columns in the input signal matrix.

Output Arguments

`outsignal` — Output signal
matrix

Output signal, returned with the same dimensions as `insignal`.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Create Default AWGN Channel System Object

Create an AWGN channel System object with the default configuration. Pass signal data through this channel.

Create an AWGN channel object and signal data.

```
awgnchan = comm.AWGNChannel;
insignal = randi([0 1],100,1);
```

Send the input signal through the channel.

```
outsignal = awgnchan(insignal);
```

Add White Gaussian Noise to 8-PSK Signal

Modulate an 8-PSK signal, add white Gaussian noise, and plot the signal to visualize the effects of the noise.

Create a M-PSK modulator System object™. The default modulation order for the object is 8.

```
pskModulator = comm.PSKModulator;
```

Modulate the signal.

```
modData = pskModulator(randi([0 7],2000,1));
```

Add white Gaussian noise to the modulated signal by passing the signal through an additive white Gaussian noise (AWGN) channel.

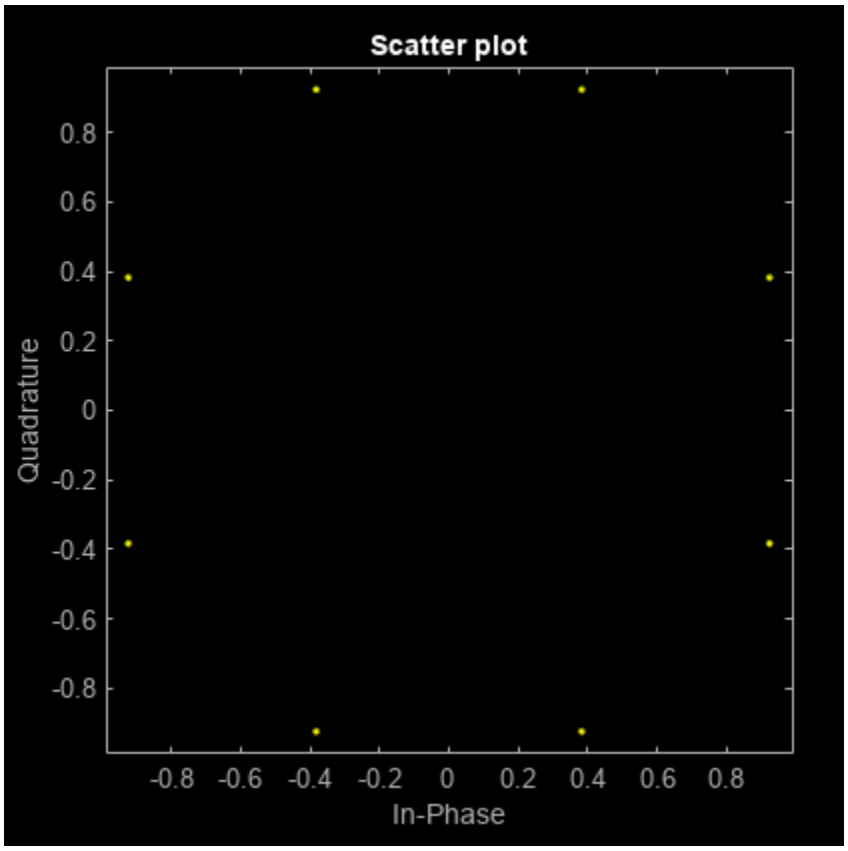
```
channel = comm.AWGNChannel('EbNo',20,'BitsPerSymbol',3);
```

Transmit the signal through the AWGN channel.

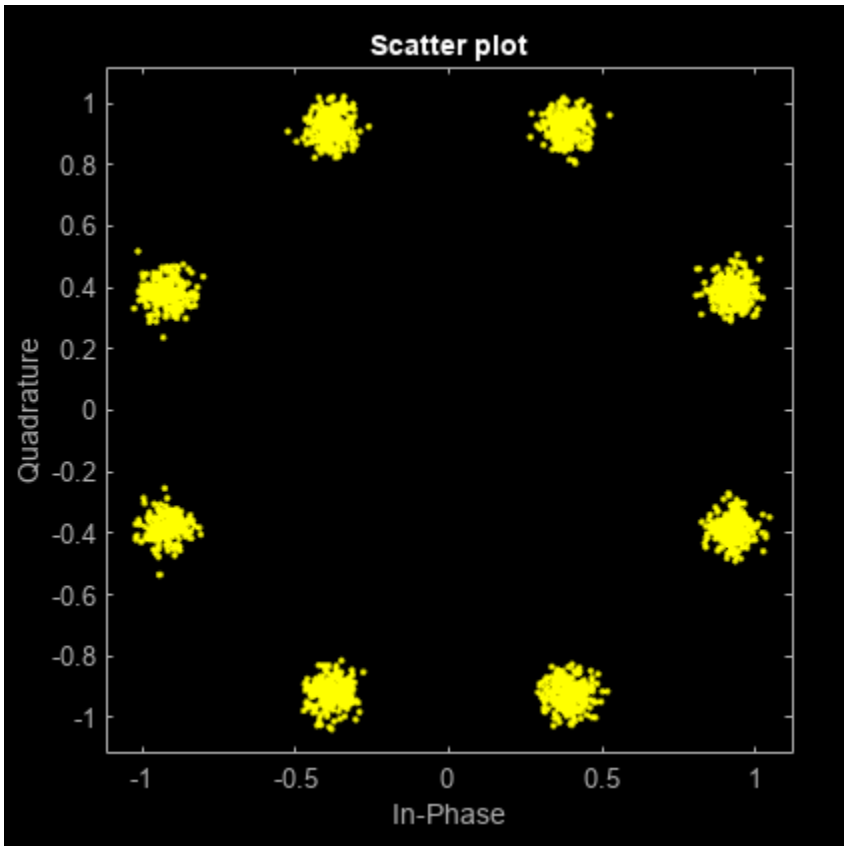
```
channelOutput = channel(modData);
```

Plot the noiseless and noisy data by using scatter plots to visualize the effects of the noise.

```
scatterplot(modData)
```



```
scatterplot(channelOutput)
```



Change the `EbNo` property to 10 dB to increase the noise.

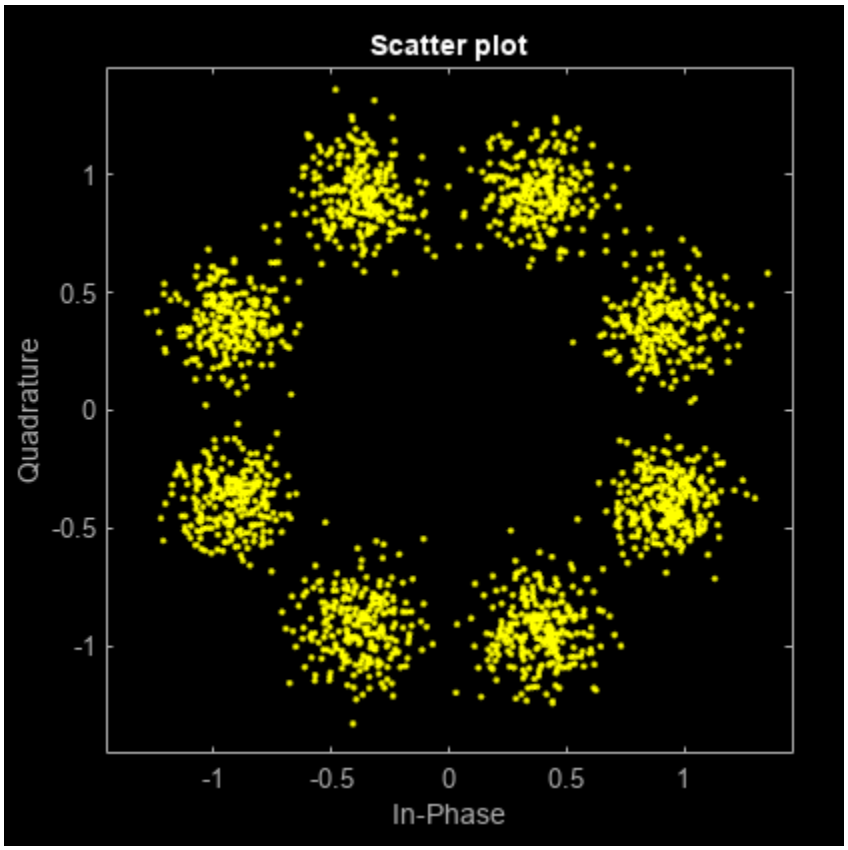
```
channel.EbNo = 10;
```

Pass the modulated data through the AWGN channel.

```
channelOutput = channel(modData);
```

Plot the channel output. You can see the effects of increased noise.

```
scatterplot(channelOutput)
```



Process Signals When Number of Channels Changes

Pass a single-channel and multichannel signal through an AWGN channel System object™.

Create an AWGN channel System object with the Eb/No ratio set for a single channel input. In this case, the `EbNo` property is a scalar.

```
channel = comm.AWGNChannel('EbNo',15);
```

Generate random data and apply QPSK modulation.

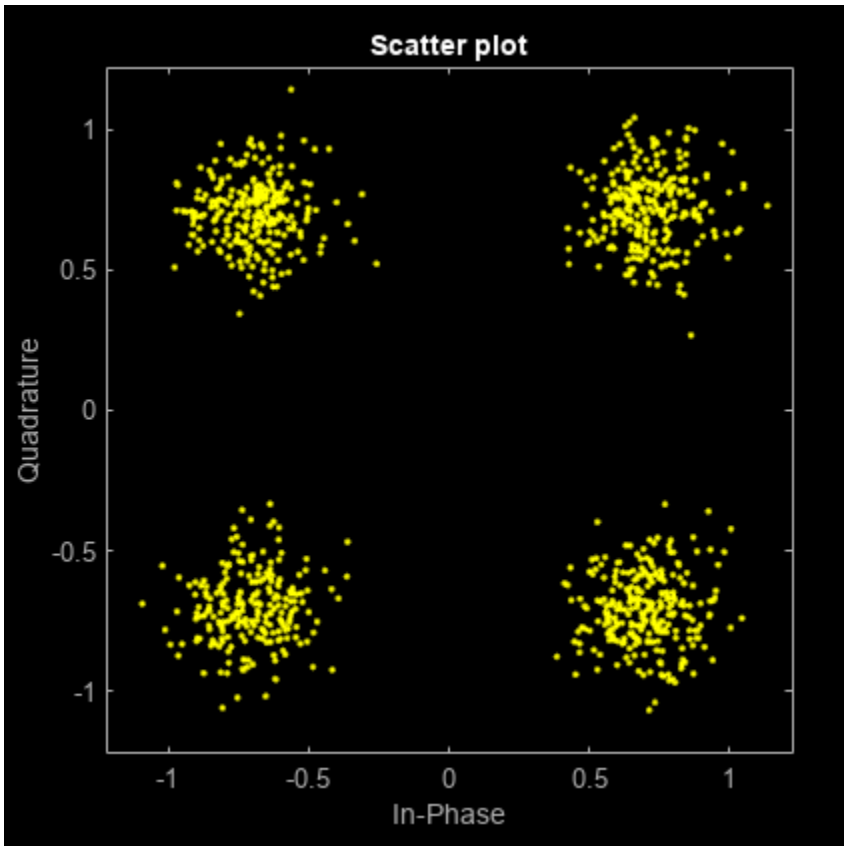
```
data = randi([0 3],1000,1);
modData = pskmod(data,4,pi/4);
```

Pass the modulated data through the AWGN channel.

```
rxSig = channel(modData);
```

Plot the noisy constellation.

```
scatterplot(rxSig)
```



Generate two-channel input data and apply QPSK modulation.

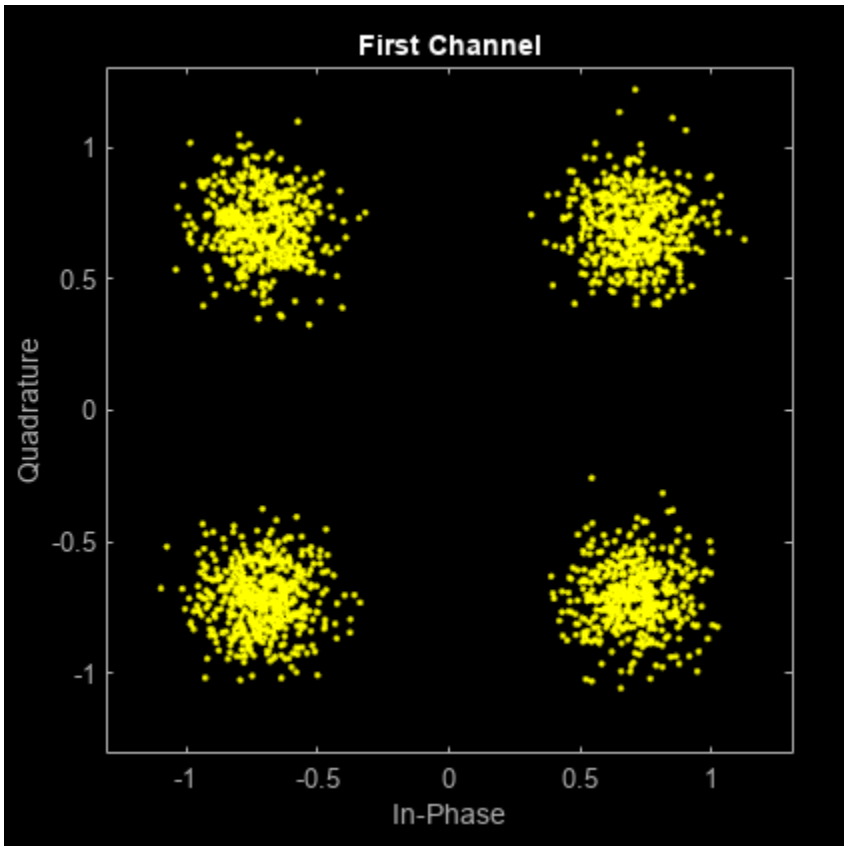
```
data = randi([0 3],2000,2);
modData = pskmod(data,4,pi/4);
```

Pass the modulated data through the AWGN channel.

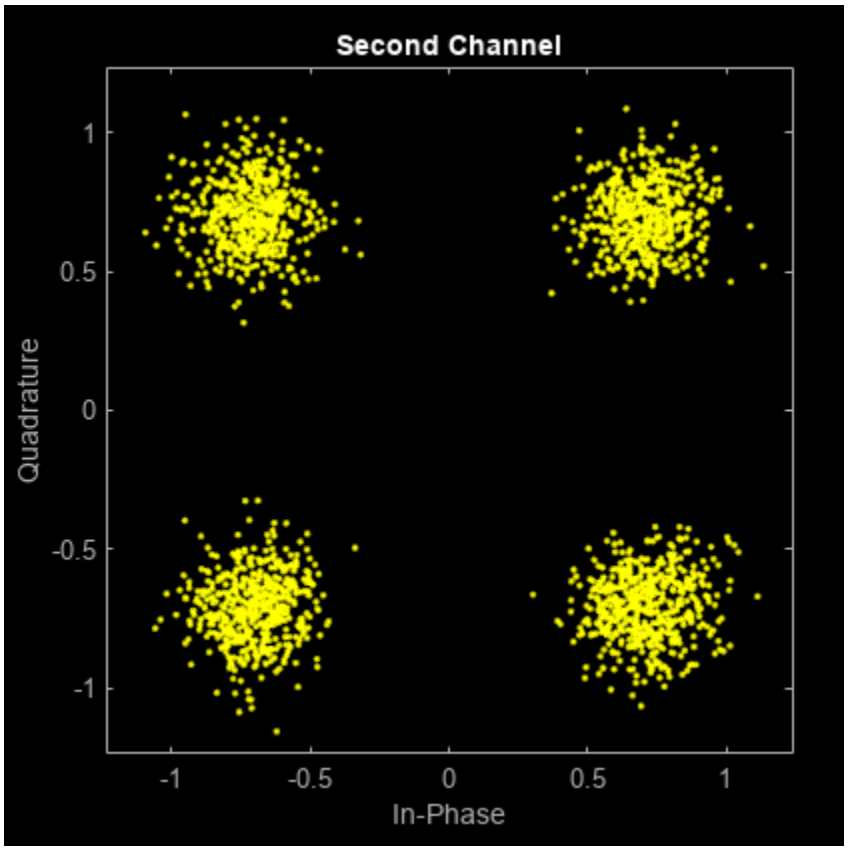
```
rxSig = channel(modData);
```

Plot the noisy constellations. Each channel is represented as a single column in `rxSig`. The plots are nearly identical, because the same Eb/No value is applied to both channels.

```
scatterplot(rxSig(:,1))
title('First Channel')
```



```
scatterplot(rxSig(:,2))
title('Second Channel')
```



Modify the AWGN channel object to apply a different Eb/No value to each channel. To apply different values, set the `EbNo` property to a 1-by-2 vector. When changing the dimension of the `EbNo` property, you must release the AWGN channel object.

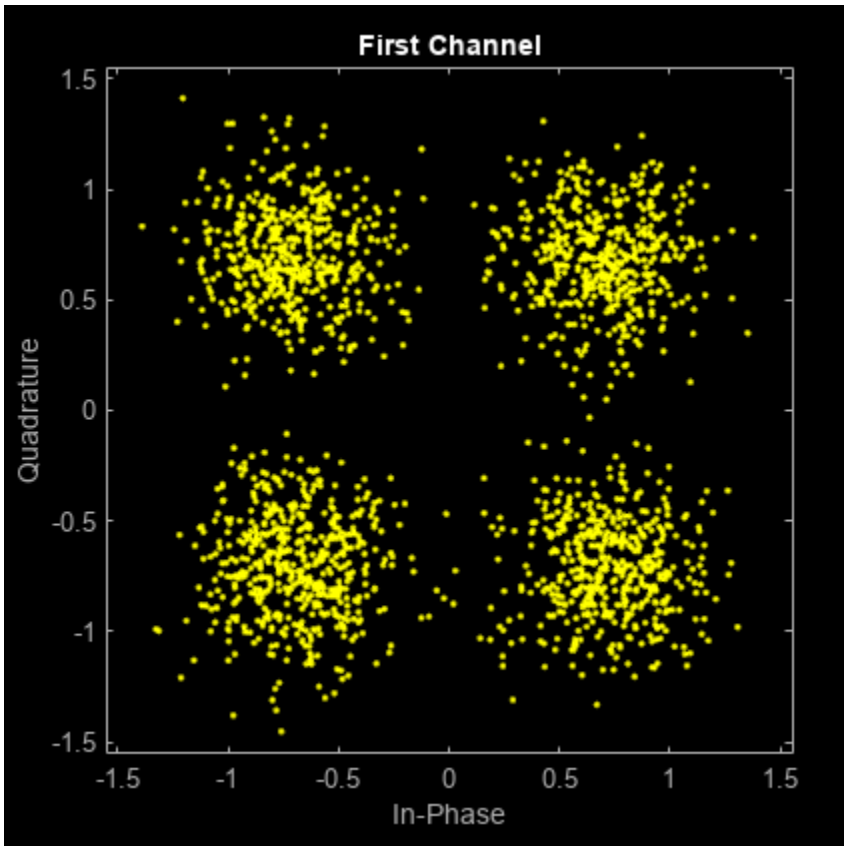
```
release(channel)
channel.EbNo = [10 20];
```

Pass the data through the AWGN channel.

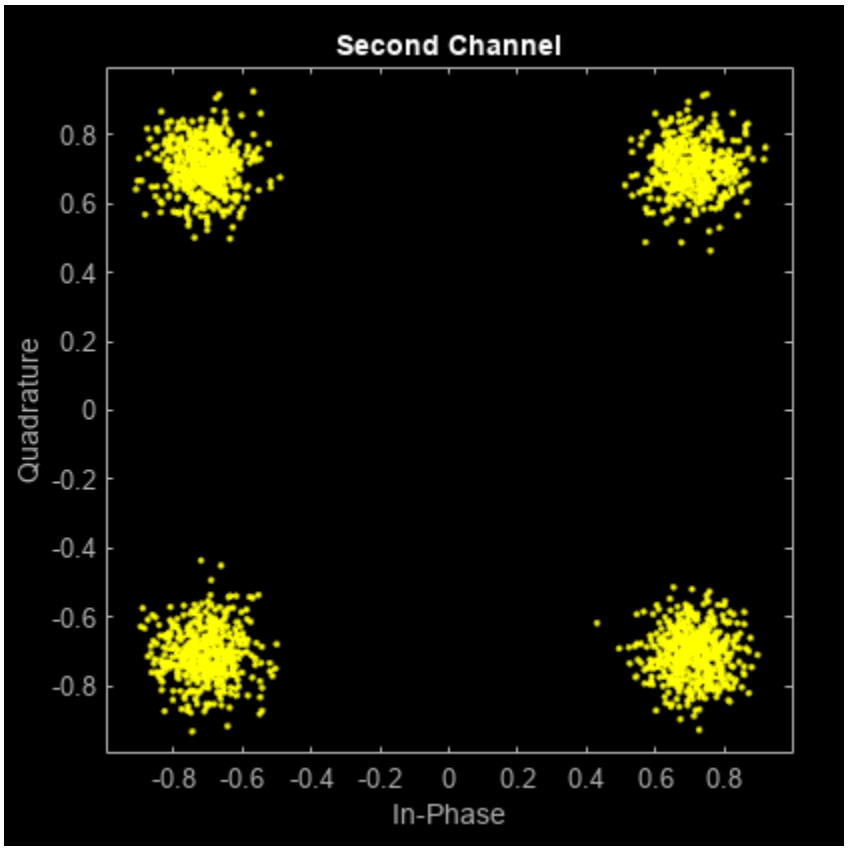
```
rxSig = channel(modData);
```

Plot the noisy constellations. The first channel has significantly more noise due to its lower Eb/No value.

```
scatterplot(rxSig(:,1))
title('First Channel')
```



```
scatterplot(rxSig(:,2))
title('Second Channel')
```



Add AWGN Using Noise Variance Input Port

Apply the noise variance input as a scalar or a row vector, with a length equal to the number of channels of the current signal input.

Create an AWGN channel System object™ with the `NoiseMethod` property set to `'Variance'` and the `VarianceSource` property set to `'Input port'`.

```
channel = comm.AWGNChannel('NoiseMethod','Variance', ...
'VarianceSource','Input port');
```

Generate random data for two channels and apply 16-QAM modulation.

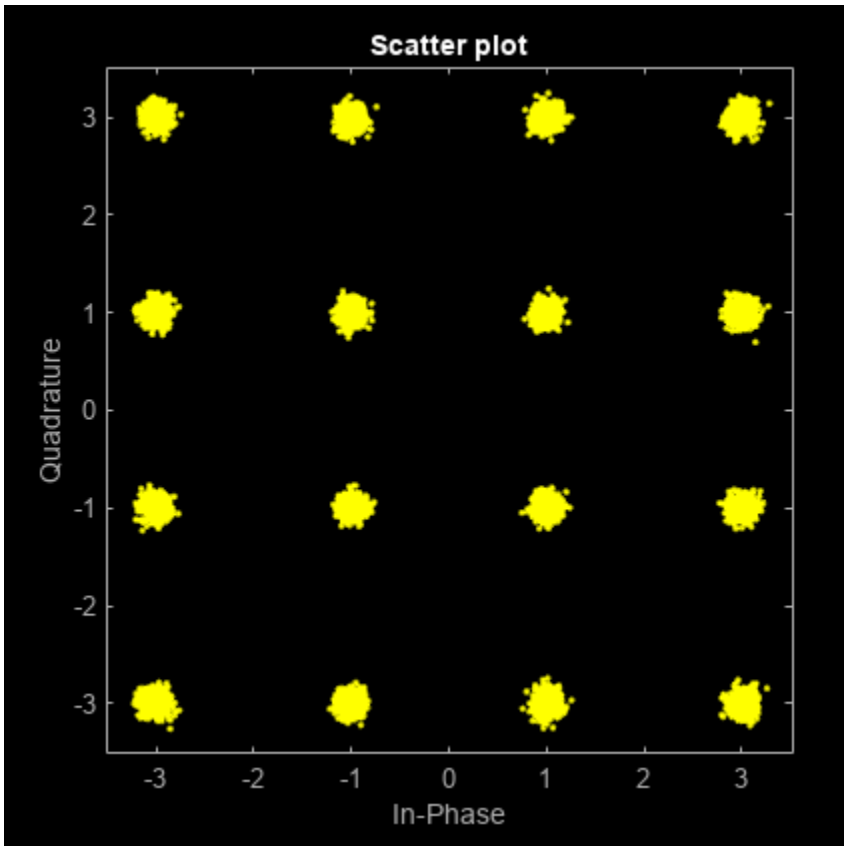
```
data = randi([0 15],10000,2);
txSig = qammod(data,16);
```

Pass the modulated data through the AWGN channel. The AWGN channel object processes data from two channels. The variance input is a 1-by-2 vector.

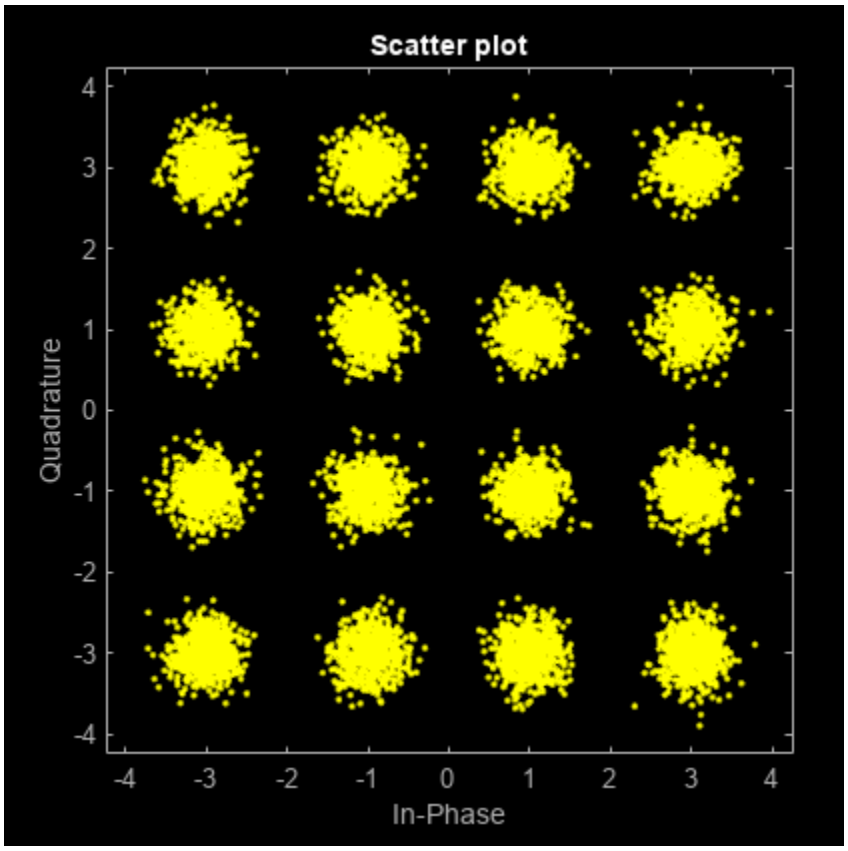
```
rxSig = channel(txSig,[0.01 0.1]);
```

Plot the constellation diagrams for the two channels. The second signal is noisier because its variance is ten times larger.

```
scatterplot(rxSig(:,1))
```

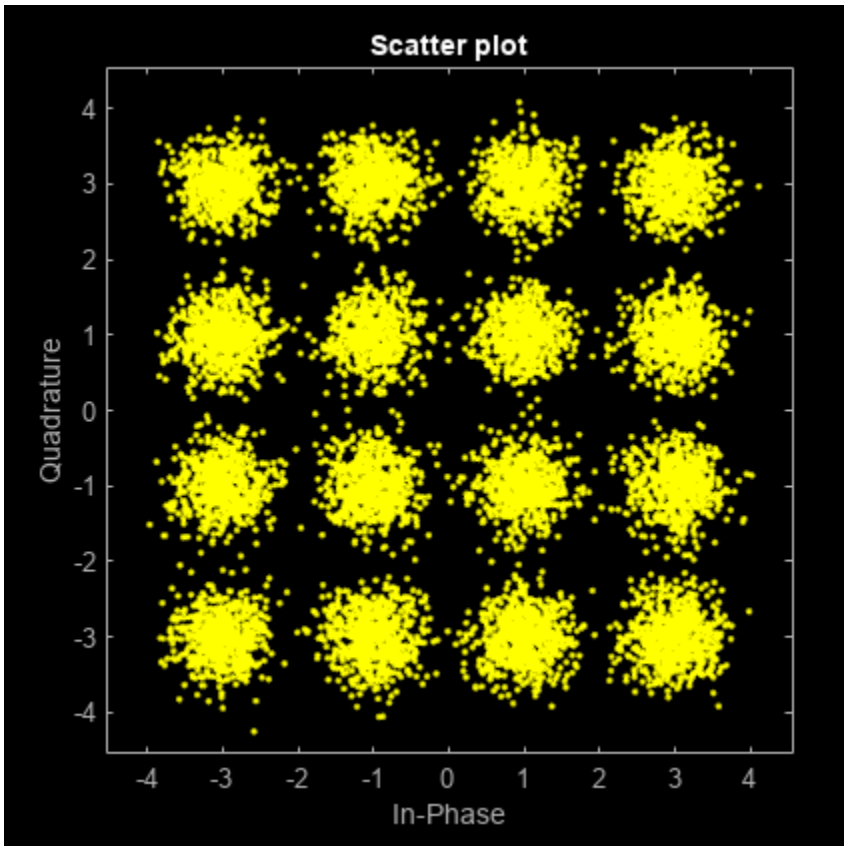


```
scatterplot(rxSig(:,2))
```

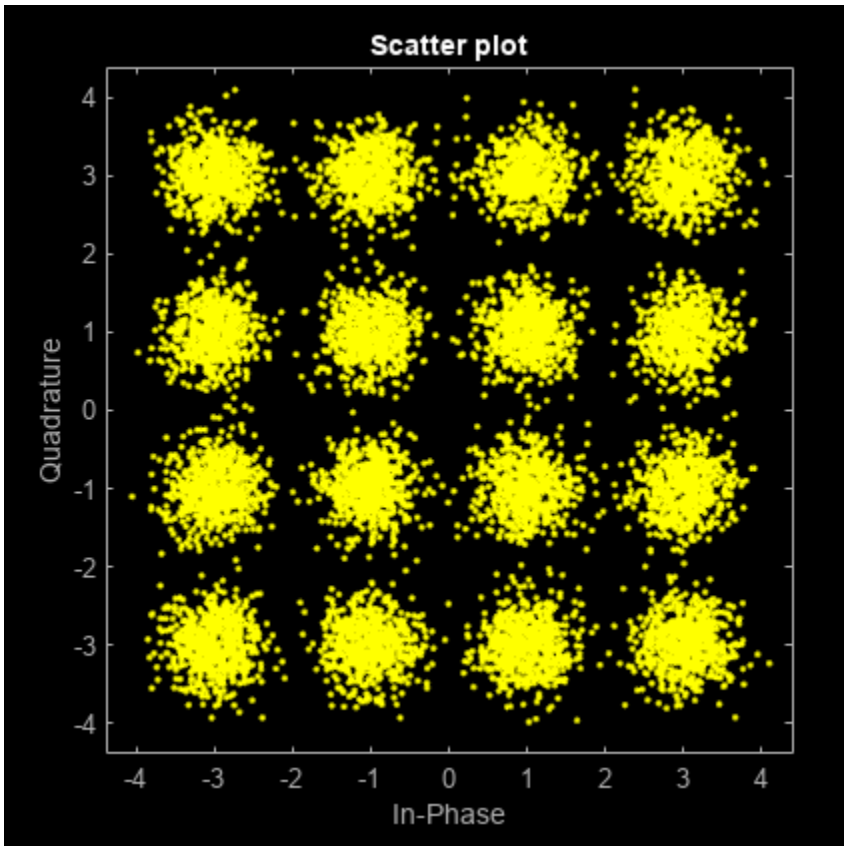


Repeat the process where the noise variance input is a scalar. The same variance is applied to both channels. The constellation diagrams are nearly identical.

```
rxSig = channel(txSig,0.2);
scatterplot(rxSig(:,1))
```



```
scatterplot(rxSig(:,2))
```



Set Random Number Seed for Repeatability

Specify a seed to produce the same outputs when using a random stream in which you specify the seed.

Create an AWGN channel System object™. Set the `NoiseMethod` property to `'Variance'`, the `RandomStream` property to `'mt19937ar with seed'`, and the `Seed` property to `99`.

```
channel = comm.AWGNChannel( ...
    'NoiseMethod','Variance', ...
    'RandomStream','mt19937ar with seed', ...
    'Seed',99);
```

Pass data through the AWGN channel.

```
y1 = channel(zeros(8,1));
```

Pass another all-zeros vector through the channel.

```
y2 = channel(zeros(8,1));
```

Because the seed changes between function calls, the output is different.

```
isequal(y1,y2)
```

```
ans = logical
   0
```

Reset the AWGN channel object by calling the `reset` function. The random data stream is reset to the initial seed of 99.

```
reset(channel);
```

Pass the all-zeros vector through the AWGN channel.

```
y3 = channel(zeros(8,1));
```

Confirm that the two signals are identical.

```
isequal(y1,y3)
```

```
ans = logical
   1
```

Algorithms

Relationship Between Eb/No, Es/No, and SNR Modes

For uncoded complex input signals, `comm.AWGNChannel` relates E_b/N_0, E_s/N_0, and SNR according to these equations:

$E_s/N_0 = N_{sps} \times SNR$

$E_s/N_0 = E_b/N_0 + 10\log_{10}(k)$ in dB

where

- E_s represents the signal energy in joules.
- E_b represents the bit energy in joules.
- N_0 represents the noise power spectral density in watts/Hz.
- N_{sps} represents the number of samples per symbol, `SamplesPerSymbol`.
- k represents the number of information bits per input symbol, `BitsPerSymbol`.

For real signal inputs, the `comm.AWGNChannel` relates E_s/N_0 and SNR according to this equation:

$E_s/N_0 = 0.5\ (N_{sps}) \times SNR$

Note

- All values of power assume a nominal impedance of 1 ohm.
- The equation for the real case differs from the corresponding equation for the complex case by a factor of 2. Specifically, the object uses a noise power spectral density of $N_0/2$ watts/Hz for real input signals, versus N_0 watts/Hz for complex signals.

For more information, see AWGN Channel Noise Level.

Specifying Variance Directly or Indirectly

To directly specify the variance of the noise generated by `comm.AWGNChannel`, specify `VarianceSource` as:

- `"Property"`, then set `NoiseMethod` to `"Variance"` and specify the variance with the `Variance` property.
- `"Input port"`, then specify the variance level for the object as an input with an input argument, `var`.

To specify variance indirectly, that is, to have it calculated by `comm.AWGNChannel`, specify `VarianceSource` as `"Property"` and the `NoiseMethod` as:

- `"Signal to noise ratio (Eb/No)"`, where the object uses these properties to calculate the variance:
  - `EbNo`, the ratio of bit energy to noise power spectral density
  - `BitsPerSymbol`
  - `SignalPower`, the actual power of the input signal samples
  - `SamplesPerSymbol`
- `"Signal to noise ratio (Es/No)"`, where the object uses these properties to calculate the variance:
  - `EsNo`, the ratio of signal energy to noise power spectral density
  - `SignalPower`, the actual power of the input signal samples
  - `SamplesPerSymbol`
- `"Signal to noise ratio (SNR)"`, where the object uses these properties to calculate the variance:
  - `SNR`, the ratio of signal power to noise power
  - `SignalPower`, the actual power of the input signal samples

Changing the number of samples per symbol (`SamplesPerSymbol`) affects the variance of the noise added per sample, which also causes a change in the final error rate.

$$NoiseVariance = \texttt{SignalPower} \times \texttt{SamplesPerSymbol} / 10^{(\texttt{EsNo}/10)}$$

Tip Select the number of samples per symbol based on what constitutes a symbol and the oversampling applied to it. For example, a symbol could have 3 bits and be oversampled by 4. For more information, see AWGN Channel Noise Level.

Version History

comm.BarkerCode

Package: comm

Generate bipolar Barker code

Description

The comm.BarkerCode System object generates a bipolar Barker code. Barker codes have low autocorrelation properties. The short length and low correlation sidelobes make Barker codes useful for frame synchronization in digital communications systems. For more information, see “Barker Codes” on page 3-69.

To generate a Barker code:

1. Create the comm.BarkerCode object and set its properties.
2. Call the object, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
barkerCode = comm.BarkerCode
barkerCode = comm.BarkerCode(Name,Value)
```

Description

barkerCode = comm.BarkerCode creates a bipolar Barker code generator System object to generate a Barker code.

barkerCode = comm.BarkerCode(Name,Value) sets properties using one or more name-value pairs. For example, comm.BarkerCode('Length',11,'SamplesPerFrame','11') configures a bipolar Barker code generator System object to output a length 11 Barker code in an 11-sample frame. Enclose each property name in quotes.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Length — Length of generated code
7 (default) | 1 | 2 | 3 | 4 | 5 | 11 | 13

Length of the generated code, specified as 1, 2, 3, 4, 5, 7, 11, or 13. For more information, see “Barker Codes” on page 3-69.

Example: `'Length',2` outputs the Barker code [–1;1].

Data Types: `double`

`SamplesPerFrame` — Samples per output frame
1 (default) | positive integer

Samples per output frame, specified as a positive integer. If `SamplesPerFrame` is *M*, the object outputs a frame containing *M* samples comprised of length *N* Barker code sequences. If necessary, the object repeats the code sequence to reach *M* samples. *N* is the length of the generated code, which is set by the `Length` property.

Data Types: `double`

`OutputDataType` — Output data type
`double` (default) | `int8`

Output data type, specified as `double` or `int8`.

Data Types: `char` | `string`

Usage

Note For versions earlier than R2016b, use the `step` function to run the System object™ algorithm. The arguments to `step` are the object you created, followed by the arguments shown in this section.

For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Syntax

```
y = barkerCode
```

Description

`y = barkerCode` outputs a Barker code frame, as a column vector. If the frame length exceeds the Barker code length, the object fills the frame by repeating the Barker code.

Set the data type of the output with the `OutputDataType` property.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to comm.BarkerCode

clone	Create duplicate System object
isLocked	Determine if System object is in use

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Generate Barker Code Sequence

Create a Barker code System object with 10 samples per frame.

```
barker = comm.BarkerCode('SamplesPerFrame',10)
```

```
barker =
  comm.BarkerCode with properties:

            Length: 7
    SamplesPerFrame: 10
     OutputDataType: 'double'
```

Generate multiple frames by using the default Barker code sequence of length 7. The code wraps within the frame and continues in the next frame.

```
for ii = 1:2
    seq = barker()
end
```

```
seq = 10×1

    -1
    -1
    -1
     1
     1
    -1
     1
    -1

     1
    -1
    -1
```

```
    -1
     1
     1
    -1
```

Compute Barker Code Sidelobe Level

Compute the peak sidelobe level for each Barker code.

```
CodeLength = [1 2 3 4 5 7 11 13]';
psl = zeros(length(CodeLength),1);
barker = comm.BarkerCode;
for ii=1:length(CodeLength)
    spf = CodeLength(ii);
    barker.Length = CodeLength(ii);
    barker.SamplesPerFrame = spf;
    seq = barker();
    sll_dB = 20*log10(abs(xcorr(seq)));
    psl(ii) = -(max(sll_dB));
    release(barker);
end
Sidelobe_dB = psl;
T = table(CodeLength,Sidelobe_dB)
```

```
T=8×2 table
    CodeLength    Sidelobe_dB
    __________    ___________

         1               0
         2          -6.0206
         3          -9.5424
         4          -12.041
         5          -13.979
         7          -16.902
        11          -20.828
        13          -22.279
```

More About

Barker Codes

Barker codes have a maximum autocorrelation sequence, which has off-peak autocorrelations no larger than 1.

A correlation sidelobe is the correlation of a codeword with a time-shifted version of itself. The correlation sidelobe, C_k, for a k-symbol shift of an N-bit code sequence, $\{X_j\}$, is

$$C_k = \sum_{j=1}^{N-k} X_j X_{j+k}$$

For j=1, 2, 3,..., N, X_j is an individual code symbol that is equal to +1 or –1. The adjacent symbols are assumed to be 0.

The output code is in a bipolar format with 0 and 1 mapped to 1 and –1. The maximum known Barker code length is 13. The short length and low correlation sidelobes make Barker codes useful for frame synchronization in digital communications systems. The Barker code generator outputs the Barker codes listed in this table.

Barker Code Length	Barker Code	Sidelobe Level
1	[–1]	0 dB
2	[–1; 1]	–6 dB
3	[–1; –1; 1]	–9.5 dB
4	[–1; –1; 1; –1]	–12 dB
5	[–1; –1; –1; 1; –1]	–14 dB
7	[–1; –1; –1; 1; 1; –1; 1]	–16.9 dB
11	[–1; –1; –1; 1; 1; 1; –1; 1; 1; –1; 1]	–20.8 dB
13	[–1; –1; –1; –1; –1; 1; 1; –1; –1; 1; –1; 1; –1]	–22.3 dB

comm.BasebandFileReader

Package: comm

Read baseband signal from file

Description

The comm.BasebandFileReader System object reads a baseband signal from a specific type of binary file written by the comm.BasebandFileWriter System object. Baseband signals are typically downconverted from a nonzero center frequency to 0 Hz. The SampleRate and CenterFrequency properties are saved when the file is created. The comm.BasebandFileReader object automatically reads the sample rate, center frequency, number of channels, and any descriptive data and saves them to its read-only properties.

To read a baseband file from a file:

1. Create the comm.BasebandFileReader object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
bbr = comm.BasebandFileReader
bbr = comm.BasebandFileReader(fname)
bbr = comm.BasebandFileReader(fname,spf)
bbr = comm.BasebandFileReader(___,Name=Value)
```

Description

bbr = comm.BasebandFileReader creates a baseband file reader System object to read a baseband signal from a specific type of binary file written by the comm.BasebandFileWriter System object.

bbr = comm.BasebandFileReader(fname) sets the Filename property to fname.

bbr = comm.BasebandFileReader(fname,spf) also sets the SamplesPerFrame property to spf.

bbr = comm.BasebandFileReader(___,Name=Value) sets properties using one or more name-value arguments in addition to an input argument combination from any of the previous syntaxes. For example, SampleRate=2 sets the sample rate of the baseband file reader to 2.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`Filename` — Name of baseband file to read

`'example.bb'` (default) | string scalar | character vector

Name of the baseband file to read, specified as a string scalar or character vector. The object saved and displays the absolute path.

Tips

If the file is not on the MATLAB path, specify the absolute path.

Data Types: `string` | `char`

`SampleRate` — Sample rate of saved baseband signal

`1` (default) | positive scalar

This property is read-only.

Sample rate of the saved baseband signal in Hz, returned as a positive scalar.

Data Types: `double`

`CenterFrequency` — Center frequency of saved baseband signal

`100000000` (default) | positive scalar | row vector

This property is read-only.

Center frequency of the saved baseband signal in Hz, returned as a positive scalar or row vector. When this property is a row vector, each element is the center frequency of a channel in a multichannel signal.

Data Types: `double`

`NumChannels` — Number of channels in saved baseband signal

`1` (default) | positive integer

This property is read-only.

Number of channels in the saved baseband signal, returned as a positive integer.

Data Types: `double`

`Metadata` — Data describing baseband signal

`struct()` (default) | structure

This property is read-only.

Data describing the baseband signal, returned as a structure of fields defined when creating the baseband file writer. If the file has no descriptive data, this property is an empty structure.

Data Types: `struct`

`SamplesPerFrame` — Number of samples per output frame
`100` (default) | positive integer

Number of samples per output frame, specified as a positive integer or `Inf`. When this property is `Inf`, the output frame contains all of the samples in the baseband file.

Data Types: `double`

`CyclicRepetition` — Option to repeatedly read baseband file
`false` or `0` (default) | `true` or `1`

Option to repeatedly read the baseband file, specified as a logical `0` (`false`) or `1` (`true`).

- When this property is `false`, the object appends zeros to the last frame if it is partially filled. Then, the object returns all-zero frames.
- When this property is `true`, the object repeatedly reads the file, starting from the first sample.

Data Types: `logical`

Usage

Syntax

```
samples = bbr()
```

Description

`samples = bbr()` reads the baseband signal file from the file specified by the `Filename` property.

Output Arguments

`samples` — Baseband samples
matrix

Baseband samples read from the file, returned as an `SamplesPerFrame`-by-`NumChannels` matrix of complex values read from the baseband signal file specified by `Filename`. When the `SamplesPerFrame` property is `Inf`, the output matrix contains all of the samples in the baseband signal file.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `comm.BasebandFileReader`

info Characteristic information about baseband file reader

isDone End-of-data status

Common to All System Objects

step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

Examples

Reading Data with Single Call to Baseband File Reader Object

Read a baseband signal from file using a single call to the `comm.BasebandFileReader` System object. To read all samples from the file in one call to the object, you can set the samples per frame equal to `inf` or to the number of samples in the data file.

Create a baseband file reader object setting the samples per frame to `inf`. Use the `info` method to gain additional information about `bbr`. The file contains 10,000 samples of type `'double'`. No samples have been read.

```
bbr1 = comm.BasebandFileReader('baseband_samples_1ghz.bb',SamplesPerFrame=inf)
```

```
bbr1 =
  comm.BasebandFileReader with properties:

            Filename: 'C:\TEMP\Bdoc22b_2054784_6060\ibB18F8B\28\tpc33da15b\comm-ex94749964\baseba
          SampleRate: 1
     CenterFrequency: 100000000
         NumChannels: 1
            Metadata: [1x1 struct]
     SamplesPerFrame: Inf
    CyclicRepetition: false
```

```
info(bbr1)
```

```
ans = struct with fields:
    NumSamplesInData: 10000
            DataType: 'double'
      NumSamplesRead: 0
```

Now read the entire contents of the `baseband_samples_1ghz.bb` file with a single call to the `bbr` object. Confirm that all the samples have been read.

```
samples1 = bbr1();
info(bbr1)
```

```
ans = struct with fields:
    NumSamplesInData: 10000
            DataType: 'double'
      NumSamplesRead: 10000
```

Release the baseband file reader resources.

```
release(bbr1)
```

Alternatively, to read all samples from the file in one call to the object, you can set the samples per frame equal to the number of samples in the data file. To do this you must updates the samples per frame setting (`bbr.SamplesPerFrame`) to the value of `NumSamplesInData` returned by the `info` object function.

Create a baseband file reader object and display the structure retuned by the `info` object function.

```
bbr2 = comm.BasebandFileReader('baseband_samples_1ghz.bb')
```

```
bbr2 =
  comm.BasebandFileReader with properties:

            Filename: 'C:\TEMP\Bdoc22b_2054784_6060\ibB18F8B\28\tpc33da15b\comm-ex94749964\baseba
          SampleRate: 1
     CenterFrequency: 100000000
         NumChannels: 1
            Metadata: [1x1 struct]
     SamplesPerFrame: 100
    CyclicRepetition: false
```

```
bbrinfo = info(bbr2)
```

```
bbrinfo = struct with fields:
    NumSamplesInData: 10000
            DataType: 'double'
      NumSamplesRead: 0
```

```
bbr2.SamplesPerFrame = bbrinfo.NumSamplesInData
```

```
bbr2 =
  comm.BasebandFileReader with properties:

            Filename: 'C:\TEMP\Bdoc22b_2054784_6060\ibB18F8B\28\tpc33da15b\comm-ex94749964\baseba
          SampleRate: 1
     CenterFrequency: 100000000
         NumChannels: 1
            Metadata: [1x1 struct]
     SamplesPerFrame: 10000
    CyclicRepetition: false
```

Now read the entire contents of the `baseband_samples_1ghz.bb` file with a single call to the `bbr` object. Confirm that all the samples have been read and compare the samples read by `bbr1` and `bbr2`.

```
samples2 = bbr2();
info(bbr2)
```

```
ans = struct with fields:
    NumSamplesInData: 10000
            DataType: 'double'
      NumSamplesRead: 10000
```

```
isequal(samples1,samples2)
```

```
ans = logical
   1
```

Release the baseband file reader resources.

```
release(bbr2)
```

Read Data with Multiple Calls to Baseband File Reader

Read a baseband signal from a file by using multiple calls to the baseband file reader System object™.

Create a baseband file reader object.

```
bbr = comm.BasebandFileReader('baseband_samples_1ghz.bb')
```

```
bbr =
  comm.BasebandFileReader with properties:

            Filename: 'C:\TEMP\Bdoc22b_2054784_6060\ibB18F8B\28\tpc33da15b\comm-ex87872352\baseba
          SampleRate: 1
     CenterFrequency: 100000000
         NumChannels: 1
            Metadata: [1x1 struct]
     SamplesPerFrame: 100
    CyclicRepetition: false
```

Use the `info` object function to gain additional information about the baseband file reader. The file contains 10,000 samples of data type `double`. No samples have been read.

```
info(bbr)
```

```
ans = struct with fields:
    NumSamplesInData: 10000
            DataType: 'double'
      NumSamplesRead: 0
```

The baseband file (`baseband_samples_1ghz.bb`) contains 10,000 samples. Because the number of samples per frame is set to 100 in the baseband file reader object, reading the entire contents of the baseband file requires multiple calls to the object. To read all of the samples from the file, use the `isDone` object function to terminate a `while` loop.

```
y = [];
while ~isDone(bbr)
    x = bbr();
    y = cat(1,y,x);
end
```

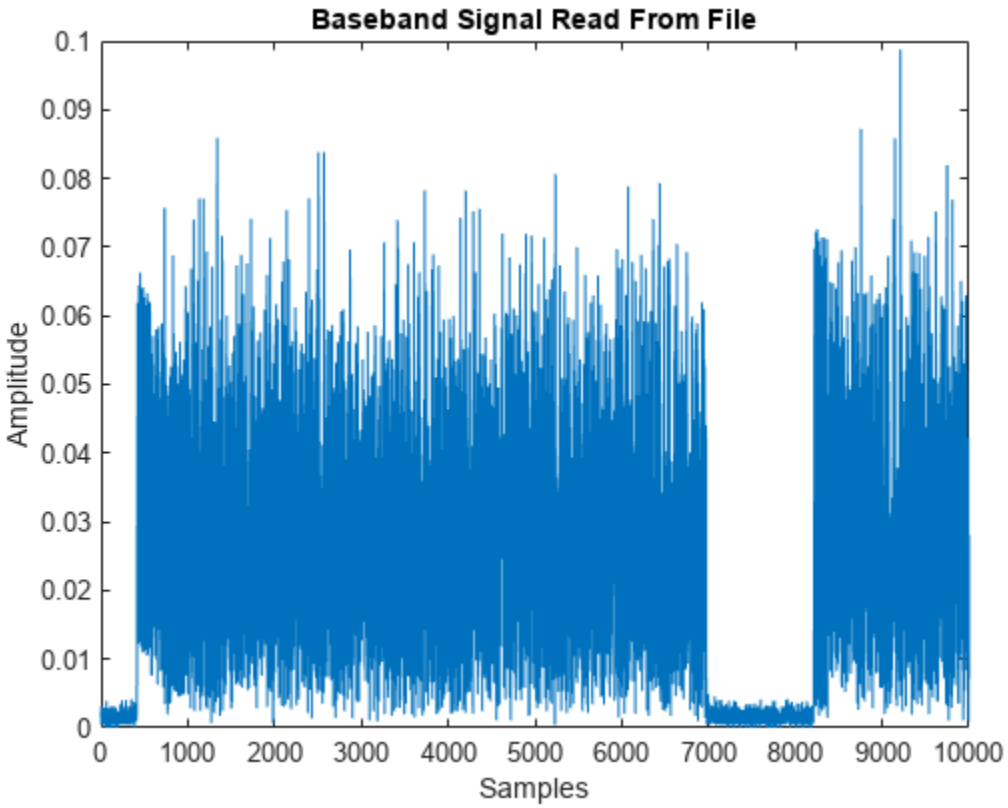
Use the `info` obejct function to confirm that all of the samples have been read from the file. The total number of samples and the number of samples read are the same.

```
info(bbr)
```

```
ans = struct with fields:
    NumSamplesInData: 10000
            DataType: 'double'
      NumSamplesRead: 10000
```

Plot the absolute magnitude of the baseband data.

```
plot(abs(y))
title('Baseband Signal Read From File')
xlabel('Samples')
ylabel('Amplitude')
```



Release the baseband file reader resources.

```
release(bbr)
```

`comm.BasebandFileWriter`

comm.BasebandFileWriter

Package: comm

Write baseband signal to file

Description

The comm.BasebandFileWriter System object writes a specific type of binary file to store baseband signal data. Baseband signals are typically down-converted from a nonzero center frequency to 0 Hz. The SampleRate and CenterFrequency properties are saved when the file is created.

To write a baseband signal to a file:

1. Create the comm.BasebandFileWriter object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
bbw = comm.BasebandFileWriter
bbw = comm.BasebandFileWriter(fname)
bbw = comm.BasebandFileWriter(fname,fs)
bbw = comm.BasebandFileWriter(fname,fs,fc)
bbw = comm.BasebandFileWriter(fname,fs,fc,md)
bbw = comm.BasebandFileWriter(___,Name=Value)
```

Description

bbw = comm.BasebandFileWriter creates a baseband file writer System object to write a baseband signal to a specific type of binary file.

bbw = comm.BasebandFileWriter(fname) sets the Filename property to fname.

bbw = comm.BasebandFileWriter(fname,fs) also sets the SampleRate property to fs.

bbw = comm.BasebandFileWriter(fname,fs,fc) also sets the CenterFrequency property to fc.

bbw = comm.BasebandFileWriter(fname,fs,fc,md) also sets the Metadata property to md.

bbw = comm.BasebandFileWriter(___,Name=Value) sets properties using one or more name-value arguments in addition to an input argument combination from any of the previous syntaxes. For example, SampleRate=2 sets the sample rate of the baseband file writer to 2.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`Filename` — Name of baseband file to write
`'untitled.bb'` (default) | string scalar | character vector

Name of the baseband file to write, specified as a string scalar or character vector. The filename can include a relative or absolute path.

Data Types: `string` | `char`

`SampleRate` — Sample rate of output baseband signal
`1` (default) | positive scalar

Sample rate of the output baseband signal in Hz, specified as a positive scalar.

Data Types: `double`

`CenterFrequency` — Center frequency of baseband signal
`100000000` (default) | positive scalar | row vector

Center frequency of the baseband signal in Hz, specified as a positive scalar or row vector. When this property is a row vector, each element is the center frequency of a channel in a multichannel signal.

Data Types: `double`

`Metadata` — Data describing baseband signal
empty structure (default) | structure

Data describing the baseband signal, specified as a structure. The structure can have any number of fields and any field name. The field values can be of any numeric, logical, or character data type and have any number of dimensions.

Data Types: `struct`

`NumSamplesToWrite` — Number of samples to save
`Inf` (default) | positive integer

Number of samples to save, specified as a positive integer or `Inf`.

- To write all of the baseband signal samples to a file, set this property to `Inf`.
- To write only the last `NumSamplesToWrite` samples to a file, set this property to a positive integer.

Data Types: `double`

Usage

Syntax

```
bbw(samples)
```

Description

`bbw(samples)` writes one frame of baseband samples to the file specified by the `Filename` property. The number of samples written to the file is determined by the `NumSamplesToWrite` property.

Input Arguments

`samples` — Baseband signal to write

matrix

Baseband signal to write to the file, specified as an N_{sample}-by-N_{channel} matrix of numeric values. N_{sample} is the number of baseband samples and N_{channel} is the number of channels in the input signal. If `NumSamplesToWrite` is `Inf`, the object writes all of the samples in the input signal to the file.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `comm.BasebandFileWriter`

info	Characteristic information about baseband file writer

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Write Baseband Signal to File

Create a baseband file writer object specifying a sample rate of 1 kHz and a 0 Hz center frequency.

```
bbw = comm.BasebandFileWriter('baseband_data.bb',1000,0);
```

Save the date for today in the `Metadata` structure.

```
bbw.Metadata = struct('Date',date);
```

Generate two channels of QPSK-modulated data.

```
d = randi([0 3],1000,2);
x = pskmod(d,4,pi/4,'gray');
```

Write the baseband data to file `baseband_data.bb`.

```
bbw(x)
```

Display information about the baseband file writer. Then, release the object.

```
info(bbw)
```

```
ans = struct with fields:
             Filename: 'C:\TEMP\Bdoc22b_2054784_6060\ibB18F8B\29\tp337054fe\comm-ex66490302\basel
      SamplesPerFrame: 1000
          NumChannels: 2
             DataType: 'double'
    NumSamplesWritten: 1000
```

```
release(bbw)
```

Create a baseband file reader object to read the saved data. Display the metadata from the file.

```
bbr = comm.BasebandFileReader('baseband_data.bb', ...
    'SamplesPerFrame',100);
bbr.Metadata
```

```
ans = struct with fields:
    Date: '31-Aug-2022'
```

Read the data from the file.

```
z = [];

while ~isDone(bbr)
    y = bbr();
    z = cat(1,z,y);
end
```

Display information about the baseband file reader. Then, release object.

```
info(bbr)
```

```
ans = struct with fields:
    NumSamplesInData: 1000
            DataType: 'double'
      NumSamplesRead: 1000
```

```
release(bbr)
```

Confirm that the original modulated data `x`, matches the data `z`, read from file `baseband_data.bb`.

```
isequal(x,z)
```

```
ans = logical
   1
```

Tips

- `comm.BasebandFileWriter` writes baseband signals to uncompressed binary files. To share these files, you can compress them to a zip file using the `zip` function. For more information, see “Create and Extract from Zip Archives”.

comm.BCHDecoder

Package: comm

Decode data using BCH decoder

Description

The BCHDecoder object recovers a binary message vector from a binary BCH codeword vector. For proper decoding, the codeword and message length values in this object must match the properties in the corresponding comm.BCHEncoder System object.

To decode a binary message from a BCH codeword:

1. Define and set up your BCH decoder object. See “Construction” on page 3-84.
2. Call step to recover a binary message vector from a binary BCH codeword vector according to the properties of comm.BCHDecoder. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

dec = comm.BCHDecoder creates a BCH decoder System object, dec, that performs BCH decoding.

dec = comm.BCHDecoder(N,K) creates a BCH decoder object, dec, with the CodewordLength property set to N and the MessageLength property set to K.

dec = comm.BCHDecoder(N,K,GP) creates a BCH decoder object, dec, with the CodewordLength property set to N, the MessageLength property set to K, and the GeneratorPolynomial property set to GP.

dec = comm.BCHDecoder(N,K,GP,S) creates a BCH decoder object, dec, with the CodewordLength property set to N, the MessageLength property set to K, the GeneratorPolynomial property set to GP, and the ShortMessageLength property set to S.

dec = comm.BCHDecoder(N,K,GP,S,Name,Value) creates a BCH decoder object, dec, with the CodewordLength property set to N, the MessageLength property set to K, the GeneratorPolynomial property set to GP, the ShortMessageLength property set to S, and each specified property Name set to the specified Value.

dec = comm.BCHDecoder(Name,Value) creates a BCH decoder object, dec, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

Properties

`CodewordLength`

Codeword length

Specify the codeword length of the BCH code as a double-precision positive integer scalar. The default is `15`. The values of the `CodewordLength` and `MessageLength` on page 3-0 properties must produce a valid narrow-sense BCH code. For a full-length BCH code, the value of this property must take the form $2^M - 1$, where M is an integer such that $3 \le M \le 16$. The default is `15`.

`MessageLength`

Message length

Specify the message length as a double-precision positive integer scalar. The values of the `CodewordLength` on page 3-0 and `MessageLength` properties must produce a valid narrow-sense BCH code. The default is `5`.

`ShortMessageLengthSource`

Short message length source

Specify the source of the shortened message as either `Auto` or `Property`. When this property is set to `Auto`, the BCH code is defined by the `CodewordLength` on page 3-0 , `MessageLength` on page 3-0 , `GeneratorPolynomial` on page 3-0 , and `PrimitivePolynomial` on page 3-0 properties. When `ShortMessageLengthSource` is set to `Property`, you must specify the `ShortMessageLength` on page 3-0 property, which is used with the other properties to define the BCH code. The default is `Auto`.

`ShortMessageLength`

Shortened message length

Specify the length of the shortened message as a double-precision positive integer scalar whose value must be less than or equal to `MessageLength` on page 3-0 . When `ShortMessageLength` < `MessageLength`, the BCH code is shortened. The default is `5`.

`GeneratorPolynomialSource`

Source of generator polynomial

Specify the source of the generator polynomial as either `Auto` or `Property`. Set this property to `Auto` to create the generator polynomial automatically. Set `GeneratorPolynomialSource` to `Property` to specify a generator polynomial using the `GeneratorPolynomial` on page 3-0 property. The default is `Auto`.

`GeneratorPolynomial`

Generator polynomial

Specify the generator polynomial as a binary double-precision row vector, a binary Galois field row vector that represents the coefficients of the generator polynomial in order of descending powers, or as a polynomial character vector. The length of the generator polynomial requires a value of `CodewordLength` on page 3-0 –`MessageLength` on page 3-0 `+1`. This property applies when you set `GeneratorPolynomialSource` on page 3-0 to `Property`. The default is `'X^10 + X^8 + X^5 + X^4 + X^2 + X + 1'`, which is the result of `bchgenpoly(15,5,[],'double')` and corresponds to a `15,5` code.

`CheckGeneratorPolynomial`

Enable generator polynomial checking

Set this property to `true` to perform a generator polynomial check the first time you call the `step` method. The default is `true`. This check verifies that the specified generator polynomial is valid. For larger codes, disabling the check reduces processing time. As a best practice, perform the check at least once before setting this property to `false`. This property applies when you set `GeneratorPolynomialSource` on page 3-0 to `Property`. The default is `true`.

`PrimitivePolynomialSource`

Source of primitive polynomial

Specify the source of the primitive polynomial as `Auto` or `Property`. Set this property to `Auto` to create a primitive polynomial of degree *M*=`ceil(log2(CodewordLength on page 3-0 +1))`. Set `PrimitivePolynomialSource` to `Property` to specify a polynomial using the `PrimitivePolynomial` on page 3-0 property. The default is `Auto`.

`PrimitivePolynomial`

Primitive polynomial

Specify the primitive polynomial of order M, that defines the finite Galois field GF(2). Use a double-precision, binary row vector with the coefficients of the polynomial in order of descending powers or a polynomial character vector. This property applies when you set the `PrimitivePolynomialSource` on page 3-0 property to `Property`. The default is `'X^4 + X + 1'`, which is the result of `int2bit`(`primpoly`(4),5)'.

`PuncturePatternSource`

Source of puncture pattern

Specify the source of the puncture pattern as `None` or `Property`. Set this property to `None` to disable puncturing. Set it to `Property` to decode punctured codewords. This decoding is based on a puncture pattern vector you specify in the `PuncturePattern` on page 3-0 property. The default is `None`.

`PuncturePattern`

Puncture pattern vector

Specify the pattern that the object uses to puncture the encoded data. Use a double-precision binary column vector of length `CodewordLength` on page 3-0 –`MessageLength` on page 3-0 . Zeros in the puncture pattern vector indicate the position of the parity bits that the object punctures or excludes from each codeword. This property applies when you set `PuncturePatternSource` on page 3-0 to `Property`. The default is `[ones(8,1); zeros(2,1)]`.

`ErasuresInputPort`

Enable erasures input

Set this property to `true` to specify a vector of erasures as a `step` method input. The erasures vector is a double-precision or logical binary column vector that indicates which bits of the input codewords to erase or ignore. Values of `1` in the erasures vector correspond to erased bits in the same position of the (possibly punctured) input codewords. Set this property to `false` to disable erasures. The default is `false`.

`NumCorrectedErrorsOutputPort`

Output number of corrected errors

Set this property to `true` so that the `step` method outputs the number of corrected errors. The default is `true`.

Input and Output Signal Lengths in BCH and RS System Objects

The notation `y = c * x` denotes that `y` is an integer multiple of `x`.

The number of punctures equals the number of zeros in the puncture vector.

M is the degree of the primitive polynomial. Each group of M bits represents an integer between `0` and 2^M-1 that belongs to the finite Galois field `GF(`2^M`)`.

Methods

step Decode data using a BCH decoder

Common to All System Objects	
release	Allow System object property value changes

Examples

Compute Errors for 8-DPSK-Modulated Signal with BCH Forward Error Correction Applied

Transmit a BCH-encoded, 8-DPSK-modulated bit stream through an AWGN channel, and then demodulate, decode, and count errors in the received signal.

```
enc = comm.BCHEncoder;
mod = comm.DPSKModulator('BitInput',true);
chan = comm.AWGNChannel( ...
    'NoiseMethod','Signal to noise ratio (SNR)', ...
    'SNR',10);
demod = comm.DPSKDemodulator('BitOutput',true);
dec = comm.BCHDecoder;
errorRate = comm.ErrorRate('ComputationDelay',3);

for counter = 1:20
  data = randi([0 1],30,1);
  encodedData = enc(data);
  modSignal = mod(encodedData);
  receivedSignal = chan(modSignal);
  demodSignal = demod(receivedSignal);
  receivedBits = dec(demodSignal);
  errorStats = errorRate(data,receivedBits);
end
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
  errorStats(1),errorStats(2))
```

```
Error rate = 0.015075
Number of errors = 9
```

Transmit and Receive a BPSK-Modulated Signal

Transmit and receive a BPSK-modulated signal encoded with a shortened BCH code, then count errors.

Specify the codeword, message, and shortened message lengths.

```
N = 255;
K = 239;
S = 63;
```

Create a BCH (255,239) generator polynomial. Use the generator polynomial to create a BCH encoder and decoder pair. The BCH code is based on the AMR standard.

```
gp = bchgenpoly(255,239);
bchEncoder = comm.BCHEncoder(N,K,gp,S);
bchDecoder = comm.BCHDecoder(N,K,gp,S);
```

Create an error rate counter.

```
errorRate = comm.ErrorRate('ComputationDelay',3);
```

Main processing loop.

```
for counter = 1:20
  data = randi([0 1],630,1);                % Generate binary data
  encodedData = bchEncoder(data);           % BCH encode data
  modSignal = pskmod(encodedData,2);        % BPSK modulate
  receivedSignal = awgn(modSignal,5);       % Pass through AWGN channel
  demodSignal = pskdemod(receivedSignal,2); % BSPK demodulate
  receivedBits = bchDecoder(demodSignal);   % BCH decode data
```

```
  errorStats = errorRate(data,receivedBits); % Compute error statistics
end
```

Display the error statistics.

```
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
  errorStats(1), errorStats(2))
```

```
Error rate = 0.000318
Number of errors = 4
```

Shorten a BCH Code

Shorten a (31,26) BCH code to an (11,6) BCH code and use it to encode and decode random binary data.

Create a BCH encoder and decoder pair for a (31,26) code. Specify the generator polynomial, $x^5 + x^2 + 1$, and a shortened message length of 6.

```
enc = comm.BCHEncoder(31,26,'x5+x2+1',6);
dec = comm.BCHDecoder(31,26,'x5+x2+1',6);
```

Encode and decode random binary data and verify that the decoded bit stream matches the original data.

```
x = randi([0 1],60,1);
y = step(enc,x);
z = step(dec,y);
isequal(x,z)
```

```
ans = logical
   1
```

step

System object: `comm.BCHDecoder`
Package: `comm`

Decode data using a BCH decoder

Syntax

```
Y = step(H,X)
[Y,ERR] = step(H,X)
Y = step(H,X,ERASURES)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` decodes input binary codewords in `X` using a (`CodewordLength`,`MessageLength`) BCH decoder with the corresponding narrow-sense generator polynomial. The step method returns the estimated message in `Y`. This syntax applies when you set the `NumCorrectedErrorsOutputPort` property to false. The input and output length of the step function equal the values listed in the table in “Input and Output Signal Lengths in BCH and RS System Objects” on page 3-87.

`[Y,ERR] = step(H,X)` returns the number of corrected errors in output `ERR` when you set the `NumCorrectedErrorsOutputPort` property to `true`. A non- negative value in the *i*-th element of the `ERR` output vector denotes the number of corrected errors in the *i*-th input codeword. A value of `-1` in the *i*-th element of the `ERR` output indicates that a decoding error occurred for the *i*-th input codeword. A decoding error occurs when an input codeword has more errors than the error correction capability of the BCH code.

`Y = step(H,X,ERASURES)` uses `ERASURES` as the erasures pattern input when you set the `ErasuresInputPort` property to `true`. The object decodes the binary encoded data input, `X`, and treats as erasures the bits of the input codewords specified by the binary column vector, `ERASURES`. The length of `ERASURES` must equal the length of `X`, and its elements must be of data type double or logical. Values of `1` in the erasures vector correspond to erased bits in the same position of the (possibly punctured) input codewords.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.BCHEncoder

Package: comm

Encode data using BCH encoder

Description

The BCHEncoder object creates a BCH code with specified message and codeword lengths.

To encode data using a BCH coding scheme:

1. Define and set up your BCH encoder object. See “Construction” on page 3-94.
2. Call step to create a BCH code with message and codeword lengths specified according to the properties of comm.BCHEncoder. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

enc = comm.BCHEncoder creates a BCH encoder System object, enc, that performs BCH encoding.

enc = comm.BCHEncoder(N,K) creates a BCH encoder object, enc, with the CodewordLength property set to N and the MessageLength property set to K.

enc = comm.BCHEncoder(N,K,GP) creates a BCH encoder object, enc, with the CodewordLength property set to N, the MessageLength property set to K and the GeneratorPolynomial property set to GP.

enc = comm.BCHEncoder(N,K,GP,S) creates a BCH encoder object, enc, with the CodewordLength property set to N, the MessageLength property set to K, the GeneratorPolynomial property set to GP and the ShortMessageLength property set to S.

enc = comm.BCHEncoder(N,K,GP,S,Name,Value) creates a BCH encoder object, enc, with the CodewordLength property set to N, the MessageLength property set to K, the GeneratorPolynomial property set to GP, the ShortMessageLength property set to S, and each specified property Name set to the specified Value.

enc = comm.BCHEncoder(Name,Value) creates a BCH encoder object, enc, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

Properties

Note The input and output signal lengths are listed in “Input and Output Signal Lengths in BCH and RS System Objects” on page 3-87 on the comm.BCHDecoder reference page.

`CodewordLength`

Codeword length

Specify the codeword length of the BCH code as a double-precision positive integer scalar. The default is `15`. The values of the `CodewordLength` and `MessageLength` on page 3-0 properties must produce a valid narrow-sense BCH code. For a full-length BCH code, the value of the property must use the form $2^M - 1$, where M is an integer such that $3 \le M \le 16$. The default is `15`.

`MessageLength`

Message length

Specify the message length as a double-precision positive integer scalar. The values of the `CodewordLength` on page 3-0 and `MessageLength` properties must produce a valid narrow-sense BCH code. The default is `5`.

`ShortMessageLengthSource`

Short message length source

Specify the source of the shortened message as either `Auto` or `Property`. When this property is set to `Auto`, the BCH code is defined by the `CodewordLength` on page 3-0 , `MessageLength` on page 3-0 , `GeneratorPolynomial` on page 3-0 , and `PrimitivePolynomial` on page 3-0 properties. When `ShortMessageLengthSource` is set to `Property`, you must specify the `ShortMessageLength` on page 3-0 property that is used with the other properties to define the RS code. The default is `Auto`.

`ShortMessageLength`

Shortened message length

Specify the length of the shortened message as a double-precision positive integer scalar whose value must be less than or equal to `MessageLength` on page 3-0 . When `ShortMessageLength` < `MessageLength`, the BCH code is shortened. The default is `5`.

`GeneratorPolynomialSource`

Source of generator polynomial

Specify the source of the generator polynomial as either `Auto` or `Property`. Set this property to `Auto` to create the generator polynomial automatically. Set it to `Property` to specify a generator polynomial using the `GeneratorPolynomial` on page 3-0 property. The default is `Auto`.

`GeneratorPolynomial`

Generator polynomial

Specify the generator polynomial as a binary double-precision row vector, a binary Galois row vector that represents the coefficients of the generator polynomial in order of descending powers, or as a

polynomial character vector. The length of the generator polynomial requires a value of `CodewordLength` on page 3-0 `-MessageLength` on page 3-0 `+1`. This property applies when you set `GeneratorPolynomialSource` on page 3-0 to `Property`. The default is `'X^10 + X^8 + X^5 + X^4 + X^2 + X + 1'`, which is the result of `bchgenpoly(15,5,[],'double')` and corresponds to a (15,5) code.

`CheckGeneratorPolynomial`

Enable generator polynomial checking

Set this property to `true` to perform a generator polynomial check the first time you call the `step` method. This check verifies that the specified generator polynomial is valid. For larger codes, disabling the check reduces processing time. As a best practice, perform the check at least once before setting this property to false. This property applies when you set `GeneratorPolynomialSource` on page 3-0 to `Property`. The default is `true`.

`PrimitivePolynomialSource`

Source of primitive polynomial

Specify the source of the primitive polynomial as one of `Auto` or `Property`. Set this property to `Auto` to create a primitive polynomial of degree *M*=`ceil(log2(CodewordLength on page 3-0 +1))`. Set it to `Property` to specify a polynomial using the `PrimitivePolynomial` on page 3-0 property. The default is `Auto`

`PrimitivePolynomial`

Primitive polynomial

Specify the primitive polynomial of order M, that defines the finite Galois field GF(2). Use a double-precision, binary row vector with the coefficients of the polynomial in order of descending powers or as a polynomial character vector. This property applies when you set the `PrimitivePolynomialSource` on page 3-0 property to `Property`. The default is `'X^4 + X + 1'`, which is the result of `int2bit(primpoly(4),5)'`.

`PuncturePatternSource`

Source of puncture pattern

Specify the source of the puncture pattern as one of `None` or `Property`. Set this property to `None` to disable puncturing. Set it to `Property` to decode punctured codewords. This decoding is based on a puncture pattern vector you specify in the `PuncturePattern` on page 3-0 property. The default is `None`.

`PuncturePattern`

Puncture pattern vector

Specify the pattern that the object uses to puncture the encoded data. Use a double-precision binary column vector of length `CodewordLength` on page 3-0 `-MessageLength` on page 3-0 . Zeros in

the puncture pattern vector indicate the position of the parity bits that the object punctures or excludes from each codeword. This property applies when you set `PuncturePatternSource` on page 3-0 to `Property`. The default is `[ones(8,1); zeros(2,1)]`.

Methods

step	Encode data using a BCH encoder

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Compute Errors for 8-DPSK-Modulated Signal with BCH Forward Error Correction Applied

Transmit a BCH-encoded, 8-DPSK-modulated bit stream through an AWGN channel, and then demodulate, decode, and count errors in the received signal.

```
enc = comm.BCHEncoder;
mod = comm.DPSKModulator('BitInput',true);
chan = comm.AWGNChannel( ...
    'NoiseMethod','Signal to noise ratio (SNR)', ...
    'SNR',10);
demod = comm.DPSKDemodulator('BitOutput',true);
dec = comm.BCHDecoder;
errorRate = comm.ErrorRate('ComputationDelay',3);

for counter = 1:20
  data = randi([0 1],30,1);
  encodedData = enc(data);
  modSignal = mod(encodedData);
  receivedSignal = chan(modSignal);
  demodSignal = demod(receivedSignal);
  receivedBits = dec(demodSignal);
  errorStats = errorRate(data,receivedBits);
end
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
  errorStats(1),errorStats(2))
```

```
Error rate = 0.015075
Number of errors = 9
```

Transmit and Receive a BPSK-Modulated Signal

Transmit and receive a BPSK-modulated signal encoded with a shortened BCH code, then count errors.

Specify the codeword, message, and shortened message lengths.

```
N = 255;
K = 239;
S = 63;
```

Create a BCH (255,239) generator polynomial. Use the generator polynomial to create a BCH encoder and decoder pair. The BCH code is based on the AMR standard.

```
gp = bchgenpoly(255,239);
bchEncoder = comm.BCHEncoder(N,K,gp,S);
bchDecoder = comm.BCHDecoder(N,K,gp,S);
```

Create an error rate counter.

```
errorRate = comm.ErrorRate('ComputationDelay',3);
```

Main processing loop.

```
for counter = 1:20
  data = randi([0 1],630,1);                 % Generate binary data
  encodedData = bchEncoder(data);            % BCH encode data
  modSignal = pskmod(encodedData,2);         % BPSK modulate
  receivedSignal = awgn(modSignal,5);        % Pass through AWGN channel
  demodSignal = pskdemod(receivedSignal,2);  % BSPK demodulate
  receivedBits = bchDecoder(demodSignal);    % BCH decode data
  errorStats = errorRate(data,receivedBits); % Compute error statistics
end
```

Display the error statistics.

```
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
  errorStats(1), errorStats(2))
```

```
Error rate = 0.000318
Number of errors = 4
```

Shorten a BCH Code

Shorten a (31,26) BCH code to an (11,6) BCH code and use it to encode and decode random binary data.

Create a BCH encoder and decoder pair for a (31,26) code. Specify the generator polynomial, $x^5 + x^2 + 1$, and a shortened message length of 6.

```
enc = comm.BCHEncoder(31,26,'x5+x2+1',6);
dec = comm.BCHDecoder(31,26,'x5+x2+1',6);
```

Encode and decode random binary data and verify that the decoded bit stream matches the original data.

```
x = randi([0 1],60,1);
y = step(enc,x);
z = step(dec,y);
isequal(x,z)
```

```
ans = logical
   1
```

step

System object: comm.BCHEncoder
Package: comm

Encode data using a BCH encoder

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` encodes input binary data, `X`, using a (`CodewordLength`,`MessageLength`) BCH encoder with the corresponding narrow-sense generator polynomial and returns the result in vector `Y`. The input and output length of the step function equal the values listed in the table in “Input and Output Signal Lengths in BCH and RS System Objects” on page 3-87.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.BPSKDemodulator

Package: comm

Demodulate using BPSK method

Description

The comm.BPSKDemodulator System object demodulates a signal that was modulated using the binary phase shift keying method. The object maps the points exp(jθ) or -exp(jθ) to 0 and 1, respectively. The PhaseOffset property specifies the value of θ in radians.

To demodulate BPSK-modulated signal data:

1. Create the comm.BPSKDemodulator object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
bpskdemodulator = comm.BPSKDemodulator
bpskdemodulator = comm.BPSKDemodulator(Name,Value)
bpskdemodulator = comm.BPSKDemodulator(phase,Name,Value)
```

Description

`bpskdemodulator = comm.BPSKDemodulator` creates a demodulator System object that demodulates the input signal using the BPSK method.

`bpskdemodulator = comm.BPSKDemodulator(Name,Value)` creates a BPSK demodulator System object with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

`bpskdemodulator = comm.BPSKDemodulator(phase,Name,Value)` creates a BPSK demodulator System object with the `PhaseOffset` property is set to `phase`, and the other specified properties set to the specified values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`PhaseOffset` — Phase of zeroth point of constellation
`0` (default) | scalar

Phase of zeroth point of the constellation in radians, specified as a scalar.

Data Types: `double`

`DecisionMethod` — Demodulation decision method
`'Hard decision'` (default) | `'Log-likelihood ratio'` | `'Approximate log-likelihood ratio'`

Demodulation decision method, specified as `'Hard decision'`, `'Log-likelihood ratio'`, or `'Approximate log-likelihood ratio'`.

Data Types: `char` | `string`

`VarianceSource` — Source of noise variance
`'Property'` (default) | `'Input port'`

Source of noise variance, specified as one of `'Property'` or `'Input port'`.

Dependencies

To enable this property set the `DecisionMethod` property to `'Log-likelihood ratio'` or `'Approximate log-likelihood ratio'`.

Data Types: `char` | `string`

`Variance` — Noise variance
1 (default) | nonzero scalar

Noise variance, specified as a nonzero scalar. When the noise variance or signal power result in computations involving extreme positive or negative magnitudes, see “BPSK Soft Demodulation” on page 3-107 for demodulation decision type considerations.

Tunable: Yes

Dependencies

To enable this property set the `VarianceSource` property to `'Property'`.

Data Types: `double`

`OutputDataType` — Output datatype
`'Full precision'` (default) | `'Smallest unsigned integer'` | `'double'` | `'single'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'logical'` | ...

Output datatype, specified as one of these options.

- When you set this property to `'Full precision'`, the output data type is the same as that of the input when the input data type is single or double precision. If the input data is of a fixed-point type, then the output data type works as if you had set this property to `'Smallest unsigned integer'`.

- When you set the `DecisionMethod` property to `'Log-liklihood ratio'` or `'Approximate log-liklihood ratio`, the output data type is the same as that of the input and the input data type must be single or double precision.

  Note For integer data type inputs, the Fixed-Point Designer™ software is required when this property is set to `'Full precision'` or `'Smallest unsigned integer'`.

- `'Full precision'`
- `'Smallest unsigned integer'`
- `'double'`
- `'single'`
- `'int8'`
- `'uint8'`
- `'int16'`
- `'uint16'`
- `'int32'`
- `'uint32'`
- `'logical'`

Dependencies

To enable this property set the `DecisionMethod` property to `'Hard decision'`.

Data Types: `char`

Fixed-Point Properties

`DerotateFactorDataType` — Data type of derotate factor

`'Same word length as input'` (default) | `'Custom'`

Data type of derotate factor, specified as one of `'Same word length as input'` | `'Custom'`.

Dependencies

To enable this property set the `DecisionMethod` property to `'Hard decision'`. Additionally, the object uses the derotate factor in the computations only when the input must be of a fixed-point type, and the `PhaseOffset` property value is not a multiple of π/2.

Data Types: `char` | `string`

`CustomOutputDataType` — Fixed-point data type of output

`numerictype([],16)` (default) | `numerictype` object

Fixed-point data type of output, specified as a `numerictype` object with a signedness of Auto.

Dependencies

To enable this property set the `OutputDataType` property to `'Custom'`.

Data Types: `fi`

Usage

Syntax

```
data = bpskdemodulator(waveform)
```

Description

`data = bpskdemodulator(waveform)` applies BPSK demodulation to the modulated waveform and returns the demodulated input signal.

Input Arguments

`waveform` — BPSK Modulated baseband signal

column vector | matrix

BPSK Modulated baseband signal, specified as a column vector or matrix of the same size as the input signal. For more information about the output datatype, see the `OutputDataType` property.

Data Types: `double` | `single` | `fi`
Complex Number Support: Yes

Output Arguments

`data` — Output signal data

column vector | matrix

Output signal data, returned as a column vector or matrix. The `OutputDataType` specifies the data type for the output data.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `comm.BPSKDemodulator`

constellation	Calculate or plot ideal signal constellation

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Demodulate BPSK Signal and Calculate Errors

Generate a BPSK signal, pass it through an AWGN channel, demodulate the signal, and compute the error statistics.

Create BPSK modulator and demodulator System objects.

```
bpskModulator = comm.BPSKModulator;
bpskDemodulator = comm.BPSKDemodulator;
```

Create an error rate calculator System object.

```
errorRate = comm.ErrorRate;
```

Generate 50-bit random data frames, apply BPSK modulation, pass the signal through an AWGN channel, demodulate the received data, and compile the error statistics.

```
for counter = 1:100
    % Transmit a 50-symbol frame
    txData = randi([0 1],50,1);            % Generate data
    modSig = bpskModulator(txData);        % Modulate
    rxSig = awgn(modSig,5);                % Pass through AWGN
    rxData = bpskDemodulator(rxSig);       % Demodulate
    errorStats = errorRate(txData,rxData); % Collect error stats
end
```

Display the cumulative error statistics.

```
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))
```

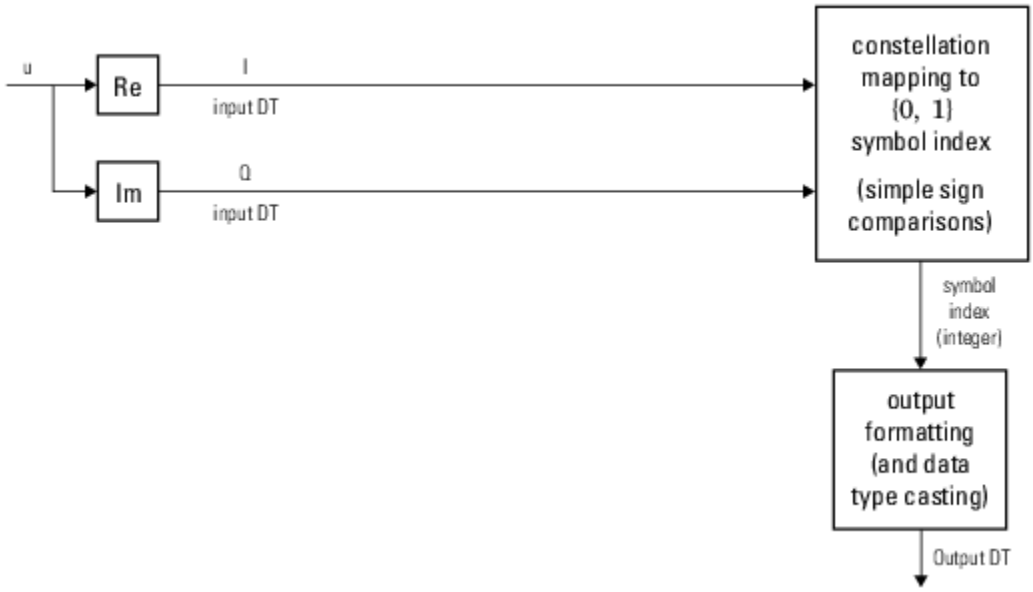
```
Error rate = 0.005600
Number of errors = 28
```

More About

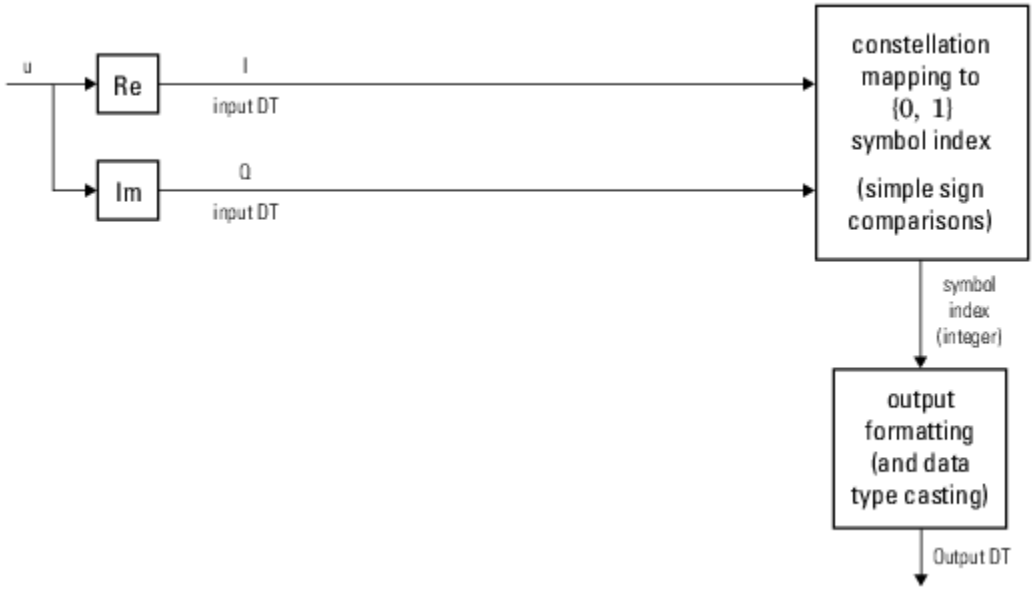
BPSK Hard-Decision Demodulation

When applying hard demodulation, the input signal type and phase offset are considered.

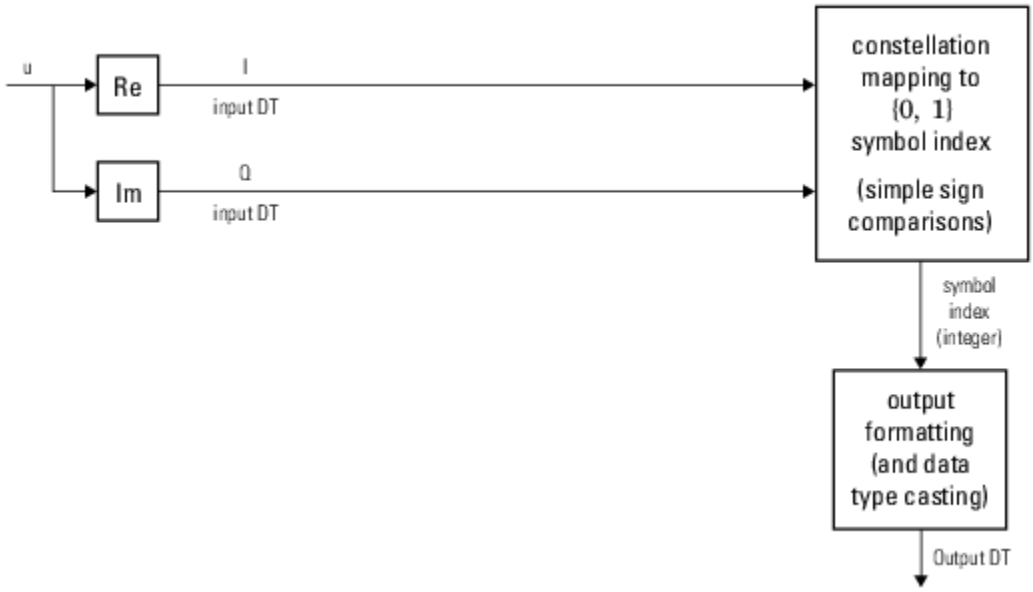
This figure shows the hard decision BPSK demodulator for a floating-point or fixed-point signal and trivial phase offset (multiple of π/2)



This figure shows the hard decision BPSK demodulator for a floating-point signal and nontrivial phase offset



This figure shows the hard decision BPSK demodulator for a fixed-point signal and nontrivial phase offset



BPSK Soft Demodulation

For soft demodulation, two soft-decision log-likelihood ratio (LLR) algorithms are available: exact LLR and approximate LLR. The exact LLR algorithm is more accurate but has slower execution speed than the approximate LLR algorithm. For further description of these algorithms, see the “Hard- vs. Soft-Decision Demodulation” topic.

Note The exact LLR algorithm computes exponentials using finite precision arithmetic. For computations involving very large positive or negative magnitudes, the exact LLR algorithm yields:

- `Inf` or `-Inf` if the noise variance is a very large value
- `NaN` if the noise variance and signal power are both very small values

The approximate LLR algorithm does not compute exponentials. You can avoid `Inf`, `-Inf`, and `NaN` results by using the approximate LLR algorithm.

Version History

Introduced in R2012a

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

HDL Code Generation
Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

`double` and `single` data types are supported for simulation, but not for HDL code generation.

To generate HDL code from predefined System objects, see “HDL Code Generation from Viterbi Decoder System Object” (HDL Coder).

comm.IQImbalanceCompensator

Package: comm

Compensate for IQ imbalance

Description

The `comm.IQImbalanceCompensator` System object compensates for the imbalance between the in-phase and quadrature (IQ) components of a modulated signal. The adaptive algorithm inherent to the IQ imbalance compensator is compatible with *M*-PSK, *M*-QAM, and OFDM modulation schemes, where *M*>2. For more information, see “Algorithms” on page 3-120.

Note The output of the compensator might be scaled and rotated, that is, multiplied by a complex number, relative to the reference constellation. In practice, this transformation is not an issue because, before demodulation, receivers correct for it by using channel estimation.

To compensate for IQ imbalance:

1. Create the `comm.IQImbalanceCompensator` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
iqcomp = comm.IQImbalanceCompensator
iqcomp = comm.IQImbalanceCompensator(Name=Value)
```

Description

`iqcomp = comm.IQImbalanceCompensator` creates a compensator System object that compensates for the imbalance between the in-phase and quadrature components of the input signal.

`iqcomp = comm.IQImbalanceCompensator(Name=Value)` creates an IQ imbalance compensator object and sets properties using one or more name-value arguments. For example, `comm.IQImbalanceCompensator(CoefficientSource="Input port")` specifies that the compensator coefficients must be provided when you call the object. For this configuration, all other properties are disabled.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`CoefficientSource` — Source of compensator coefficients

`"Estimated from input signal"` (default) | `"Input port"`

Source of the compensator coefficients, specified as either `"Estimated from input signal"` or `"Input port"`.

- If this property is set to `"Estimated from input signal"`, the compensator uses an adaptive algorithm and the input signal to estimate the compensator coefficient.
- If this property is set to `"Input port"`, all other properties are disabled and the compensator coefficients must be provided as input argument `c` when you call the object.

`InitialCoefficent` — Initial coefficient used to compensate for IQ imbalance

`0+0i` (default) | scalar

Initial coefficient used to compensate for IQ imbalance, specified as a complex scalar.

Dependencies

To enable this property, set the `CoefficientSource` property to `"Estimated from input signal"`.

Data Types: `double`
Complex Number Support: Yes

`StepSizeSource` — Source of step size for coefficient adaptation

`"Property"` (default) | `"Input port"`

Source of the step size to use for coefficient adaptation, specified as either `"Property"` or `"Input port"`.

- If this property is set to `"Property"`, specify the step size through the `StepSize` property.
- If this property is set to `"Input port"`, specify the step size as input argument `s` when calling the object.

`StepSize` — Adaptation step size

`1e-5` (default) | scalar

Adaptation step size, specified as a scalar. The value of this property is the step size that the algorithm uses when estimating the IQ imbalance. For more information, see “Algorithms” on page 3-120.

Tunable: Yes

Dependencies

To enable this property, set the `StepSizeSource` to `"Property"`.

Data Types: `double`

`AdaptInputPort` — Option to adapt compensator coefficient
`false` or `0` (default) | `true` or `1`

Option to adapt the compensator coefficient from an input argument, specified as a logical `0` (`false`) or `1` (`true`).

- If this property is `false`, the coefficients update after each output sample.
- If this property is `true`, you must provide a logical value for the input argument `a` to enable and disable coefficient adaptation.

`CoefficientOutputPort` — Option to output compensator coefficients
`false` or `0` (default) | `true` or `1`

Option to output the compensator coefficients, specified as a logical `0` (`false`) or `1` (`true`).

- When this logical property is `false`, the IQ imbalance compensator coefficients are not available as output when you call the object.
- When this logical property is `true`, the IQ imbalance compensator coefficients are available as output `coef` when you call the object.

Usage

Syntax

```
y = iqcomp(x)
y = iqcomp(x,c)
y = iqcomp(x,s)
y = iqcomp(x,a)
y = iqcomp(x,s,a)
[y,estcoef] = iqcomp(x, ___ )
```

Description

`y = iqcomp(x)` compensates for IQ imbalance of the input signal. The compensator coefficient is estimated from `x` by a blind adaptive algorithm.

`y = iqcomp(x,c)` accepts input compensation coefficients, `c`, instead of generating them internally. This syntax applies when the `CoefficientSource` property is set to `Input port`. When using this syntax, adaptive estimation of the compensator coefficient is disabled.

`y = iqcomp(x,s)` accepts input step size, `s`. This syntax applies when the `StepSizeSource` property is set to `Input port`.

`y = iqcomp(x,a)` accepts the adaptation control signal, `a`, to enable or disable coefficient updates. This syntax applies when the `AdaptInputPort` property is set to `true`.

`y = iqcomp(x,s,a)` accepts the step size, `s`, and the adaptation control signal, `a`, to enable and disable coefficient updates. This syntax applies when the `StepSizeSource` property is set to `Input port` and the `AdaptInputPort` property is set to `true`.

`[y,estcoef] = iqcomp(x, ___ )` also returns estimated compensation coefficients with input arguments from any of the previous syntaxes. This syntax applies when the `CoefficientOutputPort` property is set to `Input port`.

Input Arguments

x — Input signal

scalar | column vector

Input signal, specified as a scalar or a column vector.

Data Types: `double` | `single`

c — Compensator coefficients

scalar | column vector

Compensator coefficients, specified as a scalar or a column vector the same length as input signal `x`.

Dependencies

To enable this input, set the `CoefficientSource` property to `"Input port"`.

Data Types: `single` | `double`

s — Step size

scalar

Step size for blind adaptive estimation of compensator coefficient, specified as a scalar.

Dependencies

To enable this input, set the `StepSizeSource` property to `"Input port"`.

Data Types: `single` | `double`

a — Adaptation control signal

logical scalar

Adaptation control signal, specified as a logical scalar.

- If this property is `true`, then the compensator coefficient will be adapted.
- If this property is `false`, then the compensator coefficient will remain unchanged.

Dependencies

To enable this input, set the `AdaptInputPort` property to `"Input port"`.

Data Types: `logical`

Output Arguments

y — IQ imbalance compensated signal

scalar | column vector

IQ imbalance compensated signal, returned as a scalar or column vector with the same size as input signal `x`.

coef — Estimated compensator coefficient

scalar | column vector

Estimated compensator coefficient, returned as a scalar or column vector with the same size as input signal `x`.

- If `a` is `true`, the returned compensator coefficient adapts when you call the object.
- If `a` is `false`, then the returned compensator coefficient remains unchanged from the last time you called the object.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Remove IQ Imbalance from QPSK Signal

Mitigate the impacts of amplitude and phase imbalance on a QPSK modulated signal by using the `comm.IQImbalanceCompensator` System object™.

Generate random data symbols and apply QPSK modulation.

```
M = 4;                          % QPSK
spf = 1e6;                      % Samples per frame
data = randi([0 M-1],spf,1);
txSig = pskmod(data,M,pi/4);
```

Create a constellation diagram object to display the QPSK signal before and after IQ imbalance compensation. The reference constellation for the object does not require an update because the default QPSK reference constellation matches the transmitted signal.

```
cdscope = comm.ConstellationDiagram( ...
    NumInputPorts=2, ...
    ShowLegend=true, ...
    ChannelNames=["Impaired signal","IQ imbalance compensated"]);
```

Create an IQ imbalance compensator.

```
iqImbComp = comm.IQImbalanceCompensator;
```

Apply amplitude and phase imbalance to the transmitted signal.

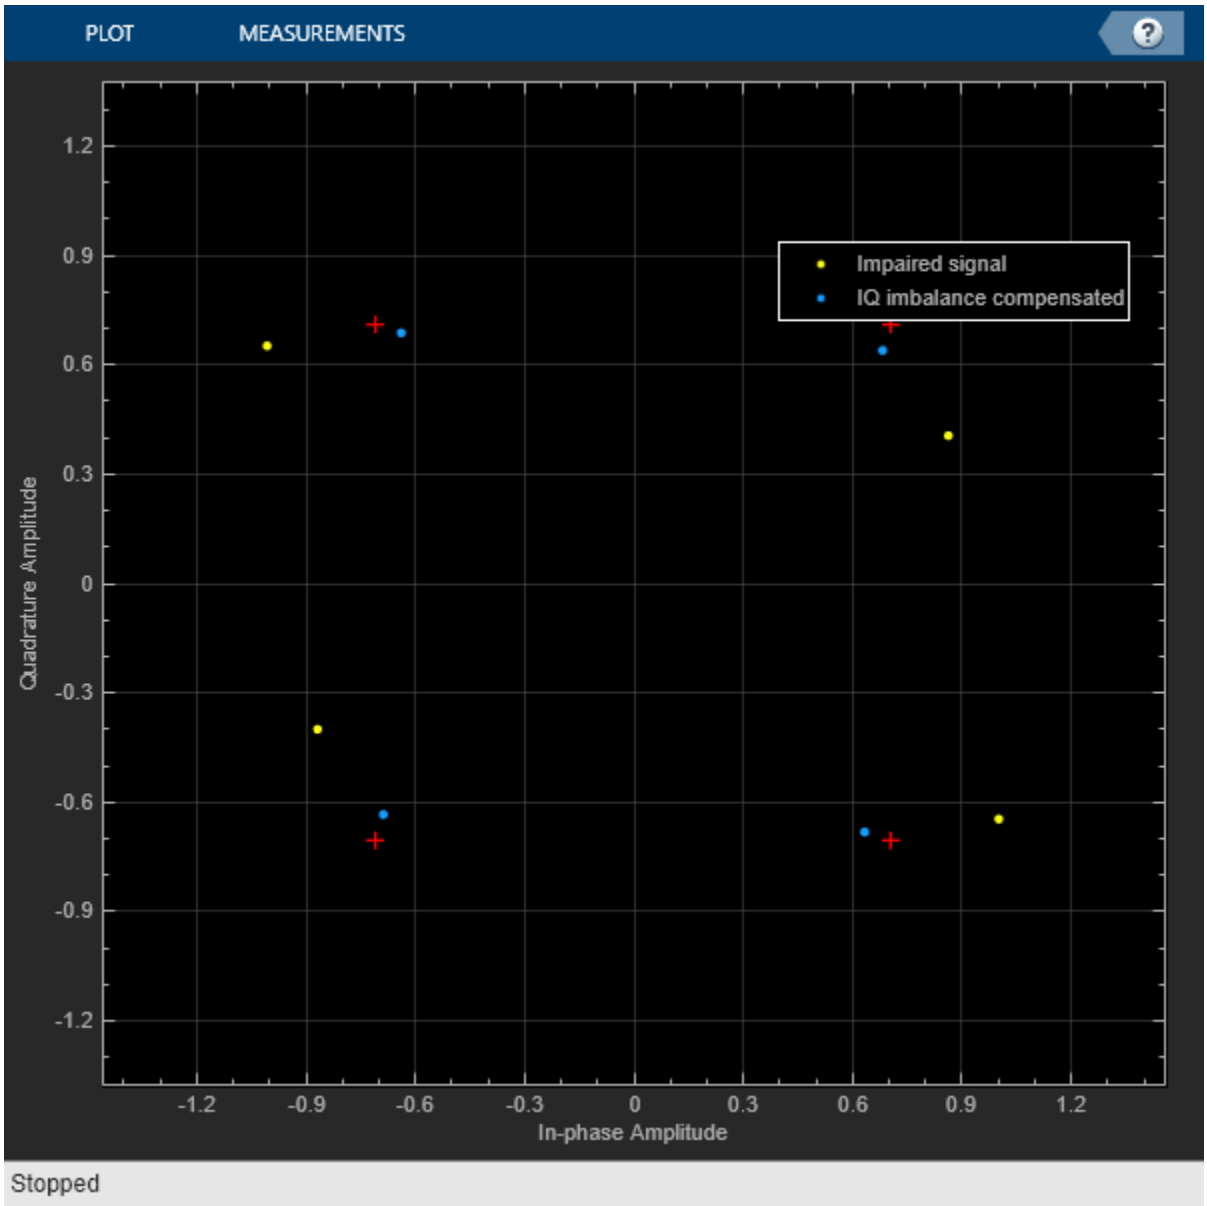
```
ampImb = 5;                             % dB
phImb = 15;                             % deg
rxSig = iqimbal(txSig,ampImb,phImb);
```

On the receiver side, apply the IQ compensation algorithm to the impaired signal.

```
compSig = iqImbComp(rxSig);
```

To display the impaired signal and the IQ impairment compensated signal, load the last 1000 symbols of the signals into the constellation diagram object. The impaired signal constellation shows IQ amplitude and phase impairments. The impairment compensated signal constellation nearly aligns with the reference constellation.

```
cdscope(rxSig(spf - 1000:end),compSig(spf - 1000:end))
release(cdscope)
```



Remove IQ Imbalance from 8-PSK Signal Using External Coefficients

Compensate for an amplitude and phase imbalance on an 8-PSK signal by using the `comm.IQImbalanceCompensator` System object™ with external coefficients.

Generate an 8-PSK reference constellation. Create a constellation diagram System object. Configure the constellation diagram object to display only the last 100 data symbols of two input signals and provide the reference constellation.

```
refconst = pskmod(0:7,8,0);
cdscope = comm.ConstellationDiagram(...
    NumInputPorts=2, ...
    SymbolsToDisplaySource="Property", ...
    SymbolsToDisplay=100, ...
    ReferenceConstellation=refconst, ...
    ChannelNames=["Uncompensated","Compensated"]);
```

Create an I/Q imbalance compensator object with an input port for the algorithm coefficients.

```
iqcomp = comm.IQImbalanceCompensator( ...
    CoefficientSource="Input port");
```

Generate random data symbols and apply 8-PSK modulation.

```
data = randi([0 7],1000,1);
txSig = pskmod(data,8,0);
```

Apply amplitude and phase imbalance to the transmitted signal.

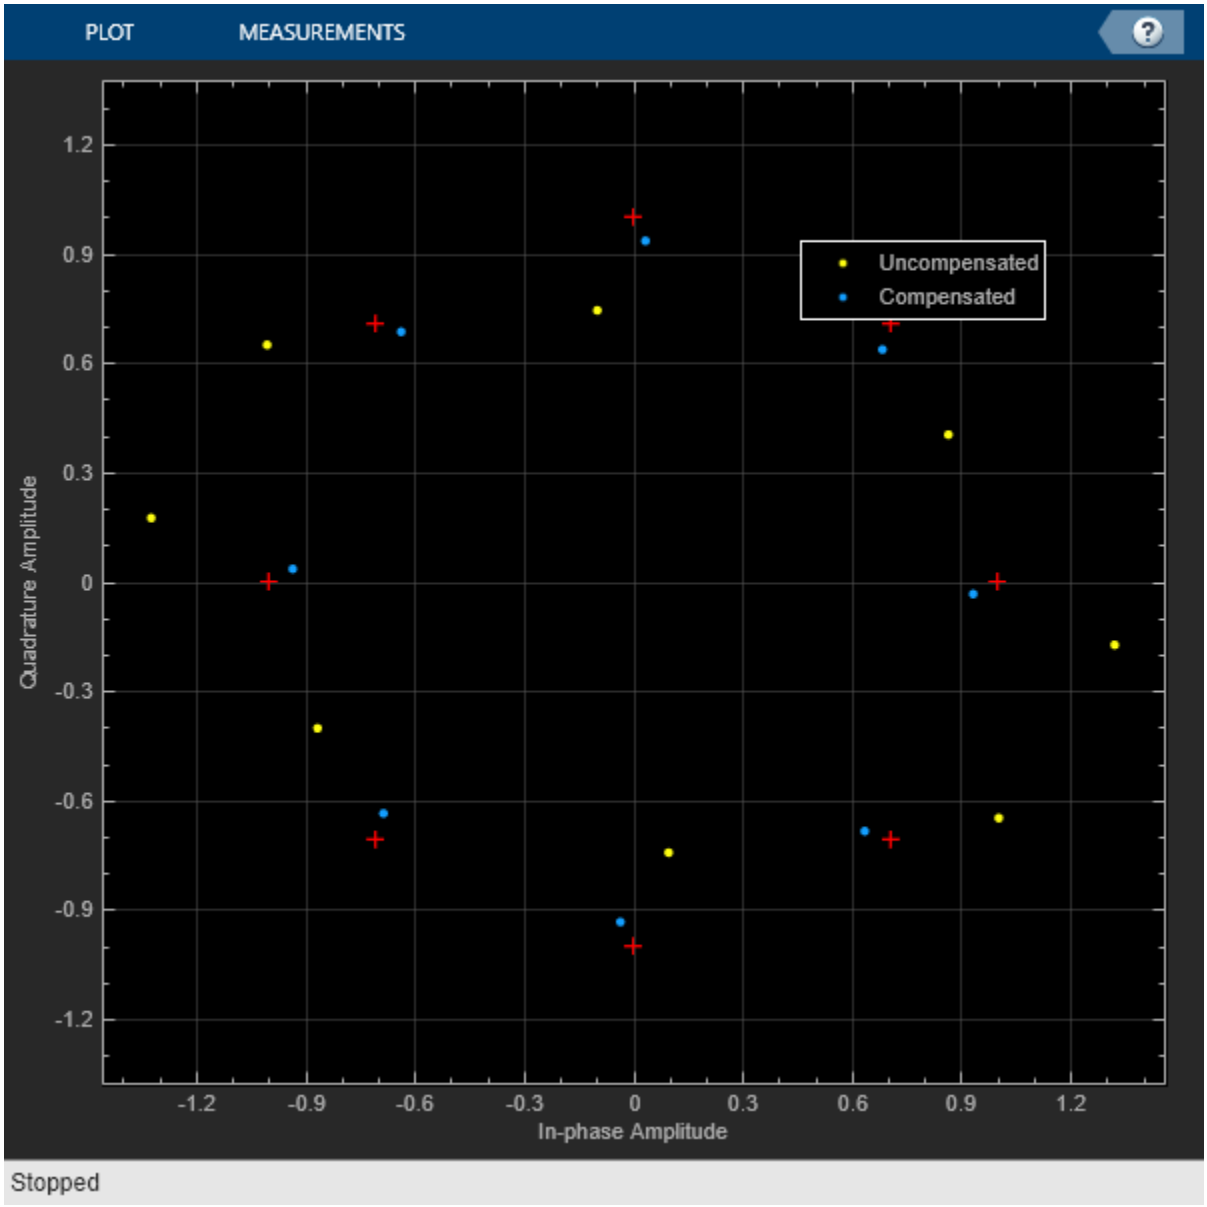
```
ampImb = 5;                          % dB
phImb = 15;                          % degrees
rxSig = iqimbal(txSig,ampImb,phImb);
```

Use the `iqimbal2coef` function to determine the compensation coefficient given the amplitude and phase imbalance.

```
compCoef = iqimbal2coef(ampImb,phImb);
```

Apply the compensation coefficient to the received signal when calling the `iqcomp` object. Display the resulting constellations for the uncompensated and compensated signal. You can see severe IQ imbalance in the uncompensated signal and the compensated signal constellation is nearly aligned with the reference constellation.

```
compSig = iqcomp(rxSig,compCoef);
cdscope(rxSig,compSig)
release(cdscope)
```



Remove IQ Imbalance from QAM Signal

Remove an IQ imbalance from a 64-QAM signal and make the estimated coefficients externally available while setting the algorithm step size from an input port.

Create a constellation diagram object. Use name-value pairs to ensure that the constellation diagram displays only the last 256 data symbols, set the axes limits, and specify the reference constellation.

```
M = 64;
refC = qammod(0:M-1,M);
cdscope = comm.ConstellationDiagram(...
    NumInputPorts=2, ...
```

```
    SymbolsToDisplaySource="Property", ...
    SymbolsToDisplay=256, ...
    XLimits=[-10 10], ...
    YLimits=[-10 10], ...
    ReferenceConstellation=refC, ...
    ChannelNames=["Uncompensated","Compensated"]);
```

Create an IQ imbalance compensator System object™ in which the step size is specified as an input argument and the estimated coefficients are made available through an output port.

```
iqImbComp = comm.IQImbalanceCompensator( ...
    StepSizeSource="Input port", ...
    CoefficientOutputPort=true);
```

Generate random data symbols and apply 64-QAM modulation.

```
nSym = 30000;
data = randi([0 M-1],nSym,1);
txSig = qammod(data,M);
```

Apply amplitude and phase imbalance to the transmitted signal.

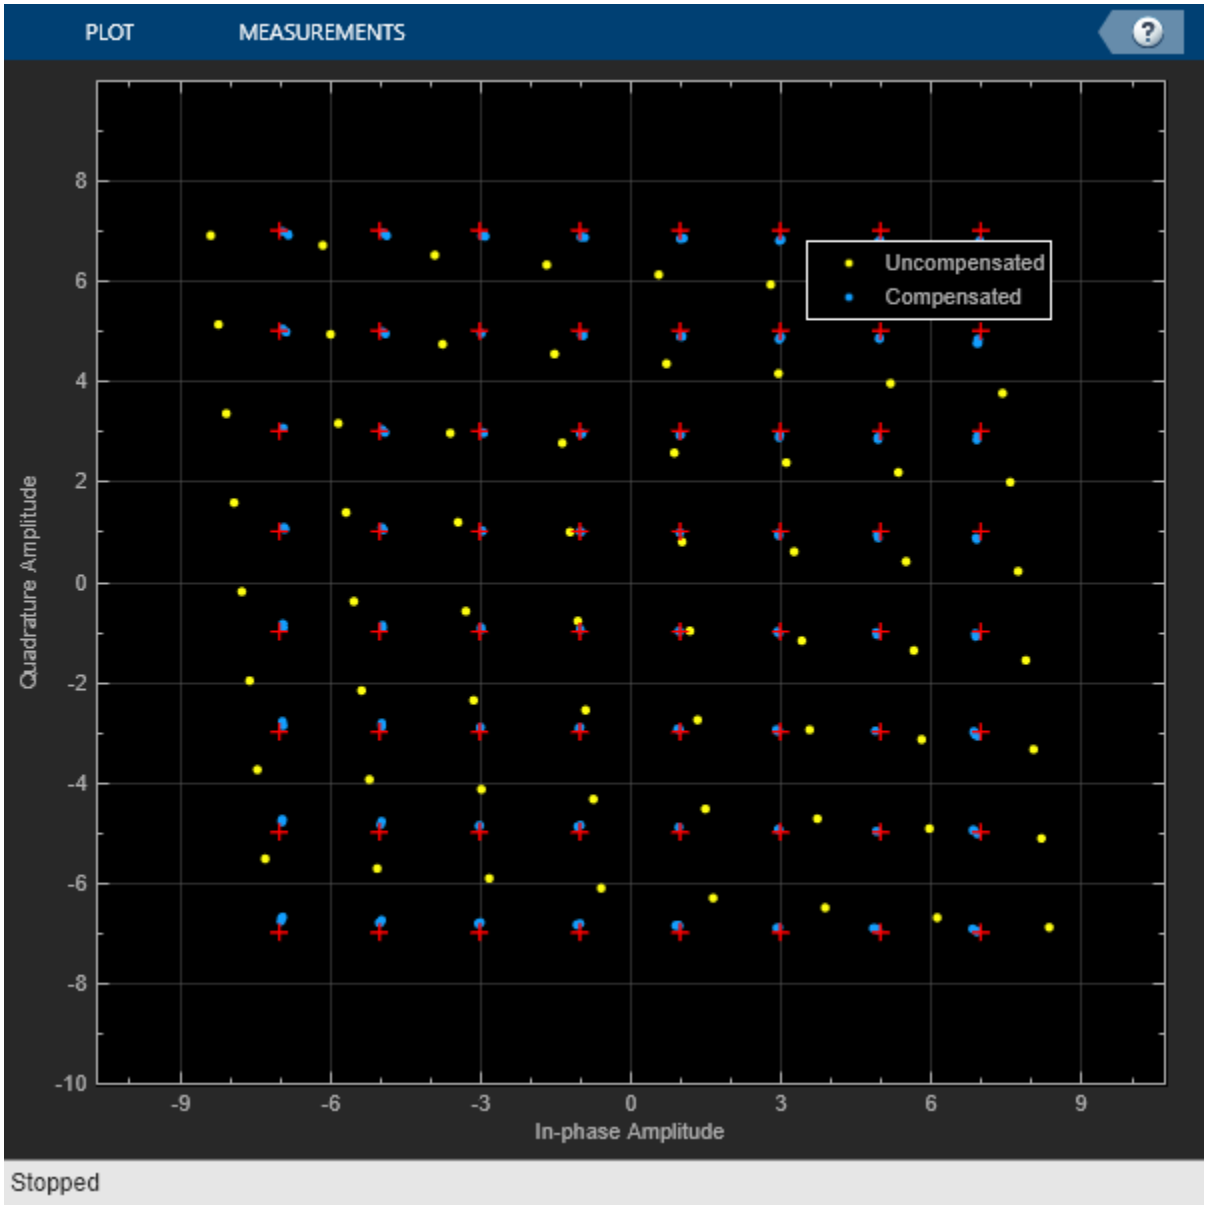
```
ampImb = 2;                          % dB
phImb = 10;                          % deg
rxSig = iqimbal(txSig,ampImb,phImb);
```

Specify the step size parameter for the IQ imbalance compensator.

```
stepSize = 1e-5;
```

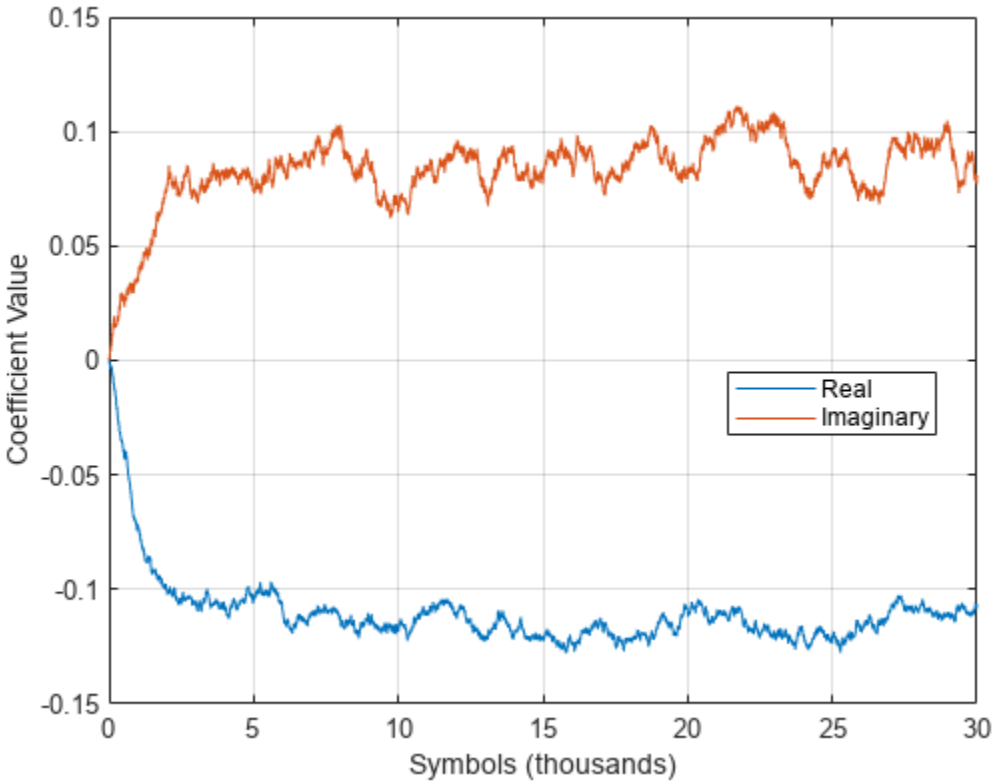
Compensate for the IQ imbalance while setting the step size with an input argument. Plot the constellation diagram of the received signal. You can see that the compensated signal constellation is now nearly aligned with the reference constellation.

```
[compSig,estCoef] = iqImbComp(rxSig,stepSize);
cdscope(rxSig,compSig)
release(cdscope)
```



Plot the real and imaginary values of the estimated coefficients. The output coefficients show the simulation reaches a steady-state solution after approximately 5000 symbols.

```
plot((1:nSym)'/1000,[real(estCoef),imag(estCoef)])
grid
xlabel('Symbols (thousands)')
ylabel('Coefficient Value')
legend('Real','Imaginary','location','best')
```



Control Adaptation Algorithm for IQ Imbalance Compensator

Control the adaptation algorithm of the IQ imbalance compensator using an external argument.

Apply QPSK modulation to random data symbols.

```
data = randi([0 3],600,1);
txSig = pskmod(data,4,pi/4,'gray');
```

Create an IQ imbalance compensator in which the adaptation algorithm is controlled through an input port, the step size is specified through the `StepSize` property, and the estimated coefficients are made available through an output port.

```
iqImbComp = comm.IQImbalanceCompensator( ...
    AdaptInputPort=true, ...
    StepSize=0.001, ...
    CoefficientOutputPort=true);
```

Apply amplitude and phase imbalance to the transmitted signal.

```
ampImb = 5; % dB
phImb = 15; % deg
gainI = 10.^(0.5*ampImb/20);
gainQ = 10.^(-0.5*ampImb/20);
imbI = real(txSig)*gainI*exp(-0.5i*phImb*pi/180);
```

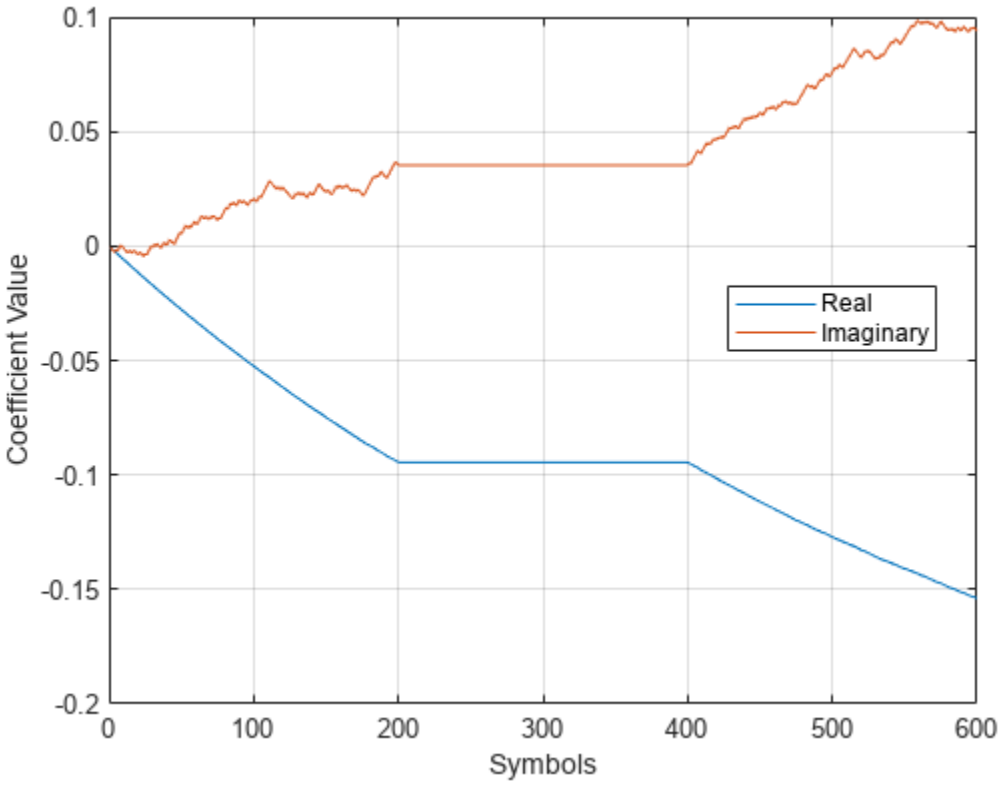
```
imbQ = imag(txSig)*gainQ*exp(1i*(pi/2 + 0.5*phImb*pi/180));
rxSig = imbI + imbQ;
```

Break the compensation operation into three segments in which the compensator is enabled for the first 200 symbols, disabled for the next 200 symbols, and enabled for the last 200 symbols. Save the coefficient data in three vectors.

```
[~,estCoef1] = iqImbComp(rxSig(1:200),true);
[~,estCoef2] = iqImbComp(rxSig(201:400),false);
[~,estCoef3] = iqImbComp(rxSig(401:600),true);
```

Concatenate the complex algorithm coefficients and plot their real and imaginary parts. Observe that the coefficients do not adapt when the compensator is disabled.

```
estCoef = [estCoef1; estCoef2; estCoef3];
plot((1:600)',[real(estCoef) imag(estCoef)])
grid
xlabel('Symbols')
ylabel('Coefficient Value')
legend('Real','Imaginary','location','best')
```

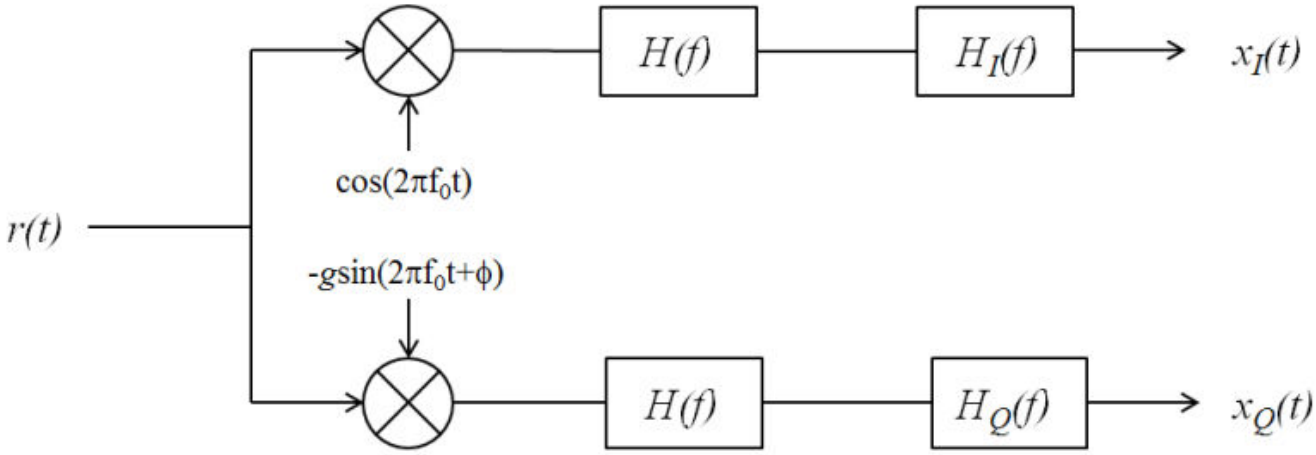


Algorithms

Imbalance between the in-phase and quadrature components of signal output from RF receivers can be cost-effectively compensated rather than improving the analog front-end RF hardware. Direct

conversion receivers, in particular, introduce IQ imbalance. A circularity-based blind compensation algorithm is used as the basis for the IQ imbalance compensator.

A generalized IQ imbalance model is shown, where g is the amplitude imbalance and ϕ is the phase imbalance. For no impairment, $g = 1$ and $\phi = 0$. In the figure, $H(f)$ is the nominal frequency response of the branches due to, for example, low-pass filters. $H_I(f)$ and $H_Q(f)$ represent the portions of the in-phase and quadrature amplitude and phase responses that differ from the nominal response. With perfect matching, $H_I(f) = H_Q(f) = 1$.



Let $z(t)$ be the ideal baseband equivalent signal of the received signal, $r(t)$, where its Fourier transform is denoted as $Z(f)$. Given the generalized IQ imbalance model, the Fourier transform of the imbalanced signal, $x(t) = x_I(t) + x_Q(t)$, is

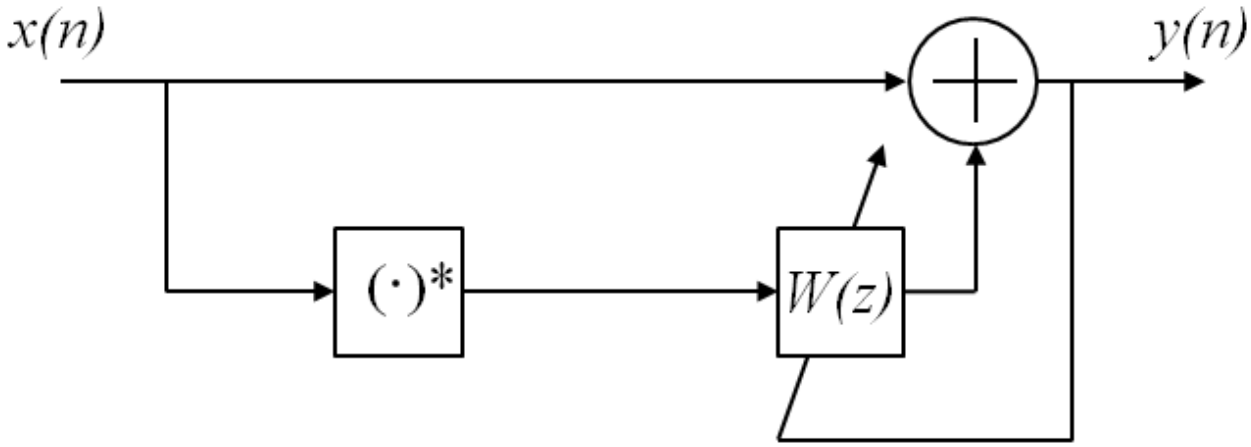
$$X(f) = G_1(f)Z(f) + G_2(f)Z^*(-f)$$

where $G_1(f)$ and $G_2(f)$ are the direct and conjugate components of the IQ imbalance. These components are defined as

$$G_1(f) = \left[H_I(f) + H_Q(f)g\exp(-j\phi)\right]/2$$
$$G_2(f) = \left[H_I(f) + H_Q(f)g\exp(j\phi)\right]/2$$

Applying the inverse Fourier transform to $X(f)$, the signal model becomes $x(t) = g_1(t) \times z(t) + g_2(t) \times z^*(t)$.

This transformation suggests the compensator structure as shown in which discrete-time notation expresses the variables. The compensated signal is expressed as $y(n) = x(n) + wx^*(n)$.



An algorithm of the form

$$\begin{cases} y(n) = x(n) + w(n)x^*(n) \\ w(n+1) = w(n) - My^2(n) \end{cases}$$

is used to determine the weights because it ensures that the output is proper, that is, the condition, $E[y^2(n)] = 0$ is satisfied. For further details, see [1]. The initial value of w is determined by the initial compensator coefficient, which has a default value of `0 + 0i`. M is the adaptation step size as described in `StepSize`.

Version History

Introduced in R2014b

comm.BPSKModulator

Package: comm

Modulate using BPSK method

Description

The comm.BPSKModulator object modulates using the binary phase shift keying method. The output is a baseband representation of the modulated signal. The input signal must be a discrete-time binary-valued signal. If the input bit is 0 or 1, then the modulated symbol is exp(jθ) or -exp(jθ), respectively. The PhaseOffset property specifies the value of θ in radians.

To modulate a signal using BPSK method:

1. Create the comm.BPSKModulator object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
bpskmodulator = comm.BPSKModulator
bpskmodulator = comm.BPSKModulator(Name,Value)
bpskmodulator = comm.BPSKModulator(phase,Name,Value)
```

Description

bpskmodulator = comm.BPSKModulator creates a modulator System object to modulate input signals using the binary phase shift keying (BPSK) method.

bpskmodulator = comm.BPSKModulator(Name,Value) creates a BPSK modulator object with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

bpskmodulator = comm.BPSKModulator(phase,Name,Value) creates a BPSK modulator object with the PhaseOffset property set to phase, and the other specified properties set to the specified values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`PhaseOffset` — Phase of zeroth point of constellation

`0` (default) | scalar

Phase of zeroth point of the constellation in radians, specified as a scalar.

Data Types: `double`

`OutputDataType` — Output datatype

`'double'` (default) | `'single'` | `'Custom'`

Output datatype, specified as `'double'`, `'single'` or `'Custom'`.

Data Types: `char`

Fixed-Point Properties

`CustomOutputDataType` — Fixed-point data type of output

`numerictype([],16)` (default) | `numerictype` object

Fixed-point data type of the output, specified as a `numerictype` object with a signedness of Auto.

Dependencies

This property applies when you set the `OutputDataType` property to `'Custom'`.

Usage

Syntax

```
waveform = bpskmodulator(data)
```

Description

`waveform = bpskmodulator(data)` applies BPSK modulation to the input data and returns the modulated BPSK baseband signal.

Input Arguments

`data` — Input signal data

column vector | matrix

Input signal data, specified as a column vector or matrix.

Data Types: `double`

Output Arguments

`waveform` — BPSK modulated baseband signal

column vector | matrix

BPSK modulated baseband signal, returned as a column vector or matrix of the same size as the input signal. For more information about the output datatype, see the `OutputDataType` property.

Data Types: `double` | `single` | `fi`

Complex Number Support: Yes

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `comm.BPSKModulator`

constellation	Calculate or plot ideal signal constellation

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

BPSK Data Scatter Plot

This example creates binary data, modulates it, and then displays the data using a scatter plot.

Create binary data symbols.

```
data = randi([0 1],100,1);
```

Create a BPSK modulator System object.

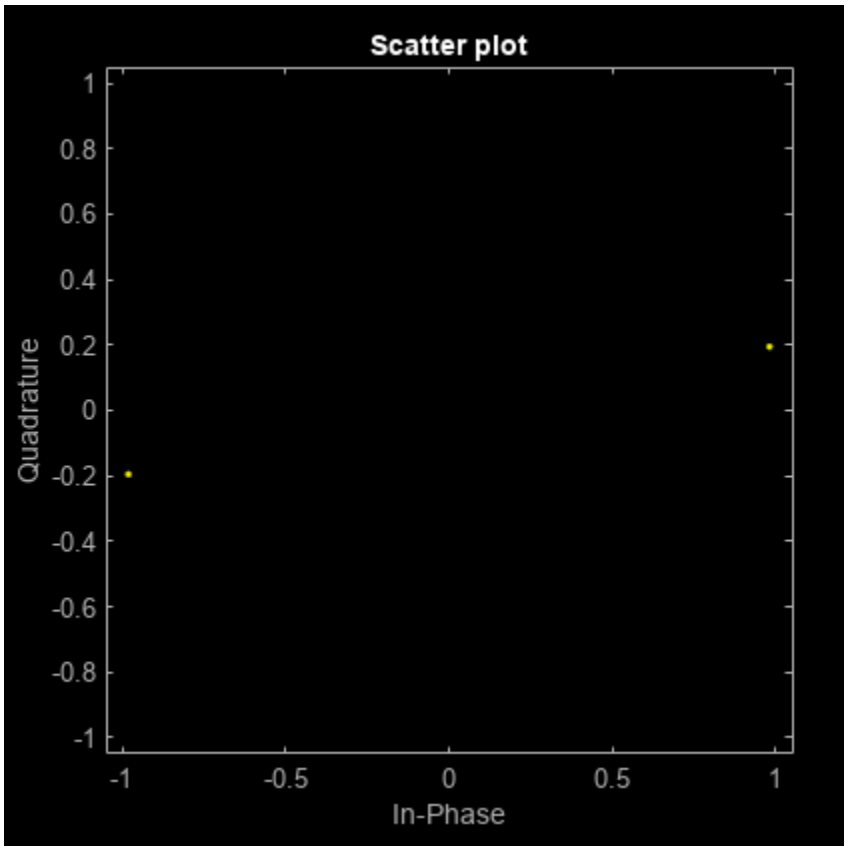
```
bpskModulator = comm.BPSKModulator;
```

Change the phase offset to pi/16.

```
bpskModulator.PhaseOffset = pi/16;
```

Modulate and plot the data.

```
modData = bpskModulator(data);
scatterplot(modData)
```



Algorithms

Phase modulation is a linear baseband modulation technique in which the message modulates the phase of a constant amplitude signal. Binary Phase Shift Keying (BPSK) is a two phase modulation scheme, where the 0's and 1's in a binary message are represented by two different phase states in the carrier signal

$$s_n(t) = \sqrt{\frac{2E_b}{T_b}}\cos(2\pi f_c t + \phi_n),$$

for $(n-1)T_b \le t \le nT_b,\ \text{n} = 1, 2,\ 3, \ldots$where:

- $\phi_n = \pi m$, $m \in \{0,1\}$.
- E_b is the energy per bit.
- T_b is the bit duration.
- f_c is the carrier frequency.

In MATLAB, the baseband representation of a BPSK signal is

$$s_n(t) = e^{-i\phi_n} = \cos(\pi n)\,.$$

The BPSK signal has two phases: 0 and π. The probability of a bit error in an AWGN channel is

$$P_b = Q\left(\sqrt{\frac{2E_b}{N_0}}\right),$$

where N_0 is the noise power spectral density.

BPSK Modulator Baseband

comm.OFDMModulator

Package: comm

Modulate signal using OFDM method

Description

The OFDMModulator object modulates a signal using the orthogonal frequency division multiplexing method. The output is a baseband representation of the modulated signal.

To modulate a signal using OFDM:

1. Create the comm.OFDMModulator object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
hMod = comm.OFDMModulator
hMod = comm.OFDMModulator(Name,Value)
hMod = comm.OFDMModulator(hDemod)
```

Description

hMod = comm.OFDMModulator creates an OFDM modulator System object.

hMod = comm.OFDMModulator(Name,Value) specifies “Properties” on page 3-129 using one of more name-value pair arguments. Enclose each property name in quotes. For example, comm.OFDMModulator('NumSymbols',8) specifies eight OFDM symbols in the time-frequency grid.

hMod = comm.OFDMModulator(hDemod) sets the OFDM modulator system object properties based on the specified OFDM demodulator system object comm.OFDMDemodulator.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

FFTLength — Number of FFT points
64 (default) | positive integer

Number of Fast Fourier Transform (FFT) points, specified as a positive integer. The length of the FFT, N_{FFT}, must be greater than or equal to 8 and is equivalent to the number of subcarriers.

Data Types: `double`

`NumGuardBandCarriers` — Number of subcarriers to the left and right guard bands
`[6;5]` (default) | two-element column vector of integers

Number of subcarriers allocated to the left and right guard bands, specified as a two-element column vector of integers. The number of subcarriers must fall within $[0, \lfloor N_{FFT}/2 \rfloor - 1]$. This vector has the form $[N_{leftG}, N_{rightG}]$, where N_{leftG} and N_{rightG} specify the left and right guard bands, respectively.

Data Types: `double`

`InsertDCNull` — Option to insert DC null
`false` or `0` (default) | `true` or `1`

Option to insert DC null, specified as a numeric or logical `0` (`false`) or `1` (`true`). The DC subcarrier is the center of the frequency band and has the index value:

- (`FFTLength` / 2) + 1 when `FFTLength` is even
- (`FFTLength` + 1) / 2 when `FFTLength` is odd

`PilotInputPort` — Option to specify pilot input
`false` or `0` (default) | `true` or `1`

Option to specify pilot input, specified as a numeric or logical `0` (`false`) or `1` (`true`). If this property is `1` (`true`), you can assign individual subcarriers for pilot transmission. If this property is `0` (`false`), pilot information is assumed to be embedded in the input data.

`PilotCarrierIndices` — Pilot subcarrier indices
`[12; 26; 40; 54]` (default) | column vector

Pilot subcarrier indices, specified as a column vector. If the PilotCarrierIndices property is set to `1` (`true`), you can specify the indices of the pilot subcarriers. You can assign the indices to the same or different subcarriers for each symbol. Similarly, the pilot carrier indices can differ across multiple transmit antennas. Depending on the desired level of control for index assignments, the dimensions of the property vary. Valid pilot indices fall in the range

$$[N_{leftG} + 1,\ N_{FFT}/2] \cup \left[N_{FFT}/2 + 2,\ N_{FFT} - N_{rightG}\right],$$

where the index value cannot exceed the number of subcarriers. When the pilot indices are the same for every symbol and transmit antenna, the property has dimensions N_{pilot}-by-1. When the pilot indices vary across symbols, the property has dimensions N_{pilot}-by-N_{sym}. If you transmit only one symbol but multiple transmit antennas, the property has dimensions N_{pilot}-by-1-by-N_t., where N_t. is the number of transmit antennas. If the indices vary across the number of symbols and transmit antennas, the property has dimensions N_{pilot}-by-N_{sym}-by-N_t. If the number of transmit antennas is greater than one, ensure that the indices per symbol must be mutually distinct across antennas to minimize interference.

To enable this property, set the `PilotInputPort` property to `1` (`true`).

`CyclicPrefixLength` — Length of cyclic prefix
`16` (default) | positive integer | row vector

Length of cyclic prefix, specified as a positive integer. If you specify a scalar, the prefix length is the same for all symbols through all antennas. If you specify a row vector of length N_{sym}, the prefix length can vary across symbols but remains the same through all antennas.

Data Types: `double`

`Windowing` — Option to apply raised cosine window between OFDM symbols
`false` or `0` (default) | `true` or `1`

Option to apply raised cosine window between OFDM symbols, specified as `true` or `false`. Windowing is the process in which the OFDM symbol is multiplied by a raised cosine window before transmission to more quickly reduce the power of out-of-band subcarriers. Windowing reduces spectral regrowth.

`WindowLength` — Length of raised cosine window
`1` (default) | positive scalar

Length of raised cosine window, specified as a positive scalar. This value must be less than or equal to the minimum cyclic prefix length. For example, in a configuration of four symbols with cyclic prefix lengths 12, 14, 16, and 18, the window length must be less than or equal to 12.

To enable this property, set the `Windowing` property to `1` (`true`).

`NumSymbols` — Number of OFDM symbols
`1` (default) | positive integer

Number of OFDM symbols in the time-frequency grid, specified as a positive integer.

`NumTransmitAntennnas` — Number of transmit antennas
`1` (default) | positive integer

Number of transmit antennas, used to transmit the OFDM modulated signal, specified as a positive integer.

Usage

Syntax

```
waveform = hMod(insignal)
waveform = hMod(data,pilot)
```

Description

`waveform = hMod(insignal)` applies OFDM modulation the specified baseband signal and returns the modulated OFDM baseband signal.

`waveform = hMod(data,pilot)` assigns the pilot signal, `pilot`, into the frequency subcarriers specified by the PilotCarrierIndices property value of the `hMod` system object. To enable this syntax set the PilotCarrierIndices property to `true`.

Input Arguments

`insignal` — Input baseband signal

matrix | 3-D array

Input baseband signal, specified as a matrix or 3-D array of numeric values. The input baseband signal must be of size N_f-by-N_{sym}-by-N_t. where N_f is the number of frequency subcarriers excluding guard bands and DC null.

Data Types: `double`
Complex Number Support: Yes

`data` — Input data

matrix | 3-D array

Input data, specified as a matrix or 3-D array. The input must be a numeric of size N_d-by-N_{sym}-by-N_t. where N_d is the number of data subcarriers in each symbol. For more information on how N_d is calculated, see the PilotCarrierIndices property.

Data Types: `double`
Complex Number Support: Yes

`pilot` — Pilot signal

3-D array

Pilot signal, specified as a 3-D array of numeric values. The pilot signal must be of size N_{pilot}-by-N_{sym}-by-N_t.

Data Types: `double`
Complex Number Support: Yes

Output Arguments

`waveform` — OFDM Modulated baseband signal

2-D array

OFDM Modulated baseband signal, returned as a 2-D array. If the `CyclicPrefixLength` property is a scalar, the output `waveform` is of size $((N_{FFT}+CP_{len})*N_{sym})$-by-$N_t$. Otherwise, the size is $(N_{FFT}*N_{sym}+\sum(CP_{len}))$-by-$N_t$.

Data Types: `double`
Complex Number Support: Yes

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `comm.OFDMModulator`

info	Provide dimensioning information for OFDM modulator
showResourceMapping	Show the subcarrier mapping of the OFDM symbols created by the OFDM modulator System object

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Create and Modify OFDM Modulator

Create and display an OFDM modulator System object™ with default property values.

```
hMod = comm.OFDMModulator
```

```
hMod =
  comm.OFDMModulator with properties:

               FFTLength: 64
    NumGuardBandCarriers: [2x1 double]
            InsertDCNull: false
          PilotInputPort: false
      CyclicPrefixLength: 16
               Windowing: false
              NumSymbols: 1
     NumTransmitAntennas: 1
```

Modify the number of subcarriers and symbols.

```
hMod.FFTLength = 128;
hMod.NumSymbols = 2;
```

Verify that the number of subcarriers and the number of symbols changed.

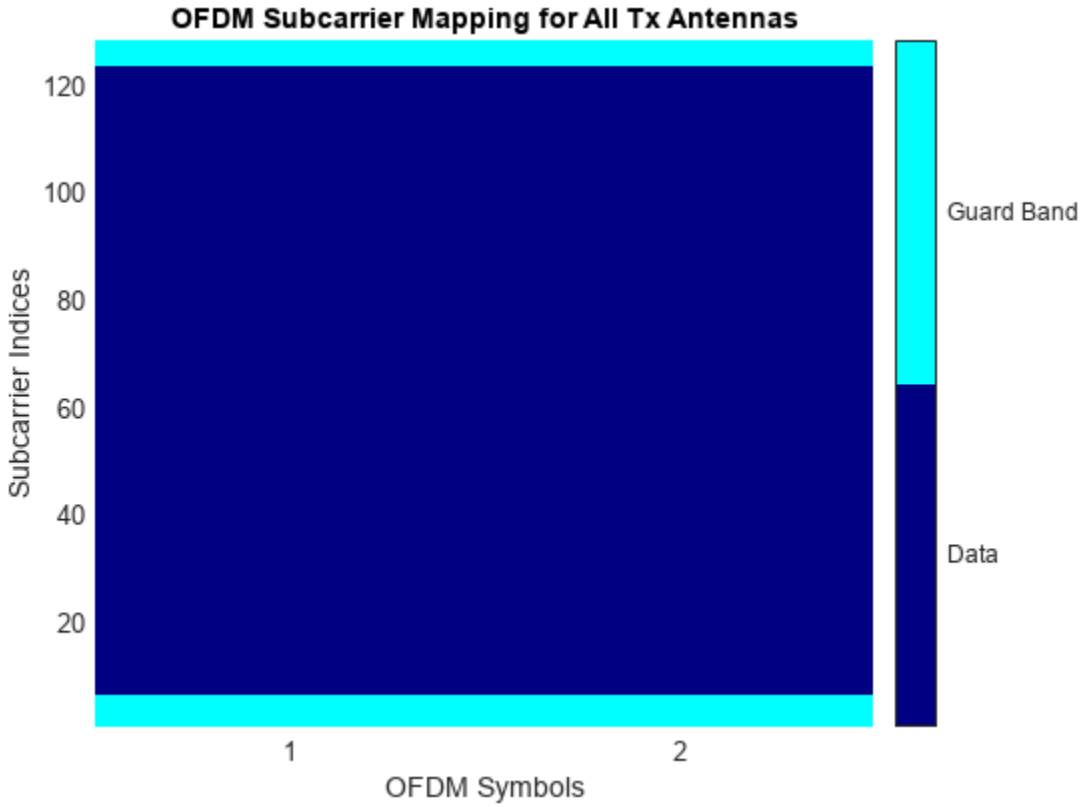
```
disp(hMod)
```

```
  comm.OFDMModulator with properties:

               FFTLength: 128
    NumGuardBandCarriers: [2x1 double]
            InsertDCNull: false
          PilotInputPort: false
      CyclicPrefixLength: 16
               Windowing: false
              NumSymbols: 2
     NumTransmitAntennas: 1
```

Use the `showResourceMapping` object function to show the mapping of data, pilot, and null subcarriers in the time-frequency space.

```
showResourceMapping(hMod)
```



Create OFDM Modulator from OFDM Demodulator

Create an OFDM demodulator System object™ with default property values. Then, specify pilot indices for a single symbol and two transmit antennas.

Setting the `PilotCarrierIndices` property of the demodulator affects the number of transmit antennas in the OFDM modulator when you use the demodulator in the creation of the modulator. The number of receive antennas in the demodulator is uncorrelated with the number of transmit antennas.

```
ofdmDemod = comm.OFDMDemodulator;
ofdmDemod.PilotOutputPort = true;
ofdmDemod.PilotCarrierIndices = ...
    cat(3,[12; 26; 40; 54],[13; 27; 41; 55]);
```

Use the OFDM demodulator to construct the OFDM modulator.

```
ofdmMod = comm.OFDMModulator(ofdmDemod);
```

Display the properties of the OFDM modulator and demodulator, verifying that the applicable properties match.

```
disp(ofdmMod)
```

```
  comm.OFDMModulator with properties:

              FFTLength: 64
    NumGuardBandCarriers: [2x1 double]
           InsertDCNull: false
         PilotInputPort: true
     PilotCarrierIndices: [4x1x2 double]
      CyclicPrefixLength: 16
                Windowing: false
               NumSymbols: 1
     NumTransmitAntennas: 2
```

```
disp(ofdmDemod)
```

```
  comm.OFDMDemodulator with properties:

              FFTLength: 64
    NumGuardBandCarriers: [2x1 double]
         RemoveDCCarrier: false
         PilotOutputPort: true
     PilotCarrierIndices: [4x1x2 double]
      CyclicPrefixLength: 16
               NumSymbols: 1
      NumReceiveAntennas: 1
```

Visualize Time-Frequency Resource Assignments for OFDM Modulator

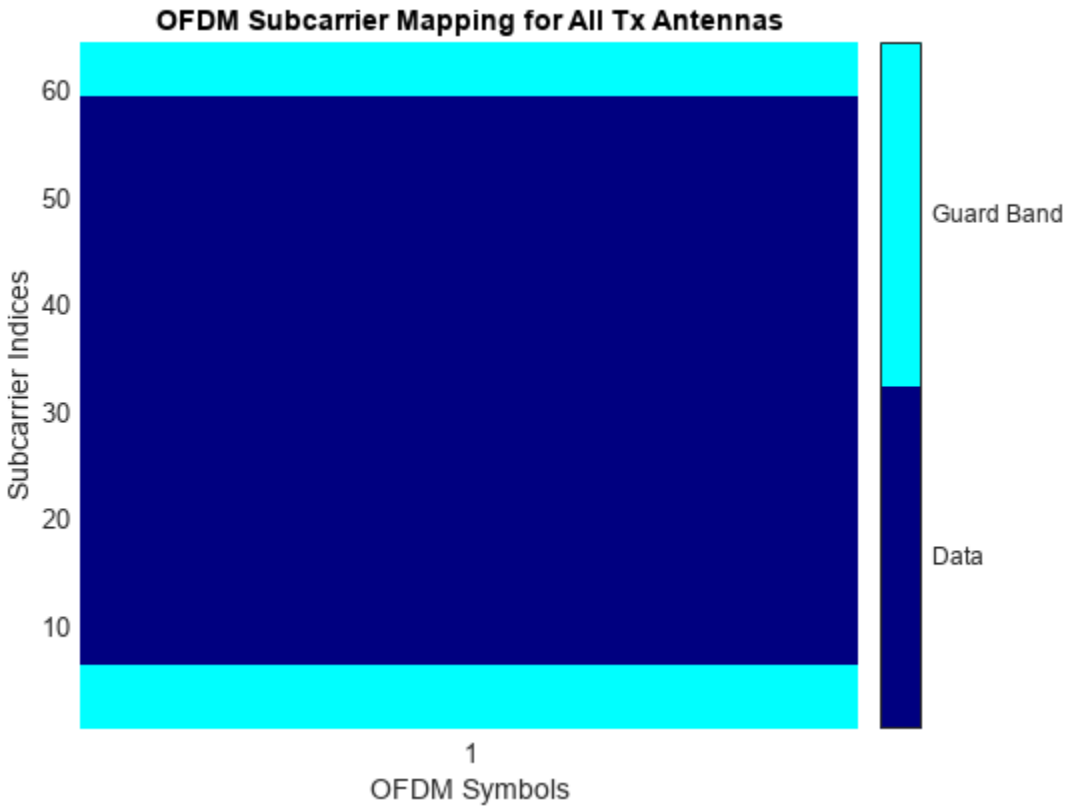
The `showResourceMapping` method displays the time-frequency resource mapping for each transmit antenna.

Construct an OFDM modulator.

```
mod = comm.OFDMModulator;
```

Apply the `showResourceMapping` method.

```
showResourceMapping(mod)
```

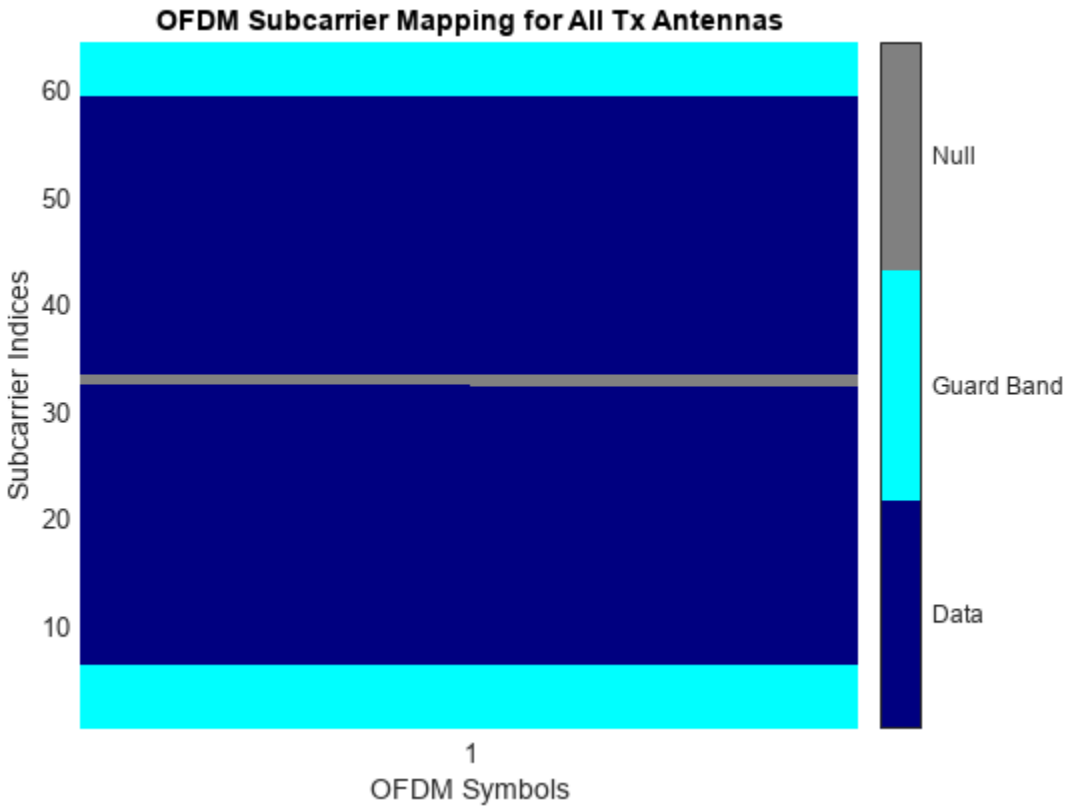


Insert a DC null.

```
mod.InsertDCNull = true;
```

Show the resource mapping after adding the DC null.

```
showResourceMapping(mod)
```



Create OFDM Modulator and Specify Pilots

Create an OFDM modulator and specify the subcarrier indices for the pilot signals. Specify the indices for each symbol and transmit antenna. When the number of transmit antennas is greater than one, set different pilot indices for each symbol between antennas.

Create an OFDM modulator System object, specifying two symbols and inserting a DC null.

```
mod = comm.OFDMModulator('FFTLength',128,'NumSymbols',2,...
    'InsertDCNull',true);
```

Enable the pilot input port so you can specify the pilot indices.

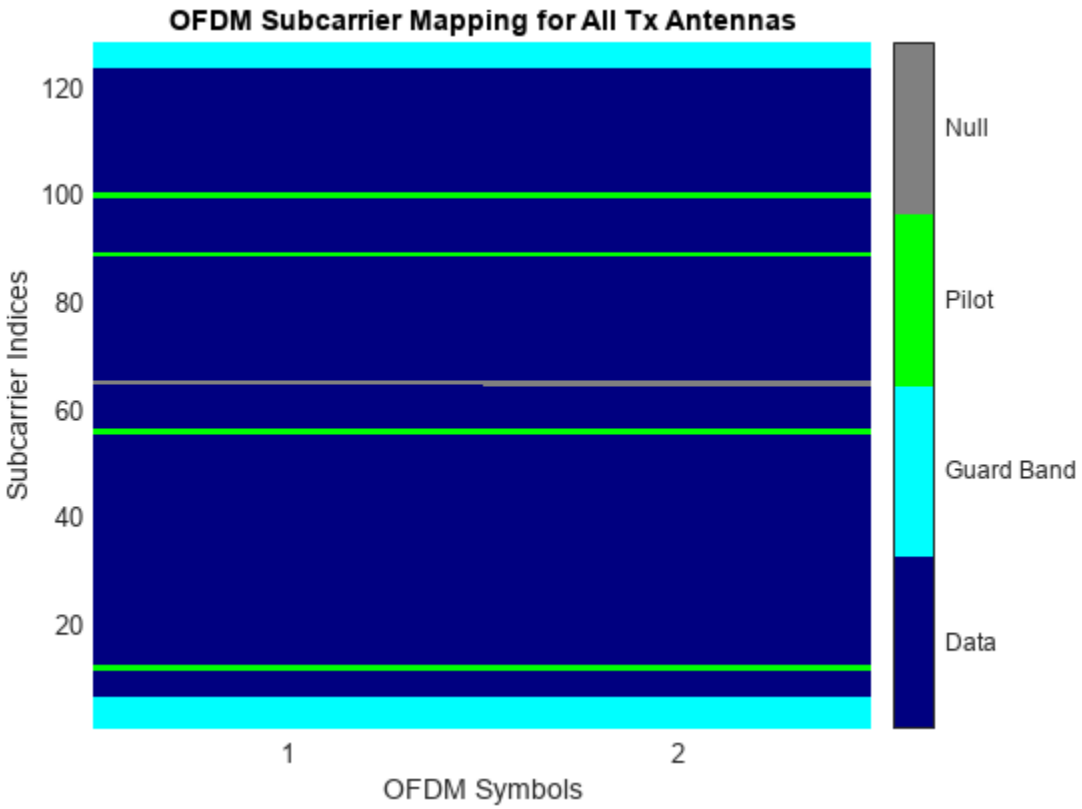
```
mod.PilotInputPort = true;
```

Specify the same pilot indices for both symbols.

```
mod.PilotCarrierIndices = [12; 56; 89; 100];
```

Visualize the placement of the pilot signals and nulls in the OFDM time-frequency grid by using the `showResourceMapping` object function.

```
showResourceMapping(mod)
```

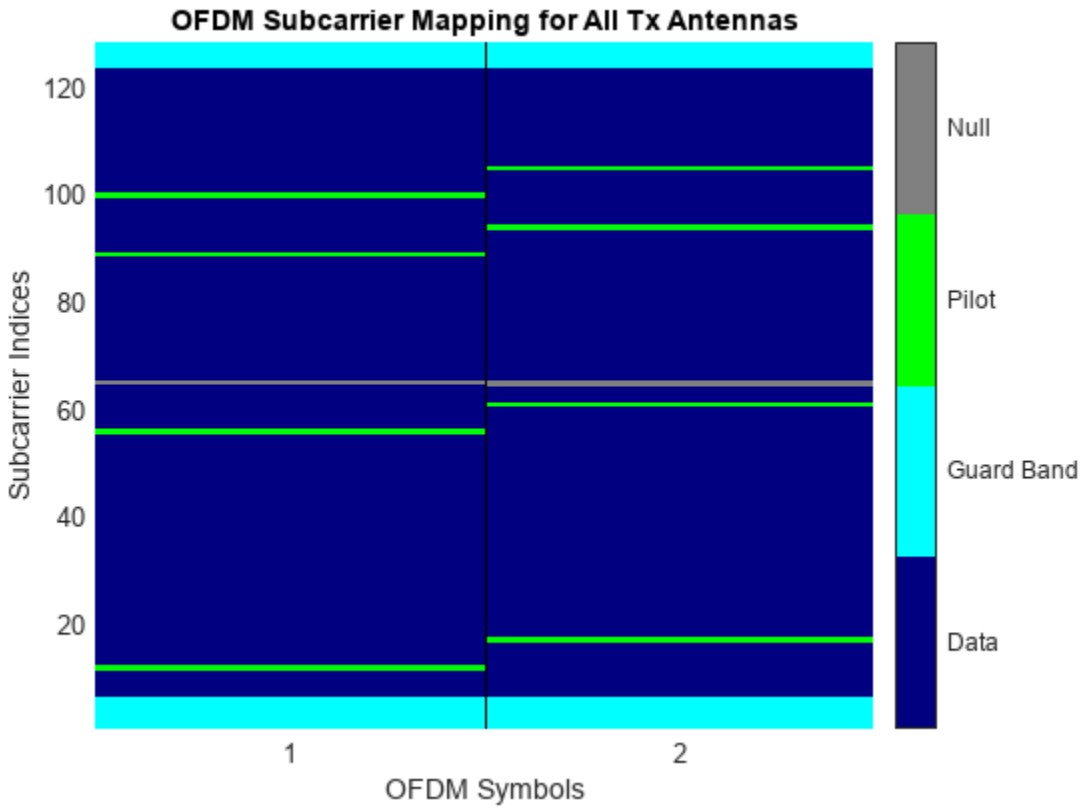


Specify different indices for the second symbol by concatenating a second column of pilot indices to the `PilotCarrierIndices` property.

```
mod.PilotCarrierIndices = cat(2,mod.PilotCarrierIndices, ...
    [17; 61; 94; 105]);
```

Verify that the pilot subcarrier indices differ between the two symbols.

```
showResourceMapping(mod)
```



Increase the number of transmit antennas to two.

```
mod.NumTransmitAntennas = 2;
```

Specify the pilot indices for each of the two transmit antennas. To provide indices for multiple antennas while minimizing interference among the antennas, set the `PilotCarrierIndices` property as a 3-D array such that the indices for each symbol differ among antennas.

```
mod.PilotCarrierIndices = cat(3,[20; 50; 70; 110], [15; 60; 75; 105]);
```

Display the resource mapping for the two transmit antennas. The gray lines denote the insertion of custom nulls. The nulls are created by the object to minimize interference among the pilot symbols from different antennas.

```
showResourceMapping(mod)
```

Create OFDM Modulator with Varying Cyclic Prefix Lengths

Specify the length of the cyclic prefix for each OFDM symbol.

Create an OFDM modulator, specifying five symbols, four left and three right guard-band subcarriers, and the cyclic prefix length for each OFDM symbol.

```
mod = comm.OFDMModulator('NumGuardBandCarriers',[4;3],...
    'NumSymbols',5,...
    'CyclicPrefixLength',[12 10 14 11 13]);
```

Display the properties of the OFDM modulator, verifying that the cyclic prefix length changes across symbols.

```
disp(mod)
```

```
  comm.OFDMModulator with properties:

              FFTLength: 64
    NumGuardBandCarriers: [2x1 double]
           InsertDCNull: false
         PilotInputPort: false
      CyclicPrefixLength: [12 10 14 11 13]
              Windowing: false
```

```
            NumSymbols: 5
     NumTransmitAntennas: 1
```

Determine OFDM Modulator Data Dimensions

Get the OFDM modulator data dimensions by using the `info` object function.

Construct an OFDM modulator System object™ with user-specified pilot indices, an inserted DC null, and specify two transmit antennas.

```
hMod = comm.OFDMModulator('NumGuardBandCarriers',[4;3], ...
    'PilotInputPort',true, ...
    'PilotCarrierIndices',cat(3,[12; 26; 40; 54], ...
    [11; 25; 39; 53]), ...
    'InsertDCNull',true, ...
    'NumTransmitAntennas',2);
```

Use the `info` object function to get the modulator input data, pilot input data, and output data sizes.

```
info(hMod)
```

```
ans = struct with fields:
     DataInputSize: [48 1 2]
    PilotInputSize: [4 1 2]
        OutputSize: [80 2]
```

Create OFDM Modulated Data

Generate OFDM modulated symbols for use in link-level simulations.

Construct an OFDM modulator with an inserted DC null, seven guard-band subcarriers, and two symbols having different pilot indices for each symbol.

```
mod = comm.OFDMModulator( ...
    'NumGuardBandCarriers',[4;3], ...
    'PilotInputPort',true, ...
    'PilotCarrierIndices',[12 11; 26 27; 40 39; 54 55], ...
    'NumSymbols',2, ...
    'InsertDCNull',true);
```

Determine input data, pilot, and output data dimensions.

```
modDim = info(mod);
```

Generate random data symbols for the OFDM modulator. The structure variable, `modDim`, determines the number of data symbols.

```
dataIn = complex( ...
    randn(modDim.DataInputSize),randn(modDim.DataInputSize));
```

Create a pilot signal that has the correct dimensions.

```
pilotIn = complex( ...
    rand(modDim.PilotInputSize),rand(modDim.PilotInputSize));
```

Apply OFDM modulation to the data and pilot signals.

```
modData = mod(dataIn,pilotIn);
```

Use the OFDM modulator object to create the corresponding OFDM demodulator.

```
demod = comm.OFDMDemodulator(mod);
```

Demodulate the OFDM signal and output the data and pilot signals.

```
[dataOut, pilotOut] = demod(modData);
```

Verify that, within a tight tolerance, the input data and pilot symbols match the output data and pilot symbols.

```
isSame = (max(abs([dataIn(:) - dataOut(:); ...
    pilotIn(:) - pilotOut(:)])) < 1e-10)
```

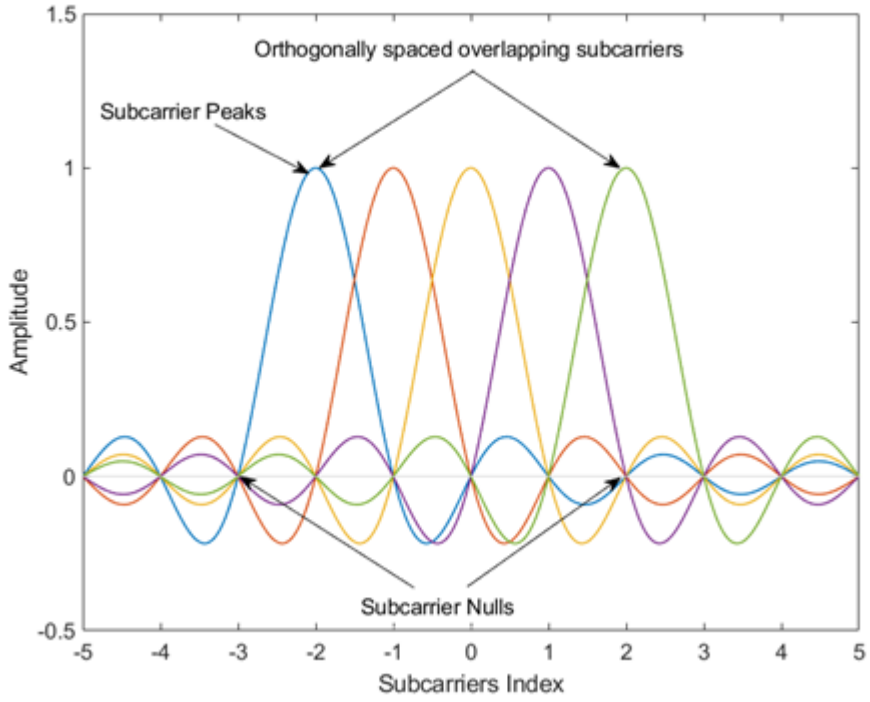
```
isSame = logical
   1
```

More About

Orthogonal Frequency Division Multiplexing

OFDM operation divides a high-rate data stream into lower data rate substreams by decomposing the transmission frequency band into *N* contiguous individually modulated subcarriers. Multiple parallel and orthogonal subcarriers carry the samples with almost the same bandwidth as a wideband channel. By using narrow orthogonal subcarriers, the OFDM signal gains robustness over a frequency-selective fading channel and eliminates adjacent subcarrier interference. Intersymbol interference (ISI) is reduced because the lower data rate substreams have symbol durations larger than the channel delay spread.

This image shows a frequency domain representation of orthogonal subcarriers in an OFDM waveform.



The transmitter applies inverse fast Fourier transform (IFFT) to N symbols at a time. Typically, the output of the IFFT is the sum of the N orthogonal sinusoids:

$$x(t) = \sum_{k=0}^{N-1} X_k e^{j2\pi k\Delta f t}, \quad 0 \le t \le T,$$

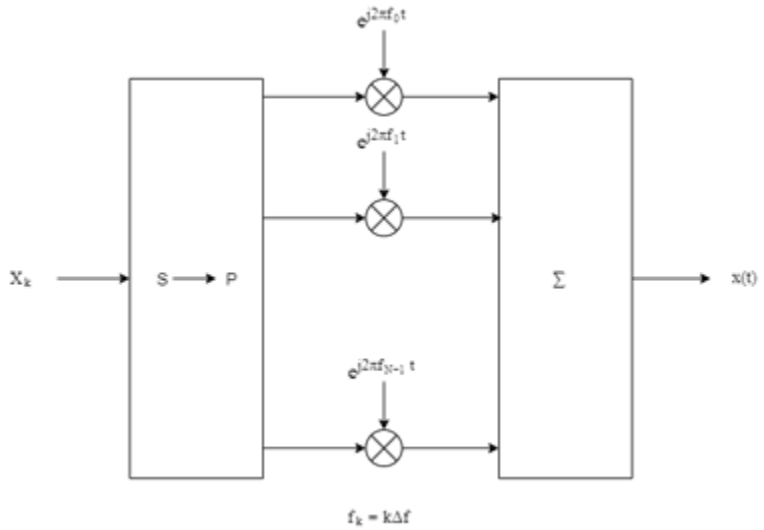
where $\{X_k\}$ are data symbols, and T is the OFDM symbol time. The data symbols X_k are typically complex and can be from any digital modulation alphabet (for example, QPSK, 16-QAM, 64-QAM, ...).

Note The MATLAB implementation of the discrete Fourier transform normalizes the output of the IFFT by $1/N$. For more information, see “Discrete Fourier Transform of Vector” on the `ifft` reference page.

The subcarrier spacing is $\Delta f = 1/T$, ensuring that the subcarriers are orthogonal over each symbol period, as shown below:

$$\frac{1}{T}\int_0^T \left(e^{j2\pi m\Delta f t}\right)^* \left(e^{j2\pi n\Delta f t}\right) dt = \frac{1}{T}\int_0^T e^{j2\pi (m-n)\Delta f t}\, dt = 0 \quad \text{for } m \ne n\,.$$

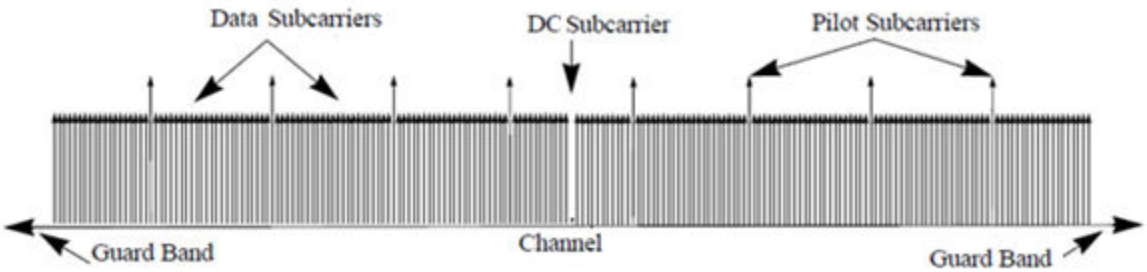
An OFDM modulator consists of a serial-to-parallel conversion followed by a bank of N complex modulators, individually corresponding to each OFDM subcarrier.



Subcarrier Allocation, Guard Bands and Guard Intervals

Individual OFDM subcarriers are allocated as data, pilot, or null subcarriers.

As shown here, subcarriers are designated as data, DC, pilot, or guard band subcarriers.

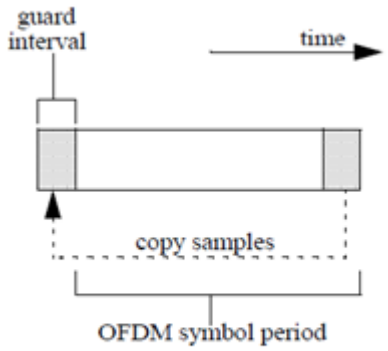


- Data subcarriers transmit user data.
- Pilot subcarriers are used for channel estimation.
- Null subcarriers transmit no data. Subcarriers with no data are used to provide a DC null and serve as buffers between OFDM resource blocks.
  - The null DC subcarrier is the center of the frequency band with an index value of (`nfft`/2 + 1) if `nfft` is even, or ((`nfft` + 1) / 2) if `nfft` is odd.
  - The guard bands provide buffers between adjacent signals in neighboring bands to reduce interference caused by spectral leakage.

Null subcarriers enable you to model guard bands and DC subcarrier locations for specific standards, such as the various 802.11 formats, LTE, WiMAX, or for custom allocations. You can allocate the location of nulls by assigning a vector of null subcarrier indices.

Similar to guard bands, guard intervals are used in OFDM to protect the integrity of transmitted signals by reducing intersymbol interference.

Assignment of guard intervals is analogous to the assignment of guard bands. You can model guard intervals to provide temporal separation between OFDM symbols. The guard intervals help preserve intersymbol orthogonality after the signal passes through time-dispersive channels. Guard intervals are created by using cyclic prefixes. Cyclic prefix insertion copies the last part of an OFDM symbol as the first part of the OFDM symbol.



As long as the span of the time dispersion does not exceed the duration of the cyclic prefix, the benefit of cyclic prefix insertion is maintained.

Inserting a cyclic prefix results in a fractional reduction of user data throughput because the cyclic prefix occupies bandwidth that could be used for data transmission.

Raised Cosine Windowing

While the cyclic prefix creates a guard period in time domain to preserve orthogonality, an OFDM symbol rarely begins with the same amplitude and phase exhibited at the end of the prior OFDM symbol causing spectral regrowth and therefore, spreading of signal bandwidth due to intermodulation distortion. To limit this spectral regrowth, it is desired to create a smooth transition between the last sample of a symbol and the first sample of the next symbol. This can be done by using a cyclic suffix and raised cosine windowing.

To create the cyclic suffix, the first N_{WIN} samples of a given symbol are appended to the end of that symbol. However, in order to comply with the 802.11g standard, for example, the length of a symbol cannot be arbitrarily lengthened. Instead, the cyclic suffix must overlap in time and is effectively summed with the cyclic prefix of the following symbol. This overlapped segment is where windowing is applied. Two windows are applied, one of which is the mathematical inverse of the other. The first raised cosine window is applied to the cyclic suffix of symbol k and decreases from 1 to 0 over its duration. The second raised cosine window is applied to the cyclic prefix of symbol k+1 and increases from 0 to 1 over its duration. This process provides a smooth transition from one symbol to the next.

The raised cosine window, $w(t)$, in the time domain can be expressed as:

$$w(t) = \begin{cases} 1,\ 0 \le |t| < \dfrac{T - T_W}{2} \\ \dfrac{1}{2}\left\{1 + \cos\left[\dfrac{\pi}{T_W}\left(|t| - \dfrac{T - T_W}{2}\right)\right]\right\}, \dfrac{T - T_W}{2} \le |t| \le \dfrac{T + T_W}{2} \\ 0, \text{otherwise} \end{cases}$$

where:

- T is the OFDM symbol duration including the guard interval.
- T_W is the duration of the window.

Adjust the length of the cyclic suffix via the window length setting property, with suffix lengths set between 1 and the minimum cyclic prefix length. While windowing improves spectral regrowth, it does so at the expense of multipath fading immunity. This occurs because redundancy in the guard band is reduced because the guard band sample values are compromised by the smoothing.

The following figures display the application of raised cosine windowing.

OFDM Modulator Baseband

comm.OFDMDemodulator

Package: comm

Demodulate using OFDM method

Description

The OFDMDemodulator object demodulates using the orthogonal frequency division multiplexing method. The output is a baseband representation of the modulated signal, which was input into the OFDMModulator companion object.

To demodulate an OFDM signal:

1. Define and set up the OFDM demodulator object. See “Construction” on page 3-149.
2. Call step to demodulate a signal according to the properties of comm.OFDMDemodulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

H = comm.OFDMDemodulator creates a demodulator System object, H, that demodulates an input signal by using the orthogonal frequency division demodulation method.

H = comm.OFDMDemodulator(Name,Value) creates an OFDM demodulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.OFDMDemodulator(hMod) creates an OFDM demodulator object, H, whose properties are determined by the corresponding OFDM modulator object, hMod.

Properties

FFTLength

The length of the FFT, N_{FFT}, is equivalent to the number of subcarriers used in the modulation process. FFTLength must be ≥ 8.

Specify the number of subcarriers. The default is 64.

NumGuardBandCarriers

The number of guard band subcarriers allocated to the left and right guard bands.

Specify the number of left and right subcarriers as nonnegative integers in [0,$N_{FFT}/2 - 1$] where you specify the left, N_{leftG}, and right, N_{rightG}, guard bands independently in a 2-by-1 column vector. The default values are `[6; 5]`.

`RemoveDCCarrier`

A `logical` variable that when `true`, mandates removal of a DC subcarrier. The default value is `false`.

`PilotOutputPort`

A `logical` property that controls whether to separate the pilot signals and make them available at an additional output port. The location of each pilot output symbol is determined by the pilot subcarrier indices specified in the `PilotCarrierIndices` property. When false, pilot symbols may be present but embedded in the data. The default value is `false`.

`PilotCarrierIndices`

If the `PilotOutputPort` property is `true`, output separate pilot signals located at the indices specified by the `PilotCarrierIndices` property. If the indices are a 2-D array, the pilot carriers across all the transmit antennas per symbol are the same. If there is more than one transmit antenna (this information is not known by the demodulator), the pilots from different transmit antennas may interfere with each other. To avoid this, specify the pilot carrier indices as a 3-D array with different pilot indices for each symbol across the antennas. This avoids interference between pilots from different transmit antennas, since, on a per-symbol basis, each transmit antenna has different pilot carriers and the OFDM modulator creates custom nulls at the appropriate locations. The size of the third dimension of the `PilotCarrierIndices` property gives the number of transmit antennas.

`CyclicPrefixLength`

The cyclic prefix length property specifies the length of the OFDM cyclic prefix. If you specify a scalar, the prefix length is the same for all symbols through all antennas. If you specify a row vector of length N_{sym}, the prefix length can vary across symbols but remains the same length through all antennas. The default value is `16`.

`NumSymbols`

This property specifies the number of symbols, N_{sym}. Specify N_{sym} as a positive integer. The default value is `1`.

`NumReceiveAntennnas`

This property determines the number of antennas, N_R, used to receive the OFDM modulated signal. Specify N_R as a positive integer. The default value is `1`.

Methods

info	Provide dimensioning information for the OFDM method
showResourceMapping	Show the subcarrier mapping of the OFDM symbols created by the OFDM demodulator System object
step	Demodulate using OFDM method

Common to All System Objects	
`release`	Allow System object property value changes
`reset`	Reset internal states of System object

When using `reset`, this method resets the windowed suffix from the last symbol in the previously processed frame.

Examples

Create and Modify OFDM Demodulator

Construct an OFDM demodulator System object™ with default properties. Modify some of the properties.

Construct the OFDM demodulator.

```
demod = comm.OFDMDemodulator
```

```
demod =
  comm.OFDMDemodulator with properties:

               FFTLength: 64
    NumGuardBandCarriers: [2x1 double]
         RemoveDCCarrier: false
         PilotOutputPort: false
      CyclicPrefixLength: 16
              NumSymbols: 1
      NumReceiveAntennas: 1
```

Modify the number of subcarriers and symbols.

```
demod.FFTLength = 128;
demod.NumSymbols = 2;
```

Verify that the number of subcarriers and the number of symbols changed.

```
demod
```

```
demod =
  comm.OFDMDemodulator with properties:

               FFTLength: 128
    NumGuardBandCarriers: [2x1 double]
         RemoveDCCarrier: false
         PilotOutputPort: false
```

```
      CyclicPrefixLength: 16
              NumSymbols: 2
      NumReceiveAntennas: 1
```

Create OFDM Demodulator from OFDM Modulator

Create an OFDM demodulator System object™ from an existing OFDM modulator System object.

Construct an OFDM modulator using default parameters.

```
mod = comm.OFDMModulator('NumTransmitAntennas',4);
```

Construct the corresponding OFDM demodulator from the modulator, `mod`.

```
demod = comm.OFDMDemodulator(mod);
```

Display the properties of the modulator and verify that they match those of the demodulator.

```
mod
```

```
mod =
  comm.OFDMModulator with properties:

                FFTLength: 64
    NumGuardBandCarriers: [2x1 double]
            InsertDCNull: false
          PilotInputPort: false
      CyclicPrefixLength: 16
               Windowing: false
              NumSymbols: 1
     NumTransmitAntennas: 4
```

```
demod
```

```
demod =
  comm.OFDMDemodulator with properties:

                FFTLength: 64
    NumGuardBandCarriers: [2x1 double]
         RemoveDCCarrier: false
         PilotOutputPort: false
      CyclicPrefixLength: 16
              NumSymbols: 1
      NumReceiveAntennas: 1
```

Note that the number of transmit antennas is independent of the number of receive antennas.

Visualize Time-Frequency Resource Assignments

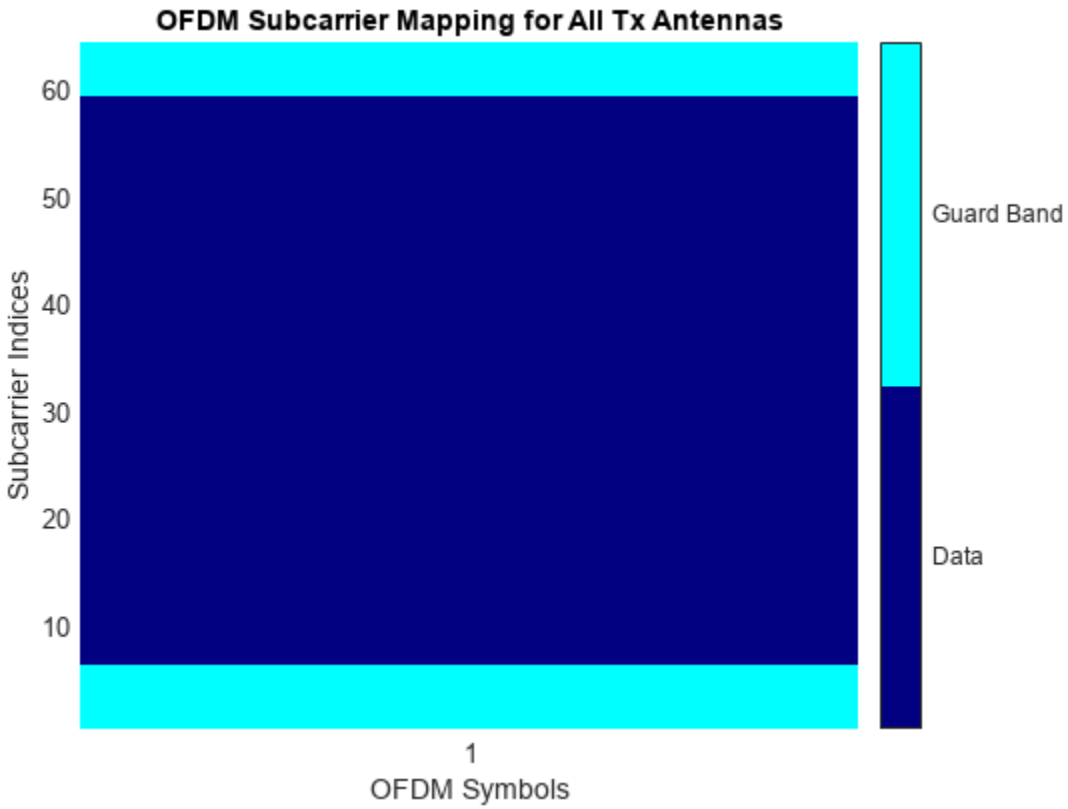
The `showResourceMapping` method shows the time-frequency resource mapping for each transmit antenna.

Construct an OFDM demodulator.

```
demod = comm.OFDMDemodulator;
```

Apply the `showResourceMapping` method.

```
showResourceMapping(demod)
```

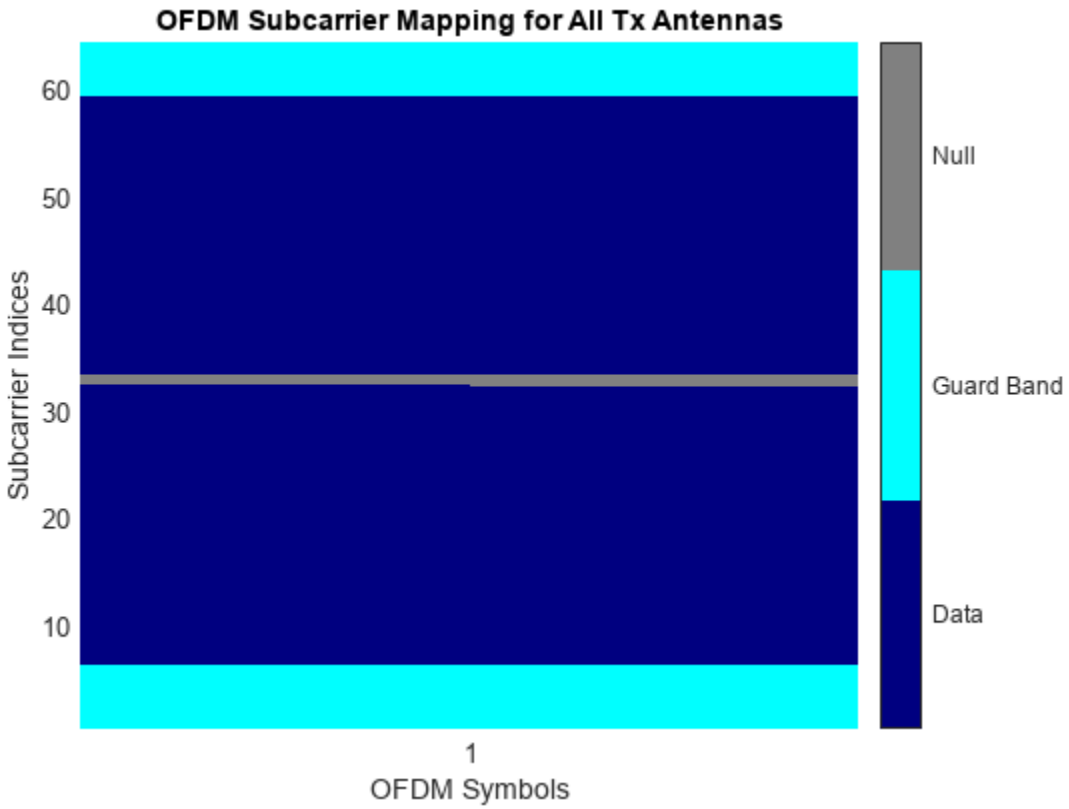


Remove the DC subcarrier.

```
demod.RemoveDCCarrier = true;
```

Show the resource mapping after removing the DC subcarrier.

```
showResourceMapping(demod)
```



Demodulate OFDM Data

Construct an OFDM modulator with an inserted DC null, seven guard-band subcarriers, and two symbols that have different pilot indices for each symbol.

```
mod = comm.OFDMModulator( ...
    'NumGuardBandCarriers',[4;3], ...
    'PilotInputPort',true, ...
    'PilotCarrierIndices', ...
    cat(2,[12; 26; 40; 54],[11; 27; 39; 55]), ...
    'NumSymbols',2, ...
    'InsertDCNull',true);
```

Determine input data, pilot, and output data dimensions.

```
modDim = info(mod)
```

```
modDim = struct with fields:
     DataInputSize: [52 2]
    PilotInputSize: [4 2]
        OutputSize: [160 1]
```

Generate random data symbols for the OFDM modulator. Determine the number of data symbols by using the structure variable, `modDim`.

```
dataIn = complex( ...
    randn(modDim.DataInputSize),randn(modDim.DataInputSize));
```

Create a pilot signal that has the correct dimensions.

```
pilotIn = complex( ...
    rand(modDim.PilotInputSize),rand(modDim.PilotInputSize));
```

Apply OFDM modulation to the data and pilot signals.

```
modSig = mod(dataIn,pilotIn);
```

Use the OFDM modulator object to create the corresponding OFDM demodulator.

```
demod = comm.OFDMDemodulator(mod);
```

Demodulate the OFDM signal and output the data and pilot signals.

```
[dataOut,pilotOut] = demod(modSig);
```

Verify that the input data and pilot symbols match the output data and pilot symbols.

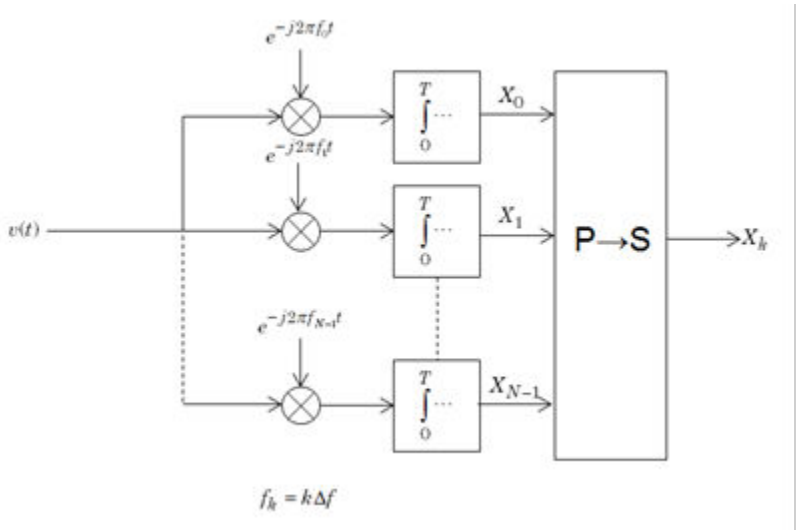
```
isSame = (max(abs([dataIn(:) - dataOut(:); ...
    pilotIn(:) - pilotOut(:)])) < 1e-10)
```

```
isSame = logical
   1
```

Algorithms

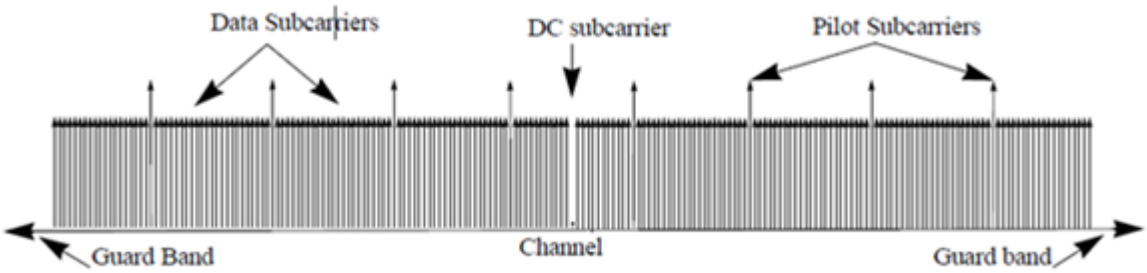
The orthogonal frequency division multiplexing (OFDM) demodulator System object demodulates an OFDM input signal by using an FFT operation that results in *N* parallel data streams.

The figure shows an OFDM demodulator. It consists of a bank of *N* correlators with one assigned to each OFDM subcarrier followed by a parallel-to-serial conversion.



Guard Bands and Intervals

There are three types of OFDM subcarriers: data, pilot, and null. Data subcarriers are used for transmitting data while pilot subcarriers are used for channel estimation. There is no transmission on null subcarriers, which are used to provide a DC null as well as to provide buffers between OFDM resource blocks. These buffers are referred to as guard bands whose purpose is to prevent inter-symbol interference. The allocation of nulls and guard bands varies depending upon the standard, e.g., 802.11n differs from LTE. Consequently, the OFDM modulator object allows the user to assign subcarrier indices as required.



Analogous to the concept of guard bands, the OFDM modulator object supports guard intervals that provide temporal separation between OFDM symbols so that the signal does not lose orthogonality due to time-dispersive channels. As long as the guard interval is longer than the delay spread, each symbol does not interfere with other symbols. Guard intervals are created by using cyclic prefixes in which the last part of an OFDM symbol is copied and inserted as the first part of the OFDM symbol. The benefit of cyclic prefix insertion is maintained as long as the span of the time dispersion does not exceed the duration of the cyclic prefix. The OFDM modulator object enables the cyclic prefix length to be set. The drawback in using a cyclic prefix is increased overhead.

Blocks

OFDM Demodulator Baseband

Functions

`ofdmdemod`

info

System object: `comm.OFDMDemodulator`
Package: `comm`

Provide dimensioning information for the OFDM method

Syntax

```
Y = info(H)
```

Description

`Y = info(H)` provides data dimensioning information for the OFDM demodulator System object, `H`. It returns the expected dimensions for data input into the OFDM demodulator, for the pilot output, and for the data output from the demodulator. The output, `Y`, is a structure containing three fields: `InputSize`, `DataOutputSize`, and `PilotOutputSize`.

Y.InputSize

Gives the dimensions of the demodulator input data, $[(N_{FFT} + N_{CP}) \times N_{sym}]$-by-$N_r$, where N_{FFT} is the number of subcarriers, N_{CP} is the length of the cyclic prefix, N_{sym} is the number of symbols, and N_r is the number of receive antennas.

Y.DataOutputSize

Shows the dimensions of the demodulator output data, N_{data}-by-N_{sym}-by-N_r, where N_{data} is the number of data subcarriers such that $N_{data} = N_{FFT} - N_{leftG} - N_{rightG} - N_{DCNull} - N_{pilot} - N_{custNull}$. The variables are defined as follows:

N_{FFT}	Number of subcarriers
N_{leftG}	Number of subcarriers in the left guard band
N_{rightG}	Number of subcarriers in the right guard band
N_{DCNull}	Number of subcarriers in the DC null (either 0 or 1)
N_{pilot}	Number of pilot subcarriers
$N_{custNull}$	Number of subcarriers used for custom nulls

Y.PilotOutputSize

Provides the dimensions of the pilot signal output array, N_{pilot}-by-N_{sym}-by-N_r or N_{pilot}-by-N_{sym}-by-N_t-by-N_r, depending on the number of transmit antennas.

showResourceMapping

System object: `comm.OFDMDemodulator`
Package: `comm`

Show the subcarrier mapping of the OFDM symbols created by the OFDM demodulator System object

Syntax

```
showResourceMapping(H)
showResourceMapping(H,CI)
```

Description

`showResourceMapping(H)` shows a visualization of the subcarrier mapping for the OFDM symbols used by the OFDM demodulator System object, `H`. The subcarrier indices are numbered from 1 to N_{FFT}.

`showResourceMapping(H,CI)` shows the resource mapping where the optional argument, `CI`, is used to number the subcarrier indices that will be displayed. `CI` is a 1x2 integer row vector such that `diff(CI)` = $N_{FFT} - 1$.

step

System object: comm.OFDMDemodulator
Package: comm

Demodulate using OFDM method

Syntax

```
Y = step(H,X)
[Y,PILOT] = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` demodulates input data, `X`, with the OFDM demodulator System object, `H`, and returns the baseband demodulated output, `Y`. The input is a double-precision, real or complex, 2-D matrix of symbols whose dimensions are a function of the number of subcarriers, the cyclic prefix length, and the number of receive antennas. You can determine the dimensions by using the `info` method. The output, `Y`, is a double-precision, complex, 3-D array.

`[Y,PILOT] = step(H,X)` separates the `PILOT` signal on the subcarriers specified by the PilotCarrierIndices property value of `H`. This syntax applies when the PilotOutputPort property of `H` is true. `PILOT` is a double-precision, complex, 3-D array.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.CarrierSynchronizer

Package: `comm`

Compensate for carrier frequency offset

Description

The `comm.CarrierSynchronizer` System object compensates for carrier frequency and phase offsets in signals that use single-carrier modulation schemes. The carrier synchronizer algorithm is compatible with BPSK, QPSK, OQPSK, 8-PSK, PAM, and rectangular QAM modulation schemes.

Note

- This System object does not resolve phase ambiguities created by the synchronization algorithm. As indicated in this table, the potential phase ambiguity introduced by the synchronizer depends on the modulation type:

Modulation	Phase Ambiguity (degrees)
`'BPSK'` or `'PAM'`	0, 180
`'OQPSK'`, `'QPSK'`, or `'QAM'`	0, 90, 180, 270
`'8PSK'`	0, 45, 90, 135, 180, 225, 270, 315

  The “Examples” on page 3-0 demonstrate carrier synchronization and resolution of phase ambiguity.

- For best results, apply carrier synchronization to non-oversampled signals, as demonstrated in “Correct Phase and Frequency Offset for 16-QAM Using Coarse and Fine Synchronization” on page 3-169.

To compensate for frequency and phase offsets in signals that use single-carrier modulation schemes:

1. Create the `comm.CarrierSynchronizer` object and set its properties.
2. Call the object, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
carrSynch = comm.CarrierSynchronizer
carrSynch = comm.CarrierSynchronizer(Name,Value)
```

Description

`carrSynch = comm.CarrierSynchronizer` creates a System object that compensates for carrier frequency offset and phase offset in signals that use single-carrier modulation schemes.

`carrSynch = comm.CarrierSynchronizer(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`Modulation` — Modulation type
`'QAM'` (default) | `'8PSK'` | `'BPSK'` | `'OQPSK'` | `'PAM'` | `'QPSK'`

Modulation type, specified as `'QAM'`, `'8PSK'`, `'BPSK'`, `'OQPSK'`, `'PAM'`, or `'QPSK'`.

Example: `comm.CarrierSynchronizer('Modulation','QPSK')` creates a carrier synchronizer System object to use with a QPSK modulated signal.

Tunable: No

`ModulationPhaseOffset` — Modulation phase offset method
`'Auto'` (default) | `'Custom'`

Modulation phase offset method, specified as `'Auto'` or `'Custom'`.

- `'Auto'` — Apply the traditional offset for the specified modulation type.

Modulation	Phase Offset (radians)
`'BPSK'`, `'QAM'`, or `'PAM'`	0
`'OQPSK'` or `'QPSK'`	$\pi/4$
`'8PSK'`	$\pi/8$

- `'Custom'` — Specify a user-defined phase offset with the CustomPhaseOffset property.

Tunable: Yes

`CustomPhaseOffset` — Custom phase offset
`0` (default) | scalar

Custom phase offset in radians, specified as a scalar.

Dependencies

This property applies when the ModulationPhaseOffset property is set to `'Custom'`.

Data Types: `double`

`SamplesPerSymbol` — Number of samples per symbol
`2` (default) | positive integer

Number of samples per symbol, specified as a positive integer.

Tunable: Yes

Data Types: `double`

`DampingFactor` — Damping factor of loop
`0.707` (default) | positive scalar

Damping factor of the loop, specified as a positive scalar.

Tunable: Yes

Data Types: `double`

`NormalizedLoopBandwidth` — Normalized bandwidth of loop
`0.01` (default) | scalar

Normalized bandwidth of the loop, specified as a scalar in the range (0,1]. The loop bandwidth is normalized by the sample rate of the synchronizer.

Decreasing the loop bandwidth reduces the synchronizer convergence time but also reduces the pull-in range of the synchronizer.

Tunable: Yes

Data Types: `double`

Usage

Syntax

```
[outSig,phErr] = carrSynch(inSig)
```

Description

`[outSig,phErr] = carrSynch(inSig)` compensates for frequency offset and phase offset in the input signal. This System object returns a compensated output signal and an estimate of the phase error.

Input Arguments

`inSig` — Input signal
scalar | column vector

Input signal, specified as a complex scalar or a column vector of complex values.

Data Types: `double` | `single`

Complex Number Support: Yes

Output Arguments

`outSig` — Output signal

scalar (default) | column vector

Output signal, returned as a scalar or column vector with the same data type and length as `inSig`. The output signal adjusts the input signal compensating for carrier frequency and phase offsets in signals that use single-carrier modulation schemes.

`phErr` — Phase error estimate

scalar (default) | column vector

Phase error estimate in radians, returned as a scalar or column vector with the same length as `inSig`.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `comm.CarrierSynchronizer`

info	Characteristic information about carrier synchronizer
clone	Create duplicate System object
isLocked	Determine if System object is in use

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Correct Phase and Frequency Offset in QPSK Link

Correct phase and frequency offsets of a QPSK signal passed through an AWGN channel. Using preambles, resolve phase ambiguity.

Define the simulation parameters.

```
M = 4; % Modulation order
rng(1993) % For repeatable results
barker = comm.BarkerCode(...
    'Length',13,'SamplesPerFrame',13);  % For preamble
msgLen = 1e4;
numFrames = 10;
frameLen = msgLen/numFrames;
```

Add preambles to each frame, which are used later when performing phase ambiguity resolution. Generate random data symbols, and apply QPSK modulation.

```
preamble = (1+barker())/2;  % Length 13, unipolar
data = zeros(msgLen,1);
for idx = 1 : numFrames
    payload = randi([0 M-1],frameLen-barker.Length,1);
    data((idx-1)*frameLen + (1:frameLen)) = [preamble; payload];
end

modSig = pskmod(data,4,pi/4);
```

Create a `comm.PhaseFrequencyOffset` System object™ to introduce phase and frequency offsets to the modulated input signal. Set the phase offset to `45` degrees, frequency offset to 1 kHz, and sample rate to 10 kHz. The frequency offset is set to 1% of the sample rate.

```
pfo = comm.PhaseFrequencyOffset( ...
    'PhaseOffset',45, ...
    'FrequencyOffset',1e4, ...
    'SampleRate',1e6);
```

Create a carrier synchronizer System object to use for correcting the phase and frequency offsets with samples per symbol set to 1.

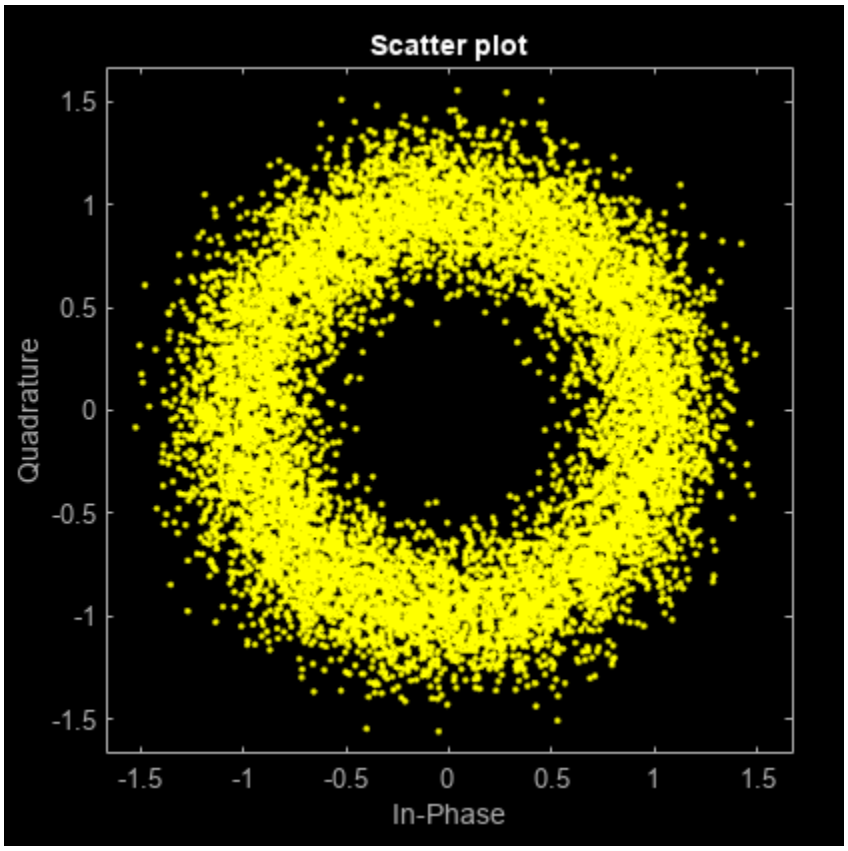
```
carrierSync = comm.CarrierSynchronizer( ...
    'SamplesPerSymbol',1, ...
    'Modulation','QPSK');
```

Apply phase and frequency offsets using the `pfo` System object, and then pass the signal through an AWGN channel to add white Gaussian noise.

```
modSigOffset = pfo(modSig);
rxSig = awgn(modSigOffset,12);
```

Display the scatter plot of the received signal. The data appear in a circle instead of being grouped around the reference constellation points due to the frequency offset.

```
scatterplot(rxSig)
```



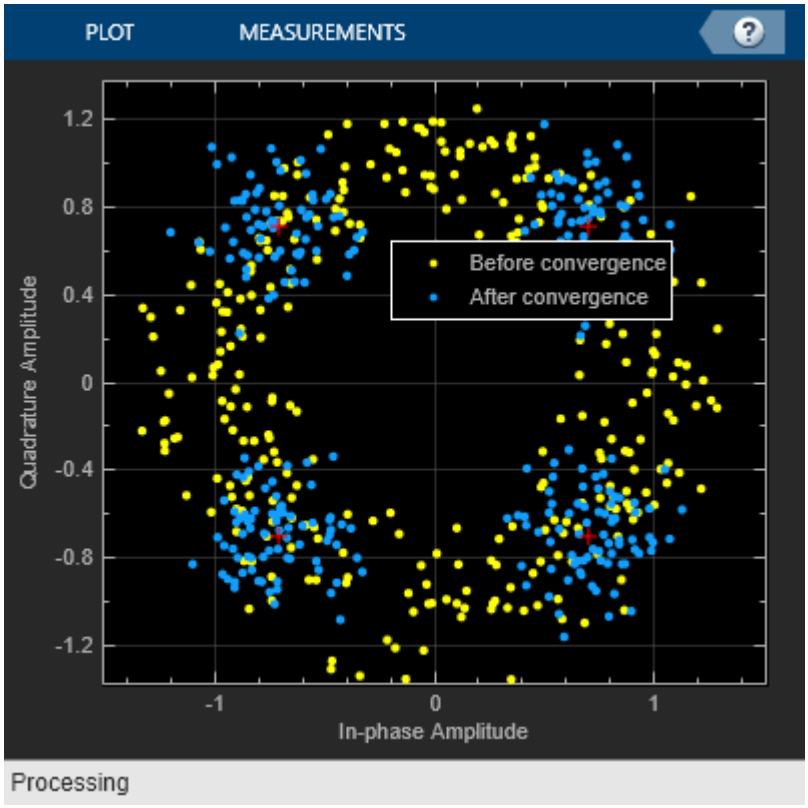
Use the `carrierSync` System object to correct the phase and frequency offset in the received signal.

```
syncSignal = carrierSync(rxSig);
```

Use a constellation diagram to display the first and last 1000 symbols of the synchronized signal. Before convergence of the synchronizer loop, the plotted symbols are not grouped around the reference constellation points. After convergence, the plotted symbols are grouped around the reference constellation points.

```
constDiag = comm.ConstellationDiagram( ...
    'SymbolsToDisplaySource','Property', ...
    'SymbolsToDisplay',300, ...
    'ChannelNames',{'Before convergence','After convergence'}, ...
    'ShowLegend',true, ...
    'Position',[400 400 400 400]);

constDiag([syncSignal(1:1000) syncSignal(9001:10000)]);
```



Demodulate the synchronized signal. Compute and display the total bit errors and BER.

```
syncData = pskdemod(syncSignal,4,pi/4);
[syncDataTtlErr,syncDataBER] = biterr( ...
    data(6000:end),syncData(6000:end))
```

```
syncDataTtlErr = 8001

syncDataBER = 0.9999
```

Phase ambiguity in the received signal might cause bit errors. Using the preamble, determine phase ambiguity. Remove this phase ambiguity from the synchronized signal to reduce bit errors.

```
idx = 9000 + (1:barker.Length);
phOffset = angle(modSig(idx) .* conj(syncSignal(idx)));
phOffset = round((2/pi) * phOffset); % -1, 0, 1, +/-2
phOffset(phOffset==-2) = 2; % Prep for mean operation
phOffset = mean((pi/2) * phOffset); % -pi/2, 0, pi/2, or pi
disp(['Estimated mean phase offset = ', ...
    num2str(phOffset*180/pi),' degrees'])
```

```
Estimated mean phase offset = 180 degrees
```

```
resPhzSig = exp(1i*phOffset) * syncSignal;
```

Demodulate the signal after resolving the phase ambiguity. Recompute and display the updated total bit errors and BER. Removing the phase ambiguity reduces the BER dramatically.

```
resPhzData = pskdemod(resPhzSig,4,pi/4);
[resPhzTtlErr, resPhzBER] = biterr( ...
    data(6000:end),resPhzData(6000:end))

resPhzTtlErr = 1

resPhzBER = 1.2497e-04
```

Estimate Frequency Offset in an 8-PSK Link

Estimate the frequency offset introduced into a noisy 8-PSK signal using a carrier synchronizer System object™.

Define the simulation parameters.

```
M = 8;                  % Modulation order
fs = 1e6;               % Sample rate (Hz)
foffset = 1000;         % Frequency offset (Hz)
phaseoffset = 15;       % Phase offset (deg)
snrdb = 20;             % Signal-to-noise ratio (dB)
```

Create a `comm.PhaseFrequencyOffset` System object to introduce phase and frequency offsets to a modulated signal.

```
pfo = comm.PhaseFrequencyOffset('PhaseOffset',phaseoffset, ...
    'FrequencyOffset',foffset,'SampleRate',fs);
```

Create a carrier synchronizer System object to use for correcting the phase and frequency offsets. Set the `Modulation` property to `8PSK`.

```
carrierSync = comm.CarrierSynchronizer('Modulation','8PSK');
```

Generate random data and apply 8-PSK modulation.

```
data = randi([0 M-1],5000,1);
modSig = pskmod(data,M,pi/M);
```

Apply phase and frequency offsets using the pfo System object, and pass the signal through an AWGN channel to add Gaussian white noise.

```
modSigOffset = pfo(modSig);
rxSig = awgn(modSigOffset,snrdb);
```

Use the carrier synchronizer to estimate the phase offset of the received signal.

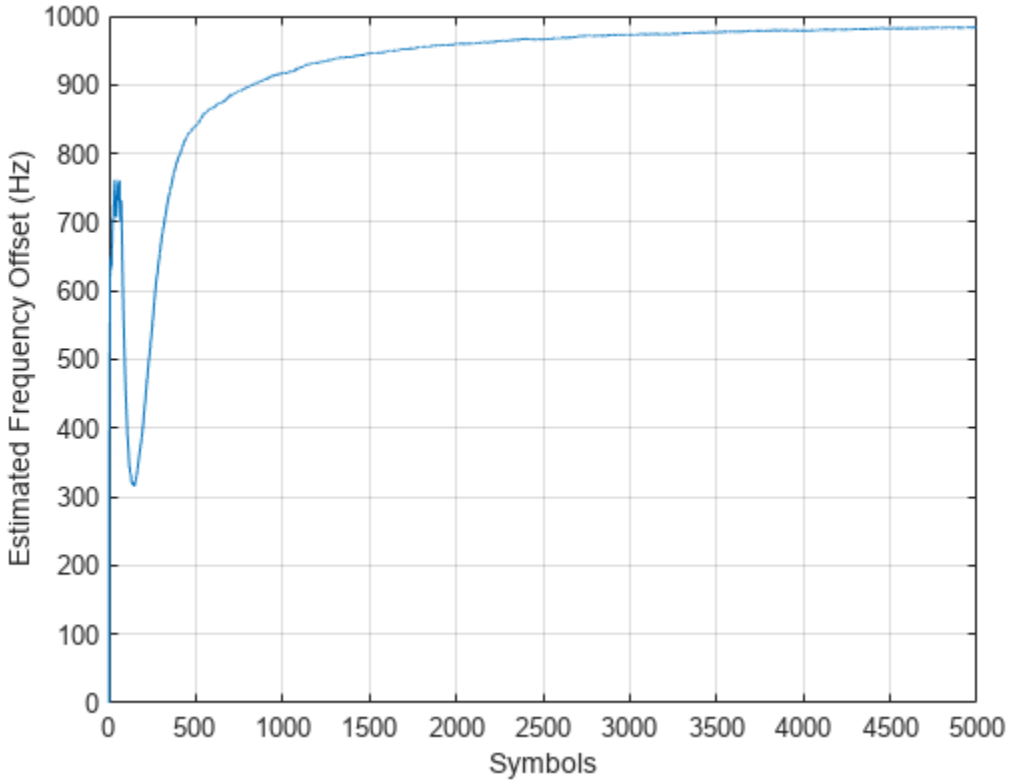
```
[~,phError] = carrierSync(rxSig);
```

Determine the frequency offset by using the `diff` function to compute an approximate derivative of the phase error. The derivative must be scaled by 2π because the phase error is measured in radians.

```
estFreqOffset = diff(phError)*fs/(2*pi);
```

Plot the running mean of the estimated frequency offset. After the synchronizer converges to a solution, the mean value of the estimate is approximately equal to the input frequency offset value of 1000 Hz.

```
rmean = cumsum(estFreqOffset)./(1:length(estFreqOffset))';
plot(rmean)
xlabel('Symbols')
ylabel('Estimated Frequency Offset (Hz)')
grid
```



Correct Phase and Frequency Offset for 16-QAM Using Coarse and Fine Synchronization

Compensation of significant phase and frequency offsets for a 16-QAM signal in an AWGN channel is accomplished in two steps. First, correct the coarse frequency offset using the estimate provided by the coarse frequency compensator, and then fine-tune the correction using carrier synchronization. Because of the coarse frequency correction, the carrier synchronizer converges quickly even though the normalized bandwidth is set to a low value. Lower normalized bandwidth values enable better correction for small residual carrier offsets. After applying phase and frequency offset corrections to the received signal, resolve phase ambiguity using the preambles.

Define the simulation parameters.

```
fs = 10000;                  % Sample rate (Hz)
sps = 4;                     % Samples per symbol
M = 16;                      % Modulation order
k = log2(M);                 % Bits per symbol
rng(1996)                    % Set seed for repeatable results
barker = comm.BarkerCode(... % For preamble
```

```
    'Length',13,'SamplesPerFrame',13);
msgLen = 1e4;
numFrames = 10;
frameLen = msgLen/numFrames;
```

Generate data payloads and add the preamble to each frame. The preamble is later used for phase ambiguity resolution.

```
preamble = (1+barker())/2;  % Length 13, unipolar
data = zeros(msgLen, 1);
for idx = 1 : numFrames
    payload = randi([0 M-1],frameLen-barker.Length,1);
    data((idx-1)*frameLen + (1:frameLen)) = [preamble; payload];
end
```

Create a System object™ for the transmit pulse shape filtering, the receive pulse shape filtering, the QAM coarse frequency compensation, the carrier synchronization, and a constellation diagram.

```
txFilter = comm.RaisedCosineTransmitFilter( ...
    'OutputSamplesPerSymbol',sps);
rxFilter = comm.RaisedCosineReceiveFilter(...
    'InputSamplesPerSymbol',sps, ...
    'DecimationFactor',sps);
coarse = comm.CoarseFrequencyCompensator( ...
    'SampleRate',fs, ...
    'FrequencyResolution',10);
fine = comm.CarrierSynchronizer( ...
    'DampingFactor',0.4, ...
    'NormalizedLoopBandwidth',0.001, ...
    'SamplesPerSymbol',1, ...
    'Modulation','QAM');
axislimits = [-6 6];
constDiagram = comm.ConstellationDiagram( ...
    'ReferenceConstellation',qammod(0:M-1,M), ...
    'ChannelNames',{'Before convergence','After convergence'}, ...
    'ShowLegend',true, ...
    'XLimits',axislimits, ...
    'YLimits',axislimits);
```

Also create a System object for the AWGN channel, and the phase and frequency offset to add impairments to the signal. A phase offset greater than 90 degrees is added to induce a phase ambiguity that results in a constellation quadrant shift.

```
ebn0 = 8;
freqoffset = 110;
phaseoffset = 110;
awgnChannel = comm.AWGNChannel( ...
    'EbNo',ebn0, ...
    'BitsPerSymbol',k, ...
    'SamplesPerSymbol',sps);
pfo = comm.PhaseFrequencyOffset( ...
    'FrequencyOffset',freqoffset, ...
    'PhaseOffset',phaseoffset, ...
    'SampleRate',fs);
```

Generate random data symbols, apply 16-QAM modulation, and pass the modulated signal through the transmit pulse shaping filter.

```
txMod = qammod(data,M);
txSig = txFilter(txMod);
```

Apply phase and frequency offsets using the `pfo` System object, and then pass the signal through an AWGN channel to add white Gaussian noise.

```
txSigOffset = pfo(txSig);
rxSig = awgnChannel(txSigOffset);
```

The coarse frequency compensator System object provides a rough correction for the frequency offset. For the conditions in this example, correcting the frequency offset of the received signal correction to within 10 Hz of the transmitted signal is sufficient.

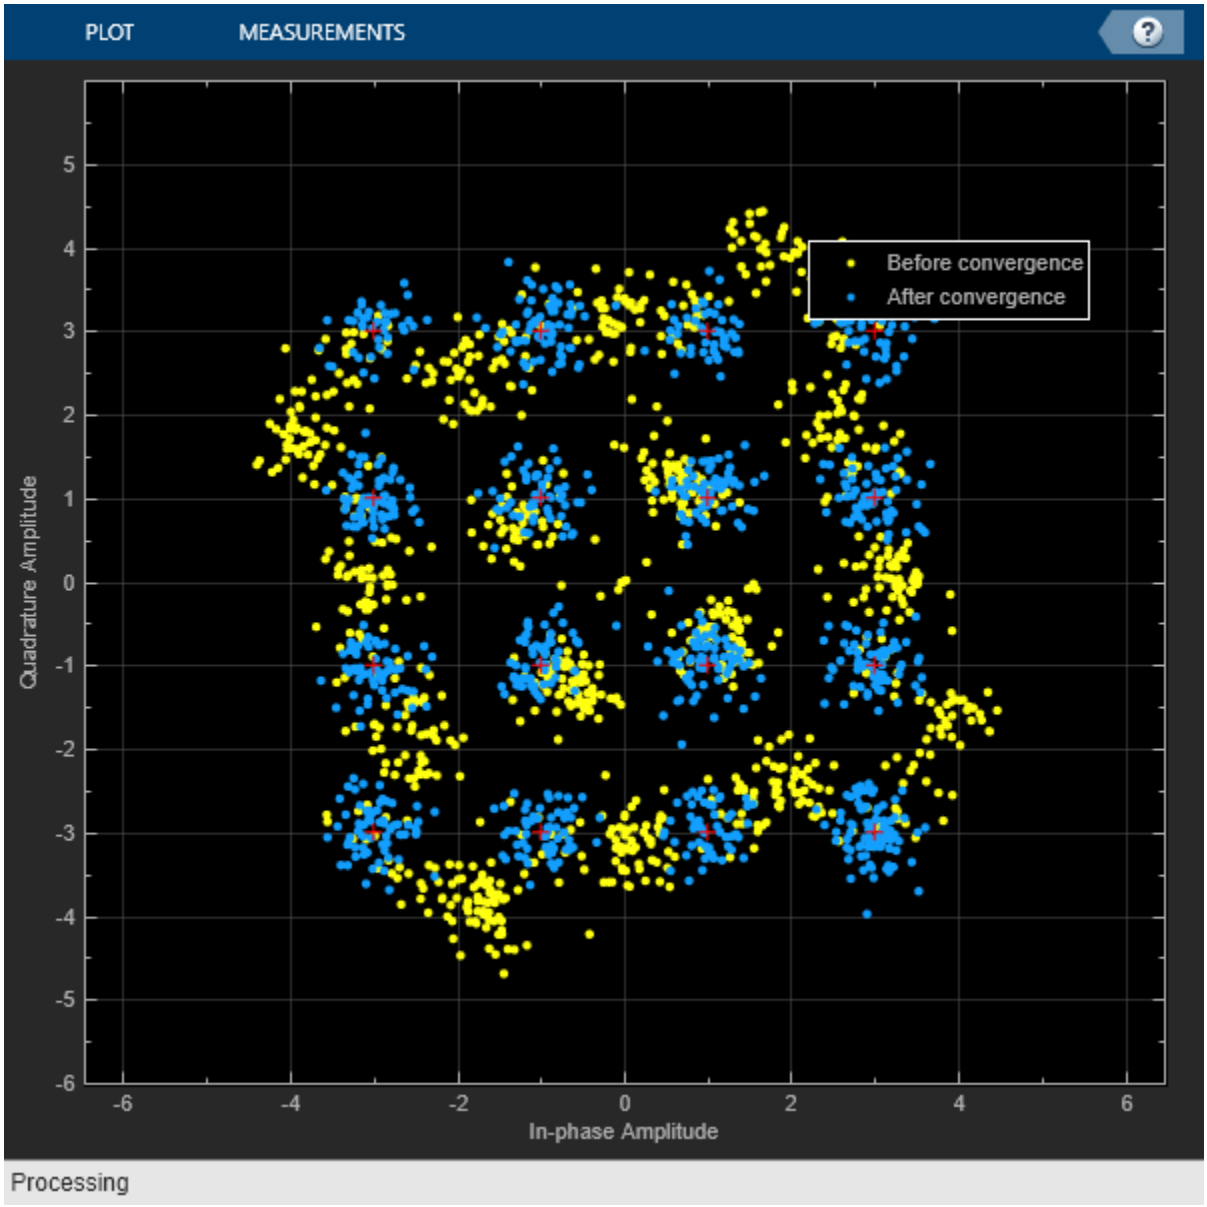
```
syncCoarse = coarse(rxSig);
```

Pass the signal through the receive pulse shaping filter, and apply fine frequency correction.

```
rxFiltSig = fine(rxFilter(syncCoarse));
```

Display the constellation diagram of the first and last 1000 symbols in the signal. Before convergence of the synchronization loop, the spiral nature of the diagram indicates that the frequency offset is not corrected. After the carrier synchronizer has converged to a solution, the symbols are aligned with the reference constellation.

```
constDiagram([rxFiltSig(1:1000) rxFiltSig(9001:end)])
```



Demodulate the signal. Account for the signal delay caused by the transmit and receive filters to align the received data with the transmitted data. Compute and display the total bit errors and BER. When checking the bit errors, use the later portion of the received signal to be sure the synchronization loop has converged.

```
rxData = qamdemod(rxFiltSig,M);
delay = (txFilter.FilterSpanInSymbols + ...
    rxFilter.FilterSpanInSymbols) / 2;
idxSync = 2000; % Check BER after synchronization loop has converged
[syncDataTtlErr,syncDataBER] = biterr( ...
    data(idxSync:end-delay),rxData(idxSync+delay:end))
```

```
syncDataTtlErr = 16116
```

```
syncDataBER = 0.5042
```

Depending on the random data used, there may be bit errors resulting from phase ambiguity in the received signal after the synchronization loop converges and locks. In this case, you can use the preamble to determine and then remove the phase ambiguity from the synchronized signal to reduce bit errors. If phase ambiguity is minimal, the number of bit errors may be unchanged.

```
idx = 9000 + (1:barker.Length);
phOffset = angle(txMod(idx) .* conj(rxFiltSig(idx+delay)));

phOffsetEst = mean(phOffset);
disp(['Phase offset = ',num2str(rad2deg(phOffsetEst)),' degrees'])
```

```
Phase offset = -90.1401 degrees
```

```
resPhzSig = exp(1i*phOffsetEst) * rxFiltSig;
```

Demodulate the signal after resolving the phase ambiguity. Recompute the total bit errors and BER.

```
resPhzData = qamdemod(resPhzSig,M);
[resPhzTtlErr,resPhzBER] = biterr( ...
    data(idxSync:end-delay),resPhzData(idxSync+delay:end))
```

```
resPhzTtlErr = 5
```

```
resPhzBER = 1.5643e-04
```

MSK Signal Recovery

Model channel impairments such as timing phase offset, carrier frequency offset, and carrier phase offset for a minimum shift keying (MSK) signal. Use `comm.MSKTimingSynchronizer` and `comm.CarrierSynchronizer` System objects to synchronize such signals at the receiver. The MSK timing synchronizer recovers the timing offset, while a carrier synchronizer recovers the carrier frequency and phase offsets.

Initialize system variables by running the MATLAB® script `configureMSKSignalRecoveryEx`. Define the logical control variable `recoverTimingPhase` to enable timing phase recovery, and `recoverCarrier` to enable carrier frequency and phase recovery.

```
configureMSKSignalRecoveryEx;
recoverTimingPhase = true;
recoverCarrier = true;
```

Modeling Channel Impairments

Specify the sample delay, `timingOffset`, that the channel model applies. Create a variable fractional delay object to introduce the timing delay to the transmitted signal.

```
timingOffset = 0.2;
varDelay = dsp.VariableFractionalDelay;
```

Create a `comm.PhaseFrequencyOffset` System object™ to introduce carrier phase and frequency offsets to a modulated signal. Because the MSK modulator upsamples the transmitted symbols, set the `SampleRate` property to the ratio of the `samplesPerSymbol` and the sample time, `Ts`.

```
freqOffset = 50;
phaseOffset = 30;
```

```
pfo = comm.PhaseFrequencyOffset(...
    'FrequencyOffset',freqOffset, ...
    'PhaseOffset',phaseOffset, ...
    'SampleRate',samplesPerSymbol/Ts);
```

Set the simulated SNR to 20 dB. Since the MSK modulator generates symbols with 1 Watt of power, the signal power is 1 W or 0 dB W, which is the default value for the `awgn` channel signal power input.

```
SNR = 20;
```

Timing Phase, Carrier Frequency, and Carrier Phase Synchronization

Create an MSK timing synchronizer to recover symbol timing phase using a fourth-order nonlinearity method.

```
timeSync = comm.MSKTimingSynchronizer(...
    'SamplesPerSymbol',samplesPerSymbol, ...
    'ErrorUpdateGain',0.02);
```

Create a carrier synchronizer to recover both carrier frequency and phase. Because the MSK constellation is QPSK with a 0-degree phase offset, set the `comm.CarrierSynchronizer` accordingly.

```
phaseSync = comm.CarrierSynchronizer(...
    'Modulation','QPSK', ...
    'ModulationPhaseOffset','Custom', ...
    'CustomPhaseOffset',0, ...
    'SamplesPerSymbol',1);
```

Stream Processing Loop

The simulation modulates data using MSK modulation. The modulated symbols pass through the channel model, which applies timing delay, carrier frequency and phase shift, and additive white Gaussian noise. The receiver performs timing phase and carrier frequency and phase recovery. Finally, the signal symbols are demodulated and the bit error rate is calculated. The `plotResultsMSKSignalRecoveryEx` script generates scatter plots in this order to show these effects:

1. Channel impairments
2. Timing synchronization
3. Carrier synchronization

At the end of the simulation, the example displays the timing phase, frequency, and phase estimates as a function of simulation time.

```
for p = 1:numFrames
    %------------------------------------------------------
    % Generate and modulate data
    %------------------------------------------------------
    txBits = randi([0 1],samplesPerFrame,1);
    txSym = modem(txBits);
    %------------------------------------------------------
    % Transmit through channel
    %------------------------------------------------------
    %
    % Add timing offset
    rxSigTimingOff = varDelay(txSym,timingOffset*samplesPerSymbol);
```

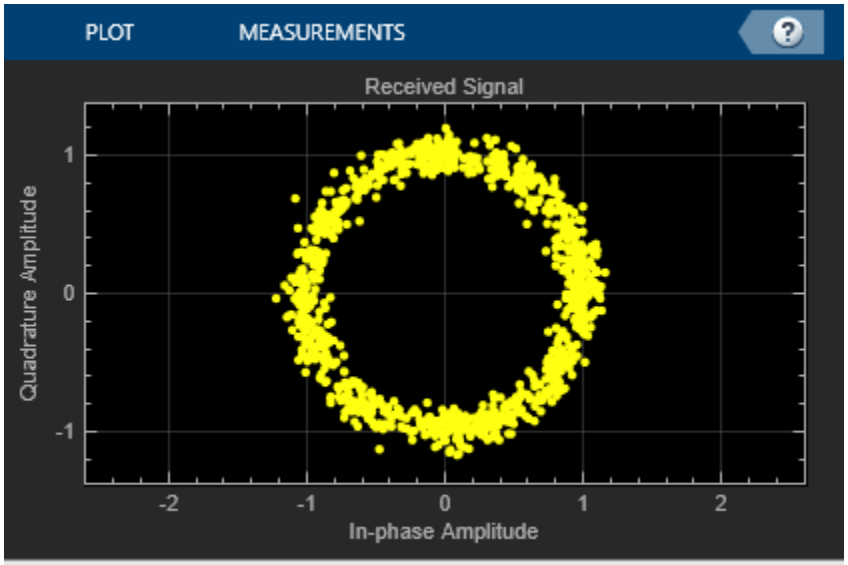
```
%
% Add carrier frequency and phase offset
rxSigCFO = pfo(rxSigTimingOff);
%
% Pass the signal through an AWGN channel
rxSig = awgn(rxSigCFO,SNR);
%
% Save the transmitted signal for plotting
plot_rx = rxSig;
%
%-----------------------------------------------------
% Timing recovery
%-----------------------------------------------------
if recoverTimingPhase
    % Recover symbol timing phase using
    % fourth-order nonlinearity method
    [rxSym,timEst] = timeSync(rxSig);
    % Calculate the timing delay estimate for each sample
    timEst = timEst(1)/samplesPerSymbol;
else
    % Do not apply timing recovery and
    % simply downsample the received signal
    rxSym = downsample(rxSig,samplesPerSymbol);
    timEst = 0;
end

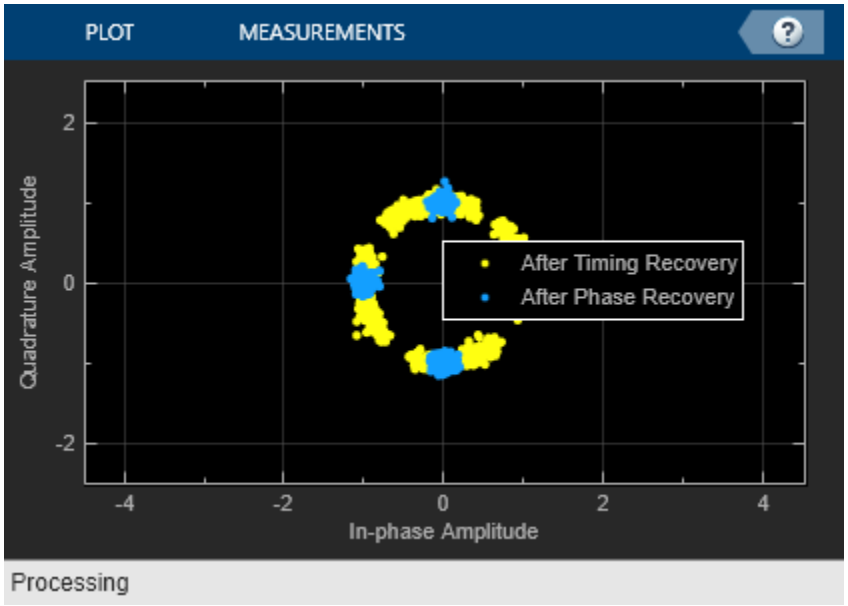
% Save the timing synchronized received signal for plotting
plot_rxTimeSync = rxSym;

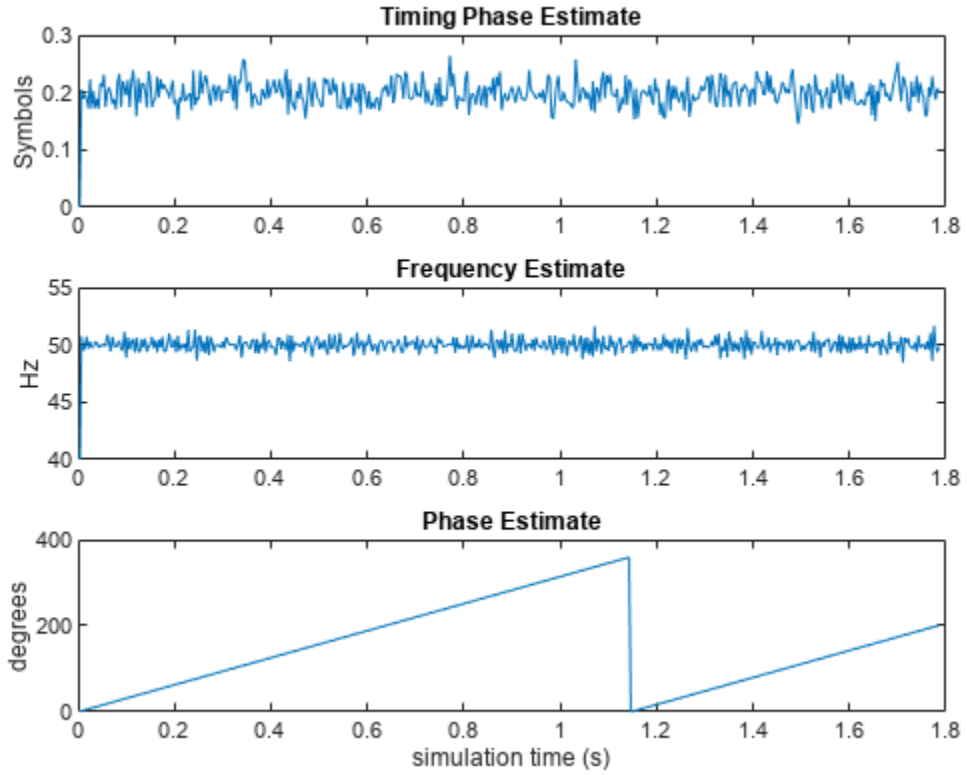
%-----------------------------------------------------
% Carrier frequency and phase recovery
%-----------------------------------------------------
if recoverCarrier
    % The following script applies carrier frequency and
    % phase recovery using a second order phase-locked
    % loop (PLL), and removes phase ambiguity
    [rxSym,phEst] = phaseSync(rxSym);
    removePhaseAmbiguityMSKSignalRecoveryEx;
    freqShiftEst = mean(diff(phEst)/(Ts*2*pi));
    phEst = mod(mean(phEst),360); % in degrees
else
    freqShiftEst = 0;
    phEst = 0;
end

% Save the phase synchronized received signal for plotting
plot_rxPhSync = rxSym;
%-----------------------------------------------------
% Demodulate the received symbols
%-----------------------------------------------------
rxBits = demod(rxSym);
%-----------------------------------------------------
% Calculate the bit error rate
%-----------------------------------------------------
errorStats = BERCalc(txBits,rxBits);
%-----------------------------------------------------
% Plot results
%-----------------------------------------------------
```

```
    plotResultsMSKSignalRecoveryEx;
end
```







Display the bit error rate and the total number of symbols processed by the error rate calculator.

```
BitErrorRate = errorStats(1)
```

```
BitErrorRate = 4.0001e-06
```

```
TotalNumberOfSymbols = errorStats(3)
```

```
TotalNumberOfSymbols = 499982
```

Conclusion and Further Experimentation

The recovery algorithms are demonstrated by using constellation plots taken after timing, carrier frequency, and carrier phase synchronization.

Open the script to create a writable copy of this example and its supporting files. Then, to show the effects of the recovery algorithms, you can enable and disable the logical control variables `recoverTimingPhase` and `recoverCarrier` and rerun the simulation.

Appendix

This example uses these scripts:

- `configureMSKSignalRecoveryEx`
- `plotResultsMSKSignalRecoveryEx`

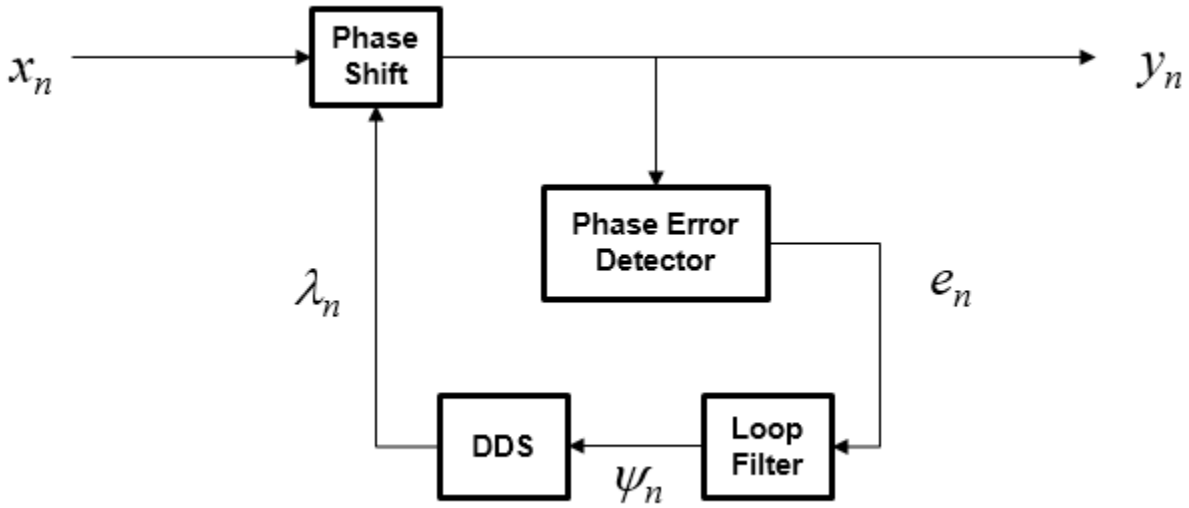
- `removePhaseAmbiguityMSKSignalRecoveryEx`

Algorithms

The `comm.CarrierSynchronizer` System object is a closed-loop compensator that uses the PLL-based algorithm described in [1]. The output of the synchronizer, y_n, is a frequency-shifted version of the complex input signal, x_n, for the nth sample. The synchronizer output is

$$y_n = x_n e^{i\lambda_n},$$

where λ_n is the output of the direct digital synthesizer (DDS). The DDS is the discrete-time version of a voltage-controlled oscillator and is a core component of discrete-time phase locked loops. In the context of this System object, the DDS works as an integration filter.



To correct for the frequency offset, first the algorithm determines the phase error, e_n. The value of the phase error depends on the modulation scheme.

Modulation	Phase Error
QAM or QPSK	$e_n = \text{sgn}(\text{Re}\{x_n\}) \times \text{Im}\{x_n\} - \text{sgn}(\text{Im}\{x_n\}) \times \text{Re}\{x_n\}$ For a detailed description of this equation, see [1].
BPSK or PAM	$e_n = \text{sgn}(\text{Re}\{x_n\}) \times \text{Im}\{x_n\}$ For a detailed description of this equation, see [1].

Modulation	Phase Error
8-PSK	$e_n =$ $\begin{cases} \text{sgn}(\text{Re}\{x_n\}) \times \text{Im}\{x_n\} - (\sqrt{2}-1)\text{sgn}(\text{Im}\{x_n\}) \times \text{Re}\{x_n\}, & \text{for} \\ (\sqrt{2}-1)\text{sgn}(\text{Re}\{x_n\}) \times \text{Im}\{x_n\} - \text{sgn}(\text{Im}\{x_n\}) \times \text{Re}\{x_n\}, & \text{for} \end{cases}$ For a detailed description of this equation, see [2].
OQPSK	$e_n = \text{sgn}\left(\text{Re}\left\{x_{\text{n-SamplePerSymbol/2}}\right\}\right) \times \text{Im}\left\{x_{\text{n-SamplePerSymbol/2}}\right\} - \text{sgn}(\text{Im}\{x_n\}) \times \text{Re}\{x_n\}$

To ensure system stability, the phase error passes through a biquadratic loop filter governed by

$$\psi_n = g_I e_n + \psi_{n-1} ,$$

where ψ_n is the output of the loop filter at sample n, and g_I is the integrator gain. The integrator gain is determined from the equation

$$g_I = \frac{4\left(\theta^2/d\right)}{K_p K_0} \quad ,$$

where θ, d, K_0, and K_p are determined from the System object properties. Specifically,

$$\theta = \frac{B_n T}{\left(\zeta + \frac{1}{4\zeta}\right)} \text{ and } d = 1 + 2\zeta\theta + \theta^2,$$

where B_n is the normalized loop bandwidth, and ζ is the damping factor. The phase recovery gain, K_0, is equal to the number of samples per symbol. The modulation type determines the phase error detector gain, K_p.

Modulation	K_p
BPSK, PAM, QAM, QPSK, or OQPSK	2
8-PSK	1

The output of the loop filter is then passed to the DDS. The DDS is another biquadratic loop filter whose expression is based on the forward Euler integration rule

$$\lambda_n = (g_P e_{n-1} + \psi_{n-1}) + \lambda_{n-1} ,$$

where g_P is the proportional gain that is expressed as

$$g_P = \frac{4\zeta(\theta/d)}{K_p K_0} .$$

The `info` object function of this System object returns estimates of the normalized pull-in range, the maximum frequency lock delay, and the maximum phase lock delay. The normalized pull-in range, $(\Delta f)_{\text{pull-in}}$, is expressed in radians and estimated as

$$(\Delta f)_{\text{pull-in}} \approx \min(1, 2\pi\sqrt{2}\zeta B_n) .$$

The expression for $(\Delta f)_{\text{pull-in}}$ becomes less accurate as $2\pi\sqrt{2}\zeta B_{\text{n}}$ approaches 1.

The maximum frequency lock delay, T_{FL}, and phase lock delay, T_{PL}, are expressed in samples and estimated as

$$T_{\text{FL}} \approx 4\frac{(\Delta f)_{\text{pull-in}}^2}{B_{\text{n}}^3} \text{ and } T_{\text{PL}} \approx \frac{1.3}{B_{\text{n}}} .$$

comm.CCDF

Package: comm

Complementary cumulative distribution function (CCDF) measurements

Description

The comm.CCDF System object obtains the CCDF measurements of an input signal. The CCDF measures the probability that the instantaneous power of the signal is a specified level above its average power.

To obtain the CCDF measurements of an input signal:

1. Create the comm.CCDF object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
ccdf = comm.CCDF
ccdf = comm.CCDF(Name,Value)
```

Description

ccdf = comm.CCDF creates a CCDF measurement System object.

ccdf = comm.CCDF(Name,Value) sets properties on page 3-181 using one or more name-value arguments. For example, comm.CCDF('NumPoints',2000) creates a CCDF measurement object with 2000 CCDF points.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

NumPoints — Number of CCDF points
1000 (default) | positive integer

Number of CCDF points, specified as a positive integer. This property and the MaximumPowerLimit property control the size of the histogram bins that the object uses to estimate CCDF curves. The size

of the histogram bins determines the resolution of the curves. All input channels have the same number of CCDF points.

Data Types: `double`

`MaximumPowerLimit` — Maximum expected input signal power limit
`50` (default) | numeric scalar | numeric row vector

Maximum expected input signal power limit, specified as one of these options.

- Numeric scalar — All channels in the input signal have the same expected maximum power.
- Numeric row vector — The *i*th element of the vector is the maximum expected power for the *i*th channel in the input signal.

For each input channel, the object obtains the CCDF results by integrating a histogram of instantaneous input signal powers. The object sets the bins of the histogram so that the last bin collects all power occurrences that are equal to or greater than the power specified by this property. The object issues a warning if an input signal exceeds its specified maximum power limit.

This property and the `NumPoints` property control the size of the histogram bins that the object uses to estimate CCDF curves. The size of the histogram bins determines the resolution of the curves.

To specify the units for this property, use the `PowerUnits` property.

Data Types: `double`

`PowerUnits` — Power measurement units
`'dBm'` (default) | `'dBW'` | `'Watts'`

Power measurement units, specified as one of these values.

- `'dBm'` or `'dBW'` — The object returns relative power values in a dB scale.
- `'Watts'` — The object returns relative power values in a linear scale.

This property determines the power units of the `MaximumPowerLimit` property.

Data Types: `char` | `string`

`AveragePowerOutputPort` — Option to enable average power measurement output
`0` or `false` (default) | `1` or `true`

Option to enable average power measurement output, specified as a logical value `0` (`false`) or `1` (`true`). When you set this property to `true`, the object returns the running average power measurements.

Data Types: `logical` | `double`

`PeakPowerOutputPort` — Option to enable peak power measurement output
`0` or `false` (default) | `1` or `true`

Option to enable peak power measurement output, specified as a logical value `0` (`false`) or `1` (`true`). When you set this property to `true`, the object returns the running peak power measurements.

Data Types: `logical` | `double`

`PAPROutputPort` — Option to enable PAPR measurement output
`0` or `false` (default) | `1` or `true`

Option to enable peak-to-average power (PAPR) measurement output, specified as a logical value `0` (`false`) or `1` (`true`). When you set this property to `true`, the object returns the running PAPR measurements.

Data Types: `logical` | `double`

Usage

Syntax

```
[ccdfy,ccdfx] = ccdf(signal)
[ccdfy,ccdfx,avg] = ccdf(signal)
[ccdfy,ccdfx,peak] = ccdf(signal)
[ccdfy,ccdfx,papr] = ccdf(signal)
[ccdfy,ccdfx,avg,peak,papr] = ccdf(signal)
```

Description

`[ccdfy,ccdfx] = ccdf(signal)` returns the *y*-axis and *x*-axis points of the CCDF curve of each channel in input `signal`.

`[ccdfy,ccdfx,avg] = ccdf(signal)` returns also the average power measurements of each channel in the input signal. To use this syntax, set the `AveragePowerOutputPort` property to `true`.

`[ccdfy,ccdfx,peak] = ccdf(signal)` returns also the peak power measurements of each channel in the input signal. To use this syntax, set the `PeakPowerOutputPort` property to `true`.

`[ccdfy,ccdfx,papr] = ccdf(signal)` returns the PAPR measurements of each channel in the input signal. To use this syntax, set the `PAPROutputPort` property to `true`.

`[ccdfy,ccdfx,avg,peak,papr] = ccdf(signal)` returns all CCDF measurements. To use this syntax, set the `AveragePowerOutputPort`, `PeakPowerOutputPort`, and `PAPROutputPort` properties to `true`.

Input Arguments

`signal` — Input signal
matrix of complex numbers

Input signal, specified as an *M*-by-*N* matrix of complex numbers. *M* is the number of time samples. *N* is the number of input channels.

Data Types: `double`
Complex Number Support: Yes

Output Arguments

`ccdfy` — *y*-axis points of CCDF curves
numeric matrix

y-axis points of the CCDF curve of each channel, returned as a numeric matrix of the form (`NumPoints`+1)-by-*N*, where *N* is the number of columns in input `signal`. The *i*th column of the matrix contains the probability values measured for the channel in the *i*th column of `signal`. The probability values are percentages in the range [0, 100].

Data Types: `double`

`ccdfx` — *x*-axis points of CCDF curves
numeric matrix

x-axis points of the CCDF curve of each channel, returned as a numeric matrix of the form (`NumPoints`+1)-by-*N*. *N* is the number of channels in input `signal`. The *i*th column of the matrix contains the instantaneous-to-average power ratios for the channel in the *i*th column of `signal`.

Data Types: `double`

`avg` — Average power measurements
numeric column vector

Average power measurement for each channel, returned as a numeric column vector. The *i*th element corresponds to the average power measurement for the channel in the *i*th column of the input `signal`. The object returns this value in the units specified by the `PowerUnits` property.

Data Types: `double`

`peak` — Peak power measurements
numeric column vector

Peak power measurement of each channel, returned as a numeric column vector. The *i*th element corresponds to the peak power measurement for the channel in the *i*th column of the input `signal`. The object returns this value in the units specified by the `PowerUnits` property.

Data Types: `double`

`papr` — PAPR measurements
numeric column vector

PAPR measurement of each channel, returned as a numeric column vector. The *i*th element corresponds to the PAPR measurement for the channel in the *i*th column of the input `signal`. The object returns this value in the units specified by the `PowerUnits` property.

Data Types: `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `comm.CCDF`

getPercentileRelativePower	Relative power value for given percentile using CCDF
getProbability	Probability of relative power value using CCDF
plot	2-D line plots of CCDF curves

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Obtain CCDF Curves for 16-QAM and QPSK Signals

Generate 16-QAM and QPSK modulated signals.

```
qamTxSig = qammod(randi([0 15],20e3,1),16,'UnitAveragePower',true);
qpskTxSig = pskmod(randi([0 3],20e3,1),4,pi/4);
```

Pass the signals through an AWGN channel.

```
qamRxSig = awgn(qamTxSig,15);
qpskRxSig = awgn(qpskTxSig,15);
```

Create a CCDF measurement object enabling outputs for the average power measurements and peak power measurements.

```
ccdf = comm.CCDF(...
    'AveragePowerOutputPort',true, ...
    'PeakPowerOutputPort',true);
```

Obtain the CCDF measurements of the two waveforms.

```
[ccdfy,ccdfx,avg,peak] = ccdf([qamRxSig qpskRxSig]);
```

Plot the CCDF curves for both signals.

```
plot(ccdf)
legend('16-QAM','QPSK')
```

Objects

`comm.ACPR` | `comm.EVM` | `comm.MER`

comm.CoarseFrequencyCompensator

Package: `comm`

Compensate for frequency offset of PAM, PSK, or QAM signal

Description

The `comm.CoarseFrequencyCompensator` System object compensates for the frequency offset of received signals using an open-loop technique.

To compensate for the frequency offset of a PAM, PSK, or QAM signal:

1. Create the `comm.CoarseFrequencyCompensator` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
coarseFreqComp = comm.CoarseFrequencyCompensator
coarseFreqComp = comm.CoarseFrequencyCompensator(Name,Value)
```

Description

`coarseFreqComp = comm.CoarseFrequencyCompensator` creates a coarse frequency offset compensator System object. This object uses an open-loop technique to estimate and compensate for the carrier frequency offset in a received signal. For more information about the estimation algorithm options, see “Algorithms” on page 3-195.

`coarseFreqComp = comm.CoarseFrequencyCompensator(Name,Value)` specifies properties using one or more name-value arguments. For example, `Modulation='QPSK'` specifies quadrature phase-shift keying modulation.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`Modulation` — Modulation type

`'QAM'` (default) | `'8PSK'` | `'BPSK'` | `'OQPSK'` | `'PAM'` | `'QPSK'`

Modulation type, specified as one of,

- `'BPSK'` – Binary phase shift keying
- `'QPSK'` – Quadrature phase shift keying
- `'OQPSK'` – Offset quadrature phase shift keying
- `'8PSK'` – 8-phase shift keying
- `'PAM'` – Pulse amplitude modulation
- `'QAM'` – Quadrature amplitude modulation

Data Types: `char` | `string`

`Algorithm` — Algorithm used to estimate frequency offset

`'FFT-based'` (default) | `'Correlation-based'`

Algorithm used to estimate the frequency offset, specified as `'FFT-based'` or `'Correlation-based'`.

Dependency

To enable this property, set `Modulation` to `'BPSK'`, `'QPSK'`, `'8PSK'`, or `'PAM'`. This table shows the valid combinations of the modulation type and the estimation algorithm.

Modulation	FFT-Based Algorithm	Correlation-Based Algorithm
BPSK, QPSK, 8PSK, PAM	Yes	Yes
OQPSK, QAM	Yes	No

Use the correlation-based algorithm for HDL implementations and for other situations in which you want to avoid using an FFT.

Data Types: `char` | `string`

`FrequencyResolution` — Frequency resolution

`0.001` (default) | positive scalar

Frequency resolution for the offset frequency estimation in hertz, specified as a positive scalar. This property establishes the FFT length used to perform spectral analysis and must be less than the sample rate.

Data Types: `double`

`MaximumFrequencyOffset` — Maximum measurable frequency offset

`0.05` (default) | positive scalar

Maximum measurable frequency offset in hertz, specified as a positive scalar.

The value of this property must be less than f_{samp} / M. For more details, see “Correlation-Based Estimation” on page 3-195.

Dependency

To enable this property, set the `Algorithm` property to `'Correlation-based'`.

Data Types: `double`

`SampleRate` — Sample rate
1 (default) | positive scalar

Sample rate in samples per second, specified as a positive scalar.

Data Types: `double`

`SamplesPerSymbol` — Samples per symbol
4 (default) | even integer, greater than or equal to 4

Samples per symbol, specified as an even positive integer greater than or equal to 4.

Dependency

To enable this property, set `Modulation` to `'OQPSK'`.

Usage

Syntax

```
y = coarseFreqComp(x)
[y,estimate] = coarseFreqComp(x)
```

Description

`y = coarseFreqComp(x)` returns a signal that compensates for the carrier frequency offset of the input signal.

`[y,estimate] = coarseFreqComp(x)` returns a scalar estimate of the frequency offset.

Input Arguments

`x` — Input signal
column vector

Input signal, specified as a column vector.

Data Types: `single` | `double`

Output Arguments

`y` — Compensated output signal
complex column vector

Compensated output signal, returned as a complex column vector with the same dimensions and data type as the input `x`.

`estimate` — Estimate of frequency offset
scalar

Estimate of the frequency offset, returned as a scalar.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `comm.CoarseFrequencyCompensator`

info	Characteristic information about coarse frequency compensator
clone	Create duplicate System object
isLocked	Determine if System object is in use

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Compensate for Frequency Offset in QPSK Signal

Compensate for a 4 kHz frequency offset imposed on a noisy QPSK signal.

Set up the example parameters.

```
nSym = 2048;       % Number of input symbols
sps = 4;           % Samples per symbol
nSamp = nSym*sps;  % Number of samples
fs = 80000;        % Sampling frequency (Hz)
```

Create a square root raised cosine transmit filter.

```
txfilter = comm.RaisedCosineTransmitFilter( ...
    RolloffFactor=0.2, ...
    FilterSpanInSymbols=8, ...
    OutputSamplesPerSymbol=sps);
```

Create a phase frequency offset object to introduce the 4 kHz frequency offset.

```
freqOffset = comm.PhaseFrequencyOffset( ...
    FrequencyOffset=-4000, ...
    SampleRate=fs);
```

Create a coarse frequency compensator object to compensate for the offset.

```
freqComp = comm.CoarseFrequencyCompensator( ...
    Modulation="qpsk", ...
    SampleRate=fs, ...
    FrequencyResolution=1);
```

Generate QPSK symbols, filter the modulated data, pass the signal through an AWGN channel, and apply the frequency offset.

```
data = randi([0 3],nSym,1);
modData = pskmod(data,4,pi/4);
txSig = txfilter(modData);
rxSig = awgn(txSig,20,"measured");
offsetData = freqOffset(rxSig);
```

Compensate for the frequency offset using the coarse frequency compensator. When the frequency offset is high, applying coarse frequency compensation prior to receive filtering is benefitial because filtering suppresses energy in the useful spectrum.

```
[compensatedData,estFreqOffset] = freqComp(offsetData);
```

Display the estimate of the frequency offset.

```
estFreqOffset
```

```
estFreqOffset = -4.0001e+03
```

Return information about the coarse frequency compensator System object. To obtain the FFT length, you must call coarse frequency compensator System object prior to calling the `info` object function.

```
freqCompInfo = info(freqComp)
```

```
freqCompInfo = struct with fields:
    FFTLength: 131072
    Algorithm: 'FFT-based'
```

Create a spectrum analyzer object and plot the offset and compensated spectra. Verify that the compensated signal has a center frequency at 0 Hz and that the offset signal has a center frequency at -4 kHz.

```
sa = spectrumAnalyzer( ...
    SampleRate=fs, ...
    ShowLegend=true, ...
    ChannelNames=["Offset Signal","Compensated Signal"]);
sa([offsetData compensatedData])
release(sa)
```

Compensate for Frequency Offset Using Coarse and Fine Compensation

Correct for a phase and frequency offset in a noisy QAM signal using a carrier synchronizer. Then correct for the offsets using both a carrier synchronizer and a coarse frequency compensator.

Set the example parameters.

```
fs = 10000;   % Symbol rate (Hz)
sps = 4;      % Samples per symbol
M = 16;       % Modulation order
k = log2(M);  % Bits per symbol
EbNo = 20;    % Eb/No (dB)
SNR = convertSNR(EbNo,"ebno",BitsPerSymbol=k,SamplesPerSymbol=sps);
```

Create a constellation diagram object to visualize the effects of the offset compensation techniques. Specify the constellation diagram to display only the last 4000 samples.

```
constdiagram = comm.ConstellationDiagram( ...
    'ReferenceConstellation',qammod(0:M-1,M), ...
    'SamplesPerSymbol',sps, ...
    'SymbolsToDisplaySource','Property', ...
    'SymbolsToDisplay',4000, ...
    'XLimits',[-5 5], ...
    'YLimits',[-5 5]);
```

Introduce a frequency offset of 400 Hz and a phase offset of 30 degrees.

```
phaseFreqOffset = comm.PhaseFrequencyOffset( ...
    'FrequencyOffset',400, ...
    'PhaseOffset',30, ...
    'SampleRate',fs);
```

Generate random data symbols and apply 16-QAM modulation.

```
data = randi([0 M-1],10000,1);
modSig = qammod(data,M);
```

Create a raised cosine filter object and filter the modulated signal.

```
txfilter = comm.RaisedCosineTransmitFilter( ...
    'OutputSamplesPerSymbol',sps, ...
    'Gain',sqrt(sps));
txSig = txfilter(modSig);
```

Apply the phase and frequency offset, and then pass the signal through the AWGN channel.

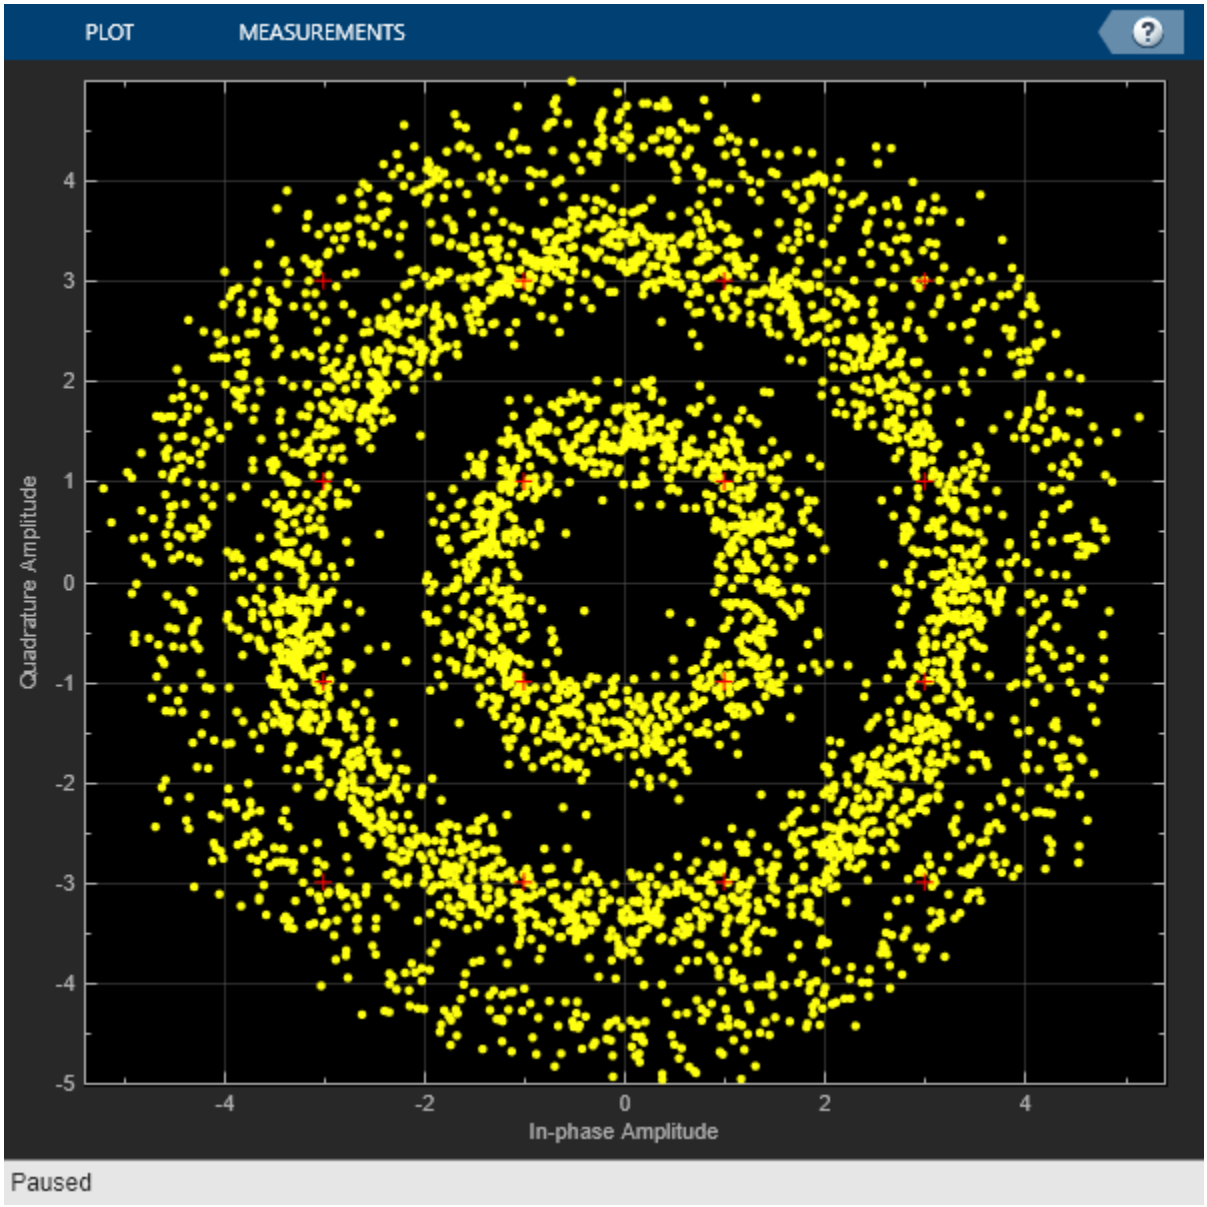
```
freqOffsetSig = phaseFreqOffset(txSig);
rxSig = awgn(freqOffsetSig,SNR);
```

Apply fine frequency correction to the signal by using the carrier synchronizer.

```
fineSync = comm.CarrierSynchronizer( ...
    'DampingFactor',0.7, ...
    'NormalizedLoopBandwidth',0.005, ...
    'SamplesPerSymbol',sps, ...
    'Modulation','QAM');
rxData = fineSync(rxSig);
```

Display the constellation diagram of the last 4000 symbols.

```
constdiagram(rxData)
```



Even with time to converge, the spiral nature of the plot shows that the carrier synchronizer has not yet compensated for the large frequency offset. The 400 Hz offset is 1% of the sample rate.

Repeat the process with a coarse frequency compensator inserted before the carrier synchronizer.

Create a coarse frequency compensator to reduce the frequency offset to a manageable level.

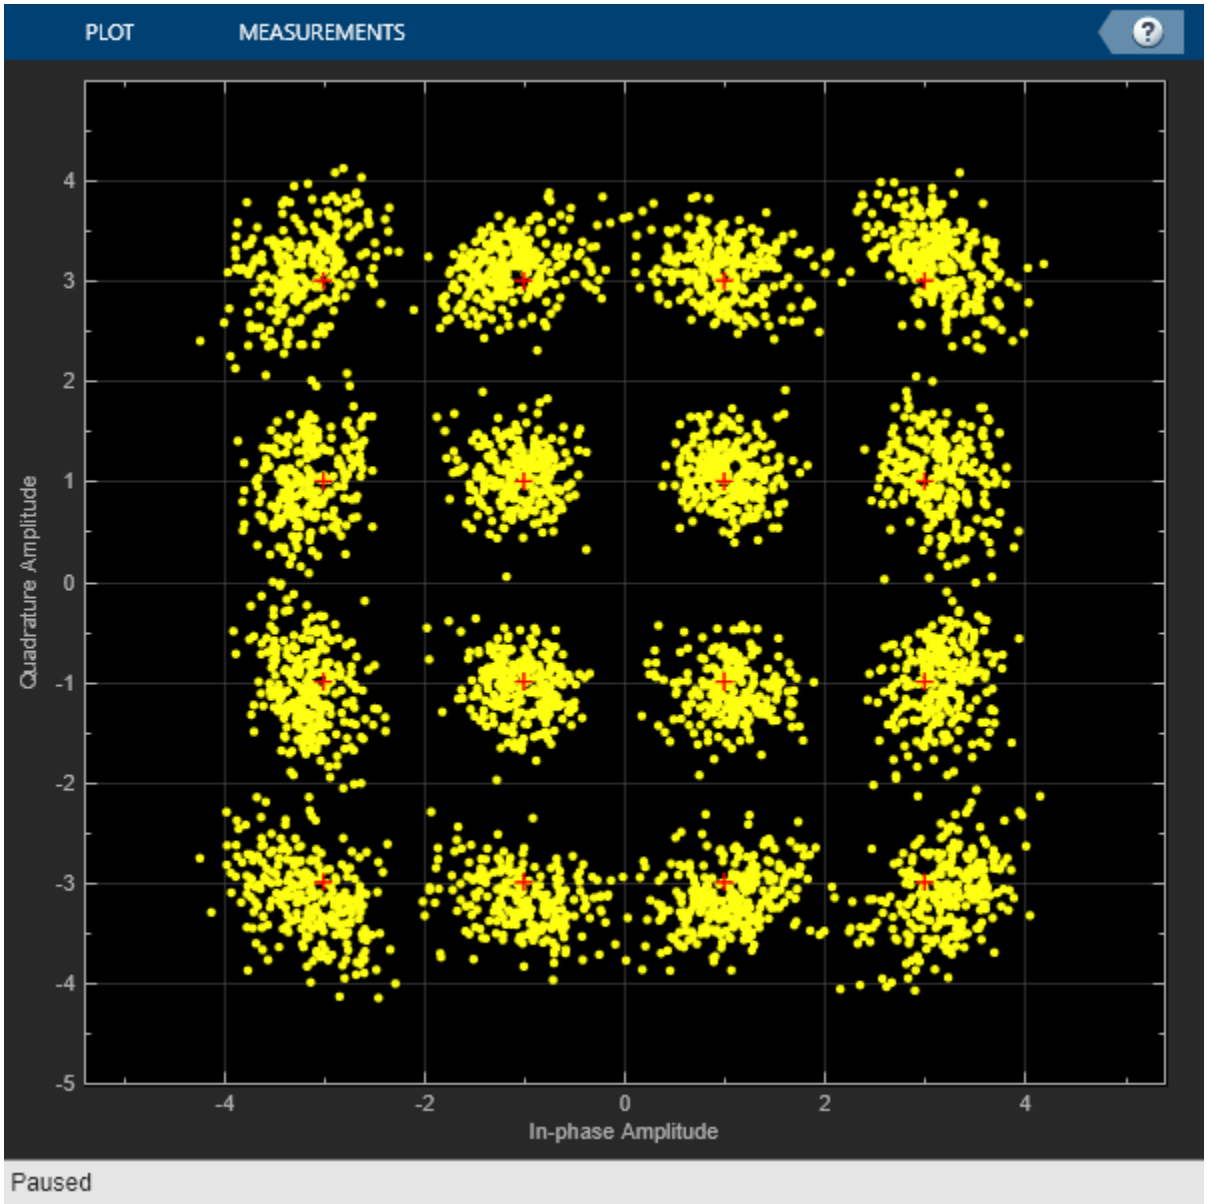
```
coarseSync = comm.CoarseFrequencyCompensator( ...
    'Modulation','QAM', ...
    'FrequencyResolution',1, ...
    'SampleRate',fs*sps);
```

Pass the received signal to the coarse frequency compensator and then to the carrier synchronizer.

```
syncCoarse = coarseSync(rxSig);
rxData = fineSync(syncCoarse);
```

Plot the constellation diagram of the signal after coarse and fine frequency compensation. The received data now aligns with the reference constellation.

```
constdiagram(rxData)
```



Algorithms

Correlation-Based Estimation

Reference [1] describes the correlation-based estimation algorithm used to estimate the frequency offset for PSK and PAM signals. To determine the frequency offset, Δf, the algorithm performs a maximum likelihood (ML) estimation of the complex-valued oscillation $\exp(j2\pi\Delta ft)$. The observed signal, r_k, is represented as

$$r_k = e^{j(2\pi\Delta f k T_s + \theta)},\ 1 \le k \le N$$

T_s is the sampling interval, θ is an unknown random phase, and N is the number of samples. The ML estimation of the frequency offset is equivalent to seeking the maximum of the likelihood function,

$$\Lambda(\Delta f) \approx \left| \sum_{i=1}^{N} r_i e^{-j2\pi\Delta f i T_s} \right|^2 = \sum_{k=1}^{N} \sum_{m=1}^{N} r_k r_m^* e^{-j2\pi\Delta f T_s (k-m)}$$

After simplifying, the problem is expressed as a discrete Fourier transform, weighted by a parabolic windowing function. It is expressed as

$$\mathrm{Im}\left\{ \sum_{k=1}^{N-1} k(N-k) R(k) e^{j2\pi\Delta\widehat{f} T_s} \right\} = 0$$

R(k) denotes the estimated autocorrelation of the sequence r_k and is represented as

$$R(k) \triangleq \frac{1}{N-k} \sum_{i=k+1}^{N} r_i r_{i-k}^*,\ 0 \le k \le N-1$$

The term *k(N–k)* is the parabolic windowing function. In [1], it is shown that *R(k)* is a poor estimate of the autocorrelation of r_k when $k = 0$ or when k is close to N. Consequently, the windowing function can be expressed as a rectangular sequence of 1s for $k = 1, 2, \ldots, L$, where $L \le N - 1$. The result is a modified ML estimation strategy in which

$$\mathrm{Im}\left\{ \sum_{k=1}^{L} R(k) e^{-j2\pi\Delta\widehat{f} k T_s} \right\} = 0$$

This equation results in an estimate of $\Delta\widehat{f}$ in which

$$\Delta\widehat{f} \cong \frac{f_{samp}}{\pi(L+1)} \arg\left\{ \sum_{k=1}^{L} R(k) \right\}$$

The sampling frequency, f_{samp}, is the reciprocal of T_s. The number of elements used to compute the autocorrelation sequence, L, are determined as

$$L = \mathrm{round}\left(\frac{f_{samp}}{f_{max}} \right) - 1$$

f_{max} is the maximum expected frequency offset. and `round` is the nearest integer function. The frequency offset estimate improves when $L \ge 7$ and leads to the recommendation that $f_{max} \le f_{samp} / (4M)$.

FFT-Based Estimation

FFT-based estimation algorithms can be used to estimate the frequency offset for various modulation types. The coarse frequency compensator implementation supports these modulation methods by using the algorithm noted.

- For `BPSK`, `QPSK`, `8PSK`, `PAM`, or `QAM` modulation, the coarse frequency compensator uses the FFT-based algorithm described in [2]. The algorithm estimates $\Delta\widehat{f}$ by using a periodogram of the m^{th} power of the received signal and is given as

$$\Delta\widehat{f} = \frac{f_{samp}}{N \cdot m}\underset{f}{\operatorname{argmax}}\left|\sum_{k=0}^{N-1} r^m(k)e^{-j2\pi kt/N}\right|, \quad \left(-\frac{R_{sym}}{2} \le f \le \frac{R_{sym}}{2}\right)$$

where m is the modulation order, $r(k)$ is the received sequence, R_{sym} is the symbol rate, and N is the number of samples. The algorithm searches for a frequency that maximizes the time average of the mth power of the received signal multiplied by various frequencies in the range of [$-R_{sym}/2$, $R_{sym}/2$]. Because the form of the algorithm is the definition of the discrete Fourier transform of $r^m(t)$, searching for a frequency that maximizes the time average is equivalent to searching for a peak line in the spectrum of $r^m(t)$. The number of points required by the FFT is

$$N = 2^{\left\lceil \log_2\left(\frac{f_{samp}}{f_r}\right)\right\rceil}$$

where f_r is the desired frequency resolution.

- For OQPSK modulation, the coarse frequency compensator uses the FFT-based algorithm described in [4]. The algorithm searches for spectral peaks at ±200 kHz around the symbol rate. This technique locates desired peaks in the presence of interference from spectral content around baseband frequencies due to filtering.

Blocks
Coarse Frequency Compensator

info

Package: comm

Characteristic information about coarse frequency compensator

Syntax

```
infostruct = info(coarseFreqComp)
```

Description

`infostruct = info(coarseFreqComp)` returns characteristic information for the specified coarse frequency compensator.

Examples

Compensate for Frequency Offset in QPSK Signal

Compensate for a 4 kHz frequency offset imposed on a noisy QPSK signal.

Set up the example parameters.

```
nSym = 2048;       % Number of input symbols
sps = 4;           % Samples per symbol
nSamp = nSym*sps;  % Number of samples
fs = 80000;        % Sampling frequency (Hz)
```

Create a square root raised cosine transmit filter.

```
txfilter = comm.RaisedCosineTransmitFilter( ...
    RolloffFactor=0.2, ...
    FilterSpanInSymbols=8, ...
    OutputSamplesPerSymbol=sps);
```

Create a phase frequency offset object to introduce the 4 kHz frequency offset.

```
freqOffset = comm.PhaseFrequencyOffset( ...
    FrequencyOffset=-4000, ...
    SampleRate=fs);
```

Create a coarse frequency compensator object to compensate for the offset.

```
freqComp = comm.CoarseFrequencyCompensator( ...
    Modulation="qpsk", ...
    SampleRate=fs, ...
    FrequencyResolution=1);
```

Generate QPSK symbols, filter the modulated data, pass the signal through an AWGN channel, and apply the frequency offset.

```
data = randi([0 3],nSym,1);
modData = pskmod(data,4,pi/4);
```

```
txSig = txfilter(modData);
rxSig = awgn(txSig,20,"measured");
offsetData = freqOffset(rxSig);
```

Compensate for the frequency offset using the coarse frequency compensator. When the frequency offset is high, applying coarse frequency compensation prior to receive filtering is benefitial because filtering suppresses energy in the useful spectrum.

```
[compensatedData,estFreqOffset] = freqComp(offsetData);
```

Display the estimate of the frequency offset.

```
estFreqOffset
```

```
estFreqOffset = -4.0001e+03
```

Return information about the coarse frequency compensator System object. To obtain the FFT length, you must call coarse frequency compensator System object prior to calling the `info` object function.

```
freqCompInfo = info(freqComp)
```

```
freqCompInfo = struct with fields:
    FFTLength: 131072
    Algorithm: 'FFT-based'
```

Create a spectrum analyzer object and plot the offset and compensated spectra. Verify that the compensated signal has a center frequency at 0 Hz and that the offset signal has a center frequency at -4 kHz.

```
sa = spectrumAnalyzer( ...
    SampleRate=fs, ...
    ShowLegend=true, ...
    ChannelNames=["Offset Signal","Compensated Signal"]);
sa([offsetData compensatedData])
release(sa)
```

Input Arguments

`coarseFreqComp` — Coarse frequency compensator

`CoarseFrequencyCompensator` System object

Coarse frequency compensator specified as a `comm.CoarseFrequencyCompensator` System object.

Output Arguments

`infostruct` — Characteristic information about coarse frequency compensator

structure

Characteristic information about coarse frequency compensator, returned as a structure containing these fields.

`FFTLength` — Number of FFT samples

scalar

Number of fast Fourier transform (FFT) samples, returned as a scalar. Appears only when `Algorithm` is `FFT-based`.

Dependency

To enable this field, set the `Algorithm` property of the `coarseFreqComp` input to `'FFT-based'`.

`Algorithm` — Algorithm used to estimate frequency offset
`'FFT-based'` | `'Correlation-based'`

Algorithm used to estimate frequency offset, returned as `'FFT-based'` or `'Correlation-based'`. This value matches the `Algorithm` property of the `coarseFreqComp` input.

`MaxLag` — Number of samples used to estimate the autocorrelation
positive integer

Number of samples used to estimate the autocorrelation, returned as a positive integer.

Dependency

To enable this field, set the `Algorithm` property of the `coarseFreqComp` input to `'Correlation-based'`.

Data Types: `struct`

`comm.CoarseFrequencyCompensator`

comm.ChannelFilter

Package: `comm`

Filter signal using multipath gains at specified path delays

Description

Use the `comm.ChannelFilter` System object to filter a signal using multipath gains at specified path delays.

To filter a signal using multipath gains:

1. Create the `comm.ChannelFilter` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
chanFilt = comm.ChannelFilter
chanFilt = comm.ChannelFilter(Name,Value)
```

Description

`chanFilt = comm.ChannelFilter` creates a multipath channel filter System object to filter an input signal with path gains at the specified path delays

`chanFilt = comm.ChannelFilter(Name,Value)` sets properties using one or more name-value pairs. For example, `'SampleRate',1e6` sets the sampling rate to `1` MHz. Enclose each property name in quotes.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`SampleRate` — Sample rate

1 Hz (default) | real positive scalar

Sample rate of the input signal, specified as a real, positive scalar.

Data Types: `double`

`PathDelays` — Discrete path delays

`0` (default) | real scalar | real vector

Delays of the discrete paths in seconds, specified as a real scalar or vector.

Data Types: `double`

`FilterDelaySource` — Channel filter delay source

`'Auto'` (default) | `'Custom'`

Channel filter delay source, specified as either `'Auto'` or `'Custom'`.

- Set `FilterDelaySource` to `'Auto'` to specify the channel filter delay as the minimum possible value.
- Set `FilterDelaySource` to `'Custom'` to specify the channel filter delay as a custom value. The custom value cannot be smaller than the minimum possible value.

Data Types: `char`

`FilterDelay` — Channel filter delay

`7` (default) | real non-negative integer scalar

Channel filter delay in samples, specified as a real, non-negative, integer scalar.

Dependencies

To enable this property, set the `FilterDelaySource` property to `'Custom'`. The specified value must be no smaller than the automatically determined channel filter delay when you set `FilterDelaySource` to `'Auto'`.

Data Types: `double`

`NormalizeChannelOutputs` — Normalize outputs by number of receive antennas

`1` or `true` (default) | `0` or `false`

Normalize outputs by number of receive antennas, specified as a logical `1` (`true`) or `0` (`false`).

Data Types: `logical`

Usage

Syntax

```
y = chanFilt(x,g)
```

Description

`y = chanFilt(x,g)` filters input signal `x`, through a multipath channel with path gains `g`, at the path delay locations specified by the PathDelays property.

Input Arguments

`x` — Input signal

matrix

Input signal, specified as a matrix. The argument `x` must be a N_s-by-N_t matrix, where N_s is the number of samples and N_t is the number of transmit antennas.

Data Types: `double`

g — Path gain
array

Path gain, specified as an array. The input G must be a N_s-by-N_p-by-N_t-by-N_r or 1-by-N_p-by-N_t-by-N_r array, where N_r is the number of receive antennas and N_p is the number of paths, i.e., the length of the PathDelays property.

Data Types: `double`

Output Arguments

y — Channel output
matrix

Channel output, returned as a N_s-by-N_r matrix.

Data Types: `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `comm.ChannelFilter`

info Return characteristic information about channel filter

Common to All System Objects

step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

Examples

Explore Spatial Diversity of Channel in Distributed MIMO System

In a distributed MIMO system, explore spatial diversity by transmitting the same signal from two geographically separated transmitters and combining the received signals at one receiver. Use ray tracing to analyze the propagation paths and gains from each transmitter to receiver.

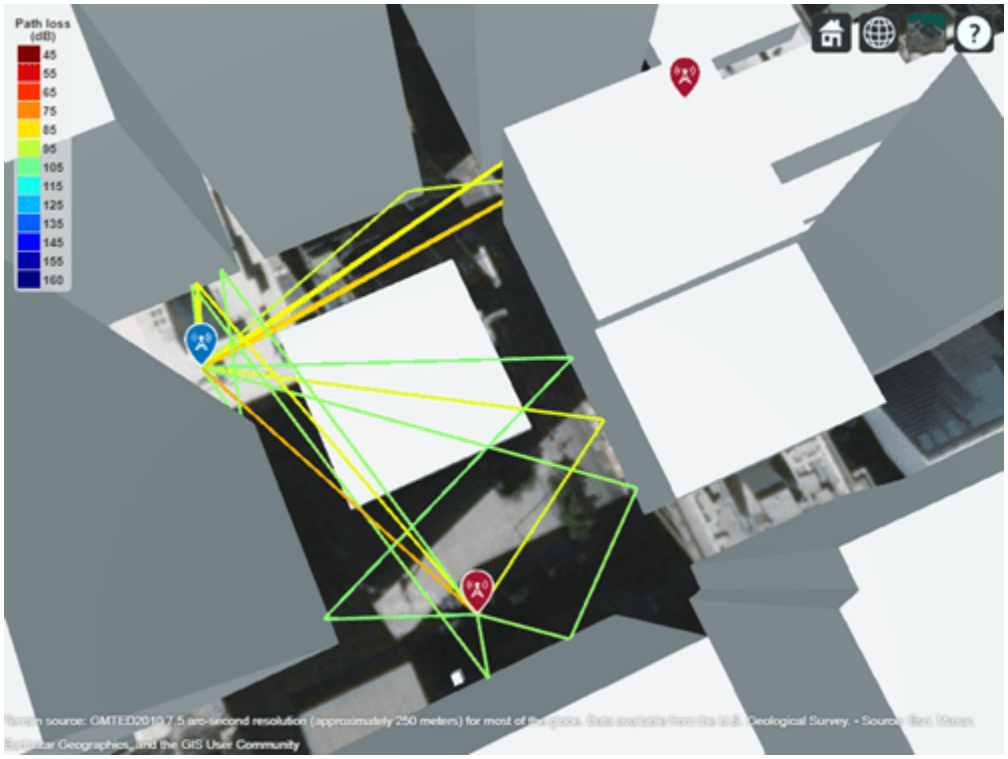
Perform Ray Tracing

Import buildings data for Chicago into `siteviewer` from an OpenStreetMap® (osm) file. For more information about the osm file, see [1] on page 3-208. Place two transmitter and one receiver sites in the city.

```
sv = siteviewer("buildings","Chicago.osm");
rx = rxsite("Name","Receiver", ...
    "Latitude",41.878543,"Longitude",-87.630599, ...
    "AntennaHeight",1.5);
show(rx);
tx1 = txsite("Name","Transmitter #1", ...
    "Latitude",41.878996,"Longitude",-87.629361);
show(tx1);
tx2 = txsite("Name","Transmitter #2", ...
    "Latitude",41.880142,"Longitude",-87.630850);
show(tx2);
```

Perform ray tracing from each transmitter site to the receiver site with up to second order reflection. Plot the computed rays.

```
rays  = raytrace([tx1, tx2],rx);
plot([rays{:}]);
```



Ray tracing finds several ray paths to the receiver from each transmitter. From the map we can visually see the first transmitter is closer to the receiver than the second transmitter. We can also see the first transmitter has more reflected paths to the receiver. Display the propagation delays associated with each transmitter.

```
pd1 = [rays{1}.PropagationDelay]
```

```
pd1 = 1×10
10^-6 ×

    0.3830    0.3839    0.5476    0.6482    0.5485    0.5486    0.6572    0.6945    0.7140    0.8
```

```
pd2 = [rays{2}.PropagationDelay]
```

```
pd2 = 1×5
10^-6 ×

    0.5967    0.5973    0.6059    0.6066    0.6255
```

Construct one channel filter for each transmitter site. Specify a sample rate of 30 MHz and use the minimum delay among the seven rays as the reference of time 0.

```
chanFilt1 = comm.ChannelFilter( ...
    "SampleRate",30e6, ...
    "PathDelays",pd1-min([pd1, pd2]))
```

```
chanFilt1 =
  comm.ChannelFilter with properties:

                SampleRate: 30000000
                PathDelays: [0 8.7598e-10 1.6459e-07 2.6516e-07 1.6553e-07 1.6565e-07 2.7417e-07
          FilterDelaySource: 'Auto'
    NormalizeChannelOutputs: true
```

```
chanFilt2 = comm.ChannelFilter( ...
    "SampleRate",30e6, ...
    "PathDelays",pd2-min([pd1, pd2]))
```

```
chanFilt2 =
  comm.ChannelFilter with properties:

                SampleRate: 30000000
                PathDelays: [2.1372e-07 2.1434e-07 2.2294e-07 2.2357e-07 2.4247e-07]
          FilterDelaySource: 'Auto'
    NormalizeChannelOutputs: true
```

The individual channel filters for the two transmitters yield different filter delay values. Use the `info` object function of `comm.ChannelFilter` to show the filter delay of the two channel filters.

```
fd1 = chanFilt1.info.ChannelFilterDelay
```

```
fd1 = 7
```

```
fd2 = chanFilt2.info.ChannelFilterDelay
```

```
fd2 = 1
```

The two channel filters must have the same filter delay to combine the channel outputs at the receiver site. Customize the filter delay for each channel filter to use the larger value of the individually computed delay values.

```
set(chanFilt1,"FilterDelaySource","Custom", ...
    "FilterDelay",max(fd1,fd2));
set(chanFilt2,"FilterDelaySource","Custom", ...
    "FilterDelay",max(fd1,fd2));
```

Apply Receive Signal Combining

Set up system parameters, assigning only one isotropic antenna at each site.

```
Nt = 1;    % Number of transmit elements
Ns = 1000; % Samples per frame
M  = 64;   % Modulation order
```

Retrieve path gains from the computed rays. Assume the sites are static and no Doppler shift is introduced.

```
pg1  = 10.^(-[rays{1}.PathLoss]/20) .* ...
    exp(1i*[rays{1}.PhaseShift]);
pg2  = 10.^(-[rays{2}.PathLoss]/20) .* ...
    exp(1i*[rays{2}.PhaseShift]);
```

Generate a frame of random 64-QAM signals. Perform channel filtering for each transmitter site and receive signal combining. The combined 2x1 distributed MIMO channel has a filter delay of max(`fd1`,`fd2`).

```
x  = qammod(randi([0, M-1],Ns,Nt),M);
y = chanFilt1(x,pg1) + chanFilt2(x,pg2);
```

Appendix

[1] The osm file is downloaded from https://www.openstreetmap.org, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), https://opendatacommons.org/licenses/odbl/.

Perform Channel Filtering for an LTE 2x2 EVA Profile

Construct a channel filter object with the LTE Extended Vehicular A model (EVA) delay profile.

```
chanFilt = comm.ChannelFilter( ...
    'SampleRate', 30.72e6, ...
    'PathDelays', [0 30 150 310 370 710 1090 1730 2510]*1e-9);
```

Set up system parameters. There are two transmit and receive antennas.

```
[Nt, Nr] = deal(2);
Ns = 30720;
Np = length(chanFilt.PathDelays);
M  = 256;
```

Generate random 256-QAM signal and complex path gains.

```
x = qammod(randi([0, M-1], Ns, Nt), M);
g = complex(rand(Ns, Np, Nt, Nr), rand(Ns, Np, Nt, Nr));
```

Filter the signal with path gains for the EVA delay profile.

```
y = chanFilt(x, g);
```

Reciprocal Downlink and Uplink Transmissions in MIMO Channel

Using one MIMO channel System object™ and two identically configured channel filter System objects, switch a link-level simulation between 3-by-2 downlink and reciprocal 2-by-3 uplink signal transmissions.

Define system parameters.

```
modOrder = 256;        % Modulation order
Nant1 = 3;             % Number of 'transmit' antennas
Nant2 = 2;             % Number of 'receive' antennas
Rs = 1e6;              % Sample rate
pd = [0 1.5 2.3]*1e-6; % Path delays
frmLen = 1e3;          % Frame length
```

Create a MIMO channel System object™, configuring it for path gain generation by disabling channel filtering.

```
chan = comm.MIMOChannel( ...
    'SampleRate',Rs, ...
    'PathDelays',pd, ...
    'AveragePathGains',[1.5 1.2 0.2], ...
    'MaximumDopplerShift',300, ...
    'SpatialCorrelationSpecification','none', ...
    'NumTransmitAntennas',Nant1, ...
    'NumReceiveAntennas',Nant2, ...
    'ChannelFiltering',false, ...
    'NumSamples',frmLen);
```

Create identical channel filter System objects for both transmission directions: one channel filter for the `Nant1`-by-`Nant2` downlink channel (3 transmit antennas to 2 receive antennas) and a reciprocal channel filter for the `Nant2`-by-`Nant1` uplink channel (2 transmit antennas to 3 receive antennas).

```
chanFiltDownlink = comm.ChannelFilter( ...
    'SampleRate',Rs, ...
    'PathDelays',pd);
chanFiltUplink = clone(chanFiltDownlink);
```

Downlink Transmission

Generate random path gains for one frame of the downlink 3-by-2 channel. Pass randomly generated 256-QAM signals through the 3-by-2 downlink channel.

```
pgDownlink = chan();
x = qammod(randi([0 modOrder-1],frmLen,Nant1),modOrder);
yDL = chanFiltDownlink(x,pgDownlink);
```

Uplink Transmission

Switch the link direction. Run the channel object to generate another frame of path gains, permuting its 3rd (Tx) and 4th (Rx) dimensions for the reciprocal uplink 2-by-3 channel. Pass randomly generated 256-QAM signals through the 2-by-3 reciprocal uplink channel.

```
pgUplink = permute(chan(),[1 2 4 3]);
x = qammod(randi([0 modOrder-1],frmLen,Nant2),modOrder);
yUL = chanFiltUplink(x,pgUplink);
```

Downlink and Uplink Array Dimensions

Show the sizes of the downlink and uplink path gain arrays returned by the MIMI channel object as an N_S-by-N_P-by-N_T-by-N_R array.

- N_S is the number of samples.
- N_P is the number of path delays.
- N_T is the number of transmit antennas. `Nant1` for downlink and `Nant2` for uplink.
- N_R is the number of receive antennas. `Nant2` for downlink and `Nant1` for uplink.

```
size(pgDownlink)
```

```
ans = 1×4

        1000           3           3           2
```

```
size(pgUplink)
```

```
ans = 1×4

        1000           3           2           3
```

Show the size of the channel output matrices returned by the MIMI channel object as an N_S-by-N_R matrix. N_S is the number of samples. N_R is the number of receive antennas.

```
size(yDL)
```

```
ans = 1×2

        1000           2
```

```
size(yUL)
```

```
ans = 1×2

        1000           3
```

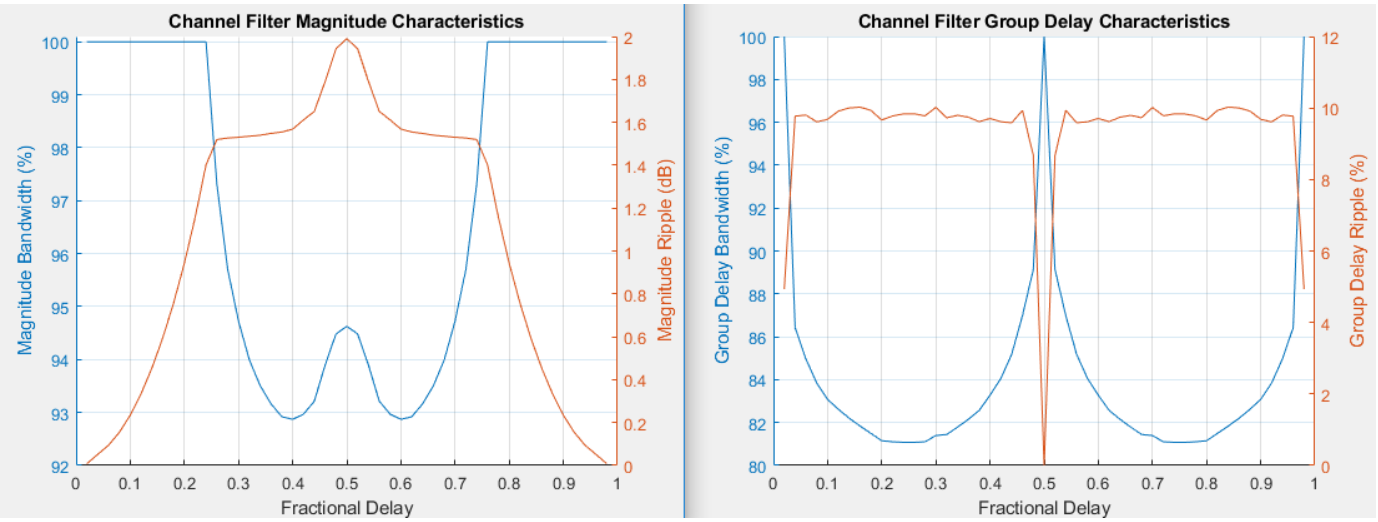
Algorithms

The channel filter implements a fractional delay (FD) finite impulse response (FIR) bandpass filter with a length of 16 coefficients for each candidate fractional delay at 0, 0.02, 0.04, ..., 0.98.

Each discrete path is rounded to its nearest candidate fractional delay, so the delay error limit is 1% of the sample time. To achieve a group delay bandwidth exceeding 80% and a magnitude bandwidth exceeding 90%, the algorithm selects the optimal FIR coefficient values for each fractional delay, while satisfying the following criteria:

- Group delay ripple ≤ 10%
- Magnitude ripple ≤ 2 dB
- Magnitude bandedge attenuation = 3 dB

The plots show bandwidths that satisfy the design criteria for group delay ripple, magnitude ripple, and magnitude bandedge attenuation.



For additional information, see the article *A Matlab-based Object-Oriented Approach to Multipath Fading Channel Simulation* at MATLAB Central.

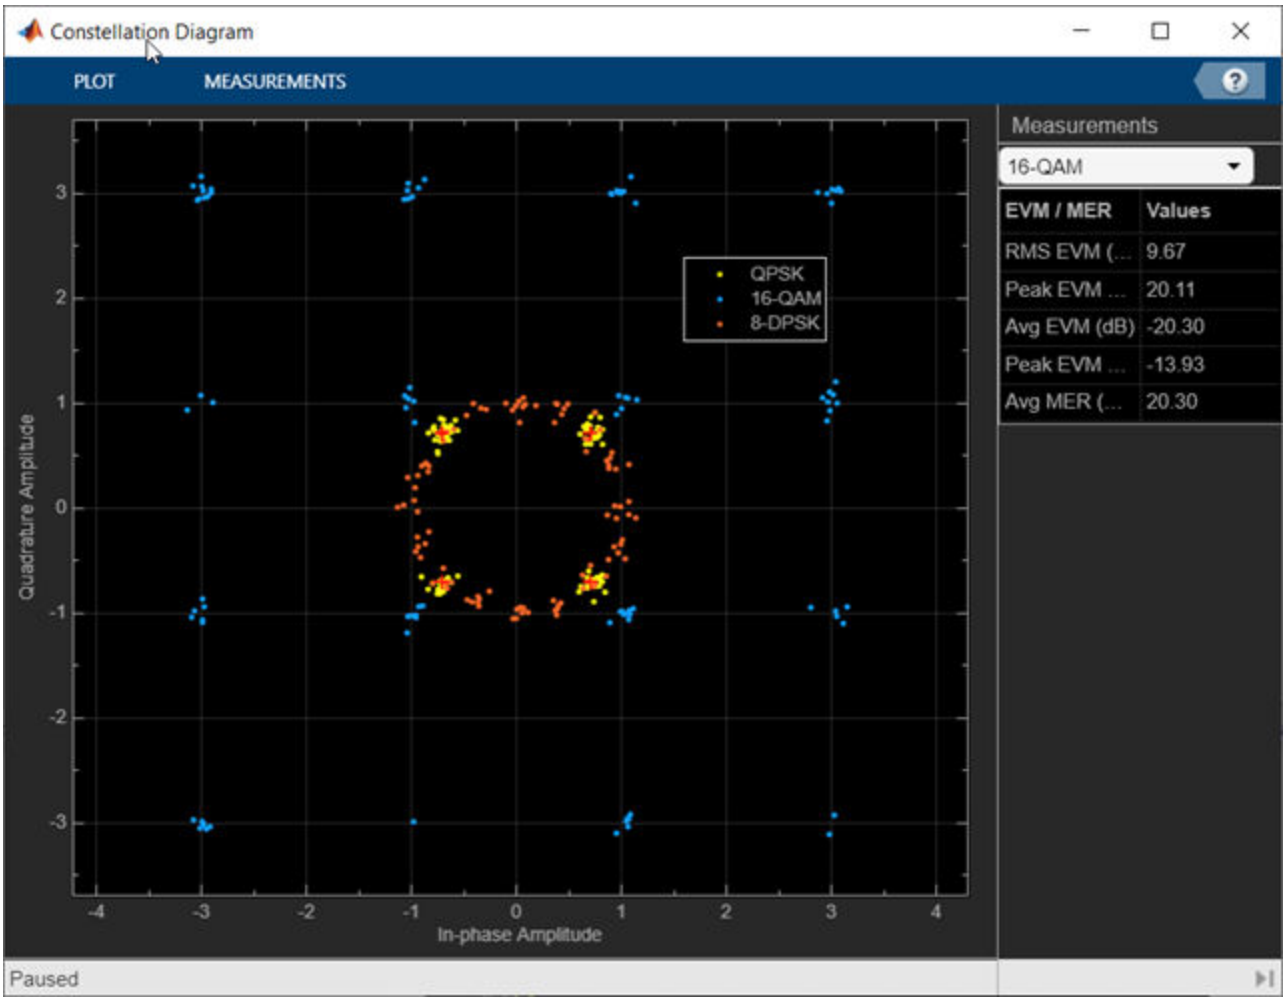
comm.ConstellationDiagram

Package: `comm`

Display and analyze input signals in IQ-plane

Description

The `comm.ConstellationDiagram` System object displays real- and complex-valued floating- and fixed-point signals in the IQ plane. Specifically, the IQ-plane displays the in-phase and quadrature components of modulated signals on the real and imaginary axis of an xy-plot. Use this System object to perform qualitative and quantitative analysis on modulated single-carrier signals.



In the Constellation Diagram window, you can:

- Input and plot multiple signals on a single constellation diagram. To define a reference constellation for each input signal, use the `ReferenceConstellation` property.

- Select signals in the legend to toggle visibility of individual channels. To display the legend, use the `ShowLegend` property. For a multichannel signal, specify the input as a matrix with individual signals defined in the columns of the matrix.
- Display calculated error vector magnitude (EVM) and modulation error ratio (MER) measurements for individual signals. To view and configure the measurements, select **EVM/MER** on the **Measurements** tab. When multiple signals are input, you can select which signal to use for measurements in the **Channel** section.

To display constellation diagrams for input signals:

1. Create the `comm.ConstellationDiagram` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
constdiag = comm.ConstellationDiagram
constdiag = comm.ConstellationDiagram(Name,Value)
```

Description

`constdiag = comm.ConstellationDiagram` returns a constellation diagram System object that displays real- and complex-valued floating- and fixed-point signals in the IQ plane.

`constdiag = comm.ConstellationDiagram(Name,Value)` sets properties using one or more name-value arguments. For example, `'SamplesPerSymbol',10` specifies 10 samples for each plotted symbol.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`Name` — Title of Constellation Diagram window

`'Constellation Diagram'` (default) | character vector | string scalar

Title of the Constellation Diagram window, specified as a character vector or string scalar.

Tunable: Yes

Data Types: `char` | `string`

`ShowTrajectory` — Option to plot signal trajectory
`false` or `0` (default) | `true` or `1`

Option to plot the signal trajectory, specified as a logical `0` (`false`) or `1` (`true`). Setting this property to `true` displays the trajectory between constellation points for the plotted signals. To view the signal trajectory, select **Trajectory** on the **Plot** tab.

Tunable: Yes

Data Types: `logical`

`ShowReferenceConstellation` — Option to display reference constellation
`true` or `1` (default) | `false` or `0`

Option to display the reference constellation, specified as a logical `1` (`true`) or `0` (`false`).

Tunable: Yes

Data Types: `logical`

`EnableMeasurements` — Option to calculate and display EVM and MER measurements
`false` or `0` (default) | `true` or `1`

Option to calculate and display the EVM and MER measurements, specified as a logical `0` (`false`) or `1` (`true`).

Tunable: Yes

Data Types: `logical`

`NumInputPorts` — Number of input signals
1 (default) | integer in the range [1, 20]

Number of input signals, specified as an integer in the range [1, 20]. Each input signal, whether it is a multichannel signal or a single channel signal, becomes a separate channel in the scope.

The total number of channels cannot exceed 20. When you specify multichannel input signals, the maximum number of input signals is limited by the total number of input channels that you define.

When you call the object, the number of inputs that you specify must equal the value of this property.

Tips

To define `ReferenceConstellation` values for multiple input signals, you must first set the `NumInputPorts` value.

Data Types: `double`

Symbol configuration

`SamplesPerSymbol` — Number of samples used to represent each symbol
1 (default) | positive integer

Number of samples used to represent each symbol, specified as a positive integer. The signal is downsampled by the value of this property before it is plotted.

Tunable: Yes

Data Types: `double`

`SampleOffset` — Number of samples to skip before plotting points

`0` (default) | nonnegative integer

Number of samples to skip before plotting points, specified as a nonnegative integer less than the `SamplesPerSymbol` property value. This value specifies the number of samples to skip when `SamplesPerSymbol` is greater than 1.

Tunable: Yes

Data Types: `double`

`SymbolsToDisplaySource` — Source of symbols to display

`'Input frame length'` (default) | `'Property'`

Source of symbols to display, specified as one of these values.

- `'Input frame length'` — The number of symbols to display is equal to the input frame length divided by the `SamplesPerSymbol` property value.
- `'Property'` — The `SymbolsToDisplay` property specifies the maximum number of symbols to display.

Tunable: Yes

Data Types: `char` | `string`

`SymbolsToDisplay` — Maximum number of symbols to display

`256` (default) | positive integer

Maximum number of symbols to display, specified as a positive integer. Use this property to limit the maximum number of symbols that the constellation diagram displays when you input long signals. The object plots the most recently received symbols.

Tunable: Yes

Dependencies

To enable this property, set `SymbolsToDisplaySource` to `'Property'`.

Data Types: `double`

Display configuration

`ColorFading` — Option to add color fading effect

`false` or `0` (default) | `true` or `1`

Option to add color fading effect, specified as a logical `0` (`false`) or `1` (`true`). When you set this property to `true`, the points in the display fade as the interval of time after they are first plotted increases. This animation resembles an oscilloscope display.

Tunable: Yes

Data Types: `logical`

`XLimits` — *x*-axis limits
`[-1.375 1.375]` (default) | two-element row vector

x-axis limits, specified as a two-element row vector of the form [*xmin xmax*]. The first element is the minimum x-axis value, and the second element is the maximum x-axis value.

Tunable: Yes

Data Types: `double`

`YLimits` — *y*-axis limits
`[-1.375 1.375]` (default) | two-element row vector

y-axis limits, specified as a two-element row vector of the form [*ymin ymax*]. The first element is the minimum y-axis value, and the second element is the maximum y-axis value.

Tunable: Yes

Data Types: `double`

`XLabel` — *x*-axis label
`'In-phase Amplitude'` (default) | character vector | string scalar

x-axis label, specified as a character vector or string scalar.

Tunable: Yes

Data Types: `char` | `string`

`YLabel` — *y*-axis label
`'Quadrature Amplitude'` (default) | character vector | string scalar

y-axis label, specified as a character vector or string scalar.

Tunable: Yes

Data Types: `char` | `string`

`Title` — Plot title
`''` (default) | character vector | string scalar

Plot title, specified as a character vector or string scalar.

Tunable: Yes

Data Types: `char` | `string`

`ShowLegend` — Option to display legend
`false` or `0` (default) | `true` or `1`

Option to display the legend, specified as a logical `0` (`false`) or `1` (`true`). The names listed in the legend are the signal names specified by the `ChannelNames` property. The legend does not display until you call the object with an input signal.

In the scope legend, click a signal name to toggle the signal visibility in the scope.

Tunable: Yes

Data Types: `logical`

`ChannelNames` — Names for input channels
`{''}` (default) | cell array of strings or character vectors

Names for the input channels, specified as a cell array of strings or character vectors. If you do not specify names, the object labels the channels as `Channel 1`, `Channel 2`, etc.

These names appear in the legend, the **Measurements** tab, and the **Measurements Setting** pane.

Example: `{'8-QAM','8-PSK'}` specifies the names for two input channels to `8-QAM` and `8-PSK`.

Tunable: Yes

Data Types: `cell`

`ShowGrid` — Option to show grid
`true` or `1` (default) | `false` or `0`

Option to show grid on the constellation diagram, specified as a logical `1` (`true`) or `0` (`false`).

Tunable: Yes

Data Types: `logical`

`ShowTicks` — Option to show tick labels
`false` or `0` (default) | `true` or `1`

Option to show tick labels on the constellation diagram axes, specified as a logical `0` (`false`) or `1` (`true`).

Tunable: Yes

Data Types: `logical`

`Position` — Scope window position and size
600-by-600 pixel window at center of screen (default) | four-element row vector

Scope window position and size in pixels, specified as a four-element row vector of the form [*left bottom width height*]. The first two elements in the vector indicate the location of the lower-left

corner, and the second elements two specify the size of the window. The default value for the location depends on the screen resolution.

Tunable: Yes

Data Types: `double`

Reference constellation

`ReferenceConstellation` — Reference constellations

`[0.7071+0.7071i -0.7071+0.7071i -0.7071-0.7071i 0.7070-0.7071i]` (default) | row vector | cell array

Reference constellations for the input signals, specified as a row vector or cell array of vectors defining the ideal constellation points for each input signal. Input signals can be single channel or multichannel. You can define one reference constellation for each input signal.

- When you specify a row vector, the values apply for all input signals.
- When you specify a cell array, you can specify individual reference constellations for each input signal.

The EVM and MER measurements use the specified reference constellation to calculate the signal quality of the modulated input signal. For more information about the signal quality measurements, see “EVM and MER Measurements” on page 3-226.

Tunable: Yes

Dependencies

To define `ReferenceConstellation` values for multiple input signals, you must first set the `NumInputPorts` value.

Data Types: `double`
Complex Number Support: Yes

`ReferenceColor` — Color for reference display constellation

`[1 0 0]` (red) (default) | three-element row vector | cell array

Color for reference display constellation, specified as a three-element row vector indicating RGB component colors or as a cell array containing RGB component colors for each input signal.

Tunable: Yes

Data Types: `double`

`ReferenceMarker` — Marker for reference constellation display

`'+'` (default) | `'o'` | `'*'` | `'.'` | `'x'` | ...

Marker for the reference constellation display, specified as one of the values listed in this table.

Marker	Description	Resulting Marker
`"o"`	Circle	○

Marker	Description	Resulting Marker
`"+"`	Plus sign	
`"*"`	Asterisk	
`"."`	Point	
`"x"`	Cross	
`"_"`	Horizontal line	
`"|"`	Vertical line	
`"square"`	Square	
`"diamond"`	Diamond	
`"^"`	Upward-pointing triangle	
`"v"`	Downward-pointing triangle	
`">"`	Right-pointing triangle	
`"<"`	Left-pointing triangle	
`"pentagram"`	Pentagram	
`"hexagram"`	Hexagram	
`"none"`	No markers	Not applicable

Tunable: Yes

Measurement settings

`MeasurementInterval` — Window length for EVM and MER measurements
`'Current display'` (default) | `'All displays'` | ...

Window length for the EVM and MER measurements, specified as `'Current display'`, `'All displays'`, or an integer in the range [2, `SymbolsToDisplay`].

For more information, see “EVM and MER Measurements” on page 3-226.

Tunable: Yes

Data Types: `char` | `string` | `double`

`EVMNormalization` — EVM normalization method
`'Average constellation power'` (default) | `'Peak constellation power'`

EVM normalization method, specified as `'Average constellation power'` or `'Peak constellation power'`. For more information, see “EVM and MER Measurements” on page 3-226.

Tunable: Yes

Usage

Syntax

```
constdiag(signal1, ..., signalN)
```

Description

`constdiag(signal1, ..., signalN)` displays up to *N* signals in one constellation diagram, where *N* is the `NumInputPorts` property value.

Input Arguments

`signal1, ..., signalN` — Signals (as separate arguments)
column vectors | matrices

Signals, specified as separate arguments of N_{sym}-by-1 column vectors or N_{sym}-by-$N_{channel}$ matrices. N_{sym} is the number of symbols, and $N_{channel}$ is the number of input signal channels. Signals can have different data types and dimensions.

You must specify *N* input arguments, where *N* is the `NumInputPorts` property value. You can visualize up to 20 individual or collective signal channels in the constellation diagram. For example, if you create a two-channel signal for every input, then you can define up to 10 input arguments.

Example: `[sig1_1,sig1_2],sig2` specifies two signals, provided that `sig1_1`, `sig1_2`, and `sig2` are single channel column vector signals. the first, `[sig1_1,sig1_2]`, specifies a two-channel signal (constructed by concatenating two column vectors into a matrix). The second signal, `sig2`, specifies a single channel.

Data Types: `double`
Complex Number Support: Yes

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to Scopes

show	Show scope window
hide	Hide scope window
isVisible	Determine visibility of scope window

Common to All System Objects

step	Run System object algorithm

release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Display Amplitude-Imbalanced QPSK Constellation

QPSK-modulate random data symbols and apply an amplitude imbalance to the signal. Pass the signal through a noisy channel. Display the resultant constellation.

Create a constellation diagram System object. Because the default reference constellation for the object is QPSK, setting additional properties is not necessary.

```
constDiagram = comm.ConstellationDiagram;
```

Generate random data symbols, and then apply QPSK modulation.

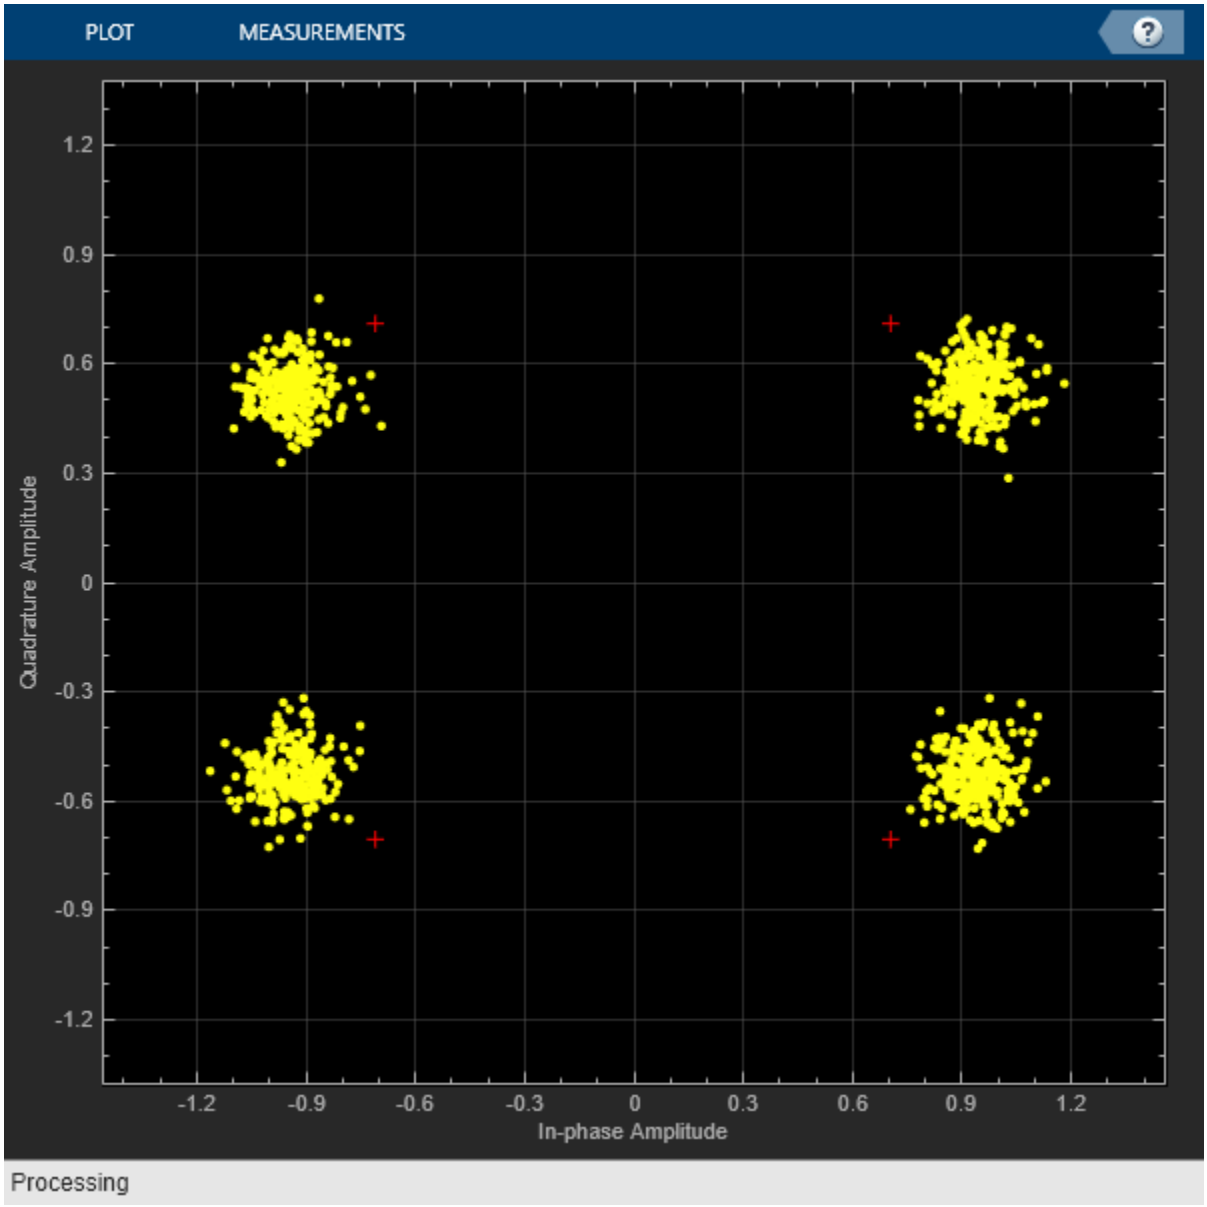
```
data = randi([0 3],1000,1);
modData = pskmod(data,4,pi/4);
```

Apply an amplitude imbalance to the modulated signal.

```
txSig = iqimbal(modData,5);
```

Pass the transmitted signal through an AWGN channel, and then display the constellation diagram. The data points shift from their ideal locations.

```
rxSig = awgn(txSig,20);
constDiagram(rxSig)
```



Display 16-QAM Constellation

Apply 16-QAM modulation, transmit data using an AWGN channel, and display the signal constellation.

Create a 16-QAM reference constellation.

```
M = 16;
refC = qammod(0:M-1,M);
```

Create a constellation diagram System object, specifying the constellation reference points and axes limits.

```
constDiagram = comm.ConstellationDiagram('ReferenceConstellation',refC, ...
    'XLimits',[-4 4],'YLimits',[-4 4]);
```

Generate random 16-ary data symbols.

```
data = randi([0 M-1],1000,1);
```

Apply 16-QAM modulation.

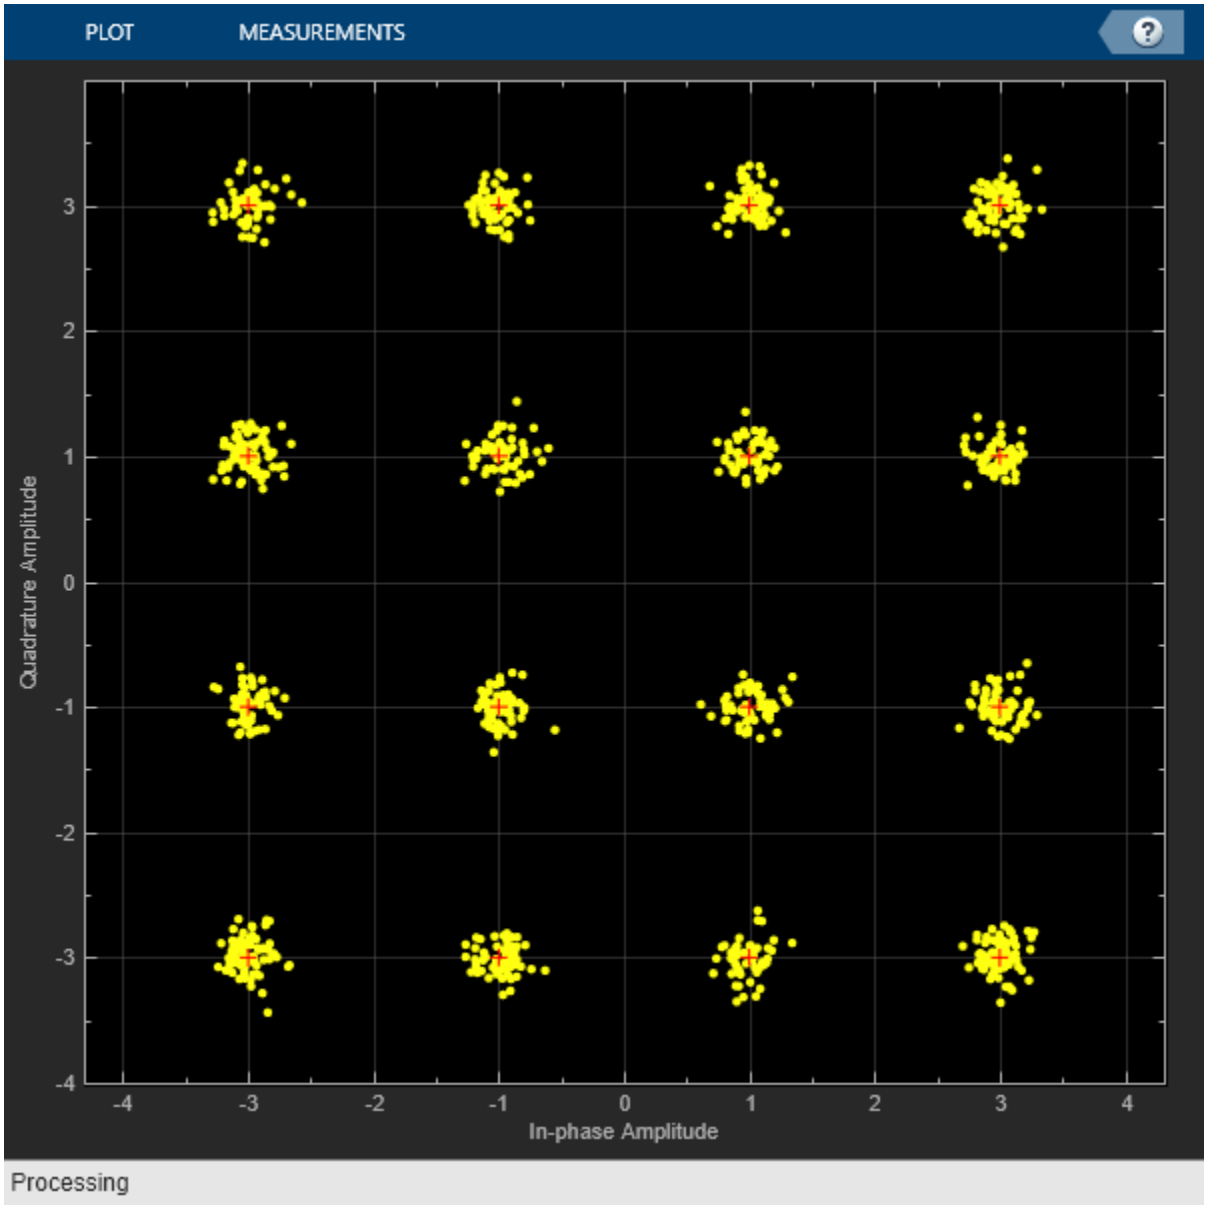
```
sym = qammod(data,M);
```

Pass the modulated signal through an AWGN channel.

```
rcv = awgn(sym,15);
```

Display the constellation diagram.

```
constDiagram(rcv)
```



Display Constellation of Multi-Input Signals

Display the constellation of multi-input and multichannel modulated signals. Plot a multichannel signal with two 16-QAM signals for the first input and one 8-PSK signal for the second input.

Create a 16-QAM and an 8-PSK reference constellation.

```
M = 16;
refQAM = qammod(0:M-1,M);
S = 8;
refPSK = pskmod(0:S-1,S,pi/8);
```

Create a constellation diagram System object, specifying reference constellations for the two input signals. The object applies a single reference constellation for all the channels of an individual multichannel signal input, but separate input signals can specify separate reference constellations.

```
constDiag = comm.ConstellationDiagram(2, ...
    'ReferenceConstellation',{refQAM,refPSK}, ...
    'ShowLegend',true, ...
    'XLimits',[-6 6],'YLimits',[-6 6], ...
    'ChannelNames', ...
    {'16-QAM, SNR 10 dB','16-QAM, SNR 20 dB','8-PSK'});
```

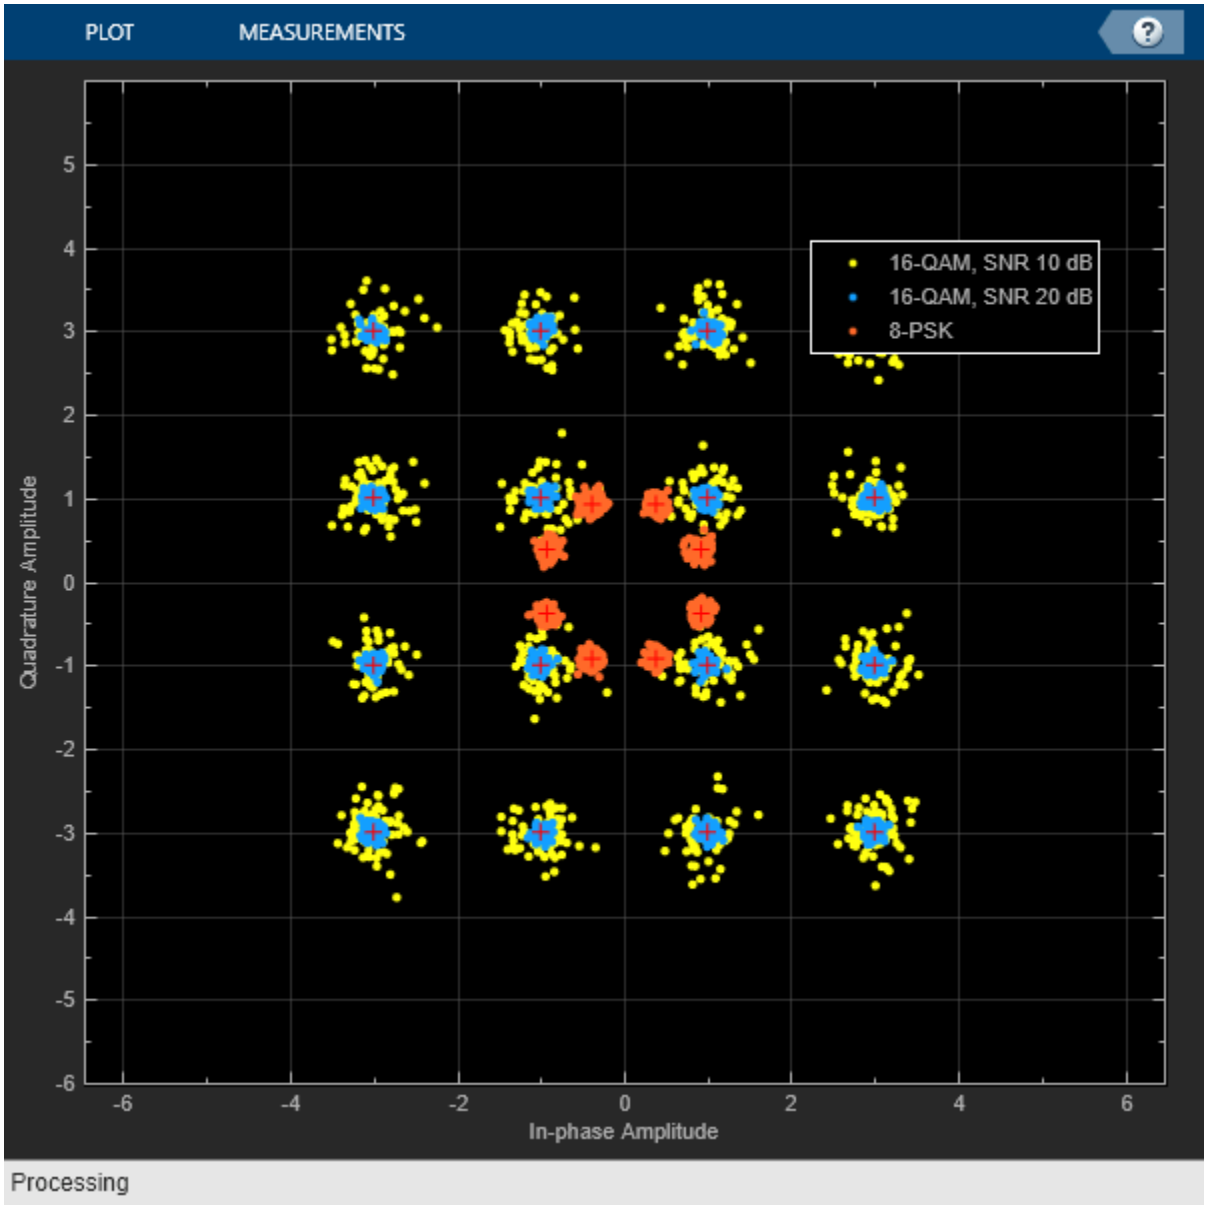
Generate random data symbols, modulate the symbols, and add AWGN with two different SNRs to yield two received signals. Use SNR values of 10 and 20 dB.

```
d = randi([0 M-1],1000,1);
dQAM = qammod(d,M);
rcv1_1 = awgn(dQAM,10);
rcv1_2 = awgn(dQAM,20);
d = randi([0 S-1],1000,1);
dPSK = pskmod(d,S,pi/8);
rcv2 = awgn(dPSK,20);
```

For the first input, create a multichannel signal by concatenating the two received 16-QAM signals. For the second input uses a single channel 8-PSK signal.

Display the constellation diagram of the multi-input and multichannel signals.

```
constDiag([rcv1_1,rcv1_2],rcv2);
```



More About

EVM and MER Measurements

The **Measurements** pane displays the EVM and MER signal quality measurement settings and the calculation results for the specified signal channel.

- EVM — An error vector is a vector in the IQ plane from the ideal constellation point to the actual point at the receiver. The EVM calculations include root mean square (RMS), peak, and average values.

You can normalize the EVM_{RMS} and EVM_{Average} calculations by the average or peak constellation power method as computed using these algorithms.

EVM Normalization Method	Algorithm
Average constellation power	$EVM_k = 100\sqrt{\frac{e_k}{P_{\text{avg}}}}$ EVM_{RMS}, in percent, for average constellation power normalization: $EVM_{\text{RMS}}(\%) = 100\sqrt{\frac{\frac{1}{N}\sum_{k=1}^{N}(e_k)}{P_{\text{avg}}}}$
Peak constellation power	$EVM_k = 100\sqrt{\frac{e_k}{P_{\text{max}}}}$ EVM_{RMS}, in percent, for peak constellation power normalization: $EVM_{\text{RMS}}(\%) = 100\sqrt{\frac{\frac{1}{N}\sum_{k=1}^{N}(e_k)}{P_{\text{max}}}}$

The **Measurements** pane shows the RMS and peak *EVM* in percent and the average and peak *EVM* decibels for the selected input channel. The *EVM* in decibels is computed as *EVM* (dB) = 10 - log10(EVM_{MS}) = 20 - log10(EVM_{RMS}), where:

- $e_k = (I_k - \tilde{I}_k)^2 + (Q_k - \tilde{Q}_k)^2$
- I_k is the in-phase value of the kth symbol in the input vector.
- Q_k is the quadrature phase value of the kth symbol in the input vector.
- I_k and Q_k represent ideal (reference) symbol values. $\tilde{I}_k$ and $\tilde{Q}_k$ represent measured (received) symbol values.
- N is the input vector length.
- P_{avg} is the value for average constellation power.
- P_{max} is the value for peak constellation power.
- $EVM_{\text{RMS}} = \sqrt{EVM_{\text{MS}}}$

The maximum *EVM* value in a vector is $EVM_{\text{max}} = \max_{k \in [1, \ldots, N]}\{EVM_k\}$, where k is the kth symbol in a vector of length N.

- *MER* — *MER* is the ratio of the average power of the transmitted signal to the average power of the error vector. The **Measurements** pane indicates average *MER* measurement result in decibels for the selected signal channel.

  MER is a measure of the SNR in a modulated signal, calculated in dB. The *MER* over N symbols is

$$MER = 10 \times \log_{10}\left(\frac{\sum_{k=1}^{N}\left(I_k^2 + Q_k^2\right)}{\sum_{k=1}^{N}(e_k)}\right) \text{dB},$$

where:

- $e_k = (I_k - \tilde{I}_k)^2 + (Q_k - \tilde{Q}_k)^2$
- I_k is the in-phase value of the kth symbol in the input vector.
- Q_k is the quadrature phase value of the kth symbol in the input vector.
- I_k and Q_k represent ideal (reference) values. $\tilde{I}_k$ and $\tilde{Q}_k$ represent measured (received) symbols.

Tips

- To capture a simple signal constellation snapshot, use the `scatterplot` function.
- To calculate signal quality, show signal trajectory, capture constellations for multiple signals, or maintain state between calls, use a `comm.ConstellationDiagram` System object.

Version History

Introduced in R2013a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Supports MEX code generation by treating the calls to the object as extrinsic. Does not support code generation for standalone applications.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

comm.ConvolutionalDeinterleaver

Package: `comm`

Deinterleave symbols using set of shift registers with specified delays

Description

The `comm.ConvolutionalDeinterleaver` System object deinterleaves the symbols in the input sequence by using a set of shift registers, each with its own specified delay. The `comm.ConvolutionalDeinterleaver` object must have the same number of registers as the associated interleaver. For information about delays, see “Delays of Convolutional Interleaving and Deinterleaving” on page 3-232.

To deinterleave symbols using a set of shift registers with specified delays:

1. Create the `comm.ConvolutionalDeinterleaver` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
deintrlvr = comm.ConvolutionalDeinterleaver
deintrlvr = comm.ConvolutionalDeinterleaver(Name=Value)
```

Description

`deintrlvr = comm.ConvolutionalDeinterleaver` creates a default convolutional deinterleaver System object.

`deintrlvr = comm.ConvolutionalDeinterleaver(Name=Value)` sets “Properties” on page 3-229 using one or more name-value arguments. For example, `NumRegisters=10` specifies 10 internal shift registers.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`NumRegisters` — Number of internal shift registers
6 (default) | positive integer

Number of internal shift registers, specified as a positive integer.

Data Types: `double`

`RegisterLengthStep` — Symbol capacity difference of each successive shift register
`2` (default) | positive integer

Symbol capacity difference of each successive shift register, specified as a positive integer. The last register holds zero symbols.

Data Types: `double`

`InitialConditions` — Initial conditions of shift registers
`0` (default) | scalar | column vector

Initial conditions of the shift registers, specified as one of these options.

- Scalar — All shift registers, except the last one, store the same specified value.
- Column vector — If the length of the column vector equals the value of the `NumRegisters` property, then the *k*th shift register stores the *(N–k+1)*th element of the specified vector. *N* is the total number of shift registers (`NumRegisters`).

Because the first shift register has zero delay, the object ignores the first element of this property.

Data Types: `double`

Usage

Syntax

```
deintrlvseq = deintrlvr(intrlvseq)
```

Description

`deintrlvseq = deintrlvr(intrlvseq)` deinterleaves the input sequence of symbols, by using a set of shift registers. The object outputs the deinterleaved sequence of symbols. For information about delays, see “Delays of Convolutional Interleaving and Deinterleaving” on page 3-232.

Input Arguments

`intrlvseq` — Interleaved sequence of symbols
column vector

Interleaved sequence of symbols, specified as a column vector. This sequence must be one that was interleaved using the `comm.ConvolutionalInterleaver` System object.

Data Types: `numeric` | `logical` | `fi`

Output Arguments

`deintrlvseq` — Deinterleaved sequence of symbols
column vector

Deinterleaved sequence of symbols, returned as a column vector of the same data type and size as the `intrlvseq` argument.

Data Types: `numeric` | `logical` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Convolutionally Interleave and Deinterleave Sequence

Create a convolutional interleaver System object, specifying the number of shift registers and register length step.

```
intrlvr = comm.ConvolutionalInterleaver(NumRegisters=2, ...
                                        RegisterLengthStep=3);
```

Create a convolutional deinterleaver System object, specifying the number of shift registers and register length step.

```
deintrlvr = comm.ConvolutionalDeinterleaver(NumRegisters=2, ...
                                            RegisterLengthStep=3);
```

Generate a random data sequence. Pass the data sequence through the interleaver and then the deinterleaver.

```
data = (0:20)';
intrlvData = intrlvr(data);
deintrlvData = deintrlvr(intrlvData);
```

Display the original sequence, interleaved sequence, and restored sequence.

```
[data,intrlvData,deintrlvData]
```

```
ans = 21×3

     0     0     0
     1     0     0
     2     2     0
     3     0     0
     4     4     0
     5     0     0
     6     6     0
```

```
     7     1     1
     8     8     2
     9     3     3
     ⋮
```

The delay through the interleaver and deinterleaver pair is equal to the product of the `NumRegisters` and `RegisterLengthStep` properties.

```
intrlvDelay = intrlvr.NumRegisters*intrlvr.RegisterLengthStep
```

```
intrlvDelay = 6
```

After accounting for this delay, verify that the original and deinterleaved data are identical.

```
numSymErrors = symerr(data(1:end-intrlvDelay), ...
                      deintrlvData(1+intrlvDelay:end))
```

```
numSymErrors = 0
```

More About

Delays of Convolutional Interleaving and Deinterleaving

The total delay due to a convolutional interleaver and deinterleaver pair is $N \times slope \times (N - 1)$.

- N is the number of registers and equals the value of the `NumRegisters` property
- *slope* is the register length step and equals the value of the `RegisterLengthStep` property

This diagram shows the structure of a general convolutional interleaver comprised of a set of shift registers, each having a specified delay shown as D(1), D(2),..., D(N), and a commutator to switch input and output symbols through registers. The kth shift register holds D(k) symbols, where k = 1, 2, 3, ... N. The kth shift register has a delay value of ((k–1) × *slope*). With each new input symbol, the commutator switches to a new register and shifts in the new symbol while shifting out the oldest symbol in that register. When the commutator reaches the Nth register, upon the next new input, the commutator returns to the first register.

comm.ConvolutionalEncoder

Package: `comm`

Convolutionally encode binary data

Description

The `comm.ConvolutionalEncoder` System object encodes a sequence of binary input vectors to produce a sequence of binary output vectors.

To convolutionally encode binary data:

1. Create the `comm.ConvolutionalEncoder` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
convencoder = comm.ConvolutionalEncoder
convencoder = comm.ConvolutionalEncoder(trellis)
convencoder = comm.ConvolutionalEncoder( ___ ,Name,Value)
```

Description

`convencoder = comm.ConvolutionalEncoder` creates a convolutional encoder System object.

`convencoder = comm.ConvolutionalEncoder(trellis)` sets the `TrellisStructure` property to `trellis`.

`convencoder = comm.ConvolutionalEncoder( ___ ,Name,Value)` sets “Properties” on page 3-234 using one or more name-value arguments in addition to any argument combinations in previous syntaxes. For example, `'TerminationMethod','Continuous'` specifies the termination method as continuous to retain the encoder states at the end of each input vector for use with the next input vector.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`TrellisStructure` — Trellis description of convolutional code

`poly2trellis(7, [171 133])` (default) | structure

Trellis description of the convolutional code, specified as a structure that contains the trellis description for a rate K / N code. K is the number of input bit streams, and N is the number of output bit streams.

You can either use the `poly2trellis` function to create the trellis structure or create it manually. For more about this structure, see "Trellis Description of a Convolutional Code" and the `istrellis` function.

The trellis structure contains these fields.

`numInputSymbols` — Number of symbols input to encoder

2^K

Number of symbols input to the encoder, specified as an integer equal to 2^K, where K is the number of input bit streams.

Data Types: `double`

`numOutputSymbols` — Number of symbols output from encoder

2^N

Number of symbols output from the encoder, specified as an integer equal to 2^N, where N is the number of output bit streams.

Data Types: `double`

`numStates` — Number of states in encoder

power of 2

Number of states in the encoder, specified as a power of 2.

Data Types: `double`

`nextStates` — Next states

matrix of integers

Next states for all combinations of current states and current inputs, specified as a matrix of integers. The matrix size must be `numStates` by 2^K.

Data Types: `double`

`outputs` — Outputs

matrix of octal numbers

Outputs for all combinations of current states and current inputs, specified as a matrix of octal numbers. The matrix size must be `numStates` by 2^K.

Data Types: `double`

Data Types: `struct`

`TerminationMethod` — Termination method of encoded frame

`'Continuous'` (default) | `'Truncated'` | `'Terminated'`

Termination method of the encoded frame, specified as one of these values.

- `'Continuous'` — The System object retains the encoder states at the end of each input vector for use with the next input vector.
- `'Truncated'` — The System object treats each input vector independently. The encoder states are reset at the start of each input vector. If you set the `InitialStateInputPort` property to `0` (`false`), the object resets its states to the all-zeros state. If you set the `InitialStateInputPort` property to `1`(`true`), the object resets its states to the values you specify in the `InitialStateInputPort` input.
- `'Terminated'` — The System object treats each input vector independently. For each input vector, the object uses extra bits to set the encoder states to all-zeros states at the end of the vector. For a rate *K*/*N* code, the object outputs a vector of length $N \times {}^{(L+S)}/_{K}$, where S = *constraintLength* – 1 (or, in the case of multiple constraint lengths, S = **sum**(*constraintLength*(*i*)–1)). L is the length of the input. *constraintLength* – 1 is defined as log2(NumStates).

Data Types: `char` | `string`

`ResetInputPort` — Option to enable encoder reset input
`false` or `0` (default) | `true` or `1`

Option to enable the encoder reset input, specified as a logical `1`(`true`) or `0` (`false`). Set this property to `1` (`true`) to enable the additional input to the object. When this additional reset input is a nonzero value, the internal states of the encoder reset to their initial conditions.

Dependencies

To enable this property, set the `TerminationMethod` property to `'Continuous'`.

Data Types: `logical`

`DelayedResetAction` — Option to delay output reset
`false` or `0` (default) | `true` or `1`

Option to delay the output reset, specified as one of these logical values.

- `1` (`true`) — The reset of the internal states of the encoder occurs after the object computes the encoded data.
- `0` (`false`) — The reset of the internal states of the encoder occurs before the object computes the encoded data.

Dependencies

To enable this property, set the `ResetInputPort` property to `1` (`true`).

Data Types: `logical`

`InitialStateInputPort` — Option to enable initial state input
`false` or `0` (default) | `true` or `1`

Option to enable the initial state input, specified as a logical `1` (`true`) or `0` (`false`). When you set this property to `1` (`true`), the object enables you to specify the initial state of the encoder for each input vector.

Dependencies

To enable this property, set the `TerminationMethod` property to `'Truncated'`.

Data Types: `logical`

`FinalStateOutputPort` — Option to enable final state output

`false` or `0` (default) | `true` or `1`

Option to enable the final state output, specified as a logical `1` (`true`) or `0` (`false`). Set this property to `1` (`true`) to obtain the final state of the encoder as an output.

Dependencies

To enable this property, set the `TerminationMethod` property to `'Continuous'` or `'Truncated'`.

Data Types: `logical`

`PuncturePatternSource` — Source of puncture pattern

`'None'` (default) | `'Property'`

Source of the puncture pattern, specified as one of these values.

- `'None'` — The object does not apply puncturing.
- `'Property'` — The object punctures the code. This puncturing is based on the puncture pattern vector that you specify for the `PuncturePattern` property.

Dependencies

To enable this property, set the `TerminationMethod` property to `'Continuous'` or `'Truncated'`.

Data Types: `char` | `string`

`PuncturePattern` — Puncture pattern vector

`[1;1;0;1;0;1]` (default) | column vector

Puncture pattern vector to puncture the encoded data, specified as a column vector. The vector must contain `1`s and `0`s, where `0` indicates the position of punctured bits or excluded bits.

Dependencies

To enable this property, set the `TerminationMethod` property to `'Continuous'` or `'Truncated'` and the `PuncturePatternSource` property to `'Property'`.

Data Types: `double`

Usage

Syntax

```
codeword = convencoder(message)
codeword = convencoder(message,initstate)
codeword = convencoder(message,resetstate)
[codeword,finalstate] = convencoder(message)
```

Description

`codeword = convencoder(message)` encodes the input message using the convolutional encoding scheme specified by the trellis structure. `codeword` is the encoded codeword. `message` and `codeword` are column vectors of numeric, logical, or unsigned fixed-point values with word length 1 (fi (Fixed-Point Designer) object).

`codeword = convencoder(message,initstate)` specifies the initial state of the encoder for each input vector. To enable this syntax, set the `TerminationMethod` property to `'Truncated'` and the `InitialStateInputPort` property to `1` (`true`).

`codeword = convencoder(message,resetstate)` specifies the input to reset the internal states of the encoder. To enable this syntax, set the `TerminationMethod` property to `'Continuous'` and the `ResetInputPort` property to `1` (`true`).

`[codeword,finalstate] = convencoder(message)` also returns the final state of the encoder. To enable this syntax, set the `FinalStateOutputPort` property to `1` (`true`) and the `TerminationMethod` property to `'Continuous'` or `'Truncated'`.

Input Arguments

`message` — Input message

binary-valued column vector

Input message, specified as a binary-valued column vector.

Data Types: `double` | `int8` | `fi(data,0,1)`

`initstate` — Initial state of encoder

integer

Initial state of the encoder, specified as an integer.

Dependencies

To enable this argument, set the `TerminationMethod` property to `'Truncated'` and the `InitialStateInputPort` property to `1` (`true`).

Data Types: `double`

`resetstate` — Reset for internal states of encoder

`false` or `0` (default) | `true` or `1`

Reset for internal states of the encoder, specified as a numeric or logical `1` (`true`) or `0` (`false`).

Dependencies

To enable this argument, set the `TerminationMethod` property to `'Continuous'` and the `ResetInputPort` property to `1` (`true`).

Data Types: `double` | `logical`

Output Arguments

`codeword` — Convolutionally encoded message
binary-valued column vector

Convolutionally encoded message, returned as a binary-valued column vector. This output vector has the same data type and orientation as input `message`.

When the convolutional encoder represents a rate K/N code, the length of the input vector equals $K \times L$ for some positive integer L. The object sets the length of this output vector, to $L \times N$.

Data Types: `double` | `int8` | `fi(data,0,1)`

`finalstate` — Final state of encoder
integer

Final state of the encoder, returned as an integer.

Dependencies

To enable this argument, set the `TerminationMethod` property to `'Continuous'` or `'Truncated'`.

Data Types: `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Encode and Decode 8-DPSK Modulated Data

Transmit a convolutionally encoded 8 differential phase shift keying (DPSK) modulated bit stream through an additive white Gaussian noise (AWGN) channel. Then, demodulate and decode the modulated bit stream using a Viterbi decoder.

Create the necessary System objects.

```
conEnc = comm.ConvolutionalEncoder;
modDPSK = comm.DPSKModulator('BitInput',true);
chan = comm.AWGNChannel('NoiseMethod','Signal to noise ratio (SNR)','SNR',10);
demodDPSK = comm.DPSKDemodulator('BitOutput',true);
vDec = comm.ViterbiDecoder('InputFormat','Hard');
error = comm.ErrorRate('ComputationDelay',3,'ReceiveDelay',34);
```

Process the data by following these steps.

1. Generate random bits.
2. Convolutionally encode the data.
3. Apply DPSK modulation.
4. Pass the modulated signal through an AWGN channel.
5. Demodulate the noisy signal.
6. Decode the data using a Viterbi algorithm.
7. Collect error statistics.

```
for counter = 1:20
    data = randi([0 1],30,1);
    encodedData = conEnc(data);
    modSignal = modDPSK(encodedData);
    receivedSignal = chan(modSignal);
    demodSignal = demodDPSK(receivedSignal);
    receivedBits = vDec(demodSignal);
    errors = error(data,receivedBits);
end
```

Display the number of errors.

```
errors(2)
```

```
ans = 3
```

Convolutionally Encode and Viterbi Decode with Puncture Pattern Matrix

Encode and decode a sequence of bits using a convolutional encoder and a Viterbi decoder with a defined puncture pattern. Verify that the input and output bits are identical.

Define a puncture pattern matrix, and then reshape it into vector form for use with the encoder and decoder System objects.

```
pPatternMat = [1 0 1;1 1 0];
pPatternVec = reshape(pPatternMat,6,1);
```

Create a convolutional encoder and a Viterbi decoder in which the puncture pattern is defined by `pPatternVec`.

```
conEnc = comm.ConvolutionalEncoder('PuncturePatternSource','Property','PuncturePattern',pPatternV
viDec = comm.ViterbiDecoder('InputFormat','Hard','PuncturePatternSource','Property', ...
        'PuncturePattern',pPatternVec);
```

Create an error rate counter with the appropriate receive delay.

```
error = comm.ErrorRate('ReceiveDelay',viDec.TracebackDepth);
```

Encode a sequence of random bits, and then decode the encoded message.

```
dataIn = randi([0 1],600,1);
dataEncoded = conEnc(dataIn);
dataOut = viDec(dataEncoded);
```

Verify that no errors exist in the output data.

```
errStats = error(dataIn,dataOut);
errStats(2)
```

```
ans = 0
```

High Rate Convolutional Codes for Turbo Coding

Concatenated convolutional codes offer high reliability and have gained in prominence and usage as turbo codes. The `comm.TurboEncoder` and `comm.TurboDecoder` System objects support rate 1/n convolutional codes only. This example shows the parallel concatenation of two rate 2/3 convolutional codes to achieve an effective rate 1/3 turbo code by using `comm.ConvolutionalEncoder` and `comm.APPDecoder` System objects.

System Parameters

```
blkLength = 1024;   % Block length
EbNo = 0:5;         % Eb/No values to loop over
numIter = 3;        % Number of decoding iterations
maxNumBlks = 1e2;   % Maximum number of blocks per Eb/No value
```

Convolutional Encoder/Decoder Parameters

```
trellis = poly2trellis([5 4],[23 35 0; 0 5 13]);
k = log2(trellis.numInputSymbols);      % number of input bits
n = log2(trellis.numOutputSymbols);     % number of output bits
intrIndices = randperm(blkLength/k)';   % Random interleaving
decAlg = 'True App';                    % Decoding algorithm
modOrder = 2;                           % PSK-modulation order
```

Initialize System Objects

Initialize Systems object™ for convolutional encoding, APP Decoding, BPSK modulation and demodulation, AGWN channel, and error rate computation. The demodulation output soft bits using a log-likelihood ratio method.

```
cEnc1 = comm.ConvolutionalEncoder( ...
    'TrellisStructure',trellis, ...
    'TerminationMethod','Truncated');
cEnc2 = comm.ConvolutionalEncoder( ...
    'TrellisStructure',trellis, ...
    'TerminationMethod','Truncated');
cAPPDec1 = comm.APPDecoder( ...
    'TrellisStructure',trellis, ...
    'TerminationMethod','Truncated', ...
    'Algorithm',decAlg);
cAPPDec2 = comm.APPDecoder( ...
```

```
    'TrellisStructure',trellis, ...
    'TerminationMethod','Truncated', ...
    'Algorithm',decAlg);

bpskMod = comm.BPSKModulator;
bpskDemod = comm.BPSKDemodulator( ...
    'DecisionMethod','Log-likelihood ratio', ...
    'VarianceSource','Input port');

awgnChan = comm.AWGNChannel( ...
    'NoiseMethod','Variance', ...
    'VarianceSource','Input port');

bitError = comm.ErrorRate; % BER measurement
```

Frame Processing Loop

Loop through a range of E_b/N_0 values to generate results for BER performance. The `helperTurboEnc` and `helperTurboDec` helper functions on page 3-243 perform the turbo encoding and decoding.

```
ber = zeros(length(EbNo),1);
bitsPerSymbol = log2(modOrder);
turboEncRate = k/(2*n);

for ebNoIdx = 1:length(EbNo)
    % Calculate the noise variance from EbNo
    EsNo = EbNo(ebNoIdx) + 10*log10(bitsPerSymbol);
    SNRdB = EsNo + 10*log10(turboEncRate); % Account for code rate
    noiseVar = 10^(-SNRdB/10);

    for  numBlks = 1:maxNumBlks
        % Generate binary data
        data = randi([0 1],blkLength,1);

        % Turbo encode the data
        [encodedData,outIndices] = helperTurboEnc( ...
            data,cEnc1,cEnc2, ...
            trellis,blkLength,intrIndices);

        % Modulate the encoded data
        modSignal = bpskMod(encodedData);

        % Pass the modulated signal through an AWGN channel
        receivedSignal = awgnChan(modSignal,noiseVar);

        % Demodulate the noisy signal using LLR to output soft bits
        demodSignal = bpskDemod(receivedSignal,noiseVar);

        % Turbo decode the demodulated data
        receivedBits = helperTurboDec( ...
            -demodSignal,cAPPDec1,cAPPDec2, ...
            trellis,blkLength,intrIndices,outIndices,numIter);

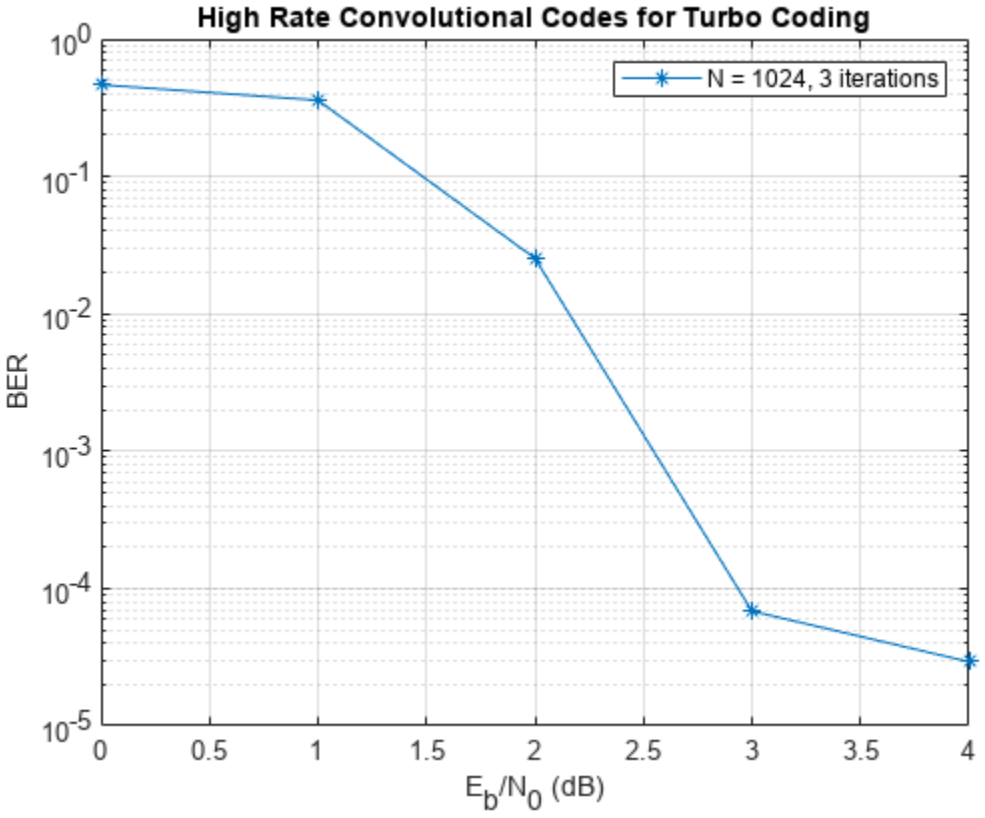
        % Calculate the error statistics
        errorStats = bitError(data,receivedBits);
    end
```

```
    ber(ebNoIdx) = errorStats(1);
    reset(bitError);
end
```

Display Results

While the practical wireless systems, such as LTE and CCSDS, specify base rate-1/n convolutional codes for turbo codes, the results show use of higher rate convolutional codes as turbo codes is viable.

```
figure;
semilogy(EbNo, ber, '*-');
grid on;
xlabel('E_b/N_0 (dB)');
ylabel('BER');
title('High Rate Convolutional Codes for Turbo Coding');
legend(['N = ' num2str(blkLength) ', ' num2str(numIter) ' iterations']);
```



Helper Functions

```
function [yEnc,outIndices] = helperTurboEnc( ...
    data,hCEnc1,hCEnc2,trellis,blkLength,intrIndices)
% Turbo encoding using two parallel convolutional encoders.
% No tail bits handling and assumes no output stream puncturing.

    % Trellis parameters
    k = log2(trellis.numInputSymbols);
    n = log2(trellis.numOutputSymbols);
```

```
    cLen = blkLength*n/k;

    punctrVec = [0;0;0;0;0;0];      % assumes all streams are output
    N = length(find(punctrVec==0));

    % Encode random data bits
    y1 = hCEnc1(data);
    y2 = hCEnc2( ...
        reshape(intrlv(reshape(data,k,[])',intrIndices)',[],1));
    y1D = reshape(y1(1:cLen),n,[]);
    y2D = reshape(y2(1:cLen),n,[]);
    yDTemp = [y1D; y2D];
    y = yDTemp(:);

    % Generate output indices vector using puncturing vector
    idx = 0 : 2*n : (blkLength - 1)*2*(n/k);
    punctrVecIdx = find(punctrVec==0);

    x = zeros(rCodLen,1);
    x(inIndices) = yEnc;

    % Generate output of first encoder
    yD = reshape(x(1:rCodLen),2*n,[]);
    lc1D = yD(1:n, :);
    Lc1_in = lc1D(:);

    % Generate output of second encoder
    lc2D   = yD(n+1:2*n, :);
    Lc2_in = lc2D(:);

    % Initialize unencoded data input
    Lu1_in = zeros(blkLength,1,typeyEnc);

    % Turbo Decode
    out1 = zeros(blkLength/k,k,typeyEnc);
    for iterIdx = 1 : numIter
        [Lu1_out, ~] = cAPPDec1(Lu1_in,Lc1_in);
        tmp = Lu1_out(1:blkLength);
        Lu2_in = reshape(tmp,k,[])';
        [Lu2_out, ~] = cAPPDec2( ...
            reshape(Lu2_in(intrIndices, :)',[],1),Lc2_in);
        out1(intrIndices, :) = reshape(Lu2_out(1:blkLength),k,[])';
```

```
        Lu1_in = reshape(out1',[],1);
    end
    % Calculate llr and decoded bits for the final iteration
    llr = reshape(out1', [], 1) + Lu1_out(1:blkLength);
    yDec = cast((llr>=0), typeyEnc);
end
```

More About

Convolutional Coding

Convolutional coding is an error-control coding that has memory. Specifically, the computations and coded output depend on the current set of input symbols and on a number of previous input symbols that varies depending on the trellis configuration. A convolutional encoder outputs *N* bits for every *K* input bits. The input can have varying multiples of *K* bits over a simulation.

Using a MATLAB trellis structure that defines a set of generator polynomials, you can model nonsystematic, systematic feedforward, or systematic feedback convolutional codes. For more information and examples that demonstrate various convolutional code architectures, see the "Convolutional Codes" topic.

To decode the convolutionally coded output, you can use:

- The `vitdec` function or `comm.ViterbiDecoder` System object — Uses the Viterbi algorithm with hard-decision and soft-decision decoding
- The `comm.APPDecoder` System object — Uses an *a posteriori* probability decoder for the soft output decoding of convolutional codes

comm.ConvolutionalInterleaver

Package: comm

Permute symbols using set of shift registers with specified delays

Description

The comm.ConvolutionalInterleaver System object permutes the symbols in the input sequence by using a set of shift registers, each with its own delay value. For information about delays, see “Delays of Convolutional Interleaving and Deinterleaving” on page 3-250.

To permute symbols using a set of shift registers with specified delays:

1. Create the comm.ConvolutionalInterleaver object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
intrlvr = comm.ConvolutionalInterleaver
intrlvr = comm.ConvolutionalInterleaver(Name=Value)
```

Description

intrlvr = comm.ConvolutionalInterleaver creates a default convolutional interleaver System object.

intrlvr = comm.ConvolutionalInterleaver(Name=Value) sets “Properties” on page 3-247 using one or more name-value arguments. For example, NumRegisters=10 specifies 10 internal shift registers.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

NumRegisters — Number of internal shift registers
6 (default) | positive integer

Number of internal shift registers, specified as a positive integer.

Data Types: `double`

`RegisterLengthStep` — Number of additional symbols that fit in each successive shift register
2 (default) | positive integer

Number of additional symbols that fit in each successive shift register, specified as a positive integer. The first register holds zero symbols.

Data Types: `double`

`InitialConditions` — Initial conditions of shift registers
`0` (default) | scalar | column vector

Initial conditions of the shift registers, specified as one of these options.

- Scalar — All shift registers, except the first one, store the same specified value.
- Column vector — If the length of the column vector equals the value of the `NumRegisters` property, then the *k*th shift register stores the *k*th element of the specified vector.

You do not need to specify a value for the first shift register, which has zero delay. Because the first shift register has zero delay, the object ignores the first element of this property.

Data Types: `double`

Usage

Syntax

```
intrlvseq = intrlvr(inputseq)
```

Description

`intrlvseq = intrlvr(inputseq)` permutes the input sequence of symbols by using a set of shift registers. The object outputs the interleaved sequence of symbols.

For information about delays, see “Delays of Convolutional Interleaving and Deinterleaving” on page 3-250.

Input Arguments

`inputseq` — Sequence of symbols
column vector

Sequence of symbols, specified as a column vector.

Data Types: `numeric` | `logical` | `fi`

Output Arguments

`intrlvseq` — Interleaved sequence of symbols
column vector

Interleaved sequence of symbols, returned as a column vector of the same data type and size as the `inputseq` input.

Data Types: `numeric` | `logical` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Convolutionally Interleave and Deinterleave Sequence

Create a convolutional interleaver System object, specifying the number of shift registers and register length step.

```
intrlvr = comm.ConvolutionalInterleaver(NumRegisters=2, ...
                                        RegisterLengthStep=3);
```

Create a convolutional deinterleaver System object, specifying the number of shift registers and register length step.

```
deintrlvr = comm.ConvolutionalDeinterleaver(NumRegisters=2, ...
                                            RegisterLengthStep=3);
```

Generate a random data sequence. Pass the data sequence through the interleaver and then the deinterleaver.

```
data = (0:20)';
intrlvData = intrlvr(data);
deintrlvData = deintrlvr(intrlvData);
```

Display the original sequence, interleaved sequence, and restored sequence.

```
[data,intrlvData,deintrlvData]
```

```
ans = 21×3

     0     0     0
     1     0     0
     2     2     0
     3     0     0
     4     4     0
     5     0     0
     6     6     0
```

```
     7     1     1
     8     8     2
     9     3     3
     ⋮
```

The delay through the interleaver and deinterleaver pair is equal to the product of the `NumRegisters` and `RegisterLengthStep` properties.

```
intrlvDelay = intrlvr.NumRegisters*intrlvr.RegisterLengthStep
```

```
intrlvDelay = 6
```

After accounting for this delay, verify that the original and deinterleaved data are identical.

```
numSymErrors = symerr(data(1:end-intrlvDelay), ...
                      deintrlvData(1+intrlvDelay:end))
```

```
numSymErrors = 0
```

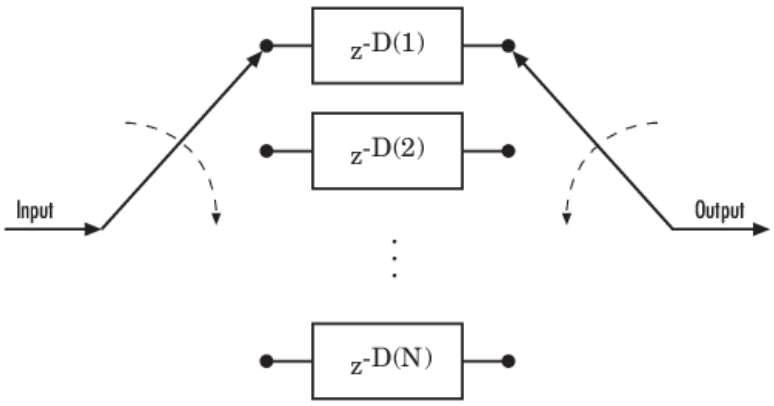
More About

Delays of Convolutional Interleaving and Deinterleaving

The total delay due to a convolutional interleaver and deinterleaver pair is $N \times slope \times (N - 1)$.

- N is the number of registers and equals the value of the `NumRegisters` property
- *slope* is the register length step and equals the value of the `RegisterLengthStep` property

This diagram shows the structure of a general convolutional interleaver comprised of a set of shift registers, each having a specified delay shown as D(1), D(2),..., D(N), and a commutator to switch input and output symbols through registers. The kth shift register holds D(k) symbols, where k = 1, 2, 3, ... N. The kth shift register has a delay value of ((k–1) × *slope*). With each new input symbol, the commutator switches to a new register and shifts in the new symbol while shifting out the oldest symbol in that register. When the commutator reaches the Nth register, upon the next new input, the commutator returns to the first register.



For more information, see “Interleaving”.

comm.CPFSKDemodulator

Package: comm

Demodulate using CPFSK method and Viterbi algorithm

Description

The CPFSKDemodulator object demodulates a signal that was modulated using the continuous phase frequency shift keying method. The input is a baseband representation of the modulated signal.

To demodulate a signal that was modulated using the continuous phase frequency shift keying method:

1. Define and set up your CPFSK demodulator object. See “Construction” on page 3-252 .
2. Call step to demodulate the signal according to the properties of comm.CPFSKDemodulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

H = comm.CPFSKDemodulator creates a demodulator System object, H. This object demodulates the input continuous phase frequency shift keying (CPFSK) modulated data using the Viterbi algorithm.

H = comm.CPFSKDemodulator(Name,Value) creates a CPFSK demodulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.CPFSKDemodulator(M,Name,Value) creates a CPFSK demodulator object, H. This object has the ModulationOrder property set to M, and the other specified properties set to the specified values.

Properties

ModulationOrder

Size of symbol alphabet

Specify the size of the symbol alphabet. The value of this property requires a power of two, real, integer scalar. The default is 4.

BitOutput

Output data as bits

Specify whether the output consists of groups of bits or integer values. The default is `false`.

When you set this property to `false`, the `step` method outputs a column vector of length equal to *N*/`SamplesPerSymbol` on page 3-0 and with elements that are integers between –(`ModulationOrder` on page 3-0 –1) and `ModulationOrder`–1. In this case, *N*, is the length of the input signal, which indicates the number of input baseband modulated symbols.

When you set this property to `true`, the `step` method outputs a binary column vector of length equal to *P*×(*N*/`SamplesPerSymbol`), where *P* = **log2**(`ModulationOrder`). The output contains length-*P* bit words. In this scenario, the object first maps each demodulated symbol to an odd integer value, *K*, between –(`ModulationOrder`-1) and `ModulationOrder`–1. The object then maps *K* to the nonnegative integer (*K*+`ModulationOrder`–1)/2. Finally, the object maps each nonnegative integer to a length-*P* binary word, using the mapping specified in the `SymbolMapping` on page 3-0 property.

`SymbolMapping`

Symbol encoding

Specify the mapping of the modulated symbols as one of `Binary` | `Gray`. The default is `Binary`. This property determines how the object maps each demodulated integer symbol value (in the range 0 and `ModulationOrder` on page 3-0 –1) to a *P*-length bit word, where *P* = `ModulationOrder` on page 3-0 (`ModulationOrder`).

When you set this property to `Binary`, the object uses a natural binary-coded ordering.

When you set this property to `Gray`, the object uses a Gray-coded ordering.

This property applies when you set the `BitOutput` on page 3-0 property to `true`.

`ModulationIndex`

Modulation index

Specify the modulation index. The default is `0.5`. The value of this property can be a scalar, *h*, or a column vector, [h_0, h_1, …. h_{H-1}]

where H-1 represents the length of the column vector.

When h_i varies from interval to interval, the object operates in multi-h. When the object operates in multi-h, h_i must be a rational number.

`InitialPhaseOffset`

Initial phase offset

Specify the initial phase offset of the input modulated waveform in radians as a real, numeric scalar. The default is `0`.

`SamplesPerSymbol`

Number of samples per input symbol

Specify the expected number of samples per input symbol as a positive, integer scalar. The default is 8.

`TracebackDepth`

Traceback depth for Viterbi algorithm

Specify the number of trellis branches that the Viterbi algorithm uses to construct each traceback path as a positive, integer scalar. The default is 16. The value of this property is also the value of the output delay. That value is the number of zero symbols that precede the first meaningful demodulated symbol in the output.

`OutputDataType`

Data type of output

Specify the output data type as one of `int8` | `int16` | `int32` | `double`, when you set the `BitOutput` on page 3-0 property to false. The default is `double`.

When you set the `BitOutput` property to `true`, specify the output data type as one of `logical` | `double`.

Methods

step Demodulate using CPFSK method and Viterbi algorithm

Common to All System Objects	
`release`	Allow System object property value changes
`reset`	Reset internal states of System object

Examples

Demodulate CPFSK Modulated Signal Encoded with Gray Symbol Mapping

Create a CPFSK modulator, an AWGN channel, and a CPFSK demodulator. Configure the modulator and demodulator with modulation order set to 8, bit input, and Gray-encoded symbol mapping.

```
M = 8;
cpfskMod = comm.CPFSKModulator(M,'BitInput',true, ...
    'SymbolMapping','Gray');
awgnChan = comm.AWGNChannel('NoiseMethod', ...
    'Signal to noise ratio (SNR)', ...
    'SNR',0);
cpfskDemod = comm.CPFSKDemodulator(M,'BitOutput',true, ...
    'SymbolMapping','Gray');
```

Define simulation parameters. Create an error rate calculator, accounting for the delay caused by the Viterbi algorithm used by the CPFSK demodulator.

```
numFrames = 1000; % Number of frames transmitted
k = log2(M);      % Bits per symbol
```

```
spf = 100;        % Symobls per frame

delay = log2(M)*cpfskDemod.TracebackDepth;
errorRate = comm.ErrorRate( ...
    'ReceiveDelay',delay);
for counter = 1:numFrames
    data = randi([0 1],k*spf,1);
    modSignal = cpfskMod(data);
    noisySignal = awgnChan(modSignal);
    receivedData = cpfskDemod(noisySignal);
    errorStats = errorRate(data,receivedData);
end

fprintf('Error rate = %f\nNumber of errors = %d\n', ...
    errorStats(1),errorStats(2))
```

```
Error rate = 0.004247
Number of errors = 1274
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the CPFSK Demodulator Baseband block reference page. The object properties correspond to the block parameters. For CPFSK the phase shift per symbol is $\pi \times h$, where h is the modulation index.

`comm.CPFSKModulator` | `comm.CPMModulator` | `comm.CPMDemodulator`

step

System object: `comm.CPFSKDemodulator`
Package: `comm`

Demodulate using CPFSK method and Viterbi algorithm

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` demodulates input data, `X`, with the CPFSK demodulator System object, `H`, and returns `Y`. Input `X` must be a double or single precision, column vector with a length equal to an integer multiple of the number of samples per symbol specified in the `SamplesPerSymbol` property. Depending on the `BitOutput` property value, output `Y` can be integer or bit valued.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.CPFSKModulator

Package: comm

Modulate using CPFSK method

Description

The CPFSKModulator object modulates using the continuous phase frequency shift keying method. The output is a baseband representation of the modulated signal.

To modulate a signal using the continuous phase frequency shift keying method:

1. Define and set up your CPFSK modulator object. See “Construction” on page 3-257.
2. Call step to modulate the signal according to the properties of comm.CPFSKModulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

H = comm.CPFSKModulator creates a modulator System object, H. This object modulates the input signal using the continuous phase frequency shift keying (CPFSK) modulation method.

H = comm.CPFSKModulator(Name,Value) creates a CPFSK modulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.CPFSKModulator(M,Name,Value) creates a CPFSK modulator object, H. This object has the ModulationOrder property set to M, and the other specified properties set to the specified values.

Properties

ModulationOrder

Size of symbol alphabet

Specify the size of the symbol alphabet. The value of this property requires a power of two, real, integer scalar. The default is 4.

BitInput

Assume bit inputs

Specify whether the input is bits or integers. The default is false. When you set this property to false, the step method input must be a double-precision or signed integer data type column vector.

This vector comprises odd integer values between –(`ModulationOrder` on page 3-0 –1) and `ModulationOrder`–1.

When you set this property to `true`, the `step` method input must be a column vector of *P*-length bit words, where *P* = **log2**(`ModulationOrder`). The input data must be double precision or logical data type. The object maps each bit word to an integer `K` between `0` and `ModulationOrder`–1, using the mapping specified in the `SymbolMapping` on page 3-0 property. The object then maps the integer *K* to the intermediate value 2*K*–(`ModulationOrder`–1) and proceeds as in the case when you set the `BitInput` on page 3-0 property to `false`.

`SymbolMapping`

Symbol encoding

Specify the mapping of bit inputs as one of `Binary` | `Gray`. The default is `Binary`. This property determines how the object maps each input *P*-length bit word, where *P* = **log2**(`ModulationOrder` on page 3-0), to an integer between `0` and `ModulationOrder`–1.

When you set this property to `Binary`, the object uses a natural binary-coded ordering.

When you set this property to `Gray`, the object uses a Gray-coded ordering.

This property applies when you set the `BitInput` on page 3-0 property to true.

`ModulationIndex`

Modulation index

Specify the modulation index. The default is `0.5`. The value of this property can be a scalar, h, or a column vector, $[h_0, h_1, \ldots. h_{\text{H-1}}]$

where H-1 represents the length of the column vector. The phase shift over a symbol is $\pi \times h$.

When h_i varies from interval to interval, the object operates in multi-h. When the object operates in multi-h, h_i must be a rational number.

`InitialPhaseOffset`

Initial phase offset

Specify the initial phase of the modulated waveform in radians as a real, numeric scalar. The default is `0`.

`SamplesPerSymbol`

Number of samples per output symbol

Specify the upsampling factor at the output as a real, positive, integer scalar. The default is `8`. The upsampling factor is the number of output samples that the step method produces for each input sample.

`OutputDataType`

Data type of output

Specify output data type as one of `double` | `single`. The default is `double`.

Methods

step	Modulate using CPFSK method

Common to All System Objects	
`release`	Allow System object property value changes
`reset`	Reset internal states of System object

Examples

Demodulate CPFSK Modulated Signal Encoded with Gray Symbol Mapping

Create a CPFSK modulator, an AWGN channel, and a CPFSK demodulator. Configure the modulator and demodulator with modulation order set to 8, bit input, and Gray-encoded symbol mapping.

```
M = 8;
cpfskMod = comm.CPFSKModulator(M,'BitInput',true, ...
    'SymbolMapping','Gray');
awgnChan = comm.AWGNChannel('NoiseMethod', ...
    'Signal to noise ratio (SNR)', ...
    'SNR',0);
cpfskDemod = comm.CPFSKDemodulator(M,'BitOutput',true, ...
    'SymbolMapping','Gray');
```

Define simulation parameters. Create an error rate calculator, accounting for the delay caused by the Viterbi algorithm used by the CPFSK demodulator.

```
numFrames = 1000; % Number of frames transmitted
k = log2(M);      % Bits per symbol
spf = 100;        % Symobls per frame

delay = log2(M)*cpfskDemod.TracebackDepth;
errorRate = comm.ErrorRate( ...
    'ReceiveDelay',delay);
for counter = 1:numFrames
    data = randi([0 1],k*spf,1);
    modSignal = cpfskMod(data);
    noisySignal = awgnChan(modSignal);
    receivedData = cpfskDemod(noisySignal);
    errorStats = errorRate(data,receivedData);
end

fprintf('Error rate = %f\nNumber of errors = %d\n', ...
    errorStats(1),errorStats(2))
```

```
Error rate = 0.004247
Number of errors = 1274
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the CPFSK Modulator Baseband block reference page. The object properties correspond to the block parameters. For CPFSK the phase shift per symbol is $\pi \times h$, where h is the modulation index.

Version History

Introduced in R2012a

`comm.CPFSKDemodulator` | `comm.CPMModulator` | `comm.CPMDemodulator`

step

System object: `comm.CPFSKModulator`
Package: `comm`

Modulate using CPFSK method

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` modulates input data, `X`, with the CPFSK modulator System object, `H`. It returns the baseband modulated output, `Y`. Depending on the value of the `BitInput` property, input `X` can be an integer or bit valued column vector with data types double, signed integer, or logical. The length of output vector, `Y`, is equal to the number of input samples times the number of samples per symbol specified in the `SamplesPerSymbol` property.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.CPMDemodulator

Package: comm

Demodulate signal using CPM method and Viterbi algorithm

Description

The comm.CPMDemodulator System object demodulates an input signal that was modulated using the continuous phase modulation (CPM) method. The input is a baseband representation of the modulated signal. For more information about the demodulation and filtering applied, see "CPM Demodulation Method" on page 3-268 and "Pulse Shape Filtering" on page 3-269.

To demodulate a signal that was modulated using the CPM method:

1. Create the comm.CPMDemodulator object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
cpmdemod = comm.CPMDemodulator
cpmdemod = comm.CPMDemodulator(Name,Value)
cpmdemod = comm.CPMDemodulator(M,Name,Value)
```

Description

cpmdemod = comm.CPMDemodulator creates a demodulator System object to demodulate input CPM signals using the Viterbi algorithm.

cpmdemod = comm.CPMDemodulator(Name,Value) sets properties using one or more name-value arguments. For example, 'SymbolMapping','Gray' specifies gray-ordered symbol mapping for the modulated symbols.

cpmdemod = comm.CPMDemodulator(M,Name,Value) sets the ModulationOrder property to M and optional name-value arguments.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`ModulationOrder` — Modulation order

4 (default) | power of two scalar

Modulation order, specified as a power-of-two scalar. The modulation order, $M = 2^k$ specifies the number of points in the signal constellation, where k is a positive integer indicating the number of bits per symbol.

Data Types: `double`

`BitOutput` — Option to output data as bits

`0` or `false` (default) | `1` or `true`

Option to output data as bits, specified as a logical `0` (`false`) or `1` (`true`).

- Set this property to `false` to output data as integers.
- Set this property to `true` to output data as bits.

For more information, see “Integer-Valued and Binary-Valued Output Signals” on page 3-270.

Data Types: `logical`

`SymbolMapping` — Symbol encoding

`'Binary'` (default) | `'Gray'`

Symbol encoding mapping of constellation bits, specified as `'Binary'` or `'Gray'`.

- Set this property to `'Binary'` to map symbols using natural binary-coded ordering.
- Set this property to `'Gray'` to map symbols using Gray-coded ordering.

For more information, see “Integer-Valued and Binary-Valued Output Signals” on page 3-270.

Dependencies

To enable this property, set the `BitOutput` property to `true`.

`ModulationIndex` — Modulation index

`0.5` (default) | nonnegative scalar | column vector

Modulation index, specified as a nonnegative scalar or column vector. For more information, see “CPM Demodulation Method” on page 3-268.

Data Types: `double`

`FrequencyPulse` — Type of frequency pulse shaping

`'Rectangular'` (default) | `'Raised Cosine'` | `'Spectral Raised Cosine'` | `'Gaussian'` | `'Tamed FM'`

Type of frequency pulse shaping used by the modulator to smooth the phase transitions of the modulated signal, specified as `'Rectangular'`, `'Raised Cosine'`, `'Spectral Raised Cosine'`, `'Gaussian'`, or `'Tamed FM'`. For more information, see “Pulse Shape Filtering” on page 3-269.

`MainLobeDuration` — Main lobe duration

`1` (default) | positive integer

Main lobe duration of the largest lobe in the spectral raised cosine pulse, specified as a positive integer representing the number of symbol intervals used by the demodulator to pulse-shape the modulated signal.

Dependencies

To enable this property, set the `FrequencyPulse` property to `'Spectral Raised Cosine'`.

Data Types: `double`

`RolloffFactor` — Roll-off factor

`0.2` (default) | scalar in the range [0, 1]

Roll-off factor of the spectral raised cosine pulse, specified as a scalar in the range [0, 1].

Dependencies

To enable this property, set the `FrequencyPulse` property to `'Spectral Raised Cosine'`.

Data Types: `double`

`BandwidthTimeProduct` — Product of bandwidth and symbol time of Gaussian pulse shape

`0.3` (default) | positive scalar

Product of the bandwidth and symbol time of the Gaussian pulse shape, specified as a positive scalar. Use `BandwidthTimeProduct` to reduce the bandwidth, at the expense of increased intersymbol interference.

Dependencies

To enable this property, set the `FrequencyPulse` property to `'Gaussian'`.

Data Types: `double`

`PulseLength` — Length of frequency pulse shape

`1` (default) | positive integer

Length of the frequency pulse shape in symbol intervals, specified as a positive integer. For more information on the frequency pulse length, refer to *LT* in “Pulse Shape Filtering” on page 3-269.

Data Types: `double`

`SymbolPrehistory` — Symbol prehistory

`1` (default) | scalar | vector

Symbol prehistory, specified as scalar or vector with odd integer elements in the range [–(`ModulationOrder` – 1), (`ModulationOrder` – 1)]. This property defines the data symbols used by the modulator prior to the first call of the object, in reverse chronological order.

- A scalar value expands to a vector of length `PulseLength` – 1.
- For a vector, the length must be `PulseLength` – 1.

Data Types: `double`

`InitialPhaseOffset` — Initial phase offset
`0` (default) | scalar

Initial phase offset in radians of the modulated waveform, specified as a scalar.

Data Types: `double`

`SamplesPerSymbol` — Number of samples per input symbol
8 (default) | positive integer

Number of samples per input symbol, specified as a positive integer. This property represents the number of samples input for each integer or binary word output. For all nonbinary schemes, as defined by the pulse shapes, this value must be greater than 1.

Data Types: `double`

`TracebackDepth` — Traceback depth for Viterbi algorithm
16 (default) | positive integer

Traceback depth for the Viterbi algorithm, specified as a positive integer representing the number of trellis branches that the Viterbi algorithm uses to construct each traceback path. The value of this property is also the output delay and the number of zero symbols that precede the first meaningful demodulated symbol in the output. For more information, see “Traceback Depth and Output Delays” on page 3-271.

Data Types: `double`

`OutputDataType` — Data type of output
`'double'` (default) | `'logical'` | `'int8'` | `'int16'` | `'int32'`

Data type of the output, specified as one of these values.

- When you set the `BitOutput` property to `false`, you can set the output data type to `'double'`, `'int8'`, `'int16'`, or `'int32'`.
- When you set the `BitOutput` property to `true`, you can set the output data type to `'logical'` or `'double'`.

Usage

Syntax

```
y = cpmdemod(x)
```

Description

`y = cpmdemod(x)` applies CPM demodulation method to the input signal and returns the demodulated signal.

Input Arguments

x — CPM-modulated signal

column vector

CPM-modulated signal, specified as a column vector with a length equal to an integer multiple of the `SamplesPerSymbol` property.

Data Types: `double` | `single`

Output Arguments

y — Output signal

column vector | matrix

Output signal, returned as a column vector or matrix. To specify whether the object outputs values as integers or bits, use the `BitOutput` property. To specify the output data type, use the `OutputDataType` property.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

CPM Modulate and Demodulate Signal with Gray Mapping and Bit Inputs

Create CPM modulator, and CPM demodulator System objects.

```
cpmmodulator = comm.CPMModulator(8, ...
    'BitInput',true, ...
    'SymbolMapping','Gray');
cpmdemodulator = comm.CPMDemodulator(8, ...
    'BitOutput',true, ...
    'SymbolMapping','Gray');
```

Create an error rate calculator System object™, that accounts for the delay caused by the Viterbi algorithm.

```
    delay = log2(cpmdemodulator.ModulationOrder) ...
        * cpmdemodulator.TracebackDepth;
    errorRate = comm.ErrorRate('ReceiveDelay',delay);
```

Transmit 100 3-bit words and print the error rate results.

```
    for counter = 1:100
        data = randi([0 1],300,1);
        modSignal = cpmmodulator(data);
        noisySignal = awgn(modSignal,0);
        receivedData = cpmdemodulator(noisySignal);
        errorStats = errorRate(data,receivedData);
    end
    fprintf('Error rate = %f\nNumber of errors = %d\n', ...
      errorStats(1),errorStats(2))
```

```
Error rate = 0.004006
Number of errors = 120
```

Apply GFSK Modulation and Demodulation

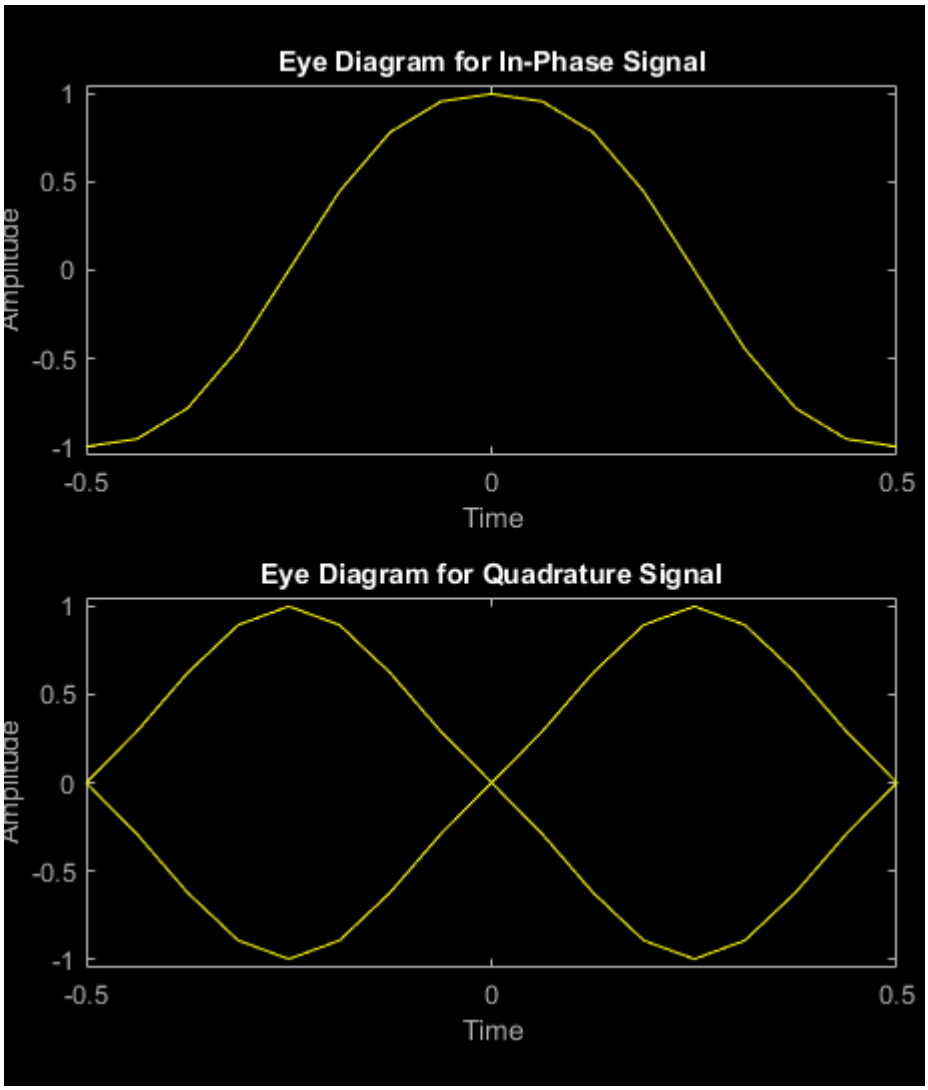
Using the `comm.CPMModulator` and `comm.CPMDemodulator` System objects, apply Gaussian frequency-shift keying (GFSK) modulation and demodulation to random bit data.

Create a GFSK modulator and demodulator pair.

```
gfskMod = comm.CPMModulator( ...
    'ModulationOrder',2, ...
    'FrequencyPulse','Gaussian', ...
    'BandwidthTimeProduct',0.5, ...
    'ModulationIndex',1, ...
    'BitInput',true);
gfskDemod = comm.CPMDemodulator( ...
    'ModulationOrder',2, ...
    'FrequencyPulse','Gaussian', ...
    'BandwidthTimeProduct',0.5, ...
    'ModulationIndex',1, ...
    'BitOutput',true);
```

Generate random bit data and apply GFSK modulation. Use a scatter plot to view the constellation.

```
numSym = 100;
x = randi([0 1],numSym*gfskMod.SamplesPerSymbol,1);
y = gfskMod(x);
eyediagram(y,16)
```



Demodulate the GFSK-modulated data. To verify that the demodulated signal data is equal to the original data, account for the delay introduced by the Gaussian filtering in the GFSK modulation and demodulation processes.

```
z = gfskDemod(y);
delay = finddelay(x,z);
isequal(x(1:end-delay),z(delay+1:end))
```

```
ans = logical
   1
```

More About

CPM Demodulation Method

The CPM demodulation method process consists of a correlator followed by a maximum-likelihood sequence detector (MLSD) that searches the paths through the state trellis for the minimum

Euclidean distance path. When the modulation index is rational ($h = m / p$), a finite number of phase states exist in the symbol. The implementation uses the Viterbi algorithm to perform MLSD.

$\{h_i\}$ is a sequence of modulation indices that moves cyclically through a set of indices $\{h_0, h_1, h_2, \ldots, h_{H-1}\}$.

- $h_i = m_i / p_i$ is the modulation index in proper rational form.
- m_i is the numerator of the modulation index.
- p_i is the denominator of the modulation index.
- m_i and p_i are relatively prime positive numbers.
- The least common multiple (LCM) of $\{p_0, p_1, p_2, \ldots, p_{H-1}\}$ is denoted as p.
- $h_i = m'_i / p$.

$\{h_i\}$ determines the number of phase states,

$$numPhaseStates = \begin{Bmatrix} p, & \text{for all even } m'_i \\ 2p, & \text{for any odd } m'_i \end{Bmatrix},$$

and affects the number of trellis states,

$numStates = numPhaseStates \times M^{(L-1)}$,

- L is the pulse length.
- M is the modulation order.

CPM Method

The input to the demodulator is a baseband representation of the modulated signal:

$$s(t) = \exp\left[j 2\pi \sum_{i=0}^{n} \alpha_i h_i q(t - iT) \right], \text{ and}$$
$$nT < t < (n+1)T.$$

where:

- $\{\alpha_i\}$ is a sequence of M-ary data symbols selected from the alphabet ±1, ±3, ±(M–1).
- M must have the form 2^k for some positive integer k, where M is the modulation order and specifies the size of the symbol alphabet.
- $\{h_i\}$ is a sequence of modulation indices. h_i moves cyclically through a set of indices $\{h_0, h_1, h_2, \ldots, h_{H-1}\}$. When H=1, only one modulation index exists, h_0, which is denoted as h.

Pulse Shape Filtering

The CPM method uses pulse shaping to smooth the phase transitions of the modulated signal. The function $q(t)$ is the phase response obtained from the frequency pulse, $g(t)$, through this relation: $q(t) = \int_{-\infty}^{t} g(t)dt$.

The specified frequency pulse shape corresponds to these pulse shape expressions for $g(t)$.

Pulse Shape	Expression
Rectangular	$g(t) = \begin{cases} \frac{1}{2LT}, & 0 \le t \le LT \\ 0 & \text{otherwise} \end{cases}$
Raised cosine	$g(t) = \begin{cases} \frac{1}{2LT}\left[1 - \cos\left(\frac{2\pi t}{LT}\right)\right], & 0 \le t \le LT \\ 0 & \text{otherwise} \end{cases}$
Spectral raised cosine	$g(t) = \frac{1}{L_{\text{main}}T}\frac{\sin\left(\frac{2\pi t}{L_{\text{main}}T}\right)}{\frac{2\pi t}{L_{\text{main}}T}}\frac{\cos\left(\beta\frac{2\pi t}{L_{\text{main}}T}\right)}{1-\left(\frac{4\beta}{L_{\text{main}}T}t\right)^2}, \quad 0 \le \beta \le 1$
Gaussian	$g(t) = \frac{1}{2T}\left\{Q\left[2\pi B_b\frac{t-\frac{T}{2}}{\sqrt{\ln 2}}\right] - Q\left[2\pi B_b\frac{t+\frac{T}{2}}{\sqrt{\ln 2}}\right]\right\}$, where $Q(t) = \int_t^\infty \frac{1}{\sqrt{2\pi}}e^{-\tau^2/2}d\tau$
Tamed FM (tamed frequency modulation)	$g(t) = \frac{1}{8}[g_0(t-T) + 2g_0(t) + g_0(t+T)]$, where $g_0(t) \approx \frac{1}{T}\left[\frac{\sin(\frac{\pi t}{T})}{\frac{\pi t}{T}} - \frac{\pi^2}{24}\frac{2\sin\left(\frac{\pi t}{T}\right) - \frac{2\pi t}{T}\cos\left(\frac{\pi t}{T}\right) - \left(\frac{\pi t}{T}\right)^2\sin\left(\frac{\pi t}{T}\right)}{\left(\frac{\pi t}{T}\right)^3}\right]$

- L_{main} is the main lobe pulse duration in symbol intervals.
- β is the roll-off factor of the spectral raised cosine.
- B_b is the product of the bandwidth and the Gaussian pulse.
- The duration of the pulse, *LT*, is the pulse length in symbol intervals. As defined by the expressions, the spectral raised cosine, Gaussian, and tamed FM pulse shapes have infinite length. For all practical purposes, *LT* specifies the truncated finite length.
- *T* is the symbol durations.
- *Q(t)* is the complementary cumulative distribution function.

For more information on pulse shape filtering, see [1].

Integer-Valued and Binary-Valued Output Signals

When you set the `BitOutput` property to `false`:

- The object outputs an integer column vector of length equal to *N*/`SamplesPerSymbol`, where *N* is the length of the input signal and indicates the number of input baseband modulated symbols. The output values are odd integers in the range [–(`ModulationOrder`–1), (`ModulationOrder`–1)].
- You cannot set the `OutputDataType` property to `'logical'`.

When you set the `BitOutput` property to `true`:

- The object outputs a binary column vector of length equal to $k \times (N$ / `SamplesPerSymbol`), where k = log2(`ModulationOrder`) and N is the number of input baseband modulated symbols (specifically, the length of the input signal).

  The `SymbolMapping` property determines how the object maps integers in the range [0, `ModulationOrder` – 1] to k-length bit word. The binary word mapping options are natural binary-coded ordering or Gray-coded ordering.
- You can set the `OutputDataType` property to only `'double'` or `'logical'`.
- The object follows this process.

  1. Map each demodulated symbol to an odd integer L in the range [–(`ModulationOrder`–1), (`ModulationOrder`–1)].
  2. Map L to the nonnegative integer (L + `ModulationOrder`–1)/2.
  3. Map each nonnegative integer to a k-length binary word. The binary word mapping options are natural binary-coded ordering or Gray-coded ordering, as specified by the `SymbolMapping` property.

Traceback Depth and Output Delays

The traceback depth is the number of trellis branches used to construct each traceback path. Traceback depth influences the output delay, which is the number of zero symbols that precede the first meaningful demodulated value in the output.

The optimal traceback depth setting depends on minimum squared Euclidean distance calculations. Alternatively, you can choose a typical value, dependent on the number of states, using the five-times-the-constraint-length rule, which corresponds to $5\log_2(numStates)$.

For a binary raised cosine pulse shape with a pulse length of 3 and h=2/3, applying this rule ($5\log_2(3 \times 2^2) = 18$ gives a result that is close to the optimum value of 20.

comm.CPMModulator

Package: comm

Modulate signal using CPM method

Description

The comm.CPMModulator System object modulates an input signal using the continuous phase modulation (CPM) method. The output is a baseband representation of the modulated signal. For more information about the modulation and filtering applied, see “CPM Method” on page 3-281 and “Pulse Shape Filtering” on page 3-282.

To modulate a signal using the CPM method:

1. Create the comm.CPMModulator object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
cpmmod = comm.CPMModulator
cpmmod = comm.CPMModulator(Name,Value)
cpmmod = comm.CPMModulator(M,Name,Value)
```

Description

cpmmod = comm.CPMModulator creates a modulator System object to modulate input signals using the CPM method.

cpmmod = comm.CPMModulator(Name,Value) sets properties using one or more name-value arguments. For example, 'SymbolMapping','Gray' specifies gray-ordered symbol mapping for the modulated symbols.

cpmmod = comm.CPMModulator(M,Name,Value) sets the ModulationOrder property to M and optional name-value arguments.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`ModulationOrder` — Modulation order

4 (default) | power of two scalar

Modulation order, specified as a power-of-two scalar. The modulation order, $M = 2^k$ specifies the number of points in the signal constellation, where k is a positive integer indicating the number of bits per symbol.

Data Types: `double`

`BitInput` — Option to input data as bits

`0` or `false` (default) | `1` or `true`

Option to input data as bits, specified as a logical `0` (`false`) or `1` (`true`).

- When you set this property to `false`, the input must be a column vector of odd integer values in the range [–(`ModulationOrder` – 1), (`ModulationOrder` – 1)].
- When you set this property to `true`, the input must be a column vector of k-length bit words, where k = log2(`ModulationOrder`). For more information, see “Symbol Sets” on page 3-282.

Data Types: `logical`

`SymbolMapping` — Symbol mapping

`'Binary'` (default) | `'Gray'`

Symbol mapping of constellation bits, specified as `'Binary'` or `'Gray'`. For more information, see “Symbol Sets” on page 3-282.

- Set this property to `'Binary'` to map symbols using natural binary-coded ordering.
- Set this property to `'Gray'` to map symbols using Gray-coded ordering.

Dependencies

To enable this property, set the `BitInput` property to `true`.

`ModulationIndex` — Modulation index

`0.5` (default) | nonnegative scalar | column vector

Modulation index, specified as a nonnegative scalar or column vector. For more information, see “CPM Method” on page 3-281.

Data Types: `double`

`FrequencyPulse` — Type of frequency pulse shaping

`'Rectangular'` (default) | `'Raised Cosine'` | `'Spectral Raised Cosine'` | `'Gaussian'` | `'Tamed FM'`

Type of frequency pulse shaping used by the modulator to smooth the phase transitions of the modulated signal, specified as `'Rectangular'`, `'Raised Cosine'`, `'Spectral Raised Cosine'`, `'Gaussian'`, or `'Tamed FM'`. For more information, see “Pulse Shape Filtering” on page 3-282.

`MainLobeDuration` — Main lobe duration

`1` (default) | positive integer

Main lobe duration of the largest lobe in the spectral raised cosine pulse, specified as a positive integer representing the number of symbol intervals used by the modulator to pulse-shape the modulated signal.

Dependencies

To enable this property, set the `FrequencyPulse` property to `'Spectral Raised Cosine'`.

Data Types: `double`

`RolloffFactor` — Roll-off factor

`0.2` (default) | scalar in the range [0, 1]

Roll-off factor of the spectral raised cosine pulse, specified as a scalar in the range [0, 1].

Dependencies

To enable this property, set the `FrequencyPulse` property to `'Spectral Raised Cosine'`.

Data Types: `double`

`BandwidthTimeProduct` — Product of bandwidth and symbol time of Gaussian pulse shape

`0.3` (default) | positive scalar

Product of the bandwidth and symbol time of the Gaussian pulse shape, specified as a positive scalar. Use `BandwidthTimeProduct` to reduce the bandwidth, at the expense of increased intersymbol interference.

Dependencies

To enable this property, set the `FrequencyPulse` property to `'Gaussian'`.

Data Types: `double`

`PulseLength` — Length of frequency pulse shape

`1` (default) | positive integer

Length of the frequency pulse shape in symbol intervals, specified as a positive integer. For more information on the frequency pulse length, refer to *LT* in “Pulse Shape Filtering” on page 3-282.

Data Types: `double`

`SymbolPrehistory` — Symbol prehistory

`1` (default) | scalar | vector

Symbol prehistory, specified as scalar or vector with odd integer elements in the range [–(`ModulationOrder` – 1), (`ModulationOrder` – 1)]. This property defines the data symbols used by the modulator prior to the first call of the object, in reverse chronological order.

- A scalar value expands to a vector of length `PulseLength` – 1.
- For a vector, the length must be `PulseLength` – 1.

Data Types: `double`

`InitialPhaseOffset` — Initial phase offset
`0` (default) | scalar

Initial phase offset in radians of the modulated waveform, specified as a scalar.

Data Types: `double`

`SamplesPerSymbol` — Number of samples per output symbol
8 (default) | positive integer

Number of samples per output symbol, specified as a positive integer. This property represents the number of samples output for each integer or binary word input. For all nonbinary schemes, as defined by the pulse shapes, this value must be greater than 1.

Data Types: `double`

`OutputDataType` — Data type of output
`'double'` (default) | `'single'`

Data type of the output, specified as `'double'` or `'single'`.

Usage

Syntax

```
y = cpmmod(x)
```

Description

`y = cpmmod(x)` applies CPM method to the input signal and returns the modulated CPM baseband signal.

Input Arguments

`x` — Input signal
column vector | matrix

Input signal data, specified as a column vector or matrix of integers or bits. For more information, see the `BitInput` property.

Data Types: `double` | `single` | `int` | `logical`

Output Arguments

`y` — CPM-modulated baseband signal
column vector

CPM-modulated baseband signal, returned as a column vector. The length of this output vector is equal to the number of input samples times the number of samples per symbol specified in the `SamplesPerSymbol` property. To specify the output data type use the `OutputDataType` property.

Data Types: `double` | `single`
Complex Number Support: Yes

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

CPM Modulate and Demodulate Signal with Gray Mapping and Bit Inputs

Create CPM modulator, and CPM demodulator System objects.

```
cpmmodulator = comm.CPMModulator(8, ...
    'BitInput',true, ...
    'SymbolMapping','Gray');
cpmdemodulator = comm.CPMDemodulator(8, ...
    'BitOutput',true, ...
    'SymbolMapping','Gray');
```

Create an error rate calculator System object™, that accounts for the delay caused by the Viterbi algorithm.

```
delay = log2(cpmdemodulator.ModulationOrder) ...
    * cpmdemodulator.TracebackDepth;
errorRate = comm.ErrorRate('ReceiveDelay',delay);
```

Transmit 100 3-bit words and print the error rate results.

```
for counter = 1:100
    data = randi([0 1],300,1);
    modSignal = cpmmodulator(data);
    noisySignal = awgn(modSignal,0);
    receivedData = cpmdemodulator(noisySignal);
    errorStats = errorRate(data,receivedData);
end
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
  errorStats(1),errorStats(2))
```

```
Error rate = 0.004006
Number of errors = 120
```

Apply GFSK Modulation and Demodulation

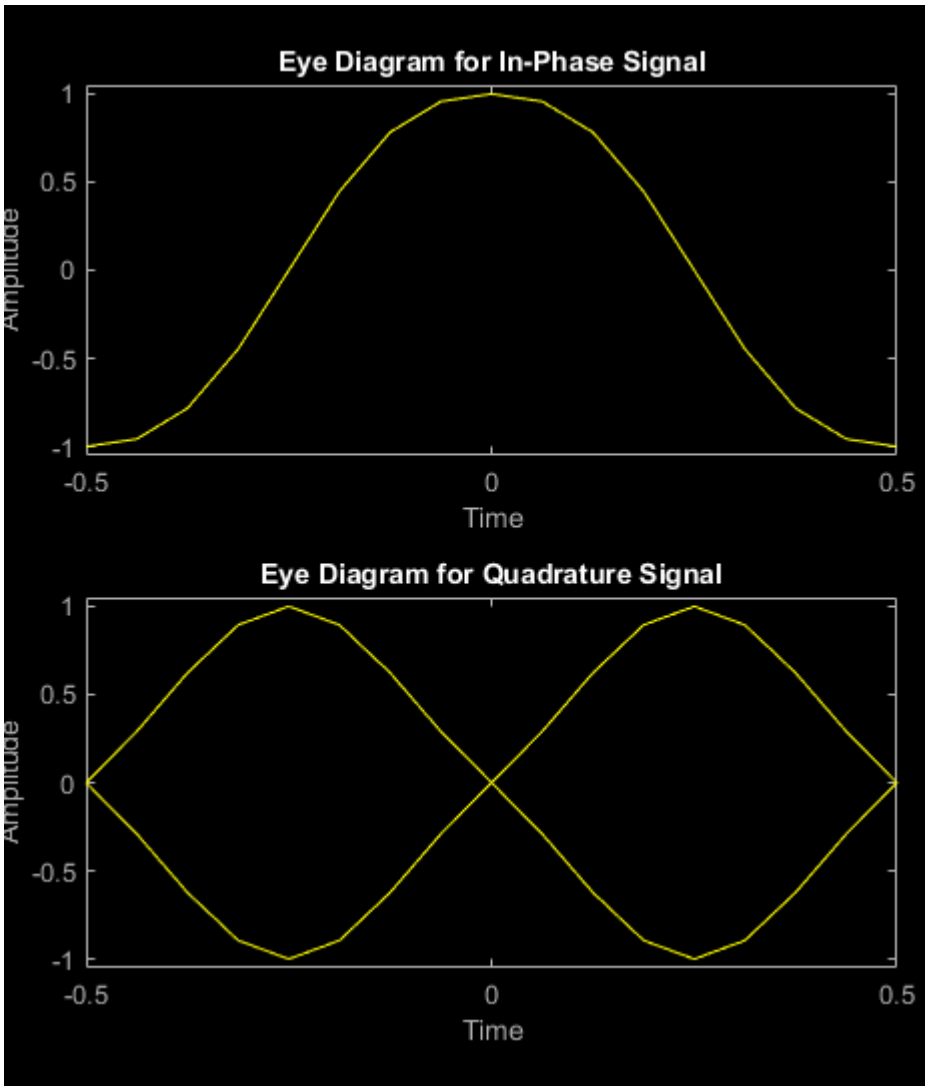
Using the `comm.CPMModulator` and `comm.CPMDemodulator` System objects, apply Gaussian frequency-shift keying (GFSK) modulation and demodulation to random bit data.

Create a GFSK modulator and demodulator pair.

```
gfskMod = comm.CPMModulator( ...
    'ModulationOrder',2, ...
    'FrequencyPulse','Gaussian', ...
    'BandwidthTimeProduct',0.5, ...
    'ModulationIndex',1, ...
    'BitInput',true);
gfskDemod = comm.CPMDemodulator( ...
    'ModulationOrder',2, ...
    'FrequencyPulse','Gaussian', ...
    'BandwidthTimeProduct',0.5, ...
    'ModulationIndex',1, ...
    'BitOutput',true);
```

Generate random bit data and apply GFSK modulation. Use a scatter plot to view the constellation.

```
numSym = 100;
x = randi([0 1],numSym*gfskMod.SamplesPerSymbol,1);
y = gfskMod(x);
eyediagram(y,16)
```



Demodulate the GFSK-modulated data. To verify that the demodulated signal data is equal to the original data, account for the delay introduced by the Gaussian filtering in the GFSK modulation and demodulation processes.

```
z = gfskDemod(y);
delay = finddelay(x,z);
isequal(x(1:end-delay),z(delay+1:end))
```

```
ans = logical
   1
```

Plot Phase Tree for Continuous Phase Modulation

Plot the phase tree diagram for signals that have applied continuous phase modulation (CPM). A *phase tree diagram* superimposes many curves, each of which plots the phase of a modulated signal

over time. The distinct curves result from different inputs to the modulator. This example defines settings for the CPM modulator, applies symbol mapping, and plots the results. Each curve represents a different instance of simulating the CPM modulator with a distinct (constant) input signal.

Define parameters for the example and create a CPM modulator System object™.

```
M = 2;                    % Modulation order
modindex = 2/3;           % Modulation index
sps = 8;                  % Samples per symbol
L = 5;                    % Symbols to display
pmat = zeros(L*sps,M^L); % Empty phase matrix

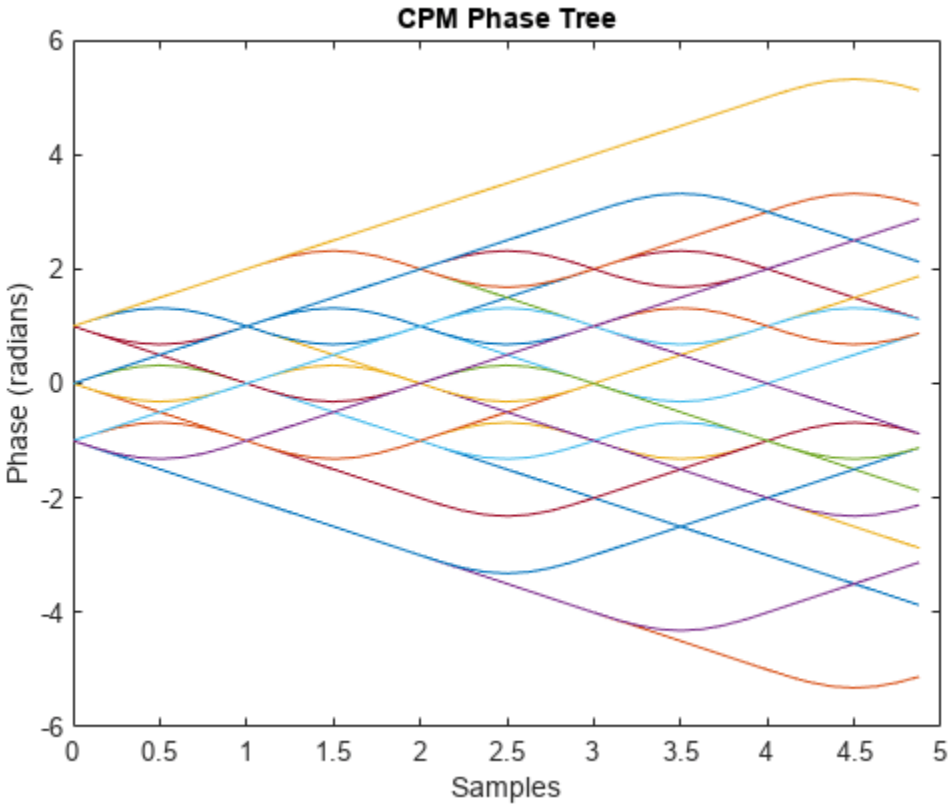
cpm = comm.CPMModulator(M, ...
    ModulationIndex=modindex, ...
    FrequencyPulse="Raised Cosine", ...
    PulseLength=2, ...
    SamplesPerSymbol=sps);
```

Use a `for`-loop to apply the mapping of the input symbol to the CPM symbols, mapping `0` to -(`M-1`), `1` to -(`M-2`), and so on. Populate the columns of the phase matrix with the unwrapped phase angle of the modulated symbols.

```
for ip_sig = 0:(M^L)-1
    s = int2bit(ip_sig,L,1);
    s = 2*s + 1 - M;
    x = cpm(s);
    pmat(:,ip_sig+1) = unwrap(angle(x(:)));
end
pmat = pmat/(pi*modindex);
t = (0:L*sps-1)'/sps;
```

Plot the CPM phase tree.

```
plot(t,pmat);
title('CPM Phase Tree')
xlabel('Samples')
ylabel('Phase (radians)')
```



More About

CPM Method

The output of the modulator is a baseband representation of the modulated signal:

$$s(t) = \exp\left[j\,2\pi \sum_{i=0}^{n} \alpha_i h_i q(t - iT)\right], \text{ and}$$

$$nT < t < (n+1)T\,.$$

where:

- $\{\alpha_i\}$ is a sequence of M-ary data symbols selected from the alphabet ±1, ±3, ±(M–1).
- M must have the form 2^k for some positive integer k, where M is the modulation order and specifies the size of the symbol alphabet.
- $\{h_i\}$ is a sequence of modulation indices. h_i moves cyclically through a set of indices $\{h_0, h_1, h_2, \ldots, h_{H\text{-}1}\}$. When H=1, only one modulation index exists, h_0, which is denoted as h.

The phase shift over a symbol is π × h.

When h_i varies from interval to interval, the object operates in multi-h. To ensure a finite number of phase states, h_i must be a rational number.

Pulse Shape Filtering

The CPM method uses pulse shaping to smooth the phase transitions of the modulated signal. The function $q(t)$ is the phase response obtained from the frequency pulse, $g(t)$, through this relation: $q(t) = \int_{-\infty}^{t} g(t)dt$.

The specified frequency pulse shape corresponds to these pulse shape expressions for $g(t)$.

Pulse Shape	Expression
Rectangular	$g(t) = \begin{cases} \frac{1}{2LT}, & 0 \le t \le LT \\ 0 & \text{otherwise} \end{cases}$
Raised cosine	$g(t) = \begin{cases} \frac{1}{2LT}\left[1 - \cos\left(\frac{2\pi t}{LT}\right)\right], & 0 \le t \le LT \\ 0 & \text{otherwise} \end{cases}$
Spectral raised cosine	$g(t) = \frac{1}{L_{\text{main}}T}\frac{\sin\left(\frac{2\pi t}{L_{\text{main}}T}\right)}{\frac{2\pi t}{L_{\text{main}}T}}\frac{\cos\left(\beta\frac{2\pi t}{L_{\text{main}}T}\right)}{1-\left(\frac{4\beta}{L_{\text{main}}T}t\right)^2}, \quad 0 \le \beta \le 1$
Gaussian	$g(t) = \frac{1}{2T}\left\{Q\left[2\pi B_b\frac{t-\frac{T}{2}}{\sqrt{\ln 2}}\right] - Q\left[2\pi B_b\frac{t+\frac{T}{2}}{\sqrt{\ln 2}}\right]\right\}$, where $Q(t) = \int_t^{\infty}\frac{1}{\sqrt{2\pi}}e^{-\tau^2/2}d\tau$
Tamed FM (tamed frequency modulation)	$g(t) = \frac{1}{8}[g_0(t-T) + 2g_0(t) + g_0(t+T)]$, where $g_0(t) \approx \frac{1}{T}\left[\frac{\sin(\frac{\pi t}{T})}{\frac{\pi t}{T}} - \frac{\pi^2}{24}\frac{2\sin\left(\frac{\pi t}{T}\right) - \frac{2\pi t}{T}\cos\left(\frac{\pi t}{T}\right) - \left(\frac{\pi t}{T}\right)^2\sin\left(\frac{\pi t}{T}\right)}{\left(\frac{\pi t}{T}\right)^3}\right]$

- L_{main} is the main lobe pulse duration in symbol intervals.
- β is the roll-off factor of the spectral raised cosine.
- B_b is the product of the bandwidth and the Gaussian pulse.
- The duration of the pulse, LT, is the pulse length in symbol intervals. As defined by the expressions, the spectral raised cosine, Gaussian, and tamed FM pulse shapes have infinite length. For all practical purposes, LT specifies the truncated finite length.
- T is the symbol durations.
- $Q(t)$ is the complementary cumulative distribution function.

For more information on pulse shape filtering, see [1].

Symbol Sets

In binary input mode, the object processing follows this procedure.

1. Divide the input bits into k-length bit words and map each bit-group to an integer, L, in the range $[0, M - 1]$. $k = \log2(M)$ and M is the modulation order specified by the `ModulationOrder` property. The binary word mapping options are natural binary-coded ordering or Gray-coded ordering, as specified by the `SymbolMapping` property.
2. Map each integer L to signed integers as $2L–(M–1)$.
3. Proceed with modulation processing as in the integer input mode.

Version History

Introduced in R2012a

comm.CRCDetector

Package: comm

Detect errors in input data using CRC

Description

The comm.CRCDetector System object computes cyclic redundancy check (CRC) checksums for an entire received codeword. For successful CRC detection in a communications system link, you must align the property settings of the comm.CRCDetector System object with the paired comm.CRCGenerator System object. For more information, see “CRC Syndrome Detector Operation” on page 3-289.

To detect errors in the received codeword containing CRC sequence bits:

1. Create the comm.CRCDetector object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
crcdetector = comm.CRCDetector
crcdetector = comm.CRCDetector(Name,Value)
crcdetector = comm.CRCDetector(poly,Name,Value)
```

Description

crcdetector = comm.CRCDetector creates a CRC code detector System object. This object detects errors in the received codewords according to a specified generator polynomial.

crcdetector = comm.CRCDetector(Name,Value) sets properties using one or more name-value pairs. For example, comm.CRCDetector('Polynomial','z^16 + z^14 + z + 1') configures the CRC code detector System object to use the CRC-16 cyclic redundancy check bits when checking for CRC code errors in the received codewords. Enclose each property name in quotes.

crcdetector = comm.CRCDetector(poly,Name,Value) creates a CRC code detector System object. This object has the Polynomial property set to poly, and the other specified properties set to the specified values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`Polynomial` — Generator polynomial

`'z^16 + z^12 + z^5 + 1'` (default) | polynomial character vector | binary row vector | integer row vector

Generator polynomial for the CRC algorithm, specified as one of the following:

- A polynomial character vector such as `'z^3 + z^2 + 1'`.
- A binary row vector that represents the coefficients of the generator polynomial in order of descending power. The length of this vector is (N+1), where N is the degree of the generator polynomial. For example, `[1 1 0 1]` represents the polynomial $x^3 + z^2 + 1$.
- An integer row vector containing the exponents of z for the nonzero terms in the polynomial in descending order. For example, `[3 2 0]` represents the polynomial $z^3 + z^2 + 1$.

For more information, see “Representation of Polynomials in Communications Toolbox”.

Some commonly used generator polynomials include:

CRC method	Generator polynomial
CRC-32	`'z^32 + z^26 + z^23 + z^22 + z^16 + z^12 + z^11 + z^10 + z^8 + z^7 + z^5 + z^4 + z^2 + z + 1'`
CRC-24	`'z^24 + z^23 + z^14 + z^12 + z^8 + 1'`
CRC-16	`'z^16 + z^15 + z^2 + 1'`
Reversed CRC-16	`'z^16 + z^14 + z + 1'`
CRC-8	`'z^8 + z^7 + z^6 + z^4 + z^2 + 1'`
CRC-4	`'z^4 + z^3 + z^2 + z + 1'`

Example: `'z^7 + z^2 + 1'`, `[1 0 0 0 0 1 0 1]`, and `[7 2 0]` represent the same polynomial, $p(z) = z^7 + z^2 + 1$.

Data Types: `double` | `char`

`InitialConditions` — Initial states of internal shift register

`0` (default) | `1` | binary row vector

Initial states of the internal shift register, specified as a binary scalar or a binary row vector with a length equal to the degree of the generator polynomial. A scalar value is expanded to a row vector of equal length to the degree of the generator polynomial.

Data Types: `logical`

`DirectMethod` — Use direct algorithm for CRC checksum calculations

`false` (default) | `true`

Use direct algorithm for CRC checksum calculations, specified as `false` or `true`.

When you set this property to `true`, the object uses the direct algorithm for CRC checksum calculations. When you set this property to `false`, the object uses the non-direct algorithm for CRC checksum calculations.

For more information on direct and non-direct algorithms, see “Error Detection and Correction”.

Data Types: `logical`

`ReflectInputBytes` — Reflect input bytes
`false` (default) | `true`

Reflect input bytes, specified as `false` or `true`. Set this property to `true` to flip the received codeword on a bytewise basis before entering the data into the shift register.

When you set this property to `true`, the received codeword length divided by the value of the `ChecksumsPerFrame` property must be an integer and a multiple of 8.

Data Types: `logical`

`ReflectChecksums` — Reflect checksums before final XOR
`false` (default) | `true`

Reflect checksums before final XOR, specified as `false` or `true`. Set this property to `true` to flip the CRC checksums around their centers after the received codeword is completely through the shift register.

When you set this property to `true`, the object flips the CRC checksums around their centers before the final XOR.

Data Types: `logical`

`FinalXOR` — Final XOR
0 (default) | binary scalar | binary vector

Final XOR, specified as a binary scalar or a binary row vector with a length equal to the degree of the generator polynomial. The XOR operation runs using the value of the `FinalXOR` property and the CRC checksum before comparing with the input checksum. A scalar value is expanded to a row vector of equal length to the degree of the generator polynomial. A setting of `0` is equivalent to no XOR operation.

Data Types: `logical`

`ChecksumsPerFrame` — Number of checksums calculated
1 (default) | positive integer

Number of checksums calculated for each received codeword frame, specified as a positive integer. for more information, see “CRC Syndrome Detector Operation” on page 3-289.

Data Types: `double`

Usage

Syntax

```
out = crcdetector(codeword)
[msg,err] = crcdetector(codeword)
```

Description

`out = crcdetector(codeword)` checks CRC code bits for each received codeword frame, removes the checksums, and then concatenates subframes to the output frame.

`[msg,err] = crcdetector(codeword)` also returns the checksum error signal computed when checking CRC code bits for each codeword subframe.

Input Arguments

`codeword` — Received codeword

binary column vector

Received codeword, specified as a binary column vector.

Data Types: `double` | `logical`

Output Arguments

`out` — Output frame

binary column vector

Output frame, returned as a binary column vector that inherits the data type of the input signal. The message word output contains the received codeword with the checksums removed.

The length of the output frame is $n - k * r$ bits, where n is the size of the received codeword, k is the number of checksums per frame, and r is the degree of the generator polynomial.

`err` — Checksum error signal

binary column vector

Checksum error signal, returned as a binary column vector that inherits the data type of the input signal. The length of `Err` equals the value of `ChecksumsPerFrame`. For each checksum computation, an element value of 0 in `err` indicates no checksum error, and an element value of 1 in `err` indicates a checksum error.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step Run System object algorithm

release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

CRC Detection of Errors in a Random Message

Pass binary data through a CRC generator, introduce a bit error, and detect the error using a CRC detector.

Create a random binary vector.

```
x = randi([0 1],12,1);
```

Encode the input message frame using a CRC generator with the `ChecksumsPerFrame` property set to 2. This subdivides the incoming frame into two equal-length subframes.

```
crcgenerator = comm.CRCGenerator([1 0 0 1],'ChecksumsPerFrame',2);
codeword = crcgenerator(x);
```

Decode the codeword and verify that there are no errors in either subframe.

```
crcdetector = comm.CRCDetector([1 0 0 1],'ChecksumsPerFrame',2);
[~, err] = crcdetector(codeword)
```

```
err = 2×1

     0
     0
```

Introduce an error in the second subframe by inverting the last element of subframe 2. Pass the corrupted codeword through the CRC detector and verify that the error is detected in the second subframe.

```
codeword(end) = not(codeword(end));
[~,err] = crcdetector(codeword)
```

```
err = 2×1

     0
     1
```

Cyclic Redundancy Check of Noisy BPSK Data Frames

Use a CRC code to detect frame errors in a noisy BPSK signal.

Create a CRC generator and detector pair using a standard CRC-4 polynomial, $z^4 + z^3 + z^2 + z + 1$.

```
poly = 'z4+z3+z2+z+1';
crcgenerator = comm.CRCGenerator(poly);
crcdetector = comm.CRCDetector(poly);
```

Generate 12-bit frames of binary data and append the CRC bits. Based on the degree of the polynomial, 4 bits are appended to each frame. Apply BPSK modulation and pass the signal through an AWGN channel. Demodulate and use the CRC detector to determine if the frame is in error.

```
numFrames = 20;
frmError = zeros(numFrames,1);

for k = 1:numFrames
    data = randi([0 1],12,1);                 % Generate binary data
    encData = crcgenerator(data);                   % Append CRC bits
    modData = pskmod(encData,2);              % BPSK modulate
    rxSig = awgn(modData,5);                  % AWGN channel, SNR = 5 dB
    demodData = pskdemod(rxSig,2);            % BPSK demodulate
    [~,frmError(k)] = crcdetector(demodData); % Detect CRC errors
end
```

Identify the frames in which CRC code bit errors are detected.

```
find(frmError)
```

```
ans = 6
```

More About

Cyclic Redundancy Check Coding

Cyclic redundancy check (CRC) coding is an error-control coding technique for detecting errors that occur when a data frame is transmitted. Unlike block or convolutional codes, CRC codes do not have a built-in error-correction capability. Instead, when a communications system detects an error in a received codeword, the receiver requests the sender to retransmit the codeword.

In CRC coding, the transmitter applies a rule to each data frame to create extra CRC bits, called the *checksum* or *syndrome*, and then appends the checksum to the data frame. After receiving a transmitted codeword, the receiver applies the same rule to the received codeword. If the resulting checksum is nonzero, an error has occurred and the transmitter should resend the data frame.

When the number of checksums per frame is greater than 1, the input data frame is divided into subframes, the rule is applied to each data subframe, and individual checksums are appended to each subframe. The subframe codewords are concatenated to output one frame.

For a discussion of the supported CRC algorithms, see “Cyclic Redundancy Check Codes”.

CRC Syndrome Detector Operation

The CRC syndrome detector outputs the received message frame and a checksum error vector according to the specified generator polynomial and number of checksums per frame.

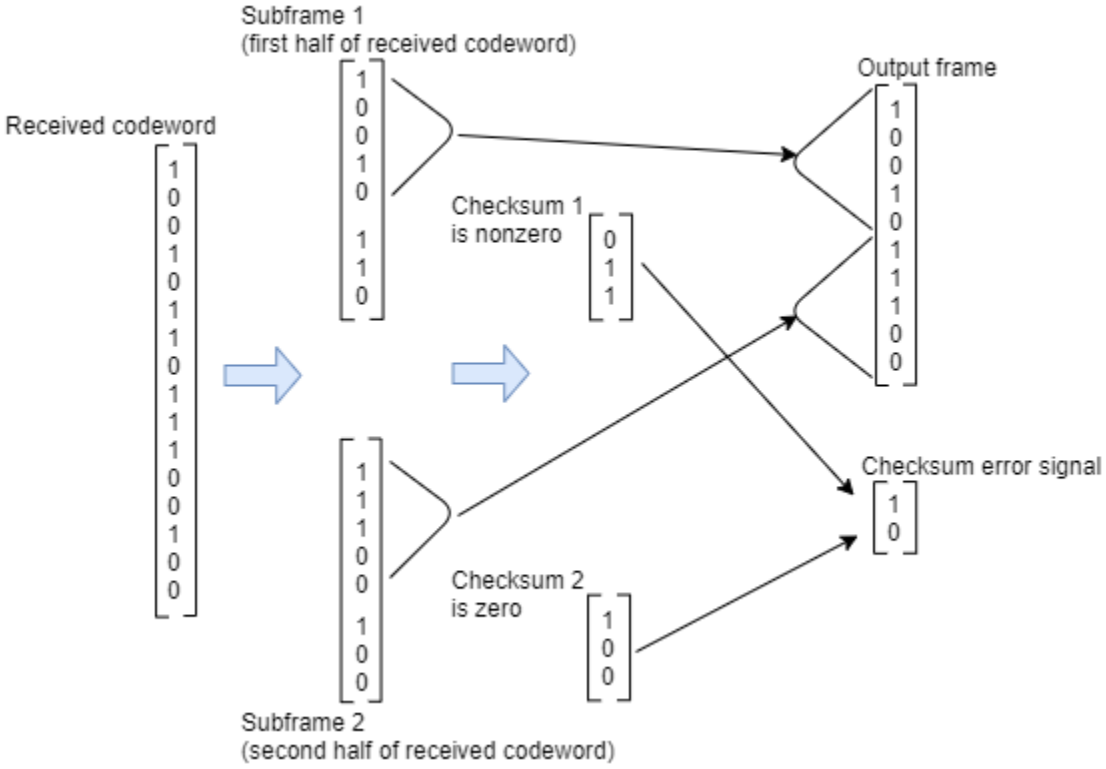
The checksum bits are removed from each subframe, so that the resulting the output frame length is $n - k \times r$, where n is the size of the received codeword, k is the number of checksums per frame, and r is the degree of the generator polynomial. The input frame must be evenly divisible by k.

For a specific initial state of the internal shift register:

1 The received codeword is divided into k equal sized subframes.

2. The CRC is removed from each of the k subframes and compared to the checksum calculated on the received codeword subframes.
3. The output frame is assembled by concatenating the subframe bits of the k subframes and then output as a column vector.
4. The checksum error is output as a binary column vector of length k. An element value of 0 indicates an error-free received subframe, and an element value of 1 indicates an error occurred in the received subframe.

For the scenario shown here, a 16-bit codeword is received, a third degree generator polynomial computes the CRC checksum, the initial state is 0, and the number of checksums per frame is 2.



Since the number of checksums per frame is 2 and the generator polynomial degree is 3, the received codeword is split in half and two checksums of size 3 are computed, one for each half of the received codeword. The initial states are not shown, because an initial state of `[0]` does not affect the output of the CRC algorithm. The output frame contains the concatenation of the two halves of the received codeword as a single vector of size 10. The checksum error signal output contains a 2-by-1 binary frame vector whose entries depend on whether the computed checksums are zero. As shown in the figure, the first checksum is nonzero and the second checksum is zero, indicating an error occurred in reception of the first half of the codeword.

Generate CRC code bits and append to input data

Description

The comm.CRCGenerator System object generates cyclic redundancy check (CRC) code bits for each input frame and appends them to the frame. For more information, see “CRC Generator Operation” on page 3-300.

To generate CRC code bits for each input frame and append them to the frame:

1. Create the comm.CRCGenerator object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
crcgenerator = comm.CRCGenerator
crcgenerator = comm.CRCGenerator(Name,Value)
crcgenerator = comm.CRCGenerator(poly,Name,Value)
```

Description

crcgenerator = comm.CRCGenerator creates a CRC code generator System object. This object generates CRC bits according to a specified generator polynomial and appends them to the input frame.

crcgenerator = comm.CRCGenerator(Name,Value) sets properties using one or more name-value pairs. For example, comm.CRCGenerator('Polynomial','z^16 + z^14 + z + 1') configures the CRC generator System object to append CRC-16 cyclic redundancy check bits to the input frame. Enclose each property name in quotes.

crcgenerator = comm.CRCGenerator(poly,Name,Value) creates a CRC code generator System object. This object has the Polynomial property set to poly, and the other specified properties set to the specified values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`Polynomial` — Generator polynomial
`'z^16 + z^12 + z^5 + 1'` (default) | polynomial character vector | binary row vector | integer row vector

Generator polynomial for the CRC algorithm, specified as one of the following:

- A polynomial character vector such as `'z^3 + z^2 + 1'`.
- A binary row vector that represents the coefficients of the generator polynomial in order of descending power. The length of this vector is (N+1), where N is the degree of the generator polynomial. For example, `[1 1 0 1]` represents the polynomial $z^3 + z^2 + 1$.
- An integer row vector containing the exponents of z for the nonzero terms in the polynomial in descending order. For example, `[3 2 0]` represents the polynomial $z^3 + z^2 + 1$.

For more information, see “Representation of Polynomials in Communications Toolbox”.

Some commonly used generator polynomials include:

CRC method	Generator polynomial
CRC-32	`'z^32 + z^26 + z^23 + z^22 + z^16 + z^12 + z^11 + z^10 + z^8 + z^7 + z^5 + z^4 + z^2 + z + 1'`
CRC-24	`'z^24 + z^23 + z^14 + z^12 + z^8 + 1'`
CRC-16	`'z^16 + z^15 + z^2 + 1'`
Reversed CRC-16	`'z^16 + z^14 + z + 1'`
CRC-8	`'z^8 + z^7 + z^6 + z^4 + z^2 + 1'`
CRC-4	`'z^4 + z^3 + z^2 + z + 1'`

Example: `'z^7 + z^2 + 1'`, `[1 0 0 0 0 1 0 1]`, and `[7 2 0]` represent the same polynomial, $p(z) = z^7 + z^2 + 1$.

Data Types: `double` | `char`

`InitialConditions` — Initial states of internal shift register
`0` (default) | `1` | binary row vector

Initial states of the internal shift register, specified as a binary scalar or a binary row vector with a length equal to the degree of the generator polynomial. A scalar value is expanded to a row vector of equal length to the degree of the generator polynomial.

Data Types: `logical`

`DirectMethod` — Use direct algorithm for CRC checksum calculations
`false` (default) | `true`

Use direct algorithm for CRC checksum calculations, specified as `false` or `true`.

When you set this property to `true`, the object uses the direct algorithm for CRC checksum calculations. When you set this property to `false`, the object uses the non-direct algorithm for CRC checksum calculations.

For more information on direct and non-direct algorithms, see “Error Detection and Correction”.

Data Types: `logical`

`ReflectInputBytes` — Reflect input bytes
`false` (default) | `true`

Reflect input bytes, specified as `false` or `true`. Set this property to `true` to flip the input frame on a bytewise basis before entering the data into the shift register.

When you set this property to `true`, the input frame length divided by the value of the `ChecksumsPerFrame` property must be an integer and a multiple of 8.

Data Types: `logical`

`ReflectChecksums` — Reflect checksums before final XOR
`false` (default) | `true`

Reflect checksums before final XOR, specified as `false` or `true`. Set this property to `true` to flip the CRC checksums around their centers after the input data are completely through the shift register.

Data Types: `logical`

`FinalXOR` — Final XOR
0 (default) | binary scalar | binary vector

Final XOR, specified as a binary scalar or a binary row vector with a length equal to the degree of the generator polynomial. The XOR operation runs using the value of the `FinalXOR` property and the CRC checksum before comparing with the input checksum. A scalar value is expanded to a row vector of equal length to the degree of the generator polynomial. A setting of `0` is equivalent to no XOR operation.

Data Types: `logical`

`ChecksumsPerFrame` — Number of checksums calculated for each frame
1 (default) | positive integer

Number of checksums calculated for each frame, specified as a positive integer. For more information, see “CRC Generator Operation” on page 3-300.

Data Types: `double`

Usage

Syntax

```
codeword = crcgenerator(x)
```

Description

`codeword = crcgenerator(x)` generates CRC code bits for each input frame and appends them to the frame.

Input Arguments

x — Input signal

binary column vector

Input signal, specified as a binary column vector. The length of the input frame must be a multiple of the value of the `ChecksumsPerFrame` property. If the input data type is double, the least significant bit is used as the binary value. For more information, see “CRC Generator Operation” on page 3-300.

Data Types: `double` | `logical`

Output Arguments

codeword — Output codeword frame

binary column vector

Output codeword frame, returned as a binary column vector that inherits the data type of the input signal. The output contains the input frames with the CRC code sequence bits appended.

The length of the output codeword frame is $m + k * r$, where m is the size of the input message, k is the number of checksums per input frame, and r is the degree of the generator polynomial. For more information, see “CRC Generator Operation” on page 3-300.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Generate CRC-8 Checksum

Generate a CRC-8 checksum for the example shown in 802.11™-2016[1] on page 3-296, section 21.3.10.3 and compare with the expected CRC.

Create a CRC Generator System object™. To align with the CRC calculation in 802.11-20016, the System object sets the generator polynomial as $z^8 + z^2 + z + 1$, initial states to 1, direct method, and final XOR to 1.

```
crc8 = comm.CRCGenerator('Polynomial','z^8 + z^2 + z + 1', ...
    'InitialConditions',1,'DirectMethod',true,'FinalXOR',1)

crc8 =
  comm.CRCGenerator with properties:

           Polynomial: 'z^8 + z^2 + z + 1'
    InitialConditions: 1
         DirectMethod: true
    ReflectInputBytes: false
     ReflectChecksums: false
              FinalXOR: 1
    ChecksumsPerFrame: 1
```

Process one input frame according to the example from the 802.11-2016 standard in section 21.3.10.3. In the example, the input bit stream {m0, ... m22} is {1 0 0 1 1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 1 1} and the expected CRC checksum {c7, ... c0} is {0 0 0 1 1 1 0 0}.

```
x = [1 0 0 1 1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 1 1]';
expectedChecksum = [0 0 0 1 1 1 0 0]';
checksumLength = length(expectedChecksum);
```

The generated CRC checksum is compared to the expected checksum.

```
codeword = crc8(x);
checksum = codeword(end-checksumLength+1:end);
isequal(checksum,expectedChecksum)

ans = logical
   1
```

CRC Detection of Errors in a Random Message

Pass binary data through a CRC generator, introduce a bit error, and detect the error using a CRC detector.

Create a random binary vector.

```
x = randi([0 1],12,1);
```

Encode the input message frame using a CRC generator with the `ChecksumsPerFrame` property set to 2. This subdivides the incoming frame into two equal-length subframes.

```
crcgenerator = comm.CRCGenerator([1 0 0 1],'ChecksumsPerFrame',2);
codeword = crcgenerator(x);
```

Decode the codeword and verify that there are no errors in either subframe.

```
crcdetector = comm.CRCDetector([1 0 0 1],'ChecksumsPerFrame',2);
[~, err] = crcdetector(codeword)
```

```
err = 2×1

     0
     0
```

Introduce an error in the second subframe by inverting the last element of subframe 2. Pass the corrupted codeword through the CRC detector and verify that the error is detected in the second subframe.

```
codeword(end) = not(codeword(end));
[~,err] = crcdetector(codeword)
```

```
err = 2×1

     0
     1
```

Cyclic Redundancy Check of Noisy BPSK Data Frames

Use a CRC code to detect frame errors in a noisy BPSK signal.

Create a CRC generator and detector pair using a standard CRC-4 polynomial, $z^4 + z^3 + z^2 + z + 1$.

```
poly = 'z4+z3+z2+z+1';
crcgenerator = comm.CRCGenerator(poly);
crcdetector = comm.CRCDetector(poly);
```

Generate 12-bit frames of binary data and append the CRC bits. Based on the degree of the polynomial, 4 bits are appended to each frame. Apply BPSK modulation and pass the signal through an AWGN channel. Demodulate and use the CRC detector to determine if the frame is in error.

```
numFrames = 20;
frmError = zeros(numFrames,1);

for k = 1:numFrames
    data = randi([0 1],12,1);                % Generate binary data
    encData = crcgenerator(data);                 % Append CRC bits
    modData = pskmod(encData,2);             % BPSK modulate
    rxSig = awgn(modData,5);                 % AWGN channel, SNR = 5 dB
    demodData = pskdemod(rxSig,2);           % BPSK demodulate
    [~,frmError(k)] = crcdetector(demodData); % Detect CRC errors
end
```

Identify the frames in which CRC code bit errors are detected.

```
find(frmError)
```

```
ans = 6
```

CRC-16-CCITT Generator for X.25

Create a CRC-16-CCITT generator as described in Section 2.2.7.4 of ITU-T Recommendation X-25[1] on page 3-298 using the input data and expected frame check sequence (FCS) from Example 2 in Appendix I, I.1.

Create an unnumbered acknowledgement (UA) response frame where address = B and F = 1.

```
Address = [1 0 0 0 0 0 0 0];
UA = [1 1 0 0 1 1 1 0];
input = [Address UA]';
expectedChecksum = [1 1 0 0 0 0 0 1 1 1 1 0 1 0 1 0]'; % Expected FCS
checksumLength = 16;

crcGen = comm.CRCGenerator(...
    'Polynomial','X^16 + X^12 + X^5 + 1',...
    'InitialConditions',1,...
    'DirectMethod',true,...
    'FinalXOR',1);
crcSeq = crcGen(input);
checkSum =  crcSeq(end-checksumLength+1:end);
```

Compare calculated checksum with the expected checksum.

```
isequal(expectedChecksum,checkSum)
```

```
ans = logical
   1
```

CRC-32 Generator for Ethernet

Create a CRC-32 code for the frame check sequence (FCS) field for Ethernet as described in Section 3.2.9 of the IEEE Standard for Ethernet[1] on page 3-299.

```
rng(1865);  % Seed for repeatable results
```

Initialize a message with random data to represent the protected fields of the MAC frame, specifically the destination address, source address, length or type field, MAC client data, and padding.

```
data = randi([0,1],100,1);
```

Specify the CRC-32 generating polynomial used for encoding Ethernet messages.

```
poly = [32,26,23,22,16,12,11,10,8,7,5,4,2,1,0];
```

Calculate the CRC by following the steps specified in the standard and using the nondirect method to generate the CRC code.

```
% Section 3.2.9 step a) and b)
dataN = [not(data(1:32));data(33:end)];
crcGen1 = comm.CRCGenerator(...
    'Polynomial',poly, ...
    'InitialConditions',0, ...
    'DirectMethod',false, ...
    'FinalXOR',1);
% Section 3.2.9 step c), d) and e)
seq = crcGen1(dataN);
csNondirect = seq(end-31:end);
```

Calculate the CRC by following the steps specified in the standard and using the direct method to generate the CRC code.

```
crcGen2 = comm.CRCGenerator( ...
    'Polynomial',poly, ...
    'InitialConditions',1, ...
    'DirectMethod',true, ...
    'FinalXOR',1);
txSeq = crcGen2(data);
csDirect = txSeq(end-31:end);
```

Compare the generated CRC codes by using the nondirect and direct methods.

```
disp([csNondirect';csDirect']);
```

```
  Columns 1 through 13

     1     1     1     0     1     1     0     0     1     0     0     1     0
     1     1     1     0     1     1     0     0     1     0     0     1     0

  Columns 14 through 26

     1     0     0     1     0     1     0     1     1     0     0     0     1
     1     0     0     1     0     1     0     1     1     0     0     0     1

  Columns 27 through 32

     1     1     0     0     1     0
     1     1     0     0     1     0
```

```
isequal(csNondirect,csDirect)
```

```
ans = logical
   1
```

```
rng('default');  % Reset the random number generator
```

More About

Cyclic Redundancy Check Coding

Cyclic redundancy check (CRC) coding is an error-control coding technique for detecting errors that occur when a data frame is transmitted. Unlike block or convolutional codes, CRC codes do not have a built-in error-correction capability. Instead, when a communications system detects an error in a received codeword, the receiver requests the sender to retransmit the codeword.

In CRC coding, the transmitter applies a rule to each data frame to create extra CRC bits, called the *checksum* or *syndrome*, and then appends the checksum to the data frame. After receiving a transmitted codeword, the receiver applies the same rule to the received codeword. If the resulting checksum is nonzero, an error has occurred and the transmitter should resend the data frame.

When the number of checksums per frame is greater than 1, the input data frame is divided into subframes, the rule is applied to each data subframe, and individual checksums are appended to each subframe. The subframe codewords are concatenated to output one frame.

For a discussion of the supported CRC algorithms, see “Cyclic Redundancy Check Codes”.

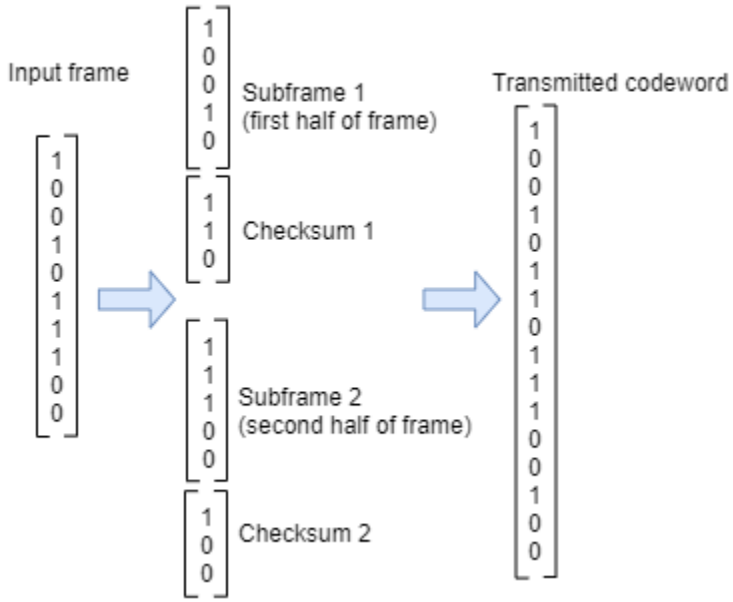
CRC Generator Operation

The CRC generator appends CRC checksums to the input frame according to the specified generator polynomial and number of checksums per frame.

For a specific initial state of the internal shift register and k checksums per input frame:

1. The input signal is divided into k subframes of equal size.
2. Each of the k subframes are prefixed with the initial states vector.
3. The CRC algorithm is applied to each subframe.
4. The resulting checksums are appended to the end of each subframe.
5. The subframes are concatenated and output as a column vector.

For the scenario shown here, a 10-bit frame is input, a third degree generator polynomial computes the CRC checksum, the initial state is 0, and the number of checksums per frame is 2.



The input frame is divided into two subframes of size 5 and checksums of size 3 are computed and appended to each subframe. The initial states are not shown, because an initial state of `[0]` does not affect the output of the CRC algorithm. The output transmitted codeword frame has the size 5 + 3 + 5 + 3 = 16.

comm.DBPSKDemodulator

Package: comm

Demodulate using DBPSK method

Description

The DBPSKDemodulator object demodulates a signal that was modulated using the differential binary phase shift keying method. The input is a baseband representation of the modulated signal.

To demodulate a signal that was modulated using differential binary phase shift keying:

1. Define and set up your DBPSK demodulator object. See “Construction” on page 3-303.
2. Call step to demodulate a signal according to the properties of comm.DBPSKDemodulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

H = comm.DBPSKDemodulator creates a demodulator System object, H. This object demodulates the input signal using the differential binary phase shift keying (DBPSK) method.

H = comm.DBPSKDemodulator(Name,Value) creates a DBPSK demodulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.DBPSKDemodulator(PHASE,Name,Value) creates a DBPSK demodulator object, H. This object has the PhaseRotation property set to PHASE and the other specified properties set to the specified values.

Properties

PhaseRotation

Additional phase shift

Specify the additional phase difference between previous and current modulated bits in radians as a real scalar. The default is 0. This value corresponds to the phase difference between previous and current modulated bits when the input is zero.

OutputDataType

Data type of output

Specify output data type as one of `Full precision` | `Smallest unsigned integer` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `logical`. The default is `Full precision`. When you set this property to `Full precision`, the output data type has the same data type as the input. In this case, that value must be a double- or single-precision data type.

Methods

step Demodulate using DBPSK method

Common to All System Objects	
`release`	Allow System object property value changes
`reset`	Reset internal states of System object

Examples

DBPSK Signal in AWGN

Create a DBPSK modulator and demodulator pair.

```
dbpskmod = comm.DBPSKModulator(pi/4);
dpbpskdemod = comm.DBPSKDemodulator(pi/4);
```

Create an error rate calculator. Set the `ComputationDelay` property to `1` to account for the one bit transient caused by the differential modulation

```
errorRate = comm.ErrorRate('ComputationDelay',1);
```

Main processing loop steps:

- Generate 50-bit frames
- DBPSK modulate
- Pass through AWGN channel
- DBPSK demodulate
- Collect error statistics

```
for counter = 1:100
    txData = randi([0 1],50,1);
    modSig = dbpskmod(txData);
    rxSig = awgn(modSig,7);
    rxData = dpbpskdemod(rxSig);
    errorStats = errorRate(txData,rxData);
end
```

Display the error statistics.

```
ber = errorStats(1)
```

```
ber = 0.0040
```

```
numErrors = errorStats(2)
```

```
numErrors = 20
```

```
numBits = errorStats(3)
```

```
numBits = 4999
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the DBPSK Demodulator Baseband block reference page. The object properties correspond to the block parameters.

step

System object: comm.DBPSKDemodulator
Package: comm

Demodulate using DBPSK method

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` demodulates input data, `X`, with the DBPSK demodulator System object, `H`, and returns `Y`. Input `X` must be a double or single precision data type scalar or column vector.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.DBPSKModulator

Package: comm

Modulate using DBPSK method

Description

The DBPSKModulator object modulates using the differential binary phase shift keying method. The output is a baseband representation of the modulated signal.

To modulate a signal using differential binary phase shift keying:

1. Define and set up your DBPSK modulator object. See “Construction” on page 3-307.
2. Call step to modulate a signal according to the properties of comm.DBPSKModulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

H = comm.DBPSKModulator creates a modulator System object, H. This object modulates the input signal using the differential binary phase shift keying (DBPSK) method.

H = comm.DBPSKModulator(Name,Value) creates a DBPSK modulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.DBPSKModulator(PHASE,Name,Value) creates a DBPSK modulator object, H. This object has the PhaseRotation property set to PHASE, and the other specified properties set to the specified values.

Properties

PhaseRotation

Additional phase shift

Specify the additional phase difference between previous and current modulated bits in radians as a real scalar value. The default is 0. This value corresponds to the phase difference between previous and current modulated bits when the input is zero.

OutputDataType

Data type of output

Specify output data type as one of `double` | `single`. The default is `double`.

Methods

`comm.DBPSKDemodulator` | `comm.DQPSKModulator`

step

System object: `comm.DBPSKModulator`
Package: `comm`

Modulate using DBPSK method

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` modulates input data, `X`, with the DBPSK modulator System object, `H`. It returns the baseband modulated output, `Y`. The input must be a numeric or logical data type column vector of bits.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.Descrambler

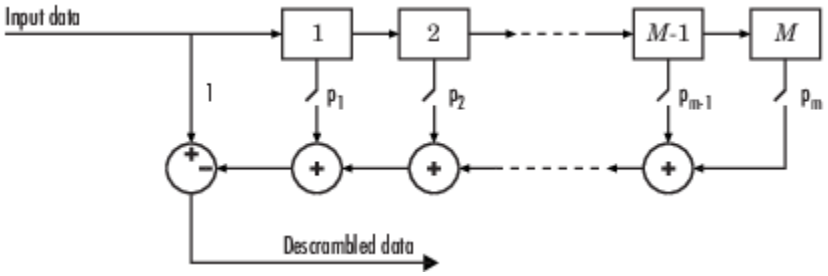
Package: comm

Descramble input signal

Description

The comm.Descrambler System object applies multiplicative descrambling to input data. It performs the inverse operation of the comm.Scrambler object used in the transmitter.

This schematic shows the multiplicative descrambler operation. The adders and subtracter operate modulo *N*, where *N* is the value specified by the Calculation base property.



At each time step, the input causes the contents of the registers to shift sequentially. Using the Polynomial property, you specify the on or off state for each switch in the descrambler. To make the comm.Descrambler object reverse the operation of the comm.Scrambler object, use the same property settings in both objects. If there is no signal delay between the scrambler and the descrambler, then the InitialConditions in the two objects must be the same.

Note To apply additive descrambling to input data, you can use the comm.PNSequence System object and the xor function. For an example, see “Additive Scrambling of Input Data” on page 3-1034.

To descramble an input signal:

1. Create the comm.Descrambler object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
descrambler = comm.Descrambler
descrambler = comm.Descrambler(base,poly,cond)
descrambler = comm.Descrambler( ___ ,Name,Value)
```

Description

`descrambler = comm.Descrambler` creates a descrambler System object. This object descrambles the input data by using a linear feedback shift register that you specify with the Polynomial property.

`descrambler = comm.Descrambler(base,poly,cond)` creates the descrambler object with the CalculationBase property set to `base`, the Polynomial property set to `poly`, and the InitialConditions property set to `cond`.

Example: `comm.Descrambler(8,'1 + x^-2 + x^-3 + x^-5 + x^-7',[0 3 2 2 5 1 7])` sets the calculation base to 8, and the descrambler polynomial and initial conditions as specified.

`descrambler = comm.Descrambler( ___ ,Name,Value)` sets properties using one or more name-value pairs and either of the previous syntaxes. Enclose each property name in single quotes.

Example: `comm.Descrambler('CalculationBase',2)`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`CalculationBase` — Range of input data

4 (default) | nonnegative integer

Range of input data used in the descrambler for modulo operations, specified as a nonnegative integer. The input and output of this object are integers from `0` to `CalculationBase` – `1`.

Data Types: `double`

`Polynomial` — Connections for linear feedback shift registers

`'1 + x^-1 + x^-2 + x^-4'` (default) | character vector | integer vector | binary vector

Connections for linear feedback shift registers in the descrambler, specified as a character vector, integer vector, or binary vector. The `Polynomial` property defines if each switch in the descrambler is on or off. Specify the polynomial as:

- A character vector, such as `'1 + x^-6 + x^-8'`. For more details on specifying polynomials in this way, see “Representation of Polynomials in Communications Toolbox”.
- An integer vector, such as `[0 -6 -8]`, listing the descrambler coefficients in order of descending powers of x^{-1}, where $p(x^{-1}) = 1 + p_1x^{-1} + p_2x^{-2} + ...$
- A binary vector, such as `[1 0 0 0 0 0 1 0 1]`, listing the powers of x that appear in the polynomial that have a coefficient of 1. In this case, the order of the descramble polynomial is one less than the binary vector length.

Example: `'1 + x^-6 + x^-8'`, `[0 -6 -8]`, and `[1 0 0 0 0 0 1 0 1]` all represent this polynomial:

$p(x^{-1}) = 1 + x^{-6} + x^{-8}$

Data Types: `double` | `char`

`InitialConditionsSource` — Initial conditions source

`'Property'` (default) | `'Input port'`

- `'Property'` – Specify descrambler initial conditions by using the InitialConditions property.
- `'Input port'` – Specify descrambler initial conditions by using an additional input argument, initcond, when calling the object.

Data Types: `char`

`InitialConditions` — Initial conditions of descrambler registers

`[0 1 2 3]` (default) | nonnegative integer vector

Initial conditions of descrambler registers when the simulation starts, specified as a nonnegative integer vector. The length of `InitialConditions` must equal the order of the Polynomial property. The vector element values must be integers from `0` to CalculationBase – `1`.

Dependencies

This property is available when InitialConditionsSource is set to `'Property'`.

`ResetInputPort` — Descrambler state reset port

`false` (default) | `true`

Descrambler state reset port, specified as `false` or `true`. If `ResetInputPort` is `true`, you can reset the descrambler object by using an additional input argument, reset, when calling the object.

Dependencies

This property is available when InitialConditionsSource is set to `'Property'`.

Usage

Syntax

```
descrambledOut = descrambler(signal)
descrambledOut = descrambler(signal,initcond)
descrambledOut = descrambler(signal,reset)
```

Description

`descrambledOut = descrambler(signal)` descrambles the input signal. The output is the same data type and length as the input vector.

`descrambledOut = descrambler(signal,initcond)`provides an additional input with values specifying the initial conditions of the linear feedback shift register.

This syntax applies when you set the InitialConditionsSource property of the object to `'Input port'`.

`descrambledOut = descrambler(signal,reset)` provides an additional input indicating whether to reset the state of the descrambler.

This syntax applies when you set the InitialConditionsSource property of the object to `'Property'` and the ResetInputPort to `true`.

Input Arguments

`signal` — Input signal
column vector

Input signal, specified as a column vector.

Example: `descrambledOut = descrambler([0 1 1 0 1 0])`

Data Types: `double` | `logical`

`initcond` — Initial register condition
nonnegative integer column vector

Initial descrambler register conditions when the simulation starts, specified as a nonnegative integer column vector. The length of `initcond` must equal the order of the Polynomial property. The vector element values must be integers from `0` to CalculationBase – `1`.

Example: `descrambledOut = descrambler(signal,[0 1 1 0])` corresponds to possible initial register states for a descrambler with a polynomial order of 4 and a calculation base of 2 or higher.

Data Types: `double`

`reset` — Reset initial state of descrambler
scalar

Reset initial state of the descrambler when the simulation starts, specified as a scalar. When the value of `reset` is nonzero, the object is reset before it is called.

Example: `descrambledOut = descrambler(signal,0)` descrambles the input signal without resetting the descrambler states.

Data Types: `double`

Output Arguments

`out` — Descrambled output
column vector

Descrambled output, returned as a column vector with the same data type and length as signal.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step Run System object algorithm

release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Scramble and Descramble Data

Scramble and descramble 8-ary data using `comm.Scrambler` and `comm.Descrambler` System objects™ having a calculation base of 8.

Create scrambler and descrambler objects, specifying the calculation base, polynomial, and initial conditions using input arguments. The scrambler and descrambler polynomials are specified with different but equivalent data formats.

```
N = 8;
scrambler = comm.Scrambler(N,'1 + x^-2 + x^-3 + x^-5 + x^-7', ...
    [0 3 2 2 5 1 7]);
descrambler = comm.Descrambler(N,[1 0 1 1 0 1 0 1], ...
    [0 3 2 2 5 1 7]);
```

Scramble and descramble random integers. Display the original data, scrambled data, and descrambled data sequences.

```
data = randi([0 N-1],5,1);
scrData = scrambler(data);
deScrData = descrambler(scrData);
[data scrData deScrData]
```

```
ans = 5×3

     6     7     6
     7     5     7
     1     7     1
     7     0     7
     5     3     5
```

Verify that the descrambled data matches the original data.

```
isequal(data,deScrData)
```

```
ans = logical
   1
```

Scramble and Descramble Data with Changing Initial Conditions

Scramble and descramble quaternary data while changing the initial conditions between function calls.

Create scrambler and descrambler System objects having a calculation base of 4. Set the `InitialConditionsSource` property to `'Input port'` so you can set the initial conditions as an argument to the object.

```
N = 4;
scrambler = comm.Scrambler( ...
    N,'1 + z^-3', ...
    'InitialConditionsSource','Input port');
descrambler = comm.Descrambler( ...
    N,'1 + z^-3', ...
    'InitialConditionsSource','Input port');
```

Preallocate memory for the error vector which will be used to store errors output by the `symerr` function.

```
errVec = zeros(10,1);
```

Scramble and descramble random integers while changing the initial conditions, `initCond`, each time the loop executes. Use the `symerr` function to determine if the scrambling and descrambling operations result in symbol errors.

```
for k = 1:10
    initCond = randperm(3)';
    data = randi([0 N-1],5,1);
    scrData = scrambler(data,initCond);
    deScrData = descrambler(scrData,initCond);
    errVec(k) = symerr(data,deScrData);
end
```

Examine `errVec` to verify that the output from the descrambler matches the original data.

```
errVec
```

```
errVec = 10×1

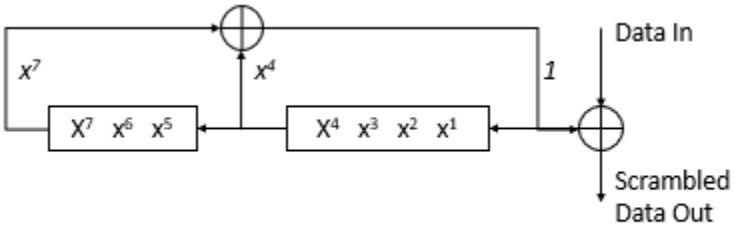
     0
     0
     0
     0
     0
     0
     0
     0
     0
     0
```

Additive Scrambling of Input Data

Digital communications systems commonly use additive scrambling to randomize input data to aid in timing synchronization and power spectral requirements. The `comm.Scrambler` System object™ implements multiplicative scrambling but does not support additive scrambling. To perform additive scrambling you can use the `comm.PNSequence` System object. This example implements the additive scrambling specified in IEEE 802.11™ by scrambling input data with an output sequence generated

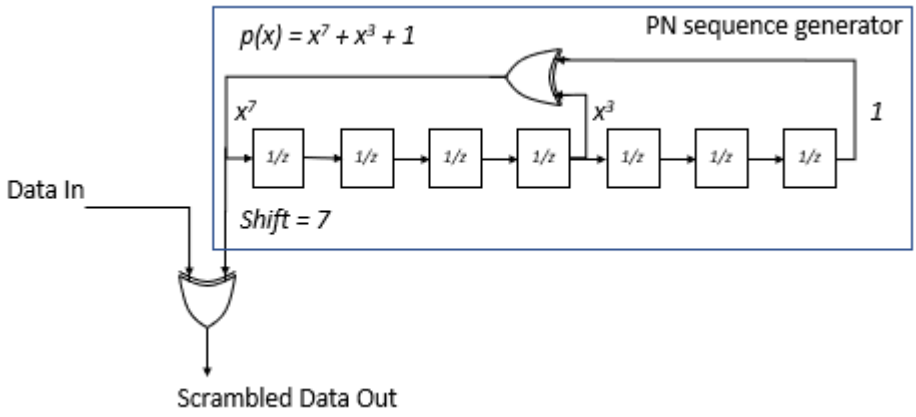
by the comm.PNSequence System object. For a Simulink® model that implements a similar workflow, see the “Additive Scrambling of Input Data in Simulink” example.

This figure shows an additive scrambler, that uses the generator polynomial $x^7 + x^4 + 1$, as specified in figure 17-7 of IEEE 802.11 Section 17.3.5.5 [1] on page 3-318.



IEEE 802.11™ section 17.3.5.5 PHY DATA scrambler and descrambler (Figure 17-7 Data Scrambler)

Comparing the shift register specified in 802.11 with the shift register implementated using a comm.PNSequence System object, note that the two shift register schematics are mirror images of each other. Therefore, when configuring the comm.PNSequence System object to implement an additive scrambler, you must reverse values for the generator polynomial, the initial states, and the mask output. To take the output of the register from the leading end, specify a shift value of 7.



For more information about the 802.11 scrambler, see [1] on page 3-318 and the `wlanScramble` (WLAN Toolbox) reference page.

Define variables for the generator polynomial, shift value for the output, an initial shift register state, a frame of input data, and a variable containing the 127-bit scrambler sequence specified in section 17.3.5.5 of the IEEE 802.11 standard. Create a PN sequence object that initializes the registers by using an input argument.

```
genPoly = 'x^7 + x^3 + 1';   % Generator polynomial
shift = 7;                   % Shift value for output
spf = 127;                   % Samples per frame
initState = [1 1 1 1 1 1 1]; % Initial shift register state
dataIn = randi([0 1],spf,1);
ieee802_11_scram_seq = logical([ ...
    0 0 0 0 1 1 1 0 1 1 1 1 0 0 1 0 1 1 0 0 1 ...
    0 0 1 0 0 0 0 0 0 1 0 0 0 1 0 0 1 1 0 0 0 ...
    1 0 1 1 1 0 1 0 1 1 0 1 1 0 0 0 0 0 1 1 0 ...
```

```
    0 1 1 0 1 0 1 0 0 1 1 1 0 0 1 1 1 1 0 1 1 ...
    0 1 0 0 0 0 1 0 1 0 1 0 1 1 1 1 1 0 1 0 0 ...
    1 0 1 0 0 0 1 1 0 1 1 1 0 0 0 1 1 1 1 1 1 1])';

pnSeq = comm.PNSequence( ...
    Polynomial=genPoly, ...
    InitialConditionsSource="Input Port", ...
    Mask=shift, ...
    SamplesPerFrame=spf, ...
    OutputDataType="logical");
pnsequence = pnSeq(initState);
```

Compare the PN sequence object output to the IEEE 802.11 127-bit scrambler sequence to confirm the generated PN sequence matches the 802.11 specified sequence.

```
isequal(ieee802_11_scram_seq,pnsequence)
```

```
ans = logical
   1
```

Scramble input data according to the 802.11 specified additive scrambler by modulo-adding input data with the PN sequence output.

```
scrambledOut = xor(dataIn,pnSeq(initState));
```

Descramble the scrambled data by applying the same scrambler and initial conditions to the scrambled data.

```
descrambledData = xor(scrambledOut,pnSeq(initState));
```

Verify that the descrambled data matches the input data.

```
isequal(dataIn,descrambledData)
```

```
ans = logical
   1
```

comm.DifferentialDecoder

Package: comm

Decode binary signal using differential decoding

Description

The DifferentialDecoder object decodes the binary input signal. The output is the logical difference between the consecutive input element within a channel.

To decode a binary signal using differential decoding:

1. Define and set up your differential decoder object. See “Construction” on page 3-320.
2. Call step to decode a binary signal according to the properties of comm.DifferentialDecoder. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

H = comm.DifferentialDecoder creates a differential decoder System object, H. This object decodes a binary input signal that was previously encoded using a differential encoder.

H = comm.DifferentialDecoder(Name,Value) creates object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

Properties

InitialCondition

Initial value used to generate initial output

Specify the initial condition as a real scalar. This property can have a logical, numeric, or fixed-point (embedded.fi object) data type. The default is 0. The object treats nonbinary values as binary signals.

Methods

step Decode binary signal using differential decoding

Common to All System Objects	
release	Allow System object property value changes
reset	Reset internal states of System object

Examples

Decode Differentially Encoded Signal

Create a differential encoder and decoder pair.

```
diffEnc = comm.DifferentialEncoder;
diffDec = comm.DifferentialDecoder;
```

Generate random binary data. Differentially encode and decode the data.

```
data = randi([0 1],100,1);
encData = diffEnc(data);
decData = diffDec(encData);
```

Determine the number of errors between the original data and the decoded data.

```
numErrors = biterr(data,decData)
```

```
numErrors = 0
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Differential Decoder block reference page. The object properties correspond to the block parameters, except:
The object only supports single channel, column vector inputs.

`comm.DifferentialEncoder`

step

System object: `comm.DifferentialDecoder`
Package: `comm`

Decode binary signal using differential decoding

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` decodes the differentially encoded input data, `X`, and returns the decoded data, `Y`. The input `X` must be a column vector of data type logical, numeric, or fixed-point (embedded.fi objects). `Y` has the same data type as `X`. The object treats non-binary inputs as binary signals. The object computes the initial output value by performing an Xor operation of the value in the `InitialCondition` property and the first element of the vector you input the first time you call the step method.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.DifferentialEncoder

Package: `comm`

Encode binary signal using differential coding

Description

The `DifferentialEncoder` object encodes the binary input signal within a channel. The output is the logical difference between the current input element and the previous output element.

To encode a binary signal using differential coding:

1. Define and set up your differential encoder object. See “Construction” on page 3-323.
2. Call `step` to encode a binary signal according to the properties of `comm.DifferentialEncoder`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.DifferentialEncoder` creates a differential encoder System object, `H`. This object encodes a binary input signal by calculating its logical difference with the previously encoded data.

`H = comm.DifferentialEncoder(Name,Value)` creates object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`InitialCondition`

Initial value used to generate initial output

Specify the initial condition as a real scalar. This property can have a logical, numeric, or fixed-point (embedded.fi object) data type. The default is `0`. The object treats nonbinary values as binary signals.

Methods

Encode binary signal using differential coding

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` encodes the binary input data, `X`, and returns the differentially encoded data, `Y`. The input `X` must be a column vector of data type logical, numeric, or fixed-point (embedded.fi objects). `Y` has the same data type as `X`. The object treats non-binary inputs as binary signals. The object computes the initial output value by performing an Xor operation of the value in the `InitialCondition` property and the first element of the vector you input the first time you call the step method.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.DiscreteTimeVCO

Package: comm

Generate variable frequency sinusoid

Description

The DiscreteTimeVCO (voltage-controlled oscillator) object generates a signal whose frequency shift from the quiescent frequency property is proportional to the input signal. The input signal is interpreted as a voltage.

To generate a variable frequency sinusoid:

1. Define and set up your discrete time voltage-controlled oscillator object. See “Construction” on page 3-326 .
2. Call step to generate a variable frequency sinusoid according to the properties of comm.DiscreteTimeVCO. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

H = comm.DiscreteTimeVCO creates a discrete-time voltage-controlled oscillator (VCO) System object, H. This object generates a sinusoidal signal with the frequency shifted from the specified quiescent frequency to a value proportional to the input signal.

H = comm.DiscreteTimeVCO(Name,Value) creates a discrete-time VCO object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

Properties

OutputAmplitude

Amplitude of output signal

Specify the amplitude of the output signal as a double- or single-precision, scalar value. The default is 1. This property is tunable.

QuiescentFrequency

Frequency of output signal when input is zero

Specify the quiescent frequency of the output signal in Hertz, as a double- or single-precision, real, scalar value. The default is 10. This property is tunable.

`Sensitivity`

Sensitivity of frequency shift of output signal

Specify the sensitivity of the output signal frequency shift to the input as a double- or single-precision, real, scalar value. The default is `1`. This value scales the input voltage and, consequently, the shift from the quiescent frequency value. The property measures Sensitivity in Hertz per volt. This property is tunable.

`InitialPhase`

Initial phase of output signal

Specify the initial phase of the output signal, in radians, as a double or single precision, real, scalar value. The default is `0`.

`SampleRate`

Sample rate of input

Specify the sample rate of the input, in Hertz, as a double- or single-precision, positive, scalar value. The default is `100`.

Methods

step Generate variable frequency sinusoid

Common to All System Objects	
`release`	Allow System object property value changes
`reset`	Reset internal states of System object

Examples

Generate FSK Signal Using Discrete Time VCO

Create a signal source System object™.

```
reader = dsp.SignalSource;
```

Generate random data and apply rectangular pulse shaping.

```
reader.Signal = randi([0 7],10,1);
reader.Signal = rectpulse(reader.Signal,100);
```

Create a signal logger and discrete time VCO System objects.

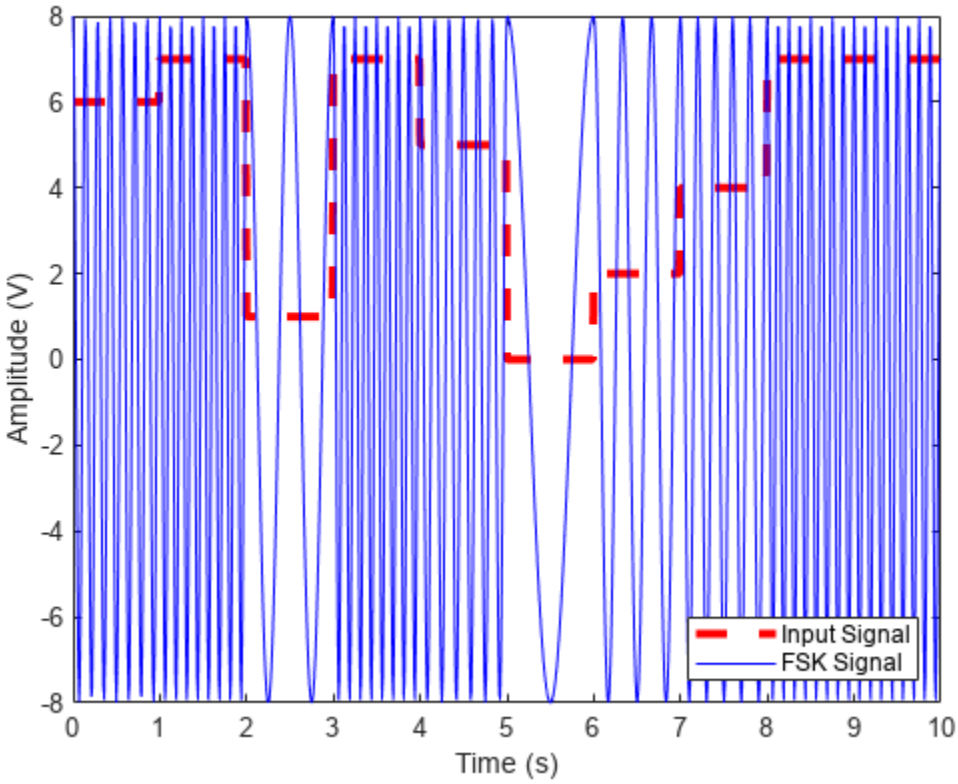
```
logger = dsp.SignalSink;
discreteVCO = comm.DiscreteTimeVCO( ...
    'OutputAmplitude',8, ...
    'QuiescentFrequency',1);
```

Generate an FSK signal.

```
while(~isDone(reader))
    sig = reader();
    y = discreteVCO(sig);
    logger(y);
end
oscsig = logger.Buffer;
```

Plot the generated FSK signal.

```
t = (0:length(oscsig)-1)'/discreteVCO.SampleRate;
plot(t,reader.Signal,'--r', 'LineWidth',3)
hold on
plot(t,oscsig,'-b');
hold off
xlabel('Time (s)')
ylabel('Amplitude (V)')
legend('Input Signal','FSK Signal','location','se')
```



Algorithms

This object implements the algorithm, inputs, and outputs as described on the Discrete-Time VCO block reference page. However, this object and the corresponding block may not generate the exact same outputs for single-precision inputs or property values due to the following differences in casting strategies and arithmetic precision issues:

- The block always casts the result of intermediate mathematical operations to the input data type. The object does not cast intermediate results and MATLAB decides the data type. The object casts the final output to the input data type.
- You can specify the `SampleRate` object property in single-precision or double-precision. The block does not allow this.
- In arithmetic operations with more than two operands with mixed data types, the result may differ depending on the order of operation. Thus, the following calculation may also contribute to the difference in the output of the block and the object:

  input * sensitivity * `sampleTime`
- The block performs this calculation from left to right. However, since sensitivity * `sampleTime` is a one-time calculation, the object calculates this in the following manner:

  input * (sensitivity * `sampleTime`)

`comm.CarrierSynchronizer`

step

System object: comm.DiscreteTimeVCO
Package: comm

Generate variable frequency sinusoid

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` generates a sinusoidal signal, `Y`, with frequency shifted, from the value you specify in the `QuiescentFrequency` property, to a value proportional to the input signal, `X`. The input, `X`, must be a double or single precision, real, scalar value. The output, `Y`, has the same data type and size as the input, `X`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.DPD

Package: comm

Digital predistorter

Description

The comm.DPD System object applies digital predistortion (DPD) to a complex baseband signal by using a memory polynomial to compensate for nonlinearities in a power amplifier. For more information, see “Digital Predistortion” on page 3-335.

To predistort signals:

1. Create the comm.DPD object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
dpd = comm.DPD
dpd = comm.DPD(Name,Value)
```

Description

dpd = comm.DPD creates a digital predistorter System object to predistort a signal.

dpd = comm.DPD(Name,Value) sets properties using one or more name-value pairs. For example, comm.DPD('PolynomialType','Cross-term memory polynomial') configures the predistorter System object to predistort the input signal by using a memory polynomial with cross terms. Enclose each property name in quotes.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

PolynomialType — Polynomial type

'Memory polynomial' (default) | 'Cross-term memory polynomial'

Polynomial type used for predistortion, specified as one of these values:

- `'Memory polynomial'` — Predistorts the input signal by using a memory polynomial without cross terms.
- `'Cross-term memory polynomial'` — Predistorts the input signal by using a memory polynomial with cross terms.

For more information, see “Digital Predistortion” on page 3-335.

`Coefficients` — Memory-polynomial coefficients
`complex([1 0 0 0 0; 0 0 0 0 0; 0 0 0 0 0])` (default) | matrix

Memory-polynomial coefficients, specified as a matrix. The number of rows in the matrix must equal the memory depth of the memory polynomial.

- If `PolynomialType` is `'Memory polynomial'`, the number of columns in the matrix is the degree of the memory polynomial.
- If `PolynomialType` is `'Cross-term memory polynomial'`, the number of columns in the matrix must equal $m(n\text{-}1)+1$. m is the memory depth of the polynomial, and n is the degree of the memory polynomial.

For more information, see “Digital Predistortion” on page 3-335.

Data Types: `double`
Complex Number Support: Yes

Usage

Syntax

```
out = dpd(in)
```

Description

`out = dpd(in)` predistorts a complex baseband signal by using a memory polynomial to compensate for nonlinearities in a power amplifier.

Input Arguments

`in` — Input baseband signal
column vector

Input baseband signal, specified as a column vector.

Data Types: `double`
Complex Number Support: Yes

Output Arguments

`out` — Predistorted baseband signal
column vector

Predistorted baseband signal, returned as a column vector of the same length as the input signal.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Predistort Power Amplifier Input Signal

Apply digital predistortion (DPD) to a power amplifier input signal. The DPD coefficient estimator System object uses a captured signal containing power amplifier input and output signals to determine the predistortion coefficient matrix.

Load a file containing the input and output signals for the power amplifier.

```
load('commpowamp_dpd_data.mat','PA_input','PA_output')
```

Generate a DPD coefficient estimator System object and a raised cosine transmit filter System object.

```
estimator = comm.DPDCoefficientEstimator( ...
    'DesiredAmplitudeGaindB',10, ...
    'PolynomialType','Memory polynomial', ...
    'Degree',5,'MemoryDepth',3,'Algorithm','Least squares');

rctFilt = comm.RaisedCosineTransmitFilter('OutputSamplesPerSymbol',2);
```

Estimate the digital predistortion memory-polynomial coefficients.

```
coef = estimator(PA_input,PA_output);
```

Generate a DPD System object using `coef`, the estimated coefficients output from the DPD coefficient estimator, as for the coefficient matrix.

```
dpd = comm.DPD('PolynomialType','Memory polynomial', ...
    'Coefficients',coef);
```

Generate 2000 random symbols and apply 16-QAM modulation to the signal. Apply raised cosine transmit filtering to the modulated signal.

```
s = randi([0,15],2000,1);
u = qammod(s,16);
x = rctFilt(u);
```

Apply digital predistortion to the data. The DPD System object returns a predistorted signal to provide as input to the power amplifier.

```
y = dpd(x);
```

Format of Coefficient Matrix for Digital Predistortion Memory Polynomial

This example shows the format of the coefficient matrix for the DPD memory polynomial by using a randomly generated coefficient matrix. Steps in the example include:

- Creation of a digital predistorter System object configured using a memory polynomial coefficient matrix with the memory depth set to 3 and the polynomial degree set to 5 consisting of random values.
- Predistortion of a signal using the memory-polynomial coefficient matrix.
- Comparison of one predistorted output element to the corresponding input element that has been manually computed using the memory-polynomial coefficient matrix.

Create a coefficient matrix representing a predistorter with the output equal to the input by generating a 3-by-5 coefficient matrix of zeros and setting the `coef(1,1)` element to `1`. Add small random complex nonlinear terms to the coefficient matrix.

```
coef = zeros(3,5);
coef(1,1) = 1;
coef = coef + 0.01*(randn(3,5)+1j*randn(3,5));
```

Create a DPD System object using the memory polynomial coefficient matrix, `coef`.

```
dpd = comm.DPD( ...
    'PolynomialType','Memory polynomial', ...
    'Coefficients',coef);
```

Generate an input signal and predistort it using the `dpd` System object.

```
x = randn(20,1) + 1j*randn(20,1);
y = dpd(x);
```

Compare the manually distorted output for an input corresponding output element `y(18)` to show how the coefficient matrix is used to calculate that particular output value.

```
u = x(18:-1:(18-3+1));
isequal(y(18),sum(sum(coef .* ...
    [u u.*abs(u) u.*(abs(u).^2) u .* (abs(u).^3) u .* (abs(u).^4)])))
```

```
ans = logical
   1
```

Format of Cross-Term Coefficient Matrix for Digital Predistortion Memory Polynomial

This example shows the format of the coefficient matrix for the DPD memory polynomial by using a randomly generated coefficient matrix. Steps in the example include:

- Creation of a digital predistorter System object configured using a cross-term memory polynomial coefficient matrix with the memory depth set to 3 and the polynomial degree set to 5 consisting of random values.

- Predistortion of a signal using the cross-term memory polynomial coefficient matrix.
- Comparison of one predistorted output element to the corresponding input element that has been manually computed using the cross-term memory polynomial coefficient matrix.

Create a coefficient matrix representing a predistorter with the output equal to the input by generating a 3-by-5 coefficient matrix of zeros and setting the `coef(1,1)` element to `1`. Add small random complex nonlinear terms to the coefficient matrix.

```
coef = zeros(3,3*(5-1)+1);
coef(1,1) = 1;
coef = coef + 0.01*(randn(3,13) + 1j*randn(3,13));
```

Create a DPD System object using the cross-term memory polynomial coefficient matrix, `coef`.

```
dpd = comm.DPD( ...
    'PolynomialType','Cross-term memory polynomial', ...
    'Coefficients',coef);
```

Generate an input signal and predistort it using the `dpd` System object.

```
x = randn(20,1) + 1j*randn(20,1);
y = dpd(x);
```

Compare the manually distorted output for an input corresponding output element `y(18)` to show how the coefficient matrix is used to calculate that particular output value.

```
u = x(18:-1:(18-3+1));
isequal(y(18),sum(sum(coef .* ...
    [u u*abs(u.') u*(abs(u.').^2) u*(abs(u.').^3) u*(abs(u.').^4)])))
```

```
ans = logical
   1
```

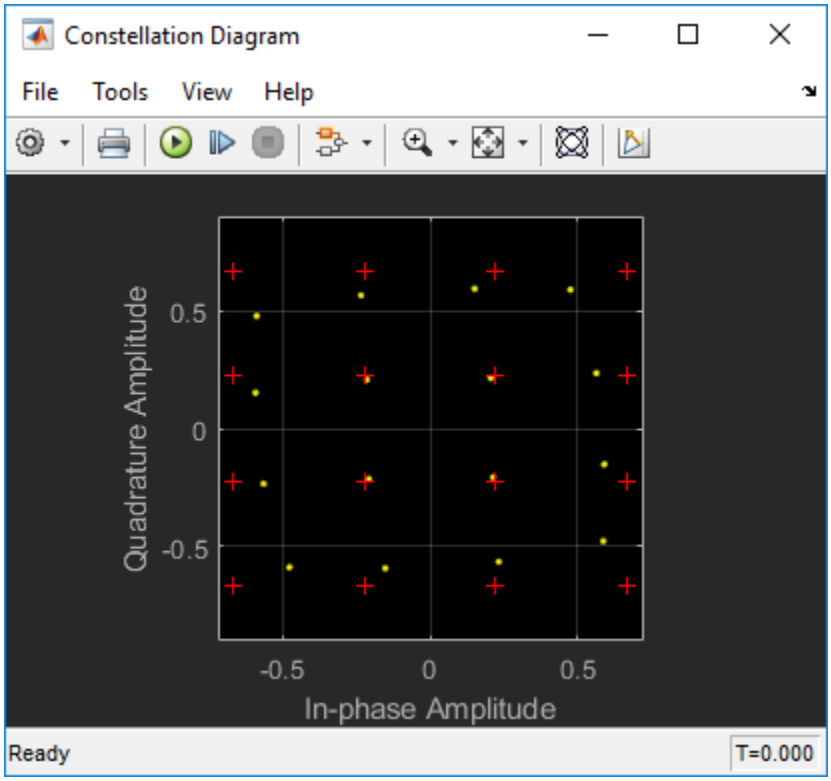
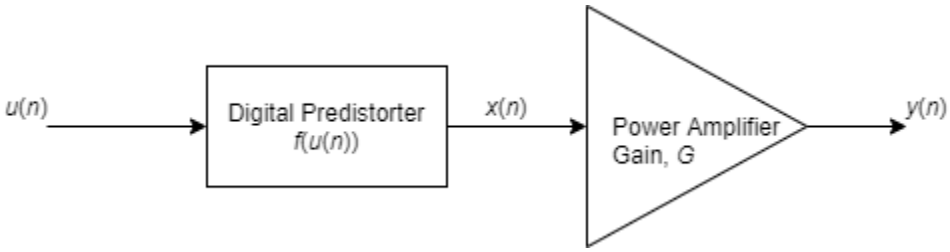
More About

Digital Predistortion

Wireless communication transmissions commonly require wide bandwidth signal transmission over a wide signal dynamic range. To transmit signals over a wide dynamic range and achieve high efficiency, RF power amplifiers (PAs) commonly operate in their nonlinear region. As this constellation diagram shows, the nonlinear behavior of a PA causes signal constellation distortions that pinch the amplitude (AM-AM distortion) and twist phase (AM-PM distortion) of constellation points proportional to the amplitude of the constellation point.



The goal of digital predistortion is to find a nonlinear function that linearizes the net effect of the PA nonlinear behavior at the PA output across the PA operating range. When the PA input is $x(n)$, and the predistortion function is $f(u(n))$, where $u(n)$ is the true signal to be amplified, the PA output is approximately equal to $G \times u(n)$, where G is the desired amplitude gain of the PA.



The digital predistorter can be configured to use a memory polynomial with or without cross terms.

- The memory polynomial with cross terms predistorts the input signal as

$$x(n) = f(u(n)) \triangleq \sum_{m=0}^{M-1} c_m \times u(n\text{-}m) + \sum_{m=0}^{M-1} \sum_{j=0}^{M-1} \sum_{k=0}^{K-1} a_{mjk} \times u(n\text{-}m) \times \left| u(n\text{-}j) \right|^k .$$

  The memory polynomial with cross terms has $(M+M \times M \times (K\text{-}1))$ coefficients for c_m and a_{mjk}.
- The memory polynomial without cross terms predistorts the input signal as

$$x(n) = f(u(n)) \triangleq \sum_{m=0}^{M-1} \sum_{k=0}^{K-1} a_{mk} \times u(n\text{-}m) \times \left| u(n\text{-}m) \right|^k .$$

The polynomial without cross terms has $M \times K$ coefficients for a_{mk}.

Estimating Predistortion Function and Coefficients

The DPD coefficient estimation uses an indirect learning architecture to find function $f(u(n))$ to predistort input signal $u(n)$ which precedes the PA input.

The DPD coefficient estimation algorithm models nonlinear PA memory effects based on the work in reference papers by Morgan, et al [1], and by Schetzen [2], using the theoretical foundation developed for Volterra systems.

Specifically, the inverse mapping from the PA output normalized by the PA gain, $\{y(n)/G\}$, to the PA input, $\{x(n)\}$, provides a good approximation to the function $f(u(n))$, needed to predistort $\{u(n)\}$ to produce $\{x(n)\}$.

Referring to the memory polynomial equations above, estimates are computed for the memory-polynomial coefficients:

- c_m and a_{mjk} for a memory polynomial with cross terms
- a_{mk} for a memory polynomial without cross terms

The memory-polynomial coefficients are estimated by using a least squares fit algorithm or a recursive least squares algorithm. The least squares fit algorithm or a recursive least squares algorithms use the memory polynomial equations above for a memory polynomial with or without cross terms, by replacing $\{u(n)\}$ with $\{y(n)/G\}$. The function order and dimension of the coefficient matrix are defined by the degree and depth of the memory polynomial.

For an example that details the process of accurately estimating memory-polynomial coefficients and predistorting a PA input signal, see “Digital Predistortion to Compensate for Power Amplifier Nonlinearities”.

For background reference material, see the works listed in [1] and [2].

comm.DPDCoefficientEstimator

Package: `comm`

Estimate memory-polynomial coefficients for digital predistortion

Description

The `comm.DPDCoefficientEstimator` System object estimates the coefficients of a memory polynomial for digital pre-distortion (DPD) of a nonlinear power amplifier, given the baseband equivalent input and baseband equivalent output of the power amplifier. For more information, see “Digital Predistortion” on page 3-345.

To compute predistortion coefficients:

1. Create the `comm.DPDCoefficientEstimator` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
estimator = comm.DPDCoefficientEstimator
estimator = comm.DPDCoefficientEstimator(Name,Value)
```

Description

`estimator = comm.DPDCoefficientEstimator` creates a digital predistortion coefficient estimator System object to estimate the coefficients of a memory polynomial for digital predistortion (DPD) of a nonlinear power amplifier.

`estimator = comm.DPDCoefficientEstimator(Name,Value)` sets properties using one or more name-value pairs. For example, `comm.DPDCoefficientEstimator('PolynomialType','Cross-term memory polynomial')` configures the predistortion coefficient estimator System object to estimate the coefficients for a memory-polynomial with cross terms. Enclose each property name in quotes.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`DesiredAmplitudeGaindB` — Desired amplitude gain
`10` (default) | scalar

Desired amplitude gain in dB, specified as a scalar. This property value expresses the desired signal gain at the compensated amplifier output.

In addition to linearization, the DPD should make the combined gain between the DPD input and the power amplifier output as close as possible to the expected gain. Therefore, set this property based on the expected gain of the power amplifier that you obtain during PA characterization.

Tunable: Yes

Data Types: `double`

`PolynomialType` — Polynomial type
`'Memory polynomial'` (default) | `'Cross-term memory polynomial'`

Polynomial type used for predistortion, specified as one of these values:

- `'Memory polynomial'` — Computes predistortion coefficients by using a memory polynomial without cross terms
- `'Cross-term memory polynomial'` — Computes predistortion coefficients by using a memory polynomial with cross terms

For more information, see “Digital Predistortion” on page 3-345.

`Degree` — Memory-polynomial degree
`5` (default) | positive integer

Memory-polynomial degree, specified as a positive integer.

Data Types: `double`

`MemoryDepth` — Memory-polynomial depth
`3` (default) | positive integer

Memory-polynomial depth in samples, specified as a positive integer.

Data Types: `double`

`Algorithm` — Estimation algorithm
`'Least squares'` (default) | `'Recursive least squares'`

Adaptive algorithm used for equalization, specified as one of these values:

- `'Least squares'` — Estimate the memory polynomial coefficients by using a least squares algorithm
- `'Recursive least squares'` — Estimate the memory polynomial coefficients by using a recursive least squares algorithm

For algorithm reference material, see the works listed in [1] and [2].

Data Types: `char` | `string`

`ForgettingFactor` — Forgetting factor
`0.99` (default) | scalar in the range (0, 1]

Forgetting factor used by the recursive least squares algorithm, specified as a scalar in the range (0, 1]. Decreasing the forgetting factor reduces the convergence time but causes the output estimates to be less stable.

Tunable: Yes

Dependencies

To enable this property, set Algorithm to `'Recursive least squares'`.

Data Types: `double`

`InitialCoefficientEstimate` — Initial coefficient estimate

`[ ]` (default) | matrix

Initial coefficient estimate for the recursive least squares algorithm, specified as a matrix.

- If `InitialCoefficientEstimate` is an empty matrix, the initial coefficient estimate for the recursive least squares algorithm is chosen automatically to correspond to a memory polynomial that is an identity function, so that the output is equal to input.
- If `InitialCoefficientEstimate` is a nonempty matrix, the number of rows must be equal to `MemoryDepth`.
  - If `PolynomialType` is `'Memory polynomial'`, the number of columns is the degree of the memory polynomial.
  - If `PolynomialType` is `'Cross-term memory polynomial'`, the number of columns must equal $m(n\text{-}1)+1$. m is the memory depth of the polynomial, and n is the degree of the memory polynomial.

For more information, see “Digital Predistortion” on page 3-345.

Dependencies

To enable this property, set Algorithm to `'Recursive least squares'`.

Data Types: `double`
Complex Number Support: Yes

Usage

Syntax

```
coef = estimator(paIn,paOut)
```

Description

`coef = estimator(paIn,paOut)` estimates the coefficients of a memory polynomial for use by the `comm.DPD` System object to predistort a complex baseband signal by using a memory-polynomial to compensate for nonlinearities in a power amplifier.

Input Arguments

`paIn` — Power amplifier baseband equivalent input

column vector

Power amplifier baseband equivalent input, specified as a column vector.

Data Types: `double`
Complex Number Support: Yes

`paOut` — Power amplifier baseband equivalent output
column vector

Power amplifier baseband equivalent output, specified as a column vector of the same length as `paIn`.

Data Types: `double`
Complex Number Support: Yes

Output Arguments

`coef` — Memory-polynomial coefficients
matrix

Memory-polynomial coefficients, returned as a matrix. For more information, see “Digital Predistortion” on page 3-345.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Predistort Power Amplifier Input Signal

Apply digital predistortion (DPD) to a power amplifier input signal. The DPD coefficient estimator System object uses a captured signal containing power amplifier input and output signals to determine the predistortion coefficient matrix.

Load a file containing the input and output signals for the power amplifier.

```
load('commpowamp_dpd_data.mat','PA_input','PA_output')
```

Generate a DPD coefficient estimator System object and a raised cosine transmit filter System object.

```
estimator = comm.DPDCoefficientEstimator( ...
    'DesiredAmplitudeGaindB',10, ...
    'PolynomialType','Memory polynomial', ...
    'Degree',5,'MemoryDepth',3,'Algorithm','Least squares');
```

```
rctFilt = comm.RaisedCosineTransmitFilter('OutputSamplesPerSymbol',2);
```

Estimate the digital predistortion memory-polynomial coefficients.

```
coef = estimator(PA_input,PA_output);
```

Generate a DPD System object using `coef`, the estimated coefficients output from the DPD coefficient estimator, as for the coefficient matrix.

```
dpd = comm.DPD('PolynomialType','Memory polynomial', ...
    'Coefficients',coef);
```

Generate 2000 random symbols and apply 16-QAM modulation to the signal. Apply raised cosine transmit filtering to the modulated signal.

```
s = randi([0,15],2000,1);
u = qammod(s,16);
x = rctFilt(u);
```

Apply digital predistortion to the data. The DPD System object returns a predistorted signal to provide as input to the power amplifier.

```
y = dpd(x);
```

Format of Coefficient Matrix for Digital Predistortion Memory Polynomial

This example shows the format of the coefficient matrix for the DPD memory polynomial by using a randomly generated coefficient matrix. Steps in the example include:

- Creation of a digital predistorter System object configured using a memory polynomial coefficient matrix with the memory depth set to 3 and the polynomial degree set to 5 consisting of random values.
- Predistortion of a signal using the memory-polynomial coefficient matrix.
- Comparison of one predistorted output element to the corresponding input element that has been manually computed using the memory-polynomial coefficient matrix.

Create a coefficient matrix representing a predistorter with the output equal to the input by generating a 3-by-5 coefficient matrix of zeros and setting the `coef(1,1)` element to `1`. Add small random complex nonlinear terms to the coefficient matrix.

```
coef = zeros(3,5);
coef(1,1) = 1;
coef = coef + 0.01*(randn(3,5)+1j*randn(3,5));
```

Create a DPD System object using the memory polynomial coefficient matrix, `coef`.

```
dpd = comm.DPD( ...
    'PolynomialType','Memory polynomial', ...
    'Coefficients',coef);
```

Generate an input signal and predistort it using the `dpd` System object.

```
x = randn(20,1) + 1j*randn(20,1);
y = dpd(x);
```

Compare the manually distorted output for an input corresponding output element `y(18)` to show how the coefficient matrix is used to calculate that particular output value.

```
u = x(18:-1:(18-3+1));
isequal(y(18),sum(sum(coef .* ...
    [u u.*abs(u) u.*(abs(u).^2) u .* (abs(u).^3) u .* (abs(u).^4)])))
```

```
ans = logical
   1
```

Format of Cross-Term Coefficient Matrix for Digital Predistortion Memory Polynomial

This example shows the format of the coefficient matrix for the DPD memory polynomial by using a randomly generated coefficient matrix. Steps in the example include:

isequal(y(18),sum(sum(coef .* ...
    [u u*abs(u.') u*(abs(u.').^2) u*(abs(u.').^3) u*(abs(u.').^4)])))
```

```
ans = logical
   1
```

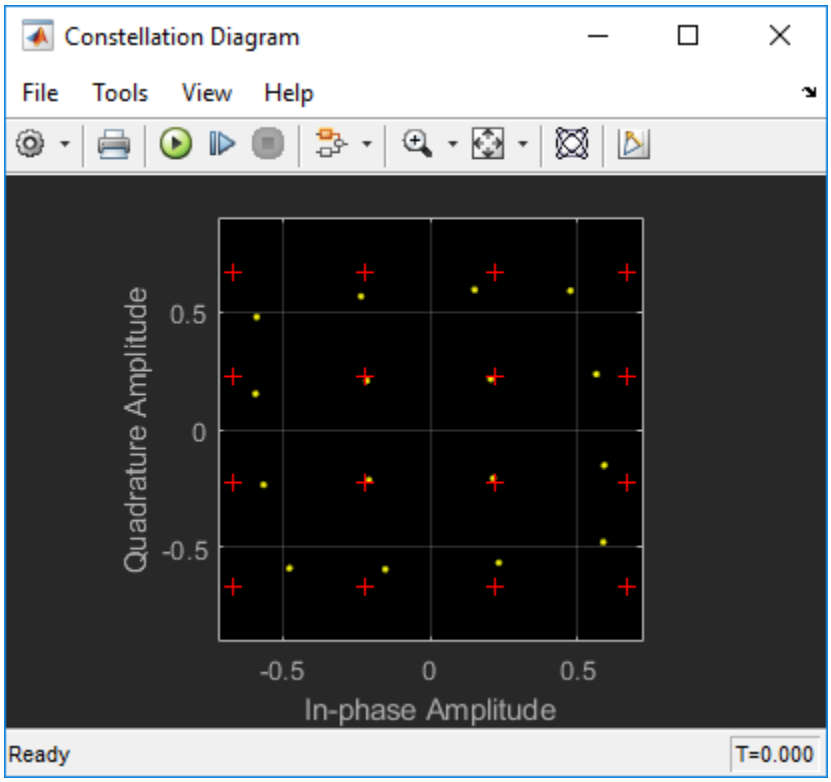
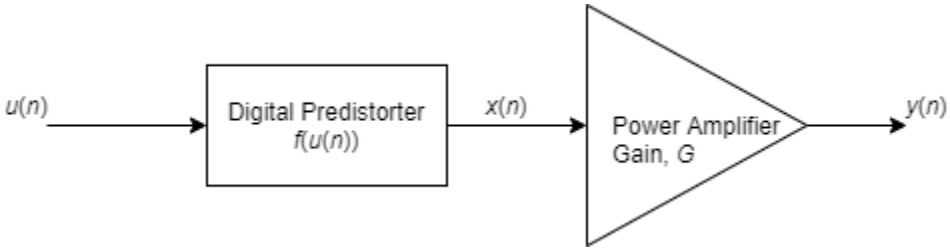
More About

Digital Predistortion

Wireless communication transmissions commonly require wide bandwidth signal transmission over a wide signal dynamic range. To transmit signals over a wide dynamic range and achieve high efficiency, RF power amplifiers (PAs) commonly operate in their nonlinear region. As this constellation diagram shows, the nonlinear behavior of a PA causes signal constellation distortions that pinch the amplitude (AM-AM distortion) and twist phase (AM-PM distortion) of constellation points proportional to the amplitude of the constellation point.



The goal of digital predistortion is to find a nonlinear function that linearizes the net effect of the PA nonlinear behavior at the PA output across the PA operating range. When the PA input is $x(n)$, and the predistortion function is $f(u(n))$, where $u(n)$ is the true signal to be amplified, the PA output is approximately equal to $G \times u(n)$, where G is the desired amplitude gain of the PA.



The digital predistorter can be configured to use a memory polynomial with or without cross terms.

- The memory polynomial with cross terms predistorts the input signal as

$$x(n) = f(u(n)) \triangleq \sum_{m=0}^{M-1} c_m \times u(n\text{-}m) + \sum_{m=0}^{M-1} \sum_{j=0}^{M-1} \sum_{k=0}^{K-1} a_{mjk} \times u(n\text{-}m) \times \left|u(n\text{-}j)\right|^k .$$

  The memory polynomial with cross terms has $(M+M\times M\times (K\text{-}1))$ coefficients for c_m and a_{mjk}.
- The memory polynomial without cross terms predistorts the input signal as

$$x(n) = f(u(n)) \triangleq \sum_{m=0}^{M-1} \sum_{k=0}^{K-1} a_{mk} \times u(n\text{-}m) \times \left|u(n\text{-}m)\right|^k .$$

  The polynomial without cross terms has $M\times K$ coefficients for a_{mk}.

Estimating Predistortion Function and Coefficients

The DPD coefficient estimation uses an indirect learning architecture to find function $f(u(n))$ to predistort input signal $u(n)$ which precedes the PA input.

The DPD coefficient estimation algorithm models nonlinear PA memory effects based on the work in reference papers by Morgan, et al [1], and by Schetzen [2], using the theoretical foundation developed for Volterra systems.

Specifically, the inverse mapping from the PA output normalized by the PA gain, $\{y(n)/G\}$, to the PA input, $\{x(n)\}$, provides a good approximation to the function $f(u(n))$, needed to predistort $\{u(n)\}$ to produce $\{x(n)\}$.

Referring to the memory polynomial equations above, estimates are computed for the memory-polynomial coefficients:

- c_m and a_{mjk} for a memory polynomial with cross terms
- a_{mk} for a memory polynomial without cross terms

The memory-polynomial coefficients are estimated by using a least squares fit algorithm or a recursive least squares algorithm. The least squares fit algorithm or a recursive least squares algorithms use the memory polynomial equations above for a memory polynomial with or without cross terms, by replacing $\{u(n)\}$ with $\{y(n)/G\}$. The function order and dimension of the coefficient matrix are defined by the degree and depth of the memory polynomial.

For an example that details the process of accurately estimating memory-polynomial coefficients and predistorting a PA input signal, see “Digital Predistortion to Compensate for Power Amplifier Nonlinearities”.

Demodulate using M-ary DPSK method

Description

The DPSKDemodulator object demodulates a signal that was modulated using the M-ary differential phase shift keying method. The input is a baseband representation of the modulated signal. The input and output for this object are discrete-time signals. This object accepts a scalar-valued or column vector input signal.

To demodulate a signal that was modulated using differential phase shift keying:

1. Define and set up your DPSK modulator object. See “Construction” on page 3-348.
2. Call step to demodulate a signal according to the properties of DPSKDemodulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

H = comm.DPSKDemodulator creates a demodulator System object, H. This object demodulates the input signal using the *M*-ary differential phase shift keying (M-DPSK) method.

H = comm.DPSKDemodulator(Name,Value) creates an M-DPSK demodulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.DPSKDemodulator(M,PHASE,Name,Value) creates an M-DPSK demodulator object, H. This object has the ModulationOrder property set to M, the PhaseRotation property set to PHASE, and the other specified properties set to the specified values.

Properties

ModulationOrder

Number of points in signal constellation

Specify the number of points in the signal constellation as a positive, integer scalar value. The default is 8.

PhaseRotation

Additional phase shift

Specify the additional phase difference between previous and current modulated symbols in radians as a real scalar value. The default is `pi/8`. This value corresponds to the phase difference between previous and current modulated symbols when the input is zero.

`BitOutput`

Output data as bits

Specify whether the output consists of groups of bits or integer symbol values. The default is `false`. When you set this property to `true` the `step` method outputs a column vector of bit values. The length of this column vector is equal to **log2**(`ModulationOrder` on page 3-0) times the number of demodulated symbols.

When you set this property to `false`, the `step` method outputs a column vector. The length of this column vector is equal to that of the input data vector. The output contains integer symbol values between `0` and `ModulationOrder`-`1`.

`SymbolMapping`

Constellation encoding

Specify how the object maps an integer or group of **log2**(`ModulationOrder` on page 3-0) bits to the corresponding symbol as one of `Binary` | `Gray`. The default is `Gray`. When you set this property to `Gray`, the object uses a Gray-encoded signal constellation. When you set this property to `Binary`, the input integer m, between ($0 \le m \le$ `ModulationOrder`–1) maps to the current symbol. This mapping uses **exp**($j\times$`PhaseRotation` + $j\times 2 \times \pi \times$m/ModulationOrder)×(previously modulated symbol).

`OutputDataType`

Data type of output

Specify the output data type as one of `Full precision` | `Smallest unsigned integer` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32`. The default is `Full precision`. When you set this property to `Full precision`, the input data type is single or double precision, the output data is the same as that of the input. When you set the `BitOutput` on page 3-0 property to true, `logical` data type becomes a valid option.

Methods

step Demodulate using M-ary DPSK method

Common to All System Objects	
`release`	Allow System object property value changes
`reset`	Reset internal states of System object

Examples

8-DPSK Signal in AWGN

Create a DPSK modulator and demodulator pair. Create an AWGN channel object having three bits per symbol.

```
dpskmod = comm.DPSKModulator(8,pi/8,'BitInput',true);
dpskdemod = comm.DPSKDemodulator(8,pi/8,'BitOutput',true);
channel = comm.AWGNChannel('EbNo',10,'BitsPerSymbol',3);
```

Create an error rate calculator. Set the `ComputationDelay` property to `1` to account for the one bit transient caused by the differential modulation

```
errorRate = comm.ErrorRate('ComputationDelay',1);
```

Main processing loop steps:

- Generate 50 3-bit frames
- 8-DPSK modulate
- Pass through AWGN channel
- 8-DPSK demodulate
- Collect error statistics

```
for counter = 1:100
    txData = randi([0 1],150,1);
    modSig = dpskmod(txData);
    rxSig = channel(modSig);
    rxData = dpskdemod(rxSig);
    errorStats = errorRate(txData,rxData);
end
```

Display the error statistics.

```
ber = errorStats(1)
```

```
ber = 0.0098
```

```
numErrors = errorStats(2)
```

```
numErrors = 147
```

```
numBits = errorStats(3)
```

```
numBits = 14999
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the M-DPSK Demodulator Baseband block reference page. The object properties correspond to the block parameters.

`comm.DPSKModulator` | `comm.DBPSKDemodulator` | `comm.DQPSKDemodulator`

step

System object: `comm.DPSKDemodulator`
Package: `comm`

Demodulate using M-ary DPSK method

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` demodulates input data, `X`, with the DPSK demodulator System object, `H`, and returns `Y`. Input `X` must be a double or single precision data type scalar or column vector. Depending on the `BitOutput` property value, output `Y` can be integer or bit valued.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.DPSKModulator

Package: comm

Modulate using M-ary DPSK method

Description

The DPSKModulator object modulates using the M-ary differential phase shift keying method. The output is a baseband representation of the modulated signal.

To modulate a signal using differential phase shift keying:

1. Define and set up your DPSK modulator object. See “Construction” on page 3-353.
2. Call step to modulate a signal according to the properties of comm.DPSKModulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

H = comm.DPSKModulator creates a modulator System object, H. This object modulates the input signal using the M-ary differential phase shift keying (M-DPSK) method.

H = comm.DPSKModulator(Name,Value) creates an M-DPSK modulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.DPSKModulator(M,PHASE,Name,Value) creates an M-DPSK modulator object, H. This object has the ModulationOrder property set to M, the PhaseRotation property set to PHASE, and the other specified properties set to the specified values.

Properties

ModulationOrder

Number of points in signal constellation

Specify the number of points in the signal constellation as a positive, integer scalar value. The default is 8.

PhaseRotation

Additional phase shift

Specify the additional phase difference between previous and current modulated symbols in radians as a real scalar value. The default is `pi/8`. This value corresponds to the phase difference between previous and current modulated symbols when the input is zero.

`BitInput`

Assume bit inputs

Specify whether the input is bits or integers. The default is `false`. When you set this property to `true`, the `step` method input must be a column vector of bit values whose length is an integer multiple of **log2**(`ModulationOrder` on page 3-0). This vector contains bit representations of integers between `0` and `ModulationOrder`–`1`. When you set this property to `false`, the `step` method input requires a column vector of integer symbol values between `0` and `ModulationOrder`–`1`.

`SymbolMapping`

Constellation encoding

Specify how the object maps an integer or group of **log2**(`ModulationOrder` on page 3-0) input bits to the corresponding symbol as one of `Binary` | `Gray`. The default is `Gray`. When you set this property to `Gray`, the object uses a Gray-encoded signal constellation. When you set this property to `Binary`, the input integer m, between ($0 \le m \le$ `ModulationOrder`–1) shifts the output phase. This shift is (`PhaseRotation` on page 3-0 $+ 2 \times \pi \times m/$`ModulationOrder`) radians from the previous output phase. The output symbol uses **exp**($j\times$`PhaseRotation` + $j\times 2 \times \pi \times$m/ModulationOrder)$\times$ (previously modulated symbol).

`OutputDataType`

Data type of output

Specify output data type as one of `double` | `single`. The default is `double`.

Methods

step Modulate using M-ary DPSK method

Common to All System Objects	
`release`	Allow System object property value changes
`reset`	Reset internal states of System object

Examples

8-DPSK Signal in AWGN

Create a DPSK modulator and demodulator pair. Create an AWGN channel object having three bits per symbol.

```
dpskmod = comm.DPSKModulator(8,pi/8,'BitInput',true);
dpskdemod = comm.DPSKDemodulator(8,pi/8,'BitOutput',true);
channel = comm.AWGNChannel('EbNo',10,'BitsPerSymbol',3);
```

Create an error rate calculator. Set the `ComputationDelay` property to `1` to account for the one bit transient caused by the differential modulation

```
errorRate = comm.ErrorRate('ComputationDelay',1);
```

Main processing loop steps:

- Generate 50 3-bit frames
- 8-DPSK modulate
- Pass through AWGN channel
- 8-DPSK demodulate
- Collect error statistics

```
for counter = 1:100
    txData = randi([0 1],150,1);
    modSig = dpskmod(txData);
    rxSig = channel(modSig);
    rxData = dpskdemod(rxSig);
    errorStats = errorRate(txData,rxData);
end
```

Display the error statistics.

```
ber = errorStats(1)
```

```
ber = 0.0098
```

```
numErrors = errorStats(2)
```

```
numErrors = 147
```

```
numBits = errorStats(3)
```

```
numBits = 14999
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the M-DPSK Modulator Baseband block reference page. The object properties correspond to the block parameters.

step

System object: `comm.DPSKModulator`
Package: `comm`

Modulate using M-ary DPSK method

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` modulates input data, `X`, with the DPSK modulator System object, `H`. It returns the baseband modulated output, `Y`. Depending on the value of the `BitInput` property, input `X` can be an integer or bit valued column vector with numeric or logical data types.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.DQPSKDemodulator

Package: comm

Demodulate using DQPSK method

Description

The DQPSKDemodulator object demodulates a signal that was modulated using the differential quadrature phase shift keying method. The input is a baseband representation of the modulated signal.

To demodulate a signal that was modulated using differential quadrature phase shift keying:

1. Define and set up your DQPSK modulator object. See “Construction” on page 3-358.
2. Call step to demodulate a signal according to the properties of DQPSKDemodulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

H = comm.DQPSKDemodulator creates a demodulator System object, H. This object demodulates the input signal using the differential quadrature phase shift keying (DQPSK) method.

H = comm.DQPSKDemodulator(Name,Value) creates a DQPSK demodulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.DQPSKDemodulator(PHASE,Name,Value) creates a DQPSK demodulator object, H. This object has the PhaseRotation property set to PHASE and the other specified properties set to the specified values.

Properties

PhaseRotation

Additional phase shift

Specify the additional phase difference between previous and current modulated symbols in radians as a real scalar. The default is pi/4. This value corresponds to the phase difference between previous and current modulated symbols when the input is zero.

BitOutput

Output data as bits

Specify whether the output consists of groups of bits or integer symbol values. The default is `false`. When you set this property to `true` the `step` method outputs a column vector of bit values with length equal to twice the number of demodulated symbols. When you set this property to `false`, the `step` method outputs a column vector, of length equal to the input data vector, that contains integer symbol values between `0` and `3`.

`SymbolMapping`

Constellation encoding

Specify how the object maps an integer or group of 2 bits to the corresponding symbol as one of `Binary` | `Gray`. The default is `Gray`. When you set this property to `Gray`, the object uses a Gray-encoded signal constellation. When you set this property to `Binary`, the integer m, between $0 \le m \le 3$ maps to the current symbol as **exp**($j\times$`PhaseRotation` on page 3-0 $+ j\times 2 \times \pi \times {}^{m}/_{4}) \times$ (previously modulated symbol).

`OutputDataType`

Data type of output

Specify the output data type as one of `Full precision` | `Smallest unsigned integer` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32`. The default is `Full precision`. When you set this property to `Full precision` the output has the same data type as that of the input. In this case, the input data type is single- or double-precision value. When you set the `BitOutput` on page 3-0 property to `true`, `logical` data type becomes a valid option.

Methods

step Demodulate using DQPSK method

Common to All System Objects	
`release`	Allow System object property value changes
`reset`	Reset internal states of System object

Examples

DQPSK Signal in AWGN

Create a DQPSK modulator and demodulator pair. Create an AWGN channel object having two bits per symbol.

```
dqpskmod = comm.DQPSKModulator('BitInput',true);
dqpskdemod = comm.DQPSKDemodulator('BitOutput',true);
channel = comm.AWGNChannel('EbNo',6,'BitsPerSymbol',2);
```

Create an error rate calculator. Set the `ComputationDelay` property to `1` to account for the one bit transient caused by the differential modulation

```
errorRate = comm.ErrorRate('ComputationDelay',1);
```

Main processing loop steps:

- Generate 50 2-bit frames
- 8-DPSK modulate
- Pass through AWGN channel
- 8-DPSK demodulate
- Collect error statistics

```
for counter = 1:100
    txData = randi([0 1],100,1);
    modSig = dqpskmod(txData);
    rxSig = channel(modSig);
    rxData = dqpskdemod(rxSig);
    errorStats = errorRate(txData,rxData);
end
```

Display the error statistics.

```
ber = errorStats(1)
```

```
ber = 0.0170
```

```
numErrors = errorStats(2)
```

```
numErrors = 170
```

```
numBits = errorStats(3)
```

```
numBits = 9999
```

Algorithms

step

System object: `comm.DQPSKDemodulator`
Package: `comm`

Demodulate using DQPSK method

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` demodulates input data, `X`, with the DQPSK demodulator System object, `H`, and returns `Y`. Input `X` must be a single or double precision data type scalar or column vector. Depending on the `BitOutput` property value, output `Y` can be integer or bit valued.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.DQPSKModulator

Package: comm

Modulate using DQPSK method

Description

The DQPSKModulator object modulates using the differential quadrature phase shift keying method. The output is a baseband representation of the modulated signal.

To modulate a signal using differential quadrature phase shift keying:

1. Define and set up your DQPSK modulator object. See “Construction” on page 3-362.
2. Call step to modulate a signal according to the properties of comm.DQPSKModulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

H = comm.DQPSKModulator creates a modulator System object, H. This object modulates the input signal using the differential quadrature phase shift keying (DQPSK) method.

H = comm.DQPSKModulator(Name,Value) creates a DQPSK modulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.DQPSKModulator(PHASE,Name,Value) creates a DQPSK modulator object, H. This object has the PhaseRotation property set to PHASE and the other specified properties set to the specified values.

Properties

PhaseRotation

Additional phase shift

Specify the additional phase difference between previous and current modulated symbols in radians as a real scalar value. The default is pi/4. This value corresponds to the phase difference between previous and current modulated symbols when the input is zero.

BitInput

Assume bit inputs

Specify whether the input is bits or integers. The default is `false`. When you set this property to true, the step method input must be a column vector of bit values. The length of this vector is an integer multiple of two. This vector contains bit representations of integers between `0` and `3`. When you set this property to `false`, the `step` method input must be a column vector of integer symbol values between `0` and `3`.

`SymbolMapping`

Constellation encoding

Specify how the object maps an integer or group of two input bits to the corresponding symbol as one of `Binary` | `Gray`. The default is `Gray`. When you set this property to `Gray`, the object uses a Gray-encoded signal constellation. When you set this property to `Binary`, the input integer m, between $0 \le m \le 3$ shifts the output phase. This shift is (`PhaseRotation` on page 3-0 $+ 2 \times \pi \times m/4$) radians from the previous output phase. The output symbol is **exp**($j \times$`PhaseRotation` $+ j \times 2 \times \pi \times m/4$)×(previously modulated symbol).

`OutputDataType`

Data type of output

Specify output data type as one of `double` | `single`. The default is `double`.

Methods

step	Modulate using DQPSK method

Common to All System Objects	
`release`	Allow System object property value changes
`reset`	Reset internal states of System object

Examples

DQPSK Signal in AWGN

Create a DQPSK modulator and demodulator pair. Create an AWGN channel object having two bits per symbol.

```
dqpskmod = comm.DQPSKModulator('BitInput',true);
dqpskdemod = comm.DQPSKDemodulator('BitOutput',true);
channel = comm.AWGNChannel('EbNo',6,'BitsPerSymbol',2);
```

Create an error rate calculator. Set the `ComputationDelay` property to `1` to account for the one bit transient caused by the differential modulation

```
errorRate = comm.ErrorRate('ComputationDelay',1);
```

Main processing loop steps:

- Generate 50 2-bit frames
- 8-DPSK modulate
- Pass through AWGN channel
- 8-DPSK demodulate
- Collect error statistics

```
for counter = 1:100
    txData = randi([0 1],100,1);
    modSig = dqpskmod(txData);
    rxSig = channel(modSig);
    rxData = dqpskdemod(rxSig);
    errorStats = errorRate(txData,rxData);
end
```

Display the error statistics.

```
ber = errorStats(1)
```

```
ber = 0.0170
```

```
numErrors = errorStats(2)
```

```
numErrors = 170
```

```
numBits = errorStats(3)
```

```
numBits = 9999
```

step

System object: `comm.DQPSKModulator`
Package: `comm`

Modulate using DQPSK method

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` modulates input data, `X`, with the DQPSK modulator System object, `H`. It returns the baseband modulated output, `Y`. Depending on the value of the `BitInput` property, input `X` can be an integer or bit valued column vector with numeric or logical data types.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.ErrorRate

Package: `comm`

Compute bit or symbol error rate of input data

Description

The `comm.ErrorRate` object compares input data from a transmitter with input data from a receiver and calculates the error rate as a running statistic. To obtain the error rate, the object divides the total number of unequal pairs of data elements by the total number of input data elements from one source.

To compute the error rate:

1. Create the `comm.ErrorRate` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
errorRate = comm.ErrorRate
errorRate = comm.ErrorRate(Name=Value)
```

Description

`errorRate = comm.ErrorRate` creates an error rate calculator System object. This object computes the error rate of the received data by comparing it to the transmitted data.

`errorRate = comm.ErrorRate(Name=Value)` sets "Properties" on page 3-366 using one or more name-value arguments. For example, `ReceiveDelay = 5` specifies that the received data lags behind the transmitted data by five samples.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`ReceiveDelay` — Received signal delay

`0` (default) | nonnegative integer

Number of samples by which the received data lags behind the transmitted data, specified as a nonnegative integer. Use this property to align the samples for comparison in the transmitted and received input data vectors.

Data Types: `double`

`ComputationDelay` — Computation delay
`0` (default) | nonnegative scalar

Number of data samples that the object ignores at the beginning of the comparison, specified as a nonnegative integer. Use this property to ignore the transient behavior of both input signals.

Data Types: `double`

`Samples` — Samples to consider
`Entire frame` (default) | `Custom` | `Input port`

Samples to consider, specified as one of these values.

- `Entire frame` — Compare all the samples of the received data to those of the transmitted frame
- `Custom` — Set the indices of the samples to consider when making comparisons in the `CustomSamples` property
- `Input port` — Set the indices of the samples to consider when making comparisons in the `ind` input

Data Types: `char` | `string`

`CustomSamples` — Sample indices
`[]` (default) | positive integer | column vector of positive integers

Indices of the samples to consider when comparing data, specified as a positive integer or column vector of positive integers. The default value is an empty vector, which corresponds to the object using all samples from the received frame.

Dependencies

To enable this property, set the `Samples` property to `Custom`.

Data Types: `double`

`ResetInputPort` — Enable `reset` input
`false` or `0` (default) | `true` or `1`

Enable the `reset` input, specified as a logical `1` (`true`) or `0` (`false`).

Data Types: `logical`

Usage

Syntax

```
y = errorRate(tx,rx)
```

```
y = errorRate(tx,rx,ind)
y = errorRate( ___ ,reset)
```

Description

`y = errorRate(tx,rx)` counts the number of differences between transmitted and received data vectors `tx` and `rx`, respectively.

`y = errorRate(tx,rx,ind)` counts the number of differences between the transmitted and received data vectors based on sample indices `ind`. To enable this syntax, set the `Samples` property to `Input port`.

`y = errorRate( ___ ,reset)` resets the error count when you set the `reset` input as a nonzero value. To enable this syntax, set the `ResetInputPort` property to `1` (`true`).

Input Arguments

`tx` — Transmitted data

scalar | column vector

Transmitted data vector, specified as a scalar or column vector.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

`rx` — Received data

scalar | column vector

Received data vector, specified as a scalar or column vector.

Note If you specify the `tx` or `rx` input as a scalar, the object compares this value with all elements of the other input. If you specify both inputs as vectors, they must have the same size and data type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

`ind` — Sample indices

positive integer | column vector of positive integers

Indices of the samples to consider when comparing data, specified as a positive integer or column vector of positive integers.

Dependencies

To enable this input, set the `Samples` property to `Input port`.

Data Types: `single` | `double`

`reset` — Reset error count

scalar

Reset error count, specified as a logical `1` (`true`) or `0` (`false`). To reset the error count between calls to the object, set this property to a nonzero value.

Dependencies

To enable this input, set the `ResetInputPort` property to `1` (`true`).

Data Types: `double` | `logical`

Output Arguments

y — Difference between transmitted and received data

column vector

Difference between transmitted and received data, returned as a column vector of the form `[R; N; S]`, where

- R is the error rate
- N is the number of errors
- S is the number of samples compared

Data Types: `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Examples

Calculate Error Statistics

Create two binary vectors and determine the error statistics.

Create a bit error rate counter object.

```
errorRate = comm.ErrorRate;
```

Create a binary data vector.

```
tx = [1 0 1 0 1 0 1 0 1 0]';
```

Introduce errors to the first and last bits.

```
rx = tx;
rx(1) = ~rx(1);
rx(end) = ~rx(end);
```

Calculate the difference between the transmitted and received data.

```
y = errorRate(tx,rx);
```

Display the bit error rate.

```
y(1)
```

```
ans = 0.2000
```

Display the number of errors.

```
y(2)
```

```
ans = 2
```

Display the total number samples used for comparison.

```
y(3)
```

```
ans = 10
```

Calculate BER Between Transmitted and Received Signal

Create an 8-DPSK modulator and demodulator pair that work with binary data.

```
dpskModulator = comm.DPSKModulator( ...
    ModulationOrder=8,BitInput=true);
dpskDemodulator = comm.DPSKDemodulator( ...
    ModulationOrder=8,BitOutput=true);
```

Create an error rate calculator, accounting for the three bit (one symbol) transient caused by the differential modulation.

```
errorRate = comm.ErrorRate( ...
    ComputationDelay=3,Samples="Input port");
```

Calculate and display the BER for 10 frames for the specified sample indices.

```
BER = zeros(10,1);
ind = (1:3:96)';

for i = 1:10
    tx = randi([0 1],96,1);      % Generate binary data
    modData = dpskModulator(tx); % Modulate
    rxSig = awgn(modData,7);     % Pass through AWGN channel
    rx = dpskDemodulator(rxSig); % Demodulate
    y = errorRate(tx,rx,ind);    % Compute error statistics
    BER(i) = y(1);               % Save BER data
end
BER
```

```
BER = 10×1

    0.0645
    0.0952
    0.0947
    0.0945
    0.0943
    0.0890

Error Rate Calculation

comm.DecisionFeedbackEqualizer

Package: comm

Equalize modulated signals using decision feedback filtering

Description

The comm.DecisionFeedbackEqualizer System object uses a decision feedback filter tap delay line with a weighted sum to equalize modulated signals transmitted through a dispersive channel. The equalizer object adaptively adjusts tap weights based on the selected algorithm. For more information, see “Algorithms” on page 3-403.

To equalize modulated signals using a decision feedback filter:

1. Create the comm.DecisionFeedbackEqualizer object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
dfe = comm.DecisionFeedbackEqualizer
dfe = comm.DecisionFeedbackEqualizer(Name,Value)
```

Description

dfe = comm.DecisionFeedbackEqualizer creates a decision feedback equalizer System object to adaptively equalize a signal.

dfe = comm.DecisionFeedbackEqualizer(Name,Value) sets properties using one or more name-value pairs. For example, comm.DecisionFeedbackEqualizer('Algorithm','RLS') configures the equalizer object to update tap weights using the recursive least squares (RLS) algorithm. Enclose each property name in quotes.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Algorithm — Adaptive algorithm
'LMS' (default) | 'RLS' | 'CMA'

Adaptive algorithm used for equalization, specified as one of these values:

- `'LMS'` — Update the equalizer tap weights using the “Least Mean Square (LMS) Algorithm” on page 3-405.
- `'RLS'` — Update the equalizer tap weights using the “Recursive Least Square (RLS) Algorithm” on page 3-405.
- `'CMA'` — Update the equalizer tap weights using the “Constant Modulus Algorithm (CMA)” on page 3-405.

Data Types: `char` | `string`

`NumForwardTaps` — Number of forward equalizer taps

`5` (default) | positive integer

Number of forward equalizer taps, specified as a positive integer. The number of forward equalizer taps must be greater than or equal to the value of the `InputSamplesPerSymbol` property.

Data Types: `double`

`NumFeedbackTaps` — Number of feedback equalizer taps

`3` (default) | positive integer

Number of feedback equalizer taps, specified as a positive integer.

Data Types: `double`

`StepSize` — Step size

`0.01` (default) | positive scalar

Step size used by the adaptive algorithm, specified as a positive scalar. Increasing the step size reduces the equalizer convergence time but causes the equalizer output estimates to be less stable.

Tip To determine the maximum step size allowed, use the `maxstep` object function.

Tunable: Yes

Dependencies

To enable this property, set Algorithm to `'LMS'` or `'CMA'`.

Data Types: `double`

`ForgettingFactor` — Forgetting factor

`0.99` (default) | scalar in the range (0, 1]

Forgetting factor used by the adaptive algorithm, specified as a scalar in the range (0, 1]. Decreasing the forgetting factor reduces the equalizer convergence time but causes the equalizer output estimates to be less stable.

Tunable: Yes

Dependencies

To enable this property, set Algorithm to `'RLS'`.

Data Types: `double`

`InitialInverseCorrelationMatrix` — Initial inverse correlation matrix

`0.1` (default) | scalar | matrix

Initial inverse correlation matrix, specified as a scalar or an N_{Taps}-by-N_{Taps} matrix. N_{Taps} is equal to the sum of the NumForwardTaps and NumFeedbackTaps property values. If you specify `InitialInverseCorrelationMatrix` as a scalar, a, the equalizer sets the initial inverse correlation matrix to a times the identity matrix: a(`eye`(N_{Taps})).

Dependencies

To enable this property, set Algorithm to `'RLS'`.

Data Types: `double`

`Constellation` — Signal constellation

`pskmod(0:3,4,pi/4)` (default) | vector

Signal constellation, specified as a vector. The default value is a QPSK constellation generated using this code: `pskmod(0:3,4,pi/4)`.

Data Types: `double`

`ReferenceTap` — Reference tap

`3` (default) | positive integer

Reference tap, specified as a positive integer less than or equal to the NumForwardTaps property value. The equalizer uses the reference tap location to track the main energy of the channel.

Data Types: `double`

`InputDelay` — Input signal delay

`0` (default) | nonnegative integer

Input signal delay in samples relative to the reset time of the equalizer, specified as a nonnegative integer. If the input signal is a vector of length greater than 1, then the input delay is relative to the start of the input vector. If the input signal is a scalar, then the input delay is relative to the first call of the System object and to the first call of the System object after calling the `release` or `reset` object function.

Data Types: `double`

`InputSamplesPerSymbol` — Number of input samples per symbol

`1` (default) | positive integer

Number of input samples per symbol, specified as a positive integer. Setting this property to any number greater than one effectively creates a fractionally spaced equalizer.

Data Types: `double`

`TrainingFlagInputPort` — Enable training control input

`0` or `false` (default) | `1` or `true`

Enable training control input, specified as a logical `0` (`false`) or `1` (`true`). Setting this property to `true` enables the equalizer training flag input `tf`.

Data Types: `logical`

`AdaptAfterTraining` — Update tap weights when not training

`1` or `true` (default) | `0` or `false`

Update tap weights when not training, specified as a logical `1` (`true`) or `0` (`false`). If this property is set to `true`, the System object uses decision directed mode to update equalizer tap weights. If this property is set to `false`, the System object keeps the equalizer tap weights unchanged after training.

Data Types: `logical`

`AdaptWeightsSource` — Source of adapt tap weights request

`'Property'` (default) | `'Input port'`

Source of adapt tap weights request, specified as one of these values:

- `'Property'` — Specify this value to use the AdaptWeights property to control when the System object adapts tap weights.
- `'Input port'` — Specify this value to use the `aw` input to control when the System object adapts tap weights.

Dependencies

To enable this property, set Algorithm to `'CMA'`.

Data Types: `char` | `string`

`AdaptWeights` — Adapt tap weights

`1` or `true` (default) | `0` or `false`

Adapt tap weights, specified as a logical `1` (`true`) or `0` (`false`). If this property is set to `true`, the System object updates the equalizer tap weights. If this property is set to `false`, the System object keeps the equalizer tap weights unchanged.

Dependencies

To enable this property, set AdaptWeightsSource to `'Property'` and set AdaptAfterTraining to `true`.

Data Types: `logical`

`InitialWeightsSource` — Source for initial tap weights

`'Auto'` (default) | `'Property'`

Source for initial tap weights, specified as one of these values:

- `'Auto'` — Initialize the tap weights to the algorithm-specific default values, as described in the InitialWeights property.
- `'Property'` — Initialize the tap weights using the InitialWeights property value.

Data Types: `char` | `string`

`InitialWeights` — Initial weights

`0` or `[0;0;1;0;0]` (default) | scalar | vector

Initial weights used by the adaptive algorithm, specified as a scalar or vector. The default is `0` when the Algorithm property is set to `'LMS'` or `'RLS'`. The default is `[0;0;1;0;0]` when the Algorithm property is set to `'CMA'`.

If you specify `InitialWeights` as a scalar, the equalizer uses scalar expansion to create a vector of length N_{Taps} with all values set to `InitialWeights`. N_{Taps} is equal to the sum of the

NumForwardTaps and NumFeedbackTaps property values. If you specify `InitialWeights` as a vector, the vector length must be N_{Taps}.

Data Types: `double`

`WeightUpdatePeriod` — Tap weight update period
1 (default) | positive integer

Tap weight update period in symbols, specified as a positive integer. The equalizer updates the tap weights after processing this number of symbols.

Data Types: `double`

Usage

Syntax

```
y = dfe(x,tsym)
y = dfe(x,tsym,tf)
y = dfe(x)
y = dfe(x,aw)
[y,err] = dfe(___)
[y,err,weights] = dfe(___)
```

Description

`y = dfe(x,tsym)` equalizes input signal `x` by using training symbols `tsym`. The output is the equalized symbols. To enable this syntax, set the Algorithm property to `'LMS'` or `'RLS'`.

`y = dfe(x,tsym,tf)` also specifies training flag `tf`. The System object starts training when `tf` changes from `false` to `true` (at the rising edge). The System object trains until all symbols in `tsym` are processed. The input `tsym` is ignored when `tf` is `false`. To enable this syntax, set the Algorithm property to `'LMS'` or `'RLS'` and TrainingFlagInputPort property to `true`.

`y = dfe(x)` equalizes input signal `x`. To enable this syntax, set the Algorithm property to `'CMA'`.

`y = dfe(x,aw)` also specifies adapts weights flag `aw`. If `aw` is `true`, the System object adapts the equalizer tap weights. If `aw` is `false`, the System object keeps the weights unchanged. To enable this syntax, set the Algorithm property to `'CMA'` and AdaptWeightsSource property to `'Input port'`.

`[y,err] = dfe(___)` also returns error signal `err` using input arguments from any of the previous syntaxes.

`[y,err,weights] = dfe(___)` also returns `weights`, the tap weights from the last tap weight update, using input arguments from any of the previous syntaxes.

Input Arguments

`x` — Input signal
column vector

Input signal, specified as a column vector. The input signal vector length must be equal to an integer multiple of the InputSamplesPerSymbol property value. For more information, see “Symbol Tap Spacing” on page 3-403.

Data Types: `double`
Complex Number Support: Yes

`tsym` — Training symbols

column vector

Training symbols, specified as a column vector of length less than or equal to the length of input `x`. The input `tsym` is ignored when `tf` is `false`.

Dependencies

To enable this argument, set the Algorithm property to `'LMS'` or `'RLS'`.

Data Types: `double`

`tf` — Training flag

`1` or `true` | `0` or `false`

Training flag, specified as a logical `1` (`true`) or `0` (`false`). The System object starts training when `tf` changes from `false` to `true` (at the rising edge). The System object trains until all symbols in `tsym` are processed. The input `tsym` is ignored when `tf` is `false`.

Dependencies

To enable this argument, set the Algorithm property to `'LMS'` or `'RLS'` and TrainingFlagInputPort property to `true`.

Data Types: `logical`

`aw` — Adapt weights flag

`1` or `true` | `0` or `false`

Adapt weights flag, specified as a logical `1` (`true`) or `0` (`false`). If `aw` is `true`, the System object adapts weights. If `aw` is `false`, the System object keeps the weights unchanged.

Dependencies

To enable this argument, set the Algorithm property to `'CMA'` and AdaptWeightsSource property to `'Input port'`.

Data Types: `logical`

Output Arguments

`y` — Equalized symbols

column vector

Equalized symbols, returned as a column vector that has the same length as input signal `x`.

`err` — Error signal

column vector

Error signal, returned as a column vector that has the same length as input signal `x`.

`weights` — Tap weights

column vector

Tap weights, returned as a column vector that has N_{Taps} elements. N_{Taps} is equal to the sum of the NumForwardTaps and NumFeedbackTaps property values. `weights` contains the tap weights from the last tap weight update.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `comm.DecisionFeedbackEqualizer`

isLocked	Determine if System object is in use
clone	Create duplicate System object
info	Characteristic information about the equalizer object
maxstep	Maximum step size for LMS equalizer convergence
mmseweights	Linear equalizer MMSE tap weights

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Decision Feedback Equalize BPSK-Modulated Signal

Create a BPSK modulator and an equalizer System object™, specifying a decision feedback LMS equalizer having eight forward taps, five feedback taps, and a step size of 0.03.

```
bpsk = comm.BPSKModulator;
eqdfe_lms = comm.DecisionFeedbackEqualizer('Algorithm','LMS', ...
    'NumForwardTaps',8,'NumFeedbackTaps',5,'StepSize',0.03);
```

Change the reference tap index of the equalizer.

```
eqdfe_lms.ReferenceTap = 4;
```

Build a set of test data. Receive the data by convolving the signal.

```
x = bpsk(randi([0 1],1000,1));
rxsig = conv(x,[1 0.8 0.3]);
```

Use `maxstep` to find the maximum permitted step size.

```
mxStep = maxstep(eqdfe_lms,rxsig)
```

```
mxStep = 0.1028
```

Equalize the received signal. Use the first 200 symbols as the training sequence.

```
y = eqdfe_lms(rxsig,x(1:200));
```

Decision Feedback Equalize QPSK-Modulated Signal

Apply decision feedback equalization using the least mean squares (LMS) algorithm to recover QPSK symbols passed through a delayed multipath AWGN channel.

Initialize simulation variables.

```
M = 4; % QPSK
numSymbols = 10000;
numTrainingSymbols = 1000;
chtaps = [1 0.5*exp(1i*pi/6) 0.1*exp(-1i*pi/8)];
```

Generate QPSK-modulated symbols. Apply delayed multipath channel filtering and AWGN impairments to the symbols.

```
data = randi([0 M-1], numSymbols, 1);
tx = pskmod(data, M, pi/4);
rx = awgn(filter(chtaps,1,tx),25,'measured');
```

Create a decision feedback equalizer System object and display the default configuration. Adjust the reference tap to 1. Check the maximum permitted step size. Equalize the impaired symbols.

```
eq = comm.DecisionFeedbackEqualizer
```

```
eq =
  comm.DecisionFeedbackEqualizer with properties:

               Algorithm: 'LMS'
          NumForwardTaps: 5
         NumFeedbackTaps: 3
                StepSize: 0.0100
            Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i ... ]
             ReferenceTap: 3
               InputDelay: 0
    InputSamplesPerSymbol: 1
    TrainingFlagInputPort: false
       AdaptAfterTraining: true
     InitialWeightsSource: 'Auto'
       WeightUpdatePeriod: 1
```

```
eq.ReferenceTap = 1;

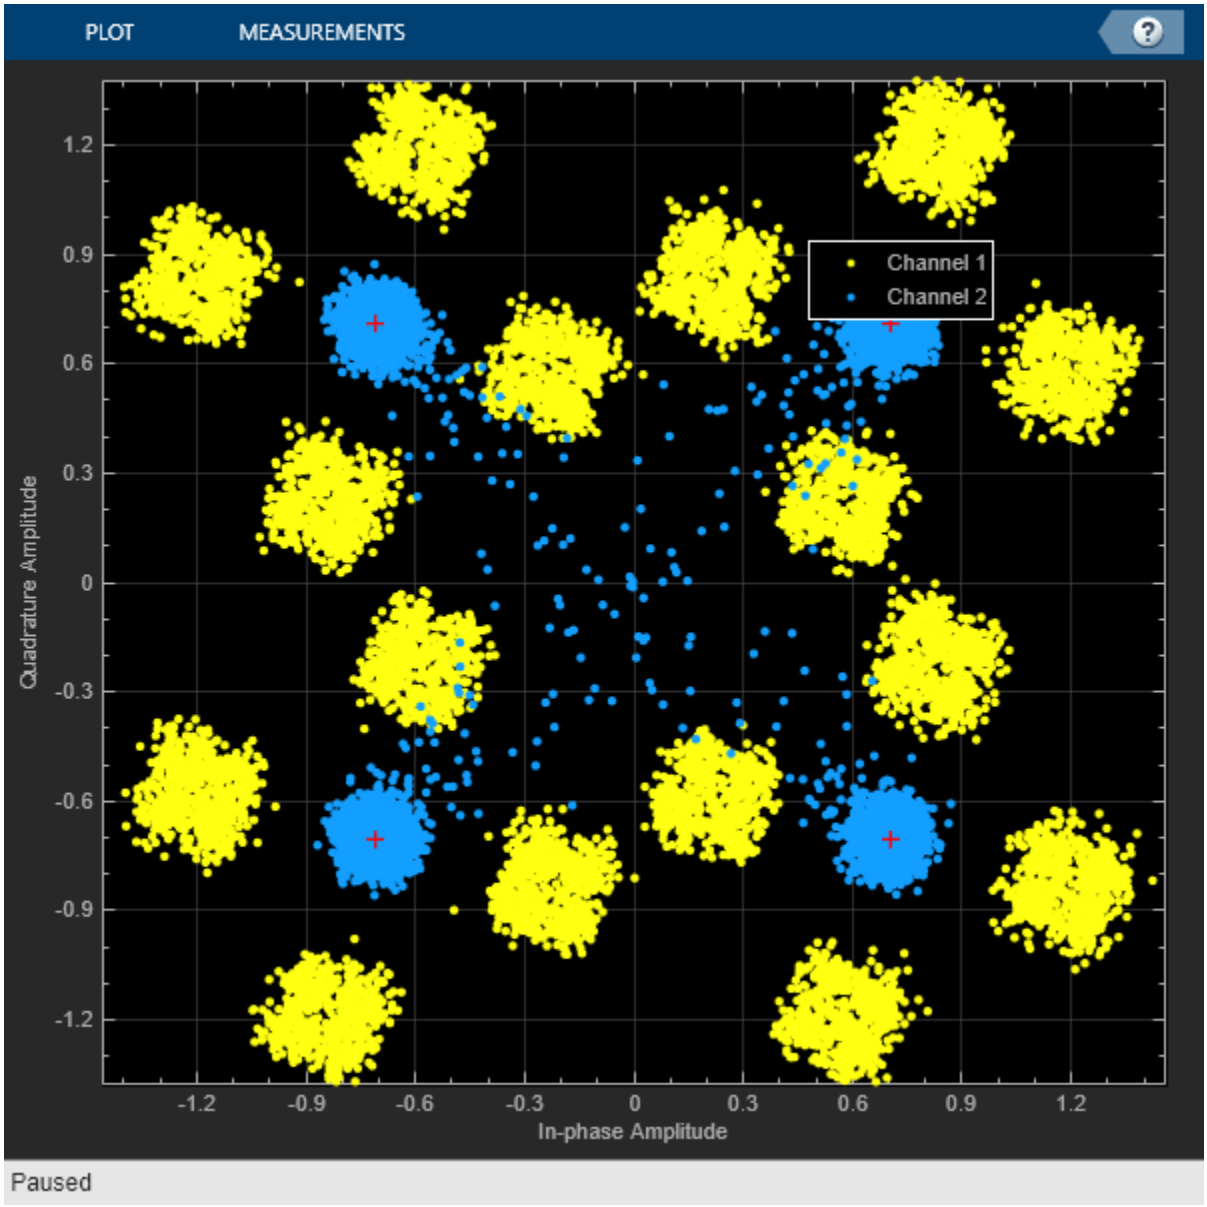
mxStep = maxstep(eq,rx)
```

```
mxStep = 0.2149
```

```
[y,err,weights] = eq(rx,tx(1:numTrainingSymbols));
```

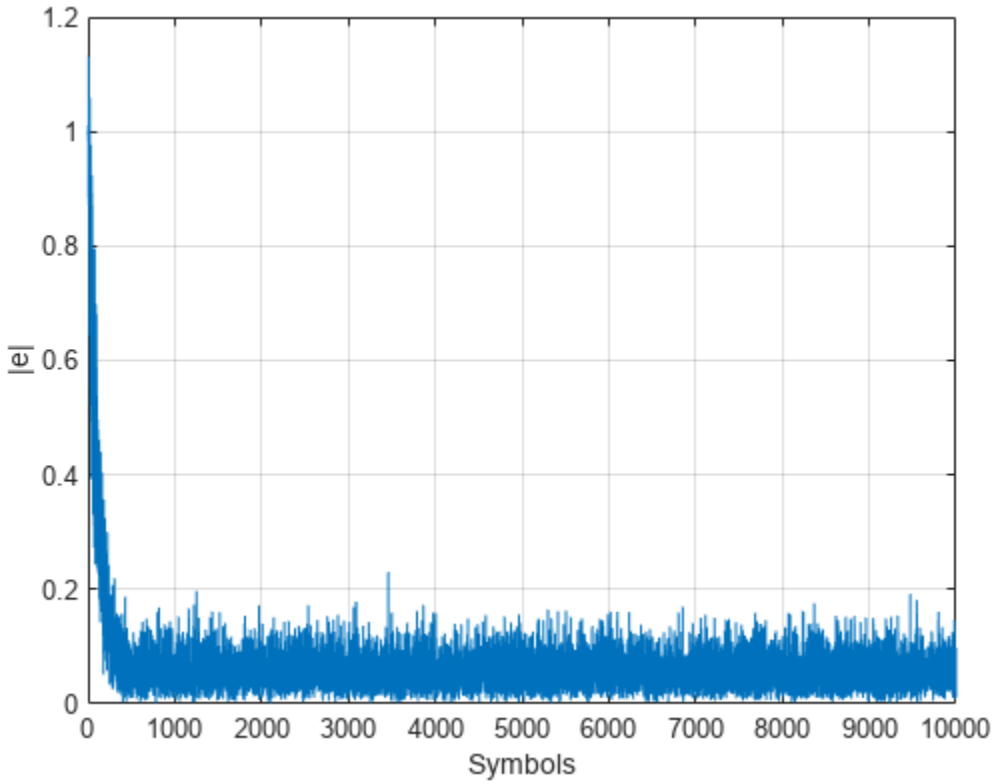
Plot the constellation of the impaired and equalized symbols.

```
constell = comm.ConstellationDiagram('NumInputPorts',2);
constell(rx,y)
```



Plot the equalizer error signal and compute the error vector magnitude of the equalized symbols.

```
plot(abs(err))
grid on; xlabel('Symbols'); ylabel('|e|')
```



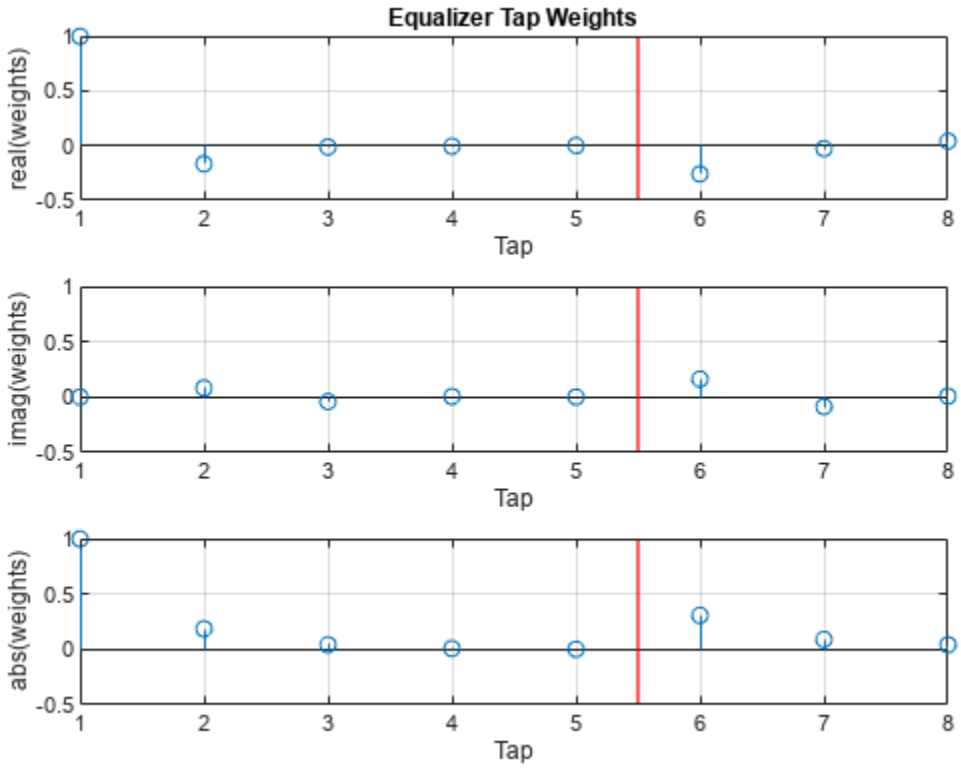
```
errevm = comm.EVM;
evm = errevm(tx,y)
```

```
evm = 10.1288
```

Plot the equalizer tap weights.

```
subplot(3,1,1);
stem(real(weights));
ylabel('real(weights)');
xlabel('Tap');
grid on;
axis([1 8 -0.5 1])
line([eq.NumForwardTaps+0.5 eq.NumForwardTaps+0.5], ...
    [-0.5 1],'Color','r','LineWidth',1)
title('Equalizer Tap Weights')
subplot(3,1,2);
stem(imag(weights));
ylabel('imag(weights)');
xlabel('Tap');
grid on;
axis([1 8 -0.5 1])
line([eq.NumForwardTaps+0.5 eq.NumForwardTaps+0.5], ...
    [-0.5 1],'Color','r','LineWidth',1)
subplot(3,1,3);
stem(abs(weights));
ylabel('abs(weights)');
xlabel('Tap');
```

```
grid on;
axis([1 8 -0.5 1])
line([eq.NumForwardTaps+0.5 eq.NumForwardTaps+0.5], ...
    [-0.5 1],'Color','r','LineWidth',1)
```



Decision Feedback Equalize System Using Different Training Schemes

Demonstrate decision feedback equalization using the least mean squares (LMS) algorithm to recover QPSK symbols passed through an AWGN channel. Apply different equalizer training schemes and show the symbol error magnitude.

System Setup

Simulate a QPSK-modulated system subject to AWGN. Transmit packets composed of 200 training symbols and 1800 random data symbols. Configure a decision feedback LMS equalizer to recover the packet data.

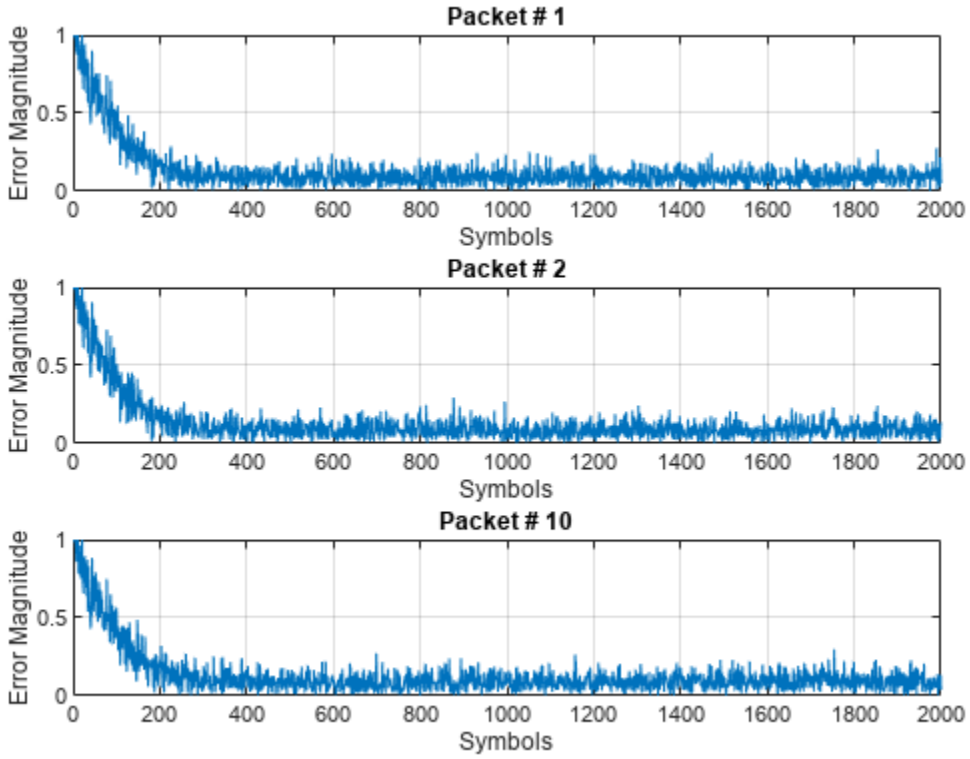
```
M = 4;
numTrainSymbols = 200;
numDataSymbols = 1800;
SNR = 20;
trainingSymbols = ...
    pskmod(randi([0 M-1],numTrainSymbols,1),M,pi/4);
numPkts = 10;
```

```
dfeq = comm.DecisionFeedbackEqualizer( ...
    'Algorithm','LMS', ...
    'NumForwardTaps',5, ...
    'NumFeedbackTaps',4, ...
    'ReferenceTap',3, ...
    'StepSize',0.01);
```

Train the Equalizer at the Beginning of Each Packet with Reset

Process each packet using prepended training symbols. Reset the equalizer after processing each packet. Resetting the equalizer after each packet forces the equalizer to train taps with no a priori knowledge. Equalizer error signal plots for the first, second, and last packet show higher symbol errors at the start of each packet.

```
jj = 1;
figure
for ii = 1:numPkts
    b = randi([0 M-1],numDataSymbols,1);
    dataSym = pskmod(b,M,pi/4);
    packet = [trainingSymbols;dataSym];
    rx = awgn(packet,SNR);
    [~,err] = dfeq(rx,trainingSymbols);
    reset(dfeq)
    if (ii ==1 || ii == 2 ||ii == numPkts)
        subplot(3,1,jj)
        plot(abs(err))
        ylim([0 1])
        title(['Packet # ',num2str(ii)])
        xlabel('Symbols');
        ylabel('Error Magnitude');
        grid on;
        jj = jj+1;
    end
end
```

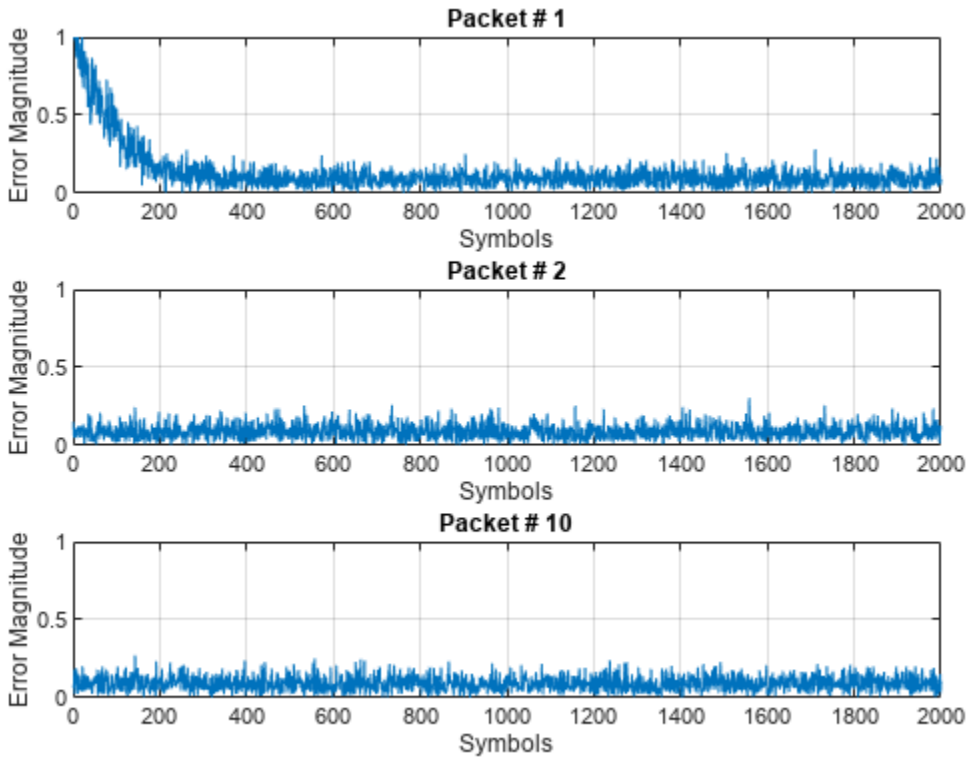


Train the Equalizer at the Beginning of Each Packet Without Reset

Process each packet using prepended training symbols. Do not reset the equalizer after each packet is processed. By not resetting after each packet, the equalizer retains tap weights from training prior packets. Equalizer error signal plots for the first, second, and last packet show that after the initial training on the first packet, subsequent packets have less symbol errors at the start of each packet.

```
release(dfeq)
jj = 1;
figure
for ii = 1:numPkts
    b = randi([0 M-1],numDataSymbols,1);
    dataSym = pskmod(b,M,pi/4);
    packet = [trainingSymbols;dataSym];
    channel = 1;
    rx = awgn(packet*channel,SNR);
    [~,err] = dfeq(rx,trainingSymbols);
    if (ii ==1 || ii == 2 ||ii == numPkts)
        subplot(3,1,jj)
        plot(abs(err))
        ylim([0 1])
        title(['Packet # ',num2str(ii)])
        xlabel('Symbols');
        ylabel('Error Magnitude');
        grid on;
        jj = jj+1;
```

```
    end
end
```



Train the Equalizer Periodically

Systems with signals subject to time-varying channels require periodic equalizer training to maintain lock on the channel variations. Specify a system that has 200 symbols of training for every 1800 data symbols. Between training, the equalizer does not update tap weights. The equalizer processes 200 symbols per packet.

```
Rs = 1e6;
fd = 20;
spp = 200; % Symbols per packet
b = randi([0 M-1],numDataSymbols,1);
dataSym = pskmod(b,M,pi/4);
packet = [trainingSymbols; dataSym];
stream = repmat(packet,10,1);
tx = (0:length(stream)-1)'/Rs;
channel = exp(1i*2*pi*fd*tx);
rx = awgn(stream.*channel,SNR);
```

Set the `AdaptAfterTraining` property to `false` to stop the equalizer tap weight updates after the training phase.

```
release(dfeq)
dfeq.AdaptAfterTraining = false
```

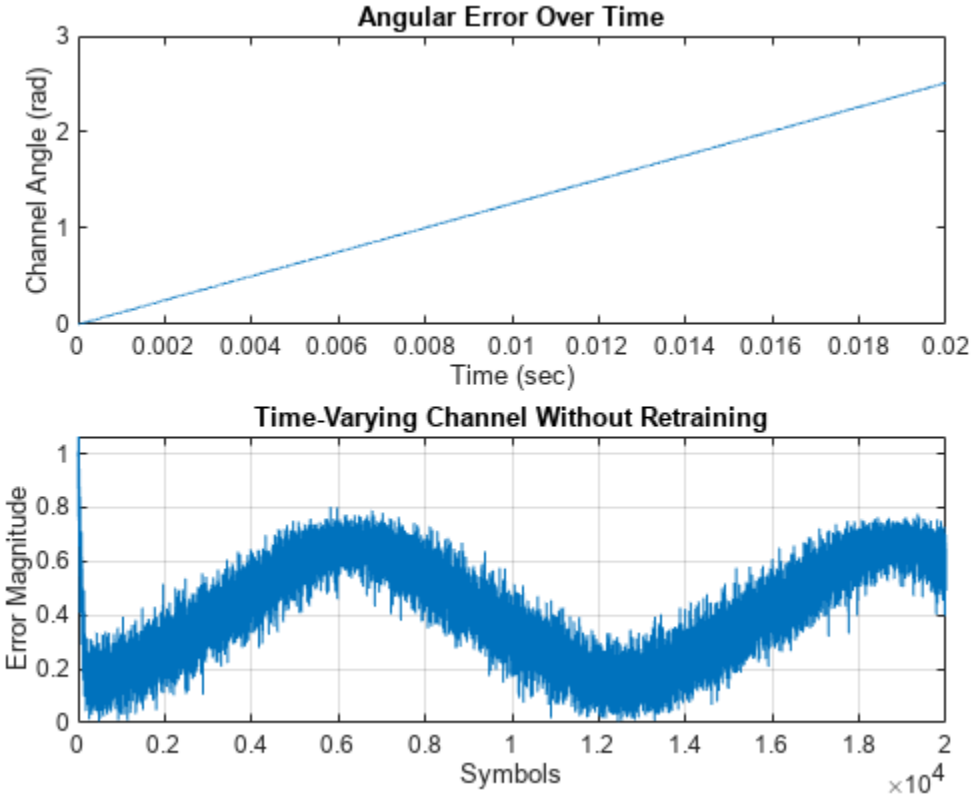
```
dfeq =
  comm.DecisionFeedbackEqualizer with properties:

               Algorithm: 'LMS'
          NumForwardTaps: 5
         NumFeedbackTaps: 4
                StepSize: 0.0100
           Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i ... ]
            ReferenceTap: 3
              InputDelay: 0
    InputSamplesPerSymbol: 1
    TrainingFlagInputPort: false
       AdaptAfterTraining: false
     InitialWeightsSource: 'Auto'
       WeightUpdatePeriod: 1
```

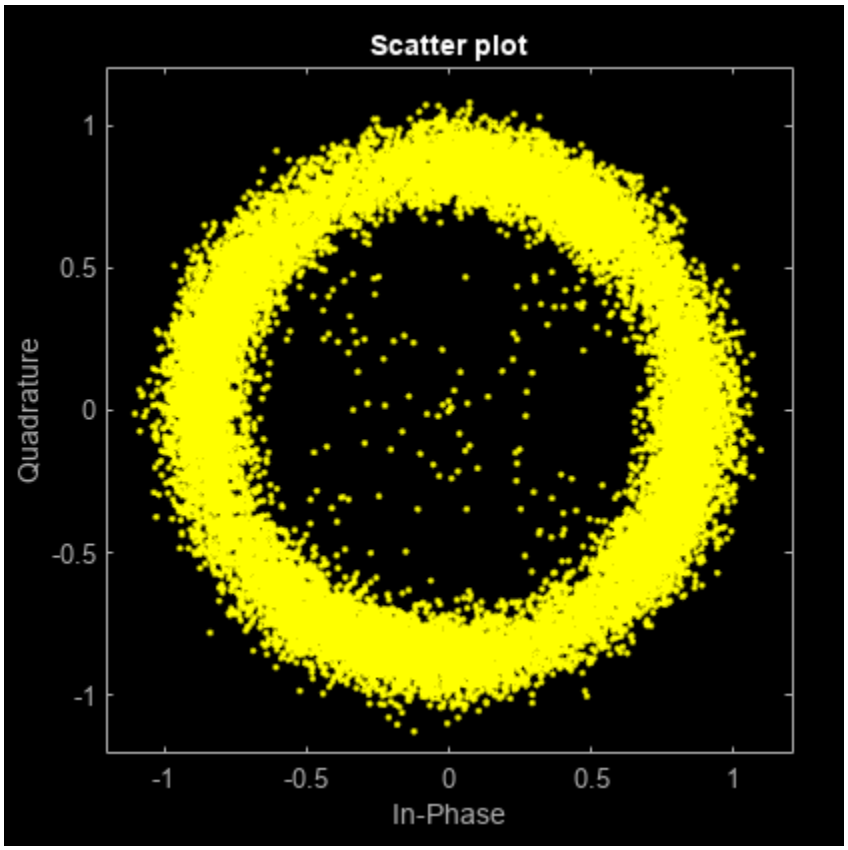
Equalize the impaired data. Plot the angular error from the channel, the equalizer error signal, and signal constellation. As the channel varies, the equalizer output does not remove the channel effects. Also, the output constellation rotates out of sync, resulting in bit errors.

```
[y,err] = dfeq(rx,trainingSymbols);

figure
subplot(2,1,1)
plot(tx, unwrap(angle(channel)))
xlabel('Time (sec)')
ylabel('Channel Angle (rad)')
title('Angular Error Over Time')
subplot(2,1,2)
plot(abs(err))
xlabel('Symbols')
ylabel('Error Magnitude')
grid on
title('Time-Varying Channel Without Retraining')
```



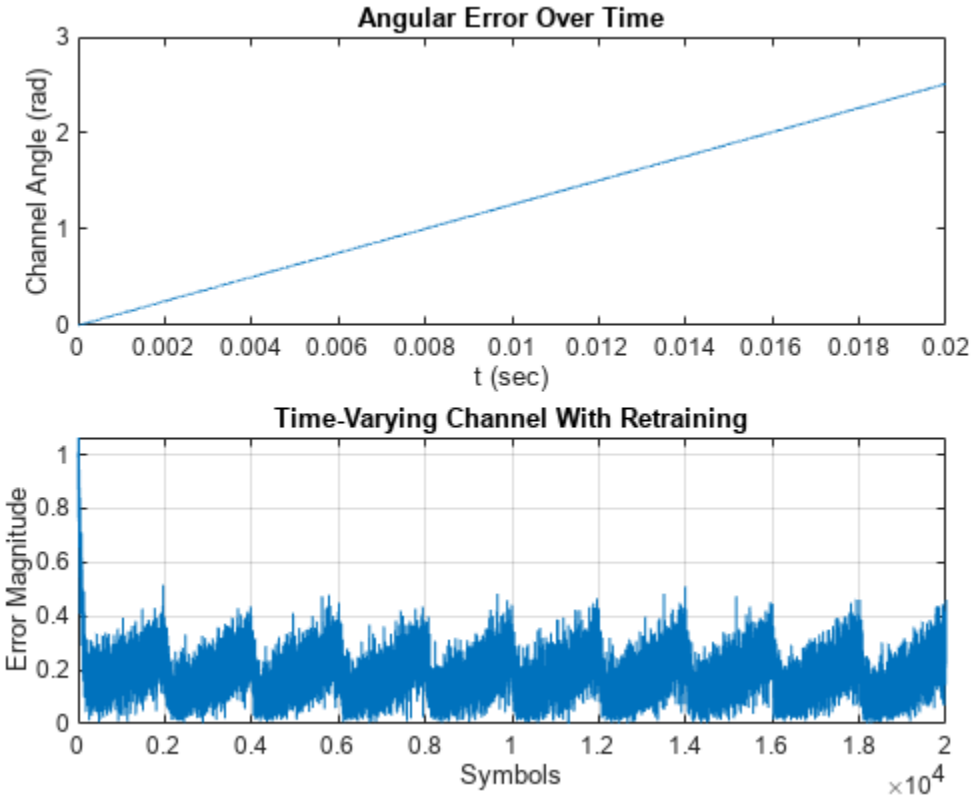
```
scatterplot(y)
```



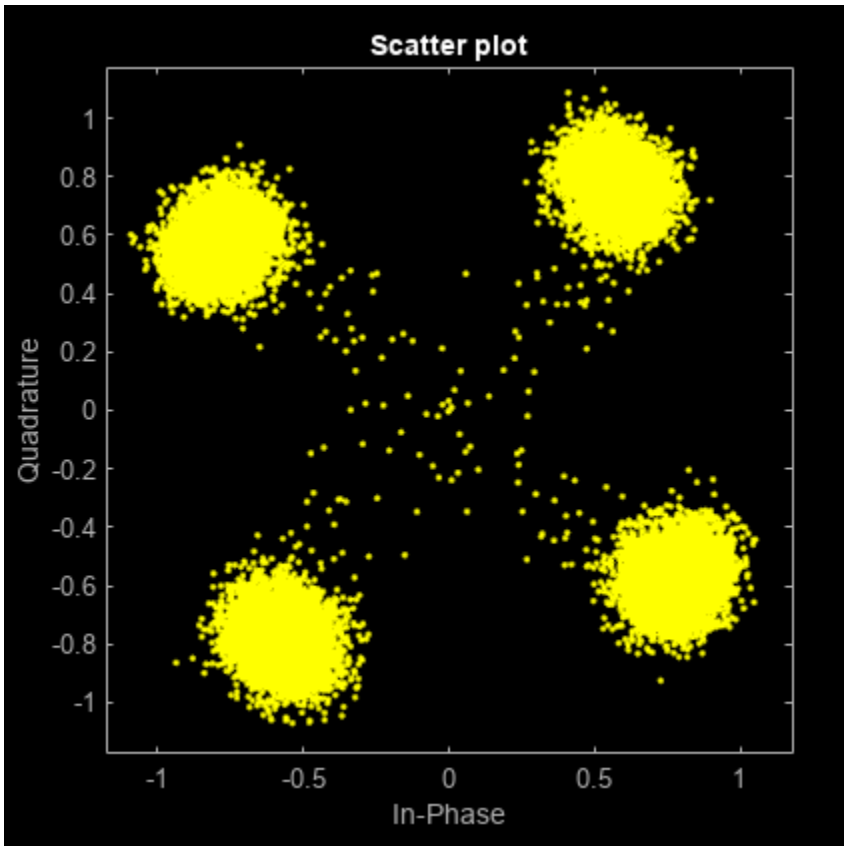
Set the `TrainingInputPort` property to `true` to configure the equalizer to retrain the taps when signaled by the `trainFlag` input. The equalizer trains only when `trainFlag` is `true`. After every 2000 symbols, the equalizer retrains the taps and keeps lock on variations of the channel. Plot the angular error from the channel, the equalizer error signal, and signal constellation. As the channel varies, the equalizer output removes the channel effects. Also, the output constellation does not rotate out of sync, and bit errors are reduced.

```
release(dfeq)
dfeq.TrainingFlagInputPort = true;
symbolCnt = 0;
numPackets = length(rx)/spp;
trainFlag = true;
trainingPeriod = 2000;
eVec = zeros(size(rx));
yVec = zeros(size(rx));
for p=1:numPackets
    [yVec((p-1)*spp+1:p*spp,1),eVec((p-1)*spp+1:p*spp,1)] = ...
        dfeq(rx((p-1)*spp+1:p*spp,1), ...
        trainingSymbols,trainFlag);
    symbolCnt = symbolCnt + spp;
    if symbolCnt >= trainingPeriod
        trainFlag = true;
        symbolCnt = 0;
    else
        trainFlag = false;
    end
end
```

```
figure
subplot(2,1,1)
plot(tx, unwrap(angle(channel)))
xlabel('t (sec)')
ylabel('Channel Angle (rad)')
title('Angular Error Over Time')
subplot(2,1,2)
plot(abs(eVec))
xlabel('Symbols')
ylabel('Error Magnitude')
grid on
title('Time-Varying Channel With Retraining')
```



```
scatterplot(yVec)
```



Decision Feedback Equalize Delayed Signal

Simulate a system with delay between the transmitted symbols and received samples. Typical systems have transmitter and receiver filters that result in a delay. This delay must be accounted for to synchronize the system. In this example, the system delay is introduced without transmit and receive filters. Decision feedback equalization, using the least mean squares (LMS) algorithm, recovers QPSK symbols.

Initialize simulation variables.

```
M = 4; % QPSK
numSymbols = 10000;
numTrainingSymbols = 1000;
mpChan = [1 0.5*exp(1i*pi/6) 0.1*exp(-1i*pi/8)];
systemDelay = dsp.Delay(20);
snr = 24;
```

Generate QPSK-modulated symbols. Apply multipath channel filtering, a system delay, and AWGN to the transmitted symbols.

```
data = randi([0 M-1],numSymbols,1);
tx = pskmod(data,M,pi/4); % OQPSK
delayedSym = systemDelay(filter(mpChan,1,tx));
rx = awgn(delayedSym,snr,'measured');
```

Create equalizer and EVM System objects. The equalizer System object specifies a decision feedback equalizer using the LMS algorithm.

```
dfeq = comm.DecisionFeedbackEqualizer('Algorithm','LMS', ...
    'NumForwardTaps',9,'NumFeedbackTaps',6,'ReferenceTap',5);
evm = comm.EVM('ReferenceSignalSource', ...
    'Estimated from reference constellation');
```

Equalize Without Adjusting Input Delay

Equalize the received symbols.

```
[y1,err1,wts1] = dfeq(rx,tx(1:numTrainingSymbols,1));
```

Find the delay between the received symbols and the transmitted symbols by using the `finddelay` function.

```
rxDelay = finddelay(tx,rx)
```

```
rxDelay = 20
```

Display the equalizer information. The latency value indicates the delay introduced by the equalizer. Calculate the total delay as the sum of `rxDelay` and the equalizer latency.

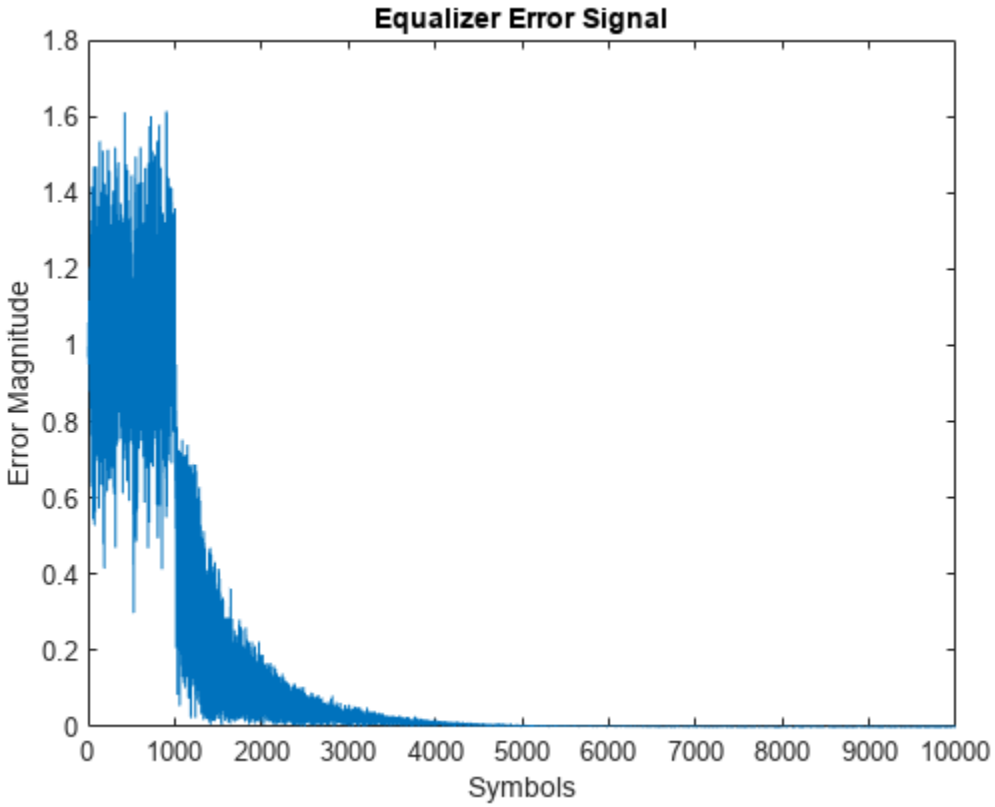
```
eqInfo = info(dfeq)
```

```
eqInfo = struct with fields:
    Latency: 4
```

```
totalDelay = rxDelay + eqInfo.Latency;
```

Until the equalizer output converges, the symbol error rate is high. Plot the error output, `err1`, to determine when the equalized output converges.

```
plot(abs(err1))
xlabel('Symbols')
ylabel('Error Magnitude')
title('Equalizer Error Signal')
```



The plot shows excessive errors for the first 2000 symbols. When demodulating symbols and computing symbol errors, account for the unconverged output and the system delay between the equalizer output and transmitted symbols.

```
dataRec1 = pskdemod(y1(2000+totalDelay:end),M,pi/4);
symErrWithDelay = symerr(data(2000:end-totalDelay),dataRec1)
```

```
symErrWithDelay = 5977
```

```
evmWithDelay = evm(y1)
```

```
evmWithDelay = 26.3288
```

The error rate and EVM are high because the receive delay was not accounted for in the equalizer System object.

Adjust Input Delay in Decision Feedback Equalizer

Equalize the received data by using the delay value to set the `InputDelay` property. Since `InputDelay` is a nontunable property, you must release the `dfeq` System object to reconfigure the `InputDelay` property. Equalize the received symbols.

```
release(dfeq)
dfeq.InputDelay = rxDelay
```

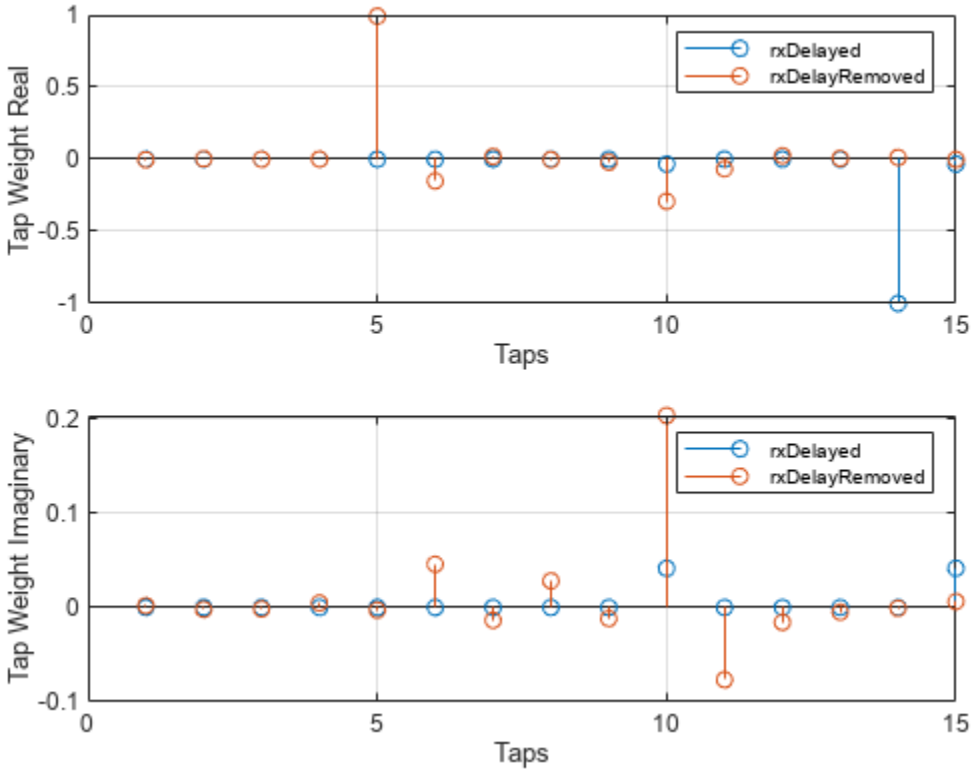
```
dfeq =
  comm.DecisionFeedbackEqualizer with properties:
```

```
                Algorithm: 'LMS'
          NumForwardTaps: 9
         NumFeedbackTaps: 6
                StepSize: 0.0100
           Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i ... ]
            ReferenceTap: 5
              InputDelay: 20
    InputSamplesPerSymbol: 1
    TrainingFlagInputPort: false
       AdaptAfterTraining: true
     InitialWeightsSource: 'Auto'
       WeightUpdatePeriod: 1
```

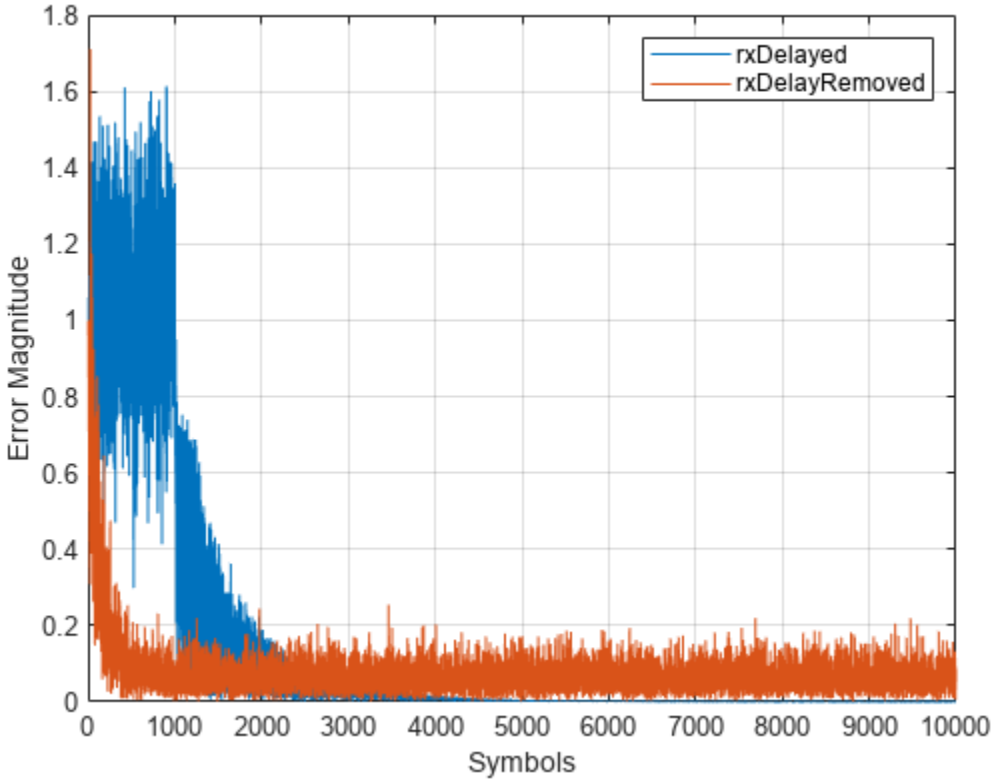
```
[y2,err2,wts2] = dfeq(rx,tx(1:numTrainingSymbols,1));
```

Plot the tap weights and equalized error magnitude. A stem plot shows the equalizer tap weights before and after the system delay is removed. A 2-D line plot shows the slower equalizer convergence for the delayed signal, as compared to the signal with the delay removed.

```
subplot(2,1,1)
stem([real(wts1),real(wts2)])
xlabel('Taps')
ylabel('Tap Weight Real')
legend('rxDelayed','rxDelayRemoved')
grid on
subplot(2,1,2)
stem([imag(wts1),imag(wts2)])
xlabel('Taps')
ylabel('Tap Weight Imaginary')
legend('rxDelayed','rxDelayRemoved')
grid on
```



```
figure
plot([abs(err1),abs(err2)])
xlabel('Symbols')
ylabel('Error Magnitude')
legend('rxDelayed','rxDelayRemoved')
grid on
```



Plot error output of the equalized signals, `rxDelayed` and `rxDelayRemoved`. For the signal that has the delay removed, the equalizer converges during the 1000 symbol training period. When demodulating symbols and computing symbol errors, to account for the unconverged output and the system delay between the equalizer output and transmitted symbols, skip the first 500 symbols. Reconfiguring the equalizer to account for the system delay enables better equalization of the signal, and reduces symbol errors and the EVM.

```
eqInfo = info(dfeq)
```

```
eqInfo = struct with fields:
    Latency: 4
```

```
totalDelay = rxDelay + eqInfo.Latency;
dataRec2 = pskdemod(y2(500+totalDelay:end),M,pi/4);
symErrDelayRemoved = symerr(data(500:end-totalDelay),dataRec2)
```

```
symErrDelayRemoved = 0
```

```
evmDelayRemoved = evm(y2(500+totalDelay:end))
```

```
evmDelayRemoved = 7.5200
```

Decision Feedback Equalize Symbols Using EVM-Based Training

Recover QPSK symbols with a decision equalizer, using the constant modulus algorithm (CMA) and EVM-based taps training. When using blind equalizer algorithms, such as CMA, you can train the

equalizer taps using the `AdaptWeights` property to start and stop training. Use helper functions to generate plots and apply phase correction.

Initialize system variables.

```
rng(123456);
M = 4; % QPSK
numSymbols = 100;
numPackets = 5000;
refTap = 3;
nFwdTaps = 5;
nFdbkTaps = 4;
ttlTaps = nFwdTaps + nFdbkTaps;
raylChan = comm.RayleighChannel( ...
    'PathDelays',[0 1], ...
    'AveragePathGains',[0 -12], ...
    'MaximumDopplerShift',1e-5);
SNR = 50;
adaptWeights = true;
```

Create the equalizer and EVM System objects. The equalizer System object specifies a decision feedback equalizer using the CMA adaptive algorithm. Call the helper function to initialize figure plots.

```
dfeq = comm.DecisionFeedbackEqualizer( ...
    'Algorithm','CMA', ...
    'NumForwardTaps',nFwdTaps, ...
    'NumFeedbackTaps',nFdbkTaps, ...
    'ReferenceTap',refTap, ...
    'StepSize',0.03, ...
    'AdaptWeightsSource','Input port')
```

```
dfeq =
  comm.DecisionFeedbackEqualizer with properties:

                Algorithm: 'CMA'
          NumForwardTaps: 5
         NumFeedbackTaps: 4
                StepSize: 0.0300
           Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i ... ]
            ReferenceTap: 3
    InputSamplesPerSymbol: 1
       AdaptWeightsSource: 'Input port'
     InitialWeightsSource: 'Auto'
       WeightUpdatePeriod: 1
```

```
info(dfeq)
```

```
ans = struct with fields:
    Latency: 2
```

```
evm = comm.EVM('ReferenceSignalSource', ...
    'Estimated from reference constellation');
[errPlot,evmPlot,scatSym,adaptState] = ...
    initFigures(numPackets,ttlTaps);
```

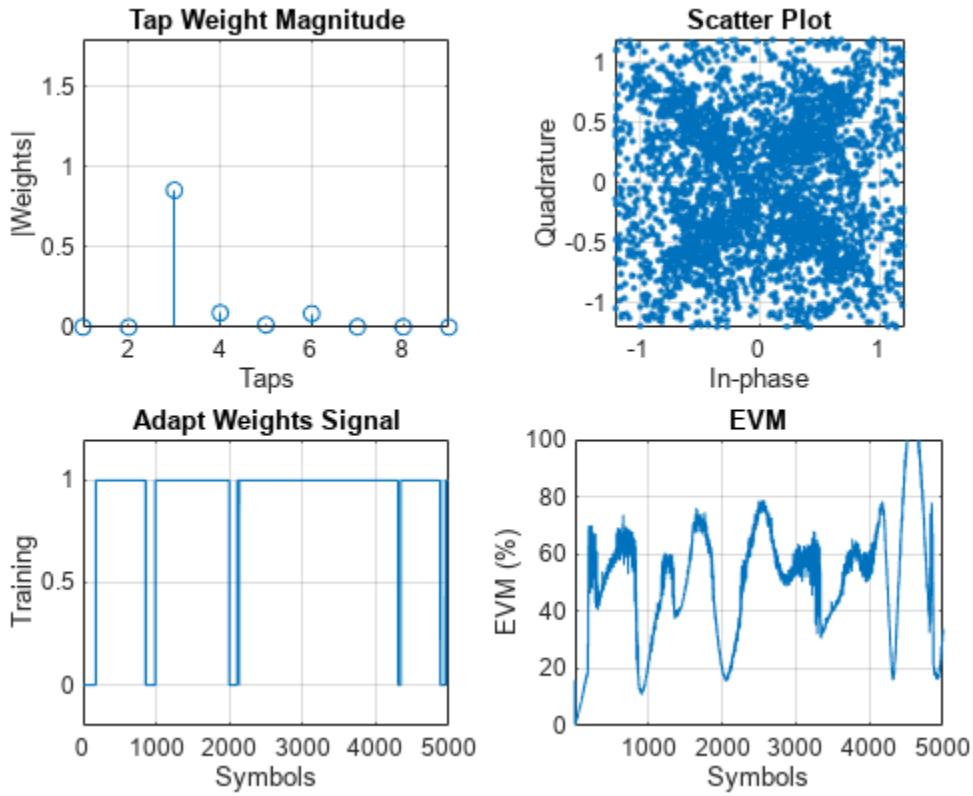
Equalization Loop

Follow these steps to implement the equalization loop.

1. Generate OQPSK data packets.
2. Apply Rayleigh fading and AWGN to the transmission data.
3. Apply equalization to the received data and phase correction to the equalizer output.
4. Estimate the EVM and toggle the `adaptWeights` flag to `true` or `false` based on the EVM level.
5. Update the figure plots.

```
for p=1:numPackets
    data = randi([0 M-1],numSymbols,1);
    tx = pskmod(data,M,pi/4);
    rx = awgn(raylChan(tx),SNR);
    rxDelay = finddelay(rx,tx);
    [y,err,wts] = dfeq(rx,adaptWeights);
    y = phaseCorrection(y);
    evmEst = evm(y);
    adaptWeights = (evmEst > 20);

    updateFigures(errPlot,evmPlot,scatSym,adaptState, ...
        wts,y(end),evmEst,adaptWeights,p,numPackets)
end
```



`rxDelay`

```
rxDelay = 0
```

The figure plots show that, as the EVM varies, the equalizer toggles in and out of decision-directed weight adaptation mode.

Helper Functions

This helper function initializes figures that show a quad plot of simulation results.

```
function [errPlot,evmPlot,scatter,adaptState] = ...
    initFigures(numPkts,ttlTaps)
yVec = nan(numPkts,1);
evmVec = nan(numPkts,1);
wVec = zeros(ttlTaps,1);
adaptVec = nan(numPkts,1);

figure
subplot(2,2,1)
evmPlot = stem(wVec);
grid on; axis([1 ttlTaps 0 1.8])
xlabel('Taps');
ylabel('|Weights|');
title('Tap Weight Magnitude')

subplot(2,2,2)
scatter = plot(yVec, '.');
axis square;
axis([-1.2 1.2 -1.2 1.2]);
grid on;
xlabel('In-phase');
ylabel('Quadrature');
title('Scatter Plot');
subplot(2,2,3)
adaptState = plot(adaptVec);
grid on;
axis([0 numPkts -0.2 1.2])
ylabel('Training');
xlabel('Symbols');
title('Adapt Weights Signal')
subplot(2,2,4)
errPlot = plot(evmVec);
grid on;
axis([1 numPkts 0 100])
xlabel('Symbols');
ylabel('EVM (%)');
title('EVM')
end
```

This helper function updates the figures.

```
function updateFigures(errPlot,evmPlot,scatSym, ...
    adaptState,w,y,evmEst,adaptWts,p,numFrames)
persistent yVec evmVec adaptVec

if p == 1
    yVec = nan(numFrames,1);
    evmVec = nan(numFrames,1);
    adaptVec = nan(numFrames,1);
```

```
end

yVec(p) = y;
evmVec(p) = evmEst;
adaptVec(p) = adaptWts;

errPlot.YData = abs(evmVec);
evmPlot.YData = abs(w);
scatSym.XData = real(yVec);
scatSym.YData = imag(yVec);
adaptState.YData = adaptVec;
drawnow limitrate
end
```

This helper function applies phase correction.

```
function y = phaseCorrection(y)
a = angle(y((real(y) > 0) & (imag(y) > 0)));
a(a < 0.1) = a(a < 0.1) + pi/2;
theta = mean(a) - pi/4;
y = y * exp(-1i*theta);
end
```

Decision Feedback Equalize Packetized Signals in Fading Environments

Recover QPSK symbols in fading environments with a decision feedback equalizer, using the least mean squares (LMS) algorithm. Use the `reset` object function to equalize independent packets. Use helper functions to generate plots. This example also shows symbol-based processing and frame-based processing.

Setup

Initialize system variables, create the equalizer System object, and initialize the plot figures.

```
M = 4; % QPSK
numSym = 1000;
numTrainingSym = 100;
numPackets = 5;
refTap = 5;
nFwdTaps = 9;
nFdbkTaps = 4;
ttlTaps = nFwdTaps + nFdbkTaps;
stepsz = 0.01;
ttlNumSym = numSym + numTrainingSym;
raylChan = comm.RayleighChannel( ...
    'PathDelays',[0 1], ...
    'AveragePathGains',[0 -9], ...
    'MaximumDopplerShift',0, ...
    'PathGainsOutputPort',true);
SNR = 35;
rxVec = zeros(ttlNumSym,numPackets);
txVec = zeros(ttlNumSym,numPackets);
yVec = zeros(ttlNumSym,1);
eVec = zeros(ttlNumSym,1);

dfeq1 = comm.DecisionFeedbackEqualizer( ...
```

```
    'Algorithm','LMS', ...
    'NumForwardTaps',nFwdTaps, ...
    'NumFeedbackTaps',nFdbkTaps, ...
    'ReferenceTap',refTap, ...
    'StepSize',stepsz, ...
    'TrainingFlagInputPort',true);

[errPlot,wStem,hStem,scatPlot] = ...
    initFigures(ttlNumSym,ttlTaps, ...
    raylChan.AveragePathGains);
```

Symbol-Based Processing

For symbol-based processing, provide one symbol at the input of the equalizer. Reset the equalizer state and channel after processing each packet.

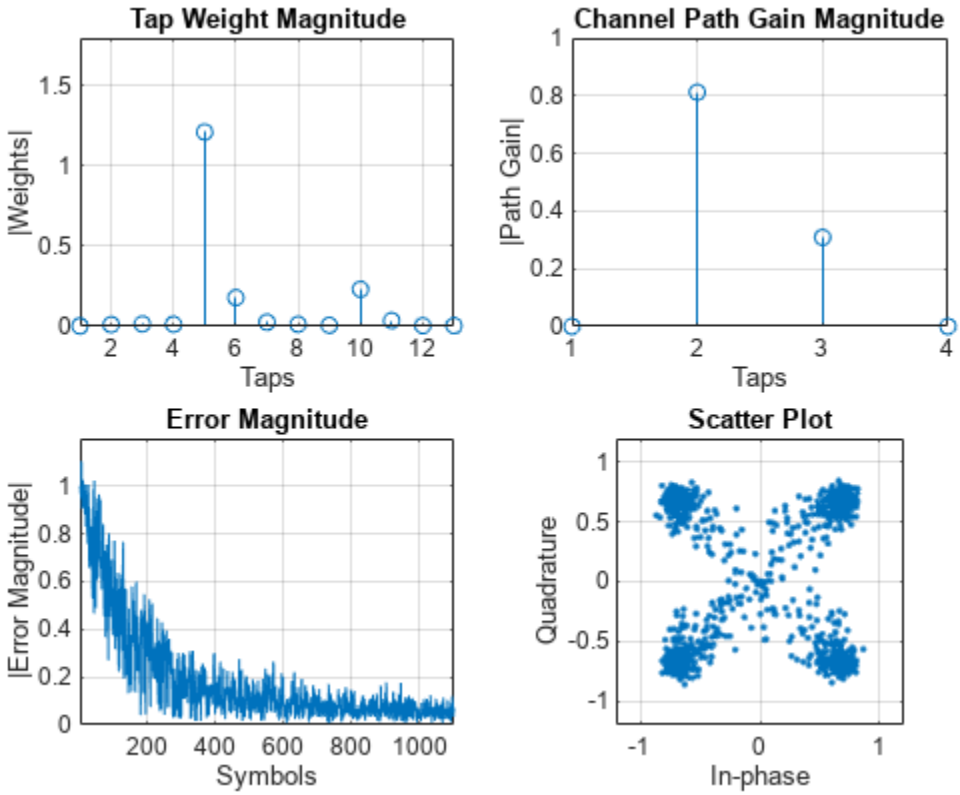
```
for p = 1:numPackets
    trainingFlag = true;
    for q=1:ttlNumSym
        data = randi([0 M-1],1,1);
        tx = pskmod(data,M,pi/4);
        [xc,pg] = raylChan(tx);
        rx = awgn(xc,25);
        [y,err,wts] = dfeq1(rx,tx,trainingFlag);
```

Disable training after processing `numTrainingSym` training symbols.

```
        if q == numTrainingSym
            trainingFlag = false;
        end
        updateFigures(errPlot,wStem,hStem, ...
            scatPlot,err,wts,y,pg,q,ttlNumSym);
        txVec(q,p) = tx;
        rxVec(q,p) = rx;
    end
```

After processing each packet, reset the channel System object to get a new realization of channel taps and the equalizer System object to restore the default taps weights.

```
    reset(raylChan)
    reset(dfeq1)
end
```



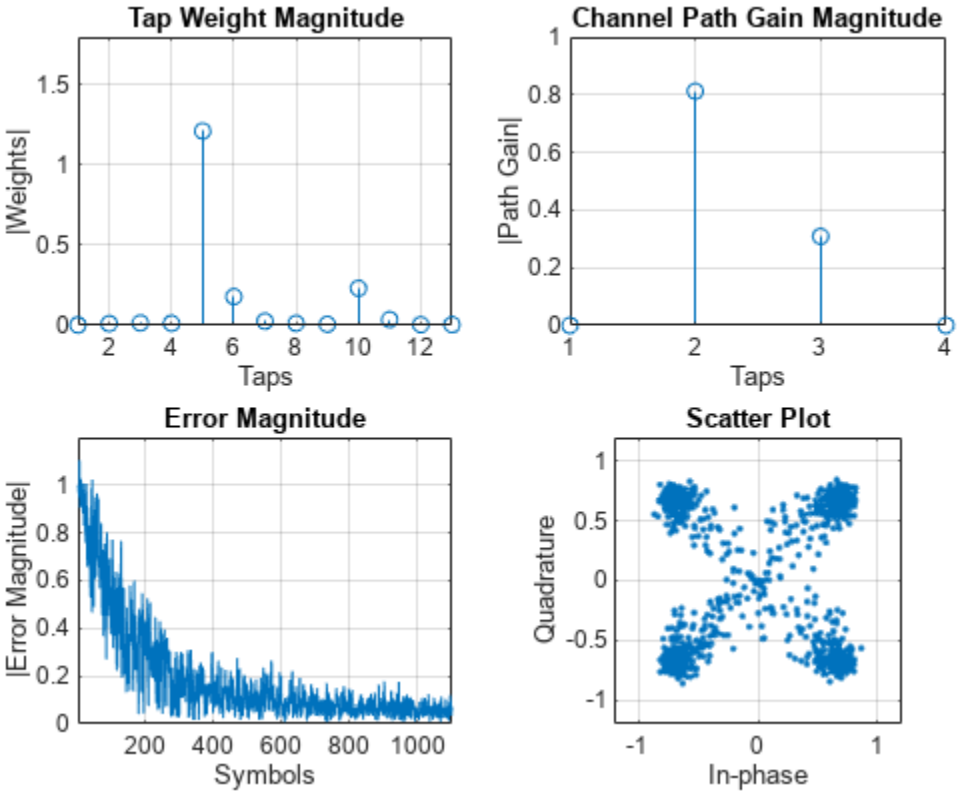
Packet-Based Processing

For packet-based processing, provide one packet at the input of the equalizer. Each packet contains `ttlNumSym` symbols. Because the training duration is less than the packet length, you do not need to specify the start-training input.

```
yVecPkt = zeros(ttlNumSym,numPackets);
errVecPkt = zeros(ttlNumSym,numPackets);
wgtVecPkt = zeros(ttlTaps,numPackets);
dfeq2 = comm.DecisionFeedbackEqualizer( ...
    'Algorithm','LMS', ...
    'NumForwardTaps',nFwdTaps, ...
    'NumFeedbackTaps',nFdbkTaps, ...
    'ReferenceTap',refTap, ...
    'StepSize',stepsz);
for p = 1:numPackets
    [yVecPkt(:,p),errVecPkt(:,p),wgtVecPkt(:,p)] = ...
        dfeq2(rxVec(:,p),txVec(1:numTrainingSym,p));
    for q=1:ttlNumSym
        updateFigures(errPlot,wStem,hStem,scatPlot, ...
            errVecPkt(q,p),wgtVecPkt(:,p),yVecPkt(q,p), ...
            pg,q,ttlNumSym);
    end
```

After processing each packet, reset the channel System object to get a new realization of channel taps and the equalizer System object to restore the default taps weights.

```
    reset(raylChan)
    reset(dfeq2)
end
```



Helper Functions

This helper function initializes the figures.

```
function [errPlot,wStem,hStem,scatPlot] = ...
    initFigures(ttlNumSym,ttlTap,pg)
yVec = nan(ttlNumSym,1);
eVec = nan(ttlNumSym,1);
wVec = zeros(ttlTap,1);
figure;
subplot(2,2,1);
wStem = stem(wVec);
axis([1 ttlTap 0 1.8]);
grid on;
xlabel('Taps');
ylabel('|Weights|');
title('Tap Weight Magnitude')
subplot(2,2,2);
hStem = stem([0 abs(pg) 0]);
grid on;
xlabel('Taps');
ylabel('|Path Gain|');
title('Channel Path Gain Magnitude')
subplot(2,2,3);
```

```
errPlot = plot(eVec);
axis([1 ttlNumSym 0 1.2]);
grid on
xlabel('Symbols');
ylabel('|Error Magnitude|');
title('Error Magnitude')
subplot(2,2,4);
scatPlot = plot(yVec,'.');
axis square;
axis([-1.2 1.2 -1.2 1.2]);
grid on;
xlabel('In-phase');
ylabel('Quadrature');
title(sprintf('Scatter Plot'));
end
```

This helper function updates the figures.

```
function updateFigures(errPlot,wStem,hStem,scatPlot, ...
    err,wts,y,pg,p,ttlNumSym)
persistent yVec eVec
if p == 1
    yVec = nan(ttlNumSym,1);
    eVec = nan(ttlNumSym,1);
end
yVec(p) = y;
eVec(p) = abs(err);
errPlot.YData = abs(eVec);
wStem.YData = abs(wts);
hStem.YData = [0 abs(pg) 0];
scatPlot.XData = real(yVec);
scatPlot.YData = imag(yVec);
drawnow limitrate
end
```

More About

Symbol Tap Spacing

You can configure the equalizer to operate as a symbol-spaced equalizer or as a fractional symbol-spaced equalizer.

- To operate the equalizer at a symbol-spaced rate, specify the number of samples per symbol as 1. Symbol-rate equalizers have taps spaced at the symbol duration. Symbol-rate equalizers are sensitive to timing phase.
- To operate the equalizer at a fractional symbol-spaced rate, specify the number of input samples per symbol as an integer greater than 1 and provide an input signal oversampled at that sampling rate. Fractional symbol-spaced equalizers have taps spaced at an integer fraction of the input symbol duration. Fractional symbol-spaced equalizers are not sensitive to timing phase.

Algorithms

Decision Feedback Equalizers

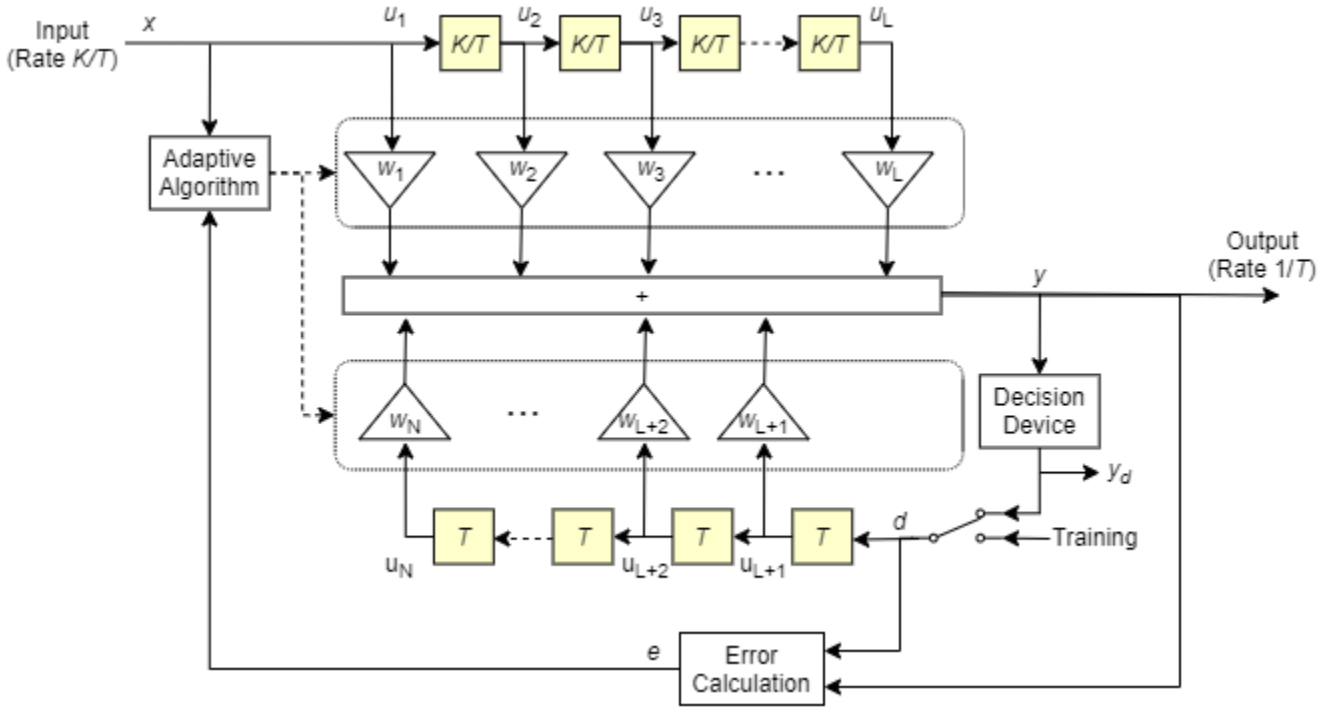
A decision feedback equalizer (DFE) is a nonlinear equalizer that reduces intersymbol interference (ISI) in frequency-selective channels. If a null exists in the frequency response of a channel, DFEs do

not enhance the noise. A DFE consists of a tapped delay line that stores samples from the input signal and contains a forward filter and a feedback filter. The forward filter is similar to a linear equalizer. The feedback filter contains a tapped delay line whose inputs are the decisions made on the equalized signal. Once per symbol period, the equalizer outputs a weighted sum of the values in the delay line and updates the weights to prepare for the next symbol period.

DFEs can be symbol-spaced or fractional symbol-spaced.

- For a symbol-spaced equalizer, the number of samples per symbol, *K*, is 1. The output sample rate equals the input sample rate.
- For a fractional symbol-spaced equalizer, the number of samples per symbol, *K*, is an integer greater than 1. Typically, *K* is 4 for fractional symbol-spaced equalizers. The output sample rate is 1/*T* and the input sample rate is *K*/*T*. Tap weight updating occurs at the output rate.

This schematic shows a fractional symbol-spaced DFE with a total of *N* weights, a symbol period of *T*, and *K* samples per symbol. The filter has *L* forward weights and *N*-*L* feedback weights. The forward filter is at the top, and the feedback filter is at the bottom. If *K* is 1, the result is a symbol-spaced DFE instead of a fractional symbol-spaced DFE.



In each symbol period, the equalizer receives *K* input samples at the forward filter and one decision or training sample at the feedback filter. The equalizer then outputs a weighted sum of the values in the forward and feedback delay lines and updates the weights to prepare for the next symbol period.

Note The algorithm for the Adaptive Algorithm block in the schematic jointly optimizes the forward and feedback weights. Joint optimization is especially important for convergence in the recursive least square (RLS) algorithm.

For more information, see “Equalization”.

Least Mean Square (LMS) Algorithm

For the LMS algorithm, in the previous schematic, w is a vector of all weights w_i, and u is a vector of all inputs u_i. Based on the current set of weights, the LMS algorithm creates the new set of weights as

$$w_{\text{new}} = w_{\text{current}} + (StepSize)\, ue^*.$$

The step size used by the adaptive algorithm is specified as a positive scalar. Increasing the step size reduces the equalizer convergence time but causes the equalized output signal to be less stable. To determine the maximum step size allowed when using the LMS adaptive algorithm, use the `maxstep` object function. The * operator denotes the complex conjugate and the error calculation $e = d - y$.

Recursive Least Square (RLS) Algorithm

For the RLS algorithm, in the previous schematic, w is the vector of all weights w_i, and u is the vector of all inputs u_i. Based on the current set of inputs, u, and the inverse correlation matrix, P, the RLS algorithm first computes the Kalman gain vector, K, as

$$K = \frac{Pu}{(ForgettingFactor) + u^H Pu}.$$

The forgetting factor used by the adaptive algorithm is specified as a scalar in the range (0, 1]. Decreasing the forgetting factor reduces the equalizer convergence time but causes the equalized output signal to be less stable. H denotes the Hermitian transpose. Based on the current inverse correlation matrix, the new inverse correlation matrix is

$$P_{\text{new}} = \frac{(1 - Ku^H)P_{\text{current}}}{ForgettingFactor}.$$

Based on the current set of weights, the RLS algorithm creates the new set of weights as

$$w_{\text{new}} = w_{\text{current}} + K^* e.$$

The * operator denotes the complex conjugate and the error calculation $e = d - y$.

Constant Modulus Algorithm (CMA)

For the CMA adaptive algorithm, in the previous schematic, w is the vector of all weights w_i, and u is the vector of all inputs u_i. Based on the current set of weights, the CMA adaptive algorithm creates the new set of weights as

$$w_{\text{new}} = w_{\text{current}} + (StepSize)\, u^* e.$$

The step size used by the adaptive algorithm is specified as a positive scalar. Increasing the step size reduces the equalizer convergence time but causes the equalized output signal to be less stable. To determine the maximum step size allowed by the CMA adaptive algorithm, use the `maxstep` object function. The * operator denotes the complex conjugate and the error calculation $e = y(R - |y|^2)$, where R is a constant related to the signal constellation.

Package: `comm`

Equalize modulated signals using linear filtering

Description

The `comm.LinearEqualizer` System object uses a linear filter tap delay line with a weighted sum to equalize modulated signals transmitted through a dispersive channel. The equalizer object adaptively adjusts tap weights based on the selected algorithm. For more information, see “Algorithms” on page 3-448.

To equalize modulated signals using a linear filter:

1. Create the `comm.LinearEqualizer` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
lineq = comm.LinearEqualizer
lineq = comm.LinearEqualizer(Name,Value)
```

Description

`lineq = comm.LinearEqualizer` creates a linear equalizer System object to adaptively equalize a signal.

`lineq = comm.LinearEqualizer(Name,Value)` sets properties using one or more name-value pairs. For example, `comm.LinearEqualizer('Algorithm','RLS')` configures the equalizer object to update tap weights using the recursive least squares (RLS) algorithm. Enclose each property name in quotes.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`Algorithm` — Adaptive algorithm
`'LMS'` (default) | `'RLS'` | `'CMA'`

Adaptive algorithm used for equalization, specified as one of these values:

- `'LMS'` — Update the equalizer tap weights using the “Least Mean Square (LMS) Algorithm” on page 3-449.
- `'RLS'` — Update the equalizer tap weights using the “Recursive Least Square (RLS) Algorithm” on page 3-449.
- `'CMA'` — Update the equalizer tap weights using the “Constant Modulus Algorithm (CMA)” on page 3-449.

Data Types: `char` | `string`

`NumTaps` — Number of equalizer taps

`5` (default) | positive integer

Number of equalizer taps, specified as a positive integer. The number of equalizer taps must be greater than or equal to the value of the `InputSamplesPerSymbol` property.

Data Types: `double`

`StepSize` — Step size

`0.01` (default) | positive scalar

Step size used by the adaptive algorithm, specified as a positive scalar. Increasing the step size reduces the equalizer convergence time but causes the equalizer output estimates to be less stable.

Tip To determine the maximum step size allowed, use the `maxstep` object function.

Tunable: Yes

Dependencies

To enable this property, set Algorithm to `'LMS'` or `'CMA'`.

Data Types: `double`

`ForgettingFactor` — Forgetting factor

`0.99` (default) | scalar in the range (0, 1]

Forgetting factor used by the adaptive algorithm, specified as a scalar in the range (0, 1]. Decreasing the forgetting factor reduces the equalizer convergence time but causes the equalizer output estimates to be less stable.

Tunable: Yes

Dependencies

To enable this property, set Algorithm to `'RLS'`.

Data Types: `double`

`InitialInverseCorrelationMatrix` — Initial inverse correlation matrix

`0.1` (default) | scalar | matrix

Initial inverse correlation matrix, specified as a scalar or an N_{Taps}-by-N_{Taps} matrix. N_{Taps} is equal to the NumTaps property value. If you specify `InitialInverseCorrelationMatrix` as a scalar, a, the equalizer sets the initial inverse correlation matrix to a times the identity matrix: a(`eye`(N_{Taps})).

Dependencies

To enable this property, set Algorithm to `'RLS'`.

Data Types: `double`

`Constellation` — Signal constellation

`pskmod(0:3,4,pi/4)` (default) | vector

Signal constellation, specified as a vector. The default value is a QPSK constellation generated using this code: `pskmod(0:3,4,pi/4)`.

Data Types: `double`

`ReferenceTap` — Reference tap

`3` (default) | positive integer

Reference tap, specified as a positive integer less than or equal to the NumTaps property value. The equalizer uses the reference tap location to track the main energy of the channel.

Data Types: `double`

`InputDelay` — Input signal delay

`0` (default) | nonnegative integer

Input signal delay in samples relative to the reset time of the equalizer, specified as a nonnegative integer. If the input signal is a vector of length greater than 1, then the input delay is relative to the start of the input vector. If the input signal is a scalar, then the input delay is relative to the first call of the System object and to the first call of the System object after calling the `release` or `reset` object function.

Data Types: `double`

`InputSamplesPerSymbol` — Number of input samples per symbol

`1` (default) | positive integer

Number of input samples per symbol, specified as a positive integer. Setting this property to any number greater than one effectively creates a fractionally spaced equalizer. For more information, see “Symbol Tap Spacing” on page 3-447.

Data Types: `double`

`TrainingFlagInputPort` — Enable training control input

`0` or `false` (default) | `1` or `true`

Enable training control input, specified as a logical `0` (`false`) or `1` (`true`). Setting this property to `true` enables the equalizer training flag input tf.

Data Types: `logical`

`AdaptAfterTraining` — Update tap weights when not training

`1` or `true` (default) | `0` or `false`

Update tap weights when not training, specified as a logical `1` (`true`) or `0` (`false`). If this property is set to `true`, the System object uses decision directed mode to update equalizer tap weights. If this property is set to `false`, the System object keeps the equalizer tap weights unchanged after training.

Data Types: `logical`

`AdaptWeightsSource` — Source of adapt tap weights request

`'Property'` (default) | `'Input port'`

Source of adapt tap weights request, specified as one of these values:

- `'Property'` — Specify this value to use the AdaptWeights property to control when the System object adapts tap weights.
- `'Input port'` — Specify this value to use the `aw` input to control when the System object adapts tap weights.

Dependencies

To enable this property, set Algorithm to `'CMA'`.

Data Types: `char` | `string`

`AdaptWeights` — Adapt tap weights

`1` or `true` (default) | `0` or `false`

Adapt tap weights, specified as a logical `1` (`true`) or `0` (`false`). If this property is set to `true`, the System object updates the equalizer tap weights. If this property is set to `false`, the System object keeps the equalizer tap weights unchanged.

Dependencies

To enable this property, set AdaptWeightsSource to `'Property'` and set AdaptAfterTraining to `true`.

Data Types: `logical`

`InitialWeightsSource` — Source for initial tap weights

`'Auto'` (default) | `'Property'`

Source for initial tap weights, specified as

- `'Auto'` — Initialize the tap weights to the algorithm-specific default values, as described in the InitialWeights property.
- `'Property'` — Initialize the tap weights using the InitialWeights property value.

Data Types: `char` | `string`

`InitialWeights` — Initial tap weights

`0` or `[0;0;1;0;0]` (default) | scalar | column vector

Initial tap weights used by the adaptive algorithm, specified as a scalar or vector. The default is `0` when the Algorithm property is set to `'LMS'` or `'RLS'`. The default is `[0;0;1;0;0]` when the Algorithm property is set to `'CMA'`.

If you specify `InitialWeights` as a vector, the vector length must be equal to the NumTaps property value. If you specify `InitialWeights` as a scalar, the equalizer uses scalar expansion to create a vector of length NumTaps with all values set to `InitialWeights`.

Dependencies

To enable this property, set InitialWeightsSource to `'Property'`.

Data Types: `double`

`WeightUpdatePeriod` — Tap weight update period

`1` (default) | positive integer

Tap weight update period in symbols, specified as a positive integer. The equalizer updates the tap weights after processing this number of symbols.

Data Types: `double`

Usage

Syntax

```
y = lineq(x,tsym)
y = lineq(x,tsym,tf)

y = lineq(x)
y = lineq(x,aw)
```

Description

`y = lineq(x,tsym)` equalizes input signal `x` by using training symbols `tsym`. The output is the equalized symbols. To enable this syntax, set the Algorithm property to `'LMS'` or `'RLS'`.

`y = lineq(x,tsym,tf)` also specifies training flag `tf`. The System object starts training when `tf` changes from `false` to `true` (at the rising edge). The System object trains until all symbols in `tsym` are processed. The input `tsym` is ignored when `tf` is `false`. To enable this syntax, set the Algorithm property to `'LMS'` or `'RLS'` and TrainingFlagInputPort property to `true`.

`y = lineq(x)` equalizes input signal `x`. To enable this syntax, set the Algorithm property to `'CMA'`.

`y = lineq(x,aw)` also specifies adapts weights flag `aw`. If `aw` is `true`, the System object adapts the equalizer tap weights. If `aw` is `false`, the System object keeps the weights unchanged. To enable this syntax, set the Algorithm property to `'CMA'` and AdaptWeightsSource property to `'Input port'`.

`[y,err] = lineq( ___ )` also returns error signal `err` using input arguments from any of the previous syntaxes.

`[y,err,weights] = lineq( ___ )` also returns `weights`, the tap weights from the last tap weight update, using input arguments from any of the previous syntaxes.

Input Arguments

`x` — Input signal

column vector

Input signal, specified as a column vector. The input signal vector length must be equal to an integer multiple of the InputSamplesPerSymbol property value. For more information, see “Symbol Tap Spacing” on page 3-447.

Data Types: `double`
Complex Number Support: Yes

`tsym` — Training symbols

column vector

Training symbols, specified as a column vector of length less than or equal to the length of input `x`. The input `tsym` is ignored when `tf` is `false`.

Dependencies

To enable this argument, set the Algorithm property to `'LMS'` or `'RLS'`.

Data Types: `double`
Complex Number Support: Yes

`tf` — Training flag

`1` or `true` | `0` or `false`

Training flag, specified as a logical `1` (`true`) or `0` (`false`). The System object starts training when `tf` changes from `false` to `true` (at the rising edge). The System object trains until all symbols in `tsym` are processed. The input `tsym` is ignored when `tf` is `false`.

Dependencies

To enable this argument, set the Algorithm property to `'LMS'` or `'RLS'` and TrainingFlagInputPort property to `true`.

Data Types: `logical`

`aw` — Adapt weights flag

`1` or `true` | `0` or `false`

Adapt weights flag, specified as a logical `1` (`true`) or `0` (`false`). If `aw` is `true`, the System object adapts weights. If `aw` is `false`, the System object keeps the weights unchanged.

Dependencies

To enable this argument, set the Algorithm property to `'CMA'` and AdaptWeightsSource property to `'Input port'`.

Data Types: `logical`

Output Arguments

`y` — Equalized symbols

column vector

Equalized symbols, returned as a column vector that has the same length as input signal `x`.

`err` — Error signal

column vector

Error signal, returned as a column vector that has the same length as input signal `x`.

`weights` — Tap weights

column vector

Tap weights, returned as a column vector that has NumTaps elements. `weights` contains the tap weights from the last tap weight update.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `comm.LinearEqualizer`

isLocked	Determine if System object is in use
clone	Create duplicate System object
info	Characteristic information about the equalizer object
maxstep	Maximum step size for LMS equalizer convergence
mmseweights	Linear equalizer MMSE tap weights

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Linearly Equalize BPSK-Modulated Signal

Create a BPSK modulator and an equalizer System object™, specifying a linear LMS equalizer having eight taps and a step size of 0.03.

```
bpsk = comm.BPSKModulator;
eqlms = comm.LinearEqualizer( ...
    'Algorithm','LMS', ...
    'NumTaps',8, ...
    'StepSize',0.03);
```

Change the reference tap index of the equalizer.

```
eqlms.ReferenceTap = 4;
```

Build a set of test data. Receive the data by convolving the signal.

```
x = bpsk(randi([0 1],1000,1));
rxsig = conv(x,[1 0.8 0.3]);
```

Use `maxstep` to find the maximum permitted step size.

```
mxStep = maxstep(eqlms,rxsig)
```

```
mxStep = 0.1384
```

Equalize the received signal. Use the first 200 symbols as the training sequence.

```
y = eqlms(rxsig,x(1:200));
```

Linearly Equalize QPSK-Modulated Signal

Apply linear equalization using the least mean squares (LMS) algorithm to recover QPSK symbols passed through a multipath AWGN channel.

Initialize simulation variables.

```
M = 4; % QPSK
numSymbols = 10000;
numTrainingSymbols = 1000;
chtaps = [1 0.5*exp(1i*pi/6) 0.1*exp(-1i*pi/8)];
```

Generate QPSK-modulated symbols. Apply multipath channel filtering and AWGN impairments to the symbols.

```
data = randi([0 M-1],numSymbols,1);
tx = pskmod(data,M,pi/4);
rx = awgn(filter(chtaps,1,tx),25,'measured');
```

Create a linear equalizer System object and display the default configuration. Adjust the reference tap to 1. Check the maximum permitted step size. Equalize the impaired symbols.

```
eq = comm.LinearEqualizer
```

```
eq =
  comm.LinearEqualizer with properties:

               Algorithm: 'LMS'
                 NumTaps: 5
                StepSize: 0.0100
           Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i ... ]
            ReferenceTap: 3
              InputDelay: 0
    InputSamplesPerSymbol: 1
    TrainingFlagInputPort: false
       AdaptAfterTraining: true
     InitialWeightsSource: 'Auto'
       WeightUpdatePeriod: 1
```

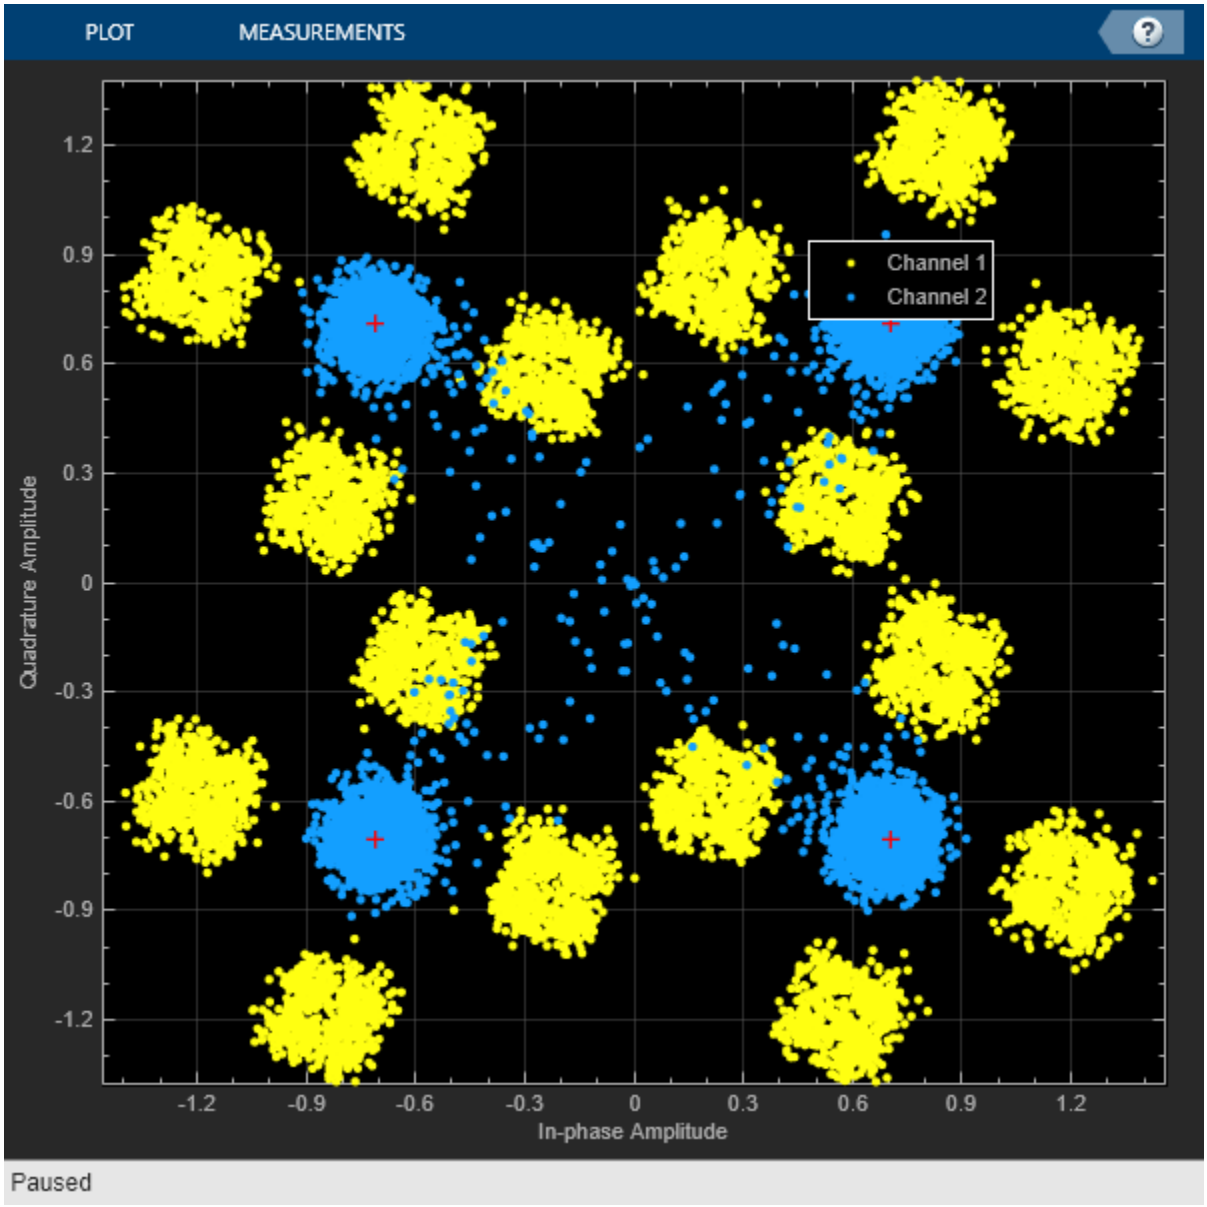
```
eq.ReferenceTap = 1;
mxStep = maxstep(eq,rx)
```

```
mxStep = 0.3171
```

```
[y,err,weights] = eq(rx,tx(1:numTrainingSymbols));
```

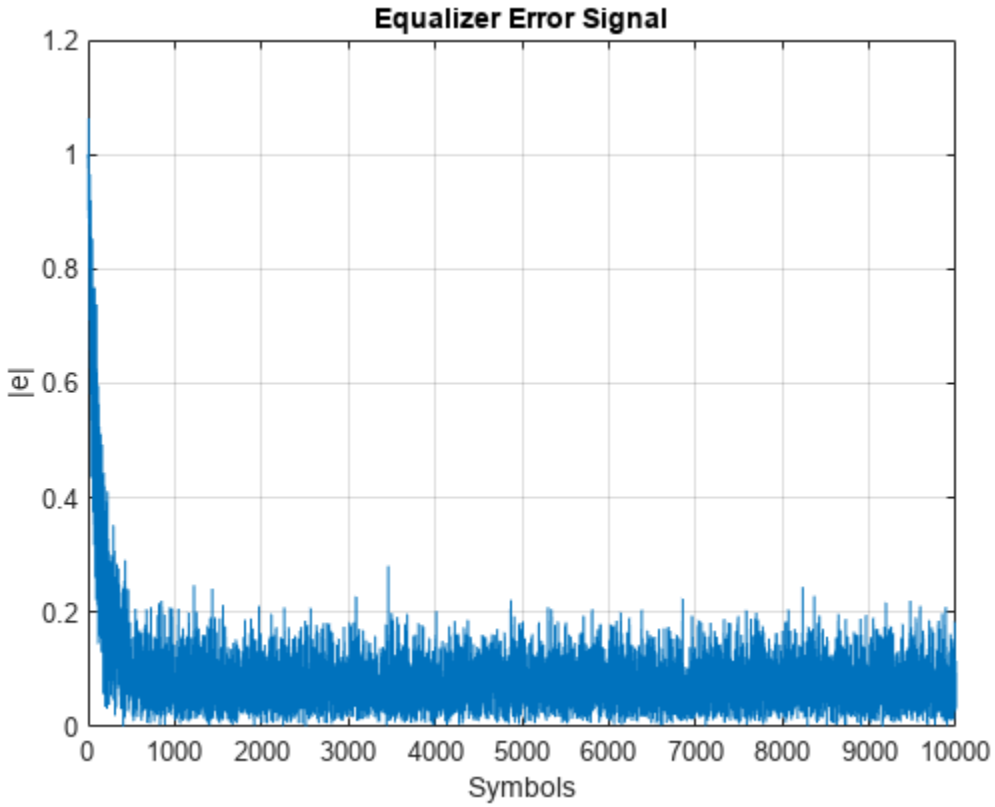
Plot the constellation of the impaired and equalized symbols.

```
constell = comm.ConstellationDiagram('NumInputPorts',2);
constell(rx,y);
```



Plot the equalizer error signal and compute the error vector magnitude (EVM) of the equalized symbols.

```
plot(abs(err));
grid on;
xlabel('Symbols');
ylabel('|e|');
title('Equalizer Error Signal');
```

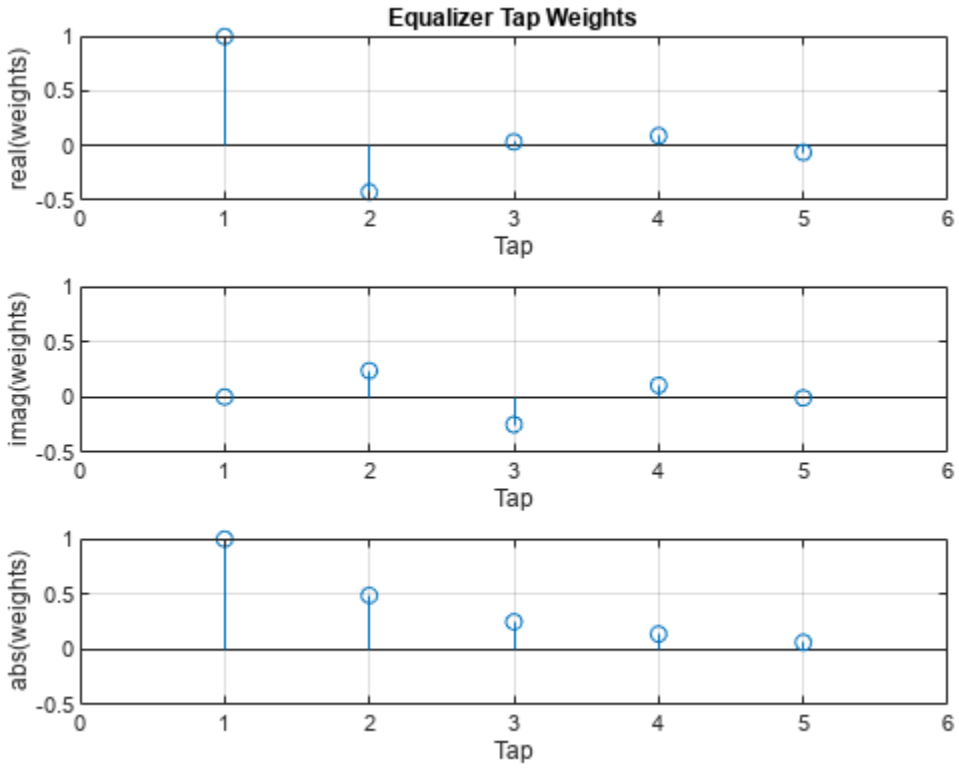


```
errevm = comm.EVM;
evm = errevm(tx,y)
```

```
evm = 11.7853
```

Plot the equalizer tap weights.

```
subplot(3,1,1);
stem(real(weights));
ylabel('real(weights)');
xlabel('Tap');
grid on;
axis([0 6 -0.5 1]);
title('Equalizer Tap Weights');
subplot(3,1,2);
stem(imag(weights));
ylabel('imag(weights)');
xlabel('Tap');
grid on;
axis([0 6 -0.5 1]);
subplot(3,1,3);
stem(abs(weights));
ylabel('abs(weights)');
xlabel('Tap');
grid on;
axis([0 6 -0.5 1]);
```



Linearly Equalize System by Using Different Training Schemes

Demonstrate linear equalization by using the least mean squares (LMS) algorithm to recover QPSK symbols passed through an AWGN channel. Apply different equalizer training schemes and show the symbol error magnitude.

System Setup

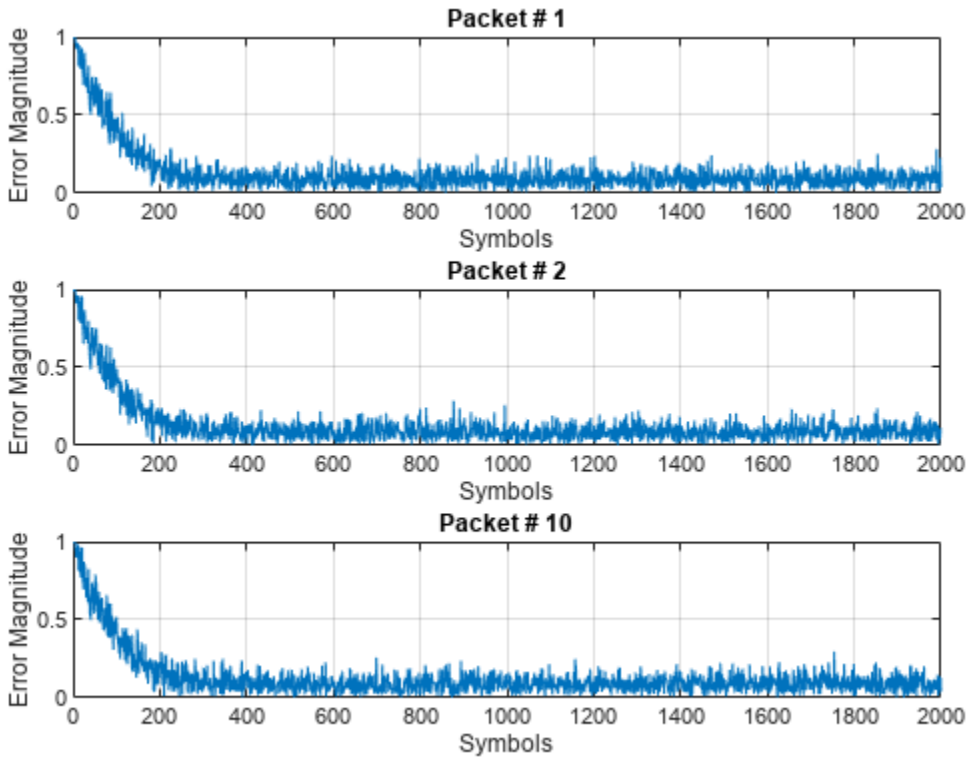
Simulate a QPSK-modulated system subject to AWGN. Transmit packets composed of 200 training symbols and 1800 random data symbols. Configure a linear LMS equalizer to recover the packet data.

```
M = 4;
numTrainSymbols = 200;
numDataSymbols = 1800;
SNR = 20;
trainingSymbols = pskmod(randi([0 M-1],numTrainSymbols,1),M,pi/4);
numPkts = 10;
lineq = comm.LinearEqualizer('Algorithm','LMS', ...
    'NumTaps',5,'ReferenceTap',3,'StepSize',0.01);
```

Train the Equalizer at the Beginning of Each Packet with Reset

Use prepended training symbols when processing each packet. After processing each packet, reset the equalizer. This reset forces the equalizer to train the taps with no previous knowledge. Equalizer error signal plots for the first, second, and last packet show higher symbol errors at the start of each packet.

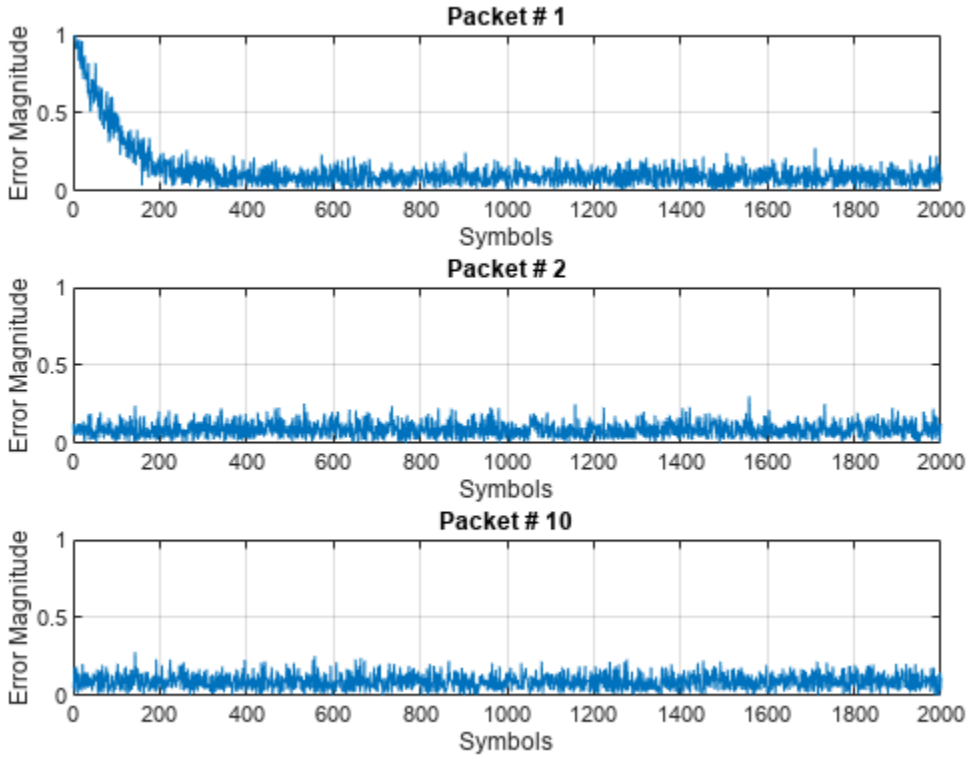
```
jj = 1;
figure
for ii = 1:numPkts
    b = randi([0 M-1],numDataSymbols,1);
    dataSym = pskmod(b,M,pi/4);
    packet = [trainingSymbols;dataSym];
    rx = awgn(packet,SNR);
    [~,err] = lineq(rx,trainingSymbols);
    reset(lineq)
    if (ii ==1 || ii == 2 ||ii == numPkts)
        subplot(3,1,jj)
        plot(abs(err))
        title(['Packet # ',num2str(ii)])
        xlabel('Symbols')
        ylabel('Error Magnitude')
        axis([0,length(packet),0,1])
        grid on;
        jj = jj+1;
    end
end
```



Train the Equalizer at the Beginning of Each Packet Without Reset

Process each packet using prepended training symbols. Do not reset the equalizer after each packet is processed. By not resetting after each packet, the equalizer retains tap weights from training prior packets. Equalizer error signal plots for the first, second, and last packet show that after the initial training on the first packet, subsequent packets have fewer symbol errors at the start of each packet.

```
release(lineq)
jj = 1;
figure
for ii = 1:numPkts
    b = randi([0 M-1],numDataSymbols,1);
    dataSym = pskmod(b,M,pi/4);
    packet = [trainingSymbols;dataSym];
    channel = 1;
    rx = awgn(packet*channel,SNR);
    [~,err] = lineq(rx,trainingSymbols);
    if (ii ==1 || ii == 2 ||ii == numPkts)
        subplot(3,1,jj)
        plot(abs(err))
        title(['Packet # ',num2str(ii)])
        xlabel('Symbols')
        ylabel('Error Magnitude')
        axis([0,length(packet),0,1])
        grid on;
        jj = jj+1;
    end
end
```



Train the Equalizer Periodically

Systems with signals subject to time-varying channels require periodic equalizer training to maintain lock on the channel variations. Specify a system that has 200 symbols of training for every 1800 data symbols. Between training, the equalizer does not update tap weights. The equalizer processes 200 symbols per packet.

```
Rs = 1e6;
fd = 20;
spp = 200; % Symbols per packet
b = randi([0 M-1],numDataSymbols,1);
dataSym = pskmod(b,M,pi/4);
packet = [trainingSymbols; dataSym];
stream = repmat(packet,10,1);
tx = (0:length(stream)-1)'/Rs;
channel = exp(1i*2*pi*fd*tx);
rx = awgn(stream.*channel,SNR);
```

Set the `AdaptAfterTraining` property to `false` to stop the equalizer tap weight updates after the training phase.

```
release(lineq)
lineq.AdaptAfterTraining = false
```

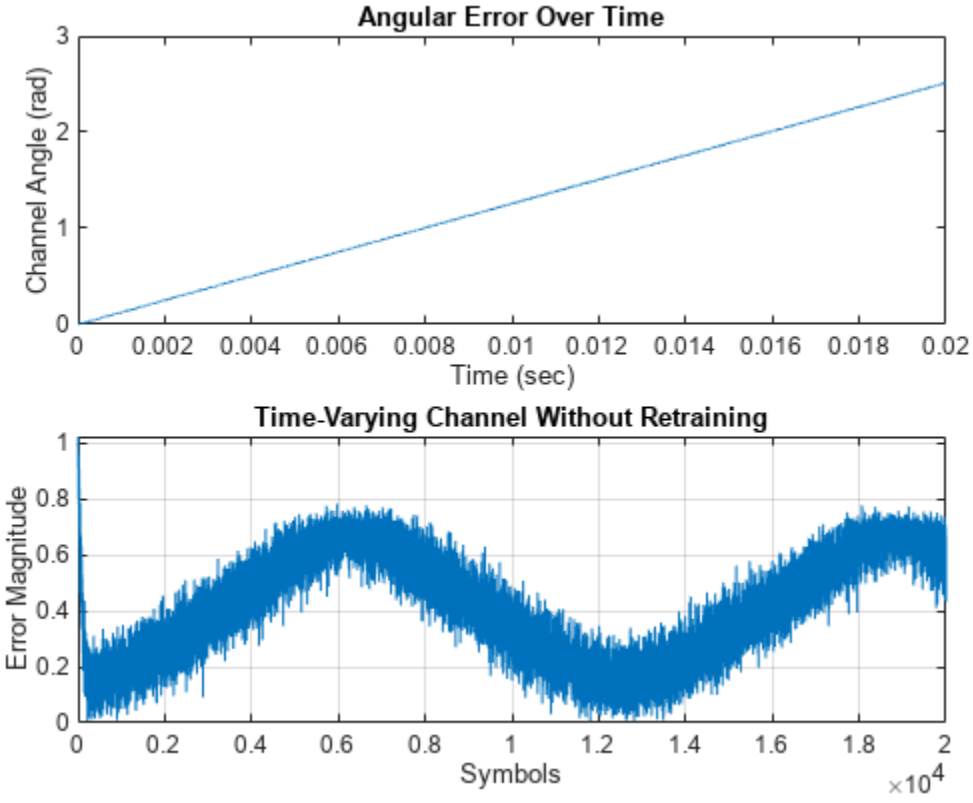
```
lineq =
  comm.LinearEqualizer with properties:
```

```
              Algorithm: 'LMS'
                NumTaps: 5
               StepSize: 0.0100
          Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i ... ]
           ReferenceTap: 3
             InputDelay: 0
  InputSamplesPerSymbol: 1
  TrainingFlagInputPort: false
     AdaptAfterTraining: false
   InitialWeightsSource: 'Auto'
     WeightUpdatePeriod: 1
```

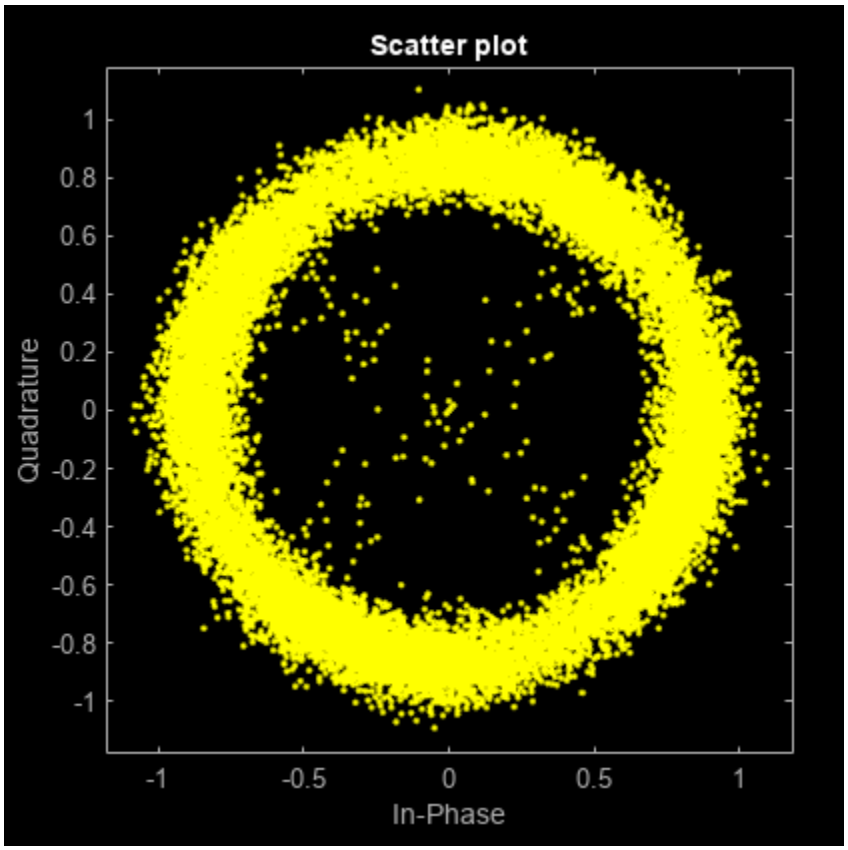
Equalize the impaired data. Plot the angular error from the channel, the equalizer error signal, and signal constellation. As the channel varies, the equalizer output does not remove the channel effects. The output constellation rotates out of sync, resulting in bit errors.

```
[y,err] = lineq(rx,trainingSymbols);

figure
subplot(2,1,1)
plot(tx, unwrap(angle(channel)))
xlabel('Time (sec)')
ylabel('Channel Angle (rad)')
title('Angular Error Over Time')
subplot(2,1,2)
plot(abs(err))
xlabel('Symbols')
ylabel('Error Magnitude')
grid on
title('Time-Varying Channel Without Retraining')
```



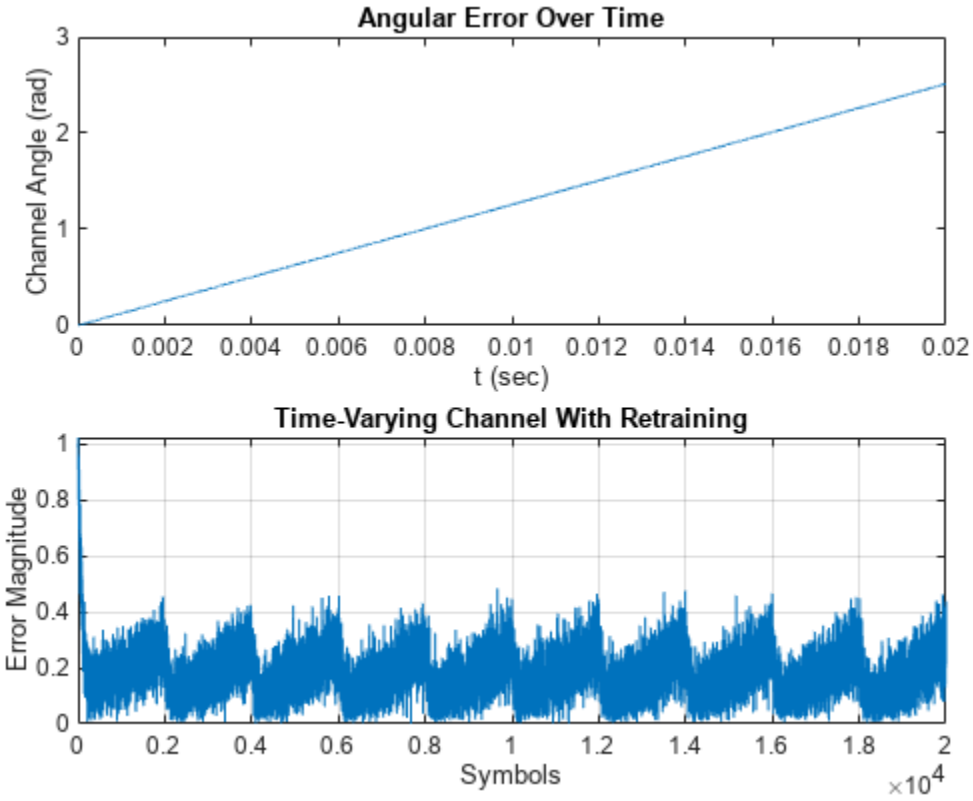
```
scatterplot(y)
```



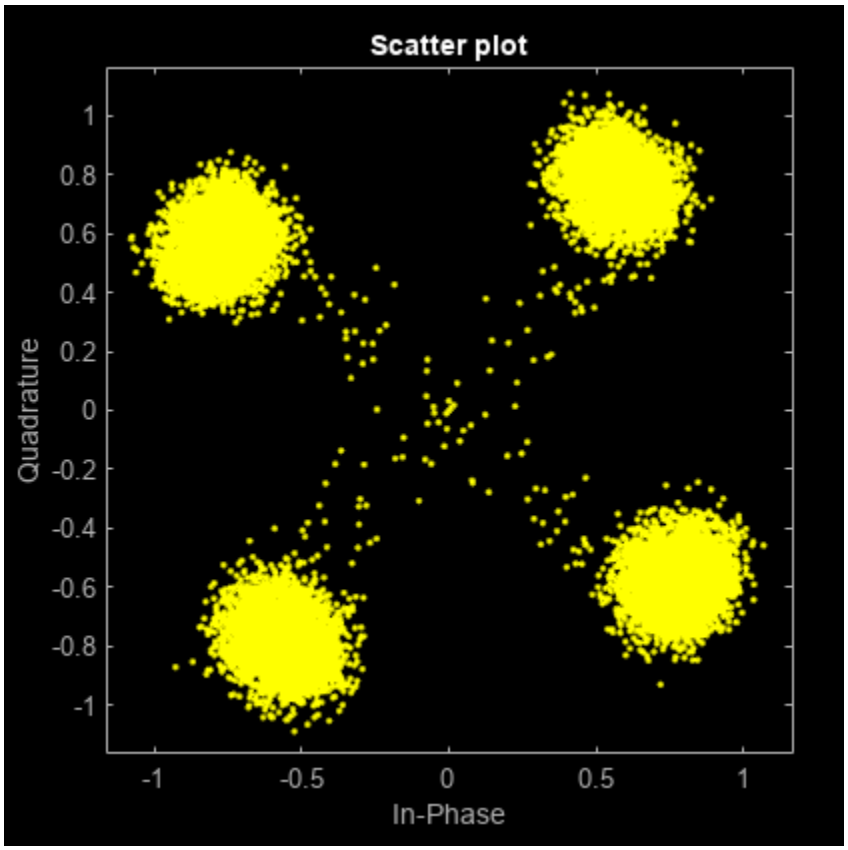
Set the `TrainingInputPort` property to `true` to configure the equalizer to retrain the taps when signaled by the `trainFlag` input. The equalizer trains only when `trainFlag` is `true`. After every 2000 symbols, the equalizer retrains the taps and keeps lock on variations of the channel. Plot the angular error from the channel, equalizer error signal, and signal constellation. As the channel varies, the equalizer output removes the channel effects. The output constellation does not rotate out of sync and bit errors are reduced.

```
release(lineq)
lineq.TrainingFlagInputPort = true;
symbolCnt = 0;
numPackets = length(rx)/spp;
trainFlag = true;
trainingPeriod = 2000;
eVec = zeros(size(rx));
yVec = zeros(size(rx));
for p=1:numPackets
    [yVec((p-1)*spp+1:p*spp,1),eVec((p-1)*spp+1:p*spp,1)] = ...
        lineq(rx((p-1)*spp+1:p*spp,1),trainingSymbols,trainFlag);
    symbolCnt = symbolCnt + spp;
    if symbolCnt >= trainingPeriod
        trainFlag = true;
        symbolCnt = 0;
    else
        trainFlag = false;
    end
end
figure
```

```
subplot(2,1,1)
plot(tx, unwrap(angle(channel)))
xlabel('t (sec)')
ylabel('Channel Angle (rad)')
title('Angular Error Over Time')
subplot(2,1,2)
plot(abs(eVec))
xlabel('Symbols')
ylabel('Error Magnitude')
grid on
title('Time-Varying Channel With Retraining')
```



```
scatterplot(yVec)
```



Linearly Equalize Delayed Signal

Simulate a system with delay between the transmitted symbols and received samples. Typical systems have transmitter and receiver filters that result in a delay. This delay must be accounted for to synchronize the system. In this example, the system delay is introduced without transmit and receive filters. Linear equalization, using the least mean squares (LMS) algorithm, recovers QPSK symbols.

Initialize simulation variables.

```
M = 4; % QPSK
numSymbols = 10000;
numTrainingSymbols = 1000;
mpChan = [1 0.5*exp(1i*pi/6) 0.1*exp(-1i*pi/8)];
systemDelay = dsp.Delay(20);
snr = 24;
```

Generate QPSK-modulated symbols. Apply multipath channel filtering, a system delay, and AWGN to the transmitted symbols.

```
data = randi([0 M-1],numSymbols,1);
tx = pskmod(data,M,pi/4); % OQPSK
delayedSym = systemDelay(filter(mpChan,1,tx));
rx = awgn(delayedSym,snr,'measured');
```

Create equalizer and EVM System objects. The equalizer System object specifies a linear equalizer that uses the LMS algorithm.

```
lineq = comm.LinearEqualizer('Algorithm','LMS', ...
    'NumTaps',9,'ReferenceTap',5);
evm = comm.EVM('ReferenceSignalSource', ...
    'Estimated from reference constellation');
```

Equalize Without Adjusting Input Delay

Equalize the received symbols.

```
[y1,err1,wts1] = lineq(rx,tx(1:numTrainingSymbols,1));
```

Find the delay between the received symbols and the transmitted symbols by using the `finddelay` function.

```
rxDelay = finddelay(tx,rx)
```

```
rxDelay = 20
```

Display the equalizer information. The latency value indicates the delay introduced by the equalizer. Calculate the total delay as the sum of `rxDelay` and the equalizer latency.

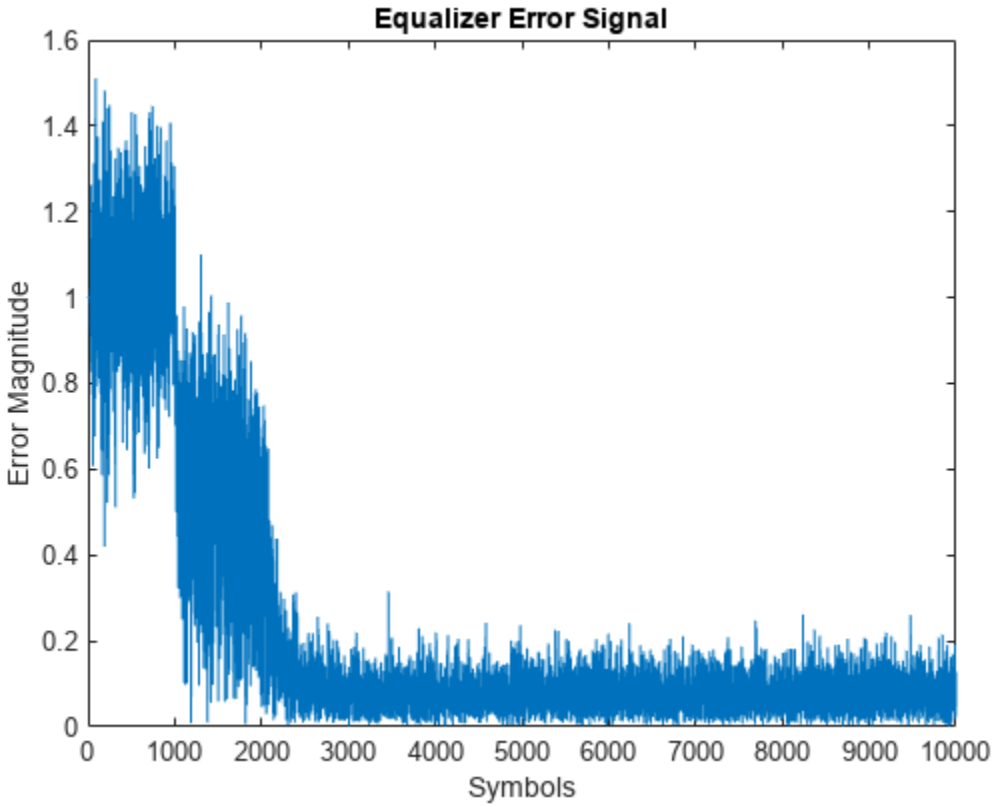
```
eqInfo = info(lineq)
```

```
eqInfo = struct with fields:
    Latency: 4
```

```
totalDelay = rxDelay + eqInfo.Latency;
```

Until the equalizer output converges, the symbol error rate is high. Plot the error output, `err1`, to determine when the equalized output converges.

```
plot(abs(err1))
xlabel('Symbols')
ylabel('Error Magnitude')
title('Equalizer Error Signal')
```



The plot shows excessive errors beyond the 1000 symbols training period. When demodulating symbols and computing symbol errors, to account for the unconverged output and the system delay between the equalizer output and transmitted symbols, skip the first 2000 symbols.

```
dataRec1 = pskdemod(y1(2000+totalDelay:end),M,pi/4);
symErrWithDelay = symerr(data(2000:end-totalDelay),dataRec1)
```

```
symErrWithDelay = 5999
```

```
evmWithDelay = evm(y1)
```

```
evmWithDelay = 33.0110
```

The error rate and EVM are high because the receive delay was not accounted for in the equalizer System object.

Adjust Input Delay in Equalizer

Equalize the received data by using the delay value to set the `InputDelay` property. Because `InputDelay` is a nontunable property, you must release the `lineq` System object to reconfigure the `InputDelay` property. Equalize the received symbols.

```
release(lineq)
lineq.InputDelay = rxDelay
```

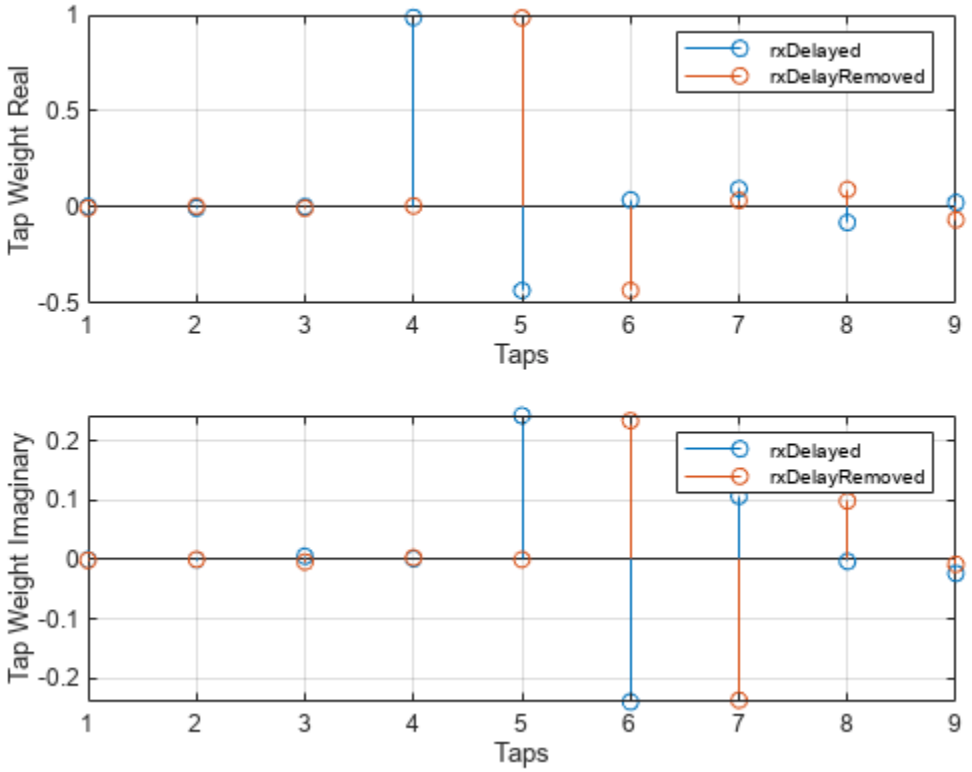
```
lineq =
  comm.LinearEqualizer with properties:
```

```
                Algorithm: 'LMS'
                  NumTaps: 9
                 StepSize: 0.0100
            Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i ... ]
             ReferenceTap: 5
               InputDelay: 20
    InputSamplesPerSymbol: 1
    TrainingFlagInputPort: false
       AdaptAfterTraining: true
     InitialWeightsSource: 'Auto'
       WeightUpdatePeriod: 1
```

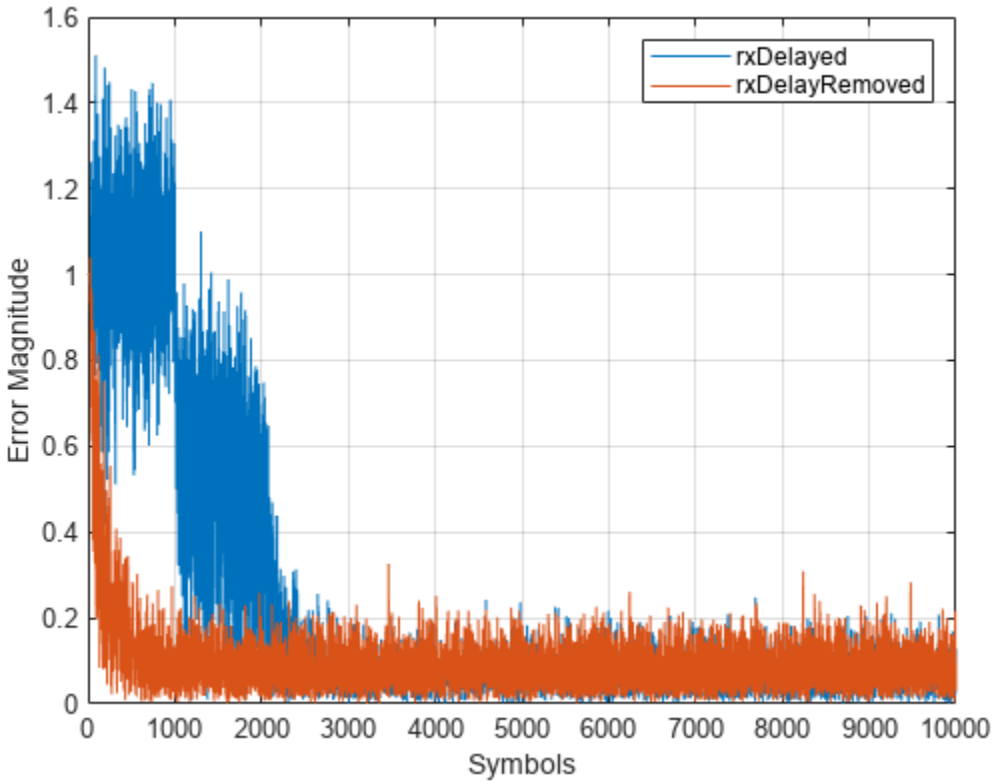
```
[y2,err2,wts2] = lineq(rx,tx(1:numTrainingSymbols,1));
```

Plot the tap weights and equalized error magnitude. A stem plot shows the equalizer tap weights before and after the system delay is removed. A 2-D line plot shows the slower equalizer convergence for the delayed signal as compared to the signal with the delay removed.

```
subplot(2,1,1)
stem([real(wts1),real(wts2)])
xlabel('Taps')
ylabel('Tap Weight Real')
legend('rxDelayed','rxDelayRemoved')
grid on
subplot(2,1,2)
stem([imag(wts1),imag(wts2)])
xlabel('Taps')
ylabel('Tap Weight Imaginary')
legend('rxDelayed','rxDelayRemoved')
grid on
```



```
figure
plot([abs(err1),abs(err2)])
xlabel('Symbols')
ylabel('Error Magnitude')
legend('rxDelayed','rxDelayRemoved')
grid on
```



Plot error output of the equalized signals, `rxDelayed` and `rxDelayRemoved`. For the signal that has the delay removed, the equalizer converges during the 1000 symbol training period. When demodulating symbols and computing symbol errors, to account for the unconverged output and the system delay between the equalizer output and transmitted symbols, skip the first 500 symbols. Reconfiguring the equalizer to account for the system delay enables better equalization of the signal, and reduces symbol errors and the EVM.

```
eqInfo = info(lineq)
```

```
eqInfo = struct with fields:
    Latency: 4
```

```
totalDelay = rxDelay + eqInfo.Latency;
dataRec2 = pskdemod(y2(500+totalDelay:end),M,pi/4);
symErrDelayRemoved = symerr(data(500:end-totalDelay),dataRec2)
```

```
symErrDelayRemoved = 0
```

```
evmDelayRemoved = evm(y2(500+totalDelay:end))
```

```
evmDelayRemoved = 9.5660
```

Linearly Equalize Symbols By Using EVM-Based Training

Recover QPSK symbols with a linear equalizer by using the constant modulus algorithm (CMA) and EVM-based taps training. When using blind equalizer algorithms, such as CMA, train the equalizer

taps by using the `AdaptWeights` property to start and stop training. Helper functions are used to generate plots and apply phase correction.

Initialize system variables.

```
rng(123456);
M = 4; % QPSK
numSymbols = 100;
numPackets = 5000;
raylChan = comm.RayleighChannel( ...
    'PathDelays',[0 1], ...
    'AveragePathGains',[0 -12], ...
    'MaximumDopplerShift',1e-5);
SNR = 50;
adaptWeights = true;
```

Create the equalizer and EVM System objects. The equalizer System object specifies a linear equalizer by using the CMA adaptive algorithm. Call the helper function to initialize figure plots.

```
lineq = comm.LinearEqualizer( ...
    'Algorithm','CMA', ...
    'NumTaps',5, ...
    'ReferenceTap',3, ...
    'StepSize',0.03, ...
    'AdaptWeightsSource','Input port')
```

```
lineq =
  comm.LinearEqualizer with properties:

                Algorithm: 'CMA'
                  NumTaps: 5
                 StepSize: 0.0300
            Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i ... ]
             ReferenceTap: 3
    InputSamplesPerSymbol: 1
       AdaptWeightsSource: 'Input port'
     InitialWeightsSource: 'Auto'
       WeightUpdatePeriod: 1
```

```
info(lineq)
```

```
ans = struct with fields:
    Latency: 2
```

```
evm = comm.EVM('ReferenceSignalSource', ...
    'Estimated from reference constellation');
[errPlot,evmPlot,scatSym,adaptState] = ...
    initFigures(numPackets,lineq);
```

Equalization Loop

To implement the equalization loop:

1. Generate PSK data packets.
2. Apply Rayleigh fading and AWGN to the transmission data.

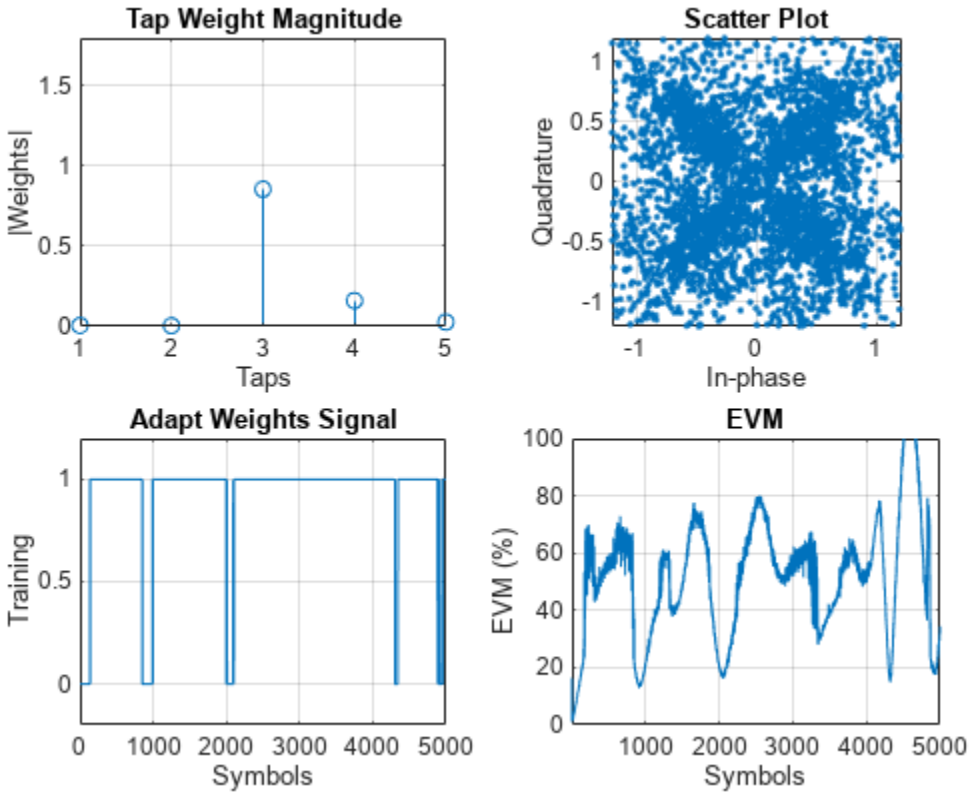
3 Apply equalization to the received data and phase correction to the equalizer output.

4 Estimate the EVM and toggle the `adaptWeights` flag to `true` or `false` based on the EVM level.

5 Update the figure plots.

```
for p=1:numPackets
    data = randi([0 M-1],numSymbols,1);
    tx = pskmod(data,M,pi/4);
    rx = awgn(raylChan(tx),SNR);
    rxDelay = finddelay(rx,tx);
    [y,err,wts] = lineq(rx,adaptWeights);
    y = phaseCorrection(y);
    evmEst = evm(y);
    adaptWeights = (evmEst > 20);

    updateFigures(errPlot,evmPlot,scatSym,adaptState, ...
        wts,y(end),evmEst,adaptWeights,p,numPackets)
end
```



```
rxDelay
```

```
rxDelay = 0
```

The figure plots show that, as the EVM varies, the equalizer toggles in and out of decision-directed weight adaptation mode.

Helper Functions

This helper function initializes figures that show a quad plot of simulation results.

```
function [errPlot,evmPlot,scatter,adaptState] = ...
    initFigures(numPkts,lineq)
yVec = nan(numPkts,1);
evmVec = nan(numPkts,1);
wVec = zeros(lineq.NumTaps,1);
adaptVec = nan(numPkts,1);

figure
subplot(2,2,1)
evmPlot = stem(wVec);
grid on; axis([1 lineq.NumTaps 0 1.8])
xlabel('Taps');
ylabel('|Weights|');
title('Tap Weight Magnitude')

subplot(2,2,2)
scatter = plot(yVec, '.');
axis square;
axis([-1.2 1.2 -1.2 1.2]);
grid on
xlabel('In-phase');
ylabel('Quadrature');
title('Scatter Plot');
subplot(2,2,3)
adaptState = plot(adaptVec);
grid on;
axis([0 numPkts -0.2 1.2])
ylabel('Training');
xlabel('Symbols');
title('Adapt Weights Signal')
subplot(2,2,4)
errPlot = plot(evmVec);
grid on;
axis([1 numPkts 0 100])
xlabel('Symbols');
ylabel('EVM (%)');
title('EVM')
end
```

This helper function updates figures.

```
function updateFigures(errPlot,evmPlot,scatSym, ...
    adaptState,w,y,evmEst,adaptWts,p,numFrames)
persistent yVec evmVec adaptVec

if p == 1
    yVec = nan(numFrames,1);
    evmVec = nan(numFrames,1);
    adaptVec = nan(numFrames,1);
end

yVec(p) = y;
evmVec(p) = evmEst;
adaptVec(p) = adaptWts;
```

```
errPlot.YData = abs(evmVec);
evmPlot.YData = abs(w);
scatSym.XData = real(yVec);
scatSym.YData = imag(yVec);
adaptState.YData = adaptVec;
drawnow limitrate
end
```

This helper function applies phase correction.

```
function y = phaseCorrection(y)
a = angle(y((real(y) > 0) & (imag(y) > 0)));
a(a < 0.1) = a(a < 0.1) + pi/2;
theta = mean(a) - pi/4;
y = y * exp(-1i*theta);
end
```

Linearly Equalize Packetized Signals in Fading Environments

Recover QPSK symbols in fading environments with a linear equalizer, using the least mean squares (LMS) algorithm. Use the `reset` object function to equalize independent packets. Use helper functions to generate plots. This example also shows symbol-based processing and frame-based processing.

Setup

Initialize system variables, create an equalizer System object, and initialize the plot figures.

```
M = 4; % QPSK
numSym = 1000;
numTrainingSym = 100;
numPackets = 5;
numTaps = 9;
ttlNumSym = numSym + numTrainingSym;
raylChan = comm.RayleighChannel( ...
    'PathDelays',[0 1], ...
    'AveragePathGains',[0 -9], ...
    'MaximumDopplerShift',0, ...
    'PathGainsOutputPort',true);
SNR = 35;
rxVec = zeros(ttlNumSym,numPackets);
txVec = zeros(ttlNumSym,numPackets);
yVec = zeros(ttlNumSym,1);
eVec = zeros(ttlNumSym,1);

lineq1 = comm.LinearEqualizer( ...
    'Algorithm','LMS', ...
    'NumTaps',numTaps, ...
    'ReferenceTap',5, ...
    'StepSize',0.01, ...
    'TrainingFlagInputPort',true);

[errPlot,wStem,hStem,scatPlot] = initFigures(ttlNumSym,lineq1, ...
    raylChan.AveragePathGains);
```

Symbol-Based Processing

For symbol-based processing, provide one symbol at the input of the equalizer. Reset the equalizer state and channel after processing each packet.

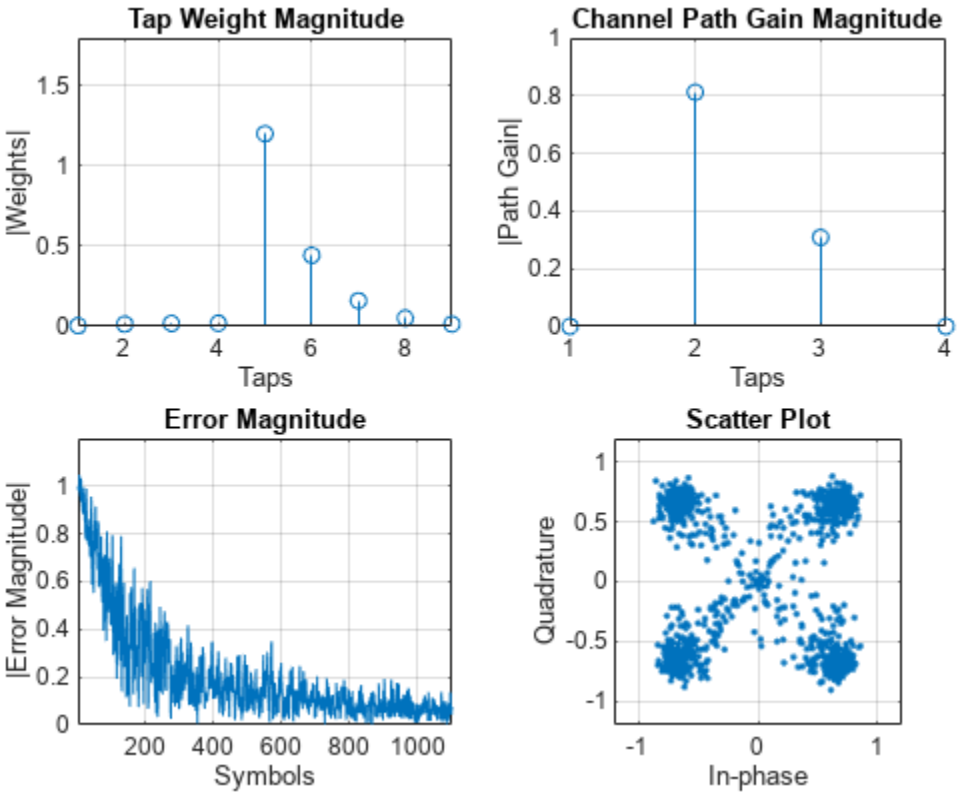
```
for p = 1:numPackets
    trainingFlag = true;
    for q=1:ttlNumSym
        data = randi([0 M-1],1,1);
        tx = pskmod(data,M,pi/4);
        [xc,pg] = raylChan(tx);
        rx = awgn(xc,25);
        [y,err,wts] = lineq1(rx,tx,trainingFlag);
```

Disable training after processing `numTrainingSym` training symbols.

```
        if q == numTrainingSym
            trainingFlag = false;
        end
        updateFigures(errPlot,wStem,hStem,scatPlot,err, ...
            wts,y,pg,q,ttlNumSym);
        txVec(q,p) = tx;
        rxVec(q,p) = rx;
    end
```

After processing each packet, reset the channel System object to get a new realization of channel taps and the equalizer System object to restore the default set of tap weights.

```
    reset(raylChan)
    reset(lineq1)
end
```



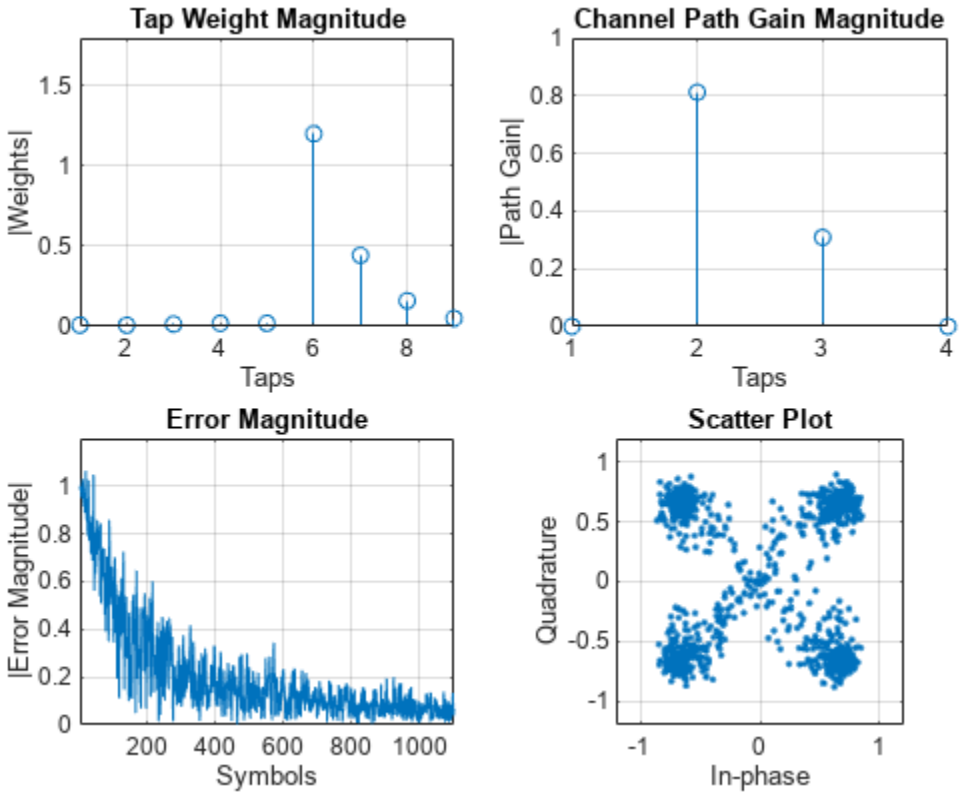
Packet-Based Processing

For packet-based processing, provide one packet at the input of the equalizer. Each packet contains `ttlNumSym` symbols. Because the training duration is less than the packet length, you do not need to specify the start-training input.

```
yVecPkt = zeros(ttlNumSym,numPackets);
errVecPkt = zeros(ttlNumSym,numPackets);
wgtVecPkt = zeros(numTaps,numPackets);
lineq2 = comm.LinearEqualizer('Algorithm','LMS', ...
    'NumTaps',9,'ReferenceTap',6,'StepSize',0.01);
for p = 1:numPackets
    [yVecPkt(:,p),errVecPkt(:,p),wgtVecPkt(:,p)] = ...
        lineq2(rxVec(:,p),txVec(1:numTrainingSym,p));
    for q=1:ttlNumSym
        updateFigures(errPlot,wStem,hStem,scatPlot, ...
            errVecPkt(q,p),wgtVecPkt(:,p), ...
            yVecPkt(q,p),pg,q,ttlNumSym);
    end
```

After processing each packet, reset the channel System object to get a new realization of channel taps and the equalizer System object to restore the default set of tap weights.

```
    reset(raylChan)
    reset(lineq2)
end
```



Helper Functions

The helper function initializes the figures.

```
function [errPlot,wStem,hStem,scatPlot] = ...
    initFigures(ttlNumSym,lineq,pg)
yVec = nan(ttlNumSym,1);
eVec = nan(ttlNumSym,1);
wVec = zeros(lineq.NumTaps,1);
figure;
subplot(2,2,1);
wStem = stem(wVec);
axis([1 lineq.NumTaps 0 1.8]);
grid on;
xlabel('Taps');
ylabel('|Weights|');
title('Tap Weight Magnitude');
subplot(2,2,2);
hStem = stem([0 abs(pg) 0]);
grid on;
xlabel('Taps');
ylabel('|Path Gain|');
title('Channel Path Gain Magnitude');
subplot(2,2,3);
errPlot = plot(eVec);
axis([1 ttlNumSym 0 1.2]);
grid on;
xlabel('Symbols');
```

```
ylabel('|Error Magnitude|');
title('Error Magnitude');
subplot(2,2,4);
scatPlot = plot(yVec,'.');
axis square;
axis([-1.2 1.2 -1.2 1.2]);
grid on;
xlabel('In-phase');
ylabel('Quadrature');
title(sprintf('Scatter Plot'));
end
```

This helper function updates the figures.

```
function updateFigures(errPlot,wStem,hStem,scatPlot, ...
    err,wts,y,pg,p,ttlNumSym)
persistent yVec eVec
if p == 1
    yVec = nan(ttlNumSym,1);
    eVec = nan(ttlNumSym,1);
end
yVec(p) = y;
eVec(p) = abs(err);
errPlot.YData = abs(eVec);
wStem.YData = abs(wts);
hStem.YData = [0 abs(pg) 0];
scatPlot.XData = real(yVec);
scatPlot.YData = imag(yVec);
drawnow limitrate
end
```

Nonadaptive Linear Equalization

Use the linear equalizer in nonadaptive mode. Use the `mmseweights` object function to calculate the minimum mean squared error (MMSE) solution and use the weights returned as the set of tap weights for the linear equalizer.

Initialize simulation variables.

```
M = 4; % QPSK
numSymbols = 10000;
numTrainingSymbols = 1000;
chtaps = [1 0.5*exp(1i*pi/6) 0.1*exp(-1i*pi/8)];
EbN0 = 20;
```

Generate QPSK modulated symbols. Apply delayed multipath channel filtering and AWGN impairments to the symbols.

```
data = randi([0 M-1], numSymbols, 1);
tx = pskmod(data, M, pi/4);
rx = awgn(filter(chtaps,1,tx),25,'measured');
```

Create a linear equalizer System object configured to use CMA algorithm, set the `AdaptWeights` property to `false`, and the `InitialWeightsSource` property to `Property`. Calculate the MMSE weights. Set the initial tap weights to the calculated MMSE weights. Equalize the impaired symbols.

```
eq = comm.LinearEqualizer( ...
    'Algorithm','CMA', ...
    'AdaptWeights',false, ...
    'InitialWeightsSource','Property')
```

```
eq =
  comm.LinearEqualizer with properties:

               Algorithm: 'CMA'
                 NumTaps: 5
                StepSize: 0.0100
           Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i ... ]
    InputSamplesPerSymbol: 1
       AdaptWeightsSource: 'Property'
             AdaptWeights: false
     InitialWeightsSource: 'Property'
           InitialWeights: [5x1 double]
       WeightUpdatePeriod: 1
```

```
wgts = mmseweights(eq,chtaps,EbN0)
```

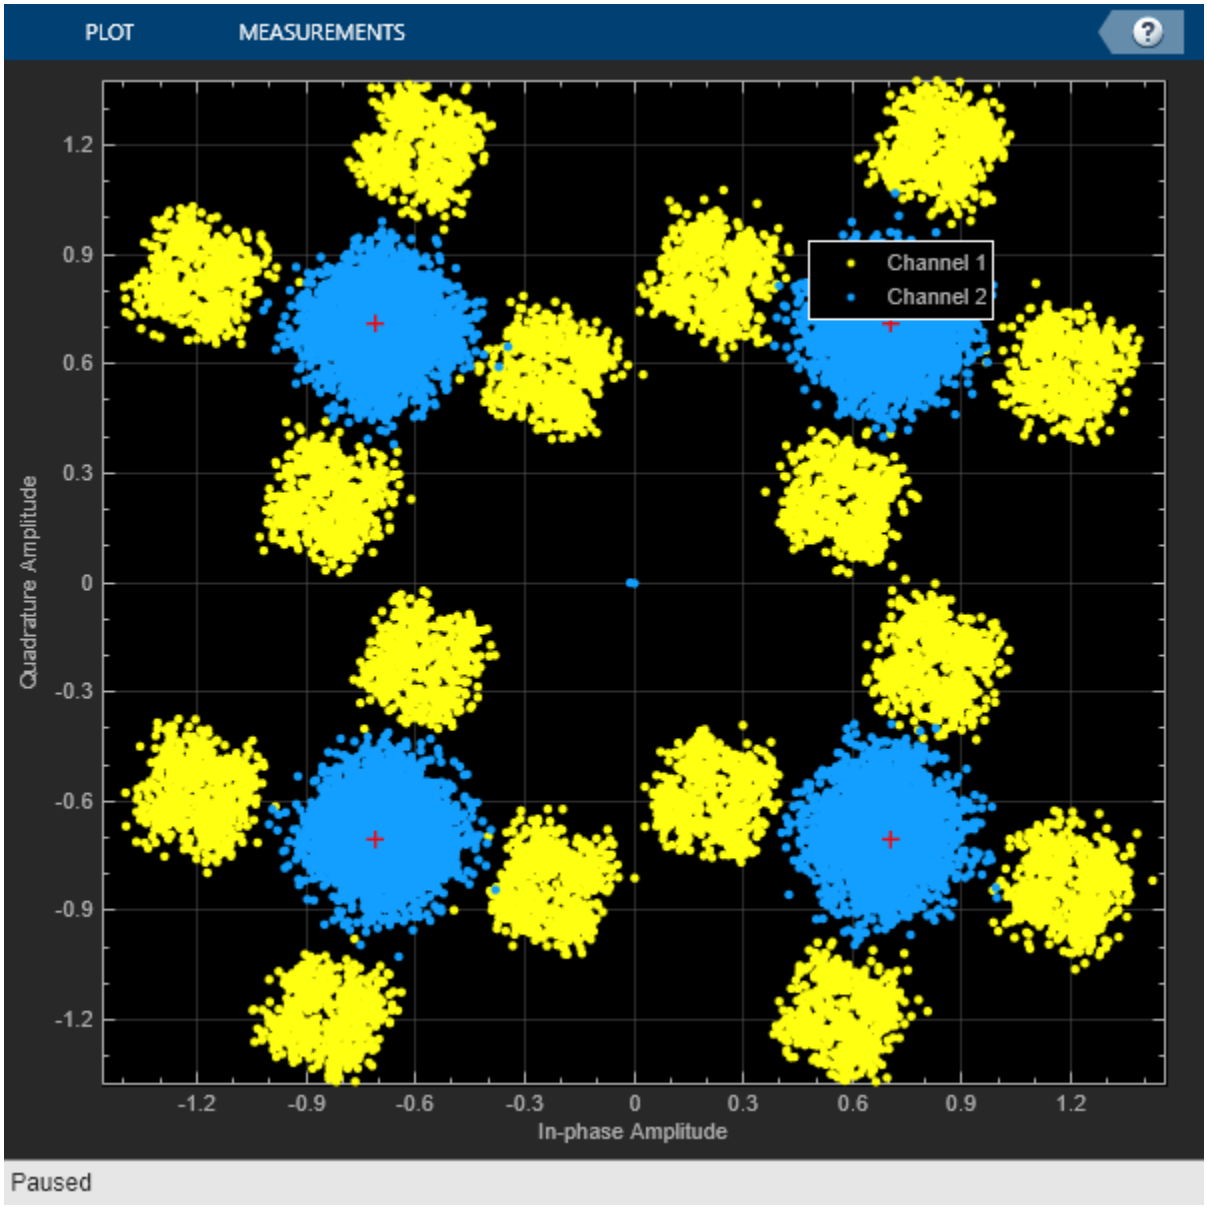
```
wgts = 5×1 complex

   0.0005 - 0.0068i
   0.0103 + 0.0117i
   0.9694 - 0.0019i
  -0.3987 + 0.2186i
   0.0389 - 0.1756i
```

```
eq.InitialWeights = wgts;
[y,err,weights] = eq(rx);
```

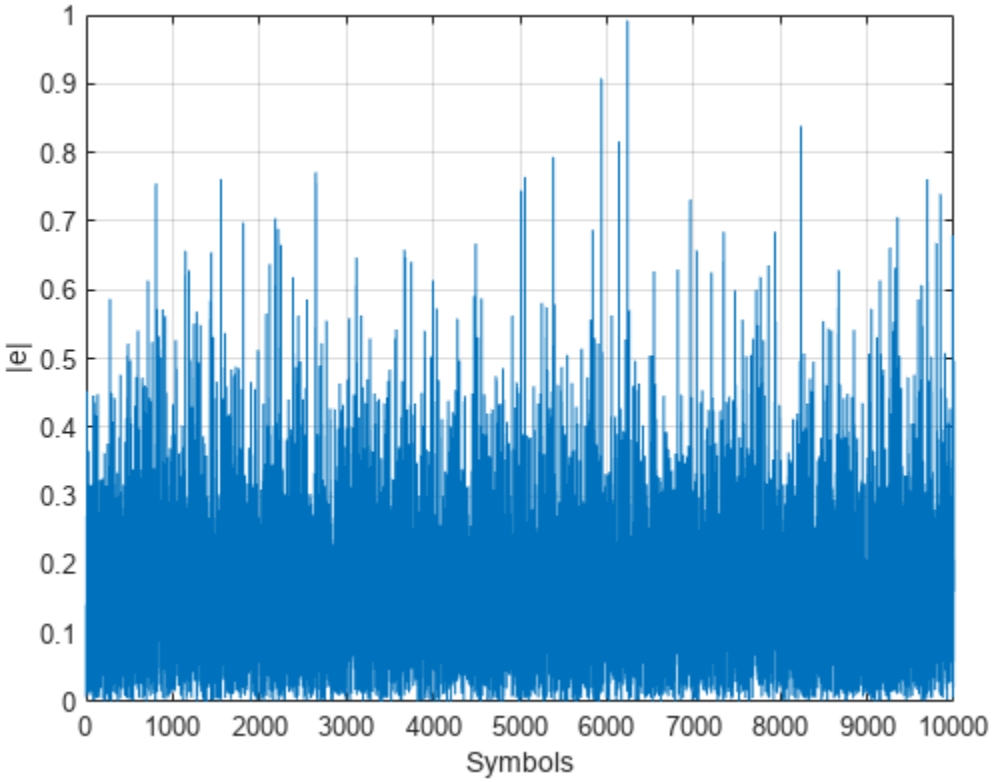
Plot constellation of impaired and equalized symbols.

```
constell = comm.ConstellationDiagram('NumInputPorts',2);
constell(rx,y);
```



Plot the equalizer error signal and compute the error vector magnitude of the equalized symbols.

```
plot(abs(err));
grid on;
xlabel('Symbols');
ylabel('|e|');
```



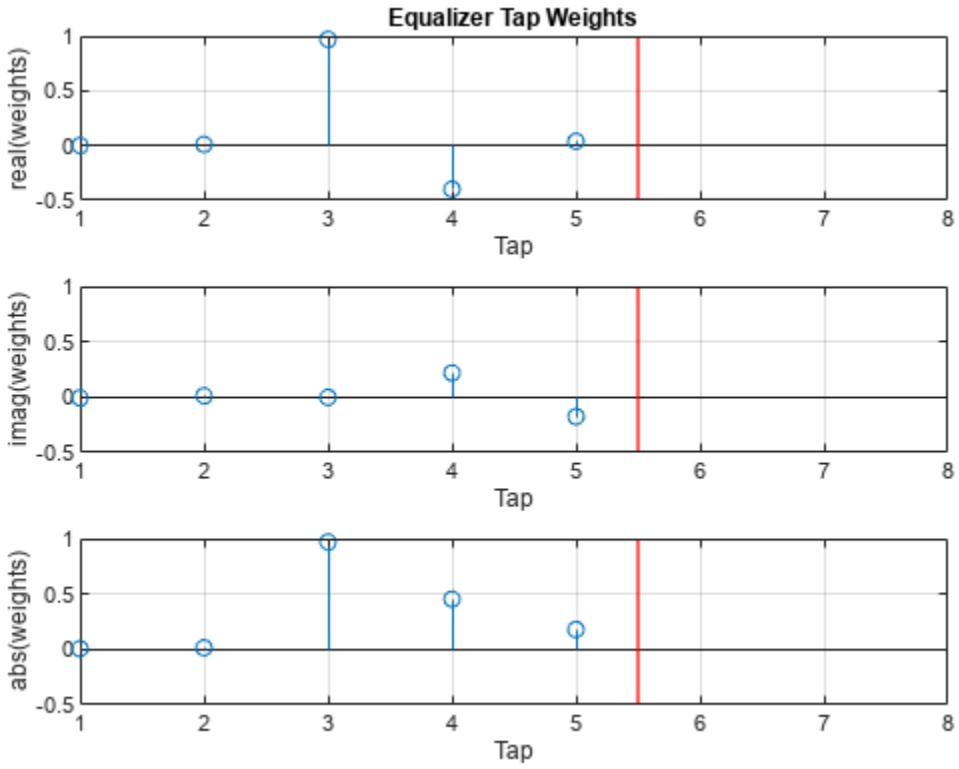
```
errevm = comm.EVM;
evm = errevm(tx,y)
```

```
evm = 139.1636
```

Plot equalizer tap weights.

```
subplot(3,1,1);
stem(real(weights));
ylabel('real(weights)');
xlabel('Tap');
grid on;
axis([1 8 -0.5 1]);
line([eq.NumTaps+0.5 eq.NumTaps+0.5],[-0.5 1], ...
    'Color','r','LineWidth',1);
title('Equalizer Tap Weights');
subplot(3,1,2);
stem(imag(weights));
ylabel('imag(weights)');
xlabel('Tap');
grid on;
axis([1 8 -0.5 1]);
line([eq.NumTaps+0.5 eq.NumTaps+0.5],[-0.5 1], ...
    'Color','r','LineWidth',1);
subplot(3,1,3);
stem(abs(weights));
ylabel('abs(weights)');
xlabel('Tap');
```

```
grid on;
axis([1 8 -0.5 1]);
line([eq.NumTaps+0.5 eq.NumTaps+0.5], ...
    [-0.5 1],'Color','r','LineWidth',1);
```



Linearly Equalize Signals Sample-by-Sample

Demonstrate linear equalization by using the least mean squares (LMS) algorithm to recover QPSK symbols passed through an AWGN channel. Process the signal sample-by-sample.

System Setup

Simulate a QPSK-modulated system subject to AWGN. Transmit packets composed of 200 training symbols and 1800 random data symbols. Configure a linear LMS equalizer to recover the packet data.

```
M = 4;
numTrainSymbols = 200;
numDataSymbols = 1800;
SNR = 20;
trainingSymbols = ...
    pskmod(randi([0 M-1],numTrainSymbols,1),M,pi/4);
numPkts = 10;
lineq = comm.LinearEqualizer( ...
    'Algorithm','LMS', ...
  'NumTaps',5, ...
```

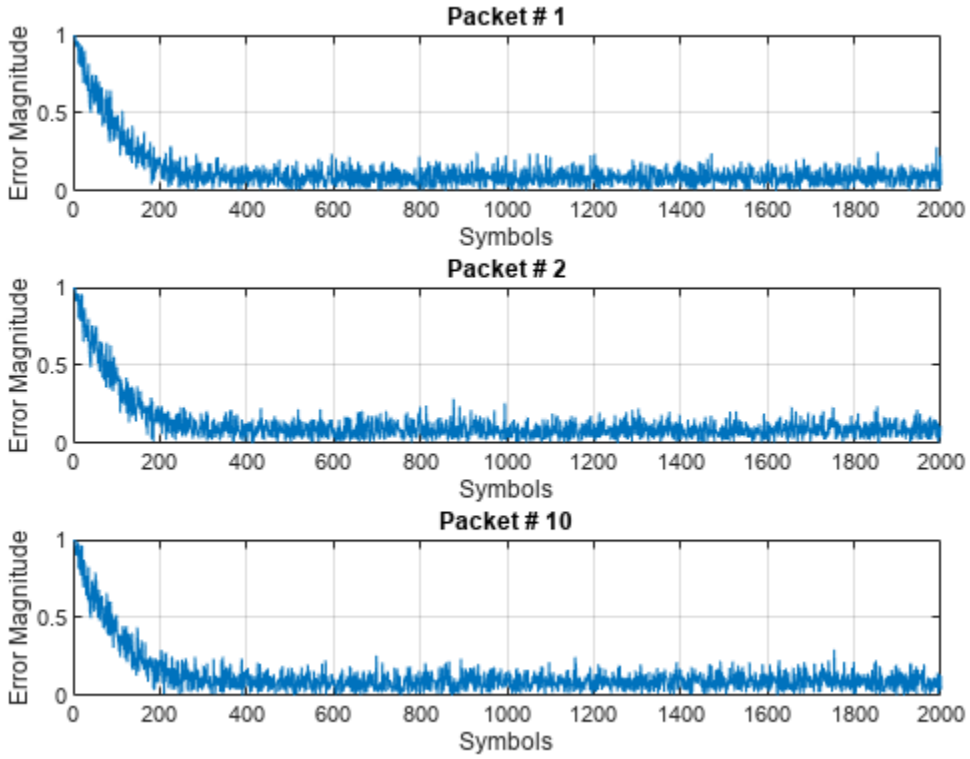
```
  'ReferenceTap',3, ...
  'StepSize',0.01, ...
  'TrainingFlagInputPort',true);
```

Main Loop

Use prepended training symbols when processing each packet. After processing each packet, reset the equalizer. This reset forces the equalizer to train the taps with no previous knowledge. Equalize the received signal sample-by-sample. For each packet, use the first 200 symbols for training.

```
subPlotCnt = 1;
figure
for ii = 1:numPkts
  b = randi([0 M-1],numDataSymbols,1);
  dataSym = pskmod(b,M,pi/4);
  packet = [trainingSymbols;dataSym];
  rx = awgn(packet,SNR);
  y = zeros(numDataSymbols+numTrainSymbols,1);
  err = zeros(numDataSymbols+numTrainSymbols,1);
  for jj = 1:numDataSymbols+numTrainSymbols
    if jj <= numTrainSymbols
      [y(jj),err(jj)] = ...
          lineq(rx(jj),trainingSymbols(jj),true);
    else
      [y(jj),err(jj)] = lineq(rx(jj),1i,false);
    end
  end
  reset(lineq)

  if (ii ==1 || ii == 2 ||ii == numPkts)
    subplot(3,1,subPlotCnt)
    plot(abs(err))
    title(['Packet # ',num2str(ii)])
    xlabel('Symbols')
    ylabel('Error Magnitude')
    axis([0,length(packet),0,1])
    grid on;
    subPlotCnt = subPlotCnt+1;
  end
end
```



Linearly Equalize Packet Using Multiple Passes

Demonstrate linear equalization by using the least mean squares (LMS) algorithm to recover QPSK symbols passed through an AWGN channel. Process a packet that has training symbols at the beginning in multiple passes. Compare results to equalization processing the full packet in a single pass.

System Setup

Simulate a QPSK-modulated system subject to AWGN. Transmit packets composed of 200 training symbols and 1800 random data symbols. Configure a linear LMS equalizer to recover the packet data.

```
M = 4;
numTrainSymbols = 200;
numDataSymbols = 1800;
SNR = 20;
trainingSymbols = ...
    pskmod(randi([0 M-1],numTrainSymbols,1),M,pi/4);
b = randi([0 M-1],numDataSymbols,1);
dataSym = pskmod(b,M,pi/4);
packet = [trainingSymbols;dataSym];
rx = awgn(packet,SNR);
lineq = comm.LinearEqualizer( ...
    'Algorithm','LMS', ...
    'NumTaps',5, ...
```

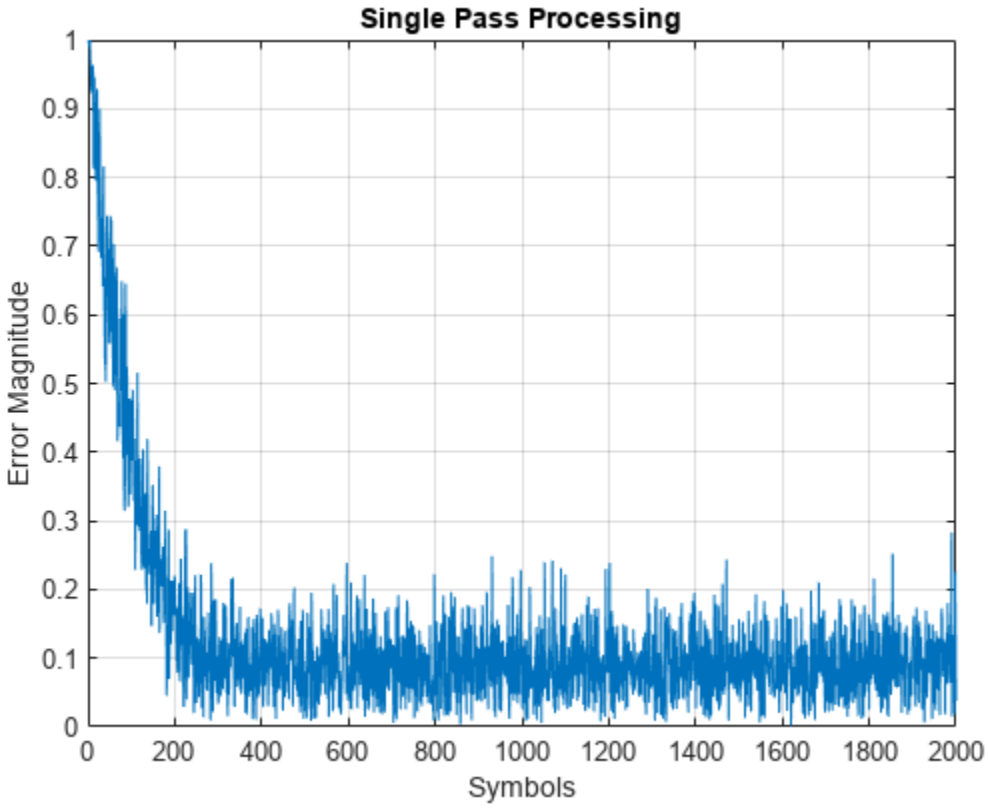
```
    'ReferenceTap',3, ...
    'StepSize',0.01);
```

Process Packet in One Pass

Use prepended training symbols when processing each packet. After processing each packet, reset the equalizer. This reset forces the equalizer to train the taps with no previous knowledge. Equalize the received signal sample-by-sample. For each packet, use the first 200 symbols for training.

```
subPlotCnt = 1;
figure
[y1,err1] = lineq(rx,trainingSymbols);
reset(lineq)

plot(abs(err1))
title("Single Pass Processing")
xlabel('Symbols')
ylabel('Error Magnitude')
axis([0,length(packet),0,1])
grid on;
```



Process Packet in Multiple Passes

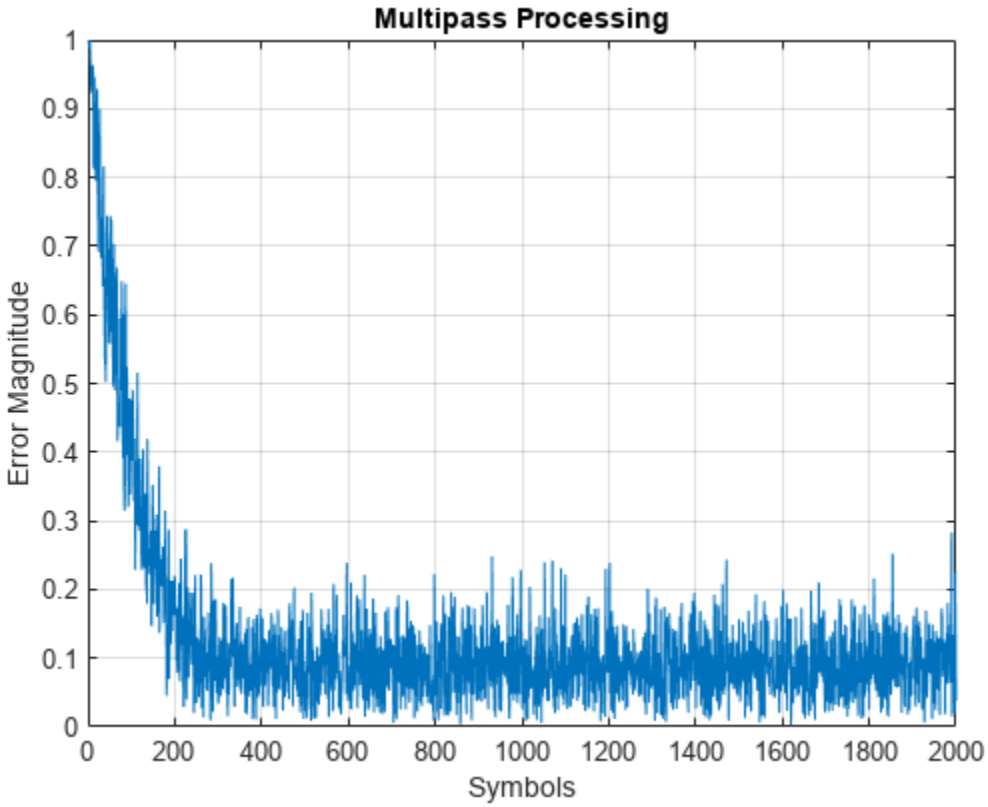
Use prepended training symbols when processing each packet. After processing each packet, reset the equalizer. This reset forces the equalizer to train the taps with no previous knowledge. Equalize the received signal sample-by-sample. For each packet, use the first 200 symbols for training.

```
lineq = comm.LinearEqualizer( ...
    'Algorithm','LMS', ...
    'NumTaps',5, ...
    'ReferenceTap',3, ...
    'StepSize',0.01, ...
    'TrainingFlagInputPort',true);

frameLen = 100;
numFrames = (numDataSymbols+numTrainSymbols) / frameLen;

figure
y2 = zeros(numDataSymbols+numTrainSymbols,1);
err2 = zeros(numDataSymbols+numTrainSymbols,1);
idx = 1:frameLen;
symbolCnt = 0;
for jj = 1:numFrames
    if symbolCnt < numTrainSymbols
        [y2(idx),err2(idx)] = ...
            lineq(rx(idx),trainingSymbols(idx),true);
    else
        [y2(idx),err2(idx)] = ...
            lineq(rx(idx),1i*ones(frameLen,1),false);
    end
    idx = idx + frameLen;
    symbolCnt = symbolCnt + frameLen;
end
reset(lineq)

plot(abs(err2))
title("Multipass Processing")
xlabel('Symbols')
ylabel('Error Magnitude')
axis([0,length(packet),0,1])
grid on;
```



Results from equalization using single pass and multipass approaches match.

```
outputsEqual = isequal(y1,y2)
```

```
outputsEqual = logical
   1
```

```
errorsEqual = isequal(err1,err2)
```

```
errorsEqual = logical
   1
```

More About

Symbol Tap Spacing

You can configure the equalizer to operate as a symbol-spaced equalizer or as a fractional symbol-spaced equalizer.

- To operate the equalizer at a symbol-spaced rate, specify the number of samples per symbol as 1. Symbol-rate equalizers have taps spaced at the symbol duration. Symbol-rate equalizers are sensitive to timing phase.
- To operate the equalizer at a fractional symbol-spaced rate, specify the number of input samples per symbol as an integer greater than 1 and provide an input signal oversampled at that sampling

rate. Fractional symbol-spaced equalizers have taps spaced at an integer fraction of the input symbol duration. Fractional symbol-spaced equalizers are not sensitive to timing phase.

Algorithms

Linear Equalizers

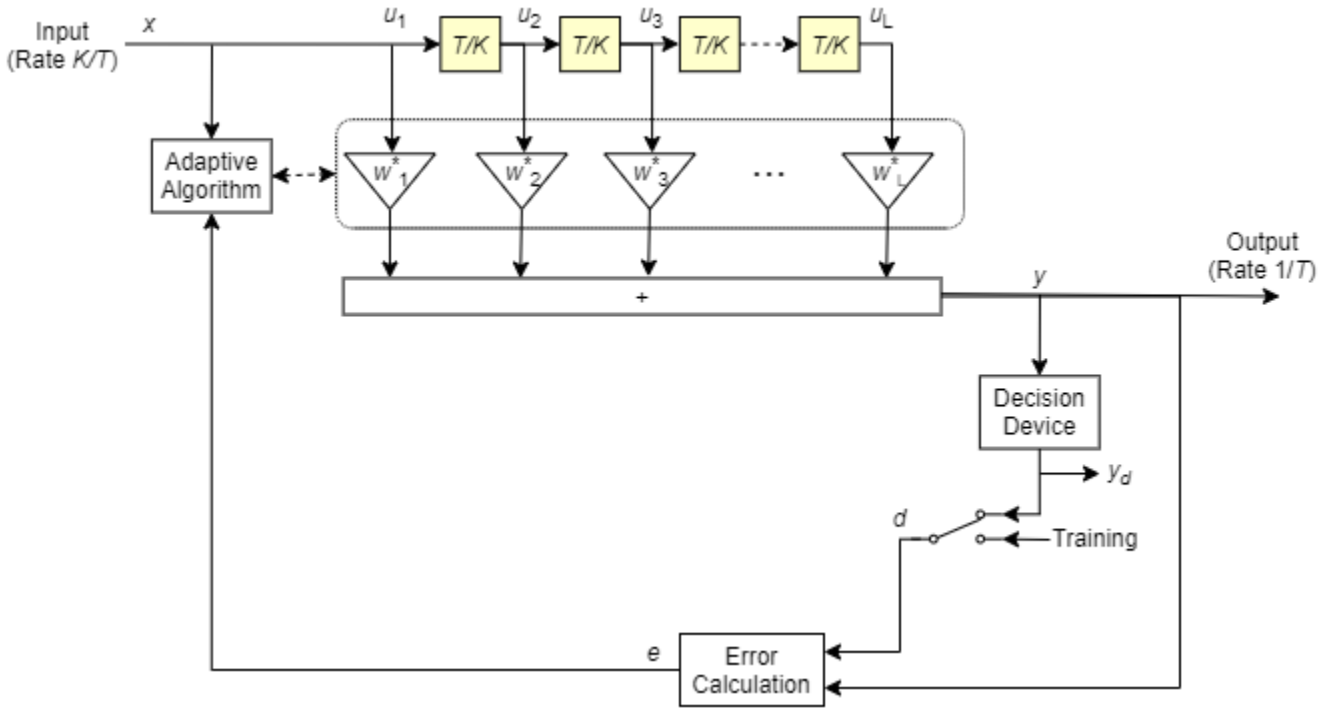
Linear equalizers can remove intersymbol interference (ISI) when the frequency response of a channel has no null. If a null exists in the frequency response of a channel, linear equalizers tend to enhance the noise. In this case, use decision feedback equalizers to avoid enhancing the noise.

A linear equalizer consists of a tapped delay line that stores samples from the input signal. Once per symbol period, the equalizer outputs a weighted sum of the values in the delay line and updates the weights to prepare for the next symbol period.

Linear equalizers can be symbol-spaced or fractional symbol-spaced.

- For a symbol-spaced equalizer, the number of samples per symbol, K, is 1. The output sample rate equals the input sample rate.
- For a fractional symbol-spaced equalizer, the number of samples per symbol, K, is an integer greater than 1. Typically, K is 4 for fractionally spaced equalizers. The output sample rate is $1/T$ and the input sample rate is K/T, where T is the symbol period. Tap-weight updating occurs at the output rate.

This schematic shows a linear equalizer with L weights, a symbol period of T, and K samples per symbol. If K is 1, the result is a symbol-spaced linear equalizer instead of a fractional symbol-spaced linear equalizer.



In each symbol period, the equalizer receives K input samples at the tapped delay line. The equalizer then outputs a weighted sum of the values in the tapped delay line and updates the weights to prepare for the next symbol period.

For more information, see “Equalization”.

Least Mean Square (LMS) Algorithm

For the LMS algorithm, in the previous schematic, w is a vector of all weights w_i, and u is a vector of all inputs u_i. Based on the current set of weights, the LMS algorithm creates the new set of weights as

$$w_{\text{new}} = w_{\text{current}} + (StepSize)\, ue^*.$$

The step size used by the adaptive algorithm is specified as a positive scalar. Increasing the step size reduces the equalizer convergence time but causes the equalized output signal to be less stable. To determine the maximum step size allowed when using the LMS adaptive algorithm, use the `maxstep` object function. The * operator denotes the complex conjugate and the error calculation $e = d - y$.

Recursive Least Square (RLS) Algorithm

For the RLS algorithm, in the previous schematic, w is the vector of all weights w_i, and u is the vector of all inputs u_i. Based on the current set of inputs, u, and the inverse correlation matrix, P, the RLS algorithm first computes the Kalman gain vector, K, as

$$K = \frac{Pu}{(ForgettingFactor) + u^H Pu}.$$

The forgetting factor used by the adaptive algorithm is specified as a scalar in the range (0, 1]. Decreasing the forgetting factor reduces the equalizer convergence time but causes the equalized output signal to be less stable. H denotes the Hermitian transpose. Based on the current inverse correlation matrix, the new inverse correlation matrix is

$$P_{\text{new}} = \frac{(1 - Ku^H)P_{\text{current}}}{ForgettingFactor}.$$

Based on the current set of weights, the RLS algorithm creates the new set of weights as

$$w_{\text{new}} = w_{\text{current}} + K^* e.$$

The * operator denotes the complex conjugate and the error calculation $e = d - y$.

Constant Modulus Algorithm (CMA)

For the CMA adaptive algorithm, in the previous schematic, w is the vector of all weights w_i, and u is the vector of all inputs u_i. Based on the current set of weights, the CMA adaptive algorithm creates the new set of weights as

$$w_{\text{new}} = w_{\text{current}} + (StepSize)\, u^* e.$$

The step size used by the adaptive algorithm is specified as a positive scalar. Increasing the step size reduces the equalizer convergence time but causes the equalized output signal to be less stable. To determine the maximum step size allowed by the CMA adaptive algorithm, use the `maxstep` object function. The * operator denotes the complex conjugate and the error calculation $e = y(R - |y|^2)$, where R is a constant related to the signal constellation.

comm.EVM

Package: comm

Measure error vector magnitude (EVM) of received signal

Description

The comm.EVM System object measures the root mean squared (RMS) EVM, maximum EVM, and percentile EVM of a received signal.

To measure the EVM of a received signal:

1. Create the comm.EVM object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
evm = comm.EVM
evm = comm.EVM(Name=Value)
```

Description

evm = comm.EVM creates an EVM measurement System object.

evm = comm.EVM(Name=Value) sets properties using one or more name-value arguments. For example, ReferenceSignalSource="Estimated from reference constellation" configures the object to measure the EVM of a received signal relative to a reference constellation.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Normalization — Normalization method
'Average reference signal power' (default) | 'Average constellation power' | 'Peak constellation power'

Normalization method used in EVM calculation, specified as 'Average reference signal power', 'Average constellation power', or 'Peak constellation power'.

Data Types: `char` | `string`

`AverageConstellationPower` — Average constellation power
1 (default) | positive scalar

Average constellation power in Watts, specified as a positive scalar.

Dependencies

To enable this property, set the `Normalization` property to `'Average constellation power'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`PeakConstellationPower` — Peak constellation power
1 (default) | positive scalar

Peak constellation power in Watts, specified as a positive scalar.

Dependencies

To enable this property, set the `Normalization` property to `'Peak constellation power'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`ReferenceSignalSource` — Reference signal source
`'Input port'` (default) | `'Estimated from reference constellation'`

Reference signal source, specified as `'Input port'` or `'Estimated from reference constellation'`. To provide an explicit reference signal against which to measure received signal, set this property to `'Input port'`. To measure the EVM of the received signal against a reference constellation, set this property to `'Estimated from reference constellation'`.

Data Types: `char` | `string`

`ReferenceConstellation` — Reference constellation
`[0.7071 - 0.7071i; -0.7071 - 0.7071i; -0.7071 + 0.7071i; 0.7071 + 0.7071i]` (default) | vector

Reference constellation, specified as a vector. The default value corresponds to a quadrature phase-shift keying (QPSK) constellation with unit average power. You can derive constellation points by using modulation functions or objects. For example, to derive the reference constellation for a 16-point quadrature amplitude modulated (16-QAM) signal, use the `qammod` function.

Example: `qammod(0:15,16)`

Dependencies

To enable this property, set the `ReferenceSignalSource` property to `'Estimated from reference constellation'`.

Data Types: `double`
Complex Number Support: Yes

`MeasurementIntervalSource` — Measurement interval source
`'Input length'` (default) | `'Entire history'` | `'Custom'` | `'Custom with periodic reset'`

Measurement interval source for RMS and maximum EVM measurements, specified as one of these values.

- `'Input length'` — Measure EVM using only the current samples.
- `'Entire history'` — Measure EVM for all samples.
- `'Custom'` — Measure EVM over an interval you specify and use a sliding window.
- `'Custom with periodic reset'` — Measure EVM over an interval you specify and reset the object after measuring over each interval.

Data Types: `char` | `string`

`MeasurementInterval` — Measurement interval

`100` (default) | positive integer

Measurement interval, specified as a positive integer.

Dependencies

To enable this property, set the `MeasurementIntervalSource` property to `'Custom'` or `'Custom with periodic reset'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`AveragingDimensions` — Averaging dimensions

`1` (default) | vector of integers in the range [1, 3]

Averaging dimensions over which the object averages the EVM measurements, specified as a vector of integers in the range [1, 3]. For example, to average across the rows, set this property to `2`.

This object supports variable-size inputs of the dimensions across which the averaging takes place. However, the input size for the non-averaged dimensions must remain constant between calls to the object. For example, if the input has size `[1000 3 2]` and you set this property to `[1 3]`, the output size is `[1 3 1]`, and the number of elements in the second dimension must remain fixed at `3`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`MaximumEVMOutputPort` — Option to return maximum EVM measurements

`false` or `0` (default) | `true` or `1`

Option to return maximum EVM measurements, specified as a logical `1` (`true`) or `0` (`false`).

Data Types: `logical`

`XPercentileEVMOutputPort` — Option to return *X*-percentile EVM measurements

`false` or `0` (default) | `true` or `1`

Option to return *X*-percentile EVM measurements, that is, the value below which *X*% of EVM measurements fall, specified as a logical `1` (`true`) or `0` (`false`). When you set this property to `1` (`true`), *X*-percentile EVM measurements persist until you reset the object. The object performs these measurements by using all of the input frames since the last reset.

Data Types: `logical`

`XPercentileValue` — Value below which *X*% of EVM measurements fall
`95` (default) | scalar in the range [0, 100]

Value below which *X*% of EVM measurements fall, specified as a scalar in the range [0, 100].

Dependencies

To enable this property, set the `XPercentileEVMOutputPort` property to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`SymbolCountOutputPort` — Option to return number of accumulated symbols
`false` or `0` (default) | `true` or `1`

Option to return the number of accumulated symbols that the object uses to measure the *X*-percentile EVM since the last reset, specified as a logical `1` (`true`) or `0` (`false`).

Dependencies

To enable this property, set the `XPercentileEVMOutputPort` property to `true`.

Data Types: `logical`

Usage

Syntax

```
rmsEVM = evm(refSym,rxSym)
[rmsEVM,maxEVM] = evm(refSym,rxSym)
[___,xEVM] = evm(refSym,rxSym)
[___,numSym] = evm(refSym,rxSym)
[___] = evm(rxSym)
```

Description

`rmsEVM = evm(refSym,rxSym)` measures the percentage RMS EVM of received signal `rxSym` relative to reference signal `refSym` over the measurement interval specified in the `MeasurementIntervalSource` and `MeasurementInterval` properties.

`[rmsEVM,maxEVM] = evm(refSym,rxSym)` also measures the maximum percentage EVM over the configured measurement interval.

To use this syntax, set the `MaximumEVMOutputPort` property to `true`.

`[___,xEVM] = evm(refSym,rxSym)` also measures the value below which *X*% of EVM measurements fall using all input frames since the last reset, regardless of measurement interval configuration. Set the value of *X* in the `XPercentileValue` property. For example, if you set the `XPercentileValue` to `95`, then 95% of all EVM measurements since the last reset fall below the value of `xEVM`. You can use this syntax with any previous output argument combination.

To use this syntax, set the `XPercentileEVMOutputPort` property to `true`.

`[ ___ ,numSym] = evm(refSym,rxSym)` also returns the number of symbols used to measure the *X*-percentile EVM. To use this syntax, set the `XPercentileEVMOutputPort` and `SymbolCountOutputPort` properties to `true`.

`[ ___ ] = evm(rxSym)` measures the EVM of the received signal relative to the reference signal specified in the `ReferenceConstellation` property. You can use this syntax with any previous output argument combination.

To use this syntax, set the `ReferenceSignalSource` property to `'Estimated from reference constellation'` and the `ReferenceConstellation` property to a vector of length equal to that of the `rxSym` input.

Input Arguments

`refSym` — Reference signal

scalar | vector | matrix | 3-D array

Reference signal, specified as a scalar, vector, matrix, or 3-D array. If you specify this input, the object measures the EVM of the `rxSym` input by using this input as a reference constellation.

The dimensions of this input must match those of the `rxSym` input. The object uses each element of this input as the reference symbol for the corresponding element of the `rxSym` input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`
Complex Number Support: Yes

`rxSym` — Received signal

scalar | vector | matrix | 3-D array

Received signal, specified as a scalar, vector, matrix, or 3-D array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`
Complex Number Support: Yes

Output Arguments

`rmsEVM` — Percentage RMS EVM of received signal

scalar in the range [0, 100]

Percentage RMS EVM of the received signal over the configured measurement interval, returned as a scalar in the range [0, 100].

Data Types: `double`

`maxEVM` — Maximum percentage EVM

scalar in the range [0, 100]

Maximum percentage EVM over the configured measurement interval, returned as a scalar in the range [0, 100].

Data Types: `double`

`xEVM` — Value below which *X*% of EVM measurements fall

scalar in the range [0, 100]

Value below which *X*% of EVM measurements fall since the last reset, returned as a scalar in the range [0, 100]. Set the value of *X* in the `XPercentileValue` property.

Data Types: `double`

`numSym` — Number of symbols
positive integer

Number of symbols that the object uses to measure the `xEVM` output, returned as a positive integer.

Data Types: `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Measure EVM Using Reference Constellation

Generate random data symbols and apply 8-PSK modulation.

```
d = randi([0 7],2000,1);
txSig = pskmod(d,8,pi/8);
```

Pass the modulated signal through an additive white Gaussian noise (AWGN) channel.

```
rxSig = awgn(txSig,30);
```

Create an EVM object. Measure the RMS EVM using the transmitted signal as the reference.

```
evm = comm.EVM;
rmsEVM1 = evm(txSig,rxSig);
```

Release the EVM measurement System object. Configure the object to estimate the EVM of the received signal against a reference constellation.

```
release(evm)
evm.ReferenceSignalSource = "Estimated from reference constellation";
evm.ReferenceConstellation = pskmod(0:7,8,pi/8);
```

Measure the RMS EVM using only the received signal as an input, and then verify that the two EVM results match.

```
rmsEVM2 = evm(rxSig);
isequal(rmsEVM1,rmsEVM2)
```

```
ans = logical
   1
```

Measure EVM Across Different Dimensions

Create OFDM modulator and demodulator System objects.

```
ofdmmod = comm.OFDMModulator(FFTLength=32,NumSymbols=4);
ofdmdemod = comm.OFDMDemodulator(FFTLength=32,NumSymbols=4);
```

Determine the number of subcarriers and symbols in the OFDM signal.

```
ofdmDims = info(ofdmmod);
numSC = ofdmDims.DataInputSize(1);
numSym = ofdmDims.DataInputSize(2);
```

Generate random symbols and apply QPSK modulation.

```
msg = randi([0 3],numSC,numSym);
rxSym = pskmod(msg,4,pi/4);
```

OFDM modulate the QPSK signal. Pass the signal through an AWGN channel. Demodulate the noisy signal.

```
txSig = ofdmmod(rxSym);
rxSig = awgn(txSig,10,"measured");
refSym = ofdmdemod(rxSig);
```

Configure an EVM measurement System object to average the EVM measurement over the subcarriers. Measure the EVM. The four entries correspond to each of the four OFDM symbols.

```
evm = comm.EVM(AveragingDimensions=1);
rmsEVM = evm(refSym,rxSym)
```

```
rmsEVM = 1×4

   28.3317   25.7689   21.7944   23.5579
```

Configure the EVM measurement System object to average the EVM measurement over the OFDM symbols. Measure the EVM. The 21 entries correspond to each of the 21 subcarriers.

```
evm = comm.EVM(AveragingDimensions=2);
rmsEVM = evm(refSym,rxSym);
disp(rmsEVM')
```

```
  Columns 1 through 7

   28.5667   16.3509   21.3003   22.6700   25.4878   26.7996   28.4253

  Columns 8 through 14

   32.7493   34.5155   19.7745   18.7687   21.5631   20.2539   12.2082

  Columns 15 through 21
```

```
   25.3397   43.9916   26.8119   22.6613   29.5975   19.3420   16.1452
```

Measure the EVM and average over both the subcarriers and the OFDM symbols.

```
evm = comm.EVM(AveragingDimensions=[1 2]);
rmsEVM = evm(refSym,rxSym)
```

```
rmsEVM = 24.8838
```

Plot Time-Varying EVM for OFDM Signal

Calculate and plot the EVM of an OFDM signal. The signal consists of two packets separated by an interval.

Create System objects to:

- OFDM-modulate a signal.
- Introduce phase noise.
- Plot time-varying signals.

```
ofdmmod = comm.OFDMModulator(FFTLength=256,NumSymbols=2);

pnoise = comm.PhaseNoise(Level=-60,FrequencyOffset=20,SampleRate=1000);

tscope = timescope(YLabel="EVM (%)",YLimits=[0 40], ...
    SampleRate=1000,TimeSpanSource="Property",TimeSpan=1.2, ...
    ShowGrid=true);
```

Configure an EVM measurement System object to generate a time-varying estimate of the EVM.

```
evm = comm.EVM(MaximumEVMOutputPort=false, ...
    ReferenceSignalSource="Input port", ...
    AveragingDimensions=2);
```

Determine the input data dimensions of the OFDM modulator.

```
modDims = info(ofdmmod);
```

Create QPSK-modulated random data for the first packet. Apply OFDM modulation.

```
data = randi([0 3],modDims.DataInputSize);
qpskSig = pskmod(data,4,pi/4);
txSig1 = ofdmmod(qpskSig);
```

Create a second data packet.

```
data = randi([0 3],modDims.DataInputSize);
qpskSig = pskmod(data,4,pi/4);
txSig2 = ofdmmod(qpskSig);
```

Concatenate the two packets and include an interval with no transmitted data.

```
txSig = [txSig1; zeros(112,1); txSig2];
```

Apply I/Q amplitude and phase imbalance to the transmitted signal.

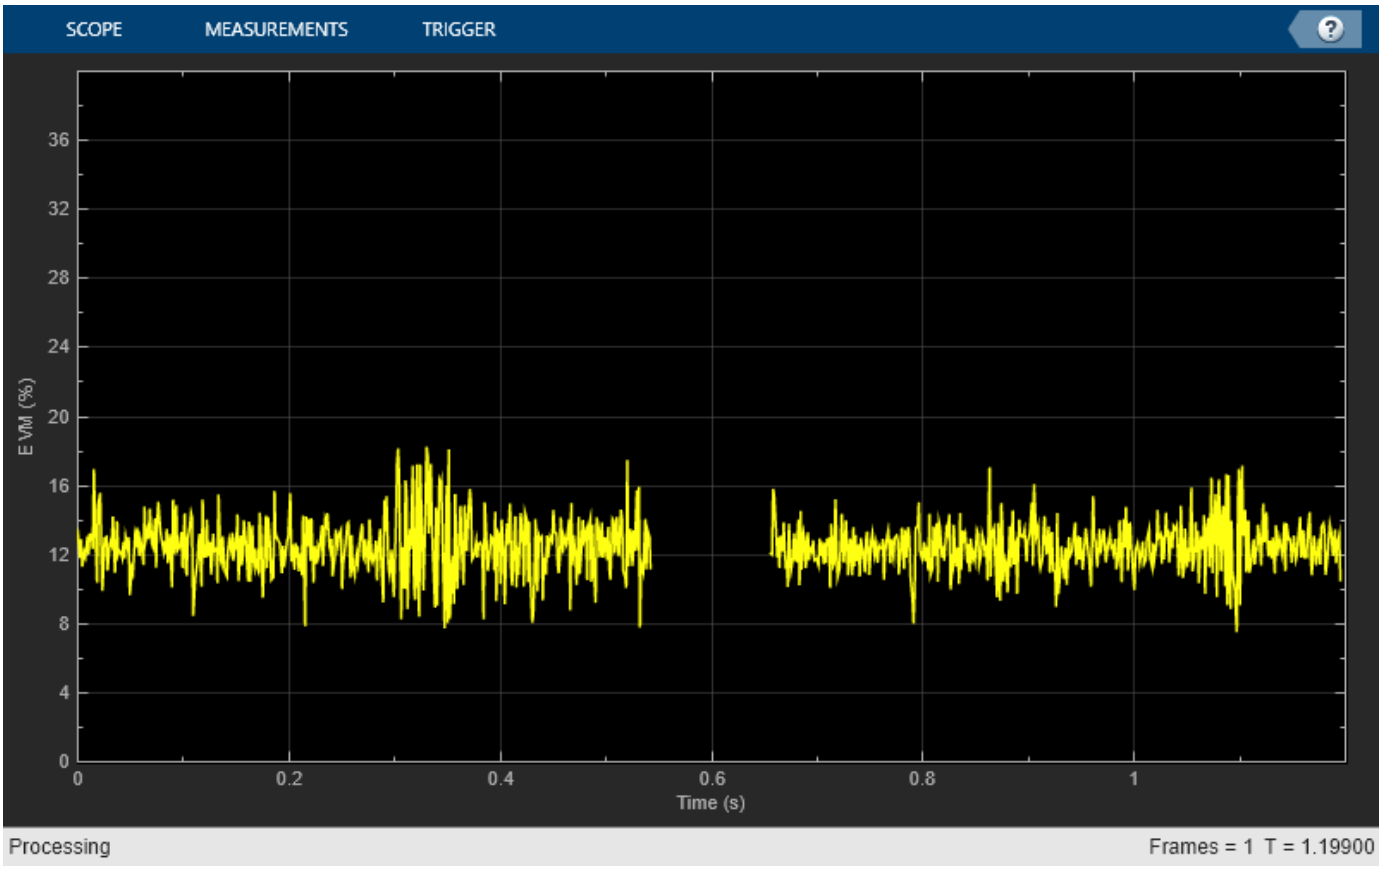
```
rxSigIQimb = iqimbal(txSig,2,5);
```

Apply phase noise.

```
rxSig = pnoise(rxSigIQimb);
```

Measure and plot the EVM of the received signal.

```
e = evm(txSig,rxSig);
tscope(e)
```



Measure EVM of Noisy 16-QAM Modulated Signal

Configure an EVM object to output maximum EVM, 90th percentile EVM, and symbol count.

```
evm = comm.EVM(MaximumEVMOutputPort=true, ...
    XPercentileEVMOutputPort=true,XPercentileValue=90, ...
    SymbolCountOutputPort=true);
```

Generate random data symbols. Apply 16-QAM modulation. The modulated signal serves as the reference for the subsequent EVM measurements.

```
data = randi([0 15],1000,1);
refSym = qammod(data,16,UnitAveragePower=true);
```

Pass the modulated signal through an AWGN channel.

```
rxSym = awgn(refSym,20);
```

Measure the EVM of the noisy signal.

```
[rmsEVM,maxEVM,pctEVM,numSym] = evm(refSym,rxSym)
```

```
rmsEVM = 9.8775
```

```
maxEVM = 26.8385
```

```
pctEVM = 14.9750
```

```
numSym = 1000
```

Measure EVM Using Custom Measurement Interval

Measure the EVM of a noisy 8-PSK signal using two types of custom measurement interval and display the results.

Set the number of frames, `M`, and the number of subframes per frame, `K`.

```
M = 2;
K = 5;
```

Set the number of symbols in a subframe. Calculate the corresponding frame length.

```
sfLen = 100;
frmLen = K*sfLen;
```

Create an EVM measurement System object, specifying a custom measurement interval equal to the frame length.

```
evm1 = comm.EVM(MeasurementIntervalSource="Custom", ...
    MeasurementInterval=frmLen);
```

Configure the object to measure EVM using an 8-PSK reference constellation.

```
evm1.ReferenceSignalSource = "Estimated from reference constellation";
evm1.ReferenceConstellation = pskmod(0:7,8,pi/8);
```

Create an EVM measurement System object, specifying a 500-symbol measurement interval with a periodic reset. Configure the object to measure EVM using an 8-PSK reference constellation.

```
evm2 = comm.EVM(...
    MeasurementIntervalSource="Custom with periodic reset", ...
    MeasurementInterval=frmLen);
evm2.ReferenceSignalSource = ...
    "Estimated from reference constellation";
evm2.ReferenceConstellation = pskmod(0:7,8,pi/8);
```

Initialize the EVM and signal-to-noise ratio (SNR) arrays.

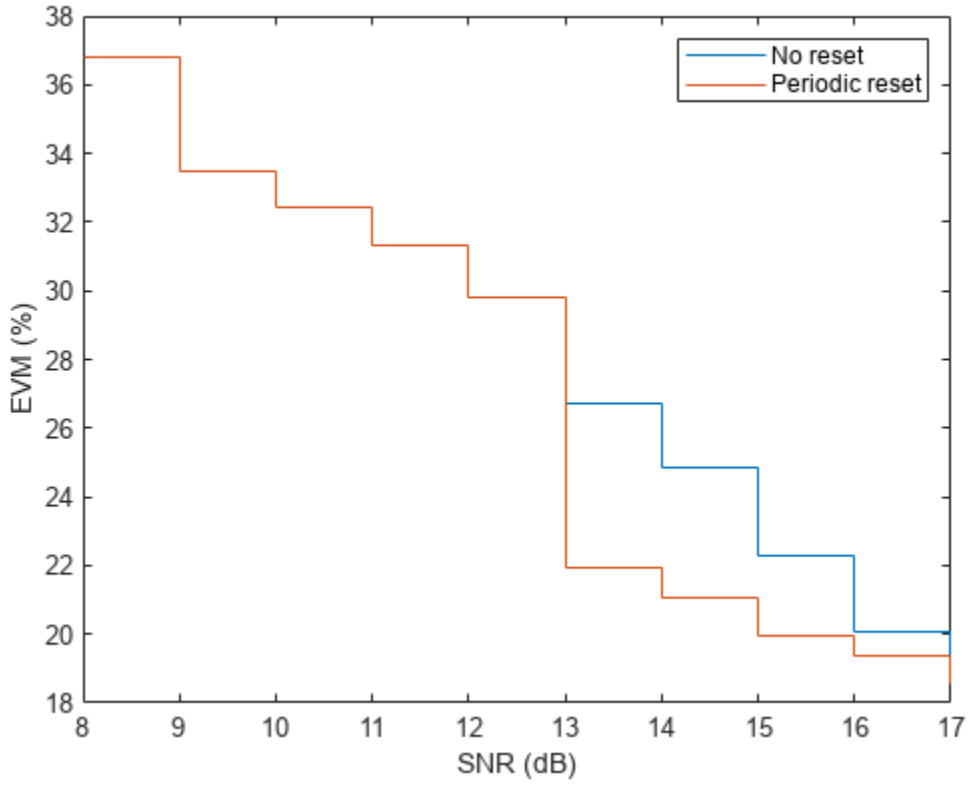
```
rmsEVM1 = zeros(K,M);
rmsEVM2 = zeros(K,M);
snrdB = zeros(K,M);
```

Measure the EVM for a noisy 8-PSK signal using both objects. The SNR increases by 1 dB from subframe to subframe. The `evm1` object uses the 500 most recent symbols to compute the estimate. In this case, the object uses a sliding window so that it processes an entire frame of data. The `evm2` object clears the symbols each time it begins processing a new frame.

```
for m = 1:M
    for k = 1:K
        data = randi([0 7],sfLen,1);
        txSig = pskmod(data,8,pi/8);
        snrdB(k,m) = k + (m-1)*K + 7;
        rxSig = awgn(txSig,snrdB(k,m));
        rmsEVM1(k,m) = evm1(rxSig);
        rmsEVM2(k,m) = evm2(rxSig);
    end
end
```

Display the EVM measured using the two approaches. The windowing used in the first case provides an averaging across the subframes. In the second case, the EVM object resets after the first frame so that the calculated EVM values more accurately reflect the current SNR.

```
stairs(snrdB(:),[rmsEVM1(:) rmsEVM2(:)])
xlabel('SNR (dB)')
ylabel('EVM (%)')
legend('No reset','Periodic reset')
```



Estimate Received EVM

Generate filtered QAM data and pass it through an AWGN channel. Compute the symbol error rate, and estimate the EVM of the received signal.

Create channel and filter System objects.

```
M = 16;
refConst = qammod(0:M-1,M);
channel = comm.AWGNChannel( ...
    NoiseMethod="Signal to noise ratio (SNR)", ...
    SNR=15,SignalPower=10);

txfilter = comm.RaisedCosineTransmitFilter(OutputSamplesPerSymbol=4);
rxfilter = comm.RaisedCosineReceiveFilter(InputSamplesPerSymbol=4, ...
    DecimationFactor=4);
```

Create an EVM measurement System object to calculate RMS and maximum EVM.

```
evm = comm.EVM(MaximumEVMOutputPort=true, ...
    ReferenceSignalSource="Estimated from reference constellation", ...
    ReferenceConstellation=refConst);
```

Create an error rate measurement System object and account for the signal delay through the transmit and receive filters. For a filter, the group delay is equal to half of the `FilterSpanInSymbols` property.

```
rxd = (txfilter.FilterSpanInSymbols + rxfilter.FilterSpanInSymbols)/2;
errorRate = comm.ErrorRate(ReceiveDelay=rxd);
```

Perform these channel operations:

- Generate random data symbols.
- Apply 16-QAM.
- Filter the modulated data through a raised cosine transmit filter.
- Pass the transmitted signal through an AWGN channel.
- Filter the received data through a raised cosine receive filter.
- Demodulate the filtered data.

```
txData = randi([0 15],1000,1);
modData = qammod(txData,M);
txSig = txfilter(modData);
rxSig = channel(txSig);
filtSig = rxfilter(rxSig);
rxData = qamdemod(filtSig,M);
```

Calculate the error statistics and display the symbol error rate.

```
errStats = errorRate(txData,rxData);
symErrRate = errStats(1)
```

```
symErrRate = 0.0222
```

Measure and display the received RMS EVM and maximum EVM values. Take the filter delay into account by deleting the first `rxd+1` symbols. Because the received signal contains symbol errors, the EVM might not be totally accurate.

```
[rmsEVM,maxEVM] = evm(filtSig(rxd+1:end))
```

```
rmsEVM = 17.2966
```

```
maxEVM = 40.1595
```

Measure EVM of OFDM Signal with Nonlinear Impairment

Measure the RMS and maximum EVM of a distorted OFDM waveform and visualize the received symbols by using a constellation diagram.

Generate an OFDM waveform with 64-QAM for random data.

```
M = 64;
nfft = 64;
nSym = 10;
cpLen = 10;
data = randi([0 (M - 1)]',nfft,nSym);
txSym = qammod(data,M,UnitAveragePower=1);
txWaveform = ofdmmod(txSym,nfft,cpLen);
```

Apply nonlinear distortion to the signal by creating a memoryless nonlinearity System object.

```
gain = 2;
nonlinearity = comm.MemorylessNonlinearity(Method="Rapp model", ...
    LinearGain=gain);
rxWaveform = nonlinearity(txWaveform);
```

Recover the distorted symbols by performing OFDM demodulation.

```
rxSym = ofdmdemod(rxWaveform,nfft,cpLen);
```

Measure the RMS and maximum EVM per OFDM symbol of the received signal.

```
refSym = qammod((0:(M - 1))',M,UnitAveragePower=1);
evm = comm.EVM(MaximumEVMOutputPort=1, ...
    ReferenceSignalSource="Estimated from reference constellation", ...
    ReferenceConstellation=refSym, ...
    Normalization="Average constellation power");
[rmsEVM,maxEVM] = evm(rxSym);
disp(rmsEVM')
```

```
    8.0933
    7.4962
    7.7542
    7.7335
    7.5719
    7.9262
    7.7042
    8.6034
    8.0817
    7.6852
```

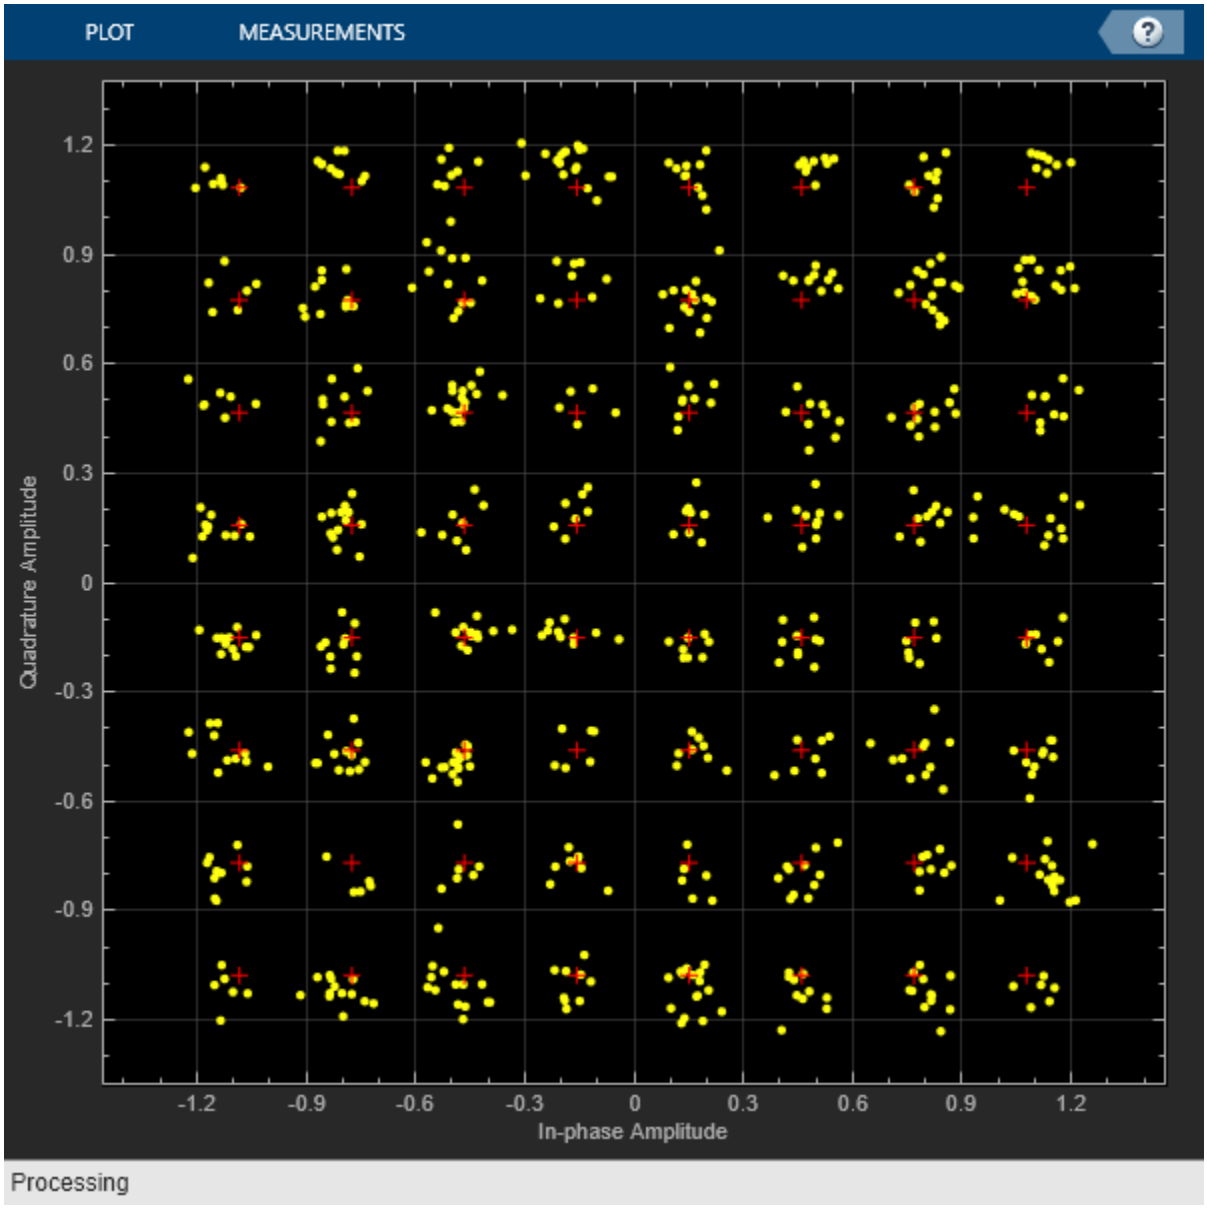
```
disp(maxEVM')
```

```
   18.8246
   15.6412
```

```
   15.9905
   13.0713
   14.0164
   15.5771
   17.0201
   19.4699
   18.2106
   16.7549
```

Visualize the received symbols on a constellation diagram.

```
constellation = comm.ConstellationDiagram( ...
    Name="Constellation Diagram of Received Symbols", ...
    ReferenceConstellation=refSym(:));
constellation(rxSym(:))
```



Algorithms

The implementation supports three normalization methods. You can normalize measurements according to the average power of the reference signal, average constellation power, or peak constellation power. Different industry standards follow one of these normalization methods.

The algorithm calculates the RMS EVM value differently for each normalization method.

EVM Normalization Method	Algorithm
Reference signal	$EVM_{\mathrm{RMS}} = \sqrt{\frac{\frac{1}{N}\sum_{k=1}^{N}(e_k)}{\frac{1}{N}\sum_{k=1}^{N}(I_k^2 + Q_k^2)}} \times 100$
Average power	$EVM_{\mathrm{RMS}}(\%) = 100\sqrt{\frac{\frac{1}{N}\sum_{k=1}^{N}(e_k)}{P_{\mathrm{avg}}}}$
Peak power	$EVM_{\mathrm{RMS}}(\%) = 100\sqrt{\frac{\frac{1}{N}\sum_{k=1}^{N}(e_k)}{P_{\mathrm{max}}}}$

In these equations:

- $e_k = e_k = (I_k - \tilde{I}_k)^2 + (Q_k - \tilde{Q}_k)^2$
- I_k is the in-phase measurement of the kth symbol in the burst.
- Q_k is the quadrature phase measurement of the kth symbol in the burst.
- N is the input vector length.
- P_{avg} is the average constellation power.
- P_{max} is the peak constellation power.
- I_k and Q_k represent ideal (reference) values. $\tilde{I}_k$ and $\tilde{Q}_k$ represent measured (received) symbols.

The maximum EVM is the maximum EVM value in a frame or $EVM_{\mathrm{max}} = \max_{k \in [1,\ldots,N]}\{EVM_k\}$, where k is the kth symbol in a burst of length N.

The definition for EVM_k depends on which normalization method you select for computing measurements. The implementation supports these algorithms.

EVM Normalization Method	Algorithm
Reference signal	$EVM_k = \sqrt{\frac{e_k}{\frac{1}{N}\sum_{k=1}^{N}(I_k^2 + Q_k^2)}} \times 100$

EVM Normalization Method	Algorithm
Average power	$EVM_k = 100\sqrt{\frac{e_k}{P_{\text{avg}}}}$
Peak power	$EVM_k = 100\sqrt{\frac{e_k}{P_{\text{max}}}}$

The implementation computes the X-percentile EVM by creating a histogram of the incoming EVM_k values. This output provides the EVM value below which X% of the EVM values fall.

comm.EyeDiagram

Package: `comm`

(Removed) Display eye diagram of time-domain signals

Note has been removed. To display the eye diagram of a signal, use the `eyediagram` function instead. For more details on the recommended workflow, see “Compatibility Considerations”.

Description

The `comm.EyeDiagram` System object displays multiple traces of a modulated signal to produce an eye diagram. You can use the object to reveal the modulation characteristics of the signal, such as the effects of pulse shaping or channel distortions. The eye diagram can measure signal characteristics and plot horizontal and vertical bathtub curves when the jitter and noise comply with the dual-Dirac model [1].

To display the eye diagram of an input signal:

1. Create the `comm.EyeDiagram` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
ed = comm.EyeDiagram
ed = comm.EyeDiagram(Name,Value)
```

Description

`ed = comm.EyeDiagram` creates an eye diagram System object with default property values.

`ed = comm.EyeDiagram(Name,Value)` sets properties using one or more name-value pair argument. Enclose each property name in single quotes. Unspecified properties have default values.

Example: `comm.EyeDiagram('SampleRate',2,'DisplayMode','2D color histogram')`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Name — Title of eye diagram window
`'Eye Diagram'` (default) | character vector

Title of eye diagram window, specified as a character vector.

Tunable: Yes

Data Types: `char`

SampleRate — Sample rate of input signal
`1` (default) | positive real-valued scalar

Sample rate of the input signal in hertz, specified as a positive real-valued scalar.

Data Types: `double`

SamplesPerSymbol — Number of samples per symbol
`8` (default) | positive integer

Number of samples per symbol, specified as a positive integer.

Tunable: Yes

Data Types: `double`

SampleOffset — Number of samples to skip before plotting the first point
`0` (default) | nonnegative integer

Number of samples to skip before plotting the first point, specified as a nonnegative integer. To avoid irregular behavior, specify the offset to be less than the product of the SamplesPerSymbol and SymbolsPerTrace properties.

Tunable: Yes

Data Types: `double`

SymbolsPerTrace — Number of symbols per trace
`2` (default) | positive integer

Number of symbols per trace, specified as a positive integer. To obtain eye measurements and visualize bathtub curves, use the default value of `2`.

Tunable: Yes

Data Types: `double`

TracesToDisplay — Number of traces to display
`40` (default) | positive integer

Number of traces to display, specified as a positive integer.

Tunable: Yes

Dependencies

To enable this property, set DisplayMode property to `'Line plot'`.

Data Types: `double`

`DisplayMode` — Eye diagram display mode
`'Line plot'` (default) | `'2D color histogram'`

Eye diagram display mode, specified as one of these values.

- `'Line plot'` — Overlay traces by plotting one line for each of the last TracesToDisplay traces.
- `'2D color histogram'` — Display a color gradient that shows how often the input matches different time and amplitude values.

Tunable: Yes

Data Types: `char`

`EnableMeasurements` — Option to enable eye diagram measurements
`false` (default) | `true`

Option to enable eye diagram measurements, specified as `true` or `false`. Set this property to `true` to display the measurement pane and calculations in the eye diagram.

Tunable: Yes

Data Types: `logical`

`ShowBathtub` — Option to enable visualization of bathtub curves
`'None'` (default) | `'Horizontal'` | `'Vertical'` | `'Both'`

Option to enable visualization of bathtub curves, specified as `'None'`, `'Horizontal'`, `'Vertical'`, or `'Both'`.

Tunable: Yes

Dependencies

To enable this property, set the EnableMeasurements property to `true`.

Data Types: `char`

`OverlayHistogram` — Histogram overlay
`'None'` (default) | `'Jitter'` | `'Noise'`

Histogram overlay, specified as `'None'`, `'Jitter'`, or `'Noise'`.

- To overlay a horizontal histogram on the eye diagram, set this property to `'Jitter'`.
- To overlay a vertical histogram on the eye diagram, set this property to `'Noise'`.
- To display no histogram overlay, set this property to `'None'`.

Tunable: Yes

Dependencies

To enable this property, set the DisplayMode property to `'2D color histogram'` and EnableMeasurements property to `true`.

Data Types: `char`

`DecisionBoundary` — Amplitude level threshold

`0` (default) | real-valued scalar

Amplitude level threshold in volts, specified as a real-valued scalar. This property separates the different signaling regions for horizontal (jitter) histograms. Jitter histograms reset when this property changes.

For non-return-to-zero (NRZ) signals, set `DecisionBoundary` to 0. For return-to-zero (RZ) signals, set `DecisionBoundary` to half the maximum amplitude.

Tunable: Yes

Dependencies

To enable this property, set the EnableMeasurements property to `true`.

Data Types: `double`

`EyeLevelBoundaries` — Time range for calculating eye levels

`[40 60]` (default) | two-element row vector

Time range for calculating eye levels, specified as a two-element row vector. Specify the vector values as percentages of the symbol duration.

Tunable: Yes

Dependencies

To enable this property, set the EnableMeasurements property to `true`.

Data Types: `double`

`RiseFallThresholds` — Amplitude levels of the rise and fall transitions

`[10 90]` (default) | two-element row vector

Amplitude levels of the rise and fall transitions, specified as a two-element row vector. Specify the vector values as percentages of the eye amplitude. The crossing histograms of the rise and fall thresholds reset when this property changes.

Tunable: Yes

Dependencies

To enable this property, set the EnableMeasurements property to `true`.

Data Types: `double`

`Hysteresis` — Amplitude tolerance of the horizontal crossings

`0` (default) | real-valued scalar

Amplitude tolerance of the horizontal crossings in volts, specified as a real-valued scalar. Increase this value to provide more tolerance to spurious crossings due to noise. Jitter and the rise and fall histograms reset when this property changes.

Tunable: Yes

Dependencies

To enable this property, set the EnableMeasurements property to `true`.

Data Types: `double`

`BERThreshold` — BER used for eye measurements

`1e-12` (default) | scalar in the range [0, 0.5]

Bit error rate (BER) used for eye measurements, specified as a scalar in the range [0, 0.5]. The System object uses this value to measure the random jitter, the total jitter, horizontal eye openings, and vertical eye openings.

Tunable: Yes

Dependencies

To enable this property, set the EnableMeasurements property to `true`.

Data Types: `double`

`BathtubBER` — BER values used to calculate openings of bathtub curves

`[0.5 10.^-(1:12)]` (default) | vector

BER values used to calculate the openings of bathtub curves, specified as a vector of elements in the range [0, 0.5]. Horizontal and vertical eye openings are calculated for each of the values specified by this property.

Tunable: Yes

Dependencies

To enable this property, set the EnableMeasurements property to `true` and ShowBathtub property to `'Both'`, `'Horizontal'`, or `'Vertical'`.

Data Types: `double`

`MeasurementDelay` — Duration of initial data discarded from measurements

`0` (default) | nonnegative scalar

Duration of initial data discarded from measurements in seconds, specified as a nonnegative scalar.

Dependencies

To enable this property, set the EnableMeasurements property to `true`.

Data Types: `double`

`OversamplingMethod` — Oversampling method

`'None'` (default) | `'Input interpolation'` | `'Histogram interpolation'`

Oversampling method, specified as `'None'`, `'Input interpolation'`, or `'Histogram interpolation'`.

To plot eye diagrams as quickly as possible, set `OversamplingMethod` to `'None'`. The drawback to not oversampling is that the plots look pixelated when the number of symbols per trace is small.

To create smoother, less-pixelated plots using a small number of symbols per trace, set `OversamplingMethod` to `'Input interpolation'` or `'Histogram interpolation'`. In this case, `'Input interpolation'` is the faster interpolation method and produces good results when the signal-to-noise ratio (SNR) is high. With a low SNR, this oversampling method is not recommended because it introduces a bias to the centers of the histogram ranges. `'Histogram`

`interpolation'` is not as fast as the other techniques, but it provides good results even when the SNR is low.

Tunable: Yes

Dependencies

To enable this property, set the DisplayMode property to `'2D color histogram'`.

Data Types: `char`

`ColorScale` — Color scale of the histogram

`'Linear'` (default) | `'Logarithmic'`

Color scale of the histogram, specified as `'Linear'` or `'Logarithmic'`. Change this property if certain areas of the histogram include a disproportionate number of points. Use the `'Logarithmic'` option for eye diagrams with sharp peaks, where the signal repetitively matches specific time and amplitude values.

Tunable: Yes

Dependencies

To enable this property, set the DisplayMode property to `'2D color histogram'`.

Data Types: `char`

`ColorFading` — Color fading

`false` (default) | `true`

Color fading, specified as `true` or `false`. To fade the points in the display as the interval of time after they are first plotted increases, set this property to `true`. This animation resembles an oscilloscope.

Tunable: Yes

Dependencies

To enable this property, set the DisplayMode property to `'Line plot'`.

Data Types: `logical`

`ShowImaginaryEye` — Show imaginary signal component

`false` (default) | `true`

Show imaginary signal component, specified as `true` or `false`. To view the imaginary or quadrature component of the input signal, set this property to `true`.

Tunable: Yes

Dependencies

To enable this property, set the EnableMeasurements property to `false`.

Data Types: `logical`

`YLimits` — *Y*-axis limits

`[-1.1 1.1]` (default) | two-element row vector

Y-axis limits of the eye diagram in volts, specified as a two-element vector. The first element corresponds to *ymin* and the second to *ymax*. The second element must be greater than the first.

Tunable: Yes

Data Types: `double`

`ShowGrid` — Option to enable grid display
`false` (default) | `true`

Option to enable grid display on the eye diagram, specified as `true` or `false`. To display a grid on the eye diagram, set this property to `true`.

Tunable: Yes

Data Types: `logical`

`Position` — Scope window position
four-element row vector

Scope window position in pixels, specified as a four-element row vector of the form [*left bottom width height*].

Tunable: Yes

Data Types: `double`

Usage

Syntax

```
ed(x)
```

Description

`ed(x)` displays and analyzes input signal `x` in an eye diagram.

Input Arguments

`x` — Input signal
vector | matrix

Input signal to be analyzed and displayed in the eye diagram, specified as a vector or matrix. `x` can be either a real or complex vector, or a real two-column matrix.

Data Types: `double`
Complex Number Support: Yes

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `comm.EyeDiagram`

show	Show scope window
hide	Hide scope window
horizontalBathtub	(Removed) Horizontal bathtub curve
verticalBathtub	(Removed) Vertical bathtub curve
jitterHistogram	(Remove) Jitter histogram
noiseHistogram	(Removed) Noise histogram
measurements	(Removed) Measure eye diagram parameters

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Eye Diagram of Filtered QPSK Signal

Specify the sample rate and the number of output samples per symbol parameters.

```
fs = 1000;
sps = 4;
```

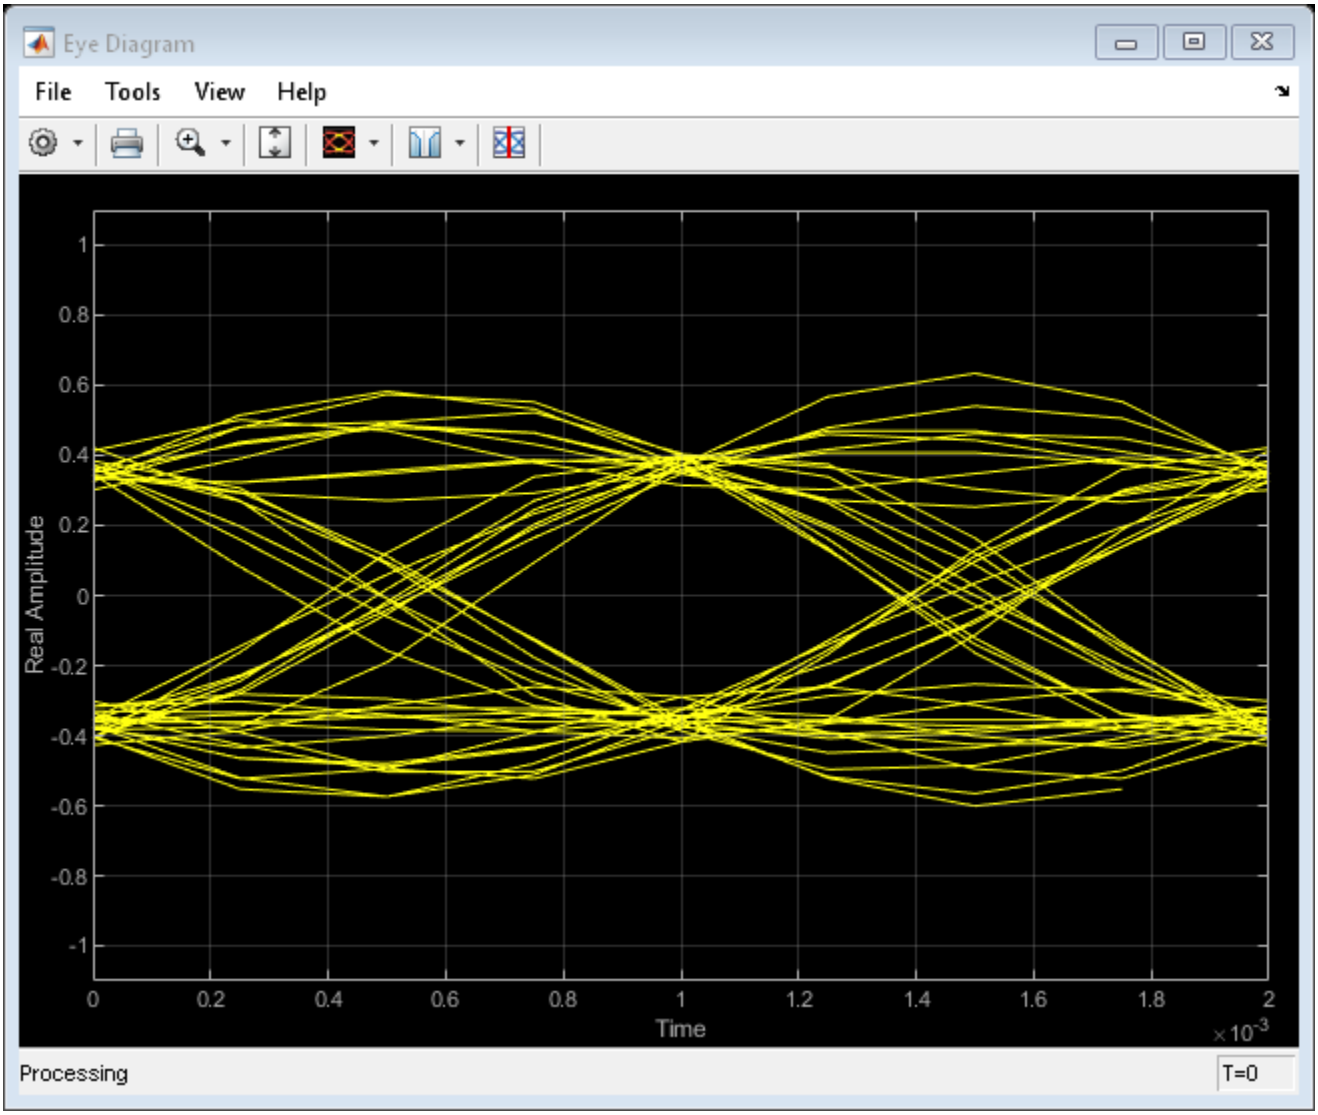
Create transmit filter and eye diagram objects.

```
txfilter = comm.RaisedCosineTransmitFilter(...
    'OutputSamplesPerSymbol',sps);
ed = comm.EyeDiagram('SampleRate',fs*sps,'SamplesPerSymbol',sps);
```

Generate random symbols and apply QPSK modulation. Then filter the modulated signal and display the eye diagram.

```
data = randi([0 3],1000,1);
modSig = pskmod(data,4,pi/4);

txSig = txfilter(modSig);
ed(txSig)
```



More About

Measurements

Measurements assume that the eye diagram object has valid data. A valid eye diagram has two distinct eye crossing points and two distinct eye levels.

To open the measurements pane, click on the **Eye Measurements** button or select **Tools > Measurements > Eye Measurements** from the toolbar menu.

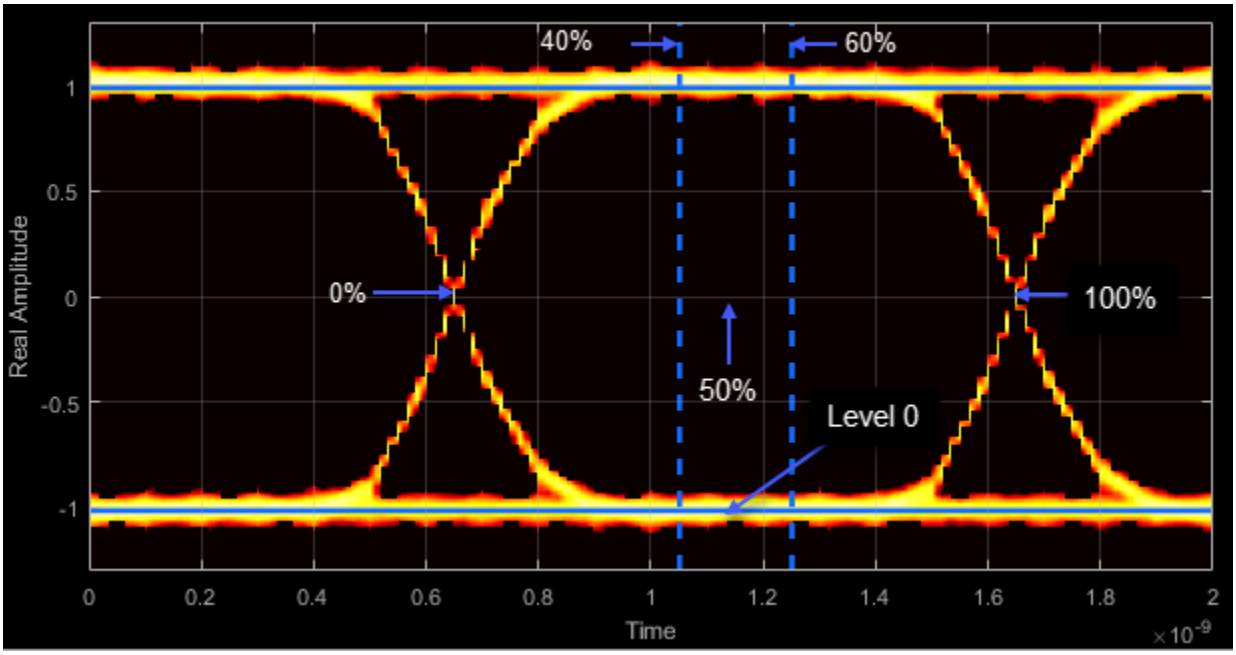
Note

- For amplitude measurements, at least one bin per vertical histogram must reach 10 hits before the measurement is taken, ensuring higher accuracy.
- For time measurements, at least one bin per horizontal histogram must reach 10 hits before the measurement is taken.

- When an eye crossing time measurement falls within the [-0.5/Fs, 0) seconds interval, the time measurement wraps to the end of the eye diagram, i.e., the measurement wraps by $2\times T_s$ seconds (where T_s is the symbol time). For a complex signal case, the analyze method issues a warning if the crossing time measurement of the in-phase branch wraps while that of the quadrature branch does not (or vice versa). To avoid time-wrapping or a warning, add a half-symbol duration delay to the current value in the `MeasurementDelay` property of the eye diagram object. This additional delay repositions the eye in the approximate center of the scope.

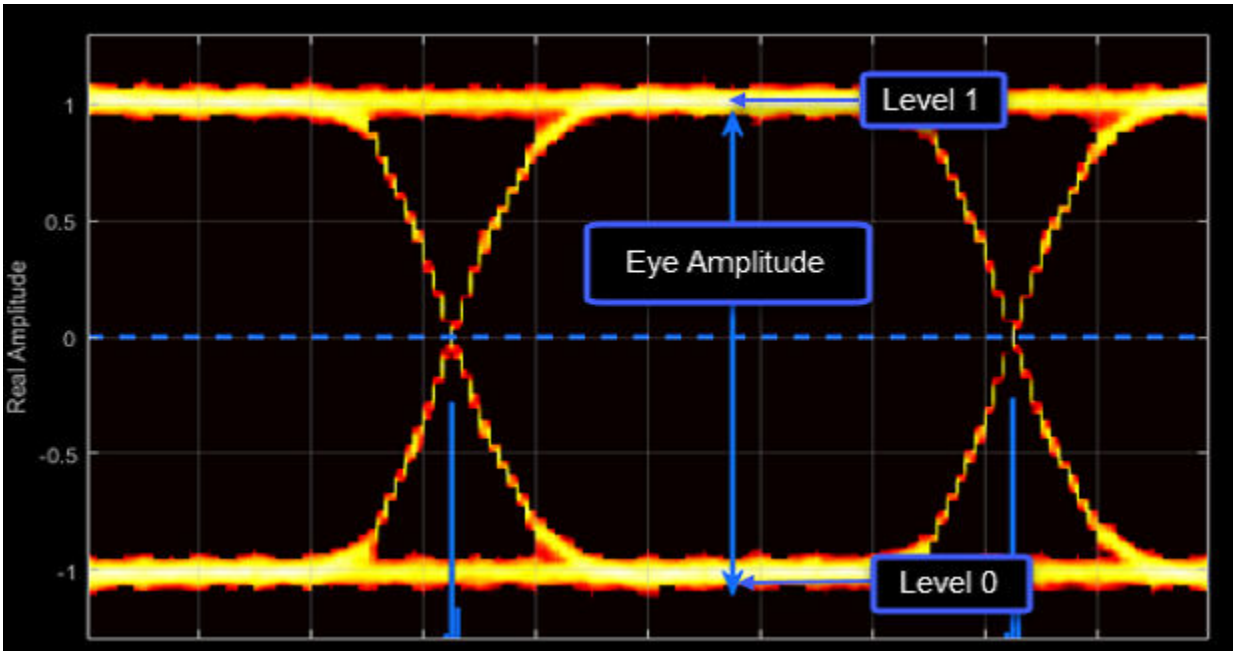
Eye Levels - Amplitude level used to represent data bits

Eye level is the amplitude level used to represent data bits. For the displayed NRZ signal, the levels are –1 V and +1 V. The eye levels are calculated by averaging the 2-D histogram within the eye level boundaries. For example, when the EyeLevelBoundaries property is set to `[40 60]`, that is, 40% and 60% of the symbol duration, the eye levels are calculated by estimating the mean value of the vertical histogram in this window marked by the eye level boundaries.



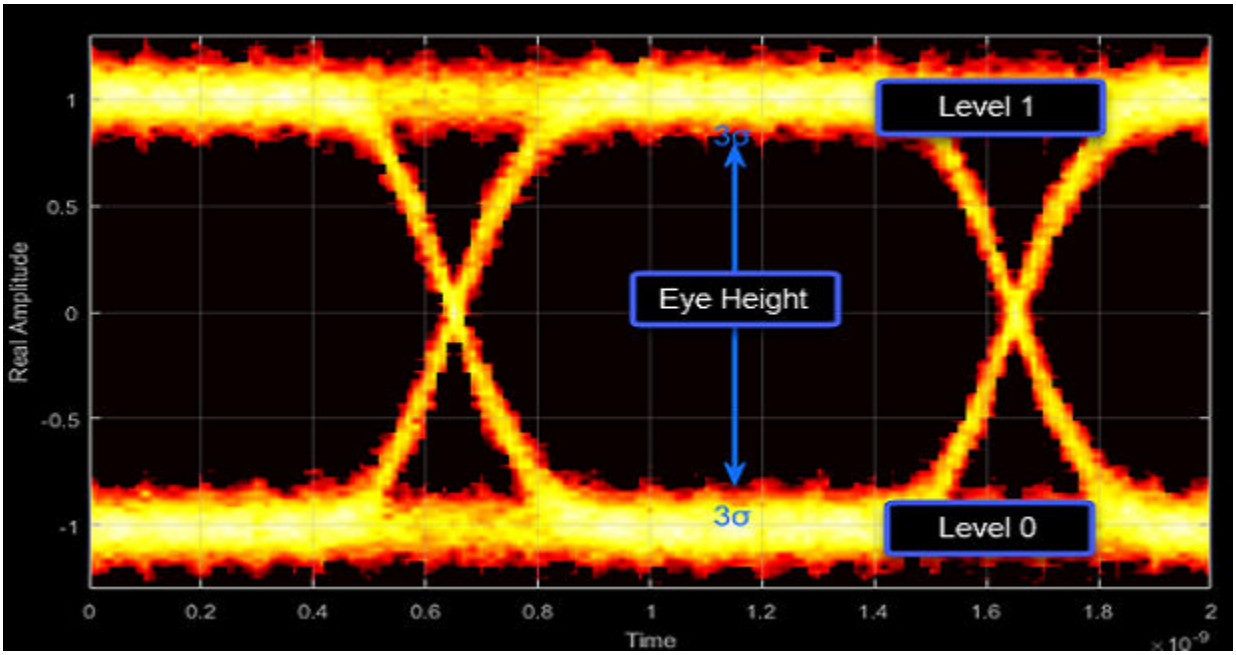
Eye Amplitude - Distance between eye levels

Eye amplitude is the distance in V between the mean value of two eye levels.



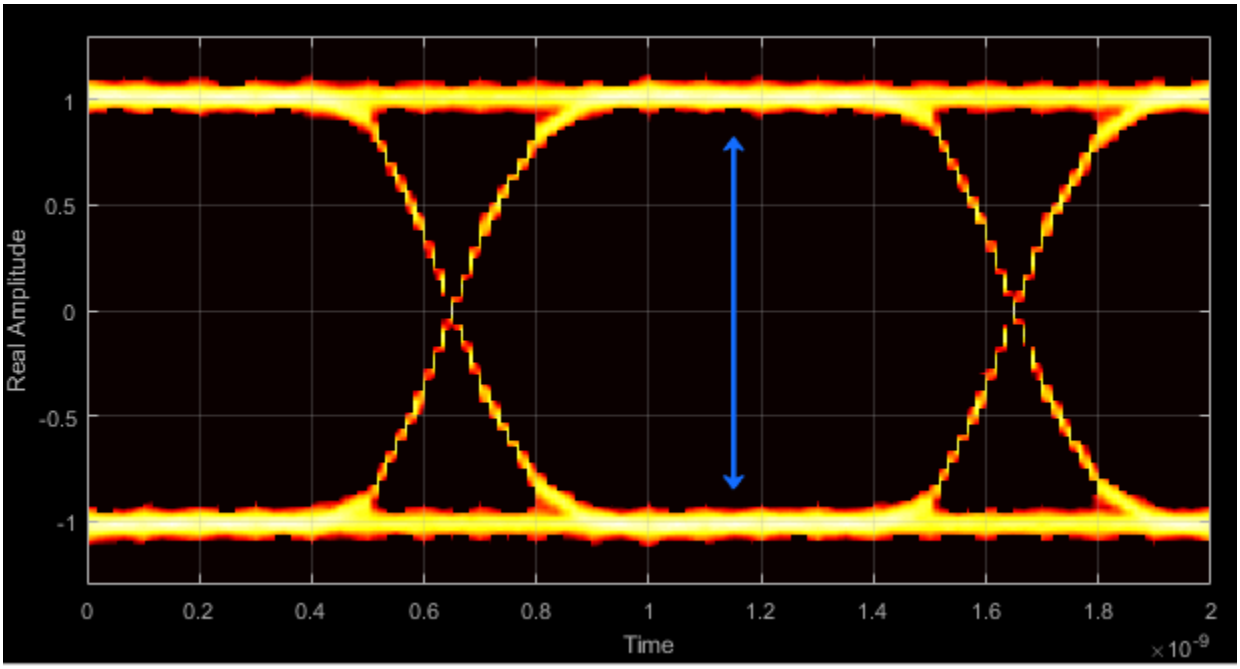
Eye Height - Statistical minimum distance between eye levels

Eye height is the distance between μ – 3σ of the upper eye level and μ + 3σ of the lower eye level. μ is the mean of the eye level, and σ is the standard deviation.



Vertical Opening - Distance between BER threshold points

The vertical opening is the distance between the two points that correspond to the BERThreshold property. For example, for a BER threshold of 10^{-12}, these points correspond to the 7σ distance from each eye level.



Eye SNR - Signal-to-noise ratio

The eye SNR is the ratio of the eye level difference to the difference of the vertical standard deviations corresponding to each eye level:

$$\text{SNR} = \frac{L_1 - L_0}{\sigma_1 - \sigma_0},$$

where L_1 and L_0 represent the means of the upper and lower eye levels and σ_1 and σ_0 represent their standard deviations.

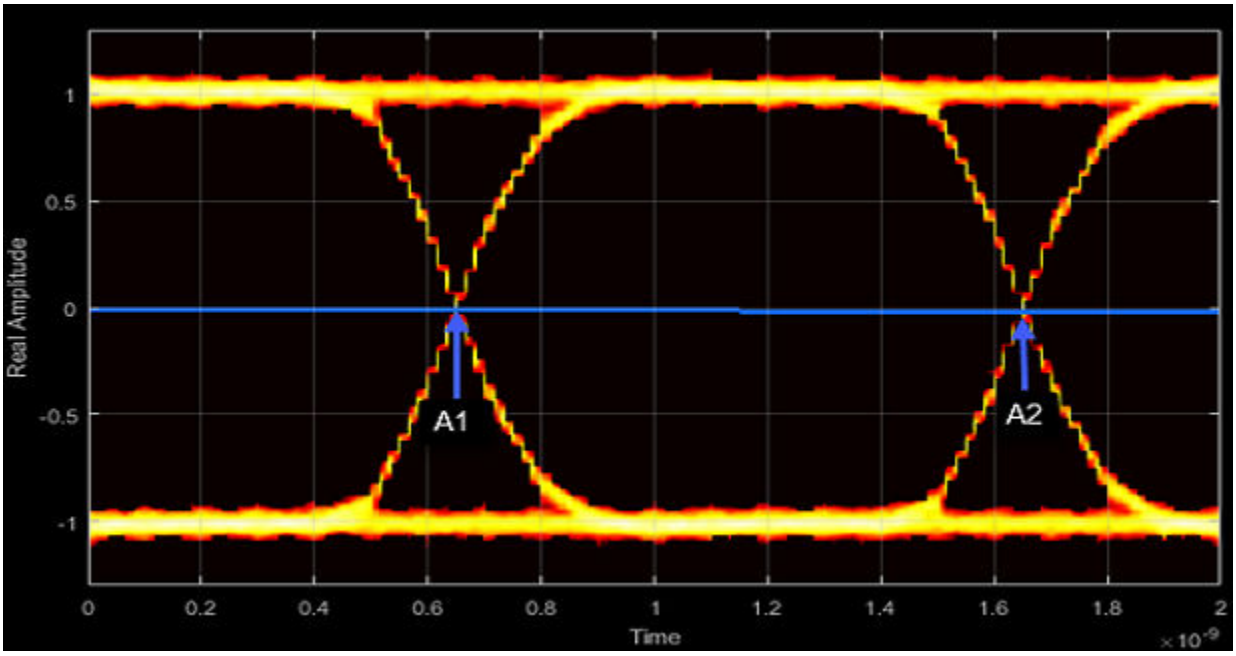
Q Factor - Quality factor

The Q factor is the quality factor and is calculated using the same formula as the eye SNR. However, the standard deviations of the vertical histograms are replaced with those computed with the dual-Dirac analysis.

Crossing Levels - Amplitude levels for eye crossings

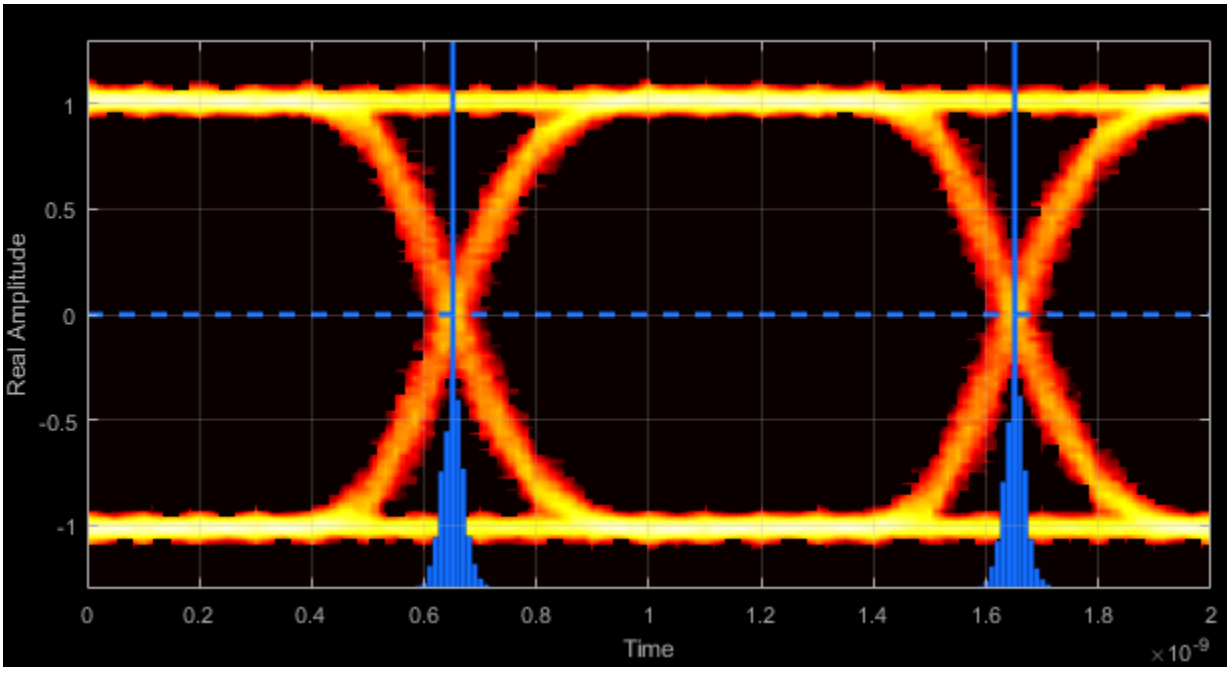
The crossing levels are the amplitude levels at which the eye crossings occur.

The level at which the input signal crosses the amplitude value is specified by the DecisionBoundary property.



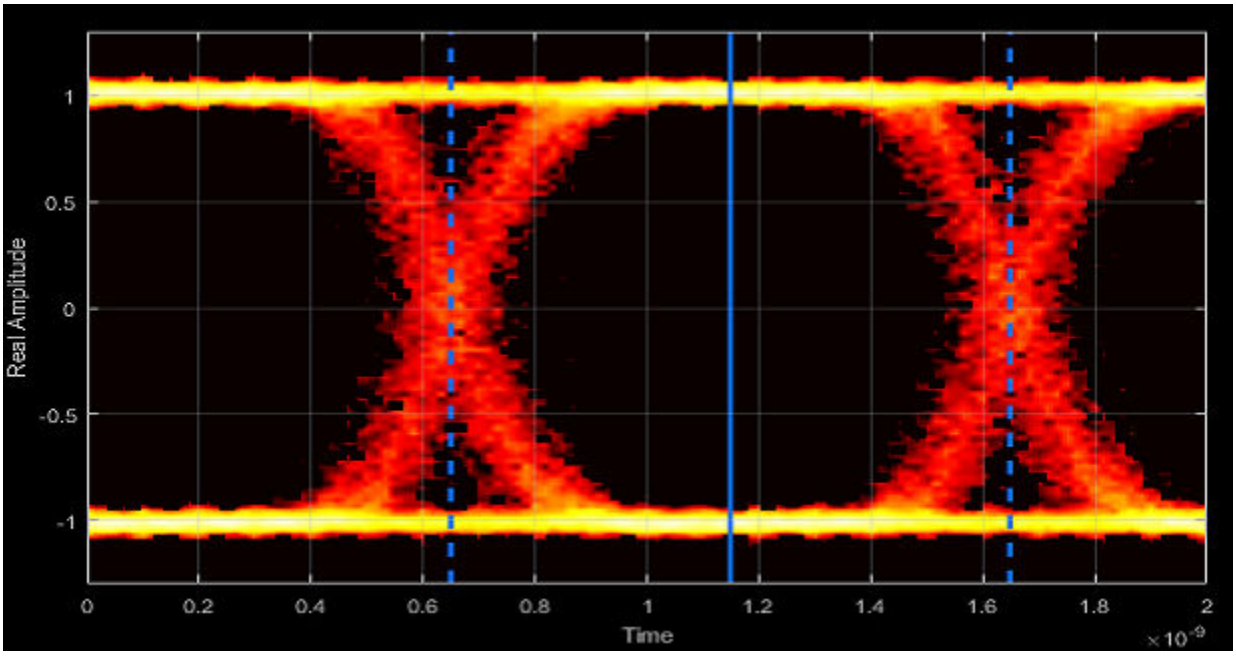
Crossing Times - Times for which crossings occur

The crossing times are the times at which the crossings occur. The times are computed as the mean values of the horizontal (jitter) histograms.



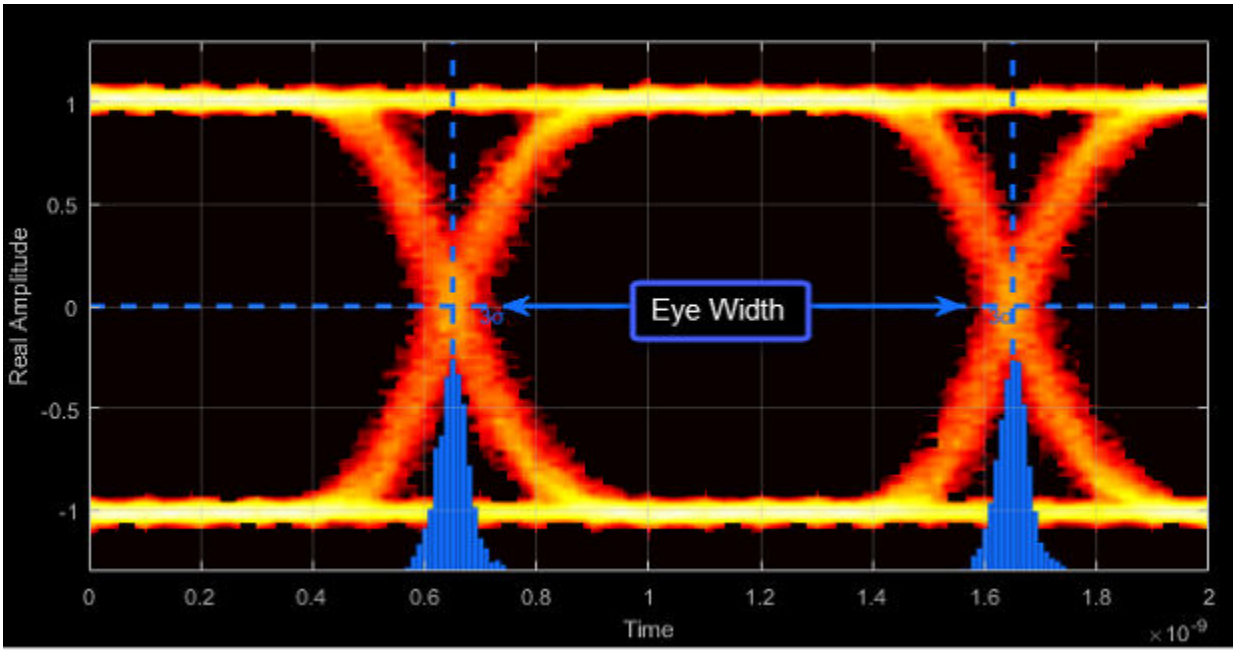
Eye Delay - Mean time between eye crossings

Eye delay is the midpoint between the two crossing times.



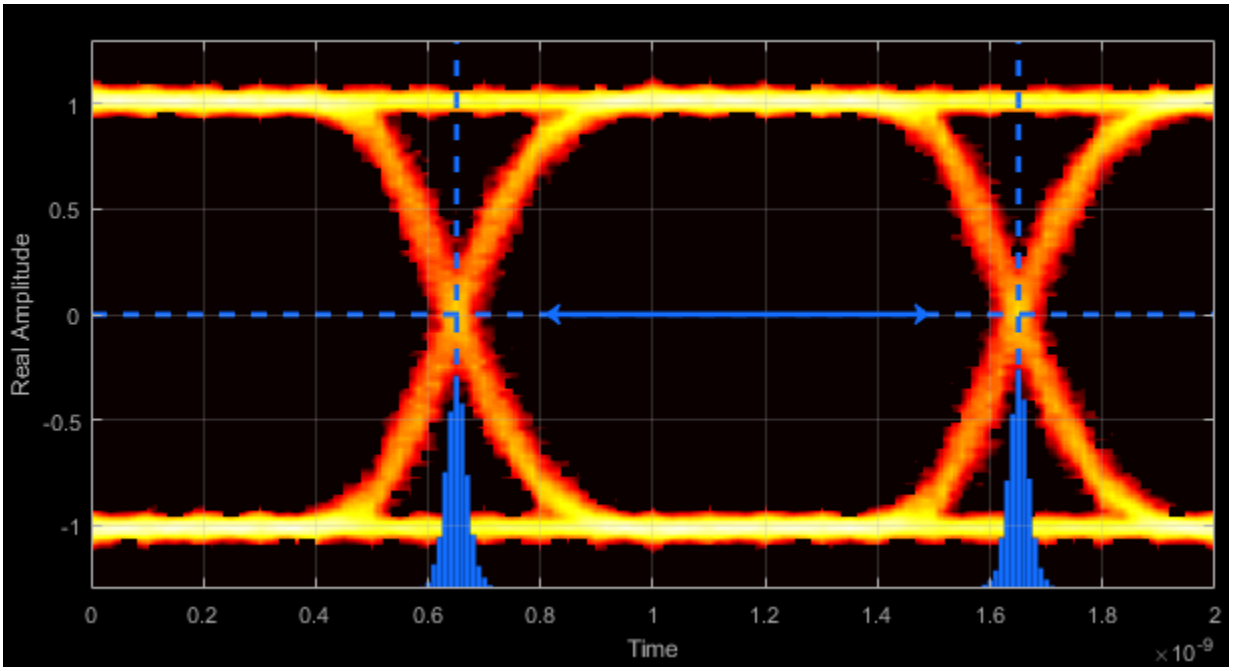
Eye Width - Statistical minimum time between eye crossings

Eye width is the horizontal distance between μ + 3σ of the left crossing time and μ – 3σ of the right crossing time. μ is the mean of the jitter histogram, and σ is the standard deviation.



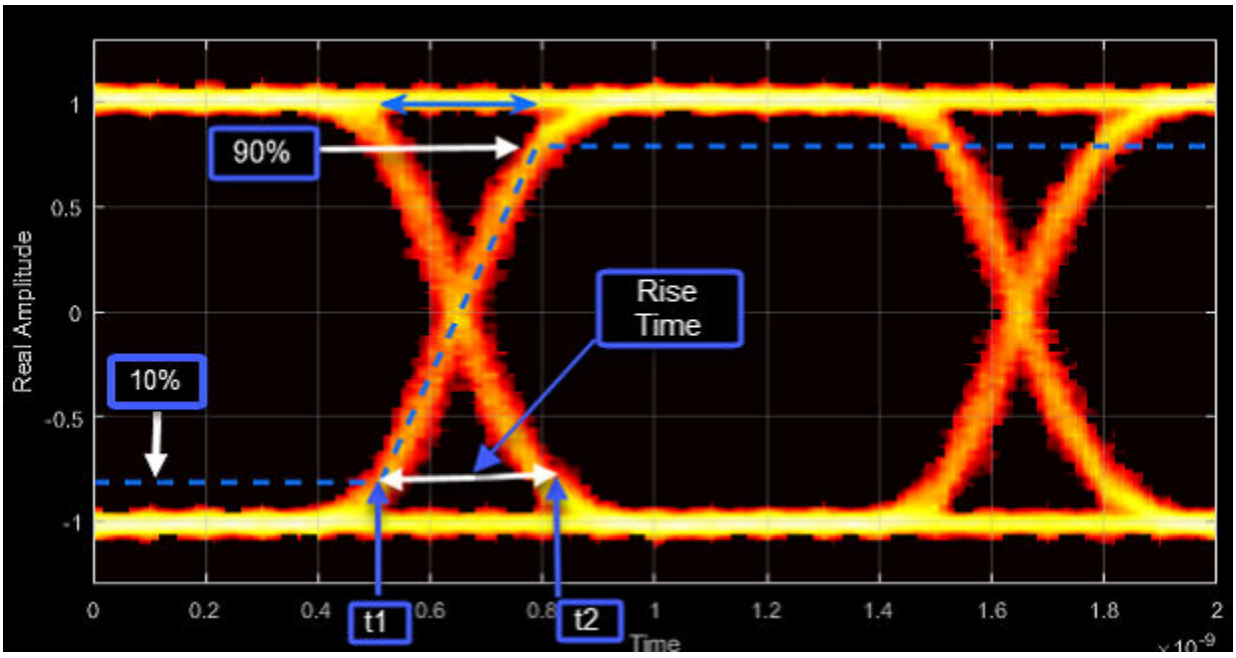
Horizontal Opening - Time between BER threshold points

The horizontal opening is the distance between the two points that correspond to the BERThreshold property. For example, for a 10^{-12} BER, these two points correspond to the 7σ distance from each crossing time.



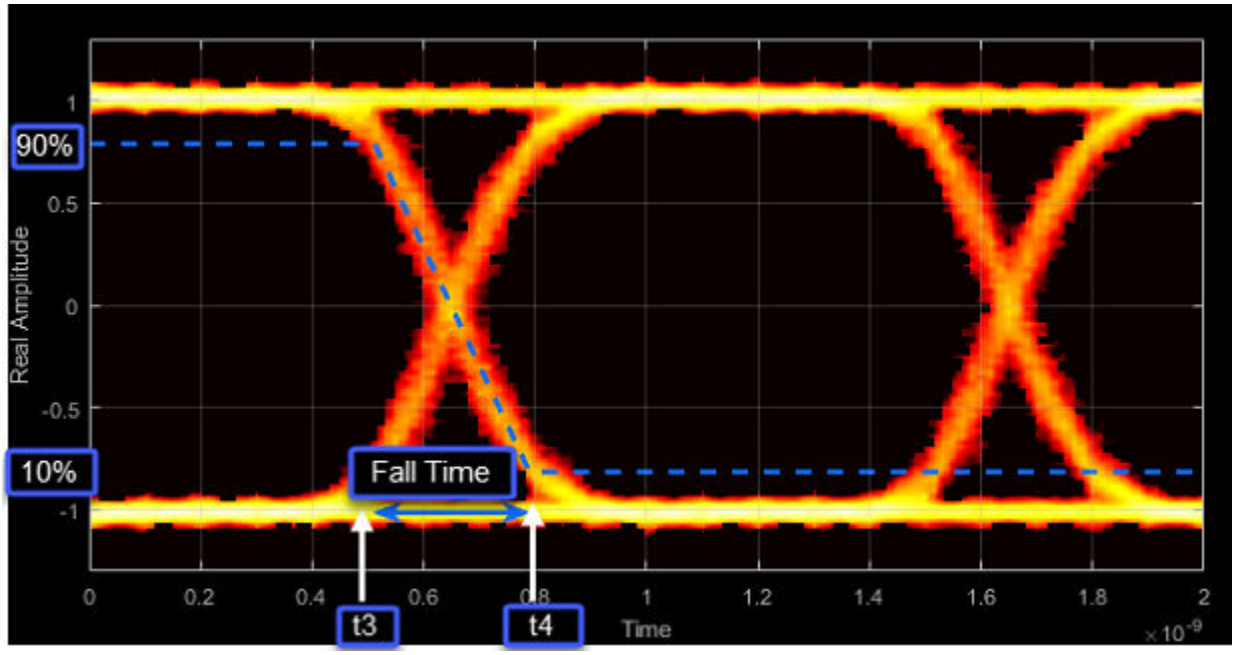
Rise Time - Time to transition from low to high

Rise time is the mean time between the low and high rise/fall thresholds defined in the eye diagram. The default thresholds are 10% and 90% of the eye amplitude.



Fall Time - Time to transition from high to low

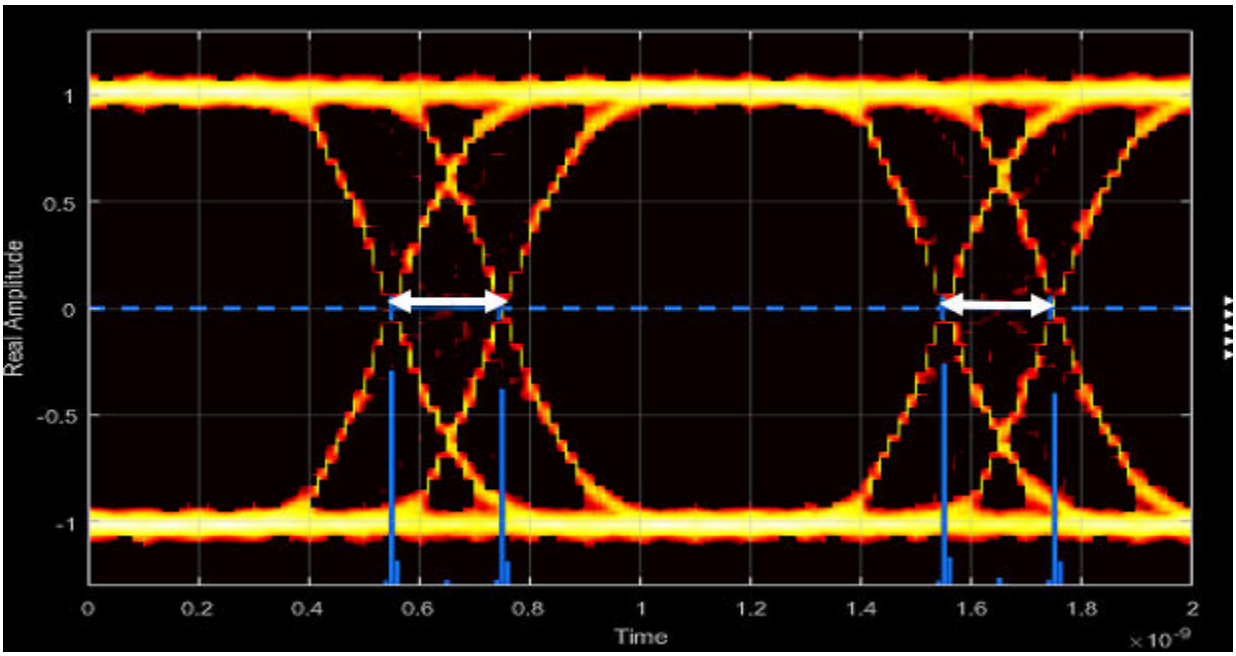
Fall time is the mean time between the high and low rise/fall thresholds defined in the eye diagram. The default thresholds are 10% and 90% of the eye amplitude.



Deterministic Jitter - Deterministic deviation from ideal signal timing

Jitter is the deviation of a signal's timing event from its intended (ideal) occurrence in time [2]. Jitter can be represented with a dual-Dirac model. A dual-Dirac model assumes that the jitter has two components: deterministic jitter (DJ) and random jitter (RJ).

DJ is the distance between the two peaks of the dual-Dirac histograms. The probability density function (PDF) of DJ is composed of two delta functions.



Random Jitter - Random deviation from ideal signal timing

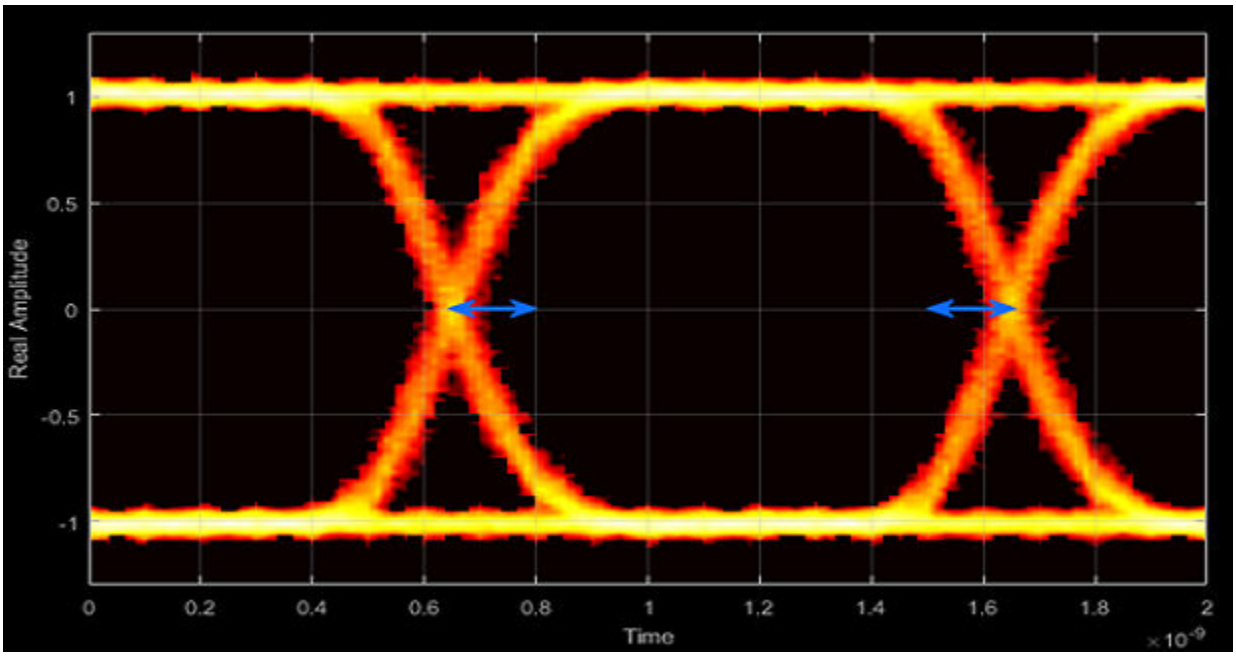
RJ is the Gaussian unbounded jitter component. The random component of jitter is modeled as a zero-mean Gaussian random variable with a specified standard-deviation of σ. The RJ is computed as:

$$\mathrm{RJ} = (Q_L + Q_R)\sigma\,,$$

where

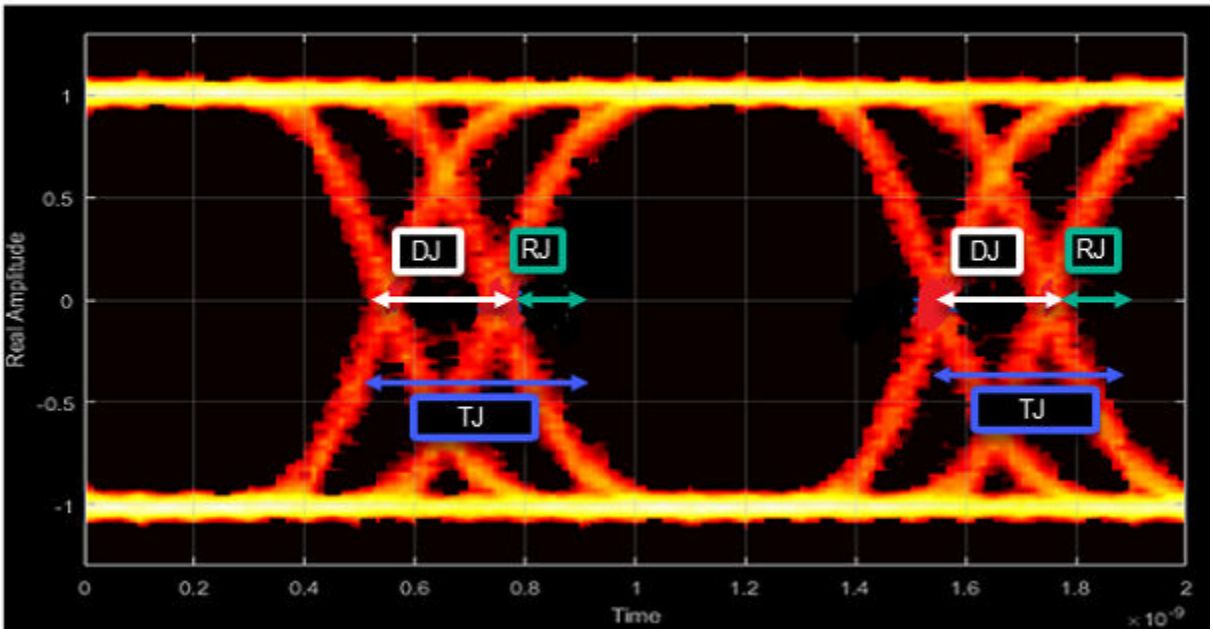
$$Q = \sqrt{2}\mathrm{erfc}^{-1}\left(2\frac{BER}{\rho}\right).$$

BER is the specified BER threshold. ρ is the amplitude of the left and right Dirac function, which is determined from the bin counts of the jitter histograms.

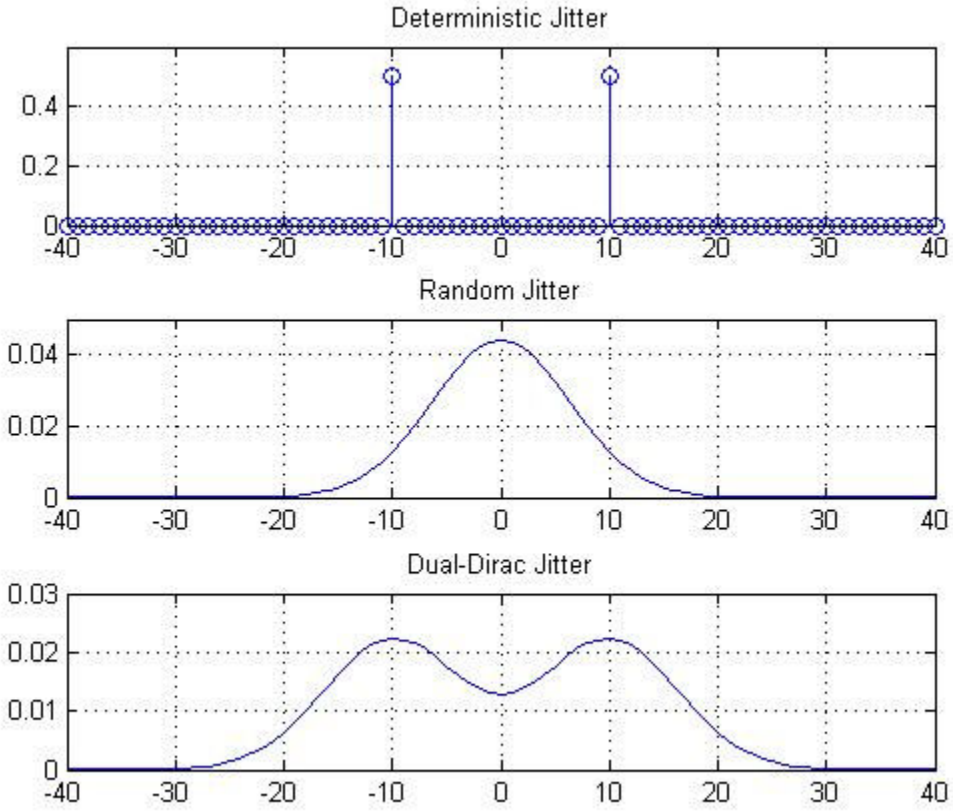


Total Jitter - Deviation from ideal signal timing

Total jitter (TJ) is the sum of the deterministic and random jitter, such that TJ = DJ + RJ.

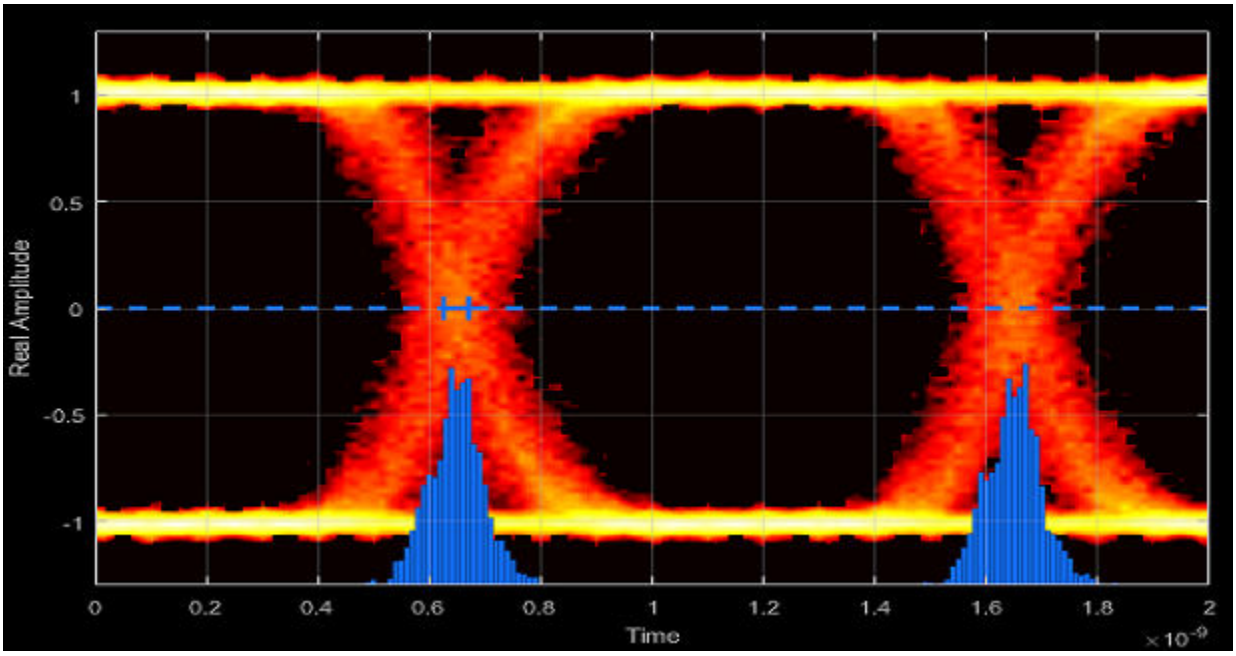


The total jitter PDF is the convolution of the DJ PDF and the RJ PDF.



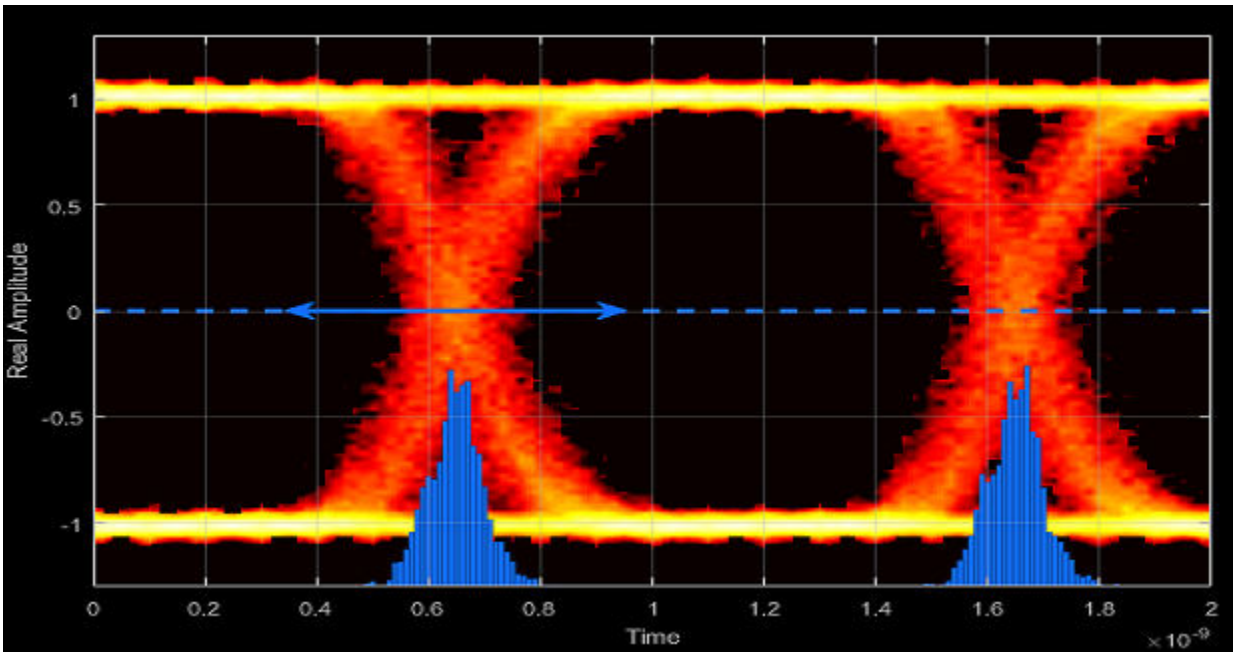
RMS Jitter - Standard deviation of jitter

RMS jitter is the standard deviation of the jitter calculated in the horizontal (jitter) histogram at the decision boundary.



Peak-to-Peak Jitter - Distance between extreme data points of histogram

Peak-to-peak jitter is the maximum horizontal distance between the left and right nonzero values in the horizontal histogram of each crossing time.



Version History

Introduced in R2016b

`comm.EyeDiagram` has been removed
Errors starting in R2022a

comm.EyeDiagram has been removed. To display the eye diagram of a signal, use the `eyediagram` function instead.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Supports MEX code generation by treating the calls to the object as extrinsic. Does not support code generation for standalone applications.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

horizontalBathtub

Package: comm

(Removed) Horizontal bathtub curve

Syntax

```
s = horizontalBathtub(ed)
```

Description

`s = horizontalBathtub(ed)` returns a structure containing information of horizontalBathtub curve for the System object.

Note This method is available when both of these conditions apply:

- `EnableMeasurements` is `true`
- `ShowBathtub` is `'Horizontal'` or `'Both'`

Examples

Horizontal and Vertical Bathtub Curve Methods

Display the eye diagram for a waveform having dual-dirac and random jitter. Generate and plot the horizontal and vertical bathtub curves.

Specify the sample rate, the samples per symbol, and the number of traces parameters.

```
fs = 1000;
sps = 200;
numTraces = 1000;
```

Create an eye diagram object.

```
ed = comm.EyeDiagram('SampleRate',fs,'SamplesPerSymbol',sps, ...
    'SampleOffset',sps/2,'DisplayMode','2D color histogram', ...
    'ColorScale','Logarithmic','EnableMeasurements',true, ...
    'ShowBathtub','Both','YLimits',[-1.2 1.2]);
```

Generate a waveform having dual-dirac and random jitter. Specify 3 ms rise and fall times.

```
src = commsrc.pattern('SamplesPerSymbol',sps, ...
    'RiseTime',3e-3,'FallTime', 3e-3);
src.Jitter = commsrc.combinedjitter('RandomJitter','on', ...
    'DiracJitter','on','DiracDelta',[-5e-04 5e-04],'RandomStd',2e-4);
```

Generate two symbols for each trace.

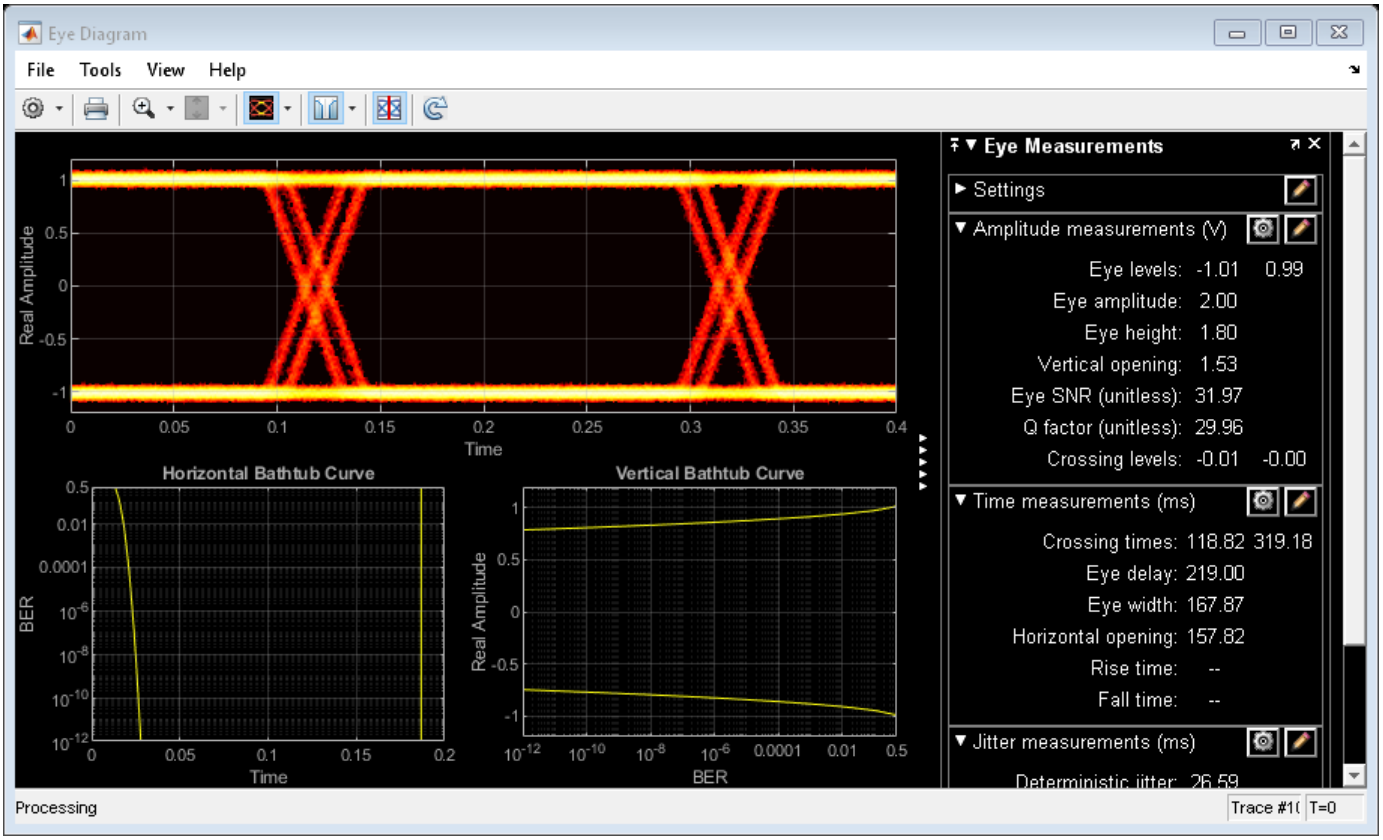
```
x = src.generate(numTraces*2);
```

Pass the signal through an AWGN channel with a fixed seed for repeatable results.

```
randStream = RandStream('mt19937ar','Seed',5489);
y = awgn(x,30,'measured',randStream);
```

Display the eye diagram.

```
ed(y)
```



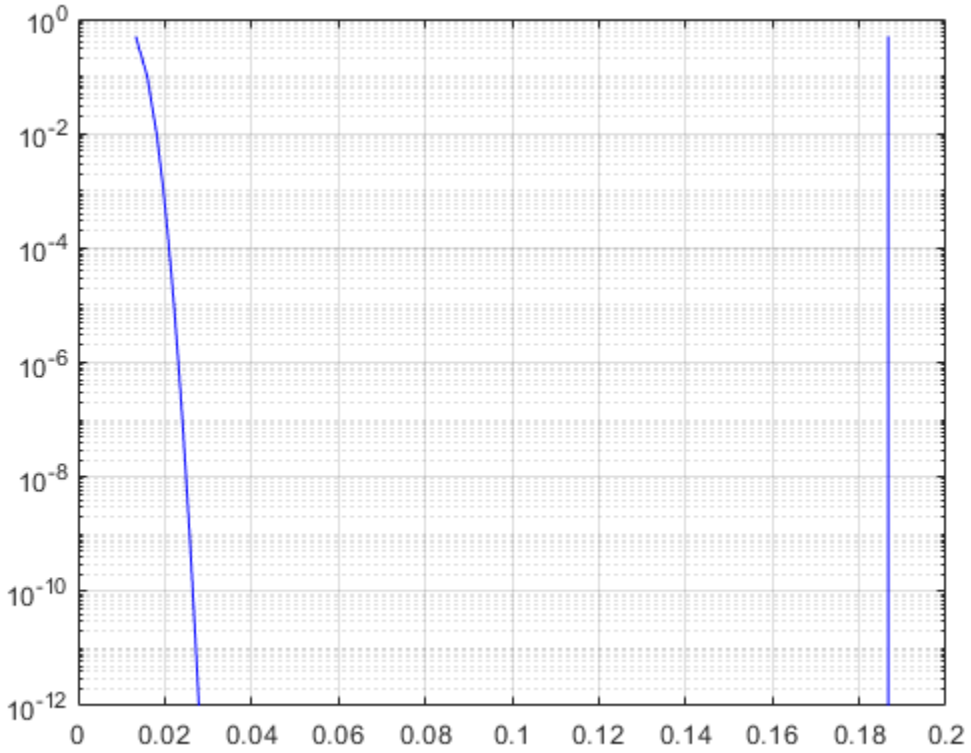
Generate the horizontal bathtub data for the eye diagram. Plot the curve.

```
hb = horizontalBathtub(ed)
semilogy([hb.LeftThreshold],[hb.BER],'b', ...
    [hb.RightThreshold],[hb.BER],'b')
grid
```

```
hb =

  1x13 struct array with fields:

    BER
    LeftThreshold
    RightThreshold
```



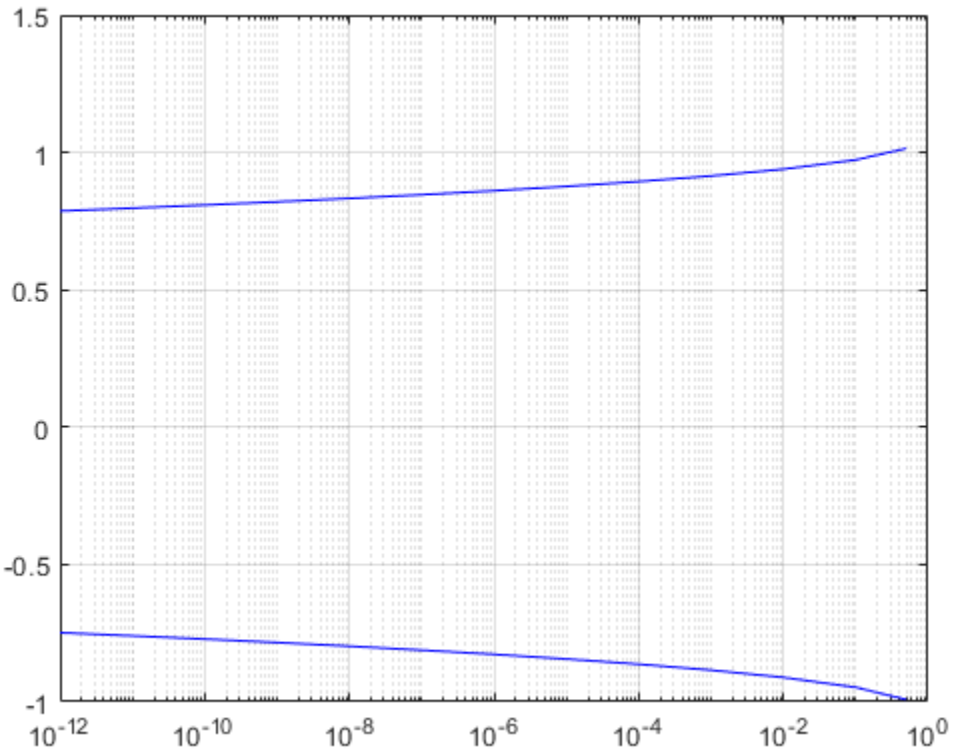
Generate the vertical bathtub data for the eye diagram. Plot the curve.

```
vb = verticalBathtub(ed)
semilogx([vb.BER],[vb.LowerThreshold],'b', ...
    [vb.BER],[vb.UpperThreshold],'b')
grid
```

```
vb =

  1x13 struct array with fields:

    BER
    UpperThreshold
    LowerThreshold
```



Input Arguments

ed — Eye Diagram System object

System object

Eye Diagram System object, where you get the bathtub curve information from.

Output Arguments

s — Structure containing information

struct

Structure containing information about the horizontal bathtub curve.

BER — Bit error rate values

scalar

Bit error rate values, mapped on the Y-axis of the horizontalBathtub plot against the corresponding `LeftThreshold` and `RightThreshold` values on the x-axis, specified as a scalar.

Data Types: `double`

`LeftThreshold` — Left threshold values

scalar

Left threshold values, mapped on the x-axis in the plot against corresponding BER values on the x-axis.

Data Types: `double`

`RightThreshold` — Right threshold values
scalar

Right threshold values, mapped on the x-axis in the plot against corresponding BER values on the x-axis.

Data Types: `double`

Version History

jitterHistogram

Package: comm

(Remove) Jitter histogram

Syntax

```
jh = jitterHistogram(ed)
```

Description

`jh = jitterHistogram(ed)` returns the bin counts for decision boundary crossings set in eye diagram System object.

Note This method is available when `EnableMeasurements` is `true`.

Examples

Jitter and Noise Histogram Methods

Display the eye diagram for a waveform having dual-dirac and random jitter. Plot the jitter and noise histograms.

Specify the sample rate, the samples per symbol, and the number of traces parameters.

```
fs = 1000;
sps = 200;
numTraces = 1000;
```

Create an eye diagram object.

```
ed = comm.EyeDiagram('SampleRate',fs,'SamplesPerSymbol',sps, ...
    'SampleOffset',sps/2, ...
    'DisplayMode','2D color histogram','ColorScale','Logarithmic', ...
    'EnableMeasurements',true,'YLimits',[-1.2 1.2]);
```

Generate a waveform having dual-dirac and random jitter. Specify 3 ms rise and fall times.

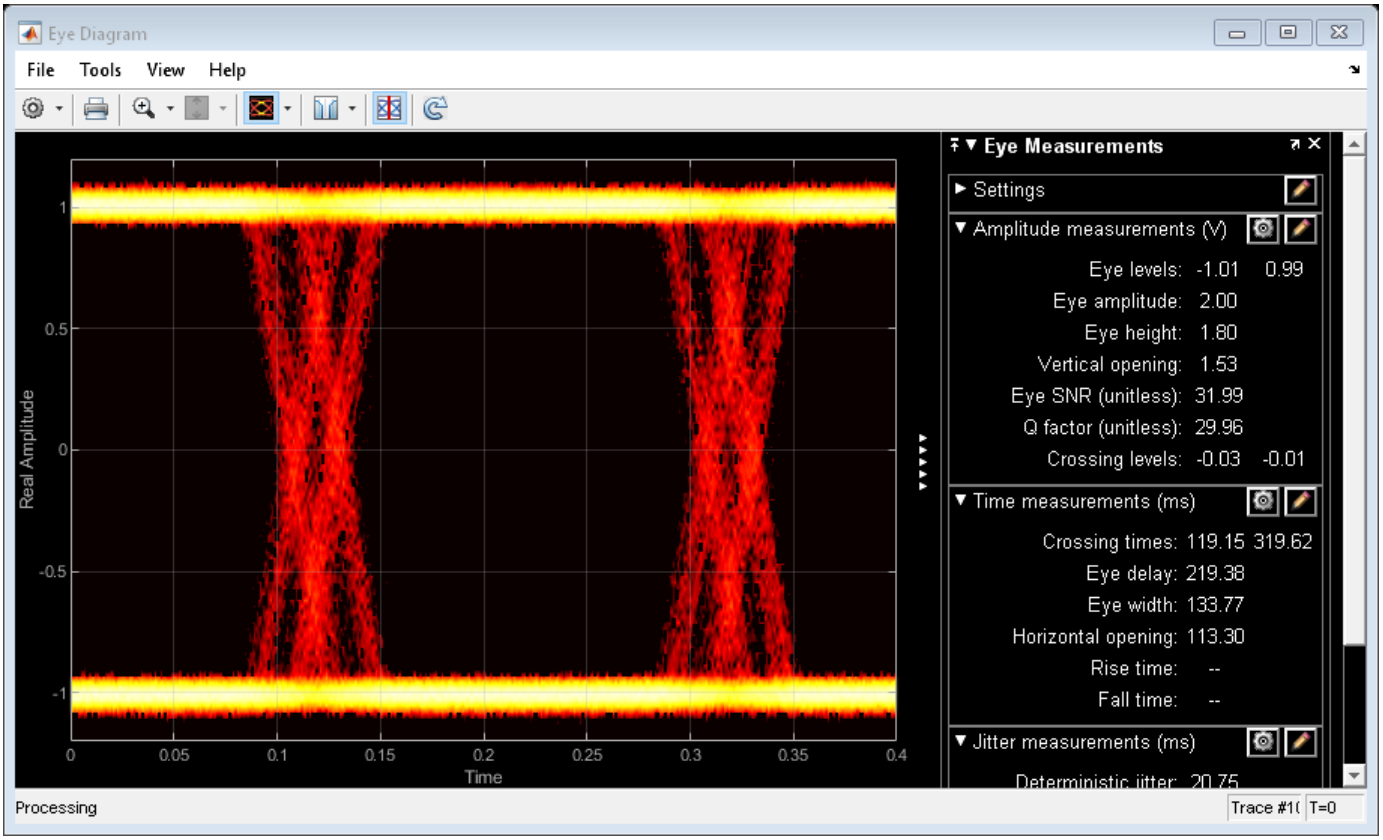
```
src = commsrc.pattern('SamplesPerSymbol',sps, ...
    'RiseTime',3e-3,'FallTime', 3e-3);
src.Jitter = commsrc.combinedjitter('RandomJitter','on', ...
    'DiracJitter','on','DiracDelta',[-10e-04 10e-04],'RandomStd',5e-4);
```

Generate two symbols for each trace.

```
x = src.generate(numTraces*2);
```

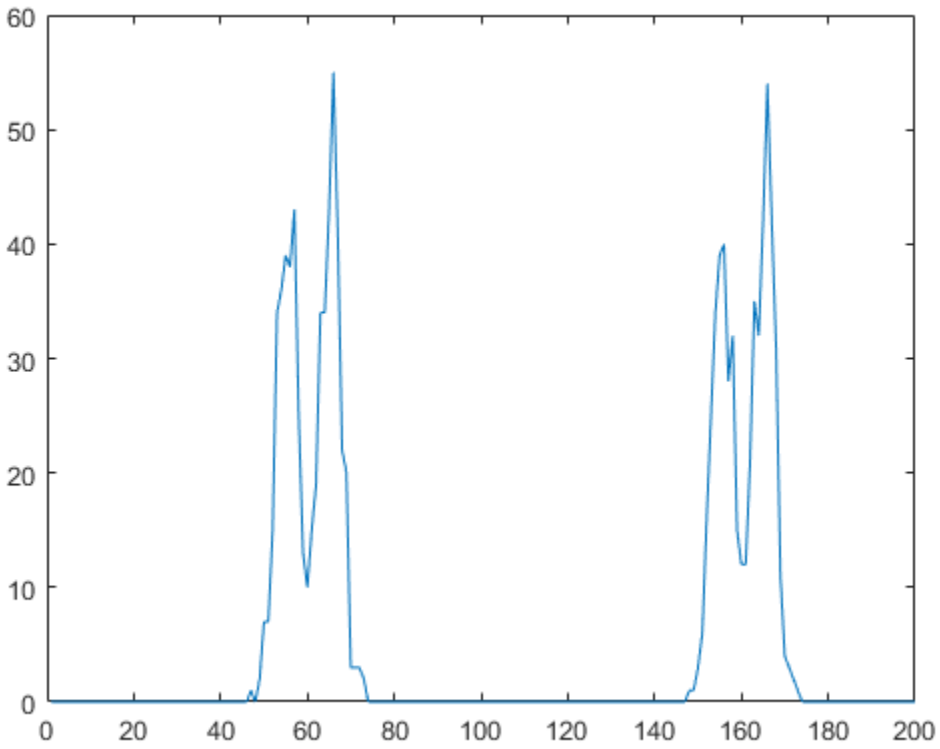
Pass the signal through an AWGN channel with a fixed seed for repeatable results.

```
randStream = RandStream('mt19937ar','Seed',5489);
y = awgn(x,30,'measured',randStream);
ed(y)
```



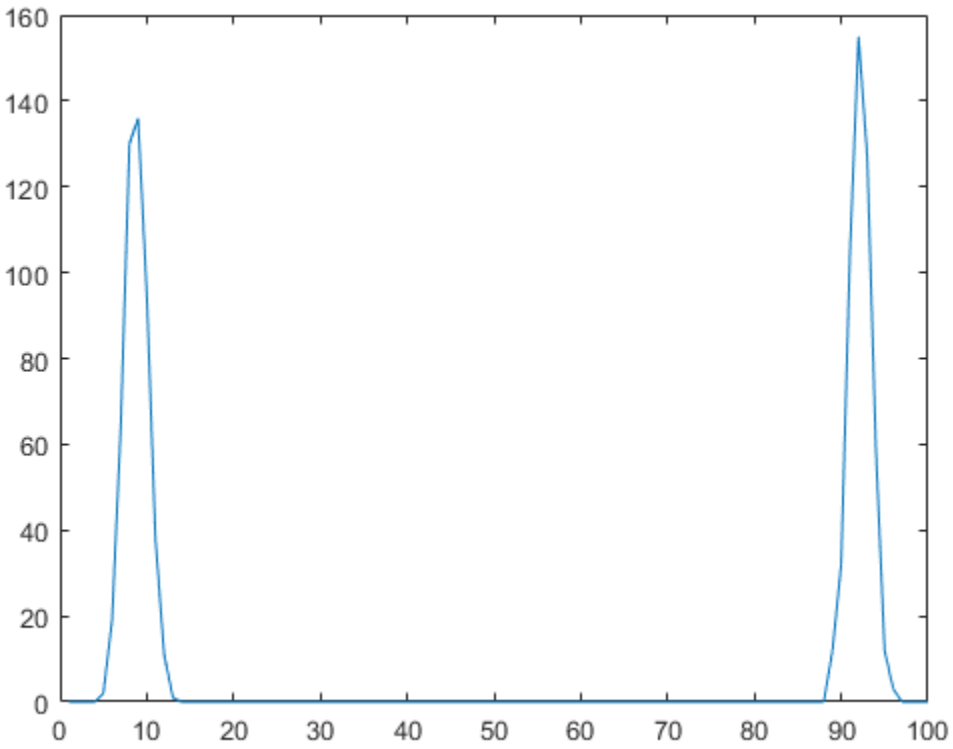
Calculate the jitter histogram count for each bin by using the `jitterHistogram` method. Plot the histogram.

```
jbins = jitterHistogram(ed);
plot(jbins)
```



Calculate the noise histogram count for each bin by using the `noiseHistogram` method. Plot the histogram.

```
nbins = noiseHistogram(ed);
plot(nbins)
```



Input Arguments

`ed` — Eye Diagram System object

System object

Eye Diagram System object, where the count for decision boundary crossings is set.

Output Arguments

`jh` — Jitter histogram

nonnegative integer

Jitter histogram, which represent the counts for decision boundary crossings, specified as a nonnegative integer.

Data Types: `double`

Version History

Introduced in R2016b

`comm.EyeDiagram` has been removed

Errors starting in R2022a

jitterHistogram has been removed. To display the eye diagram of a signal, use the `eyediagram` function instead.

`noiseHistogram`

measurements

Package: comm

(Removed) Measure eye diagram parameters

Syntax

```
m = measurements(ed)
```

Description

`m = measurements(ed)` returns the parameter measurements calculated by eye diagram System object.

Note This method is available when `EnableMeasurements` is `true`.

Examples

Rise and Fall Time of NRZ Signal

Create a combined jitter object having random jitter with a 2e-4 standard deviation.

```
jtr = commsrc.combinedjitter('RandomJitter','on','RandomStd',2e-4);
```

Generate an NRZ signal having random jitter and 3 ms rise and fall times.

```
genNRZ = commsrc.pattern('Jitter',jtr,'RiseTime',3e-3,'FallTime',3e-3);
x = generate(genNRZ,2000);
```

Pass the signal through an AWGN channel with fixed seed for repeatable results.

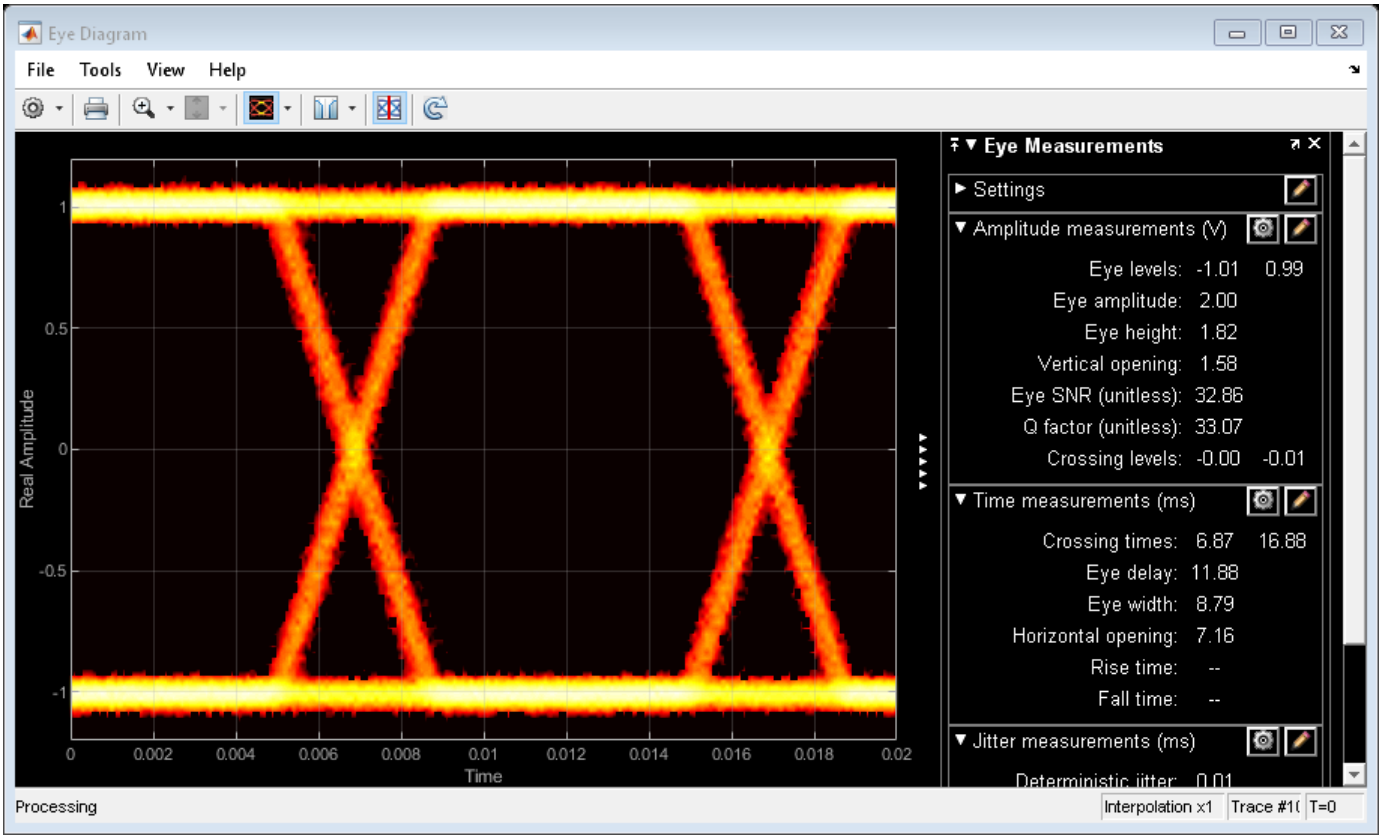
```
randStream = RandStream('mt19937ar','Seed',5489);
y = awgn(x,30,'measured',randStream);
```

Create an eye diagram object. Enable the measurements.

```
ed = comm.EyeDiagram('SamplesPerSymbol',genNRZ.SamplesPerSymbol, ...
    'SampleRate',genNRZ.SamplingFrequency, ...
    'SampleOffset',genNRZ.SamplesPerSymbol/2, ...
    'EnableMeasurements',true,'DisplayMode','2D color histogram', ...
    'OversamplingMethod','Input interpolation', ...
    'ColorScale','Logarithmic','YLimits',[-1.2 1.2]);
```

To compute the rise and fall times, determine the rise and fall thresholds from the eye level and eye amplitude measurements. Plot the eye diagram to calculate these parameters.

```
ed(y)
```



Pass the signal through the eye diagram object again to measure the rise and fall times.

```
ed(y)
hide(ed)
```

Display the data by using the measurements method.

```
eyestats = measurements(ed);
riseTime = eyestats.RiseTime
fallTime = eyestats.FallTime
```

```
riseTime =

    0.0030

fallTime =

    0.0030
```

The measured values match the 3 ms specification.

Input Arguments

ed — Eye Diagram System object

System object

Eye Diagram System object, where the parameter measurements are calculated.

Output Arguments

`m` — Eye Diagram parameters measurement

struct

Eye Diagram parameters measurement, returned as a structure containing all 18 parameters mentioned in “Measurements” on page 3-475, along with their values.

Data Types: `double`

Version History

Introduced in R2016b

`comm.EyeDiagram` has been removed

Errors starting in R2022a

noiseHistogram

Package: comm

(Removed) Noise histogram

Syntax

```
nh = noiseHistogram(ed)
```

Description

`nh = noiseHistogram(ed)` returns the bin counts for the signal values at the vertical opening (eye delay) as set in eye diagram System object.

Note This method is available when both of these conditions apply:

- `EnableMeasurements` is `true`
- `DisplayMode` is `'2D color histogram'`

Examples

Jitter and Noise Histogram Methods

Display the eye diagram for a waveform having dual-dirac and random jitter. Plot the jitter and noise histograms.

Specify the sample rate, the samples per symbol, and the number of traces parameters.

```
fs = 1000;
sps = 200;
numTraces = 1000;
```

Create an eye diagram object.

```
ed = comm.EyeDiagram('SampleRate',fs,'SamplesPerSymbol',sps, ...
    'SampleOffset',sps/2, ...
    'DisplayMode','2D color histogram','ColorScale','Logarithmic', ...
    'EnableMeasurements',true,'YLimits',[-1.2 1.2]);
```

Generate a waveform having dual-dirac and random jitter. Specify 3 ms rise and fall times.

```
src = commsrc.pattern('SamplesPerSymbol',sps, ...
    'RiseTime',3e-3,'FallTime', 3e-3);
src.Jitter = commsrc.combinedjitter('RandomJitter','on', ...
    'DiracJitter','on','DiracDelta',[-10e-04 10e-04],'RandomStd',5e-4);
```

Generate two symbols for each trace.

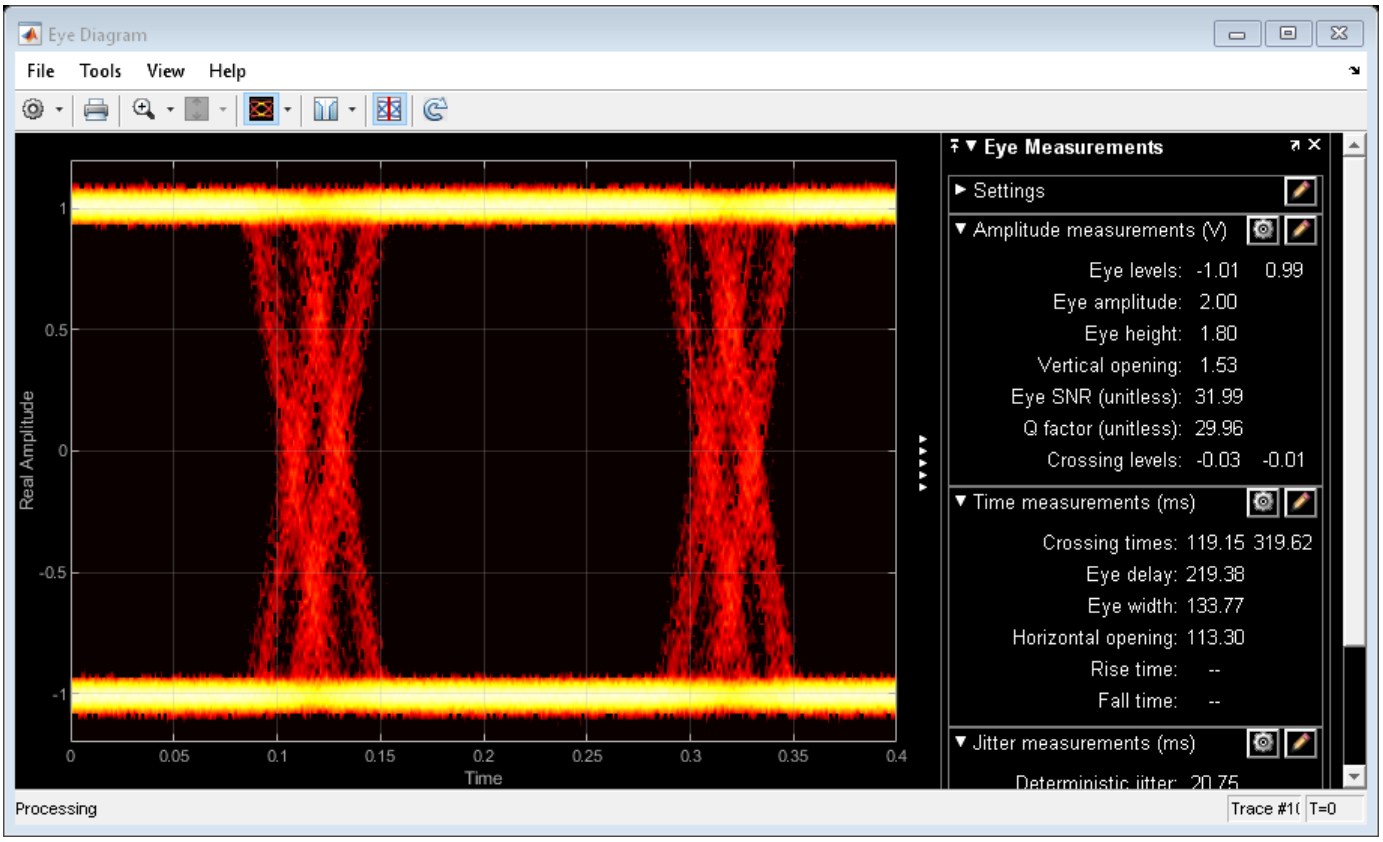
x = src.generate(numTraces*2);
```

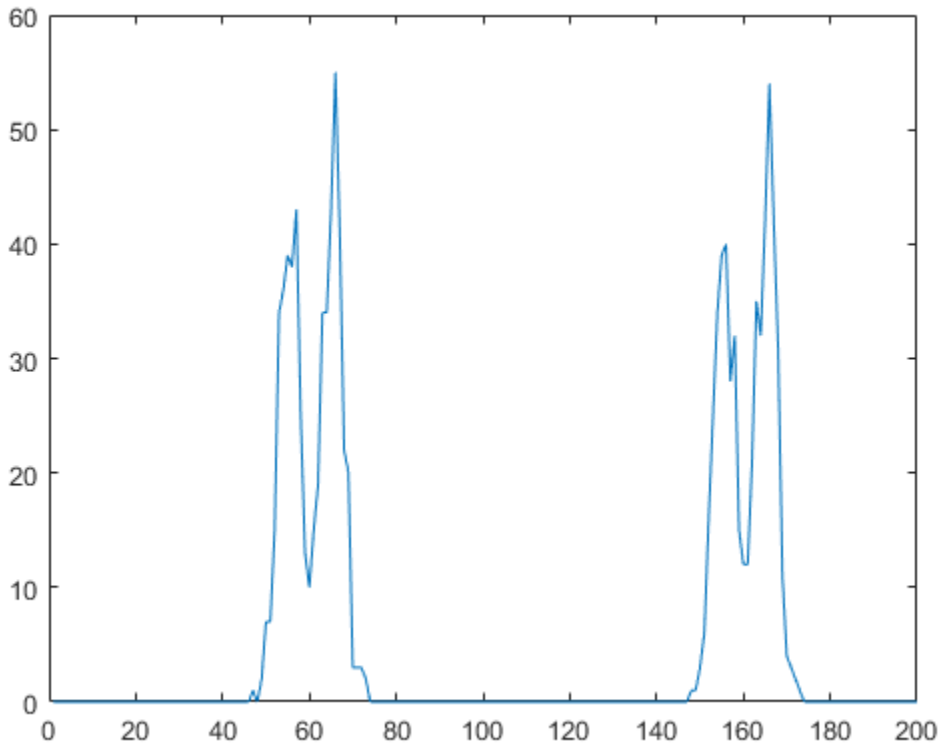
Pass the signal through an AWGN channel with a fixed seed for repeatable results.

```
randStream = RandStream('mt19937ar','Seed',5489);
y = awgn(x,30,'measured',randStream);
ed(y)
```



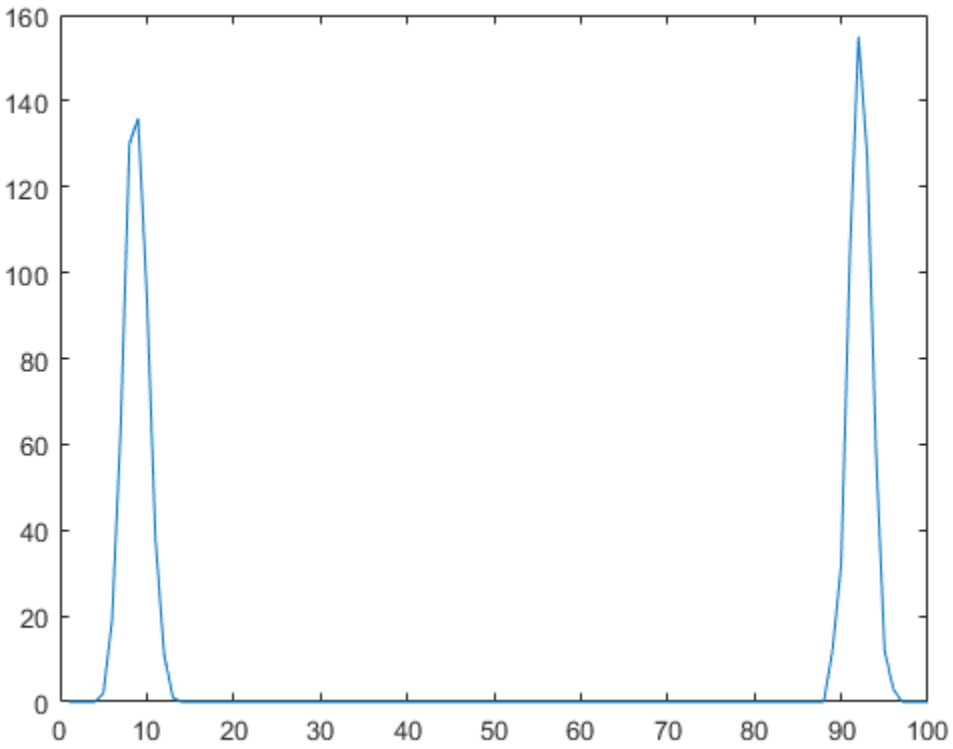
Calculate the jitter histogram count for each bin by using the `jitterHistogram` method. Plot the histogram.

```
jbins = jitterHistogram(ed);
plot(jbins)
```



Calculate the noise histogram count for each bin by using the `noiseHistogram` method. Plot the histogram.

```
nbins = noiseHistogram(ed);
plot(nbins)
```



Input Arguments

ed — Eye Diagram System object

System object

Eye Diagram System object, where the counts for signal values at the eye delay is set.

Output Arguments

nh — Noise histogram

nonnegative integer

Noise histogram, which represent the counts for the signal values at the vertical opening (eye delay), specified as a nonnegative integer.

Data Types: `double`

Version History

Introduced in R2016b

`comm.EyeDiagram` has been removed

Errors starting in R2022a

verticalBathtub

Package: comm

(Removed) Vertical bathtub curve

Syntax

```
s = verticalBathtub(ed)
```

Description

`s = verticalBathtub(ed)` returns a structure containing information of verticalBathtub curve for the System object.

Note This method is available when both of these conditions apply:

- `EnableMeasurements` is `true`
- `ShowBathtub` is `'Vertical'` or `'Both'`

Examples

Horizontal and Vertical Bathtub Curve Methods

Display the eye diagram for a waveform having dual-dirac and random jitter. Generate and plot the horizontal and vertical bathtub curves.

Specify the sample rate, the samples per symbol, and the number of traces parameters.

```
fs = 1000;
sps = 200;
numTraces = 1000;
```

Create an eye diagram object.

```
ed = comm.EyeDiagram('SampleRate',fs,'SamplesPerSymbol',sps, ...
    'SampleOffset',sps/2,'DisplayMode','2D color histogram', ...
    'ColorScale','Logarithmic','EnableMeasurements',true, ...
    'ShowBathtub','Both','YLimits',[-1.2 1.2]);
```

Generate a waveform having dual-dirac and random jitter. Specify 3 ms rise and fall times.

```
src = commsrc.pattern('SamplesPerSymbol',sps, ...
    'RiseTime',3e-3,'FallTime', 3e-3);
src.Jitter = commsrc.combinedjitter('RandomJitter','on', ...
    'DiracJitter','on','DiracDelta',[-5e-04 5e-04],'RandomStd',2e-4);
```

Generate two symbols for each trace.

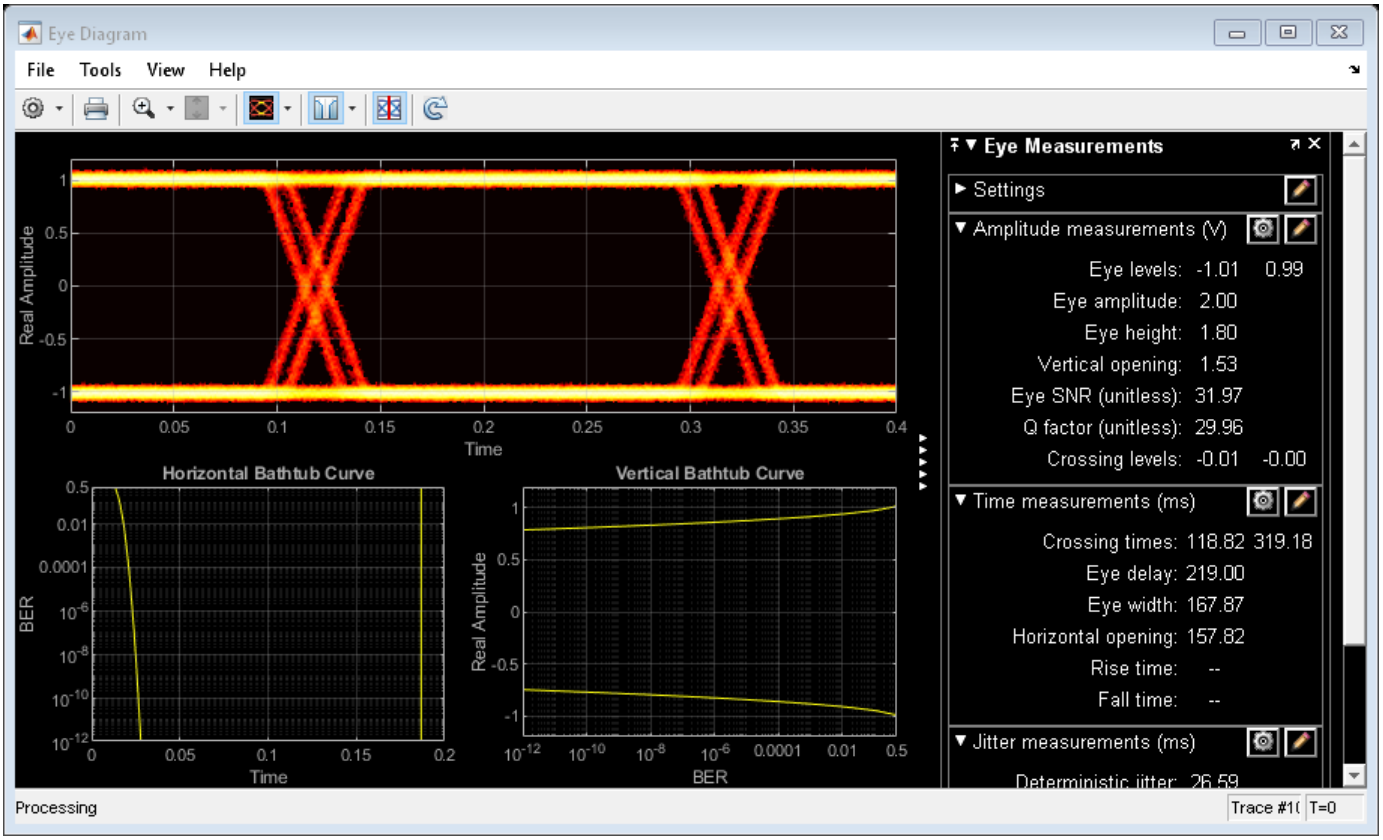
```
x = src.generate(numTraces*2);
```

Pass the signal through an AWGN channel with a fixed seed for repeatable results.

```
randStream = RandStream('mt19937ar','Seed',5489);
y = awgn(x,30,'measured',randStream);
```

Display the eye diagram.

```
ed(y)
```



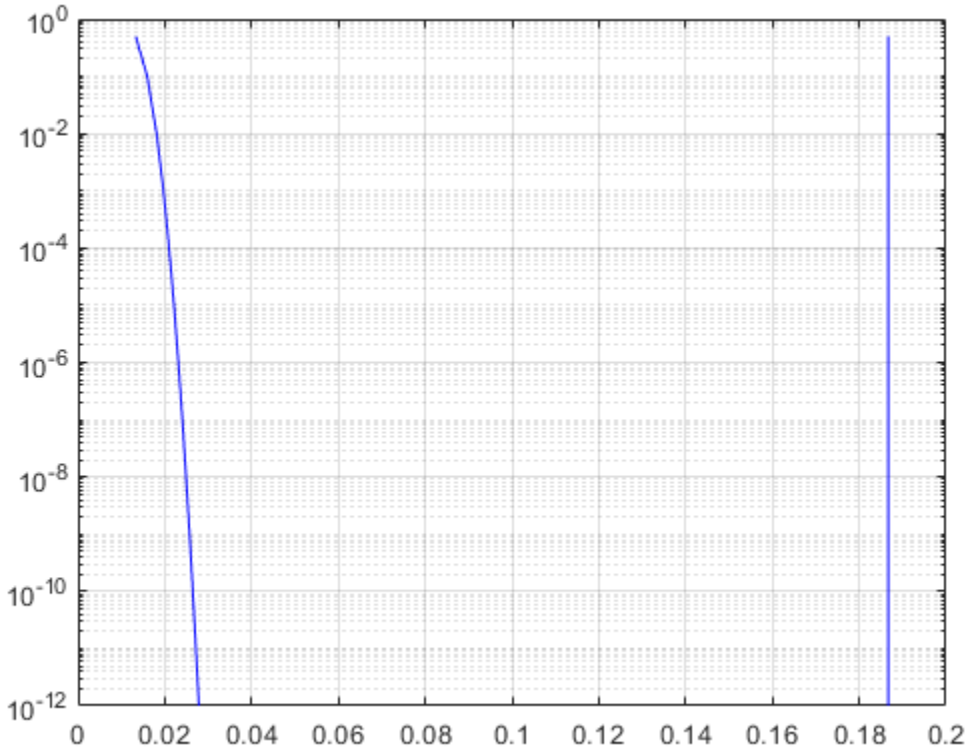
Generate the horizontal bathtub data for the eye diagram. Plot the curve.

```
hb = horizontalBathtub(ed)
semilogy([hb.LeftThreshold],[hb.BER],'b', ...
    [hb.RightThreshold],[hb.BER],'b')
grid
```

```
hb =

  1x13 struct array with fields:

    BER
    LeftThreshold
    RightThreshold
```



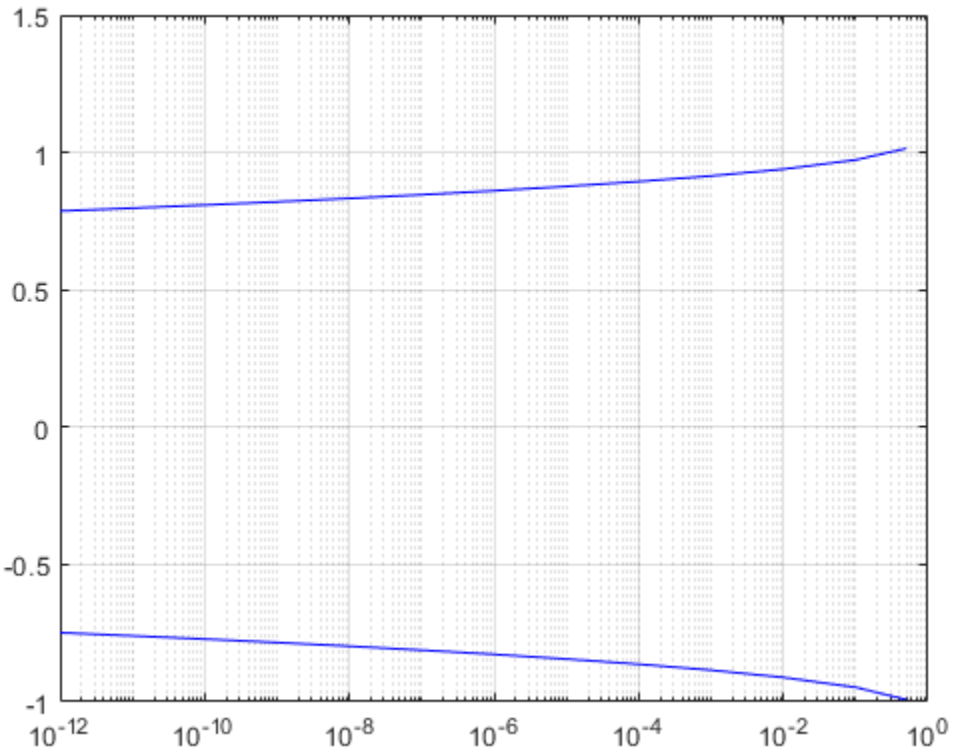
Generate the vertical bathtub data for the eye diagram. Plot the curve.

```
vb = verticalBathtub(ed)
semilogx([vb.BER],[vb.LowerThreshold],'b', ...
    [vb.BER],[vb.UpperThreshold],'b')
grid
```

```
vb =

  1x13 struct array with fields:

    BER
    UpperThreshold
    LowerThreshold
```



Input Arguments

ed — Eye Diagram System object

System object

Eye Diagram System object, where you get the bathtub curve information from.

Output Arguments

s — Structure containing information

struct

Structure containing information about the vertical bathtub curve.

BER — Bit error rate values

scalar

Bit error rate values, mapped on the Y-axis of the verticalBathtub plot against the corresponding `UpperThreshold` and `LowerThreshold` values on the x-axis, specified as a scalar.

Data Types: `double`

UpperThreshold — Upper threshold value

scalar

Upper threshold value, mapped on the x-axis in the plot against its corresponding BER value on the x-axis.

Data Types: `double`

`LowerThreshold` — Lower threshold value
scalar

Lower threshold value, mapped on the x-axis in the plot against its corresponding BER value on the x-axis.

Data Types: `double`

Version History

Introduced in R2016b

`comm.EyeDiagram` has been removed
Errors starting in R2022a

comm.FMBroadcastDemodulator

Package: comm

Demodulate broadcast FM audio signal

Description

The comm.FMBroadcastDemodulator System object demodulates a complex broadcast FM-modulated signal and filters the signal with a de-emphasis filter to produce an audio signal. For more details, see “Algorithms” on page 3-518.

To demodulate a broadcast FM audio signal:

1. Create the comm.FMBroadcastDemodulator object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
fmbdemodulator = comm.FMBroadcastDemodulator
fmbdemodulator = comm.FMBroadcastDemodulator(Name,Value)
fmbdemodulator = comm.FMBroadcastDemodulator(fmbmodulator)
```

Description

`fmbdemodulator = comm.FMBroadcastDemodulator` creates an FM broadcast demodulator System object.

`fmbdemodulator = comm.FMBroadcastDemodulator(Name,Value)` sets properties using one or more name-value arguments. For example, `fmbdemodulator = comm.FMBroadcastDemodulator('SampleRate',400e3)` specifies a sample rate of 400 kHz.

`fmbdemodulator = comm.FMBroadcastDemodulator(fmbmodulator)` sets properties based on the configuration of the input comm.FMBroadcastModulator System object, `fmbmodulator`.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`SampleRate` — Sample rate
`240e3` (default) | positive scalar

Sample rate of the input of the demodulator in Hz, specified as a positive scalar. The sample rate must be greater than twice the frequency deviation (that is, `SampleRate` > 2×`FrequencyDeviation`).

Data Types: `double`

`FrequencyDeviation` — Peak deviation of the input signal frequency
`75e3` (default) | positive scalar

Peak deviation of the input signal frequency in Hz, specified a positive scalar. The frequency deviation must be less than half the sample rate (that is, `FrequencyDeviation` < `SampleRate`/2).

The system bandwidth B_T = 2×(`FrequencyDeviation` + B_M), where B_M is the message bandwidth in Hz. For more information, see “Algorithms” on page 3-518.

FM broadcast standards specify a value of 75 kHz in the United States and 50 kHz in Europe.

Data Types: `double`

`FilterTimeConstant` — De-emphasis highpass filter time constant
`7.5e-05` (default) | positive scalar

De-emphasis highpass filter time constant in seconds, specified as a positive scalar. FM broadcast standards specify a value of 75 µs in the United States and 50 µs in Europe.

Data Types: `double`

`Stereo` — Option to enable stereo demodulation
`false` or `0` (default) | `true` or `1`

Option to enable stereo demodulation, specified as a logical `0` (`false`) or `1` (`true`).

- `false` — The output is mono audio.
- `true` — The object performs stereo decoding and outputs stereo audio.

For more information, see “Multiplexed Stereo and RDS (or RBDS) FM Signal” on page 3-519.

Data Types: `logical`

`PlaySound` — Option to enable audio playback
`false` or `0` (default) | `true` or `1`

Option to enable audio playback, specified as a logical `0` (`false`) or `1` (`true`). To playback the output signal on the default audio device connected to the computer, set this property to `true`.

Data Types: `logical`

`AudioSampleRate` — Sample rate of output audio signal
`48000` (default) | positive scalar

Sample rate of the output audio signal in Hz, specified as a positive scalar.

Data Types: `double`

`BufferSize` — Size of buffer

`4096` (default) | positive integer

Size of the buffer in samples, specified as a positive integer. This property specifies the size of the buffer used by the System object for communication with the audio device.

Dependencies

To enable this property, set the `PlaySound` property to `true`.

Data Types: `double`

`RBDS` — Option to enable RDS (or RBDS) waveform demodulation

`false` or `0` (default) | `true` or `1`

Option to enable RDS (or RBDS) waveform demodulation, specified as a logical `0` (`false`) or `1` (`true`). If you set this property set to `true`, the object demodulates the RDS (or RBDS) waveform. For more information, see “Multiplexed Stereo and RDS (or RBDS) FM Signal” on page 3-519.

Data Types: `logical`

`RBDSSamplesPerSymbol` — Oversampling factor of RDS (or RBDS) output signal

`10` (default) | positive integer

Oversampling factor of the RDS (or RBDS) output signal, specified as a positive integer. The sample rate of RDS (or RBDS) broadcast data is 1187.5 Hz. The RDS (or RBDS) signal sample rate is `RBDSSamplesPerSymbol` × `1187.5` Hz.

Dependencies

To enable this property, set the `RBDS` property to `true`.

Data Types: `double`

`RBDSCostasLoop` — Option to recover phase of RDS (or RBDS) signal

`false` or `0` (default) | `true` or `1`

Option to recover phase of the RDS (or RBDS) signal, specified as a logical `0` (`false`) or `1` (`true`).

To recover the phase of the RDS (or RBDS) signal by using a Costas loop, set this property to `true`. For radio stations that do not lock the 57 kHz RDS (or RBDS) signal in phase with the third harmonic of the 19 kHz pilot tone, a Costas loop helps recover the phase of the RDS (or RBDS) signal.

Dependencies

To enable this property, set the `RBDS` property to `true`.

Data Types: `logical`

Usage

Syntax

```
audiosig = fmbdemodulator(insig)
[audiosig,rbdssig] = fmbdemodulator(insig)
```

Description

`audiosig = fmbdemodulator(insig)` demodulates an FM-modulated baseband audio signal and filters this signal with a de-emphasis filter to produce an audio signal.

`[audiosig,rbdssig] = fmbdemodulator(insig)` also demodulates a baseband RBDS signal at 57 kHz. To enable this syntax, set the `RBDS` property to `true`.

Input Arguments

`insig` — FM-modulated baseband audio signal

column vector

FM-modulated baseband audio signal, specified as a column vector. For information about signal length restrictions, see “Limitations” on page 3-518.

Data Types: `double` | `single`
Complex Number Support: Yes

Output Arguments

`audiosig` — Audio signal

N-element column vector | *M*-by-*N* matrix

Audio signal, returned as a column vector or an *M*-by-*N* matrix. *M* is the number of stereo channels. *N* is the number of samples in the audio signal per channel. The output has the same data type as the input signal, `insig`.

If you set the `Stereo` property to `true`, the audio signal must have at least two channels and the System object performs stereo encoding before de-emphasis filtering. The length of the output is $N \times$ `(AudioSampleRate/SampleRate)`.

`rbdssig` — RBDS signal

column vector

RBDS signal, returned as a column vector with the same data type as the input signal.

Data Types: `double` | `single`
Complex Number Support: Yes

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to comm.FMBroadcastDemodulator

info Information about FM broadcast modulator or demodulator

Common to All System Objects

step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

Examples

FM Broadcast Streaming Audio Signal

Play back an audio file after applying FM broadcast modulation and demodulation using System objects to process the data in streaming mode.

Load the audio file `guitartune.wav` by using an audio file reader System object™ with the samples per frame set to 4410.

```
audiofilereader = dsp.AudioFileReader('guitartune.wav', ...
    'SamplesPerFrame',4410);
```

Create FM broadcast modulator and demodulator objects. Set the sample rate of the output audio signal to match the sample rate of the input audio signal. Set the sample rate of the demodulator to match the specified sample rate of the modulator. Enable audio playback for the broadcast demodulator.

```
fmbMod = comm.FMBroadcastModulator( ...
    'AudioSampleRate',audiofilereader.SampleRate, ...
    'SampleRate',240e3);
fmbDemod = comm.FMBroadcastDemodulator( ...
    'AudioSampleRate',audiofilereader.SampleRate, ...
    'SampleRate',240e3,'PlaySound',true);
```

Read the audio data in frames of length 4410, apply FM broadcast modulation, demodulate the FM signal, and play back the demodulated signal (`demodData`).

```
while ~isDone(audiofilereader)
    audioData = audiofilereader();
    modData = fmbMod(audioData);
    demodData = fmbDemod(modData); % Demodulate and play signal
end
```

FM Broadcast Modulate and Demodulate an RBDS Waveform

Generate an RBDS waveform, FM broadcast modulate the RBDS waveform with an audio signal, and FM broadcast demodulate the FM signal.

Specify parameters for an RBDS waveform with 19 groups per frame and 10 samples per symbol. The sample rate of the RBDS waveform is given by 1187.5 x 10. Set the audio sample rate to 1187.5 x 40.

```
groupLen = 104;
sps = 10;
groupsPerFrame = 19;
rbdsFrameLen = groupLen*sps*groupsPerFrame;
afrRate = 40*1187.5;
rbdsRate = 1187.5*sps;
outRate = 4*57000;
```

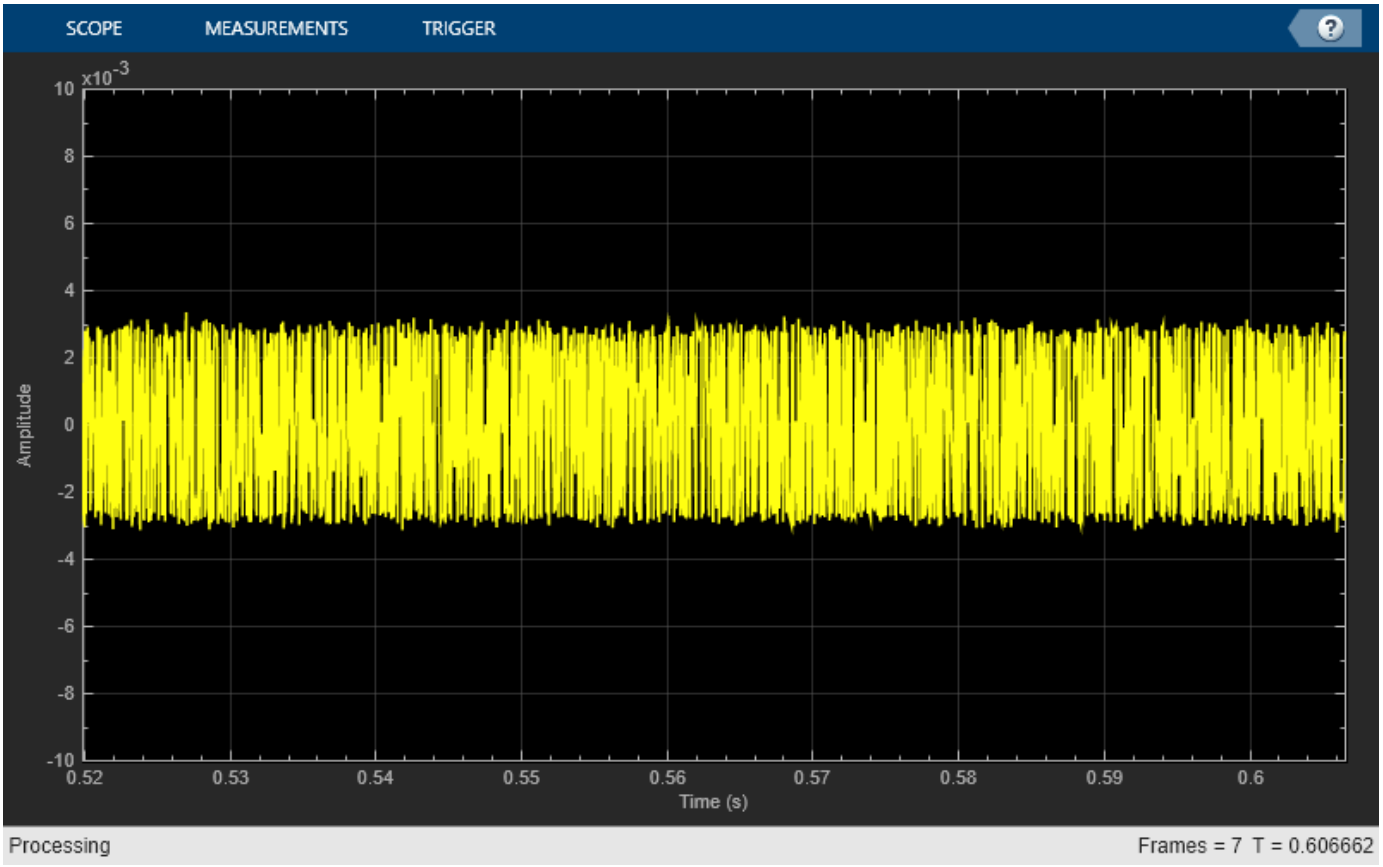
Load the audio file `guitartune.wav` by using an audio file reader System object™ while setting the samples per frame. Create RBDS waveform generator, FM broadcast modulator, FM broadcast demodulator, and time scope System objects. Configure the modulator and demodulator objects to process a stereo audio file and an RBDS waveform.

```
afr = dsp.AudioFileReader( ...
    'rbds_capture_47500.wav', ...
    'SamplesPerFrame',rbdsFrameLen*afrRate/rbdsRate);
rbds = comm.RBDSWaveformGenerator( ...
    'GroupsPerFrame',groupsPerFrame, ...
    'SamplesPerSymbol',sps);

fmMod = comm.FMBroadcastModulator( ...
    'AudioSampleRate',afr.SampleRate, ...
    'SampleRate',outRate,...
    'Stereo',true, ...
    'RBDS',true, ...
    'RBDSSamplesPerSymbol',sps);
fmDemod = comm.FMBroadcastDemodulator( ...
    'SampleRate',outRate,...
    'Stereo',true, ...
    'RBDS',true, ...
    'PlaySound',true);
scope = timescope( ...
    'SampleRate',outRate, ...
    'YLimits',10^-2*[-1 1]);
```

Read the audio signal. Generate RBDS information at the same configured rate as audio. FM broadcast modulate the stereo audio signal with RBDS information. Add additive white Gaussian noise. FM-demodulate the audio signal and RBDS waveforms. View the waveforms in a time scope.

```
for idx = 1:7
    input = afr();
    rbdsWave = rbds();
    yFM = fmMod([input input],rbdsWave);
    rcv = awgn(yFM,40);
    [audioRcv, rbdsRcv] = fmDemod(rcv);
    scope(rbdsRcv);
end
```



Limitations

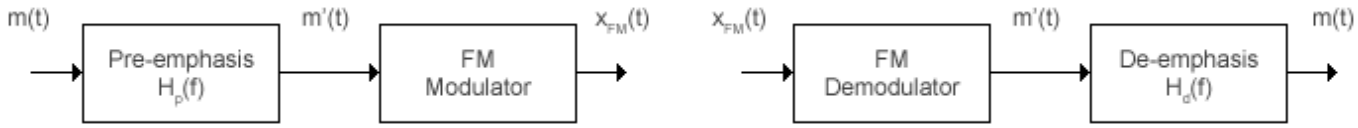
The length of the input signal, `insig`, must be an integer multiple of the `AudioDecimationFactor` property. If you set the `RBDS` property to `true`, the length of the input signal, `insig`, also must be an integer multiple of `RBDSDecimationFactor`. For more information on the `AudioDecimationFactor` and `RBDSDecimationFactor` properties, see the `info` object function.

Algorithms

The comm.FMBroadcastDemodulator System object includes the functionality of the `comm.FMDemodulator` System object, plus de-emphasis filtering and the ability to receive stereophonic signals.

Filtering

FM amplifies high-frequency noise and degrades the overall signal-to-noise ratio. To compensate, FM broadcasters insert a pre-emphasis filter before FM modulation to amplify the high-frequency content. The FM receiver has a reciprocal de-emphasis filter after the FM demodulator to attenuate high-frequency noise and restore a flat signal spectrum. This figure shows the order of processing operations.



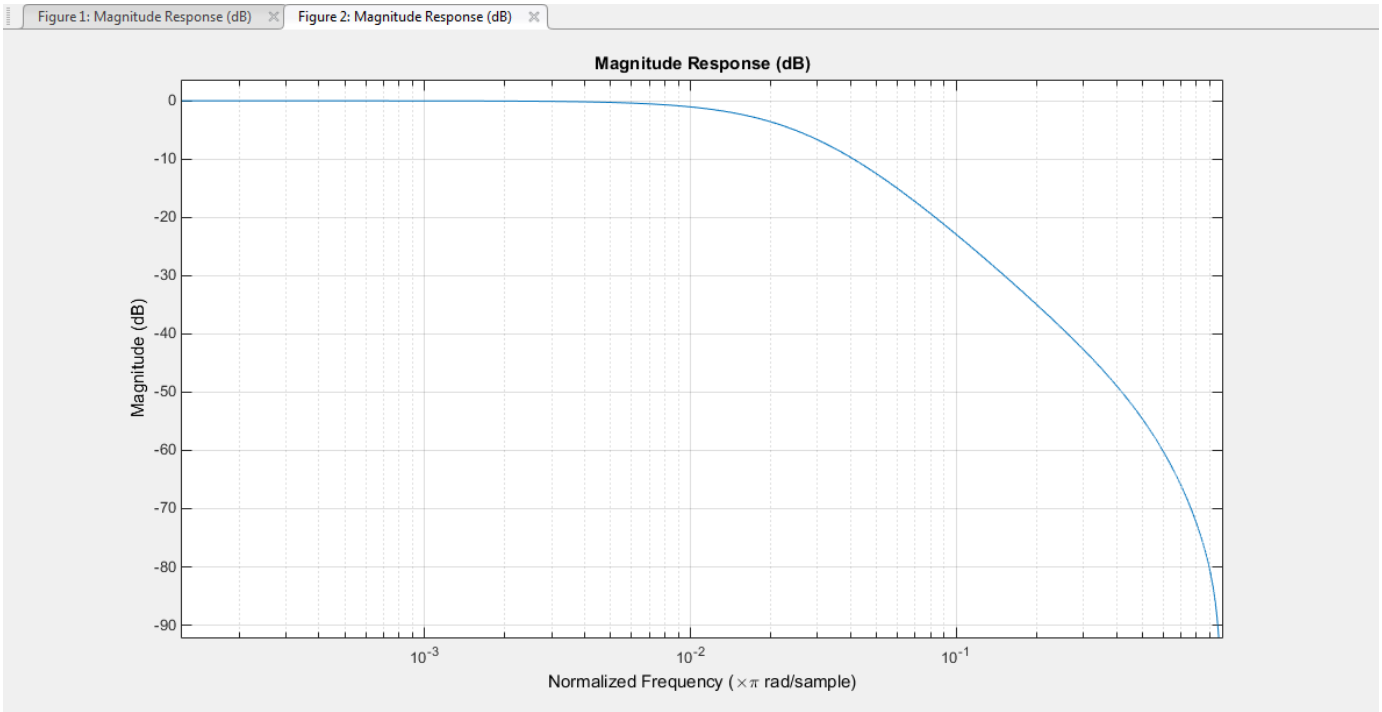
The pre-emphasis filter has a highpass characteristic transfer function given by

$$H_{\mathrm{p}}(f) = 1 + j2\pi f\tau_{\mathrm{s}}\,,$$

where τ_s is the filter time constant. The time constant is 75 µs in the United States and 50 µs in Europe. Similarly, the transfer function for the lowpass de-emphasis filter is given by

$$H_{\mathrm{d}}(f) = \frac{1}{1 + j2\pi f\tau_{\mathrm{s}}}\,.$$

For an audio sample rate of 44.1 kHz, the de-emphasis filter has the response shown in this figure.



Multiplexed Stereo and RDS (or RBDS) FM Signal

FM broadcast supports stereophonic and monophonic operations. To support stereo transmission:
