Tip This parameter is tunable (Simulink) when you set either:

- **Sample mode** to Continuous.
 - **Sample mode** to Discrete and **Computation method** to Trigonometric fcn.
-

Tunable: Yes

Sample mode — Continuous or discrete sampling mode

Discrete (default) | Continuous

Specify the sampling mode as Continuous or Discrete:

- Continuous

In continuous mode, the sinusoid in the i th channel, y_i , is computed as a continuous function,

$$y_i = A_i \sin(2\pi f_i t + \phi_i) \quad (\text{real})$$

or

$$y_i = A_i e^{j(2\pi f_i t + \phi_i)} \quad (\text{complex})$$

and the block's output is continuous. In this mode, the block operates the same as the Simulink Sine Wave block with **Sample time** set to 0. This mode offers high accuracy, but requires trigonometric function evaluations at each simulation step, which is computationally expensive. Also, because this method tracks absolute simulation time, a discontinuity will eventually occur when the time value reaches its maximum limit.

Note also that many DSP System Toolbox blocks do not accept continuous-time inputs.

- Discrete

In discrete mode, the block can generate discrete-time output by directly evaluating the trigonometric function, by table lookup, or by a differential method. For more information on these computation methods, see “Algorithms” on page 2-1177.

Output complexity — Real or complex waveform

Real (default) | Complex

The type of waveform to generate: Real specifies a real sine wave, Complex specifies a complex exponential.

Computation method — Method for computing discrete-time sinusoids

Trigonometric fcn (default) | Table lookup | Differential

The method by which discrete-time sinusoids are generated: `Trigonometric fcn`, `Table lookup`, or `Differential`. For more information on each of the available options, see “Algorithms” on page 2-1177.

Dependencies

This parameter is only visible when you set the **Sample mode** to `Discrete`.

Note To generate fixed-point sinusoids, you must set the **Computation method** to `Table lookup`.

Optimize table for — Optimize for speed or memory

Speed (default) | Memory

Optimizes the table of sine values for `Speed` or `Memory`. When optimized for speed, the table contains k elements, and when optimized for memory, the table contains $k/4$ elements, where k is the number of input samples in one full period of the sine wave.

Dependencies

This parameter is only visible when you set the **Computation method** parameter to `Table lookup`.

Sample time — Sample period

1/1000 (default) | scalar

The period with which the sine wave is sampled, T_s , as a finite scalar, greater than zero. The output frame period of the block is MT_s , where you specify M in the **Samples per frame** parameter.

Dependencies

To enable this parameter, set **Sample mode** to `Discrete`.

Samples per frame — Samples per frame

1 (default) | positive integer

The number of consecutive samples from each sinusoid to buffer into the output frame, M , specified as a positive scalar integer. This parameter is not tunable.

The block output is an M -by- N matrix with frame period MT_s , where you specify T_s in the **Sample time** parameter.

Dependencies

To enable this parameter, set **Sample mode** to `Discrete`.

Resetting states when re-enabled — State behavior inside enabled subsystems

Restart at time zero (default) | Catch up to simulation time

This parameter determines the behavior of the Sine Wave block when an enabled subsystem is reenabled. The block can either reset itself to its starting state (**Restart at time zero**), or resume generating the sinusoid based on the current simulation time (**Catch up to simulation time**).

Dependencies

This parameter only applies when the Sine Wave block is located inside an enabled subsystem and the **States when enabling** parameter of the Enable block is set to **reset**.

Data Types

Output data type — Output data type

`double (default) | single | fixdt(1,16) | fixdt(1,16,0) | <data type expression> | Inherit:Inherit via back propagation`

Select how you would like to specify the data type properties of the **Output data type**. You can choose:

- **Inherit** — Lets you specify a rule for inheriting a data type, for example, `Inherit: Inherit via back propagation`
- **Built in**— Lets you specify a built in data type, for example, `double`
- **Fixed point** — Lets you specify the fixed-point attributes of the data type.
- **Expression** — Lets you specify an expression that evaluates to a valid data type, for example, `fixdt(1,16)`

Block Characteristics

Data Types	<code>double fixed point integer single</code>
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Algorithms

When you select **Discrete** from the **Sample mode** parameter, the secondary **Computation method** parameter provides three options for generating the discrete sinusoid: **Trigonometric fcn**, **Table lookup**, and **Differential**.

Trigonometric Fcn

The trigonometric function method computes the sinusoid in the i th channel, y_i , by sampling the continuous function

$$y_i = A_i \sin(2\pi f_i t + \phi_i) \text{ (real)}$$

or

$$y_i = A_i e^{j(2\pi f_i t + \phi_i)} \text{ (complex)}$$

with a period of T_s , where you specify T_s in the **Sample time** parameter. This mode of operation has the same benefits and liabilities as the **Continuous** sample mode.

At each sample time, the block evaluates the sine function at the appropriate time value *within the first cycle* of the sinusoid. By constraining trigonometric evaluations to the first cycle of each sinusoid, the block avoids the imprecision of computing the sine of very large numbers, and eliminates the possibility of discontinuity during extended operations (when an absolute time variable might overflow). This method therefore avoids the memory demands of the table lookup method at the expense of many more floating-point operations.

Table Lookup

The table lookup method precomputes the *unique* samples of every output sinusoid at the start of the simulation, and recalls the samples from memory as needed. Because a table of finite length can only be constructed when all output sequences repeat, the method requires that the period of every sinusoid in the output be evenly divisible by the sample period. That is, $1/(f_i T_s) = k_i$ must be an integer value for every channel $i = 1, 2, \dots, N$.

When the **Optimize table for** parameter is set to **Speed**, the table constructed for each channel contains k_i elements. When the **Optimize table for** parameter is set to **Memory**, the table constructed for each channel contains $k_i/4$ elements.

For long output sequences, the table lookup method requires far fewer floating-point operations than any of the other methods, but can demand considerably more memory, especially for high sample rates (long tables). This method is recommended for models that are intended to emulate or generate code for DSP hardware, and that therefore must be optimized for execution speed.

Note The lookup table for this block is constructed from double-precision floating-point values. Thus, when you use the **Table lookup** computation mode, the maximum amount of precision you can achieve in your output is 53 bits. Setting the word length of the **Output** or **User-defined** data type to values greater than 53 bits does not improve the precision of your output.

Tip To generate fixed-point sinusoids, you must select **Table Lookup**.

Differential

The differential method uses an incremental algorithm. This algorithm computes the output samples based on the output values computed at the previous sample time (and precomputed update terms) by using the following identities.

$$\sin(t + T_s) = \sin(t)\cos(T_s) + \cos(t)\sin(T_s)$$

$$\cos(t + T_s) = \cos(t)\cos(T_s) - \sin(t)\sin(T_s)$$

The update equations for the sinusoid in the i th channel, y_i , can therefore be written in matrix form as

$$\begin{bmatrix} \sin\{2\pi f_i(t + T_s) + \phi_i\} \\ \cos\{2\pi f_i(t + T_s) + \phi_i\} \end{bmatrix} = \begin{bmatrix} \cos(2\pi f_i T_s) & \sin(2\pi f_i T_s) \\ -\sin(2\pi f_i T_s) & \cos(2\pi f_i T_s) \end{bmatrix} \begin{bmatrix} \sin(2\pi f_i t + \phi_i) \\ \cos(2\pi f_i t + \phi_i) \end{bmatrix}$$

where you specify T_s in the **Sample time** parameter. Since T_s is constant, the right-hand matrix is a constant and can be computed once at the start of the simulation. The value of $A_i \sin[2\pi f_i(t+T_s)+\phi_i]$ is then computed from the values of $\sin(2\pi f_i t + \phi_i)$ and $\cos(2\pi f_i t + \phi_i)$ by a simple matrix multiplication at each time step.

This mode offers reduced computational load, but is subject to drift over time due to cumulative quantization error. Because the method is not contingent on an absolute time value, there is no danger of discontinuity during extended operations (when an absolute time variable might overflow).

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The Sine Wave block references absolute simulation time when configured in continuous sample mode.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has one default HDL architecture.

Restrictions

For HDL code generation, you must select the following Sine Wave block settings:

- **Computation method:** Table lookup
- **Sample mode:** Discrete

Output:

- The output port cannot have data types `single` or `double`.

Complex Data Support

This block supports code generation for complex signals.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

If the input is fixed point, it must be a signed integer or signed fixed point with a power-of-two slope and zero bias.

Singular Value Decomposition

Factor matrix using singular value decomposition

Library

Math Functions / Matrices and Linear Algebra / Matrix Factorizations

dspfactors

Description

The Singular Value Decomposition block factors the M -by- N input matrix A such that

$$A = U \cdot \text{diag}(S) \cdot V^*$$

where

- U is an M -by- P matrix
- V is an N -by- P matrix
- S is a length- P vector
- P is defined as $\min(M,N)$

When

- $M = N$, U and V are both M -by- M unitary matrices
- $M > N$, V is an N -by- N unitary matrix, and U is an M -by- N matrix whose columns are the first N columns of a unitary matrix
- $N > M$, U is an M -by- M unitary matrix, and V is an N -by- M matrix whose columns are the first M columns of a unitary matrix

In all cases, S is an unoriented vector of positive singular values having length P .

Length- N row inputs are treated as length- N columns.

Note that the first (maximum) element of output S is equal to the 2-norm of the matrix A .

Parameters

Show singular vector ports

Select to enable the U and V output ports.

Show error status port

Select to enable the E output port, which reports a failure to converge. The possible values you can receive on the port are:

- 0 — The singular value decomposition calculation converges.
- 1 — The singular value decomposition calculation does not converge.

If the singular value decomposition calculation fails to converge, the output at ports U, S, and V are undefined matrices of the correct size.

Simulate using

Type of simulation to run. You can set this parameter to:

- Interpreted execution (default)

Simulate model using the MATLAB interpreter. This option shortens startup time.

- Code generation

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Sort

Sort input elements by value

Library: DSP System Toolbox / Statistics

Description

The Sort block ranks the values of the input elements along each channel (column) in an **Ascending** or a **Descending** order, based on the **Sort order** you specify. Complex inputs are sorted by their magnitude, which is the sum of the squares of the real and imaginary components of the input. You can choose the **Sort algorithm** to be either **Quick sort** or **Insertion sort**. The quick sort algorithm uses a recursive sort method and is faster at sorting more than 32 elements. The insertion sort algorithm uses a nonrecursive method and is faster at sorting fewer than 32 elements. When you generate code, use the insertion sort algorithm to avoid recursive function calls.

The **Mode** parameter specifies the block's mode of operation, which you can set to **Value**, **Index**, or **Value and Index**.

Ports

Input

Port_1 — Data input

vector | matrix

The block accepts real-valued or complex-valued multichannel inputs. The input data type must be double precision, single precision, integer, or fixed point, with power-of-two slope and zero bias.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Val — Sorted data

vector | matrix

The block sorts the data along each channel and outputs the sorted data through this port. The size, data type, and complexity of the sorted data matches that of the input data. The block sorts complex inputs according to their magnitude.

Dependencies

To enable this port, set the **Mode** parameter to **Value** and **index** or **Value**.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Idx — Index of the sorted data

vector | matrix

The output at this port contains the indices of the sorted data.

Dependencies

To enable this port, set the **Mode** parameter to `Value` and `index` or `Index`.

Data Types: `uint32`

Parameters

Main Tab

Mode — Specify whether block returns values, indices, or both

`Value` and `Index` (default) | `Value` | `Index`

When the **Mode** parameter is set to:

- `Value` — The block sorts the elements in each channel of the M -by- N input matrix in an ascending or descending order, based on what you specify in the **Sort order** parameter. The output at each sample time, *Val*, is an M -by- N matrix that contains the sorted columns of the input.

The block sorts complex inputs according to their magnitude.

- `Index` — The block sorts the elements in each channel of the M -by- N input matrix, and outputs the index array, *I*. Each element in *I* is an integer of type `uint32` that indexes the sorted value in the corresponding column of the input.
- `Value` and `index` — The block outputs the sorted values of the input data, *Val*, and the corresponding indices in the index array, *I*.

Sort order — Order of sorting

`Ascending` (default) | `Descending`

Specify to sort the input data in either ascending or descending order.

Sort algorithm — Sort method

`Quick sort` (default) | `Insertion sort`

The quick sort algorithm uses a recursive sort method and is faster at sorting more than 32 elements. The insertion sort algorithm uses a nonrecursive method and is faster at sorting fewer than 32 elements. When you generate code, to avoid recursive function calls, use the insertion sort algorithm.

Data Types Tab

Note To use these parameters, the data input must be complex and fixedpoint. For all other inputs, the parameters on the **Data Types** tab are ignored.

Rounding mode — Method of rounding operation

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding mode for fixed-point operations. For more details, see rounding mode.

Saturate on integer overflow — Method of overflow action

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on **saturate** and **wrap**, see **overflow mode for fixed-point operations**.

Product output — Product output data type

Inherit: Same as input (default) | fixdt([],16,0)

The squares of the real and imaginary parts of the complex input are stored in the **Product output** data type.

You can set this parameter to:

- **Inherit: Same as input** — The product output data type is the same as the input data type.
- **fixdt([],16,0)** — The product output data type is an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Product output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

Accumulator — Accumulator data type

Inherit: Same as product output (default) | Inherit: Same as input | fixdt([],16,0)

The result of the sum of the squares of the real and imaginary parts of the complex input are stored in the **Accumulator** data type.

You can set this parameter to:

- **Inherit: Same as product output** — The accumulator data type is the same as the product output data type.
- **Inherit: Same as input** — The accumulator data type is the same as the input data type.
- **fixdt([],16,0)** — The accumulator data type is an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block.

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Algorithms

Sort

The block produces results identical to the MATLAB `sort` function.

The output of the block is equivalent to the following MATLAB code, when **Sort order** is set to:

- Ascending — `[Val,I] = sort(u,'ascend')`
- Descending — `[Val,I] = sort(u,'descend')`

where:

- `u` is the data input.
- `Val` is the sorted output.
- `I` is the index of the sorted output.

When the input is complex, the block sorts the data according to the magnitude. The block computes the magnitude by taking the sum of the squares of the real and imaginary components of the complex input. This is identical to calling the `sort` function as `[Val,I] = sort(u,...,'ComparisonMethod','abs')`.

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

The parameters on the **Data Types** tab are used only for complex fixed-point inputs. Complex inputs are sorted by their magnitude, which is the sum of the squares of the real and imaginary components of the input. The results of the squares of the real and imaginary parts are stored in the **Product output** data type. The result of the sum of the squares is stored in the **Accumulator** data type. The parameters on the **Data Types** tab are ignored for all other inputs.

Spectrum Analyzer

Display frequency spectrum

Library: DSP System Toolbox / Sinks
 DSP System Toolbox HDL Support / Sinks

Description

The Spectrum Analyzer block, referred to here as the scope, displays the frequency spectra of signals.

You can use the Spectrum Analyzer block in models running in Normal or Accelerator simulation modes. You can also use the Spectrum Analyzer block in models running in Rapid Accelerator or External simulation modes, with some limitations.

You can use the Spectrum Analyzer block inside all subsystems and conditional subsystems. Conditional subsystems include enabled subsystems, triggered subsystems, enabled and triggered subsystems, and function-call subsystems. See “Conditionally Executed Subsystems Overview” (Simulink) for more information.

Measurements

- Cursors — Measure signal values using vertical and horizontal cursors.

- **Peak Finder** — Find maxima, showing the x-axis values at which they occur.
- **Channel Measurements** — Measure the occupied bandwidth or adjacent channel power ratio (ACPR).
- **Distortion Measurements** — Measure harmonic distortion and intermodulation distortion.
- **CCDF Measurements** — Measure the complimentary cumulative distribution function. CCDF measurements show the probability of a signal’s instantaneous power being a specified level above the signal’s average power.
- **“Spectral Masks”** — Visualize spectrum limits and compare spectrum values to specification values.

Programmatic Control

You can configure and display Spectrum Analyzer settings from the command line with the `SpectrumAnalyzerConfiguration` object.

Ports

Input

Port_1 — Signals to visualize

scalar | vector | matrix | array

Connect the signals you want to visualize. You can have up to 96 input ports. Input signals can have these characteristics:

- **Signal Domain** — Frequency or time signals
- **Type** — Discrete (sample-based and frame-based).
- **Data type** — Any data type that Simulink supports. See “Data Types Supported by Simulink” (Simulink).
- **Dimension** — One dimensional (vector), two dimensional (matrix), or multidimensional (array). Input must have fixed number of channels. See “Signal Dimensions” (Simulink) and “Determine Signal Dimensions” (Simulink).

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Spectrum Settings

The **Spectrum Settings** pane appears at the right side of the Spectrum Analyzer window. These settings control how the spectrum is calculated. To show the Spectrum Settings, in the Spectrum

Analyzer menu, select **View > Spectrum Settings** or use the  button in the toolbar.

Main options

Input domain — Domain of the input signal

Time (default) | Frequency

The domain of the input signal you want to visualize. If you visualize time-domain signals, the signal is transformed to the frequency spectrum based on the algorithm specified by the `Method` parameter.

Programmatic Use

See `InputDomain`.

Type — Type of spectrum to display

Power (default) | Power density | RMS

Power — Spectrum Analyzer shows the power spectrum.

Power density — Spectrum Analyzer shows the power spectral density. The power spectral density is the magnitude of the spectrum normalized to a bandwidth of 1 hertz.

RMS — Spectrum Analyzer shows the root mean squared spectrum.

Tunable: Yes

Dependency

To use this parameter, set **Input domain** to `Time`.

Programmatic Use

See `SpectrumType`.

View — Spectrum view

Spectrum (default) | Spectrogram | Spectrum and spectrogram

Spectrum — Spectrum Analyzer shows the spectrum.

Spectrogram — Spectrum Analyzer shows the spectrogram, which displays frequency content over time. The most recent spectrogram update is at the bottom of the display, and time scrolls from the bottom to the top of the display.

Spectrum and spectrogram — Spectrum Analyzer shows both the spectrum and spectrogram.

Tunable: Yes

Programmatic Use

See `ViewType`.

Sample rate — Sample rate of the input signal in hertz

Inherited (default) | positive scalar

Sample rate of the input signal in hertz, specified as either

- `Inherited` to use the same sample rate as the input signal.
- `Positive scalar`. The specified sample rate must be at least twice the input signal sample rate. Otherwise, you might see unexpected behavior in your signal visualization due to aliasing.

Programmatic Use

See `SampleRate`.

Method — Spectrum estimation method

Filter Bank (default) | Welch

Select Welch or Filter Bank as the spectrum estimation method. For more details about the two spectrum estimation algorithms, see “Algorithms” on page 2-1207.

Tunable: No**Dependency**

To use this parameter, set **Input domain** to Time.

Programmatic Use

See Method.

Full frequency span — Use entire Nyquist frequency interval

on (default) | off

Select this check box to compute and plot the spectrum over the entire “Nyquist frequency interval” on page 2-1211.

Tunable: Yes**Dependency**

To use this parameter, set **Input domain** to Time.

Programmatic Use

See FrequencySpan.

Span (Hz) — Frequency span in hertz

10e3 (default) | real positive scalar

Specify the frequency span in hertz. Use this parameter with the **CF (Hz)** parameter to define the frequency span around a center frequency. This parameter defines the range of values shown on the Frequency axis in the Spectrum Analyzer window.

Tunable: Yes**Dependencies**

To use this parameter, you must:

- Set **Input domain** to Time.
- Clear the **Full frequency span** check box.
- Set the **Span (Hz)/Fstart (Hz)** drop-down to Span (Hz).

Programmatic Use

See FrequencySpan and Span.

CF (Hz) — Center frequency in hertz

0 (default) | scalar

Specify the center frequency, in hertz. Use this parameter with the **Span (Hz)** parameter to define the frequency span around a center frequency. This parameter defines the value shown at the middle point of the Frequency axis on the Spectrum Analyzer window.

Tunable: Yes

Dependencies

To use this parameter, you must:

- Set **Input domain** to Time.
- Clear the **Full frequency span** check box.
- Set the **Span (Hz)/Fstart (Hz)** drop-down to **Span (Hz)**.

Programmatic Use

See CenterFrequency.

FStart (Hz) — Start frequency in hertz

-5e3 (default) | scalar

Specify the start frequency in hertz. Use this parameter with the **Fstop (Hz)** parameter to define the range of frequency-axis values using start frequency and stop frequency. This parameter defines the value shown at the leftmost side of the Frequency axis on the Spectrum Analyzer window.

Tunable: Yes

Dependencies

To use this parameter, you must:

- Set **Input domain** to Time.
- Clear the **Full frequency span** check box.
- Set the **Span (Hz)/FStart (Hz)** drop-down to **FStart (Hz)**.

Programmatic Use

See StartFrequency.

FStop (Hz) — Stop frequency in hertz

5e3 (default) | scalar

Specify the stop frequency, in hertz. Use this parameter with the **Fstart (Hz)** parameter to define the range of Frequency axis values. This parameter defines the value shown at the rightmost side of the Frequency axis on the Spectrum Analyzer window.

Tunable: Yes

Dependencies

To use this parameter, you must:

- Set **Input domain** to Time.
- Clear the **Full frequency span** check box.
- Set the **Span (Hz)/FStart (Hz)** drop-down to **Fstart (Hz)**.

Programmatic Use

See StopFrequency.

Frequency (Hz) — Frequency vector

Auto (default) | Input port | monotonically increasing vector

Set the frequency vector which determines the x-axis of the display.

- **Auto** — The frequency vector is calculated from the length of the input. See “Frequency Vector” on page 2-1212.
- **Input port** — When selected, an input port appears on the block for the frequency vector input.
- **Custom vector** — Enter a custom vector as the frequency vector. The length of the custom vector must be equal to the frame size of the input signal.

Tunable: No

Dependency

To use this parameter, set **Input domain** to Frequency.

Programmatic Use

See FrequencyVector.

RBW (Hz) — Resolution bandwidth

Auto (default) | Input port | positive scalar

The resolution bandwidth in hertz. This parameter defines the smallest positive frequency that can be resolved. By default, this parameter is set to **Auto**. In this case, the Spectrum Analyzer determines the appropriate value to ensure that there are 1024 RBW intervals over the specified frequency span.

If you set this parameter to a numeric value, the value must allow at least two RBW intervals over the specified frequency span. In other words, the ratio of the overall frequency span to RBW must be greater than two:

$$\frac{span}{RBW} > 2$$

For frequency input only, you can use an input port to set the RBW value.

Tunable: Yes

Dependency

To use this parameter, set either:

- **Input domain** to Time and the **RBW (Hz)/Window length/Number of frequency bands** drop-down to RBW (Hz).
- **Input domain** to Frequency.

Programmatic Use

See RBW.

Input units — Units of frequency input

Auto (default) | dBm | dBV | dBW | Vrms | Watts

Select the units of the frequency-domain input. This property allows the Spectrum Analyzer to scale frequency data if you choose a different display unit with the **Units** property.

Tunable: No

Dependency

This option is only available when **Input domain** is set to Frequency.

Programmatic Use

See InputUnits.

Window length — Length of window in samples

1024 (default) | integer greater than 2

The length of the window, in samples. The window length used to control the frequency resolution and compute the spectral estimates. The window length must be an integer greater than 2.

Dependencies

To use this parameter, set:

- **Method** to Welch
- Set the **RBW (Hz)/Window length/Number of frequency bands** drop-down to Window Length

Dependency

To use this parameter, set **Input domain** to Time.

Programmatic Use

See WindowLength.

Number of frequency bands — FFT length

Auto (default) | positive integer

Specify the fast Fourier transform (FFT) length to control the number of frequency bands. If the value is Auto, the Spectrum Analyzer uses the entire frame size to estimate the spectrum. If you specify the number of frequency bands, you set the input buffer size.

Dependencies

To use this parameter, set:

- **Method** to Filter Bank
- Set the **RBW (Hz)/Window length/Number of frequency bands** drop-down to Number of frequency bands

Programmatic Use

See FFTLength

Taps per band — Number of filter taps

12 (default) | positive even integer

Specify the number of filter taps or coefficients for each frequency band. This number must be a positive even integer. This value corresponds to the number of filter coefficients per polyphase branch. The total number of filter coefficients is equal to *Taps Per Band + FFT Length*.

Dependency

To use this parameter, you must set the **RBW (Hz)/Window length/Number of frequency bands** drop-down to **Number of frequency bands**.

Programmatic Use

See NumTapsPerBand.

NFFT — Number of FFT points

Auto (default) | positive integer

Specify the length of the FFT that Spectrum Analyzer uses to compute spectral estimates. Acceptable options are **Auto** or a positive integer.

The **NFFT** value must be greater than or equal to the value of the **Window length** parameter. By default, when **NFFT** is set to **Auto**, the Spectrum Analyzer sets **NFFT** equal to the value of **Window length**. When in **RBW** mode, the specified **RBW** value is used to calculate an FFT length that equals the window length.

When this parameter is set to a positive integer, this parameter is equivalent to the *n* parameter of the `fft` function.

Dependencies

To use this parameter, you must set the **RBW (Hz)/Window length/Number of frequency bands** drop-down to **Window length**.

Programmatic Use

See FFTLength.

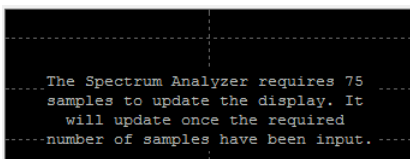

Samples/update — Required number of input samples

positive scalar

This property is read-only.

The number of input samples required to compute one spectral update. You cannot modify this parameter; it is shown in the spectrum analyzer for informational purposes only. This parameter is directly related to **RBW (Hz)/Window length/Number of frequency bands**.

If the input does not have enough samples to achieve the resolution bandwidth that you specify, Spectrum Analyzer produces a message on the display.

```

-----
The Spectrum Analyzer requires 75
samples to update the display. It
will update once the required
number of samples have been input.
-----

```

Spectrogram Settings

Channel — Spectrogram channel

channel name

Select the signal channel for which the spectrogram settings apply.

Dependencies

To use this option, set **View** to Spectrogram or Spectrum and spectrogram.

Programmatic Use

See SpectrogramChannel.

Time res. (s) — Time resolution in seconds

Auto (default) | positive number

Time resolution is the amount of data, in seconds, used to compute a spectrogram line. The minimum attainable resolution is the amount of time it takes to compute a single spectral estimate. The tooltip displays the minimum attainable resolution given the current settings.

The time resolution value is determined based on frequency resolution method, the RBW setting, and the time resolution setting.

Method	Frequency Resolution Method	Frequency Resolution Setting	Time Resolution Setting	Resulting Time Resolution in Seconds
Welch or Filter Bank	RBW (Hz)	Auto	Auto	1/RBW
Welch or Filter Bank	RBW (Hz)	Auto	Manually entered	Time Resolution
Welch or Filter Bank	RBW (Hz)	Manually entered	Auto	1/RBW
Welch or Filter Bank	RBW (Hz)	Manually entered	Manually entered	Must be equal to or greater than the minimum attainable time resolution, 1/RBW. Several spectral estimates are combined into one spectrogram line to obtain the desired time resolution. Interpolation is used to obtain time resolution values that are not integer multiples of 1/RBW.
Welch	Window length	—	Auto	1/RBW

Method	Frequency Resolution Method	Frequency Resolution Setting	Time Resolution Setting	Resulting Time Resolution in Seconds
Welch	Window length	—	Manually entered	Must be equal to or greater than the minimum attainable time resolution. Several spectral estimates are combined into one spectrogram line to obtain the desired time resolution. Interpolation is used to obtain time resolution values that are not integer multiples of 1/RBW.
Filter Bank	Number of frequency bands	—	Auto	1/RBW
Filter Bank	Number of frequency bands	—	Manually entered	Must be equal to or greater than the minimum attainable time resolution, 1/RBW.

Tunable: Yes

Dependency

To use this option, set **View** to Spectrogram or Spectrum and spectrogram.

Programmatic Use

See TimeResolution.

Time span — Time span in seconds

Auto (default) | positive scalar

The time span over which the Spectrum Analyzer displays the spectrogram specified in seconds. The time span is the product of the desired number of spectral lines and the time resolution. The tooltip displays the minimum allowable time span, given the current settings. If the time span is set to Auto, 100 spectral lines are used.

Tunable: Yes

Dependency

To use this option, set **View** to Spectrogram or Spectrum and spectrogram.

Programmatic Use

See TimeSpan.

Window Options

Overlap (%) — Segment overlap percentage

0 (default) | scalar between 0 and 100

This parameter defines the amount of overlap between the previous and current buffered data segments. The overlap creates a window segment that is used to compute a spectral estimate. The value must be greater than or equal to zero and less than 100.

Tunable: Yes

Programmatic Use

See `OverlapPercent`.

Window — Windowing method

Hann (default) | Rectangular | Blackman-Harris | Chebyshev | Flat Top | Hamming | Kaiser | custom window function name

The windowing method to apply to the spectrum. Windowing is used to control the effect of sidelobes in spectral estimation. The window you specify affects the window length required to achieve a resolution bandwidth and the required number of samples per update. For more information about windowing, see “Windows”.

Tunable: Yes

Programmatic Use

See `Window`.

Attenuation — Sidelobe attenuation

60 (default) | scalar greater than or equal to 45

The sidelobe attenuation in decibels (dB). The value must be greater than or equal to 45.

Dependency

This parameter applies only when you set the **Window** parameter to Chebyshev or Kaiser.

Programmatic Use

See `SidelobeAttenuation`.

NENBW — Normalized effective noise bandwidth

scalar

This property is read-only.

The normalized effective noise bandwidth of the window. You cannot modify this parameter; it is shown for informational purposes only. This parameter is a measure of the noise performance of the window. The value is the width of a rectangular filter that accumulates the same noise power with the same peak power gain.

The rectangular window has the smallest NENBW, with a value of 1. All other windows have a larger NENBW value. For example, the Hann window has an NENBW value of approximately 1.5.

Trace Options

Units — Spectrum units

dBm (default) | dBW | Watts | Vrms | dBV | dBFS

The units of the spectrum. The available values depend on the value of the “Type” on page 2-0 parameter.

Tunable: Yes

Programmatic Use

See SpectrumUnits.

Full scale — Full scale for dBFS units

Auto (default) | positive real scalar

The full scale used for the decibel full scale (dBFS) units. By default, the Spectrum Analyzer uses the entire spectrum scale. Specify a positive real scalar for the dBFS full scale.

Tunable: Yes

Dependencies

To enable this parameter, set:

- **Input domain** to Time
- **Units** to dBFS

Programmatic Use

See FullScale.

Averaging method — Smoothing method

Exponential (default) | Running

Specify the smoothing method as:

- **Exponential** — Weighted average of samples. Use the **Forgetting factor** property to specify the weighted forgetting factor.
- **Running** — Running average of the last n samples. Use the **Averages** property to specify n .

Programmatic Use

See AveragingMethod.

Averages — Number of spectral averages

1 (default) | positive integer

Specify the number of spectral averages as a positive integer. The spectrum analyzer computes the current power spectrum estimate by computing a running average of the last N power spectrum estimates. This parameter defines the number of spectral averages, N .

Dependencies

This parameter applies only when:

- **View** is Spectrum or Spectrum and spectrogram.
- **Averaging method** is Running.

Programmatic Use

See SpectralAverages.

Forgetting factor — Weighting forgetting factor

0.9 (default) | scalar in the range (0,1]

Specify the exponential weighting as a scalar value greater than 0 and less than or equal to 1.

Dependency

This parameter applies only when the **Averaging method** is Exponential.

Programmatic Use

See ForgettingFactor.

Reference load — Reference load

1 (default) | positive real scalar

The reference load in ohms that the Spectrum Analyzer uses as a reference to compute power values.

Programmatic Use

See ReferenceLoad.

Scale — Scale of frequency axis

Linear (default) | Logarithmic

Choose a linear or logarithm scale for the frequency axis. When the frequency span contains negative frequency values, you cannot choose the logarithmic option.

Programmatic Use

See FrequencyScale.

Offset — Constant frequency offset

0 (default) | scalar

The constant frequency offset to apply to the entire spectrum, or a vector of frequencies to apply to each spectrum for multiple inputs. The offset parameter is added to the values on the Frequency axis in the Spectrum Analyzer window. This parameter is not used in any spectral computations. You must take the parameter into consideration when you set the **Span (Hz)** and **CF (Hz)** parameters to ensure that the frequency span is within the Nyquist frequency interval.

Dependency

To use this parameter, set **Input domain** to Time.

Programmatic Use

See MaskFrequencyOffset.

Normal trace — Normal trace view

on (default) | off

When this check box is selected, the Spectrum Analyzer calculates and plots the power spectrum or power spectrum density. Spectrum Analyzer performs a smoothing operation by averaging several spectral estimates.

Dependencies

To clear this check box, you must first select either the **Max hold trace** or the **Min hold trace** parameter. This parameter applies only when **View** is `Spectrum` or `Spectrum and spectrogram`.

Programmatic Use

See `PlotNormalTrace`.

Max hold trace — Maximum hold trace view

off (default) | on

Select this check box to enable Spectrum Analyzer to plot the maximum spectral values of all the estimates obtained.

Dependency

This parameter applies only when **View** is `Spectrum` or `Spectrum and spectrogram`.

Programmatic Use

See `PlotMaxHoldTrace`.

Min hold trace — Minimum hold trace view

off (default) | on

Select this check box to enable Spectrum Analyzer to plot the minimum spectral values of all the estimates obtained.

Dependency

This parameter applies only when **View** is `Spectrum` or `Spectrum and spectrogram`.

Programmatic Use

See `PlotMinHoldTrace`.

Two-sided spectrum — Enable two-sided spectrum view

off (default) | on

Select this check box to enable a two-sided spectrum view. In this view, both negative and positive frequencies are shown. If you clear this check box, Spectrum Analyzer shows a one-sided spectrum with only positive frequencies. Spectrum Analyzer requires that this parameter is selected when the input signal is complex-valued.

Programmatic Use

See `PlotAsTwoSidedSpectrum`.

Configuration Properties

The **Configuration Properties** dialog box controls visual aspects of the Spectrum Analyzer. To open the Configuration Properties, in the Spectrum Analyzer menu, select **View > Configuration**

Properties or select the  button in the toolbar drop-down.

Title — Display title

character vector | string

Specify the display title. Enter %<SignalLabel> to use the signal labels in the Simulink model as the axes titles.

Tunable: Yes

Programmatic Use

See Title.

Show Legend — Display signal legend

off (default) | on

Show signal legend. The names listed in the legend are the signal names from the model. For signals with multiple channels, a channel index is appended after the signal name. Continuous signals have straight lines before their names and discrete signals have step-shaped lines.

From the legend, you can control which signals are visible. This control is equivalent to changing the visibility in the **Style** parameters. In the scope legend, click a signal name to hide the signal in the scope. To show the signal, click the signal name again. To show only one signal, right-click the signal name, which hides all other signals. To show all signals, press **ESC**.

Note The legend only shows the first 20 signals. Any additional signals cannot be viewed or controlled from the legend.

Dependency

To enable this parameter, set **View** to Spectrum or Spectrum and spectrogram.

Programmatic Use

See ShowLegend.

Show grid — Show internal grid lines

on (default) | off

Show internal grid lines on the Spectrum Analyzer

Programmatic Use

See ShowGrid.

Y-limits (minimum) — Y-axis minimum

-80 (default) | scalar

Specify the minimum value of the y-axis.

Programmatic Use

See YLimits.

Y-limits (maximum) — Y-axis maximum

20 (default) | scalar

Specify the maximum value of the y-axis.

Programmatic Use

See YLimits.

Y-label — Y-axis label

character vector | string

To display signal units, add (%<SignalUnits>) to the label. At the beginning of a simulation, Simulink replaces (%SignalUnits) with the units associated with the signals. For example, if you have a signal for velocity with units of m/s enter

Velocity (%<SignalUnits>)

Programmatic Use

See YLabel.

Color map — Spectrogram colormap

jet(256) (default) | hot(256) | bone(256) | cool(256) | copper(256) | gray(256) | parula(256) | 3-column matrix

Select the colormap for the spectrogram, or enter a three-column matrix expression for the colormap. For more information about colormaps, see colormap.

Tunable: Yes

Dependency

To use this parameter, set **View** to Spectrogram or Spectrum and spectrogram.

Color-limits (minimum) — Spectrogram minimum

-80 (default) | scalar

Specify the signal power for the minimum color value of the spectrogram.

Tunable: Yes

Dependency

To use this parameter, set **View** to Spectrogram or Spectrum and spectrogram.

Programmatic Use

See ColorLimits.

Color-limits (maximum) — Spectrogram maximum

20 (default) | scalar

Specify the signal power for the maximum color value of the spectrogram.

Tunable: Yes

Dependency

To use this parameter, set **View** to Spectrogram or Spectrum and spectrogram.

Programmatic Use

See ColorLimits.

Style

The **Style** dialog box controls how the Spectrum Analyzer appears. To open the Style properties, in the Spectrum Analyzer menu, select **View > Style** or select the  button in the toolbar drop-down.

Figure color – Window background

gray (default) | color picker

Specify the color that you want to apply to the background of the scope figure.

Plot type – Plot type

Line (default) | Stem

Specify whether to display a Line or Stem plot.

Programmatic Use

See PlotType.

Axes colors – Axes background color

black (default) | color picker

Specify the color that you want to apply to the background of the axes.

Properties for line – Channel for visual property settings

channel names

Specify the channel for which you want to modify the visibility, line properties, and marker properties.

Visible – Channel visibility

on (default) | off

Specify whether the selected channel is visible. If you clear this check box, the line disappears. You can also change signal visibility using the scope legend.

Line – Line style

line, 0.5, yellow (default)

Specify the line style, line width, and line color for the selected channel.

Marker – Data point markers

none (default)

Specify marks for the selected channel to show at its data points. This parameter is similar to the 'Marker' property for plots. You can choose any of the marker symbols from the drop-down.

Axes Scaling

The **Axes Scaling** dialog box controls the axes limits of the Spectrum Analyzer. To open the Axes Scaling properties, in the Spectrum Analyzer menu, select **Tools > Axes Scaling > Axes Scaling Properties**.

Axes scaling/Color scaling – Automatic axes scaling

Auto (default) | Manual | After N Updates

Specify when the scope automatically scales the y-axis. If the spectrogram is displayed, specify when the scope automatically scales the color axis. By default, this parameter is set to **Auto**, and the scope does not shrink the y-axis limits when scaling the axes or color. You can select one of the following options:

- **Auto** — The scope scales the axes or color as needed, both during and after simulation. Selecting this option shows the **Do not allow Y-axis limits to shrink** or **Do not allow color limits to shrink**.
- **Manual** — When you select this option, the scope does not automatically scale the axes or color. You can manually scale the axes or color in any of the following ways:
 - Select **Tools > Scaling Properties**.
 - Press one of the **Scale Axis Limits** toolbar buttons.
 - When the scope figure is the active window, press **Ctrl+A**.
- **After N Updates** — Selecting this option causes the scope to scale the axes or color after a specified number of updates. This option is useful, and most efficient, when your frequency signal values quickly reach steady-state after a short period. Selecting this option shows the **Number of updates** edit box where you can modify the number of updates to wait before scaling.

Tunable: Yes

Programmatic Use

See `AxesScaling`.

Do not allow Y-axis/color limits to shrink — Axes scaling limits

on (default) | off

When you select this parameter, the y-axis is allowed to grow during axes scaling operations. If the spectrogram is displayed, selecting this parameter allows the color limits to grow during axis scaling. If you clear this check box, the y-axis or color limits can shrink during axes scaling operations.

Dependency

This parameter appears only when you select **Auto** for the **Axis scaling** or **Color scaling** parameter. When you set the **Axis scaling** or **Color scaling** parameter to **Manual** or **After N Updates**, the y-axis or color limits can shrink.

Number of updates — Number of updates before scaling

10 (default) | positive number

The number of updates after which the axes scale, specified as a positive integer. If the spectrogram is displayed, this parameter specifies the number of updates after which the color axes scales.

Tunable: Yes

Dependency

This parameter appears only when you set **Axis scaling/Color scaling** to **After N Updates**.

Programmatic Use

See `AxesScalingNumUpdates`.

Scale limits at stop — Scale axes at stop

off (default) | on

Select this check box to scale the axes when the simulation stops. If the spectrogram is displayed, select this check box to scale the color when the simulation stops. The y-axis is always scaled. The x-axis limits are only scaled if you also select the **Scale X-axis limits** check box.

Data range (%) — Percent of axes

100 (default) | number in the range [1,100]

Set the percentage of the axis that the scope uses to display the data when scaling the axes. If the spectrogram is displayed, set the percentage of the power values range within the colormap. Valid values are from 1 through 100. For example, if you set this parameter to 100, the scope scales the axis limits such that your data uses the entire axis range. If you then set this parameter to 30, the scope increases the y-axis or color range such that your data uses only 30% of the axis range.

Tunable: Yes

Align — Alignment along axes

Center (default) | Bottom | Top | Left | Right

Specify where the scope aligns your data along the axis when it scales the axes. If the spectrogram is displayed, specify where the scope aligns your data along the axis when it scales the color. If you are using CCDF Measurements, the x axis is also configurable.

Tunable: Yes

Block Characteristics

Data Types	Boolean double enumerated fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Algorithms

Spectrum Estimation — Welch's Method

When you choose the Welch method, the power spectrum estimate is averaged modified periodograms.

Given the signal input, x , the Spectrum Analyzer does the following:

- 1 Multiplies x by the given window and scales the result by the window power. The Spectrum Analyzer uses the RBW or the Window Length setting in the **Spectrum Settings** pane to determine the data window length.
- 2 Computes the FFT of the signal, Y , and takes the square magnitude using $Z = Y \cdot \text{conj}(Y)$.
- 3 Computes the current power spectrum estimate by taking the moving average of the last N number of Z 's, and scales the answer by the sample rate.

Spectrum Analyzer requires that a minimum number of samples to compute a spectral estimate. This number of input samples required to compute one spectral update is shown as **Samples/update** in

the **Main options** pane. This value is directly related to resolution bandwidth, RBW , by the following equation, or to the window length, by the equation shown in step 2.

$$N_{samples} = \frac{\left(1 - \frac{O_p}{100}\right) \times NENBW \times F_s}{RBW}$$

The normalized effective noise bandwidth, $NENBW$, is a factor that depends on the windowing method. Spectrum Analyzer shows the value of $NENBW$ in the **Window Options** pane of the **Spectrum Settings** pane. Overlap percentage, O_p , is the value of the **Overlap %** parameter in the **Window Options** pane of the **Spectrum Settings** pane. F_s is the sample rate of the input signal. Spectrum Analyzer shows sample rate in the **Main Options** pane of the **Spectrum Settings** pane.

- 1 When in **RBW (Hz)** mode, the window length required to compute one spectral update, N_{window} , is directly related to the resolution bandwidth and normalized effective noise bandwidth:

$$N_{window} = \frac{NENBW \times F_s}{RBW}$$

When in **Window Length** mode, the window length is used as specified.

- 2 The number of input samples required to compute one spectral update, $N_{samples}$, is directly related to the window length and the amount of overlap by the following equation.

$$N_{samples} = \left(1 - \frac{O_p}{100}\right) N_{window}$$

When you increase the overlap percentage, fewer new input samples are needed to compute a new spectral update. For example, if the window length is 100, then the number of input samples required to compute one spectral update is given as shown in the following table.

O_p	$N_{samples}$
0%	100
50%	50
80%	20

- 3 The normalized effective noise bandwidth, $NENBW$, is a window parameter determined by the window length, N_{window} , and the type of window used. If $w(n)$ denotes the vector of N_{window} window coefficients, then $NENBW$ is given by the following equation.

$$NENBW = N_{window} \times \frac{\sum_{n=1}^{N_{window}} w^2(n)}{\left[\sum_{n=1}^{N_{window}} w(n)\right]^2}$$

- 4 When in **RBW (Hz)** mode, you can set the resolution bandwidth using the value of the **RBW (Hz)** parameter on the **Main options** pane of the **Spectrum Settings** pane. You must specify a value to ensure that there are at least two RBW intervals over the specified frequency span. The ratio of the overall span to RBW must be greater than two:

$$\frac{span}{RBW} > 2$$

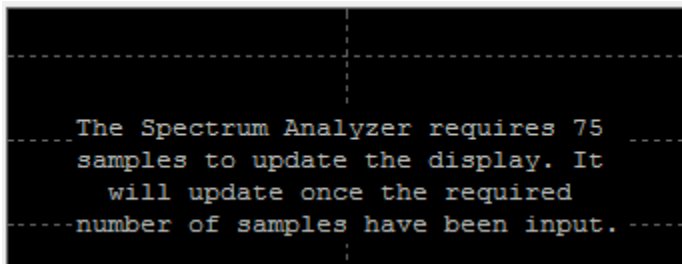

By default, the **RBW (Hz)** parameter on the **Main options** pane is set to **Auto**. In this case, the Spectrum Analyzer determines the appropriate value to ensure that there are 1024 RBW intervals over the specified frequency span. When you set **RBW (Hz)** to **Auto**, *RBW* is calculated as:

$$RBW_{auto} = \frac{span}{1024}$$

- 5 When in **Window Length** mode, you specify N_{window} and the resulting *RBW* is:

$$\frac{NENBW \times F_s}{N_{window}}$$

Sometimes, the number of input samples provided are not sufficient to achieve the resolution bandwidth that you specify. When this situation occurs, Spectrum Analyzer displays a message:

Spectrum Analyzer removes this message and displays a spectral estimate when enough data has been input.

Note The number of FFT points (N_{fft}) is independent of the window length (N_{window}). You can set them to different values if N_{fft} is greater than or equal to N_{window} .

Spectrum Estimation — Filter Bank

When you choose the **Filter Bank** method, the Spectrum Analyzer uses an analysis filter bank to estimate the power spectrum.

The filter bank splits the broadband input signal, $x(n)$, of sample rate fs , into multiple narrow band signals, $y_0(m)$, $y_1(m)$, ..., $y_{M-1}(m)$, of sample rate fs/M .

The variable M represents the number of frequency bands in the filter bank. When the frequency resolution method is set to **NumFrequencyBands**, M is equal to the value you specify for the number of frequency bands. When the frequency resolution method is set to **RBW**, M is equal to the number of data points that are needed to achieve the specified RBW value or 1024, whichever is larger. The number of taps per frequency band specifies the number of filter coefficients for each frequency band of the filter bank. The total number of filter coefficients is equal to number of taps per band times the number of frequency bands, M . For more information on the analysis filter bank and how it is implemented, see the “More About” on page 4-198 and the “Algorithm” on page 4-200 sections in `dsp.Channelizer`.

After the broadband input signal is split into multiple narrow bands, the Spectrum Analyzer computes the power in each narrow band using the following equation. Each Z_i value becomes the estimate of the power over that narrow frequency band.

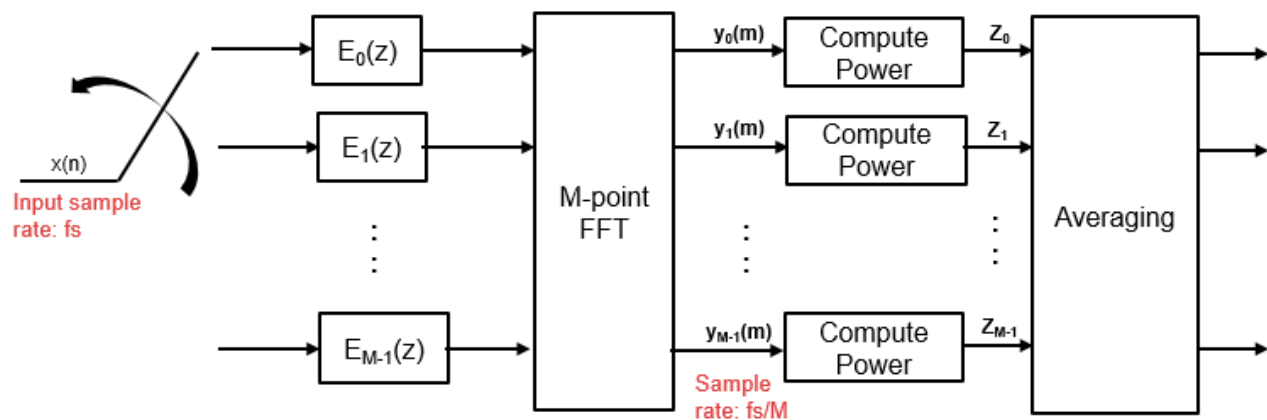

$$Z_i = \frac{1}{L} \sum_{m=0}^{L-1} |y_i[m]|^2$$

L is length of the narrow band signal, $y_i(m)$, and $i = 1, 2, \dots, M-1$.

The power values in all the narrow bands (denoted by the Z_i) form the Z vector.

$$Z = [Z_0, Z_1, Z_2, \dots, Z_{M-1}]$$

The current Z vector is averaged with the previous Z vectors using one of the two moving average methods: Running or Exponential weighting. The output of the averaging operation forms the spectral estimate vector.

The Spectrum Analyzer uses the **RBW (Hz)** or the **Number of frequency band** property in the **Spectrum Settings** pane to determine the input frame length.

Spectrum Analyzer requires a minimum number of samples to compute a spectral estimate. This number of input samples required to compute one spectral update is shown as **Samples/update** in the **Main options** pane. This value is directly related to resolution bandwidth, RBW , by the following equation.

$$N_{samples} = \frac{F_s}{RBW}$$

F_s is the sample rate of the input signal. Spectrum Analyzer shows sample rate in the **Main Options** pane of the **Spectrum Settings** pane.

- 1 When in **RBW (Hz)** mode, you can set the resolution bandwidth using the value of the **RBW (Hz)** parameter on the **Main options** pane of the **Spectrum Settings** pane. You must specify a value to ensure that there are at least two RBW intervals over the specified frequency span. The ratio of the overall span to RBW must be greater than two:

$$\frac{span}{RBW} > 2$$

By default, the **RBW** parameter on the **Main options** pane is set to Auto. In this case, the Spectrum Analyzer determines the appropriate value to ensure that there are 1024 RBW

intervals over the specified frequency span. Thus, when you set **RBW** to Auto, it is calculated by the following equation. $RBW_{auto} = \frac{span}{1024}$

- 2 When in **Number of frequency bands** mode, you specify the input frame size. When the number of frequency bands is Auto, the resulting RBW is:

$$RBW = \frac{F_s}{\text{Input Frame Size}}$$

When the number of frequency bands is manually specified, the resulting RBW is:

$$RBW = \frac{F_s}{\text{FFTLength}}$$

Sometimes, the number of input samples provided are not sufficient to achieve the resolution bandwidth that you specify. When this situation occurs, Spectrum Analyzer displays a message:

Spectrum Analyzer removes this message and displays a spectral estimate when enough data has been input.

Nyquist frequency interval

When the `PlotAsTwoSidedSpectrum` property is set to `true`, the interval is

$$\left[-\frac{\text{SampleRate}}{2}, \frac{\text{SampleRate}}{2} \right] + \text{FrequencyOffset} \text{ hertz.}$$

When the `PlotAsTwoSidedSpectrum` property is set to `false`, the interval is

$$\left[0, \frac{\text{SampleRate}}{2} \right] + \text{FrequencyOffset} \text{ hertz.}$$

Periodogram and Spectrogram

Spectrum Analyzer calculates and plots the power spectrum, power spectrum density, and RMS computed by the modified Periodogram estimator. For more information about the Periodogram method, see `periodogram`.

Power Spectral Density — The power spectral density (PSD) is given by the following equation.

$$\text{PSD}(f) = \frac{1}{P} \sum_{p=1}^P \frac{\left| \sum_{n=1}^{N_{FFT}} x^p[n] e^{-j2\pi f(n-1)T} \right|^2}{F_s \times \sum_{n=1}^{N_{window}} w^2[n]}$$

In this equation, $x[n]$ is the discrete input signal. On every input signal frame, Spectrum Analyzer generates as many overlapping windows as possible, with each window denoted as $x^{(p)}[n]$, and computes their periodograms. Spectrum Analyzer displays a running average of the P most current periodograms.

Power Spectrum — The power spectrum is the product of the power spectral density and the resolution bandwidth, as given by the following equation.

$$P_{\text{Spectrum}}(f) = \text{PSD}(f) \times \text{RBW} = \text{PSD}(f) \times \frac{F_s \times N \text{ENBW}}{N_{\text{window}}} = \frac{1}{P} \sum_{p=1}^P \frac{\left| \sum_{n=1}^{N_{\text{FFT}}} x^{(p)}[n] e^{-j2\pi f(n-1)T} \right|^2}{\left[\sum_{n=1}^{N_{\text{window}}} w[n] \right]^2}$$

Spectrogram — You can plot any power as a spectrogram. Each line of the spectrogram is one periodogram. The time resolution of each line is $1/\text{RBW}$, which is the minimum attainable resolution. Achieving the resolution you want may require combining several periodograms. You then use interpolation to calculate noninteger values of $1/\text{RBW}$. In the spectrogram display, time scrolls from top to bottom, so the most recent data is shown at the top of the display. The offset shows the time value at which the center of the most current spectrogram line occurred.

Frequency Vector

When set to Auto, the frequency vector for frequency-domain input is calculated by the software.

When the `PlotAsTwoSidedSpectrum` property is set to true, the frequency vector is:

$$\left[-\frac{\text{SampleRate}}{2}, \frac{\text{SampleRate}}{2} \right]$$

When the `PlotAsTwoSidedSpectrum` property is set to false, the frequency vector is:

$$\left[0, \frac{\text{SampleRate}}{2} \right]$$

Occupied BW

The *Occupied BW* is calculated as follows.

- 1 Calculate the total power in the measured frequency range.
- 2 Determine the lower frequency value. Starting at the lowest frequency in the range and moving upward, the power distributed in each frequency is summed until this result is

$$\frac{100 - \text{OccupiedBW}\%}{2}$$

of the total power.

- 3 Determine the upper frequency value. Starting at the highest frequency in the range and moving downward, the power distributed in each frequency is summed until the result reaches

$$\frac{100 - \text{OccupiedBW}\%}{2}$$

of the total power.

- 4 The bandwidth between the lower and upper power frequency values is the occupied bandwidth.
- 5 The frequency halfway between the lower and upper frequency values is the center frequency.

Distortion Measurements

The *Distortion Measurements* are computed as follows.

- 1 Spectral content is estimated by finding peaks in the spectrum. When the algorithm detects a peak, it records the width of the peak and clears all monotonically decreasing values. That is, the algorithm treats all these values as if they belong to the peak. Using this method, all spectral content centered at DC (0 Hz) is removed from the spectrum and the amount of bandwidth cleared (W_0) is recorded.
- 2 The fundamental power (P_1) is determined from the remaining maximum value of the displayed spectrum. A local estimate (Fe_1) of the fundamental frequency is made by computing the central moment of the power near the peak. The bandwidth of the fundamental power content (W_1) is recorded. Then, the power from the fundamental is removed as in step 1.
- 3 The power and width of the higher-order harmonics (P_2, W_2, P_3, W_3 , etc.) are determined in succession by examining the frequencies closest to the appropriate multiple of the local estimate (Fe_1). Any spectral content that decreases monotonically about the harmonic frequency is removed from the spectrum first before proceeding to the next harmonic.
- 4 Once the DC, fundamental, and harmonic content is removed from the spectrum, the power of the remaining spectrum is examined for its sum ($P_{remaining}$), peak value ($P_{maxspur}$), and median value ($P_{estnoise}$).
- 5 The sum of all the removed bandwidth is computed as $W_{sum} = W_0 + W_1 + W_2 + \dots + W_n$.

The sum of powers of the second and higher-order harmonics are computed as $P_{harmonic} = P_2 + P_3 + P_4 + \dots + P_n$.

- 6 The sum of the noise power is estimated as:

$$P_{noise} = (P_{remaining} \cdot dF + P_{est.noise} \cdot W_{sum}) / RBW$$

Where dF is the absolute difference between frequency bins, and RBW is the resolution bandwidth of the window.

- 7 The metrics for SNR, THD, SINAD, and SFDR are then computed from the estimates.

$$THD = 10 \cdot \log_{10} \left(\frac{P_{harmonic}}{P_1} \right)$$

$$SINAD = 10 \cdot \log_{10} \left(\frac{P_1}{P_{harmonic} + P_{noise}} \right)$$

$$SNR = 10 \cdot \log_{10} \left(\frac{P_1}{P_{noise}} \right)$$

$$SFDR = 10 \cdot \log_{10} \left(\frac{P_1}{\max(P_{maxspur}, \max(P_2, P_3, \dots, P_n))} \right)$$

Harmonic Measurements

- 1 The harmonic distortion measurements use the spectrum trace shown in the display as the input to the measurements. The default Hann window setting of the Spectrum Analyzer may exhibit leakage that can completely mask the noise floor of the measured signal.

The harmonic measurements attempt to correct for leakage by ignoring all frequency content that decreases monotonically away from the maximum of harmonic peaks. If the window leakage covers more than 70% of the frequency bandwidth in your spectrum, you may see a blank reading (-) reported for **SNR** and **SINAD**. If your application can tolerate the increased equivalent noise bandwidth (ENBW), consider using a Kaiser window with a high attenuation (up to 330 dB) to minimize spectral leakage.

- 2 The DC component is ignored.
- 3 After windowing, the width of each harmonic component masks the noise power in the neighborhood of the fundamental frequency and harmonics. To estimate the noise power in each region, Spectrum Analyzer computes the median noise level in the nonharmonic areas of the spectrum. It then extrapolates that value into each region.
- 4 N^{th} order intermodulation products occur at $A*F1 + B*F2$,
 where $F1$ and $F2$ are the sinusoid input frequencies and $|A| + |B| = N$. A and B are integer values.
- 5 For intermodulation measurements, the third-order intercept (TOI) point is computed as follows, where P is power in decibels of the measured power referenced to 1 milliwatt (dBm):

- $TOI_{lower} = P_{F1} + (P_{F2} - P_{(2F1-F2)})/2$
- $TOI_{upper} = P_{F2} + (P_{F1} - P_{(2F2-F1)})/2$
- $TOI = (TOI_{lower} + TOI_{upper})/2$

Averaging Method

The moving average is calculated using one of the two methods:

- Running — For each frame of input, average the last N -scaled Z vectors, which are computed by the algorithm. The variable N is the value you specify for the number of spectral averages. If the algorithm does not have enough Z vectors, the algorithm uses zeros to fill the empty elements.

- **Exponential** — The moving average algorithm using the exponential weighting method updates the weights and computes the moving average recursively for each Z vector that comes in by using the following recursive equations:

$$w_N = \lambda w_{N-1} + 1$$

$$\bar{z}_N = \left(1 - \frac{1}{w_N}\right)\bar{z}_{N-1} + \left(\frac{1}{w_N}\right)z_N$$

- λ — Forgetting factor
- w_N — Weighting factor applied to the current Z vector
- z_N — Current Z vector
- \bar{z}_{N-1} — Moving average until the previous Z vector
- $\left(1 - \frac{1}{w_N}\right)\bar{z}_{N-1}$ — Effect of the previous Z vectors on the average
- \bar{z}_N — Moving average including the current Z vector

Version History

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

This block can be used for simulation visibility in systems that generate code, but is not included in the generated code.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block can be used for simulation visibility in subsystems that generate HDL code, but is not included in the hardware implementation.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

This block can be used for simulation visibility in systems that generate PLC code, but is not included in the generated code.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

This block accepts fixed-point input, but converts it to `double` for display.

Spectrum Estimator

Estimate power spectrum or power-density spectrum

Library

Estimation / Power Spectrum Estimation

dspspect3

Description

The Spectrum Estimator block outputs the power spectrum or power-density spectrum of a real or complex input signal, using the Welch method of averaged modified periodograms and the filter bank approach.

When you choose the filter bank approach, the block uses an analysis filter bank to estimate the power spectrum. The filter bank approach produces a spectral estimate with a higher resolution, a more accurate noise floor, and more precise peaks than the Welch method, with low or no spectral leakage. They come at the expense of increased computation and slower tracking.

When you choose the Welch method, the block computes the averaged modified periodograms to compute the spectral estimate. The block buffers the input data into overlapping segments. Use the block parameters to set the length of the data segments, the amount of data overlap between consecutive segments, and other features of the power spectrum.

For more information on the Welch method and the filter bank method, see “Algorithms” on page 2-1225.

Each column of the input signal is treated as a separate channel. If the input is a two-dimensional signal, the first dimension represents the channel length (or frame size) and the second dimension represents the number of channels. If the input is a one-dimensional signal, then it is interpreted as a single channel.

Parameters

Main Tab

Method

Specify the spectral estimation method.

- **Filter bank** (default) — An analysis filter bank splits the broadband input signal into multiple narrow subbands. The block computes the power in each narrow frequency band, and the computed value is the spectral estimate over the respective frequency band.

- **Welch** — The block uses the Welch averaged modified periodograms method to compute the power spectrum over the narrow subbands.

Number of taps per band

Specify the number of filter coefficients, or taps, for each frequency band. This value corresponds to the number of filter coefficients per polyphase branch. The total number of filter coefficients is equal to **Number of taps per band** times the FFT length.

This parameter applies when you set **Method** to `Filter bank`. The default is 12.

Spectrum type

Type of spectrum to compute. You can set this parameter to:

- **Power** (default) — Compute the power spectrum.
- **Power density** — Compute the power spectral density.

This parameter is nontunable.

Frequency resolution method

Frequency resolution method. You can set this parameter to:

- **Auto** (default) — The Spectrum Estimator block computes the resolution bandwidth (RBW) so that the frequency span fits 1024 RBW intervals.
 - **Welch method** — The window length, *winLen*, is calculated using $winLen = NENBW \times Fs/RBW$. *NENBW* is the equivalent noise bandwidth of the window and *Fs* is the sample rate.
 - **Filter bank method** — The FFT length is the ceiling of the ratio of **Sample rate (Hz)** to the computed resolution bandwidth.
- **RBW** — Specify the resolution bandwidth, which is used to determine the window length (Welch method) or the FFT length (filter bank method). When the block uses the Welch method, the behavior is equivalent to that of the Spectrum Analyzer block. The window length is calculated using $winLen = NENBW \times Fs/RBW$. *NENBW* is the equivalent noise bandwidth of the window and *Fs* is the sample rate. The FFT length is equal to the ceiling of the ratio of **Sample rate (Hz)** to **RBW (Hz)**.
- **Window length** — Specify the window or segment length to use in the Welch algorithm. This option appears when you set **Method** to `Welch`.
- **Number of frequency bands** — Specify the number of polyphase branches of the analysis filter bank. This value corresponds to the FFT length that the filter bank uses. This option appears when you set **Method** to `Filter bank`.

This parameter is nontunable.

RBW (Hz)

Resolution bandwidth, specified as a positive scalar in Hz. The default is 5. This parameter applies when you set **Frequency resolution method** to `RBW`. The ceiling of the ratio of the frequency span to RBW must be greater than 2.

This parameter is nontunable.

Number of bands source

Source of the number of frequency bands. This parameter applies when you set **Method** to `Filter bank` and **Frequency resolution method** to `Number of frequency bands`. You can set this parameter to:

- Same as input frame length (default) — The FFT length is set to the frame size of the input.
- Specify on dialog — The FFT length is the value you specify in **Number of bands**.

This parameter is nontunable.

Number of bands

Number of frequency bands, or the FFT length the filter bank uses to compute the power spectral estimate, specified as a positive scalar. The default is 1024. This parameter applies when you set **Method** to Filter bank, **Frequency resolution method** to Number of frequency bands, and **Number of bands source** to Specify on dialog. This parameter is nontunable.

Window length source

Source of the window length value. This parameter applies when you set **Method** to Welch and **Frequency resolution method** to Window length. You can set this parameter to:

- Same as input frame length (default) — Window length is set to the frame size of the input. Specify this option to obtain behavior equivalent to that of the Periodogram block.
- Specify on dialog — Window length is the value you specify in the **Window length** parameter.

This parameter is nontunable.

Window length

Length of the window used to compute the spectrum estimate, specified as a positive integer scalar greater than 2. The default is 1024. This parameter applies when you set **Method** to Welch, **Frequency resolution method** to Window length, and **Window length source** to Specify on dialog. This parameter is nontunable.

FFT length source

Source of the FFT length value. This parameter applies when you set **Method** to Welch and **Frequency resolution method** to Window length. You can set this parameter to:

- Auto (default) — The block sets the FFT length to the frame size of the input.
- Property — The block sets the FFT length to the value you specify in **FFT length**.

This parameter is nontunable.

FFT length

Length of the FFT used to compute the spectrum estimates, specified as a positive integer scalar. This parameter applies when you set **Method** to Welch, **Frequency resolution method** to Window length, and **FFT length source** to Property. The default is 1024. This parameter is nontunable.

Inherit sample rate from input

When you select this check box, the block sample rate is computed as N/T_s , where N is the frame size of the input signal and T_s is the sample time of the input signal.

This check box applies when you do one of the following:

- Set **Method** to Welch and **Frequency resolution method** to Window length.
- Set **Method** to Filter bank and **Frequency resolution method** to Number of frequency bands.

When you clear this check box, the block sample rate is the value you specify in **Sample rate (Hz)**. By default, this check box is selected. This parameter is nontunable.

Sample rate (Hz)

Sample rate of the input signal, specified as a positive scalar. The default is 44100. This parameter applies when you do one of the following:

- Set **Frequency resolution method** to Auto or RBW.
- Set **Method** to Welch, **Frequency resolution method** to Window length, and clear the **Inherit sample rate from input** check box.
- Set **Method** to Filter bank, **Frequency resolution method** to Number of frequency bands, and clear the **Inherit sample rate from input** check box.

This parameter is nontunable.

Window function

Window function the Welch algorithm uses, specified as one of Chebyshev | Flat Top | Hamming | Hann | Kaiser | Rectangular. This parameter appears when you set **Method** to Welch. The default is Hann. This parameter is nontunable.

Sidelobe attenuation of window (dB)

Sidelobe attenuation of the window, specified as a real positive scalar greater than or equal to 45, in dB. The default is 60. This parameter appears when you set **Method** to Welch and **Window function** to Chebyshev or Kaiser. This parameter is nontunable.

Averaging method

Specify the averaging method as Exponential (default) or Running. In the exponential method, the block computes the average over samples weighted by an exponentially decaying forgetting factor. In the running averaging method, the block computes an equally weighted average of specified number of spectrum estimates defined by **Number of spectral averages** parameter.

Number of spectral averages

Number of spectral averages, specified as a positive integer scalar. The default is 1. The spectrum estimator computes the current power spectrum estimate by averaging the last N power spectrum estimates, where N is the number of spectral averages defined in **Number of spectral averages**. This parameter is nontunable.

This parameter applies when **Averaging method** is set to Running.

Specify forgetting factor from input port

Select this check box to specify the forgetting factor from an input port. When you do not select this check box, the forgetting factor is specified through the **Forgetting factor** parameter.

This parameter applies when **Averaging method** is set to Exponential.

Forgetting factor

Specify the exponential weighting forgetting factor as a scalar value greater than zero and smaller than or equal to one. The default is 0.9.

This parameter applies when you set **Averaging method** to Exponential and clear the **Specify forgetting factor from input port** parameter.

Advanced Tab

Window overlap (%)

Percentage of overlap between successive data windows, specified as a scalar from 0 and 100. The default value is 0. To enable this parameter, on the **Main Tab**, set **Method** to **Welch**. This parameter is nontunable.

Reference load (ohms)

Load used as a reference to compute the power values, specified as a real positive scalar expressed in ohms. The default value is 1. This parameter is nontunable.

Frequency range

Frequency range of the spectrum estimator. You can set this parameter to:

- **One-sided** — The spectrum estimator computes the one-sided spectrum of a real input signal. When the FFT length, `NFFT`, is even, the spectrum estimate has length $(NFFT/2) + 1$ and is computed over the frequency range $[0 \text{ SampleRate}/2]$. `SampleRate` is the sample rate of the input signal. When `NFFT` is odd, the spectrum estimate has length $(NFFT + 1)/2$ and is computed over the frequency range $[0 \text{ SampleRate}/2)$.
- **Two-sided** — The spectrum estimator computes the two-sided spectrum of a complex or real input signal. The length of the spectrum estimate is equal to the FFT length. The spectrum estimate is computed over the frequency range $[0 \text{ SampleRate})$, where `SampleRate` is the sample rate of the input signal.
- **Centered (default)** — The spectrum estimator computes the centered two-sided spectrum of a complex or real input signal. The length of the spectrum estimate is equal to the FFT length. The spectrum estimate is computed over the frequency range $(-\text{SampleRate}/2 \text{ SampleRate}/2]$ when the FFT length is even and $(-\text{SampleRate}/2 \text{ SampleRate}/2)$ when the FFT length is odd.

This parameter is nontunable.

Power units

Units used to measure power. You can set this parameter to:

- **'Watts'** (default) — The spectrum estimator measures power in watts.
- **'dBw'** — The spectrum estimator measures power in decibel-watts.
- **'dBm'** — The spectrum estimator measures power in decibel-milliwatts.

This parameter is nontunable.

Output max-hold spectrum

When you select this check box, the block computes the max-hold spectrum of the input signal by keeping, at each frequency bin, the maximum value of all the power spectrum estimates. By default, this check box is not selected. This parameter is nontunable.

Output min-hold spectrum

When you select this check box, the block computes the min-hold spectrum of the input signal by keeping, at each frequency bin, the minimum value of all the power spectrum estimates. By default, this check box is not selected. This parameter is nontunable.

Output frequency vector

When you select this check box, the block outputs the frequency vector. By default, this check box is not selected. This parameter is nontunable.

Output effective RBW

When you select this check box, the block computes the effective resolution bandwidth. By default, this check box is not selected. This parameter is nontunable.

Simulate using

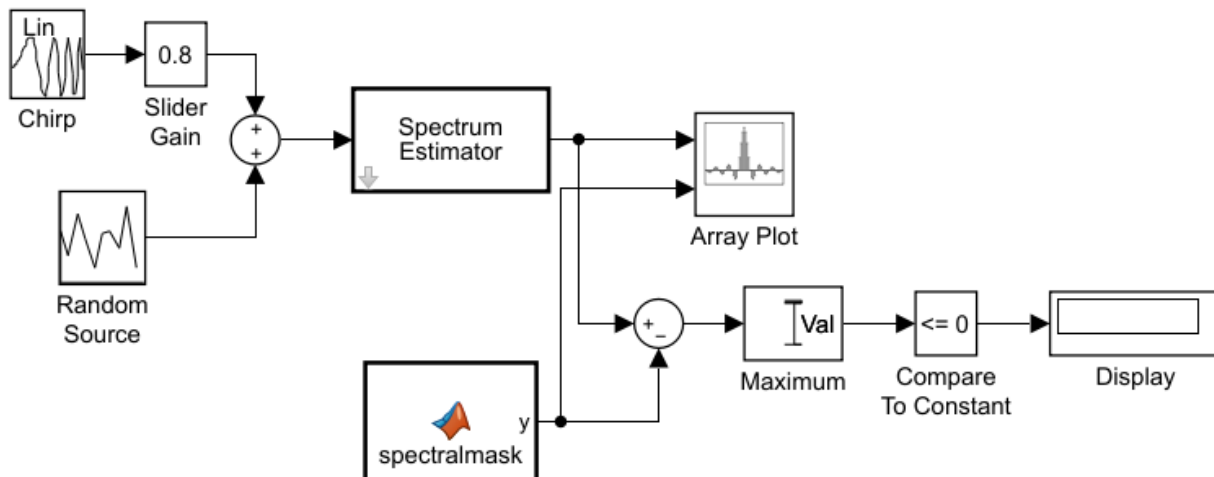

Type of simulation to run. You can set this parameter to:

- **Code generation** (default) — Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than **Interpreted execution**.
- **Interpreted execution** — Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than **Code generation**.

Example

Estimate the Power Spectral Density (PSD) of a chirp signal using the Spectrum Estimator block. Compare the PSD data with a Bluetooth® spectral mask and determine if the PSD data complies with the mask.

Estimate the Power Spectral Density

Copyright 2015 the Mathworks, Inc.

To view the complete model, enter `ex_psd_spectralmask` in the MATLAB command prompt.

Input Signal

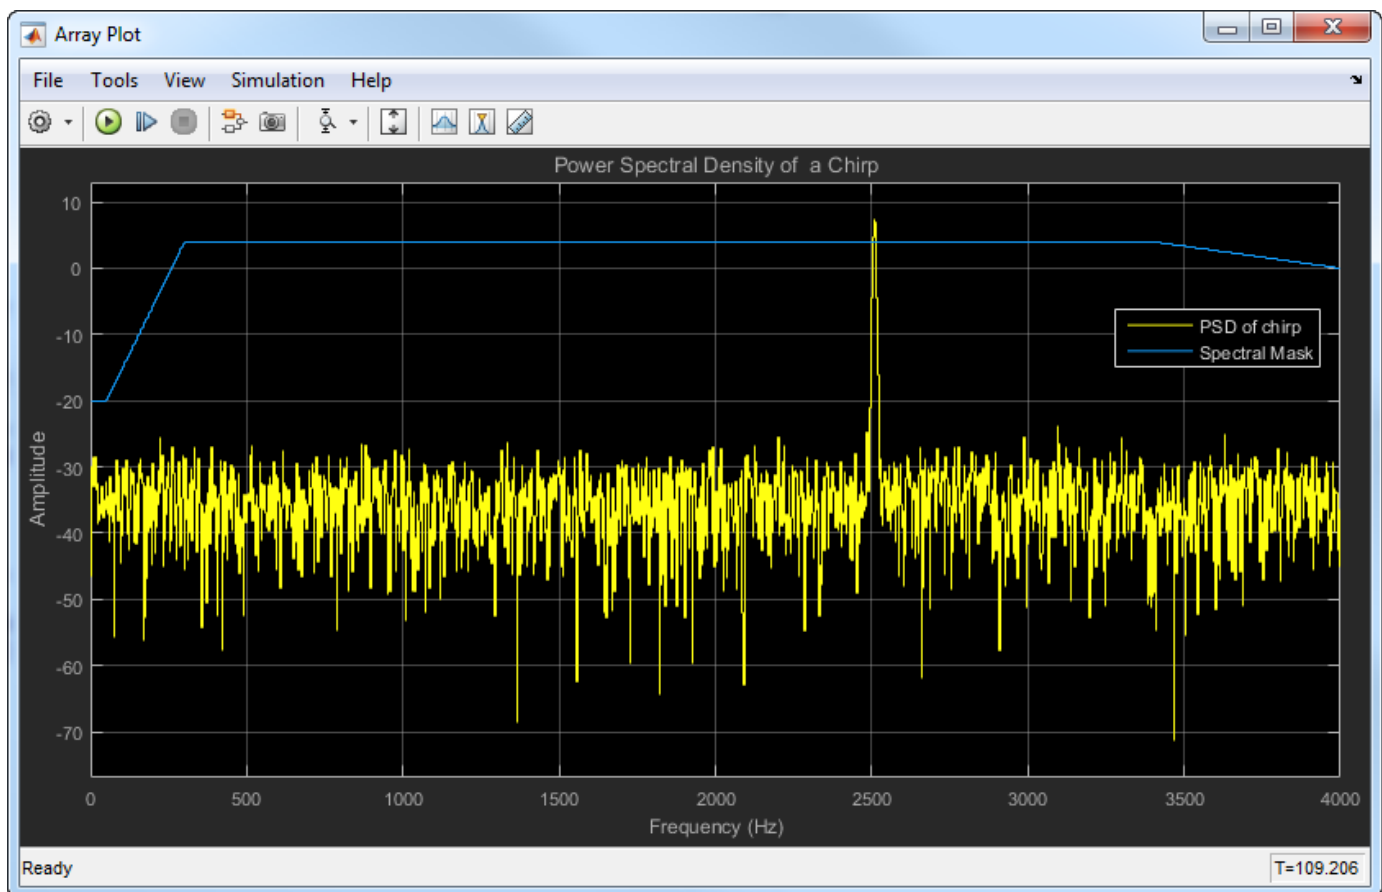

The input to the Spectrum Estimator block is a chirp signal embedded in Gaussian noise with zero mean and a variance of 0.01 . The chirp signal is amplified with a gain factor in the range $[0 \ 1]$.

Spectral Mask

The Spectral mask is created using the MATLAB Function block. The mask is based on the Bluetooth standard described in [5].

Live Processing

The Spectrum Estimator block estimates the PSD of the chirp. In this example, the PSD data is compared with the spectral mask. The Display block shows a 1 or 0, depending on whether the spectral data is within the mask or not. During simulation, you can change the power in the input signal by moving the slider in the Slider Gain block. Simultaneously, you can view this change in the Array Plot block.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point

Algorithms

Welch's Method of Averaged Modified Periodograms

When you choose the Welch method, the power spectrum estimate is averaged modified periodograms.

Given the signal input, x :

- 1 Multiply x by the window and scale the result by the window power.
- 2 Compute the FFT of the signal, Y , and take the square magnitude using $Z = Y .* \text{conj}(Y)$.
- 3 Compute the current power spectrum estimate by taking the moving average of the last N number of Z 's, and scaling the answer by the sample rate. For details on the moving average methods, see "Averaging Method" on page 2-1226.

Filter Bank

The filter-bank-based spectrum estimator uses an analysis filter bank to estimate the power spectrum. The filter bank splits a broadband input signal, $x(n)$, of sample rate fs into multiple narrow band signals, $y_0(m)$, $y_1(m)$, ..., $y_{M-1}(m)$, of sample rate fs/M .

The variable M represents the number of frequency bands in the filter bank. When you specify FFT length, M equals the FFT length. When you do not specify FFT length, M is equal to the number of rows in the input signal. The number of taps per frequency band sets the number of filter coefficients for each frequency band of the filter bank. The total number of filter coefficients is equal to number of taps per band times the number of frequency bands M . For more information on the analysis filter bank and how it is implemented, see the "More About" on page 4-198 and the "Algorithm" on page 4-200 sections in `dsp.Channelizer`.

After the broadband input signal is split into multiple narrow bands, the spectrum estimator computes the power in each narrow band using the following equation. Each Z_i value becomes the estimate of the power over that narrow frequency band.

$$Z_i = \frac{1}{L} \sum_{m=0}^{L-1} |y_i[m]|^2$$

L is length of the narrow band signal $y_i(m)$, where $i = 1, 2, \dots, M-1$.

The power values in all the narrow bands (denoted by Z_i) form the Z vector.

$$Z = [Z_0, Z_1, Z_2, \dots, Z_{M-1}]$$

The filter bank estimator algorithm averages the current Z vector with the previous Z vectors using one of the two moving average methods: running or exponential weighting. The output of the averaging operation forms the spectral estimate vector. For details on the two averaging methods, see "Averaging Method" on page 2-1226.

Averaging Method

The moving average is calculated using one of the two methods:

- **Running** — For each frame of input, average the last N -scaled Z vectors, which are computed by the algorithm. The variable N is the value you specify for the number of spectral averages. If the algorithm does not have enough Z vectors, the algorithm uses zeros to fill the empty elements.

Input frame size:
[1000 1]

Number of spectral averages (N): 6

1000 elements

Z vector	Z_1	3	4	5	4
	Z_2	5	6	7	8
	Z_3	8	4	2	9
	Z_4	3	2	7	3
	Z_5	0	0	0	0
	Z_6	0	0	0	0

Output: $(Z_1+Z_2+\dots+Z_6)/6$	3.167	2.667	3.5	4
---------------------------------	-------	-------	-----	-----	-----	-----	-----	---

- **Exponential** — The moving average algorithm using the exponential weighting method updates the weights and computes the moving average recursively for each Z vector that comes in by using the following recursive equations:

$$w_N = \lambda w_{N-1} + 1$$

$$\bar{z}_N = \left(1 - \frac{1}{w_N}\right)\bar{z}_{N-1} + \left(\frac{1}{w_N}\right)z_N$$

- λ – Forgetting factor
- w_N – Weighting factor applied to the current Z vector
- z_N – Current Z vector
- \bar{z}_{N-1} – Moving average until the previous Z vector
- $\left(1 - \frac{1}{w_N}\right)\bar{z}_{N-1}$ – Effect of the previous Z vectors on the average
- \bar{z}_N – Moving average including the current Z vector

Stack

Store inputs into LIFO register

Library

Signal Management / Buffers

dspbuff3

Description

The Stack block stores a sequence of input samples in a last in, first out (LIFO) register. The register capacity is set by the **Stack depth** parameter, and inputs can be scalars, vectors, or matrices.

The block *pushes* the input at the In port onto the top of the stack when a trigger event is received at the Push port. When a trigger event is received at the Pop port, the block *pops* the top element off the stack and holds the Out port at that value. The last input to be pushed onto the stack is always the first to be popped off.

A trigger event at the optional Rst port empties the stack contents. When you select **Clear output port on reset**, then a trigger event at the Rst port empties the stack *and* sets the value at the Out port to zero. This setting also applies when a disabled subsystem containing the Stack block is reenabled; the Out port value is only reset to zero in this case when you select **Clear output port on reset**.

When two or more of the control input ports are triggered at the same time step, the operations are executed in the following order:

- 1 Rst
- 2 Push
- 3 Pop

The rate of the trigger signal must be the same as the rate of the data signal input. You specify the triggering event for the Push, Pop, and Rst ports in the **Trigger type** pop-up menu:

- **Rising edge** — Triggers execution of the block when the trigger input does one of the following:
 - Rises from a negative value to a positive value or zero
 - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)

- **Falling edge** — Triggers execution of the block when the trigger input does one of the following:
 - Falls from a positive value to a negative value or zero
 - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)

- **Either edge** — Triggers execution of the block when the trigger input is a **Rising edge** or **Falling edge** (as described above).
- **Non-zero sample** — Triggers execution of the block at each sample time that the trigger input is not zero.

Note If your model contains any referenced models that use a Stack block with the **Push full stack** parameter set to `Dynamic reallocation`, you cannot simulate your top-level model in Simulink Accelerator mode.

The **Push full stack** parameter specifies the block's behavior when a trigger is received at the Push port but the register is full. The **Pop empty stack** parameter specifies the block's behavior when a trigger is received at the Pop port but the register is empty. The following options are available for both cases:

- **Ignore** — Ignore the trigger event, and continue the simulation.
- **Warning** — Ignore the trigger event, but display a warning message in the MATLAB command window.
- **Error** — Display an error dialog box and terminate the simulation.

Note The **Push full stack** and **Pop empty stack** parameters are diagnostic parameters. Like all diagnostic parameters on the Configuration Parameters dialog box, they are set to `Ignore` in the code generated for this block by Simulink Coder code generation software.

The **Push full stack** parameter additionally offers the **Dynamic reallocation** option, which dynamically resizes the register to accept as many additional inputs as memory permits. To find out how many elements are on the stack at a given time, enable the Num output port by selecting the **Show number of stack entries port** parameter.

Note When `Dynamic reallocation` is selected, the **System target file** parameter on the **Code Generation** pane of the Model Configuration Parameters dialog box must be set to `grt_malloc.tlc` – Generic Real-Time Target with dynamic memory allocation.

Examples

Example 1

The table below illustrates the Stack block's operation for a **Stack depth** of 4, **Trigger type** of `Either edge`, and **Clear output port on reset** enabled. Because the block triggers on both rising and falling edges in this example, each transition from 1 to 0 or 0 to 1 in the Push, Pop, and Rst columns below represents a distinct trigger event. A 1 in the Empty column indicates an empty buffer, while a 1 in the Full column indicates a full buffer.

In	Push	Pop	Rst	Stack	Out	Empty	Full	Num
1	0	0	0	top  bottom	0	1	0	0
2	1	0	0	top  bottom	0	0	0	1
3	0	0	0	top  bottom	0	0	0	2
4	1	0	0	top  bottom	0	0	0	3
5	0	0	0	top  bottom	0	0	1	4

In	Push	Pop	Rst	Stack	Out	Empty	Full	Num
6	0	1	0	top  bottom	5	0	0	3
7	0	0	0	top  bottom	4	0	0	2
8	0	1	0	top  bottom	3	0	0	1
9	0	0	0	top  bottom	2	1	0	0
10	1	0	0	top  bottom	2	0	0	1
11	0	0	0	top  bottom	2	0	0	2
12	1	0	1	top  bottom	0	0	0	1

Note that at the last step shown, the Push and Rst ports are triggered simultaneously. The Rst trigger takes precedence, and the stack is first cleared and then pushed.

Parameters

Stack depth

The number of entries that the LIFO register can hold.

Trigger type

The type of event that triggers the block's execution. The rate of the trigger signal must be the same as the rate of the data signal input.

Push full stack

Response to a trigger received at the Push port when the register is full. Inputs to this port must have the same built-in data type as inputs to the Pop and Rst input ports.

When Dynamic reallocation is selected, the **System target file** parameter on the **Code Generation** pane of the Model Configuration Parameters dialog box must be set to `grt_malloc.tlc` – Generic Real-Time Target with dynamic memory allocation.

Pop empty stack

Response to a trigger received at the Pop port when the register is empty. Inputs to this port must have the same built-in data type as inputs to the Push and Rst input ports.

Show empty stack indicator port

Enable the Empty output port, which is high (1) when the stack is empty, and low (0) otherwise.

Show full stack indicator port

Enable the Full output port, which is high (1) when the stack is full, and low (0) otherwise. The Full port remains low when you select **Dynamic reallocation** from the **Push full stack** parameter.

Show number of stack entries port

Enable the Num output port, which tracks the number of entries currently on the stack. When inputs to the In port are double-precision values, the outputs from the Num port are double-precision values. Otherwise, the outputs from the Num port are 32-bit unsigned integer values.

Show reset port to clear internal stack buffer

Enable the Rst input port, which empties the stack when the trigger specified by the **Trigger type** is received. Inputs to this port must have the same built-in data type as inputs to the Push and Pop input ports.

Clear output port on reset

Reset the Out port to zero (in addition to clearing the stack) when a trigger is received at the Rst input port.

Supported Data Types

Port	Supported Data Types
In	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Push	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers <p>Inputs to this port must have the same built-in data type as inputs to the Pop and Rst input ports</p>

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The following limitations apply:

- Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.
- When `Dynamic reallocation` is selected, the **System target file** parameter on the **Code Generation** pane of the Configuration Parameters dialog box must be set to `grt_malloc.tlc` - Generic Real-Time Target with dynamic memory allocation.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Topics

“Queues”

Standard Deviation

Standard deviation of input or sequence of inputs

Library: DSP System Toolbox / Statistics

Description

The Standard Deviation block computes the standard deviation of each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the standard deviation of the entire input. You can specify the dimension using the **Find the standard deviation value over** parameter. The Standard Deviation block can also track the standard deviation in a sequence of inputs over a period of time. To track the standard deviation in a sequence of inputs, select the **Running standard deviation** parameter.

Note The **Running** mode in the Standard Deviation block will be removed in a future release. To compute the running standard deviation in Simulink, use the Moving Standard Deviation block instead.

Ports

Input

In — Data input

vector | matrix | N -D array

The block accepts real-valued or complex-valued multichannel and multidimensional inputs.

This port is unnamed until you select the **Running standard deviation** parameter and set the **Reset port** parameter to any option other than None.

Data Types: single | double

Rst — Reset port

scalar

Specify the reset event that causes the block to reset the running standard deviation. The sample time of the **Rst** input must be a positive integer multiple of the input sample time.

Dependencies

To enable this port, select the **Running standard deviation** parameter and set the **Reset port** parameter to any option other than None.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean

Output

Port_1 — Standard deviation along the specified dimension

scalar | vector | matrix | N -D array

The data type of the output matches the data type of the input.

When you do not select the **Running standard deviation** parameter, the block computes the standard deviation in each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the standard deviation of the entire input at each individual sample time. Each element in the output array y is the standard deviation of the corresponding column, row, or entire input. The output array y depends on the setting of the **Find the standard deviation value over** parameter. Consider a three-dimensional input signal of size M -by- N -by- P . When you set **Find the standard deviation value over** to:

- **Entire input** — The output at each sample time is a scalar that contains the standard deviation of the M -by- N -by- P input matrix.
- **Each row** — The output at each sample time consists of an M -by-1-by- P array, where each element contains the standard deviation of each vector over the second dimension of the input. For an M -by- N matrix input, the output at each sample time is an M -by-1 column vector.
- **Each column** — The output at each sample time consists of a 1-by- N -by- P array, where each element contains the standard deviation of each vector over the first dimension of the input. For an M -by- N matrix input, the output at each sample time is a 1-by- N row vector.

In this mode, the block treats length- M unoriented vector inputs as M -by-1 column vectors.

- **Specified dimension** — The output at each sample time depends on the value of the **Dimension** parameter. If you set the **Dimension** to 1, the output is the same as when you select **Each column**. If you set the **Dimension** to 2, the output is the same as when you select **Each row**. If you set the **Dimension** to 3, the output at each sample time is an M -by- N matrix containing the standard deviation of each vector over the third dimension of the input.

When you select **Running standard deviation**, the block tracks the standard deviation of each channel in a time sequence of inputs. In this mode, you must also specify a value for the **Input processing** parameter.

- **Elements as channels (sample based)** — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size M -by- N -by- P , the block outputs an M -by- N -by- P array. Each element y_{ijk} of the output contains the standard deviation of the element u_{ijk} for all inputs since the last reset.

When a reset event occurs, the running standard deviation y_{ijk} in the current frame is reset to the element u_{ijk} .

- **Columns as channels (frame based)** — The block treats each column of the input as a separate channel. This option does not support input signals with more than two dimensions. For a two-dimensional input signal of size M -by- N , the block outputs an M -by- N matrix. Each element y_{ij} of the output contains the standard deviation of the elements in the j th column of all inputs since the last reset, up to and including the element u_{ij} of the current input.

When a reset event occurs, the running standard deviation for each channel becomes the standard deviation of all the samples in the current input frame, up to and including the current input sample.

Data Types: single | double

Parameters

Main Tab

Running standard deviation — Option to select running standard deviation

off (default) | on

When you select the **Running standard deviation** parameter, the block tracks the standard deviation value of each channel in a time sequence of inputs.

Find the standard deviation value over — Dimension over which the block computes the standard deviation

Each column (default) | Entire input | Each row | Specified dimension

- **Each column** — The block outputs the standard deviation over each column.
- **Each row** — The block outputs the standard deviation over each row.
- **Entire input** — The block outputs the standard deviation over the entire input.
- **Specified dimension** — The block outputs the standard deviation over the dimension, specified in the **Dimension** parameter.

Dependencies

To enable this parameter, clear the **Running standard deviation** parameter.

Dimension — Custom dimension

1 (default) | scalar

Specify the dimension (one-based value) of the input signal over which the standard deviation is computed. The value of this parameter must be greater than 0 and less than the number of dimensions in the input signal.

Dependencies

To enable this parameter, set **Find the standard deviation value over** to **Specified dimension**.

Input processing — Method to process the input in running mode

Columns as channels (frame based) (default) | Elements as channels (sample based)

- **Columns as channels (frame based)** — The block treats each column of the input as a separate channel. This option does not support input signals with more than two dimensions. For a two-dimensional input signal of size M -by- N , the block outputs an M -by- N matrix. Each element y_{ij} of the output contains the standard deviation of the elements in the j th column of all inputs since the last reset, up to and including the element u_{ij} of the current input.

When a reset event occurs, the running standard deviation for each channel becomes the standard deviation of all the samples in the current input frame, up to and including the current input sample.

- **Elements as channels (sample based)** — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size M -by- N -by- P , the block outputs an

M -by- N -by- P array. Each element y_{ijk} of the output contains the standard deviation of the element u_{ijk} for all inputs since the last reset.

When a reset event occurs, the running standard deviation y_{ijk} in the current frame is reset to the element u_{ijk} .

Variable-Size Inputs

When your inputs are of variable size, and you select the **Running standard deviation** parameter, then:

- If you set the **Input processing** parameter to `Elements as channels (sample based)`, the state is reset.
- If you set the **Input processing** parameter to `Columns as channels (frame based)`, then:
 - When the input size difference is in the number of channels (number of columns), the state is reset.
 - When the input size difference is in the length of channels (number of rows), no reset occurs and the running operation is carried out as usual.

Dependencies

To enable this parameter, select the **Running standard deviation** parameter.

Reset port — Reset event

None (default) | Rising edge | Falling edge | Either edge | Non-zero sample

The block resets the running standard deviation whenever a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer multiple of the input sample time.

When a reset event occurs while the **Input processing** parameter is set to `Elements as channels (sample based)`, the running standard deviation for each channel is initialized to the value in the corresponding channel of the current input. Similarly, when the **Input processing** parameter is set to `Columns as channels (frame based)`, the running standard deviation for each channel becomes the standard deviation of all the samples in the current input frame, up to and including the current input sample.

Use this parameter to specify the reset event.

- `None` — Disables the **Rst** port.
- `Rising edge` — Triggers a reset operation when the **Rst** input does one of the following:
 - Rises from a negative value to either a positive value or zero.
 - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.

- **Falling edge** — Triggers a reset operation when the **Rst** input does one of the following:
 - Falls from a positive value to a negative value or zero.
 - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.

- **Either edge** — Triggers a reset operation when the **Rst** input is a Rising edge or Falling edge.
- **Non-zero sample** — Triggers a reset operation at each sample time, when the **Rst** input is not zero.

Note When running simulations in the Simulink multitasking mode, reset signals have a one-sample latency. Therefore, when the block detects a reset event, there is a one-sample delay at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Dependencies

To enable this parameter, select the **Running standard deviation** parameter.

More About

Standard Deviation

The standard deviation of a discrete-time signal is the square root of the variance of the signal.

Standard deviation gives a measure of deviation of the signal from its mean value.

For purely real or imaginary input, u , of size M -by- N , the standard deviation is given by the following equation:

$$y = \sigma = \sqrt{\frac{\sum_{i=1}^M \sum_{j=1}^N |u_{ij}|^2 - \frac{\left| \sum_{i=1}^M \sum_{j=1}^N u_{ij} \right|^2}{M*N}}{M*N - 1}}$$

- u_{ij} is the input data element at indices i, j .
- M is the length of the j th column.
- N is the number of columns.

For complex inputs, the standard deviation is given by the following equation:

$$\sigma = \sqrt{\sigma_{Re}^2 + \sigma_{Im}^2}$$

- σ_{Re}^2 is the variance of the real part of the complex input.
- σ_{Im}^2 is the variance of the imaginary part of the complex input.

Algorithms

Standard Deviation

When you clear the **Running standard deviation** parameter in the block and specify a dimension, the block produces results identical to the MATLAB `std` function, when it is called as `y = std(u, D)`.

- u is the data input.
- D is the dimension.
- y is the standard deviation along the specified dimension.

The standard deviation along the entire input is identical to calling the `std` function as `y = std(u(:))`.

For a complex input signal, the standard deviation is the square root of the sum of the variances of the real and imaginary parts.

$$\sigma = \sqrt{\sigma_{\text{Re}}^2 + \sigma_{\text{Im}}^2}$$

Blocks

Moving Standard Deviation

SVD Solver

Solve $AX = B$ using singular value decomposition

Library: DSP System Toolbox / Math Functions / Matrices and Linear Algebra / Linear System Solvers

Description

The SVD Solver block solves the linear system $AX = B$. The linear system can be overdetermined, underdetermined, or exactly determined. The block solves the system by applying singular value decomposition (SVD) factorization to the input matrix at the **A** port.

Ports

Input

A — Input **A** matrix

M-by-*N* matrix

Specify the input matrix *A* as an *M*-by-*N* matrix through this port. Inputs *A* and *B* must have the same number of rows.

Data Types: single | double

B — **B** matrix

M-by-*L* matrix | *M*-by-1 vector

Specify the matrix *B* in the $AX = B$ equation as an *M*-by-*L* matrix or an *M*-by-1 vector.

When you specify an *M*-by-1 vector, the block treats the length-*M* unoriented vector input at port **B** as an *M*-by-1 matrix. Inputs *A* and *B* must have the same number of rows.

Data Types: single | double

Output

X — Solution to system of equations

N-by-*L* matrix

The output at the **X** port is the *N*-by-*L* matrix *X*. The block computes *X* to minimize the sum of the squares of the elements of $B - AX$ (the residual).

When *B* is a vector, this solution minimizes the vector 2-norm of the residual. When *B* is a matrix, this solution minimizes the matrix Frobenius norm of the residual. In this case, the columns of *X* are the solutions to the *L* corresponding systems $AX_k = B_k$, where B_k is the *k*th column of *B*, and X_k is the *k*th column of *X*.

X is known as the minimum-norm-residual solution to $AX = B$. The minimum-norm-residual solution is unique for overdetermined and exactly determined linear systems, but the solution is not unique for

underdetermined linear systems. Thus when you apply the SVD Solver block to an underdetermined system, the block computes X to minimize the number of nonzero entries in X .

Data Types: `single` | `double`

E — Show error status report

logical scalar

The block returns a logical scalar value of 0 if the singular value decomposition calculation converges, and a logical scalar value of 1 if the singular value decomposition calculation does not converge.

Data Types: `Boolean`

Parameters

Show error status port (E) — Select to report failure to converge

`off` (default) | `on`

Select to enable the **E** output port, which reports the failure to converge as one of the following:

- 0 — The singular value decomposition calculation converges.
- 1 — The singular value decomposition calculation does not converge.

If the singular value decomposition calculation fails to converge, the output at port **X** is an undefined matrix of the expected size.

Time Scope

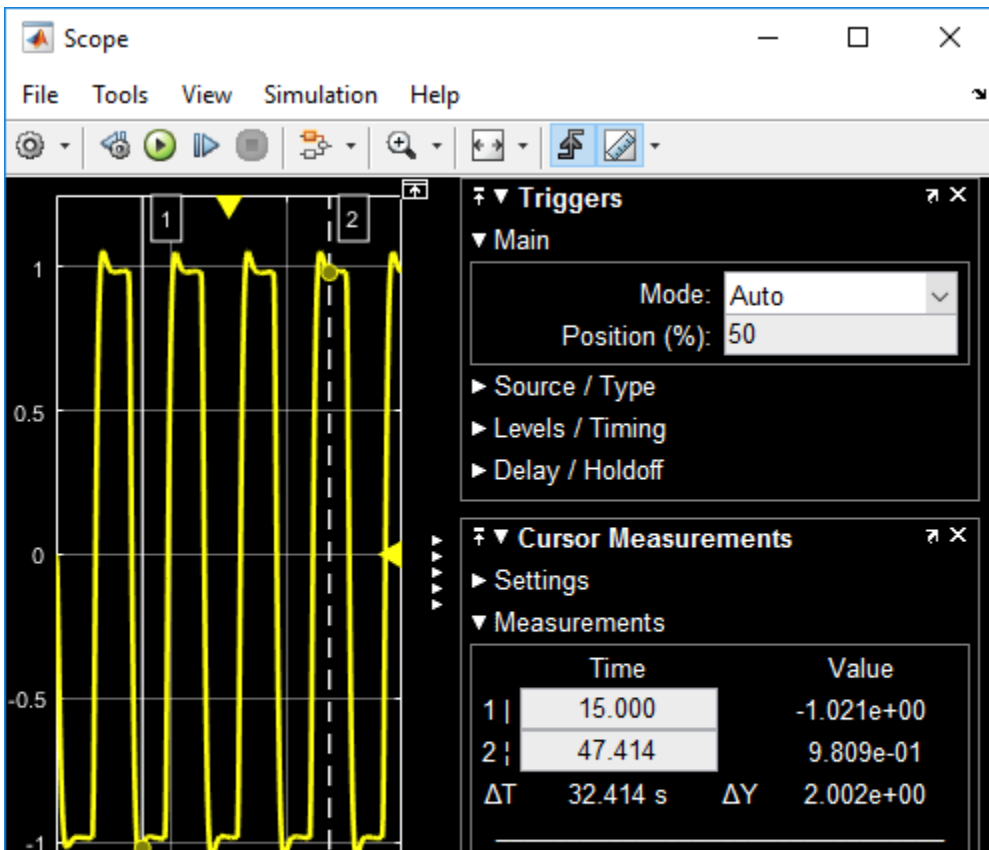

Display and analyze signals generated during simulation and log signal data to MATLAB

Library: DSP System Toolbox / Sinks
DSP System Toolbox HDL Support / Sinks

Description

The Simulink Scope block and DSP System Toolbox Time Scope block display time domain signals.

The two blocks have identical functionality, but different default settings. The Time Scope is optimized for discrete time processing. The Scope is optimized for general time-domain simulation. For a side-by-side comparison, see “Simulink Scope Versus DSP System Toolbox Time Scope” (Simulink).

Oscilloscope features:

- Triggers — Set triggers to sync repeating signals and pause the display when events occur.
- Cursor Measurements — Measure signal values using vertical and horizontal cursors.
- Signal Statistics — Display the maximum, minimum, peak-to-peak difference, mean, median, and RMS values of a selected signal.
- Peak Finder — Find maxima, showing the x-axis values at which they occur.
- Bilevel Measurements — Measure transitions, overshoots, undershoots, and cycles.

You must have a Simscape™ or DSP System Toolbox license to use the Peak Finder, Bilevel Measurements, and Signal Statistics.

Scope display features:

- Simulation control — Debug models from a Scope window using **Run**, **Step Forward**, and **Step Backward** toolbar buttons.
- Multiple signals — Plot multiple signals on the same y-axis (display) using multiple input ports.
- Multiple y-axes (displays) — Display multiple y-axes. All the y-axes have a common time range on the x-axis.
- Modify parameters — Modify scope parameter values before and during a simulation.
- Axis autoscaling — Autoscale axes during or at the end of a simulation. Margins are drawn at the top and bottom of the axes.
- Display data after simulation — Scope data is saved during a simulation. If a scope is closed at the start of a simulation, when you open the scope after a simulation, the scope displays simulation results for attached input signals.

Note If you have a high sample rate or long simulation time, you may run into issues with memory or system performance because the scope saves data internally. To limit the amount of data saved for scope visualization, use the Limit data points to last property.

For information on controlling a scope programmatically, see “Control Scope Blocks Programmatically” (Simulink).

Limitations

- Do not use scope blocks in a Library. If you place a scope block inside a library block with a locked link or in a locked library, Simulink displays an error when trying to open the scope window. To display internal data from a library block, add an output port to the library block, and then connect the port to a Scope block in your model.
- If you step through a model, the scope only updates when the scope block runs. This means that the time shown in the status bar may not match the model time.
- When connected to a constant signal, a scope block may plot a single point.
- The scope shows gaps in the display when the signal value is NaN.

- When you visualize multiple frame-based signals in the scope, some samples of signals with a frame size of 1 might not be displayed. To visualize these signals, move the signals with frame size of 1 to a separate scope.
- Scope displays have limitations in Rapid Accelerator mode. See “Behavior of Scopes and Viewers with Rapid Accelerator Mode” (Simulink)
- When the Scope is in a ForEach subsystem, the scope only displays the last index.

Ports

Input

Port_1 — Signal or signals to visualize

scalar | vector | matrix | array | bus | nonvirtual bus

Connect the signals you want to visualize. You can have up to 96 input ports. Input signals can have these characteristics:

- **Type** — Continuous (sample-based) or discrete (sample-based and frame-based).
- **Data type** — Any data type that Simulink supports. See “Data Types Supported by Simulink” (Simulink).
- **Dimension** — Scalar, one dimensional (vector), two dimensional (matrix), or multidimensional (array). Display multiple channels within one signal depending on the dimension. See “Signal Dimensions” (Simulink) and “Determine Signal Dimensions” (Simulink).

Input Limitations

- When the input is a constant signal, the scope plots a single point.
- The scope shows gaps in the display when the signal value is NaN.
- When you visualize multiple frame-based signals in the scope, some samples of signals with a frame size of 1 might not be displayed. To visualize these signals, move the signals with frame size of 1 to a separate scope.

Bus Support

You can connect nonvirtual bus and arrays of bus signals to a scope. To display the bus signals, use normal or accelerator simulation mode. The scope displays each bus element signal in the order the elements appear in the bus, from the top to the bottom. Nested bus elements are flattened.

To log nonvirtual bus signals with a scope, set the **Save format** parameter to **Dataset**. You can use any **Save format** to log virtual bus signals.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Properties

Configuration Properties

The Configuration Properties dialog box controls various properties about the scope displays. From the scope menu, select **View > Configuration Properties**.

Main**Open at simulation start — Specify when scope window opens**

off (default for Scope) | on (default for Time Scope)

Select this check box to open the scope window when simulation starts.

Programmatic Use

See `OpenAtSimulationStart`.

Display the full path — Display block path on scope title bar

off (default) | on

Select this check box to display the block path in addition to the block name.

Number of input ports — Number of input ports on scope block

1 (default) | integer

Specify number of input ports on a Scope block, specified as an integer. The maximum number of input ports is 96.

Programmatic Use

See `NumInputPorts`.

Layout — Number and arrangement of displays

1-by-1 display (default) | an arrangement of m-by-n axes

Specify number and arrangement of displays. The maximum layout is 16 rows by 16 columns.

To expand the layout grid beyond 4 by 4, click within the dialog box and drag. Maximum of 16 rows by 16 columns.

If the number of displays is equal to the number of ports, signals from each port appear on separate displays. If the number of displays is less than the number of ports, signals from additional ports appear on the last display. For layouts with multiple columns and rows, ports are mapped down then across.

Programmatic Use

See `LayoutDimensions`.

Sample time — Simulation interval between scope updates

-1 (for inherited) (default) | positive real number

Specify the time interval between updates of the scope display. This property does not apply to floating scopes and scope viewers. For a more detailed explanation of sample time with the scope, see “Sample Time with Scope Blocks” (Simulink)

Programmatic Use

See `SampleTime`.

Input processing — Channel or element signal processing

`Elements as channels (sample based)` (default for Scope) | `Columns as channels (frame based)` (default for Time Scope)

- `Elements as channels (sample based)` - Process each element as a unique sample.
- `Columns as channels (frame based)` - Process signal values in a channel as a group of values from multiple time intervals. Frame-based processing is available only with discrete input signals.

Programmatic Use

See `FrameBasedProcessing`.

Maximize axes — Maximize size of plots

`Off` (default for Scope) | `Auto` (default for Time Scope) | `On`

- `Auto` - If “Title” on page 2-0 and “Y-label” on page 2-0 properties are not specified, maximize all plots.
- `On` - Maximize all plots. Values in **Title** and **Y-label** are hidden.
- `Off` - Do not maximize plots.

Programmatic Use

See `MaximizeAxes`.

Time**Time span — Length of x-axis to display**

`Auto` (default) | `User defined` | `One frame period`

- `Auto` — Difference between the simulation start and stop times.

The block calculates the beginning and end times of the time range using the “Time display offset” on page 2-0 and “Time span” on page 2-0 properties. For example, if you set the **Time display offset** to 10 and the **Time span** to 20, the scope sets the time range from 10 to 30.

- **User defined** — Enter any value less than the total simulation time.
- **One frame period** — Use the frame period of the input signal to the Time Scope block. This option is only available when the **Input processing** parameter is set to **Columns as channels** (frame based).

Programmatic Use

See `TimeSpan`.

Time span overrun action — Display data beyond visible x-axis

Wrap (default) | Scroll

Specify how to display data beyond the visible x-axis range.

You can see the effects of this option only when plotting is slow with large models or small step sizes.

- **Wrap** — Draw a full screen of data from left to right, clear the screen, and then restart drawing the data from the left.
- **Scroll** — Move data to the left as new data is drawn on the right. This mode is graphically intensive and can affect run-time performance.

Programmatic Use

See `TimeSpanOverrunAction`.

Time units — x-axis units

None (default for Scope) | Metric (default for Time Scope) | Seconds

- **Metric** — Display time units based on the length of “Time span” on page 2-0 .
- **Seconds** — Display time in seconds.
- **None** — Do not display time units.

Programmatic Use

See `TimeUnits`.

Time display offset — x-axis offset

0 (default) | scalar | vector

Offset the x-axis by a specified time value, specified as a real number or vector of real numbers.

For input signals with multiple channels, you can enter a scalar or vector:

- **Scalar** — Offset all channels of an input signal by the same time value.
- **Vector** — Independently offset the channels.

Programmatic Use

See `TimeDisplayOffset`.

Time-axis labels — Display of x-axis labels

Bottom Displays Only (default for Scope) | All (default for Time Scope) | None

Specify how x-axis (time) labels display:

- All — Display x-axis labels on all y-axes.
- None — Do not display labels. Selecting None also clears the **Show time-axis label** check box.
- Bottom displays only — Display x-axis label on the bottom y-axis.

Dependencies

To enable this property, set:

- “Show time-axis label” on page 2-0 to on.
- “Maximize axes” on page 2-0 to off.

The “Active display” on page 2-0 property determines which display is affected.

Programmatic Use

See TimeAxisLabels.

Show time-axis label — Display or hide x-axis labels

off (default for Scope) | on (default for Time Scope)

Select this check box to show the x-axis label for the active display

Dependencies

To enable this property, set “Time-axis labels” on page 2-0 to All or Bottom Displays Only.

The “Active display” on page 2-0 property determines which display is affected.

Programmatic Use

See ShowTimeAxisLabel.

Display

Active display — Selected display

1 (default) | positive integer

Selected display. Use this property to control which display is changed when changing style properties and axes-specific properties.

Specify the desired display using a positive integer that corresponds to the column-wise placement index. For layouts with multiple columns and rows, display numbers are mapped down and then across.

Programmatic Use

See ActiveDisplay.

Title — Display name

%<SignalLabel> (default) | string

Title for a display. The default value %<SignalLabel> uses the input signal name for the title.

Dependency

The “Active display” on page 2-0 property determines which display is affected.

Programmatic Use

See Title.

Show Legend – Display signal legend

off (default) | on

Toggle signal legend. The names listed in the legend are the signal names from the model. For signals with multiple channels, a channel index is appended after the signal name. Continuous signals have straight lines before their names, and discrete signals have step-shaped lines.

From the legend, you can control which signals are visible. This control is equivalent to changing the visibility in the **Style** properties. In the scope legend, click a signal name to hide the signal in the scope. To show the signal, click the signal name again. To show only one signal, right-click the signal name, which hides all other signals. To show all signals, press **Esc**.

Note The legend only shows the first 20 signals. Any additional signals cannot be controlled from the legend.

Dependency

The “Active display” on page 2-0 property determines which display is affected.

Programmatic Use

See ShowLegend.

Show grid – Show internal grid lines

on (default) | off

Select this check box to show grid lines.

Dependency

The “Active display” on page 2-0 property determines which display is affected.

Programmatic Use

See ShowGrid.

Plot signals as magnitude and phase – Split display into magnitude and phase plots

off (default) | on

- On — Display magnitude and phase plots. If the signal is real, plots the absolute value of the signal for the magnitude. The phase is 0 degrees for positive values and 180 degrees for negative values. This feature is useful for complex-valued input signals. If the input is a real-valued signal, selecting this check box returns the absolute value of the signal for the magnitude.

- Off — Display signal plot. If the signal is complex, plots the real and imaginary parts on the same y-axis.

Dependency

The “Active display” on page 2-0 property determines which display is affected.

Programmatic Use

See `PlotAsMagnitudePhase`.

Y-limits (Minimum) — Minimum y-axis value

-10 (default) | real scalar

Specify the minimum value of the y-axis as a real number.

Tunable: Yes

Dependency

If you select **Plot signals as magnitude and phase**, this property only applies to the magnitude plot. The y-axis limits of the phase plot are always [-180 180].

The “Active display” on page 2-0 property determines which display is affected.

Programmatic Use

See `YLimits`.

Y-limits (Maximum) — Maximum y-axis value

10 (default) | real scalar

Specify the maximum value of the y-axis as a real number.

Tunable: Yes

Dependency

If you select **Plot signals as magnitude and phase**, this property only applies to the magnitude plot. The y-axis limits of the phase plot are always [-180 180].

The “Active display” on page 2-0 property determines which display is affected.

Programmatic Use

See `YLimits`.

Y-label — Y-axis label

none (default for Scope) | Amplitude (default for Time Scope) | string

Specify the text to display on the y-axis. To display signal units, add (`%<SignalUnits>`) to the label. At the beginning of a simulation, Simulink replaces (`%SignalUnits`) with the units associated with the signals.

Example: For a velocity signal with units of m/s, enter `Velocity (%<SignalUnits>)`.

Dependency

If you select **Plot signals as magnitude and phase**, this property does not apply. The y-axes are labeled Magnitude and Phase.

The “Active display” on page 2-0 property determines which display is affected.

Programmatic Use

See YLabel.

Logging**Limit data points to last – Limit buffered data values**

off and 5000 (default) | on | positive integer

Limit data saved by the scope internally. By default all data points are saved so that you can view the scope visualization after the simulation finishes. For simulations with **Stop time** set to `inf`, consider selecting **Limit data points to last**.

Note If you do not select **Limit data points to last** and you have a high sample rate or long simulation time, you may run into issues with memory or system performance.

When you select this property, the scope saves the latest n data points, where n the specified number of data points.

- Off — Save and plot all data values.
- On — Save specified number of data values for each signal. If the signal is frame-based, the number of buffered data values is the specified number of data values multiplied by the frame size.

In some cases, selecting this property can have the effect of plotting signals for less than the entire time range of a simulation (for example if your sample time is small). If the scope plots a portion of your signals, consider increasing the number of data points to save.

This property limits the data values plotted in the scope and the data values saved to a MATLAB variable specified in “Variable name” on page 2-0 .

Programmatic Use

See `DataLoggingLimitDataPoints` and `DataLoggingMaxPoints`.

Decimation – Reduce amount of scope data to display and save

off, 2 (default) | on | positive integer

- On — Plot and log (save) scope data every N th data point, where N is the decimation factor entered in the text box. A value of 1 buffers all data values.
- Off — Save all scope data values.

Dependency

To enable this property, select “Log data to workspace” (Simulink).

This property limits the data values plotted in the scope and the data values saved to a MATLAB variable specified in “Variable name” on page 2-0 .

Programmatic Use

See `DataLoggingDecimateData` and `DataLoggingDecimation`.

Log data to workspace — Save data to MATLAB workspace

off (default) | on

Select this check box to enable logging and enable the **Variable name**, **Save format**, and **Decimation** properties. This property does not apply to floating scopes and scope viewers.

For an example of saving signals to the MATLAB Workspace using a Scope block, see “Save Simulation Data Using Scope Block” (Simulink).

Programmatic Use

See `DataLogging`.

Variable name — Name of saved data variable

`ScopeData` (default) | string

Specify a variable name for saving scope data in the MATLAB workspace. This property does not apply to floating scopes and scope viewers.

Dependency

To enable this property, select “Log data to workspace” (Simulink).

Programmatic Use

See `DataLoggingVariableName`.

Save format — MATLAB variable format

`Dataset` (default) | `Structure With Time` | `Structure` | `Array`

Select variable format for saving data to the MATLAB workspace. This property does not apply to floating scopes and scope viewers.

- `Dataset` — Save data as a `Dataset` object, by default a `timeseries` object.
- `Structure With Time` — Save data as a structure with associated time information.
- `Structure` — Save data as a structure.
- `Array` — Save data as an array with associated time information. This format does not support variable-size data.

Dependency

To enable this property, select “Log data to workspace” (Simulink).

Programmatic Use

See `DataLoggingSaveFormat`.

Axes Scaling Properties

The **Axes Scaling** dialog controls the axes limits of the scope. To open the Axes Scaling properties, in the scope menu, select **Tools > Axes Scaling > Axes Scaling Properties**.

Axes scaling — Y-axis scaling mode

Manual (default) | Auto | After N Updates

- **Manual** — Manually scale the y-axis range with the **Scale Y-axis Limits** toolbar button.
- **Auto** — Scale the y-axis range during and after simulation. Selecting this option displays the **Do not allow Y-axis limits to shrink** check box. If you want the y-axis range to increase and decrease with the maximum value of a signal, set **Axes scaling** to Auto and clear the **Do not allow Y-axis limits to shrink** check box.
- **After N Updates** — Scale y-axis after the number of time steps specified in the **Number of updates** text box (10 by default). Scaling occurs only once during each run.

Programmatic Use

See AxesScaling.

Do not allow Y-axis limits to shrink — When y-axis limits can change

on (default) | off

Allow y-axis range limits to increase but not decrease during a simulation.

Dependency

To use this property, set **Axes scaling** to Auto.

Number of updates — Number of updates before scaling

10 (default) | integer

Set this property to delay auto scaling the y-axis.

Dependency

To use this property, set **Axes scaling** to After N Updates.

Programmatic Use

See AxesScalingNumUpdates.

Scale axes limits at stop — When y-axis limits can change

on (default) | off

- **On** — Scale axes when simulation stops.
- **Off** — Scale axes continually.

Dependency

To use this property, set **Axes scaling** to Auto.

Y-axis Data range (%) — Percent of y-axis to use for plotting

80 (default) | integer between [1, 100]

Specify the percentage of the y-axis range used for plotting data. If you set this property to 100, the plotted data uses the entire y-axis range.

Y-axis Align — Alignment along y-axis

Center (default) | Top | Bottom

Specify where to align plotted data along the y-axis data range when **Y-axis Data range** is set to less than 100 percent.

- **Top** — Align signals with the maximum values of the y-axis range.
- **Center** — Center signals between the minimum and maximum values.
- **Bottom** — Align signals with the minimum values of the y-axis range.

Autoscale X-axis limits — Scale x-axis range limits

off (default) | on

Scale x-axis range to fit all signal values. If **Axes scaling** is set to Auto, the data currently within the axes is scaled, not the entire signal in the data buffer.

X-axis Data range (%) — Percent of x-axis to use for plotting

100 (default) | integer in the range [1, 100]

Specify the percentage of the x-axis range to plot data on. For example, if you set this property to 100, plotted data uses the entire x-axis range.

X-axis Align — Alignment along x-axis

Center (default) | Left | Right

Specify where to align plotted data along the x-axis data range when **X-axis Data range** is set to less than 100 percent.

- **Right** — Align signals with the maximum values of the x-axis range.
- **Center** — Center signals between the minimum and maximum values.
- **Left** — Align signals with the minimum values of the x-axis range.

Style Properties

To open the Style dialog box, from the scope menu, select **View > Style**.

Figure color — Background color for window

black (default) | color

Background color for the scope.

Plot type — How to plot signal

Auto (default for Scope) | Line (default for Time Scope) | Stairs | Stem

When you select **Auto**, the plot type is a line graph for continuous signals, a stair-step graph for discrete signals, and a stem graph for Simulink message signals.

Axes colors — Background and axes color for individual displays

black (default) | color

Select the background color for axes (displays) with the first color palette. Select the grid and label color with the second color palette.

Preserve colors for copy to clipboard — Copy scope without changing colors

off (default) | on

Specify whether to use the displayed color of the scope when copying.

When you select **File > Copy to Clipboard**, the software changes the color of the scope to be printer friendly (white background, visible lines). If you want to copy and paste the scope with the colors displayed, select this check box.

Properties for line — Line to change

Channel 1 (default)

Select active line for setting line style properties.

Visible — Line visibility

on (default) | off

Show or hide a signal on the plot.

Dependency

The values of “Active display” on page 2-0 and “Properties for line” on page 2-0 determine which line is affected.

Line — Line style

solid line (default style) | 0.75 (default width) | yellow (default color)

Select line style, width, and color.

Dependency

The values of “Active display” on page 2-0 and “Properties for line” on page 2-0 determine which line is affected.

Marker — Data point marker style

None (default) | marker shape

Select marker shape.

Dependency

The values of “Active display” on page 2-0 and “Properties for line” on page 2-0 determine which line is affected.

Block Characteristics

Data Types	Boolean bus ^a double enumerated fixed point half integer single
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

^a Virtual bus not supported. Nonvirtual bus supported only in normal and accelerator mode simulation. Data logging for nonvirtual bus supported only in the dataset format

Tips

If you run your simulation for a long time, you may run into out-of-memory issues because the scope saves data. To limit the amount of data saved for scope visualization, use the Limit data points to last property.

Version History

Introduced in R2015b

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

This block can be used for simulation visibility in systems that generate code, but is not included in the generated code.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block can be used for simulation visibility in subsystems that generate HDL code, but is not included in the hardware implementation.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

This block can be used for simulation visibility in systems that generate code, but is not included in the generated code.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

This block accepts fixed-point input, but converts it to `double` for display.

Toeplitz

Generate matrix with Toeplitz symmetry

Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

dspmtx3

Description

The Toeplitz block generates a Toeplitz matrix from inputs defining the first column and first row. The top input (*Col*) is a vector containing the values to be placed in the first *column* of the matrix, and the bottom input (*Row*) is a vector containing the values to be placed in the first *row* of the matrix.

```
y = toeplitz(Col,Row) % Equivalent MATLAB code
```

The other elements of the matrix obey the relationship

$$y(i,j) = y(i-1,j-1)$$

and the output has dimension $[\text{length}(\text{Col}) \ \text{length}(\text{Row})]$. The $y(1,1)$ element is inherited from the *Col* input. For example, the following inputs

```
Col = [1 2 3 4 5]
Row = [7 7 3 3 2 1 3]
```

produce the Toeplitz matrix

$$\begin{bmatrix} 1 & 7 & 3 & 3 & 2 & 1 & 3 \\ 2 & 1 & 7 & 3 & 3 & 2 & 1 \\ 3 & 2 & 1 & 7 & 3 & 3 & 2 \\ 4 & 3 & 2 & 1 & 7 & 3 & 3 \\ 5 & 4 & 3 & 2 & 1 & 7 & 3 \end{bmatrix}$$

When you select the **Symmetric** check box, the block generates a symmetric (Hermitian) Toeplitz matrix from a single input, *u*, defining both the first row and first column of the matrix.

```
y = toeplitz(u) % Equivalent MATLAB code
```

The output has dimension $[\text{length}(u) \ \text{length}(u)]$. For example, the Toeplitz matrix generated from the input vector $[1 \ 2 \ 3 \ 4]$ is

$$\begin{bmatrix} 1 & 2 & 3 & 4 \\ 2 & 1 & 2 & 3 \\ 3 & 2 & 1 & 2 \\ 4 & 3 & 2 & 1 \end{bmatrix}$$

The Toeplitz block supports real and complex floating-point and fixed-point inputs.

Parameters

Symmetric

When selected, enables the single-input configuration for symmetric Toeplitz matrix output.

Saturate on integer overflow

When you generate a symmetric Toeplitz matrix with this block, if the input vector is complex, the output is a symmetric Hermitian matrix whose elements satisfy the relationship

$$y(i, j) = \text{conj}(y(j, i))$$

For fixed-point signals the conjugate operation could result in an overflow. When you select this parameter, overflows saturate. This parameter is only visible with the **Symmetric** parameter is selected. This parameter is ignored for floating-point signals.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers (real signals only)
Toep Col	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Toep Row	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

To Audio Device

Write audio data to computer's audio device

Compatibility

Note The To Audio Device block will be removed in a future release. Existing instances of the block continue to run. For new models, use the Audio Device Writer block instead.

Library

Sinks

dspsnks4

Description

The To Audio Device block sends audio data to your computer's audio device. This block is not supported for use with the Simulink Model block.

Use the **Device** parameter to specify the device to which you want to send the audio data. This parameter is automatically populated based on the audio devices installed on your system.

Select the **Inherit sample rate from input** check box if you want the block to inherit the sample rate of the audio signal from the input to the block. If you clear this check box, the **Sample rate (Hz)** parameter appears on the block. Use this parameter to specify the number of samples per second in the signal.

The range of supported audio device sample rates and data type formats, depend on both the sound card and the API which is chosen for the sound card.

Use the **Device data type** to specify the data type of the audio data that is sent to the device. You can choose:

- 8-bit integer
- 16-bit integer
- 24-bit integer
- 32-bit float
- Determine from input data type

If you choose Determine from input data type, the following table summarizes the block's behavior.

Input Data Type	Device Data Type
Double-precision floating point or single-precision floating point	32-bit floating point
32-bit integer	24-bit integer
16-bit integer	16-bit integer
8-bit integer	8-bit integer

If you choose **Determine** from **input data type** and the device does not support the input data type, the block uses the next lowest-precision data type supported by the device.

The generated code for this block relies on prebuilt .dll files. You can run this code outside the MATLAB environment, or redeploy it, but be sure to account for these extra .dll files when doing so. The packNGo function creates a single zip file containing all of the pieces required to run or rebuild this code. See packNGo for more information.

Buffering

The To Audio Device block buffers the data from a Simulink signal using the process illustrated by the following figure.

- 1 At the start of the simulation, the queue is filled with silence. Specify the size of this queue using the **Queue duration (seconds)** parameter. As Simulink runs, the block appends Simulink frames to the bottom of the queue.
- 2 At each time step, the blocks sends a buffer of samples from the top of the queue to the audio device. Select the **Automatically determine buffer size** check box to allow the block to use a conservative buffer size. See the From Audio Device block reference page for the equation the block uses to calculate this buffer size. If you clear this check box, the **Buffer size (samples)** parameter appears on the block. Use this parameter to specify the size of the buffer in samples.
- 3 The block writes the buffer of audio data to the device. If the queue did not contain enough data to completely fill the buffer, the block fills the remaining portion of the buffer with zeros. This data has a the data type specified by the **Device data type** parameter.

When the simulation throughput rate is lower than the hardware throughput rate, the queue, which is initially full, becomes empty. If the queue is empty, the block sends zeros (silence) to the audio device. You can monitor inserted zeroes using the optional **Under run** output port. When the simulation throughput rate is higher than the hardware throughput rate, the To Audio Device block waits to write data to the queue.

To minimize the chance of dropouts, the block checks to make sure the queue duration is at least as large as the maximum of the buffer size and the frame size. If it is not, the queue duration is automatically set to this maximum value.

Channel Mapping

The term Channel Mapping refers to a 1-to-1 mapping that associates channels on the selected audio device to channels of the data. When you play audio, channel mapping allows you to specify which channel of the audio device directs input to a specific channel of audio data. You can specify channel mapping as a vector of output channel indices corresponding to each output channel of data being written. The default value in the **Device Output Channels** parameter is 1:MAXOUTPUTCHANNELS. If you do not select the default mapping, you must specify the **Device Output Channels** parameter in the dialog box.

Example: The selected output audio device contains 8 channels. The data being output has dimensions $N \times 3$ (3-channel data). You want the output to be redirected as follows:

- First data channel to Audio Device channel 3
- Second data channel to Audio Device channel 1
- Third data channel to Audio Device channel 8

Thus, you would specify the **Device Output Channels** as [3 1 8].

Troubleshooting

Not Keeping Up in Real Time

When Simulink cannot keep up with an audio device that is operating in real time, the queue becomes empty and gaps occur in the audio data that the block sends to the device. Select the **Output number of samples by which the queue was underrun** check box to add an output port indicating when the queue was empty. Here are several ways to deal with this situation:

- *Increase the queue duration.*

The **Queue duration (seconds)** parameter specifies the duration of the signal, in seconds, that can be buffered during the simulation. This is the maximum length of time that the block's data supply can lag the hardware's data demand.

- *Increase the buffer size.*

The size of the buffer processed in each interrupt from the audio device affects the performance of your model. If the buffer is too small, a large portion of hardware resources are used to write data to the device. If the buffer is too big, Simulink must wait for the device to empty the buffer before it can write the data to the queue, which introduces latency.

- *Increase the simulation throughput rate.*

Two useful methods for improving simulation throughput rates are increasing the signal frame size and compiling the simulation into native code:

- Increase frame sizes and use frame-based processing throughout the model to reduce the amount of block-to-block communication overhead. This can increase throughput rates in many cases. However, larger frame sizes generally result in greater model latency due to initial buffering operations.
- Generate executable code with Simulink Coder code generation software. Native code runs much faster than Simulink and should provide rates adequate for real-time audio processing.

Other ways to improve throughput rates include simplifying the model and running the simulation on a faster PC processor. For other ideas on improving simulation performance, see “Delay and Latency” and “Optimize Performance” (Simulink).

Running an Executable Outside MATLAB

To run your generated standalone executable application in Shell, you need to set your environment to the following:

Platform	Command
Mac	<pre>setenv DYLD_LIBRARY_PATH \$LD_LIBRARY_PATH: \$MATLABROOT/bin/ maci64 (csh/tcsh) export DYLD_LIBRARY_PATH \$LD_LIBRARY_PATH: \$MATLABROOT/bin/ maci64 (Bash)</pre>
Linux	<pre>setenv LD_LIBRARY_PATH \$LD_LIBRARY_PATH: \$MATLABROOT/bin/ glnxa64 (csh/tcsh) export LD_LIBRARY_PATH \$LD_LIBRARY_PATH: \$MATLABROOT/bin/ glnxa64 (Bash)</pre>
Windows	<pre>set PATH = \$MATLABROOT\bin\win64;%PATH %</pre>

Channel-to-Speaker Mapping on Windows Operating Systems

The To Audio Device and From Audio Device blocks can support multiple channels. On Windows operating systems, the channel-to-speaker mapping is defined as listed below. This mapping only applies when your sound card is properly configured and capable of receiving the audio data you send. If the number of channels on the card does not match the number of channels on the block, or if you specify a data type for the **Device data type** parameter that is not supported by your device, the Windows mixer intervenes to translate from one format to another. If the Windows mixer does intervene, the channel-to-speaker mapping might differ from what is specified here.

- Single channel input — Front center speaker

On systems with two speakers, the front center channel is split between the right and left speakers.

- Multichannel input — Channels are assigned to speakers as follows:
 - One channel — Front center
 - Two channels — Front left, front right
 - Four channels — Front left, front right, rear left, rear right
 - Six channels — Front left, front right, front center, low frequency, rear left, rear right
 - Eight channels — Front left, front right, front center, low frequency, rear left, rear right, front left center, front right center
 - For all other channel combinations, the channel assignment is dictated by the audio card.

Audio Hardware API

The To Audio Device and From Audio Device blocks use the open-source PortAudio library in order to communicate with the audio hardware on a given computer. The PortAudio library supports a range of API's designed to communicate with the audio hardware on a given platform. The following API choices were made when building the PortAudio library for the DSP System Toolbox product:

- Windows: DirectSound, WDM-KS, ASIO
- Linux: ALSA, OSS
- Mac: CoreAudio

For Windows, the default is DirectSound, for Linux, the default is ALSA, and for Mac there is only one choice.

To determine the audio hardware API currently selected, type the following command in the MATLAB command prompt.

```
getpref('dsp','portaudioHostApi')
```

The output is a scalar indicating the choice of the API.

- 1 — DirectSound
- 3 — ASIO
- 7 — OSS
- 8 — ALSA
- 11 — WDM-KS

To select a particular API, type the following command in the MATLAB command prompt.

```
setpref('dsp','portaudioHostApi',N)
```

where N is a scalar. Choose N based on the API choice above.

Parameters

Device

Specify which device to send the audio data to.

Inherit sample rate from input

Select this check box if you want the block to inherit the sample rate of the audio signal from the input to the block.

Sample rate (Hz)

Specify the number of samples per second in the signal. This parameter is visible when the **Inherit sample rate from input** check box is cleared.

Device data type

Specify the data type of the audio data sent to the device.

Automatically determine buffer size

Select this check box to allow the block to calculate a conservative buffer size.

Buffer size (samples)

Specify the size of the buffer. This parameter is visible when the **Automatically determine buffer size** check box is cleared.

Queue duration (seconds)

Specify the size of the queue in seconds.

Use default mapping between Data and Device Output Channels

Select this check box to have the default mapping, where the data from the first channel of audio device is sent to the first channel of the input data, data from second channel of audio device is sent to second channel of data and so on. The maximum number of channels in the input data is determined by the **Number of channels** property.

Device Output Channels

Specify the channel mapping. This parameter is visible when the **Use default mapping between Device Input Channels and Data** check box is disabled.

Output number of samples by which the queue was underrun

Select this check box to output the number of zero samples inserted into the audio stream due to queue underrun since the last transfer of a frame to the audio device. You can use this value to debug throughput problems and adjust the queues and buffers in your model. To learn how to improve throughput, see “Troubleshooting” on page 2-1267.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • 32-bit signed integers • 16-bit signed integers • 8-bit unsigned integers
Underrun	32-bit unsigned integer

To Multimedia File

Stream video frames and audio samples to multimedia file

Library

Sinks

dspnsks4

Description

The To Multimedia File block writes video frames, audio samples, or both to a multimedia (.avi, .wav, .wma, .mp4, .ogg, .flac, or .wmv) file.

You can compress the video frames or audio samples by selecting a compression algorithm. You can connect as many of the input ports as you want. Therefore, you can control the type of video and/or audio the multimedia file receives.

Note This block supports code generation for platforms that have file I/O available. You cannot use this block with Simulink Desktop Real-Time software, because that product does not support file I/O.

This block performs best on platforms with Version 11 or later of Windows Media Player software. This block supports only uncompressed RGB24 AVI files on Linux and Mac platforms.

Windows 7 UAC (User Account Control), may require administrative privileges to encode WMV and WMA files.

The generated code for this block relies on prebuilt library files. You can run this code outside the MATLAB environment, or redeploy it, but be sure to account for these extra library files when doing so. The packNGo function creates a single zip file containing all of the pieces required to run or rebuild this code. See packNGo for more information.

To run an executable file that was generated from a model containing this block, you may need to add precompiled shared library files to your system path. See “Understanding C Code Generation in DSP System Toolbox” for details.

Cross-Platform Supported File Formats for Audio Files

Audio files can be of the following formats on all platforms:

- WAV
- FLAC

- OGG
- OPUS
- MPEG4 (only on Windows 7 and macOS)

The default format is WAV. This block supports MPEG-4 AAC audio files on Windows 7, and macOS. You can use both M4A and MP4 extensions.

The following platform specific restrictions apply when writing these files:

Windows 7

- Only sample rates of 44100 and 48000 Hz are supported.
- Only mono or stereo outputs are allowed for MPEG-4 AAC file format. For all other formats, more than two audio output channels are allowed.
- The output data is padded on both the front and back of the signal, with extra samples of silence.

Windows AAC encoder places sharp fade-in and fade-out on audio signal, causing signal to be slightly longer in samples when written to disk.

- A minimum of 1025 samples per channel must be written to the MPEG-4 AAC file.

macOS

- Only mono or stereo outputs are allowed for MPEG-4 AAC file format. For all other formats, more than two audio output channels are allowed.
- Not all sampling rates are supported, although the Mac Audio Toolbox API do not explicitly specify a restriction.

Linux

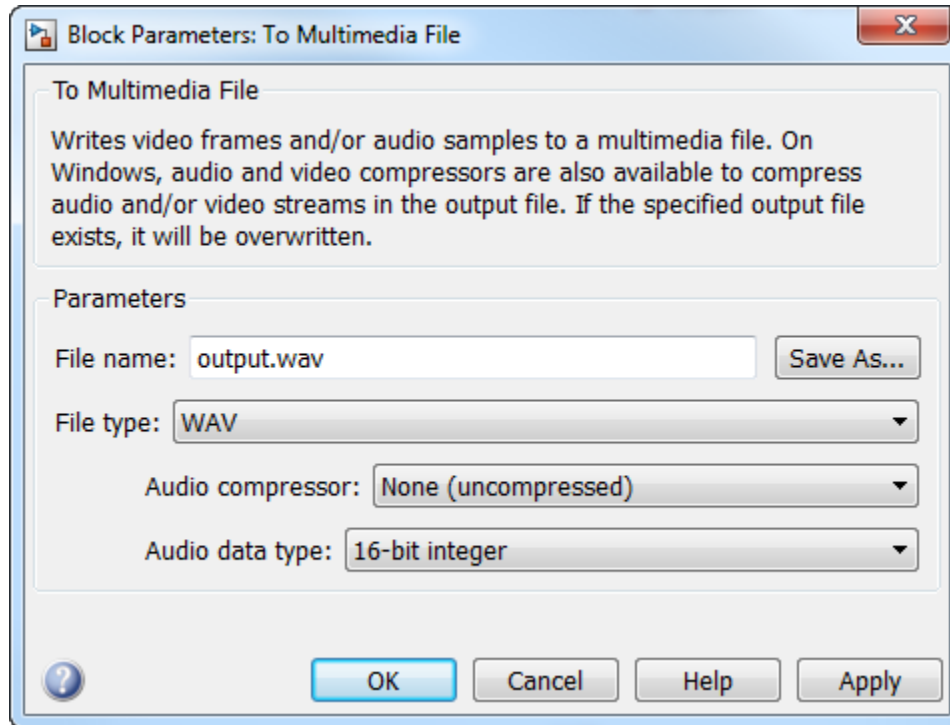

- To support OPUS file format on a Linux machine, you must have `libsndfile 1.0.29` or a later version installed. On Windows and Mac, this file is shipped with MATLAB and is available under `$MATLABROOT/bin/<platform>`.

Ports

Port	Description
Image	M -by- N -by-3 matrix RGB, Intensity, or YCbCr 4:2:2 signal.
R, G, B	Matrix that represents one plane of the RGB video stream. Inputs to the R, G, or B port must have the same dimensions and data type.
Audio	M -by- N matrix. M is the number of samples in each channel, and N is the number of channels.
Y, Cb, Cr	Matrix that represents one frame of the YCbCr video stream. The Y, Cb, and Cr ports use the following dimensions: $Y: M \times N$ $Cb: M \times \frac{N}{2}$ $Cr: M \times \frac{N}{2}$

Dialog Box

The **Main** pane of the To Multimedia File block dialog appears as follows.

File name

Specify the name of the multimedia file. The block saves the file in your current folder. To specify a different file or location, click the **Save As...** button.

File type

Specify the file type of the multimedia file. You can select AVI, WAV, MJ2000, WMA, WMV, MPEG4, FLAC, OGG, or OPUS. By default, the **File type** is set to WAV.

Write

Specify whether the block writes video frames, audio samples, or both to the multimedia file. You can select **Video and audio**, **Video only**, or **Audio only**. This parameter is visible only when you set **File type** to AVI, MPEG4, OGG or OPUS.

Audio compressor

Select the type of compression algorithm to use to compress the audio data. This compression reduces the size of the multimedia file. Choose **None (uncompressed)** to save uncompressed audio data to the multimedia file.

Note The other items available in this parameter list are the audio compression algorithms installed on your system. For information about a specific audio compressor, see the documentation for that compressor.

Audio data type

Select the audio data type. You can use the **Audio data type** parameter only for uncompressed wave files.

Video compressor

Select the type of compression algorithm to use to compress the video data. This compression reduces the size of the multimedia file. Choose **None (uncompressed)** to save uncompressed video data to the multimedia file.

Note The other items available in this parameter list are the video compression algorithms installed on your system. For information about a specific video compressor, see the documentation for that compressor.

Compression Factor (>1)

Specify the compression factor as an integer scalar greater than 1. This parameter is applicable only when the **File type** is set to MJ2000 and **Video compressor** is set to Lossy. By default, this parameter is set to 10.

File color format

Select the color format of the data stored in the file. You can select either RGB or YCbCr 4:2:2.

Image signal

Specify how the block accepts a color video signal. If you select **One multidimensional signal**, the block accepts an *M*-by-*N*-by-*P* color video signal, where *P* is the number of color planes, at one port. If you select **Separate color signals**, additional ports appear on the block. Each port accepts one *M*-by-*N* plane of an RGB video stream.

Video Quality (0-100)

Quality of the video specified as an integer scalar in the range [0 100]. This parameter is applicable only when **File name** is set to MPEG4 and **Write** is set to **Video only**. By default, this parameter is set to 75.

Troubleshooting**Running an Executable Outside MATLAB**

To run your generated standalone executable application in Shell, you need to set your environment to the following:

Platform	Command
Mac	<pre>setenv DYLD_LIBRARY_PATH "\$ {DYLD_LIBRARY_PATH}:\$MATLABROOT/bin/ maci64" (csh/tcsh) export DYLD_LIBRARY_PATH= \$DYLD_LIBRARY_PATH:\$MATLABROOT/bin/ maci64 (Bash)</pre> <p>For more information, see Append library path to "DYLD_LIBRARY_PATH" in MAC.</p>

Platform	Command
Linux	<pre>setenv LD_LIBRARY_PATH \$ {LD_LIBRARY_PATH}:\$MATLABROOT/bin/ glnxa64 (csh/tcsh) export LD_LIBRARY_PATH= \$LD_LIBRARY_PATH:\$MATLABROOT/bin/ glnxa64 (Bash)</pre>
Windows	<pre>set PATH=%PATH%;%MATLABROOT%\bin\win64</pre>

Supported Data Types

For the block to display video data properly, double- and single-precision floating-point pixel values must be between 0 and 1. Any other data type requires the pixel values between the minimum and maximum values supported by their data type.

Check the specific codecs you are using for supported audio rates.

Port	Supported Data Types	Supports Complex Values?
Image	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Boolean • 8-, 16- 32-bit signed integers • 8-, 16- 32-bit unsigned integers 	No
R, G, B	Same as Image port	No
Audio	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • 16-bit signed integers • 32-bit signed integers • 8-bit unsigned integers 	No
Y, Cb, Cr	Same as Image port	No

Version History

Introduced before R2006a

Support for OPUS audio file format

The To Multimedia File block supports OPUS file format (.opus).

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- Host computer only. Excludes Simulink Desktop Real-Time code generation.
- The executable generated from this block relies on prebuilt dynamic library files (.dll files) included with MATLAB. Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

To Wave Device (Obsolete)

Send audio data to standard Windows audio device in real time

Library

dspwin32

Description

Note The To Wave Device block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the To Audio Device block.

The To Wave Device block sends audio data to a standard Windows audio device in real time. It is compatible with most popular Windows hardware, including Sound Blaster cards. The data is sent to the hardware in uncompressed pulse code modulation (PCM) format, and should typically be sampled at one of the standard Windows audio device rates: 8000, 11025, 22050, or 44100 Hz. Some hardware might support other rates in addition to these.

Note Models that contain both the To Wave Device block and the From Wave Device block require a duplex-capable sound card.

The **Use default audio device** check box allows the To Wave Device block to detect and use the system's default audio hardware. You should select this option for systems that have a single sound device installed, or when the default sound device on a multiple-device system is your desired target. When the default sound device is *not* your desired output device, clear **Use default audio device**, and set the desired hardware in the **Audio device** parameter. This parameter lists the names of the installed audio devices.

The block input can contain audio data from a mono or stereo signal. A mono signal is represented as either a sample-based scalar or a frame-based length- M vector, where M is frame size. A stereo signal is represented as a sample-based length-2 vector or a frame-based M -by-2 matrix.

When the input data type is `uint8`, the block conveys the signal samples to the audio device using 8 bits. When the input data type is `double`, `single`, `int16`, or fixed point with a word length of 16 and a fraction length of 15, the block conveys the signal samples to the audio device using 16 bits by default. For inputs of data type `double` and `single`, you can also set the block to convey the signal samples using 24 bits by selecting the **Enable 24-bit output for double- and single-precision input signals** check box. The 24-bit sample width requires more memory but in general yields better fidelity.

The amplitude of the input must be in a valid range that depends on the input data type, as shown in the following table. Amplitudes outside the valid range are clipped to the nearest allowable value.

Input Data Type	Valid Input Amplitude Range
double	$-1 \leq \textit{amplitude} < 1$
single	$-1 \leq \textit{amplitude} < 1$
int16	$-32768 \leq \textit{amplitude} \leq 32767$
uint8	$0 \leq \textit{amplitude} \leq 255$
Fixed point with a word length of 16 and a fraction length of 15	$-1 \leq \textit{amplitude} \leq 1 - 2^{-15}$

Buffering

Because audio devices generate real-time audio output, the Simulink environment must maintain a continuous flow of data to a device throughout simulation. Delays in passing data to the audio hardware can result in hardware errors or distortion of the output. This means that the To Wave Device block must in principle supply data to the audio hardware as quickly as the hardware reads the data. However, the To Wave Device block often *cannot* match the throughput rate of the audio hardware, especially when the simulation is running within Simulink rather than as generated code. Simulink execution speed can vary during the simulation as the host operating system services other processes. The block must therefore rely on a buffering strategy to ensure that signal data is available to the hardware on demand.

Note This block requires real-time execution of the parent model for best performance.

The following block parameters control the memory management for this block:

- **Queue duration**
- **Automatically determine internal buffer size** or **User-defined internal buffer size**
- **Initial output delay**

The **Queue duration** parameter defines the overall size of the block's buffer. The block reads in chunks of data in the size of the input dimensions and stores them in the buffer. The internal buffer size defines the dimensions of the block output to the hardware. You can define the internal buffer size yourself in the **User-defined internal buffer size parameter**. If you select **Automatically determine internal buffer size** instead, the internal buffer size is calculated for you according to the following rules:

- If the input to the block has a frame size of 32 samples or larger, the internal buffer size be the same as the input frame size.
- If the input to the block has a frame size smaller than 32 samples, the internal buffer size is based on the input sample rate according to the following table, where

$$F_s = \textit{samplingfrequency} = \frac{1}{\textit{samptime}}$$

F_s (Hz)	Internal Buffer Size (samples)
$F_s < 8000$	$\min(64, 2 * F_s)$
$8000 \leq F_s < 22,050$	128
$22,050 \leq F_s < 44,100$	256
$44,100 \leq F_s < 96,000$	512
$F_s \geq 96,000$	1024

To minimize the chance of dropouts, the block checks to make sure that the queue duration is at least as big as twice the internal buffer size. If it is not, the queue duration is automatically set to twice the internal buffer size.

The **Initial output delay** parameter enables you to preload the buffer before the block starts to output data to the audio device, which can be helpful for models that do not run in real time. However, for real-time applications, it is best to set the initial output delay to zero (one frame of delay), or as close to zero as possible.

Troubleshooting

If you are getting undesirable audio output using the To Wave Device block, first determine whether your model can run in real time. Replace the To Wave Device block with a To Wave File block, run the model, and compare the model's simulation stop time to the elapsed time on your watch. If the model simulation stop time is less than the elapsed time on your watch, your model can probably run in real time. Then,

- If your model can run in real time,
 - 1 Select **Automatically determine internal buffer size**. This alone might solve the problem. If not,
 - 2 Try increasing the **Queue duration** parameter to a relatively large value, such as 0.5 s.

If one or both of these options restores desirable audio output, you can try reducing the internal buffer size and/or queue duration until the quality of the audio output again degrades.

- If your model is not running in real time, try to make it run in real time by
 - 1 Optimizing the model (using a more efficient implementation), or
 - 2 Using a Simulink "Acceleration" (Simulink) mode, or
 - 3 Generating stand-alone code

If none of these are possible, but the model only runs for a short period of time, set the **Queue duration** parameter to a size equal to a significant fraction of the model stop time and use a similarly large initial delay. This is not an optimal solution, but might work in some cases.

Parameters

Queue duration (seconds)

Specify the overall buffer size. To minimize the chance of dropouts, the block checks to make sure that the queue duration is at least as large as twice the internal buffer size. If it is not, the queue duration is automatically set to twice the internal buffer size.

Automatically determine internal buffer size

Select to have the block automatically select the internal buffer size for you. For details, see “Buffering” on page 2-1278.

User-defined internal buffer size (samples)

Define the internal buffer size, or the size of the chunks of data sent by the block to the audio hardware device.

This parameter is only visible when **Automatically determine internal buffer size** is not selected.

Initial output delay (seconds)

Specify the amount of time by which to delay the initial output to the audio device. During this time data accumulates in the block's buffer. Any value less than or equal to the queue duration specifies the smallest possible initial delay, which is a single frame.

Use default audio device

Select to direct audio output to the system's default audio device.

Audio device

This parameter lists the names of the installed audio devices. Specify the name of the audio device to receive the audio output. Select **Use default audio device** when the system has only a single audio card installed.

This parameter is only enabled when the **Use default audio device** check box is not selected.

Enable 24-bit output for double and single precision input signals

Select to output 24-bit data when inputs are double- or single-precision. Otherwise, the block outputs 16-bit data for double- and single-precision inputs.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Signed fixed point with a word length of 16 and a fraction length of 15 • 16-bit signed integers • 8-bit unsigned integers

Version History

Introduced in R2008b

To Wave File (Obsolete)

Write audio data to file in Microsoft Wave (.wav) format

Library

dspwin32

Description

Note The To Wave File block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the To Multimedia File block.

The To Wave File block streams audio data to a Microsoft Wave (.wav) file in the uncompressed pulse code modulation (PCM) format. For compatibility reasons, the sample rate of the discrete-time input signal should typically be one of the standard Windows audio device rates (8000, 11025, 22050, or 44100 Hz), although the block supports arbitrary rates.

The input to the block, u , can contain audio data with one or more channels. A signal with C channels is represented as a sample-based length- C vector or a frame-based M -by- C matrix. The amplitude of the input should be in the range ± 1 . Values outside this range are clipped to the nearest allowable value.

```
wavwrite(u,Fs,bits,'filename')    % Equivalent MATLAB code
```

Note AVI files are the only supported file type for non-Windows platforms.

Parameters

File name

Specify the path and name of the file to write. Paths can be relative or absolute. You do not need to specify the .wav extension.

Sample width (bits)

Specify the number of bits used to represent the signal samples in the file. The higher sample width settings require more memory but yield better fidelity for double- and single-precision inputs:

- 8 — Allocates 8 bits to each sample, allowing a resolution of 256 levels
- 16 — Allocates 16 bits to each sample, allowing a resolution of 65536 levels
- 24 — Allocates 24 bits to each sample, allowing a resolution of 16777216 levels

- 32 — Allocates 32 bits to each sample, allowing a resolution of 2^{32} levels ranging from -1 to 1

The 8-, 16-, and 24-bit modes output integer data, while the 32-bit mode outputs single-precision floating-point data.

Minimum number of samples for each write to file

Specify the number of consecutive samples, L , to write with each file access. To reduce the required number of file accesses, the block writes L consecutive samples to the file during each access for $L \geq M$. For $L < M$, the block instead writes M consecutive samples during each access. Larger values of L result in fewer file accesses, which reduces run-time overhead.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Signed fixed point with a word length of 16 and a fraction length of 15 • 16-bit signed integers • 8-bit unsigned integers

Triggered Delay Line (Obsolete)

Buffer sequence of inputs into frame-based output

Library

dspobslib

Description

Note The Triggered Delay Line block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the Delay Line block.

The Triggered Delay Line block acquires a collection of M_0 input samples into a frame, where you specify M_0 in the **Delay line size** parameter. The block buffers a single sample from input 1 whenever it is triggered by the control signal at input 2 (⚡). When the next triggering event occurs, the newly acquired input sample is appended to the output frame so that the new output overlaps the previous output by M_0-1 samples. Between triggering events the block ignores input 1 and holds the output at its last value.

You specify the triggering event at input 2 in the **Trigger type** pop-up menu:

- **Rising edge** triggers execution of the block when the trigger input rises from a negative value to zero or a positive value, or from zero to a positive value.
- **Falling edge** triggers execution of the block when the trigger input falls from a positive value to zero or a negative value, or from zero to a negative value.
- **Either edge** triggers execution of the block when either a rising or falling edge (as described above) occurs.

The Triggered Delay Line block has zero latency, so the new input appears at the output in the same simulation time step. The output frame period is the same as the input sample period, $T_{fo}=T_{si}$.

Sample-Based Operation

In sample-based operation, the Triggered Delay Line block buffers a sequence of sample-based length- N vector inputs (1-D, row, or column) into a sequence of overlapping sample-based M_0 -by- N matrix outputs, where you specify M_0 in the **Delay line size** parameter ($M_0>1$). That is, each input vector becomes a *row* in the sample-based output matrix. When $M_0=1$, the input is simply passed through to the output, and retains the same dimension. Sample-based full-dimension matrix inputs are not accepted.

Frame-Based Operation

In frame-based operation, the Triggered Delay Line block rebuffers a sequence of frame-based M_f -by- N matrix inputs into an sequence of overlapping frame-based M_0 -by- N matrix outputs, where M_0 is

the output frame size specified by the **Delay line size** parameter (that is, the number of consecutive samples from the input frame to rebuffer into the output frame). M_o can be greater or less than the input frame size, M_i . Each of the N input channels is rebuffered independently.

Initial Conditions

The Triggered Delay Line block's buffer is initialized to the value specified by the **Initial condition** parameter. The block always outputs this buffer at the first simulation step ($t=0$). When the block's output is a vector, the **Initial condition** can be a vector of the same size or a scalar value to be repeated across all elements of the initial output. When the block's output is a matrix, the **Initial condition** can be a matrix of the same size or a scalar to be repeated across all elements of the initial output.

Parameters

Trigger type

The type of event that triggers the block's execution.

Delay line size

The length of the output frame (number of rows in output matrix), M_o .

Initial condition

The value of the block's initial output, a scalar, vector, or matrix.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Trigger	<ul style="list-style-type: none"> • Any data type supported by the Trigger block
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Triggered Signal From Workspace

Import signal samples from MATLAB workspace when triggered

Library: DSP System Toolbox / Signal Operations

Description

The Triggered Signal From Workspace block imports signal samples from the MATLAB workspace into the Simulink model when triggered by the control signal at the input port (⚡). The **Signal** parameter specifies the name of a MATLAB workspace variable containing the signal to import, or any valid MATLAB expression defining a matrix or 3-D array.

Ports

Input

trigger — Trigger signal

scalar | vector | matrix

Triggering input signal, specified as a scalar, vector, or matrix. This port is labelled with ⚡.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 — Signal imported from workspace

scalar | vector | matrix | 3-D array

The block outputs the signal imported from the workspace when triggered by the control signal at the input port.

When the **Signal** parameter specifies an M -by- N matrix ($M \neq 1$), each of the N columns is treated as a distinct channel. You specify the frame size in the **Samples per frame** parameter, M_o . When triggered, the block outputs an M_o -by- N matrix containing M_o consecutive samples from each signal channel. For convenience, an imported row vector ($M=1$) is treated as a single channel, so the output dimension is M_o -by-1.

When the **Signal** parameter specifies an M -by- N -by- P array, the block generates a single page of the array (an M -by- N matrix) at each trigger time. The **Samples per frame** parameter must be set to 1.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Parameters

Signal — Signal to import

1:10 (default) | MATLAB workspace variable | MATLAB expression

The name of the MATLAB workspace variable from which to import the signal, or a valid MATLAB expression specifying the signal.

When the **Signal** parameter specifies an M -by- N matrix ($M \neq 1$), each of the N columns is treated as a distinct channel. You specify the frame size in the **Samples per frame** parameter, M_0 . When triggered, the block outputs an M_0 -by- N matrix containing M_0 consecutive samples from each signal channel. For convenience, an imported row vector ($M=1$) is treated as a single channel, so the output dimension is M_0 -by-1.

When the **Signal** parameter specifies an M -by- N -by- P array, the block generates a single page of the array (an M -by- N matrix) at each trigger time. The **Samples per frame** parameter must be set to 1.

Trigger type — Type of triggering event

Rising edge (default) | Falling edge | Either edge

The type of event that triggers the block to execute.

- **Rising edge** triggers execution of the block when the trigger input rises from a negative value to zero or a positive value, or from zero to a positive value.
- **Falling edge** triggers execution of the block when the trigger input falls from a positive value to zero or a negative value, or from zero to a negative value.
- **Either edge** triggers execution of the block when either a rising or falling edge occurs.

Initial output — Initial output value

0 (default) | scalar | vector | matrix

The value to output until the first trigger event is received. Between trigger events, the block holds the output value constant at its most recent value (that is, no linear interpolation takes place). For single-channel signals, the **Initial output** can be a vector of length M_0 or a scalar to repeat across the M_0 elements of the initial output frames. For matrix outputs (M_0 -by- N or M -by- N), the **Initial output** parameter value can be a matrix of the same size or a scalar to be repeated across all elements of the initial output.

Samples per frame — Samples per frame

1 (default) | positive integer

The number of samples, M_0 , to buffer into each output frame specified as a positive integer scalar. This value must be 1 when you specify a 3-D array in the **Signal** parameter.

Form output after final data value by — Values to output after final imported signal value

Setting to zero (default) | Holding final value | Cyclic repetition

Specifies the output after all of the specified signal samples have been generated.

- When you specify **Setting To Zero**, the block generates zero-valued outputs for the duration of the simulation after generating the last frame of the signal.
- When you specify **Holding Final Value**, the block repeats the final sample for the duration of the simulation after generating the last frame of the signal.

- When you specify **Cyclic Repetition**, the block repeats the signal from the beginning after generating the last frame. When there are not enough samples at the end of the signal to fill the final frame, the block zero-pads the final frame as necessary to ensure that the output for each cycle is identical. For example, the *i*th frame of one cycle contains the same samples as the *i*th frame of any other cycle.

The block does not extrapolate the imported signal beyond the last sample.

Blocks

Signal From Workspace | To Workspace | Triggered To Workspace

Triggered To Workspace

Write input sample to MATLAB workspace when triggered

Library

Sinks

dspsnks4

Description

The Triggered To Workspace block creates a matrix or array variable in the MATLAB workspace, where it stores the acquired inputs at the end of a simulation. The block overwrites an existing variable with the same name.

When you set the **Save 2-D signals as** parameter to 2-D array (concatenate along first dimension, the block saves an M -by- N input as a P -by- N matrix, where P is the **Maximum number of rows** parameter. When the simulation progresses long enough for the block to acquire more than P samples, the block stores only the most recent P samples. The **Decimation factor**, D , allows you to store only every D th input matrix.

When you set the **Save 2-D signals as** parameter to 3-D array (concatenate along third dimension, the block saves an M -by- N input as a three-dimensional array in which each M -by- N page represents a single sample from each of the $M*N$ channels (the most recent input matrix occupies the last page). The maximum size of this variable is limited to M -by- N -by- P , where P is the **Maximum number of rows** parameter. When the simulation progresses long enough for the block to acquire more than P inputs, it stores only the last P inputs. The **Decimation factor**, D , allows you to store only every D th input matrix.

The block acquires and buffers a single frame from input 1 whenever it is triggered by the control signal at input 2 (↗). At all other times, the block ignores input 1. You specify the triggering event at input 2 in the **Trigger type** pop-up menu:

- **Rising edge** triggers execution of the block when the trigger input rises from a negative value to zero or a positive value, or from zero to a positive value.
- **Falling edge** triggers execution of the block when the trigger input falls from a positive value to zero or a negative value, or from zero to a negative value.
- **Either edge** triggers execution of the block when either a rising or falling edge (as described above) occurs.

To save a record of the sample time corresponding to each sample value, open the Configuration Parameters dialog box. In the **Select** pane, click **Data Import/Export** and select the **Time** check box.

The nontriggered version of this block is the To Workspace block.

Parameters

Trigger type

The type of event that triggers the block's execution.

Variable name

The name of the workspace variable in which to store the data.

Maximum number of rows

The maximum number of rows (one row per time step) to be saved, P .

Decimation

The decimation factor, D .

Save 2-D signals as

Specify whether the block saves 2-D signals as a 2-D or 3-D array in the MATLAB workspace:

- 2-D array (concatenate along first dimension) — When you select this option, the block vertically concatenates each M -by- N matrix input with the previous input to produce a 2-D output array.
- 3-D array (concatenate along third dimension) — When you select this option, the block saves an M -by- N input signal as a 3-D array. The maximum size of this 3-D array is limited to M -by- N -by- P , where P is the **Maximum number of rows** parameter. When the simulation progresses long enough for the block to acquire more than P inputs, the block stores only the last P inputs. The **Decimation factor**, D , allows you to store only every D th input matrix.

Log fixed-point data as a fi object

Select to log fixed-point data to the MATLAB workspace as a Fixed-Point Designer `fi` object. Otherwise, fixed-point data is logged to the workspace as `double`.

Supported Data Types

Port	Supported Data Types

Two-Channel Analysis Subband Filter

Decompose signal into high-frequency and low-frequency subbands

Library

Filtering / Multirate Filters

`dspmlti4`

Description

The Two-Channel Analysis Subband Filter block decomposes the input into high-frequency and low-frequency subbands, each with half the bandwidth and half the sample rate of the input.

The block filters the input with a pair of highpass and lowpass FIR filters, and then downsamples the results by 2, as illustrated in the following figure.

The block implements the FIR filtering and downsampling steps together using a polyphase filter structure, which is more efficient than the straightforward filter-then-decimate algorithm shown in the preceding figure. Each subband is the first phase of the respective polyphase filter. You can implement a multilevel dyadic analysis filter bank by connecting multiple copies of this block or by using the Dyadic Analysis Filter Bank block. See “Creating Multilevel Dyadic Analysis Filter Banks” on page 2-1294 for more information.

You must provide a vector of filter coefficients for the lowpass and highpass FIR filters. Each filter should be a half-band filter that passes the frequency band that the other filter stops.

See the following topics for more information about this block:

- “Specifying the FIR Filters” on page 2-1292
- “Frame-Based Processing” on page 2-1293
- “Sample-Based Processing” on page 2-1293
- “Latency” on page 2-1293
- “Creating Multilevel Dyadic Analysis Filter Banks” on page 2-1294

Specifying the FIR Filters

You must provide the vector of numerator coefficients for the lowpass and highpass filters in the **Lowpass FIR filter coefficients** and **Highpass FIR filter coefficients** parameters.

For example, to specify a filter with the following transfer function, enter the vector $[b(1) \ b(2) \ \dots \ b(m)]$.

$$H(z) = B(z) = b_1 + b_2z^{-1} + \dots + b_mz^{-(m-1)}$$

Each filter should be a half-band filter that passes the frequency band that the other filter stops. You can use the Two-Channel Synthesis Subband Filter block to reconstruct the input to this block. To do so, you must design perfect reconstruction filters to use in the synthesis subband filter.

The best way to design perfect reconstruction filters is to use the Wavelet Toolbox `wfilters` function in to design both the filters both in this block and in the Two-Channel Synthesis Subband Filter block. You can also use other DSP System Toolbox and Signal Processing Toolbox functions.

The Two-Channel Analysis Subband Filter block initializes all filter states to zero.

Frame-Based Processing

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block accepts an M -by- N matrix. The block treats each column of the input as the high- or low-frequency subbands of the corresponding output channel. You can use the **Rate options** parameter to specify how the block resamples the input:

- When you set the **Rate options** parameter to `Enforce single-rate processing`, the input to the block can be an M -by- N matrix, where M is a multiple of two. The block treats each column of the input as an independent channel and decomposes each channel over time. The block outputs two matrices, where each column of the output is the high- or low-frequency subband of the corresponding input column. To maintain the input sample rate, the block decreases the output frame size by a factor of two.
- When you set the **Rate options** parameter to `Allow multirate processing`, the block treats an M_i -by- N matrix input as N independent channels and decomposes each channel over time. The block outputs two M -by- N matrices, where each column of the output is the high- or low-frequency subband of the corresponding input column. The input and output frame sizes are the same, but the frame rate of the output is half that of the input. Thus, the overall sample rate of the output is half that of the input.

In this mode, the block has one frame of latency, as described in the “Latency” on page 2-1293 section.

Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats an M -by- N matrix input as $M \cdot N$ independent channels. The block decomposes each channel over time and outputs two M -by- N matrices whose sample rates are half the input sample rate. Each element in the output matrix is the high- or low-frequency subband output of the corresponding element of the input matrix.

Depending on the setting of your Simulink configuration parameters, the output may have one sample of latency, as described in the “Latency” on page 2-1293 section.

Latency

When you set the **Input processing** parameter to `Columns as channels (frame based)` and the **Rate options** parameter to `Enforce single-rate processing`, the Two-Channel Analysis

Subband Filter block always has zero-tasking latency. Zero-tasking latency means that the block propagates the first input sample (received at time $t=0$) as the first output sample.

When you set the **Rate options** parameter to `Allow multirate processing`, the Two-Channel Analysis Subband Filter block may exhibit latency. The amount of latency depends on the setting of the **Input processing** parameter of this block, and the setting of the Simulink **Treat each discrete rate as a separate task** configuration parameter. The following table summarizes the conditions that produce latency when the block is performing multirate processing.

Input processing	Treat each discrete rate as a separate task	Latency
Elements as channels (sample based)	Off	None.
	On	One sample. The first output sample in each channel always has a value of 0.
Columns as channels (frame based)	On or Off	One frame. All samples in the first output frame have a value of 0.

Note For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Creating Multilevel Dyadic Analysis Filter Banks

The Two-Channel Analysis Subband Filter block is the basic unit of a dyadic analysis filter bank. You can connect several of these blocks to implement an n -level filter bank, as illustrated in the following figure. For a review of dyadic analysis filter banks, see the Dyadic Analysis Filter Bank block reference page.

When you create a filter bank by connecting multiple copies of this block, the output values of the filter bank differ depending on whether there is latency. Though the output values differ, both sets of values are valid; the difference arises from changes in latency. See the “Latency” on page 2-1293 section for more information about when latency can occur in the Two-Channel Analysis Subband Filter block.

In some cases, rather than connecting several Two-Channel Analysis Subband Filter blocks, you can use the Dyadic Analysis Filter Bank block, which is faster and requires less memory. In particular, the Dyadic Analysis Filter Bank block is more efficient under the following conditions:

- The frame size of the signal you are decomposing is a multiple of 2^n .
- You are decomposing the signal into $n+1$ or 2^n subbands.

In all other cases, use Two-Channel Analysis Subband Filter blocks to implement your filter banks.

3-Level Dyadic Analysis Filter Banks

Conceptual illustration

Two-Channel Analysis Subband Filter block implementation

Both implementations of the dyadic analysis filter bank decompose a frame-based signal with frame size a multiple of 2^n into $n+1$ subbands, where $n = 3$.

In this case, the Dyadic Analysis Filter Bank block's implementation is more efficient.

Use the Two-Channel Analysis Subband Filter block implementation for other cases, such as to handle sample-based inputs, or to handle frame-based inputs whose frame size is not a multiple of 2^n .

Dyadic Analysis Filter Bank block implementation

The Dyadic Analysis Filter Bank block allows you to specify the filter bank filters by providing vectors of filter coefficients, just as this block does. The Dyadic Analysis Filter Bank block provides an additional option of using wavelet-based filters that the block designs by using a wavelet you specify.

Fixed-Point Data Types

The Two-Channel Analysis Subband Filter Bank block is composed of two FIR Decimation blocks as shown in the following diagram.

For fixed-point signals, you can set the coefficient, product output, accumulator, and output data types of the FIR Decimation blocks as discussed in "Parameters" on page 2-1295. For a diagram showing the usage of these data types, see the FIR Decimation block reference page.

Parameters

Main Tab

Lowpass FIR filter coefficients

Specify a vector of lowpass FIR filter coefficients, in descending powers of z . The lowpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Highpass FIR filter coefficients** parameter. The default values of this parameter specify a filter

based on a third-order Daubechies wavelet. When you use the Two-Channel Synthesis Subband Filter block to reconstruct the input to this block, you need to design perfect reconstruction filters to use in the synthesis subband filter. For more information, see “Specifying the FIR Filters” on page 2-1292.

Highpass FIR filter coefficients

Specify a vector of highpass FIR filter coefficients, in descending powers of z . The highpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Lowpass FIR filter coefficients** parameter. The default values of this parameter specify a filter based on a third-order Daubechies wavelet. When you use the Two-Channel Synthesis Subband Filter block to reconstruct the input to this block, you need to design perfect reconstruction filters to use in the synthesis subband filter. For more information, see “Specifying the FIR Filters” on page 2-1292.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** (default) — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

Rate options

Specify the rate processing rule for the block. You can set this parameter to one of the following options:

- **Enforce single-rate processing** — When you select this option, the block treats each column of the input as an independent channel and decomposes each channel over time. The output has the same sample rate as the input, but the output frame size is half that of the input frame size. To select this option, you must set the **Input processing** parameter to **Columns as channels (frame based)**.
- **Allow multirate processing** — When you select this option, the input and output of the block are the same size, but the sample rate of the output is half that of the input.

Some settings of this parameter cause the block to have nonzero latency. See “Latency” on page 2-1293 for more information.

Data Types Tab

Rounding mode

Select the rounding mode for fixed-point operations. The filter coefficients do not obey this parameter; they are always rounded to **Nearest**.

Note The **Rounding mode** and **Saturate on integer overflow** settings have no effect on numerical results when all the following conditions exist:

- **Product output** is **Inherit**: **Inherit via internal rule**
- **Accumulator** is **Inherit**: **Inherit via internal rule**
- **Output** is **Inherit**: **Same as accumulator**

With these data type settings, the block is effectively operating in full precision mode.

Saturate on integer overflow

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see `overflow mode for fixed-point operations`.

Note The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numeric results when all these conditions are met:

- **Product output** data type is `Inherit: Inherit via internal rule`.
- **Accumulator** data type is `Inherit: Inherit via internal rule`.

With these data type settings, the block operates in full-precision mode.

Coefficients

Specify the coefficients data type. See “Fixed-Point Data Types” on page 2-1295 and “Multiplication Data Types” for illustrations depicting the use of the coefficients data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Coefficients** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Coefficients Minimum

Specify the minimum value of the filter coefficients. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Automatic scaling of fixed-point data types

Coefficients Maximum

Specify the maximum value of the filter coefficients. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Automatic scaling of fixed-point data types

Product output

Specify the product output data type. See “Fixed-Point Data Types” on page 2-1295 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.

Note The actual product output word length may be equal to or greater than the calculated ideal product output word length, depending on the settings on the **Hardware Implementation** pane of the Configuration Parameters dialog box.

- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Accumulator

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-1295 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Output

Specify the output data type. See “Fixed-Point Data Types” on page 2-1295 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Data Types of Signals” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Output Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Output Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed only)
- 8-, 16-, and 32-bit signed integers

Two-Channel Synthesis Subband Filter

Reconstruct signal from high-frequency and low-frequency subbands

Library

Filtering / Multirate Filters

`dspmlti4`

Description

The Two-Channel Synthesis Subband Filter block reconstructs a signal from its high-frequency and low-frequency subbands, each with half the bandwidth and half the sample rate of the original signal. Use this block to reconstruct signals decomposed by the Two-Channel Analysis Subband Filter block.

The block upsamples the high- and low-frequency subbands by 2, and then filters the results with a pair of highpass and lowpass FIR filters, as illustrated in the following figure.

The block implements the FIR filtering and downsampling steps together using a polyphase filter structure, which is more efficient than the straightforward interpolate-then-filter algorithm shown in the preceding figure. You can implement a multilevel dyadic synthesis filter bank by connecting multiple copies of this block or by using the Dyadic Synthesis Filter Bank block. For more information, see “Creating Multilevel Dyadic Synthesis Filter Banks” on page 2-1302.

You must provide a vector of filter coefficients for the lowpass and highpass FIR filters. Each filter should be a half-band filter that passes the frequency band that the other filter stops. You can use this block to reconstruct the output of a Two-Channel Analysis Subband Filter block. To do so, you must design the filters in this block such that they perfectly reconstruct the outputs of the analysis filters.

See the following topics for more information about this block:

- “Specifying the FIR Filters” on page 2-1301
- “Frame-Based Processing” on page 2-1301
- “Sample-Based Processing” on page 2-1301
- “Latency” on page 2-1302
- “Creating Multilevel Dyadic Synthesis Filter Banks” on page 2-1302

Specifying the FIR Filters

You must provide the vector of numerator coefficients for the lowpass and highpass filters in the **Lowpass FIR filter coefficients** and **Highpass FIR filter coefficients** parameters.

For example, to specify a filter with the following transfer function, enter the vector $[b(1) \ b(2) \ \dots \ b(m)]$.

$$H(z) = B(z) = b_1 + b_2z^{-1} + \dots + b_mz^{-(m-1)}$$

Each filter should be a half-band filter that passes the frequency band that the other filter stops. You can use this block to reconstruct the output of a Two-Channel Analysis Subband Filter block. To do so, you must design the filters in this block such that they perfectly reconstruct the outputs of the analysis filters.

The best way to design perfect reconstruction filters is to use the Wavelet Toolbox `wfilters` function for the filters in both this block *and* in the corresponding Two-Channel Analysis Subband Filter block. You can also use DSP System Toolbox and Signal Processing Toolbox functions.

The Two-Channel Synthesis Subband Filter block initializes all filter states to zero.

Frame-Based Processing

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block accepts any two M -by- N matrices with the same frame rates. The block treats each column of the input as the high- or low-frequency subbands of the corresponding output channel. You can use the **Rate options** parameter to specify how the block resamples the input:

- When you set the **Rate options** parameter to `Enforce single-rate processing`, the input to the block can be any two M -by- N matrices with the same frame rate. The block treats each input column as the high- or low-frequency subbands of the corresponding output channel. The input to the topmost input port should contain the high-frequency subbands. The block outputs one matrix, where each column is reconstructed from the corresponding columns of each input matrix. The input and output frame *rates* are the same, but the frame *size* of the output is twice that of the input.
- When you set the **Rate options** parameter to `Allow multirate processing`, the block treats each column of the input as the high- or low-frequency subbands of the corresponding output channel. The input to the topmost input port should contain the high-frequency subbands. The block outputs one matrix, where each column is reconstructed from the corresponding columns of the input matrices. The input and output frame *sizes* are the same, but the frame *rate* of the output is twice that of the input. Thus, the overall sample rate of the output is twice that of the input sample rate.

In this mode, the block has one frame of latency, as described in the “Latency” on page 2-1302 section.

Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block accepts any two M -by- N matrices with the same sample rates. The block treats each M -by- N matrix as $M \cdot N$ independent subbands. Each element of the input matrices is the high- or low-frequency subband of the corresponding channel in the output matrix. The input to the topmost input port should contain the high-frequency subbands. The block outputs one matrix with the same

dimensions as the input matrices, but a sample rate that is twice that of the input. The block reconstructs each element of the output from the corresponding elements in the input matrices.

Depending on the setting of your Simulink configuration parameters, the output may have one sample of latency, as described in the “Latency” on page 2-1302 section.

Latency

When you set the **Input processing** parameter to `Columns as channels (frame based)` and the **Rate options** parameter to `Enforce single-rate processing`, the Two-Channel Synthesis Subband Filter block always has zero-tasking latency. Zero-tasking latency means that the block propagates the first input sample (received at time $t = 0$) as the first output sample.

When you set the **Rate options** parameter to `Allow multirate processing`, the Two-Channel Synthesis Subband Filter block may exhibit latency. The amount of latency depends on the setting of the **Input processing** parameter of this block and the setting of the Simulink **Treat each discrete rate as a separate task** configuration parameter. The following table summarizes the conditions that produce latency when the block is performing multirate processing.

Input processing	Treat each discrete rate as a separate task	Latency
Elements as channels (sample based)	Off	None.
	On	One sample. The first output sample in each channel always has a value of 0.
Columns as channels (frame based)	Off or On	One frame. All samples in the first output frame have a value of 0.

Note For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Creating Multilevel Dyadic Synthesis Filter Banks

The Two-Channel Synthesis Subband Filter block is the basic unit of a dyadic synthesis filter bank. You can connect several of these blocks to implement an n -level filter bank, as illustrated in the following figure. For a review of dyadic synthesis filter banks, see the Dyadic Synthesis Filter Bank block reference page.

When you create a filter bank by connecting multiple copies of this block, the output values of the filter bank differ depending on whether there is latency. Though the output values differ, both sets of values are valid; the difference arises from changes in latency. See the “Latency” on page 2-1302 section for more information about when latency can occur in the Two-Channel Analysis Subband Filter block.

In some cases, rather than connecting several Two-Channel Analysis Subband Filter blocks, you can use the Dyadic Analysis Filter Bank block, which is faster and requires less memory. In particular, the Dyadic Analysis Filter Bank block is more efficient under the following conditions:

- You are reconstructing a signal from 2^n or $n + 1$ subbands.
- The frame size of the signal you are reconstructing is a multiple of 2^n .

- The properties of the subbands you are working with match those of the outputs of the Dyadic Analysis Filter Bank block. These properties are described in the Dyadic Analysis Filter Bank reference page.

3-Level Dyadic Synthesis Filter Banks

Conceptual illustration

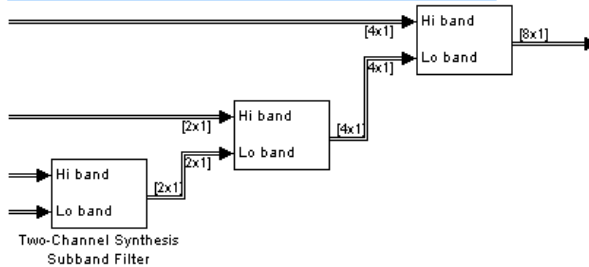

Both implementations of the dyadic analysis filter bank reconstruct a frame-based signal from $n+1$ subbands, where $n = 3$.

In this case, the Dyadic Synthesis Filter Bank block's implementation is more efficient, since the input subbands have the properties of the outputs of a Dyadic Analysis Filter Bank block.

Use the Two-Channel Synthesis Subband Filter block implementation for other cases, such as to handle separate sample-based vectors or matrices of subbands (rather than a single sample-based vector or matrix of concatenated subbands), or to output sample-based signals.

Two-Channel Synthesis Subband Filter block implementation

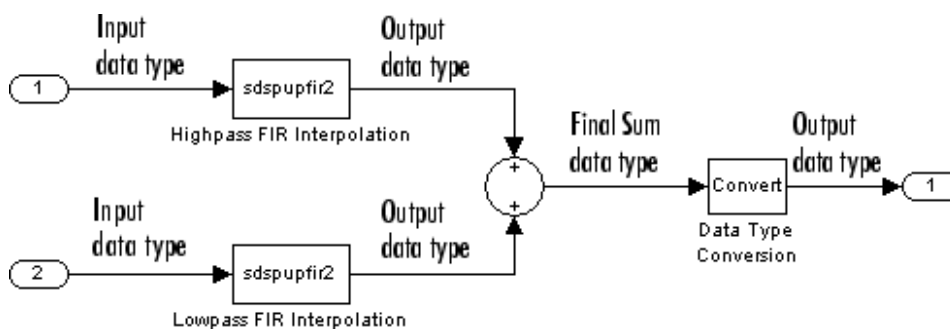

Dyadic Synthesis Filter Bank block implementation

The Dyadic Synthesis Filter Bank block allows you to specify the filter bank filters by providing vectors of filter coefficients, just as this block does. The Dyadic Synthesis Filter Bank block provides an additional option of using wavelet-based filters that the block designs by using a wavelet you specify.

Fixed-Point Data Types

The Two-Channel Synthesis Subband Filter block is composed of two FIR Interpolation blocks as shown in the following diagram.

For fixed-point signals, you can set the coefficient, product output, accumulator, and output data types used in the FIR Interpolation blocks as discussed in "Parameters" on page 2-1304. For a diagram showing the usage of these data types within the FIR blocks, see the FIR Interpolation block reference page.

In addition, the inputs to the Sum block shown in the previous diagram are accumulated using the accumulator data type. The output of the Sum block is then cast from the accumulator data type to the output data type. Therefore the output of the Two-Channel Synthesis Subband Filter block is in

the output data type. You also set these data types in the block dialog box as discussed in the “Parameters” on page 2-1304 section.

Parameters

Main Tab

Lowpass FIR filter coefficients

A vector of lowpass FIR filter coefficients, in descending powers of z . The lowpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Highpass FIR filter coefficients** parameter. To use this block to reconstruct the output of a Two-Channel Analysis Subband Filter block, you must design the filters in this block to perfectly reconstruct the outputs of the analysis filters. For more information, see “Specifying the FIR Filters” on page 2-1301.

Highpass FIR filter coefficients

A vector of highpass FIR filter coefficients, in descending powers of z . The highpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Lowpass FIR filter coefficients** parameter. To use this block to reconstruct the output of a Two-Channel Analysis Subband Filter block, you must design the filters in this block to perfectly reconstruct the outputs of the analysis filters. For more information, see “Specifying the FIR Filters” on page 2-1301.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** (default) — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

Rate options

Specify the rate processing rule for the block. You can set this parameter to one of the following options:

- **Enforce single-rate processing** — When you select this option, the block treats each column of the input as an independent channel and reconstructs each channel over time. The output has the same sample rate as the input, but the output frame size is twice that of the input frame size. To select this option, you must set the **Input processing** parameter to **Columns as channels (frame based)**.
- **Allow multirate processing** — When you select this option, the input and output of the block are the same size, but the sample rate of the output is twice that of the input.

Some settings of this parameter cause the block to have nonzero latency. See “Latency” on page 2-1302 for more information.

Data Types Tab

Rounding mode

Select the rounding mode for fixed-point operations. The filter coefficients do not obey this parameter; they always round to **Nearest**.

Note The **Rounding mode** and **Saturate on integer overflow** settings have no effect on numerical results when all the following conditions exist:

- **Product output** is Inherit: Inherit via internal rule
- **Accumulator** is Inherit: Inherit via internal rule
- **Output** is Inherit: Same as accumulator

With these data type settings, the block is effectively operating in full precision mode.

Saturate on integer overflow

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

Note The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numeric results when all these conditions are met:

- **Product output** data type is Inherit: Inherit via internal rule.
- **Accumulator** data type is Inherit: Inherit via internal rule.

With these data type settings, the block operates in full-precision mode.

Coefficients

Specify the coefficients data type. See “Fixed-Point Data Types” on page 2-1303 and “Multiplication Data Types” for illustrations depicting the use of the coefficients data type in this block. You can set it to:

- A rule that inherits a data type, for example, Inherit: Same word length as input
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Coefficients** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Coefficients Minimum

Specify the minimum value of the filter coefficients. The default value is [] (unspecified). Simulink software uses this value to perform:

- Automatic scaling of fixed-point data types

Coefficients Maximum

Specify the maximum value of the filter coefficients. The default value is [] (unspecified). Simulink software uses this value to perform:

- Automatic scaling of fixed-point data types

Product output

Specify the product output data type. See “Fixed-Point Data Types” on page 2-1303 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.

Note The actual product output word length may be equal to or greater than the calculated ideal product output word length, depending on the settings on the **Hardware Implementation** pane of the Configuration Parameters dialog box.

- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Accumulator

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-1303 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Output

Specify the output data type. See “Fixed-Point Data Types” on page 2-1303 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Data Types of Signals” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Output Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Output Maximum

Specify the maximum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed only)
- 8-, 16-, and 32-bit signed integers

UDP Receive

Receive UDP packets on a given IP port

Library: DSP System Toolbox / Sources

Description

The UDP Receive block receives UDP packets from an IP network port and saves them to its buffer. With each sample, the block outputs the contents of a single UDP packet as a data vector. The local IP port number on which the block receives the UDP packets is tunable in the generated code.

The generated code for this block relies on prebuilt `.dll` files. You can run this code outside the MATLAB environment or redeploy it, but you must account for the extra `.dll` files. The `packNGo` function creates a ZIP file that contains the pieces required to run or rebuild this code. For more details, see “How To Run a Generated Executable Outside MATLAB”.

Ports

Output

Message — Data received

vector

Data received by the UDP Receive block, returned as a one-dimensional vector of the data type specified in **Data type for Message**. If you select **Message is complex**, the block treats the received message as complex data.

This port is unnamed until you clear the **Output variable-size signal** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

Length — Length of data packet

scalar

Length of the data packet received, returned as a scalar. This value is determined by the value of the **Maximum length for Message** parameter.

Dependencies

This port appears only when you clear the **Output variable-size signal** parameter.

Data Types: `uint16`

Parameters

Local IP port — Number of IP port

25000 (default) | scalar in the range [1, 65535]

Specify the IP port number on which to receive UDP packets. This parameter is tunable in the generated code but is not tunable during simulation.

On Linux, to set the IP port number below 1024, run MATLAB with root privileges. For example, at the Linux command line, enter `sudo matlab`.

Remote IP address ('0.0.0.0' to accept all) — IP address from which to accept packets

'0.0.0.0' (default) | IP address

Specify the IP address from which to accept UDP packets. Specify a specific IP address to block UDP packets from other addresses. To accept packets from any IP address, specify '0.0.0.0'.

Receive buffer size (bytes) — Size of buffer that receives UDP packets

8192 (default) | scalar in the range [1, 67108864]

Specify the size of the buffer, in bytes, that receives the UDP packets. Make the buffer large enough to avoid data loss caused by buffer overflows.

Maximum length for Message — Maximum length of output data

255 (default) | scalar

Specify the maximum length, in vector elements, of the data output vector. Set this parameter to a value equal to or greater than the data size of a UDP packet. The system truncates data that exceeds this length.

If you disable **Output variable-size signal**, the block output is the length specified by this parameter.

Data type for Message — Data type of message

uint8 (default) | single | double | int8 | int16 | int32 | uint16 | uint32 | boolean

Specify the data type of the vector elements in the message output. Match the data type to the data input used to create the UDP packets.

Message is complex — Message data complexity

off (default) | on

Specify whether the block receives a message as complex data. Select this parameter to receive a message as complex data. Clear this parameter if a received message is real data.

Output variable-size signal — Message output that varies in length

on (default) | off

Specify whether your model supports signals of varying length. If your model supports signals of varying length, select this parameter. In that case:

- The output vector varies in length, depending on the amount of data in the UDP packet.
- The block emits the data vector from a single unlabeled output.

If your model does not support signals of varying length, clear this parameter. In that case:

- The block emits a fixed-length output that is the same length as specified by **Maximum length for Message**.

- If the UDP packet contains less data than the fixed-length output, the difference contains invalid data.
- The block emits the data vector from the **Message** output.
- The block emits the length of the valid data from the **Length** output.

If you disable this parameter, the block emits output that is the length specified by **Maximum length for Message**.

Sample time (seconds) — Frequency of calls to block

1 (default) | scalar

Specify the frequency at which the scheduler calls the UDP Receive block, in seconds. Enter a value greater than zero. In real-time operation, setting this parameter to a smaller value reduces the likelihood of dropped UDP messages.

Block Characteristics

Data Types	Boolean double integer single
Direct Feedthrough	no

Variable-Size Signals	yes
Zero-Crossing Detection	no

Version History

Introduced in R2010a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- The executable generated from this block relies on prebuilt dynamic library files (.dll files) included with MATLAB. Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed ZIP file. Using this ZIP file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.
- The **Local IP port** parameter is tunable in the generated code, but not tunable during simulation. You can control the parameter tunability in the generated code in several ways. One of the ways is to configure the parameter as a tunable field of a global structure in the generated code. Other ways include applying a built-in storage class or custom storage class to a `Simulink.Parameter` object and using this object to set the value of the block parameter. For details, see “Create Tunable Calibration Parameter in the Generated Code” (Simulink Coder).

UDP Send

Topics

“How To Run a Generated Executable Outside MATLAB”

UDP Send

Send UDP message

Library: DSP System Toolbox / Sinks

Description

The UDP Send block transmits an input data vector as a UDP packet to a remote IP network port. The remote IP port number to which the block sends the UDP packets is tunable in the generated code.

Some Simulink blocks and .exe files built from models that contain those blocks require shared libraries, such as .dll files on Windows. The UDP Send block requires the `networkdevice.dll` library file. To meet this requirement, follow the example on the `packNGo` function page to package the code files for your model. The resulting compressed folder contains the .dll files that the model requires, including `networkdevice.dll`. To run this type of .exe file outside of a MATLAB environment, place the required .dll files in the same folder as the .exe file or place them in a folder on the Windows system path. For more details, see “How To Run a Generated Executable Outside MATLAB”.

Ports

Input

Input — Input data vector

vector

Specify the input data vector that the block transmits as a UDP packet.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

Parameters

Remote IP address ('255.255.255.255' for broadcast) — IP address from which to accept UDP packets

'127.0.0.1' (default) | IP address | string

Specify the IP address or host name to which to send UDP packets. If you specify a host name, specify it as a string. To broadcast a UDP packet, specify '255.255.255.255'.

Remote IP port — Number of remote IP port

25000 (default) | scalar in the range [1, 65535]

Specify the IP port number to which to send UDP packets. This parameter is tunable in the generated code but is not tunable during simulation.

On Linux, to set the IP port number below 1024, run MATLAB with root privileges. For example, at the Linux command line, enter `sudo matlab`.

Local IP port source — Source of local IP port

Automatically determine (default) | Specify via dialog

Specify whether the block uses a local port number that the system assigns or that you specify by using the **Local IP port** parameter. For the system to assign the port number, select **Automatically determine**. If the receiving address expects UDP packets from a specific port number, select **Specify via dialog** and specify the port number by using the **Local IP port** parameter.

Local IP port — Number of local IP port

-1 (default) | scalar in the range [1, 65535]

Specify the IP port number from which the block sends UDP packets. Use this parameter when the receiving address expects messages from a specific port number.

Parameter Dependencies

To enable this parameter, set **Local IP port source** to **Specify via dialog**.

Send buffer size (bytes) — Size of buffer that sends UDP packets

8192 (default) | scalar in the range [1, 67108864]

Specify the size of the buffer, in bytes, that sends the UDP packets. Make the buffer large enough to avoid data loss caused by buffer overflows.

Unbuffer

Unbuffer input frame into sequence of scalar outputs

Library

Signal Management / Buffers

dspbuff3

Description

The Unbuffer block unbuffers an M_i -by- N input into a 1-by- N output. That is, inputs are unbuffered row-wise so that each matrix row becomes an independent time-sample in the output. The rate at which the block receives inputs is generally less than the rate at which the block produces outputs.

The block adjusts the output rate so that the *sample period* is the same at both the input and output, $T_{so}=T_{si}$. Therefore, the output sample period for an input of frame size M_i and frame period T_{fi} is T_{fi}/M_i , which represents a *rate* M_i times higher than the input frame rate. In the example above, the block receives inputs only once every three sample periods, but produces an output once every sample period. To rebuffer inputs to a larger or smaller frame size, use the Buffer block.

In the model below, the block unbuffers a four-channel input with a frame size of three. The **Initial conditions** parameter is set to zero and the tasking mode is set to multitasking, so the first three outputs are zero vectors.

Zero Latency

The Unbuffer block has *zero-tasking latency* in Simulink single-tasking mode. Zero-tasking latency means that the first input sample (received at $t=0$) appears as the first output sample.

Nonzero Latency

For *multitasking* operation, the Unbuffer block's buffer is initialized with the value specified by the **Initial conditions** parameter, and the block begins unbuffering this frame at the start of the simulation. Inputs to the block are therefore delayed by one buffer length, or M_i samples.

The **Initial conditions** parameter can be one of the following:

- A scalar to be repeated for the first M_i output samples of every channel
- A length- M_i vector containing the values of the first M_i output samples for every channel
- An M_i -by- N matrix containing the values of the first M_i output samples in each of N channels

Note For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Parameters

Initial conditions

The value of the block's initial output for cases of nonzero latency. You can specify a scalar, vector, or matrix.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The Unbuffer block supports code generation for Simulink Real-Time. The code generated for this target is executed concurrently. To generate this code, set the system target file of the model to `slrealtime.tlc`.

To set the system target file:

- 1 In the Simulink model window, on the **Modeling** tab, click **Model Settings**.
- 2 In the Model Settings > **Code Generation** pane, set the **System target file** to `slrealtime.tlc`.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Uniform Decoder

Decode integer input into floating-point output

Library

Quantizers

dspquant2

Description

The Uniform Decoder block performs the inverse operation of the Uniform Encoder block, and reconstructs quantized floating-point values from encoded integer input. The block adheres to the definition for uniform decoding specified in ITU-T Recommendation G.701.

Inputs can be real or complex values of the following six integer data types: `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`.

The block first casts the integer input values to floating-point values, and then uniquely maps (decodes) them to one of 2^B uniformly spaced floating-point values in the range $[-V, (1-2^{1-B})V]$, where you specify B in the **Bits** parameter (as an integer between 2 and 32) and V is a floating-point value specified by the **Peak** parameter. The smallest input value representable by B bits (0 for an unsigned input data type; -2^{B-1} for a signed input data type) is mapped to the value $-V$. The largest input value representable by B bits (2^B-1 for an unsigned input data type; $2^{B-1}-1$ for a signed input data type) is mapped to the value $(1-2^{1-B})V$. Intermediate input values are linearly mapped to the intermediate values in the range $[-V, (1-2^{1-B})V]$.

To correctly decode values encoded by the Uniform Encoder block, the **Bits** and **Peak** parameters of the Uniform Decoder block should be set to the same values as the **Bits** and **Peak** parameters of the Uniform Encoder block. The **Overflow mode** parameter specifies the Uniform Decoder block's behavior when the integer input is outside the range representable by B bits. When you select **Saturate**, *unsigned* input values greater than 2^B-1 saturate at 2^B-1 ; *signed* input values greater than $2^{B-1}-1$ or less than -2^{B-1} saturate at those limits. The real and imaginary components of complex inputs saturate independently.

When you select **Wrap**, *unsigned* input values, u , greater than 2^B-1 are wrapped back into the range $[0, 2^B-1]$ using $\text{mod-}2^B$ arithmetic.

$$u = \text{mod}(u, 2^B)$$

Signed input values, u , greater than $2^{B-1}-1$ or less than -2^{B-1} are wrapped back into that range using $\text{mod-}2^B$ arithmetic.

$$u = (\text{mod}(u+2^B/2, 2^B) - (2^B/2))$$

The real and imaginary components of complex inputs wrap independently.

The **Output type** parameter specifies whether the decoded floating-point output is single or double precision. Either level of output precision can be used with any of the six integer input data types.

Examples

See example model `ex_uniform_decoder`.

In this example, the input to the block is the `uint8` output of a Uniform Encoder block. This block has comparable settings: **Peak** = 2, **Bits** = 3, and **Output type** = `Unsigned`. (Comparable settings ensure that inputs to the Uniform Decoder block do not saturate or wrap. See the example on the Uniform Encoder block reference page for more about these settings.)

The real and complex components of each input are independently mapped to one of 2^3 distinct levels in the range `[-2.0, 1.5]`.

```
0 is mapped to -2.0
1 is mapped to -1.5
2 is mapped to -1.0
3 is mapped to -0.5
4 is mapped to  0.0
5 is mapped to  0.5
6 is mapped to  1.0
7 is mapped to  1.5
```

Parameters

Peak

Specify the largest amplitude represented in the encoded input. To correctly decode values encoded with the Uniform Encoder block, set the **Peak** parameters in both blocks to the same value.

Bits

Specify the number of input bits, `B`, used to encode the data. (This can be less than the total number of bits supplied by the input data type.) To correctly decode values encoded with the Uniform Encoder block, set the **Bits** parameters in both blocks to the same value.

Overflow mode

Specify the block's behavior when the integer input is outside the range representable by `B` bits. Out-of-range inputs can either saturate at the extreme value, or wrap back into range.

Output type

Specify the precision of the floating-point output, `single` or `double`.

Uniform Encoder

Quantize and encode floating-point input into integer output

Library

Quantizers

dspquant2

Description

The Uniform Encoder block performs the following two operations on each floating-point sample in the input vector or matrix:

- 1 Quantizes the value using the same precision
- 2 Encodes the quantized floating-point value to an integer value

In the first step, the block quantizes an input value to one of 2^B uniformly spaced levels in the range $[-V, (1-2^{1-B})V]$, where you specify B in the **Bits** parameter and you specify V in the **Peak** parameter. The quantization process rounds both positive and negative inputs *downward* to the nearest quantization level, with the exception of those that fall exactly on a quantization boundary. The real and imaginary components of complex inputs are quantized independently.

The number of bits, B , can be any integer value between 2 and 32, inclusive. Inputs greater than $(1-2^{1-B})V$ or less than $-V$ saturate at those respective values. The real and imaginary components of complex inputs saturate independently.

In the second step, the quantized floating-point value is uniquely mapped (encoded) to one of 2^B integer values. When the **Output type** is set to **Unsigned integer**, the smallest quantized floating-point value, $-V$, is mapped to the integer 0, and the largest quantized floating-point value, $(1-2^{1-B})V$, is mapped to the integer 2^B-1 . Intermediate quantized floating-point values are linearly (uniformly) mapped to the intermediate integers in the range $[0, 2^B-1]$. For efficiency, the block automatically selects an *unsigned* output data type (`uint8`, `uint16`, or `uint32`) with the minimum number of bits equal to or greater than B .

When the **Output type** is set to **Signed integer**, the smallest quantized floating-point value, $-V$, is mapped to the integer -2^{B-1} , and the largest quantized floating-point value, $(1-2^{1-B})V$, is mapped to the integer $2^{B-1}-1$. Intermediate quantized floating-point values are linearly mapped to the intermediate integers in the range $[-2^{B-1}, 2^{B-1}-1]$. The block automatically selects a *signed* output data type (`int8`, `int16`, or `int32`) with the minimum number of bits equal to or greater than B .

Inputs can be real or complex, double or single precision. The output data types that the block uses are shown in the table below. Note that most of the DSP System Toolbox blocks accept only double-precision inputs. Use the Simulink Data Type Conversion block to convert integer data types to double precision. See “About Data Types in Simulink” (Simulink) for a complete discussion of data types, as well as a list of Simulink blocks capable of reduced-precision operations.

Bits	Unsigned Integer	Signed Integer
2 to 8	uint8	int8
9 to 16	uint16	int16
17 to 32	uint32	int32

The Uniform Encoder block operations adhere to the definition for uniform encoding specified in ITU-T Recommendation G.701.

Examples

See example model `ex_uniform_encoder`.

In this example, the following parameters are set:

- **Peak** = 2
- **Bits** = 3
- **Output type** = Unsigned

The following figure illustrates uniform encoding.

The real and complex components of each input (horizontal axis) are independently quantized to one of 2^3 distinct levels in the range $[-2, 1.5]$. These components are then mapped to one of 2^3 integer values in the range $[0, 7]$.

-2.0 is mapped to 0
 -1.5 is mapped to 1
 -1.0 is mapped to 2
 -0.5 is mapped to 3
 0.0 is mapped to 4
 0.5 is mapped to 5
 1.0 is mapped to 6
 1.5 is mapped to 7

This table shows the results for a few particular inputs.

Input	Quantized Input	Output	Notes
1.6	1.5+0.0i	7+4i	

Input	Quantized Input	Output	Notes
-0.4	-0.5+0.0i	3+4i	
-3.2	-2.0+0.0i	4i	Saturation (real)
0.4-1.2i	0.0-1.5i	4+i	
0.4-6.0i	0.0-2.0i	4	Saturation (imaginary)
-4.2+3.5i	-2.0+2.0i	7i	Saturation (real and imaginary)

The output data type is automatically set to `uint8`, the most efficient format for this input range.

Parameters

Peak

The largest input amplitude to be encoded, V . Real or imaginary input values greater than $(1-2^{1-B})V$ or less than $-V$ saturate (independently for complex inputs) at those limits.

Bits

Specify the number of bits, B , needed to represent the integer output. The number of levels at which the block quantizes the floating-point input is 2^B .

Output type

The data type of the block's output, `Unsigned integer` or `Signed integer`. Unsigned outputs are `uint8`, `uint16`, or `uint32`, while signed outputs are `int8`, `int16`, or `int32`.

Unwrap

Unwrap signal phase

Library: DSP System Toolbox / Signal Operations

Description

The Unwrap block unwraps each channel of the input by adding or subtracting appropriate multiples of 2π to each channel element. The block recognizes phase discontinuities larger than the value of the **Tolerance** parameter. For more information on phase unwrapping, see “Definition of Phase Unwrap” on page 2-1329.

Ports

Input

Port_1 — Signal input

scalar | vector | matrix

Signal input to unwrap, specified as a scalar, vector, or matrix. The input must have radian phase entries.

Data Types: single | double

Output

Port_1 — Signal output

scalar | vector | matrix

Unwrapped signal output, returned as a scalar, vector, or matrix.

The block preserves the input size and dimension, and the output port rate equals the input port rate.

Data Types: single | double

Parameters

Tolerance (radians) — Jump size

π (default) | scalar value

The jump size that the block recognizes as a true phase discontinuity. The default is set to π (rather than a smaller value) to avoid altering legitimate signal features. To increase the block's sensitivity, set the **Tolerance** to a value slightly less than π .

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32

Input processing — Method to process the input

Columns as channels (frame based) (default) | Elements as channels (sample based)

Specify how the block should process the input. You can set this parameter to one of these options:

- **Columns as channels (frame based)** (default) — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

Reset initial phase to zero for each input frame — **Checking successive frames**
off (default) | on

When you clear this parameter, the block ignores boundaries between input frames and does not reset the initial phase value to zero each time a new input is received. In this mode, the block continuously unwraps the data in each column of the input.

This figure illustrates how the block unwraps data when you clear this parameter.

When you select this parameter, the block treats each frame of input data independently and resets the initial phase value for each new input frame.

This figure illustrates how the block unwraps data when you select this parameter.

For more information, see “Frame-Based Processing” on page 2-1331.

Dependencies

To enable this parameter, set the **Input processing** parameter to **Columns as channels** (frame based). In sample-based processing mode, the block does not reset the initial phase value to zero for each new input. See “Sample-Based Processing” on page 2-1332 for more information.

Block Characteristics

Data Types	double single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

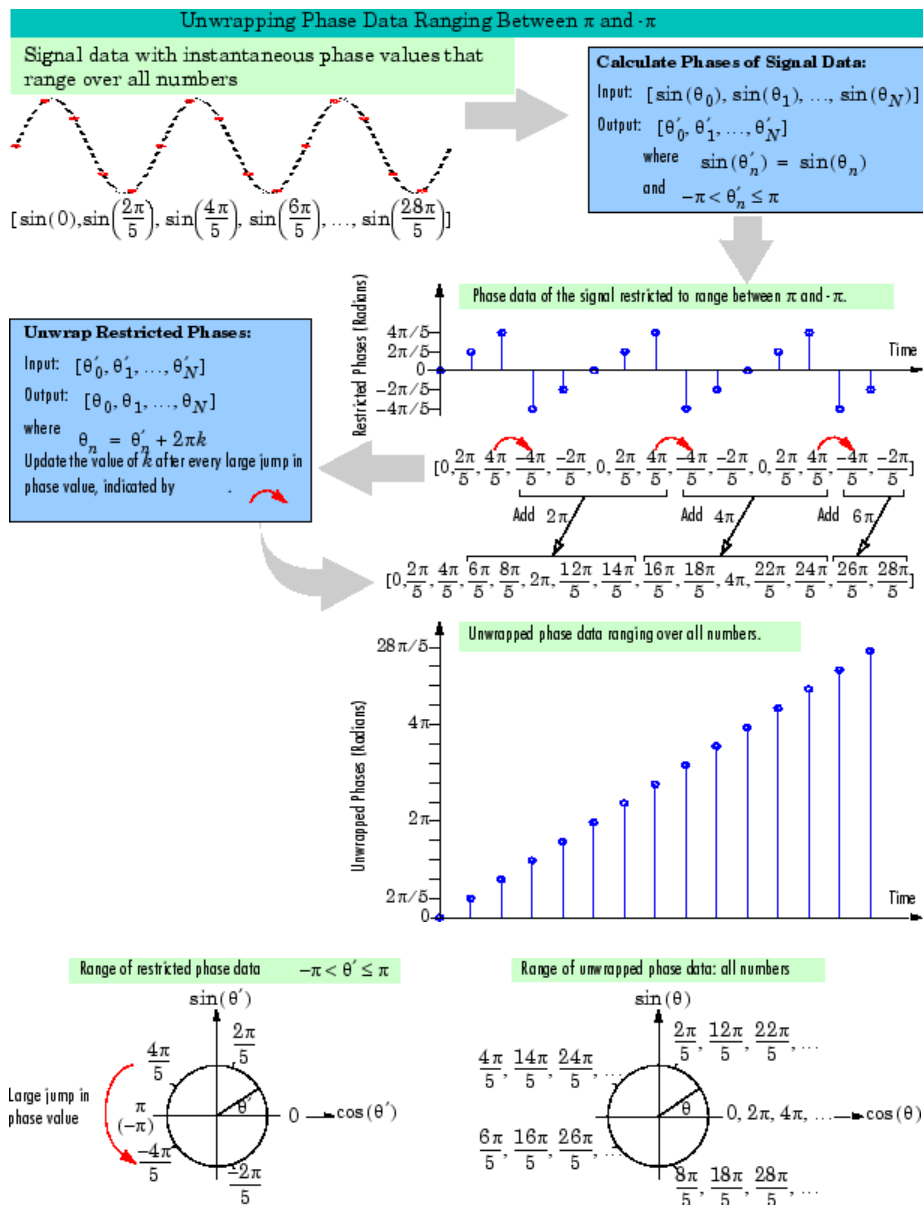

More About

Definition of Phase Unwrap

Phase unwrap or unwrap is a process often used to reconstruct a signal's original phase. Unwrap algorithms add appropriate multiples of 2π to each phase input to restore original phase values, as illustrated in the diagram. For more information on the unwrap algorithm used by this block, see “Unwrap Method” on page 2-1330.

Algorithms that compute the phase of a signal often only output phases between $-\pi$ and π . For instance, such algorithms compute the phase of $\sin(2\pi + 3)$ to be 3, since $\sin(3) = \sin(2\pi + 3)$, and

since the actual phase, $2\pi + 3$, is not between $-\pi$ and π . Such algorithms compute the phases of $\sin(-4\pi + 3)$ and $\sin(16\pi + 3)$ to be 3 as well.

Unwrap Method

The Unwrap block unwraps each channel of its input matrix or input vector by adding $2\pi k$ to each successive channel element, and updating k at each *phase jump*. A phase jump occurs when the difference between two adjacent phase value entries exceeds the value of the **Tolerance** parameter.

This code shows how the block unwraps the data in a given input channel u .

```
k=0; % initialize k to 0
i=1; % initialize the counter to 1
alpha=pi; % set alpha to the desired Tolerance. In this case, pi

for i = 1:(size(u)-1)
    yout(i,:) = u(i) + (2*pi*k); % add 2*pi*k to ui
```

```

if((abs(u(i+1)-u(i)))>(abs(alpha))) %if diff is greater than alpha, increment or decrement k
    if u(i+1)<u(i) % if the phase jump is negative, increment k
        k=k+1;
    else % if the phase jump is positive, decrement k
        k=k-1;
    end
end
end
end
yout((i+1,:)=u(i+1)+(2*pi*k); % add 2*pi*k to the last element of the input

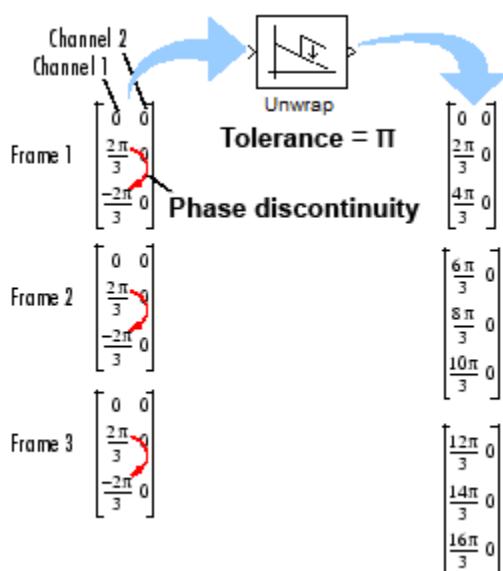

```

Frame-Based Processing

When you configure the block to perform frame-based processing, by setting the **Input processing** parameter to **Columns as channels (frame based)**, the block supports two different unwrap modes. In both modes, the block adds $2\pi k$ to each input channel's elements, and updates k at each phase discontinuity. The difference between the two modes is how often the block resets the initial phase value (k) to zero. You can choose to unwrap data across frame boundaries (default), or to unwrap only within input frames, by resetting the initial phase value each time a new input frame is received.

Unwrapping Across Frame Boundaries

In the default mode, the block ignores boundaries between input frames, and continues to unwrap the data in each channel without resetting the initial phase value to zero. To specify this mode, clear the **Reset initial phase to zero for each input frame** parameter. This figure illustrates how the block unwraps data in this mode.

Unwrapping Within Frames

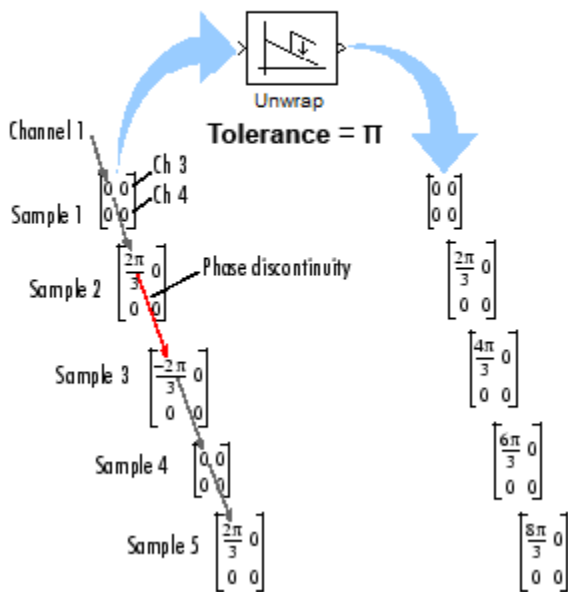

When you select the **Reset initial phase to zero for each input frame** parameter, the block treats each frame of input data independently. In this mode, the block resets the initial phase value to zero each time a new input frame is received. This figure illustrates how the block unwraps data in this mode.

Sample-Based Processing

When you configure the block to perform sample-based processing, by setting the **Input processing** parameter to Elements as channels (sample based), the block treats each element of the input as an individual channel. The block unwraps the data in each channel of the input, and does not reset the initial phase to zero each time a new input is received. This figure illustrates how the block unwraps data when performing sample-based processing.

Sample-Based Unwrap Mode

Upsample

Resample input at higher rate by inserting zeros

Library: DSP System Toolbox / Signal Operations
 DSP System Toolbox HDL Support / Signal Operations

Description

The Upsample block resamples each channel of the M_I -by- N input at a rate L times higher than the input sample rate by inserting $L-1$ zeros between consecutive samples. Specify the integer L in the **Upsample factor** parameter. Use the **Sample offset** parameter D to delay the output samples by a specific number of sample periods. Doing so enables you to select any of the L possible output phases. The value you specify in the **Sample offset** parameter must be an integer in the range $0 \leq D < (L - 1)$.

You can use this block inside triggered subsystems when you set the **Rate options** parameter to Enforce single-rate processing.

Ports

Input

Port_1 – Input signal

scalar | vector | matrix

Specify the input signal as a real or a complex-valued scalar, vector, or a matrix signal.

When you set **Input processing** to Columns as channels (frame based) and **Rate options** to Enforce single-rate processing, the input can be a variable-size signal. That is, the frame size (number of rows) and the number of channels (columns) of the signal can change during simulation.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point

Output

Port_1 – Upsampled signal

scalar | vector | matrix

The Upsample block outputs a signal that has the same data type and complexity as the input signal. The size of the output depends on the value of the **Upsample factor**, L parameter and the setting of the **Rate options** parameter.

If **Upsample factor** is set to L and **Rate options** is set to:

- Enforce single-rate processing -- The block maintains the input sample rate by increasing the output frame size by a factor of L .

- **Allow multirate processing** -- The block resamples the signal such that the output sample rate is L times faster than the input sample rate. The output signal has the same frame size as the input signal.

When the input is a variable-size signal, the output is also a variable-size signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Parameters

Upsample factor, L — Upsample factor

3 (default) | positive integer

Specify the upsample factor L by which to increase the input sample rate as a positive integer.

Sample offset (0 to $L-1$) — Sample offset

0 (default) | integer in the range $[0, L-1]$

Specify the sample offset D as an integer in the range $[0, L-1]$.

Input processing — Method to process input signals

`Columns as channels (frame based)` (default) | `Elements as channels (sample based)`

Specify how the block should process the input. You can set this parameter to one of these options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel. In this mode, the block can perform single-rate or multirate processing.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel. In this mode, the block always performs multirate processing.

Rate options — Method by which block upsamples input

`Enforce single-rate processing` (default) | `Allow multirate processing`

Specify the method by which the block upsamples the input. You can select one of the following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the input sample rate by increasing the output frame size by a factor of L . To select this option, you must set the **Input processing** parameter to `Columns as channels (frame based)`.
- `Allow multirate processing` — When you select this option, the block resamples the signal such that the output sample rate is L times faster than the input sample rate.

Initial conditions — Initial conditions

0 (default) | scalar | vector | matrix

Specify the value with which the block is initialized for cases of nonzero latency as a scalar, vector, or a matrix. The scalar value appears in the output as the sample $D+1$. If this parameter is set to a

vector or a matrix, the size of this parameter should be the same as that of the input. This parameter appears only when you configure the block to perform multirate processing.

Dependencies

To enable this parameter, set **Rate options** to Allow multirate processing.

Block Characteristics

Data Types	Boolean double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

More About

Frame-Based Processing

When you set the **Input processing** parameter to Columns as channels (frame based), the block upsamples each column of the input over time. In this mode, the block can perform either single-rate or multirate processing. You can use the **Rate options** parameter to specify how the block upsamples the input.

- When you set the **Rate options** parameter to Enforce single-rate processing, the input and output of the block have the same sample rate. In this mode, the block outputs a signal with a proportionally larger frame size than the input. For upsampling by a factor of L , the output frame size is L times larger than the input frame size ($M_o = M_i * L$), but the input and output frame rates are equal.

For an example of single-rate upsampling, see “Upsample Signal In Single-Rate Processing Mode”.

- When you set the **Rate options** parameter to Allow multirate processing, the block treats an M_i -by- N matrix input as N independent channels. The block upsamples each column of the input over time by keeping the frame size constant ($M_i = M_o$), and making the output frame period (T_{fo}) L times shorter than the input frame period ($T_{fi} = T_{fo} / L$).

See the “Upsample Signal In Multirate Frame-Based Processing Mode” example to see the Upsample block in this mode.

Sample-Based Processing

When you set the **Input processing** parameter to Elements as channels (sample based), the block treats an M -by- N matrix input as $M * N$ independent channels, and upsamples each channel over time. In this mode, the block always performs multirate processing. The output sample rate is L times higher than the input sample rate ($T_{so} = T_{si} / L$), and the input and output sizes are identical.

Zero Latency

The Upsample block has *zero-tasking latency* for all single-rate operations. The block is in a single-rate mode if you set the **Upsample factor** parameter to 1 or if you set the **Input processing**

parameter to `Columns as channels (frame based)` and the **Rate options** parameter to `Enforce single-rate processing`.

The Upsample block also has zero-tasking latency for multirate operations if you run your model in Simulink single-tasking mode.

Zero-tasking latency means that the block propagates the first input (received at $t=0$) immediately after the consecutive zeros D , which you specify in the **Sample offset** parameter. This output ($D+1$) is followed in turn by the $L-1$ inserted zeros and the next input sample.

Nonzero Latency

The Upsample block has tasking latency for a multirate multitasking operation:

- In multirate sample-based processing mode, the initial condition for each channel appears as output sample $D+1$, and is followed by $L-1$ inserted zeros. The channel's first input appears as output sample $D+L+1$. The **Initial conditions** parameter can be an M_i -by- N matrix containing one value for each channel, or a scalar value that the block applies to all signal channels.
- In multirate frame-based processing mode, the first row of the initial condition matrix appears as output sample $D+1$, and is followed by $L-1$ inserted rows of zeros, the second row of the initial condition matrix, and so on. The first row of the first input matrix appears in the output as sample M_iL+D+1 . The **Initial conditions** parameter can be an M_i -by- N matrix, or a scalar value that the block repeats across all elements of the input matrix.

Note For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Version History

Introduced before R2006a

Support for variable-size input signal

Starting in R2022b, when you set **Input processing** to `Columns as channels (frame based)` and **Rate options** to `Enforce single-rate processing`, the input can be a variable-size signal. That is, the frame size (number of rows) and the number of channels (columns) of the signal can change during simulation.

When the input is a variable-size signal, the output is also a variable-size signal.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

Best Practices

Consider whether your model can use the Repeat block instead of the Upsample block. The Repeat block uses fewer hardware resources, so as a best practice use the Upsample block only when your algorithm requires zero-padding upsampling.

See also “Multirate Model Requirements for HDL Code Generation” (HDL Coder).

HDL Architecture

This block has one default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Restrictions

Input processing set to `Columns as channels (frame based)` is not supported.

Complex Data Support

This block supports code generation for complex signals.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Variable Bandwidth FIR Filter

Design tunable bandwidth FIR filter

Library

Filtering / Filter Designs

dspfdesign

Description

The Variable Bandwidth FIR Filter block filters each channel of the input signal over time using specified FIR filter specifications. This block offers tunable filter design parameters, which enable you to tune the filter characteristics while the simulation is running.

The block designs the FIR filter according to the filter parameters set in the block dialog box. The output port properties, such as datatype, complexity, and dimension, are identical to the input port properties.

Each column of the input signal is treated as a separate channel. If the input is a two-dimensional signal, the first dimension represents the channel length (or frame size) and the second dimension represents the number of channels. If the input is a one-dimensional signal, then it is interpreted as a single channel.

This block supports variable-size input, enabling you to change the channel length during simulation. To enable variable-size input, clear the **Inherit sample rate from input** check box. The number of channels must remain constant.

This block also supports SIMD code generation. For details, see “Code Generation” on page 2-1343.

Algorithms

This block brings the capabilities of `dsp.VariableBandwidthFIRFilter` System object to the Simulink environment.

The FIR filter is designed using the window method. For information on the algorithms used by the Variable Bandwidth FIR Filter block, see the “Algorithms” on page 4-1252 section of `dsp.VariableBandwidthFIRFilter`.

Examples

- “System Identification Using RLS Adaptive Filtering”

Parameters

FIR filter order

Order of the FIR filter, specified as a positive integer scalar. The default is 30. This parameter is nontunable.

Filter type

Type of FIR filter. You can set this parameter to:

- Lowpass (default)
- Highpass
- Bandpass
- Bandstop

This parameter is nontunable.

Specify cutoff frequency from input port

When you select this check box, the cutoff frequency is input through the **Fcut** port. When you clear this check box, the cutoff frequency is specified on the block dialog through the **Filter Cutoff frequency (Hz)** parameter.

This parameter applies when you set **Filter type** to Lowpass or Highpass.

Filter Cutoff frequency (Hz)

Cutoff frequency of the FIR filter, specified as a real positive scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter type** to Lowpass or Highpass, and clear the **Specify cutoff frequency from input port** parameter. The default is 1000. This parameter is tunable.

Specify center frequency from input port

When you select this check box, the center frequency is input through the **Fc** port. When you clear this check box, the center frequency is specified on the block dialog through the **Filter center frequency (Hz)** parameter.

This parameter applies when you set **Filter type** to Bandpass or Bandstop.

Filter center frequency (Hz)

Center frequency of the FIR filter, specified as a real positive scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter type** to Bandpass or Bandstop, and clear the **Specify center frequency from input port** parameter. The default is 10000. This parameter is tunable.

Specify bandwidth from input port

When you select this check box, the filter bandwidth is input through the **BW** port. When you clear this check box, the filter bandwidth is specified on the block dialog through the **Filter bandwidth (Hz)** parameter.

This parameter applies when you set **Filter type** to Bandpass or Bandstop.

Filter bandwidth (Hz)

Bandwidth of the FIR filter, specified as a real positive scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter type** to Bandpass or Bandstop, and clear the **Specify bandwidth from input port** parameter. The default is 2000. This parameter is tunable.

Window function

Window function used to design the FIR filter. You can set this parameter to:

- Hann (default)
- Hamming
- Chebyshev
- Kaiser

This parameter is nontunable.

Chebyshev window sidelobe attenuation (dB)

Sidelobe attenuation of chebyshev window, specified as a real positive scalar. This parameter applies when you set **Window function** to Chebyshev. The default is 60. This parameter is nontunable.

Kaiser window parameter

Kaiser window parameter, specified as a real scalar. This parameter applies when you set **Window function** to Kaiser. The default is 0.5. This parameter is nontunable.

Inherit sample rate from input

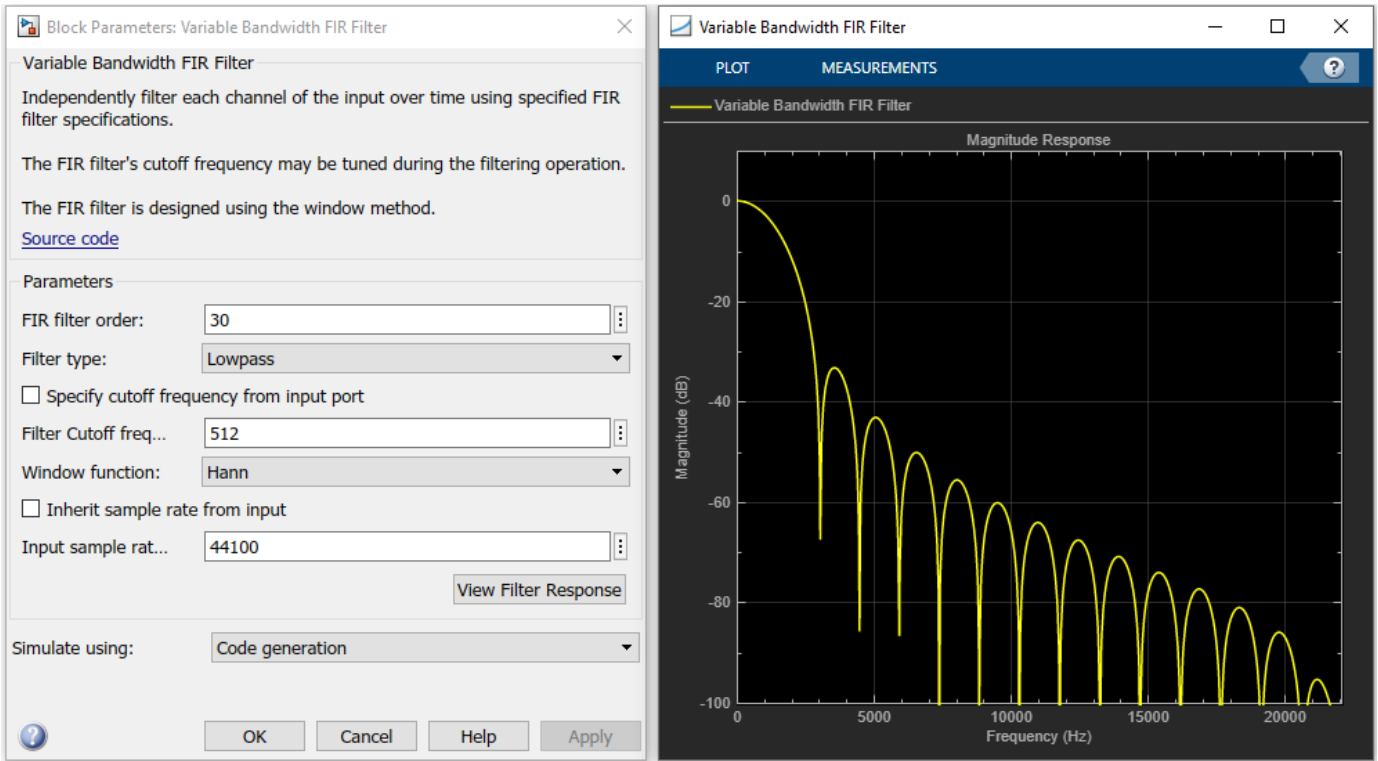

When you select this check box, the block's sample rate is computed as N / T_s , where N is the frame size of the input signal and T_s is the sample time of the input signal. When you clear this check box, the block's sample rate is the value specified in **Input sample rate (Hz)**. By default, this check box is selected.

Input sample rate (Hz)

Sample rate of the input signal, specified as a positive scalar. The default is 44100. This parameter applies when you clear the **Inherit sample rate from input** check box. This parameter is nontunable.

View Filter Response

Opens the Dynamic Filter Visualizer window and displays the magnitude and phase response of the variable bandwidth FIR filter. The response is based on the parameters you select in the Block Parameters dialog box. To update the response while the visualizer is running, modify the parameters in the dialog box and click **Apply**.

You can configure the plot settings and the frequency response measurements from the interface of the visualizer.

On the **Plot** tab, you can enable the legend, specify to plot both magnitude and phase responses of the filter, modify the plot settings, generate a script to re-create the plot, and even save or share the settings.

On the **Measurements** tab, you can enable data cursors, and display the peak values of the filter response.

For more details on the Dynamic Filter Visualizer interface and its tools, see “Configure Dynamic Filter Visualizer”.

Simulate using

Type of simulation to run. You can set this parameter to:

- Code generation (default)

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.

- Interpreted execution

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The Variable Bandwidth FIR Filter block supports SIMD code generation using Intel AVX2 technology when the input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

Variable Bandwidth IIR Filter

Design tunable bandwidth IIR filter

Library

Filtering / Filter Designs

dspfdesign

Description

The Variable Bandwidth IIR Filter block filters each channel of the input signal over time using specified IIR filter specifications. This block offers tunable filter design parameters, which enable you to tune the filter characteristics while the simulation is running.

The block designs the IIR filter according to the filter parameters set in the block dialog box. The output port properties, such as datatype, complexity, and dimension, are identical to the input port properties.

Each column of the input signal is treated as a separate channel. If the input is a two-dimensional signal, the first dimension represents the channel length (or frame size) and the second dimension represents the number of channels. If the input is a one-dimensional signal, then it is interpreted as a single channel.

This block supports variable-size input, enabling you to change the channel length during simulation. To enable variable-size input, clear the **Inherit sample rate from input** check box. The number of channels must remain constant.

Algorithms

This block brings the capabilities of `dsp.VariableBandwidthIIRFilter` System object to the Simulink environment.

The IIR filter is designed using the elliptical method. The IIR filter is tuned using IIR spectral transformations based on allpass filters. For more information on the algorithms used by the Variable Bandwidth IIR Filter block, see the 'Algorithms' section of `dsp.VariableBandwidthIIRFilter`.

Examples

- “Tunable Lowpass Filtering of Noisy Input in Simulink”

Parameters

Filter type

Type of IIR filter. You can set this parameter to:

- Lowpass (default)
- Highpass
- Bandpass
- Bandstop

This parameter is nontunable.

IIR filter order

Order of the IIR filter, specified as a positive integer scalar. The default is 8. This parameter is nontunable.

Specify passband frequency from input port

When you select this check box, the filter passband frequency is input through the **Fp** port. When you clear this check box, the passband frequency is specified on the block dialog through the **Filter passband frequency (Hz)** parameter.

This parameter applies when you set **Filter type** to Lowpass or Highpass.

Filter passband frequency (Hz)

Passband frequency of the IIR filter, specified as a real positive scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter type** to Lowpass or Highpass, and clear the **Specify passband frequency from input port** parameter. The default is 1000. This parameter is tunable.

Specify center frequency from input port

When you select this check box, the center frequency of the IIR filter is input through the **Fc** port. When you clear this check box, the center frequency is specified on the block dialog through the **Filter center frequency (Hz)** parameter.

This parameter applies when you set **Filter type** to Bandpass or Bandstop.

Filter center frequency (Hz)

Center frequency of the IIR filter, specified as a real positive scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter type** to Bandpass or Bandstop, and clear the **Specify center frequency from input port** parameter. The default is 10000. This parameter is tunable.

Specify bandwidth from input port

When you select this check box, the bandwidth of the IIR filter is input through the **BW** port. When you clear this check box, the filter bandwidth is specified on the block dialog through the **Filter bandwidth (Hz)** parameter.

This parameter applies when you set **Filter type** to Bandpass or Bandstop.

Filter bandwidth (Hz)

Bandwidth of the IIR filter, specified as a real positive scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter type** to Bandpass or Bandstop, and clear the **Specify bandwidth from input port** parameter. The default is 2000. This parameter is tunable.

Filter passband ripple (dB)

Passband ripple of the IIR filter, specified as a real positive scalar. The default is 1. This parameter is nontunable.

Filter Stopband attenuation (dB)

Stopband attenuation of the IIR filter, specified as a real positive scalar. The default is 60. This parameter is nontunable.

Inherit sample rate from input

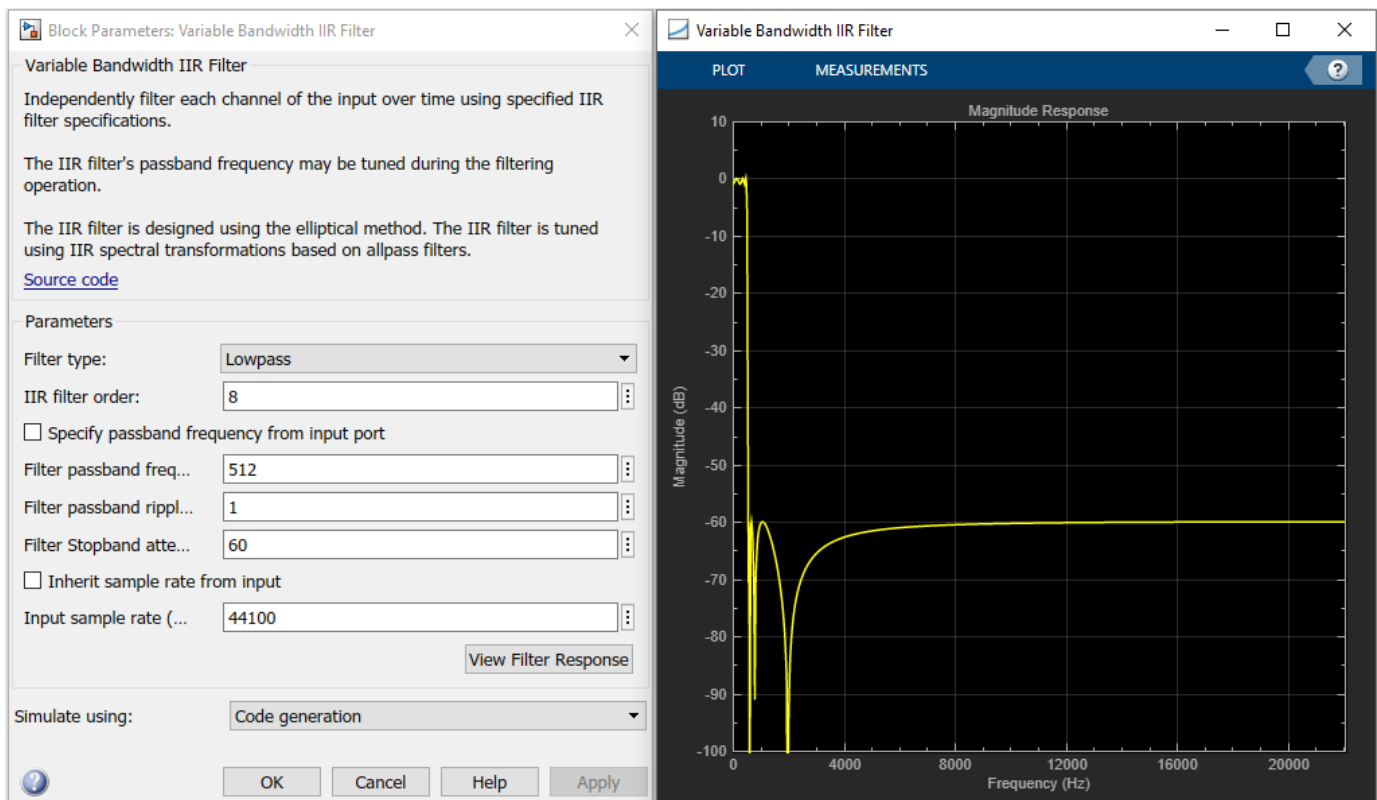

When you select this check box, the block's sample rate is computed as N / T_s , where N is the frame size of the input signal and T_s is the sample time of the input signal. When you clear this check box, the block's sample rate is the value specified in **Input sample rate (Hz)**. By default, this check box is selected.

Input sample rate (Hz)

Sample rate of the input signal, specified as a positive scalar. The default is 44100. This parameter applies when you clear the **Inherit sample rate from input** check box. This parameter is nontunable.

View Filter Response

Opens the Dynamic Filter Visualizer window and displays the magnitude and phase response of the variable bandwidth IIR filter. The response is based on the parameters you select in the Block Parameters dialog box. To update the response while the visualizer is running, modify the parameters in the dialog box and click **Apply**.

You can configure the plot settings and the frequency response measurements from the interface of the visualizer.

On the **Plot** tab, you can enable the legend, specify to plot both magnitude and phase responses of the filter, modify the plot settings, generate a script to re-create the plot, and even save or share the settings.

On the **Measurements** tab, you can enable data cursors, and display the peak values of the filter response.

For more details on the Dynamic Filter Visualizer interface and its tools, see “Configure Dynamic Filter Visualizer”.

Simulate using

Type of simulation to run. You can set this parameter to:

- Code generation (default)

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.

- Interpreted execution

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

Variable Fractional Delay

Delay input by time-varying fractional number of sample periods

Library: DSP System Toolbox / Signal Operations

Description

The Variable Fractional Delay block delays the input signal by a specified number of fractional samples along each channel of the input. The block can also concurrently compute multiple delayed versions (taps) of the same signal. For an example, see “Delay Signal Using Multitap Fractional Delay”.

When the delay has a fractional value, the block interpolates the input signal to obtain new samples at noninteger sampling intervals. You can set **Interpolation mode** parameter to one of **Linear**, **FIR**, or **Farrow**. The block supports time-varying delay values. That is, the delay value can vary within a frame from sample to sample.

The block assumes that the input values at the **Delay** port are between D_{min} and D_{max} , where D_{min} appears in the **Valid delay range** section on the **Main** tab of the block dialog, and D_{max} is the value of the **Maximum delay (Dmax) in samples** parameter. The block clips delay values less than D_{min} to D_{min} and delay values greater than D_{max} to D_{max} .

You must consider additional factors when selecting valid **Delay** values for the **FIR** and **Farrow** interpolation modes. For details, see “Algorithms” on page 2-1363.

Ports

Input

In — Data input

vector | matrix

Specify the data input as a vector or matrix. The data input must have the same data type as the delay input.

This block supports variable-size input signal. That is, you can change the number of input rows during the simulation. However, the number of channels must remain constant.

Example: [1 2 3 4;5 1 4 2;2 6 2 3;1 2 3 2;3 4 5 6;1 2 3 1]

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Delay — Delay input

scalar | vector | matrix | N-D array

Specify the delay input as a scalar, vector, matrix, or N-D array. The delay can be an integer or a fractional value. The block interpolates the signal to obtain new samples at noninteger sampling intervals. The delay input must have the same data type as the data input.

This block supports variable-size delay signal. That is, you can change one or both of the dimensions of the delay signal during simulation. However, the block must make sure that the resulting number of output channels remains constant throughout the simulation.

When the **Input processing** parameter is set to **Columns as channels (frame based)**, the table below shows the effect of the dimension of the delay input on the data input. For an example, see “Delay Signal Using Multitap Fractional Delay”.

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N (unoriented, one channel)	scalar	Unoriented (N)	One delay value applied to the input channel
N (unoriented, one channel)	Unoriented (N)	Unoriented (N)	Delay value varies within the frame from sample to sample
N (unoriented, one channel)	1-by- P	N -by- P	P taps. Each column in the output is a delayed version of the input. The delay value is specified by the corresponding element in the delay input vector.
N (unoriented, one channel)	N -by- P	N -by- P	P taps. In addition, delay varies within each frame from sample to sample.
N -by-1 (one channel with frame size equal to N)	scalar	N -by-1	One delay value applied to the input channel
N -by-1 (one channel with frame size equal to N)	Unoriented (N)	N -by-1	Delay value varies within the frame from sample to sample
N -by-1 (one channel with frame size equal to N)	N -by-1	N -by-1	Delay value varies within the frame from sample to sample
N -by-1 (one channel with frame size equal to N)	1-by- P	N -by- P	P taps. Each column in the output is a delayed version of the input. The delay value is specified by the corresponding element in the delay input vector.
N -by-1 (one channel with frame size equal to N)	N -by- P	N -by- P	P taps. In addition, delay varies within each frame from sample to sample.
N -by- L (L channels with frame size equal to N)	scalar	N -by- L	One delay value applied to all input channels

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N -by- L (L channels with frame size equal to N)	1-by- L	N -by- L	Unique delay value for each input channel
N -by- L (L channels with frame size equal to N)	N -by-1	N -by- L	Delay value varies within the frame from sample to sample. Same set of delay values for all channels.
N -by- L (L channels with frame size equal to N)	N -by- L	N -by- L	Delay value varies within the frame from sample to sample. Different delay values for each input channel.
N -by- L (L channels with frame size equal to N)	1-by-1-by- P	N -by- L -by- P	L channels. P taps per channel. Same delay for all channels.
N -by- L (L channels with frame size equal to N)	1-by- L -by- P	N -by- L -by- P	L channels. P taps per channel. Taps vary across channels.
N -by- L (L channels with frame size equal to N)	N -by-1-by- P	N -by- L -by- P	L channels. P taps per channel. Delay varies within the frame from sample to sample. Same set of delay values for each channel.
N -by- L (L channels with frame size equal to N)	N -by- L -by- P	N -by- L -by- P	L channels. P taps per channel. Delay varies within the frame from sample to sample. Different set of delay values for each channel.

When the **Input processing** parameter is set to `Elements as channels (sample based)`, the table below shows the effect of the dimension of the delay input on the data input.

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N (unoriented, one channel)	scalar	Unoriented (N)	One delay value applied to the input channel
N (unoriented, one channel)	Unoriented (N)	Unoriented (N)	Delay value varies within the frame from sample to sample
N -by-1 (one channel with frame size equal to N)	scalar	N -by-1	One delay value applied to the input channel

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N -by-1 (one channel with frame size equal to N)	Unoriented (N)	N -by-1	Delay value varies within the frame from sample to sample
N -by-1 (one channel with frame size equal to N)	N -by-1	N -by-1	Delay value varies within the frame from sample to sample
N -by- L (L channels with N samples in each channel)	scalar	N -by- L	One delay value applied to all input channels
N -by- L (L channels with N samples in each channel)	1-by- L	N -by- L	Unique delay value for each input channel
N -by- L (L channels with N samples in each channel)	N -by-1	N -by- L	Delay value varies within the frame from sample to sample. Same set of delay values for all channels.
N -by- L (L channels with N samples in each channel)	N -by- L	N -by- L	Delay value varies within the frame from sample to sample. Different delay values for each input channel.

Example: [2 3 4 5]

Example: [2.5]

Example: [5.6]

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 – Delayed output

vector | matrix

Delayed output, returned as a vector or matrix. The data type and complexity of the output match the data type and complexity of the data input.

When the **Input processing** parameter is set to `Columns as channels (frame based)`, the table below shows the effect of the dimension of the delay input on the data input.

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N (unoriented, one channel)	scalar	Unoriented (N)	One delay value applied to the input channel

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N (unoriented, one channel)	Unoriented (N)	Unoriented (N)	Delay value varies within the frame from sample to sample
N (unoriented, one channel)	1-by- P	N -by- P	P taps. Each column in the output is a delayed version of the input. The delay value is specified by the corresponding element in the delay input vector.
N (unoriented, one channel)	N -by- P	N -by- P	P taps. In addition, delay varies within each frame from sample to sample.
N -by-1 (one channel with frame size equal to N)	scalar	N -by-1	One delay value applied to the input channel
N -by-1 (one channel with frame size equal to N)	Unoriented (N)	N -by-1	Delay value varies within the frame from sample to sample
N -by-1 (one channel with frame size equal to N)	N -by-1	N -by-1	Delay value varies within the frame from sample to sample
N -by-1 (one channel with frame size equal to N)	1-by- P	N -by- P	P taps. Each column in the output is a delayed version of the input. The delay value is specified by the corresponding element in the delay input vector.
N -by-1 (one channel with frame size equal to N)	N -by- P	N -by- P	P taps. In addition, delay varies within each frame from sample to sample.
N -by- L (L channels with frame size equal to N)	scalar	N -by- L	One delay value applied to all input channels
N -by- L (L channels with frame size equal to N)	1-by- L	N -by- L	Unique delay value for each input channel
N -by- L (L channels with frame size equal to N)	N -by-1	N -by- L	Delay value varies within the frame from sample to sample. Same set of delay values for all channels.

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N -by- L (L channels with frame size equal to N)	N -by- L	N -by- L	Delay value varies within the frame from sample to sample. Different delay values for each input channel.
N -by- L (L channels with frame size equal to N)	1-by-1-by- P	N -by- L -by- P	L channels. P taps per channel. Same delay for all channels.
N -by- L (L channels with frame size equal to N)	1-by- L -by- P	N -by- L -by- P	L channels. P taps per channel. Taps vary across channels.
N -by- L (L channels with frame size equal to N)	N -by-1-by- P	N -by- L -by- P	L channels. P taps per channel. Delay varies within the frame from sample to sample. Same set of delay values for each channel.
N -by- L (L channels with frame size equal to N)	N -by- L -by- P	N -by- L -by- P	L channels. P taps per channel. Delay varies within the frame from sample to sample. Different set of delay values for each channel.

When the **Input processing** parameter is set to **Elements as channels (sample based)**, the table below shows the effect of the dimension of the delay input on the data input.

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N (unoriented, one channel)	scalar	Unoriented (N)	One delay value applied to the input channel
N (unoriented, one channel)	Unoriented (N)	Unoriented (N)	Delay value varies within the frame from sample to sample
N -by-1 (one channel with frame size equal to N)	scalar	N -by-1	One delay value applied to the input channel
N -by-1 (one channel with frame size equal to N)	Unoriented (N)	N -by-1	Delay value varies within the frame from sample to sample
N -by-1 (one channel with frame size equal to N)	N -by-1	N -by-1	Delay value varies within the frame from sample to sample

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N -by- L (L channels with N samples in each channel)	scalar	N -by- L	One delay value applied to all input channels
N -by- L (L channels with N samples in each channel)	1-by- L	N -by- L	Unique delay value for each input channel
N -by- L (L channels with N samples in each channel)	N -by-1	N -by- L	Delay value varies within the frame from sample to sample. Same set of delay values for all channels.
N -by- L (L channels with N samples in each channel)	N -by- L	N -by- L	Delay value varies within the frame from sample to sample. Different delay values for each input channel.

Example: [0 0 0 0;0 0 0 0;1 0 0 0;5 2 0 0;2 1 3 0;1 6 4 4]

Example: [0 0 0 0;0 0 0 0;0.5 1.0 1.5 2.0;3 1.5 3.5 3.0;3.5 3.5 3.0 2.5;1.5 4.0 2.5 2.5]

Example: [0 0 0 0;0 0 0 0;0 0 0 0;0 0 0 0;0.4 0.8 1.2 1.6]

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Interpolation mode — Method of interpolation

Linear (default) | FIR | Farrow

Specify the method of interpolation. Using this method, the block interpolates the signal to obtain new samples at noninteger sampling intervals.

- **Linear** -- Linear interpolation. In this mode, the block stores the $D_{\max}+1$ most recent samples the **In** port receives for each channel. D_{\max} is the value you specify in the **Maximum delay (Dmax) in samples** parameter.
- **FIR** -- Polyphase FIR interpolation. In this mode, the block stores the $D_{\max}+P+1$ most recent samples the **In** port receives for each channel. P is the value you specify in the **Interpolation filter half-length (P)** parameter.
- **Farrow** -- LaGrange method. In this mode, the block stores the $D_{\max}+\frac{N}{2}+1$ most recent samples the **In** port receives for each channel. N is the value you specify in the **Farrow filter length (N)** parameter.

For more details on these methods, see “Algorithms” on page 2-1363.

Interpolation filter half-length (P) — Half length of interpolation filter

4 (default) | positive integer in the range [1 65535]

Half-length of the FIR interpolation filter. For periodic signals, a larger value of this property, which indicates a higher order filter, yields a better estimate of the delayed output sample. A property value of 4 to 6, which corresponds to a 7th-order to 11th-order filter, is usually adequate.

Example: 6

Example: 10

Dependencies

This parameter applies only when you set **Interpolation mode** to FIR.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Interpolation points per input sample — Number of interpolation points per input sample

10 (default) | positive integer in the range [2, 65,535]

Number of interpolation points per input sample at which a unique FIR interpolation filter is computed.

Example: 20

Example: 5

Dependencies

This parameter applies only when you set **Interpolation mode** to FIR.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Normalized input bandwidth (0 to 1) — Normalized input bandwidth

1 (default) | real scalar in the range (0, 1]

Normalized input bandwidth at which to constrain the interpolated output samples. A value of 1 equals the Nyquist frequency, or half the sampling frequency, F_s . Use this property to take advantage of the bandlimited frequency content of the input. For example, if the input signal does not have frequency content above $F_s/4$, you can specify a value of 0.5.

Example: 0.5

Example: 0.8

Dependencies

This parameter applies only when you set **Interpolation mode** to FIR.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Farrow filter length (N) — Length of Farrow filter

4 (default) | integer greater than or equal to 2

Length of the FIR filter implemented using the Farrow structure. If the length equals 2, the filter performs linear interpolation.

Example: 4

Example: 10

Dependencies

This parameter applies only when you set **Interpolation mode** to Farrow.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32

Maximum delay (Dmax) in samples — Maximum delay

100 (default) | integer in the range [0 65535]

Maximum delay the block can produce, D_{max} . Input delay values exceeding this maximum are clipped to D_{max} .

Example: 200

Example: 500

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32

Input processing — Method to process the input

Columns as channels (frame based) (default) | Elements as channels (sample based)

Specify how the block should process the input. You can set this parameter to one of the following options:

- **Columns as channels (frame based) (default)** — When you select this option, the block treats each column of the input as a separate channel. The block treats each of the R input columns as independent channels containing M_i sequential time samples.

The input to the **Delay** port, v , contains floating-point values that specify the number of sample intervals to delay the current input.

The input to the **Delay** port can be a scalar value to uniformly delay every sample in every channel. It can also be a length- M column vector, containing one delay for each sample in the input frame. The block applies the set of delays contained in the vector identically to every channel of a multichannel input. The **Delay** port entry can also be a length- R row vector, containing one delay for each channel. Finally, the **Delay** port entry can be an M -by- R matrix, containing a different delay for each corresponding element of the input.

For example, if v is the M_i -by-1 matrix $[v(1) \ v(2) \ \dots \ v(M_i)]'$, the earliest sample in the current frame is delayed by $v(1)$ fractional sample intervals, the following sample in the frame is delayed by $v(2)$ fractional sample intervals, and so on. The block applies the set of fractional delays contained in v identically to every channel of a multichannel input.

- **Elements as channels (sample based)** -- When you select this option, the block treats each element of the input as a separate channel. The block treats each element of the N -D input array, u , as an independent channel. The input to the **Delay** port, v , must either be an N -D array of the same size and dimension as the input u , or be a scalar value, such that $D_{min} \leq v \leq D_{max}$.

For example, consider an M -by- R input matrix. The block treats each of the $M \times R$ matrix elements as independent channels. The input to the **Delay** port can be an M -by- R matrix of floating-point

values in the range $D_{min} \leq v \leq D_{max}$ that specifies the number of sample intervals to delay each channel of the input, or it can be a scalar floating-point value, $D_{min} \leq v \leq D_{max}$, by which to equally delay all channels.

In sample-based processing mode, the block treats an unoriented vector input as an M -by-1 matrix. In this mode, the output is also an unoriented vector.

InitialConditions — Initial values in the memory

0 (default) | scalar | 1-by- R -by- D array | 1-by- R -by- $(D+L)$ array

Specify the values with in the block's memory at the start of the simulation. The dimensions of this parameter can vary depending on whether you want fixed or time-varying initial conditions. The block treats each of the R input columns as a frame containing M sequential time samples from an independent channel.

For an M -by- R input matrix, u , you can set this parameter as follows:

- To specify fixed initial conditions, set this parameter to a scalar value. The block initializes every sample of every channel in memory using the value you specify.
- The dimensions you specify for time-varying initial conditions depend on the interpolation method. To specify different time-varying initial conditions for each channel, set this parameter as follows:
 - If you set the **Interpolation mode** to Linear, set the **Initial conditions** to an array of size 1-by- R -by- D , where D is the value in **Maximum delay (Dmax) in samples** parameter.
 - If you set the **Interpolation mode** to FIR or Farrow, set the **Initial conditions** to an array of size 1-by- R -by- $(D+L)$, where D is the value of the maximum delay. For FIR interpolation, L is the value of the interpolation filter half length. For Farrow interpolation, L equals floor of half the value of the farrow filter length (floor(farrow filter length/2)).

Example: 1

Example: randn(1,3,104)

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32

Disable direct feedthrough by increasing minimum possible delay by one — Disable direct feedthrough

off (default) | on

Select this box to disable direct feedthrough by increasing the minimum possible delay value. When you set the **Input processing** parameter to Columns as channels (frame based), the block increases the minimum possible delay value by *frame size* - 1. Similarly, when you set the **Input processing** parameter to Elements as channels (sample based), the block increases the minimum possible delay value by one sample.

Checking this box allows you to use the Variable Fractional Delay block in feedback loops.

For small input delay values — Action to take for small input delay values

Clip to the minimum value necessary for centered kernel (default) | Use off-centered kernel | Switch to linear interpolation if kernel cannot be centered

Specify the block's behavior when the input delay values are too small to center the kernel.

You can specify how the block handles input delay values that are too small for the kernel to be centered using one of the following choices:

- In both FIR and Farrow interpolation modes, you can select **Clip to the minimum value necessary for centered kernel**. This option forces the block to increase D_{min} to the smallest value necessary to keep the kernel centered.
- In FIR interpolation mode, you can select **Switch to linear interpolation if kernel cannot be centered**. This option forces the block to preserve the value of D_{min} and compute all interpolated values using **Linear** interpolation.
- In Farrow interpolation mode, you can select **Use off-centered kernel**. This option forces the block to preserve the value of D_{min} and compute the interpolated values using a farrow filter with an off-centered kernel.

Dependencies

This parameter applies only when **Interpolation mode** is set to FIR or Farrow.

Valid delay range (in samples) — Range of valid delay values

[0 100] (default) | [D_{min} D_{max}]

This property is read-only.

The delay range values [D_{min} D_{max}] are calculated (in samples) by the block based on the current parameter settings. D_{min} is the smallest possible valid delay value (in samples). The block clips all input delay values less than D_{min} to D_{min} . D_{max} is the maximum valid delay value (in samples). The block clips all input delay values greater than D_{max} to D_{max} .

When the **Interpolation mode** is set to one of the following:

- **Linear** -- D_{min} equal 0. D_{max} equals the value you specify in the **Maximum delay (Dmax) in samples** parameter.
- **FIR** -- D_{min} equals $P - 1$, where P is the value you specify in **Interpolation filter half-length (P)**. D_{max} equals the value you specify in the **Maximum delay (Dmax) in samples** parameter.
- **Farrow** -- D_{min} equals $N/2 - 1$, where N is the value you specify in **Farrow filter length (N)**. D_{max} equals the value you specify in the **Maximum delay (Dmax) in samples** parameter.

Example: [1 100]

Example: [2 100]

Example: [3 100]

Fixed-Point Properties

Fixed-Point Properties

Rounding mode — Rounding method for fixed-point operations

Zero (default) | Ceiling | Convergent | Floor | Nearest | Round | Simplest

Specify the rounding mode for fixed-point operations as one of the following:

- Zero
- Ceiling

- Convergent
- Floor
- Nearest
- Round
- Simplest

For more details, see rounding mode.

Saturate on integer overflow — Method of overflow action

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

Coefficients — Data type of the coefficients

Same word length as input (default) | Specify word length

Specify the data type of the filter coefficients as one of the following:

- **Same word length as input** -- The word length of the filter coefficients matches that of the input to the block. The fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- **Specify word length** -- Specify the word length of the coefficients, in bits. In this mode, the fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.

For more information on the coefficients data type this block uses, see the “Fixed Point” on page 2-1366 section.

Product output — Data type of the product output

Same as first input (default) | Binary point scaling

Specify the data type of the product output as one of the following:

- **Same as first input** -- The block specifies the product output data type to be the same as that of the data input.
- **Binary point scaling** -- Specify the word length and the fraction length of the product output, in bits.

For more information on the product output data type, see “Multiplication Data Types” and the “Fixed Point” on page 2-1366 section.

Accumulator — Data type of accumulation operation

Same as product output (default) | Same as first input | Binary point scaling

Specify the data type of an accumulation operation as one of the following:

- **Same as product output** -- The block specifies the accumulator data type to be the same as that of the product output data type.

- `Same as first input` -- The block specifies the accumulator data type to be the same as that of the data input.
- `Binary point scaling` -- Specify the word length and the fraction length of the accumulator output, in bits.

For more information on the accumulator data type this block uses, see the “Fixed Point” on page 2-1366.

Product output polyval — Data type of the product polynomial value

Same as `first input` (default) | `Binary point scaling`

Specify the data type of the product polynomial value as one of the following:

- `Same as first input` -- The block specifies the product polynomial value data type to be the same as that of the data input.
- `Binary point scaling` -- Specify the word length and the fraction length of the product output polynomial, in bits.

For more information on the product polynomial value data type this block uses, see the “Fixed Point” on page 2-1366 section.

Dependencies

This property applies when you set **Interpolation mode** to Farrow.

Accumulator polyval — Data type of the accumulator polynomial value

Same as `first input` (default) | `Binary point scaling`

Specify the data type of the accumulator polynomial value as one of the following:

- `Same as first input` -- The block specifies the accumulator polynomial value data type to be the same as that of the data input.
- `Binary point scaling` -- Specify the word length and the fraction length of the accumulator polynomial value, in bits.

For more information on the accumulator polynomial value data type that this block uses, see the “Fixed Point” on page 2-1366 section.

Dependencies

This property applies when you set **Interpolation mode** to Farrow.

Multiplicand polyval — Data type of multiplicand polynomial value

Same as `first input` (default) | `Binary point scaling`

Specify the data type of the multiplicand polynomial value as one of the following:

- `Same as first input` -- The block specifies the multiplicand polynomial value data type to be the same as that of the data input.
- `Binary point scaling` -- Specify the word length and the fraction length of the multiplicand polynomial value, in bits.

For more information on the multiplicand polynomial value data type this block uses, see the “Fixed Point” on page 2-1366 section.

Dependencies

This property applies when you set **Interpolation mode** to Farrow.

Output — Data type of block output

Same as accumulator (default) | Same as first input | Binary point scaling

Specify the data type of the block output as one of the following:

- `Same as accumulator` -- The block specifies the output data type to be the same as that of the accumulator output data type.
- `Same as first input` -- The block specifies the output data type to be the same as that of the data input.
- `Binary point scaling` -- Specify the word length and the fraction length of the block output, in bits.

For more information on the output data type this block uses, see the “Fixed Point” on page 2-1366 section.

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

Algorithms

The delay value specified at the **Delay** port serves as an index into the block's memory, U , which stores, at a minimum, the $D_{\max}+1$ most recent samples received at the **In** port for each channel. For example, an integer delay of 5 on a scalar input sequence retrieves and outputs the fifth most recent input sample from the block's memory, $U(6)$. The block computes fractional delays by interpolating between stored samples. The block uses a linear, FIR, or farrow interpolation method to interpolate signal values at noninteger sample intervals.

Linear Interpolation Mode

For noninteger delays, at each sample time, the linear interpolation method uses the two samples in memory nearest to the specified delay to compute a value for the sample at that time.

For a vector data input, the output vector, y , is computed using the following relation:

$$\begin{aligned} v_i &= \text{floor}(v) \\ v_f &= v - v_i \\ y(i) &= U(i - v_i - 1) * v_f + U(i - v_i) * (1 - v_f) \end{aligned}$$

where,

- i -- Index of the current sample
- v -- Fractional delay
- v_i -- Integer part of the delay
- v_f -- Fractional part of the delay
- U -- Input data vector
- y -- Output data vector
- $U(i - v_i)$, $U(i - v_i - 1)$ -- Two samples in memory nearest to the specified delay
- $i - v_i$ -- Distance, in samples, between the current index and the nearest point in the interpolation line.

The variable fractional delay stores the $D_{max} + 1$ most recent samples received at the input for each channel, where D_{max} is the maximum delay specified. U represents the stored samples.

FIR Interpolation Mode

In the FIR interpolation mode, the block stores the $D_{max} + P + 1$ most recent samples received at the input for each channel, where P is the specified interpolation filter half-length.

In this mode, the block provides a discrete set of fractional delays:

$$v + \frac{i}{L}, \quad v \geq P - 1, \quad i = 0, 1, \dots, L - 1$$

If v is less than $P - 1$, the behavior depends on the **For small input delay values** parameter. You can specify the block's behavior when the input delay value is too small to center the kernel (less than $P - 1$), by setting the **For small input delay values** parameter:

- **Clip to the minimum value necessary for centered kernel** -- The FIR interpolation method remains in use. The small input delay values are clipped to the smallest value necessary to center the kernel.
- **Switch to linear interpolation if kernel cannot be centered** -- Fractional delays are computed using linear interpolation when the input delay value is less than $P - 1$.

In the FIR interpolation mode, the algorithm implements a polyphase structure to compute a value for each sample at the specified delay. Each arm of the structure corresponds to a different delay value. The output computed for each sample corresponds to the output of the arm with a delay value nearest to the specified input delay. Therefore, only a discrete set of delays is actually possible. The number of coefficients in each of the L filter arms of the polyphase structure is $2P$. In most cases, using values of P between 4 and 6 provides you with reasonably accurate interpolation values.

The `designMultirateFIR` function designs the FIR interpolation filter.

For example, when you set the following values:

- Interpolation filter half-length (P) to 4
- Interpolation points per input sample to 10
- Normalized input bandwidth to 1
- Stopband attenuation to 80 dB

The filter coefficients are given by:

```
b = designMultirateFIR(10,1,4,80);
```

The algorithm then implements this filter as a polyphase structure.

Increasing the filter half length (P) increases the accuracy of the interpolation, but also increases the number of computations performed per input sample. The amount of memory needed to store the filter coefficients increases too. Increasing the interpolation points per sample (L) increases the number of representable discrete delay points, but also increases the simulation's memory requirements. The computational load per sample is not affected.

The normalized input bandwidth from 0 to 1 allows you to take advantage of the bandlimited frequency content of the input. For example, if you know that the input signal does not have frequency content above $F_s/4$, you can specify 0.5 normalized bandwidth to constrain the frequency content of the output to that range.

Note You can consider each of the L interpolation filters to correspond to one output phase of an upsample-by- L FIR filter. Therefore, the normalized input value improves the stopband in critical regions and relaxes the stopband requirements in frequency regions without signal energy.

Farrow Interpolation Mode

In the farrow interpolation mode, the block stores the $D_{max}+N/2+1$ most recent samples received at the input for each channel, where N is the specified farrow filter length.

The algorithm uses the LaGrange method to interpolate values.

To increase the minimum possible delay value, select the **Disable direct feedthrough by increasing minimum possible delay by one** check box. Checking this box prevents algebraic loops from occurring when you use the block inside a feedback loop.

To specify the behavior when the input delay value is too small to center the kernel (less than $\frac{N}{2} - 1$), use the Farrow small delay action setting.

- **Clip to the minimum value necessary for centered kernel** -- The block clips small input delay values to the smallest value necessary to keep the kernel centered. This increases D_{min} but yields more accurate interpolation values.
- **Use off-centered kernel** -- The fractional delays are computed using a Farrow filter with an off-centered kernel. This mode does not increase D_{min} , but the results for input delay values less than $\frac{N}{2} - 1$ are less accurate than the results achieved by keeping the kernel centered.

Version History

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

The diagrams in the following sections show the data types used within the Variable Fractional Delay for fixed-point signals.

Although you can specify most of these data types, the following data types are computed internally by the block and cannot be directly specified on the block dialog box.

Data Type	Word Length	Fraction Length
vf data type	Same word length as the coefficients	Same as the word length
HoldInteger data type	Same word length as the input delay value	0 bits
Integer data type	32 bits	0 bits

Note When the input is fixed point, all internal data types are signed fixed point.

To compute the integer (v_i) and fractional (v_f) parts of the input delay value (v), the Variable Fractional Delay block uses the following equations:

$$D_{min} < v < D_{max} \Rightarrow \begin{cases} v_i = \text{floor}(v) \\ v_f = v - v_i \end{cases}$$

$$v \leq D_{min} \Rightarrow \begin{cases} v_i = D_{min} \\ v_f = 0 \end{cases}$$

$$v \geq D_{max} \Rightarrow \begin{cases} v_i = D_{max} \\ v_f = 0 \end{cases}$$

Linear Interpolation Mode

The following diagram shows the fixed-point data types used by the Linear interpolation mode of the Variable Fractional Delay block.

FIR Interpolation Mode

The following diagram illustrates how the Variable Fractional Delay block selects the arm of the polyphase filter structure that most closely matches the fractional delay value (v_f).

The following diagram shows the fixed-point data types used by the variable fractional delay algorithm in the FIR interpolation mode.

You can set the coefficient, product output, accumulator, and output data types in the block. This diagram shows that input data is stored in the input buffer with the same data type and scaling as the input. The block stores filtered data and any initial conditions in the output buffer using the output data type and scaling that you set.

When at least one of the inputs to the multiplier is real, the output of the multiplier is in the product output data type. When both inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication, see “Multiplication Data Types”.

Farrow Interpolation Mode

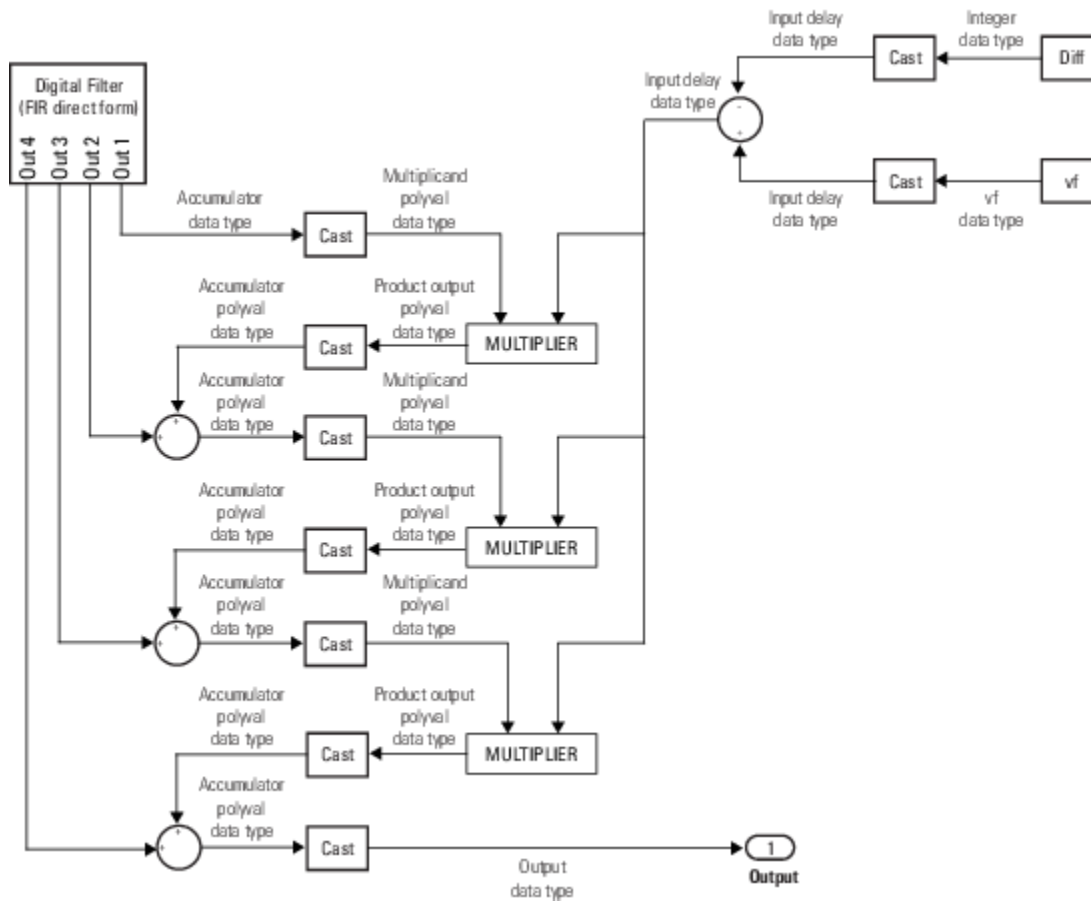

The following diagram shows the fixed-point data types used by the Farrow interpolation mode when:

- Farrow filter length is set to 4
- Farrow small delay action is set to Clip to the minimum value necessary for centered kernel

The following diagram shows the fixed-point data types used by the Farrow interpolation mode when:

- Farrow filter length is set to 4.
- Farrow small delay action is set to Use off-centered kernel.

$Diff$ is computed from the integer part of the delay value (v_i) and the farrow filter length (N) according to the following equation:

$$Diff = v_i - \left(\frac{N - 1}{2} \right)$$

$$Diff \geq 0 \Rightarrow Diff = 0$$

$$Diff < 0 \Rightarrow Diff = -Diff$$

The following diagram shows the fixed-point data types used by the Digital Filter's FIR direct form filter.

Description

Note The Variable Integer Delay block has been replaced with the Simulink Variable Integer Delay block. Existing instances of the DSP block will continue to operate, but certain functionality will be disabled in future releases. See “Functionality being removed or replaced for blocks and System objects”.

The Variable Integer Delay block delays the discrete-time input at the In port by the integer number of sample intervals specified by the input to the Delay port. The sample rate of the input signal at the Delay port must be the same as the sample rate of the input signal at the In port. When these sample rates are not the same, you need to insert a Zero-Order Hold or Rate Transition block in order to make the sample rates identical. When you set the **Input processing** parameter to **Elements as channels (sample based)**, the delay for an N-D input can be a scalar value to uniformly delay every sample in every channel, or a matrix containing one delay value for each channel of the input. When you set the **Input processing** parameter to **Columns as channels (frame based)**, the delay can be a scalar value to uniformly delay every sample in every channel, a vector containing one delay value for each sample in the input frame, or a vector containing one delay value for each channel in the input frame.

The delay values should be in the range of 0 to D , where D is the **Maximum delay**. Delay values greater than D or less than 0 are clipped to those respective values and noninteger delays are rounded to the nearest integer value.

The Variable Integer Delay block differs from the Delay block in the following ways.

Variable Integer Delay Block	Delay Block
The delay is provided as an input to the Delay port.	You specify the delay as a parameter setting in the dialog box.
Delay can vary with time; for example, when the block performs frame-based processing, the n th element's delay in the first input frame can differ from the n th element's delay in the second input frame.	Delay cannot vary with time; for example, when the block performs frame-based processing, the n th element's delay is the same for every input frame.

Variable Integer Delay Block	Delay Block
When you use the Variable Integer Delay block in a feedback loop, you must check the Disable direct feedthrough by increasing minimum possible delay by one check box. This prevents the occurrence of an algebraic loop when the delay of the Variable Integer Delay block is driven to zero.	You can use the Delay block to break an algebraic loop.

Sample-Based Processing

When you set the **Input processing** parameter to **Elements as channels (sample based)**, the Variable Integer Delay block supports N-D input arrays. When the input is an M -by- N -by- P array, the block treats each of the $M*N*P$ elements as independent channels, and applies the delay at the Delay port to each channel.

The Variable Integer Delay block stores the $D+1$ most recent samples received at the In port for each channel. At each sample time the block outputs the stored sample(s) indexed by the input to the Delay port.

For example, when the input to the In port, u , is a scalar signal, the block stores a vector, U , of the $D+1$ most recent signal samples. When the current input sample is $U(1)$, the previous input sample is $U(2)$, and so on, then the block's output is

```
y = U(v+1); % Equivalent MATLAB code
```

where v is the input to the Delay port. A delay value of 0 ($v=0$) causes the block to pass through the sample at the In port in the same simulation step that it is received. The block's memory is initialized to the **Initial conditions** value at the start of the simulation (see below).

The next figure shows the block output for a scalar ramp sequence at the In port, a **Maximum delay** of 5, an **Initial conditions** of 0, and a variety of different delays at the Delay port.

The current input at each time step is immediately stored in memory as $U(1)$. This allows the current input to be available at the output for a delay of 0 ($v=0$).

The **Initial conditions** parameter specifies the values in the block's memory at the start of the simulation. Unlike the Delay block, the Variable Integer Delay block does not have a fixed initial delay period during which the initial conditions appear at the output. Instead, the initial conditions are propagated to the output only when they are indexed in memory by the value at the Delay port. Both fixed and time-varying initial conditions can be specified in a variety of ways to suit the dimensions of the input sequence.

Fixed Initial Conditions

The settings in this section specify fixed initial conditions. For a fixed initial condition, the block initializes each of D samples in memory to the value entered in the **Initial conditions** parameter. A fixed initial condition in sample-based mode can be specified in one of the following ways:

- Scalar value with which to initialize every sample of every channel in memory. For a general M -by- N input and the parameter settings in this figure,

the block initializes 100 M -by- N matrices in memory with zeros.

- Array of size M -by- N -by- D . In this case, you can specify different fixed initial conditions for each channel. See the Array bullet in “Time-Varying Initial Conditions” on page 2-1373 below for details.

Time-Varying Initial Conditions

The following settings specify time-varying initial conditions. For a time-varying initial condition, the block initializes each of D samples in memory to one of the values entered in the **Initial conditions** parameter. This allows you to specify a unique output value for each sample in memory. A time-varying initial condition in sample-based mode can be specified in one of the following ways:

- Vector containing D elements with which to initialize memory samples $U(2:D+1)$, where D is the **Maximum delay**. For a scalar input and the parameters in the next figure, the block initializes $U(2:6)$ with values $[-1, -1, -1, 0, 1]$.

- Array of dimension M -by- N -by- D with which to initialize memory samples $U(2:D+1)$, where D is the **Maximum delay** and M and N are the number of rows and columns, respectively, in the input matrix. For a 2-by-3 input and the following parameters, the block initializes memory locations $U(2:5)$ with values

$$\mathbf{U}(2) = \begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix}, \quad \mathbf{U}(3) = \begin{bmatrix} 2 & 2 & 2 \\ 2 & 2 & 2 \end{bmatrix}, \quad \mathbf{U}(4) = \begin{bmatrix} 3 & 3 & 3 \\ 3 & 3 & 3 \end{bmatrix}, \quad \mathbf{U}(5) = \begin{bmatrix} 4 & 4 & 4 \\ 4 & 4 & 4 \end{bmatrix}$$

An M -by- N -by- P -by- D array can be entered for the **Initial Conditions** parameter when the input is an M -by- N -by- P array. The (M,N,P,T) th sample of the **Initial Conditions** matrix provides the initial condition value for the (M,N,P) th channel of the input matrix at delay = $D-t+1$ samples.

Frame-Based Processing

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the input can be an M -by- N matrix. The block treats each of the N input columns as independent channels containing M sequential time samples.

In this mode, the input at the Delay port can be a scalar value to uniformly delay every sample in every channel. It can also be a length- M column vector containing one delay value for each sample in the input frame(s). The set of delays contained in the vector is applied identically to every channel of a multichannel input. The Delay port entry can also be a length- N row vector, containing one delay for each channel. Finally, the Delay port entry can be an M -by- N matrix, containing a different delay for each corresponding element of the input.

Vector v does not specify when the samples in the current input frame will appear in the output. Rather, v indicates which previous input samples (stored in memory) should be included in the current output frame. The first sample in the current output frame is the input sample $v(1)$ intervals earlier in the sequence, the second sample in the current output frame is the input sample $v(2)$ intervals earlier in the sequence, and so on.

The illustration below shows how this works for an input with a sample period of 1 and frame size of 4. The **Maximum delay** (D_{max}) is 5, and the **Initial conditions** parameter is set to -1. The delay input changes from $[1 \ 3 \ 0 \ 5]$ to $[2 \ 0 \ 0 \ 2]$ after the second input frame. The samples in each output frame are the values in memory indexed by the elements of v :

$$\begin{aligned} y(1) &= U(v(1)+1) \\ y(2) &= U(v(2)+1) \\ y(3) &= U(v(3)+1) \\ y(4) &= U(v(4)+1) \end{aligned}$$

The **Initial conditions** parameter specifies the values in the block's memory at the start of the simulation. Both fixed and time-varying initial conditions can be specified.

Fixed Initial Conditions

The settings shown in this section specify fixed initial conditions. For a fixed initial condition, the block initializes each of D samples in memory to the value entered in the **Initial conditions** parameter. A fixed initial condition in frame-based mode can be one of the following:

- Scalar value with which to initialize every sample of every channel in memory. For a general M -by- N input with the parameter settings below, the block initializes five samples in memory with zeros.

Maximum delay (samples):	5
Initial conditions:	0

- Array of size 1-by- N -by- D . In this case, you can specify different fixed initial conditions for each channel. See the Array bullet in “Time-Varying Initial Conditions” on page 2-1375 below for details.

Time-Varying Initial Conditions

The following setting specifies a time-varying initial condition. For a time-varying initial condition, the block initializes each of D samples in memory to one of the values entered in the **Initial conditions** parameter. This allows you to specify a unique output value for each sample in memory. When the block is performing frame-based processing, you can specify a time-varying initial condition in the following ways:

- Vector containing D elements. In this case, all channels have the same set of time-varying initial conditions specified by the entries of the vector. For the ramp input $[1:100; 1:100]'$ with a

frame size of 4, delay of 5, and the following parameter settings, the block outputs the following sequence of frames at the start of the simulation:

$$\begin{bmatrix} -1 & -1 \\ -2 & -2 \\ -3 & -3 \\ -4 & -4 \end{bmatrix}, \begin{bmatrix} -5 & -5 \\ 1 & 1 \\ 2 & 2 \\ 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 \\ 5 & 5 \\ 6 & 6 \\ 7 & 7 \end{bmatrix}, \dots$$

- Array of size 1-by- N -by- D . In this case, you can specify different time-varying initial conditions for each channel. For the ramp input `[1:100; 1:100]'` with a frame size of 4, delay of 5, and the following parameter settings, the block outputs the following sequence of frames at the start of the simulation:

$$\begin{bmatrix} -1 & -11 \\ -2 & -22 \\ -3 & -33 \\ -4 & -44 \end{bmatrix}, \begin{bmatrix} -5 & -55 \\ 1 & 1 \\ 2 & 2 \\ 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 \\ 5 & 5 \\ 6 & 6 \\ 7 & 7 \end{bmatrix}, \dots$$

By specifying a 1-by- N -by- D initial condition array such that each 1-by- N vector entry is identical, you can implement different fixed initial conditions for each channel.

Examples

See “Basic Algorithmic Delay” in the *DSP System Toolbox User's Guide*.

Parameters

Maximum delay

The maximum delay that the block can produce for any sample. Delay input values exceeding this maximum are clipped at the maximum.

Initial conditions

The values with which the block's memory is initialized.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

Note The Inherited (this choice will be removed - see release notes) option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

Disable direct feedthrough by increasing minimum possible delay by one

Select this box to disable direct feedthrough by adding one to the minimum possible delay value. When you set the **Input processing** parameter to Columns as channels (frame based), the block increases the minimum possible delay value by *frame size* - 1. Similarly, when you set the **Input processing** parameter to Elements as channels (sample based), the block increases the minimum possible delay value by one sample.

Checking this box allows you to use the Variable Integer Delay block in feedback loops.

Supported Data Types

Port	Supported Data Types
In	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Delay	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Out	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Variable Selector

Select subset of rows or columns from input

Library: DSP System Toolbox / Signal Management / Indexing
 DSP System Toolbox HDL Support / Signal Management

Description

The Variable Selector block extracts a subset of rows or columns from the M -by- N input matrix u at each input port. You specify the number of input and output ports in the **Number of input signals** parameter.

When an element of the indexing vector references a nonexistent row or column of the input, the block implements the action that you specify by using the **Invalid index** parameter.

When the indexing vector elements are of the Boolean data type, the block performs logical indexing. Select **Fill empty spaces in outputs (for logical indexing)** to access the **Fill values** parameter. These values are appended to the output to make it as long as the input elements.

Note The Variable Selector block always copies the selected input rows or columns to a contiguous block of memory (unlike the Simulink Selector block).

Ports

Input

InN — Nth input signal

scalar | vector | matrix

Nth input signal, where N is the number of inputs specified in the “Number of input signals” on page 2-0 parameter.

When the input is an unoriented vector, the “Select” on page 2-0 parameter is ignored and the output is an unoriented vector of length L containing those elements specified by the length- L indexing vector.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Idx — Index vector

scalar | vector

Specify a scalar value or vector containing the indices of the input rows or columns that appear in the output matrix.

Dependencies

This port appears only when you set the “Selector mode” on page 2-0 to **Variable**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated`

Output

OutN — Nth Output signal

`scalar` | `vector` | `matrix`

Nth output signal, corresponding to the Nth input signal, where *N* is the number of inputs specified in the “Number of input signals” on page 2-0 parameter. The output is returned as a scalar, vector, or matrix as the same type, size, and complexity as the corresponding input.

For variable and fixed indexing modes, the row selection operation is equivalent to

```
y = u(idx,:) % Equivalent MATLAB code
```

and the column selection operation is equivalent to

```
y = u(:,idx) % Equivalent MATLAB code
```

where `idx` is the length-*L* indexing vector. The row selection output size is *L*-by-*N* and the column selection output size is *M*-by-*L*. Input rows or columns can appear any number of times in the output, or not at all.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated`

Parameters

Number of input signals — Number of inputs

1 (default) | positive integer

Specify the number of input signals as a positive integer. An input port is created on the block for each input signal.

Select — Select dimension

`Rows` (default) | `Columns`

Specify the dimension of the input to select, `Rows` or `Columns`.

When **Select** is set to:

- `Rows` -- The block extracts rows from each input matrix.
- `Columns` -- The block extracts columns from each input matrix.

When the input is an unoriented vector, the **Select** parameter is ignored. The output is an unoriented vector of length *L* containing those elements specified by the length-*L* indexing vector.

Selector mode — Indexing mode

`Variable` (default) | `Fixed`

Specify the type of indexing operation to perform, **Variable** or **Fixed**.

When **Selector mode** is set to:

- **Variable** -- The length- L vector input to the “Idx” on page 2-0 port selects L rows or columns of each input to pass through to the output. You can update the elements of the indexing vector at each sample time, but the vector length must remain the same throughout the simulation.
- **Fixed** -- The **Idx** port is disabled. The length- L vector that you specified in the “Elements” on page 2-0 parameter selects L rows or columns of each input to pass through to the output. The **Elements** parameter is tunable, so you can change the values of the indexing vector elements at any time during the simulation but the vector length must remain the same.

Elements — Selected elements

[1 3] (default) | scalar | vector

Specify a vector containing the indices of the input rows or columns that appear in the output matrix.

Tunable: Yes

Dependencies

This parameter appears only when you set the “Selector mode” on page 2-0 to **Fixed**.

Index mode — Index mode

Zero-based (default) | One-based

When set to **One-based**, an index value of 1 refers to the first row or column of the input. When set to **Zero-based**, an index value of 0 refers to the first row or column of the input.

Invalid index — Error handling

Clip Index (default) | Clip and Warn | Generate Error

Specify how the block handles an invalid index value. You can select one of these options:

- **Clip index** — Clip the index to the nearest valid value and do not issue an alert.

For example, if the block receives a 64-by-4 input and the “Select” on page 2-0 parameter is set to:

- **Rows** -- The block clips an index of 72 to 64.
- **Columns** -- The block clips an index of 72 to 4.

In both cases, the block clips an index of -2 to 1.

- **Clip and warn** — Clip the index to the nearest valid value and display a warning message at the MATLAB command line.
- **Generate error** — Display an error dialog box and terminate the simulation.

Tunable: Yes

Fill empty spaces in outputs (for logical indexing) – Fill in empty spaces in outputs

on (default) | off

When the indexing vector elements are of a Boolean data type, the block performs logical indexing. Logical indexing can cause empty spaces in the output. Select this parameter to designate values to be appended to the output in the “Fill values” on page 2-0 parameter.

Fill values – Fill values

0 (default) | scalar value | integer

Specify the fill values when the block performs logical indexing.

Dependencies

This parameter appears only when you select the “Fill empty spaces in outputs (for logical indexing)” on page 2-0 parameter.

Block Characteristics

Data Types	Boolean double enumerated fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the memcpy or memset function (string.h) under certain conditions.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has one default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Complex Data Support

This block supports code generation for complex signals.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Variance

Variance of input or sequence of inputs

Library: DSP System Toolbox / Statistics

Description

The Variance block computes the unbiased variance of each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the variance of the entire input. You can specify the dimension using the **Find the variance value over** parameter. The Variance block can also track the variance in a sequence of inputs over a period of time. To track the variance in a sequence of inputs, select the **Running variance** parameter.

Note The **Running** mode in the Variance block will be removed in a future release. To compute the running variance in Simulink, use the Moving Variance block instead.

Ports

Input

In — Data input

vector | matrix | N -D array

The block accepts real-valued or complex-valued multichannel and multidimensional inputs.

This port is unnamed until you select the **Running variance** parameter and set the **Reset port** parameter to any option other than None.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Rst — Reset port

scalar

Specify the event that causes the block to reset the running variance. The sample time of the **Rst** input must be a positive integer multiple of the input sample time.

Dependencies

To enable this port, select the **Running variance** parameter and set the **Reset port** parameter to any option other than None.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean

Output

Port_1 — Variance along the specified dimension

scalar | vector | matrix | N -D array

When you do not select the **Running variance** parameter, the block computes the variance in each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the variance of the entire input at each individual sample time. Each element in the output array y is the variance of the corresponding column, row, or entire input. The output array y depends on the setting of the **Find the variance value over** parameter.

Consider a three-dimensional input signal of size M -by- N -by- P . When you set **Find the variance value over** to:

- **Entire input** — The output at each sample time is a scalar that contains the variance of the M -by- N -by- P input matrix.
- **Each row** — The output at each sample time consists of an M -by-1-by- P array, where each element contains the variance of each vector over the second dimension of the input. For an M -by- N matrix input, the output at each sample time is an M -by-1 column vector.
- **Each column** — The output at each sample time consists of a 1-by- N -by- P array, where each element contains the variance of each vector over the first dimension of the input. For an M -by- N matrix input, the output at each sample time is a 1-by- N row vector.

In this mode, the block treats length- M unoriented vector inputs as M -by-1 column vectors.

- **Specified dimension** — The output at each sample time depends on the value of the **Dimension** parameter. If you set the **Dimension** to 1, the output is the same as when you select **Each column**. If you set the **Dimension** to 2, the output is the same as when you select **Each row**. If you set the **Dimension** to 3, the output at each sample time is an M -by- N matrix containing the variance of each vector over the third dimension of the input.

When you select **Running variance**, the block tracks the variance of each channel in a time sequence of inputs. In this mode, you must also specify a value for the **Input processing** parameter. When you set **Input processing** to:

- **Elements as channels (sample based)** — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size M -by- N -by- P , the block outputs an M -by- N -by- P array. Each element y_{ijk} of the output contains the variance of the element u_{ijk} for all inputs since the last reset.

When a reset event occurs, the running variance y_{ijk} in the current frame is reset to the element u_{ijk} .

- **Columns as channels (frame based)** — The block treats each column of the input as a separate channel. This option does not support input signals with more than two dimensions. For a two-dimensional input signal of size M -by- N , the block outputs an M -by- N matrix. Each element y_{ij} of the output contains the variance of the elements in the j th column of all inputs since the last reset, up to and including the element u_{ij} of the current input.

When a reset event occurs, the running variance for each channel becomes the variance of all the samples in the current input frame, up to and including the current input sample.

The data type of the output matches the data type of the input.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Main Tab

Running variance — Option to select running variance

off (default) | on

When you select the **Running variance** parameter, the block tracks the variance value of each channel in a time sequence of inputs.

Find the variance value over — Dimension over which variance is computed

Each column (default) | Entire input | Each row | Specified dimension

- **Each column** — The block outputs the variance over each column.
- **Each row** — The block outputs the variance over each row.
- **Entire input** — The block outputs the variance over the entire input.
- **Specified dimension** — The block outputs the variance over the dimension specified in the **Dimension** parameter.

Dependencies

To enable this parameter, clear the **Running variance** parameter.

Dimension — Custom dimension

1 (default) | scalar

Specify the dimension (one-based value) of the input signal over which the variance is computed. The value of this parameter must be greater than 0 and less than or equal to the number of dimensions in the input signal.

Dependencies

To enable this parameter, set **Find the variance value over** to **Specified dimension**.

Input processing — Method to process the input in running mode

Columns as channels (frame based) (default) | Elements as channels (sample based)

- **Columns as channels (frame based)** — The block treats each column of the input as a separate channel. This option does not support input signals with more than two dimensions. For a two-dimensional input signal of size M -by- N , the block outputs an M -by- N matrix. Each element y_{ij} of the output contains the variance of the elements in the j th column of all inputs since the last reset, up to and including the element u_{ij} of the current input.

When a reset event occurs, the running variance for each channel becomes the variance of all the samples in the current input frame, up to and including the current input sample.

- **Elements as channels (sample based)** — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size M -by- N -by- P , the block outputs an M -by- N -by- P array. Each element y_{ijk} of the output contains the variance of the element u_{ijk} for all inputs since the last reset.

When a reset event occurs, the running variance y_{ijk} in the current frame is reset to the element u_{ijk} .

Variable-Size Inputs

When your inputs are of variable size, and you select the **Running variance** parameter, then:

- If you set the **Input processing** parameter to **Elements as channels (sample based)**, the state is reset.
- If you set the **Input processing** parameter to **Columns as channels (frame based)**, then:
 - When the input size difference is in the number of channels (number of columns), the state is reset.
 - When the input size difference is in the length of channels (number of rows), the state is not reset, and the running operation is carried out as usual.

Dependencies

To enable this parameter, select the **Running variance** parameter.

Reset port — Reset event

None (default) | Rising edge | Falling edge | Either edge | Non-zero sample

The block resets the running variance whenever a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer multiple of the input sample time.

When a reset event occurs while the **Input processing** parameter is set to **Elements as channels (sample based)**, the running variance for each channel is initialized to the value in the corresponding channel of the current input. Similarly, when the **Input processing** parameter is set to **Columns as channels (frame based)**, the running variance for each channel becomes the variance of all the samples in the current input frame, up to and including the current input sample.

Use this parameter to specify the reset event.

- **None** — Disables the **Rst** port.
- **Rising edge** — Triggers a reset operation when the **Rst** input does one of the following:
 - Rises from a negative value to either a positive value or zero.
 - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.

- **Falling edge** — Triggers a reset operation when the **Rst** input does one of the following:
 - Falls from a positive value to a negative value or zero.
 - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.

- **Either edge** — Triggers a reset operation when the **Rst** input is a Rising edge or Falling edge.
- **Non-zero sample** — Triggers a reset operation at each sample time, when the **Rst** input is not zero.

Note When running simulations in the Simulink multitasking mode, reset signals have a one-sample latency. Therefore, when the block detects a reset event, there is a one-sample delay at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Dependencies

To enable this parameter, select the **Running variance** parameter.

Data Types Tab

Note To use these parameters, the data input must be fixed point. For all other inputs, the parameters on the **Data Types** tab are ignored.

Rounding mode — Method of rounding operation

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more details, see rounding mode.

Saturate on integer overflow — Method of overflow action

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

Input-squared product output — Data type of the input-squared term

Same as input (default) | Binary point scaling

The squares of the input elements are stored in the **Input-squared product output** data type. If the input is complex, the squares of the real and imaginary parts of the input are stored in this data type. For more details, see “Fixed Point” on page 2-1390.

You can set this parameter to:

- **Inherit: Same as input** — The data type is same as the input data type.
- **Binary point scaling** — The **Input-squared product output** data type uses binary point scaling. If you select this option, the block displays the fields to specify the **Word length** and **Fraction length**. The **Signedness** is inherited from the input.

Input-sum-squared product — Data type of the input-sum-squared term

Same as input-squared product (default) | Binary point scaling

The squares of the sum of the input elements are stored in the **Input-sum-squared product** data type. If the input is complex, the squares of the sum of the real parts and the squares of the sum of the imaginary parts are stored in this data type. For more details, see “Fixed Point” on page 2-1390.

You can set this parameter to:

- **Same as input-squared product** — The data type is the same as the input squared-product data type.
- **Binary point scaling** — The **Input-sum-squared product** data type uses binary point scaling. If you select this option, the block displays the fields to specify the **Word length** and **Fraction length**. The **Signedness** is inherited from the input.

Accumulator — Accumulator data type

Same as input-squared product (default) | Same as input | Binary point scaling

Accumulator specifies the data type of the output of an accumulation operation in the Variance block. See “Fixed Point” on page 2-1390 for illustrations depicting the use of the accumulator data type in this block.

You can set this parameter to:

- **Same as input-squared product** — The accumulator data type is the same as the input-squared product data type.
- **Same as input** — The accumulator data type is the same as the input data type.
- **Binary point scaling** — The **Accumulator** data type uses binary point scaling. If you select this option, the block displays the fields to specify the **Word length** and **Fraction length**. The **Signedness** is inherited from the input.

Output — Output data type

Same as input-squared product (default) | Same as accumulator | Same as input | Binary point scaling

Output specifies the data type of the output of the Variance block. See “Fixed Point” on page 2-1390 for information about the use of the output data type in this block. You can set it to:

- Same as input-squared product — The output data type is the same as the input-squared product data type.
- Same as accumulator — The output data type is the same as the accumulator data type.
- Same as input — The output data type is the same as the input data type.
- Binary point scaling — The **Output** data type uses binary point scaling. If you select this option, the block displays the fields to specify the **Word length** and **Fraction length**. The **Signedness** is inherited from the input.

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block.

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

More About

Variance

The variance of a discrete-time signal is the square of the standard deviation of the signal. Variance gives a measure of deviation of the signal from its mean value.

For purely real or imaginary input, u , of size M -by- N , the variance is given by:

$$y = \sigma^2 = \frac{\sum_{i=1}^M \sum_{j=1}^N |u_{ij}|^2 - \frac{\left| \sum_{i=1}^M \sum_{j=1}^N u_{ij} \right|^2}{M*N}}{M*N - 1}.$$

where,

- u_{ij} is the input data element at indices i, j .
- M is the length of the j th column.
- N is the number of columns.

For complex inputs, the variance is given by the following equation:

$$\sigma^2 = \sigma_{\text{Re}}^2 + \sigma_{\text{Im}}^2$$

where,

- σ_{Re}^2 is the variance of the real part of the complex input.
- σ_{Im}^2 is the variance of the imaginary part of the complex input.

Algorithms

Variance

When you clear the **Running variance** parameter in the block and specify a dimension, the block produces results identical to the MATLAB `var` function when it is called as `y = var(u,theta,D)`, where,

- `u` is the data input.
- `D` is the dimension.
- `y` is the variance along the specified dimension.

When this block calculates the variance along the entire input, the result is identical to calling the `var` function as `y = var(u(:))`.

For a complex input signal, the variance is the sum of the variances of the real and imaginary parts.

$$\sigma^2 = \sigma_{\text{Re}}^2 + \sigma_{\text{Im}}^2$$

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

For purely real or imaginary input u of size M -by- N , the variance is given by:

$$y = \sigma^2 = \frac{\sum_{i=1}^M \sum_{j=1}^N |u_{ij}|^2 - \frac{\left| \sum_{i=1}^M \sum_{j=1}^N u_{ij} \right|^2}{M*N}}{M*N - 1}.$$

The following diagram shows the data types used within the Variance block when the input is fixed-point.

For complex inputs, the variance is given by the following equation:

$$\sigma^2 = \sigma_{\text{Re}}^2 + \sigma_{\text{Im}}^2$$

Vector Quantizer Decoder

Find vector quantizer codeword that corresponds to given, zero-based index value

Library

Quantizers

dspquant2

Description

The Vector Quantizer Decoder block associates each input index value with a codeword, a column vector of quantized output values defined in the **Codebook values** parameter. When you input multiple index values into this block, the block outputs a matrix of quantized output vectors. This matrix is created by horizontally concatenating the codeword vectors that correspond to each index value.

You can select how you want to enter the codebook values using the **Source of codebook** parameter. When you select **Specify via dialog**, you can type the codebook values into the block parameters dialog box. Select **Input port** and port C appears on the block. The block uses the input to port C as the **Codebook values** parameter.

The **Codebook values** parameter is a k -by- N matrix of values, where $k \geq 1$ and $N \geq 1$. Each column of this matrix is a codeword vector, and each codeword vector corresponds to an index value. The index values are zero based; therefore, the first codeword vector corresponds to an index value of 0, the second codeword vector corresponds to an index value of 1, and so on.

The input to this block is a vector of index values, where $0 \leq \text{index} < N$ and N is the number of columns of the codebook matrix. Use the **Action for out of range index value** parameter to determine how the block behaves when an input index value is out of this range. When you want any index values less than 0 to be set to 0 and any index values greater than or equal to N to be set to $N-1$, select **Clip**. When you want to be warned when any index values less than 0 are set to 0 and any index values greater than or equal to N are set to $N-1$, select **Clip and warn**. When you want the simulation to stop and display an error when the index values are out of range, select **Error**.

Data Type Support

The input to the block can be the index values and the codebook values. The data type of the index input to the block at port I can be `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`. The data type of the codebook values can be `double`, `single`, or `Fixed-point`.

The output of the block is the quantized output values. These quantized output values always have the same data type as the codebook values. When the codebook values are specified via an input port,

the block assigns the same data type to the Q(U) output port. When the codebook values are specified via the dialog, use the **Codebook and output data type** parameter to specify the data type of the Q(U) output port. The data type of the codebook and quantized output can be Same as input, double, single, Fixed-point, User-defined, or Inherit via back propagation.

Dialog Box

The **Main** pane of the Vector Quantizer Decoder block dialog appears as follows.

Action for out of range index value

Choose the behavior of the block when an input index value is out of range, where $0 \leq \text{index} < N$ and N is the length of the codebook vector. Select **Clip** when you want any index values less than 0 to be set to 0 and any index values greater than or equal to N to be set to $N-1$. Select **Clip and warn** when you want to be warned when any index values less than 0 are set to 0 and any index values greater than or equal to N are set to $N-1$. Select **Error** when you want the simulation to stop and display an error when the index values are out of range.

Source of codebook

Choose **Specify via dialog** to type the codebook values into the block parameters dialog box. Select **Input port** to specify the codebook values using the block's input port, C.

Codebook values

Enter a k -by- N matrix of quantized output values, where $1 \leq k$ and $1 \leq N$. Each column of your matrix corresponds to an index value. This parameter is visible if, from the **Source of codebook** list, you select **Specify via dialog**.

The **Data Types** pane of the Vector Quantizer Decoder block dialog appears as follows.

Codebook and output data type

Specify the data type of the codebook and quantized output values. You can select one of the following:

- A rule that inherits a data type, for example, `Inherit: Same as input`.
- A built in data type, such as `double`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Data Types of Signals” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

This parameter is available only when you set the **Source of codebook** parameter to `Specify via dialog`. If you set the **Source of codebook** parameter to `Input port`, the output values have the same data type as the input codebook values.

Vector Quantizer Design

(Removed) Design vector quantizer using Vector Quantizer Design Tool (VQDTool)

Note The Vector Quantizer Design block has been removed.

Library

Quantizers

dspquant2

Description

Double-click on the Vector Quantizer Design block to start VQDTool, a GUI that allows you to design and implement a vector quantizer. You can also start VQDTool by typing `vqdtool` at the MATLAB command prompt. Based on your specifications, VQDTool iteratively calculates the codebook values that minimize the mean squared error between the training set and the codebook until the stopping criteria for the design process is satisfied. The block uses the resulting codebook values to implement your vector quantizer.

For the **Training Set** parameter, enter a k -by- M matrix of values you want to use to train the quantizer codebook. The variable k , where $k \geq 1$, is the length of each training vector. It also represents the dimension of your quantizer. The variable M , where $M \geq 2$, is the number of training vectors. This data can be created using a MATLAB function, such as the default value `randn(10,1000)`, or it can be any variable defined in the MATLAB workspace.

You have two choices for the **Source of initial codebook** parameter. Select **Auto-generate** to have the block choose the values of the initial codebook. In this case, the block picks N random training vectors as the initial codebook, where N is the **Number of levels** parameter and $N \geq 2$. When you select **User defined**, enter the initial codebook values in the **Initial codebook** field. The initial codebook matrix must have the same number of rows as the training set. Each column of the codebook is a codeword, and your codebook must have at least two codewords.

For the given training set and initial codebook, the block performs an iterative process, using the Generalized Lloyd Algorithm (GLA), to design a final codebook. For each iteration of the GLA, the block first associates each training vector with its nearest codeword by calculating the distortion. You can specify one of the two possible methods for calculating distortion using the **Distortion measure** parameter.

When you select **Squared error** for the **Distortion measure** parameter, the block finds the nearest codeword by calculating the squared error (unweighted). Consider the codebook $CB = [CW_1 \ CW_2 \ \dots \ CW_N]$. This codebook has N codewords; each codeword has k elements. The i -th codeword is defined as $CW_i = [a_{1i} \ a_{2i} \ \dots \ a_{ki}]$. The training set has M columns and is defined as $U = [U_1 \ U_2 \ \dots \ U_M]$, where the p -th training vector is $U_p = [u_{1p} \ u_{2p} \ \dots \ u_{kp}]'$. The squared error (unweighted) is calculated using the equation

$$D = \sum_{j=1}^k (a_{ji} - u_{jp})^2$$

When you select **Weighted squared error** for the **Distortion measure** parameter, enter a vector or matrix for the **Weighting factor** parameter. When the weighting factor is a vector, its length must be equal to the number of rows in the training set. This weighting factor is used for each training vector. When the weighting factor is a matrix, it must be the same size as the training set matrix. The block finds the nearest codeword by calculating the weighted squared error. If the weighting factor for the p -th column of the training vector, U_p , is defined as $W_p = [w_{1p} \ w_{2p} \ \dots \ w_{kp}]'$, then the weighted squared error is defined by the equation

$$D = \sum_{j=1}^k w_{jp}(a_{ji} - u_{jp})^2$$

Once the block has associated all the training vectors with their nearest codeword vectors, the block calculates the mean squared error for the codebook and checks to see if the stopping criteria for the process has been satisfied.

The two possible options for the **Stopping criteria** parameter are **Relative threshold** and **Maximum iteration**. When you want the design process to stop when the fractional drop in the squared error is below a certain value, select **Relative threshold**. Then, type the maximum acceptable fractional drop in the **Relative threshold** field. The fraction drop in the squared error is defined as

$$\frac{\text{error at previous iteration} - \text{error at current iteration}}{\text{error at previous iteration}}$$

When you want the design process to stop after a certain number of iterations, choose **Maximum iteration**. Then, enter the maximum number of iterations you want the block to perform in the **Maximum iteration** field. For **Stopping criteria**, you can also choose **Whichever comes first** and enter **Relative threshold** and **Maximum iteration** values. The block stops iterating as soon as one of these conditions is satisfied.

When a training vector has the same distortion for two different codeword vectors, the algorithm uses the **Tie-breaking rule** parameter to determine which codeword vector the training vector is associated with. When you want the training vector to be associated with the lower indexed codeword, select **Lower indexed codeword**. To associate the training vector with the higher indexed codeword, select **Higher indexed codeword**.

With each iteration, the block updates the codeword values in order to minimize the distortion. The **Codebook update method** parameter defines the way the block calculates these new codebook values.

Note If, for the **Distortion measure** parameter, you choose **Squared error**, the **Codebook update method** parameter is set to **Mean**.

If, for the **Distortion measure** parameter, you choose **Weighted squared error** and you choose **Mean** for the **Codebook update method** parameter, the new codeword vector is found as follows. Suppose there are three training vectors associated with one codeword vector. The training vectors are

$$TS_1 = \begin{bmatrix} 1 \\ 2 \end{bmatrix}, TS_3 = \begin{bmatrix} 10 \\ 12 \end{bmatrix}, \text{ and } TS_7 = \begin{bmatrix} 11 \\ 12 \end{bmatrix}.$$

The new codeword vector is calculated as $CW_{new} = \begin{bmatrix} \frac{1 + 10 + 11}{3} \\ \frac{2 + 12 + 12}{3} \end{bmatrix}$

where the denominator is the number of training vectors associated with this codeword. If, for the **Codebook update method** parameter, you choose **Centroid** and you specify the weighting factors

$$W_1 = \begin{bmatrix} 0.1 \\ 0.2 \end{bmatrix}, W_3 = \begin{bmatrix} 1 \\ 0.6 \end{bmatrix}, \text{ and } W_7 = \begin{bmatrix} 0.3 \\ 0.4 \end{bmatrix}, \text{ the new codeword vector is calculated as}$$

$$CW_{new} = \begin{bmatrix} \frac{(0.1)(1) + (1)(10) + (0.3)(11)}{0.1 + 1 + 0.3} \\ \frac{(0.2)(2) + (0.6)(12) + (0.4)(12)}{0.2 + 0.6 + 0.4} \end{bmatrix}$$

Click **Design and Plot** to design the quantizer with the parameter values specified on the left side of the GUI. The performance curve and the entropy of the quantizer are updated and displayed in the figures on the right side of the GUI.

Note You must click **Design and Plot** to apply any changes you make to the parameter values in the VQDTool dialog box.

The following is an example of how the block calculates the entropy of the quantizer at each iteration. Suppose you have a codebook with four codewords and a training set with 200 training vectors. Also suppose that, at the i -th iteration, 40 training vectors are associated with the first codeword, 60 training vectors are associated with the second codeword, 20 training vectors are associated with the third codeword, and 80 training vectors are associated with the fourth codeword. The probability that a training vector is associated with the first codeword is $\frac{40}{200}$. The probabilities that training vectors are associated with the second, third, and fourth codewords are $\frac{60}{200}$, $\frac{20}{200}$, and $\frac{80}{200}$, respectively. The GUI uses these probabilities to calculate the entropy according to the equation

$$H = \sum_{i=1}^N -p_i \log_2 p_i$$

where N is the number of codewords. Based on these probabilities, the GUI calculates the entropy of the quantizer at the i -th iteration as

$$H = - \left(\frac{40}{200} \log_2 \frac{40}{200} + \frac{60}{200} \log_2 \frac{60}{200} + \frac{20}{200} \log_2 \frac{20}{200} + \frac{80}{200} \log_2 \frac{80}{200} \right)$$

$$H = 1.8464$$

VQDTool can export parameter values that correspond to the figures displayed in the GUI. Click the **Export Outputs** button, or press **Ctrl+E**, to export the **Final Codebook**, **Mean Square Error**, and **Entropy** values to the workspace, a text file, or a MAT-file.

In the **Model** section of the GUI, specify the destination of the block that will contain the parameters of your quantizer. For **Destination**, select **Current model** to create a block with your parameters in

the model you most recently selected. Type `gcs` in the MATLAB Command Window to display the name of your current model. Select **New model** to create a block in a new model file.

From the **Block type** list, select **Encoder** to design a Vector Quantizer Encoder block. Select **Decoder** to design a Vector Quantizer Decoder block. Select **Both** to design a Vector Quantizer Encoder block and a Vector Quantizer Decoder block.

In the **Encoder block name** field, enter a name for the Vector Quantizer Encoder block. In the **Decoder block name** field, enter a name for the Vector Quantizer Decoder block. When you have a Vector Quantizer Encoder and/or Decoder block in your destination model with the same name, select the **Overwrite target block** check box to replace the block's parameters with the current parameters. When you do not select this check box, a new Vector Quantizer Encoder and/or Decoder block is created in your destination model.

Click **Generate Model**. VQDTool uses the parameters that correspond to the current plots to set the parameters of the Vector Quantizer Encoder and/or Decoder blocks.

Parameters

Training Set

Enter the samples of the signal you would like to quantize. This data set can be a MATLAB function or a variable defined in the MATLAB workspace. The typical length of this data vector is $1e5$.

Source of initial codebook

Select **Auto-generate** to have the block choose the initial codebook values. Choose **User defined** to enter your own initial codebook values.

Number of levels

Enter the number of codeword vectors, N , in your codebook matrix, where $N \geq 2$.

Initial codebook

Enter your initial codebook values. From the **Source of initial codebook** list, select **User defined** in order to activate this parameter. The codebook must have the same number of rows as the training set. You must provide at least two codeword vectors.

Distortion measure

When you select **Squared error**, the block finds the nearest codeword by calculating the squared error (unweighted). When you select **Weighted squared error**, the block finds the nearest codeword by calculating the weighted squared error.

Weighting factor

Enter a vector or matrix. The block uses these values to compute the weighted squared error. When the weighting factor is a vector, its length must be equal to the number of rows in the training set. This weighting factor is used for each training vector. When the weighting factor is a matrix, it must be the same size as the training set matrix. The individual weighting factors cannot be negative. The weighting factor vector or matrix cannot contain all zeros.

Stopping criteria

Choose **Relative threshold** to enter the maximum acceptable fractional drop in the squared quantization error. Choose **Maximum iteration** to specify the number of iterations at which to stop. Choose **Whichever comes first** and the block stops the iteration process as soon as the relative threshold or maximum iteration value is attained.

Relative threshold

This parameter is available when you choose `Relative threshold` or `Whichever comes first` for the **Stopping criteria** parameter. Enter the value that is the maximum acceptable fractional drop in the squared quantization error.

Maximum iteration

This parameter is available when you choose `Maximum iteration` or `Whichever comes first` for the **Stopping criteria** parameter. Enter the maximum number of iterations you want the block to perform.

Tie-breaking rules

When a training vector has the same distortion for two different codeword vectors, select `Lower indexed codeword` to associate the training vector with the lower indexed codeword. Select `Higher indexed codeword` to associate the training vector with the higher indexed codeword.

Codebook update method

When you choose `Mean`, the new codeword vector is calculated by taking the average of all the training vector values that were associated with the original codeword vector. When you choose `Centroid`, the block calculates the new codeword vector by taking the weighted average of all the training vector values that were associated with the original codeword vector. Note that if, for the **Distortion measure** parameter, you choose `Squared error`, the **Codebook update method** parameter is set to `Mean`.

Destination

Choose `Current model` to create a Vector Quantizer block in the model you most recently selected. Type `gcs` in the MATLAB Command Window to display the name of your current model. Choose `New model` to create a block in a new model file.

Block type

Select `Encoder` to design a Vector Quantizer Encoder block. Select `Decoder` to design a Vector Quantizer Decoder block. Select `Both` to design a Vector Quantizer Encoder block and a Vector Quantizer Decoder block.

Encoder block name

Enter a name for the Vector Quantizer Encoder block.

Decoder block name

Enter a name for the Vector Quantizer Decoder block.

Overwrite target block

When you do not select this check box and a Vector Quantizer Encoder and/or Decoder block with the same block name exists in the destination model, a new Vector Quantizer Encoder and/or Decoder block is created in the destination model. When you select this check box and a Vector Quantizer Encoder and/or Decoder block with the same block name exists in the destination model, the parameters of these blocks are overwritten by new parameters.

Generate Model

Click this button and VQDTool uses the parameters that correspond to the current plots to set the parameters of the Vector Quantizer Encoder and/or Decoder blocks.

Design and Plot

Click this button to design a quantizer using the parameters on the left side of the GUI and to update the performance curve and entropy plots on the right side of the GUI.

You must click **Design and Plot** to apply any changes you make to the parameter values in the VQDTool GUI.

Export Outputs

Click this button, or press **Ctrl+E**, to export the **Final Codebook**, **Mean Squared Error**, and **Entropy** values to the workspace, a text file, or a MAT-file.

Supported Data Types

- Double-precision floating point

Vector Quantizer Encoder

For given input, find index of nearest codeword based on Euclidean or weighted Euclidean distance measure

Library

Quantizers

dspquant2

Description

The Vector Quantizer Encoder block compares each input column vector to the codeword vectors in the codebook matrix. Each column of this codebook matrix is a codeword. The block finds the codeword vector nearest to the input column vector and returns its zero-based index. This block supports real floating-point and fixed-point signals on all input ports.

The block finds the nearest codeword by calculating the distortion. The block uses two methods for calculating distortion: Euclidean squared error (unweighted) and weighted Euclidean squared error. Consider the codebook, $CB = [CW_1 \ CW_2 \ \dots \ CW_N]$. This codebook has N codewords; each codeword has k elements. The i -th codeword is defined as a column vector, $CW_i = [a_{1i} \ a_{2i} \ \dots \ a_{ki}]$. The multichannel input has M columns and is defined as $U = [U_1 \ U_2 \ \dots \ U_M]$, where the p -th input column vector is $U_p = [u_{1p} \ u_{2p} \ \dots \ u_{kp}]$. The squared error (unweighted) is calculated using the equation

$$D = \sum_{j=1}^k (a_{ji} - u_{jp})^2$$

The weighted squared error is calculated using the equation

$$D = \sum_{j=1}^k w_j (a_{ji} - u_{jp})^2$$

where the weighting factor is defined as $W = [w_1 \ w_2 \ \dots \ w_k]$. The index of the codeword that is associated with the minimum distortion is assigned to the input column vector.

You can select how you want to enter the codebook values using the **Source of codebook** parameter. When you select **Specify via dialog**, you can type the codebook values into the block parameters dialog box. Select **Input port** and port C appears on the block. The block uses the input to port C as the **Codebook** parameter.

The **Codebook** parameter is an k -by- N matrix of values, where $k \geq 1$ and $N \geq 1$. Each input column vector is compared to this codebook. Each column of the codebook matrix is a codeword, and each

codeword has an index value. The first codeword vector corresponds to an index value of 0, the second codeword vector corresponds to an index value of 1, and so on. The codeword vectors must have the same number of rows as the input, U.

For the **Distortion measure** parameter, select **Squared error** when you want the block to calculate the distortion by evaluating the Euclidean distance between the input column vector and each codeword in the codebook. Select **Weighted squared error** when you want to use a weighting factor to emphasize or deemphasize certain input values.

For the **Source of weighting factor** parameter, select **Specify via dialog** to enter a weighting factor vector in the dialog box. Choose **Input port** to specify the weighting factor using port W.

Use the **Weighting factor** parameter to emphasize or deemphasize certain input values when calculating the distortion measure. For example, consider the p -th input column vector, U_p , as previously defined. When you want to neglect the effect of the first element of this vector, enter $[0 \ 1 \ 1 \ \dots \ 1]$ as the **Weighting factor** parameter. This weighting factor is used to calculate the weighted squared error using the equation

$$D = \sum_{j=1}^k w_j (a_{ji} - u_{jp})^2$$

Because of the weighting factor used in this example, the weighted squared error is not affected by the first element of the input matrix. Therefore, the first element of the input column vector no longer impacts the choice of index value output by the Vector Quantizer Encoder block.

Use the **Index output data type** parameter to specify the data type of the index values output at port I. The data type of the index values can be `int8`, `uint8`, `int16`, `uint16`, `int32`, or `uint32`.

When an input vector is equidistant from two codewords, the block uses the **Tie-breaking rule** parameter to determine which index value the block chooses. When you want the input vector to be represented by the lower index valued codeword, select **Choose the lower index**. To represent the input column vector by the higher index valued codeword, select **Choose the higher index**.

Select the **Output codeword** check box to output at port Q(U) the codeword vectors that correspond to each index value. When the input is a matrix, the corresponding codeword vectors are horizontally concatenated into a matrix.

Select the **Output quantization error** check box to output at port D the quantization error that results when the block represents the input column vector by its nearest codeword. When the input is a matrix, the quantization error values are horizontally concatenated.

The Vector Quantizer Encoder block accepts real floating-point and fixed-point inputs. For more information on the data types accepted by each port, see “Data Type Support” on page 2-1403 or “Supported Data Types” on page 2-1406.

Data Type Support

The input data values, codebook values, and weighting factor values are input to the block at ports U, C, and W, respectively. The data type of the input data values, codebook values, and weighting factor values can be `double`, `single`, or `Fixed-point`. The input data, codebook values, and weighting factor must be the same data type.

The outputs of the block are the index values, output codewords, and quantization error. Use the **Index output data type** parameter to specify the data type of the index output from the block at

port I. The data type of the index can be `int8`, `uint8`, `int16`, `uint16`, `int32`, or `uint32`. The data type of the output codewords and the quantization error can be `double`, `single`, or `Fixed-point`. The block assigns the data type of the output codewords and the quantization error based on the data type of the input data.

Fixed-Point Data Types

The following diagram shows the data types used within the Vector Quantizer Encoder block for fixed-point signals.

You can set the product output, accumulator, and index output data types in the block dialog as discussed below.

Dialog Box

Main Tab

Source of codebook

Choose `Specify via dialog` to type the codebook values into the block parameters dialog box. Select `Input port` to specify the codebook values using the block's input port, `C`.

Codebook

Enter a k -by- N matrix of values, where $1 \leq k$ and $1 \leq N$, to which your input column vector or matrix is compared. This parameter is visible if, from the **Source of codebook** list, you select `Specify via dialog`.

Distortion measure

Select `Squared error` when you want the block to calculate the distortion by evaluating the Euclidean distance between the input column vector and each codeword in the codebook. Select `Weighted squared error` when you want the block to calculate the distortion by evaluating a weighted Euclidean distance using a weighting factor to emphasize or deemphasize certain input values.

Source of weighting factor

Select `Specify via dialog` to enter a value for the weighting factor in the dialog box. Choose `Input port` and specify the weighting factor using port `W` on the block. This parameter is visible if, for the **Distortion measure** parameter, you select `Weighted squared error`.

Weighting factor

Enter a vector of values. This vector must have length equal to the number of rows of the input, `U`. This parameter is visible if, for the **Source of weighting factor** parameter, you select `Specify via dialog`.

Tie-breaking rule

Set this parameter to determine the behavior of the block when an input column vector is equidistant from two codewords. When you want the input column vector to be represented by the lower index valued codeword, select `Choose the lower index`. To represent the input column vector by the higher index valued codeword, select `Choose the higher index`.

Output codeword

Select this check box to output the codeword vectors nearest to the input column vectors.

Output quantization error

Select this check box to output the quantization error value that results when the block represents the input column vector by the nearest codeword.

Index output data type

Select `int8`, `uint8`, `int16`, `uint16`, `int32`, or `uint32` as the data type of the index output at port I. To inherit the index output data type, select `Inherit via back propagation`.

Data Types Tab**Rounding mode**

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

Overflow mode

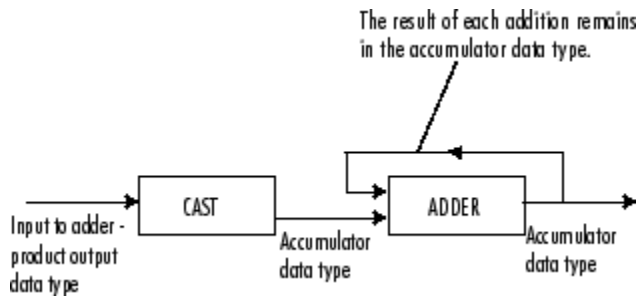

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

Product output

As depicted above, the output of the multiplier is placed into the product output data type and scaling. Use this parameter to specify how you would like to designate this product output word and fraction lengths.

- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the product output, in bits.

Accumulator

As depicted above, inputs to the accumulator are cast to the accumulator data type. The output of the adder remains in the accumulator data type as each element of the input is added to it. Use this parameter to specify how you would like to designate the accumulator word and fraction lengths.

- When you select `Same as product output`, these characteristics match those of the product output.
- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the accumulator, in bits.

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

If the input is fixed point, it must be a signed integer or signed fixed point with a power-of-two slope and zero bias.

Waterfall

(To be removed) View vectors of data over time

Note The Waterfall block will be removed in a future release. Use a different scope instead, see “Scopes and Data Logging”.

Library: DSP System Toolbox / Obsolete Blocks

Description

The Waterfall block displays multiple vectors of data at one time. These vectors represent the input data at consecutive sample times.

The data is displayed in 3D in the Waterfall window. By default, the x -axis represents amplitude, the y -axis represents samples, and the z -axis represents time. You can adjust the number of sample vectors that the block displays, move and resize the Waterfall window, and modify block parameter values during the simulation. The Waterfall window has toolbar buttons that enable you to zoom in on the displayed data, suspend the data capture, freeze the scope display, save the scope position, and export data to the workspace.

The toolbar buttons are labeled on the Waterfall window as it appears when you double-click a Waterfall block.

Ports

Input

Port_1 — Signal or signals to visualize

scalar | vector | matrix | array

The Waterfall block accepts most numeric data types as input. However, the input is converted to double-precision before the block processes the data. The Waterfall block displays only real-valued, double-precision vectors of data.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

Parameters

You can control the display and behavior of the Waterfall window using the Parameters dialog box. To open the Parameters dialog box, click the Scope parameters button.

You can alter the Waterfall parameters while the simulation is running. However, when you make changes to values in text boxes, you must click **Enter** or click outside the text box for the block to accept your changes.

Display

These parameters control the Waterfall display.

Display traces — Number of data vectors to display

6 (default) | positive integer

Number of data vectors to display in the Waterfall window, specified as a positive integer.

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: NumTraces

Type: positive scalar specified as a character vector

Update interval — Number of vectors to store

1 (default) | positive integer

Number of vectors the block should store before it displays them to the window, specified as a positive integer.

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: UpdateInterval

Type: positive scalar specified as a character vector

Colormap — Colors of display

autumn (default) | gray | hot | pink | jet | copper | red | white

Colors for the displayed data, specified as a valid colormap.

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: CMapStr

Type: character vector

Type: valid colormap name, see `map`

Transparency — Transparency of oldest and newest data vectors

newest: opaque, oldest: transparent (default)

Transparency of the oldest and newest data vectors, specified with the sliders. The leftmost position makes the data vector transparent. The rightmost position makes the data vector opaque. The intermediate data vectors transition between the two chosen transparency values.

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: TNewest and TOldest

Type: number between [0,1] specified as a character vector

Axes

These parameters control the axes in the Waterfall window.

Y Min — Minimum value of y-axis

-1 (default) | integer

Minimum value of the y-axis specified as an integer.

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: YMin

Type: character vector

Y Max — Maximum value of y-axis

1 (default) | integer

Maximum value of the y-axis specified as an integer

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: YMax

Type: character vector

Axis color — Color of axes

'w' (default) | RGB triplet | specified color name | hexadecimal color code

Color of the axes, specified as a RGB triplet, specified color name, or hexadecimal color code.

RGB triplets and hexadecimal color codes are useful for specifying custom colors.

- An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range $[0, 1]$; for example, $[0.4 \ 0.6 \ 0.7]$.
- A hexadecimal color code is a character vector or a string scalar that starts with a hash symbol (#) followed by three or six hexadecimal digits, which can range from 0 to F. The values are not case sensitive. Thus, the color codes '#FF8800', '#ff8800', '#F80', and '#f80' are equivalent.

Alternatively, you can specify some common colors by name. This table lists the named color options, the equivalent RGB triplets, and hexadecimal color codes.

Color Name	Short Name	RGB Triplet	Hexadecimal Color Code	Appearance
"red"	"r"	[1 0 0]	"#FF0000"	
"green"	"g"	[0 1 0]	"#00FF00"	
"blue"	"b"	[0 0 1]	"#0000FF"	
"cyan"	"c"	[0 1 1]	"#00FFFF"	
"magenta"	"m"	[1 0 1]	"#FF00FF"	
"yellow"	"y"	[1 1 0]	"#FFFF00"	
"black"	"k"	[0 0 0]	"#000000"	
"white"	"w"	[1 1 1]	"#FFFFFF"	

Here are the RGB triplets and hexadecimal color codes for the default colors MATLAB uses in many types of plots.

RGB Triplet	Hexadecimal Color Code	Appearance
[0 0.4470 0.7410]	"#0072BD"	
[0.8500 0.3250 0.0980]	"#D95319"	
[0.9290 0.6940 0.1250]	"#EDB120"	
[0.4940 0.1840 0.5560]	"#7E2F8E"	
[0.4660 0.6740 0.1880]	"#77AC30"	
[0.3010 0.7450 0.9330]	"#4DBEEE"	
[0.6350 0.0780 0.1840]	"#A2142F"	

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: `AxisColor`

Type: character vector within a character vector

Example: `set_param(block, 'AxisColor', char("'b'))`

X Axis — x-axis label

`Samples (default) | string`

Enter the x-axis label.

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: `XLabel`

Type: character vector

Y Axis — y-axis label

`Amplitude (default) | string`

Enter the y-axis label.

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: `YLabel`

Type: character vector

Z Axis — z-axis label

`Time (default) | string`

Enter the z-axis label.

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: `ZLabel`

Type: character vector

Data History

These parameters control how many input data vectors the Waterfall block stores. They also control how the data is exported to the MATLAB workspace.

History traces — Number of vectors to store

10 (default) | positive integer

Number of vectors (traces) that you want the block to store, specified as a positive integer.

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: HistoryLength**Type:** positive integer specified as a character vector**When the buffer is full — Behavior of full buffer**

Overwrite (default) | Suspend | Extend

Use this parameter to control the behavior of the block when the buffer is full:

- **Overwrite** — The old data is replaced with the new data.
- **Suspend** — The block stops storing data in the buffer; but the simulation continues to run.
- **Extend** — The block extends the buffer so that it can continue to store all the input data.

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: HistoryFull**Type:** character vector**Data logging — Export data from block**

Selected (default) | All visible | All history

Use this parameter to control which data is exported from the block:

- **Selected** — The selected data vector is exported.
- **All visible** — All of the data vectors displayed in the Waterfall window are exported.
- **All history** — All of the data vectors stored in the history buffer of the block are exported.

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: ExportMode**Type:** character vector**Export variable — Variable name of exported data**

ExportData (default) | valid MATLAB variable name

Name of the variable that represents your data in the MATLAB workspace.

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: MLExportName**Type:** character vector**Export at end of simulation — Automatically export data**

off (default) | on

Select this check box to automatically export the data to the MATLAB workspace when the simulation stops.

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: `AutoExport`

Values: `'off'` | `'on'`

Triggering

These parameters control when the Waterfall block starts and stops capturing data.

Begin recording — When to start capturing data

Immediately (default) | After T seconds | After N inputs | User-defined

This parameter controls when the Waterfall block starts capturing data:

- **Immediately** — The Waterfall window captures the input data as soon as the simulation starts.
- **After T seconds** — The **Time, T** parameter appears in the dialog box. Enter the number of seconds the block should wait before it begins capturing data.
- **After N inputs** — The **Count, N** parameter appears in the dialog box. Enter the number of inputs the block should receive before it begins capturing data.
- **User-defined** — The **Function name** parameter appears in the dialog box. Enter the name of a MATLAB function that defines when the block should begin capturing data. For more information about how you define this function, see “Scope Trigger Function”.

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: `TrigStartMode` | `TrigStartT` | `TrigStartN` | `TrigStartFcn`

Type: character vector

Stop recording — When to stop capturing data

Never (default) | After T seconds | After N inputs | User-defined

This parameter controls when the Waterfall block stops capturing data:

- **Never** — The block captures the input data as long as the simulation is running.
- **After T seconds** — The **Time, T** parameter appears in the dialog box. Enter the number of seconds the block should wait before it stops capturing data.
- **After N inputs** — The **Count, N** parameter appears in the dialog box. Enter the number of inputs the block should receive before it stops capturing data.
- **User-defined** — The **Function name** parameter appears in the dialog box. Enter the name of a MATLAB function that defines when the block should stop capturing data. For more information about how you define this function, see “Scope Trigger Function”.

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: `TrigStopMode` | `TrigStopT` | `TrigStopN` | `TrigStopFcn`

Type: character vector

Re-arm trigger — When to capture data

Never (default) | After T seconds | After N inputs | User-defined

This parameter controls when the Waterfall block begins waiting to capture data.

- **Never** — The Waterfall Scope block starts and stops capturing data as defined by the **Begin recording** and **Stop recording** parameters.
- **After T seconds** — The **Time, T** parameter appears in the dialog box. Enter the number of seconds the block should wait before it begins waiting to capture data.
- **After N inputs** — The **Count, N** parameter appears in the dialog box. Enter the number of inputs the block should receive before it begins waiting to capture data.
- **User-defined** — The **Function name** parameter appears in the dialog box. Enter the name of a MATLAB function that defines when the block should begin waiting to capture data. For more information about how you define this function, see “Scope Trigger Function”.

Dependency

To enable this parameter, set **Stop recording** to After T seconds, After N inputs, or User-defined.

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: TrigRearmMode | TrigRearmT | TrigRearmN | TrigRearmFcn

Type: character vector

Transform

These parameters transform the input data to the Waterfall block. The result of the transform is displayed in the Waterfall window.

The block assumes that the input to the block corresponds to the **Transform** parameter you select. For example, when you choose **Complex-> Angle**, the block assumes that the input is complex. But the block does not produce an error when the input is not complex. Therefore, you must verify the format of your input data to guarantee that a meaningful result is displayed in the Waterfall window.

Transform — Transformation to apply to input

None (default) | Amplitude-> dB | Complex-> Mag Lin | Complex-> Mag dB | ...

Choose a transform that you would like to apply to the input of the Waterfall block:

- **None** — The input is displayed as it is received by the block.
- **Amplitude-> dB** — The block converts the input amplitude into decibels.
- **Complex-> Mag Lin** — The block converts the complex input into linear magnitude.
- **Complex-> Mag dB** — The block converts the complex input into magnitude in decibels.
- **Complex-> Angle** — The block converts the complex input into phase.
- **FFT-> Mag Lin Fs/2** — The block takes the linear magnitude of the FFT input and plots it from 0 to the Nyquist frequency.
- **FFT-> Mag dB Fs/2** — The block takes the magnitude of the FFT input, converts it to decibels, and plots it from 0 to the Nyquist frequency.
- **FFT-> Angle Fs/2** — The block converts the FFT input into phase and plots it from 0 to the Nyquist frequency.

- Power -> dB — The block converts the input power into decibels.
- User-defined fcn — see “Function” on page 2-0 .
- User-defined expr — see “Expression” on page 2-0 .

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: XFormMode

Type: character vector

Function — Custom transformation function

abs (default)

Enter a function that you would like to apply to the input of the Waterfall block. For more information about how you define this function, see “Scope Transform Function”.

Dependency

To enable this parameter, set **Transform** to User-defined fcn.

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

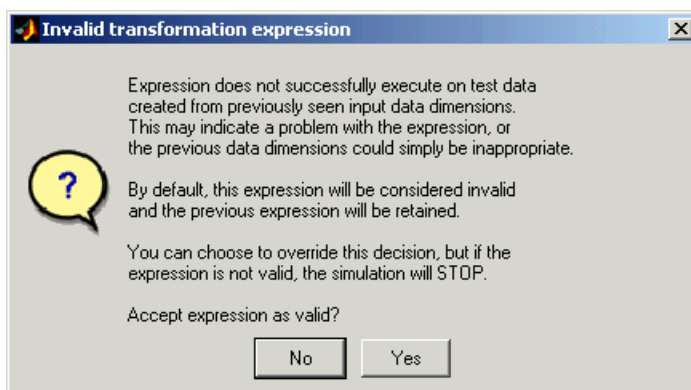

Block Parameter: XFormFcn

Type: character vector

Expression — Custom transformation expression

(u+1)/2 (default) | expression with real-valued output

Enter an expression that you would like to apply to the input of the Waterfall block. The result of this expression must be real-valued. When you write the expression, be sure to include only one unknown variable. The block assumes this unknown variable represents the input to the block. When the block believes your expression is invalid, this window appears.

When you click **No**, your expression is not applied to the input. When you click **Yes** and your expression is invalid, your simulation stops and Simulink displays an error.

Dependency

To enable this parameter, set **Transform** to User-defined expr.

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: XFormExpr

Type: character vector

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced before R2006a

Waterfall block will be removed

Not recommended starting in R2020b

The Waterfall block will be removed in a future release. Use a different scope instead, see “Scopes and Data Logging”.

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

This block can be used for simulation visibility in systems that generate code, but is not included in the generated code.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block can be used for simulation visibility in subsystems that generate HDL code, but is not included in the hardware implementation.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

This block can be used for simulation visibility in systems that generate code, but is not included in the generated code.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

This block accepts fixed-point input, but converts it to `double` for display.

Scope | Time Scope | Spectrum Analyzer

Wavelet Scattering

Model wavelet scattering network in Simulink

Library: DSP System Toolbox / Feature Extractors

Description

The Wavelet Scattering block creates a framework for wavelet time scattering in the Simulink environment. Use this block to derive low-variance features from real-valued data and then use those features in machine learning and deep learning applications. The block uses predefined wavelet filters to compute the scalogram and applies an averaging filter to the scalogram for feature extraction. For more information, see “Wavelet Scattering” (Wavelet Toolbox). To perform wavelet scattering in MATLAB, use the `waveletScattering` function.

The Wavelet Scattering block requires Wavelet Toolbox.

Ports

Input

Input — Input signal

vector | matrix

Specify the input signal as a vector or a matrix. The block treats each column in the matrix as a separate channel. For example, the block treats a 1-by- N_{chann} row vector as N_{chann} separate channels.

When the input data type is `single`, the block performs internal operations in single-precision. The input data type determines the precision of the scattering decomposition in the filter banks.

The input frame length does not have to match the signal length specified in the block dialog box. The block uses a buffer to feed the wavelet scattering algorithm with frames of length **Signal length (samples)**. If the input frame size does not match the signal length, the block runs in multirate mode.

Data Types: `single` | `double`

Output

Output — Output signal

matrix | 3-D array

Output signal, returned as a matrix or a 3-D array.

For a column vector input, the output dimensions are N_{path} -by- N_{scat} , where N_{path} is the number of scattering paths and N_{scat} is the number of scattering coefficients in each path, or the resolution of the scattering coefficients.

For matrix inputs, the output dimensions are N_{path} -by- N_{scat} -by- N_{chann} , where N_{chann} is the number of columns in the input.

Data Types: `single` | `double`

Parameters

Signal length (samples) — Signal length in samples

1024 (default) | positive integer ≥ 16

Specify the signal length in samples as a positive integer ≥ 16 .

The input frame length does not have to match the signal length. The block uses a buffer to feed the wavelet scattering algorithm with frames of length **Signal length**. If the input frame size does not match the signal length, the block runs in multirate mode.

Data Types: `double`

Overlap length (Samples) — Overlap length in samples

0 (default) | positive integer

Specify the overlap (in samples) between consecutive frames of a signal as a nonnegative integer.

Data Types: `double`

Specify sample rate — Specify sample rate

off (default) | on

Specify the sample rate on the block dialog using the `Sample rate (Hz)` parameter. If you do not select this check box, the frequencies are in cycles/sample and the Nyquist frequency is $\frac{1}{2}$.

Data Types: `Boolean`

Sample rate (Hz) — Sample rate

16e3 (default) | positive scalar

Specify the sample rate in Hz as a positive scalar.

Dependencies

To enable this parameter, select the **Specify sample rate** parameter.

Data Types: `double`

Invariance scale (samples) — Scattering transform invariance scale in samples

512 (default) | positive integer

Specify the scattering transform invariance scale in samples as a positive integer. Invariance scale specifies the translation invariance of the scattering transform.

If you do not specify the sample rate, invariance scale is measured in samples. If you specify the sample rate, invariance scale is measured in seconds.

Invariance scale cannot exceed the signal length. If signal length is 1000 samples and you do not specify a sample rate, the maximum value of the invariance scale is 1000 samples.

Dependencies

To enable this parameter, clear the **Specify sample rate** parameter.

Data Types: double

Invariance scale (s) — Scattering transform invariance scale in seconds

0.032 (default) | positive scalar

Specify the scattering transform invariance scale in samples as a positive scalar. Invariance scale specifies the translation invariance of the scattering transform.

If you do not specify the sample rate, invariance scale is measured in samples. If you specify the sample rate, invariance scale is measured in seconds. By default, invariance scale is one-half the signal length.

Invariance scale cannot exceed the signal length. If signal length is 1000 samples and you specify a sample rate of 200 Hz, then the maximum value of the invariance scale is 5.

Dependencies

This parameter appears only when you select the **Specify sample rate** parameter.

Data Types: double

Quality factors — Quality factors for scattering filter banks

[8,1] (default) | positive integer | vector of monotonically decreasing positive integers

Specify the quality factors for the scattering filter banks as a positive integer or a vector of monotonically decreasing positive integers. A filter bank quality factor is the number of wavelet filters per octave. Quality factors cannot exceed 32 and must be greater than or equal to 1.

By default, the wavelet scattering network the block creates has two filter banks. The first filter bank has a quality factor of eight wavelets per octave and the second filter bank has a quality factor of 1 wavelet per octave.

Data Types: double

Reduce the number of scattering paths — Optimize scattering transform

off (default) | on

Specify whether to optimize the scattering transform and reduce the number of scattering paths.

When you select this parameter, the algorithm reduces the number of scattering paths to compute based on a bandwidth consideration. The scattering transform excludes scattering paths of order 2 and greater that do not satisfy this criterion:

The center frequency minus $\frac{1}{2}$ the 3-dB bandwidth of the wavelet filter in the $(i+1)^{\text{th}}$ filter bank must overlap 0 (DC) plus $\frac{1}{2}$ the 3-dB bandwidth of the wavelet filter in the i^{th} filter bank.

If this criterion is not satisfied, the higher-order path is excluded. Selecting the **Reduce the number of scattering paths** parameter can significantly reduce the number of scattering paths and computational complexity of the scattering transform for most networks.

Data Types: Boolean

Oversampling factor — Oversampling factor

0 (default) | nonnegative integer | Inf

Specify the oversampling factor as a nonnegative integer or Inf.

The oversampling factor specifies the factor by which the number of scattering coefficients per signal increase on a \log_2 scale. By default, the **Oversampling factor** is set to 0, which corresponds to critically downsampling the coefficients. To obtain a fully undecimated scattering transform, set **Oversampling factor** to Inf.

Setting **Oversampling factor** to a value that results in more coefficients than samples is equivalent to setting **Oversampling factor** to Inf. Increasing the **Oversampling factor** significantly increases the computational complexity and memory requirements of the scattering transform.

If you set **Oversampling factor** to 2, the scattering transform returns 2^2 times as many coefficients for each scattering path with respect to the critically sampled number.

Data Types: double

Boundary signal extension — Signal extension method

periodic (default) | reflection

Specify the signal extension method to apply at the boundary as:

- **periodic** — Extend signal periodically to length $2^{\text{ceil}(\log_2(N))}$, where N is the signal length.
- **reflection** — Extend signal by reflection to length $2^{\text{ceil}(\log_2(2N))}$, where N is the signal length.

The signal is extended to match the length of the wavelet filters. The length of the filters are powers of two.

The signal extension method is for internal operations. Results are downsampled back onto the scale of the original signal before being returned.

Scattering coefficients

Include zeroth-order coefficients — Include zeroth-order coefficients

off (default) | on

Specify whether to include the zeroth-order coefficients.

Data Types: Boolean

Normalization — Coefficient normalization

none (default) | parent

Specify the type of normalization to apply to the scattering coefficients as **none** or **parent**. If specified as **parent**, scattering coefficients of order greater than 0 are normalized by their parents along the scattering path.

Transform — Transformation on coefficients

none (default) | log

Specify the type of transformation to apply to the scattering coefficients as none or log.

Block Characteristics

Data Types	double single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced in R2022b

Window Function

Compute and apply window to input signal

Library: DSP System Toolbox / Signal Operations

Description

The Window Function block has three modes of operation that enable you to apply a window, or compute a window, or compute and apply a window to an input signal. You can select the mode via the **Operation** parameter. In each mode, the block first creates a window vector w by sampling the window specified in the **Window type** parameter.

Ports

Input

In — Input signal

vector | matrix | N -D array

Input signal, specified as a vector, matrix, or an N -D array. When the input is fixed point, it can be signed only.

This port is enabled only when you set **Operation** to either `Apply window to input` or `Generate and apply window`.

This port is unnamed when you set **Operation** to `Apply window to input`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

Output

Out — Output

vector | matrix | N -D array

Output signal, returned as a vector, matrix, or an N -D array.

The **Out** port is enabled only when **Operation** is set to:

- `Apply window to input` -- The block computes an M -by-1 window vector w and applies it to the M -by- N input, where M is the number of rows in the input signal.

- **Generate and apply window** -- The block generates an M -by-1 window vector w and applies it to the input.

The output signal has the same dimensions as the input signal. For more details, see “Operation” on page 2-0 .

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

Win — Window output

vector

Window output, returned as a vector. When **Operation** is set to **Apply window to input** or **Generate and apply window**, the window vector is of the same length as the number of rows in the input signal. When **Operation** is set to **Generate window**, the length of window vector is determined by the **Window length** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

Parameters

Main

Operation — Modes of operation

`Apply window to input (default)` | `Generate window` | `Generate and apply window`

The Window Function block has three modes of operation that you can select through the **Operation** parameter. In each mode, the block first creates a window vector w by sampling the window specified in the **Window type** parameter at M discrete points. The operation modes are:

- **Apply window to input**

In this mode, the block computes an M -by-1 window vector w and applies it to the input. The output y always has the same dimension as the input.

When the input is an M -by- N matrix u , the window is multiplied element-wise with each of the N channels in the input matrix u . This is equivalent to the following MATLAB code:

```
y = repmat(w,1,N) .* u % Equivalent MATLAB code
```

The window is always applied to the first dimension:

$$y(i, j, \dots, k) = w(i) * u(i, j, \dots, k) \quad i = 1, \dots, M, \quad j = 1, \dots, N, \quad \dots, \quad k = 1, \dots, P$$

A length- M unoriented vector input is treated as an M -by-1 vector.

- **Generate window**

In this mode, the block generates an unoriented window vector w with length M specified by the **Window length** parameter. The **In** port is disabled for this mode.

- **Generate and apply window**

In this mode, the block generates an M -by-1 window vector w and applies it to the input. The block produces two outputs:

- At the **Out** port, the block produces the result of the multiplication y , which has the same dimension as the input.

- At the **Win** port, the block produces the M -by-1 window vector w .

When the input is an M -by- N matrix u , the window is multiplied element-wise with each of the N channels in the input matrix u . This is equivalent to the following MATLAB code:

```
y = repmat(w,1,N) .* u % Equivalent MATLAB code
```

The window is always applied to the first dimension:

$$y(i, j, \dots, k) = w(i) * u(i, j, \dots, k) \quad i = 1, \dots, M, \quad j = 1, \dots, N, \quad \dots, \quad k = 1, \dots, P$$

A length- M 1-D vector input is treated as an M -by-1 vector.

Window type — Type of window

Hamming (default) | Bartlett | Blackman | ...

This table lists the available window types.

Window Type	Description
Bartlett	Computes a Bartlett window. $w = \text{bartlett}(M)$
Blackman	Computes a Blackman window. $w = \text{blackman}(M)$
Boxcar	Computes a rectangular window. $w = \text{rectwin}(M)$
Chebyshev	Computes a Chebyshev window with stopband ripple R . $w = \text{chebwin}(M, R)$
Hamming	Computes a Hamming window. $w = \text{hamming}(M)$
Hann	Computes a Hann window (also known as a Hanning window). $w = \text{hann}(M)$
Hanning	Obsolete. This window type is included only for compatibility with older models. Use the Hann Window type instead of Hanning whenever possible.
Kaiser	Computes a Kaiser window with the Kaiser parameter β . $w = \text{kaiser}(M, \beta)$
Taylor	Computes a Taylor window. $w = \text{taylorwin}(M)$
Triang	Computes a triangular window. $w = \text{triang}(M)$

Window Type	Description
User Defined	<p>Computes the user-defined window function specified by the entry in the Window function name parameter, <code>usrwin</code>.</p> <pre>w = usrwin(M) % Window takes no extra parameters w = usrwin(M,x₁,...,x_n) % Window takes extra parameters {x₁ ... x_n}</pre>

Sampling – Type of sampling

Symmetric (default) | Periodic

Specify the window sampling for generalized-cosine windows.

For the generalized-cosine windows (Blackman, Hamming, Hann, and Hanning), the **Sampling** parameter determines whether the window samples are computed in a periodic or a symmetric manner. For example, when **Sampling** is set to **Symmetric**, a Hamming window of length M is computed as:

```
w = hamming(M) % Symmetric (aperiodic) window
```

When **Sampling** is set to **Periodic**, the same window is computed as:

```
w = hamming(M+1) % Periodic (asymmetric) window
w = w(1:M)
```

Tunable (Simulink) in simulation only.

Dependencies

This parameter is visible only when you select Blackman, Hamming, Hann, or Hanning for the **Window type** parameter.

Sample mode – Sample mode

Continuous (default) | Discrete

Specify the sample mode for the block, **Continuous** or **Discrete**, when it is in the **Generate window mode**. In the **Apply window to input** and **Generate and apply window modes**, the block inherits the sample mode from its driving block.

Dependencies

This parameter is visible only when you select **Generate window** for the **Operation** parameter.

Sample time – Sample time

1 (default) | real scalar

Specify the sample time for the block when **Operation** is set to **Generate window** and **Sample mode** is set to **Discrete**. When **Operation** is set to **Apply window to input** and **Generate and apply window**, the block inherits the sample time from its driving block.

Dependencies

This parameter is visible only when you set **Sample mode** to **Discrete**.

Window length — Length of window

64 (default) | positive integer

Specify the length of the window to apply.

Dependencies

This parameter is visible only when you select **Generate window** for the **Operation** parameter. Otherwise, the window vector length is computed to match the length of the first dimension of the input.

Stopband attenuation in dB — Stopband attenuation in dB

50 (default) | nonnegative scalar

Specify the level of stopband attenuation R_s in decibels.

Tunable (Simulink) in simulation only.

Dependencies

This parameter is visible only when you select **Chebyshev** for the **Window type** parameter.

Beta — Kaiser window β parameter

10 (default) | real scalar

Specify the Kaiser window β parameter. Increasing β widens the mainlobe and decreases the amplitude of the window sidelobes in the window's frequency magnitude response.

Tunable (Simulink) in simulation only.

Dependencies

This parameter is visible only when you select **Kaiser** for the **Window type** parameter.

Number of sidelobes — Number of sidelobes

4 (default) | positive integer

Specify the number of sidelobes as a scalar integer value greater than zero.

Dependencies

This parameter is visible only when you select **Taylor** for the **Window type** parameter.

Maximum sidelobe level relative to mainlobe (dB) — Maximum sidelobe level relative to mainlobe

-30 (default) | scalar less than or equal to zero

Specify in decibels the maximum sidelobe level relative to the mainlobe. This parameter must be a scalar less than or equal to zero. The default value of -30 produces sidelobes with peaks 30 dB down from the mainlobe peak.

Dependencies

This parameter is visible only when you select Taylor for the **Window type** parameter.

Window function name — Window function name

hamming (default) | character vector

Specify the name of the user-defined window function to be calculated by the block. The output window vector returned by the custom window function must be of data type double.

Dependencies

This parameter is visible only when you select User defined for the **Window type** parameter.

Specify additional arguments to the hamming function — Specify additional arguments to the window function

off (default) | on

Select to enable the **Cell array of additional arguments** parameter, when the user-defined window requires parameters other than the window length.

Dependencies

This parameter is visible only when you select User defined for the **Window type** parameter.

Cell array of additional arguments — Additional arguments

{'symmetric'} (default) | cell array

Specify the extra parameters required by the user-defined window function, besides the window length.

Dependencies

This parameter is only available when you select the **Specify additional arguments to the hamming function** parameter. The entry must be a cell array.

Data Types

When the **Operation** parameter on the **Main** tab is set to Generate window, the following parameters appear.

Window data type — Window data type

double (default) | single | Fixed-point | User-defined | Inherit via back propagation

Specify the window data type in one of the following ways:

- double
- single
- Fixed-point -- To specify the window data type and scaling in the **Signed**, **Word length**, **Set fraction length in output to**, and **Fraction length** parameters.
- User-defined -- To specify the window data type and scaling in the **User-defined data type**, **Set fraction length in output to**, and **Fraction length** parameters.

- **Inherit via back propagation** -- To set the window data type and scaling to match the following block.

Signed — Window output is signed

on (default) | off

Select to output a signed fixed-point signal. Otherwise, the signal is unsigned.

Dependencies

This parameter appears only when you set **Window data type** to Fixed-point.

Word length — Word length

16 (default) | positive integer in the range [2 128]

Specify the word length of the fixed-point window data type in bits.

Dependencies

This parameter is visible only when you set **Window data type** to Fixed-point.

User-defined data type (e.g. sfix(16), float('single')) — user-defined data type

sfix(16) (default) | built-in data type | fixed-point data type

Specify any built-in or fixed-point data type. You can specify fixed-point data types using the `fixdt` function.

Dependencies

This parameter is only visible when you set **Window data type** to User-defined.

Set fraction length in output to — Scaling of fixed-point window data type

Best precision (default) | User-defined

Specify the scaling of the fixed-point window data type by using either of these methods:

- Choose **Best precision** to have the window data type scaling automatically set such that the output signal has the best possible precision.
- Choose **User-defined** to specify the window data type scaling in the **Fraction length** parameter.

Dependencies

This parameter is visible only when you set **Window data type** to Fixed-point or User-defined, and when the specified window data type is a fixed-point data type.

Fraction length — User-defined fraction length

15 (default) | integer

Specify the fraction length of the fixed-point window data type in bits.

Dependencies

This parameter is visible only when you set **Window data type** to Fixed-point or User-defined, and when you set **Set fraction length in output to** to User-defined.

When the **Operation** parameter on the **Main** tab is set to either Apply window to input or Generate and apply window, the following parameters appear.

Rounding mode — Rounding mode

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Select the rounding mode for fixed-point operations.

The window vector w does not obey this parameter. It always rounds to Nearest.

Note The **Rounding mode** and **Overflow mode** settings have no effect on numerical results when both of these conditions exist:

- **Product output** is Inherit via internal rule
- **Output** is Same as product output

With these data type settings, the block is effectively operating in a full-precision mode.

Overflow mode — Overflow mode

Wrap (default) | Saturate

Select the overflow mode for fixed-point operations.

The window vector w does not obey this parameter. It is always saturated.

Window — Window data type

Same word length as input (default) | Specify word length | Binary point scaling | Slope and bias scaling

Choose how you specify the word length and fraction length of the window vector w .

When you select:

- **Same word length as input** -- The word length of the window vector elements is the same as the word length of the input. The fraction length is automatically set to the best precision possible.
- **Specify word length** -- You can enter the word length of the window vector elements in bits. The fraction length is automatically set to the best precision possible.
- **Binary point scaling** -- You can enter the word length and the fraction length of the window vector elements in bits.
- **Slope and bias scaling** -- You can enter the word length, in bits, and the slope of the window vector elements. This block requires power-of-two slope and a bias of zero.

The window vector does not obey the **Rounding mode** and **Overflow mode** parameters. It is always saturated and rounded to Nearest.

Product output — Product output data type

Inherit via internal rule (default) | Same as input | Binary point scaling | Slope and bias scaling

Use this parameter to specify how you want to designate the product output word and fraction lengths.

When you select:

- **Inherit via internal rule** -- The product output word length and fraction length are calculated automatically. For information on how the product output word and fraction lengths are calculated when an internal rule is used, see “Inherit via Internal Rule”.
- **Same as input** -- These characteristics match those of the input to the block.
- **Binary point scaling** -- You can enter the word length and the fraction length of the product output in bits.
- **Slope and bias scaling** -- You can enter the word length in bits and the slope of the product output. This block requires power-of-two slope and a bias of zero.

Output — Output data type

Same as product output (default) | Same as input | Binary point scaling | Slope and bias scaling

Choose how you specify the word length and fraction length of the output of the block.

When you select:

- **Same as product output** -- These characteristics match those of the product output.
- **Same as input** -- These characteristics match those of the input to the block.
- **Binary point scaling** -- You can enter the word length and the fraction length of the output in bits.
- **Slope and bias scaling** -- You can enter the word length in bits and the slope of the output. This block requires power-of-two slope and a bias of zero.

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	yes

Zero-Crossing Detection	no
--------------------------------	----

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

If the input is fixed point, it must be a signed integer or signed fixed point with a power-of-two slope and zero bias.

The following diagram shows the data types used within the Window Function block for fixed-point signals for each of the three operating modes.

Apply window to input

The input data type comes from the driving block. You can set the window, product output, and output data types in the block dialog. In this mode, the window vector is not output from the block.

Generate window

In this mode, the block acts as a source. The window vector is output in the window data type you specify in the block dialog.

Generate and apply window

The input data type comes from the driving block. You can set the window, product output, and output data types in the block dialog. In this mode, the window vector is output from the block.

You can set the window, product output, and output data types in the block dialog box.

Blocks

FFT

Yule-Walker AR Estimator

Compute estimate of autoregressive (AR) model parameters using Yule-Walker method

Library

Estimation / Parametric Estimation

dspparest3

Description

The Yule-Walker AR Estimator block uses the Yule-Walker AR method, also called the autocorrelation method, to fit an autoregressive (AR) model to the windowed input data by minimizing the forward prediction error in the least squares sense. This formulation leads to the Yule-Walker equations, which are solved by the Levinson-Durbin recursion. Block outputs are always nonsingular.

The Yule-Walker AR Estimator block can output the AR model coefficients as polynomial coefficients, reflection coefficients, or both. The input can be a row vector, a column vector, or an unoriented vector which is assumed to be the output of an AR system driven by white noise. The block accepts matrices, and treats each column of the matrix as a channel. If the input is a row vector of length N , the input is treated as N different channels. If the input is an unoriented vector, the input is treated as a single channel. The block computes the normalized estimate of the AR system parameters, $A(z)$, independently for each successive input frame.

$$H(z) = \frac{\sqrt{G}}{A(z)} = \frac{\sqrt{G}}{1 + a(2)z^{-1} + \dots + a(p+1)z^{-p}}$$

When you select **Inherit estimation order from input dimensions**, the order p of the all-pole model is one less than the length of each input channel. Otherwise, the order is the value specified by the **Estimation order** parameter. To guarantee a valid output, you must set the **Estimation order** parameter to be a scalar less than or equal to half the input channel length. The Yule-Walker AR Estimator and Burg AR Estimator blocks return similar results for large frame sizes.

When **Output(s)** is set to A, port A is enabled. For each channel, port A outputs a column of length $p + 1$ that contains the normalized estimate of the AR model coefficients in descending powers of z

[1 a(2) ... a(p+1)]

When **Output(s)** is set to K, port K is enabled. For each channel, port K outputs a length- p column whose elements are the AR model reflection coefficients. When **Output(s)** is set to A and K, both port A and K are enabled, and each port outputs the respective AR model coefficients for each channel.

The square of the model gain, G , is provided at port G. G is a scalar for each channel.

See the Burg AR Estimator block reference page for a comparison of the Burg AR Estimator, Covariance AR Estimator, Modified Covariance AR Estimator, and Yule-Walker AR Estimator blocks.

Parameters

Output(s)

The type of AR model coefficients output by the block. The block can output polynomial coefficients (A), reflection coefficients (K), or both (A and K).

Inherit estimation order from input dimensions

When selected, sets the estimation order p to one less than the length of each input channel.

Estimation order

The order of the AR model, p . This parameter is enabled when you do not select **Inherit estimation order from input dimensions**.

Yule-Walker Method

Power spectral density estimate using Yule-Walker method

Library

Estimation / Power Spectrum Estimation

dpspect3

Description

The Yule-Walker Method block estimates the power spectral density (PSD) of the input using the Yule-Walker AR method. This method, also called the autocorrelation method, fits an autoregressive (AR) model to the windowed input data. It does so by minimizing the forward prediction error in the least squares sense. This formulation leads to the Yule-Walker equations, which the Levinson-Durbin recursion solves. Block outputs are always nonsingular.

The input must be a column vector. This input represents a frame of consecutive time samples from a single-channel signal. The block outputs a column vector containing the estimate of the power spectral density of the signal at N_{fft} equally spaced frequency points. The frequency points are in the range $[0, F_s)$, where F_s is the sampling frequency of the signal.

When you select **Inherit estimation order from input dimensions**, the order of the all-pole model is one less than the input frame size. Otherwise, the **Estimation order** parameter value specifies the order. To guarantee a valid output, the **Estimation order** parameter must be less than or equal to half the input vector length. The block computes the spectrum from the FFT of the estimated AR model parameters.

Selecting the **Inherit FFT length from estimation order** parameter specifies that N_{fft} is one greater than the estimation order. Clearing the **Inherit FFT length from estimation order** parameter allows you to use the **FFT length** parameter to specify N_{fft} as a power of 2. The block zero-pads or wraps the input to N_{fft} before computing the FFT.

When you select the **Inherit sample time from input** check box, the block computes the frequency data from the sample period of the input signal. For the block to produce valid output, the following conditions must hold:

- The input to the block is the original signal, with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** check box. You can then specify a sample time using the **Sample time of original time series** parameter.

See the Burg Method block reference for a comparison of the Burg Method, Covariance Method, Modified Covariance Method, and Yule-Walker AR Estimator blocks. The Yule-Walker AR Estimator and Burg Method blocks return similar results for large buffer lengths.

Parameters

Inherit estimation order from input dimensions

When you select this option, it sets the estimation order to one less than the length of the input vector.

Estimation order

Specify the order of the AR model. This parameter is only visible when you clear the **Inherit estimation order from input dimensions** check box.

Inherit FFT length from estimation order

When you select the **Inherit FFT length from estimation order** check box, the FFT length is one greater than the estimation order. To specify the number of points on which to perform the FFT, clear the **Inherit FFT length from estimation order** check box. You can then specify a power-of-two FFT length using the **FFT length** parameter.

FFT length

Enter the number of data points on which to perform the FFT, N_{fft} . When N_{fft} is larger than the input frame size, the block zero-pads each frame as needed. When N_{fft} is smaller than the input frame size, the block wraps each frame as needed. This parameter becomes visible only when you clear the **Inherit FFT length from input dimensions** check box.

Inherit sample time from input

When you select the **Inherit sample time from input** check box, the block computes the frequency data from the sample period of the input signal. For the block to produce valid output, the following conditions must hold:

- The input to the block is the original signal, with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** check box. You can then specify a sample time using the **Sample time of original time series** parameter.

Sample time of original time series

Specify the sample time of the original time-domain signal. This parameter becomes visible only when you clear the **Inherit sample time from input** check box.

Zero Crossing

Count number of times signal crosses zero in single time step

Library: DSP System Toolbox / Signal Operations

Description

The Zero Crossing block concludes that a signal in a given channel has passed through zero if it meets any of the following criteria, where x_i is the current value of the signal, x_{i-1} is the previous value, and so on:

- $x_i < 0$ and $x_{i-1} > 0$
- $x_i > 0$ and $x_{i-1} < 0$
- For a positive integer L , $x_i < 0$, $x_{i-1} = 0$, and $x_{i-L-1} > 0$, where $0 \leq l \leq L$.
- For a positive integer L , $x_i > 0$, $x_{i-1} = 0$, and $x_{i-L-1} < 0$, where $0 \leq l \leq L$.

For the first value of the input signal, x_{i-1} and x_{i-2} are zero. The block outputs the number of times the signal crosses zero in a single time step at the **Cnt** port.

Ports

Input

Port_1 — Data input

vector | matrix

The input signal specified as a real-valued vector or matrix.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

Output

Cnt — Number of zero crossings

scalar | row vector

The block outputs the number of zero crossings in the data input as one of these:

- Scalar -- When the data input is a column vector, the block outputs a scalar value representing the number of zero crossings in the data input.
- Row vector -- When the data input is a matrix, the block outputs a row vector with each element in the row vector representing the number of zero crossings in the corresponding column of the data input.

Data Types: uint32

Parameters

Input processing — Method to process input signals

Columns as channels (frame based) (default) | Elements as channels (sample based)

Specify how the block should process the input.

- Columns as channels (frame based) — When you select this option, the block treats each column of the input as a separate channel.
- Elements as channels (sample based) — When you select this option, the block treats each element of the input as a separate channel.

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no

Hit Crossing

Zoom FFT

High-resolution FFT of a portion of a spectrum

Library: DSP System Toolbox / Transforms

Description

The Zoom FFT block computes the fast Fourier Transform (FFT) of a signal over a portion of frequencies in the Nyquist interval. By setting an appropriate decimation factor D , and sampling rate F_s , you can choose the bandwidth of frequencies to analyze BW , where $BW = F_s/D$. You can also select a specific range of frequencies to analyze in the Nyquist interval by choosing the center frequency of the desired band.

The resolution of a signal is the ratio of F_s and the FFT length (L). Using zoom FFT, you can retain the same resolution you would achieve with a full-size FFT on your original signal by computing a small FFT on a shorter signal. The shorter signal comes from decimating the original signal. The savings come from being able to compute a much shorter FFT while achieving the same resolution. For a decimation factor of D , the new sampling rate, F_{sd} , is F_s/D , and the new frame size (and FFT length) is $L_d = L/D$. The resolution of the decimated signal is $F_{sd}/L_d = F_s/L$. To achieve a higher resolution of the shorter band, use the original FFT length, L , instead of the decimated FFT length, L_d .

Ports

Input

x — Data input

vector | matrix

Data input whose zoom FFT the block computes, specified as a vector or a matrix. The number of input rows must be a multiple of the decimation factor.

This block supports variable-size input signals, as long as the input frame size is a multiple of the decimation factor. That is, you can change the input frame size (number of rows) during the simulation. However, the number of channels (number of columns) must remain constant.

This port is unnamed until you select the **Specify center frequency from input port** parameter and click **Apply**.

Example: `randn(22,2)`

Data Types: `single` | `double`

Fc — Center frequency input

real scalar

Center frequency of the desired band in Hz, passed through this input port as a real scalar in the range $(-SampleRate/2, SampleRate/2)$. *SampleRate* is the input sample rate either inherited from the

input signal or specified through the **Input sample rate (Hz)** parameter. This port appears only when you select the **Specify center frequency from input port** check box.

This port appears only when you select the **Specify center frequency from input port** check box and click **Apply**.

Example: 0

Example: 1200

Data Types: single | double

Output Arguments

Port_1 — Zoom FFT output

vector | matrix

Zoom FFT output, returned as a vector or matrix. If you select the **Inherit FFT Length from input dimensions** check box, the output frame size equals the input frame size divided by the decimation factor. If you clear the **Inherit FFT Length from input dimensions** check box and specify the FFT length, the output frame size equals the specified FFT length. The output data type matches the input data type.

Example: randn(11,2)

Data Types: single | double

Parameters

Decimation factor — Decimation factor

2 (default) | positive integer

Decimation factor, specified as a positive integer. This value specifies the factor by which the block reduces the bandwidth of the input signal. The number of rows in the input signal must be a multiple of the decimation factor.

Example: 4

Example: 8

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Specify center frequency from input port — Flag to specify center frequency from input port

'off' (default) | 'on'

When you select this option and click **Apply**, the input port **Fc** appears on the block icon. You can pass the center frequency through this input port as a scalar.

Center frequency (Hz) — Center frequency

0 (default) | real scalar

Center frequency of the desired band in Hz, specified as a real scalar in the range $(- \text{SampleRate}/2, \text{SampleRate}/2)$. *SampleRate* is the input sample rate either inherited from the input or specified through the **Input sample rate (Hz)** parameter.

Example: 0.5

Example: 10

Dependencies

This parameter applies when you clear the **Specify center frequency from input port** check box.

Data Types: single | double

Inherit FFT Length from input dimensions — Flag to inherit FFT length from input dimensions

'on' (default) | 'off'

When you select this option, the FFT length is the ratio of the input frame size (number of rows in the input) and the **Decimation factor**.

FFT length — FFT length

64 (default) | positive scalar

FFT length, specified as a positive integer. The FFT length must be greater than or equal to the ratio of the frame size (number of input rows) and the **Decimation factor**.

Example: 24

Example: 52

Dependencies

This parameter applies when you clear the **Inherit FFT Length from input dimensions** check box.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Inherit Sample rate from input — Flag to inherit sample rate from input

'off' (default) | 'on'

When you clear this check box, the block inherits the sample rate from the input signal.

Input sample rate (Hz) — Input sample rate

44100 (default) | positive real scalar

Input sample rate in Hz, specified as positive real scalar.

Example: 44100

Example: 48000

Simulate using — Type of simulation to run

Interpreted execution (default) | Code generation

Type of simulation to run. You can set this parameter to:

- **Interpreted execution**: Simulate model using the MATLAB interpreter. This option shortens startup time.

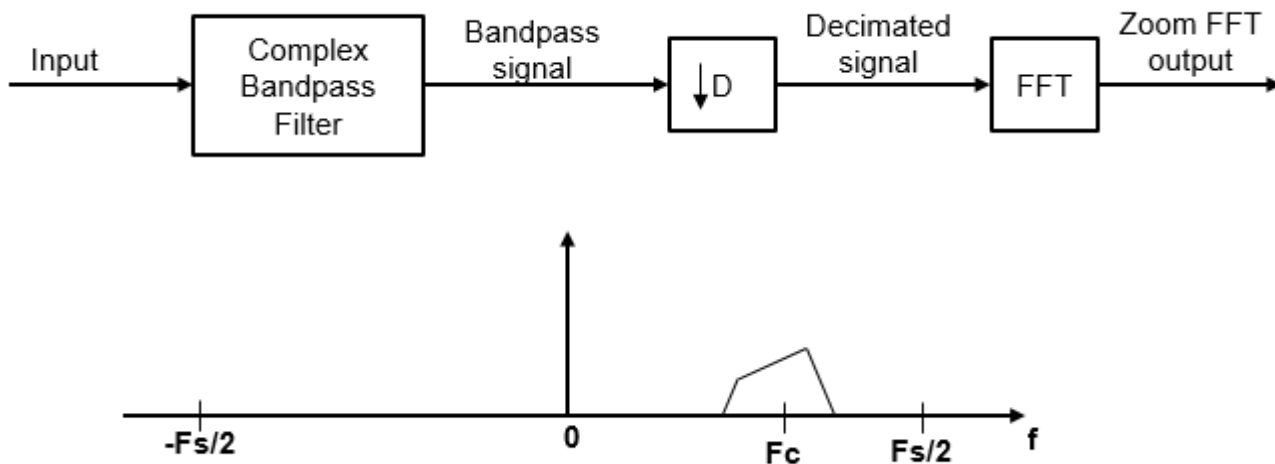

- **Code generation:** Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations as long as the model does not change. This option requires additional startup time but provides faster subsequent simulations.

Block Characteristics

Data Types	double single
Multidimensional Signals	No
Variable-Size Signals	Yes

Algorithms

The zoom FFT algorithm leverages bandpass filtering before computing the FFT of the signal. The concept of bandpass filtering is that suppose you are interested in the band $[F1, F2]$ of the original input signal, sampled at the rate F_s Hz. If you pass this signal through a complex (one-sided) bandpass filter centered at $F_c = (F1+F2)/2$, with the bandwidth $BW = F2 - F1$, and then downsample the signal by a factor of $D = \text{floor}(F_s/BW)$, the desired band comes down to the baseband.

If F_c cannot be expressed in the form of $k \times F_s/D$, where k is an integer, then the shifted, decimated spectrum is not centered at DC. In this case, the center frequency gets translated to F_d .

$$F_d = F_c - (F_s/D) \times \text{floor}((D \times F_c + F_s/2)/F_s)$$

The complex bandpass filter is obtained by first designing a lowpass filter prototype and then multiplying the lowpass coefficients with a complex exponential. This algorithm uses a multirate, multistage FIR filter as the lowpass filter prototype. To obtain the bandpass filter, the coefficients of each stage are frequency shifted. The decimation factor is the cumulative decimation factor of each stage. The complex bandpass filter followed by the decimator are implemented using an efficient polyphase structure. For more details on the design of the complex bandpass filter from the multirate multistage FIR filter prototype, see “Zoom FFT” and “Complex Bandpass Filter Design”.

Analysis Methods for Filter System Objects

Analysis Methods for Filter System Objects

Method	Description
Single-rate and Multirate Analysis	
fvtool	Filter visualization tool
info	Filter information
freqz	Frequency response of a discrete-time filter
phasez	Phase response of a discrete-time filter
zerophase	Zero-phase response of a discrete-time filter
grpdelay	Group delay of a discrete-time filter
phasedelay	Phase delay of a discrete-time filter
impz	Impulse response of a discrete-time filter
impzlength	Impulse response length
stepz	Step response of a discrete-time filter
zplane	Pole/Zero plot
cost	Cost estimate
measure	Measure filter response
order	Filter order
firtype	Determine the type (1-4) of a linear phase FIR filter
coeffs	Return filter coefficients
Multirate Analysis	
polyphase	Polyphase decomposition of multirate filters
gain	Gain of a Cascaded Integrator-Comb (CIC) filter
Second-order Sections	
scale	Scale second-order sections
scalecheck	Check scale of second-order sections
scaleopts	Create options object for sos scaling
cumsec	Vector of cumulative second-order section filters
reorder	Reorder second-order sections
sos	Convert IIR filter to Biquad filter
Code Generation	
realizemdl	Filter realization diagram
Fixed-point (supported by FIRFilter, IIRFilter, AllpoleFilter, and BiquadFilter only)	
noisepsd	Power spectral density of filter output due to roundoff noise
noisepsdopts	Create options object for noisepsd computation
freqrespest	Frequency response estimate via filtering

Method	Description
freqrespopts	Create options object for frequency response estimate
Other	
isallpass	True for allpass discrete-time filter
islinphase	True for linear discrete-time filter
ismaxphase	True if maximum phase
isminphase	True if minimum phase
isreal	True for discrete-time filter with real coefficients
isstable	True if the filter is stable
isfir	True if the filter is FIR
issos	True if filter is in second order sections form
specifyall	Specify all fixed-point properties

System Objects

powermeter

Measure power and CCDF of the power of voltage signal

Description

The `powermeter` System object computes the power measurements of a voltage signal. When you set the `ComputeCCDF` property to `true`, the object also calculates the complementary cumulative distribution function (CCDF) of the power of a voltage signal. The CCDF measurements that the object outputs are relative power and probability (in percentage). The power measurements include average power, peak power, and peak-to-average power ratio.

For more details on how the object computes the power measurements and the CCDF measurements, see “Algorithms” on page 4-11.

To measure the power and the CCDF of the power of a voltage signal:

- 1 Create the `powermeter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
meter = powermeter  
meter = powermeter(Len,Overlap,Name=Value)  
meter = powermeter(Name=Value)
```

Description

`meter = powermeter` returns a `powermeter` system object that computes power, peak-to-average power ratio (PAPR), and the complementary cumulative distribution function (CCDF) of the power of voltage signal. The CCDF helps find the probability that the instantaneous signal power exceeds a specified level above the average signal power.

`meter = powermeter(Len,Overlap,Name=Value)` sets the `WindowLength` property to `Len` and the `OverlapLength` property to `Overlap`.

To enable this syntax, set the `ComputeCCDF` property to `false`.

`meter = powermeter(Name=Value)` returns a `powermeter` system object with each specified property set to the specified value. Enclose each property name in quotes. You can use this syntax with the previous input argument.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

Measurement — Desired power measurement

'Average power' (default) | 'Peak power' | 'Peak-to-average power ratio' | 'All'

Desired power measurement, specified as 'Average power', 'Peak power', 'Peak-to-average power ratio' or 'All'.

For more details on how the object computes these measurements, see “Algorithms” on page 4-11.

ReferenceLoad — Reference load

1 (default) | positive scalar

Reference load used by the power meter to compute the power values in ohms, specified as a positive scalar.

Tunable: Yes

Data Types: `single` | `double`

ComputeCCDF — Compute CCDF

false (default) | true

Specify whether to calculate CCDF as:

- `false` -- The object does not calculate the CCDF measurements. The object computes the power measurements using the “Sliding Window Method” on page 4-11.
- `true` -- The object computes the CCDF measurements.
 - All input samples since object creation or reset are used to compute statistics. The power measurements are stationary.
 - The `WindowLength` and `OverlapLength` properties become read-only and are set to `Inf` and `0` respectively.

Data Types: `logical`

PowerRange — Power range

50 (default) | positive scalar

The x-axis range of the computed CCDF curves in dB, specified as a positive scalar. The computed CCDF curves end at the maximum relative power, namely, peak-to-average power ratio (PAPR) of the signal, and start at `PAPR - PowerRange`. For the CCDF capability of the `powermeter` object, relative power is the power in dB by which the instantaneous signal power is above the average signal power.

Dependencies

To enable this property, set the `ComputeCCDF` property to `true`.

Data Types: `single` | `double`

PowerResolution — Power Resolution in dB

0.1 (default) | positive scalar

The x-axis resolution of the computed CCDF curves in dB, specified as a positive scalar.

Dependencies

To enable this property, set the `ComputeCCDF` property to `true`.

Data Types: `single` | `double`

WindowLength — Window length

256 (default) | nonnegative integer

Sliding window length over which the measurement is computed, specified as a nonnegative integer.

Dependencies

If the `ComputeCCDF` property is `true`, then `WindowLength` property is set to `Inf` and is read-only.

Data Types: `single` | `double`

OverlapLength — Overlap length between windows

`WindowLength - 1` (default) | nonnegative integer

Overlap length between sliding windows, specified as a nonnegative integer. The value of overlap length varies in the range $[0, \text{WindowLength} - 1]$. If not specified, the overlap length is `WindowLength - 1`.

Dependencies

If the `ComputeCCDF` property is `true`, then `OverlapLength` property is set to 0 and is read-only.

Data Types: `single` | `double`

OutputPowerUnits — Output power units

'dBm' (default) | 'dBW' | 'Watts'

Units of the measured power values, specified as 'dBm', 'dBW', or 'Watts'.

Usage

Syntax

```
avgpwr = meter(x)
peakpwr = meter(x)
papr = meter(x)
[avgpwr, peakpwr, papr] = meter(x)
```

Description

`avgpwr = meter(x)` computes the average power of the input signal `x` when the `Measurement` property is set to 'Average power'. Each column of `x` is treated as an independent channel. The object computes the average power of each channel of the input signal independently.

`peakpwr = meter(x)` computes the peak power of the input signal `x` when the `Measurement` property is set to `'Peak power'`. Each column of `x` is treated as an independent channel. The object computes the peak power of each channel of the input signal independently.

`papr = meter(x)` computes the peak-to-average power ratio of the input signal `x` when the `Measurement` property is set to `'Peak-to-average power ratio'`. Each column of `x` is treated as an independent channel. The object computes the peak-to-average power ratio of each channel of the input signal independently.

`[avgpwr, peakpwr, papr] = meter(x)` computes the average power, peak power, and the peak-to-average power ratio of the input signal `x` when the `Measurement` property is set to `'All'`. Each column of `x` is treated as an independent channel. The object computes the power measurements of each channel of the input signal independently.

Input Arguments

x — Input voltage signal

vector | matrix

Input voltage signal, specified as a vector or a matrix in volts. If `x` is a matrix, the object treats each column as an independent channel and computes the power measurements along each channel.

The object also accepts variable-size inputs. That is, once the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

Data Types: `single` | `double`

Output Arguments

avgpwr — Average power

scalar | vector | matrix

Average power of the voltage signal, returned as a scalar, vector or a matrix, with the units determined by the `PowerUnits` property.

If you set the `ComputeCCDF` property to `false`, the object computes the moving average power using the “Sliding Window Method” on page 4-11.

When you input a signal of size m -by- n to the object when the `ComputeCCDF` property is set to `false`, the output has an upper bound size of $\text{ceil}(m/\text{hop size})$ -by- n . Hop size is window length – overlap length. In other cases, the output has a size of m -by- n .

When you generate code from this object, the variable-size behavior of the output in the generated code depends on the input frame length and whether the size of the input signal is fixed or variable. For more details, see “Code Generation” on page 4-14.

If you set the `ComputeCCDF` property to `true`, the object computes the stationary average power of the entire signal along each channel. In this case, the size of the output is 1-by- M , where M is the number of channels in the input signal.

For details on how the object computes the average power, see “Average Power” on page 4-11.

Data Types: `single` | `double`

peakpwr — Peak power

scalar | vector | matrix

Peak power of the voltage signal, returned as a scalar, vector or a matrix, with the units determined by the `PowerUnits` property.

If you set the `ComputeCCDF` property to `false`, the object computes the moving peak power using the “Sliding Window Method” on page 4-11.

When you input a signal of size m -by- n to the object when the `ComputeCCDF` property is set to `false`, the output has an upper bound size of $\text{ceil}(m/\text{hop size})$ -by- n . Hop size is window length – overlap length. In other cases, the output has a size of m -by- n .

When you generate code from this object, the variable-size behavior of the output in the generated code depends on the input frame length and whether the size of the input signal is fixed or variable. For more details, see “Code Generation” on page 4-14.

If you set the `ComputeCCDF` property to `true`, the object computes the stationary peak power of the entire signal along each channel. In this case, the size of the output is 1-by- M , where M is the number of channels in the input signal.

For details on how the object computes the peak power, see “Peak Power” on page 4-12.

Data Types: `single` | `double`

papr — Peak-to-average power ratio

scalar | vector | matrix

Peak-to-average power ratio of the voltage signal, returned as a scalar, vector or a matrix.

If you set the `ComputeCCDF` property to `false`, the object computes the moving peak-to-average power ratio using the “Sliding Window Method” on page 4-11.

When you input a signal of size m -by- n to the object when the `ComputeCCDF` property is set to `false`, the output has an upper bound size of $\text{ceil}(m/\text{hop size})$ -by- n . Hop size is window length – overlap length. In other cases, the output has a size of m -by- n .

When you generate code from this object, the variable-size behavior of the output in the generated code depends on the input frame length and whether the size of the input signal is fixed or variable. For more details, see “Code Generation” on page 4-14.

If you set the `ComputeCCDF` property to `true`, the object computes the stationary peak-to-average power ratio of the entire signal along each channel. In this case, the size of the output is 1-by- M , where M is the number of channels in the input signal.

For details on how the object computes the peak-to-average power ratio, see “Peak-to-Average Power Ratio” on page 4-12.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to powermeter

plotCCDF	Plot CCDF curves
ccdf	Get coordinates of CCDF curves
relativePower	Use CCDF to find relative power for specified probability
probability	Use CCDF to find probability for specified relative power

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Compute Power Measurements of Voltage Signal

Compute the power measurements of a noisy sinusoidal signal using a power meter. These measurements include average power, peak power, and peak-to-average power ratio.

Assume the maximum voltage of the signal to be 100 V. The instantaneous values of a sinusoidal waveform are given by the equation $V_i = V_{max} \times \sin(2\pi ft)$, where V_i is the instantaneous value, V_{max} is the maximum voltage of the signal, and f is the frequency of the signal in Hz.

Initialization

The input signal is a sum of two sine waves with frequencies set to 1 kHz and 10 kHz, respectively. The frame length and the sampling frequency of the generated signal is 512 samples and 44.1 kHz, respectively.

To measure the power in this signal, create a `powermeter` object. Set `Measurement` to 'All'. This setting enables the object to measure the average power, peak power, and peak-to-average power ratio. Set the length of the sliding window to 16 samples and the reference load to 50 Ohms. Use this object to measure the power in dBm units. Visualize the power measurements using the `timescope` object.

```

FrameLength = 512;
Fs = 44.1e3;
A = 100;
sine1 = dsp.SinWave(Amplitude=A, ...
    Frequency=1e3, ...
    SampleRate=44.1e3, ...
    SamplesPerFrame=FrameLength);
sine2 = dsp.SinWave(Amplitude=A, ...
    Frequency=10e3, ...
    SampleRate=44.1e3, ...
    SamplesPerFrame=FrameLength);
pm = powermeter(16,Measurement="All", ...
    ReferenceLoad=50, ...
    PowerUnits="dBm");
scope = timescope(NumInputPorts=4,SampleRate=Fs, ...
    TimeSpanSource="property", ...
    TimeSpan=96, ...
    YLabel="dBm", ...

```

```

        YLimits=[-30 90]);
title = 'Power Measurements';
scope.ChannelNames = {'Average power', ...
    'Peak power', 'Peak-to-average power ratio', ...
    'Expected Average Power'};
scope.Title = title;

```

Compute the Power Measurements

Add zero-mean white Gaussian noise with a standard deviation of 0.001 to the sum of sine waves. Vary the amplitude of the sine waves. Measure the average power, peak power, and the peak-to-average power ratio of this noisy sinusoidal signal that has a varying amplitude. For details on how the object measures these power values, see “Algorithms” on page 4-11. Compare the measured values to the expected value of the average power.

The expected value of the average power P of the noisy sinusoidal signal is given by the following equation.

$$P = \frac{A_1^2}{2R} + \frac{A_2^2}{2R} + \text{var}(\text{noise}),$$

where,

- A_1 is the amplitude of the first sinusoidal signal.
- A_2 is the amplitude of the second sinusoidal signal.
- R is the reference load in ohms.

In dBm, the expected power is computed using the following equation:

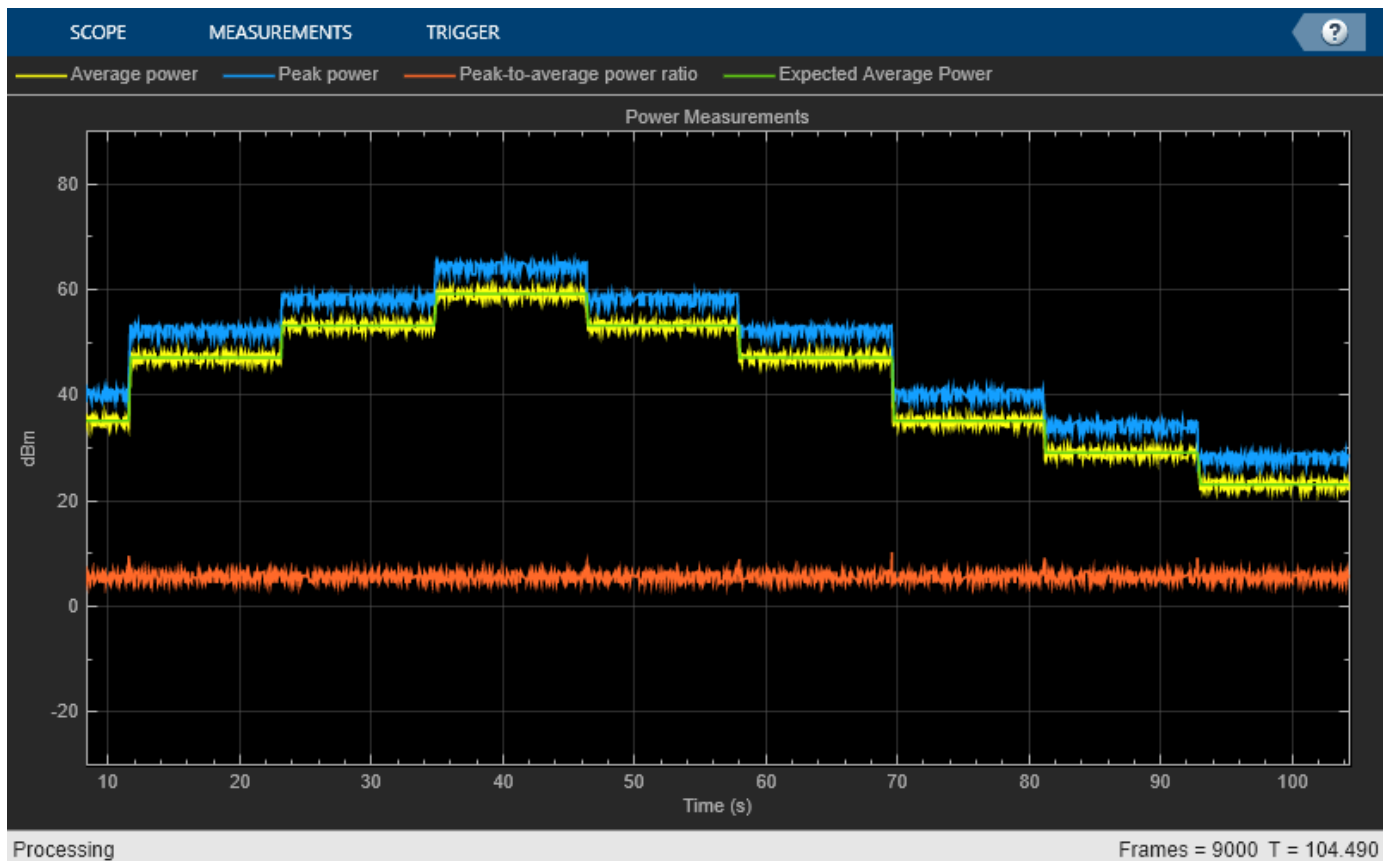

$$\text{expPwr}_{\text{dBm}} = 10\log_{10}(P) + 30.$$

Compare the expected value with the value computed by the object. All values are in dBm. These values match very closely. To verify, view the computed measurements using the `timescope` object.

```

Vect = [1/8 1/2 1 2 1 1/2 1/8 1/16 1/32];
for index = 1:length(Vect)
    V = Vect(index);
    for i = 1:1000
        x = V*sine1()+V*sine2()+0.001.*randn(FrameLength,1);
        P = (((V*A)^2)/100)+(((V*A)^2)/100)+(0.001)^2;
        expPwr = (10*log10(P)+30)*ones(FrameLength,1);
        [avgPwr,pkPwr,papr] = pm(x);
        scope(avgPwr,pkPwr,papr,expPwr);
    end
end
end

```

Compute and Plot CCDF Measurements of Voltage Signal

Compute the CCDF measurements of a voltage signal. The CCDF measurements include the relative power and the probability. Relative power is the amount of power in dB by which the instantaneous signal power is above the average signal power. Probability in percentage refers to the probability that the instantaneous signal power is above the average signal power by the relative power in dB.

Initialize a powermeter object and set the ComputeCCDF property to true. The input to the object is a random voltage signal.

```
x = complex(rand(10000,1)-0.5,rand(10000,1)-0.5);
pm = powermeter(ComputeCCDF=true)
```

```
pm =
  powermeter with properties:
    Measurement: 'Average power'
    ReferenceLoad: 1
    ComputeCCDF: true
    PowerRange: 50
    PowerResolution: 0.1000
    OutputPowerUnits: 'dBm'

  Read-only properties:
    WindowLength: Inf
```

```
OverlapLength: 0
```

By default, the powermeter object computes the average power of the signal in dBm. The reference load is 1 ohm.

```
averagePower = pm(x)
```

```
averagePower = 22.2189
```

Using the probability function, find the probability that the instantaneous power of the signal is 3 dB above the average power. The relative power in this case is 3 dB.

```
prob = probability(pm,3)
```

```
prob = 7.6009
```

Compute the relative power using the relativePower function. Verify that the relative power for the computed probability is indeed 3 dB.

```
relpwr = relativePower(pm,prob)
```

```
relpwr = 3.0000
```

Using the plotCCDF function, plot the CCDF curve. Set the reference curve to Gaussian.

```
plotCCDF(pm,GaussianReference=true)
```

Algorithms

Sliding Window Method

When you do not configure the power meter to compute the CCDF measurements, the power meter computes the moving power measurements using the sliding window method.

In the sliding window method, the block computes the power measurement over a finite duration of the signal. The window length defines the length of the data over which the algorithm computes the power value. The window moves as new data comes in. The output for each input sample is the measurement over the current sample and $Len - 1$ previous samples. Len is the length of the sliding window in samples. To compute the first output sample, the algorithm waits until it receives the hop size number of input samples. Hop size is defined as window length - overlap length. Remaining samples in the window are considered to be zero. As an example, if the window length is 5 and the overlap length is 2, then the algorithm waits until it receives 3 samples of input to compute the first sample of the output. After generating the first output, it generates the subsequent output samples for every hop size number of input samples.

For a more detailed example, see “Sliding Window Method”.

If the window is large, the power that the block computes is closer to the stationary power of the data. For data that does not change rapidly, use a long window to get a smoother measurement. For data that changes fast, use a smaller window.

When you configure the power meter to compute the CCDF measurements, the algorithm computes the stationary power of the data. It sets the window length to Inf and the overlap length to 0 , making both the parameters read-only.

Average Power

When you do not configure the power meter to compute the CCDF measurements, the power meter computes the moving average power of the voltage signal across each channel using the Sliding Window Method on page 4-11. When you do configure the power meter to compute the CCDF measurements, the power meter computes the stationary average power of the voltage signal across each channel.

These equations give the average power in dBm, dBW, and in Watts units.

$$AvgPower_{dBm} = 10\log_{10}(Avg(|x|^2)/R) + 30$$

$$AvgPower_{dBW} = 10\log_{10}(Avg(|x|^2)/R)$$

$$AvgPower_{Watts} = Avg(|x|^2)/R$$

where,

- x is the input voltage signal.
- R is the reference load (in ohms) that the block uses to compute the power value.
- Avg represents the moving average power when the power meter does not compute the CCDF measurements. The `powermeter` object in MATLAB uses the `dsp.MovingAverage` object and the Power Meter block in Simulink uses the Moving Average block.

When the power meter does compute the CCDF measurements, *Avg* represents the stationary average power across each channel.

Peak Power

When you do not configure the power meter to compute the CCDF measurements, the power meter computes the moving peak power of the voltage signal across each channel using the Sliding Window Method on page 4-11. When you do configure the power meter to compute the CCDF measurements, the power meter computes the stationary peak power of the voltage signal across each channel.

These equations give the peak power in dBm, dBW, and in Watts units.

$$PeakPower_{dBm} = 10\log_{10}(Max(|x|^2)/R) + 30$$

$$PeakPower_{dBW} = 10\log_{10}(Max(|x|^2)/R)$$

$$PeakPower_{Watts} = Max(|x|^2)/R$$

where,

- *x* is the input voltage signal.
- *R* is the reference load (in ohms) that the block uses to compute the power value.
- *Max* represents the moving peak power when the power meter does not compute the CCDF measurements. The `powermeter` object in MATLAB uses the `dsp.MovingMaximum` object and the Power Meter block in Simulink uses the Moving Maximum block.

When the power meter does compute the CCDF measurements, *Max* represents the stationary peak power across each channel.

Peak-to-Average Power Ratio

When you do not configure the power meter to compute the CCDF measurements, the power meter computes the moving peak-to-average power ratio of the voltage signal across each channel using the Sliding Window Method on page 4-11. When you do configure the power meter to compute the CCDF measurements, the power meter computes the stationary peak-to-average power ratio of the voltage signal across each channel.

These equations give the peak-to-average power ratio in dBm, dBW, and in Watts units.

$$pkAvgPwr_{dBm} = 10\log_{10}(Max(|x|^2)/Avg(|x|^2))$$

$$pkAvgPwr_{dBW} = 10\log_{10}(Max(|x|^2)/Avg(|x|^2))$$

$$pkAvgPwr_{Watts} = Max(|x|^2)/Avg(|x|^2)$$

where,

- *x* is the input voltage signal.
- *Avg* represents the moving average power when the power meter does not compute the CCDF measurements. The `powermeter` object in MATLAB uses the `dsp.MovingAverage` object and the Power Meter block in Simulink uses the Moving Average block.

When the power meter does compute the CCDF measurements, *Avg* represents the stationary average power across each channel.

- *Max* represents the moving peak power when the power meter does not compute the CCDF measurements. The `powermeter` object in MATLAB uses the `dsp.MovingMaximum` object and the Power Meter block in Simulink uses the Moving Maximum block.

When the power meter does compute the CCDF measurements, *Max* represents the stationary peak power across each channel.

Relative Power

The power meter computes the relative power only when you configure the algorithm to compute the CCDF measurements. The algorithm uses a window of infinite duration to compute the relative power.

Relative power is the amount of power in dB by which the instantaneous signal power is above the average signal power. The block calculates the relative power using these equations:

If output power is in dBm,

$$relPower = 10\log_{10}(|x|^2/R) + 30 - AvgPower_{dBm}$$

If output power is in dBW,

$$relPower = 10\log_{10}(|x|^2/R) - AvgPower_{dBW}$$

If output power is in Watts,

$$relPower = (|x|^2/R) - AvgPower_{Watts}$$

where,

- *x* is the input voltage signal.
- *R* is the reference load (in ohms) that the block uses to compute the power value.
- $|x|^2/R$ is the instantaneous signal power in Watts.
- *AvgPower* is the average power of the voltage signal. For more details on how the algorithm computes this measurement, see "Average Power" on page 2-1081.

Probability

The power meter computes the probability only when you configure the algorithm to compute the CCDF measurements. Probability in percentage refers to the probability that the instantaneous signal power is above the average signal power by the relative power in dB.

Change in variable-size behavior for output signal in generated code

Starting in R2022b, if you generate code from this object with the `ComputeCCDF` property set to `false`, and if you input a signal with a frame length that is a multiple of the hop size (window length

– overlap length), this object generates a fixed-size output signal in the generated code. For more details, see “Code Generation” on page 4-14.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- See “System Objects in MATLAB Code Generation” (MATLAB Coder).
- When you set the `ComputeCCDF` property to `false` and generate code from this object, the variable-size behavior of the output depends on the input frame length and whether the size of the input signal is fixed or variable.

See this table for more details.

Input Signal	Input Size	Output Signal
Fixed-size	m -by- n	When the input frame length is a multiple of the hop size, the output signal has a fixed-size of $(m/\text{hop size})$ -by- n . When input frame length is not a multiple of the hop size, the output signal is variable-sized and has an upper bound of $\text{ceil}(m/\text{hop size})$ -by- n .
Variable-size	m -by- n	Output is a variable-size signal. Output has an upper bound size of $\text{ceil}(m/\text{hop size})$ -by- n .

dsp.AdaptiveLatticeFilter

Package: dsp

Adaptive lattice filter

Description

The `dsp.AdaptiveLatticeFilter` System object computes output, error, and coefficients using a lattice-based FIR adaptive filter.

To implement the adaptive FIR filter object:

- 1 Create the `dsp.AdaptiveLatticeFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
alf = dsp.AdaptiveLatticeFilter
alf = dsp.AdaptiveLatticeFilter(len)
alf = dsp.AdaptiveLatticeFilter(Name,Value)
```

Description

`alf = dsp.AdaptiveLatticeFilter` returns a lattice-based FIR adaptive filter System object, `alf`. This System object computes the filtered output and the filter error for a given input and desired signal.

`alf = dsp.AdaptiveLatticeFilter(len)` returns an `AdaptiveLatticeFilter` System object with the `Length` property set to `len`.

`alf = dsp.AdaptiveLatticeFilter(Name,Value)` returns an `AdaptiveLatticeFilter` System object with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Method — Method to calculate filter coefficients

'Least-squares Lattice' (default) | 'QR-decomposition Least-squares Lattice' | 'Gradient Adaptive Lattice'

Specify the method used to calculate filter coefficients as one of 'Least-squares Lattice', 'QR-decomposition Least-squares Lattice', 'Gradient Adaptive Lattice'. The default value is 'Least-squares Lattice'. For algorithms used to implement these three different methods, refer to [1] [2]. This property is nontunable.

Length — Length of filter coefficients vector

32 (default) | positive integer

Specify the length of the FIR filter coefficients vector as a positive integer value. This property is nontunable.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

ForgettingFactor — Least-squares lattice forgetting factor

1 (default) | positive scalar

Specify the least-squares lattice forgetting factor as a scalar positive numeric value less than or equal to 1. Setting this value to 1 denotes infinite memory during adaptation.

Tunable: Yes

Dependencies

This property applies only if the Method property is set to 'Least-squares Lattice' or 'QR-decomposition Least-squares Lattice'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

StepSize — Joint process step size of gradient adaptive filter

0.1 (default) | positive scalar

Specify the joint process step size of the gradient adaptive lattice filter as a positive numeric scalar less than or equal to 1.

Tunable: Yes

Dependencies

This property applies only if the Method property is set to 'Gradient Adaptive Lattice'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

Offset — Offset for denominator of StepSize normalization term

1 (default) | nonnegative scalar

Specify an offset value for the denominator of the StepSize normalization term as a nonnegative numeric scalar. A nonzero offset helps avoid a divide-by-near-zero condition when the input signal amplitude is very small.

Tunable: Yes

Dependencies

This property applies only if the `Method` property is set to 'Gradient Adaptive Lattice'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

ReflectionStepSize — Reflection process step size

`StepSize` property value (default) | positive scalar

Specify the reflection process step size of the gradient adaptive lattice filter as a scalar numeric value between 0 and 1, both inclusive. The default value is the `StepSize` property value.

Tunable: Yes

Dependencies

Use this property only if the `Method` property is set to 'Gradient Adaptive Lattice'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

AveragingFactor — Averaging factor of energy estimator

`1 - StepSize` (default) | positive scalar

Specify the averaging factor as a positive numeric scalar less than 1. Use this property to compute the exponentially windowed forward and backward prediction error powers for the coefficient updates. The default is the value of `1 - StepSize`.

Tunable: Yes

Dependencies

This property applies only if the `Method` property is set to 'Gradient Adaptive Lattice'.

Data Types: `single` | `double`

InitialPredictionErrorPower — Initial prediction error power

`1.0` (default) | positive scalar

Specify the initial values for the prediction error vectors as a scalar positive numeric value.

If the `Method` property is set to 'Least-squares Lattice' or 'QR-decomposition Least-squares Lattice', the default value is `1.0`. If the `Method` property is set to 'Gradient Adaptive Lattice', the default value is `0.1`.

Tunable: Yes

Data Types: `single` | `double`

InitialCoefficients — Initial coefficients of filter

`0` (default) | scalar | vector

Specify the initial values of the FIR adaptive filter coefficients as a scalar or a vector of length equal to the value of the `Length` property.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

LockCoefficients — Locked status of coefficient updates`false (default) | true`

Specify whether to lock the filter coefficient values. By default, the value of this property is `false`, and the object continuously updates the filter coefficients. If this property is set to `true`, the filter coefficients do not update and their values remain the same.

Tunable: Yes

Dependencies

This property is applicable only if the `Method` property is set to `'Gradient Adaptive Lattice'`.

Usage**Syntax**`[y,err] = alf(x,d)`**Description**

`[y,err] = alf(x,d)` filters the input `x`, using `d` as the desired signal, and returns the filtered output in `y` and the filter error in `err`. The System object estimates the filter weights needed to minimize the error between the output signal and the desired signal. You can access these coefficients by accessing the `Coefficients` property of the object. This can be done only after calling the object. For example, to access the optimized coefficients of the `alf` filter, call `alf.Coefficients` after you pass the input and desired signal to the object.

Input Arguments**x — Data input**`scalar | column vector`

The signal to be filtered by the adaptive lattice filter. The input, `x`, and the desired signal, `d`, must have the same size and data type.

The input can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object.

Data Types: `single` | `double`

d — Desired signal`scalar | column vector`

The adaptive lattice filter adapts its coefficients to minimize the error, `err`, and converge the input signal `x` to the desired signal `d` as closely as possible.

The input, `x`, and the desired signal, `d`, must have the same size and data type.

The desired signal can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object.

Data Types: `single` | `double`

Complex Number Support: Yes

Output Arguments

y — Filtered output

scalar | column vector

Filtered output, returned as a scalar or a column vector. The object adapts its filter coefficients to converge the input signal x to match the desired signal d . The filter outputs the converged signal.

Data Types: `single` | `double`

err — Difference between output and desired signal

scalar | column vector

Difference between the output signal y and the desired signal d , returned as a scalar or a column vector. The objective of the adaptive lattice filter is to minimize this error. The object adapts its coefficients to converge towards optimal filter coefficients that produce an output signal that matches closely with the desired signal. To access the adaptive lattice filter coefficients, call `alf.Coefficients` after you pass the input and desired signal to the object algorithm.

Data Types: `single` | `double`

Complex Number Support: Yes

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.AdaptiveLatticeFilter

`mseSim` Estimated mean squared error for adaptive filters

Common to All System Objects

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

Examples

QPSK Adaptive Equalization Using Adaptive Lattice Filter

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Create the QPSK signal and the noise, filter them to obtain the received signal, and delay the received signal to obtain the desired signal.

```
D = 16;
b = exp(1i*pi/4)*[-0.7 1];
a = [1 -0.7];
ntr = 1000;
```

```

s = sign(randn(1,ntr+D)) + 1i*sign(randn(1,ntr+D));
n = 0.1*(randn(1,ntr+D) + 1i*randn(1,ntr+D));
r = filter(b,a,s) + n;
x = r(1+D:ntr+D);
d = s(1:ntr);

```

Use the Adaptive Lattice Filter to compute the filtered output and the filter error for the input and desired signal.

```

lam = 0.995;
del = 1;
alf = dsp.AdaptiveLatticeFilter('Length', 32, ...
    'ForgettingFactor', lam, 'InitialPredictionErrorPower', del);
[y,e] = alf(x,d);

```

Plot the In-Phase and the Quadrature components of the desired, output, and the error signals.

```

subplot(2,2,1); plot(1:ntr,real([d;y;e]));
title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('time index'); ylabel('signal value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('time index'); ylabel('signal value');

```

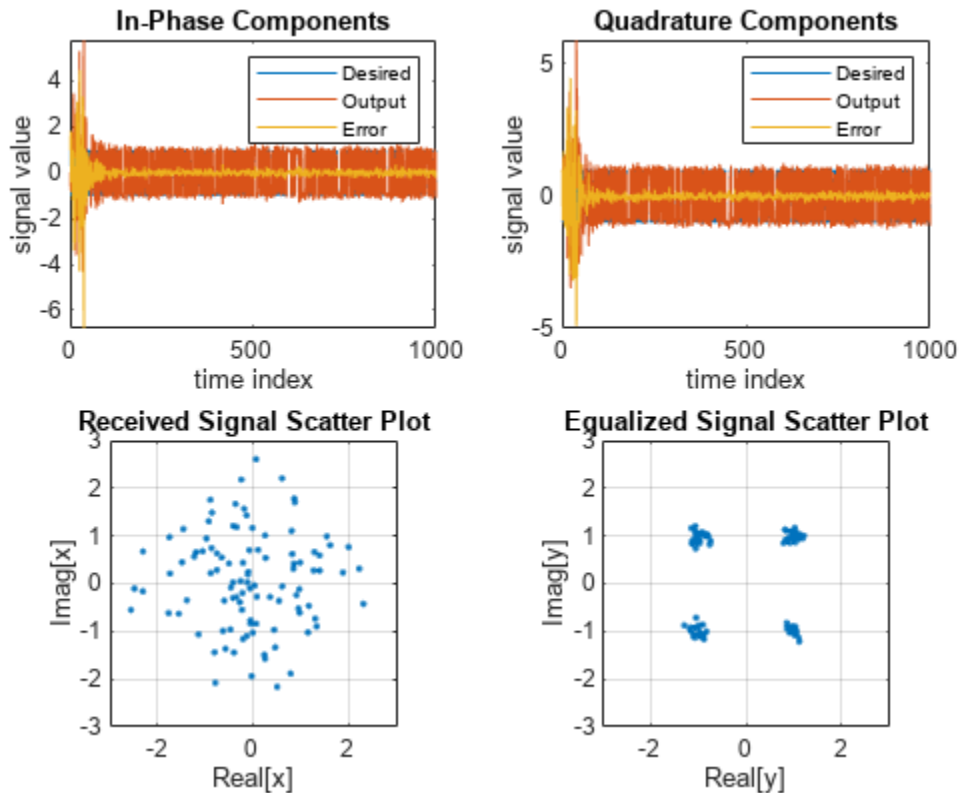

Plot the received and equalized signals' scatter plots.

```

subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot'); axis('square');
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); axis('square');
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;

```

System Identification of FIR Filter Using Adaptive Lattice Filter

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

```

ha = fir1(31,0.5);
% FIR system to be identified
fir = dsp.FIRFilter('Numerator',ha);
iir = dsp.IIRFilter('Numerator',sqrt(0.75),...
    'Denominator',[1 -0.5]);
x = iir(sign(randn(2000,25)));
% Observation noise signal
n = 0.1*randn(size(x));
% Desired signal
d = fir(x)+n;
% Filter length
l = 32;
% Decimation factor for analysis

```

```
% and simulation results
m = 5;
ha = dsp.AdaptiveLatticeFilter(l);
[simmse,meanWsim,Wsim,traceKsim] = msesim(ha,x,d,m);
plot(m*(1:length(simmse)),10*log10(simmse));
xlabel('Iteration');
ylabel('MSE (dB)');
% Plot the learning curve used for
% adaptive lattice filter used in system identification
title('Learning curve')
```

dsp.AffineProjectionFilter

Package: dsp

Compute output, error and coefficients using affine projection (AP) Algorithm

Description

The `dsp.AffineProjectionFilter` System object filters each channel of the input using AP filter implementations.

To filter each channel of the input:

- 1** Create the `dsp.AffineProjectionFilter` object and set its properties.
- 2** Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
apf = dsp.AffineProjectionFilter
apf = dsp.AffineProjectionFilter(len)
apf = dsp.AffineProjectionFilter(Name,Value)
```

Description

`apf = dsp.AffineProjectionFilter` returns an adaptive FIR filter System object, `apf`. This System object computes the filtered output and the filter error for a given input and desired signal using the affine projection (AP) algorithm.

`apf = dsp.AffineProjectionFilter(len)` returns an affine projection filter object with the `Length` property set to `len`.

`apf = dsp.AffineProjectionFilter(Name,Value)` returns an affine projection filter object with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Method — Method to calculate filter coefficients

Direct Matrix Inversion (default) | Recursive Matrix Update | Block Direct Matrix Inversion

Specify the method used to calculate filter coefficients as Direct Matrix Inversion, Recursive Matrix Update, Block Direct Matrix Inversion. This property is nontunable.

Length — Length of filter coefficients vector

32 (default) | positive integer

Specify the length of the FIR filter coefficients vector as a scalar positive integer value. This property is nontunable.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

ProjectionOrder — Projection order of affine projection algorithm

2 (default) | positive integer

Specify the projection order of the affine projection algorithm as a scalar positive integer value greater than or equal to 2. This property defines the size of the input signal covariance matrix. This property is nontunable.

Data Types: double

StepSize — Affine projection step size

1 (default) | nonnegative scalar

Specify the affine projection step size factor as a scalar nonnegative numeric value between 0 and 1, both inclusive. Setting the step size equal to one provides the fastest convergence during adaptation.

Tunable: Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

InitialCoefficients — Initial coefficients of filter

0 (default) | scalar | vector

Specify the initial values of the FIR adaptive filter coefficients as a scalar or a vector of length equal to the Length property value.

Tunable: Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

InitialOffsetCovariance — Initial values of offset input covariance matrix

1 (default) | scalar | square matrix

Specify the initial values for the offset input covariance matrix. This property must be either a scalar positive numeric value or a positive-definite square matrix with each dimension equal to the ProjectionOrder property value. If it is a scalar value, the OffsetCovariance property is initialized to a diagonal matrix with the diagonal elements equal to that scalar value. If it is a square matrix, the OffsetCovariance property is initialized to the value of that square matrix.

Tunable: Yes

Dependencies

This property is applicable only if the `Method` property is set to `Direct Matrix Inversion` or `Block Direct Matrix Inversion`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

InitialInverseOffsetCovariance — Initial values of offset input covariance matrix inverse

20 (default) | scalar | square matrix

Specify the initial values for the offset input covariance matrix inverse. This property must be either a scalar positive numeric value or a positive-definite square matrix with each dimension equal to the `ProjectionOrder` property value. If it is a scalar value, the `InverseOffsetCovariance` property is initialized to a diagonal matrix with each diagonal element equal to that scalar value. If it is a square matrix, the `InverseOffsetCovariance` property is initialized to the values of that square matrix.

Tunable: Yes

Dependencies

This property is applicable only if the `Method` property is set to `Recursive Matrix Update`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

InitialCorrelationCoefficients — Initial correlation coefficients

0 (default) | scalar | vector

Specify the initial values of the correlation coefficients of the FIR filter as a scalar or a vector of length equal to `ProjectionOrder - 1`.

Tunable: Yes

Dependencies

This property is applicable only if the `Method` property is set to `Recursive Matrix Update`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

LockCoefficients — Lock coefficient updates

false (default) | true

Specify whether the filter coefficient values should be locked. When you set this property to `true`, the filter coefficients are not updated and their values remain the same. The default value is `false` (filter coefficients are continuously updated).

Tunable: Yes

Usage**Syntax**

```
[y,err] = apf(x,d)
```

Description

`[y,err] = apf(x,d)` filters the input `x`, using `d` as the desired signal, and returns the filtered output in `y` and the filter error in `err`. The System object estimates the filter weights needed to minimize the error between the output signal and the desired signal. You can access these coefficients by accessing the `Coefficients` property of the object. This can be done only after calling the object. For example, to access the optimized coefficients of the `apf` filter, call `apf.Coefficients` after you pass the input and desired signal to the object.

Input Arguments

x — Data input

scalar | column vector

The signal to be filtered by the affine projection filter. The input, `x`, and the desired signal, `d`, must have the same size and data type.

The input can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double`

d — Desired signal

scalar | column vector

The affine projection filter adapts its coefficients to minimize the error, `err`, and converge the input signal `x` to the desired signal `d` as closely as possible.

The input, `x`, and the desired signal, `d`, must have the same size and data type.

The desired signal can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object.

Data Types: `single` | `double`

Complex Number Support: Yes

Output Arguments

y — Filtered output

scalar | column vector

Filtered output, returned as a scalar or a column vector. The object adapts its filter coefficients to converge the input signal `x` to match the desired signal `d`. The filter outputs the converged signal.

Data Types: `single` | `double`

err — Difference between output and desired signal

scalar | column vector

Difference between the output signal `y` and the desired signal `d`, returned as a scalar or a column vector. The objective of the affine projection filter is to minimize this error. The object adapts its coefficients to converge towards optimal filter coefficients that produce an output signal that matches closely with the desired signal. To access the affine projection filter coefficients, call `apf.Coefficients` after you pass the input and desired signal to the object.

Data Types: `single` | `double`

Complex Number Support: Yes

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.AffineProjectionFilter`

`mssim` Estimated mean squared error for adaptive filters

Common to All System Objects

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

Examples

QPSK Adaptive Equalization

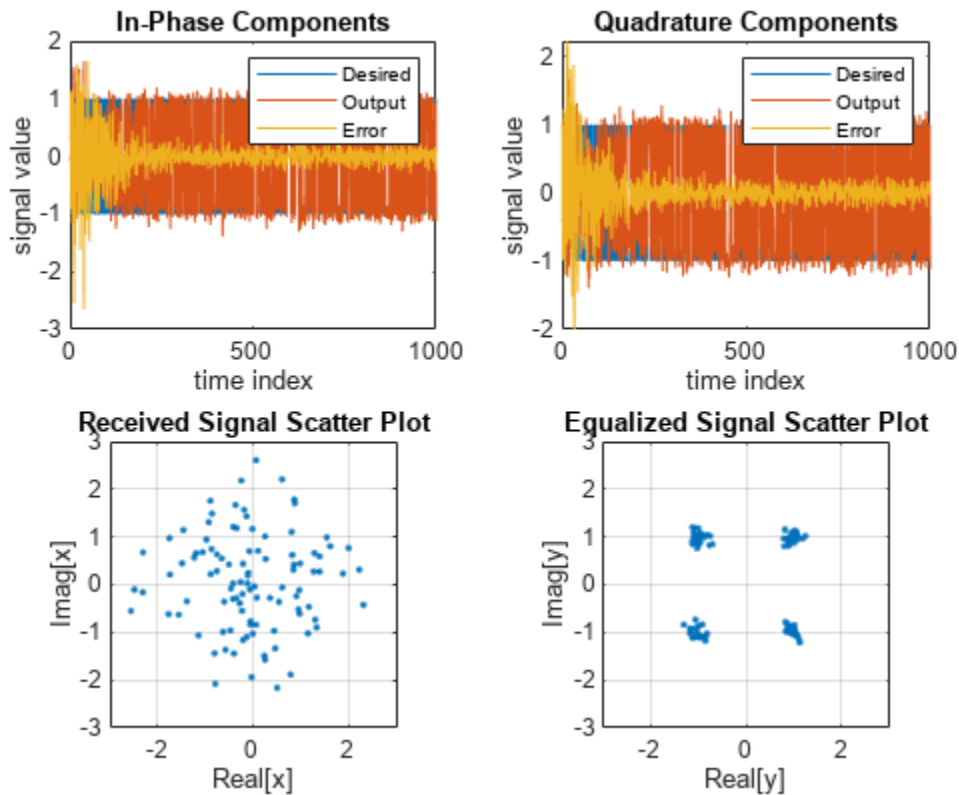

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

QPSK Adaptive Equalization Using a 32-Coefficient FIR Filter (1000 Iterations)

```
D = 16; % Number of samples of delay
b = exp(1i*pi/4)*[-0.7 1]; % Numerator coefficients of channel
a = [1 -0.7]; % Denominator coefficients of channel
ntr = 1000; % Number of iterations
s = sign(randn(1,ntr+D)) + 1i*sign(randn(1,ntr+D)); % Baseband signal
n = 0.1*(randn(1,ntr+D) + 1i*randn(1,ntr+D)); % Noise signal
r = filter(b,a,s)+n; % Received signal
x = r(1+D:ntr+D); % Input signal (received signal)
d = s(1:ntr); % Desired signal (delayed QPSK signal)
mu = 0.1; % Step size
po = 4; % Projection order
offset = 0.05; % Offset for covariance matrix
apf = dsp.AffineProjectionFilter('Length', 32, ...
    'StepSize', mu, 'ProjectionOrder', po, ...
    'InitialOffsetCovariance', offset);
[y,e] = apf(x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e]));
title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('time index'); ylabel('signal value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('time index'); ylabel('signal value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot'); axis('square');
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
```

```
title('Equalized Signal Scatter Plot'); axis('square');
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

System Identification of FIR Filter Using Affine Projection Filter

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

```
ha = fir1(31,0.5);
% FIR system to be identified
fir = dsp.FIRFilter('Numerator',ha);
iir = dsp.IIRFilter('Numerator',sqrt(0.75),...
'Denominator',[1 -0.5]);
x = iir(sign(randn(2000,25)));
% Observation noise signal
n = 0.1*randn(size(x));
% Desired signal
d = fir(x)+n;
% Filter length
l = 32;
% Affine Projection filter Step size.
mu = 0.008;
% Decimation factor for analysis
% and simulation results
m = 5;
```

```

apf = dsp.AffineProjectionFilter(l,'StepSize',mu);
[simmse,meanWsim,Wsim,traceKsim] = msesim(apf,x,d,m);
plot(m*(1:length(simmse)),10*log10(simmse));
xlabel('Iteration'); ylabel('MSE (dB)');
% Plot the learning curve for affine projection filter
% used in system identification
title('Learning curve')

```

Algorithms

The affine projection algorithm (APA) is an adaptive scheme that estimates an unknown system based on multiple input vectors [1]. It is designed to improve the performance of other adaptive algorithms, mainly those that are LMS based. The affine projection algorithm reuses old data resulting in fast convergence when the input signal is highly correlated, leading to a family of algorithms that can make trade-offs between computation complexity with convergence speed [2].

The following equations describe the conceptual algorithm used in designing AP filters:

$$\mathbf{U}ap(n) = \begin{pmatrix} u(n) & \dots & u(n-L) \\ \vdots & \ddots & \vdots \\ u(n-N) & \dots & u(n-L-N) \end{pmatrix} = (\mathbf{u}(n) \ \mathbf{u}(n-1) \ \dots \ \mathbf{u}(n-L))$$

$$\mathbf{y}ap(n) = \mathbf{U}^T ap(n) \mathbf{w}(n) = \begin{pmatrix} y(n) \\ \cdot \\ \cdot \\ \cdot \\ y(n-L) \end{pmatrix}$$

$$\mathbf{d}ap(n) = \begin{pmatrix} d(n) \\ \cdot \\ \cdot \\ \cdot \\ d(n-L) \end{pmatrix}$$

$$\mathbf{e}ap(n) = \mathbf{d}ap(n) - \mathbf{y}ap(n) = \begin{pmatrix} e(n) \\ \cdot \\ \cdot \\ \cdot \\ e(n-L) \end{pmatrix}$$

$$\mathbf{w}(n) = \mathbf{w}(n-1) + \mu \mathbf{U}ap(n) \mathbf{e}ap$$

where \mathbf{C} is either $\varepsilon \mathbf{I}$ if the initial offset covariance is a scalar ε , or \mathbf{R} if the initial offset covariance is a matrix \mathbf{R} . The variables are as follows:

Variable	Description
n	The current time index
$u(n)$	The input sample at step n
$\mathbf{U}_{ap}(n)$	The matrix of the last $L+1$ input signal vectors
$\mathbf{w}(n)$	The adaptive filter coefficients vector
$y(n)$	The adaptive filter output
$d(n)$	The desired signal
$e(n)$	The error at step n
L	The projection order
N	The filter order (i.e., filter length = $N+1$)
μ	The step size

Objects

`dsp.FIRFilter` | `dsp.LMSFilter` | `dsp.RLSFilter`

dsp.AllpassFilter

Package: dsp

Single section or cascaded allpass filter

Description

The `dsp.AllpassFilter` object filters each channel of the input using allpass filter implementations. To import this object into Simulink, use the MATLAB System block.

To filter each channel of the input:

- 1 Create the `dsp.AllpassFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
Allpass = dsp.AllpassFilter
Allpass = dsp.AllpassFilter(Name,Value)
```

Description

`Allpass = dsp.AllpassFilter` returns an allpass filter System object, `Allpass`, that filters each channel of the input signal independently using an allpass filter, with the default structure and coefficients.

`Allpass = dsp.AllpassFilter(Name,Value)` returns an allpass filter System object, `Allpass`, with each property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Structure — Internal allpass filter structure

Minimum multiplier (default) | Lattice | Wave Digital Filter

You can specify the internal allpass filter implementation structure as one of `Minimum multiplier` | `Lattice` | `Wave Digital Filter`. Each structure uses a different set of coefficients, independently stored in the corresponding object property.

AllpassCoefficients — Allpass polynomial coefficients[-2^(-1/2) 0.5] (default) | *N*-by-1 | *N*-by-2

Specify the real allpass polynomial filter coefficients. Specify this property as either an *N*-by-1 or *N*-by-2 matrix of *N* first-order or second-order allpass sections. The default value defines a stable second-order allpass filter with poles and zeros located at $\pm\pi/3$ in the Z plane.

Tunable: Yes**Dependencies**

This property is applicable only when the Structure property is set to Minimum multiplier.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

WDFCoefficients — Wave Digital Filter allpass coefficients[1/2, -2^(1/2)/3] (default) | *N*-by-1 | *N*-by-2

Specify the real allpass coefficients in the Wave Digital Filter form. Specify this property as either a *N*-by-1 or *N*-by-2 matrix of *N* first-order or second-order allpass sections. All elements must have absolute values less than or equal to 1. This value is a transformed version of the default value of AllpassCoefficients, computed using allpass2wdf(AllpassCoefficients). These coefficients define the same stable second-order allpass filter as when Structure is set to 'Minimum multiplier'.

Tunable: Yes**Dependencies**

This property is only applicable when the Structure property is set to Wave Digital Filter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

LatticeCoefficients — Lattice allpass coefficients[-2^(1/2)/3, 1/2] (default) | vector

Specify the real or complex allpass coefficients as lattice reflection coefficients. Specify this property as either a row vector (single-section configuration) or a column vector. This value is a transformed and transposed version of the default value of AllpassCoefficients, computed using transpose(tf2latc([1 h.AllpassCoefficients])). These coefficients define the same stable second-order allpass filter as when Structure is set to 'Lattice'.

Tunable: Yes**Dependencies**

This property is applicable only if the Structure property is set to Lattice.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

TrailingFirstOrderSection — Indicate if last section is first order

false (default) | true

Indicate if last section is first order or second order. When you set TrailingFirstOrderSection to true, the last section is considered to be first-order, and the second element of the last row of the *N*-by-2 matrix is ignored. When you set TrailingFirstOrderSection to false, the last section is considered to be second-order.

Usage

Syntax

```
y = Allpass(x)
```

Description

`y = Allpass(x)` filters the input signal `x` using an allpass filter to produce the output `y`. Each column of `x` is filtered independently as a separate channel over time.

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix. This object also accepts variable-size inputs. Once the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

Data Types: `single` | `double`

Output Arguments

y — Filtered output

vector | matrix

Filtered output, returned as a vector or a matrix. The size, data type, and complexity of the output signal matches that of the input signal.

Data Types: `double` | `single`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.AllpassFilter`

<code>freqz</code>	Frequency response of discrete-time filter System object
<code>fvtool</code>	Visualize frequency response of DSP filters
<code>impz</code>	Impulse response of discrete-time filter System object
<code>info</code>	Information about filter System object
<code>coeffs</code>	Returns the filter System object coefficients in a structure
<code>cost</code>	Estimate cost of implementing filter System object
<code>grpdelay</code>	Group delay response of discrete-time filter System object

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics

reset Reset internal states of System object

Examples

Lowpass Filtering using Two Allpass Filters

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Construct the Allpass Filters

```
Fs = 48000;     % in Hz
FL = 1024;
APF1 = dsp.AllpassFilter('AllpassCoefficients',...
    [-0.710525516540603   0.208818210000029]);
APF2 = dsp.AllpassFilter('AllpassCoefficients',...
    [-0.940456403667957   0.6;...
    -0.324919696232907   0],...
    'TrailingFirstOrderSection',true);
```

Construct the Transfer Function Estimator to estimate the transfer function between the random input and the Allpass filtered output

```
TFE = dsp.TransferFunctionEstimator('FrequencyRange',...
    'onesided','SpectralAverages',2);
```

Construct the ArrayPlot to plot the magnitude response

```
AP = dsp.ArrayPlot('PlotType','Line','YLimits', [-80 5],...
    'YLabel','Magnitude (dB)','SampleIncrement', Fs/FL,...
    'XLabel','Frequency (Hz)','Title','Magnitude Response',...
    'ShowLegend', true,'ChannelNames',{'Magnitude Response'});
```

Filter the Input and show the magnitude response of the estimated transfer function between the input and the filtered output

```
tic;
while toc < 5
    in = randn(FL,1);
    out = 0.5.*(APF1(in) + APF2(in));
    A = TFE(in, out);
    AP(db(A));
end
```

Algorithms

The transfer function of an allpass filter is given by

$$H(z) = \frac{c(n) + c(n-1)z^{-1} + \dots + z^{-n}}{1 + c(1)z^{-1} + \dots + c(n)z^{-n}}$$

c is allpass polynomial coefficients vector. The order, n , of the transfer function is the length of vector c .

In the minimum multiplier form and wave digital form, the allpass filter is implemented as a cascade of either second-order (biquad) sections or first-order sections. When the coefficients are specified as an N -by-2 matrix, each row of the matrix specifies the coefficients of a second-order filter. The last element of the last row can be ignored based on the trailing first-order setting. When the coefficients are specified as an N -by-1 matrix, each element in the matrix specifies the coefficient of a first-order filter. The cascade of all the filter sections forms the allpass filter.

In the lattice form, the coefficients are specified as a vector.

These structures are computationally more economical and structurally more stable compared to the generic IIR filters, such as `df1`, `df1t`, `df2`, `df2t`. For all structures, the allpass filter can be a single-section or a multiple-section (cascaded) filter. The different sections can have different orders, but they are all implemented according to the same structure.

Minimum Multiplier

This structure realizes the allpass filter with the minimum number of required multipliers, equal to the order n . It also uses $2n$ delay units and $2n$ adders. The multipliers use the specified coefficients, which are equal to the polynomial vector c in the allpass transfer function. In this second-order section of the minimum multiplier structure, the coefficients vector, c , is equal to $[0.1 \ -0.7]$.

Wave Digital Filter

This structure uses n multipliers, but only n delay units, at the expense of requiring $3n$ adders. To use this structure, specify the coefficients in wave digital filter (WDF) form. Obtain the WDF equivalent of the conventional allpass coefficients using `allpass2wdf(allpass_coefficients)`. To convert WDF coefficients into the equivalent allpass polynomial form, use `wdf2allpass(WDF_coefficients)`. In this second-order section of the WDF structure, the coefficients vector w is equal to `allpass2wdf([0.1 -0.7])`.

Lattice

This lattice structure uses $2n$ multipliers, n delay units, and $2n$ adders. To use this structure, specify the coefficients as a vector.

You can obtain the lattice equivalent of the conventional allpass coefficients using `transpose(tf2latc(1, [1 allpass_coefficients]))`. In the following second-order section of the lattice structure, the coefficients vector is computed using `transpose(tf2latc(1, [1 0.1 -0.7]))`. Use these coefficients for a filter that is functionally equivalent to the minimum multiplier structure with coefficients $[0.1 \ -0.7]$.

dsp.AllpoleFilter

Package: dsp

IIR Filter with no zeros

Description

The `dsp.AllpoleFilter` object filters each channel of the input using allpole filter implementations.

To filter each channel of the input:

- 1 Create the `dsp.AllpoleFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
allpole = dsp.AllpoleFilter
allpole = dsp.AllpoleFilter(Name,Value)
```

Description

`allpole = dsp.AllpoleFilter` returns an allpole filter System object, `allpole`, which independently filters each channel of the input over successive calls to the algorithm. This System object uses a specified allpole filter implementation.

`allpole = dsp.AllpoleFilter(Name,Value)` returns an allpole filter System object, `allpole`, with each property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Structure — Filter structure

Direct form (default) | Direct form transposed | Lattice AR

Specify the filter structure as one of | `Direct form` | `Direct form transposed` | `Lattice AR`. Analysis methods are not supported for fixed-point processing if the structure is `Direct form` or `Direct form transposed`. This property is nontunable.

Denominator — Filter denominator coefficients

[1 0.1] (default) | row vector

Specify the denominator coefficients as a numeric row vector.

Tunable: Yes**Dependencies**

This property is applicable when the Structure property is set to one of `Direct form` | `Direct form transposed`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`**ReflectionCoefficients — Lattice filter coefficients**

[0.2 0.4] (default) | row vector

Specify the lattice filter coefficients as a numeric row vector.

Tunable: Yes**Dependencies**

This property is applicable when the Structure property is set to `Lattice AR`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`**InitialConditions — Initial conditions for the filter states**

0 (default) | scalar | vector | matrix

Specify the initial conditions of the filter states.

You can specify the initial conditions as a scalar, vector, or matrix. If you specify a scalar value, this System object initializes all delay elements in the filter to that value. You can also specify a vector whose length equals the number of delay elements in the filter. When you do so, each vector element specifies a unique initial condition for the corresponding delay element. The object applies the same vector of initial conditions to each channel of the input signal.

You can also specify a matrix with the same number of rows as the number of delay elements in the filter and one column for each channel of the input signal. In this case, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel.

Tunable: YesData Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`**CoefficientsDataType — Denominator coefficients word- and fraction-length designations**

Same word length as input (default) | Custom

Specify the denominator coefficients fixed-point data type as one of `Same word length as input` | `Custom`. This property is nontunable.

ReflectionCoefficientsDataType — Reflection coefficients word- and fraction-length designations

Same word length as input (default) | Custom

Specify the reflection coefficients fixed-point data type as one of `Same word length as input` | `Custom`. This property is nontunable.

Fixed-Point Properties

ProductDataType — Product word- and fraction-length designations

Full precision (default) | Same as input | Custom

Specify the product fixed-point data type as one of | Full precision | Same as input | Custom |. This property is nontunable.

AccumulatorDataType — Accumulator word- and fraction-length designations

Full precision (default) | Same as input | Same as product | Custom

Specify the accumulator fixed-point data type to one of | Full precision | Same as input | Same as product | Custom |. This property is nontunable.

OutputDataType — Output word- and fraction-length designations

Same as input (default) | Same as accumulator | Custom

Specify the output fixed-point data type as one of | Same as accumulator | Same as input | Custom |. This property is nontunable.

StateDataType — State word- and fraction-length designations

Same as accumulator (default) | Same as input | Custom

Specify the state fixed-point data type as one of | Same as input | Same as accumulator | Custom. This property is nontunable.

CustomCoefficientsDataType — Custom denominator word- and fraction-lengths

numerictype ([], 16, 15) (default) | numerictype

Specify the denominator coefficients fixed-point type as an autosigned numerictype (Fixed-Point Designer) object. This property is nontunable.

Dependencies

This property is applicable when the CoefficientsDataType property is Custom.

CustomReflectionCoefficientsDataType — Custom reflection coefficients word- and fraction-lengths

numerictype ([], 16, 15) (default) | numerictype

Specify the denominator coefficients fixed-point type as an autosigned numerictype (Fixed-Point Designer) object. This property is nontunable.

Dependencies

This property is applicable when the ReflectionCoefficientsDataType property is Custom.

CustomProductDataType — Custom Product word- and fraction-lengths

numerictype ([], 32, 30) (default) | numerictype

Specify the product fixed-point type as an autosigned scaled numerictype object. This property is nontunable.

Dependencies

This property applies when you set the ProductDataType property to Custom.

CustomAccumulatorDataType — Custom accumulator word- and fraction-lengths`numericType([],32,30)` (default) | `numericType`

Specify the accumulator fixed-point type as an autosigned scaled `numericType` object. This property is nontunable.

Dependencies

This property applies when you set the `AccumulatorDataType` property to `Custom`.

CustomStateDataType — Custom state word- and fraction-lengths`numericType([],16,15)` (default) | `numericType`

Specify the state fixed-point type as an autosigned scaled `numericType` object. This property is nontunable.

Dependencies

This property applies when you set the `StateDataType` property to `Custom`.

CustomOutputDataType — Custom output word- and fraction-lengths`numericType([],16,15)` (default) | `numericType`

Specify the output fixed-point type as an autosigned scaled `numericType` object. This property is nontunable.

Dependencies

This property applies when you set the `OutputDataType` property to `Custom`.

Usage**Syntax**`y = allpole(x)`**Description**

`y = allpole(x)` filters the real or complex input signal `x` using an allpole filter to produce the output `y`.

Input Arguments**x — Data input**`vector` | `matrix`

Data input, specified as a vector or a matrix. This object also accepts variable-size inputs. Once the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

When the input data is of a fixed-point type, it must be signed. The allpole filter object operates on each channel of the input signal independently over successive calls to the algorithm.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

Output Arguments

y — Filtered output

vector | matrix

Filtered output, returned as a vector or a matrix. The size, data type, and complexity of the output signal matches that of the input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.AllpoleFilter

<code>freqz</code>	Frequency response of discrete-time filter System object
<code>fvtool</code>	Visualize frequency response of DSP filters
<code>impz</code>	Impulse response of discrete-time filter System object
<code>info</code>	Information about filter System object
<code>coeffs</code>	Returns the filter System object coefficients in a structure
<code>cost</code>	Estimate cost of implementing filter System object
<code>grpdelay</code>	Group delay response of discrete-time filter System object
<code>phasez</code>	Phase response of discrete-time filter System object (unwrapped)

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Lowpass filtering a waveform with two frequencies

Use an Allpole filter to apply a lowpass filter to a waveform with two sinusoidal frequencies.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

```
t = (0:1000)./8e3;
xin = sin(2*pi*1e3*t)+sin(2*pi*3e3*t);

src = dsp.SignalSource(xin', 4);
sink = dsp.SignalSink;
allpole = dsp.AllpoleFilter;
tt = (-25:25)';
xsinc = 0.4*sinc(0.4*tt);
asinc = lpc(xsinc,51);
allpole.Denominator = asinc;
```

```

sa = spectrumAnalyzer('SampleRate',8e3,...
    'Method','welch',...
    'PlotAsTwoSidedSpectrum',false,...
    'OverlapPercent',80,'SpectrumUnits','dBW',...
    'YLimits',[-150 50]);

while ~isDone(src)
    input = src();
    filteredOutput = allpole(input);
    sink(filteredOutput);
    sa(filteredOutput)
end

```

```

filteredResult = sink.Buffer;
fvtool(allpole,'Fs',8000)

```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Allpole Filter block reference page. The object properties correspond to the block parameters.

Version History

Introduced in R2012b

dsp.AnalyticSignal

Package: dsp

Analytic signals of discrete-time inputs

Description

The `dsp.AnalyticSignal` System object computes analytic signals of discrete-time inputs. The real part of the analytic signal in each channel is a replica of the real input in that channel, and the imaginary part is the Hilbert transform of the input. In the frequency domain, the analytic signal doubles the positive frequency content of the original signal while zeroing-out negative frequencies and retaining the DC component. The object computes the Hilbert transform using an equiripple FIR filter.

To compute the analytic signal of a discrete-time input:

- 1 Create the `dsp.AnalyticSignal` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
anaSig = dsp.AnalyticSignal
anaSig = dsp.AnalyticSignal(order)
anaSig = dsp.AnalyticSignal(Name,Value)
```

Description

`anaSig = dsp.AnalyticSignal` returns an analytic signal object, `anaSig`, that computes the complex analytic signal corresponding to each channel of a real M -by- N input matrix.

`anaSig = dsp.AnalyticSignal(order)` returns an analytic signal object, `anaSig`, with the "FilterOrder" on page 4-0 property set to `order`.

`anaSig = dsp.AnalyticSignal(Name,Value)` returns an analytic signal object, `anaSig`, with each specified property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

FilterOrder — Filter order used to compute Hilbert transform

100 (default) | scalar integer

Order of the equiripple FIR filter used in computing the Hilbert transform, specified as an even integer scalar greater than 3.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Usage**Syntax**

```
y = anaSig(x)
```

Description

`y = anaSig(x)` computes the analytic signal, y , of the M -by- N input matrix x , according to the equation

$$\mathbf{Y} = \mathbf{X} + jH\{\mathbf{X}\}$$

where j is the imaginary unit and $H\{\mathbf{X}\}$ denotes the Hilbert transform.

Each of the N columns in x contains M sequential time samples from an independent channel. The method computes the analytic signal for each channel.

Input Arguments**x** — Data input

vector | matrix

Data input, specified as a vector or a matrix.

Data Types: single | double

Output Arguments**y** — Analytic signal output

vector | matrix

Analytic signal output, returned as a vector or a matrix.

Data Types: single | double

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

```
step      Run System object algorithm
```

release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

Examples

Compute The Analytic Signal

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Compute the analytic signal of a sinusoidal input.

```
t = (-1:0.01:1)';  
x = sin(4*pi*t);  
anaSig = dsp.AnalyticSignal(200);  
y = anaSig(x);
```

View the analytic signal.

```
subplot(2,1,1);  
plot(t, x)  
title('Original Signal');  
subplot(2,1,2), plot(t, [real(y) imag(y)]);  
title('Analytic signal of the input')  
legend('Real signal', 'Imaginary signal', ...  
       'Location', 'best');
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Analytic Signal block reference page. The object properties correspond to the block parameters.

Version History

Introduced in R2012a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

This object also supports SIMD code generation using Intel AVX2 technology under these conditions:

- Input signal is real-valued.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

See Also

Objects

dsp.FFT | dsp.IFFT

dsp.ArrayPlot

Display vectors or arrays

Description

Display vectors or arrays where the data is uniformly spaced along the x-axis.

Creation

Syntax

```
scope = dsp.ArrayPlot  
scope = dsp.ArrayPlot(Name=Value)
```

Description

`scope = dsp.ArrayPlot` creates an Array Plot object, `scope`.

`scope = dsp.ArrayPlot(Name=Value)` sets properties using one or more name-value pairs. For example, `scope = dsp.ArrayPlot(NumInputPorts=3)`

Properties

Most properties can be changed from the `dsp.ArrayPlot` UI.

Plot Configuration

NumInputPorts — Number of input ports

1 (default) | integer between [1, 96]

Number of input ports, specified as a positive integer. Each signal coming through a separate input becomes a separate channel in the scope. You must invoke the scope with the same number of inputs as the value of this property.

XDataMode — Source of the x-data spacing

"Sample increment and X-offset" (default) | "Custom"

Specify whether to use the `SampleIncrement` and `XOffset` property values to determine spacing, or specify your own custom spacing. If you specify "Custom", you also must specify the `CustomXData` property values.

You can set this property only when creating the object.

Scope Window Use

Open the **Plot** tab, click **Settings**, and set **X-Data Mode**.

Data Types: char | string

CustomXData — X-data values

empty vector (default) | vector

Specify the desired x-data values as a row or column vector of length equal to the frame length of the individual inputs. If you use the default (empty vector) value, the x-data is uniformly spaced and set to $(0:L-1)$, where L is the frame length.

You can set this property only when creating the object.

Example: `scope = dsp.ArrayPlot(XDataMode="Custom", CustomXData=logspace(0, log10(44100/2), 1024))`

Scope Window Use

Open the **Plot** tab, click **Settings**, and set **X-Data Mode** to **Custom** and specify **Custom X-Data**.

Dependency

To use this property, set `XDataMode` to "Custom".

SampleIncrement — Sample increment of input

1 (default) | finite numeric scalar

Specify the spacing between samples along the x-axis as a finite numeric scalar. The input signal is only y-axis data. x-axis data is set automatically based on the `XOffset` and `SampleIncrement` properties.

Example: When `XOffset` is 0 and `SampleIncrement` is 1, the x-axis values are set to 0, 1, 2, 3, 4, ...

Example: When `XOffset` is -1 and `SampleIncrement` is 0.25, the x-axis values are set to -1, -0.75, -0.5, -0.25, 0, ...

Scope Window Use

Open the **Plot** tab, click **Settings**, and set **Sample Increment**.

Dependency

To use this property, set `XDataMode` to 'Sample increment and X-offset'.

XOffset — Display offset of x-axis

0 (default) | scalar

Display offset of x-axis, specified as a numeric scalar. x-axis data is set automatically based on both the `SampleIncrement` and `XOffset` values. The x-offset represents the first value on the x-axis.

Example: When `XOffset` is 0 and `SampleIncrement` is 1, the x-axis values are set to 0, 1, 2, 3, 4, ...

Example: When `XOffset` is -1 and `SampleIncrement` is 0.25, the x-axis values are set to -1, -0.75, -0.5, -0.25, 0, ...

Scope Window Use

Open the **Plot** tab, click **Settings**, and set **X-Offset**.

Dependency

To use this property, set `XDataMode` to "Sample increment and X-offset".

XScale — Scale of x-axis

"Linear" (default) | "Log"

Specify whether the scale of the x-axis is "Linear" or "Log". If `XOffset` is a negative value, you cannot set this property to "Log".

Scope Window Use

Open the **Plot** tab, click **Settings**, and set **XScale**.

Data Types: char | string

YScale — Scale of y-axis

"Linear" (default) | "Log"

Specify whether the scale of the y-axis is "Linear" or "Log".

Scope Window Use

Open the **Plot** tab, click **Settings**, and set **YScale**.

Data Types: char | string

PlotType — Control type of plot

"Stem" (default) | "Line" | "Stairs"

Specify the type of plot to use for all the input signals displayed in the scope window:

- "Stem" - The scope displays the input signal as circles with vertical lines extending down to the x-axis at each of the sampled values.
- "Line" - The scope displays the input signal as lines connecting each of the sampled values.
- "Stairs" - The scope displays the input signal as a stair-step graph. A stair-step graph is made up of only horizontal lines and vertical lines. Each horizontal line represents the signal value for a discrete sample period and is connected to two vertical lines. Each vertical line represents a change in values occurring at a sample. Stair-step graphs are useful for drawing time history graphs of digitally sampled data.

Scope Window Use

Open the **Settings** and set **Plot Type**.

AxesScaling — Axes scaling mode

"OnceAtStop" (default) | "Auto" | "Manual" | "Updates"

Specify when the scope scales the axes. Valid values are:

- "Auto" — The scope scales the axes as needed to fit the data, both during and after simulation.
- "Manual" — The scope does not scale the axes automatically.
- "OnceAtStop" — The scope scales the axes when the simulation stops.
- "Updates" — The scope scales the axes once after a set number of visual updates. The number of updates is determined by the value of the `AxesScalingNumUpdates` property.

You can set this property only when creating the object.

Scope Window Use

Hover over the array plot to see the zoom , pan , and autoscale  buttons. You can also zoom and pan using your mouse.

Data Types: char | string

AxesScalingNumUpdates — Number of updates before scaling

100 (default) | real positive integer

Specify the number of updates before scaling as a real, positive scalar integer.

Dependency

To enable this property, set `AxesScaling` to "Updates".

Data Types: double

Measurements

MeasurementChannel — Channel for which to obtain measurements

1 (default) | positive integer

Channel for which to obtain measurements, specified as a positive integer in the range [1 N], where N is the number of input channels.

Scope Window Use

Click the **Measurements** tab on the Array Plot toolstrip. In the **Channel** section, select a **Channel**.

Data Types: double

CursorMeasurements — Cursor measurements

CursorMeasurementsConfiguration object

Cursor measurements to display screen or waveform cursors, specified as a CursorMeasurementsConfiguration object.

All CursorMeasurementsConfiguration properties are tunable.

Scope Window Use

Click the **Measurements** tab on the Array Plot toolstrip and modify the cursor measurements in the **Cursors** section.

PeakFinder — Peak finder measurements

PeakFinderConfiguration object

Peak finder measurements to compute and display the largest calculated peak values, specified as a PeakFinderConfiguration object.

All PeakFinderConfiguration properties are tunable.

Scope Window Use

Click the **Measurements** tab on the Array Plot toolstrip and modify the peak finder measurements in the **Peaks** section.

SignalStatistics — Signal statistics measurements

SignalStatisticsConfiguration object

Signal statistics measurements to compute and display signal statistics, specified as a SignalStatisticsConfiguration object.

All SignalStatisticsConfiguration properties are tunable.

Scope Window Use

Click the **Measurements** tab on the Array Plot toolstrip and modify the signal statistics measurements in the **Statistics** section.

Visualization

Name — Window name

'Array Plot' (default) | character vector | string scalar

Specify the name of the scope. This name appears as the title of the scope's figure window. To specify a title of a scope plot, use the **Title** property.

Data Types: char | string

Position — Scope window position and size in pixels

screen center (default) | [left bottom width height]

Specify, in pixels, the size and location of the scope window as a four-element vector of the form `[left bottom width height]`. By default, the scope window appears in the center of your screen with a width of 800 pixels and height of 450 pixels. The default values for this property may change depending on your screen resolution.

MaximizeAxes — Maximize axes control

"Auto" (default) | "On" | "Off"

Specify whether to display the scope in maximized-axes mode. In this mode, the axes are expanded to fit into the entire display. To conserve space, labels do not appear in each display. Instead, tick-mark values appear on top of the plotted data. You can select one of the following options:

- "Auto" — The axes appear maximized in all displays only if the `Title` and `YLabel` properties are empty for every display. If you enter any value in any display for either of these properties, the axes are not maximized.
- "On" — The axes appear maximized in all displays. Any values entered into the `Title` and `YLabel` properties are hidden.
- "Off" — None of the axes appear maximized.

Scope Window Use

Hover over the array plot to see the maximize axes button .

Data Types: `char` | `string`

Title — Display title

' ' (default) | character vector | string scalar

Specify the display title as a character vector or string.

Scope Window Use

Open the **Plot** tab, click **Settings**, and set **Title**.

Data Types: `char` | `string`

ShowLegend — Show legend

false (default) | true

To show a legend with the input names, set this property to `true`.

From the legend, you can control which signals are visible. This control is equivalent to changing the visibility in the **Style** dialog box. In the scope legend, click a signal name to hide the signal in the scope. To show the signal, click the signal name again. To show only one signal, right-click the signal name. To show all signals, press **Esc**.

Note The legend only shows the first 20 signals. Any additional signals cannot be viewed or controlled from the legend.

Scope Window Use

On the **Plot** tab, click **Legend**.

Data Types: `logical`

ChannelNames — Channel names

`empty cell (default) | cell array of character vectors | array of strings`

Specify the input channel names as a cell array of character vectors or an array of strings. The names appear in the legend, **Settings**, and **Measurements** panels. If you do not specify names, the channels are labeled as `Channel 1`, `Channel 2`, etc.

Dependency

To see channel names, set `ShowLegend` to `true`.

Data Types: `char`

ShowGrid — Display grid

`true (default) | false`

Set this property to `true` to show grid lines on the plot.

Scope Window Use

Open the **Plot** tab, click **Settings**, and select **Grid**.

PlotAsMagnitudePhase — Plot signal as magnitude and phase

`false (default) | true`

- `true` - The scope plots the magnitude and phase of the input signal on two separate axes within the same active display.
- `false` - The scope plots the real and imaginary parts of the input signal on two separate axes within the same active display.

This property is useful for complex-valued input signals. Turning on this property affects the phase for real-valued input signals. When the amplitude of the input signal is nonnegative, the phase is 0 degrees. When the amplitude of the input signal is negative, the phase is 180 degrees.

Scope Window Use

On the **Plot** tab, select the **Magnitude Phase** button.

XLabel — x-axis label

`"" (default) | character vector | string scalar`

Specify the text for the scope to display below the x-axis.

Scope Window Use

Open the **Plot** tab, click **Settings**, and set **XLabel**.

Data Types: `char` | `string`

YLabel — y-axis label

`"Amplitude" (default) | character vector | string scalar`

Specify the text for the scope to display to the left of the y-axis.

Dependencies

This property applies only when `PlotAsMagnitudePhase` is `false`. When `PlotAsMagnitudePhase` is `true`, the two y-axis labels are read-only values "Magnitude" and "Phase", for the magnitude plot and the phase plot, respectively.

Scope Window Use

Open the **Plot** tab, click **Settings**, and set **YLabel**.

Data Types: `char` | `string`

YLimits — y-axis limits

`[-10,10]` (default) | `[ymin, ymax]`

Specify the y-axis limits as a two-element numeric vector, `[ymin, ymax]`.

If `PlotAsMagnitudePhase` is `false`, the default is `[-10,10]`. If `PlotAsMagnitudePhase` is `true`, the default is `[0,10]`.

Dependencies

When `PlotAsMagnitudePhase` is `true`, this property specifies the y-axis limits of only the magnitude plot. The y-axis limits of the phase plot are always `[-180,180]`.

Scope Window Use

Open the **Plot** tab, click **Settings**, and set **Y-Axis Limits** as a two-element numeric vector.

Usage**Syntax**

```
scope(signal)
scope(signal1,signal2,...,signalN)
```

Description

`scope(signal)` displays the signal in the Array Plot.

`scope(signal1,signal2,...,signalN)` displays multiple signals in the Array Plot. The signals can have a different number of channels and different frame lengths.

Input Arguments**signal — Input signal or signals to visualize**

`scalar` | `vector` | `matrix`

Specify one or more input signals to visualize in the `dsp.ArrayPlot`. Signals can have a different number of channels and different frame lengths.

Example: `scope(signal1,signal2)`

UI Customization

To customize the style of signals on the array plot, open the **Settings** and use the bottom row of options to select a signal and modify the style, width, color, and marker type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the object as the first input argument.

<code>generateScript</code>	Generate MATLAB script to create scope with current settings
<code>hide</code>	Hide scope window
<code>show</code>	Display scope window
<code>isVisible</code>	Determine visibility of scope
<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

If you want to restart the simulation from the beginning, call `reset` to clear the scope window displays. Do not call `reset` after calling `release`.

Examples

Plot a Gaussian Distribution

Create a new Array Plot object.

```
scope = dsp.ArrayPlot;
```

Configure the properties of the Array Plot object for a Gaussian distribution.

```
scope.YLimits = [0 1];  
scope.XOffset = -2.5;  
scope.SampleIncrement = 0.1;  
scope.Title = "Gaussian distribution";  
scope.XLabel = "X";  
scope.YLabel = "f(X)";
```

Call the Array Plot object to plot a Gaussian distribution.

```
scope(exp(-(-2.5:.1:2.5).*(-2.5:.1:2.5)))'
```

You can scale the y-axis to show the plot on a log scale.

```
release(scope)
scope.YScale = 'Log';
scope(exp(-(-2.5:.1:2.5).^2*(-2.5:.1:2.5)))
```

Plot Changing Filter Weights

View least mean squares (LMS) adaptive filter weights on the Array Plot figure. Watch the filter weights change as they adapt to filter a noisy input signal.

Create an LMS adaptive filter System object™.

```
lmsFilter = dsp.LMSFilter(40,Method="Normalized LMS",...
    StepSize=0.002);
```

Create and configure a `dsp.AudioFileReader` System object to read the input signal from the specified audio file.

```
signalSource = dsp.AudioFileReader("dspafx_8000.wav",...
    SamplesPerFrame=40, ...
    PlayCount=Inf,...
    OutputDataType="double");
```

Create and configure a `dsp.FIRFilter` System object to filter random white noise, creating colored noise.

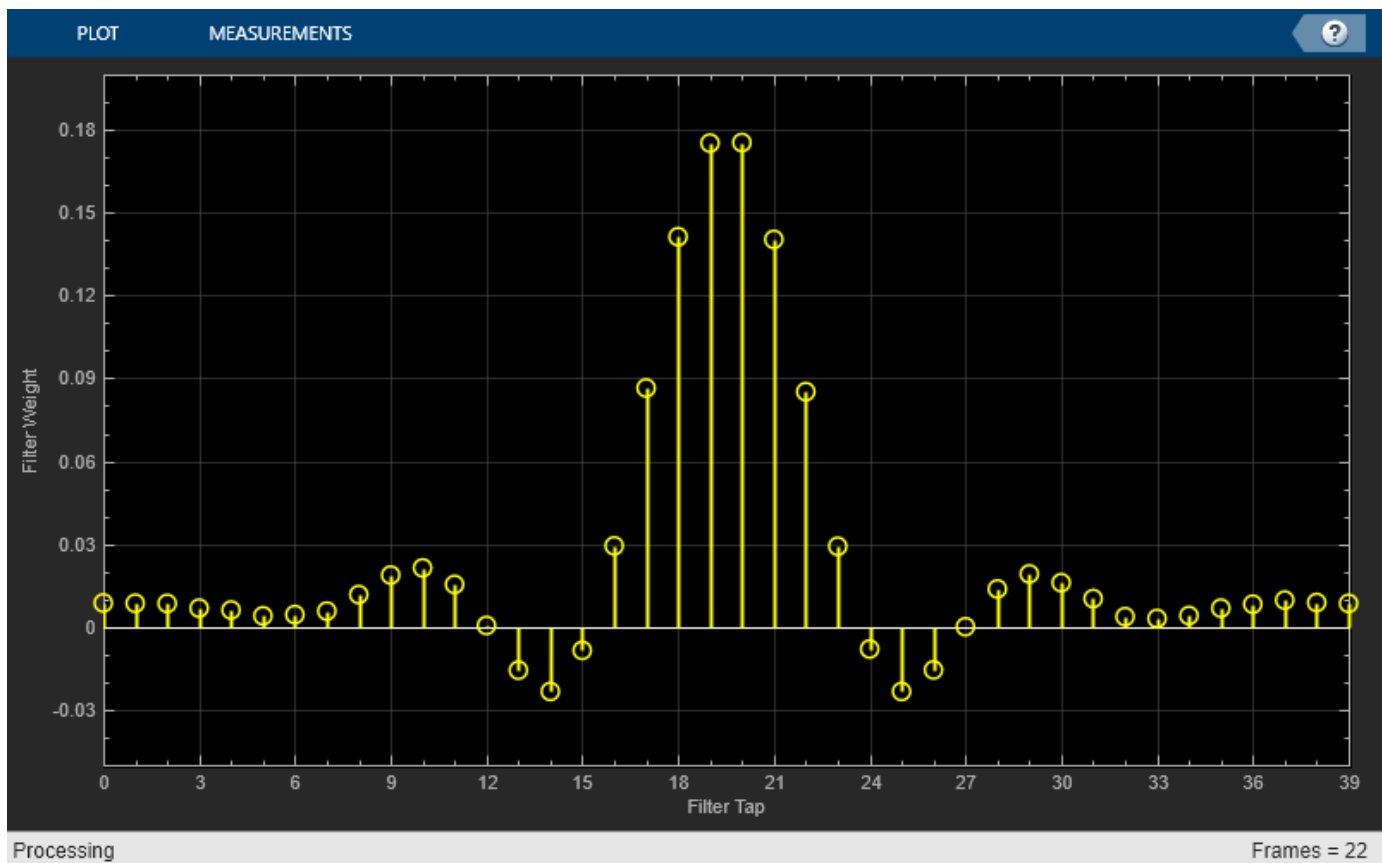

```
firFilter = dsp.FIRFilter(Numerator=fir1(39,0.25));
```

Create and configure a `dsp.ArrayPlot` object to display the adaptive filter weights.

```
scope = dsp.ArrayPlot(XLabel="Filter Tap", ...
    YLabel="Filter Weight", ...
    YLimits=[-0.05 0.2]');
```

Plot the LMS filter weights as they adapt to a desired signal. Read from the audio file, produce random data, and filter the random data. Update the filter weights and plot the filter weights.

```
numplays = 0;
while numplays < 3
    [y, eof] = signalSource();
    noise = rand(40,1);
    noisefilt = firFilter(noise);
    desired = y + noisefilt;
    [~, ~, wts] = lmsFilter(noise,desired);
    scope(wts);
    numplays = numplays + eof;
end
```

Power Spectrum of Multichannel Sinusoidal Signal

Compute the power spectrum of a multichannel sinusoidal signal using the `dsp.SpectrumEstimator` System object™. You can get the vector of frequencies at which the spectrum is estimated using the `getFrequencyVector` function. To compute the resolution bandwidth of the estimate (RBW), use the `getRBW` function.

Generate a three-channel sinusoid sampled at 1 kHz. Specify sinusoidal frequencies of 100, 200, and 300 Hz. The second and third channels have their phases offset from the first by $\pi/2$ and $\pi/4$, respectively.

```
sineSignal = dsp.SinWave('SamplesPerFrame',1000,'SampleRate',1000, ...
    'Frequency',[100 200 300],'PhaseOffset',[0 pi/2 pi/4]);
```

Estimate and plot the one-sided spectrum of the signal. Use the `dsp.SpectrumEstimator` object for the computation and the `dsp.ArrayPlot` for the plotting.

```
estimator = dsp.SpectrumEstimator('FrequencyRange','onesided');
plotter = dsp.ArrayPlot('PlotType','Line','YLimits',[0 0.75], ...
    'YLabel','Power Spectrum (watts)','XLabel','Frequency (Hz)');
```

Step through to obtain the data streams and display the spectra of the three channels.

```
y = sineSignal();
pxx = estimator(y);
plotter(pxx)
```

Get the vector of frequencies at which the spectrum is estimated in Hz, using the `getFrequencyVector` function.

```
f = getFrequencyVector(estimator);
```

Compute the resolution bandwidth (RBW) of the estimate using the `getRBW` function.

```
rbw = getRBW(estimator)
```

```
rbw =
    0.0015
```

The resolution bandwidth of the signal power spectrum is 0.0015 Hz. This frequency is the smallest frequency that can be resolved on the spectrum.

Power and Max-Hold Spectra of Noisy Sine Wave

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Generate a sine wave.

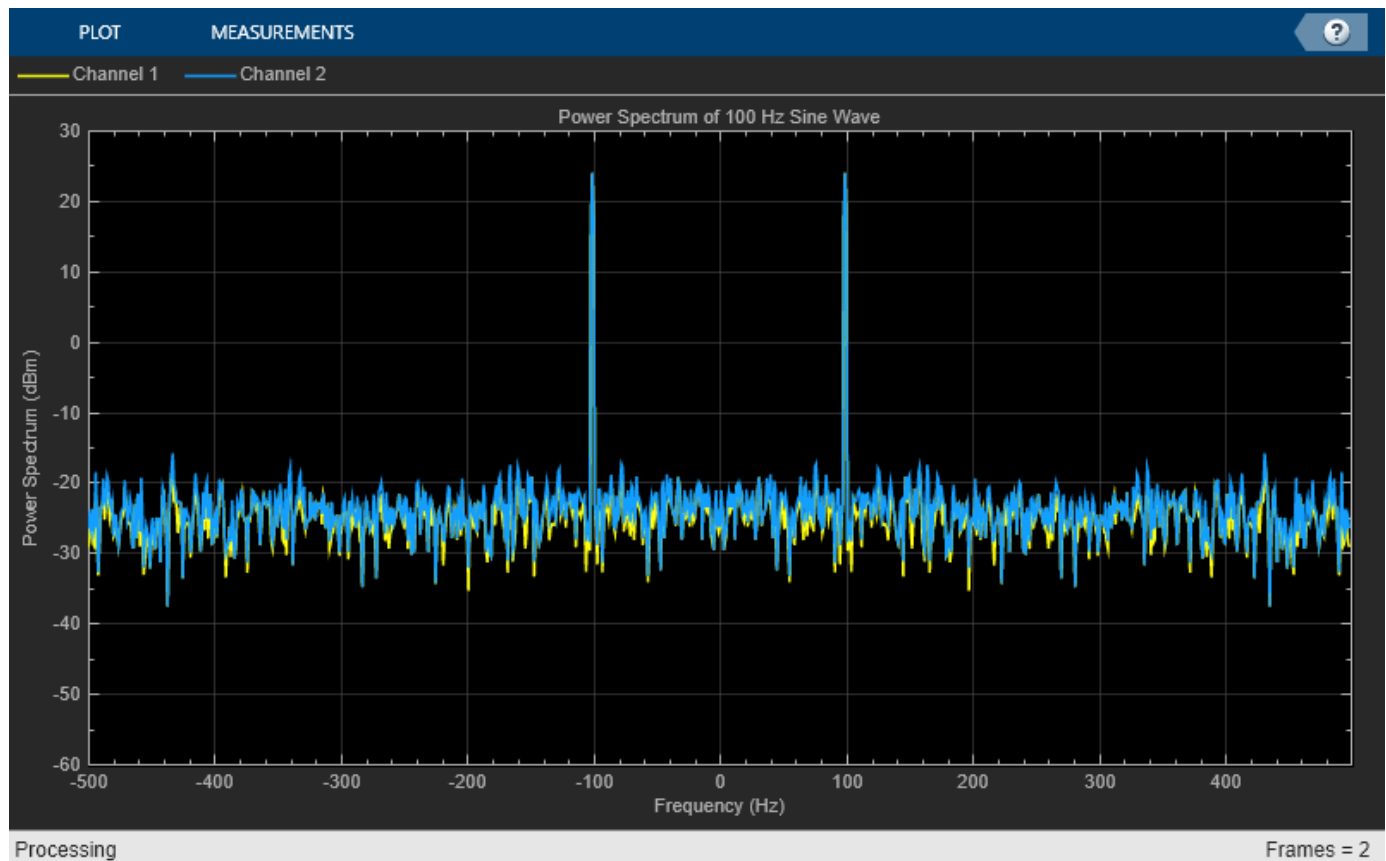

```
sineWave = dsp.SineWave('Frequency',100,...
    'SampleRate',1000, ...
    'SamplesPerFrame',1000);
```

Use the spectrum estimator to compute the power spectrum and the max-hold spectrum of the sine wave. Use the Array Plot to display the spectra.

```
SE = dsp.SpectrumEstimator(...
    'SampleRate',sineWave.SampleRate,...
    'SpectrumType','Power','PowerUnits','dBm', ...
    'FrequencyRange','centered',...
    'OutputMaxHoldSpectrum',true);
plotter = dsp.ArrayPlot('PlotType','Line',...
    'XOffset',-500, ...
    'YLimits',[-60 30],...
    'Title','Power Spectrum of 100 Hz Sine Wave', ...
    'YLabel','Power Spectrum (dBm)',...
    'XLabel','Frequency (Hz)');
```

Add random noise to the sine wave. Stream in the data, and plot the power spectrum of the signal.

```
for ii = 1:10
    x = sineWave() + 0.05*randn(1000,1);
    [Pxx,Pmax] = SE(x);
    plotter([Pxx Pmax])
end
```

Tips

- To close the Array Plot window and clear its associated data, use the MATLAB `clear` function.
- To hide or show the Array Plot window, use the `hide` and `show` functions.

Version History

Introduced in R2013a

Channel names support array of strings

Starting in R2022b, you can specify the `ChannelNames` property of the `dsp.ArrayPlot` object as an array of strings.

```
ap = dsp.ArrayPlot(ChannelNames=["Input", "Noisy Output"]);
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Supports MEX code generation by treating the calls to the object as extrinsic. Does not support code generation for standalone applications.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

dsp.ArrayVectorAdder

Package: dsp

(To be removed) Add array to vector along specified dimension

Note `dsp.ArrayVectorAdder` will be removed in a future release. Use the `+` operator instead. For more information, see “Compatibility Considerations”.

Description

The `ArrayVectorAdder` object adds an N-D array to a vector along a specified dimension. The length of the vector must equal the size of the N-D array along the specified dimension.

To add an N-D array to a vector along a specified dimension:

- 1 Define and set up your array-vector addition object. See “Construction” on page 4-70.
- 2 Call `step` to add the N-D array according to the properties of `dsp.ArrayVectorAdder`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Construction

`ava = dsp.ArrayVectorAdder` returns an array-vector addition object, `ava`, that adds a vector to an N-D array along the first dimension.

`ava = dsp.ArrayVectorAdder('PropertyName', PropertyValue, ...)` returns an array-vector addition object, `ava`, with each property set to the specified value.

Properties

Dimension

Dimension along which to add vector elements to input

Specify the dimension along which to add the input array to the elements of the vector as a positive integer. The length of the vector must match the size of the N-D array along the specified dimension. The default is 1.

VectorSource

Source of vector

Specify the source of the vector values as `|Input port | Property |`. The default is `Input port`.

Vector

Vector values

Specify the vector values. This property applies only when you set the `VectorSource` property to `Property`. The default is `[0.5 0.25]`. This property is tunable.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `| Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |`. The default is `Floor`. This property applies only if the object is not in full precision mode.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `| Wrap | Saturate |`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

VectorDataType

Vector word and fraction lengths

Specify the vector fixed-point data type as `| Same word length as input | Custom |`. This property applies when you set the `VectorSource` property to `Property`. The default is `Same word length as input`.

CustomVectorDataType

Vector word and fraction lengths

Specify the vector fixed-point type as a `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `VectorSource` property to `Property` and the `VectorDataType` property to `Custom`. The default is `numericType([], 16, 15)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as `| Full precision | Same as first input | Custom |`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when the `AccumulatorDataType` property is `Custom`. The default is `numericType([], 32, 30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as `| Same as accumulator | Same as first input | Custom |`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when the “`OutputDataType`” on page 4-0 property is `Custom`. The default is `numericType([], 16, 15)`.

Methods

`step` Add vector to N-D array

Common to All System Objects	
<code>release</code>	Allow System object property value changes

Examples

Add a Vector To a Matrix

Note If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj, x)`.

Add a 2-by-1 vector to a 2-by-2 matrix along the first dimension of the array.

```
ava = dsp.ArrayVectorAdder;
a = ones(2);
x = [1 2]';
y = ava(a, x);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Array-Vector Add block reference page. The object properties correspond to the block parameters, except:

The array-vector addition object does not have **Minimum** or **Maximum** options for data output.

Version History

Introduced in R2012a

dsp.ArrayVectorAdder System object will be removed

Warns starting in R2021b

dsp.ArrayVectorAdder System object will be removed in a future release. Use the + operator instead.

Update Code

This table shows how the System object is typically used and explains how to update existing code to use the + operator.

Discouraged Usage	Recommended Replacement
<pre>ava = dsp.ArrayVectorAdder; a = ones(2); x = [1 2]'; y = ava(a, x)</pre>	<pre>y = a + x</pre>
<pre>y = 2x2</pre>	<pre>y = 2x2</pre>

<pre> 3 3</pre>	<pre> 3 3</pre>
<p>If you are using a release prior to R2016b, replace <code>ava(a, x)</code> with <code>step(ava, a, x)</code>.</p>	

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

step

System object: dsp.ArrayVectorAdder

Package: dsp

Add vector to N-D array

Syntax

$Y = \text{step}(\text{ava}, A)$

$Y = \text{step}(\text{ava}, A, V)$

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

$Y = \text{step}(\text{ava}, A)$ returns Y , the result of adding the input array A to the elements of the vector specified in the `Vector` property along the specified dimension when the `VectorSource` property is `Property`. The length of the vector specified in the `Vector` property must equal the length of the specified dimension of A .

$Y = \text{step}(\text{ava}, A, V)$ returns Y , the result of adding the input array A to the elements of the input vector V along the specified dimension when the `VectorSource` property is `Input port`. The length of the input V must equal the length of the specified dimension of A .

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.ArrayVectorDivider

Package: dsp

(To be removed) Divide array by vector along specified dimension

Note `dsp.ArrayVectorDivider` will be removed in a future release. Use the `./` operator instead. For more information, see “Compatibility Considerations”.

Description

The `ArrayVectorDivider` object divides an array by a vector along a specified dimension.

To divide an array by a vector along a specified dimension:

- 1 Define and set up your array-vector division object. See “Construction” on page 4-75.
- 2 Call `step` to divide the array according to the properties of `dsp.ArrayVectorDivider`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`avd = dsp.ArrayVectorDivider` returns an array-vector division object, `avd`, that divides an input array by the elements of a vector along the first dimension of the array.

`avd = dsp.ArrayVectorDivider('PropertyName',PropertyValue,...)` returns an array-vector division object, `avd`, with each property set to the specified value.

Properties

Dimension

Dimension along which to divide input by vector elements

Specify the dimension along which to divide the input array by the elements of a vector as a positive integer. The default is 1.

VectorSource

Source of vector

Specify the source of the vector values as `| Input port | Property |`. The default is `Input port`.

Vector

Vector values

Specify the vector values. This property applies when you set the `VectorSource` property to `Property`. The default is `[0.5 0.25]`. This property is tunable.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `| Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `| Wrap | Saturate |`. The default is `Wrap`.

VectorDataType

Vector word and fraction lengths

Specify the vector fixed-point mode as `| Same word length as input | Custom |`. This property applies when you set the `VectorSource` property to `Property`. The default is `Same word length as input`.

CustomVectorDataType

Vector word and fraction lengths

Specify the vector fixed-point data type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `VectorSource` property to `Property` and the `VectorDataType` property to `Custom`. The default is `numericType([], 16, 15)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as `| Same as first input | Custom |`. The default is `Same as first input`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the “`OutputDataType`” on page 4-0 property to `Custom`. The default is `numericType([],16,15)`.

Methods

`step` Divide array by vector

Common to All System Objects	
<code>release</code>	Allow System object property value changes

Examples

Divide a Matrix By a Vector

Note If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

```
avd = dsp.ArrayVectorDivider;
a = ones(2);
x = [2 3]';
y = avd(a, x)
```

`y = 2×2`

```
    0.5000    0.5000
    0.3333    0.3333
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Array-Vector Divide block reference page. The object properties correspond to the block parameters, except:

The array-vector division object does not have **Minimum** or **Maximum** options for data output.

Version History

Introduced in R2012a

dsp.ArrayVectorDivider System object will be removed

Warns starting in R2021b

`dsp.ArrayVectorDivider` System object will be removed in a future release. Use the `./` operator instead.

Update Code

This table shows how the System object is typically used and explains how to update existing code to use the `./` operator.

Discouraged Usage	Recommended Replacement
<p>Column-wise array division</p> <p>By default, the object computes column-wise array division since the <code>Dimension</code> property of the object is set to 1.</p> <pre>avd = dsp.ArrayVectorDivider; a = ones(2); x = [2; 3]; y = avd(a, x)</pre> <p>$y = 2 \times 2$</p> <pre> 0.5000 0.5000 0.3333 0.3333</pre> <p>Row-wise array division</p> <p>To perform row-wise array division, set the <code>Dimension</code> property to 2 and rerun the object algorithm.</p> <pre>release(avd); avd.Dimension = 2; y = avd(a, x)</pre> <p>$y = 2 \times 2$</p> <pre> 0.5000 0.3333 0.5000 0.3333</pre> <p>If you are using a release prior to R2016b, replace <code>avd(a, x)</code> with <code>step(avd, a, x)</code>.</p>	<p>Column-wise array division</p> <pre>y = a ./ x</pre> <p>$y = 2 \times 2$</p> <pre> 0.5000 0.5000 0.3333 0.3333</pre> <p>Row-wise array division</p> <pre>y = a ./ x'</pre> <p>$y = 2 \times 2$</p> <pre> 0.5000 0.3333 0.5000 0.3333</pre>

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

step

System object: dsp.ArrayVectorDivider

Package: dsp

Divide array by vector

Syntax

$Y = \text{step}(\text{avd}, A, V)$

$Y = \text{step}(\text{avd}, A)$

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

$Y = \text{step}(\text{avd}, A, V)$ returns Y , the result of dividing the input array A by the elements of input vector V along the specified dimension when the `VectorSource` property is `Input port`. The length of the input V must equal the length of the specified dimension of A .

$Y = \text{step}(\text{avd}, A)$ returns Y , the result of dividing the input array A by the elements of the vector specified in the `Vector` property along the specified dimension when the `VectorSource` property is `Property`. The length of the vector specified in the `Vector` property must equal the length of the specified dimension of A .

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.ArrayVectorMultiplier

Package: dsp

(To be removed) Multiply array by vector along specified dimension

Note `dsp.ArrayVectorMultiplier` will be removed in a future release. Use the `.*` operator instead. For more information, see “Compatibility Considerations”.

Description

The `ArrayVectorMultiplier` object multiplies an array by a vector along a specified dimension.

To multiply an array by a vector along a specified:

- 1 Define and set up your array-vector multiplication object. See “Construction” on page 4-80.
- 2 Call `step` to multiply the array according to the properties of `dsp.ArrayVectorMultiplier`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Construction

`avm = dsp.ArrayVectorMultiplier` returns an array-vector multiplication object, `avm`, that multiplies an input N-D array by the elements of a vector along the second dimension.

`avm = dsp.ArrayVectorMultiplier('PropertyName', PropertyValue, ...)` returns an array-vector multiplication object, `avm`, with each property set to the specified value.

Properties

Dimension

Dimension along which to multiply input by vector elements

Specify the dimension along which to multiply the input array by the elements of vector as a positive integer. The default is 2.

VectorSource

Source of vector

Specify the source of the vector values as one of `Input port` or `Property`. The default is `Input port`.

Vector

Vector to multiply array

Specify the vector by which to multiply the array. This property applies when you set the VectorSource property to Property. The default is [0.5 0.25]. This property is tunable.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as Ceiling, Convergent, Floor, Nearest, Round, Simplest, Zero. The default is floor.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as Wrap or Saturate. The default is Wrap.

VectorDataType

Vector word and fraction lengths

Specify the vector fixed-point data type as Same word length as input, Custom. This property applies when you set the VectorSource property to Property. The default is Same word length as input.

CustomVectorDataType

Vector word and fraction lengths

Specify the vector fixed-point type as a numeric type object with a Signedness of Auto. This property applies when you set the VectorSource property to Property and the VectorDataType property to Custom. The default is numeric type ([], 16, 15).

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as Full precision, Same as first input, or Custom. The default is Full precision.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as `Full precision`, `Same as product`, `Same as first input`, or `Custom`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as `Same as product`, `Same as first input`, or `Custom`. The default is `Same as product`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numericType([], 16, 15)`.

Methods

`step` Multiply array by vector

Common to All System Objects	
<code>release</code>	Allow System object property value changes

Examples

Multiply a Matrix by a Vector

Note If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj, x)`.

```
avm = dsp.ArrayVectorMultiplier;
a = ones(2);
x = [2 3]';
y = avm(a, x)
```

```
y = 2×2
```

```
    2    3
    2    3
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Array-Vector Multiply block reference page. The object properties correspond to the block parameters, except:

- The array-vector multiplication object does not have **Minimum** or **Maximum** options for data output.

Version History

Introduced in R2012a

dsp.ArrayVectorMultiplier System object will be removed

Warns starting in R2021b

dsp.ArrayVectorMultiplier System object will be removed in a future release. Use the .* operator instead.

Update Code

This table shows how the System object is typically used and explains how to update existing code to use the .* operator.

Discouraged Usage	Recommended Replacement
<p>Row-wise array multiplication</p> <p>By default, the object computes row-wise array multiplication since the Dimension property of the object is set to 2.</p> <pre>avm = dsp.ArrayVectorMultiplier; a = ones(2); x = [2; 3]; y = avm(a, x)</pre> <p>y = 2×2</p> <pre> 2 3 2 3</pre> <p>Column-wise array multiplication</p> <p>To perform column-wise array multiplication, set the Dimension property to 1 and rerun the object algorithm.</p> <pre>release(avm); avm.Dimension = 1; y = avm(a, x)</pre> <p>y = 2×2</p> <pre> 2 2 3 3</pre> <p>If you are using a release prior to R2016b, replace <code>avm(a, x)</code> with <code>step(avm, a, x)</code>.</p>	<p>Row-wise array multiplication</p> <pre>y = a .* x'</pre> <p>y = 2×2</p> <pre> 2 3 2 3</pre> <p>Column-wise array multiplication</p> <pre>y = a .* x</pre> <p>y = 2×2</p> <pre> 2 2 3 3</pre>

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

step

System object: dsp.ArrayVectorMultiplier

Package: dsp

Multiply array by vector

Syntax

$Y = \text{step}(\text{avm}, A, V)$

$Y = \text{step}(\text{avm}, A)$

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

$Y = \text{step}(\text{avm}, A, V)$ returns Y , the result of multiplying the input array A by the elements of input vector V along the specified dimension when the `VectorSource` property is `Input port`. The length of the input V must equal the length of the specified dimension of A .

$Y = \text{step}(\text{avm}, A)$ returns Y , the result of multiplying the input array A by the elements of vector specified in `Vector` property along the specified dimension when the `VectorSource` property is set to `Property`. The length of the vector specified in `Vector` property must equal the length of the specified dimension of A .

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.ArrayVectorSubtractor

Package: dsp

(To be removed) Subtract vector from array along specified dimension

Note `dsp.ArrayVectorSubtractor` will be removed in a future release. Use the `-` operator instead. For more information, see “Compatibility Considerations”.

Description

The `ArrayVectorSubtractor` object subtracts a vector from an N-D array along a specified dimension.

To subtract a vector from an N-D array along a specified dimension:

- 1 Define and set up your array-vector subtraction object. See “Construction” on page 4-86.
- 2 Call `step` to subtract the vector according to the properties of `dsp.ArrayVectorSubtractor`. The behavior of `step` is specified to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Construction

`avs = dsp.ArrayVectorSubtractor` returns an array-vector subtraction object, `avs`, that subtracts the elements of a vector from an N-D input array along the first dimension.

`avs = dsp.ArrayVectorSubtractor('PropertyName', PropertyValue, ...)` returns an array-vector subtraction object, `avs`, with each property set to the specified value.

Properties

Dimension

Dimension along which to subtract vector elements from input

Specify the dimension along which to subtract the elements of the vector from the input array as an integer-valued scalar greater than 0. The default is 1.

VectorSource

Source of vector

Specify the source of the vector values as one of `Input port` or `Property`. The default is `Input port`.

Vector

Vector values

Specify the vector values. This property applies when you set the `VectorSource` property to `Property`. The default is `[0.5 0.25]`. This property is tunable.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. This property applies only if the object is not in full precision mode.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

VectorDataType

Vector word and fraction lengths

Specify the vector fixed-point data type as `Same word length as input` or `Custom`. This property applies when you set the `VectorSource` property to `Property`. The default is `Same word length as input`.

CustomVectorDataType

Vector word and fraction lengths

Specify the vector fixed-point type as a `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `VectorSource` property to `Property` and the `VectorDataType` property to `Custom`. The default is `numericType([],16,15)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `Full precision`, `Same as first input`, or `Custom`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([],32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as `Same as accumulator`, `Same as first input`, or `Custom`. The default is `Same as accumulator`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the “`OutputDataType`” on page 4-0 property to `Custom`. The default is `numericType([],16,15)`.

Methods

`step` Subtract vector from array along specified dimension

Common to All System Objects	
<code>release</code>	Allow System object property value changes

Examples

Subtract Vector From Matrix

Note If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

```

avs = dsp.ArrayVectorSubtractor;
a = ones(2);
x = [1 2]';
y = avs(a, x)

```

```

y = 2×2

```

```

    0    0
   -1   -1

```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Array-Vector Subtract block reference page. The object properties correspond to the block parameters, except:

The array-vector subtraction object does not have **Minimum** or **Maximum** options for data output.

Version History

Introduced in R2012a

dsp.ArrayVectorSubtractor System object will be removed

Warns starting in R2021b

`dsp.ArrayVectorSubtractor` System object will be removed in a future release. Use the `-` operator instead.

Update Code

This table shows how the System object is typically used and explains how to update existing code to use the `-` operator.

Discouraged Usage	Recommended Replacement
<pre> avs = dsp.ArrayVectorSubtractor; a = ones(2); x = [1 2]'; y = avs(a, x) y = 2×2 0 0 -1 -1 </pre>	<pre> y = a - x y = 2×2 0 0 -1 -1 </pre>
<p>If you are using a release prior to R2016b, replace <code>avs(a, x)</code> with <code>step(avs, a, x)</code>.</p>

step

System object: dsp.ArrayVectorSubtractor

Package: dsp

Subtract vector from array along specified dimension

Syntax

$Y = \text{step}(\text{avs}, A, V)$

$Y = \text{step}(\text{avs}, A)$

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

$Y = \text{step}(\text{avs}, A, V)$ returns Y . The value of Y results from subtracting the elements of input vector V from the input array A along the specified dimension when the `VectorSource` property is `Input port`. The length of the input V must equal the length of the specified dimension of A .

$Y = \text{step}(\text{avs}, A)$ returns Y . The value of Y results from subtracting the elements of the vector specified in the `Vector` property from the input array A along the specified dimension when the `VectorSource` property is `Property`. The length of the vector specified in the `Vector` property must equal the length of the specified dimension of A .

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.AsyncBuffer

Package: dsp

FIFO buffer

Description

The `dsp.AsyncBuffer` System object writes samples to and reads samples from a first-in, first-out (FIFO) buffer. The `write` method writes data to the buffer, and the `read` method reads data from the buffer. When creating the object, you can set the number of samples (rows) of the buffer using the `Capacity` property. The number of channels (columns) is set during the first call to `write`. Initialize the buffer by calling `write` or `setup` before the first call to `read`.

The data that you write occupies the next available space in the buffer. If the buffer is full and all the data within it is unread (`asyncBuff.NumUnreadSamples == asyncBuff.Capacity`), the object overwrites the oldest data with any new data that comes in. The buffer removes data only when the data is overwritten, so you can reread data from the past. The `dsp.AsyncBuffer` object supports writing and reading variable frame size signals. For examples, see “Read Variable Frame Sizes from Buffer” on page 4-94 and “Write Variable Frame Sizes to Buffer” on page 4-96.

To write and read samples from a FIFO buffer:

- Create a `dsp.AsyncBuffer` object and set the properties of the object.
- Call `write` to write samples to the buffer.
- Call `read` to read samples from the buffer.
- Call `peek` to read samples without changing the number of unread samples in the buffer.

Creation

Syntax

```
asyncBuff = dsp.AsyncBuffer  
asyncBuff = dsp.AsyncBuffer(cap)
```

Description

`asyncBuff = dsp.AsyncBuffer` returns an async buffer System object, `asyncBuff`, using the default properties.

`asyncBuff = dsp.AsyncBuffer(cap)` sets the `Capacity` property to `cap`.

Example: `asyncBuff = dsp.AsyncBuffer(200000);`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Capacity — Number of writable/readable rows in buffer

192000 (default) | positive integer

Number of writable/readable rows in the buffer, specified as a positive integer greater than or equal to 2. The number of rows during each write to the buffer must not exceed the capacity of the buffer. If the buffer is full and all the data within is unread, the object overwrites the oldest data with any new data that comes in. The `CumulativeOverrun` property returned by `info` gives the number of samples overrun per channel since the last call to `reset`. The number of samples overrun is the number of unread samples overwritten.

By default, this property has data type `int32`.

Example: `asyncBuff = dsp.AsyncBuffer(200000);`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

NumUnreadSamples — Number of unread samples in each channel

0 (default) | integer

This property is read-only.

Number of unread samples in each channel (column) of the buffer, specified as an integer greater than or equal to 0. The total number of unread samples in the buffer is `NumUnreadSamples × numChann`. The variable `numChann` is the number of channels in the buffer. The number of channels in the buffer is the number of data columns in the first call to `write`.

The `CumulativeUnderrun` property returned by the `info` method gives the number of samples underrun per channel since the last call to `reset`. Underrun occurs if you attempt to read more samples than available.

Example: `asyncBuff = dsp.AsyncBuffer; input = randn(512,1); numUnreadSamples = write(asyncBuff,input)`

Data Types: `int32`

Usage

To write and read samples from the async buffer:

- Create a `dsp.AsyncBuffer` object and set the properties of the object.
- Call `write` to write samples to the buffer.
- Call `read` to read samples from the buffer.
- Call `peek` to read samples without changing the number of unread samples in the buffer.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

`release(obj)`

Specific to `dsp.AsyncBuffer`

`info` Get cumulative overrun and underrun
`read` Read data from buffer
`write` Write data to buffer
`peek` Read data from buffer without changing number of unread samples

Common to All System Objects

`step` Run System object algorithm
`release` Release resources and allow changes to System object property values and input characteristics
`reset` Reset internal states of System object

Examples

Read Variable Frame Sizes from Buffer

The `dsp.AsyncBuffer` System object™ supports reading variable frame sizes from the buffer.

Create a `dsp.AsyncBuffer` System object. The input is white Gaussian noise with a mean of 0, a standard deviation of 1, and a frame size of 512 samples. Write the input to the buffer using the `write` method.

```
asyncBuff = dsp.AsyncBuffer;  
input = randn(512,1);  
write(asyncBuff,input);  
plot(input)  
hold on
```

Store the data that is read from the buffer in `outTotal`.

Plot the input signal and data that is read from the buffer in the same plot. Read data from the buffer until all samples are read. In each iteration of the loop, `randi` determines the number of samples to read. Therefore, the signal is read in as a variable-size signal. The `prevIndex` variable keeps track of the previous index value that contains the data.

```

outTotal = zeros(size(input));
prevIndex = 0;
while asyncBuff.NumUnreadSamples ~= 0
    numToRead = randi([1,64]);
    out = read(asyncBuff,numToRead);
    outTotal(prevIndex+1:prevIndex+numToRead) = out;
    prevIndex = prevIndex+numToRead;
end
plot(outTotal,'r')
hold off

```

Verify that the input data and the data read from the buffer (excluding the underrun samples, if any) are the same. The cumulative number of overrun and underrun samples in the buffer is determined by the `info` function.

```
S = info(asyncBuff)
```

```
S = struct with fields:
    CumulativeOverrun: 0
    CumulativeUnderrun: 28
```

The `CumulativeUnderrun` field shows the number of samples underrun per channel. Underrun occurs if you attempt to read more samples than available.

Write Variable Frame Sizes to Buffer

Write a sine wave of variable frame size to the buffer. Compute the FFT of the sine wave and visualize the result on an array plot.

Initialize the `dsp.AsyncBuffer`, `dsp.ArrayPlot`, and `dsp.FFT` System objects.

```
asynBuff = dsp.AsyncBuffer;
plotter = dsp.ArrayPlot;
fftObj = dsp.FFT('FFTLengthSource','Property','FFTLength',256);
```

The sine wave is generated using the `sin` function in MATLAB. The `start` and `finish` variables mark the start and finish indices of each frame. If enough data is cached, read from the buffer and perform the FFT. View the FFT on an array plot.

```
start = 1;

for Iter = 1 : 2000
    numToWrite = randi([200,800]);
    finish = start + numToWrite;

    inputData = sin(start:finish)';
    start = finish + 1;

    write(asynBuff,inputData);
    while asynBuff.NumUnreadSamples >= 256
        x = read(asynBuff,256);
        X = abs(fft0bj(x));
        plotter(log(X));
    end
end
```

Peek Data from Async Buffer

Read data from the async buffer without changing the number of unread samples using the `peek` function.

Create a `dsp.AsyncBuffer` System object™. The input is a column vector of 100 samples, 1 to 100. Write the data to the buffer.

```
asyncBuff = dsp.AsyncBuffer
asyncBuff =
  AsyncBuffer with properties:
      Capacity: 192000
  NumUnreadSamples: 0
```

```
input = (1:100)';
write(asyncBuff,input);
```

Peek at the first three samples. The output is [1 2 3]′.

```
out1 = peek(asyncBuff,3)
out1 = 3×1
     1
     2
     3
```

The `NumUnreadSamples` is 100, indicating that the peek function has not changed the number of unread samples in the buffer.

```
asyncBuff.NumUnreadSamples
ans = int32
    100
```

After peeking, read 50 samples using the `read` function. The output is [1:50]′.

```
out2 = read(asyncBuff,50)
out2 = 50×1
     1
     2
     3
     4
     5
     6
     7
     8
     9
    10
     :
```

The `NumUnreadSamples` is 50, indicating that the `read` function has changed the number of unread samples in the buffer.

```
asyncBuff.NumUnreadSamples
ans = int32
    50
```

Now peek again at the first three samples. The output is [51 52 53]'. Verify that the `NumUnreadSamples` is still 50.

```
out3 = peek(asyncBuff,3)
```

```
out3 = 3×1
```

```
51
52
53
```

```
asyncBuff.NumUnreadSamples
```

```
ans = int32
50
```

Read 50 samples again. The output now contains the sequence [51:100]'. Verify that `NumUnreadSamples` is 0.

```
out4 = read(asyncBuff)
```

```
out4 = 50×1
```

```
51
52
53
54
55
56
57
58
59
60
⋮
```

```
asyncBuff.NumUnreadSamples
```

```
ans = int32
0
```

Limitations

Before calling the `read` method, you must initialize the buffer by calling either the `write` or `setup` method. For an example, see “Why Does the `dsp.AsyncBuffer` Object Error When You Call `read` Before `write`?”

“High Resolution Spectral Analysis in MATLAB”

audioDeviceWriter

Play to sound card

Description

The `audioDeviceWriter` System object writes audio samples to an audio output device. Properties of the audio device writer specify the driver, the device, and device attributes such as sample rate, bit depth, and buffer size.

Data Flow of Audio Device Writer

- Call the object to input an audio signal frame to the `audioDeviceWriter`.
- The `audioDeviceWriter` uses the specified driver to pass the frame (device input) to the buffer of your specified audio device.
- The audio device performs digital-to-analog conversion at the specified sample rate and bit depth.
- The audio device outputs an analog chunk to your speaker.

To stream data to an audio device:

- 1 Create the `audioDeviceWriter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
deviceWriter = audioDeviceWriter
deviceWriter = audioDeviceWriter(sampleRateValue)
deviceWriter = audioDeviceWriter( ___,Name,Value)
```

Description

`deviceWriter = audioDeviceWriter` returns a System object, `deviceWriter`, that writes audio samples to an audio output device in real time.

`deviceWriter = audioDeviceWriter(sampleRateValue)` sets the `SampleRate` property to `sampleRateValue`.

`deviceWriter = audioDeviceWriter(____, Name, Value)` sets each property `Name` to the specified `Value`. Unspecified properties have default values.

Example: `deviceWriter = audioDeviceWriter(48000, 'BitDepth', '8-bit integer')` creates a System object, `deviceWriter`, that operates at a 48 kHz sample rate and an 8-bit integer bit depth.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

Driver — Driver used to access audio device (Windows only)

'DirectSound' (default) | 'ASIO' | 'WASAPI'

Driver used to access your audio device, specified as 'DirectSound', 'ASIO', or 'WASAPI'.

- ASIO drivers do not come pre-installed on Windows machines. To use the 'ASIO' driver option, install an ASIO driver outside of MATLAB.

Note If `Driver` is specified as 'ASIO', use `asioSettings` to set the sound card buffer size to the buffer size of your `audioDeviceWriter` System object.

- WASAPI drivers are supported for exclusive-mode only.

ASIO and WASAPI drivers do not provide sample rate conversion. For ASIO and WASAPI drivers, set `SampleRate` to a sample rate supported by your audio device.

This property applies only on Windows machines. Linux machines always use the ALSA driver. Mac machines always use the CoreAudio driver.

To specify nondefault `Driver` values, you must have an Audio Toolbox license. If the toolbox is not installed, specifying nondefault `Driver` values returns an error.

Data Types: `char` | `string`

Device — Device used to play audio samples

default audio device (default) | character vector | string scalar

Device used to play audio samples, specified as a character vector or string scalar. Use `getAudioDevices` to list available devices for the selected driver.

Data Types: `char` | `string`

SampleRate — Sample rate of signal sent to audio device (Hz)

44100 (default) | positive integer

Sample rate of signal sent to audio device, in Hz, specified as a positive integer. The range of `SampleRate` depends on your audio hardware.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`**BitDepth — Data type used by the device**

'16-bit integer' (default) | '8-bit integer' | '24-bit integer' | '32-bit float'

Data type used by the device, specified as a character vector or string scalar. Before performing digital-to-analog conversion, the input data is cast to a data type specified by `BitDepth`.

To specify a nondefault `BitDepth`, you must have an Audio Toolbox license. If the toolbox is not installed, specifying a nondefault `BitDepth` returns an error.

Data Types: `char` | `string`**SupportVariableSizeInput — Support variable frame size**`false` (default) | `true`

Option to support variable frame size, specified as `true` or `false`.

- `false` -- If the `audioDeviceWriter` object is locked, the input must have the same frame size at each call. The buffer size of your audio device is the same as the input frame size.
- `true` -- If the `audioDeviceWriter` object is locked, the input frame size can change at each call. The buffer size of your audio device is specified through the `BufferSize` property.

Data Types: `char`**BufferSize — Buffer size of audio device**

4096 (default) | positive integer

Buffer size of audio device, specified as a positive integer.

Note If `Driver` is specified as 'ASIO', open the ASIO UI to set the sound card buffer size to the `BufferSize` value of your `audioDeviceWriter` System object.

Dependencies

To enable this property, set `SupportVariableSizeInput` to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`**ChannelMappingSource — Source of mapping between input matrix and device channels**

'Auto' (default) | 'Property'

Source of mapping between columns of input matrix and channels of audio output device, specified as 'Auto' or 'Property'.

- 'Auto' -- Default settings determine the mapping between columns of input matrix and channels of audio output device. For example, suppose that your input is a matrix with four columns, and your audio device has four channels available. Column 1 of your input data writes to channel 1 of your device, column 2 of your input data writes to channel 2 of your device, and so on.

- 'Property' -- The ChannelMapping property determines the mapping between columns of input matrix and channels of audio output device.

Data Types: char | string

ChannelMapping — Nondefault mapping between input matrix and device channels

[1:MaximumOutputChannels] (default) | scalar | vector

Nondefault mapping between columns of input matrix and channels of output device, specified as a scalar or vector of valid channel indices.

To selectively map between columns of the input matrix and your sound card's output channels, you must have an Audio Toolbox license. If the toolbox is not installed, specifying a nondefault ChannelMapping returns an error.

Note To ensure mono output on only one channel of a stereo device, use the default ChannelMapping setting and provide a stereo signal where one channel is all zeros.

Example: outputLeftOnly = [x(:,1) zeros(size(x,1),1)];

Example: outputRightOnly = [zeros(size(x,1),1) x(:,1)];

Dependencies

To enable this property, set ChannelMappingSource to 'Property'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Usage

Syntax

```
numUnderrun = deviceWriter(audioToDevice)
```

Description

numUnderrun = deviceWriter(audioToDevice) writes one frame of audio samples, audioToDevice, to the selected audio device and returns the number of audio samples underrun since the last call to deviceWriter.

Note: When you call the audioDeviceWriter System object, the audio device specified by the Device property is locked. An audio device can be locked by only one audioDeviceWriter at a time. To release the audio device, call release on your audioDeviceWriter System object.

Input Arguments

audioToDevice — Audio to device

matrix

Audio signal to write to device, specified as a matrix. The columns of the matrix are treated as independent audio channels.

If `audioToDevice` is of data type `'double'` or `'single'`, the audio device writer clips values outside the range `[-1, 1]`. For other data types, the allowed input range is `[min, max]` of the specified data type.

Data Types: `single` | `double` | `int16` | `int32` | `uint8`

Output Arguments

numUnderrun — Number of samples underrun

scalar

Number of samples by which the audio device writer queue was underrun since the last call to `deviceWriter`.

Data Types: `uint32`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to audioDeviceWriter

<code>getAudioDevices</code>	List available audio devices
<code>info</code>	Characteristic information about audio device writer

Common to All System Objects

<code>clone</code>	Create duplicate System object
<code>isLocked</code>	Determine if System object is in use
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object
<code>step</code>	Run System object algorithm
<code>setup</code>	One-time set up tasks for System objects

Examples

Read from File and Write to Audio Device

Read an MP3 audio file and play it through your default audio output device.

Create a `dsp.AudioFileReader` object with default settings. Use the `audioinfo` function to return a structure containing information about the audio file.

```
fileReader = dsp.AudioFileReader('speech_dft.mp3');
fileInfo = audioinfo('speech_dft.mp3')

fileInfo = struct with fields:
    Filename: 'B:\matlab\toolbox\dsp\samples\speech_dft.mp3'
    CompressionMethod: 'MP3'
    NumChannels: 1
```

```
SampleRate: 22050
TotalSamples: 112893
Duration: 5.1199
  Title: []
  Comment: []
  Artist: []
BitRate: 64
```

Create an `audioDeviceWriter` object and specify the sample rate.

```
deviceWriter = audioDeviceWriter('SampleRate', fileInfo.SampleRate);
```

Call `setup` to reduce the computational load of initialization in an audio stream loop.

```
setup(deviceWriter, zeros(fileReader.SamplesPerFrame, ...
    fileInfo.NumChannels))
```

Use the `info` function to obtain the characteristic information about the device writer.

```
info(deviceWriter)
ans = struct with fields:
    Driver: 'DirectSound'
    DeviceName: 'Primary Sound Driver'
    MaximumOutputChannels: 2
```

In an audio stream loop, read an audio signal frame from the file, and write the frame to your device.

```
while ~isDone(fileReader)
    audioData = fileReader();
    deviceWriter(audioData);
end
```

Close the input file and release the device.

```
release(fileReader)
release(deviceWriter)
```

Reduce Latency due to Output Device Buffer

Latency due to the output device buffer is the time delay of writing one frame of data. Modify default properties of your `audioDeviceWriter` System object™ to reduce latency due to device buffer size.

Create a `dsp.AudioFileReader` System object to read an audio file with default settings.

```
fileReader = dsp.AudioFileReader('speech_dft.mp3');
```

Create an `audioDeviceWriter` System object and specify the sample rate to match that of the audio file reader.

```
deviceWriter = audioDeviceWriter(...
    'SampleRate', fileReader.SampleRate);
```

Calculate the latency due to your device buffer, in seconds.

```
bufferLatency = fileReader.SamplesPerFrame/deviceWriter.SampleRate %#ok
bufferLatency = 0.0464
```

Set the `SamplesPerFrame` property of your `dsp.AudioFileReader` System object to 256. Calculate the buffer latency in seconds.

```
fileReader.SamplesPerFrame = 256;
bufferLatency = fileReader.SamplesPerFrame/deviceWriter.SampleRate
bufferLatency = 0.0116
```

Determine and Decrease Underrun

Underrun refers to output signal silence, which occurs when the audio stream loop does not keep pace with the output device. Determine the underrun of an audio stream loop, add artificial computational load to the audio stream loop, and then modify properties of your `audioDeviceWriter` object to decrease underrun. Your results depend on your computer.

Create a `dsp.AudioFileReader` object, and specify the file to read. Use the `audioinfo` function to return a structure containing information about the audio file.

```
fileReader = dsp.AudioFileReader('speech_dft.mp3');
fileInfo = audioinfo('speech_dft.mp3');
```

Create an `audioDeviceWriter` object. Use the `SampleRate` of the file reader as the `SampleRate` of the device writer. Call `setup` to reduce the computational load of initialization in an audio stream loop.

```
deviceWriter = audioDeviceWriter('SampleRate',fileReader.SampleRate);
setup(deviceWriter,zeros(fileReader.SamplesPerFrame,...
    fileInfo.NumChannels))
```

Run your audio stream loop with input from file and output to device. Print the total samples underrun and the underrun in seconds.

```
totalUnderrun = 0;
while ~isDone(fileReader)
    input = fileReader();
    numUnderrun = deviceWriter(input);
    totalUnderrun = totalUnderrun + numUnderrun;
end
fprintf('Total samples underrun: %d.\n',totalUnderrun)
```

```
Total samples underrun: 0.
```

```
fprintf('Total seconds underrun: %d.\n',double(totalUnderrun)/double(deviceWriter.SampleRate))
```

```
Total seconds underrun: 0.
```

Release your `dsp.AudioFileReader` and `audioDeviceWriter` objects and set your counter variable to zero.

```
release(fileReader)
release(deviceWriter)
totalUnderrun = 0;
```

Use `pause` to mimic an algorithm that takes 0.075 seconds to process. The pause causes the audio stream loop to go slower than the device, which results in periods of silence in the output audio signal.

```
while ~isDone(fileReader)
    input = fileReader();
    numUnderrun = deviceWriter(input);
    totalUnderrun = totalUnderrun + numUnderrun;
    pause(0.075)
end
fprintf('Total samples underrun: %d.\n',totalUnderrun)
```

Total samples underrun: 68608.

```
fprintf('Total seconds underrun: %d.\n',double(totalUnderrun)/double(deviceWriter.SampleRate))
```

Total seconds underrun: 3.111474e+00.

Release your `audioDeviceReader` and `dsp.AudioFileWriter` and set the counter variable to zero.

```
release(fileReader)
release(deviceWriter)
totalUnderrun = 0;
```

Set the frame size of your audio stream loop to 2048. Because the `SupportVariableSizeInput` property of your `audioDeviceWriter` System object is set to `false`, the buffer size of your audio device is the same size as the input frame size. Increasing your device buffer size decreases underrun.

```
fileReader = dsp.AudioFileReader('speech_dft.mp3');
fileReader.SamplesPerFrame = 2048;
fileInfo = audioinfo('speech_dft.mp3');
```

```
deviceWriter = audioDeviceWriter('SampleRate',fileReader.SampleRate);
setup(deviceWriter,zeros(fileReader.SamplesPerFrame,fileInfo.NumChannels))
```

Calculate the total underrun.

```
while ~isDone(fileReader)
    input = fileReader();
    numUnderrun = deviceWriter(input);
    totalUnderrun = totalUnderrun + numUnderrun;
    pause(0.075)
end
fprintf('Total samples underrun: %d.\n',totalUnderrun)
```

Total samples underrun: 0.

```
fprintf('Total seconds underrun: %d.\n',double(totalUnderrun)/double(deviceWriter.SampleRate))
```

Total seconds underrun: 0.

The increased frame size reduces the total underrun of your audio stream loop. However, increasing the frame size also increases latency. Other approaches to reduce underrun include:

- Increasing the buffer size independent of input frame size. To increase buffer size independent of input frame size, you must first set `SupportVariableSizeInput` to `true`. This approach also increases latency.

- Decreasing the sample rate. Decreasing the sample rate reduces both latency and underrun at the cost of signal resolution.
- Choosing an optimal driver and device for your system.

Version History

Introduced in R2016a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- “System Objects in MATLAB Code Generation” (MATLAB Coder)
- The executable generated from this System object relies on prebuilt dynamic library files (.dll files) included with MATLAB. Use the `packNGo` function to package the code generated from this object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

Topics

“How To Run a Generated Executable Outside MATLAB”

“Measure Audio Latency” (Audio Toolbox)

getAudioDevices

List available audio devices

Syntax

```
devices = getAudioDevices(deviceWriter)
```

Description

`devices = getAudioDevices(deviceWriter)` returns a list of audio devices that are available and compatible with your I/O audio object, `deviceWriter`.

Input Arguments

deviceWriter — Audio I/O object

`audioDeviceWriter` object

Audio I/O object, specified as an `audioDeviceWriter` object.

Data Types: `object`

Output Arguments

devices — List of available and compatible devices

`array`

List of available and compatible devices. The list of audio devices depends on the specified `Driver` property of your object.

Data Types: `cell`

Version History

Introduced in R2016a

Objects

`audioDeviceWriter`

dsp.AudioFileReader

Package: dsp

Stream from audio file

Description

The `dsp.AudioFileReader` System object reads audio samples from an audio file.

To read audio samples from an audio file:

- 1 Create the `dsp.AudioFileReader` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
afr = dsp.AudioFileReader
afr = dsp.AudioFileReader(Filename)
afr = dsp.AudioFileReader(Name,Value)
```

Description

`afr = dsp.AudioFileReader` returns an audio file reader System object, `afr` that reads audio from an audio file.

`afr = dsp.AudioFileReader(Filename)` returns an audio file reader object, `afr`, with `Filename` property set to `Filename`.

`afr = dsp.AudioFileReader(Name,Value)` returns an audio file reader System object, `afr`, with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Filename — Name of audio file from which to read

'speech_dft.mp3' (default) | character vector | string scalar

Specify the name of an audio file as a character vector or a string scalar. If `FilenameIsTunableInCodegen` is set to `false` and the file is on MATLAB path, then you do not need to specify the full name of the file. If `FilenameIsTunableInCodegen` is set to `true`, then the file name must either exist in the current directory, or you must specify the full file path. The file name can be an http web address like `'http://audio.wgbh.org:8004/'`. For an example, see “Read and Play Back Audio File from http Web Address” on page 4-115.

The `Filename` property is tunable in generated code. That is, you can pass the name of the audio file as an input while running the code generated from this object. File attributes such as the audio format, the number of audio channels, the sample rate, and the bit rate are not tunable and must match the attributes of the prototype audio file you specify through the `CodegenPrototypeFile` property. The specified prototype audio file determines the attributes and the type of audio files that can be read by the generated code. For an example, see “Tunable Audio File Name in Generated Code” on page 4-116.

The following table lists the supported audio file formats.

Platforms	File Name Extensions
Windows	.wav, .wma, .avi, .aif, .aifc, .aiff, .mp3, .opus, .au, .snd, .mp4, .m4a, .flac, .ogg, .mov
Non-Windows	.avi, .mp3, .mp4, .m4a, .wav, .flac, .ogg, .aif, .aifc, .aiff, .opus, .au, .snd, .mov

PlayCount — Number of times to play file

1 (default) | positive integer

Specify a positive integer as the number of times to play the file.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

SamplesPerFrame — Number of samples in audio frame

1024 (default) | positive integer

Specify the number of samples in an audio frame as a positive, scalar integer value.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

OutputDataType — Data type of output

'double' (default) | 'single' | 'int16' | 'uint8'

Set the data type of the audio data output from the audio file reader object. Specify the data type as 'double', 'single', 'int16', or 'uint8'.

FilenameIsTunableInCodegen — Enable file name tunability in generated code

false (default) | true

Set this property to true to enable tunability of `Filename` in generated C/C++ code. The file with the specified `Filename` must either exist in the current directory, or you must specify the full file path.

If `FilenameIsTunableInCodegen` is set to `true`, file attributes such as the audio format, the number of audio channels, the sample rate, and the bit rate are not tunable and must match the attributes of the prototype audio file you specify through the `CodegenPrototypeFile` property. The specified prototype audio file determines the attributes and the type of audio files that can be read by the generated code. For example, if the specified prototype file is a `.wav` file, then the generated

code can only read .wav files. If the specified prototype file sample rate is 44100 Hz, then the generated code can read files with a sample rate of 44100 Hz.

Data Types: `logical`

CodegenPrototypeFile — Prototype audio file for code generation

'speech_dft.mp3' (default) | character vector | string scalar

Specify the name of the prototype audio file used in code generation as a character vector or a string scalar. Specify the full path for the file only if the file is not on the MATLAB path. The file name can be an http web address, like 'http://audio.wgbh.org:8004/'.

The attributes of the audio file specified in `Filename` (such as the audio format, the number of audio channels, the sample rate, and the bite rate) must match the attributes of the audio file specified in `CodegenPrototypeFile`. The specified prototype audio file determines the attributes and the type of audio files that can be read by the generated code. For example, if the specified prototype file is a .wav file, then the generated code can only read .wav files. If the specified prototype file sample rate is 44100 Hz, then the generated code can read files with a sample rate of 44100 Hz.

The following table lists the supported audio file formats:

Platforms	File Name Extensions
Windows	.wav, .wma, .avi, .aif, .aifc, .aiff, .mp3, .opus, .au, .snd, .mp4, .m4a, .flac, .ogg, .mov
Non-Windows	.avi, .mp3, .mp4, .m4a, .wav, .flac, .ogg, .aif, .aifc, .aiff, .opus, .au, .snd, .mov

Dependencies

This property applies only when the `FilenameIsTunableInCodegen` property is set to `true`.

SampleRate — Sampling rate of audio file

positive scalar

This property is read-only.

This property displays the sample rate, in Hz, of the audio file.

Data Types: `double`

ReadRange — Range of samples to be read

[1 inf] (default) | two-element row vector

Specify the sample range from which to read, as a vector in the form of [`StartSample` `EndSample`], where `StartSample` is the sample at which file reading starts, and `EndSample` is the sample at which file reading stops.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Usage

Syntax

```
audio = afr()
```

```
[audio,eof] = afr()
```

Description

`audio = afr()` outputs one frame of audio samples, `audio`. You can specify the number of times to play the file using the `PlayCount` property. After playing the file for the number of times you specify, `audio` contains silence.

`[audio,eof] = afr()` returns an end-of-file indicator, `eof`. `eof` is true each time the output `audio` contains the last audio sample in the file.

Output Arguments**audio — Audio samples**

column vector

One frame of audio samples, returned as a column vector of length equal to the value you specify in the `SamplesPerFrame` property. The data type of the audio output is specified in the `OutputDataType` property.

Data Types: `single` | `double` | `int16` | `uint8`

eof — End-of-file indicator

1 | 0

End-of-file indicator, returned as either a 1 or a 0. A value of 1 is output when `audio` contains the last audio sample in the file.

Data Types: `logical`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.AudioFileReader`

`info` Information about specific audio file

`isDone` End-of-file status (logical)

Common to All System Objects

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

Examples**Read and Play Back Audio File**

Read and play back an audio file using the standard audio output device.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj()` becomes `step(obj)`.

You can choose to read the entire data or specify a range of data to read from using the `ReadRange` property. By default, `ReadRange` is set to `[1 inf]`, indicating the file reader to read the entire data from the source. In this example, set `ReadRange` to `3Fs`, indicating the file reader to read the first 3 seconds of the data.

```
afr = dsp.AudioFileReader('speech_dft.mp3','ReadRange',[1 3*22050]);
adw = audioDeviceWriter('SampleRate', afr.SampleRate);

while ~isDone(afr)
    audio = afr();
    adw(audio);
end
release(afr);
release(adw);
```

Read and Play Back Audio File from http Web Address

Read audio data from an http web address using the `dsp.AudioFileReader` System object™. Play back the data using the `audioDeviceWriter` System object.

Initialization

Create an audio file reader which reads data from `http://audio.wgbh.org:8004/`. Set the sample rate of the audio device writer to be the same as that of the audio file reader.

```
afr = dsp.AudioFileReader('http://audio.wgbh.org:8004/')
```

```
afr =
    dsp.AudioFileReader with properties:

        Filename: 'http://audio.wgbh.org:8004/'
        PlayCount: 1
        SamplesPerFrame: 1024
        OutputDataType: 'double'
        SampleRate: 44100
        ReadRange: [1 Inf]
```

```
adw = audioDeviceWriter(afr.SampleRate)
```

```
adw =
    audioDeviceWriter with properties:

        Driver: 'DirectSound'
        Device: 'Default'
        SampleRate: 44100

    Show all properties
```

Read and Play Back

Read a specific amount of data from the web address directly and play the data back using the audio device writer.

```
for i = 1:1000
    audio = afr();
    adw(audio);
end
```

Close the input file and the audio output device.

```
release(afr)
release(adw)
```

Tunable Audio File Name in Generated Code

Generate a MEX file from a function named `writeAudio`. This function reads an audio signal from the `funky-stereo.wav` file, decimates the signal by a factor of 2, and writes the decimated signal to a specified output file.

The `dsp.AudioFileReader` object reads the audio signal from `funky-stereo.wav` file. The `funky-stereo.wav` file has two channels, a sample rate of 44100 Hz, and a bit rate of 1411 kbps. The `CodegenPrototypeFile` property of the object is set to `rock-stereo.wav` file. The `rock-stereo.wav` file has the same file attributes, such as the number of audio channels, sample rate, and bit rate, as the `funky-stereo.wav` file. The `dsp.FIRDecimator` object decimates the input audio signal by a factor of 2. The `dsp.AudioFileWriter` object writes the decimated signal to the output file `myoutput.wav`. Due to the decimation process, the output file has a sample rate of 22050 Hz and a bit rate of 2822 kbps.

```
type writeAudio.m

function writeAudio(readfile,writefile)

afr = dsp.AudioFileReader('FilenameIsTunableInCodegen',true,...
    'CodegenPrototypeFile','rock-stereo.wav');
afr.Filename = readfile;
% Filename is funky-stereo.wav and CodegenPrototypeFile is
% rock-stereo.wav.

firdec = dsp.FIRDecimator(2,'auto'); % decimate by 2

afw = dsp.AudioFileWriter('SampleRate',22050);
afw.Filename = writefile;
while ~isDone(afr)
    audio = afr();
    audiod = firdec(audio);
    afw(audiod);
end

release(afr);
release(afw);
end
```

For generating code, specify file names to be variable-length character vectors of maximum length 500.

```
readfilename = coder.typeof('a',[1 500],[0 1]);
writefilename = coder.typeof('b',[1 500],[0 1]);
```

Generate a MEX file using the `codegen` function.

```
codegen writeAudio -args {readfilename,writefilename}
```

Code generation successful.

```
writeAudio_mex('funky-stereo.wav','myoutput.wav');
```

Limitations

- For MP3, MPEG-4 AAC, and AVI audio files on Windows 7 or later and Linux platforms, `dsp.AudioFileReader` object can read fewer samples than expected. On Windows platforms, this is due to a limitation in the underlying Media Foundation framework. On Linux platforms, this is due to a limitation in the underlying GStreamer framework. If you require sample-accurate reading, work with WAV or FLAC files.
- To read OPUS files on a Linux machine, ensure that you have installed `libsndfile 1.0.29` or a later version. On Windows and Mac, this file is shipped with MATLAB and is available under `$MATLABROOT/bin/<platform>`.

Algorithms

This object implements the algorithm, inputs, and outputs described on the From Multimedia File block reference page. The object properties correspond to the block parameters, except:

- The object has no corresponding property for the **Inherit sample time from file** block parameter. The object always inherits the sample time from the file.
- The object has no corresponding property for the **Output end-of-file indicator** parameter. The object always outputs EOF as the last output.
- The object has no corresponding property for the **Multimedia Outputs** parameter because audio is the only supported output.
- The object has no corresponding property for the **Image signal** block parameter.
- The object has no corresponding property for the **Output color format** parameter.
- The object has no corresponding property for the **Video output data type** parameter.

Version History

Introduced in R2012a

Support for OPUS audio file format

The `dsp.AudioFileReader` object supports audio files in the OPUS file format (`.opus`).

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- See “System Objects in MATLAB Code Generation” (MATLAB Coder).
- The executable generated from this System object relies on prebuilt dynamic library files (.dll files) included with MATLAB. Use the `packNGo` function to package the code generated from this object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

Objects

`dsp.AudioFileWriter`

Topics

“How To Run a Generated Executable Outside MATLAB”

dsp.AudioFileWriter

Package: dsp

Stream to audio file

Description

The `dsp.AudioFileWriter` System object writes audio samples to an audio file.

To write audio samples to an audio file:

- 1 Create the `dsp.AudioFileWriter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
afw = dsp.AudioFileWriter
afw = dsp.AudioFileWriter(Filename)
afw = dsp.AudioFileWriter(Name,Value)
```

Description

`afw = dsp.AudioFileWriter` returns an audio file writer System object, `afw`. This object writes audio samples to an audio file.

`afw = dsp.AudioFileWriter(Filename)` returns an audio file writer System object, `afw`. This object has the `Filename` property set to `Filename`.

`afw = dsp.AudioFileWriter(Name,Value)` returns an audio file writer object with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Filename — Name of audio file to which to write

'output.wav' (default) | character vector | string scalar

Specify the name of the audio file as a character vector or a string scalar.

The `Filename` property is tunable in generated code. That is, you can pass the name of the audio file as an input while running the code generated from this object. For an example, see “Tunable Audio File Name in Generated Code” on page 4-116.

FileFormat — Audio file format

'WAV' (default) | 'AVI' | 'FLAC' | 'OGG' | 'MPEG4' | 'OPUS' | 'WMA'

Specify which audio file format the object writes. On Microsoft platforms, select one of 'AVI', 'WAV', 'FLAC', 'OGG', 'MPEG4', 'OPUS', 'WMA'. On Linux platforms, select one of 'AVI', 'WAV', 'FLAC', 'OPUS', or 'OGG'. On macOS platforms, select one of 'AVI', 'WAV', 'FLAC', 'OGG', 'OPUS', or 'MPEG4'. These abbreviations correspond to the following file formats:

- 'AVI' -- Audio-Video Interleave
- 'WAV' -- Microsoft WAVE Files
- 'WMA' -- Windows Media Audio
- 'FLAC' -- Free lossless audio Codec
- 'OGG' -- Ogg/Vorbis compressed audio file
- 'OPUS' -- Opus compressed audio file
- 'MPEG4' -- MPEG-4 AAC File — You can use both .m4a and .mp4 extensions

The default is 'WAV'.

SampleRate — Sampling rate of audio data stream

44100 (default) | positive scalar

Specify the sample rate of the input audio data as a positive, numeric scalar value.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Compressor — Algorithm that compresses audio data

'None (uncompressed)' (default) | 'CCITT A-Law' | 'CCITT u-Law' | 'GSM 6.10' | 'IMA ADPCM' | 'Microsoft ADPCM' | 'PCM'

Specify the type of compression algorithm the audio file writer uses to compress the audio data. Compression reduces the size of the audio file. Select 'None (uncompressed)' to save uncompressed audio data to the file. The other options available reflect the audio compression algorithms installed on your system. You can use tab completion to query valid Compressor options for your computer by typing `H.Compressor = '` and then pressing the tab key.

Dependencies

This property applies when writing WAV or AVI files on Windows platforms.

Data Type — Data type of the uncompressed audio

'int16' (default) | 'double' | 'single' | 'inherit' | 'int24' | 'int32' | 'uint8'

Specify the type of uncompressed audio data written to the file as 'int16', 'double', 'single', 'inherit', 'int24', 'int32', or 'uint8'.

Dependencies

This property only applies when writing uncompressed WAV files.

Usage

Syntax

```
afw(audio)
```

Description

`afw(audio)` writes one frame of audio samples, `audio`, to the output file specified by `Filename`. `audio` is either a vector for mono audio input or an M -by- N matrix for N -channel audio input respectively.

Input Arguments

audio — Audio samples

column vector | matrix

One frame of audio samples, returned as a column vector or a matrix. A column vector input indicates a mono audio input. An M -by- N matrix indicates an N -channel audio input.

If the input is fixed-point, the input must be a signed fixed-point input with power-of-two slope and zero bias.

Data Types: `single` | `double` | `int16` | `int32` | `uint8` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Write an Audio Signal to WAV File

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj()` becomes `step(obj)`.

Decimate an audio signal, and write it to disk as a WAV file.

```
afr = dsp.AudioFileReader('OutputDataType',...
    'double');
firdec = dsp.FIRDecimator; % decimate by 2
afw = dsp.AudioFileWriter...
    ('speech_dft.wav', ...
```

```
    'SampleRate', afr.SampleRate/2);  
  
while ~isDone(afr)  
    audio = afr();  
    audiod = firdec(audio);  
    afw(audiod);  
end  
  
release(afr);  
release(afw);
```

Tunable Audio File Name in Generated Code

Generate a MEX file from a function named `writeAudio`. This function reads an audio signal from the `funky-stereo.wav` file, decimates the signal by a factor of 2, and writes the decimated signal to a specified output file.

The `dsp.AudioFileReader` object reads the audio signal from `funky-stereo.wav` file. The `funky-stereo.wav` file has two channels, a sample rate of 44100 Hz, and a bit rate of 1411 kbps. The `CodegenPrototypeFile` property of the object is set to `rock-stereo.wav` file. The `rock-stereo.wav` file has the same file attributes, such as the number of audio channels, sample rate, and bit rate, as the `funky-stereo.wav` file. The `dsp.FIRDecimator` object decimates the input audio signal by a factor of 2. The `dsp.AudioFileWriter` object writes the decimated signal to the output file `myoutput.wav`. Due to the decimation process, the output file has a sample rate of 22050 Hz and a bit rate of 2822 kbps.

```
type writeAudio.m  
  
function writeAudio(readfile,writefile)  
  
afr = dsp.AudioFileReader('FilenameIsTunableInCodegen',true,...  
    'CodegenPrototypeFile','rock-stereo.wav');  
afr.FileName = readfile;  
% Filename is funky-stereo.wav and CodegenPrototypeFile is  
% rock-stereo.wav.  
  
firdec = dsp.FIRDecimator(2,'auto'); % decimate by 2  
  
afw = dsp.AudioFileWriter('SampleRate',22050);  
afw.FileName = writefile;  
while ~isDone(afr)  
    audio = afr();  
    audiod = firdec(audio);  
    afw(audiod);  
end  
  
release(afr);  
release(afw);  
end
```

For generating code, specify file names to be variable-length character vectors of maximum length 500.

```
readfilename = coder.typeof('a',[1 500],[0 1]);  
writefilename = coder.typeof('b',[1 500],[0 1]);
```

Generate a MEX file using the `codegen` function.

```
codegen writeAudio -args {readfilename,writefilename}
```

Code generation successful.

```
writeAudio_mex('funky-stereo.wav','myoutput.wav');
```

Limitations

The following platform-specific restrictions apply when writing these files:

Windows 7

- Only sample rates of 44100 Hz and 48000 Hz are supported for the MPEG-4 AAC file format. For other file formats, there is no restriction on the sample rate.
- Only mono or stereo outputs are allowed for the MPEG-4 AAC file format. For all other formats, more than two audio output channels are allowed.
- The output data is padded on both the front and back of the signal, with extra samples of silence.

Windows AAC encoder places sharp fade-in and fade-out on audio signals, causing the signals to be slightly longer in samples when written to disk.

- A minimum of 1025 samples per channel must be written to the MPEG-4 AAC file.

macOS

- Only mono or stereo outputs are allowed for MPEG-4 AAC file format. For all other formats, more than two audio output channels are allowed.
- Not all sampling rates are supported, although the Mac Audio Toolbox API does not explicitly specify a restriction.

Linux

- To support OPUS file format on a Linux machine, you must have `libsndfile 1.0.29` or a later version installed. On Windows and Mac, this file is shipped with MATLAB and is available under `$MATLABROOT/bin/<platform>`.

Algorithms

This object implements the algorithm, inputs, and outputs described on the To Multimedia File block reference page. The object properties correspond to the block parameters, except:

- The object `FileFormat` property does not support video-only file formats.
- The object has no corresponding property for the **Write** parameter. The object writes only audio content to files.
- The object has no corresponding property for the **Video compressor** parameter.
- The object has no corresponding property for the **File color format** parameter.
- The object has no corresponding property for the **Image signal** parameter.

Version History

dsp.Autocorrelator

Package: dsp

(To be removed) Autocorrelation sequence

Note `dsp.Autocorrelator` will be removed in a future release. Use `xcorr` instead. For more information, see “Compatibility Considerations”.

Description

The `Autocorrelator` object returns the autocorrelation sequence for a discrete-time, deterministic input, or the autocorrelation sequence estimate for a discrete-time, wide-sense stationary (WSS) random process at positive lags.

To obtain the autocorrelation sequence:

- 1 Create the `dsp.Autocorrelator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
ac = dsp.Autocorrelator
ac = dsp.Autocorrelator(Name,Value)
```

Description

`ac = dsp.Autocorrelator` returns an autocorrelator, `ac`, that computes the autocorrelation along the first dimension of an N -D array. By default, the autocorrelator computes the autocorrelation at lags from zero to $N - 1$, where N is the length of the input vector or the row dimension of the input matrix. Inputting a row vector results in a row of zero-lag autocorrelation sequence values, one for each column of the row vector. The default autocorrelator returns the unscaled autocorrelation and performs the computation in the time domain.

`ac = dsp.Autocorrelator(Name,Value)` returns an autocorrelator, `ac`, with each property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

MaximumLagSource — Source of maximum lag

Auto (default) | Property

Specify how to determine the range of lags for the autocorrelation as `Auto` or `Property`. If the value of `MaximumLagSource` is `Auto`, the autocorrelator computes the autocorrelation over all nonnegative lags in the interval $[0, N-1]$, where N is the length of the first dimension of the input. Otherwise, the object computes the autocorrelation using lags in the range $[0, \text{MaximumLag}]$.

MaximumLag — Maximum positive lag

1 (default) | 0 | positive integer

Specify the maximum lag as an integer greater than or equal to 0. The `MaximumLag` must be less than the length of the input data.

Dependencies

This property applies only when the `MaximumLagSource` property is `Property`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Scaling — Autocorrelation function scaling

None (default) | Biased | Unbiased | Unity at zero-lag

Specify the scaling to apply to the output as `None`, `Biased`, `Unbiased`, or `Unity at zero-lag`. Set this property to `None` to generate the autocorrelation function without scaling. This option is appropriate if you are computing the autocorrelation of a nonrandom (deterministic) input.

The `Biased` option scales the autocorrelation by $1/N$, where N is the length of the input data. Scaling by $1/N$ yields a biased, finite-sample approximation to the theoretical autocorrelation of a WSS random process. In spite of the bias, scaling by $1/N$ has the desirable property that the sample autocorrelation matrix is nonnegative definite, a property possessed by the theoretical autocorrelation matrices of all wide-sense stationary random processes. The Fourier transform of the biased autocorrelation estimate is the *periodogram*, a widely used estimate of the power spectral density of a WSS process.

The `Unbiased` option scales the estimate of the autocorrelation by $1/N - 1$. Scaling by $N - 1$ produces an unbiased estimate of the theoretical autocorrelation. However, using the unbiased option, you can obtain an estimate of the autocorrelation function that fails to have the nonnegative definite property.

Use the `Unity at zero-lag` option to normalize the autocorrelation estimate as identically one at lag zero. The default is `None`.

Method — Domain for computing autocorrelations

Time Domain (default) | Frequency Domain

Specify the domain for computing autocorrelations as `Time Domain` or `Frequency Domain`. You must set this property to `Time Domain` for fixed-point signals.

Fixed-Point Properties

FullPrecisionOverride — Full precision override for fixed-point arithmetic

true (default) | false

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

RoundingMethod — Rounding method for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`.

Dependencies

This property applies only when you set the `Method` property to `Time Domain` and the object is not in full precision mode.

OverflowAction — Overflow action for fixed-point operations

Wrap (default) | Saturate

Specify the overflow action as `Wrap` or `Saturate`.

Dependencies

This property applies only when you set the `Method` property to `Time Domain` and the object is not in full precision mode.

ProductDataType — Product word and fraction lengths

Full precision (default) | Same as input | Custom

Specify the product fixed-point data type as one of `Full precision`, `Same as input`, or `Custom`.

Dependencies

This property applies only when you set the `Method` property to `Time Domain`.

CustomProductDataType — Product word and fraction lengths

`numerictype([], 32, 30)` (default) | `numerictype`

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies only when you set the `Method` property to `Time Domain` and the `ProductDataType` property to `Custom`.

AccumulatorDataType — Accumulator word and fraction lengths

Full precision (default) | Same as product | Same as input | Custom

Specify the accumulator fixed-point data type as one of `Full precision`, `Same as product`, `Same as input`, or `Custom`.

Dependencies

This property applies only when the `Method` property is `Time Domain`.

CustomAccumulatorDataType — Accumulator word and fraction lengths`numerictype([],32,30) (default) | numerictype`

Specify the accumulator fixed-point type as a scaled `numerictype` object with a Signedness of `Auto`.

Dependencies

This property applies only when you set the `Method` property to `Time Domain` and the `AccumulatorDataType` property to `Custom`.

OutputDataType — Output word and fraction lengths`Same as accumulator (default) | Same as product | Same as input | Custom`

Specify the output fixed-point data type as `Same as accumulator`, `Same as product`, `Same as input`, or `Custom`.

Dependencies

This property applies only when the `Method` property is `Time Domain`.

CustomOutputDataType — Output word and fraction lengths`numerictype([],16,15) (default) | numerictype`

Specify the output fixed-point type as a scaled `numerictype` object with a Signedness of `Auto`.

Dependencies

This property applies only when you set the `Method` property to `Time Domain` and the `OutputDataType` property to `Custom`.

Usage**Syntax**`y = ac(x)`**Description**

`y = ac(x)` computes the autocorrelation sequence `y` for the columns of the input `x`.

Input Arguments**x — Data input**`vector | matrix | N-D array`

Data input, specified as a vector, matrix, or an *N*-D array. The object accepts real-valued or complex-valued multichannel and multidimensional inputs. The input can be a fixed-point signal when you set the `Method` property to `'Time Domain'`. When the input signal is complex, the output signal is complex.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Output Arguments

y — Autocorrelated output

vector | matrix | *N*-D array

Autocorrelated output of the two input signals. The size, data type, and complexity of the output matches that of the input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

`step` Run System object algorithm
`release` Release resources and allow changes to System object property values and input characteristics
`reset` Reset internal states of System object

Examples

Autocorrelation of Noisy Sine Wave

Note If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Compute the autocorrelation of a sine wave in white Gaussian noise with approximate 95% upper and lower confidence limits.

```
S = rng('default');
% Sine wave with period N=4
x = 1.4*cos(pi/2*(1:100))'+randn(100,1);
MaxLag = 20;
ac = dsp.Autocorrelator('MaximumLagSource',...
'Property','MaximumLag',MaxLag,'Scaling','Unity at zero-lag');
SigAutocorr = ac(x);
stem(SigAutocorr,'b','markerfacecolor',[0 0 1]);
line(1:MaxLag+1,1.96/sqrt(100)*ones(MaxLag+1,1),...
'linestyle','-','linewidth',2);
line(1:MaxLag+1,-1.96/sqrt(100)*ones(MaxLag+1,1),...
'linestyle','-','linewidth',2);
axis([1 20 -1 1]);
title('Sine Wave + Noise Autocorrelation'); xlabel('Lag');
```

As the generated figure shows, the autocorrelation estimate demonstrates the four sample periodic sine wave with excursions outside the 95% white Gaussian noise confidence limits every two samples.

More About

Autocorrelation

Autocorrelation is the correlation of a signal with itself at different points in time.

For a deterministic discrete-time sequence, $x(n)$, the autocorrelation is computed using the following relationship:

$$r_x(h) = \sum_{n=0}^{N-h-1} x^*(n)x(n+h) \quad h = 0, 1, \dots, N-1$$

where h is the lag and $*$ denotes the complex conjugate. If the input is a length N realization of a WSS stationary random process, $r_x(h)$ is an estimate of the theoretical autocorrelation:

$$\rho_x(h) = E\{x^*(n)x(n+h)\}$$

where $E\{ \}$ is the expectation operator. The Unity at zero-lag normalization divides each sequence value by the autocorrelation or autocorrelation estimate at zero lag.

$$\frac{\rho_x(h)}{\rho_x(0)} = \frac{E\{x^*(n)x(n+h)\}}{E\{|x(0)|^2\}}$$

The most commonly used estimate of the theoretical autocorrelation of a WSS random process is the biased estimate:

$$\hat{\rho}_x(h) = \frac{1}{N} \sum_{k=0}^{N-h-1} x^*(k)x(k+h)$$

Algorithms

Time-Domain Computation

When you set the computation domain to time, the algorithm computes the autocorrelation of the input signal in the time domain. The input signal can be a fixed-point signal in this domain.

The autocorrelation sequence, y , is computed using this equation:

$$y_{i,j} = \sum_{k=0}^{M-l-1} u_{k,j}^* u_{(k+i),j} \quad 0 \leq i \leq l$$

- $y_{0,j}$ is the zero-lag element in the j th column of the input.
- i is the index of the lag.
- j is the index of the input data column.
- $*$ denotes the complex conjugate.
- M is the number of elements in each column.

- l is the maximum positive lag for autocorrelation. When you choose to compute the autocorrelation with all nonnegative lags, $l=M-1$. Otherwise, l is the maximum nonnegative integer lag value specified.
- u is an M -by- N input matrix.

Frequency-Domain Computation

When you set the computation domain to frequency, the algorithm computes the autocorrelation in the frequency domain.

In this domain, the algorithm computes the autocorrelation sequence by taking the Fourier transform of the input signal, multiplying the Fourier transform with its complex conjugate, and taking the inverse Fourier transform of the product. In this domain, depending on the input length, the algorithm can require fewer computations.

dsp.BinaryFileReader

Package: dsp

Read data from binary file

Description

The `dsp.BinaryFileReader` System object reads multichannel signal data from a binary file. If the header is not empty, then the header precedes the signal data. The System object specifies the prototype of the header, and the type, size, and complexity of the data. The first time you read the file, the reader reads the header, followed by the data. On subsequent calls, the reader reads the remaining data. Once the end of file is reached, the reader returns zeros of the specified data type, size, and complexity. The reader can read signal data from a binary file that is not created by the `dsp.BinaryFileWriter` System object.

The object accepts floating-point data or integer data. To read character data and fixed-point data, see the “Write and Read Character Data” on page 4-144 and “Write and Read Fixed-Point Data” on page 4-143 examples. The input data can be real or complex. When the data is complex, the object reads the data as interleaved real and imaginary components. For an example, see “Read Complex Data” on page 4-142. The reader assumes the default endianness of the host machine. To change the endianness, you can use the `swapbytes` function. For an example, see “Change Endianness of Data” on page 4-145.

To read data from a binary file:

- 1 Create the `dsp.BinaryFileReader` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
reader = dsp.BinaryFileReader
reader = dsp.BinaryFileReader(fname)
reader = dsp.BinaryFileReader(fname,Name,Value)
```

Description

`reader = dsp.BinaryFileReader` creates a binary file reader object, `reader`, using the default properties.

`reader = dsp.BinaryFileReader(fname)` sets the `Filename` property to `fname`.

`reader = dsp.BinaryFileReader(fname,Name,Value)` with `Filename` set to `fname`, and each specified property set to the specified value. Unspecified properties have default values.

```
Example: reader =  
dsp.BinaryFileReader('myFilename.bin','SamplesPerFrame',1000,'NumChannels',2)  
;
```

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

Filename — Name of file

'Untitled.bin' (default) | character vector | string scalar

Name of the file from which the object reads the data, specified as a character vector. If the file is not on the MATLAB path, then specify the full path for the file.

HeaderStructure — Size of header

struct('Field1',[]) (default) | structure

The structure specifies the prototype of the file header, that is, the size of the header and the data type of the field values. The structure can have an arbitrary number of fields. Each field of the structure must be a real matrix of a built-in type. For example, if `HeaderStructure` is set to `struct('field1',1:10,'field2',single(1))`, the object assumes that the header is formed by 10 real double-precision values followed by 1 single-precision value. If the file contains no header, you can set this property to an empty structure, `struct([])`. To retrieve the file header, call the `readHeader` method on the reader object.

SamplesPerFrame — Number of samples per output frame

1024 (default) | positive integer

Number of samples per output frame, specified as a positive integer. `SamplesPerFrame` specifies the number of rows of the output matrix that the object returns. The size of the data is `SamplesPerFrame-by-NumChannels`. Once the end of file is reached, the reader returns zeros of the specified data type, size, and complexity.

NumChannels — Number of channels

1 (default) | positive integer

Number of channels, specified as a positive integer. `NumChannels` specifies the number of columns of the output matrix that the object returns. This property defines the number of consecutive interleaved data samples stored in the file for each time instant. The size of the data is `SamplesPerFrame-by-NumChannels`. Once the end of file is reached, if the output matrix is not full, the object fills the matrix with zeros to make it a full-sized matrix.

DataType — Type of data in file

'double' (default) | 'single' | 'int8' | 'int16' | 'int32' | 'int64' | 'uint8' | 'uint16' | 'uint32' | 'uint64'

Type of data in file, specified as a character vector. This property defines the data type of the matrix returned by the object algorithm.

IsDataComplex — Specify data complexity`false` (default) | `true`

Option to specify data complexity, specified as `false` or `true`. When this property is set to `true`, the reader treats the data as complex. The object reads the data as interleaved real and imaginary components. Consider a reader object configured to read the data as a 2-by-2 matrix. The object reads `[1 5 2 6 3 7 4 8]` as `[1 2; 3 4]+1j*[5 6; 7 8]`. If this property is set to `false`, the same object reads the data as `[1 5; 2 6]`.

Usage**Syntax**`data = reader()`**Description**

`data = reader()` reads data from the binary file in a row-major format. The data type, size, and complexity of the data are determined by the properties of the reader object. Once the end of file is reached, the output contains zeros of the specified data type, size, and complexity.

Output Arguments**data — Data output**`vector` | `matrix`

Data read by the binary file reader, returned as a vector or a matrix. The size of the data is given by `SamplesPerFrame-by-NumChannels`, where `SamplesPerFrame` and `NumChannels` are the properties of the `dsp.BinaryFileReader` object.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

`release(obj)`**Specific to dsp.BinaryFileReader**`isDone` End-of-data status`readHeader` Read file header**Common to All System Objects**`step` Run System object algorithm`release` Release resources and allow changes to System object property values and input characteristics`reset` Reset internal states of System object**Examples**

Write and Read Binary Files

Create a binary file with a custom header using the `dsp.BinaryFileWriter` System object. Write data to this file. Read the header and data using the `dsp.BinaryFileReader` System object.

Write the Data

Specify the file header as a structure with the following fields:

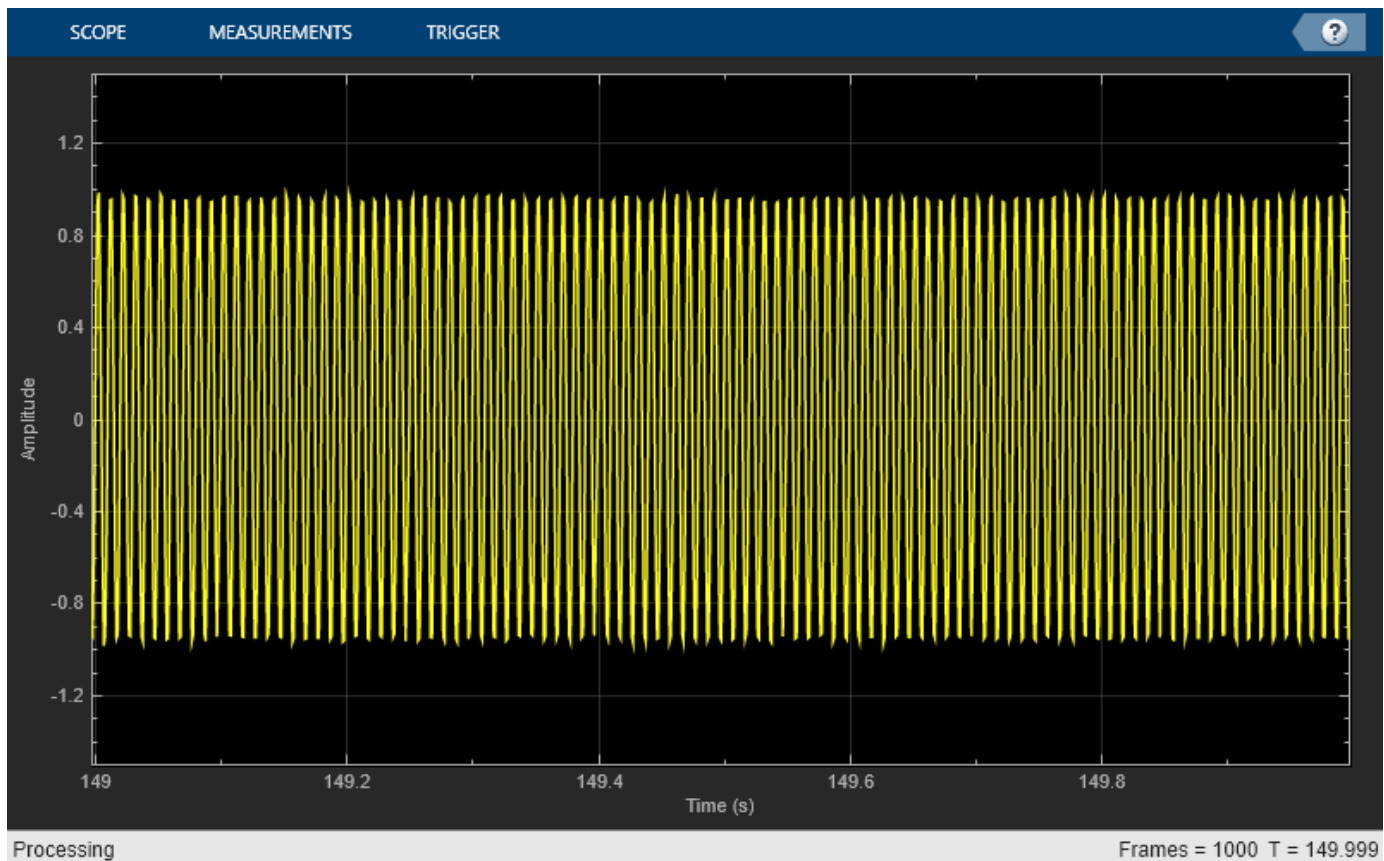

- `DataType` set to `double`.
- `Complexity` set to `false`.
- `FrameSize` (number of rows in the data matrix) set to 150.
- `NumChannels` (number of columns in the data matrix) set to 1.

Create a `dsp.BinaryFileWriter` object using this header. The object writes the header first, followed by the data, to `ex_file.bin`. The data is a noisy sine wave signal. View the data in a time scope.

```
L = 150;
header = struct('DataType','double',...
    'Complexity',false,...
    'FrameSize',L,...
    'NumChannels',1);
writer = dsp.BinaryFileWriter('ex_file.bin',...
    'HeaderStructure',header);

sine = dsp.SineWave('SamplesPerFrame',L);
scopewriter = timescope('YLimits',[-1.5 1.5],...
    'SampleRate',sine.SampleRate,...
    'TimeSpanSource','Property',...
    'TimeSpan',1);

for i = 1:1000
    data = sine() + 0.01*randn(L,1);
    writer(data);
    scopewriter(data)
end
```

Release the writer so that the reader can access the data from this file.

```
release(writer);
```

Read the Data

Read the data from the binary file, `ex_file.bin`, using the `dsp.BinaryFileReader` object. The file contains the header data followed by the actual data. The object reads the binary data until the end of file is reached. Specify the header to the reader using the `HeaderStructure` property of the reader object.

If the exact header is not known on the reader side, you must at least specify the prototype of the header. That is, the number of fields, and the data type, size, and complexity of each field in the prototype must match with the header data written to the binary file. When the `readHeader` function reads the data from the binary file, the function extracts the header information based on how the fields are specified in the header prototype. For example, a header field set to `'double'` on the writer side can be specified as any string of 6 characters on the reader side. The `readHeader` function reads this field as a string of 6 characters from the binary file, which matches with `'double'`.

```
headerPrototype = struct('DataType','datatype',...
    'Complexity',false,...
    'FrameSize',1,...
    'NumChannels',10);
reader = dsp.BinaryFileReader(...
    'ex_file.bin',...
```

```
'HeaderStructure',headerPrototype);  
headerReader = readHeader(reader)
```

```
headerReader =  
  
struct with fields:  
  
    DataType: 'double'  
    Complexity: 0  
    FrameSize: 150  
    NumChannels: 1
```

The header data extracted by the `readHeader` function is assigned to the corresponding properties of the reader object.

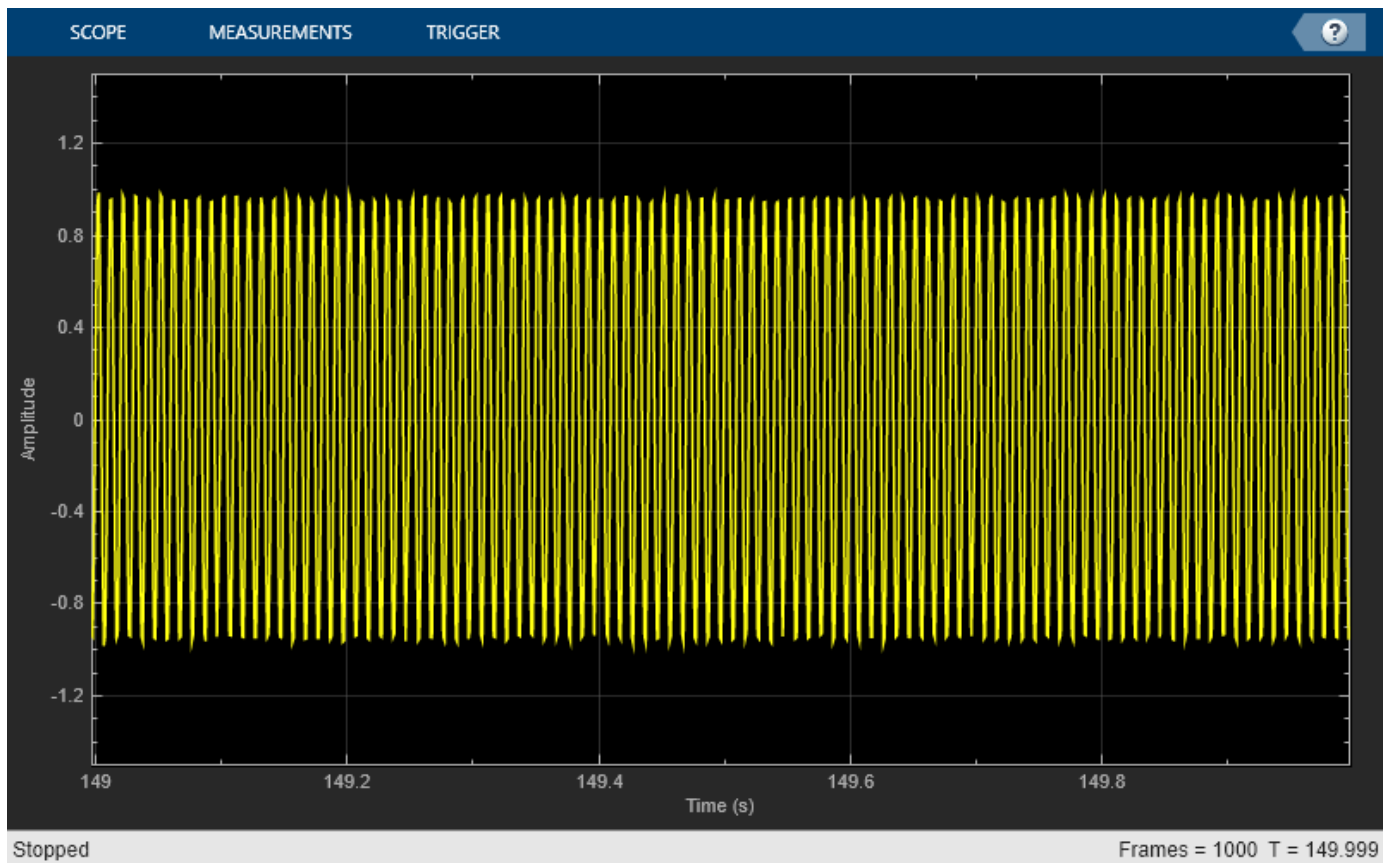

```
reader.IsDataComplex = headerReader.Complexity;  
reader.DataType = headerReader.DataType;  
reader.NumChannels = headerReader.NumChannels;  
reader.SamplesPerFrame = headerReader.FrameSize;
```

Initialize a scope on the reader side to view the extracted binary file data.

```
scopereader = timescope('YLimits',[-1.5 1.5],...  
    'SampleRate',sine.SampleRate,...  
    'TimeSpanSource','Property',...  
    'TimeSpan',1);
```

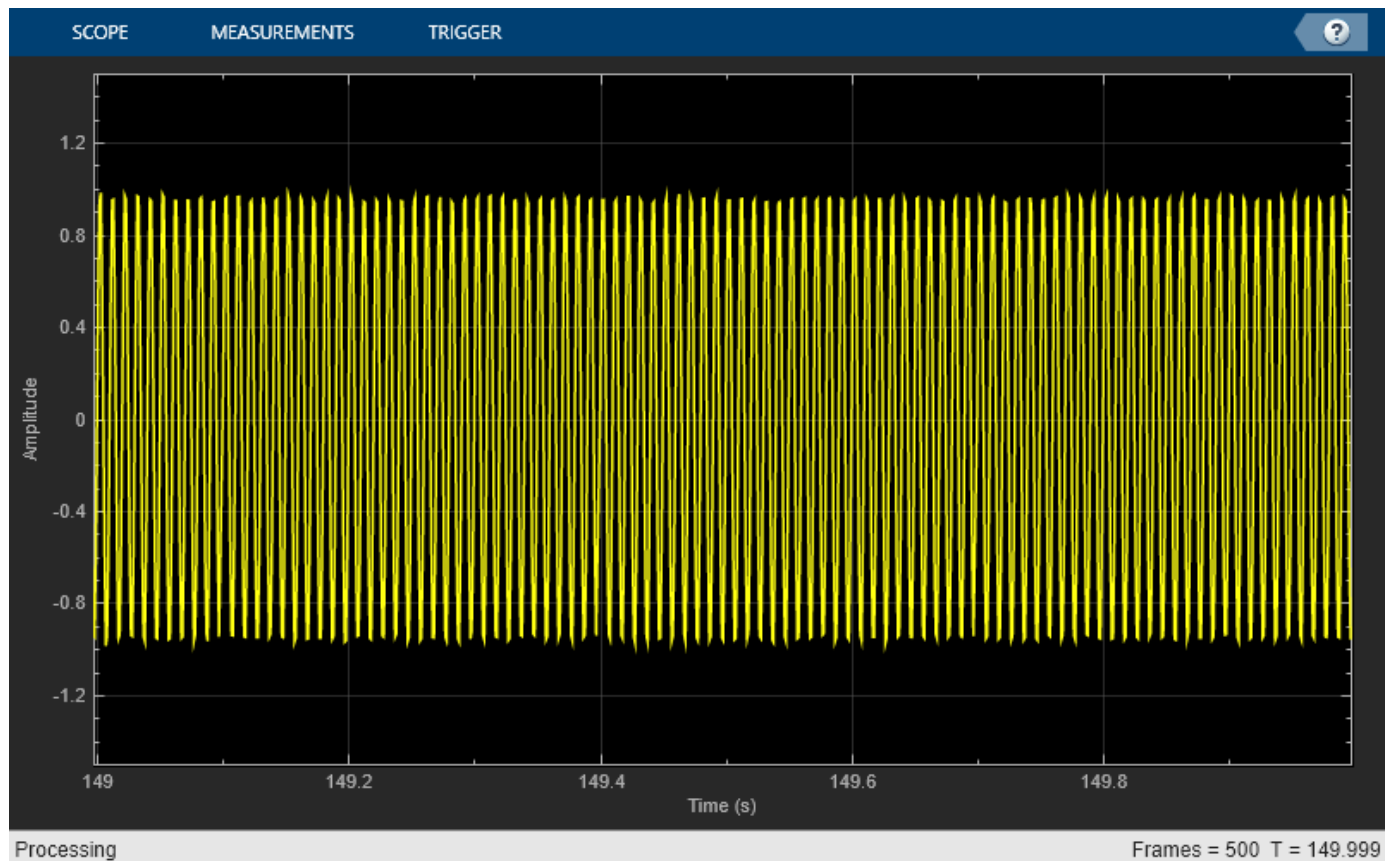

The data is read into a single channel (column) containing multiple frames, where each frame has 150 samples. View the data in a time scope.

```
while ~isDone(reader)  
    out = reader();  
    scopereader(out)  
end  
release(reader);  
release(scopereader);
```

Set the reader to read data in frames of size 300. Verify that the data read matches the data written to the file.

```
reader.SamplesPerFrame = 300;  
while ~isDone(reader)  
    out = reader();  
    scopereader(out)  
end  
release(reader);
```

Even when the reader reads data with a different frame size, the output in both time scopes matches exactly.

Write and Read Matrix Data

Use a `dsp.BinaryFileReader` System object™ to read data from a binary file in a row-major format.

Write the Data

Write the matrix `A` to the binary file `Matdata.bin` using a `dsp.BinaryFileWriter` object. The object writes the specified header followed by the data.

The header has the following format:

- `DataType` set to `double`.
- `Complexity` set to `false`.
- `FrameSize` (number of rows in the data matrix) set to 3.
- `NumChannels` (number of columns in the data matrix) set to 4.

```
A = [1 2 3 8; 4 5 6 10; 7 8 9 11];
header = struct('DataType','double',...
    'Complexity',false,...
```

```

        'FrameSize',3,...
        'NumChannels',4);
writer = dsp.BinaryFileWriter('Matdata.bin',...
    'HeaderStructure',header);
writer(A);

```

Release the writer so that the reader can access the data.

```
release(writer);
```

Read the Data

Specify the header using the `HeaderStructure` property of the reader object. If the exact header is not known, you must at least specify the prototype of the header. That is, the number of fields, and the data type, size, and complexity of each field in the prototype must match with the header data written to the binary file. The `dsp.BinaryFileReader` object reads the binary file `Matdata.bin` until the end of file is reached. Configure the System object to read the data into 4 channels, with each channel containing 5 samples. Each loop of the iteration reads a channel (or frame) of data.

```

headerPrototype = struct('DataType','double',...
    'Complexity',false,...
    'FrameSize',5,...
    'NumChannels',4);
reader = dsp.BinaryFileReader('Matdata.bin',...
    'HeaderStructure',headerPrototype,...
    'NumChannels',4,...
    'SamplesPerFrame',5);
while ~isDone(reader)
    out = reader();
    display(out)
end

```

```
out = 5×4
```

1	2	3	8
4	5	6	10
7	8	9	11
0	0	0	0
0	0	0	0

Each frame of `out` contains frames of the matrix `A`, followed by zeros to complete the frame. The original matrix `A` contains 4 channels with 3 samples in each channel. The reader is configured to read data into 4 channels, with each channel containing 5 samples. Because there are not enough samples to complete the frame, the reader object appends zeros at the end of each frame.

Read Header Data

Read the header data from a binary file using the `readHeader` function.

Write a header, followed by the data to a binary file named `myfile.dat`. The header is a 1-by-4 matrix of double precision values, followed by a 5-by-1 vector of single-precision values. The data is a sequence of 1000 double-precision values.

```

fid = fopen('myfile.dat','w');
fwrite(fid,[1 2 3 4],'double');

```

```
fwrite(fid, single((1:5).'), 'single');
fwrite(fid, (1:1000).', 'double');
fclose(fid);
```

Read the header using a `dsp.BinaryFileReader` object. Specify the expected header structure. This structure specifies only the format of the expected binary file header and does not contain the exact values.

```
reader = dsp.BinaryFileReader('myfile.dat');
s = struct('A', zeros(1,4), 'B', ones(5,1, 'single'));
reader.HeaderStructure = s;
```

Read the header using the `readHeader` function.

```
H = readHeader(reader);
fprintf('H.A: ')

H.A:

fprintf('%d ', H.A);

1 2 3 4

fprintf('\nH.A datatype: %s\n', class(H.A))

H.A datatype: double

fprintf('H.B: ')

H.B:

fprintf('%d ', H.B);

1 2 3 4 5

fprintf('\nH.B datatype: %s\n', class(H.B))

H.B datatype: single
```

Read Complex Data

Read complex data from a binary file using the `dsp.BinaryFileReader` object.

Write a sequence of numbers to a binary file named `myfile.dat`. There is no header. The data is a 2-by-4 matrix of double-precision values. `fwrite` writes the data in a column-major format. That is, the 2-by-4 matrix `[1 2 3 4; 9 10 11 12]` is written as `[1 9 2 10 3 11 4 12]` in the binary file.

```
fid = fopen('myfile.dat', 'w');
fwrite(fid, [1 2 3 4; 9 10 11 12], 'double');
fclose(fid);
```

Specify the data to be complex using the `IsDataComplex` property. The object reads the data as interleaved real and imaginary components. The `SamplesPerFrame` and `NumChannels` properties specify the number of rows and columns of the output data. The header structure is specified as empty.

```
reader = dsp.BinaryFileReader('myfile.dat', 'SamplesPerFrame', 2, ...
    'NumChannels', 2, 'IsDataComplex', true);
```

```

s = struct([]);
reader.HeaderStructure = s;
data = reader();
display(data);

data = 2x2 complex

    1.0000 + 9.0000i    2.0000 +10.0000i
    3.0000 +11.0000i    4.0000 +12.0000i

release(reader);

```

Alternatively, if you do not specify the data as complex, the reader reads the data as a SamplesPerFrame-by- NumChannel matrix of real values.

```

reader.IsDataComplex = false;
data = reader();
display(data);

data = 2x2

     1     9
     2    10

release(reader);

```

Write and Read Fixed-Point Data

The `dsp.BinaryFileWriter` and `dsp.BinaryFileReader` System objects do not support writing and reading fixed-point data. As a workaround, you can write the stored integer portion of the `fi` data, read the data, and use this value to reconstruct the `fi` data.

Write the Fixed-Point Data

Create an `fi` object to represent 100 signed random numbers with a word length of 14 and a fraction length of 12. Write the stored integer portion of the `fi` object to the data file `myFile.dat`. The built-in data type is `int16`, which can be computed using `class(storeIntData)`.

```

data = randn(100,1);
fiDataWriter = fi(data,1,14,12);
storeIntData = storedInteger(fiDataWriter);

writer = dsp.BinaryFileWriter('myFile.dat');
writer(storeIntData);

```

Release the writer so that the reader can access the data.

```
release(writer);
```

Read the Fixed-Point Data

Specify the reader to read the stored integer data as `int16` data with 100 samples per data frame. The real-world value of the fixed-point number can be represented using

$2^{(-fractionLength)(storedInteger)}$. If you know the signedness, word length, and fraction length of the fixed-point data, you can reconstruct the `fi` data using `fi(realValue, signedness, wordLength, fractionLength)`. In this example, the data is signed with a word length of 14 and a fraction length of 12.

```
reader = dsp.BinaryFileReader('Filename','myFile.dat',...
    'SamplesPerFrame',100,...
    'DataType','int16');
data = reader();
fractionLength = 12;
wordLength = 14;
realValue = 2^(-fractionLength)*double(data);

fiDataReader = fi(realValue,1,...
    wordLength,fractionLength);
```

Verify that the writer data is the same as the reader data.

```
isequal(fiDataWriter,fiDataReader)

ans = logical
     1
```

Write and Read Character Data

The `dsp.BinaryFileWriter` and `dsp.BinaryFileReader` System objects do not support writing and reading characters. As a workaround, cast character data to one of the built-in data types and write the integer data. After the reader reads the data, convert the data to a character using the `char` function.

Write the Character Data

Cast a character into `uint8` using the `cast` function. Write the cast data to the data file `myFile.dat`.

```
data = 'binary_file';
castData = cast(data,'uint8');
writer = dsp.BinaryFileWriter('myFile.dat');
writer(castData);
```

Release the writer so that the reader can access the data.

```
release(writer);
```

Read the uint8 Data

Configure the reader to read the cast data as `uint8` data.

```
reader = dsp.BinaryFileReader('myFile.dat',...
    'DataType','uint8',...
    'SamplesPerFrame',11);
readerData = reader();
charData = char(readerData);
```

Verify that the writer data is the same as the reader data. By default, the reader returns the data in a column-major format.

```
strcmp(data,charData.')
```

```
ans = logical
     1
```

Change Endianness of Data

By default, the dsp.BinaryFileReader System object™ uses the endianness of the host machine. To change the endianness, such as when the host machine that writes the data does not have the same endianness as the host machine that reads the data, use the `swapbytes` function.

Write a numeric array into `myfile.dat` in big endian format. Read the data using the dsp.BinaryFileReader object. The reader object reads the data in little endian format.

```
fid = fopen('myfile.dat','w','b');
fwrite(fid,[1 2 3 4 5 6 7 8],'double');
fclose(fid);
reader = dsp.BinaryFileReader('myfile.dat','SamplesPerFrame',8);
x = reader();
display(x);
```

```
x = 8×1
10-318 ×
```

```
0.3039
0.0003
0.0104
0.0206
0.0256
0.0307
0.0357
0.0408
```

`x` does not match the original data. Change the endianness of `x` using the `swapbytes` function.

```
y = swapbytes(x);
display(y);
```

```
y = 8×1
```

```
1
2
3
4
5
6
7
8
```

`y` matches the original data.

Package: dsp

Write data to binary files

Description

The `dsp.BinaryFileWriter` System object writes multichannel signal data to a binary file. If the header is not empty, then the header precedes the signal data. The object specifies the file name and the structure of the header. The first time you write to the file, the object writes the header, followed by the data. On subsequent calls, the object writes the remaining data. If the header is empty, then no header is written.

The object can write floating-point data and integer data. To write character data and fixed-point data, see “Write and Read Character Data” on page 4-156 and “Write and Read Fixed-Point Data” on page 4-155. The input data can be real or complex. When the data is complex, the object writes the data as interleaved real and imaginary components. For an example, see “Write and Read Fixed-Point Data” on page 4-155. By default, the writer uses the endianness of the host machine. To change the endianness, you can use the `swapbytes` function. For an example, see “Change Endianness of Data Before Writing” on page 4-156 .

To write data to a binary file:

- 1 Create the `dsp.BinaryFileWriter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
writer = dsp.BinaryFileWriter
writer = dsp.BinaryFileWriter(fname)
writer = dsp.BinaryFileWriter(fname,Name,Value)
```

Description

`writer = dsp.BinaryFileWriter` creates a binary file writer object, `writer`, using the default properties.

`writer = dsp.BinaryFileWriter(fname)` sets the `Filename` property to `fname`.

`writer = dsp.BinaryFileWriter(fname,Name,Value)` with `Filename` set to `fname` and each property `Name` set to the specified `Value`. Unspecified properties have default values.

Example: `writer = dsp.BinaryFileWriter('myFilename.bin','HeaderStructure',struct('field1',1:10,'field2',single(1)));`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Filename — Name of file

'untitled.bin' (default) | character vector | string scalar

Name of the file to which the object writes the data, specified as a character vector or a string scalar. You must specify the full path for the file.

HeaderStructure — Header to write at beginning of file

struct([]) (default) | structure

Header to write at the beginning of the file, specified as a structure. The structure can have an arbitrary number of fields. Each field of the structure must be a real matrix of a built-in type. For example, if `HeaderStructure` is set to `struct('field1',1:10,'field2',single(1))`, the object writes a header formed by 10 double-precision values, `(1:10)`, followed by one single precision value, `single(1)`. If you do not specify a header, the object sets this property to an empty structure, `struct([])`.

Usage

Syntax

```
writer(data)
```

Description

`writer(data)` writes data to the binary file in a row-major format. Each call to the algorithm writes the elements of `data` at the end of the file. At the first call to the algorithm, the object writes the header first, followed by the data. If the header is empty, then no header is written.

The input data can be real or complex. For complex data, real and imaginary parts are interleaved. For example, if the data equals `[1 2; 3 4]+1j*[5 6; 7 8]`, then the object writes the elements as `1 5 2 6 3 7 4 8`.

Input Arguments

data — Data to be written to file

vector | matrix

Data to be written to the binary file in a row-major format, specified as a vector or a matrix. The object writes the data in row-major format. For example, if the input array is `[1 2 4 5; 8 7 9 2]`, the object writes the data as `[1 2 4 5 8 7 9 2]`.

The input data can be real or complex. For complex data, real and imaginary parts are interleaved. For example, if the data equals $[1\ 2; 3\ 4]+1j*[5\ 6; 7\ 8]$, then the object writes the elements as $[1\ 5\ 2\ 6\ 3\ 7\ 4\ 8]$.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Write and Read Binary Files

Create a binary file with a custom header using the `dsp.BinaryFileWriter` System object. Write data to this file. Read the header and data using the `dsp.BinaryFileReader` System object.

Write the Data

Specify the file header as a structure with the following fields:

- `DataType` set to `double`.
- `Complexity` set to `false`.
- `FrameSize` (number of rows in the data matrix) set to 150.
- `NumChannels` (number of columns in the data matrix) set to 1.

Create a `dsp.BinaryFileWriter` object using this header. The object writes the header first, followed by the data, to `ex_file.bin`. The data is a noisy sine wave signal. View the data in a time scope.

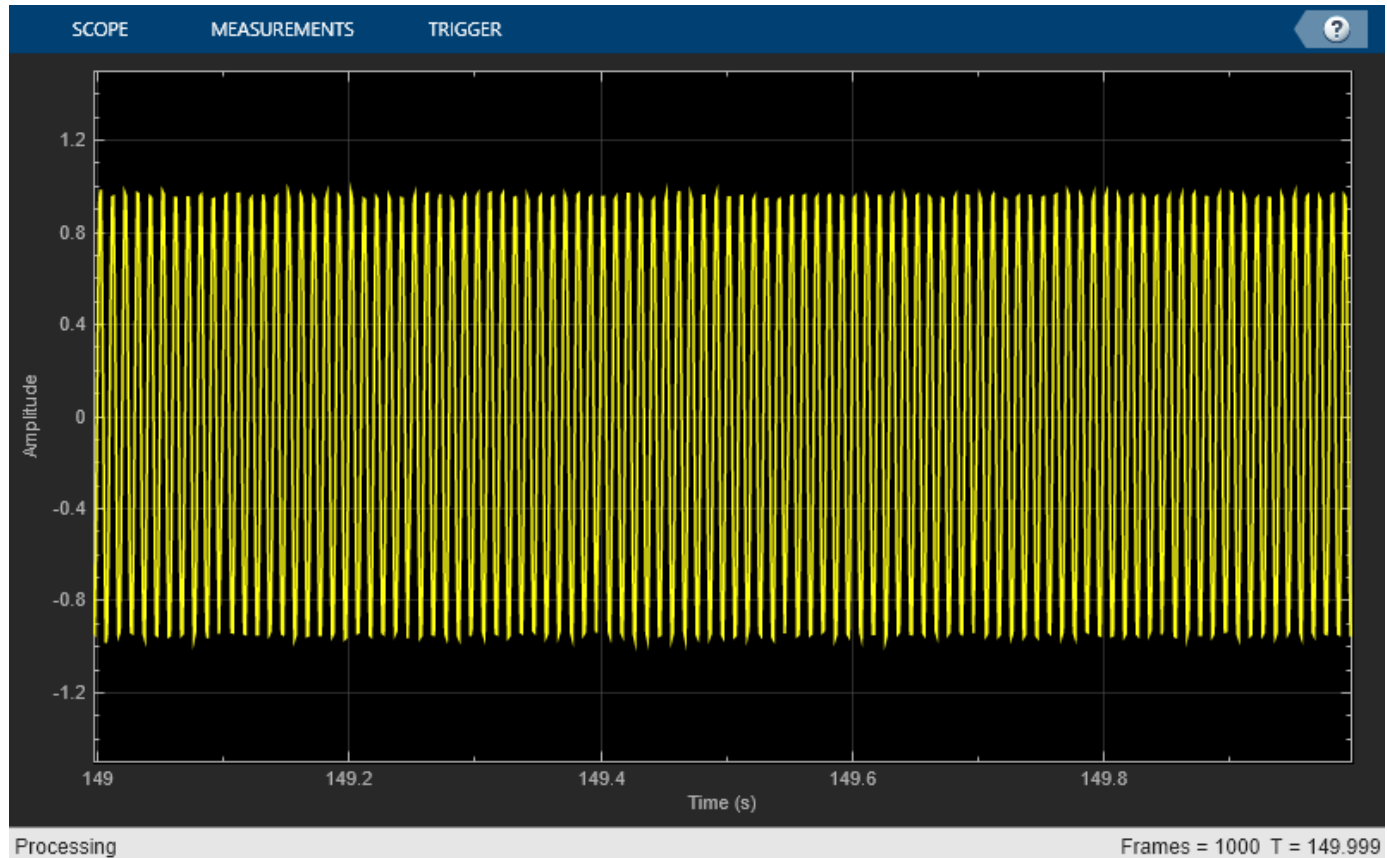

```
L = 150;
header = struct('DataType','double',...
    'Complexity',false,...
    'FrameSize',L,...
    'NumChannels',1);
writer = dsp.BinaryFileWriter('ex_file.bin',...
    'HeaderStructure',header);

sine = dsp.SinWave('SamplesPerFrame',L);
scopewriter = timescope('YLimits',[-1.5 1.5],...
    'SampleRate',sine.SampleRate,...
    'TimeSpanSource','Property',...
    'TimeSpan',1);
```

```

for i = 1:1000
    data = sine() + 0.01*randn(L,1);
    writer(data);
    scopewriter(data)
end

```

Release the writer so that the reader can access the data from this file.

```
release(writer);
```

Read the Data

Read the data from the binary file, `ex_file.bin`, using the `dsp.BinaryFileReader` object. The file contains the header data followed by the actual data. The object reads the binary data until the end of file is reached. Specify the header to the reader using the `HeaderStructure` property of the reader object.

If the exact header is not known on the reader side, you must at least specify the prototype of the header. That is, the number of fields, and the data type, size, and complexity of each field in the prototype must match with the header data written to the binary file. When the `readHeader` function reads the data from the binary file, the function extracts the header information based on how the fields are specified in the header prototype. For example, a header field set to `'double'` on the writer side can be specified as any string of 6 characters on the reader side. The `readHeader` function reads this field as a string of 6 characters from the binary file, which matches with `'double'`.

```
headerPrototype = struct('DataType','datatype',...
    'Complexity',false,...
    'FrameSize',1,...
    'NumChannels',10);
reader = dsp.BinaryFileReader(...
    'ex_file.bin',...
    'HeaderStructure',headerPrototype);
headerReader = readHeader(reader)
```

```
headerReader =
```

```
struct with fields:
```

```
    DataType: 'double'
    Complexity: 0
    FrameSize: 150
    NumChannels: 1
```

The header data extracted by the `readHeader` function is assigned to the corresponding properties of the reader object.

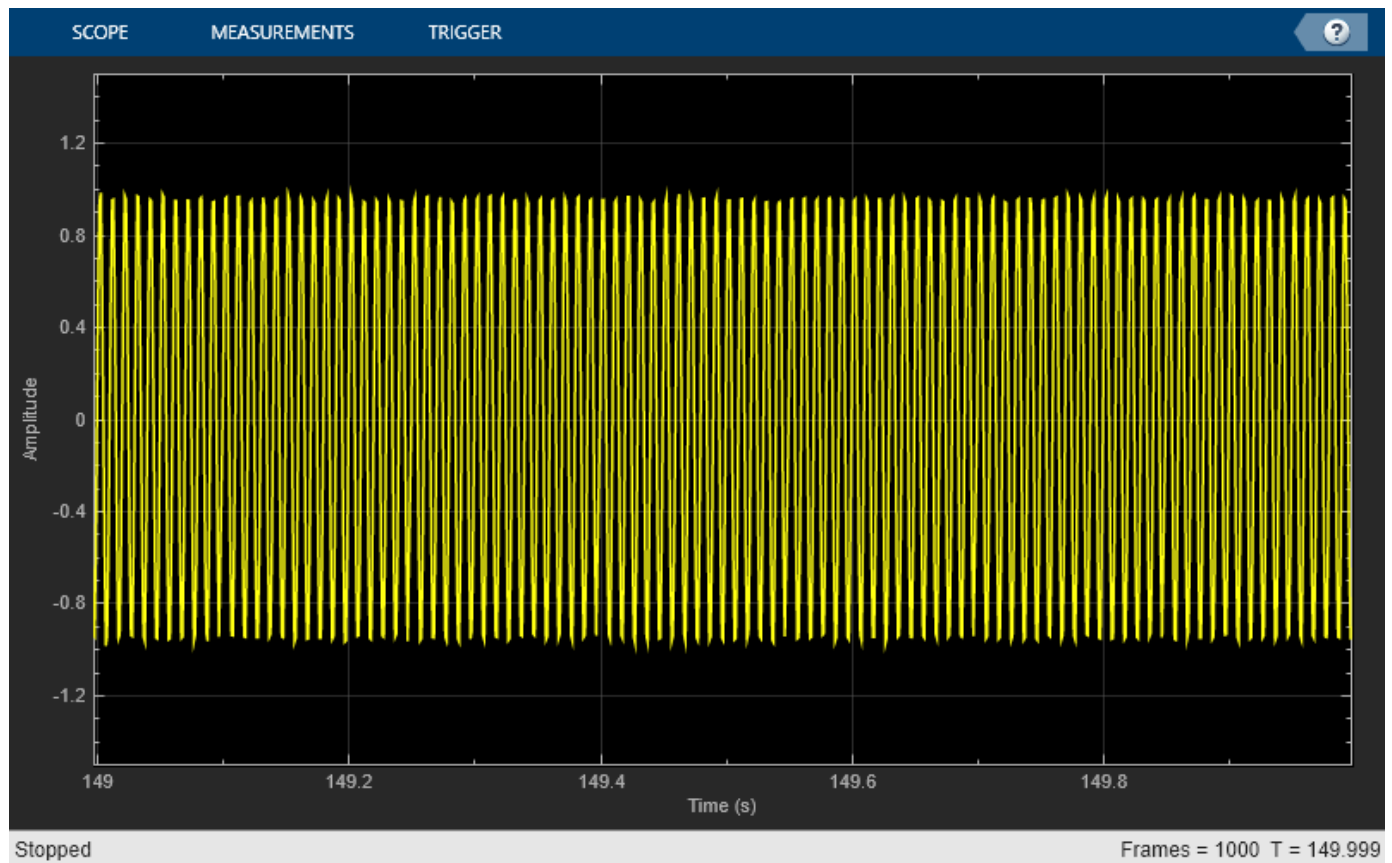

```
reader.IsDataComplex = headerReader.Complexity;
reader.DataType = headerReader.DataType;
reader.NumChannels = headerReader.NumChannels;
reader.SamplesPerFrame = headerReader.FrameSize;
```

Initialize a scope on the reader side to view the extracted binary file data.

```
scopereader = timescope('YLimits',[-1.5 1.5],...
    'SampleRate',sine.SampleRate,...
    'TimeSpanSource','Property',...
    'TimeSpan',1);
```

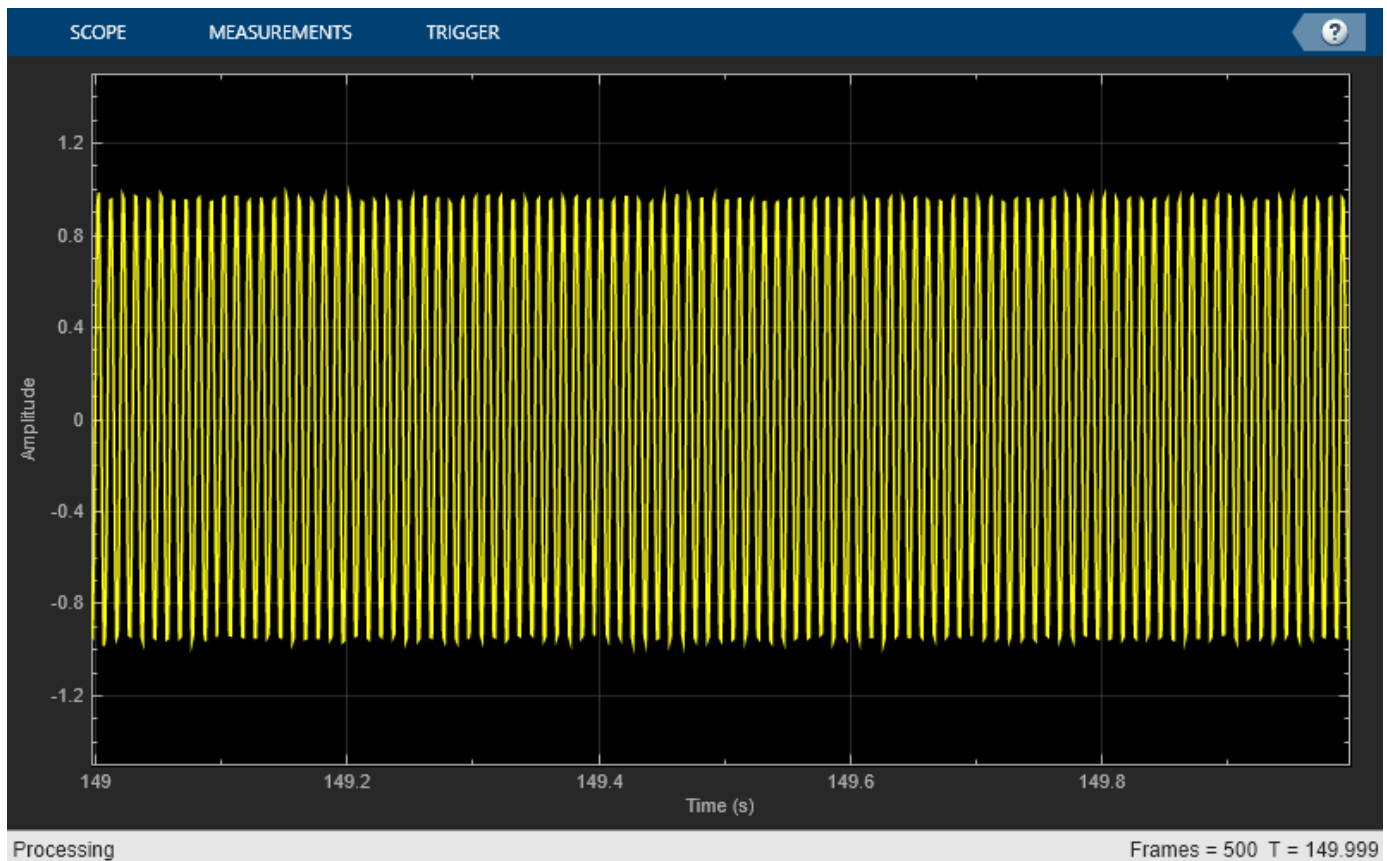

The data is read into a single channel (column) containing multiple frames, where each frame has 150 samples. View the data in a time scope.

```
while ~isDone(reader)
    out = reader();
    scopereader(out)
end
release(reader);
release(scopereader);
```

Set the reader to read data in frames of size 300. Verify that the data read matches the data written to the file.

```
reader.SamplesPerFrame = 300;  
while ~isDone(reader)  
    out = reader();  
    scopereader(out)  
end  
release(reader);
```

Even when the reader reads data with a different frame size, the output in both time scopes matches exactly.

Write and Read Matrix Data

Use a `dsp.BinaryFileReader` System object™ to read data from a binary file in a row-major format.

Write the Data

Write the matrix `A` to the binary file `Matdata.bin` using a `dsp.BinaryFileWriter` object. The object writes the specified header followed by the data.

The header has the following format:

- `DataType` set to `double`.
- `Complexity` set to `false`.
- `FrameSize` (number of rows in the data matrix) set to 3.
- `NumChannels` (number of columns in the data matrix) set to 4.

```
A = [1 2 3 8; 4 5 6 10; 7 8 9 11];
header = struct('DataType','double',...
    'Complexity',false,...
```

```
        'FrameSize',3,...
        'NumChannels',4);
writer = dsp.BinaryFileWriter('Matdata.bin',...
    'HeaderStructure',header);
writer(A);
```

Release the writer so that the reader can access the data.

```
release(writer);
```

Read the Data

Specify the header using the `HeaderStructure` property of the reader object. If the exact header is not known, you must at least specify the prototype of the header. That is, the number of fields, and the data type, size, and complexity of each field in the prototype must match with the header data written to the binary file. The `dsp.BinaryFileReader` object reads the binary file `Matdata.bin` until the end of file is reached. Configure the System object to read the data into 4 channels, with each channel containing 5 samples. Each loop of the iteration reads a channel (or frame) of data.

```
headerPrototype = struct('DataType','double',...
    'Complexity',false,...
    'FrameSize',5,...
    'NumChannels',4);
reader = dsp.BinaryFileReader('Matdata.bin',...
    'HeaderStructure',headerPrototype,...
    'NumChannels',4,...
    'SamplesPerFrame',5);
while ~isDone(reader)
    out = reader();
    display(out)
end
```

```
out = 5×4
```

```
     1     2     3     8
     4     5     6    10
     7     8     9    11
     0     0     0     0
     0     0     0     0
```

Each frame of `out` contains frames of the matrix `A`, followed by zeros to complete the frame. The original matrix `A` contains 4 channels with 3 samples in each channel. The reader is configured to read data into 4 channels, with each channel containing 5 samples. Because there are not enough samples to complete the frame, the reader object appends zeros at the end of each frame.

Write Complex Data

Create a `dsp.BinaryFileWriter` object which writes to a file named `myfile.dat`. There is no header. The data is complex.

```
writer = dsp.BinaryFileWriter('myfile.dat');
data = [1 2 3 4]+1i*[5 6 7 8];
writer(data);
release(writer);
```

Read the data using the `dsp.BinaryFileReader` System object™. To view data in the format it is written to the file, set the `IsDataComplex` property to `false`. The reader object reads the data as a sequence of numbers in a row major format. Set `SamplesPerFrame` to 1 and `NumChannels` to 8.

```
reader = dsp.BinaryFileReader('myfile.dat','SamplesPerFrame',1,...
    'NumChannels',8);
s = struct([]);
reader.HeaderStructure = s;
dataRead = reader();
```

You can see that the real and imaginary components of the original data are sample interleaved.

```
display(dataRead);
```

```
dataRead = 1×8
```

```
    1    5    2    6    3    7    4    8
```

Write and Read Fixed-Point Data

The `dsp.BinaryFileWriter` and `dsp.BinaryFileReader` System objects do not support writing and reading fixed-point data. As a workaround, you can write the stored integer portion of the `fi` data, read the data, and use this value to reconstruct the `fi` data.

Write the Fixed-Point Data

Create an `fi` object to represent 100 signed random numbers with a word length of 14 and a fraction length of 12. Write the stored integer portion of the `fi` object to the data file `myFile.dat`. The built-in data type is `int16`, which can be computed using `class(storeIntData)`.

```
data = randn(100,1);
fiDataWriter = fi(data,1,14,12);
storeIntData = storedInteger(fiDataWriter);
```

```
writer = dsp.BinaryFileWriter('myFile.dat');
writer(storeIntData);
```

Release the writer so that the reader can access the data.

```
release(writer);
```

Read the Fixed-Point Data

Specify the reader to read the stored integer data as `int16` data with 100 samples per data frame. The real-world value of the fixed-point number can be represented using $2^{(-fractionLength)(storedInteger)}$. If you know the signedness, word length, and fraction length of the fixed-point data, you can reconstruct the `fi` data using `fi(realValue,signedness,wordLength,fractionLength)`. In this example, the data is signed with a word length of 14 and a fraction length of 12.

```
reader = dsp.BinaryFileReader('Filename','myFile.dat',...
    'SamplesPerFrame',100,...
    'DataType','int16');
```

```
data = reader();
fractionLength = 12;
wordLength = 14;
realValue = 2^(-fractionLength)*double(data);
```

```
fiDataReader = fi(realValue,1,...
    wordLength,fractionLength);
```

Verify that the writer data is the same as the reader data.

```
isequal(fiDataWriter,fiDataReader)
```

```
ans = logical
     1
```

Write and Read Character Data

The `dsp.BinaryFileWriter` and `dsp.BinaryFileReader` System objects do not support writing and reading characters. As a workaround, cast character data to one of the built-in data types and write the integer data. After the reader reads the data, convert the data to a character using the `char` function.

Write the Character Data

Cast a character into `uint8` using the `cast` function. Write the cast data to the data file `myFile.dat`.

```
data = 'binary_file';
castData = cast(data,'uint8');
writer = dsp.BinaryFileWriter('myFile.dat');
writer(castData);
```

Release the writer so that the reader can access the data.

```
release(writer);
```

Read the uint8 Data

Configure the reader to read the cast data as `uint8` data.

```
reader = dsp.BinaryFileReader('myFile.dat',...
    'DataType','uint8',...
    'SamplesPerFrame',11);
readerData = reader();
charData = char(readerData);
```

Verify that the writer data is the same as the reader data. By default, the reader returns the data in a column-major format.

```
strcmp(data,charData.')
```

```
ans = logical
     1
```

Change Endianness of Data Before Writing

By default, the `dsp.BinaryFileWriter` System object™ uses the endianness of the host machine. To change the endianness, use the `swapbytes` function.

Write a numeric array into `myfile.dat` using the `dsp.BinaryFileWriter` object. Before writing the data, change the endianness of the data using the `swapbytes` function.

```
data = [1 2 3 4 2 2];  
swapData = swapbytes(data);  
writer = dsp.BinaryFileWriter('myfile.dat');  
writer(swapData);
```

dsp.BiquadFilter

Package: dsp

IIR filter using biquadratic structures

Description

The `dsp.BiquadFilter` object implements a cascade of biquadratic sections, where the coefficients for each section are supplied by a separate row of an N -by-6 second-order sections (SOS) matrix. Each row of the SOS matrix contains the numerator and denominator coefficients of the corresponding section of the filter. The resulting filter can be applied to a vector or matrix input, where each column represents a channel of data that is processed independently.

To implement an IIR filter structure using biquadratic or SOS:

- 1 Create the `dsp.BiquadFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
biquad = dsp.BiquadFilter
biquad = dsp.BiquadFilter(sosmatrix,scalevalues)
biquad = dsp.BiquadFilter(Name,Value)
```

Description

`biquad = dsp.BiquadFilter` returns a biquadratic IIR (SOS) filter System object, `biquad`, which independently filters each channel (column) of the input over time using the SOS section `[1 0.3 0.4 1 0.1 0.2]` with a direct-form II transposed structure.

`biquad = dsp.BiquadFilter(sosmatrix,scalevalues)` returns a biquadratic filter object, with the `SOSMatrix` property set to `sosmatrix` and the `ScaleValues` property set to `scalevalues`.

`biquad = dsp.BiquadFilter(Name,Value)` returns a biquadratic filter object, `biquad`, with each property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Structure — Filter structure

'Direct form II transposed' (default) | 'Direct form I' | 'Direct form I transposed' | 'Direct form II'

Specify the filter structure as 'Direct form I', 'Direct form I transposed', 'Direct form II', 'Direct form II transposed'.

SOSMatrixSource — SOS matrix source

'Property' (default) | 'Input port'

Specify the source of the SOS matrix as 'Property' or 'Input port'.

SOSMatrix — SOS matrix

[1 0.3 0.4 1 0.1 0.2] (default) | N-by-6 matrix

Specify the second-order section (SOS) matrix as an N-by-6 matrix, where N is the number of sections in the filter. Each row of the SOS matrix contains the numerator and denominator coefficients of the corresponding section of the filter. The system function, $H(z)$, of a biquad filter is:

$$H(z) = \frac{\sum_{k=0}^2 b_k z^{-k}}{1 - \sum_{l=1}^2 a_l z^{-l}}$$

The coefficients are ordered in the rows of the SOS matrix as $(b_0, b_1, b_2, 1, -a_1, -a_2)$. You can use coefficients of real or complex values. This property applies only when you set the `SOSMatrixSource` property to `Property`. The leading denominator coefficient of the biquad filter, a_0 , equals 1 for each filter section, regardless of the specified value.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

ScaleValues — Scale values for each biquad section

1 (default) | scalar | vector

Specify the scale values to apply before and after each section of a biquad filter. `ScaleValues` must be either a scalar or a vector of length N+1, where N is the number of sections. If you set this property to a scalar, the scalar value is used as the gain value only before the first filter section. The remaining gain values are set to 1. If you set this property to a vector of N+1 values, each value is used for a separate section of the filter.

Dependencies

This property applies only when you set the `SOSMatrixSource` property to `Property`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

InitialConditions — Initial conditions for direct form II structures

0 (default) | scalar | vector | matrix

Specify the initial conditions of the filter states when the `Structure` property is one of `Direct form II` | `Direct form II transposed`. The number of states or delay elements (zeros and

poles) in a direct-form II biquad filter equals twice the number of filter sections. You can specify the initial conditions as a scalar, vector, or matrix.

When you specify a scalar value, the biquad filter initializes all delay elements in the filter to that value. When you specify a vector of length equal to the number of delay elements in the filter, each vector element specifies a unique initial condition for the corresponding delay element.

The biquad filter applies the same vector of initial conditions to each channel of the input signal. When you specify a vector of length equal to the product of the number of input channels and the number of delay elements in the filter, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel. When you specify a matrix with the same number of rows as the number of delay elements in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel.

Dependencies

This property applies only when you set the `Structure` property to one of `Direct form II` or `Direct form II transposed`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

NumeratorInitialConditions — Initial conditions on zeros side

0 (default) | `scalar` | `vector` | `matrix`

Specify the initial conditions of the filter states on the side of the filter structure with the zeros. The number of states or delay elements in the numerator of a direct-form I biquad filter equals twice the number of filter sections. You can specify the initial conditions as a scalar, vector, or matrix. When you specify a scalar, the biquad filter initializes all delay elements on the zeros side in the filter to that value. When you specify a vector of length equal to the number of delay elements on the zeros side in the filter, each vector element specifies a unique initial condition for the corresponding delay element on the zeros side.

The biquad filter applies the same vector of initial conditions to each channel of the input signal. When you specify a vector of length equal to the product of the number of input channels and the number of delay elements on the zeros side in the filter, each element specifies a unique initial condition for the corresponding delay element on the zeros side in the corresponding channel. When you specify a matrix with the same number of rows as the number of delay elements on the zeros side in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay element on the zeros side in the corresponding channel.

Dependencies

This property applies only when you set the `Structure` property to one of `Direct form I` or `Direct form I transposed`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

DenominatorInitialConditions — Initial conditions on poles side

0 (default) | `scalar` | `vector` | `matrix`

Specify the initial conditions of the filter states on the side of the filter structure with the poles. The number of denominator states, or delay elements, in a direct-form I (noncanonic) biquad filter equals twice the number of filter sections. You can specify the initial conditions as a scalar, vector, or matrix. When you specify a scalar, the biquad filter initializes all delay elements on the poles side of the filter to that value. When you specify a vector of length equal to the number of delay elements on the poles

side in the filter, each vector element specifies a unique initial condition for the corresponding delay element on the poles side.

The object applies the same vector of initial conditions to each channel of the input signal. When you specify a vector of length equal to the product of the number of input channels and the number of delay elements on the poles side in the filter, each element specifies a unique initial condition for the corresponding delay element on the poles side in the corresponding channel. When you specify a matrix with the same number of rows as the number of delay elements on the poles side in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay element on the poles side in the corresponding channel.

Dependencies

This property only applies when you set the `Structure` property to one of `Direct form I` or `Direct form I transposed`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

OptimizeUnityScaleValues — Optimize unity scale values

`true` (default) | `false`

When this Boolean property is set to `true`, the biquad filter removes all unity scale gain computations. This reduces the number of computations and increases the fixed-point accuracy.

Dependencies

This property applies only when you set the `SOSMatrixSource` property to `Property`.

ScaleValuesInputPort — How to specify scale values

`true` (default) | `false`

Select how to specify scale values. By default, this property is `true`, and the scale values are specified via the input port. When this property is `false`, all scale values are 1.

Dependencies

This property applies only when the `SOSMatrixSource` property is `Input port`.

Fixed-Point Properties

RoundingMethod — Rounding method for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding method.

OverflowAction — Overflow action for fixed-point operations

`Wrap` (default) | `Saturate`

Specify the overflow action as one of `Wrap` or `Saturate`.

MultiplicandDataType — Multiplicand word and fraction lengths

`Same as output` (default) | `Custom`

Specify the multiplicand fixed-point data type as one of `Same as output` or `Custom`.

Dependencies

This property applies only when you set the `Structure` property to `Direct form I transposed`.

CustomMultiplicandDataType — Custom multiplicand word and fraction lengths`numerictype([],32,30)` (default) | `numerictype`

Specify the multiplicand fixed-point type as a scaled `numerictype` object with a Signedness of Auto.

Dependencies

This property applies only when you set the `MultiplicandDataType` property to Custom.

SectionInputDataType — Section input word and fraction lengths`Same as input` (default) | `Custom`

Specify the section input fixed-point data type as either `Same as input` or `Custom`.

CustomSectionInputDataType — Custom section input word and fraction lengths`numerictype([],16,15)` (default) | `numerictype`

Specify the section input fixed-point type as a scaled `numerictype` object with a Signedness of Auto.

Dependencies

This property applies only when you set the `SectionInputDataType` property to Custom.

SectionOutputDataType — Section output word and fraction lengths`Same as section input` (default) | `Custom`

Specify the section output fixed-point data type as either `Same as section input` or `Custom`.

CustomSectionOutputDataType — Custom section output word and fraction lengths`numerictype([],16,15)` (default) | `numerictype`

Specify the section output fixed-point type as a signed, scaled `numerictype` object with a Signedness of Auto.

Dependencies

This property applies only when you set the `SectionOutputDataType` property to Custom.

NumeratorCoefficientsDataType — Numerator coefficients word and fraction lengths`Same word length as input` (default) | `Custom`

Specify the numerator coefficients fixed-point data type as `Same word length as input` or `Custom`. Setting this property also sets the `DenominatorCoefficientsDataType` and `ScaleValuesDataType` properties to the same value.

Dependencies

This property applies only when you set the `SOSMatrixSource` property to Property.

CustomNumeratorCoefficientsDataType — Custom numerator coefficients word and fraction lengths`numerictype([],16,15)` (default) | `numerictype`

Specify the numerator coefficients fixed-point type as a `numerictype` object with a Signedness of Auto. The word length of the `CustomNumeratorCoefficientsDataType`,

CustomDenominatorCoefficientsDataType, and CustomScaleValuesDataType properties must be the same.

Dependencies

This property applies only when you set the SOSMatrixSource property to Property and the NumeratorCoefficientsDataType property to Custom.

DenominatorCoefficientsDataType — Denominator coefficients word and fraction lengths

Same word length as input (default) | Custom

Specify the denominator coefficients fixed-point data type as Same word length as input or Custom. Setting this property also sets the NumeratorCoefficientsDataType and ScaleValuesDataType properties to the same value.

Dependencies

This property applies only when you set the SOSMatrixSource property to Property.

CustomDenominatorCoefficientsDataType — Custom denominator coefficients word and fraction lengths

numericType([],16,15) (default) | numericType

Specify the denominator coefficients fixed-point type as a numericType object with a Signedness of Auto. The CustomNumeratorCoefficientsDataType, CustomDenominatorCoefficientsDataType, and CustomScaleValuesDataType properties must have the same word lengths.

Dependencies

This property applies only when you set the SOSMatrixSource property to Property and the DenominatorCoefficientsDataType property to Custom.

ScaleValuesDataType — Scale values word and fraction lengths

Same word length as input (default) | Custom

Specify the scale values fixed-point data type as Same word length as input or Custom. Setting this property also sets the NumeratorCoefficientsDataType and DenominatorCoefficientsDataType properties to the same value.

Dependencies

This property applies only when you set the SOSMatrixSource property to Property.

CustomScaleValuesDataType — Custom scale values word and fraction lengths

numericType([],16,15) (default) | numericType

Specify the scale values fixed-point type as a numericType object with a Signedness of Auto. The CustomNumeratorCoefficientsDataType, CustomDenominatorCoefficientsDataType, and CustomScaleValuesDataType properties must have the same word lengths.

Dependencies

This property applies only when you set the SOSMatrixSource property to Property and the ScaleValuesDataType property to Custom.

NumeratorProductDataType — Numerator product word and fraction lengths

Same as input (default) | Custom | Full precision

Specify the mode to determine the numerator product fixed-point data type as:

- `Same as input` (default) — The numerator product word and fraction lengths are same as that of the input.
- `Custom` — Enables the `CustomNumeratorProductDataType` property, which you can use to specify the custom numerator product data type. Specify the data type as a `numericType` object.
- `Full precision` — Use full-precision rules to specify the data type. These rules provide the most accurate fixed-point numerics. The rules prevent quantization from occurring within the object. Bits are added, as needed, so that no roundoff or overflow occurs. For more information, see “Full Precision for Fixed-Point System Objects”.

Setting this property also sets the `DenominatorProductDataType` property to the same value.

CustomNumeratorProductDataType — Custom numerator product word and fraction lengths

`numericType([], 32, 30)` (default) | `numericType`

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. The `CustomNumeratorProductDataType` and `CustomDenominatorProductDataType` properties must have the same word lengths.

Dependencies

This property applies only when you set the `NumeratorProductDataType` property to `Custom`.

DenominatorProductDataType — Denominator product word and fraction lengths

`Same as input` (default) | `Custom` | `Full precision`

Specify the mode to determine the denominator product fixed-point data type as:

- `Same as input` (default) — The denominator product word and fraction lengths are same as that of the input.
- `Custom` — Enables the `CustomDenominatorProductDataType` property, which you can use to specify the custom denominator product data type. Specify the data type as a `numericType` object.
- `Full precision` — Use full-precision rules to specify the data type. These rules provide the most accurate fixed-point numerics. The rules prevent quantization from occurring within the object. Bits are added, as needed, so that no roundoff or overflow occurs. For more information, see “Full Precision for Fixed-Point System Objects”.

Setting this property also sets the `NumeratorProductDataType` property to the same value.

CustomDenominatorProductDataType — Custom denominator product word and fraction lengths

`numericType([], 32, 30)` (default) | `numericType`

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. The `CustomNumeratorProductDataType` and `CustomDenominatorProductDataType` properties must have the same word lengths.

Dependencies

This property applies only when you set the `DenominatorProductDataType` to `Custom`.

NumeratorAccumulatorDataType — Numerator accumulator word and fraction lengths

Same as product (default) | Same as input | Custom

Specify the numerator accumulator fixed-point data type as Same as input, Same as product, or Custom. Setting this property also sets the DenominatorAccumulatorDataType property to the same value.

CustomNumeratorAccumulatorDataType — Custom numerator accumulator word and fraction lengths

numericitytype([],32,30) (default) | numericitytype

Specify the numerator accumulator fixed-point type as a scaled numericitytype object with a Signedness of Auto. The CustomNumeratorAccumulatorDataType and CustomDenominatorAccumulatorDataType properties must have the same word lengths.

Dependencies

This property applies only when you set the NumeratorAccumulatorDataType property to Custom.

DenominatorAccumulatorDataType — Denominator accumulator word and fraction lengths

Same as product (default) | Same as input | Custom

Specify the denominator accumulator fixed-point data type as Same as input, Same as product, or Custom. Setting this property also sets the NumeratorAccumulatorDataType property to the same value.

CustomDenominatorAccumulatorDataType — Custom denominator accumulator word and fraction lengths

numericitytype([],32,30) (default) | numericitytype

Specify the denominator accumulator fixed-point type as a scaled numericitytype object with a Signedness of Auto. The CustomNumeratorAccumulatorDataType and CustomDenominatorAccumulatorDataType properties must have the same word lengths.

Dependencies

This property applies only when you set the DenominatorAccumulatorDataType property to Custom.

StateDataType — State word and fraction lengths

Same as accumulator (default) | Same as input | Custom

Specify the state fixed-point data type as Same as input, Same as accumulator, or Custom.

Dependencies

This property applies when you set the “Structure” on page 4-0 property to Direct form II or Direct form II transposed.

CustomStateDataType — Custom state word and fraction lengths

numericitytype([],16,15) (default) | numericitytype

Specify the state fixed-point type as a scaled numericitytype object with a Signedness of Auto.

Dependencies

This property applies only when you set the StateDataType property to Custom.

NumeratorStateDataType — Numerator state word and fraction lengths

Same as accumulator (default) | Same as input | Custom

Specify the numerator state fixed-point data type as Same as input, Same as accumulator, or Custom. Setting this property also sets the DenominatorStateDataType property to the same value.

Dependencies

This property applies only when you set the “Structure” on page 4-0 property to Direct form I transposed.

CustomNumeratorStateDataType — Custom numerator state word and fraction lengths

numerictype([],16,15) (default) | numerictype

Specify the numerator state fixed-point type as a scaled numerictype object with a Signedness of Auto. The CustomNumeratorProductDataType and CustomDenominatorProductDataType properties must have the same word lengths.

Dependencies

This property applies only when you set the StateDataType property to Custom.

DenominatorStateDataType — Denominator state word and fraction lengths

Same as accumulator (default) | Same as input | Custom

Specify the denominator state fixed-point data type as Same as input, Same as accumulator, or Custom. Setting this property also sets the NumeratorStateDataType property to the same value.

Dependencies

This property applies only when you set the “Structure” on page 4-0 property to Direct form I transposed.

CustomDenominatorStateDataType — Custom denominator state word and fraction lengths

numerictype([],16,15) (default) | numerictype

Specify the denominator state fixed-point type as a scaled numerictype object with a Signedness of Auto. The CustomNumeratorStateDataType and CustomDenominatorStateDataType properties must have the same word lengths.

Dependencies

This property applies only when you set the StateDataType property to Custom.

OutputDataType — Output word and fraction lengths

Same as accumulator (default) | Same as input | Custom

Specify the output fixed-point data type as Same as input, Same as accumulator, or Custom.

CustomOutputDataType — Custom output word and fraction lengths

numerictype([],16,15) (default) | numerictype

Specify the output fixed-point type as a scaled numerictype object with a Signedness of Auto.

Dependencies

This property applies only when you set the “OutputDataType” on page 4-0 property to Custom.

Usage

Syntax

```
y = biquad(x)
y = biquad(x,num,den)
y = biquad(x,num,den,g)
```

Description

`y = biquad(x)` filters the input signal `x`, and outputs the filtered values, `y`. The biquad filter object filters each channel of the input signal over successive calls to the algorithm.

`y = biquad(x,num,den)` filters the input using `num` as the numerator coefficients, and `den` as the denominator coefficients of the biquad filter. This configuration applies when the `SOSMatrixSource` property is `Input port` and the `ScaleValuesInputPort` property is `false`.

`y = biquad(x,num,den,g)` specifies the scale values, `g`, of the biquad filter. This configuration applies when the `SOSMatrixSource` property is `Input Port` and the `ScaleValuesInputPort` property is `true`.

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix. This object also accepts variable-size inputs. Once the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

The data type of all the inputs must be the same. If the input is fixed-point, it must be signed fixed point with power-of-two slope and zero bias.

The complexity of `x`, `num`, and `den` must be the same.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

num — Numerator coefficients

3-by-*N* matrix

Numerator coefficients, specified as a 3-by-*N* numeric matrix, where *N* is the number of biquad filter sections. The complexity of `x`, `num`, and `den` must be the same.

The data type of all the inputs must be the same. If `num` is fixed point, it must be signed fixed point with power-of-two slope and zero bias.

Dependencies

This input applies only when you set `SOSMatrixSource` property is `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

Complex Number Support: Yes

den — Denominator coefficients

2-by-*N* matrix

Denominator coefficients, specified as a 2-by- N numeric matrix, where N is the number of biquad filter sections. The object assumes that the first denominator coefficient of each section is 1.

The data type of all the inputs must be the same. If `den` is fixed point, it must be signed fixed point with power-of-two slope and zero bias.

The complexity of `x`, `num`, and `den` must be the same.

Dependencies

This input applies only when you set `SOSMatrixSource` property is `InputPort`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`
Complex Number Support: Yes

g — Scale values

1-by- $(N + 1)$ vector

Scale values of the biquad filter, specified as a 1-by- $(N + 1)$ numeric vector, where N is the number of biquad filter sections.

The data type of all the inputs must be the same. If `g` is fixed point, it must be signed fixed point with power-of-two slope and zero bias.

Dependencies

This input applies when the `SOSMatrixSource` property is `InputPort` and the `ScaleValuesInputPort` property is `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

Output Arguments

y — Filtered output

vector | matrix

Filtered output, returned as a vector or a matrix. The size, data type, and complexity of the output signal matches that of the input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.BiquadFilter`

<code>freqz</code>	Frequency response of discrete-time filter System object
<code>fvtool</code>	Visualize frequency response of DSP filters
<code>impz</code>	Impulse response of discrete-time filter System object
<code>info</code>	Information about filter System object
<code>coeffs</code>	Returns the filter System object coefficients in a structure
<code>cost</code>	Estimate cost of implementing filter System object

scale	Scale second-order sections
scaleopts	Create an options object for second-order section scaling
scalecheck	Check scaling of biquadratic filter
cumsec	Cumulative second-order section of the biquadratic filter
generatehdl	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)
tf	Convert discrete-time filter System object to transfer function
reorder	Reorder second-order sections of biquadratic filter System object

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Filter a Signal Using Biquadratic Filter

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Use a fourth order, lowpass biquadratic filter object with a normalized cutoff frequency of 0.4 to filter high frequencies from an input signal. Display the result as a power spectrum using the Spectrum Analyzer.

```
t = (0:1000)'/8e3;
xin = sin(2*pi*0.3e3*t)+sin(2*pi*3e3*t); % Input is 0.3 &
                                         % 3kHz sinusoids
src = dsp.SignalSource(xin, 100);
sink = dsp.SignalSink;

[z,p,k] = ellip(4,1,60,.4); % Set up the filter
[sosMatrix,scaleValues] = zp2sos(z,p,k);
biquad = dsp.BiquadFilter(sosMatrix,scaleValues,Structure="Direct form I");

sa = spectrumAnalyzer(SampleRate=8e3,...
    Method="welch",...
    PlotAsTwoSidedSpectrum=false,...
    OverlapPercent=80,SpectrumUnits="dBW",...
    YLimits=[-160 -10]);

while ~isDone(src)
    input = src();
    filteredOutput = biquad(input);
    sink(filteredOutput);
    sa(filteredOutput)
end
```

```
filteredResult = sink.Buffer;  
fvtool(biquad,Fs=8000)
```

Linf-norm Scaling of a Biquadratic SOS Filter

Demonstrate the Linf-norm scaling of a biquadratic SOS filter using the `scale` function.

```
Fs = 8000;
Fcutoff = 2000;
[z,p,k] = butter(10,Fcutoff/(Fs/2));
[sosMatrix,scaleValues] = zp2sos(z,p,k);
sosFilt = dsp.SOSFilter(Structure='Direct form I', ...
    Numerator=sosMatrix(:,1:3),Denominator=sosMatrix(:,4:6), ...
    HasScaleValues=true,ScaleValues=scaleValues)
```

```
sosFilt =
    dsp.SOSFilter with properties:

        Structure: 'Direct form I'
    CoefficientSource: 'Property'
        Numerator: [5x3 double]
        Denominator: [5x3 double]
    HasScaleValues: true
        ScaleValues: [0.0029 1 1 1 1 1]
```

Show all properties

```
scale(sosFilt, 'linf', scalevalueconstraint='none', maxscalevalue=2)
```

More About

Fixed Point

The following diagrams show the data types used in the `dsp.BiquadFilter` object when the input is fixed-point. For each filter structure the object supports, the data types shown in the diagrams can be set through the respective fixed-point properties of the object.

Direct Form I

The following diagram shows the data types for one section of the filter for fixed-point signals.

The following diagrams show the fixed-point data types between filter sections.

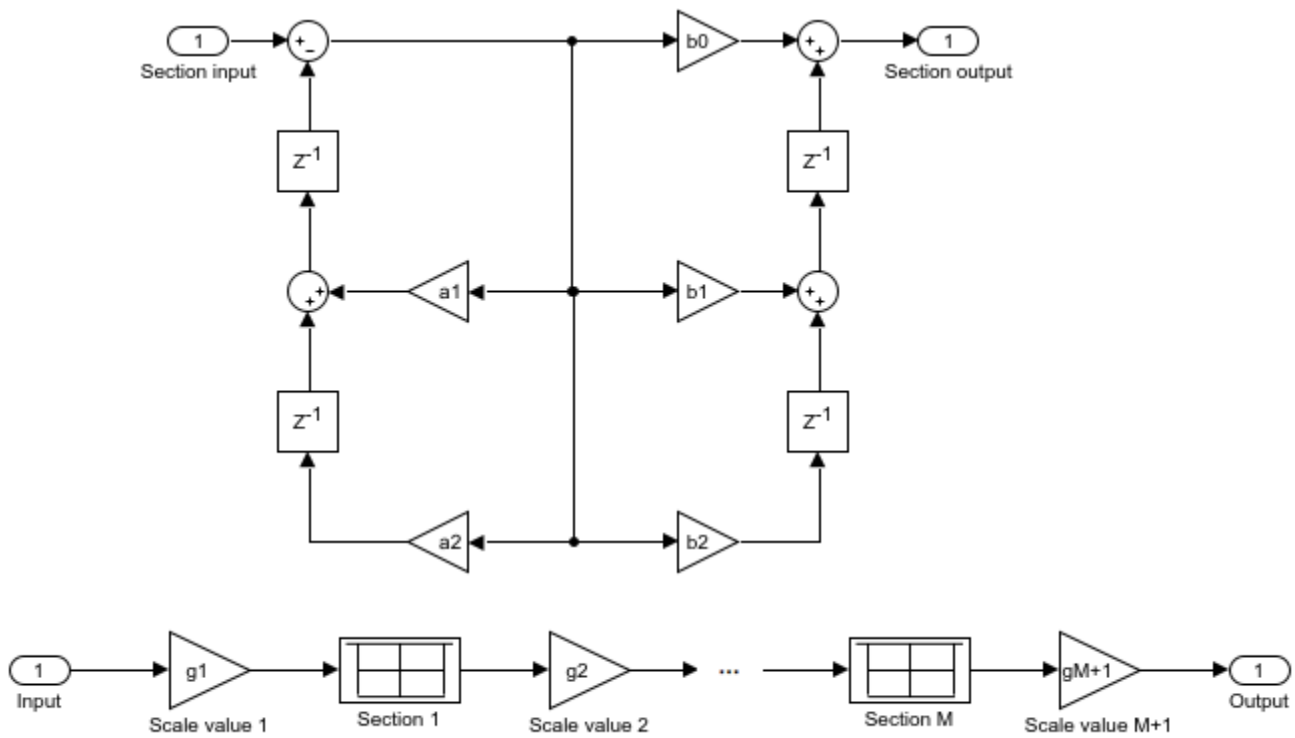

When the data is not optimized:

When you specify OptimizeUnityScaleValues to true, and scale values to 1:

Direct Form I Transposed

The following diagram shows the data types for one section of the filter for fixed-point signals.

The dashed casts are omitted when you specify `OptimizeUnityScaleValues` to true, and scale values to 1.

The following diagrams show the fixed-point data types between filter sections.

Algorithms

This object implements the algorithm, inputs, and outputs described on the Biquad Filter block reference page. The object properties correspond to the block parameters, except:

- **Coefficient source**
- **Action when the a0 values of the SOS matrix are not one** - the biquad filter object assumes the zero-th-order denominator coefficient equals 1 regardless of the specified value. The biquad filter object does not support the Error or Warn options found in the corresponding block.

Both this object and its corresponding block support variable-size input. When you call the object, it can handle an input argument which is changing in size.

Version History

Introduced in R2012a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This object supports HDL code generation with the HDL Coder or Filter Design HDL Coder™ products. For HDL Coder workflows and limitations, see “HDL Code Generation for System Objects” (HDL Coder). For Filter Design HDL Coder workflows and limitations, see “Generate HDL Code for Filter System Objects” (Filter Design HDL Coder).

dsp.BlockLMSFilter

Package: dsp

Compute output, error, and weights using block LMS adaptive algorithm

Description

The `dsp.BlockLMSFilter` System object computes output, error, and weights using the block LMS adaptive algorithm.

To compute the output, error, and weights:

- 1 Create the `dsp.BlockLMSFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
blms = dsp.BlockLMSFilter
blms = dsp.BlockLMSFilter(length,blocksize)
blms = dsp.BlockLMSFilter(Name,Value)
```

Description

`blms = dsp.BlockLMSFilter` returns an adaptive FIR filter, `blms`, that filters the input signal and computes filter weights based on the block least mean squares (LMS) algorithm.

`blms = dsp.BlockLMSFilter(length,blocksize)` returns an adaptive FIR filter, `blms`, with the `Length` property set to `length` and the `BlockSize` property set to `blocksize`.

`blms = dsp.BlockLMSFilter(Name,Value)` returns an adaptive FIR filter, `blms`, with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Length — Length of FIR filter weights vector

32 (default) | positive integer

Specify the length of the FIR filter weights vector as a positive integer scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

BlockSize — Number of samples acquired before weight adaptation

32 (default) | positive integer

Specify the number of samples of the input signal to acquire before the object updates the filter weights. The input frame length must be an integer multiple of the block size.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

StepSizeSource — Source of adaptation step size

Property (default) | Input port

Specify the source of the adaptation step size factor as Property or Input port.

StepSize — Adaptation step size

0.1 (default) | nonnegative scalar

Specify the adaptation step size factor as a scalar, nonnegative numeric value.

Tunable: Yes

Dependencies

This property applies only when you set the “StepSizeSource” on page 4-0 property to 'Property'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

LeakageFactor — Leakage factor used in leaky LMS algorithm

1 (default) | scalar

Specify the leakage factor used in leaky LMS algorithm as a scalar numeric value between 0 and 1, both inclusive. When the value is less than 1, the System object implements a leaky LMS algorithm. The default is 1, providing no leakage in the adapting algorithm.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

InitialWeights — Initial values of filter weights

0 (default) | scalar | vector

Specify the initial values of the filter weights as a scalar or a vector of length equal to the “Length” on page 4-0 property value.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

AdaptInputPort — Additional input to enable adaptation of filter weights

false (default) | true

Specify when the object should adapt the filter weights. By default, the value of this property is `false`, and the filter continuously updates the filter weights. When this property is set to `true`, an adaptation control input is provided to the object. If the value of this input is nonzero, the filter continuously updates the filter weights. If the input is zero, the filter weights remain at their current value.

WeightsResetInputPort — Additional input to enable weights reset`false (default) | true`

Specify whether the FIR filter can reset the filter weights. By default, the value of this property is `false`, and the object does not reset the weights. When this property is set to `true`, you must provide a reset control input to the object, and the `WeightsResetCondition` property applies. The object resets the filter weights based on the values of the `WeightsResetCondition` property and the reset input to the object algorithm.

WeightsResetCondition — Condition that triggers the resetting of filter weights`Non-zero (default) | Rising edge | Falling edge | Either edge`

Specify the event to reset the filter weights as one of `Rising edge`, `Falling edge`, `Either edge`, or `Non-zero`. The object resets the filter weights based on the values of this property and the reset signal input to the object algorithm.

Dependencies

This property applies only when you set the `WeightsResetInputPort` property to `true`.

WeightsOutputPort — Output filter weights`true (default) | false`

Set this property to `true` to output the adapted filter weights. The default is `true`.

Usage**Syntax**

```
[y,err,wts] = blms(x,d)
[y,err] = blms(x,d)
[ ___ ] = blms(x,d,mu)
[ ___ ] = blms(x,d,a)
[ ___ ] = blms(x,d,r)
[y,err,wts] = blms(x,d,mu,a,r)
```

Description

`[y,err,wts] = blms(x,d)` filters the input `x`, using `d` as the desired signal, and returns the filtered output in `y`. The filter error is `err`, and the estimated filter weights is `wts`. The filter weights update once for every block of data that the object processes.

`[y,err] = blms(x,d)` returns only the filtered output `y` and the filter error `err` when the `WeightsOutputPort` property is `false`.

`[___] = blms(x,d,mu)` uses `mu` as the step size when you set the `StepSizeSource` property to `Input port`. These input arguments can be used with any of the previous sets of output arguments.

`[___] = blms(x,d,a)` uses `a` as the adaptation control when you set the `AdaptInputPort` property to `true`. When `a` is nonzero, the filter continuously updates the filter weights. When `a` is zero, the filter weights remain constant.

[___] = `blms(x,d,r)` uses `r` as a reset signal when you set the `WeightsResetInputPort` property to `true`. Use the `WeightsResetCondition` property to set the reset trigger condition. If a reset event occurs, the filter resets the filter weights to their initial values.

[`y,err,wts`] = `blms(x,d,mu,a,r)` filters input `x`, using `d` as the desired signal, `mu` as the step size, `a` as the adaptation control, and `r` as the reset signal. The object returns the filtered output `y`, the filter error `err`, and the adapted filter weights `wts`. Set the properties appropriately to provide all possible inputs.

Input Arguments

x — Data input

scalar | column vector

The signal to be filtered by the block LMS filter. The input, `x`, and the desired signal, `d`, must have the same size and data type.

The input length must be an integer multiple of the `BlockSize` property value.

Data Types: `single` | `double`

d — Desired signal

scalar | column vector

The LMS filter adapts its filter weights, `wts`, to minimize the error, `err`, and converge the input signal `x` to the desired signal `d` as closely as possible.

The input, `x`, and the desired signal, `d`, must have the same size and data type.

Data Types: `single` | `double`

mu — Step size

nonnegative scalar

Adaptation step size factor, specified as a scalar, nonnegative numeric value. The data type of the step size input must match the data type of `x` and `d`.

A small step size ensures a small steady state error between the output `y` and the desired signal `d`. If the step size is small, the convergence speed of the filter decreases. To improve the convergence speed, increase the step size. Note that if the step size is large, the filter can become unstable. To compute the maximum step size the filter can accept without becoming unstable, use the `maxstep` function.

Dependencies

This property applies only when you set the “StepSizeSource” on page 4-0 property to 'Input port'.

Data Types: `single` | `double`

a — Adaptation control

scalar

Adaptation control input that controls how the filter weights are updated. If the value of this input is nonzero, the object continuously updates the filter weights. If the value of this input is zero, the filter weights remain at their current value.

Dependencies

This input is required when the `AdaptInputPort` property is set to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

r — Reset signal

scalar

Reset signal that resets the filter weights based on the values of the `WeightsResetInputPort` property.

Dependencies

This input is required when the `WeightsResetInputPort` property is set to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

Output Arguments**y — Filtered output**

scalar | column vector

Filtered output, returned as a scalar or a column vector. The object adapts its filter weights to converge the input signal `x` to match the desired signal `d`. The filter outputs the converged signal.

Data Types: `single` | `double`

err — Difference between output and desired signal

scalar | column vector

Difference between the output signal `y` and the desired signal `d`, returned as a scalar or a column vector. The data type of `err` matches the data type of `y`. The objective of the adaptive filter is to minimize this error. The object adapts its weights to converge towards optimal filter weights that produce an output signal that matches closely with the desired signal.

Data Types: `single` | `double`

wts — Adaptive filter weights

scalar | column vector

Adaptive filter weights, returned as a scalar or a column vector of length specified by the value in the `Length` property.

The data type of `wts` matches the data type of `y`.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the `System` object as the first input argument. For example, to release system resources of a `System` object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.BlockLMSFilter`

`mssim` Estimated mean squared error for adaptive filters
`maxstep` Maximum step size for LMS adaptive filter convergence

Common to All System Objects

`step` Run System object algorithm
`release` Release resources and allow changes to System object property values and input characteristics
`reset` Reset internal states of System object

Examples

Remove Noise Using Block LMS Adaptive Algorithm

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

```
blms = dsp.BlockLMSFilter(10,5);
blms.StepSize = 0.01;
blms.WeightsOutputPort = false;
filt = dsp.FIRFilter;
filt.Numerator = fir1(10,[.5, .75]);
x = randn(1000,1); % Noise
d = filt(x) + sin(0:.05:49.95)'; % Noise + Signal
[y, err] = blms(x, d);
subplot(2,1,1);
plot(d);
title('Noise + Signal');
subplot(2,1,2);
plot(err);
title('Signal');
```

System Identification of FIR Filter Using Block LMS Filter

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

```

fir = fir1(31,0.5);
% FIR system to be identified
firFilter = dsp.FIRFilter('Numerator',fir);
iirFilter = dsp.IIRFilter('Numerator',sqrt(0.75),...
    'Denominator',[1 -0.5]);
x = iirFilter(sign(randn(2000,25)));
% Observation noise signal
n = 0.1*randn(size(x));
% Desired signal
d = firFilter(x)+n;
% Filter length
l = 32;
% Block LMS Step size
mu = 0.008;
% Decimation factor for analysis
% and simulation results
m = 32;
fir = dsp.BlockLMSFilter(l,'StepSize',mu);
[simmse,meanWsim,Wsim,traceKsim] = msesim(fir,x,d,m);
plot(m*(1:length(simmse)),10*log10(simmse));

```

```
xlabel('Iteration'); ylabel('MSE (dB)');  
% Plot the learning curve for  
% block LMS filter used in system identification  
title('Learning curve')
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Block LMS Filter block reference page. The object properties correspond to the block parameters.

dsp.Channelizer

Package: dsp

Polyphase FFT analysis filter bank

Description

The `dsp.Channelizer` System object separates a broadband input signal into multiple narrow subbands using a fast Fourier transform (FFT)-based analysis filter bank. The filter bank uses a prototype lowpass filter and is implemented using a polyphase structure. You can specify the filter coefficients directly or through design parameters.

To separate a broadband signal into multiple narrow subbands:

- 1 Create the `dsp.Channelizer` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
channelizer = dsp.Channelizer
channelizer = dsp.Channelizer(M)
channelizer = dsp.Channelizer(M,D)
channelizer = dsp.Channelizer(Name,Value)
```

Description

`channelizer = dsp.Channelizer` creates a polyphase FFT analysis filter bank System object that separates a broadband input signal into multiple narrowband output signals. This object implements the inverse operation of the `dsp.ChannelSynthesizer` System object.

`channelizer = dsp.Channelizer(M)` creates an M -band polyphase FFT analysis filter bank, with the `NumFrequencyBands` property set to M .

Example: `channelizer = dsp.Channelizer(16);`

`channelizer = dsp.Channelizer(M,D)` creates an M -band polyphase FFT analysis filter bank, with the `DecimationFactor` property set to D .

Example: `channelizer = dsp.Channelizer(16,8);`

`channelizer = dsp.Channelizer(Name,Value)` creates a polyphase FFT analysis filter bank with each specified property set to the specified value. Enclose each property name in single quotes. For example, you can set `NumTapsPerBand` to 20 and `StopbandAttenuation` to 140.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Main Properties

NumFrequencyBands — Number of frequency bands

8 (default) | positive integer greater than 1

Number of frequency bands M into which the object separates the input broadband signal, specified as a positive integer greater than 1. This property corresponds to the number of polyphase branches and the FFT length used in the filter bank.

Example: 16

Example: 64

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

DecimationFactor — Decimation factor

8 (default) | positive integer

Decimation factor D specified as a positive integer less than or equal to the number of frequency bands M . The default value of this property equals the number of frequency bands specified.

If the decimation factor D equals the number of frequency bands M , then the M/D ratio equals 1, and the channelizer is known as the maximally decimated channelizer.

If the M/D ratio is greater than 1, the output sample rate is different from the channel spacing, and the channelizer is known as the non-maximally decimated channelizer. If the ratio is an integer, the channelizer is known as the integer-oversampled channelizer. If the ratio is not an integer, say $4/3$, the channelizer is known as the rationally oversampled channelizer. For more details, see "Algorithm" on page 4-200.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Specification — Filter design parameters or coefficients

"Number of taps per band and stopband attenuation" (default) | "Coefficients"

Filter design parameters or filter coefficients, specified as one of these options:

- "Number of taps per band and stopband attenuation" — Specify the filter design parameters through the `NumTapsPerBand` and `StopbandAttenuation` properties.
- "Coefficients" — Specify the filter coefficients directly using the `LowpassCoefficients` property.

NumTapsPerBand — Number of filter coefficients per frequency band

12 (default) | positive integer

Number of filter coefficients each polyphase branch uses, specified as a positive integer. The number of polyphase branches matches the number of frequency bands. The total number of filter coefficients

for the prototype lowpass filter is given by $\text{NumFrequencyBands} \times \text{NumTapsPerBand}$. For a given stopband attenuation, increasing the number of taps per band narrows the transition width of the filter. As a result, there is more usable bandwidth for each frequency band at the expense of increased computation.

Example: 8

Example: 16

Dependencies

This property applies when you set `Specification` to "Number of taps per band and stopband attenuation".

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

StopbandAttenuation — Stopband attenuation

80 (default) | positive real scalar

Stopband attenuation of the lowpass filter, specified as a positive real scalar in dB. This value controls the maximum amount of aliasing from one frequency band to the next. When the stopband attenuation increases, the passband ripple decreases. For a given stopband attenuation, increasing the number of taps per band narrows the transition width of the filter. As a result, there is more usable bandwidth for each frequency band at the expense of increased computation.

Example: 80

Dependencies

This property applies when you set `Specification` to "Number of taps per band and stopband attenuation".

Data Types: `single` | `double`

LowpassCoefficients — Coefficients of prototype lowpass filter

[1×49 double] (default) | row vector

Coefficients of the prototype lowpass filter, specified as a row vector. The default vector of coefficients is obtained using `rcosdesign(0.25,6,8,"sqrt")`. There must be at least one coefficient per frequency band. If the length of the lowpass filter is less than the number of frequency bands, the object zero-pads the coefficients.

If you specify complex coefficients, the object designs a prototype filter that is centered at a nonzero frequency, also known as a bandpass filter. The modulated versions of the prototype bandpass filter appear with respect to the prototype filter and are wrapped around the frequency range $[-F_s, F_s]$. For an example, see "Channelizer with Complex Coefficients" on page 4-196.

Tunable: Yes

Dependencies

This property applies when you set `Specification` to "Coefficients".

Data Types: `single` | `double`

Code Generation Properties

AllowArbitraryInputLength — Allow arbitrary input length in generated code

false (default) | true

Allow arbitrary frame length for fixed-size input signals in the generated code, specified as `true` or `false`. When you specify:

- `true` -- The input frame length does not have to be a multiple of the decimation factor. The output of the object in the generated code is a variable-size array.
- `false` -- The input frame length must be a multiple of the decimation factor.

When you specify variable-size signals, the input frame length can be arbitrary and the object ignores this property in the generated code. When you run this object in MATLAB, the object supports arbitrary input frame lengths for fixed-size and variable-size signals and this property does not affect the object behavior.

Data Types: `logical`

Usage

Syntax

```
channOut = channelizer(input)
```

Description

`channOut = channelizer(input)` separates the broadband input signal into a number of narrow band signals contained in the columns of the channelizer output.

Input Arguments

input — Data input

`vector` | `matrix`

Data input, specified as an L -by-1 vector or an L -by- N matrix, with $N > 1$.

Under most conditions, the number of inputs rows L can be arbitrary and does not have to be a multiple of the number of frequency bands. See this table for details.

Input Signal	When you Run Object in MATLAB	When you Generate Code Using MATLAB Coder
Fixed-size	Object supports arbitrary input frame length	Object supports arbitrary input frame length when you set <code>AllowArbitraryInputLength</code> to <code>true</code> while generating code
Variable-size	Object supports arbitrary input frame length	Object supports arbitrary input frame length

Variable-size signals change in frame length once you lock the object while the fixed-size signals remain constant. When the object does not support arbitrary frame length, the input frame length must be a multiple of the number of frequency bands.

Data Types: `single` | `double`

Output Arguments

channOut — Channelizer output

matrix | 3-D array

Channelizer output, returned as a matrix or a 3-D array.

If the input is an L -by-1 vector, then the output signal has an upper bound size of $\text{ceil}(L/M)$ -by- M , where M is the number of frequency bands. Each narrowband signal forms a column in the output.

If the input has more than one channel, that is, it is of the form L -by- N with $N > 1$, then the output signal has an upper bound size of $\text{ceil}(L/M)$ -by- M -by- N .

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.Channelizer

<code>coeffs</code>	Coefficients of prototype lowpass filter
<code>tf</code>	Return transfer function of overall prototype lowpass filter
<code>polyphase</code>	Return polyphase matrix
<code>freqz</code>	Frequency response of filters in channelizer
<code>fvtool</code>	Visualize the filters in the channelizer
<code>bandedgeFrequencies</code>	Compute the bandedge frequencies
<code>centerFrequencies</code>	Compute center frequencies
<code>getFilters</code>	Return matrix of channelizer FIR filters

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Channelize and Synthesize Sine Wave in MATLAB

Channelize and synthesize a sine wave signal with multiple frequencies using an M -channel filter bank.

The M -channel filter bank contains an analysis filter bank section and a synthesis filter bank section. The `dsp.Channelizer` object implements the analysis filter bank section. The `dsp.ChannelSynthesizer` object implements the synthesis filter bank section. These objects use an efficient polyphase structure to implement the filter bank. For more details, see **Polyphase Implementation** under **Algorithms** on the object reference pages.

Initialization

Initialize the `dsp.Channelizer` and `dsp.ChannelSynthesizer` System objects. Each object is set up with 8 frequency bands, 8 polyphase branches in each filter, 12 coefficients per polyphase branch, and a stopband attenuation of 140 dB. Use a sine wave with multiple frequencies as the input signal. View the input spectrum and the output spectrum using a spectrum analyzer.

```
offsets = [-40, -30, -20, 10, 15, 25, 35, -15];
sinewave = dsp.SineWave('ComplexOutput', true, 'Frequency', ...
    offsets+(-375:125:500), 'SamplesPerFrame', 800);

channelizer = dsp.Channelizer('StopbandAttenuation', 140);
synthesizer = dsp.ChannelSynthesizer('StopbandAttenuation', 140);
spectrumAnalyzer = spectrumAnalyzer('ShowLegend', true, ...
    'SampleRate', sinewave.SampleRate, ...
    'ChannelNames', {'Input', 'Output'}, ...
    'Title', "Input and Output Spectra");
```

Streaming

Use the channelizer to split the broadband input signal into multiple narrow bands. Then pass the multiple narrowband signals into the synthesizer, which merges these signals to form the broadband signal. Compare the spectra of the input and output signals. The input and output spectra match very closely.

```
for i = 1:5000
    x = sum(sinewave(), 2);
    y = channelizer(x);
    v = synthesizer(y);
    spectrumAnalyzer(x, v)
end
```

Channelizer with Complex Coefficients

Create a `dsp.Channelizer` object and set the `LowpassCoefficients` property to a vector of complex coefficients.

Complex Coefficients

Using `firpm`, determine the coefficients of a Park-McClellan's optimal equiripple FIR filter of order 30, and frequency and amplitude characteristics described by $F = [0 \ 0.2 \ 0.4 \ 1.0]$ and $A = [1 \ 1 \ 0 \ 0]$ vectors, respectively.

Create a complex version of these coefficients by multiplying with a complex exponential. The resultant frequency response is that of a bandpass filter at the specified frequency, in this case 0.4.

```
blowpass = firpm(30,[0 .2 .4 1],[1 1 0 0]);
N = length(blowpass)-1;
Fc = 0.4;
j = complex(0,1);
bbandpass = blowpass.*exp(j*Fc*pi*(0:N));
```

Channelizer

Create a `dsp.Channelizer` object with 4 frequency bands and set the `Specification` property to `'Coefficients'`.

```
chann = dsp.Channelizer(4, 'Specification', "Coefficients");
```

Pass the complex coefficients to the channelizer. The prototype filter is a bandpass filter with a center frequency of 0.4. The modulated versions of this filter appear with respect to the prototype filter and are wrapped around the frequency range $[-Fs Fs]$.

```
chann.LowpassCoefficients = bbandpass
```

```
chann =
```

```
  dsp.Channelizer with properties:
```

```
    Main
```

```
      NumFrequencyBands: 4
```

```
      DecimationFactor: 4
```

```
      Specification: 'Coefficients'
```

```
      LowpassCoefficients: [0.0019 + 0.0000i 0.0005 + 0.0016i ... ]
```

```
    Show all properties
```

Visualize the frequency response of the channelizer.

```
fvtool(chann)
```

More About

Analysis Filter Bank

The generic analysis filter bank consists of a series of parallel bandpass filters that split an input broadband signal, $x[n]$, into a series of narrow subbands. Each bandpass filter retains a different portion of the input signal. After the bandwidth is reduced by one of the bandpass filters, the signal is downsampled to a lower sampling rate commensurate with the new bandwidth.

Conceptual Diagram of Generic Analysis Filter Bank

Prototype Lowpass Filter

To implement the analysis filter bank efficiently, the channelizer uses a prototype lowpass filter.

The prototype lowpass filter has an impulse response of $h[n]$, a normalized two-sided bandwidth of $2\pi/M$, and a cutoff frequency of π/M . M is the number of frequency bands, that is, the branches of the analysis filter bank. This value corresponds to the FFT length that the filter bank uses. M can be high on the order of 2048 or more. The stopband attenuation determines the minimum level of interference (aliasing) from one frequency band to another. The passband ripple must be small so that the input signal is not distorted in the passband.

The prototype lowpass filter corresponds to $H_0(z)$ in the filter bank. The first branch of the filter bank contains $H_0(z)$ followed by the decimator. The other $M - 1$ branches contain filters that are modulated versions of the prototype filter. The modulation factor is given by the following equation:

$$e^{-jw_k n}, \quad w_k = 2\pi k/M, \quad k = 0, 1, \dots, M - 1$$

Using the Prototype Lowpass Filter

The transfer function of the modulated k th bandpass filter is given by:

$$H_k(z) = H_0(z e^{-jw_k}), \quad w_k = 2\pi k/M, \quad k = 1, 2, \dots, M - 1$$

This figure shows the frequency response of M filters.

To obtain the frequency response characteristics of the filter $H_k(z)$, where $k = 1, \dots, M-1$, uniformly shift the frequency response of the prototype filter, $H_0(z)$, by multiples of $2\pi/M$. Each subband filter, $H_k(z)$, $\{k = 1, \dots, M - 1\}$, is derived from the prototype filter.

Following is an equivalent representation of the frequency response diagram with ω ranging from $[-\pi, \pi]$.

Shift Narrow Subbands to Baseband

The frequency components in the input signal, $x[n]$, are translated in frequency to baseband by multiplying $x[n]$ with the complex exponentials, $e^{-j\omega_k n}$, $\omega_k = 2\pi k/M$, $k = 1, 2, \dots, M-1$, where $\omega_k = 2\pi k/M$, and $k = 1, 2, \dots, M-1$. The resulting product signals are passed through the lowpass filters, $H_0(z)$. The output of the lowpass filter is relatively narrow in bandwidth. Downsample the signal commensurate with the new bandwidth. Choose a decimation factor, $D \leq M$, where M is the number of branches of the analysis filter bank. When $D < M$, the channelizer is known as oversampled or non-maximally decimated channelizer.

The figure shows an analysis filter bank that uses the prototype lowpass filter.

$y_1[m], y_2[m], \dots, y_{M-1}[m]$ are narrow subband signals translated into baseband.

Algorithms

Polyphase Implementation

The analysis filter bank can be implemented efficiently using the polyphase structure. For more details on the analysis filter bank, see Analysis Filter Bank on page 4-198.

To derive the polyphase structure, start with the transfer function of the prototype lowpass filter:

$$H_0(z) = b_0 + b_1 z^{-1} + \dots + b_N z^{-N}$$

$N + 1$ is the length of the prototype filter.

You can rearrange this equation as follows:

$$\begin{aligned}
H_0(z) = & (b_0 + b_M z^{-M} + b_{2M} z^{-2M} + \dots + b_{N-M+1} z^{-(N-M+1)}) + \\
& z^{-1} (b_1 + b_{M+1} z^{-M} + b_{2M+1} z^{-2M} + \dots + b_{N-M+2} z^{-(N-M+1)}) + \\
& \vdots \\
& z^{-(M-1)} (b_{M-1} + b_{2M-1} z^{-M} + b_{3M-1} z^{-2M} + \dots + b_N z^{-(N-M+1)})
\end{aligned}$$

M is the number of polyphase components.

You can write this equation as:

$$H_0(z) = E_0(z^M) + z^{-1} E_1(z^M) + \dots + z^{-(M-1)} E_{M-1}(z^M)$$

$E_0(z^M), E_1(z^M), \dots, E_{M-1}(z^M)$ are polyphase components of the prototype lowpass filter $H_0(z)$.

The other filters in the filter bank, $H_k(z)$, where $k = 1, \dots, M-1$, are modulated versions of this prototype filter.

You can write the transfer function of the k^{th} modulated bandpass filter as $H_k(z) = H_0(z e^{-jw_k})$.

Replacing z with $z e^{jw_k}$,

$$H_k(z) = h_0 + h_1 e^{-jw_k} z^{-1} + h_2 e^{-j2w_k} z^{-2} \dots + h_N e^{-jNw_k} z^{-N}$$

$N + 1$ is the length of the k^{th} filter.

In polyphase form, the equation is as follows:

$$H_k(z) = \begin{bmatrix} 1 & e^{-jw_k} & e^{-j2w_k} & \dots & e^{-j(M-1)w_k} \end{bmatrix} \begin{bmatrix} E_0(z^M) \\ z^{-1} E_1(z^M) \\ \vdots \\ z^{-(M-1)} E_{M-1}(z^M) \end{bmatrix}$$

For all M channels in the filter bank, the transfer function $H(z)$ is given by:

$$H(z) = \begin{bmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & e^{-jw_1} & e^{-j2w_1} & \dots & e^{-j(M-1)w_1} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & e^{-jw_{M-1}} & e^{-j2w_{M-1}} & \dots & e^{-j(M-1)w_{M-1}} \end{bmatrix} \begin{bmatrix} E_0(z^M) \\ z^{-1} E_1(z^M) \\ \vdots \\ z^{-(M-1)} E_{M-1}(z^M) \end{bmatrix}$$

Maximally decimated channelizer

When $D = M$, the channelizer is known as the maximally decimated channelizer or critically sampled channelizer.

Here is the multirate noble identity for decimation, assuming that $D = M$.

For example, consider the first branch of the filter bank that contains the lowpass filter.

Replace $H_0(z)$ with its polyphase representation on page 4-200.

After applying the noble identity for decimation, you can replace the delays and the decimation factor with a commutator switch. The switch starts on the first branch 0 and moves in the counterclockwise direction as shown in the following diagram. The accumulator at the output receives the processed input samples from each branch of the polyphase structure and accumulates these processed samples until the switch goes to branch 0. When the switch goes to branch 0, the accumulator outputs the accumulated value.

For all M channels in the filter bank, the transfer function $H(z)$ is given by:

$$H(z) = \begin{bmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & e^{-jw_1} & e^{-j2w_1} & \dots & e^{-j(M-1)w_1} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & e^{-jw_{M-1}} & e^{-j2w_{M-1}} & \dots & e^{-j(M-1)w_{M-1}} \end{bmatrix} \begin{bmatrix} E_0(z) \\ E_1(z) \\ \vdots \\ E_{M-1}(z) \end{bmatrix}$$

The matrix on the left is a discrete Fourier transform (DFT) matrix. With the DFT matrix, the efficient implementation of the lowpass prototype-based filter bank looks like this.

When the first input sample is delivered, the switch feeds this input to the branch 0 and the channelizer computes the first set of output values. As more input samples come in, the switch moves in the counterclockwise direction through branches $M-1, M-2$, all the way up to branch 0, delivering one sample at a time to each branch. When the switch comes to branch 0, the channelizer outputs the next set of output values. This process continues as the data keeps coming in. Every time the switch comes to the first branch 0, the channelizer outputs $y_0[m], y_1[m], \dots, y_{M-1}[m]$. Each branch in the channelizer effectively outputs one sample for every M samples it receives. Hence, the sample rate at the output of the channelizer is f_s/M .

Non-maximally decimated or oversampled channelizer

When $D < M$, the channelizer is known as the non-maximally decimated channelizer or oversampled channelizer. In this configuration, the output sample rate is different from the channel spacing. The non-maximally decimated channelizers offer increased design freedom, but at the expense of increasing computational cost.

If the ratio M/D equals an integer that is greater than 1 and is less than or equal to $M-1$, the channelizer is known as integer-oversampled channelizer. If the ratio M/D is not an integer, then the channelizer is known as rationally-oversampled channelizer.

In this configuration, when the first input sample is delivered, the switch feeds this input to branch 0 and the channelizer computes the first set of output values. As more input samples come in, the switch moves in the counterclockwise direction through branches $D-1, D-2$, all the way up to branch 0, delivering one sample at a time to each branch. When the switch comes to branch 0, the channelizer outputs the next set of output values. This process continues as the data keeps coming in. Every time the switch comes to the first branch 0, the channelizer outputs $y_0[m], y_1[m], \dots, y_{M-1}[m]$.

As more data keeps coming in and the switch feeds these samples to the first D addresses, the formal contents of these addresses are shifted to the next set of D addresses, and this process of data shift continues every time there is a new set of D input samples.

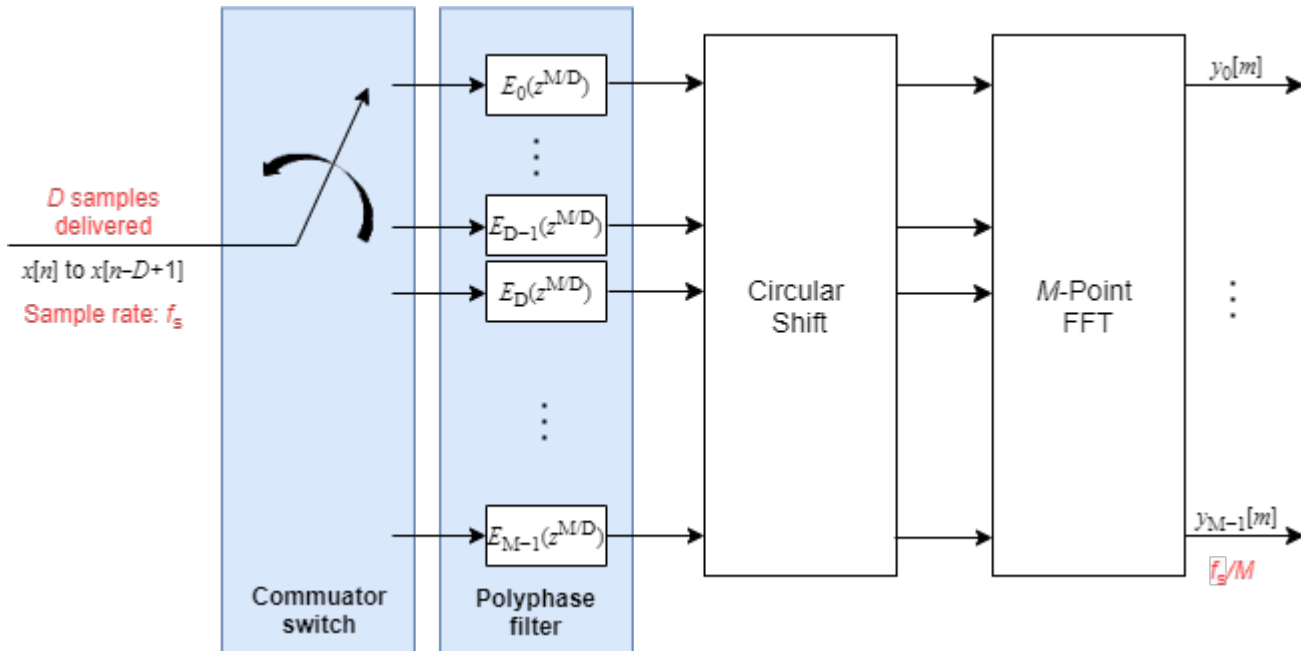

For every D input samples that are fed to the polyphase structure, the channelizer outputs M samples, $y_0[m], y_1[m], \dots, y_{M-1}[m]$. This process increases the output sample rate from f_s/M in the case of a maximally decimated channelizer, to f_s/D in the case of a non-maximally decimated channelizer.

For more details, see [2].

After each D -point data sequence is delivered to the partitioned M -stage polyphase filter, the outputs of the M stages are computed and conditioned for delivery to the M -point FFT. The data shifting

through the filter introduces frequency-dependent phase shift. To correct for this phase shift and alias all bands to DC, a circular shift buffer is inserted after the polyphase filters and before the M -point FFT.

With the commutator switch followed by M -stage polyphase filter, circular shift buffer, and a DFT matrix, the efficient implementation of the lowpass prototype-based filter bank looks like this.

Version History

Introduced in R2016b

Support for arbitrary input frame length

Starting in R2022b, this object supports an input signal with an arbitrary frame length. That is, the input frame length does not have to be a multiple of the number of frequency bands.

When you generate code, to support arbitrary frame length for fixed-size signals, you must set the `AllowArbitraryInputLength` property to `true` while generating code.

Polyphase FFT synthesis filter bank

Description

The `dsp.ChannelSynthesizer` System object merges multiple narrowband signals into a broadband signal by using an FFT based synthesis filter bank. The filter bank uses a prototype lowpass filter and is implemented using a polyphase structure. You can specify the filter coefficients directly or through design parameters.

To merge multiple narrowband signals into a broadband signal:

- 1 Create the `dsp.ChannelSynthesizer` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
synthesizer = dsp.ChannelSynthesizer  
synthesizer = dsp.ChannelSynthesizer(Name,Value)
```

Description

`synthesizer = dsp.ChannelSynthesizer` creates a synthesizer object, using the default properties.

`synthesizer = dsp.ChannelSynthesizer(Name,Value)` specifies additional properties using `Name,Value` pairs. Unspecified properties have default values.

Example: `synthesizer = dsp.ChannelSynthesizer('NumTapsPerBand',20,'StopbandAttenuation',140)`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Specification — Filter design parameters or coefficients

"Number of taps per band and stopband attenuation" (default) | "Coefficients"

Filter design parameters or filter coefficients, specified as one of these options:

- "Number of taps per band and stopband attenuation" — Specify the filter design parameters through the `NumTapsPerBand` and `StopbandAttenuation` properties.
- "Coefficients" — Specify the filter coefficients directly using `LowpassCoefficients`.

NumTapsPerBand — Number of filter coefficients per frequency band

12 (default) | positive integer

Number of filter coefficients each polyphase branch uses, specified as a positive integer. The number of polyphase branches matches the number of frequency bands. The total number of filter coefficients for the prototype lowpass filter is given by product of the number of frequency bands and `NumTapsPerBand`. For a given stopband attenuation, increasing the number of taps per band narrows the transition width of the filter. As a result, there is more usable bandwidth for each frequency band at the expense of increased computation.

Dependencies

This property applies when you set `Specification` to "Number of taps per band and stopband attenuation".

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

StopbandAttenuation — Stopband attenuation

80 (default) | positive real scalar

Stopband attenuation of the lowpass filter, specified as a positive real scalar in dB. This value controls the maximum amount of aliasing from one frequency band to the next. Larger is the stopband attenuation, smaller is the passband ripple.

Dependencies

This property applies when you set `Specification` to "Number of taps per band and stopband attenuation".

Data Types: `single` | `double`

LowpassCoefficients — Coefficients of the prototype lowpass filter

[1×49 double] (default) | row vector

Coefficients of the prototype lowpass filter, specified as a row vector. The default vector of coefficients is obtained using `rcosdesign(0.25,6,8,"sqrt")`. There must be at least one coefficient per frequency band. If the length of the lowpass filter is less than the number of frequency bands, the object zero-pads the coefficients.

If you specify complex coefficients, the object designs a prototype filter that is centered at a nonzero frequency, also known as a bandpass filter. The modulated versions of the prototype bandpass filter appear with respect to the prototype filter and are wrapped around the frequency range $[-F_s/2, F_s/2]$.

Tunable: Yes

Dependencies

This property applies when you set `Specification` to "Coefficients".

Data Types: `single` | `double`

Usage

Syntax

```
synthOut = synthesizer(input)
```

Description

`synthOut = synthesizer(input)` merges the narrowband input signals contained as columns in `input` into broadband signal, `synthOut`.

Input Arguments

input — Narrowband signals

matrix | 3-D array

Narrowband signals, specified as a matrix or a 3-D array. Each narrowband signal is stored as a column in the input signal. The number of columns in `input` corresponds to the number of frequency bands of the filter bank. If `input` is three-dimensional, each matrix corresponds to a separate channel. If M is the number of frequency bands, and `input` is an L -by- M matrix, then the output signal, `synthOut`, has dimensions $L \times M$ -by-1. If `input` has more than one channel, that is, it has dimensions L -by- M -by- N , then `synthOut` has dimensions $L \times M$ -by- N .

This object also accepts variable-size inputs. That is, once the object is locked, you can change the size of each input channel. The number of channels cannot change.

Data Types: `single` | `double`

Output Arguments

synthOut — Merged broadband signal

matrix | 3-D array

Merged broadband signal, returned as a matrix or a 3-D array. If M is the number of frequency bands, and `input` is an L -by- M matrix, then the output signal, `synthOut`, has dimensions $L \times M$ -by-1. If `input` has more than one channel, that is, it has dimensions L -by- M -by- N , then `synthOut` has dimensions $L \times M$ -by- N .

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.ChannelSynthesizer

coeffs Coefficients of prototype lowpass filter
 tf Return transfer function of overall prototype lowpass filter
 polyphase Return polyphase matrix

Common to All System Objects

step Run System object algorithm
 release Release resources and allow changes to System object property values and input characteristics
 reset Reset internal states of System object

Examples

Channelize and Synthesize Sine Wave in MATLAB

Channelize and synthesize a sine wave signal with multiple frequencies using an M -channel filter bank.

The M -channel filter bank contains an analysis filter bank section and a synthesis filter bank section. The dsp.Channelizer object implements the analysis filter bank section. The dsp.ChannelSynthesizer object implements the synthesis filter bank section. These objects use an efficient polyphase structure to implement the filter bank. For more details, see **Polyphase Implementation** under **Algorithms** on the object reference pages.

Initialization

Initialize the dsp.Channelizer and dsp.ChannelSynthesizer System objects. Each object is set up with 8 frequency bands, 8 polyphase branches in each filter, 12 coefficients per polyphase branch, and a stopband attenuation of 140 dB. Use a sine wave with multiple frequencies as the input signal. View the input spectrum and the output spectrum using a spectrum analyzer.

```
offsets = [-40, -30, -20, 10, 15, 25, 35, -15];
sinewave = dsp.SineWave('ComplexOutput', true, 'Frequency', ...
    offsets+(-375:125:500), 'SamplesPerFrame', 800);

channelizer = dsp.Channelizer('StopbandAttenuation', 140);
synthesizer = dsp.ChannelSynthesizer('StopbandAttenuation', 140);
spectrumAnalyzer = spectrumAnalyzer('ShowLegend', true, ...
    'SampleRate', sinewave.SampleRate, ...
    'ChannelNames', {'Input', 'Output'}, ...
    'Title', "Input and Output Spectra");
```

Streaming

Use the channelizer to split the broadband input signal into multiple narrow bands. Then pass the multiple narrowband signals into the synthesizer, which merges these signals to form the broadband signal. Compare the spectra of the input and output signals. The input and output spectra match very closely.

```
for i = 1:5000
    x = sum(sinewave(), 2);
    y = channelizer(x);
    v = synthesizer(y);
```

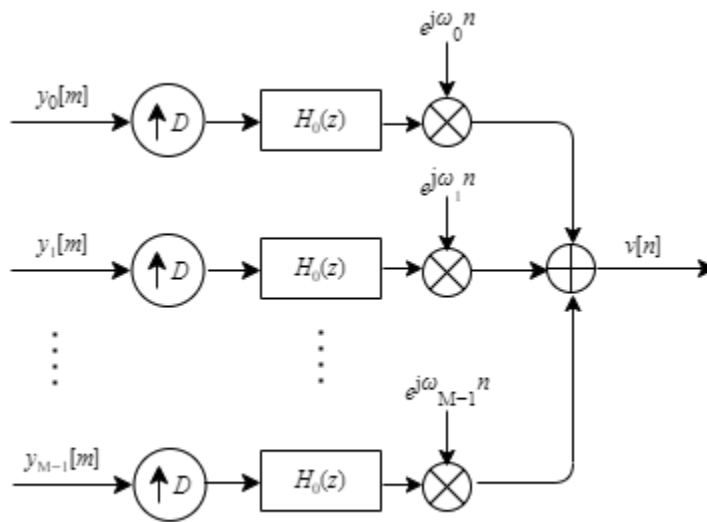

```
spectrumAnalyzer(x,v)
end
```

More About

Synthesis Filter Bank

The synthesis filter bank consists of a set of parallel bandpass filters that merge multiple input narrowband signals, $y_0[m]$, $y_1[m]$, ..., $y_{M-1}[m]$ into a single broadband signal, $v[n]$. The input narrowband signals are in the baseband. Each narrowband signal is interpolated to a higher sampling rate by using the upsampler, and then filtered by the lowpass filter. A complex exponential that follows the lowpass filter centers the baseband signal around ω_k .

Conceptual Diagram

Prototype Lowpass Filter

To implement the synthesis filter bank efficiently, the synthesizer uses a prototype lowpass filter. This filter has an impulse response of $h[n]$, a normalized two-sided bandwidth of $2\pi/M$, and a cutoff frequency of π/M . M is the number of frequency bands, that is, the branches of the synthesis filter bank. This value corresponds to the FFT length that the filter bank uses. M can be high, in the order of 2048 or more. The stopband attenuation determines the minimum level of interference (aliasing) from one frequency band to another. The passband ripple must be small so that the input signal is not distorted in the passband.

The prototype lowpass filter models the first branch of the filter bank. The other $M - 1$ branches are modeled by filters that are modulated versions of the prototype filter. The modulation factor is given by $e^{jw_k n}$, $w_k = 2\pi k/M$, $k = 0, 1, \dots, M - 1$.

The output of each bandpass filter forms a specific portion of the broadband signal. The output of all the branches are added to form the broadband signal, $v[n]$.

Algorithms

Polyphase Implementation

The synthesis filter bank can be implemented efficiently using the polyphase structure.

To derive the polyphase structure, start with the transfer function of the prototype lowpass filter.

$$H_0(z) = b_0 + b_1 z^{-1} + \dots + b_N z^{-N}$$

$N + 1$ is the length of the prototype filter.

You can rearrange this equation as follows:

$$H_0(z) = \begin{aligned} & (b_0 + b_M z^{-M} + b_{2M} z^{-2M} + \dots + b_{N-M+1} z^{-(N-M+1)}) + \\ & z^{-1} (b_1 + b_{M+1} z^{-M} + b_{2M+1} z^{-2M} + \dots + b_{N-M+2} z^{-(N-M+1)}) + \\ & \quad \vdots \\ & z^{-(M-1)} (b_{M-1} + b_{2M-1} z^{-M} + b_{3M-1} z^{-2M} + \dots + b_N z^{-(N-M+1)}) \end{aligned}$$

M is the number of polyphase components.

You can write this equation as:

$$H_0(z) = E_0(z^M) + z^{-1} E_1(z^M) + \dots + z^{-(M-1)} E_{M-1}(z^M)$$

$E_0(z^M), E_1(z^M), \dots, E_{M-1}(z^M)$ are polyphase components of the prototype lowpass filter, $H_0(z)$.

The other filters in the filter bank, $H_k(z)$, where $k = 1, \dots, M-1$, are modulated versions of this prototype filter.

You can write the transfer function of the k th modulated bandpass filter as $H_k(z) = H_0(z e^{jw_k})$. Replacing z with $z e^{jw_k}$,

$$H_k(z) = h_0 + h_1 e^{jw_k} z^{-1} + h_2 e^{j2w_k} z^{-2} \dots + h_N e^{jNw_k} z^{-N}$$

$N + 1$ is the length of the k th filter.

In polyphase form, the equation is as follows:

$$H_k(z) = \begin{bmatrix} 1 & e^{jw_k} & e^{j2w_k} & \dots & e^{j(M-1)w_k} \end{bmatrix} \begin{bmatrix} E_0(z^M) \\ z^{-1} E_1(z^M) \\ \vdots \\ z^{-(M-1)} E_{M-1}(z^M) \end{bmatrix}$$

For all M channels in the filter bank, the MIMO transfer function, $H(z)$, is given by:

$$H(z) = \begin{bmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & e^{jw_1} & e^{j2w_1} & \dots & e^{j(M-1)w_1} \\ & & \vdots & & \\ 1 & e^{jw_{M-1}} & e^{j2w_{M-1}} & \dots & e^{j(M-1)w_{M-1}} \end{bmatrix} \begin{bmatrix} E_0(z^M) \\ z^{-1} E_1(z^M) \\ \vdots \\ z^{-(M-1)} E_{M-1}(z^M) \end{bmatrix}$$

Here is the multirate noble identity for interpolation, assuming that $D = M$:

For illustration, consider the first branch of the filter bank that contains the lowpass filter.

Replace $H_0(z)$ with its polyphase representation.

After applying the noble identity for interpolation, you can replace the delays, interpolation factor, and the adder with a commutator switch.

For all the M channels in the filter bank, the MIMO transfer function, $H(z)$, is given by:

$$H(z) = \begin{bmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & e^{jw_1} & e^{j2w_1} & \dots & e^{j(M-1)w_1} \\ & & & \vdots & \\ 1 & e^{jw_{M-1}} & e^{j2w_{M-1}} & \dots & e^{j(M-1)w_{M-1}} \end{bmatrix} \begin{bmatrix} E_0(z) \\ E_1(z) \\ \vdots \\ E_{M-1}(z) \end{bmatrix}$$

The matrix on the left is an IDFT matrix. With the IDFT matrix, the efficient implementation of the lowpass prototype based filter bank looks like the following.

dsp.Chirp

Package: dsp

Generate swept-frequency cosine (chirp) signal

Description

The `Chirp` object generates a swept-frequency cosine (chirp) signal.

To generate the chirp signal:

- 1 Create the `dsp.Chirp` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
chirp = dsp.Chirp  
chirp = dsp.Chirp(Name,Value)
```

Description

`chirp = dsp.Chirp` returns a chirp signal, `chirp`, with unity amplitude.

`chirp = dsp.Chirp(Name,Value)` returns a chirp signal, `chirp`, with each specified property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Type — Frequency sweep type

`Linear` (default) | `Swept cosine` | `Logarithmic` | `Quadratic`

Specify the frequency sweep type as `Swept cosine`, `Linear`, `Logarithmic`, or `Quadratic`. This property specifies how the output instantaneous frequency sweep varies over time.

SweepDirection — Sweep direction

`Unidirectional` (default) | `Bidirectional`

Specify the sweep direction as either `Unidirectional` or `Bidirectional`.

InitialFrequency — Initial frequency (hertz)

1000 (default) | scalar greater than or equal to 0

When you set the `Type` property to `Linear`, `Quadratic`, or `Logarithmic`, this property specifies the initial instantaneous frequency in hertz of the output chirp signal. When you set the `Type` property to `Logarithmic`, the value of this property is one less than the actual initial frequency of the sweep. Also, when the sweep is logarithmic, the initial frequency must be less than the target frequency, specified by the `TargetFrequency` property.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

TargetFrequency — Target frequency (hertz)

4000 (default) | scalar greater than or equal to 0

When you set the `Type` property to `Linear`, `Quadratic`, or `Logarithmic`, this property specifies the instantaneous frequency of the output signal in hertz at the target time. When you set the `Type` property to `Swept Cosine`, the target frequency is the instantaneous frequency of the output at half the target time. Also, when the sweep is logarithmic, the target frequency must be greater than the initial frequency, specified by the `InitialFrequency` property.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

TargetTime — Target time

1 (default) | scalar greater than or equal to 0

When you set the `Type` property to `Linear`, `Quadratic`, or `Logarithmic`, this property specifies the target time in seconds at which the target frequency is reached. When you set the `Type` property to `Swept cosine`, this property specifies the time at which the sweep reaches $2f_{tgt} - f_{init}$ Hz, where f_{tgt} is the `TargetFrequency` and f_{init} is the `InitialFrequency`. The target time should not be greater than the sweep time, specified by the `SweepTime` property.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

SweepTime — Sweep time

1 (default) | scalar greater than or equal to 0

When you set the `SweepDirection` property to `Unidirectional`, the sweep time in seconds is the period of the output frequency sweep. When you set the `SweepDirection` property to `Bidirectional`, the sweep time is half the period of the output frequency sweep. The sweep time should be no less than the target time, specified by the `TargetTime`. This property must be a positive numeric scalar.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

InitialPhase — Initial phase

0 (default) | scalar greater than or equal to 0

Specify initial phase of the output in radians at time $t = 0$.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

SampleRate — Sample rate

8000 (default) | positive scalar

Specify the sampling rate of the output in hertz as a positive numeric scalar.

Data Types: `single` | `double` | `logical`

SamplesPerFrame — Samples per output frame

1 (default) | positive integer

Specify the number of samples to buffer into each output as a positive integer. The default value is 1.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

OutputDataType — Output data type

`double` (default) | `single`

Specify the output data type as `double` or `single`. The default value is `double`.

Usage

Syntax

```
y = chirp()
```

Description

`y = chirp()` returns a swept-frequency cosine output, `y`.

Output Arguments

y — Swept-frequency cosine output

scalar | column vector

Swept-frequency cosine output, returned as a scalar or a column vector. The length of the output vector equals the value you specify in the `SamplesPerFrame` property.

Data Types: `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

`step` Run System object algorithm

release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

Examples

Generate a Bidirectional Swept Chirp Signal

Note: If you are using R2016a or earlier, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

```
chirp = dsp.Chirp(...  
    'SweepDirection', 'Bidirectional', ...  
    'TargetFrequency', 25, ...  
    'InitialFrequency', 0,...  
    'TargetTime', 1, ...  
    'SweepTime', 1, ...  
    'SamplesPerFrame', 400, ...  
    'SampleRate', 400);
```

```
plot(chirp());
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Chirp block reference page. The object properties correspond to the block parameters.

dsp.CICCompensationDecimator

Package: dsp

Compensate for CIC decimation filter using FIR decimator

Description

You can compensate for the shortcomings of a CIC decimator, namely its passband droop and wide transition region, by following it with a compensation decimator. This System object lets you design and use such a filter.

To compensate for the shortcomings of a CIC filter using an FIR decimator:

- 1 Create the `dsp.CICCompensationDecimator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```

ciccompdec = dsp.CICCompensationDecimator
ciccompdec = dsp.CICCompensationDecimator(decim)
ciccompdec = dsp.CICCompensationDecimator(cic)
ciccompdec = dsp.CICCompensationDecimator(cic,decim)
ciccompdec = dsp.CICCompensationDecimator( ____,Name,Value)

```

Description

`ciccompdec = dsp.CICCompensationDecimator` returns a System object, `ciccompdec`, that applies an FIR decimator to each channel of an input signal. Using the properties of the object, the decimation filter can be designed to compensate for a preceding CIC filter.

`ciccompdec = dsp.CICCompensationDecimator(decim)` returns a CIC compensation decimator System object, with the `DecimationFactor` property set to `decim`.

`ciccompdec = dsp.CICCompensationDecimator(cic)` returns a CIC compensation decimator System object, with the `CICRateChangeFactor`, `CICNumSections`, and `CICDifferentialDelay` properties specified in the `dsp.CICDecimator` System object, `cic`.

`ciccompdec = dsp.CICCompensationDecimator(cic,decim)` returns a CIC compensation decimator System object, `ciccompdec`, with the `CICRateChangeFactor`, `CICNumSections`, and `CICDifferentialDelay` properties specified in the `dsp.CICDecimator` System object `cic`, and the `DecimationFactor` property set to `decim`.

`ciccompdec = dsp.CICCompensationDecimator(____,Name,Value)` returns a CIC compensation decimator object with each specified property set to the specified value. Enclose each property name in quotes. You can use this syntax with any previous input argument combinations.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

CICDifferentialDelay — Differential delay of the CIC filter being compensated

1 (default) | positive integer scalar

Specify the differential delay of the CIC filter being compensated as a positive integer scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

CICNumSections — Number of sections of the CIC filter being compensated

2 (default) | positive integer scalar

Specify the number of sections of the CIC filter being compensated as a positive integer scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

CICRateChangeFactor — Rate-change factor of the CIC filter being compensated

2 (default) | positive integer scalar

Specify the rate-change factor of the CIC filter being compensated as a positive integer scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

DecimationFactor — Decimation factor of compensator

2 (default) | positive integer scalar

Specify the decimation factor of the compensator System object as a positive integer scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

DesignForMinimumOrder — Design filter of minimum order or of specified order

`true` (default) | `false`

Specify whether to design a filter of minimum order or a filter of specified order as a logical scalar. The default is `true`, which corresponds to a filter of minimum order.

FilterOrder — Order of decimation compensator filter

12 (default) | positive integer scalar

Specify the order of the decimation compensator filter as a positive integer scalar.

Dependencies

This property applies only when you set the `DesignForMinimumOrder` property to `false`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

PassbandFrequency — Passband edge frequency in hertz

100000 (default) | positive real scalar

Specify the passband edge frequency as a positive real scalar expressed in hertz. PassbandFrequency must be less than $F_s/2$, where F_s is the input sample rate.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

PassbandRipple — Filter passband ripple in decibels

0.1 (default) | positive real scalar

Specify the filter passband ripple as a positive real scalar expressed in decibels.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

SampleRate — Input sample rate in hertz

1200000 (default) | positive real scalar

Specify the input sample rate as a positive real scalar expressed in hertz.

Data Types: single | double

StopbandAttenuation — Filter stopband attenuation in decibels

60 (default) | positive real scalar

Specify the filter stopband attenuation as a positive real scalar expressed in decibels.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

StopbandFrequency — Stopband edge frequency in hertz

400000 (default) | positive real scalar

Specify the stopband edge frequency as a positive real scalar expressed in hertz. StopbandFrequency must be less than $F_s/2$, where F_s is the input sample rate.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Fixed-Point Properties

CoefficientsDataType — Word and fraction lengths of coefficients

numericType(1,16) (default) | numericType object

Word and fraction lengths of coefficients, specified as a signed or unsigned numericType object. The default, numericType(1,16) corresponds to a signed numeric type object with 16-bit coefficients and a fraction length determined based on the coefficient values, to give the best possible precision.

This property is not tunable.

Word length of the output is same as the word length of the input. Fraction length of the output is computed such that the entire dynamic range of the output can be represented without overflow. For details on how the fraction length of the output is computed, see “Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters”.

RoundingMethod — Rounding method for output fixed-point operations

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see “Precision and Range”.

Usage

Syntax

```
y = ciccompdecim(x)
```

Description

`y = ciccompdecim(x)` returns the filtered and downsampled values, y , of the input signal, x .

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix. The System object treats a $K_i \times N$ input matrix as N independent channels, decimating each channel over the first dimension. The number of input rows, K_i , must be a multiple of the decimation factor.

This object does not support complex unsigned fixed-point data.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

Output Arguments

y — Filtered and downsampled signal

vector | matrix

Filtered and downsampled signal, returned as a vector or matrix. For a $K_i \times N$ input matrix, the result is a $K_o \times N$ output matrix, where $K_o = K_i / M$ and M is the decimation factor.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.CICCompensationDecimator`

<code>freqz</code>	Frequency response of discrete-time filter System object
<code>fvtool</code>	Visualize frequency response of DSP filters
<code>info</code>	Information about filter System object
<code>cost</code>	Estimate cost of implementing filter System object
<code>coeffs</code>	Returns the filter System object coefficients in a structure
<code>polyphase</code>	Polyphase decomposition of multirate filter
<code>generatehdl</code>	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)

Common to All System Objects

step Run System object algorithm
 release Release resources and allow changes to System object property values and input characteristics
 reset Reset internal states of System object

Examples

Impulse and Frequency Response of CIC Compensation Decimator

Design an CIC compensation decimator. Specify the decimation factor to be 2, passband frequency to be 4 kHz, stopband frequency to be 4.5 kHz, and the input sample rate to be 16 kHz.

```
fs = 16e3;
fPass = 4e3;
fStop = 4.5e3;
```

```
CICCompDecim = dsp.CICCompensationDecimator('DecimationFactor',2,...
    'PassbandFrequency',fPass,...
    'StopbandFrequency',fStop,...
    'SampleRate',fs);
```

Plot the impulse response. The group delay of the filter is 45.5.

```
fvtool(CICCompDecim,'Analysis','impulse')
```

Plot the magnitude and Phase response.

```
fvtool(CICCompDecim,'Analysis','freq')
```

Compensation Decimator Design

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Design a compensation decimator for an existing CIC decimator having six sections and a decimation factor of 6.

```
CICDecim = dsp.CICDecimator('DecimationFactor',6, ...
    'NumSections',6);
```

Construct the compensation decimator. Specify a decimation factor of 2, an input sample rate of 16 kHz, a passband frequency of 4 kHz, and a stopband frequency of 4.5 kHz.

```
fs = 16e3;
fPass = 4e3;
fStop = 4.5e3;
```

```
CICCompDecim = dsp.CICCompensationDecimator(CICDecim, ...
    'DecimationFactor',2,'PassbandFrequency',fPass, ...
    'StopbandFrequency',fStop,'SampleRate',fs);
```

Visualize the frequency response of the cascade. Normalize all magnitude responses to 0 dB.

```
filtCasc = dsp.FilterCascade(CICDecim,CICCompDecim);

f = fvtool(CICDecim, CICCompDecim, filtCasc, ...
    'Fs', [fs*6 fs fs*6]);

f.NormalizeMagnitudeto1 = 'on';
legend(f, 'CIC Decimator', 'CIC Compensation Decimator', ...
    'Overall Response');
```

Apply the design to a 1200-sample random input signal. Store the decimated output along the first dimension of the `y` array.

```
x = dsp.SignalSource(fi(rand(1200,1),1,16,15), 'SamplesPerFrame', 120);

y = fi(zeros(100,1),1,32,20);

for ind = 1:10
    x2 = CICDecim(x());
    y(((ind-1)*10)+1:ind*10,1) = CICCompDecim(x2);
end
```

Algorithms

The response of a CIC filter is given by:

$$H_{cic}(\omega) = \left[\frac{\sin\left(\frac{RD\omega}{2}\right)}{\sin\left(\frac{\omega}{2}\right)} \right]^N$$

R , D , and N are the rate change factor, the differential delay, and the number of sections of the CIC filter, respectively.

After decimation, the cic response has the form:okay

$$H_{cic}(\omega) = \left[\frac{\sin\left(\frac{D\omega}{2}\right)}{\sin\left(\frac{\omega}{2R}\right)} \right]^N$$

The normalized version of this last response is the one that the CIC compensator needs to compensate. Hence, the passband response of the CIC compensator should take the following form:

$$H_{ciccomp}(\omega) = \left[RD \frac{\sin\left(\frac{\omega}{2R}\right)}{\sin\left(\frac{D\omega}{2}\right)} \right]^N \text{ for } \omega \leq \omega_p < \pi$$

where ω_p is the passband frequency of the CIC compensation filter.

Notice that when $\omega/2R \ll \pi$, the previous equation for $H_{ciccomp}(\omega)$ can be simplified using the fact that $\sin(x) \cong x$:

$$H_{ciccomp}(\omega) \approx \left[\frac{\left(\frac{D\omega}{2}\right)}{\sin\left(\frac{D\omega}{2}\right)} \right]^N = \left[\text{sinc}\left(\frac{D\omega}{2}\right) \right]^{-N} \text{ for } \omega \leq \omega_p < \pi$$

This previous equation is the inverse sinc approximation to the true inverse passband response of the CIC filter.

dsp.CICCompensationInterpolator

Package: dsp

Compensate for CIC interpolation filter using FIR interpolator

Description

You can compensate for the shortcomings of a CIC interpolator, namely its passband droop and wide transition region, by preceding it with a compensation interpolator. This System object lets you design and use such a filter.

To compensate for the shortcomings of a CIC filter using an FIR interpolator:

- 1 Create the `dsp.CICCompensationInterpolator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
ciccompint = dsp.CICCompensationInterpolator  
ciccompint = dsp.CICCompensationInterpolator(interp)  
ciccompint = dsp.CICCompensationInterpolator(cic)  
ciccompint = dsp.CICCompensationInterpolator(cic,interp)  
ciccompint = dsp.CICCompensationInterpolator( __ ,Name,Value)
```

Description

`ciccompint = dsp.CICCompensationInterpolator` returns a System object, `ciccompint`, that applies an FIR interpolator to each channel of an input signal. Using the properties of the object, the interpolation filter can be designed to compensate for a subsequent CIC filter.

`ciccompint = dsp.CICCompensationInterpolator(interp)` returns a CIC compensation interpolator System object, `ciccompint`, with the `InterpolationFactor` property set to `interp`.

`ciccompint = dsp.CICCompensationInterpolator(cic)` returns a CIC compensation interpolator System object, `ciccompint`, with the `CICRateChangeFactor`, `CICNumSections`, and `CICDifferentialDelay` properties specified in the `dsp.CICInterpolator` System object `cic`.

`ciccompint = dsp.CICCompensationInterpolator(cic,interp)` returns a CIC compensation interpolator System object, `ciccompint`, with the `CICRateChangeFactor`, `CICNumSections`, and `CICDifferentialDelay` properties specified in the `dsp.CICInterpolator` System object `cic`, and the `InterpolationFactor` property set to `interp`.

`ciccompint = dsp.CICCompensationInterpolator(___, Name, Value)` returns a CIC compensation interpolator object with each specified property set to the specified value. Enclose each property name in quotes. You can use this syntax with any previous input argument combinations.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

CICDifferentialDelay — Differential delay of the CIC filter being compensated

1 (default) | positive integer scalar

Specify the differential delay of the CIC filter being compensated as a positive integer scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

CICNumSections — Number of sections of the CIC filter being compensated

2 (default) | positive integer scalar

Specify the number of sections of the CIC filter being compensated as a positive integer scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

CICRateChangeFactor — Rate-change factor of the CIC filter being compensated

2 (default) | positive integer scalar

Specify the rate-change factor of the CIC filter being compensated as a positive integer scalar. The default is 2.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

DesignForMinimumOrder — Design filter of minimum order or of specified order

`true` (default) | `false`

Specify whether to design a filter of minimum order or a filter of specified order as a logical scalar. The default is `true`, which corresponds to a filter of minimum order.

FilterOrder — Order of interpolation compensator filter

12 (default) | positive integer scalar

Specify the order of the interpolation compensator filter as a positive integer scalar.

Dependencies

This property applies only when you set the `DesignForMinimumOrder` property to `false`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

InterpolationFactor — Interpolation factor of compensator

2 (default) | positive integer scalar

Specify the interpolation factor of the compensator System object as a positive integer scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

PassbandFrequency — Passband edge frequency in hertz

100000 (default) | positive real scalar

Specify the passband edge frequency as a positive real scalar expressed in hertz. `PassbandFrequency` must be less than $F_s/2$, where F_s is the output sample rate.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

PassbandRipple — Filter passband ripple in decibels

0.1 (default) | positive real scalar

Specify the filter passband ripple as a positive real scalar expressed in decibels.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

SampleRate — Input sample rate in hertz

600000 (default) | positive real scalar

Specify the input sample rate as a positive real scalar expressed in hertz.

Data Types: `single` | `double`

StopbandAttenuation — Filter stopband attenuation in decibels

60 (default) | positive real scalar

Specify the filter stopband attenuation as a positive real scalar expressed in decibels.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

StopbandFrequency — Stopband edge frequency in hertz

400000 (default) | positive real scalar

Specify the stopband edge frequency as a positive real scalar expressed in hertz. `StopbandFrequency` must be less than $F_s/2$, where F_s is the output sample rate.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Fixed-Point Properties**CoefficientsDataType — Word and fraction lengths of coefficients**

`numericType(1,16)` (default) | `numericType` object

Word and fraction lengths of coefficients, specified as a signed or unsigned `numericType` object. The default, `numericType(1,16)` corresponds to a signed numeric type object with 16-bit coefficients and a fraction length determined based on the coefficient values, to give the best possible precision.

This property is not tunable.

Word length of the output is same as the word length of the input. Fraction length of the output is computed such that the entire dynamic range of the output can be represented without overflow. For details on how the fraction length of the output is computed, see “Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters”.

RoundingMethod — Rounding method for output fixed-point operations

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see “Precision and Range”.

Usage

Syntax

```
y = ciccompint(x)
```

Description

`y = ciccompint(x)` outputs the upsampled and filtered values, y , of the input signal, x .

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix. The System object treats a $K_i \times N$ input matrix as N independent channels, interpolating each channel over the first dimension.

This object does not support complex unsigned fixed-point data.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Output Arguments

y — Upsampled and filtered signal

vector | matrix

Upsampled and filtered signal, returned as a vector or matrix. For a $K_i \times N$ input matrix, the result is a $K_o \times N$ output matrix, where $K_o = K_i \times L$ and L is the interpolation factor.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.CICCompensationInterpolator

<code>freqz</code>	Frequency response of discrete-time filter System object
<code>fvtool</code>	Visualize frequency response of DSP filters
<code>info</code>	Information about filter System object
<code>cost</code>	Estimate cost of implementing filter System object
<code>coeffs</code>	Returns the filter System object coefficients in a structure
<code>polyphase</code>	Polyphase decomposition of multirate filter
<code>generatehdl</code>	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)

Common to All System Objects

`step` Run System object algorithm
`release` Release resources and allow changes to System object property values and input characteristics
`reset` Reset internal states of System object

Examples

Impulse and Frequency Response of CIC Compensation Interpolator

Design an CIC compensation interpolator. Specify the interpolation factor to be 2, passband frequency to be 200 Hz, stopband frequency to be 500 Hz, and the input sample rate to be 600 Hz.

```
fs = 600;  
fPass = 200;  
fStop = 500;
```

```
CICCompInterp = dsp.CICCompensationInterpolator(...  
    'InterpolationFactor',2,...  
    'PassbandFrequency',fPass,...  
    'StopbandFrequency',fStop,...  
    'SampleRate',fs);
```

Plot the impulse response. The zeroth order coefficient is delayed 6 samples, which is equal to the group delay of the filter.

```
fvtool(CICCompInterp,'Analysis','impulse')
```

Plot the magnitude and Phase response.

```
fvtool(CICCompInterp, 'Analysis', 'freq')
```

Compensation Interpolator Design

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Design a compensation interpolator for an existing CIC interpolator having six sections and an interpolation factor of 16.

```
CICInterp = dsp.CICInterpolator('InterpolationFactor',16, ...
    'NumSections',6);
```

Construct the compensation interpolator. Specify an interpolation factor of 2, an input sample rate of 600 Hz, a passband frequency of 100 Hz, and a stopband frequency of 250 Hz. Set the minimum attenuation of alias components in the stopband to be at least 80 dB.

```
fs = 600;
fPass = 100;
fStop = 250;
ast = 80;
```

```
CICCompInterp = dsp.CICCompensationInterpolator(CICInterp, ...
    'InterpolationFactor',2,'PassbandFrequency',fPass, ...
    'StopbandFrequency',fStop,'StopbandAttenuation',ast, ...
    'SampleRate',fs);
```

Visualize the frequency response of the cascade. Normalize all magnitude responses to 0 dB.

```
FC = dsp.FilterCascade(CICCompInterp, CICInterp);

f = fvtool(CICCompInterp,CICInterp,FC, ...
    'Fs', [fs*2 fs*16*2 fs*16*2]);

f.NormalizeMagnitudeTo1 = 'on';
legend(f, 'CIC Compensation Interpolator', 'CIC Interpolator', ...
    'Overall Response');
```

Apply the design to a 1000-sample random input signal.

```
x = dsp.SignalSource(fi(rand(1000,1),1,16,15), 'SamplesPerFrame', 100);

y = fi(zeros(32000,1),1,32,20);
for ind = 1:10
    x2 = CICCompInterp(x());
    y(((ind-1)*3200)+1:ind*3200) = CICInterp(x2);
end
```

Algorithms

The response of a CIC filter is given by:

$$H_{cic}(\omega) = \left[\frac{\sin\left(\frac{RD\omega}{2}\right)}{\sin\left(\frac{\omega}{2}\right)} \right]^N$$

R , D , and N are the rate change factor, the differential delay, and the number of sections of the CIC filter, respectively.

After decimation, the cic response has the form:okay

$$H_{cic}(\omega) = \left[\frac{\sin\left(\frac{D\omega}{2}\right)}{\sin\left(\frac{\omega}{2R}\right)} \right]^N$$

The normalized version of this last response is the one that the CIC compensator needs to compensate. Hence, the passband response of the CIC compensator should take the following form:

$$H_{ciccomp}(\omega) = \left[RD \frac{\sin\left(\frac{\omega}{2R}\right)}{\sin\left(\frac{D\omega}{2}\right)} \right]^N \text{ for } \omega \leq \omega_p < \pi$$

where ω_p is the passband frequency of the CIC compensation filter.

Notice that when $\omega/2R \ll \pi$, the previous equation for $H_{ciccomp}(\omega)$ can be simplified using the fact that $\sin(x) \cong x$:

$$H_{ciccomp}(\omega) \approx \left[\frac{\left(\frac{D\omega}{2}\right)}{\sin\left(\frac{D\omega}{2}\right)} \right]^N = \left[\text{sinc}\left(\frac{D\omega}{2}\right) \right]^{-N} \text{ for } \omega \leq \omega_p < \pi$$

This previous equation is the inverse sinc approximation to the true inverse passband response of the CIC filter.

Version History

Introduced in R2014b

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

This object supports code generation for ARM Cortex-M and ARM Cortex-A processors.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This object supports HDL code generation with the Filter Design HDL Coder product. For workflows and limitations, see “Generate HDL Code for Filter System Objects” (Filter Design HDL Coder).

dsp.CICDecimator

Package: dsp

Decimate signal using cascaded integrator-comb (CIC) filter

Description

The `dsp.CICDecimator` System object decimates an input signal using a cascaded integrator-comb (CIC) decimation filter. The CIC decimation filter structure consists of N sections of cascaded integrators, followed by a rate change by a factor of R , followed by N sections of cascaded comb filters. For details, see “Algorithms” on page 4-252. The `NumSections` property specifies N , the number of sections in the CIC filter. The `DecimationFactor` property specifies R , the decimation factor. The `getFixedPointInfo` function returns the word lengths and fraction lengths of the fixed-point sections and the output for the `dsp.CICDecimator` System object. You can also generate HDL code for this System object using the `generatehdl` function.

Note This object requires a Fixed-Point Designer license.

To decimate a signal using a CIC filter:

- 1 Create the `dsp.CICDecimator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
cicDecim = dsp.CICDecimator
cicDecim = dsp.CICDecimator(R,M,N)
cicDecim = dsp.CICDecimator(Name,Value)
```

Description

`cicDecim = dsp.CICDecimator` creates a CIC decimation System object that applies a CIC decimation filter to the input signal.

`cicDecim = dsp.CICDecimator(R,M,N)` creates a CIC decimation object with the `DecimationFactor` property set to R , the `DifferentialDelay` property set to M , and the `NumSections` property set to N .

`cicDecim = dsp.CICDecimator(Name,Value)` creates a CIC decimation object with each specified property set to the specified value. Enclose each property name in single quotes. You can use this syntax with any previous input argument combination.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

DecimationFactor — Decimation factor

2 (default) | positive integer

Factor by which the input signal is decimated, specified as a positive integer.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

DifferentialDelay — Differential delay of filter comb sections

1 (default) | positive integer

Differential delay value used in each of the comb sections of the filter, specified as a positive integer. For details, see “Algorithms” on page 4-252. If the differential delay is a built-in integer data type, the decimation factor must be the same integer data type or `double`. For example, if the differential delay is an `int8`, then the decimation factor must be an `int8` or `double`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

NumSections — Number of integrator and comb sections

2 (default) | positive integer

Number of integrator and comb sections of the CIC filter, specified as a positive integer. This number indicates the number of sections in either the comb part or the integrator part of the filter. The total number of sections in the CIC filter is twice the number of sections given by this property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

FixedPointDataType — Fixed-point property designations

Full precision (default) | Minimum section word lengths | Specify word lengths | Specify word and fraction lengths

Fixed-point property designations, specified as one of the following:

- **Full precision** - The word length and fraction length of the CIC filter sections and the object output operate in full precision.
- **Minimum section word lengths** - Specify the output word length through the `OutputWordLength` property. The object determines the filter section data type and the output fraction length that give the best possible precision. For details, see `getFixedPointInfo` and `cicDecimOut` argument.
- **Specify word lengths** - Specify the word lengths of the CIC filter sections and the object output through the `SectionWordLengths` and `OutputWordLength` properties. The object determines the corresponding fraction lengths to give the best possible precision. For details, see `getFixedPointInfo` and the `cicDecimOut` argument.
- **Specify word and fraction lengths** - Specify the word length and fraction length of the CIC filter sections and the object output through the `SectionWordLengths`, `SectionFractionLengths`, `OutputWordLength`, and `OutputFractionLength` properties.

SectionWordLengths — Fixed-point word lengths for each filter section`[16 16 16 16]` (default) | scalar | vector

Fixed-point word lengths to use for each filter section, specified as a scalar or a row vector of integers. The word length must be greater than or equal to 2. If you specify a scalar, the value applies to all the sections of the filter. If you specify a vector, the vector must be of length $2 \times \text{NumSections}$.

Example: 32

Example: [32 32 32 32]

Dependencies

This property applies when you set the `FixedPointDataType` property to 'Specify word lengths' or 'Specify word and fraction lengths'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

SectionFractionLengths — Fixed-point fraction lengths for each filter section`0` (default) | scalar | vector

Fixed-point fraction lengths to use for each filter section, specified as a scalar or a row vector of integers. The fraction length can be negative, 0, or positive. If you specify a scalar, the value applies to all the sections of the filter. If you specify a vector, the vector must be of length $2 \times \text{NumSections}$.

Example: -2

Example: [-2 0 5 8]

Dependencies

This property applies when you set the `FixedPointDataType` property to 'Specify word and fraction lengths'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

OutputWordLength — Fixed-point word length for filter output`32` (default) | scalar integer

Fixed-point word length to use for the filter output, specified as a scalar integer greater than or equal to 2.

Dependencies

This property applies when you set the `FixedPointDataType` property to 'Minimum section word lengths', 'Specify word lengths', or 'Specify word and fraction lengths'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

OutputFractionLength — Fixed-point fraction length for filter output`0` (default) | scalar integer

Fixed-point fraction length to use for the filter output, specified as a scalar integer.

Dependencies

This property applies when you set `FixedPointDataType` property to 'Specify word and fraction lengths'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Usage

Syntax

```
cicDecimOut = cicDecim(input)
```

Description

`cicDecimOut = cicDecim(input)` decimates the input using a CIC decimator.

Input Arguments

input — Data input

vector | matrix

Data input, specified as a vector or matrix. The number of rows in the input must be a multiple of the “DecimationFactor” on page 4-0 . If the input is of `single` or `double` data type, property settings related to the fixed-point data types are ignored.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Output Arguments

cicDecimOut — CIC decimator output

vector | matrix

Decimated output, returned as a vector or a matrix. The output frame size equals $(1 / \text{DecimationFactor}) \times \text{input frame size}$. The complexity of the output data matches that of the input data. If the input is `single` or `double`, the output data type matches the input data type.

If the input is of built-in integer data type or of fixed-point data type, the output word length and fraction length depend on the fixed-point data type setting you choose through the “FixedPointDataType” on page 4-0 property.

Full precision

When the `FixedPointDataType` is set to 'Full precision', the following relationship applies:

$$WL_{\text{output}} = WL_{\text{input}} + \text{NumSect}$$

$$FL_{\text{output}} = FL_{\text{input}}$$

where,

- WL_{output} -- Word length of the output data.
- FL_{output} -- Fraction length of the output data.
- WL_{input} -- Word length of the input data.
- FL_{input} -- Fraction length of the input data.
- NumSect -- Number of sections in the CIC filter specified through the “NumSections” on page 4-0 property.

The WL_{input} and FL_{input} are inherited from the data input you pass to the object algorithm. For built-in integer inputs, the fraction length is 0.

Minimum section word lengths

When the `FixedPointDataType` property is set to 'Minimum section word lengths', the output word length is the value you specify in the “OutputWordLength” on page 4-0 property. The output fraction length, FL_{output} , is given by:

$$FL_{\text{output}} = WL_{\text{output}} - (WL_{\text{input}} - FL_{\text{input}} + \text{NumSect})$$

Specify word and fraction lengths

When the `FixedPointDataType` property is set to 'Specify word and fraction lengths', the output word length and fraction length are the values you specify in the “OutputWordLength” on page 4-0 and “OutputFractionLength” on page 4-0 properties.

Specify word lengths

When the `FixedPointDataType` property is set to 'Specify word lengths', the output word length is the value you specify in the `OutputWordLength` property. The output fraction length, FL_{output} , is given by:

$$FL_{\text{output}} = WL_{\text{output}} - (WL_{\text{input}} - FL_{\text{input}} + \text{NumSect})$$

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.CICDecimator`

<code>generatehdl</code>	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)
<code>impz</code>	Impulse response of discrete-time filter System object
<code>freqz</code>	Frequency response of discrete-time filter System object
<code>phasez</code>	Phase response of discrete-time filter System object (unwrapped)
<code>fvtool</code>	Visualize frequency response of DSP filters
<code>gain</code>	Gain of CIC filter System object
<code>getFixedPointInfo</code>	Get fixed-point word and fraction lengths
<code>info</code>	Information about filter System object

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

For a list of filter analysis methods this object supports, type `dsp.CICDecimator.helpFilterAnalysis` in the MATLAB command prompt. For the corresponding function reference pages, see “Analysis Methods for Filter System Objects” on page 3-2.

Examples

Decimate a Signal Using a CICDecimator Object

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Create a `dsp.CICDecimator System` object™ with `DecimationFactor` set to 4. Decimate a signal from 44.1 kHz to 11.025 kHz.

```
cicdec = dsp.CICDecimator(4);
cicdec.FixedPointDataType = 'Minimum section word lengths';
cicdec.OutputWordLength = 16;
```

Create a fixed-point sinusoidal input signal of 1024 samples, with a sampling frequency of 44.1e3 Hz.

```
Fs = 44.1e3;
% 0.0232 sec signal
n = (0:1023)';
x = fi(sin(2*pi*1e3/Fs*n),true,16,15);
```

Create a `dsp.SignalSource` object.

```
src = dsp.SignalSource(x,64);
```

Decimate the output with 16 samples per frame.

```
y = zeros(16,16);
for ii = 1:16
    y(ii,:) = cicdec(src());
end
```

Plot the first frame of the original and decimated signals. Output latency is 2 samples.

```
D = cicdec.DecimationFactor;
diffDelay = cicdec.DifferentialDelay;
NumSect = cicdec.NumSections;
gainCIC = ...
    (D*diffDelay)^NumSect;
stem(n(1:56)/Fs,double(x(4:59)))
hold on;
stem(n(1:14)/(Fs/D),double(y(1,3:end))/gainCIC,...
    'r','filled')
xlabel('Time (sec)')
ylabel('Signal Amplitude')
legend('Original signal',...
    'Decimated signal',...
    'Location','north')
hold off;
```

Using the `info` method in 'long' format, obtain the word lengths and fraction lengths of the fixed-point filter sections and the filter output.

```
info(cicdec, 'long')
```

```
ans =
'Discrete-Time FIR Multirate Filter (real)
-----

```

Determine the Section and Output Word Lengths and Fraction Lengths

Using the `getFixedPointInfo` function, you can determine the word lengths and fraction lengths of the fixed-point sections and the output of the `dsp.CICDecimator` and `dsp.CICInterpolator` System objects. The data types of the filter sections and the output depend on the `FixedPointDataType` property of the filter System object™.

Full precision

Create a `dsp.CICDecimator` object. The default value of the `NumSections` property is 2. This value indicates that there are two integrator and comb sections. The WLS and FLs vectors returned by the `getFixedPointInfo` function contain five elements each. The first two elements represent the two integrator sections. The third and fourth elements represent the two comb sections. The last element represents the filter output.

```
cicD = dsp.CICDecimator
cicD =
    dsp.CICDecimator with properties:
        DecimationFactor: 2
        DifferentialDelay: 1
        NumSections: 2
        FixedPointDataType: 'Full precision'
```

By default, the `FixedPointDataType` property of the object is set to 'Full precision'. Calling the `getFixedPointInfo` function on this object with the input numeric type, `nt`, yields the following word length and fraction length vectors.

```
nt = numerictype(1,16,15)
nt =
    DataTypeMode: Fixed-point: binary point scaling
    Signedness: Signed
    WordLength: 16
    FractionLength: 15

[WLS,FLs] = getFixedPointInfo(cicD,nt) %#ok
WLS = 1x5
    18    18    18    18    18
FLs = 1x5
    15    15    15    15    15
```

For details on how the word lengths and fraction lengths are computed, see the description for *Output Arguments*.

If you lock the `cicD` object by passing an input to its algorithm, you do not need to pass the `nt` argument to the `getFixedPointInfo` function.

```
input = int64(randn(8,1))
input = 8x1 int64 column vector

     1
     2
    -2
     1
     0
    -1
     0
     0

output = cicD(input)
output =
     0
     1
     3
     0

        DataTypeMode: Fixed-point: binary point scaling
          Signedness: Signed
         WordLength: 66
    FractionLength: 0

[WLs,FLs] = getFixedPointInfo(cicD) %#ok
WLs = 1x5
    66    66    66    66    66

FLs = 1x5
     0     0     0     0     0
```

The output and section word lengths are the sum of input word length, 64 in this case, and the number of sections, 2. The output and section fraction lengths are 0 since the input is a built-in integer.

Minimum section word lengths

Release the object and change the `FixedPointDataType` property to 'Minimum section word lengths'. Determine the section and output fixed-point information when the input is fixed-point data, `fi(randn(8,2),1,24,15)`.

```
release(cicD);
cicD.FixedPointDataType = 'Minimum section word lengths'

cicD =
    dsp.CICDecimator with properties:
```

```

    DecimationFactor: 2
    DifferentialDelay: 1
        NumSections: 2
    FixedPointDataType: 'Minimum section word lengths'
    OutputWordLength: 32

```

```
inputF = fi(randn(8,2),1,24,15)
```

```
inputF =
    3.5784   -0.1241
    2.7694    1.4897
   -1.3499    1.4090
    3.0349    1.4172
    0.7254    0.6715
   -0.0630   -1.2075
    0.7148    0.7172
   -0.2050    1.6302

```

```

    DataTypeMode: Fixed-point: binary point scaling
    Signedness: Signed
    WordLength: 24
    FractionLength: 15

```

```
[WLs, FLs] = getFixedPointInfo(cicD,numericType(inputF)) %#ok
```

```
WLs = 1x5
```

```
    26    26    26    26    32
```

```
FLs = 1x5
```

```
    15    15    15    15    21
```

Specify word and fraction lengths

Change the `FixedPointDataType` property to 'Specify word and fraction lengths'. Determine the fixed-point information using the `getFixedPointInfo` function.

```
cicD.FixedPointDataType = 'Specify word and fraction lengths'
```

```
cicD =
```

```
    dsp.CICDecimator with properties:
```

```

    DecimationFactor: 2
    DifferentialDelay: 1
        NumSections: 2
    FixedPointDataType: 'Specify word and fraction lengths'
    SectionWordLengths: [16 16 16 16]
    SectionFractionLengths: 0
    OutputWordLength: 32
    OutputFractionLength: 0

```

```
[WLs, FLs] = getFixedPointInfo(cicD,numericType(inputF)) %#ok
```

```

WLs = 1x5
    16    16    16    16    32

```

```

FLs = 1x5
    0     0     0     0     0

```

The section and output word lengths and fraction lengths are assigned as per the respective fixed-point properties of the `cicD` object. These values are not determined by the input numeric type. To confirm, call the `getFixedPointInfo` function without passing the `numericType` input argument.

```
[WLs, FLs] = getFixedPointInfo(cicD) %#ok
```

```

WLs = 1x5
    16    16    16    16    32

```

```

FLs = 1x5
    0     0     0     0     0

```

Specify word lengths

To specify the word lengths of the filter section and output, set the `FixedPointDataType` property to `'Specify word lengths'`.

```
cicD.FixedPointDataType = 'Specify word lengths'
```

```

cicD =
  dsp.CICDecimator with properties:
    DecimationFactor: 2
    DifferentialDelay: 1
    NumSections: 2
    FixedPointDataType: 'Specify word lengths'
    SectionWordLengths: [16 16 16 16]
    OutputWordLength: 32

```

The `getFixedPointInfo` function requires the input numeric type because that information is used to compute the section and word fraction lengths.

```
[WLs, FLs] = getFixedPointInfo(cicD,numericType(inputF))
```

```

WLs = 1x5
    16    16    16    16    32

```

```

FLs = 1x5
    5     5     5     5    21

```

For more details on how the function computes the word and fraction lengths, see the description for *Output Arguments*.

More About

CIC Filter

CIC filters are an optimized class of linear phase FIR filters composed of a comb part and an integrator part.

The CIC decimation filter is conceptually given by a single rate CIC filter, $H(z)$ which is a lowpass anti-imaging filter, followed by a downsampler. The CIC decimation filter decreases the sample rate of an input signal by an integer factor using a cascaded integrator-comb (CIC) filter.

In a more efficient implementation, the single rate CIC filter $H(z)$ is factorized this way:

$$H(z) = \left[\sum_{k=0}^{RM-1} z^{-k} \right]^N = \frac{(1 - z^{-RM})^N}{(1 - z^{-1})^N} = \frac{1}{(1 - z^{-1})^N} \cdot \frac{(1 - z^{-RM})^N}{1} = H_I^N(z) \cdot H_C^N(z)$$

where,

- H_I is the transfer function of the integrator part of the filter containing N stages of integrators.
- H_C is the transfer function of the N sections of the cascaded comb filters, each with a width of RM .
- N is the number of sections. The number of sections in a CIC filter is defined as the number of sections in either the comb part *or* the integrator part of the filter. This value does not represent the total number of sections throughout the entire filter.
- R is the decimation factor.
- M is the differential delay.

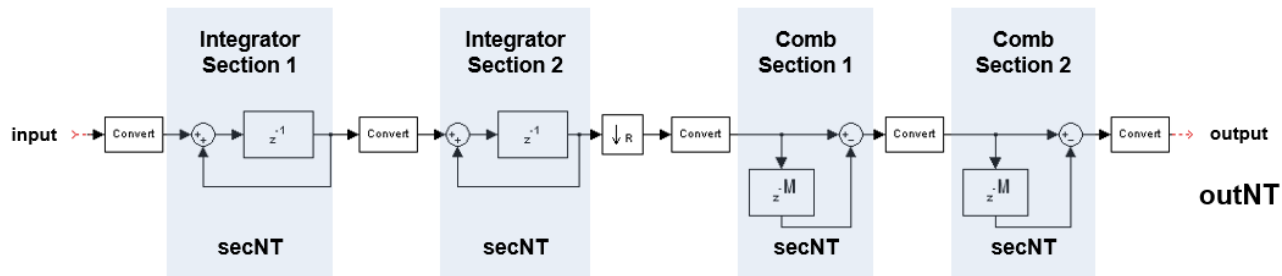

In the overall multirate realization, the algorithm applies the noble identity for decimation and moves the rate change factor, R , to follow after the N sections of the cascaded integrators. The transfer function of the resulting filter is given by the following equation:

$$H(z) = \frac{(1 - z^{-M})^N}{(1 - z^{-1})^N}$$

For a block diagram that shows the multirate implementation, see Algorithms on page 4-252.

Fixed Point

The fixed-point signal diagram shows the data types that the `dsp.CICDecimator` object uses for fixed-point signals.

where,

- `secNT = numerictype(1,secWL,secFL)`
- `outNT = numerictype(1,outWL,outFL)`
- `secWL` is the section word length you specify through the “SectionWordLengths” on page 4-0 property.
- `secFL` is the section fraction length you specify through the “SectionFractionLengths” on page 4-0 property.
- `outWL` is the output word length you specify through the “OutputWordLength” on page 4-0 property.
- `outFL` is the output fraction length you specify through the “OutputFractionLength” on page 4-0 property.

The value of `NumSections` in this diagram is 2.

Algorithms

CIC Decimation Filter

The CIC decimation filter in More About on page 4-251 is realized as a cascade of N sections of the integrators followed by a rate change factor of R , followed by N sections of comb filters.

This diagram shows two sections of cascaded integrators and two sections of cascaded comb filters. The unit delay in the integrator portion of the CIC filter can be located in either the feedforward or the feedback path. These two configurations yield identical filter frequency response. However, the numerical outputs from these two configurations are different due to the latency. This block puts the unit delay in the feedforward path of the integrator because it is a preferred configuration for HDL implementation.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See "System Objects in MATLAB Code Generation" (MATLAB Coder).

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This object supports HDL code generation with the Filter Design HDL Coder product. For workflows and limitations, see "Generate HDL Code for Filter System Objects" (Filter Design HDL Coder).

dsp.CICInterpolator

Package: dsp

Interpolate signal using cascaded integrator-comb filter

Description

The `dsp.CICInterpolator` System object interpolates an input signal using a cascaded integrator-comb (CIC) interpolation filter. The CIC interpolation filter structure consists of N sections of cascaded comb filters, followed by a rate change by a factor of R , followed by N sections of cascaded integrators. For details, see “Algorithms” on page 4-267. The `NumSections` property specifies N , the number of sections in the CIC filter. The `InterpolationFactor` property specifies R , the interpolation factor. The `getFixedPointInfo` function returns the word lengths and fraction lengths of the fixed-point sections and the output for the `dsp.CICInterpolator` System object. You can also generate HDL code for this System object using the `generatehdl` function.

Note This object requires a Fixed-Point Designer license.

To interpolate a signal using a CIC filter:

- 1 Create the `dsp.CICInterpolator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
cicInterp = dsp.CICInterpolator
cicInterp = dsp.CICInterpolator(R,M,N)
cicInterp = dsp.CICInterpolator(Name,Value)
```

Description

`cicInterp = dsp.CICInterpolator` creates a CIC interpolation System object that applies a CIC interpolation filter to the input signal.

`cicInterp = dsp.CICInterpolator(R,M,N)` creates a CIC interpolation object with the `InterpolationFactor` property set to R , the `DifferentialDelay` property set to M , and the `NumSections` property set to N .

`cicInterp = dsp.CICInterpolator(Name,Value)` creates a CIC interpolation object with each specified property set to the specified value. Enclose each property name in single quotes. You can use this syntax with any previous input argument combinations.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

InterpolationFactor — Interpolation factor

2 (default) | positive integer

Factor by which the input signal is interpolated, specified as a positive integer.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

DifferentialDelay — Differential delay of filter comb sections

1 (default) | positive integer

Differential delay value used in each of the comb sections of the filter, specified as a positive integer. For details, see “Algorithms” on page 4-267. If the differential delay is of built-in integer class data type, the interpolation factor must be the same integer data type or `double`. For example, if the differential delay is an `int8`, then the interpolation factor must be an `int8` or `double`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

NumSections — Number of integrator and comb sections

2 (default) | positive integer

Number of integrator and comb sections of the CIC filter, specified as a positive integer. This number indicates the number of sections in either the comb part or the integrator part of the filter. The total number of sections in the CIC filter is twice the number of sections given by this property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

FixedPointDataType — Fixed-point property designations

Full precision (default) | Minimum section word lengths | Specify word lengths | Specify word and fraction lengths

Fixed-point property designations, specified as one of the following:

- **Full precision** - The word length and fraction length of the CIC filter sections and the object output operate in full precision.
- **Minimum section word lengths** - Specify the output word length through the `OutputWordLength` property. The object determines the filter section data type and the output fraction length that give the best possible precision. For details, see `getFixedPointInfo` and `cicInterpOut` argument.
- **Specify word lengths** - Specify the word lengths of the CIC filter sections and the object output through the `SectionWordLengths` and `OutputWordLength` properties. The object determines the corresponding fraction lengths to give the best possible precision. For details, see `getFixedPointInfo` and the `cicInterpOut` argument.
- **Specify word and fraction lengths** - Specify the word length and fraction length of the CIC filter sections and the object output through the `SectionWordLengths`, `SectionFractionLengths`, `OutputWordLength`, and `OutputFractionLength` properties.

SectionWordLengths — Fixed-point word lengths for each filter section`[16 16 16 16]` (default) | scalar | vector

Fixed-point word lengths to use for each filter section, specified as a scalar or a row vector of integers. The word length must be greater than or equal to 2. If you specify a scalar, the value applies to all the sections of the filter. If you specify a vector, the vector must be of length $2 \times \text{NumSections}$.

Example: 32

Example: [32 32 32 32]

Dependencies

This property applies when you set the `FixedPointDataType` property to 'Specify word lengths' or 'Specify word and fraction lengths'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

SectionFractionLengths — Fixed-point fraction lengths for each filter section`0` (default) | scalar | vector

Fixed-point fraction lengths to use for each filter section, specified as a scalar or a row vector of integers. The fraction length can be negative, 0, or positive. If you specify a scalar, the value applies to all the sections of the filter. If you specify a vector, the vector must be of length $2 \times \text{NumSections}$.

Example: -2

Example: [-2 0 5 8]

Dependencies

This property applies when you set the `FixedPointDataType` property to 'Specify word and fraction lengths'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

OutputWordLength — Fixed-point word length for filter output`32` (default) | scalar integer

Fixed-point word length to use for the filter output, specified as a scalar integer greater than or equal to 2.

Dependencies

This property applies when you set the `FixedPointDataType` property to one of 'Minimum section word lengths', 'Specify word lengths', or 'Specify word and fraction lengths'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

OutputFractionLength — Fixed-point fraction length for filter output`0` (default) | scalar integer

Fixed-point fraction length to use for the filter output, specified as a scalar integer.

Dependencies

This property applies when you set the `FixedPointDataType` property to 'Specify word and fraction lengths'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Usage

Syntax

```
cicInterpOut = cicInterp(input)
```

Description

`cicInterpOut = cicInterp(input)` interpolates the input using a CIC interpolator.

Input Arguments

input — Data input

vector | matrix

Data input, specified as a vector or matrix. If the input is of `single` or `double` data type, property settings related to the fixed-point data types are ignored.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Output Arguments

cicInterpOut — CIC interpolator output

vector | matrix

Interpolated output, returned as a vector or a matrix. The output frame size equals (“InterpolationFactor” on page 4-0) × input frame size. The complexity of the output data matches that of the input data. If the input is `single` or `double`, the output data type matches the input data type.

If the input is of built-in integer data type or of fixed-point data type, the output word length and fraction length depend on the fixed-point data type setting you choose through the “FixedPointDataType” on page 4-0 property.

Full precision

When the `FixedPointDataType` property is set to 'Full precision', the following relationship applies:

$$WL_{\text{output}} = WL_{\text{input}} + NumSect$$

$$FL_{\text{output}} = FL_{\text{input}}$$

where,

- WL_{output} -- Word length of the output data.
- FL_{output} -- Fraction length of the output data.
- WL_{input} -- Word length of the input data.
- FL_{input} -- Fraction length of the input data.
- $NumSect$ -- Number of sections in the CIC filter specified through the “NumSections” on page 4-0 property.

WL_{input} and FL_{input} are inherited from the data input you pass to the object algorithm. For built-in integer inputs, the fraction length is 0.

Minimum section word lengths

When the `FixedPointDataType` property is set to 'Minimum section word lengths', the output word length is the value you specify in "OutputWordLength" on page 4-0 property. The output fraction length, FL_{output} is given by the following equation:

$$FL_{output} = WL_{output} - (WL_{input} - FL_{input} + NumSect)$$

Specify word and fraction lengths

When the `FixedPointDataType` is set to 'Specify word and fraction lengths', the output word length and fraction length are the values you specify in the "OutputWordLength" on page 4-0 and "OutputFractionLength" on page 4-0 properties.

Specify word lengths

When the `FixedPointDataType` is set to 'Specify word lengths', the output word length is the value you specify in the `OutputWordLength` property. The output fraction length, FL_{output} is given by the following equation:

$$FL_{output} = WL_{output} - (WL_{input} - FL_{input} + NumSect)$$

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.CICInterpolator`

<code>generatehdl</code>	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)
<code>impz</code>	Impulse response of discrete-time filter System object
<code>freqz</code>	Frequency response of discrete-time filter System object
<code>phasez</code>	Phase response of discrete-time filter System object (unwrapped)
<code>fvtool</code>	Visualize frequency response of DSP filters
<code>gain</code>	Gain of CIC filter System object
<code>getFixedPointInfo</code>	Get fixed-point word and fraction lengths
<code>info</code>	Information about filter System object

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

For a list of filter analysis methods this object supports, type `dsp.CICInterpolator.helpFilterAnalysis` in the MATLAB command prompt. For the

corresponding function reference pages, see “Analysis Methods for Filter System Objects” on page 3-2.

Examples

Interpolate Signal Using CICInterpolator System object

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Create a `dsp.CICInterpolator` System object™ with `InterpolationFactor` set to 2. Interpolate a fixed-point signal by a factor of 2 from 22.05 kHz to 44.1 kHz.

```
cicint = dsp.CICInterpolator(2)

cicint =
    dsp.CICInterpolator with properties:

        InterpolationFactor: 2
        DifferentialDelay: 1
        NumSections: 2
        FixedPointDataType: 'Full precision'
```

Create a `dsp.SineWave` object with `SampleRate` set to 22.05 kHz, `SamplesPerFrame` set to 32, and `OutputDataType` set to 'Custom'. To generate a fixed-point signal, set the `CustomOutputDataType` property to a `numericType` object. For the purpose of this example, set the value to `numericType([],16)`. The fraction length is computed based on the values of the generated sinusoidal signal to give the best possible precision.

To generate a fixed-point signal, set the `Method` property of the `dsp.SineWave` object to 'Table lookup'. This method of generating the sinusoidal signal requires that the period of every sinusoid in the output be evenly divisible by the sample period. That is, $1/f_i T_s = k_i$ must be an integer value for every channel $i = 1, 2, \dots, N$. The value of T_s equals $1/F_s$, the variable f_i is the frequency of the sinusoidal signal, and F_s is the sample rate of the signal. In other words, the ratio F_s/f_i must be an integer. For more details, see the “Algorithms” on page 4-1010 section on the `dsp.SineWave` object page.

In this example, F_s is set to 22050 Hz and f_i is set to 1050 Hz.

```
Fs = 22.05e3;
sine = dsp.SineWave('Frequency',1050,...
    'SampleRate',Fs,...
    'SamplesPerFrame',32,...
    'Method','Table lookup',...
    'OutputDataType','Custom')

sine =
    dsp.SineWave with properties:

        Amplitude: 1
        Frequency: 1050
        PhaseOffset: 0
        ComplexOutput: false
```

```
Method: 'Table lookup'  
TableOptimization: 'Speed'  
SampleRate: 22050  
SamplesPerFrame: 32  
OutputDataType: 'Custom'
```

Show all properties

In each loop of the iteration, stream in a frame of the fixed-point sinusoidal signal sampled at 22.05 kHz. Interpolate the streamed signal by a factor of 2. The interpolated output has 64 samples per frame.

```
for i = 1:16  
    x = sine();  
    y = cicint(x);  
end
```

The output of the CIC interpolation filter is amplified by a specific gain value. You can determine this value using the `gain` function. This gain equals the gain of the $2N^{\text{th}}$ stage of the CIC interpolation filter and equals $(I \times D)^N / I$, where I is the interpolation factor, D is the differential delay, and N is the number of sections of the CIC interpolator.

```
gainCIC = gain(cicint)  
  
gainCIC = 2
```

To adjust this amplified output and to match it to the amplitude of the original signal, divide the CIC interpolated signal with the computed gain value.

Compare the last frames of the original and the interpolated signals. While plotting, account for the output latency of 2 samples.

```
n = (0:63)';  
stem(n(1:31)/Fs,double(x(1:31)),'r','filled')  
hold on;  
I = cicint.InterpolationFactor;  
stem(n(1:61)/(Fs*I), ...  
     double(y(4:end))/gainCIC,'b')  
xlabel('Time (sec)')  
ylabel('Signal Amplitude')  
legend('Original Signal',...  
       'Interpolated Signal',...  
       'location','north')  
hold off;
```

Using the `info` function in the 'long' format, obtain the word lengths and fraction lengths of the fixed-point filter sections and the filter output.

```
info(cicint, 'long')
```

```

Determine the Section and Output Word Lengths and Fraction Lengths

Using the `getFixedPointInfo` function, you can determine the word lengths and fraction lengths of the fixed-point sections and the output of the `dsp.CICDecimator` and `dsp.CICInterpolator` System objects. The data types of the filter sections and the output depend on the `FixedPointDataType` property of the filter System object™.

Full precision

Create a `dsp.CICDecimator` object. The default value of the `NumSections` property is 2. This value indicates that there are two integrator and comb sections. The WLS and FLs vectors returned by the `getFixedPointInfo` function contain five elements each. The first two elements represent the two integrator sections. The third and fourth elements represent the two comb sections. The last element represents the filter output.

```
cicD = dsp.CICDecimator
cicD =
  dsp.CICDecimator with properties:
    DecimationFactor: 2
    DifferentialDelay: 1
    NumSections: 2
    FixedPointDataType: 'Full precision'
```

By default, the `FixedPointDataType` property of the object is set to 'Full precision'. Calling the `getFixedPointInfo` function on this object with the input numeric type, `nt`, yields the following word length and fraction length vectors.

```
nt = numericType(1,16,15)
nt =
    DataTypeMode: Fixed-point: binary point scaling
    Signedness: Signed
    WordLength: 16
    FractionLength: 15

[WLs,FLs] = getFixedPointInfo(cicD,nt) %#ok
WLs = 1x5
    18    18    18    18    18
FLs = 1x5
    15    15    15    15    15
```

For details on how the word lengths and fraction lengths are computed, see the description for *Output Arguments*.

If you lock the `cicD` object by passing an input to its algorithm, you do not need to pass the `nt` argument to the `getFixedPointInfo` function.

```
input = int64(randn(8,1))
input = 8x1 int64 column vector

     1
     2
    -2
     1
     0
    -1
     0
     0

output = cicD(input)
output =
     0
     1
     3
     0

        DataTypeMode: Fixed-point: binary point scaling
           Signedness: Signed
           WordLength: 66
        FractionLength: 0

[WLs,FLs] = getFixedPointInfo(cicD) %#ok
WLs = 1x5
    66    66    66    66    66

FLs = 1x5
     0     0     0     0     0
```

The output and section word lengths are the sum of input word length, 64 in this case, and the number of sections, 2. The output and section fraction lengths are 0 since the input is a built-in integer.

Minimum section word lengths

Release the object and change the `FixedPointDataType` property to 'Minimum section word lengths'. Determine the section and output fixed-point information when the input is fixed-point data, `fi(randn(8,2),1,24,15)`.

```
release(cicD);
cicD.FixedPointDataType = 'Minimum section word lengths'

cicD =
    dsp.CICDecimator with properties:
```

```

    DecimationFactor: 2
    DifferentialDelay: 1
        NumSections: 2
    FixedPointDataType: 'Minimum section word lengths'
    OutputWordLength: 32

```

```
inputF = fi(randn(8,2),1,24,15)
```

```
inputF =
    3.5784   -0.1241
    2.7694    1.4897
   -1.3499    1.4090
    3.0349    1.4172
    0.7254    0.6715
   -0.0630   -1.2075
    0.7148    0.7172
   -0.2050    1.6302

```

```

    DataTypeMode: Fixed-point: binary point scaling
    Signedness: Signed
    WordLength: 24
    FractionLength: 15

```

```
[WLs, FLs] = getFixedPointInfo(cicD,numericType(inputF)) %#ok
```

```
WLs = 1x5
    26    26    26    26    32

```

```
FLs = 1x5
    15    15    15    15    21

```

Specify word and fraction lengths

Change the `FixedPointDataType` property to 'Specify word and fraction lengths'. Determine the fixed-point information using the `getFixedPointInfo` function.

```
cicD.FixedPointDataType = 'Specify word and fraction lengths'
```

```

cicD =
    dsp.CICDecimator with properties:

        DecimationFactor: 2
        DifferentialDelay: 1
            NumSections: 2
        FixedPointDataType: 'Specify word and fraction lengths'
        SectionWordLengths: [16 16 16 16]
        SectionFractionLengths: 0
        OutputWordLength: 32
        OutputFractionLength: 0

```

```
[WLs, FLs] = getFixedPointInfo(cicD,numericType(inputF)) %#ok
```

```

WLs = 1x5
    16    16    16    16    32

```

```

FLs = 1x5
     0     0     0     0     0

```

The section and output word lengths and fraction lengths are assigned as per the respective fixed-point properties of the `cicD` object. These values are not determined by the input numeric type. To confirm, call the `getFixedPointInfo` function without passing the `numericType` input argument.

```
[WLs, FLs] = getFixedPointInfo(cicD) %#ok
```

```

WLs = 1x5
    16    16    16    16    32

```

```

FLs = 1x5
     0     0     0     0     0

```

Specify word lengths

To specify the word lengths of the filter section and output, set the `FixedPointDataType` property to `'Specify word lengths'`.

```
cicD.FixedPointDataType = 'Specify word lengths'
```

```

cicD =
  dsp.CICDecimator with properties:
    DecimationFactor: 2
    DifferentialDelay: 1
    NumSections: 2
    FixedPointDataType: 'Specify word lengths'
    SectionWordLengths: [16 16 16 16]
    OutputWordLength: 32

```

The `getFixedPointInfo` function requires the input numeric type because that information is used to compute the section and word fraction lengths.

```
[WLs, FLs] = getFixedPointInfo(cicD,numericType(inputF))
```

```

WLs = 1x5
    16    16    16    16    32

```

```

FLs = 1x5
     5     5     5     5    21

```

For more details on how the function computes the word and fraction lengths, see the description for *Output Arguments*.

More About

CIC Filter

CIC filters are an optimized class of linear phase FIR filters composed of a comb part and an integrator part.

The CIC interpolation filter is conceptually given by an upsampler followed by a single rate CIC filter, $H(z)$, which is a lowpass anti-imaging filter. The CIC interpolation filter increases the sample rate of an input signal by an integer factor using a cascaded integrator-comb (CIC) filter.

In a more efficient implementation, the single rate CIC filter $H(z)$ is factorized this way:

$$H(z) = \left[\sum_{k=0}^{RM-1} z^{-k} \right]^N = \frac{(1 - z^{-RM})^N}{(1 - z^{-1})^N} = \frac{(1 - z^{-RM})^N}{1} \cdot \frac{1}{(1 - z^{-1})^N} = H_C^N(z) \cdot H_I^N(z)$$

where,

- H_C is the transfer function of the N sections of the cascaded comb filters, each with a width of RM .
- H_I is the transfer function of the integrator part of the filter containing N stages of integrators.
- N is the number of sections. The number of sections in a CIC filter is defined as the number of sections in either the comb part *or* the integrator part of the filter. This value does not represent the total number of sections throughout the entire filter.
- R is the interpolation factor.
- M is the differential delay.

In the overall multirate realization, the algorithm applies the noble identity for interpolation and moves the rate change factor, R , to follow after the N sections of the cascaded comb filters.

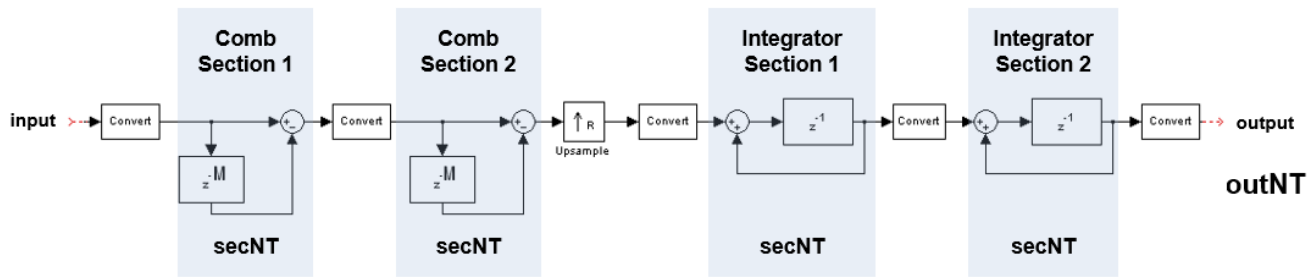

The transfer function of the resulting filter is given by the following equation:

$$H(z) = \frac{(1 - z^{-M})^N}{(1 - z^{-1})^N}$$

For a block diagram that shows the multirate implementation, see Algorithms on page 4-267.

Fixed Point

The fixed-point signal diagram shows the data types that the `dsp.CICInterpolator` object uses for fixed-point signals.

where,

- $secNT = \text{numerictype}(1, secWL, secFL)$
- $outNT = \text{numertictype}(1, outWL, outFL)$
- $secWL$ is the section word length you specify through the “SectionWordLengths” on page 4-0 property.
- $secFL$ is the section fraction length you specify through the “SectionFractionLengths” on page 4-0 property.
- $outWL$ is the output word length you specify through the “OutputWordLength” on page 4-0 property.
- $outFL$ is the output fraction length you specify through the “OutputFractionLength” on page 4-0 property.

The value of NumSections in this diagram is 2.

Algorithms

CIC Interpolation Filter

The CIC interpolation filter in More About on page 4-266 is realized as a cascade of N sections of comb filters followed by a rate change by a factor R , followed by N sections of cascaded integrators.

This diagram shows two sections of cascaded comb filters and two sections of cascaded integrators. The unit delay in the integrator portion of the CIC filter can be located in either the feedforward or the feedback path. These two configurations yield identical filter frequency response. However, the numerical outputs from these two configurations are different due to the latency. This algorithm puts the unit delay in the feedforward path of the integrator since it is a preferred configuration for HDL implementation.

dsp.ColoredNoise

Package: dsp

Generate colored noise signal

Description

The `dsp.ColoredNoise` System object generates a colored noise signal with a power spectral density (PSD) of $1/|f|^\alpha$ over its entire frequency range. The inverse frequency power, α , can be any value in the interval $[-2 \ 2]$. The type of colored noise the object generates depends on the “Color” on page 4-0 you choose. When you set `Color` to 'custom', you can specify the power density of the noise through the “InverseFrequencyPower” on page 4-0 property.

This object uses the default MATLAB random stream, `RandStream`. Reset the default stream for repeatable simulations.

To generate colored noise signal:

- 1 Create the `dsp.ColoredNoise` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
cn = dsp.ColoredNoise
cn = dsp.ColoredNoise(Name=Value)
cn = dsp.ColoredNoise(pow,samp,numChan,Name=Value)
cn = dsp.ColoredNoise(color,samp,numChan,Name=Value)
```

Description

`cn = dsp.ColoredNoise` creates a colored noise object, `cn`, that outputs a noise signal one sample or frame at a time, with a $1/|f|^\alpha$ spectral characteristic over its entire frequency range. Typical values for α are $\alpha = 1$ (pink noise) and $\alpha = 2$ (brownian noise).

`cn = dsp.ColoredNoise(Name=Value)` creates a colored noise object with each specified property set to the specified value. Enclose each property name in single quotes.

Example: `dsp.ColoredNoise(Color='pink');`

`cn = dsp.ColoredNoise(pow,samp,numChan,Name=Value)` creates a colored noise object with the `InverseFrequencyPower` property set to `pow`, the `SamplesPerFrame` property set to `samp`, and the `NumChannels` property set to `numChan`.

Example: `dsp.ColoredNoise(1,44.1e3,1,OutputDataType='single');`

`cn = dsp.ColoredNoise(color,samp,numChan,Name=Value)` creates a colored noise object with the `Color` property set to `color`, the `SamplesPerFrame` property set to `samp`, and the `NumChannels` property set to `numChan`.

Example: `dsp.ColoredNoise('pink',1024,2,OutputDataType='single');`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

Color — Noise color

'custom' (default) | 'pink' | 'white' | 'brown' | 'blue' | 'purple'

Noise color, specified as one of the following. Each color is associated with a specific inverse frequency power of the generated noise sequence.

- 'pink' -- The inverse frequency power α equals 1.
- 'white' -- $\alpha = 0$.
- 'brown' -- $\alpha = 2$. Also known as red or Brownian noise.
- 'blue' -- $\alpha = -1$. Also known as azure noise.
- 'purple' -- $\alpha = -2$. Also known as violet noise.
- 'custom' -- For noise with a custom inverse frequency power, α equals the value of the `InverseFrequencyPower` property.

`InverseFrequencyPower` α can be any value in the interval $[-2, 2]$.

Data Types: `char` | `string`

InverseFrequencyPower — Inverse frequency power

1 (default) | real scalar in $[-2, 2]$

Inverse frequency power α , specified as a real scalar in the interval $[-2, 2]$. The inverse exponent defines the PSD of the random process as $1/|f|^\alpha$. Values of `InverseFrequencyPower` greater than 0 generate lowpass noise with a singularity (pole) at $f = 0$. These processes exhibit long memory. Values of `InverseFrequencyPower` less than 0 generate highpass noise with increments that are negatively correlated. These processes are referred to as anti-persistent. Special cases include:

- 1 -- Pink noise
- 2 -- Brown, red, or Brownian noise
- 0 -- White noise process with a flat PSD
- -1 -- Blue or azure noise
- -2 -- Purple or violet noise

In a log-log plot of power as a function of frequency, processes generated by this object exhibit an approximate linear relationship with slope equal to $-\alpha$.

Dependencies

This property applies only when you set `Color` to `'custom'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

SamplesPerFrameSource — Samples per frame source

`'Property'` (default) | `'Input port'`

Source of the number of samples per frame, specified as `'Property'` or `'Input port'`.

Data Types: `char` | `string`

SamplesPerFrame — Number of samples per output channel

1024 (default) | positive integer

Number of samples per output channel, specified as a positive integer. This property determines the number of rows in the generated signal.

Dependencies

To enable this property, set `SamplesPerFrameSource` to `'Property'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

MaxSamplesPerFrame — Maximum samples per frame

192000 (default) | positive integer

Maximum number of samples per frame, specified as a positive integer.

The value you specify in the `MaxSamplesPerFrame` property acts as an upper limit to the number of samples in each frame that the object generates. If you specify a value greater than `MaxSamplesPerFrame`, the number of samples in each frame that the object generates equals the value in the `MaxSamplesPerFrame` property.

Dependencies

To enable this property, set `SamplesPerFrameSource` to `'Input port'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

NumChannels — Number of output channels

1 (default) | positive integer

Number of output channels, specified as an integer. This property determines the number of columns of the generated signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

RandomStream — Source of random number stream

`'Global stream'` (default) | `'mt19937ar with seed'`

Source of the random number stream, specified as one of the following:

- `'Global stream'` -- The current global random number stream is used for normally distributed random number generation.
- `'mt19937ar with seed'` -- The `mt19937ar` algorithm is used for normally distributed random number generation. The `reset` function reinitializes the random number stream to the value of the `Seed` property.

Data Types: `char` | `string`

Seed — Initial seed

67 (default) | nonnegative integer

Initial seed of mt19937ar random number stream generator algorithm, specified as a nonnegative integer. The `reset` function reinitializes the random number stream to the value of the `Seed` property.

Dependencies

This property applies only when you set the `RandomStream` property to `'mt19937ar with seed'`.

Data Types: `double`

BoundedOutput — Set output bounds to +1 and -1

false (default) | true

Specify the output to be bounded between +1 and -1, specified as:

- `true` -- The internal random source that generates the noise is uniform instead of Gaussian, and a gain is applied so that the absolute maximum output never exceeds 1.

If `Color` is set to `'white'`, there is no color filter applied to the output of the random source. The output is uniform noise of amplitude between +1 and -1. The output distribution of filtered noise (such as pink noise) is quasi-Gaussian.

If `Color` is set to any other option, then a coloring filter is applied to the output of the random source, followed by a gain which ensures that the absolute maximum output never exceeds 1.

- `false` -- The internal random source is Gaussian. The output is not bounded.

Data Types: `logical`

OutputDataType — Output data type

'double' (default) | 'single'

Output data type, specified as either `'double'` or `'single'`.

Data Types: `char` | `string`

Usage**Syntax**

```
noiseOut = cn()  
noiseOut = cn(L)
```

Description

`noiseOut = cn()` outputs one sample or one frame of colored noise data.

`noiseOut = cn(L)` outputs one frame of colored noise data of length `L`, where `L` is a nonnegative integer.

This syntax applies only when you set `SamplesPerFrameSource` to `'Input port'`.

Output Arguments

noiseOut — Colored noise output

vector | matrix

Colored noise output, returned as a vector or a matrix. The `SamplesPerFrame`, `NumChannels`, and the `OutputDataType` properties specify the size and data type of the output.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

`step` Run System object algorithm
`release` Release resources and allow changes to System object property values and input characteristics
`reset` Reset internal states of System object

Examples

Measure Pink Noise Power in Octave Bands

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

The output from this example shows that pink noise has approximately equal power in octave bands.

Generate a single-channel signal of pink noise that is 44,100 samples in length. Set the random number generator to the default settings for reproducible results.

```
pinkNoise = dsp.ColoredNoise(1,44.1e3,1)

pinkNoise =
    dsp.ColoredNoise with properties:
        Color: 'custom'
        InverseFrequencyPower: 1
        SamplesPerFrameSource: 'Property'
        SamplesPerFrame: 44100
        NumChannels: 1
        BoundedOutput: false
        OutputDataType: 'double'
        RandomStream: 'Global stream'

rng default;
x = pinkNoise();
```

Set the sample rate to 44.1 kHz. Measure the power in octave bands beginning with 100-200 Hz and ending with 6.400-12.8 kHz. Display the results in a table.

```

beginfreq = 100;
endfreq = 200;
count = 1;
freqinterval = zeros(7,2);
Pwr = zeros(7,1);
while(endfreq<=44.1e3/2)
    freqinterval(count,:) = [beginfreq endfreq];
    Pwr(count) = bandpower(x,44.1e3,[beginfreq endfreq]);
    beginfreq = endfreq;
    endfreq = 2*endfreq;
    count = count+1;
end
Pwr = Pwr(:);
table(freqinterval,Pwr)

```

```

ans=7x2 table
    freqinterval      Pwr
    _____      _____
    100           200      0.17549
    200           400      0.20313
    400           800      0.2438
    800          1600      0.2503
    1600         3200      0.25233
    3200         6400      0.26828
    6400        12800      0.25211

```

The pink noise has roughly equal power in octave bands.

Rerun the preceding code with 'InverseFrequencyPower' equal to 0, which generates a white noise signal. A white noise signal has a flat power spectral density, or equal power per unit frequency. Set the random number generator to the default settings for reproducible results.

```

whiteNoise = dsp.ColoredNoise(0,44.1e3,1);
rng default;
x = whiteNoise();

```

Set the sample rate to 44.1 kHz. Measure the power in octave bands beginning with 100-200 Hz and ending with 6.400-12.8 kHz. Display the results in a table.

```

beginfreq = 100;
endfreq = 200;
count = 1;
while(endfreq<=44.1e3/2)
    freqinterval(count,:) = [beginfreq endfreq];
    Pwr(count) = bandpower(x,44.1e3,[beginfreq endfreq]);
    beginfreq = endfreq;
    endfreq = 2*endfreq;
    count = count+1;
end
Pwr = Pwr(:);
table(freqinterval,Pwr)

```

```

ans=7x2 table
    freqinterval      Pwr
    _____      _____

```

100	200	0.0031417
200	400	0.0073833
400	800	0.017421
800	1600	0.035926
1600	3200	0.071139
3200	6400	0.15183
6400	12800	0.28611

White noise has approximately equal power per unit frequency, so octave bands have an unequal distribution of power. Because the width of an octave band increases with increasing frequency, the power per octave band increases for white noise.

PSD of Pink Noise Realization

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Generate a pink noise signal 2048 samples in length. The sample rate is 1 Hz. Obtain an estimate of the power spectral density using Welch's overlapped segment averaging.

```
cn = dsp.ColoredNoise('pink',SamplesPerFrame=2048);
x = cn();
Fs = 1;
[Pxx,F] = pwelch(x,hamming(128),[],[],Fs,'psd');
```

Construct the theoretical PSD of the pink noise process.

```
PSDPink = 1./F(2:end);
```

Display the Welch PSD estimate of the noise along with the theoretical PSD on a log-log plot. Plot the frequency axis with a base-2 logarithmic scale to clearly show the octaves. Plot the PSD estimate in dB, $10\log_{10}$.

```
plot(log2(F(2:end)),10*log10(Pxx(2:end)))
hold on
plot(log2(F(2:end)),10*log10(PSDPink),'r',linewidth=2)
xlabel('log_2(Hz)')
ylabel('dB')
title('Pink Noise')
grid on
legend('PSD estimate','Theoretical pink noise PSD')
hold off
```

Two-Channel Brownian Noise

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Generate two channels of Brownian noise by setting `Color` to `'brown'` and `NumChannels` to 2. Specify the number of samples in each frame as an input while running the object algorithm.

```
cn = dsp.ColoredNoise('brown',SamplesPerFrameSource='Input port',...
    NumChannels=2)
```

```
cn =
    dsp.ColoredNoise with properties:
        Color: 'brown'
        SamplesPerFrameSource: 'Input port'
        MaxSamplesPerFrame: 192000
        NumChannels: 2
        BoundedOutput: false
        OutputDataType: 'double'
        RandomStream: 'Global stream'
```

```
x = cn(2048);
subplot(2,1,1)
```

```

plot(x(:,1)); title('Channel 1'); axis tight;
subplot(2,1,2)
plot(x(:,2)); title('Channel 2'); axis tight;

```

The sample rate is 1 Hz. Obtain Welch PSD estimates for both channels. The fourth argument of `pwelch`, `NFFT`, which is the number of FFT points, is empty. Hence, `NFFT` is set to 256. For even `NFFT`, The number of FFT points used to calculate the PSD estimate is $(NFFT/2+1)$, which equals 129.

```

Fs = 1;
Pxx = zeros(129,size(x,2));
for nn = 1:size(x,2)
[Pxx(:,nn),F] = pwelch(x(:,nn),hamming(128),[],[],Fs,'psd');
end

```

Construct the theoretical PSD of a Brownian process. Plot the theoretical PSD along with both realizations on a log-log plot. Use a base-2 logarithmic scale for the frequency axis and plot the power spectral densities in dB.

```

PSDBrownian = 1./F(2:end).^2;
figure;
plot(log2(F(2:end)),10*log10(PSDBrownian),'k-.',linewidth=2);
hold on;
plot(log2(F(2:end)),10*log10(Pxx(2:end,:)));
xlabel('log_2(Hz)'); ylabel('dB');
grid on;
legend('Theoretical PSD','Channel 1', 'Channel 2');

```

Add Pink Noise at 0 dB SNR

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Note: The `audioDeviceWriter` System object™ is not supported in MATLAB Online.

This example shows how to stream in an audio file and add pink noise at a 0 dB signal-to-noise ratio (SNR). The example reads in frames of an audio file 1024 samples in length, measures the root mean square (RMS) value of the audio frame, and adds pink noise with the same RMS value as the audio frame.

Set up the System objects. Set 'SamplesPerFrame' for both the file reader and the colored noise generator to 1024 samples. Set `Color` to 'pink' to generate pink noise with a $1/|f|$ power spectral density.

```
N = 1024;
afr = dsp.AudioFileReader(FileName='speech_dft.mp3',...
    SamplesPerFrame=N);
adw = audioDeviceWriter(SampleRate=afr.SampleRate);
cn = dsp.ColoredNoise('pink',SamplesPerFrame=N);
```

Stream the audio file in 1024 samples at a time. Measure the signal RMS value for each frame, generate a frame of pink noise equal in length, and scale the RMS value of the pink noise to match the signal. Add the scaled noise to the signal and play the output.

```
while ~isDone(afr)
    audio = afr();
    speechRMS = rms(audio);
    noise = cn();
    noiseRMS = rms(noise);
    noise = noise*(speechRMS/noiseRMS);
    sigPlusNoise = audio+noise;
    adw(sigPlusNoise);
end
release(afr);
release(adw);
```

Averaged Power Spectrum of Pink Noise

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Generate two-channels of pink noise and compute the power density spectrum.

Set up the colored noise generator to generate two channels of pink noise with 1024 samples. Set up the spectrum analyzer to compute modified periodograms using a Hamming window and 50% overlap.

```
pinkNoise = dsp.ColoredNoise('pink',1024,2);
sa = spectrumAnalyzer(SpectrumType='power-density',...
    Method='welch',...
    AveragingMethod='exponential',...
    ForgettingFactor=0.95,...
    OverlapPercent=50,Window='hamming',...
    PlotAsTwoSidedSpectrum=false, ...
    FrequencyScale='log',YLimits=[-50 30]);
```

Run the simulation for 30 seconds.

```
tic
while toc < 30
    pink = pinkNoise();
    sa(pink);
end
```

More About

Colored Noise Processes

Many phenomena in diverse fields, such as hydrology and finance, produce time series with PSD functions that follow a power law of the form

$$S(f) = \frac{L(f)}{|f|^\alpha}$$

where α is a real number in the interval $[-2, 2]$ and $L(f)$ is a positive, slowly-varying or constant function. Plotting the PSD of such processes on a log-log plot displays an approximate linear relationship between the log frequency and log PSD with slope equal to $-\alpha$

$$\ln S(f) = -\alpha \ln |f| + \ln L(f).$$

It is often convenient to plot the PSD in dB as a function of the frequency on a base-2 logarithmic scale. The slope of the plot is then dB/octave. Rewriting the preceding equation, you obtain

$$10 \log S(f) = -10\alpha \frac{\ln(2) \log_2(f)}{\ln(10)} + 10 \frac{\ln(L(f))}{\ln(10)}$$

with the slope in dB/octave given by

$$-10\alpha \frac{\ln(2)\log_2(f)}{\ln(10)}$$

If $\alpha > 0$, $S(f)$ goes to infinity as the frequency, f , approaches 0. Stochastic processes with PSDs of this form exhibit long memory. Long-memory processes have autocorrelations that persist for a long time as opposed to decaying exponentially like many common time-series models. If $\alpha < 0$, the process is antipersistent and exhibits negative correlation between increments [1].

Special examples of $\frac{1}{|f|^\alpha}$ processes include:

- $\alpha = 0$ — White noise, where $L(f)$ is a constant proportional to the process variance.
- $\alpha = 1$ — Pink, or flicker noise. Pink noise has equal energy per octave. See “Measure Pink Noise Power in Octave Bands” on page 4-273 for a demonstration. The power spectral density of pink noise decreases 3 dB per octave.
- $\alpha = 2$ — brown noise, or Brownian motion. Brownian motion is a nonstationary process with stationary increments. You can think of Brownian motion as the integral of a white noise process. Even though Brownian motion is nonstationary, you can still define a generalized power spectrum, which behaves like $\frac{1}{|f|^2}$. Accordingly, power in a brown noise decreases 6 dB per octave.
- $\alpha = -1$ — blue noise. The power spectral density of blue noise increases 3 dB per octave.
- $\alpha = -2$ — violet, or purple noise. The power spectral density of violet noise increases 6 dB per octave. You can think of violet noise as the derivative of white noise process.

Algorithms

The figure shows the overall process of generating the colored noise.

The random stream generator produces a stream of white noise that is either Gaussian in distribution. A coloring filter applied to the white noise generates colored noise with a power spectral density (PSD) function given by:

$$S(f) = \frac{L(f)}{|f|^\alpha}$$

When α , the inverse frequency power, equals 0, no coloring filter is applied to the output of the random stream generator. If the bounded option is enabled, the output is uniform white noise with amplitude between +1 and -1. If the bounded output is not enabled, the output is a Gaussian white noise and the values are not bounded between +1 and -1. If α is set to any other value, then a coloring filter is applied to the output of the random stream generator. If the bounded output option is enabled, a gain g is applied to the output of the coloring filter to ensure that the absolute maximum output never exceeds 1.

For details on colored noise processes and how the value of α affects the PSD of the colored noise, see “Colored Noise Processes” on page 4-280.

When the inverse frequency power α is positive, the colored noise is generated using an autoregressive (AR) model of order 63. The AR coefficients are:

$$a_0 = 1,$$
$$a_k = (k - 1 - \frac{\alpha}{2}) \frac{a_{k-1}}{k}, \quad k = 1, 2, \dots, 63$$

Pink and brown noises are special cases, which are generated from specially tuned SOS filters of orders 12 and 10, respectively. These filters are optimized for better performance.

When the inverse frequency power α is negative, the colored noise is generated using a moving average (MA) model of order 255. The MA coefficients are:

$$b_0 = 1,$$
$$b_k = (k - 1 + \frac{\alpha}{2}) \frac{b_{k-1}}{k}, \quad k = 1, 2, \dots, 255$$

Purple noise is generated from a first order filter, $B = [1 \ -1]$.

The coloring filters applied (except pink, brown, and purple) are detailed on pp. 820-822 in [2].

Version History

Introduced in R2014a

Variable-sized output frames in `dsp.ColoredNoise` object

Starting in R2022b, `dsp.ColoredNoise` object can generate colored noise signals of variable-sized output frames.

You can specify the frame size of the output colored noise signal as a nonnegative scalar value that is less than or equal to the `MaxSamplesPerFrame` property.

dsp.ComplexBandpassDecimator

Package: dsp

Extract a frequency subband using a one-sided (complex) bandpass decimator

Description

The `dsp.ComplexBandpassDecimator` System object extracts a specific sub-band of frequencies using a one-sided, multistage, complex bandpass decimator. The object determines the bandwidth of interest using the specified `CenterFrequency`, `DecimationFactor` and `Bandwidth` values.

To extract a frequency subband using a complex bandpass decimator:

- 1 Create the `dsp.ComplexBandpassDecimator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
bpdecim = dsp.ComplexBandpassDecimator
bpdecim = dsp.ComplexBandpassDecimator(d)
bpdecim = dsp.ComplexBandpassDecimator(d,Fc)
bpdecim = dsp.ComplexBandpassDecimator(d,Fc,Fs)
bpdecim = dsp.ComplexBandpassDecimator(Name,Value)
```

Description

`bpdecim = dsp.ComplexBandpassDecimator` creates a System object that filters each channel of the input over time using a one-sided, multistage, complex bandpass decimation filter. The object determines the bandwidth of interest using the default center frequency, decimation factor, and bandwidth values.

`bpdecim = dsp.ComplexBandpassDecimator(d)` creates a complex bandpass decimator object with the `DecimationFactor` property set to `d`.

`bpdecim = dsp.ComplexBandpassDecimator(d,Fc)` creates a complex bandpass decimator object with the `DecimationFactor` property set to `d`, and the `CenterFrequency` property set to `Fc`.

`bpdecim = dsp.ComplexBandpassDecimator(d,Fc,Fs)` creates a complex bandpass decimator object with the `DecimationFactor` property set to `d`, the `CenterFrequency` property set to `Fc`, and the `SampleRate` property set to `Fs`.

Example: `dsp.ComplexBandpassDecimator(48e3/1e3,2e3,48e3);`

`bpdecim = dsp.ComplexBandpassDecimator(Name, Value)` creates a complex bandpass decimator object with each specified property set to the specified value. Enclose each property name in quotes. You can use this syntax with any previous input argument combinations.

Example: `dsp.ComplexBandpassDecimator(48e3/1e3, 2e3, 48e3, 'CenterFrequency', 1e3);`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

CenterFrequency — Center frequency in Hz

0 (default) | real scalar

Center frequency of the desired band in Hz, specified as a real, finite numeric scalar in the range $[-\text{SampleRate}/2, \text{SampleRate}/2]$.

Tunable: Yes

Data Types: `single` | `double`

Specification — Filter design parameters

'Decimation factor' (default) | 'Bandwidth' | 'Decimation factor and bandwidth'

Filter design parameters, specified as:

- 'Decimation factor' -- The object specifies the decimation factor through the `DecimationFactor` property. The bandwidth of interest (BW) is computed using the following equation:

$$BW = Fs/D$$

where

- Fs -- Sample rate specified through `SampleRate` property.
- D -- Decimation factor.
- 'Bandwidth' -- The object specifies the bandwidth through the `Bandwidth` property. The decimation factor (D) is computed using the following equation:

$$D = \text{floor}\left(\frac{Fs}{BW + TW}\right)$$

where

- Fs -- Sample rate specified through `SampleRate` property.
- BW -- Bandwidth of interest.
- TW -- Transition width specified through the `TransitionWidth` property.
- 'Decimation factor and bandwidth' -- The decimation factor and the bandwidth of interest are specified through the `DecimationFactor` and `Bandwidth` properties.

DecimationFactor — Decimation factor

2 (default) | positive integer

Factor by which to reduce the bandwidth of the input signal, specified as a positive integer. The frame size (number of rows) of the input signal must be a multiple of the decimation factor.

Dependencies

This property applies when you set `Specification` to either 'Decimation factor' or 'Decimation factor and bandwidth'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

StopbandAttenuation — Stopband attenuation in dB

80 (default) | positive scalar

Stopband attenuation of the filter in dB, specified as finite positive scalar.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

TransitionWidth — Transition width in Hz

100 (default) | positive scalar

Transition width of the filter in Hz, specified as a positive scalar.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Bandwidth — Bandwidth (Hz)

5000 (default) | real positive scalar

Width of the frequency band of interest, specified as a real positive scalar in Hz.

Dependencies

This property applies when you set `Specification` to either 'Bandwidth' or 'Decimation factor and bandwidth'.

Data Types: single | double

PassbandRipple — Passband ripple (dB)

1 (default) | positive scalar

Passband ripple of the filter, specified as a positive scalar in dB.

Dependencies

This property applies when you set `Specification` to either 'Bandwidth' or 'Decimation factor and bandwidth'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

MinimizeComplexCoefficients — Flag to minimize number of complex coefficients

true (default) | false

Flag to minimize the number of complex filter coefficients, specified as:

- `true` -- The first stage of the multistage filter is bandpass (complex coefficients) centered at the specified center frequency. The first stage is followed by a mixing stage that heterodynes the signal to DC. The remaining filter stages, all with real coefficients, follow.

- `false` -- The input signal is first passed through the different stages of the multistage filter. All stages are bandpass (complex coefficients). The signal is then heterodyned to DC if `MixToBaseband` is `true`, and the frequency offset resulting from the decimation is nonzero.

MixToBaseband — Flag to mix signal to baseband

`true` (default) | `false`

Flag to mix the signal to baseband, specified as:

- `true` -- The object heterodynes the filtered, decimated signal to DC. This mixing stage runs at the output sample rate of the filter.
- `false` -- The object skips the mixing stage.

Dependencies

This property applies when you set `MinimizeComplexCoefficients` to `false`.

SampleRate — Input sample rate in Hz

44100 (default) | real positive scalar

Sampling rate of the input signal in Hz, specified as a real positive scalar.

Data Types: `single` | `double`

Usage

Syntax

`y = bpdecim(x)`

Description

`y = bpdecim(x)` filters the real or complex input signal, `x`, to produce the output, `y`. The output contains the subband of frequencies specified by the System object properties. The System object filters each channel of the input signal independently over time. The frame size (first dimension) of `x` must be a multiple of the decimation factor.

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix. The number of rows in the input must be a multiple of the decimation factor.

Data Types: `single` | `double`

Output Arguments

y — Filtered output

vector | matrix

Output of the complex bandpass decimator, returned as a vector or a matrix. The output contains the subband of frequencies specified by the System object properties. The number of rows (frame size) in

the output signal is $1/D$ times the number of rows in the input signal, where D is the decimation factor. The number of channels (columns) does not change.

The data type of the output is same as the data type of the input. The output signal is always complex.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.ComplexBandpassDecimator`

<code>cost</code>	Implementation cost of the complex bandpass decimator
<code>freqz</code>	Frequency response of the multirate multistage filter
<code>info</code>	Information about filter System object
<code>visualizeFilterStages</code>	Visualize filter stages

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Compute Cost of Complex Bandpass Decimator

Compute the implementation cost of a complex bandpass decimator using the `cost` function.

Create a `dsp.ComplexBandpassDecimator` object. Set the `DecimationFactor` to 12, the `CenterFrequency` to 5000 Hz, and the `SampleRate` to 44,100 Hz.

```
cbp = dsp.ComplexBandpassDecimator(12,5000,44100)
```

```
cbp =  
  dsp.ComplexBandpassDecimator with properties:  
    CenterFrequency: 5000  
    Specification: 'Decimation factor'  
    DecimationFactor: 12  
    StopbandAttenuation: 80  
    TransitionWidth: 100  
    MinimizeComplexCoefficients: true  
    SampleRate: 44100
```

Compute the implementation cost of `cbp` using the `cost` function.

```
c = cost(cbp)
```

```

c = struct with fields:
    NumCoefficients: 201
    NumStates: 379
    RealMultiplicationsPerInputSample: 44.3333
    RealAdditionsPerInputSample: 43.8333

```

Compute Frequency Response of Complex Bandpass Decimator

Compute the complex frequency response of a complex bandpass decimator using the `freqz` function.

Create a `dsp.ComplexBandpassDecimator` object. Set the `DecimationFactor` to 12, the `CenterFrequency` to 5000 Hz, and the `SampleRate` to 44100 Hz. Compute and display the frequency response.

```

cbp = dsp.ComplexBandpassDecimator(12,5000,44100);
[h,f] = freqz(cbp);
plot(f,20*log10(abs(h)))
grid on
xlabel('Frequency (Hz)')
ylabel('h (dB)')

```

Filter Signal Through Complex Bandpass Decimator

Filter an input signal through a complex bandpass decimator and visualize the filtered spectrum in a spectrum analyzer.

Initialization

Create a `dsp.ComplexBandpassDecimator` System object™ with center frequency set to 2000 Hz, bandwidth of interest set to 1000 Hz, and sample rate set to 48 kHz. The decimation factor is computed as the ratio of the sample rate to the bandwidth of interest. The input to the decimator is a sine wave with a frame length of 1200 samples with tones at 1625 Hz, 2000 Hz, and 2125 Hz. Create a `spectrumAnalyzer` scope to visualize the signal spectrum.

```
Fs = 48e3;  
CF = 2000;  
BW = 1000;  
D = Fs/BW;  
FrameLength = 1200;  
bpdecim = dsp.ComplexBandpassDecimator(D,CF,Fs);  
  
sa = spectrumAnalyzer('SampleRate',Fs/D,...  
    'Method','welch',...  
    'YLimits',[-120 40],...  
    'FrequencyOffset',CF);  
  
tones = [1625 2000 2125];  
sin = dsp.SineWave('SampleRate',Fs,'Frequency',tones,...  
    'SamplesPerFrame',FrameLength);
```

Visualize Filter Stages

Using the `visualizeFilterStages` function, you can visualize the response of each individual filter stage using FVTool.

```
visualizeFilterStages(bpdecim)
```

Display Filter info

The `info` function displays information about the bandpass decimator.

```
fprintf('%s',info(bpdecim))
```

```
Overall Decimation Factor      : 48
Bandwidth                      : 1000 Hz
Number of Filters              : 5
Real multiplications per Input Sample: 14.708333
Real additions per Input Sample : 13.833333
Number of Coefficients         : 89
Filters:
  Filter 1:
  dsp.FIRDecimator - Decimation Factor : 2
  Filter 2:
  dsp.FIRDecimator - Decimation Factor : 2
  Filter 3:
  dsp.FIRDecimator - Decimation Factor : 2
  Filter 4:
  dsp.FIRDecimator - Decimation Factor : 3
  Filter 5:
  dsp.FIRDecimator - Decimation Factor : 2
```

Stream In and Filter Signal

Construct a for-loop to run for 1000 iterations. In each iteration, stream in 1200 samples (one frame) of the noisy sine wave and apply the complex bandpass decimator on each frame of the input signal. Visualize the input and output spectrum in the spectrum analyzer, sa.

```
for index = 1:1000
    x = sum(sin(),2) + 1e-4*randn(FrameLength,1);
    z = bpdecim(x);
    sa(z);
end
```

The bandpass decimator with center frequency at 2000 Hz and a bandwidth of 1000 Hz passes the three sine wave tones at 1625 Hz, 2000 Hz, and 2125 Hz.

Change the center frequency of the decimator to 2400 Hz and filter the signal.

```
release(bpdecim);
bpdecim.CenterFrequency = 2400

bpdecim =
    dsp.ComplexBandpassDecimator with properties:

        CenterFrequency: 2400
        Specification: 'Decimation factor'
        DecimationFactor: 48
        StopbandAttenuation: 80
```

```

TransitionWidth: 100
MinimizeComplexCoefficients: true
SampleRate: 48000

```

Configure the spectrum analyzer to show the bandwidth of interest, [-1900, 2900] Hz.

```

release(sa)
sa.FrequencyOffset = 2400;

```

Stream in the data and filter the signal.

```

for index = 1:1000
    x = sum(sin(),2) + 1e-4 * randn(FrameLength,1);
    z = bpdecim(x);
    sa(z);
end

```

The tones at 2000 Hz and 2125 Hz are passed through the decimator, while the tone at 1625 Hz is filtered out.

Algorithms

The complex bandpass decimator is designed by applying a complex frequency shift transformation on a lowpass prototype filter. The lowpass prototype in this case is a multirate, multistage finite impulse response (FIR) filter. The desired frequency shift applies only to the first stage. Subsequent stages scale the desired frequency shift by their respective cumulative decimation factors. For details, see “Complex Bandpass Filter Design” and “Zoom FFT”.

Version History

Introduced in R2018a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

This object also supports SIMD code generation using Intel AVX2 technology under these conditions:

- Input signal is complex-valued.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

dsp.Convolver

Package: dsp

(To be removed) Convolution of two signals

Note `dsp.Convolver` will be removed in a future release. Use `conv` instead. For more information, see “Compatibility Considerations”.

Description

The `dsp.Convolver` System object convolves the first dimension of an N -D input array, u , with the first dimension of an N -D input array, v . You can convolve the inputs in the time domain or frequency domain. In the time domain, the object convolves the first input with the second input. In the frequency domain, the object multiplies the Fourier transforms of both the inputs, and computes the inverse Fourier transform of the product. In this domain, depending on the input length, the object can require fewer computations. For more information on the two computation methods, see “Algorithms” on page 4-302.

To convolve two inputs:

- 1 Create the `dsp.Convolver` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
cnv = dsp.Convolver
cnv = dsp.Convolver(Name, Value)
```

Description

`cnv = dsp.Convolver` creates a convolution System object, `cnv`, to convolve two inputs in the time domain or frequency domain.

`cnv = dsp.Convolver(Name, Value)` creates a convolution System object, `cnv`, with each specified property set to the specified value. Enclose each property name in single quotes.

Example: `cnv = dsp.Convolver('Method', 'Frequency Domain')`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Method — Domain for computing convolutions

'Time Domain' (default) | 'Frequency Domain' | 'Fastest'

Domain in which the System object computes convolutions, specified as one of the following:

- 'Time Domain' -- Computes the convolutions in the time domain, which minimizes memory usage. For more information, see “Time-Domain Computation” on page 4-302.
- 'Frequency Domain' -- Computes the convolutions in the frequency domain, which can require fewer computations depending on the input length. For more information, see “Frequency-Domain Computation” on page 4-303.
- 'Fastest' -- Computes the convolutions in the domain that minimizes the number of computations.

Note Fixed-point signals are supported for the time domain only. To use the following fixed-point properties, set Method to 'Time Domain'.

Fixed-Point Properties

FullPrecisionOverride — Full-precision override for fixed-point arithmetic

true (default) | false

Flag to use full-precision rules for fixed-point arithmetic, specified as one of the following:

- true -- The object computes all internal arithmetic and output data types using the full-precision rules. These rules provide the most accurate fixed-point numerics. In this mode, other fixed-point properties do not apply. No quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- false -- Fixed-point data types are controlled through individual fixed-point property settings.

For more information, see “Full Precision for Fixed-Point System Objects” and “Set System Object Fixed-Point Properties”.

RoundingMethod — Rounding method

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Select the rounding mode for fixed-point operations.

Dependencies

This property applies when you set the FullPrecisionOverride property to false and at least one of the ProductDataType, AccumulatorDataType, and OutputDataType properties to any option other than 'Full precision'.

OverflowAction — Overflow action

'Wrap' (default) | 'Saturate'

The overflow action for fixed-point operations, specified as one of the following:

- 'Wrap' -- The object wraps the result of its fixed-point operations.

- 'Saturate' -- The object saturates the result of its fixed-point operations.

For more details on overflow actions, see overflow mode for fixed-point operations.

Dependencies

This property applies when you set the `FullprecisionOverride` property to `false` and at least one of the `ProductDataType`, `AccumulatorDataType`, and `OutputDataType` properties to any option other than 'Full precision'.

ProductDataType — Product output data type

'Full precision' (default) | 'Custom' | 'Same as first input'

Data type of the output of a product operation in the `dsp.Convolver` object, specified as one of the following:

- 'Full precision' -- The object computes the product output data type using the full-precision rules. These rules provide the most accurate fixed-point numerics. No quantization occurs. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- 'Custom' -- The product output data type is specified as a custom numeric type through the `CustomProductDataType` property. The rounding method and the overflow action are specified through the `RoundingMethod` and `OverflowAction` properties.
- 'Same as first input' -- The object specifies the product output data type to be the same as the first input data type.

For more information on the product output data type, see the “Fixed Point” on page 4-301 section.

CustomProductDataType — Product word and fraction lengths

`numerictype([],32,30)` (default)

The product output data type, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set `ProductDataType` to 'Custom'.

AccumulatorDataType — Accumulator data type

'Full precision' (default) | 'Custom' | 'Same as first input' | 'Same as product'

Data type of the output of an accumulation operation in the `dsp.Convolver` object, specified as one of the following:

- 'Full precision' -- The object computes the accumulator data type using the full precision rules. These rules provide the most accurate fixed-point numerics. No quantization occurs. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- 'Custom' -- The accumulator data type is specified as a custom numeric type through the `CustomAccumulatorDataType` property. The rounding method and the overflow action are specified through the `RoundingMethod` and the `OverflowAction` properties.
- 'Same as first input' -- The object specifies the accumulator data type to be the same as the first input data type.
- 'Same as product' -- The object specifies the accumulator data type to be the same as the product data type.

For more information on the accumulator data type, see the “Fixed Point” on page 4-301 section.

CustomAccumulatorDataType — Accumulator word and fraction lengths

`numericType([],32,30)` (default)

The accumulator data type, specified as an auto signed numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set `AccumulatorDataType` to 'Custom'.

OutputDataType — Output data type

'Same as accumulator' (default) | 'Custom' | 'Same as first input' | 'Same as product'

Data type of the output of the `dsp.Convolver` object, specified as one of the following:

- 'Same as accumulator' -- The object specifies the output data type to be the same as the accumulator data type. For more details on the accumulator data type, see the “AccumulatorDataType” on page 4-0 property.
- 'Custom' -- The output data type is specified as a custom numeric type through the `CustomOutputDataType` property. The rounding method and the overflow action are specified through the `RoundingMethod` and the `OverflowAction` properties.
- 'Same as first input' -- The object specifies the output data type to be the same as the first input data type.
- 'Same as product' -- The object specifies the output data type to be the same as the product data type.

For more information on the output data type, see the “Fixed Point” on page 4-301 section.

CustomOutputDataType — Output word and fraction lengths

`numericType([],16,15)` (default)

The output data type, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Dependencies

This property applies only when you set `OutputDataType` to 'Custom'.

Usage

Syntax

```
cnvOut = cnv(input1, input2)
```

Description

`cnvOut = cnv(input1, input2)` convolves the two inputs, `input1` and `input2`, along their first dimensions, and returns the convolved output, `cnvOut`.

Input Arguments

input1 — First data input

vector | matrix | N -D array

First data input, specified as a vector, matrix, or N -D array. If the input is a matrix or an array, all the dimensions of both the inputs, except for the first dimension, must be the same.

Example: `ones(10,3,2)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

input2 — Second data input

vector | matrix | N -D array

Second data input, specified as a vector, matrix, or N -D array. If the input is a matrix or an array, all the dimensions of both the inputs, except for the first dimension, must be the same.

Example: `randn(4,3,2)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

Output Arguments

cnvOut — Convolved output

vector | matrix | N -D array

The convolved output of the two inputs, returned as a vector, matrix, or N -D array.

- When both inputs are N -D arrays, the size of their first dimension can differ, but the size of all other dimensions must be equal. For example, when u is an M_u -by- N -by- P array, and v is an M_v -by- N -by- P array, the output is an (M_u+M_v-1) -by- N -by- P array.
- When one input is a column vector and the other is an N -D array, the object independently convolves the vector with the first dimension of the N -D input array. For example, when u is an M_u -by-1 column vector and v is an M_v -by- N matrix, the output is an (M_u+M_v-1) -by- N matrix.
- When u and v are column vectors with lengths M_u and M_v , the object performs the vector convolution. The output is an (M_u+M_v-1) -by-1 column vector.

When both the inputs are real, the output is real. When one or both inputs are complex, the output is complex.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics

reset Reset internal states of System object

Examples

Convolve Two Rectangular Sequences

Note If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Create a `dsp.Convolver` object.

```
conv = dsp.Convolver
```

```
conv =
  dsp.Convolver with properties:
    Method: 'Time Domain'
  Show all properties
```

Convolve two rectangular sequences.

```
x = ones(10,1);
y = conv(x,x);
```

Plot the resulting convolved sequence, which is a triangular sequence.

```
plot(y)
```

More About

Convolution

The convolution of two signals is the integral that measures the amount of overlap of one signal as it is shifted over another signal.

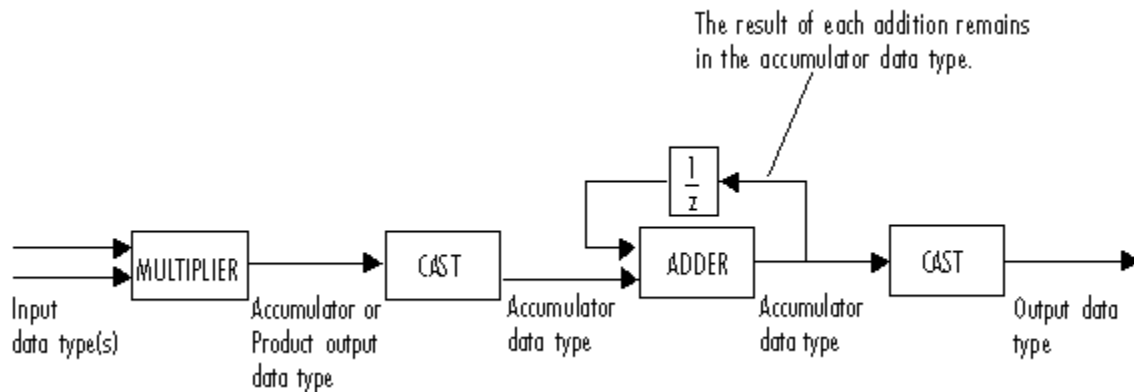

The convolution of two discrete time sequences, $u[n]$ and $v[n]$, is given by the following equation:

$$y(k) = \sum_n u(n-k)v(k)$$

Fixed Point

The following diagram shows the data types used within the `dsp.Convolver` System object for fixed-point signals.

Fixed-point signals are supported for the time domain only.

The output of the multiplier is in the product output data type when the input is real. When the input is complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”.

When one or both of the inputs are signed fixed-point signals, all internal object data types are signed fixed point. The internal data types are unsigned fixed point only when *both* inputs are unsigned fixed-point signals.

Algorithms

Time-Domain Computation

When you set the computation domain to *time*, the algorithm computes the convolution of the two inputs in the time domain.

When the two inputs, u and v , are of size M_u -by- N and M_v -by- N respectively, the j th column of the convolution output is given by the following equation:

$$y_{i,j} = \sum_{k=0}^{\max(M_u, M_v) - 1} u_{k,j} v_{(i-k),j} \quad 0 \leq i \leq (M_u + M_v - 2)$$

Inputs u and v are zero when they are indexed outside their valid ranges.

When u is an M_u -by-1 column and v an M_v -by- N matrix, the output is an $(M_u + M_v - 1)$ -by- N matrix whose j th column is computed using the following equation:

$$y_{i,j} = \sum_{k=0}^{\max(M_u, M_v) - 1} u_k v_{(i-k),j} \quad 0 \leq i \leq (M_u + M_v - 2)$$

When both the inputs are column vectors with lengths M_u and M_v , the object performs the vector convolution given by the following equation:

$$y_i = \sum_{k=0}^{\max(M_u, M_v) - 1} u_k v_{(i-k)} \quad 0 \leq i \leq (M_u + M_v - 2)$$

The output is an $(M_u + M_v - 1)$ -by-1 column vector.

Frequency-Domain Computation

When you set the computation domain to *frequency*, the algorithm computes the convolution in the frequency domain.

In this domain, the algorithm computes the convolution sequence by taking the Fourier transform of both the input signals, multiplying the Fourier transforms, and taking the inverse Fourier transform of the product. In this domain, depending on the input length, the algorithm can require fewer computations.

Version History

Introduced in R2012a

dsp.Convolver System object will be removed

Warns starting in R2021b

dsp.Convolver System object will be removed in a future release. Use the conv function instead.

Update Code

This table shows how the System object is typically used and explains how to update existing code to use the conv function.

Discouraged Usage	Recommended Replacement
<pre>cv = dsp.Convolver; x = ones(10,1); yobj = cv(x,x);</pre> <p>If you are using a release prior to R2016b, replace <code>cv(x)</code> with <code>step(cv,x)</code>.</p>	<pre>yfn = conv(x,x); isequal(yobj,yfn)</pre> <pre>ans = logical 1</pre> <p>Run the code and plot the vectors <i>yobj</i> and <i>yfn</i> using the <code>plot</code> function. Verify that the plots match.</p>

dsp.Counter

Package: dsp

(To be removed) Count up or down through specified range of numbers

Note dsp.Counter will be removed in a future release. Alternatively, you can create a variable in MATLAB® and increment the variable by 1.

Description

The Counter object counts up or down through a specified range of numbers.

To count up or down through a specified range of numbers:

- 1 Create the dsp.Counter object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
count = dsp.Counter  
count = dsp.Counter(Name, Value)
```

Description

count = dsp.Counter returns a counter System object, count, that counts up when the input is nonzero.

count = dsp.Counter(Name, Value) returns a counter System object, count, with each specified property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Direction — Count up or down

Up (default) | Down

Specify the counter direction as Up or Down.

Tunable: Yes

CountEventInputPort — Add input to specify a count event

true (default) | false

Set this property to true to enable a count event input for the internal counter. The internal counter increments or decrements whenever the count event input satisfies the condition you specify in the CountEventCondition property. When you set this property to false, the internal counter is free running, that is, the counter increments or decrements on every call to the object algorithm.

CountEventCondition — Condition that increments, decrements, or resets internal counter

Non-zero (default) | Rising edge | Falling edge | Either edge

Specify the event at the count event input that increments or decrements the counter as Rising edge, Falling edge, Either edge or Non-zero.

If you set the ResetInputPort and CountEventInputPort properties to true, the counter is reset when the event you specify for the CountEventCondition occurs.

Dependencies

This property applies only when you set the CountEventInputPort property to true.

CounterSizeSource — Source of counter size data type

Property (default) | Input port

Specify the source of the counter size data type as Property or Input port.

CounterSize — Range of integer values to count through

Maximum (default) | 8 bits | 16 bits | 32 bits

Specify the range of integer values to count through before recycling to zero as 8 bits, 16 bits, 32 bits or Maximum.

MaximumCount — Counter's maximum value

255 (default) | 0 | positive integer

Specify the counter's maximum value as a numeric scalar value.

Tunable: Yes

Dependencies

This property applies only when you set the CounterSizeSource property to Property and the CounterSize property to Maximum.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

InitialCount — Counter initial value

0 (default) | 0 | positive integer

Specify the initial value for the counter.

Tunable: Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

CountOutputPort — Output count

true (default) | false

Set this property to `true` to enable output of the internal count. The default is `true`. You cannot set both `CountOutputPort` and `HitOutputPort` to `false` at the same time.

HitOutputPort — Output hit events

true (default) | false

Set this property to `true` to enable output of the hit events. You cannot set both `CountOutputPort` and `HitOutputPort` to `false` at the same time.

HitValues — Values whose occurrence in count produce a true hit output

32 (default) | scalar integer | vector of integers

Specify an integer scalar or a vector of integers, whose occurrences in the count you want flagged as a hit.

Dependencies

This property applies only when you set the `HitOutputPort` property to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

ResetInputPort — Add input to enable internal counter reset

true (default) | false

When you set this property to `true`, specify a reset input to the object algorithm. When the reset input receives the event you specify for the `CountEventCondition` property, the counter resets. If you set the `CountEventInputPort` property to `false`, the counter resets whenever the reset input is not zero.

SamplesPerFrame — Number of samples in each output frame

1 (default) | positive integer

Specify the number of samples in each output frame.

Dependencies

This property applies only when you set the `CountEventInputPort` property to `false`, indicating a free-running counter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

CountOutputDataType — Data type of count outputdouble (default) | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32`

Specify the data type of the count output, `cnt`, as `double`, `single`, `int8`, `uint8`, `int16`, `uint16`, `int32` or `uint32`.

Dependencies

This property applies when you set the `CountOutputPort` property to `true`.

Usage

Syntax

```
[cnt, hit] = count(event, reset)
cnt = count(event, reset)
hit = count(event, reset)
[ ___ ] = count()
[ ___ ] = count(event)
```

Description

`[cnt, hit] = count(event, reset)` increments, decrements, or resets the internal counter as specified by the values of the `event` and `reset` inputs. The output argument `cnt` denotes the present value of the counter. A trigger event at the `event` input causes the counter to increment or decrement. A trigger event at the `reset` input resets the counter to its initial state.

`cnt = count(event, reset)` returns the current value of the count when you set the `CountOutputPort` property to `true` and the `HitOutputPort` property to `false`.

`hit = count(event, reset)` returns a Boolean value indicating whether the count has reached any of the values specified by the `HitValues` property. This condition applies when you set the `HitOutputPort` property to `true` and the `CountOutputPort` property to `false`.

`[___] = count()` increments or decrements the free-running internal counter when you set the `CountEventInputPort` property to `false` and the `ResetInputPort` property to `false`.

`[___] = count(event)` increments or decrements the internal counter when the `event` input matches the event you specify for the `CountEventCondition` property and you set the `ResetInputPort` property to `false`.

Input Arguments

event — Event that causes counter to increment or decrement

scalar

Event that causes the counter to increment or decrement, specified as a scalar. The `CountEventCondition` property specifies the event under which the counter value changes.

Dependencies

This input is valid only when `CountEventInputPort` is set to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

reset — Reset of internal counter

scalar

A trigger event at the reset input resets the counter to the initial state.

Dependencies

This input is valid only when `ResetInputPort` is set to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

Output Arguments

cnt — Present value of counter

scalar | column vector

Current value of the count, returned as a scalar. The data type of this output is set by the `CountOutputDataType` property. If `CountEventInputPort` is `false`, the number of elements in this output vector is determined by the value you specify in the `SamplesPerFrame` property.

Dependencies

This output is enabled only when you set the `CountOutputPort` property to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

hit — Indicates if counter matches hit values

scalar | column vector

Boolean value indicating whether the count has reached any of the values specified by the `HitValues` property. If `CountEventInputPort` is `false`, the number of elements in this output vector is determined by the value you specify in the `SamplesPerFrame` property.

Dependencies

This output is enabled when you set the `HitOutputPort` property to `true`.

Data Types: `logical`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Count the Rising Edges

Note: If you are using R2016a or earlier, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Use `dsp.Counter` System object to count at every rising edge of the input signal.

```
count = dsp.Counter('MaximumCount', 5, ...
    'CountOutputPort', true, ...
    'HitOutputPort', false, ...
    'ResetInputPort', false);
```

```
sgnl = [0 1 0 1 0 1 0 1 0 1 0 1];  
cnt = zeros(1,12);  
for ii = 1:length(sgnl)  
    cnt(ii) = count(sgnl(ii));  
end  
disp(cnt);
```

```
    0     1     1     2     2     3     3     4     4     5     5     0
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Counter block reference page. The object properties correspond to the block parameters.

- The CountEventCondition object property does not have a free-running option. Set the CountEventInputPort property to `false` to obtain the free-running option.
- The CounterSizeSource and CounterSize object properties correspond to the **Counter size** block parameter.
- The CountOutputPort and HitOutputPort correspond to the **Output** block parameter.
- There is no object property that corresponds to the **Hit data type** block parameter. The output type is logical in MATLAB. (This logical is different from the popup logical in the block. For the object, logical corresponds to Boolean in the block.)

dsp.CoupledAllpassFilter

Package: dsp

Coupled allpass IIR filter

Description

The `dsp.CoupledAllpassFilter` object implements a coupled allpass filter structure composed of two allpass filters connected in parallel. Each allpass branch can contain multiple sections. The overall filter output is computed by adding the output of the two respective branches. An optional second output can also be returned, which is power complementary to the first. For example, from the frequency domain perspective, if the first output implements a lowpass filter, the second output implements the power complementary highpass filter. For real signals, the power complementary output is computed by subtracting the output of the second branch from the first.

`dsp.CoupledAllpassFilter` supports double- and single-precision floating point and allows you to choose between different realization structures. This System object also supports complex coefficients, multichannel variable length input, and tunable filter coefficient values.

To filter each channel of the input:

- 1 Create the `dsp.CoupledAllpassFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
caf = dsp.CoupledAllpassFilter
caf = dsp.CoupledAllpassFilter(AllpassCoeffs1,AllpassCoeffs2)
caf = dsp.CoupledAllpassFilter(struc,AllpassCoeffs1,AllpassCoeffs2)
caf = dsp.CoupledAllpassFilter(Name,Value)
```

Description

`caf = dsp.CoupledAllpassFilter` returns a coupled allpass filter System object, `caf`, that filters each channel of the input signal independently. The coupled allpass filter uses the default inner structures and coefficients.

`caf = dsp.CoupledAllpassFilter(AllpassCoeffs1,AllpassCoeffs2)` returns a coupled allpass filter System object, `caf`, with `Structure` set to 'Minimum multiplier', `AllpassCoefficients1` set to `AllpassCoeffs1`, and `AllpassCoefficients2` set to `AllpassCoeffs2`.

`caf = dsp.CoupledAllpassFilter(struc,AllpassCoeffs1,AllpassCoeffs2)` returns a coupled allpass filter System object, `caf`, with `Structure` set to `struc` and the relevant coefficients set to `AllpassCoeffs1` and `AllpassCoeffs2`. `struc` can be 'Minimum multiplier' | 'Wave Digital Filter' | 'Lattice'.

`caf = dsp.CoupledAllpassFilter(Name,Value)` returns a Coupled allpass filter System object, `caf`, with each property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

Structure — Internal structure of allpass branches

'Minimum multiplier' (default) | 'Wave Digital Filter' | 'Lattice'

Specify the internal structure of allpass branches as one of 'Minimum multiplier', 'Wave Digital Filter', or 'Lattice'. Each structure uses a different pair of coefficient values, independently stored in the relevant object property.

AllpassCoefficients1 — Allpass polynomial coefficients of branch 1

[0 0.5] (default) | row vector | cell array

Specify the polynomial filter coefficients for the first allpass branch. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections.

Tunable: Yes

Dependencies

This property is applicable only if you set the Structure property to 'Minimum multiplier'.

Data Types: `single` | `double`

WDFCoefficients1 — Wave Digital Filter coefficients of branch 1

[0.5 0] (default) | row vector | cell array

Specify the Wave Digital Filter coefficients for the first allpass branch. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections.

Tunable: Yes

Dependencies

This property is applicable only if you set the Structure property to 'Wave Digital Filter'.

Data Types: `single` | `double`

LatticeCoefficients1 — Lattice coefficients of branch 1

[0.5 0] (default) | row vector | cell array

Specify the allpass lattice coefficients for the first allpass branch. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections.

Tunable: Yes

Dependencies

This property is applicable only if you set the Structure property to 'Lattice'.

Data Types: single | double

Delay — Length in samples for branch 1

0 (default) | positive integer scalar

Integer number of the delay taps in the top branch, specified as a positive integer scalar.

Tunable: Yes

Dependencies

This property is applicable only if you set the PureDelayBranch property to true.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Gain1 — Independent Branch 1 Phase Gain

1 (default) | '-1' | '0+i' | '0-i'

Gain1 is the individual branch phase gain. This property can accept only values equal to '1', '-1', '0+i', or '0-i'. This property is nontunable.

Data Types: char

AllpassCoefficients2 — Allpass polynomial coefficients of branch 2

{[]} (default) | row vector | cell array

Specify the polynomial filter coefficients for the second allpass branch. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections.

Tunable: Yes

Dependencies

This property is applicable only if you set the Structure property to 'Minimum multiplier'.

Data Types: single | double

WDFCoefficients2 — Wave Digital Filter coefficients of branch 2

{[]} (default) | row vector | cell array

Specify the Wave Digital Filter coefficients for the second allpass branch. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections.

Tunable: Yes

Dependencies

This property is applicable only if you set the Structure property to 'Wave Digital Filter'.

Data Types: single | double

LatticeCoefficients2 — Lattice coefficients of branch 2`{ [] }` (default) | row vector | cell array

Specify the allpass lattice coefficients for the second allpass branch. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections.

Tunable: Yes**Dependencies**

This property is applicable only if you set the `Structure` property to `'Lattice'`.

Data Types: `single` | `double`**Gain2 — Independent Branch 2 Phase Gain**`'1'` (default) | `'-1'` | `'0+1i'` | `'0-1i'`

Specify the value of the independent phase gain applied to branch 2. This property can accept only values equal to `'1'`, `'-1'`, `'0+i'`, or `'0-i'`. This property is nontunable.

Data Types: `char`**Beta — Coupled phase gain**`1` (default) | complex value with magnitude equal to 1

Specify the value of the phasor gain in complex conjugate form, in each of the two branches, and in complex coefficient configuration. The absolute value of this property should be 1 and its default value is 1.

Tunable: Yes**Dependencies**

This property is applicable only when the selected `Structure` property supports complex coefficients.

Data Types: `single` | `double`**PureDelayBranch — Replace allpass filter in first branch with pure delay**`false` (default) | `true`

If you set `PureDelayBranch` to `true`, the property holding the coefficients for the first allpass branch is disabled and `Delay` becomes enabled. You can use this property to improve performance, when one of the two allpass branches is known to be a pure delay (e.g. for halfband filter designs)

Data Types: `logical`**ComplexConjugateCoefficients — Allow inferring coefficients of second allpass branch as complex conjugate of first**`false` (default) | `true`

When the input signal is real, this property triggers the use of an optimized structural realization. This property enables providing complex coefficients for only the first branch. The coefficients for the second branch are automatically inferred as complex conjugate values of the first branch coefficients

Dependencies

This property is only enabled if the currently selected structure supports complex coefficients. Use it only if the filter coefficients are actually complex.

Data Types: `logical`

Usage

Syntax

```
y = caf(x)
[y, ypc] = caf(x)
```

Description

`y = caf(x)` filters the input signal `x` to produce the output `y`. When `x` is a matrix, each column is filtered independently as a separate channel over time.

`[y, ypc] = caf(x)` also returns `ypc`, the power complementary signal to the primary output `y`.

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix. This object also accepts variable-size inputs. Once the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

Data Types: `single` | `double`

Output Arguments

y — Lowpass filtered output

vector | matrix

Lowpass filtered output, returned as a vector or a matrix. The size and data type of the output signal matches that of the input signal.

Data Types: `double` | `single`

ypc — Highpass filtered output

vector | matrix

Power complimentary highpass filtered output, returned as a vector or a matrix. The size and data type of the output signal matches that of the input signal.

Data Types: `double` | `single`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.CoupledAllpassFilter

fvtool	Visualize frequency response of coupled allpass filter
getBranches	Return internal allpass branches
freqz	Frequency response of discrete-time filter System object
impz	Impulse response of discrete-time filter System object
info	Information about filter System object
coeffs	Returns the filter System object coefficients in a structure
cost	Estimate cost of implementing filter System object
grpdelay	Group delay response of discrete-time filter System object

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Allpass Realization of a Butterworth Lowpass Filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent step syntax. For example, myObject(x) becomes step(myObject,x).

Realize a Butterworth lowpass filter of order 3. Use a coupled allpass structure with inner minimum multiplier structure.

```

Fs = 48000;    % in Hz
Fc = 12000;   % in Hz
frameLength = 1024;
[b, a] = butter(3,2*Fc/Fs);
AExp = [freqz(b,a,frameLength/2); NaN];
[c1, c2] = tf2ca(b,a);
caf = dsp.CoupledAllpassFilter(c1(2:end),c2(2:end));
tfe = dsp.TransferFunctionEstimator('FrequencyRange', 'onesided',...
    'SpectralAverages', 2);
aplot = dsp.ArrayPlot('PlotType', 'Line',...
    'YLimits', [-40 5],...
    'YLabel', 'Magnitude (dB)',...
    'SampleIncrement', Fs/frameLength,...
    'XLabel', 'Frequency (Hz)',...
    'Title', 'Magnitude Response',...
    'ShowLegend', true,'ChannelNames',{'Actual','Expected'});
Niter = 200;
for k = 1:Niter
    in = randn(frameLength,1);
    out = caf(in);
    A = tfe(in,out);
    aplot(db([A,AExp]));
end

```

Allpass Realization of an Elliptic Highpass Filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Remove a low-frequency sinusoid using an elliptic highpass filter design implemented through a coupled allpass structure.

Initialize

```
Fs = 1000;
f1 = 50; f2 = 100;
Fpass = 70; Apass = 1;
Fstop = 60; Astop = 80;
filtSpecs = fdesign.highpass(Fstop,Fpass,Astop,Apass,Fs);
hpSpec = design(filtSpecs,'ellip','FilterStructure','cascadeallpass',...
    'SystemObject',true);
frameLength = 1000;
nFrames = 100;
sine = dsp.SineWave('Frequency',[f1,f2],'SampleRate',Fs,...
    'SamplesPerFrame',frameLength); % Input composed of two sinusoids.

sa = spectrumAnalyzer('SampleRate',Fs,...
    'PlotAsTwoSidedSpectrum',false,'ShowLegend',true,...
    'Method','welch','AveragingMethod','exponential',...
    'AveragingTime',100);
```

```
'Title','Original (Channel 1) Filtered (Channel 2)',...
'ChannelNames',{'Original','Filtered'});
```

Simulate

```
for k = 1:1000
    original = sum(sine(),2); % Add the two sinusoids together
    filtered = hpSpec(original);
    sa([original,filtered]);
end
release(sa)
```

View Power Complementary Output of Coupled Allpass Filter

Design a Butterworth lowpass filter of order 3. Use a coupled allpass structure with inner minimum multiplier structure.

```
Fs = 48000; % in Hz
Fc = 12000; % in Hz
frameLength = 1024;
[b,a] = butter(3,2*Fc/Fs);
AExp = [freqz(b,a,frameLength/2); NaN];
[c1,c2] = tf2ca(b,a);
caf = dsp.CoupledAllpassFilter(c1(2:end),c2(2:end));
```

Using the 'SubbandView' option of the `dsp.CoupledAllpassFilter`, you can visualize the lowpass filter output, the power complementary highpass filter output, or both using the `fvtool`.

To view the lowpass filter output, set 'SubbandView' to 1.

```
fvtool(caf, 'SubbandView', 1, 'Fs', Fs)
```

To view the highpass filter output, set 'SubbandView' to 2.

```
fvtool(caf, 'SubbandView', 2, 'Fs', Fs)
```

To view both the outputs, set 'SubbandView' to 'all', [1 2] or [1;2].

```
fvtool(caf, 'SubbandView', 'all', 'Fs', Fs);
```

Algorithms

The following three figures summarize the main structures supported by `dsp.CoupledAllpassFilter`.

- Minimum Multiplier and WDF

- Lattice

- Lattice with Complex Conjugate Coefficients

Estimate cross-spectral density

Description

The `dsp.CrossSpectrumEstimator` System object computes the cross-spectrum density of a signal, using the Welch's averaged periodogram method.

To implement the cross-spectrum estimation object:

- 1 Create the `dsp.CrossSpectrumEstimator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
cse = dsp.CrossSpectrumEstimator  
cse = dsp.CrossSpectrumEstimator(Name, Value)
```

Description

`cse = dsp.CrossSpectrumEstimator` returns a System object, `cse`, that computes the cross-power spectrum of real or complex signals using the periodogram method and Welch's averaged, modified periodogram method.

`cse = dsp.CrossSpectrumEstimator(Name, Value)` returns a `dsp.CrossSpectrumEstimator` System object, `cse`, with each specified property name set to the specified value. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

FFTLengthSource — Source of FFT length value

'Auto' (default) | 'Property'

Specify the source of the FFT length value as either 'Auto' or 'Property'. If you set this property to 'Auto', the cross-spectrum estimator sets the FFT length to the input frame size. If you set this property to 'Property', then specify the number of FFT points using the FFTLength property.

FFTLength — FFT Length

128 (default) | positive integer

Specify the length of the FFT that the cross-spectrum estimator uses to compute cross-spectral estimates as a positive, integer scalar.

Dependencies

This property applies when you set the FFTLengthSource property to 'Property'.

Data Types: double

Window — Window function

'Hann' (default) | 'Rectangular' | 'Chebyshev' | 'Flat Top' | 'Hamming' | 'Kaiser'

Specify a window function for the cross-spectrum estimator as one of 'Rectangular', 'Chebyshev', 'Flat Top', 'Hamming', 'Hann', or 'Kaiser'.

SidelobeAttenuation — Side lobe attenuation of window

60 (default) | positive scalar

Specify the side lobe attenuation of the window as a real, positive scalar, in decibels (dB).

Dependencies

This property applies when you set the Window property to 'Chebyshev' or 'Kaiser'.

Data Types: double

FrequencyRange — Frequency range of the cross-spectrum estimate

'Twosided' (default) | 'onesided' | 'centered'

Specify the frequency range of the cross-spectrum estimator as one of 'twosided', 'onesided', or 'centered'.

If you set the FrequencyRange to 'onesided', the cross-spectrum estimator computes the one-sided spectrum of real input signals, x and y . If the FFT length, N_{FFT} , is even, the length of the cross-spectral estimate is $N_{FFT}/2+1$ and is computed over the interval $[0, SampleRate/2]$. If N_{FFT} is odd, the length of the cross-spectrum estimate is equal to $(N_{FFT}+1)/2$, and the interval is $[0, SampleRate/2]$.

If you set the FrequencyRange to 'twosided', the cross-spectrum estimator computes the two-sided spectrum of complex or real input signals, x and y . The length of the cross-spectrum estimate is equal to N_{FFT} . This value is computed over $[0, SampleRate]$.

If you set the FrequencyRange to 'centered', the cross-spectrum estimator computes the centered two-sided spectrum of complex or real input signals, x and y . The length of the cross-spectrum estimate is equal to N_{FFT} , and the estimate is computed between $[-SampleRate/2, SampleRate/2]$ and $(-SampleRate/2, SampleRate/2)$ for even and odd lengths, respectively.

AveragingMethod — Averaging method

'Running' (default) | 'Exponential'

Specify the averaging method as 'Running' or 'Exponential'. In the running averaging method, the object computes an equally weighted average of a specified number of spectrum estimates defined by the `SpectralAverages` property. In the exponential method, the object computes the average over samples weighted by an exponentially decaying forgetting factor.

SpectralAverages — Number of spectral averages

8 (default) | positive integer

Specify the number of spectral averages as a positive, integer scalar. The object computes the current cross-spectral estimate by averaging the last N estimates. N is the number of spectral averages defined in the `SpectralAverages` property.

Dependencies

This property applies when you set `AveragingMethod` to 'Running'.

Data Types: double

ForgettingFactor — Forgetting factor

0.9 (default) | scalar in the range (0,1]

Specify the exponential weighting forgetting factor as a scalar value greater than zero and smaller than or equal to one.

Tunable: Yes

Dependencies

This property applies when you set `AveragingMethod` to 'Exponential'.

Data Types: single | double

SampleRate — Sample rate of input

1 (default) | positive scalar

Specify the sample rate of the input, in hertz, as a finite numeric scalar. The sample rate is the rate at which the signal is sampled in time.

Data Types: single | double

Usage**Syntax**

`pxy = cse(x,y)`

Description

`pxy = cse(x,y)` computes the cross power spectrum density, `pxy`, of the input signals, `x` and `y`.

Input Arguments**x — First data input**

vector | matrix

First data input, specified as a vector or a matrix. The inputs, `x` and `y` must have the same size and data type.

Data Types: `single` | `double`

y — Second data input

vector | matrix

Second data input, specified as a vector or a matrix. The inputs, `x` and `y` must have the same size and data type.

Data Types: `single` | `double`

Output Arguments

pxy — Cross-power spectrum density output

vector | matrix

Cross-power spectrum density output, returned as a vector or a matrix. The output has the same size and data type as the input signals.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.CrossSpectrumEstimator

`getFrequencyVector` Vector of frequencies at which estimation is done

`getRBW` Resolution bandwidth of spectrum

Common to All System Objects

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

Examples

Compute Cross-Power Spectrum of Two Noisy Sine Waves

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Generate two sine waves.

```
sin1 = dsp.SineWave('Frequency',200, 'SampleRate', 1000);
sin1.SamplesPerFrame = 1000;
sin2 = dsp.SineWave('Frequency',100, 'SampleRate', 1000);
sin2.SamplesPerFrame = 1000;
```

Use the `dsp.CrossSpectrumEstimator` System object™ to compute the cross-spectrum of the signals. Also, use the `dsp.ArrayPlot` object to display the spectra.

```

cse = dsp.CrossSpectrumEstimator('SampleRate', sin1.SampleRate,...
    'FrequencyRange','centered');
aplot = dsp.ArrayPlot('PlotType','Line','XOffset',-500,'YLimits',...
    [-150 -60],'YLabel','Power Spectrum Density (Watts/Hz)',...
    'XLabel','Frequency (Hz)',...
    'Title','Cross Power Spectrum of Two Signals');

```

Add random noise to the sine waves. Stream in the data, and plot the cross-power spectrum of the two signals.

```

for ii = 1:10
x = sin1() + 0.05*randn(1000,1);
y = sin2() + 0.05*randn(1000,1);
Pxy = cse(x, y);
aplot(20*log10(abs(Pxy)));
end

```

Algorithms

Welch's Method of Averaged Modified Periodograms

Give two signal inputs, x and y :

- 1 Multiply the inputs by the window and scale the result by the window power.
- 2 Compute FFT of the signals, X and Y , and multiply X with $\text{conj}(Y)$ using $Z = X.\text{*conj}(Y)$.

- 3 Compute the current cross power spectrum estimate by taking the moving average of the last N number of Z 's and scaling the answer by the sample rate.

For further information on the algorithms, refer to the “Averaging Method” on page 2-1215 section in Spectrum Analyzer.

dsp.Crosscorrelator

Package: dsp

(To be removed) Cross-correlation of two inputs

Note `dsp.Crosscorrelator` will be removed in a future release. Use `xcorr` instead. For more information, see “Compatibility Considerations”.

Description

The `dsp.Crosscorrelator` System object computes the cross-correlation of two N -D input arrays along the first dimension. The computation can be done in the time domain or frequency domain. You can specify the domain through the “Method” on page 4-0 property. In the time domain, the object convolves the first input signal, u , with the time-reversed complex conjugate of the second input signal, v . To compute the cross-correlation in the frequency domain, the object:

- 1 Takes the Fourier transform of both input signals, resulting in U and V .
- 2 Multiplies U and V^* , where $*$ denotes the complex conjugate.
- 3 Computes the inverse Fourier transform of the product.

If you set `Method` to 'Fastest', the object chooses the domain that minimizes the number of computations. For information on these computation methods, see “Algorithms” on page 4-337.

To obtain the cross-correlation for two discrete-time deterministic inputs:

- 1 Create the `dsp.Crosscorrelator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
xcorr = dsp.Crosscorrelator
xcorr = dsp.Crosscorrelator(Name, Value)
```

Description

`xcorr = dsp.Crosscorrelator` returns a cross-correlator object, `xcorr`, that computes the cross-correlation of two inputs in the time domain or frequency domain.

`xcorr = dsp.Crosscorrelator(Name, Value)` returns a cross-correlator object with each specified property set to the specified value. Enclose each property name in single quotes.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Method — Domain for computing correlations

'Time Domain' (default) | 'Frequency Domain' | 'Fastest'

Domain in which the System object computes the correlation, specified as one of the following:

- 'Time Domain' -- Computes the cross-correlation in the time domain, which minimizes the memory usage.
- 'Frequency Domain' -- Computes the cross-correlation in the frequency domain. For more information, see “Algorithms” on page 4-337.
- 'Fastest' -- Computes the cross-correlation in the domain that minimizes the number of computations.

To cross-correlate fixed-point signals, set this property to 'Time Domain'.

Fixed-Point Properties

Note Fixed-point signals are supported for the time domain only. To use these properties, set Method to 'Time Domain'.

FullPrecisionOverride — Full-precision override for fixed-point arithmetic

true (default) | false

Flag to use full-precision rules for fixed-point arithmetic, specified as one of the following:

- true -- The object computes all internal arithmetic and output data types using the full-precision rules. These rules provide the most accurate fixed-point numerics. In this mode, other fixed-point properties do not apply. No quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- false -- Fixed-point data types are controlled through individual fixed-point property settings.

For more information, see “Full Precision for Fixed-Point System Objects” and “Set System Object Fixed-Point Properties”.

RoundingMethod — Rounding method for fixed-point operations

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Rounding method for fixed-point operations. For more details, see rounding mode.

Dependencies

This property is not visible and has no effect on the numerical results when the following conditions are met:

- FullPrecisionOverride set to true.
- FullPrecisionOverride set to false, OutputDataType set to 'Same as accumulator', ProductDataType set to 'Full precision', and AccumulatorDataType set to 'Full precision'

Under these conditions, the object operates in full precision mode.

In addition, if Method is set to either 'Frequency Domain' or 'Fastest', the RoundingMethod property does not apply.

OverflowAction — Overflow action for fixed-point operations

'Wrap' (default) | 'Saturate'

Overflow action for fixed-point operations, specified as one of the following:

- 'Wrap' -- The object wraps the result of its fixed-point operations.
- 'Saturate' -- The object saturates the result of its fixed-point operations.

For more details on overflow actions, see overflow mode for fixed-point operations.

Dependencies

This property is not visible and has no effect on the numerical results when the following conditions are met:

- FullPrecisionOverride set to true.
- FullPrecisionOverride set to false, OutputDataType set to 'Same as accumulator', ProductDataType set to 'Full precision', and AccumulatorDataType set to 'Full precision'

Under these conditions, the object operates in full precision mode.

In addition, if Method is set to either 'Frequency Domain' or 'Fastest', the OverflowAction property does not apply.

ProductDataType — Data type of product output

'Full precision' (default) | 'Custom' | 'Same as first input'

Data type of the product output in this object, specified as one of the following:

- 'Full precision' -- The product output data type has full precision.
- 'Same as first input' -- The object specifies the product output data type to be the same as that of the first input data type.
- 'Custom' -- The product output data type is specified as a custom numeric type through the "CustomProductDataType" on page 4-0 property.

For more information on the product output data type, see "Multiplication Data Types" and the "Fixed Point" on page 4-336 section.

Dependencies

This property applies when you set FullPrecisionOverride to false.

CustomProductDataType — Word and fraction lengths of product data type

numericity([],32,30) (default)

Word and fraction lengths of the product data type, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set `FullPrecisionOverride` to `false` and “`ProductDataType`” on page 4-0 to `'Custom'`.

AccumulatorDataType — Data type of accumulation operation

`'Full precision'` (default) | `'Same as first input'` | `'Same as product'` | `'Custom'`

Data type of an accumulation operation in this object, specified as one of the following:

- `'Full precision'` -- The accumulation operation has full precision.
- `'Same as product'` -- The object specifies the accumulator data type to be the same as that of the product output data type.
- `'Same as first input'` -- The object specifies the accumulator data type to be the same as that of the first input data type.
- `'Custom'` -- The accumulator data type is specified as a custom numeric type through the “`CustomAccumulatorDataType`” on page 4-0 property.

For more information on the accumulator data type this object uses, see the “Fixed Point” on page 4-336 section.

Dependencies

This property applies when you set `FullPrecisionOverride` to `false`.

CustomAccumulatorDataType — Word and fraction lengths of accumulator data type

`numericType([],32,30)` (default)

Word and fraction lengths of the accumulator data type, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set `FullPrecisionOverride` to `false` and “`AccumulatorDataType`” on page 4-0 to `'Custom'`.

OutputDataType — Data type of object output

`'Same as accumulator'` (default) | `'Same as first input'` | `'Same as product'` | `'Custom'`

Data type of the object output, specified as one of the following:

- `'Same as accumulator'` -- The output data type is the same as that of the accumulator output data type.
- `'Same as first input'` -- The output data type is the same as that of the first input data type.
- `'Same as product'` -- The output data type is the same as that of the product output data type.
- `'Custom'` -- The output data type is specified as a custom numeric type through the “`CustomOutputDataType`” on page 4-0 property.

For more information on the output data type this object uses, see the “Fixed Point” on page 4-336 section.

Dependencies

This property applies when you set `FullPrecisionOverride` to `false`.

CustomOutputDataType — Word and fraction lengths of output data type

`numericType([],16,15)` (default)

Word and fraction lengths of the output data type, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Dependencies

This property applies only when you set `FullPrecisionOverride` to `false` and “`OutputDataType`” on page 4-0 to ‘`Custom`’.

Usage**Syntax**

```
y = xcorr(u,v)
```

Description

`y = xcorr(u,v)` computes the cross-correlation of the two input signals, `u` and `v`.

Input Arguments**u — First data input signal**

vector | matrix | *N*-D array

First data input signal, specified as a vector, matrix, or an *N*-D array. The object accepts real-valued or complex-valued multichannel and multidimensional inputs. The input can be a fixed-point signal when you set the `Method` property to ‘`Time Domain`’. When one or both of the input signals are complex, the output signal is also complex. Both data inputs must have the same data type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

v — Second data input signal

scalar | column vector | matrix

Second data input signal, specified as a vector, matrix, or an *N*-D array. The object accepts real-valued or complex-valued multichannel and multidimensional inputs. The input can be a fixed-point signal when you set the `Method` property to ‘`Time Domain`’. When one or both of the input signals are complex, the output signal is also complex. Both data inputs must have the same data type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Output Arguments**y — Cross-correlated output**

vector | matrix | *N*-D array

Cross-correlated output of the two input signals.

When the inputs are N -D arrays, the object outputs an N -D array. All the dimensions of the output array, except for the first dimension, match the input array. For example:

- When the inputs u and v have dimensions M_u -by- N -by- P and M_v -by- N -by- P , respectively, the object outputs an $(M_u + M_v - 1)$ -by- N -by- P array.
- When the inputs u and v have the dimensions M_u -by- N and M_v -by- N , the object outputs an $(M_u + M_v - 1)$ -by- N matrix.

If one input is a column vector and the other input is an N -D array, the object computes the cross-correlation of the vector with each column in the N -D array. For example:

- When the input u is an M_u -by-1 column vector and v is an M_v -by- N matrix, the object outputs an $(M_u + M_v - 1)$ -by- N matrix.
- Similarly, when u and v are column vectors with lengths M_u and M_v , respectively, the object performs the vector cross-correlation.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Cross-Correlation of Input Noise and Delayed Version

Note If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Compute the cross-correlation of a noisy input signal with its delayed version. The peak of the correlation output occurs at the lag, which corresponds to the delay between the signals.

Use `randn` to create the white Gaussian noisy input, `x`. Create a delayed version of this input, `x1`, using the `dsp.Delay` object.

```
S = rng('default');
x = randn(100,1);
delay = dsp.Delay(10);
x1 = delay(x);
```

Compute the cross-correlation between the two inputs. Plot the correlation output with respect to the lag between the inputs.

```
xcorr = dsp.Crosscorrelator;
y = xcorr(x1,x);
lags = 0:99;
stem(lags,y(100:end),'markerfacecolor',[0 0 1])
axis([0 99 -125 125])
xlabel('Lags')
title('Cross-Correlation of Input Noise and Delayed Version')
```

The correlation sequence peaks when the lag is 10, indicating that the correct delay between the two signals is 10 samples.

More About

Cross-Correlation

Cross-correlation is the measure of similarity of two discrete-time sequences as a function of the lag of one relative to the other.

For two length- N deterministic inputs or realizations of jointly wide-sense stationary (WSS) random processes, x and y , the cross-correlation is computed using the following relationship:

$$r_{xy}(h) = \begin{cases} \sum_{n=0}^{N-h-1} x(n+h)y^*(n) & 0 \leq h \leq N-1 \\ r_{yx}^*(h) & -(N-1) \leq h \leq 0 \end{cases}$$

where h is the lag and $*$ denotes the complex conjugate. If the inputs are realizations of jointly WSS stationary random processes, $r_{xy}(h)$ is an unnormalized estimate of the theoretical cross-correlation:

$$\rho_{xy}(h) = E\{x(n+h)y^*(n)\}$$

where $E\{ \}$ is the expectation operator.

Fixed Point

The diagram shows the data types the `dsp.Crosscorrelator` object uses for fixed-point signals (time domain only).

You can set the product output, accumulator, and output data types using the corresponding fixed-point properties of the object.

When the input is real, the output of the multiplier is in the product output data type. When the input is complex, the output of the multiplier is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”.

Note When one or both of the inputs are signed fixed-point signals, all internal object data types are signed fixed point. The internal object data types are unsigned fixed point only when both inputs are unsigned fixed-point signals.

Algorithms

Time-Domain Computation

When you set the computation domain to time, the algorithm computes the cross-correlation of two signals in the time domain. The input signals can be fixed-point signals in this domain.

Correlate Two 2-D Arrays

When the inputs are two 2-D arrays, the j th column of the output, y_{uv} , has these elements:

$$y_{uv}(i, j) = \sum_{k=0}^{\max(M_u, M_v) - 1} u_{k, j}^* v_{(k+i), j} \quad 0 \leq i < M_v$$

$$y_{uv}(i, j) = y_{vu}^*(-i, j) \quad -M_u < i < 0$$

where:

- * denotes the complex conjugate.
- u is an M_u -by- N input matrix.
- v is an M_v -by- N input matrix.
- $y_{u,v}$ is an $(M_u + M_v - 1)$ -by- N matrix.

Inputs u and v are zero when indexed outside their valid ranges.

Correlate a Column Vector with a 2-D Array

When one input is a column vector and the other input is a 2-D array, the algorithm independently cross-correlates the input vector with each column of the 2-D array. The j th column of the output, $y_{u,v}$, has these elements:

$$y_{uv}(i, j) = \sum_{k=0}^{\max(M_u, M_v) - 1} u_k^* v_{(k+i), j} \quad 0 \leq i < M_v$$

$$y_{uv}(i, j) = y_{vu}^*(-i, j) \quad -M_u < i < 0$$

where:

- * denotes the complex conjugate.

- u is an M_u -by-1 column vector.
- v is an M_v -by- N matrix.
- y_{uv} is an $(M_u + M_v - 1)$ -by- N matrix.

Inputs u and v are zero when indexed outside their valid ranges.

Correlate Two Column Vectors

When the inputs are two column vectors, the j th column of the output, y_{uv} , has these elements:

$$y_{uv(i)} = \sum_{k=0}^{\max(M_u, M_v) - 1} u_k^* v_{(k+i)} \quad 0 \leq i < M_v$$
$$y_{uv(i)} = y_{vu}^*(-i) \quad -M_u < i < 0$$

where:

- $*$ denotes the complex conjugate.
- u is an M_u -by-1 column vector.
- v is an M_v -by-1 column vector.
- y_{uv} is an $(M_u + M_v - 1)$ -by-1 column vector.

Inputs u and v are zero when indexed outside their valid ranges.

Frequency-Domain Computation

When you set the computation domain to frequency, the algorithm computes the cross-correlation in the frequency domain.

To compute the cross-correlation, the algorithm:

- 1 Takes the Fourier transform of both input signals, U and V .
- 2 Multiplies U and V^* , where $*$ denotes the complex conjugate.
- 3 Computes the inverse Fourier transform of the product.

In this domain, depending on the input length, the algorithm can require fewer computations.

Version History

Introduced in R2012a

dsp.Crosscorrelator System object will be removed

Warns starting in R2021b

dsp.Crosscorrelator System object will be removed in a future release. Use the `xcorr` function instead.

Update Code

This table shows how the System object is typically used and explains how to update existing code to use the `xcorr` function.

Discouraged Usage	Recommended Replacement

dsp.CumulativeProduct

Package: dsp

(To be removed) Cumulative product of channel, column, or row elements

Note `dsp.CumulativeProduct` will be removed in a future release. Use the `cumprod` function instead. For more information, see “Compatibility Considerations”.

Description

The `dsp.CumulativeProduct` System object computes the cumulative product of channel, column, or row elements.

To compute the cumulative product of channel, column, or row elements:

- 1 Create the `dsp.CumulativeProduct` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
cprod = dsp.CumulativeProduct  
cprod = dsp.CumulativeProduct(Name,Value)
```

Description

`cprod = dsp.CumulativeProduct` returns a cumulative product object, `cprod`, that computes the cumulative product of input matrix or input vector elements along the default dimension.

`cprod = dsp.CumulativeProduct(Name,Value)` returns a cumulative product object with each specified property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Dimension — Computation dimension for cumulative product

Channels (running product) (default) | Rows | Columns

Specify the computation dimension as `Channels (running product)`, `Rows`, or `Columns`.

ResetInputPort — Enable resetting cumulative product through input port

`false` (default) | `true`

Set this property to `true` to enable resetting the cumulative product. When you set this property to `true`, specify a reset signal to the object algorithm to reset the cumulative product.

Dependencies

You can access this property when the “Dimension” on page 4-0 property is set to `Channels (running product)`.

ResetCondition — Reset condition for cumulative product

`Rising edge` (default) | `Falling edge` | `Either edge` | `Non-zero`

Specify the event on the reset input port that causes resetting the cumulative product to `Rising edge`, `Falling edge`, `Either edge`, or `Non-zero`.

Dependencies

This property applies when you set the “ResetInputPort” on page 4-0 property to `true` and the “Dimension” on page 4-0 property to `Channels (running product)`.

Fixed-Point Properties

RoundingMethod — Rounding method for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding method as one of `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`.

OverflowAction — Overflow action for fixed-point operations

`Wrap` (default) | `Saturate`

Specify the overflow action as one of `Wrap` or `Saturate`.

IntermediateProductDataType — Intermediate product word and fraction lengths

`Same as input` (default) | `Custom`

Specify the intermediate product fixed-point data type as `Same as input` or `Custom`.

CustomIntermediateProductDataType — Intermediate product word and fraction lengths

`numerictype([], 16, 15)` (default) | `numerictype`

Specify the intermediate product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies when you set the `IntermediateProductDataType` property to `Custom`.

ProductDataType — Product output word and fraction lengths

`Same as input` (default) | `Custom`

Specify the product output fixed-point data type as one of | `Same as input` | `Custom` |.

CustomProductDataType — Custom product output word and fraction lengths`numericity([], 32, 30) (default) | numericity`

Specify the product output fixed-point type as a scaled `numericity` object with a `Signedness` of `Auto`.

Dependencies

This property applies when you set the `ProductDataType` property to `Custom`.

AccumulatorDataType — Accumulator word and fraction lengths`Same as input (default) | Same as product output | Custom`

Specify the accumulator fixed-point data type as `Same as product output`, `Same as input`, or `Custom`.

CustomAccumulatorDataType — Custom accumulator word and fraction lengths`numericity([], 32, 30) (default) | numericity`

Specify the accumulator fixed-point type as a scaled `numericity` object with a `Signedness` of `Auto`.

Dependencies

This property applies when you set the `AccumulatorDataType` property to `Custom`.

OutputDataType — Output word and fraction lengths`Same as input (default) | Same as product output | Custom`

Specify the output fixed-point data type as one of `| Same as product output | Same as input | Custom |`.

CustomOutputDataType — Custom output word and fraction lengths`numericity([], 16, 15) (default) | numericity`

Specify the output fixed-point type as a scaled `numericity` object with a `Signedness` of `Auto`.

Dependencies

This property applies when you set the “`OutputDataType`” on page 4-0 property to `Custom`.

Usage**Syntax**

```
y = cprod(x)
y = cprod(x,r)
```

Description

`y = cprod(x)` computes the cumulative product along the specified dimension for the input `x`.

`y = cprod(x,r)` resets the cumulative product object's state based on the `ResetCondition` property value and the value of the reset signal, `r`, when the `ResetInputPort` property is `true`.

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

r — Reset signal

scalar

Reset signal used to reset the running cumulative product, specified as a scalar. The object resets the running cumulative product if the reset signal satisfies the `ResetCondition`.

Dependencies

This input is applicable only when `Dimension` is set to `'Channels (running product)'` and `ResetInputPort` is set to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical` | `fi`

Output Arguments

y — Cumulative product

vector | matrix

Cumulative product of the input signal, returned as a vector or a matrix.

The size, data type, and complexity characteristics of the output signal match that of the input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Cumulative Product of Matrix

Note If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Use the `dsp.CumulativeProduct` object to compute the cumulative product of a matrix.

```
cprod = dsp.CumulativeProduct;  
x = magic(2)
```

$x = 2 \times 2$

```
1 3  
4 2
```

```
y = cprod(x)
```

$y = 2 \times 2$

```
1 3  
4 6
```

The cumulative product is computed column-wise along each channel.

Algorithms

This object implements the algorithm, inputs, and outputs described on the Cumulative Product block reference page. The object properties correspond to the block parameters, except the **Reset port** block parameter corresponds to both the `ResetCondition` and `ResetInputPort` object properties.

Version History

Introduced in R2012a

`dsp.CumulativeProduct` System object will be removed

Warns starting in R2021b

`dsp.CumulativeProduct` System object will be removed in a future release. Use the `cumprod` function instead.

Update Code

This table shows how the System object is typically used and explains how to update existing code to use the `cumprod` function.

dsp.CumulativeSum

Package: dsp

(To be removed) Cumulative sum of channel, column, or row elements

Note dsp.CumulativeSum will be removed in a future release. Use the cumsum function instead. For more information, see “Compatibility Considerations”.

Description

The dsp.CumulativeSum System object computes the cumulative sum of channel, column, or row elements.

To compute the cumulative sum of channel, column, or row elements:

- 1 Create the dsp.CumulativeSum object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
csum = dsp.CumulativeSum
csum = dsp.CumulativeSum(Name,Value)
```

Description

csum = dsp.CumulativeSum returns a cumulative sum System object, csum, which computes the running cumulative sum for each channel in the input.

csum = dsp.CumulativeSum(Name,Value) returns a cumulative sum object, csum, with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Dimension — Computation dimension for cumulative sum

Channels (running sum) (default) | Rows | Columns

Specify the computation dimension as `Channels` (running `sum`), `Rows`, or `Columns`.

ResetInputPort — Enable resetting cumulative sum through input port

`false` (default) | `true`

Set this property to `true` to enable resetting the cumulative sum. When you set this property to `true`, you also specify a reset input to the object algorithm to reset the cumulative sum.

ResetCondition — Reset condition for cumulative sum

`Rising edge` (default) | `Falling edge` | `Either edge` | `Non-zero`

Specify the event on the reset input port that resets the cumulative sum as `Rising edge`, `Falling edge`, `Either edge`, or `Non-zero`.

Dependencies

This property applies when you set the “ResetInputPort” on page 4-0 property to `true`.

Fixed-Point Properties**RoundingMethod — Rounding method for fixed-point operations**

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding method as one of `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`.

OverflowAction — Overflow action for fixed-point operations

`Wrap` (default) | `Saturate`

Specify the overflow action as one of `Wrap` or `Saturate`.

AccumulatorDataType — Accumulator word and fraction lengths

`Same as input` (default) | `Custom`

Specify the accumulator fixed-point data type as `Same as input` or `Custom`.

CustomAccumulatorDataType — Custom accumulator word and fraction lengths

`numerictype([], 32, 30)` (default) | `numerictype`

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies when you set the `AccumulatorDataType` property to `Custom`.

OutputDataType — Output word and fraction lengths

`Same as accumulator` (default) | `Same as input` | `Custom`

Specify the output fixed-point data type as `Same as accumulator`, `Same as input`, or `Custom`.

CustomOutputDataType — Custom output word and fraction lengths

`numerictype([], 16, 15)` (default) | `numerictype`

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies when you set the “OutputDataType” on page 4-0 property to Custom.

Usage**Syntax**

```
y = csum(x)
y = csum(x,r)
```

Description

$y = \text{csum}(x)$ computes the cumulative sum along the specified dimension for the input x .

$y = \text{csum}(x, r)$ resets the System object state based on the ResetCondition property value and the value of the reset signal, r . You can only reset the state if the ResetInputPort property is true.

Input Arguments**x — Data input**

vector | matrix

Data input, specified as a vector or a matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

r — Reset signal

scalar

Reset signal used to reset the running cumulative sum, specified as a scalar. The object resets the running cumulative sum if the reset signal satisfies the ResetCondition.

Dependencies

This input is applicable only when Dimension is set to 'Channels (running sum)' and ResetInputPort is set to true.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | logical | fi

Output Arguments**y — Cumulative sum**

vector | matrix

Cumulative sum of the input signal, returned as a vector or a matrix.

The size, data type, and complexity characteristics of the output signal match that of the input signal.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Cumulative Sum of Matrix

Note If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Use the `dsp.CumulativeSum` object to compute the cumulative sum of a matrix.

```
csum = dsp.CumulativeSum;  
x = magic(2)
```

```
x = 2×2
```

```
    1    3  
    4    2
```

```
y = csum(x)
```

```
y = 2×2
```

```
    1    3  
    5    5
```

The cumulative sum is computed column-wise along each channel.

Algorithms

This object implements the algorithm, inputs, and outputs described on the Cumulative Sum block reference page. The object properties correspond to the block properties, except the **Reset port** block parameter corresponds to both the `ResetCondition` and the `ResetInputPort` object properties.

Version History

Introduced in R2012a

dsp.CumulativeSum System object will be removed*Warns starting in R2021b*

dsp.CumulativeSum System object will be removed in a future release. Use the cumsum function instead.

Update Code

This table shows how the System object is typically used and explains how to update existing code to use the cumsum function.

Functions

cumsum

dsp.DCBlocker

Package: dsp

Block DC component (offset) from input signal

Description

The `dsp.DCBlocker` System object removes the DC offset from each channel (column) of the input signal. The operation runs over time to continually estimate and remove the DC offset.

To block the DC component of the input signal:

- 1 Create the `dsp.DCBlocker` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
dcblk = dsp.DCBlocker
dcblk = dsp.DCBlocker(Name, Value)
```

Description

`dcblk = dsp.DCBlocker` creates a DC blocker System object, `dcblk`, to block the DC component from each channel (column) of the input signal.

`dcblk = dsp.DCBlocker(Name, Value)` creates a DC blocker System object, `dcblk`, with each specified property set to the specified value. Enclose each property name in single quotes.

Example: `dcblk = dsp.DCBlocker('Algorithm','FIR')`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Algorithm — Algorithm for estimating DC offset

'IIR' (default) | 'FIR' | 'CIC' | 'Subtract mean'

Algorithm for estimating DC offset, specified as one of the following:

- 'IIR' -- The object uses a recursive estimate based on a narrow, lowpass elliptic filter. The "Order" on page 4-0 property sets the order of the filter, and the "NormalizedBandwidth" on page 4-0 property sets its bandwidth. This algorithm typically uses less memory than the FIR algorithm and is more efficient.
- 'FIR' -- The object uses a nonrecursive, moving average estimate based on a finite number of past input samples. The "Length" on page 4-0 property sets the number of samples. The FIR filter has a linear phase response and does not cause any phase distortion to the signal. The IIR filter requires less memory and is more efficient to implement.
- 'CIC' -- The object uses a CIC decimator, with a decimation factor of 1, whose differential delay is calculated using the NormalizedBandwidth property. It uses two sections to ensure that the first sidelobe attenuation is at least 25 dB below the main lobe of the filter. This algorithm requires fixed-point inputs and can be used for HDL code generation.
- 'Subtract mean' -- The object computes the means of the columns of the input matrix, and subtracts the means from the input. This method does not retain state between inputs.

You can visualize the IIR, FIR, and CIC responses by using the `fvtool` function.

NormalizedBandwidth — Normalized bandwidth of lowpass IIR or CIC filter

0.001 (default) | real scalar greater than 0 and less than 1

Normalized bandwidth of the IIR or CIC filter, specified as a real scalar greater than 0 or less than 1. The normalized bandwidth is used to estimate the DC component of the input signal.

Dependencies

This property applies only when you set the "Algorithm" on page 4-0 property to 'IIR' or 'CIC'.

Order — Order of lowpass IIR elliptic filter

6 (default) | integer greater than 3

Order of the lowpass IIR elliptic filter that is used to estimate the DC level, specified as an integer greater than 3.

Dependencies

This property applies only when you set the "Algorithm" on page 4-0 property to 'IIR'.

Length — Number of past input samples used in FIR algorithm

50 (default) | positive integer

Number of past input samples used in the FIR algorithm to estimate the running mean, specified as a positive integer.

Dependencies

This property applies only when you set the "Algorithm" on page 4-0 property to 'FIR'.

Usage

Syntax

```
dcblkOut = dcblk(input)
```

Description

`dcblkerOut = dcblker(input)` removes the DC component from each channel (column) of the input and returns the output.

Input Arguments

input — Input signal

vector | matrix | *N*-D array

Data input to the DC blocker object, specified as a vector, matrix, or *N*-D array.

Example: `t = (0:0.001:100)'; x = sin(30*pi*t) + 1;`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fi`

Output Arguments

dcblkerOut — Signal with DC component removed

vector | matrix | *N*-D array

Signal with DC component removed, returned as a vector, matrix, or *N*-D array. The output dimensions match the input dimensions.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Visualization Specific to DSP System Toolbox

`fvtool` Visualize frequency response of DSP filters

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Remove DC Component and Display Results

Note: If you are using R2016a or earlier, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Remove the DC component of an input signal using the IIR, FIR, and subtract mean estimation algorithms.

Create a signal composed of a 15 Hz tone, a 25 Hz tone, and a DC offset.

```
t = (0:0.001:100)';  
x = sin(30*pi*t) + 0.33*cos(50*pi*t) + 1;
```

Create three DC blocker objects for the three estimation algorithms.

```
dc1 = dsp.DCBlocker('Algorithm','IIR','Order', 6);  
dc2 = dsp.DCBlocker('Algorithm','FIR','Length', 100);  
dc3 = dsp.DCBlocker('Algorithm','Subtract mean');
```

For each second of time, pass the input signal through the DC blockers. By implementing the DC blockers in 1-second increments, you can observe differences in the convergence times.

```
for idx = 1 : 100  
    range = (1:1000) + 1000*(idx-1);  
    y1 = dc1(x(range));           % IIR estimate  
    y2 = dc2(x(range));           % FIR estimate  
    y3 = dc3(x(range));           % Subtract mean  
end
```

Plot the input and output data for the three DC blockers for the first second of time, and show the mean value for each signal. The mean values for the three algorithm types show that the FIR and Subtract mean algorithms converge more quickly.

```
plot(t(1:1000),x(1:1000), ...  
     t(1:1000),y1, ...  
     t(1:1000),y2, ...  
     t(1:1000),y3);  
xlabel('Time (sec)')  
ylabel('Amplitude')  
legend(sprintf('Input DC:%.3f',mean(x)), ...  
       sprintf('IIR DC:%.3f',mean(y1)), ...  
       sprintf('FIR DC:%.3f',mean(y2)), ...  
       sprintf('Subtract mean DC:%.3f',mean(y3)));
```

Frequency Response Before and After DC Blocker

Note: If you are using R2016a or earlier, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Compare the spectrum of an input signal with a DC offset to the spectrum of the same signal after applying a DC blocker. Enable the DC blocker to use the FIR estimation algorithm.

Create an input signal composed of three tones and that has a DC offset of 1. Set the sampling frequency to 1 kHz and set the signal duration to 100 seconds.

```
fs = 1000;
t = (0:1/fs:100)';
x = sin(30*pi*t) + 0.67*sin(40*pi*t) + 0.33*sin(50*pi*t) + 1;
```

Create a DC blocker object that uses the FIR algorithm to estimate the DC offset.

```
dcblker = dsp.DCBlocker('Algorithm','FIR','Length',100);
```

Create a spectrum analyzer with power units set to dBW and a frequency range of `[-30 30]` to display the frequency response of the input signal. Using the `clone` function, create a second spectrum analyzer to display the response of the output. Then, use the `Title` property of the spectrum analyzers to label them.

```

hsa = spectrumAnalyzer('SampleRate',fs, ...
    'Method','welch',...
    'AveragingMethod','exponential',...
    'SpectrumUnits','dBW','FrequencySpan','start-and-stop-frequencies',...
    'StartFrequency',-30,'StopFrequency',30,'YLimits',[-200 20],...
    'Title','Signal Spectrum');

hsb = clone(hsa);
hsb.Title = 'Signal Spectrum After DC Blocker';

```

Pass the input signal, x , through the DC blocker to generate the output signal, y .

```
y = dcbkcr(x);
```

Use the first spectrum analyzer to display the frequency characteristics of the input signal. The tones at 15, 20, and 25 Hz, and the DC component, are clearly visible.

```
hsa(x)
```

Use the second spectrum analyzer to display the frequency characteristics of the output signal. The DC component has been removed.

```
hsb(y)
```

Algorithms

The DC blocker subtracts the DC component from the input signal. You can estimate the DC component by using the IIR, FIR, CIC, or subtract mean algorithm.

IIR

Pass the input signal through an IIR lowpass elliptical filter.

The elliptical IIR filter has a passband ripple of 0.1 dB and a stopband attenuation of 60 dB. You specify the normalized bandwidth and the filter order.

FIR

Pass the input signal through an FIR filter that uses a nonrecursive moving average from a finite number of past input samples.

The FIR filter coefficients are given as $\text{ones}(1, \text{Length}) / \text{Length}$, where Length is the number of past input samples for FIR algorithm. The FIR filter structure is a direct form I transposed structure.

CIC

Pass the input signal through a CIC filter. Because the CIC filter amplifies the signal, the filter gain is estimated and subtracted from the DC estimate.

The Cascaded Integrator-Comb (CIC) filter consists of two integrator-comb pairs. These pairs help to ensure that the peak of the first sidelobe of the filter response is attenuated by at least 25 dB relative to the peak of the main lobe. The normalized 3 dB bandwidth is used to calculate the differential delay. The delay is used to determine the gain of the CIC filter. The inverse of the filter gain is used as a multiplier, which is applied to the output of the CIC filter. This ensures that the aggregate gain of the DC estimate is 0 dB.

The following equation characterizes the aggregate magnitude response of the filter and the multiplier:

$$|H(e^{j\omega})| = \left| \frac{\sin(M\frac{\pi}{2}B_{norm})}{M\sin(\frac{\pi}{2}B_{norm})} \right|^N$$

- B_{norm} is the normalized bandwidth such that $0 < B_{norm} < 1$.
- M is the differential delay in samples.
- N is the number of sections, equal to 2.

Set the differential delay, M , to the smallest integer such that $|H(e^{j\omega})| < 1/\sqrt{2}$. Once M is known, the gain of the CIC filter is calculated as M^N . Therefore, to precisely compensate for the filter gain, the multiplier is set to $(1/M)^N$.

Subtract mean

Compute the mean value of each column of the input signal and subtract the mean from the input. For example, if the input is [1 2 3 4; 3 4 5 6], then a DC Blocker set to this mode outputs [-1 -1 -1 -1; 1 1 1 1].

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See "System Objects in MATLAB Code Generation" (MATLAB Coder).

This object also supports SIMD code generation using Intel AVX2 technology when the input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

`double` and `single` data types are supported for simulation, but not for HDL code generation.

To generate HDL code from predefined System objects, see “HDL Code Generation from Viterbi Decoder System Object” (HDL Coder).

Delay input signal by fixed samples

Description

The `dsp.Delay` System object delays the input by a specified number of samples along each channel (column) of the input. You can specify the initial output of the object through the “InitialConditions” on page 4-0 property. To reset the delay, enable the “ResetCondition” on page 4-0 through the “ResetInputPort” on page 4-0 .

To delay the input:

- 1 Create the `dsp.Delay` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
delay = dsp.Delay
delay = dsp.Delay(Name,Value)
delay = dsp.Delay(len,Name,Value)
```

Description

`delay = dsp.Delay` creates a System object that delays the input by 1 sample.

`delay = dsp.Delay(Name,Value)` creates a delay System object with each specified property set to the specified value. Enclose each property name in single quotes.

Example: `delay = dsp.Delay('InitialConditionsPerChannel',true);`

`delay = dsp.Delay(len,Name,Value)` creates a delay System object, `delay`, with the `Length` property set to `len`, and other specified properties set to the specified values. Enclose each property name in single quotes.

Example: `delay = dsp.Delay(10,'ResetInputPort',true,'ResetCondition','Rising edge');`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Length — Amount of delay to apply to input signal

1 (default) | scalar positive integer | vector of positive integers

Amount of delay in samples to apply to the input signal, specified as one of the following:

- Scalar positive integer -- The object applies equal delay to all the channels.
- Vector of positive integers -- The length of the vector must equal the number of input channels (columns). The object delays each channel by the amount specified by the respective element in the delay vector.

InitialConditionsPerChannel — Enable different initial conditions per channel

false (default) | true

Enable different initial conditions per channel, specified as either:

- false -- The object applies the same initial conditions for all channels.
- true -- The object applies different initial conditions for each channel.

The value of this property must be the same as the value you choose for the `InitialConditionsPerSample` property. This value determines the size of the initial conditions array. For more details, see the “InitialConditions” on page 4-0 property.

InitialConditionsPerSample — Enables different initial conditions per sample

false (default) | true

Different initial conditions per sample, specified as either:

- false -- The object applies the same initial conditions for all samples.
- true -- The object applies different initial conditions for each sample.

The value of this property must be the same as the value you choose for the `InitialConditionsPerChannel` property. This value determines the size of the initial conditions array. For more details, see the “InitialConditions” on page 4-0 property.

InitialConditions — Initial output of the object

0 (default) | scalar | vector | matrix

Initial output of System object, specified as a scalar, vector, or a matrix. The dimensions of the initial condition matrix must be (Length property value)-by-(number of input channels).

If the input is an M -by- N matrix, the dimensions of the `InitialConditions` property value must be as follows:

<code>InitialConditionsPerChannel</code>	<code>InitialConditionsPerSample</code>	<code>InitialConditions</code>
false	false	scalar
true	true	Length-by- N matrix

ResetInputPort — Enable reset condition

false (default) | true

Enable the reset condition so that you can pass the reset control input to the object, specified as either:

- `false` -- The object does not reset the delay states.
- `true` -- You must pass a reset control input to the object by using the “ResetCondition” on page 4-0 property. The object resets the delay states based on the values of the `ResetCondition` property and the reset control that is input to the object.

ResetCondition — Event that triggers reset of delay

'Non-zero' (default) | 'Rising edge' | 'Falling edge' | 'Either edge'

Event that triggers the reset of the delay, specified as one of the following. The object resets the delay whenever a reset event is detected in its reset input.

- 'Non-zero' -- Triggers a reset operation at each sample, when the reset input is not zero.
- 'Rising edge' -- Triggers a reset operation when the reset input does one of the following:
 - Rises from a negative value to either a positive value or zero.
 - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.

- 'Falling edge' -- Triggers a reset operation when the reset input does one of the following:
 - Falls from a positive value to a negative value or zero.
 - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.

- 'Either edge' -- Triggers a reset operation when the reset input is a rising edge or a falling edge.

Dependencies

This property applies only when you set the `ResetInputPort` property to `true`.

Usage

Syntax

```
delayOut = delay(dataInput)
delayOut = delay(dataInput, resetInput)
```

Description

`delayOut = delay(dataInput)` adds delay to the data input and returns the delayed output. Each column of the input is treated as an independent channel.

`delayOut = delay(dataInput, resetInput)` adds delay to the data input and selectively resets the state of the System object based on the value of the reset input and the value of the “ResetCondition” on page 4-0 property.

To pass the reset input, set “ResetInputPort” on page 4-0 property to `true`.

```
delay = dsp.Delay('ResetInputPort', true);
...
delayOut = delay(dataInput, resetInput);
```

Input Arguments

dataInput — Data input

vector | matrix

Data input that is delayed by the object, specified as a vector or a matrix.

Example: `[1;2;3;4;5]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `fi`

resetInput — Reset input

scalar

Reset input, specified as a scalar.

Example: `2`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

Output Arguments

delayOut — Delayed output

vector | matrix

Delayed output, returned as a vector or matrix. The size and data type of the output match the size and data type of the data input.

Example: `[0;0;1;2;3]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Delay Input

Delay input by five samples by using the `dsp.Delay` System object™. By default, the initial conditions are 0.

Note: If you are using R2016a or earlier, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Delay input by 4 samples.

```
delay = dsp.Delay(4);  
input = [(1:10)' (11:20)'];  
delayOut = delay(input) %#ok
```

```
delayOut = 10x2
```

```
0     0  
0     0  
0     0  
0     0  
1    11  
2    12  
3    13  
4    14  
5    15  
6    16
```

```
release(delay);
```

Specify initial conditions for each channel and for each sample. The `InitialConditions` property must be a (*Length*)-by-(*NumChannels*) matrix.

```
delay.InitialConditionsPerChannel = true;  
delay.InitialConditionsPerSample = true;
```

```
delay.InitialConditions = [(0.1:0.1:0.4)' (0.5:0.1:0.8)'];
delayOut = delay(input) %#ok
```

```
delayOut = 10×2
```

```
0.1000    0.5000
0.2000    0.6000
0.3000    0.7000
0.4000    0.8000
1.0000   11.0000
2.0000   12.0000
3.0000   13.0000
4.0000   14.0000
5.0000   15.0000
6.0000   16.0000
```

```
release(delay);
```

Reset the delay by setting the reset event to 'Rising edge'. In this mode, a reset event occurs when the reset input:

- Rises from a negative value to 0.
- Rises from a negative value to a positive value.
- Rises from 0 to a positive value, where the rise is not a continuation from a negative value to 0.

Pass an initial reset input of 0.

```
delay.ResetInputPort = true;
delay.ResetCondition = 'Rising edge';
delayOut = delay(input,0) %#ok
```

```
delayOut = 10×2
```

```
0.1000    0.5000
0.2000    0.6000
0.3000    0.7000
0.4000    0.8000
1.0000   11.0000
2.0000   12.0000
3.0000   13.0000
4.0000   14.0000
5.0000   15.0000
6.0000   16.0000
```

Continue to run the delay. The delay samples now contain the rest of the input vector.

```
delayOut = delay(input,0) %#ok
```

```
delayOut = 10×2
```

```
7    17
8    18
9    19
10   20
1    11
2    12
```

```
3    13
4    14
5    15
6    16
```

Change the reset input to 2, indicating a rising edge.

```
delayOut = delay(input,2)
```

```
delayOut = 10×2
```

```
0.1000    0.5000
0.2000    0.6000
0.3000    0.7000
0.4000    0.8000
1.0000   11.0000
2.0000   12.0000
3.0000   13.0000
4.0000   14.0000
5.0000   15.0000
6.0000   16.0000
```

The delay values are reset to the initial conditions.

Version History

Introduced in R2012a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

double and single data types are supported for simulation, but not for HDL code generation.

To generate HDL code from predefined System objects, see “HDL Code Generation from Viterbi Decoder System Object” (HDL Coder).

dsp.DelayLine

Package: dsp

(To be removed) Rebuffer sequence of inputs with one-sample shift

Note dsp.DelayLine will be removed in a future release. There is no direct replacement. You can use the dsp.AsyncBuffer object to achieve a delay line.

Description

The dsp.DelayLine System object rebuffers a sequence of inputs with one-sample shift.

To rebuffer a sequence of inputs with one-sample shift:

- 1 Create the dsp.DelayLine object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
dline = dsp.DelayLine
dline = dsp.DelayLine(delaysize,initial)
dline = dsp.DelayLine(Name,Value)
```

Description

dline = dsp.DelayLine returns a delay line System object, dline, that buffers the input samples into a sequence of overlapping or underlapping matrix outputs.

dline = dsp.DelayLine(delaysize,initial) returns a delay line System object, dline, with the Length property set to delaysize and the InitialConditions property set to initial.

dline = dsp.DelayLine(Name,Value) returns a delay line object with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Length — Number of rows in output matrix

64 (default) | positive integer

Specify the number of rows in the output matrix as a scalar positive integer.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

InitialConditions — Initial delay line output

0 (default) | scalar | vector | matrix

Set the value of the object's initial output as one of `scalar`, `vector`, or `matrix`.

For vector outputs, you can use these options for the `InitialConditions` property:

- A vector of the same size
- A scalar value that you want repeated across all elements of the initial output

For matrix outputs, you can use these options for the `InitialConditions` property:

- A matrix of the same size
- A vector (equal to the length of the number of matrix rows) that repeats across all columns of the initial output
- A scalar that repeats across all elements of the initial output

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

DirectFeedthrough — Enable passing input data to output without extra frame delay`false` (default) | `true`

When you set this property to `true`, the input data is available immediately at the output. When you set this property to `false`, the output has a delay of one frame.

EnableOutputInputPort — Enable selective output linearization`false` (default) | `true`

The object uses a circular buffer, even though the output is linear. To obtain a valid output, the object must linearize the circular buffer. When this property is `true`, the object uses an additional Boolean input to determine if a valid output calculation is needed. If the input value is `true`, the object's output is linearized and thus valid. If the input value is `false`, the output is not linearized and is invalid. This allows the object to be more efficient when each step does not require the tapped delay line output. When you set this property to `false`, the output is always linearized and valid.

HoldPreviousValue — Hold previous valid value for invalid output`false` (default) | `true`

If you set this property to `true`, the most recent, valid value is held on the output. If you set this property to `false`, the signal on the output is invalid data.

Dependencies

This property applies only when you set the `EnableOutputInputPort` property to `true`.

Usage

Syntax

```
y = dline(x)
y = dline(x,en)
```

Description

`y = dline(x)` returns the delayed version of input `x`. `y` is an output matrix with the same number of rows as the delay line size. Each column of `x` is treated as a separate channel.

`y = dline(x,en)` selectively outputs the delayed version of input `x` depending on the Boolean input `en`. This occurs only when you set the `EnableOutputInputPort` property to `true`. If `en` is `false`, use the `HoldPreviousValue` property to specify if the object should hold the previous output value(s).

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `fi`

en — Enable output input port

`true` | `false`

Enable output input port signal, specified as a logical value.

If `en` is `false`, use the `HoldPreviousValue` property to specify if the object should hold the previous output value(s).

Dependencies

This input is valid only when you set the `EnableOutputInputPort` property to `true`.

Data Types: `logical`

Output Arguments

y — Delay line output

vector | matrix

Delay line output, returned as a vector or a matrix.

When the input is an M_i -by- N matrix, the System object rebuffers the input into a sequence of M_o -by- N matrix outputs, where M_o is the output frame size specified by the `Length` property. Depending on whether M_o is greater than, less than, or equal to the input frame size, M_i , the output frames can be underlapped or overlapped. Each of the N input channels is rebuffered independently:

- When $M_o > M_i$, the output frame overlap is the difference between the output and input frame size, $M_o - M_i$.

- When $M_o < M_i$, the output is underlapped; the object discards the first $M_i - M_o$ samples of each input frame so that only the last M_o samples are buffered into the corresponding output frame.
- When $M_o = M_i$, the output data is identical to the input data, but is delayed by the latency of the object.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

`step` Run System object algorithm
`release` Release resources and allow changes to System object property values and input characteristics
`reset` Reset internal states of System object

Examples

Delay Line

Note: If you are using R2016a or earlier, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Use a delay line object with a delay line size of 4 samples.

```
delayline = dsp.DelayLine( ...
    'Length', 4, ...
    'DirectFeedthrough', true, ...
    'InitialConditions', -2, ...
    'EnableOutputInputPort', true, ...
    'HoldPreviousValue', true);
en = logical([1 1 0 1 0]);
y = zeros(4,5);
for ii = 1:5
    y(:,ii) = delayline(ii, en(ii));
end
disp(y)
```

```
-2    -2    -2     1     1
-2    -2    -2     2     2
-2     1     1     3     3
 1     2     2     4     4
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Delay Line block reference page. The object properties correspond to the block properties.

Version History

Introduced in R2012a

dsp.DelayLine System object will be removed

Warns starting in R2021b

dsp.DelayLine System object will be removed in a future release. There is no direct replacement for this object. You can use the dsp.AsyncBuffer object to achieve a delay line.

Objects

dsp.AsyncBuffer

dsp.Differentiator

Package: dsp

Direct form FIR fullband differentiator filter

Description

The `dsp.Differentiator` System object applies a fullband differentiator filter on the input signal to differentiate all its frequency components. This object uses an FIR equiripple filter design to design the differentiator filter. The ideal frequency response of the differentiator is $D(\omega) = j\omega$ for $-\pi \leq \omega \leq \pi$. You can design the filter with minimum order with a specified order. This object supports fixed-point operations.

To filter each channel of your input:

- 1 Create the `dsp.Differentiator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
DF = dsp.Differentiator
DF = dsp.Differentiator(Name,Value)
```

Description

`DF = dsp.Differentiator` returns a differentiator, `DF`, which independently filters each channel of the input over time using the given design specifications.

`DF = dsp.Differentiator(Name,Value)` sets each property name to the specified value. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

DesignForMinimumOrder — Design minimum order filter

true (default) | false

Option to design a minimum-order filter, specified as a logical scalar. The filter has 2 degrees of freedom. When you set this property to

- `true` — The object designs the filter with the minimum order that meets the `PassbandRipple` value.
- `false` — The object designs the filter with order that you specify in the `FilterOrder` property.

This property is not tunable.

FilterOrder — Order of the filter

31 (default) | odd positive integer

Order of the filter, specified as an odd positive integer.

This property is not tunable.

Dependencies

You can specify the filter order only when `'DesignForMinimumOrder'` is set to `false`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

PassbandRipple — Maximum passband ripple

0.1 (default) | positive real scalar

Maximum passband ripple in dB, specified as a positive real scalar.

This property is not tunable.

Dependencies

You can specify the passband ripple only when `'DesignForMinimumOrder'` is set to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

ScaleCoefficients — Scale filter coefficients

`false` (default) | `true`

Option to scale the filter coefficients, specified as a logical scalar. When you set this property to `true`, the object scales the filter coefficients to preserve the input dynamic range.

This property is not tunable.

Fixed-Point Properties

CoefficientsDataType — Word and fraction lengths of coefficients

`numericType(1,16)` (default) | `numericType` object

Word and fraction lengths of coefficients, specified as a signed or unsigned `numericType` object. The default, `numericType(1,16)`, corresponds to a signed numeric type object with 16-bit coefficients. To give the best possible precision, the fraction length is computed based on the coefficient values.

This property is not tunable.

The word length of the output is the same as the word length of the input. The object computes the fraction length of the output such that the entire dynamic range of the output can be represented

without overflow. For details on how the object computes the fraction length of the output, see “Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters”.

RoundingMethod — Rounding method for output fixed-point operations

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see “Precision and Range”.

This property is not tunable.

Usage

Syntax

$y = DF(x)$

Description

$y = DF(x)$ applies a fullband differentiator filter to the input signal, x . y is a differentiated version of x .

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel. The number of rows in the input signal denotes the channel length. The data type characteristics (double, single, or fixed-point) and the real-complex characteristics (real or complex valued) must be the same for the input data and output data.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

Output Arguments

y — Differentiated signal

vector | matrix

Differentiated signal, returned as a vector or matrix of the same size, data type, and complexity as the input signal, x .

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.Differentiator

getFilter Get underlying FIR filter

Common to All System Objects

step Run System object algorithm

release Release resources and allow changes to System object property values and input characteristics

reset Reset internal states of System object

Examples

Group Delay Estimation

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Estimate the group delay of a linear phase FIR filter using a `dsp.TransferFunctionEstimator` object followed by `dsp.PhaseExtractor` and `dsp.Differentiator` objects. The group delay of a linear phase FIR filter is given by $GD = -(d\theta(\omega)/d\omega) = -\frac{N}{2}$, where $\theta(\omega)$ is the phase information of the filter, ω is the frequency vector, and N is the order of the filter.

Set Up the Objects

Create a linear phase FIR lowpass filter. Set the order to 200, the passband frequency to 255 Hz, the passband ripple to 0.1 dB, and the stopband attenuation to 80 dB. Specify a sample rate of 512 Hz.

```
Fs = 512;  
LPF = dsp.LowpassFilter('SampleRate',Fs,'PassbandFrequency',255,...  
    'DesignForMinimumOrder',false,'FilterOrder',200);
```

To estimate the transfer function of the lowpass filter, create a transfer function estimator. Specify the window to be Hann. Set the FFT length to 1024 and the number of spectral averages to 200.

```
TFE = dsp.TransferFunctionEstimator('FrequencyRange','twosided',...  
    'SpectralAverages',200,'FFTLenghtSource','Property',...  
    'FFTLenght',1024);
```

To extract the unwrapped phase from the frequency response of the filter, create a phase extractor.

```
PE = dsp.PhaseExtractor;
```

To differentiate the phase θ , create a differentiator filter. This value is used in computing the group delay.

```
DF = dsp.Differentiator;
```

To smoothen the input, create a variable bandwidth FIR filter.

```
Gain1 = 512/pi;  
Gain2 = -1;  
VBFilter = dsp.VariableBandwidthFIRFilter('CutoffFrequency',10,...  
    'SampleRate',Fs);
```

To view the group delay of the filter, create an array plot object.

```
AP = dsp.ArrayPlot('PlotType','Line','YLimits',[-500 400],...
    'YLabel','Amplitude','XLabel','Number of samples');
```

Run the Algorithm

The for-loop is the streaming loop that estimates the group delay of the filter. In the loop, the algorithm filters the input signal, estimates the transfer function of the filter, and differentiates the phase of the filter to compute the group delay.

```
Niter = 1000; % Number of iterations
for k = 1:Niter
    x = randn(512,1); % Input signal = white Gaussian noise
    y = LPF(x); % Filter noise with Lowpass FIR filter
    H = TFE(x,y); % Compute transfer function estimate
    Phase = PE(H); % Extract the Unwrapped phase
    phaseaftergain1 = Gain1*Phase;
    DiffOut = DF(phaseaftergain1); % Differentiate the phase
    phaseaftergain2 = Gain2 * DiffOut;
    VBFOut = VBFfilter(phaseaftergain2); % Smooth the group delay
    AP(VBFOut); % Display the group delay
end
```

As you can see, the group delay of the lowpass filter is 100.

Convert FM Signal to AM Signal

Create an FM wave on a 100 Hz carrier signal sampled at 1.5 kHz.

```
Fc = 1e2; % Carrier
Fs = 1.5e3; % Sample rate
sinewave = dsp.SineWave('Frequency',10,...
                        'SamplesPerFrame',1e3,...
                        'SampleRate',Fs);
```

end
```

```
release(df);
release(ts);
```

Algorithms

Differentiator Filter

Differentiator computes the derivative of a signal. The frequency response of an ideal differentiator filter is given by $D(\omega) = j\omega$, defined over the Nyquist interval $-\pi \leq \omega \leq \pi$.

The frequency response is antisymmetric and is linearly proportional to the frequency.

`dsp.Differentiator` object acts as a differentiator filter. This object condenses the two-step process into one. For the minimum order design, the object uses generalized Remez FIR filter design algorithm. For the specified order design, the object uses the Parks-McClellan optimal equiripple FIR filter design algorithm. The filter is designed as a linear phase Type-IV FIR filter with a Direct form structure.

The ideal differentiator has an antisymmetric impulse response given by $d(n) = -d(-n)$. Hence $d(0) = 0$. The differentiator must have zero response at zero frequency.

Linear-Phase FIR Differentiator Filter

The impulse response of an antisymmetric linear-phase FIR filter is given by $h(n) = -h(M - 1 - n)$, where M is the length of the filter. Because the filter is antisymmetric, you can use this type of FIR filter to design the linear-phase FIR differentiators.

Consider the design of linear-phase FIR differentiators based on the Chebyshev approximation criterion.

If M is odd, the real-valued frequency response of the FIR filter, $H_r(\omega)$, has the characteristics that $H_r(0) = 0$ and $H_r(\pi) = 0$. This filter satisfies the condition of zero response at zero frequency. However, it is not fullband because $H_r(\pi) = 0$. This differentiator has a linear response over the limited frequency range $[0, 2\pi f_p]$, where f_p is the bandwidth of the differentiator. The absolute error between the desired response and the Chebyshev approximation increases as ω increases from 0 to $2\pi f_p$.

If M is even, the real-valued frequency response of the FIR filter, $H_r(\omega)$, has the characteristics that $H_r(0) = 0$ and $H_r(\pi) \neq 0$. This filter satisfies the condition of zero response at zero frequency. It is fullband and this design results in a significantly smaller approximation error than comparable odd-length differentiators. Hence, even-length (odd order) differentiators are preferred in practical systems.

dsp.DigitalDownConverter

Package: dsp

Translate digital signal from intermediate frequency (IF) band to baseband and decimate it

Description

The `dsp.DigitalDownConverter` object translates digital signal from intermediate frequency (IF) band to baseband and decimates it.

To digitally downconvert the input signal:

- 1 Create the `dsp.DigitalDownConverter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
dwnConv = dsp.DigitalDownConverter  
dwnConv = dsp.DigitalDownConverter(Name,Value)
```

Description

`dwnConv = dsp.DigitalDownConverter` returns a digital downconverter (DDC) System object, `dwnConv`.

`dwnConv = dsp.DigitalDownConverter(Name,Value)` returns a DDC object, `dwnConv`, with the specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

SampleRate — Sample rate of input signal

30000000 (default) | positive scalar

Set this property to a positive scalar value, greater than or equal to twice the value of the `CenterFrequency` property.

Data Types: `single` | `double`

DecimationFactor — Decimation factor

100 (default) | positive integer scalar | vector of positive integers

Set this property to a positive integer scalar, or to a 1-by-2 or 1-by-3 vector of positive integers.

When you set this property to a scalar, the object automatically chooses the decimation factors for each of the three filtering stages.

When you set this property to a 1-by-2 vector, the object bypasses the third filter stage and sets the decimation factor of the first and second filtering stages to the values in the first and second vector elements respectively. Both elements of the `DecimationFactor` vector must be greater than one.

When you set this property to a 1-by-3 vector, the i th element of the vector specifies the decimation factor for the i th filtering stage. The first and second elements of the `DecimationFactor` vector must be greater than one, and the third element must be 1 or 2.

Data Types: `double`

MinimumOrderDesign — Minimum order filter design

`true` (default) | `false`

When you set this property to `true`, the object designs filters with the minimum order that meets the passband ripple, stopband attenuation, passband frequency, and stopband frequency specifications that you set using the `PassbandRipple`, `StopbandAttenuation`, `Bandwidth`, `StopbandFrequencySource`, and `StopbandFrequency` properties.

When you set this property to `false`, the object designs filters with orders that you specify in the `NumCICSections`, `SecondFilterOrder`, and `ThirdFilterOrder` properties. The filter designs meet the passband and stopband frequency specifications that you set using the `Bandwidth`, `StopbandFrequencySource`, and `StopbandFrequency` properties.

Data Types: `logical`

NumCICSections — Number of sections of CIC decimator

3 (default) | positive integer scalar

Number of sections of CIC decimator, specified as a positive integer scalar.

Dependencies

This property applies when you set the `MinimumOrderDesign` property to `false`.

Data Types: `double`

SecondFilterOrder — Order of CIC compensation filter stage

12 (default) | positive integer scalar

Order of CIC compensation filter stage, specified as a positive integer scalar.

Dependencies

This property applies when you set the `MinimumOrderDesign` property to `false`.

Data Types: `double`

ThirdFilterOrder — Order of third filter stage

10 (default) | even positive integer

Order of third filter stage, specified as an even positive integer scalar. When you set the `DecimationFactor` property to a 1-by-2 vector, the object ignores the `ThirdFilterOrder` property because the third filter stage is bypassed.

Dependencies

This property applies when you set the `MinimumOrderDesign` property to `false`.

Data Types: `double`

Bandwidth — Two-sided bandwidth of input signal in Hz

200000 (default) | positive integer scalar

Two-sided bandwidth of input signal in Hz, specified as a positive integer scalar. The object sets the passband frequency of the cascade of filters to one-half of the value that you specify in the `Bandwidth` property. Set the value of this property to less than `SampleRate/DecimationFactor`.

Data Types: `double`

StopbandFrequencySource — Source of stopband frequency

Auto (default) | Property

Specify the source of the stopband frequency as one of `Auto` | `Property`. When you set this property to `Auto`, the object places the cutoff frequency of the cascade filter response at approximately $F_c = \text{SampleRate}/M/2$ Hz, where M is the total decimation factor that you specify in the `DecimationFactor` property. The object computes the stopband frequency as $F_{stop} = F_c + TW/2$. TW is the transition bandwidth of the cascade response computed as $2 \times (F_c - F_p)$, and the passband frequency, F_p , equals `Bandwidth/2`.

StopbandFrequency — Stopband frequency in Hz

150000 (default) | positive scalar

Stopband frequency in Hz, specified as a positive scalar.

Dependencies

This property applies when you set the `StopbandFrequencySource` property to `Property`.

Data Types: `double`

PassbandRipple — Passband ripple of cascade response in dB

0.1 (default) | positive scalar

Passband ripple of cascade response in dB, specified as a positive scalar. When you set the `MinimumOrderDesign` property to `true`, the object designs the filters so that the cascade response meets the passband ripple that you specify in the `PassbandRipple` property.

Dependencies

This property applies when you set the `MinimumOrderDesign` property to `true`.

Data Types: `double`

StopbandAttenuation — Stopband attenuation of cascade response in dB

60 (default) | positive scalar

Stopband attenuation of cascade response in dB, specified as a positive scalar. When you set the `MinimumOrderDesign` property to `true`, the object designs the filters so that the cascade response meets the stopband attenuation that you specify in the `StopbandAttenuation` property.

Dependencies

This property applies when you set the `MinimumOrderDesign` property to `true`.

Data Types: `double`

Oscillator — Type of oscillator

`Sine wave` (default) | `NCO` | `Input port` | `None`

Specify the oscillator as one of `Sine wave` | `NCO` | `Input port` | `None`. When you set this property to `Sine wave`, the object frequency down converts the input signal using a complex exponential obtained from samples of a sinusoidal trigonometric function. When you set this property to `NCO`, the object performs frequency down conversion with a complex exponential obtained using a numerically controlled oscillator (NCO). When you set this property to `Input port`, the object performs frequency down conversion using the complex oscillator signal, `z`, that you pass as an input to the object. When you set this property to `None`, the mixer stage in the object is not present and the object acts as three stage cascaded decimator.

CenterFrequency — Center frequency of input signal in Hz

`14000000` (default) | positive scalar

Center frequency of input signal in Hz, specified as a positive scalar that is less than or equal to half the value of the `SampleRate` property. The object down converts the input signal from the passband center frequency you specify in the `CenterFrequency` property, to 0 Hz.

Dependencies

This property applies when you set the `Oscillator` property to `Sine wave` or `NCO`.

Data Types: `double`

NumAccumulatorBits — Number of NCO accumulator bits

`16` (default) | positive integer

Number of NCO accumulator bits, specified as a positive integer in the range [1 128].

Dependencies

This property applies when you set the `Oscillator` property to `NCO`.

Data Types: `double`

NumQuantizedAccumulatorBits — Number of NCO quantized accumulator bits

`12` (default) | positive integer

Number of NCO quantized accumulator bits, specified as an integer scalar in the range [1 128]. The value you specify in this property must be less than the value you specify in the `NumAccumulatorBits` property.

Dependencies

This property applies when you set the `Oscillator` property to `NCO`.

Data Types: `double`

Dither — Dither control for NCO`true (default) | false`

When you set this property to `true`, a number of dither bits specified in the `NumDitherBits` property will be used to apply dither to the NCO signal.

Dependencies

This property applies when you set the `Oscillator` property to `NCO`.

NumDitherBits — Number of NCO dither bits`4 (default) | positive integer`

Specify this property as an integer scalar smaller than the number of accumulator bits that you specify in the `NumAccumulatorBits` property.

Dependencies

This property applies when you set the `Oscillator` property to `NCO` and the `Dither` property to `true`.

Data Types: `double`

Fixed-Point Properties**FiltersInputDataType — Data type of input of each filter stage**`Same as input (default) | Custom`

Specify the data type at the input of the first, second, and third (if it has not been bypassed) filter stages as one of `Same as input` | `Custom`. The object casts the data at the input of each filter stage according to the value you set in this property.

CustomFiltersInputDataType — Fixed-point data type of input of each filter stage`numericType([], 16, 15) (default) | numeric type`

Specify the filters input fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`.

Dependencies

This property applies when you set the `FiltersInputDataType` property to `Custom`.

OutputDataType — Data type of output`Same as input (default) | Custom`

Specify the data type of output as `Same as input` | `Custom`.

CustomOutputDataType — Fixed-point data type of output`numericType([], 16, 15) (default) | numeric type`

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`.

Dependencies

This property applies when you set the `OutputDataType` property to `Custom`.

Usage

Syntax

```
y = dwnConv(x)
y = dwnConv(x,z)
```

Description

`y = dwnConv(x)` takes an input `x` and outputs a signal, `y` that is frequency downconverted and downsampled.

`y = dwnConv(x,z)` uses the complex input, `z`, as the oscillator signal used to frequency down convert input `x` when you set the `Oscillator` property to `Input port`.

Input Arguments

x — Data input

column vector | matrix

Data input, specified as a column vector or a matrix. The length of input `x` must be a multiple of the decimation factor. When the data type of `x` is `double` or `single` precision, the data type of `y` is the same as that of `x`. When the data type of `x` is of a fixed-point type, the data type of `y` is defined by the `OutputDataType` property.

The input can have multiple channels only if its data type is `double` or `single`. The input can be of data type `double`, `single`, signed integer, or signed fixed-point (`fi` objects).

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

z — Oscillator signal

column vector | matrix

Oscillator signal used to frequency down convert the input signal, specified as a column vector or a matrix. This input must be complex. The length of `z` must be equal to the length of `x`. `z` can be `double`, `single`, signed integer, or signed fixed-point (`fi` objects).

Dependencies

This input applies when you set the `Oscillator` property to `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

Output Arguments

y — Down converted and down sampled signal

column vector | matrix

Down converted and down sampled signal, returned as a column vector or a matrix. The length of `y` is equal to the length of `x` divided by the `DecimationFactor`. When the data type of `x` is `double` or `single` precision, the data type of `y` is the same as that of `x`. When the data type of `x` is of a fixed point type, the data type of `y` is defined by the `OutputDataType` property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.DigitalDownConverter`

<code>getDecimationFactors</code>	Get decimation factors of each filter stage of a digital down converter
<code>getFilterOrders</code>	Get orders of digital down converter or digital up converter filter cascade
<code>getFilters</code>	Get handles to digital down converter or digital up converter filter cascade objects
<code>fvtool</code>	Visualize frequency response of digital down converter or digital up converter filter cascade
<code>groupDelay</code>	Group delay of digital down converter or digital up converter filter cascade
<code>visualizeFilterStages</code>	Display response of digital down converter or digital up converter filter cascade
<code>generatehdl</code>	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Upconvert and Downconvert a Sine Wave Signal

Create a digital up converter object that up samples a 1 KHz sinusoidal signal by a factor of 20 and up converts it to 50 KHz. Create a digital down converter object that down converts the signal to 0 Hz and down samples it by a factor of 20.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Create a sine wave generator to obtain the 1 KHz sinusoidal signal with a sample rate of 6 KHz.

```
Fs = 6e3; % Sample rate
sine = dsp.SineWave('Frequency',1000,'SampleRate',...
Fs,'SamplesPerFrame',1024);
x = sine(); % generate signal
```

Create a `DigitalUpConverter` object. Use minimum order filter designs and set passband ripple to 0.2 dB and the stopband attenuation to 55 dB. Set the double sided signal bandwidth to 2 KHz.

```
upConv = dsp.DigitalUpConverter(...
'InterpolationFactor', 20,...
'SampleRate', Fs,...
'Bandwidth', 2e3,...
'StopbandAttenuation', 55,...
```

```
'PassbandRipple',0.2,...
'CenterFrequency',50e3);
```

Create a `DigitalDownConverter` object. Use minimum order filter designs and set the passband ripple to 0.2 dB and the stopband attenuation to 55 dB.

```
dwnConv = dsp.DigitalDownConverter(...
'DecimationFactor',20,...
'SampleRate', Fs*20,...
'Bandwidth', 3e3,...
'StopbandAttenuation', 55,...
'PassbandRipple',0.2,...
'CenterFrequency',50e3);
```

Create a spectrum estimator to visualize the signal spectrum before up converting, after up converting, and after down converting.

```
window = hamming(floor(length(x)/10));
figure; pwelch(x>window, [], [], Fs, 'centered')
title('Spectrum of baseband signal x')
```

Up convert the signal and visualize the spectrum

```
xUp = upConv(x); % up convert
window = hamming(floor(length(xUp)/10));
figure; pwelch(xUp>window, [], [], 20*Fs, 'centered');
title('Spectrum of up converted signal xUp')
```

Down convert the signal and visualize the spectrum

```
xDown = dwnConv(xUp); % down convert  
window = hamming(floor(length(xDown)/10));  
figure; pwelch(xDown,window,[],[],Fs,'centered')  
title('Spectrum of down converted signal xDown')
```

Visualize the response of the decimation filters

```
visualizeFilterStages(dwnConv)
```

Get Decimation Factors

Get decimation factors of each filter stage of the `dsp.DigitalDownConverter` System object™.

Create a `dsp.DigitalDownConverter` System object with the default settings. Using the `getDecimationFactors` function, obtain the decimation factors of each stage of the object.

```
dwnConv = dsp.DigitalDownConverter
```

```
dwnConv =  
dsp.DigitalDownConverter with properties:
```

```
    DecimationFactor: 100  
    MinimumOrderDesign: true  
        Bandwidth: 200000  
StopbandFrequencySource: 'Auto'  
    PassbandRipple: 0.1000  
StopbandAttenuation: 60  
    Oscillator: 'Sine wave'  
    CenterFrequency: 14000000  
    SampleRate: 30000000
```

```
Show all properties
```

```
M = getDecimationFactors(dwnConv) %#ok
```

```
M = 1×3
```

```
    25     2     2
```

The `DecimationFactor` property of the object is set to 100. The output `M` is by default a 1-by-3 vector, where each element in the vector is a factor of the overall decimation factor.

When you set the `DecimationFactor` to a 1-by-2 vector, the object bypasses the third filter stage and sets the decimation factor of the first and second filtering stages to the values in the first and second vector elements respectively.

```
dwnConv.DecimationFactor = [10 10]
```

```
dwnConv =
```

```
  dsp.DigitalDownConverter with properties:
```

```
    DecimationFactor: [10 10]
    MinimumOrderDesign: true
    Bandwidth: 200000
    StopbandFrequencySource: 'Auto'
    PassbandRipple: 0.1000
    StopbandAttenuation: 60
    Oscillator: 'Sine wave'
    CenterFrequency: 14000000
    SampleRate: 30000000
```

```
Show all properties
```

```
M = getDecimationFactors(dwnConv)
```

```
M = 1×2
```

```
    10    10
```

The output of the `getDecimationFactors` function is now a 1-by-2 vector.

More About

Fixed Point

The following block diagram represents the DDC arithmetic with signed fixed-point inputs.

- WL is the word length of the input, and FL is the fraction length of the input.
- The input of each filter is cast to the data type specified in the **FiltersInputDataType** and **CustomFiltersInputDataType** properties.
- The oscillator output is cast to a word length equal to the input word length plus one. The fraction length is equal to the input word length minus one.
- The scaling at the output of the CIC decimator consists of coarse- and fine-gain adjustments. The coarse gain is achieved using the `reinterpretcast` function on the CIC decimator output. The fine gain is achieved using full-precision multiplication.

The following figure depicts the coarse- and fine-gain operations.

If the normalization gain is G (where $0 < G \leq 1$), then:

- WL_{cic} is the word length of the CIC decimator output and FL_{cic} is the fraction length of the CIC decimator output
- $F1 = \text{abs}(\text{nextpow2}(G))$, indicating the part of G achieved using bit shifts (coarse gain)
- $F2 =$ fraction length specified by the **FiltersInputDataType** and **CustomFiltersInputDataType** properties

- `fg = fi((2^F1)*G, true, 16)`, indicating that the remaining gain cannot be achieved with a bit shift (fine gain)

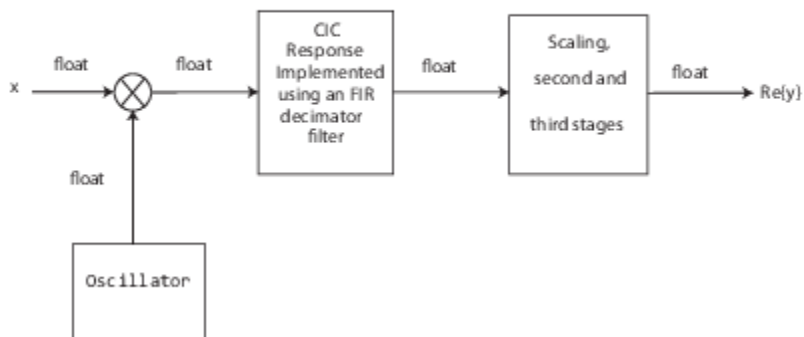

Algorithms

The object downconverts the input signal by multiplying it with a complex exponential with center frequency equal to the value in the `CenterFrequency` property. The object downsamples the frequency downconverted signal using a cascade of three decimation filters. In this case, the filter cascade consists of a CIC decimator, a CIC compensator, and a third FIR decimation stage. The following block diagram shows the architecture of the digital down converter.

The scaling section normalizes the CIC gain and the oscillator power. It may also contain a correction factor to achieve the desired ripple specification. When you set the **Oscillator** property to `InputPort`, the normalization factor does not include the oscillator power factor. Depending on the setting of the **DecimationFactor** property, you may be able to bypass the third filter stage. When the input data type is double or single, the object implements an N -section CIC decimation filter as an FIR filter with a response that corresponds to a cascade of N boxcar filters. A true CIC filter with actual comb and integrator sections is implemented when the input data is of a fixed-point type. The CIC filter is emulated with an FIR filter so that you can run simulations with floating-point data.

The following block diagram represents the DDC arithmetic with single or double-precision, floating-point inputs.

For details of fixed-point operation, see “Fixed Point” on page 4-395.

Package: dsp

Interpolate digital signal and translate it from baseband to IF band

Description

The `dsp.DigitalUpConverter` System object interpolates a digital signal, and translates it from baseband to intermediate frequency (IF) band.

To digitally upconvert the input signal:

- 1 Create the `dsp.DigitalUpConverter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
upConv = dsp.DigitalUpConverter
upConv = dsp.DigitalUpConverter(Name,Value)
```

Description

`upConv = dsp.DigitalUpConverter` returns a digital up-converter (DUC) System object, `upConv`.

`upConv = dsp.DigitalUpConverter(Name,Value)` returns a DUC System object with the specified property `Name` set to the specified value `Value`. You can specify one or more name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`. Enclose each property name in single quotes. For example, create an object that upsamples the input signal by a factor of 20, using a filter with the specified qualities.

```
upConv = dsp.DigitalUpConverter('InterpolationFactor',20,...
    'SampleRate',Fs,...
    'Bandwidth',2e3,...
    'StopbandAttenuation',55,...
    'PassbandRipple',0.2,...
    'CenterFrequency',50e3);
```

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

SampleRate — Sample rate of input signal

30000000 (default) | positive scalar

Set this property to a positive scalar value. The value of this property multiplied by the total interpolation factor must be greater than or equal to twice the value of the `CenterFrequency` property.

Data Types: `single` | `double`

InterpolationFactor — Interpolation factor

100 (default) | positive integer | vector of positive integers

Interpolation factor, specified as a positive integer, or a 1-by-2 or 1-by-3 vector of positive integers.

When you set this property to a scalar the object automatically chooses the interpolation factors for each of the three filtering stages.

When you set this property to a 1-by-2 vector, the object bypasses the first filter stage and sets the interpolation factor of the second and third filtering stages to the values in the first and second vector elements, respectively. Both elements of this `InterpolationFactor` vector must be greater than 1.

When you set this property to a 1-by-3 vector, the *i*th element of the vector specifies the interpolation factor for the *i*th filtering stage. The second and third elements of this `InterpolationFactor` vector must be greater than 1 and the first element must equal 1 or 2.

Data Types: `double`

MinimumOrderDesign — Minimum order filter design

`true` (default) | `false`

Minimum order filter design, specified as `true` or `false`.

When you set this property to `true`, the object designs filters with the minimum order that meets the passband ripple, stopband attenuation, passband frequency, and stopband frequency specifications that you set using the `PassbandRipple`, `StopbandAttenuation`, `Bandwidth`, `StopbandFrequencySource`, and `StopbandFrequency` properties.

When you set this property to `false`, the object designs filters with orders that you specify in the `FirstFilterOrder`, `SecondFilterOrder`, and `NumCICSections` properties. The filter designs meet the passband and stopband frequency specifications that you set using the `Bandwidth`, `StopbandFrequencySource`, and `StopbandFrequency` properties.

Data Types: `logical`

SecondFilterOrder — Order of CIC compensation filter stage

12 (default) | positive integer

Order of CIC compensation filter stage, specified as a positive integer.

Dependencies

To enable this property, set the `MinimumOrderDesign` property to `false`.

Data Types: double

FirstFilterOrder — Order of first filter stage

10 (default) | positive even integer

Order of first filter stage, specified as a positive even integer.

Dependencies

To enable this property, set the `MinimumOrderDesign` property to `false`. When you set the `InterpolationFactor` property to a 1-by-2 vector, the object ignores the `FirstFilterOrder` property, because the first filter stage is bypassed.

Data Types: double

NumCICSections — Number of sections of CIC interpolator

3 (default) | positive integer

Number of sections of CIC interpolator, specified as a positive integer.

Dependencies

To enable this property, set the `MinimumOrderDesign` property to `false`.

Data Types: double

Bandwidth — Two-sided bandwidth of input signal in Hz

200000 (default) | positive integer

Two-sided bandwidth of input signal in Hz, specified as a positive integer. The object sets the passband frequency of the cascade of filters to half of the value that you specify in this `Bandwidth` property.

Data Types: double

StopbandFrequencySource — Source of stopband frequency

Auto (default) | Property

Source of stopband frequency, specified as `Auto` or `Property`. When you set this property to `Auto`, the object places the cutoff frequency of the cascade filter response at approximately $F_c = \text{SampleRate}/2$ Hz and computes the stopband frequency as $F_{\text{stop}} = F_c + TW/2$. TW is the transition bandwidth of the cascade response, computed as $2 \times (F_c - F_p)$. F_p is the passband frequency computed by `Bandwidth/2`.

StopbandFrequency — Stopband frequency in Hz

150000 (default) | positive scalar

Stopband frequency in Hz, specified as a positive scalar.

Dependencies

To enable this property, set the `StopbandFrequencySource` property to `Property`.

Data Types: double

PassbandRipple — Passband ripple of cascade response in dB

0.1 (default) | positive scalar

Passband ripple of cascade response in dB, specified as a positive scalar. When you set the `MinimumOrderDesign` property to `true`, the object designs the filters so that the cascade response meets the passband ripple that you specify in this `PassbandRipple` property.

Dependencies

To enable this property, set the `MinimumOrderDesign` property to `true`.

Data Types: double

StopbandAttenuation — Stopband attenuation of cascade response in dB

60 (default) | positive scalar

Stopband attenuation of cascade response in dB, specified as a positive scalar. When you set the `MinimumOrderDesign` property to `true`, the object designs the filters so that the cascade response meets the stopband attenuation that you specify in this `StopbandAttenuation` property.

Dependencies

To enable this property, set the `MinimumOrderDesign` property to `true`.

Data Types: double

Oscillator — Type of oscillator

Sine wave (default) | NCO

Type of oscillator, specified as `Sine wave` or `NCO`. When you set this property to `Sine wave`, the object frequency-upconverts the output of the interpolation filter cascade by using a complex exponential signal obtained from samples of a sinusoidal trigonometric function. When you set this property to `NCO`, the object frequency-upconverts the output by using a complex exponential obtained from a numerically controlled oscillator (NCO).

CenterFrequency — Center frequency of output signal in Hz

14000000 (default) | positive scalar

Center frequency of output signal in Hz, specified as a positive scalar. The value of this property must be less than or equal to half the product of the `SampleRate` property and the total interpolation factor. The object up converts the input signal so that the output spectrum centers at this frequency you specify in the `CenterFrequency` property.

Data Types: double

NCO Properties**NumAccumulatorBits — Number of NCO accumulator bits**

16 (default) | integer in the range [1, 128]

Number of NCO accumulator bits, specified as an integer in the range [1, 128]. For more details, see the `dsp.NCO` System object.

Dependencies

To enable this property, set the `Oscillator` property to `NCO`.

Data Types: `double`

NumQuantizedAccumulatorBits — Number of NCO accumulator bits

12 (default) | integer in the range [1, 128]

Number of NCO accumulator bits, specified as an integer in the range [1, 128]. The value you specify for this property must be less than the value you specify in the `NumAccumulatorBits` property. For more details, see the `dsp.NCO` System object.

Dependencies

To enable this property, set the `Oscillator` property to `NCO`.

Data Types: `double`

Dither — Dither control for NCO

true (default) | false

Dither control for NCO, specified as `true` or `false`. When you set this property to `true`, the object uses the number of dither bits specified in the `NumDitherBits` property when applying dither to the NCO signal. When this property is `false`, the NCO does not apply dither to the signal. For more details, see the `dsp.NCO` System object.

Dependencies

To enable this property, set the `Oscillator` property to `NCO`.

Data Types: `logical`

NumDitherBits — Number of NCO dither bits

4 (default) | positive integer

Number of NCO dither bits, specified as a positive integer scalar smaller than the number of accumulator bits that you specify in the `NumAccumulatorBits` property. For more details, see the `dsp.NCO` System object.

Dependencies

To enable this property, set the `Oscillator` property to `NCO` and the `Dither` property to `true`.

Data Types: `double`

Fixed-Point Properties**FiltersOutputDataType — Data type at output of each filter stage**

Same as `input` (default) | `Custom`

Data type at the output of the first (if it has not been bypassed), second, and third filter stages, specified as `Same as input` or `Custom`. The object casts the data at the output of each filter stage according to the value you set in this property. For the CIC stage, the casting is done after the signal is scaled by the normalization factor.

CustomFiltersOutputDataType — Fixed-point data type at output of each filter stage

`numericType([],16,15)` (default) | `numericType` object

Fixed-point data type at output of each filter stage, specified as a scaled `numericType` object with the `Signedness` property set to `Auto`.

Dependencies

To enable this property, set the `FiltersOutputDataType` property to `Custom`.

OutputDataType — Data type of output

`Same as input` (default) | `Custom`

Data type of output, specified as `Same as input` or `Custom`.

CustomOutputDataType — Fixed-point data type of output

`numericType([],16,15)` (default) | `numericType` object

Fixed-point data type of output, specified as a scaled `numericType` object the `Signedness` property set to `Auto`.

Dependencies

To enable this property, set the `OutputDataType` property to `Custom`.

Usage**Syntax**

`y = upConv(x)`

Description

`y = upConv(x)` returns an upsampled and frequency-upconvertedred signal `y`, for a real or complex input column vector `x`.

Input Arguments**x — Input signal**

real or complex column vector

Input signal, specified as a column vector of real or complex values. The length of input `x` must be a multiple of the decimation factor. When the data type of `x` is `double` or `single`, the data type of `y` is the same as that of `x`. When the data type of `x` is of a fixed-point type, the data type of `y` is defined by the `OutputDataType` property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

Output Arguments

y — Upconverted and upsampled signal

column vector

Upconverted and upsampled signal, returned as a column vector. The length of **y** is equal to the length of **x** divided by the `InterpolationFactor`. When the data type of **x** is `double` or `single`, the data type of **y** is the same as that of **x**. When the data type of **x** is of a fixed-point type, the data type of **y** is defined by the `OutputDataType` property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.DigitalUpConverter

<code>getInterpolationFactors</code>	Get interpolation factors of each filter stage of digital upconverter
<code>getFilterOrders</code>	Get orders of digital down converter or digital up converter filter cascade
<code>getFilters</code>	Get handles to digital down converter or digital up converter filter cascade objects
<code>fvtool</code>	Visualize frequency response of digital down converter or digital up converter filter cascade
<code>groupDelay</code>	Group delay of digital down converter or digital up converter filter cascade
<code>visualizeFilterStages</code>	Display response of digital down converter or digital up converter filter cascade
<code>generatehdl</code>	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Upconvert Sine Wave Signal

Create a DUC System object™ that upsamples a 1-kHz sinusoidal signal by a factor of 20 and upconverts it to 50 kHz.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Create a sine wave generator to obtain the 1-kHz sinusoidal signal with a sample rate of 6 kHz.

```

Fs = 6e3; % Sample rate
sine = dsp.SineWave('Frequency',1000,...
    'SampleRate',Fs,...
    'SamplesPerFrame',1024);
x = sine(); % generate signal

```

Create a DUC System object. Use minimum order filter designs and set the passband ripple to 0.2 dB and stopband attenuation to 55 dB. Set the double-sided signal bandwidth to 2 kHz.

```

upConv = dsp.DigitalUpConverter(...
    'InterpolationFactor',20,...
    'SampleRate',Fs,...
    'Bandwidth',2e3,...
    'StopbandAttenuation',55,...
    'PassbandRipple',0.2,...
    'CenterFrequency',50e3);

```

Create a spectrum estimator to visualize the signal spectrum before and after upconverting.

```

window = hamming(floor(length(x)/10));
figure; pwelch(x>window, [], [], Fs, 'centered')
title('Spectrum of baseband signal x')

```

Upconvert the signal and visualize the spectrum.

```

xUp = upConv(x);
window = hamming(floor(length(xUp)/10));
figure;

```

```
pwelch(xUp>window,[],[],20*Fs,'centered')  
title('Spectrum of upconverted signal xUp')
```

Visualize the response of the interpolation filters.

```
visualizeFilterStages(upConv)
```

More About

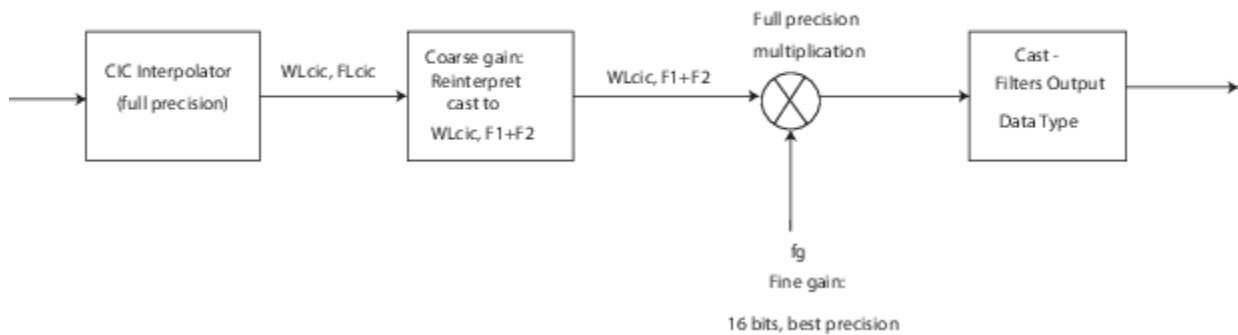

Fixed Point

The block diagram represents the DUC arithmetic with signed fixed-point inputs.

- WL is the word length of the input, and FL is the fraction length of the input.
- The output of each filter is cast to the data type specified in the `FiltersOutputDataType` and `CustomFiltersOutputDataType` properties. The casting of the CIC output occurs after the scaling factor is applied.
- The oscillator output is cast to a word length equal to the `FiltersOutputDataType` word length plus one. The fraction length is equal to the `FiltersOutputDataType` word length minus one.
- The scaling at the output of the CIC interpolator consists of coarse-gain and fine-gain adjustments. The coarse gain is achieved using the `reinterpretcast` function on the CIC interpolator output. The fine gain is achieved using full-precision multiplication.

The figure shows the coarse-gain and fine-gain operations.

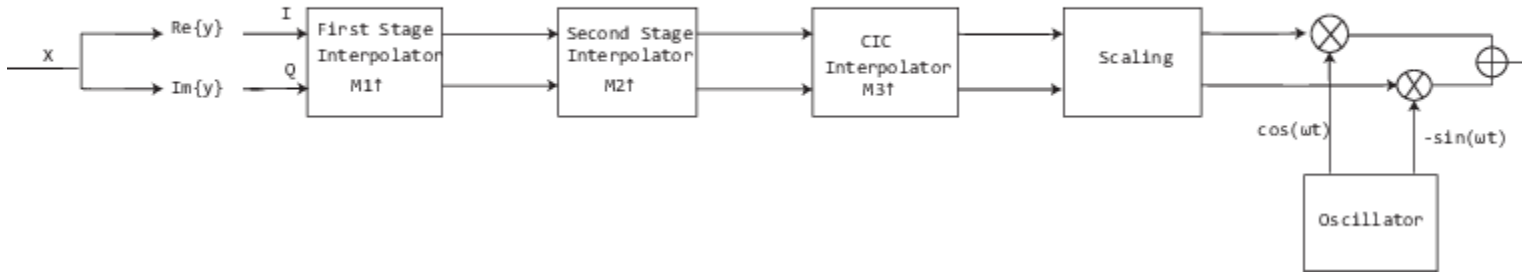

If the normalization gain is G (where $0 < G \leq 1$), then:

- WL_{cic} is the word length of the CIC interpolator output, and FL_{cic} is the fraction length of the CIC interpolator output.
- $F1 = \text{abs}(\text{nextpow2}(G))$, indicating the part of G achieved by using bit shifts (coarse gain).
- $F2$ is the fraction length specified by the `FiltersOutputDataType` and `CustomFiltersOutputDataType` properties.
- $fg = \text{fi}((2^{F1}) * G, \text{true}, 16)$, indicating that the remaining gain cannot be achieved with a bit shift (fine gain).

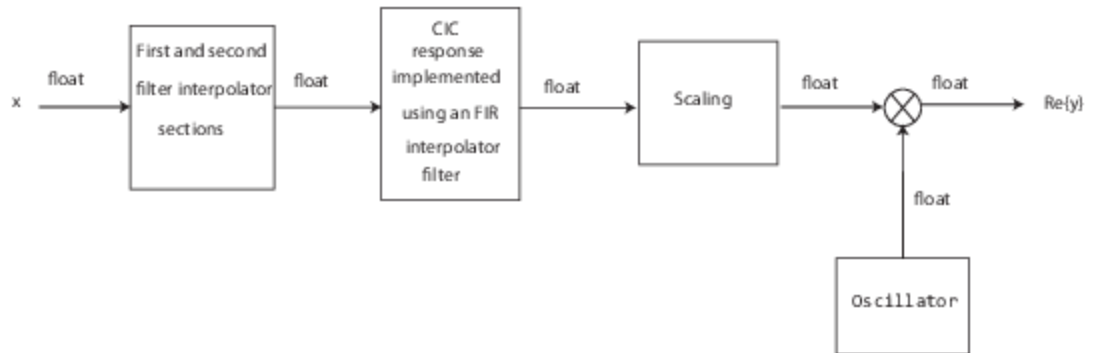

Algorithms

The object up samples the input signal using a cascade of three interpolation filters. This object frequency-upconverts the upsampled signal by multiplying it by a complex exponential with center frequency equal to the value in the `CenterFrequency` property. In this case, the filter cascade consists of a FIR interpolation stage, a second stage for CIC compensation, and a CIC interpolator. The block diagram shows the architecture of the digital up converter.

The scaling section normalizes the CIC gain and the oscillator power. It can also contain a correction factor to achieve the desired ripple specification. Depending on the setting of the `InterpolationFactor` property, you might be able to bypass the first filter stage. When the input data type is floating point, the object implements an N -section CIC interpolation filter as a FIR filter with a response that corresponds to a cascade of N boxcar filters. The CIC filter is emulated with a FIR filter so that you can run simulations with floating-point data. When the input data is fixed-point type, the object implements a true CIC filter with actual comb and integrator sections.

The diagram represents the DUC arithmetic with floating-point inputs.

For details of fixed-point operation, see “Fixed Point” on page 4-408.

Version History

Introduced in R2012a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

This object also supports SIMD code generation using Intel AVX2 technology when the input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This object supports HDL code generation with the Filter Design HDL Coder product. For workflows and limitations, see “Generate HDL Code for Filter System Objects” (Filter Design HDL Coder).

getInterpolationFactors

Package: dsp

Get interpolation factors of each filter stage of digital upconverter

Syntax

```
M = getInterpolationFactors(upConv)
```

Description

`M = getInterpolationFactors(upConv)` returns a vector, `M`, with the interpolation factors of each filter stage of digital up converter `upConv`. If the first filter stage is bypassed, then `M` is a 1-by-2 vector that contains the interpolation factors of the second and third stages. If the first filter stage is not bypassed, then `M` is a 1-by-3 vector containing the interpolation factors of the first, second, and third filter stages.

Examples

Get Interpolation Factors

Get interpolation factors of each filter stage of a `dsp.DigitalUpConverter` System object™.

Create a `dsp.DigitalUpConverter` System object with the default settings. Using the `getInterpolationFactors` function, obtain the interpolation factors of each stage of the object.

```
upConv = dsp.DigitalUpConverter

upConv =
  dsp.DigitalUpConverter with properties:

    InterpolationFactor: 100
    MinimumOrderDesign: true
    Bandwidth: 200000
    StopbandFrequencySource: 'Auto'
    PassbandRipple: 0.1000
    StopbandAttenuation: 60
    Oscillator: 'Sine wave'
    CenterFrequency: 14000000
    SampleRate: 300000
```

```
Show all properties
```

```
M = getInterpolationFactors(upConv) %#ok
```

```
M = 1×3
     2     2    25
```

The `InterpolationFactor` property of the object is set to 100. By default, the output `M` is a 1-by-3 vector, where each element in the vector is a factor of the overall interpolation factor.

When you set the `InterpolationFactor` property to a 1-by-2 vector, the object bypasses the first filter stage and sets the interpolation factor of the second and third filtering stages to the values in the first and second vector elements, respectively. The output of the `getInterpolationFactors` function is now a 1-by-2 vector.

```
upConv.InterpolationFactor = [10 10]
```

```
upConv =  
dsp.DigitalUpConverter with properties:
```

```
    InterpolationFactor: [10 10]  
    MinimumOrderDesign: true  
                Bandwidth: 200000  
StopbandFrequencySource: 'Auto'  
    PassbandRipple: 0.1000  
    StopbandAttenuation: 60  
                Oscillator: 'Sine wave'  
    CenterFrequency: 14000000  
    SampleRate: 300000
```

```
Show all properties
```

```
M = getInterpolationFactors(upConv)
```

```
M = 1×2  
    10    10
```

Input Arguments

upConv — Digital up converter

`dsp.DigitalUpConverter` System object

Digital up converter, specified as a `dsp.DigitalUpConverter` System object.

Output Arguments

M — Interpolation factors

vector

Interpolation factors of each filter stage, returned as a 1-by-2 or 1-by-3 vector. If the first filter stage is bypassed, then `M` is a 1-by-2 vector containing the interpolation factors of the second and third stages. If the first filter stage is not bypassed, then `M` is a 1-by-3 vector containing the interpolation factors of the first, second, and third filter stages.

dsp.DyadicAnalysisFilterBank

Package: dsp

Dyadic analysis filter bank

Description

The `dsp.DyadicAnalysisFilterBank` System object decomposes a broadband signal into a collection of subbands with smaller bandwidths and slower sample rates. The System object uses a series of highpass and lowpass FIR filters to provide approximate octave band frequency decompositions of the input. Each filter output is downsampled by a factor of two. With the appropriate analysis filters and tree structure, the dyadic analysis filter bank is a discrete wavelet transform (DWT) or discrete wavelet packet transform (DWPT).

To obtain approximate octave band frequency decompositions of the input:

- 1 Create the `dsp.DyadicAnalysisFilterBank` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
dydan = dsp.DyadicAnalysisFilterBank  
dydan = dsp.DyadicAnalysisFilterBank(Name, Value)
```

Description

`dydan = dsp.DyadicAnalysisFilterBank` constructs a dyadic analysis filter bank object, `dydan`, that computes the level-two discrete wavelet transform (DWT) of a column vector input. For a 2-D matrix input, the object transforms the columns using the Daubechies third-order extremal phase wavelet. The length of the input along the first dimension must be a multiple of 4.

`dydan = dsp.DyadicAnalysisFilterBank(Name, Value)` returns a dyadic analysis filter bank object, with each property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Filter — Type of filter used in subband decomposition

Custom (default) | Biorthogonal | Coiflets | Daubechies | Discrete Meyer | Haar | Reverse Biorthogonal | Symlets

Specify the type of filter used to determine the high and lowpass FIR filters in the dyadic analysis filter bank as Custom, Haar, Daubechies, Symlets, Coiflets, Biorthogonal, Reverse Biorthogonal, or Discrete Meyer. All property values except Custom require Wavelet Toolbox software. If the value of this property is Custom, the filter coefficients are specified by the values of the CustomLowpassFilter and CustomHighpassFilter properties. Otherwise, the dyadic analysis filter bank object uses the Wavelet Toolbox function `wfilters` to construct the filters. The following table lists supported wavelet filters and example syntax to construct the filters:

Filter	Example Setting	Syntax for Analysis Filters
Haar	N/A	<code>[Lo_D,Hi_D]=wfilters('haar');</code>
Daubechies extremal phase	<code>WaveletOrder=3;</code>	<code>[Lo_D,Hi_D]=wfilters('db3');</code>
Symlets (Daubechies least-asymmetric)	<code>WaveletOrder=4;</code>	<code>[Lo_D,Hi_D]=wfilters('sym4');</code>
Coiflets	<code>WaveletOrder=1;</code>	<code>[Lo_D,Hi_D]=wfilters('coif1');</code>
Biorthogonal	<code>FilterOrder='[3/1]';</code>	<code>[Lo_D,Hi_D,Lo_R,Hi_R]=... wfilters('bior3.1');</code>
Reverse biorthogonal	<code>FilterOrder='[3/1]';</code>	<code>[Lo_D,Hi_D,Lo_R,Hi_R]=... wfilters('rbior3.1');</code>
Discrete Meyer	N/A	<code>[Lo_D,Hi_D]=wfilters('dmey');</code>

CustomLowpassFilter — Lowpass FIR filter coefficients

`[0.0352 -0.0854 -0.1350 0.4599 0.8069 0.3327]` (default) | row vector

Specify a vector of lowpass FIR filter coefficients, in powers of z^{-1} . Use a half-band filter that passes the frequency band stopped by the filter specified in the CustomHighpassFilter property. The default specifies a Daubechies third-order extremal phase scaling (lowpass) filter.

Dependencies

This property applies when you set the Filter property to Custom.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

CustomHighpassFilter — Highpass FIR filter coefficients

`[-0.3327 0.8069 -0.4599 -0.1350 0.0854 0.0352]` (default) | row vector

Specify a vector of highpass FIR filter coefficients, in powers of z^{-1} . Use a half-band filter that passes the frequency band stopped by the filter specified in the CustomLowpassFilter property. The default specifies a Daubechies 3rd-order extremal phase wavelet (highpass) filter.

Dependencies

This property applies when you set the Filter property to Custom.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

WaveletOrder — Order for orthogonal wavelets

2 (default) | positive integer

Specify the order of the wavelet selected in the `Filter` property.

Dependencies

This property applies when you set the `Filter` property to an orthogonal wavelet: `Daubechies` (Daubechies extremal phase), `Symlets` (Daubechies least-asymmetric), or `Coiflets`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `fi`

FilterOrder — Analysis and synthesis filter orders for biorthogonal filters

1 / 1 (default) | 1 / 3 | 1 / 5 | 2 / 2 | 2 / 4 | 2 / 6 | 2 / 8 | 3 / 1 | 3 / 3 | 3 / 5 | 3 / 7 | 3 / 9 | 4 / 4 | 5 / 5 | 6 / 8

Specify the order of the analysis and synthesis filter orders for biorthogonal filter banks as 1 / 1, 1 / 3, 1 / 5, 2 / 2, 2 / 4, 2 / 6, 2 / 8, 3 / 1, 3 / 3, 3 / 5, 3 / 7, 3 / 9, 4 / 4, 5 / 5, or 6 / 8. Unlike orthogonal wavelets, biorthogonal wavelets require different filters for the analysis (decomposition) and synthesis (reconstruction) of an input. The first number indicates the order of the synthesis (reconstruction) filter. The second number indicates the order of the analysis (decomposition) filter.

Dependencies

This property applies when you set the `Filter` property to `Biorthogonal` or `ReverseBiorthogonal`.

Data Types: `char`

NumLevels — Number of filter bank levels used in analysis (decomposition)

2 (default) | integer greater than or equal to 1

Specify the number of filter bank analysis levels a positive integer greater than or equal to 1. A level- N asymmetric structure produces $N+1$ output subbands. A level- N symmetric structure produces 2^N output subbands. The size of the input along the first dimension must be a multiple of 2^N , where N is the number of levels.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

TreeStructure — Structure of filter bank

`Asymmetric` (default) | `Symmetric`

Specify the structure of the filter bank as `Asymmetric` or `Symmetric`. The asymmetric structure decomposes only the lowpass filter output from each level. The symmetric structure decomposes the highpass and lowpass filter outputs from each level. If the analysis filters are scaling (lowpass) and wavelet (highpass) filters, the asymmetric structure is the discrete wavelet transform, while the symmetric structure is the discrete wavelet packet transform.

When this property is `Symmetric`, the output has 2^N subbands each of size $M/2^N$. In this case, M is the length of the input along the first dimension and N is the value of the `NumLevels` property. When this property is `Asymmetric`, the output has $N+1$ subbands. The following equation gives the length of the output in the k th subband in the asymmetric case:

$$M_k = \begin{cases} \frac{M}{2^k} & 1 \leq k \leq N \\ \frac{M}{2^N} & k = N + 1 \end{cases}$$

Usage

Syntax

```
y = dydan(x)
```

Description

`y = dydan(x)` computes the subband decomposition of the input `x` and outputs the dyadic subband decomposition in `y` as a single concatenated column vector or matrix of coefficients.

Input Arguments

x — Data input

column vector | matrix

Data input, specified as a column vector or a matrix. Each column of `x` is treated as an independent input, and the number of rows of `x` must be a multiple of 2^N , where N is the number of levels specified by the `NumLevels` property.

Data Types: `single` | `double`

Output Arguments

y — Dyadic subband decomposition output

column vector | matrix

Dyadic subband decomposition output, returned as a column vector or a matrix. The elements of `y` are ordered with the highest-frequency subband first followed by subbands in decreasing frequency.

When `TreeStructure` is set to `Symmetric`, the output has 2^N subbands each of size $M/2^N$. In this case, M is the length of the input along the first dimension, and N is the value of the `NumLevels` property. When `TreeStructure` is set to `Asymmetric`, the output has $N+1$ subbands. The following equation gives the length of the output in the k th subband in the asymmetric case:

$$M_k = \begin{cases} \frac{M}{2^k} & 1 \leq k \leq N \\ \frac{M}{2^N} & k = N + 1 \end{cases}$$

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

`step` Run System object algorithm

release Release resources and allow changes to System object property values and input characteristics
 reset Reset internal states of System object

Examples

Filter Square Wave Using Dyadic Filter Banks

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Denoise square wave input using dyadic analysis and synthesis filter banks.

```
t = 0:.0001:.0511;
x= square(2*pi*30*t);
xn = x' + 0.08*randn(length(x),1);
dydanl = dsp.DyadicAnalysisFilterBank;
```

The filter coefficients correspond to a haar wavelet.

```
dydanl.CustomLowpassFilter = [1/sqrt(2) 1/sqrt(2)];
dydanl.CustomHighpassFilter = [-1/sqrt(2) 1/sqrt(2)];
dydsyn = dsp.DyadicSynthesisFilterBank;
dydsyn.CustomLowpassFilter = [1/sqrt(2) 1/sqrt(2)];
dydsyn.CustomHighpassFilter = [1/sqrt(2) -1/sqrt(2)];
C = dydanl(xn);
```

Subband outputs.

```
C1 = C(1:256); C2 = C(257:384); C3 = C(385:512);
```

Set higher frequency coefficients to zero to remove the noise.

```
x_den = dydsyn([zeros(length(C1),1);...
  zeros(length(C2),1);C3]);
```

Plot the original and denoised signals.

```
subplot(2,1,1), plot(xn); title('Original noisy Signal');
subplot(2,1,2), plot(x_den); title('Denoised Signal');
```

Subband Ordering For Asymmetric Tree Structure Using Dyadic Analysis Filter Bank

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Sampling frequency 1 kHz input length 1024

```
t = 0:.001:1.023;
x = square(2*pi*30*t);
xn = x' + 0.08*randn(length(x),1);
```

Default asymmetric structure with order 3 extremal phase wavelet

```
dydan = dsp.DyadicAnalysisFilterBank;
Y = dydan(xn);
```

Level 2 yields 3 subbands (two detail-one approximation) Nyquist frequency is 500 Hz

```
D1 = Y(1:512); % subband approx. [250, 500] Hz
D2 = Y(513:768); % subband approx. [125, 250] Hz
Approx = Y(769:1024); % subband approx. [0,125] Hz
```

Subband Ordering For Symmetric Tree Structure Using Dyadic Analysis Filter Bank

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Sampling frequency 1 kHz input length 1024.

```
t = 0:.001:1.023;
x = square(2*pi*30*t);
xn = x' + 0.08*randn(length(x),1);

dydan = dsp.DyadicAnalysisFilterBank('TreeStructure',...
'Symmetric');
Y = dydan(xn);
D1 = Y(1:256); % subband approx. [375,500] Hz
D2 = Y(257:512); % subband approx. [250,375] Hz
D3 = Y(513:768); % subband approx. [125,250] Hz
Approx = Y(769:1024); % subband approx. [0, 125] Hz
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Dyadic Analysis Filter Bank block reference page. The object properties correspond to the block parameters, except: The dyadic analysis filter bank object always concatenates the subbands into a single column vector for a column vector input, or into the columns of a matrix for a matrix input. This behavior corresponds to the block's behavior when you set the **Output** parameter to `Single port`.

dsp.DyadicSynthesisFilterBank

Package: dsp

Reconstruct signals from subbands

Description

The `dsp.DyadicSynthesisFilterBank` System object reconstructs signals from subbands with smaller bandwidths and lower sample rates. The filter bank uses a series of highpass and lowpass FIR filters to repeatedly reconstruct the signal.

To reconstruct signals from subbands with smaller bandwidths and lower sample rates:

- 1 Create the `dsp.DyadicSynthesisFilterBank` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
dydsyn = dsp.DyadicSynthesisFilterBank  
dydsyn = dsp.DyadicSynthesisFilterBank(Name, Value)
```

Description

`dydsyn = dsp.DyadicSynthesisFilterBank` returns a synthesis filter bank, `dydsyn`, that reconstructs a signal from its subbands with smaller bandwidths and smaller sample rates.

`dydsyn = dsp.DyadicSynthesisFilterBank(Name, Value)` returns a dyadic synthesis filter bank object, with each property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Filter — Type of filter used in filter bank

Custom (default) | Biorthogonal | Coiflets | Daubechies | Discrete Meyer | Haar | Reverse Biorthogonal | Symlets

Specify the type of filter used to determine the highpass and lowpass FIR filters in the filter bank as one of Custom, Haar, Daubechies, Symlets, Coiflets, Biorthogonal, Reverse

Biorthogonal, or Discrete Meyer. If you set this property to Custom, the CustomLowpassFilter and CustomHighpassFilter properties specify the filter coefficients. Otherwise, the object uses the wfilters function to construct the filters. Depending on the filter, the WaveletOrder or “FilterOrder” on page 4-0 property might apply. For a list of the supported wavelets, see the following table.

Filter	Sample Setting for Related Filter Specification Properties	Corresponding Wavelet Toolbox Function Syntax
Haar	None	wfilters('haar')
Daubechies	H.WaveletOrder = 4	wfilters('db4')
Symlets	H.WaveletOrder = 3	wfilters('sym3')
Coiflets	H.WaveletOrder = 1	wfilters('coif1')
Biorthogonal	H.FilterOrder = '[3/1]'	wfilters('bior3.1')
Reverse Biorthogonal	H.FilterOrder = '[3/1]'	wfilters('rbior3.1')
Discrete Meyer	None	wfilters('dmey')

In order to automatically design wavelet-based filters, install the Wavelet Toolbox product. Otherwise, use the CustomLowpassFilter and CustomHighpassFilter properties to specify lowpass and highpass FIR filters.

CustomLowpassFilter — Lowpass FIR filter coefficients

[0.3327 0.8069 0.4599 -0.1350 -0.0854 0.0352] (default) | row vector

Specify a vector of lowpass FIR filter coefficients, in descending powers of z . Use a half-band filter that passes the frequency band stopped by the filter specified in the CustomHighpassFilter property. To perfectly reconstruct a signal decomposed by the dsp.DyadicAnalysisFilterBank object, design the filters in the synthesis filter bank to perfectly reconstruct the outputs of the analysis filter bank. Otherwise, the reconstruction is imperfect. The default values of this property specify a perfect reconstruction filter for the default settings of the analysis filter bank (based on a third-order Daubechies wavelet).

Dependencies

This property applies when you set the Filter property to Custom.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

CustomHighpassFilter — Highpass FIR filter coefficients

[0.0352 0.0854 -0.1350 -0.4599 0.8069 -0.3327] (default) | row vector

Specify a vector of highpass FIR filter coefficients, in descending powers of z . Use a half-band filter that passes the frequency band stopped by the filter specified in the CustomLowpassFilter property. To perfectly reconstruct a signal decomposed by the dsp.DyadicAnalysisFilterBank object, design the filters in the synthesis filter bank to perfectly reconstruct the outputs of the analysis filter bank. Otherwise, the reconstruction is imperfect. The default values of this property specify a perfect reconstruction filter for the default settings of the analysis filter bank (based on a third-order Daubechies wavelet).

Dependencies

This property applies when you set the Filter property to Custom.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

WaveletOrder — Wavelet order

2 (default) | positive integer

Specify the order of the wavelet selected in the `Filter` property.

Dependencies

This property applies when you set the `Filter` property to an orthogonal wavelet: `Daubechies` (Daubechies extremal phase), `Symlets` (Daubechies least-asymmetric), or `Coiflets`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `fi`

FilterOrder — Wavelet order for synthesis filter stage

1 / 1 (default) | 1 / 3 | 1 / 5 | 2 / 2 | 2 / 4 | 2 / 6 | 2 / 8 | 3 / 1 | 3 / 3 | 3 / 5 | 3 / 7 | 3 / 9 | 4 / 4 | 5 / 5 | 6 / 8

Specify the order of the wavelet for the synthesis filter stage as:

- First order: `'[1/1]'`, `'[1/3]'`, or `'[1/5]'`.
- Second order: `'[2/2]'`, `'[2/4]'`, `'[2/6]'`, or `'[2/8]'`.
- Third order: `'[3/1]'`, `'[3/3]'`, `'[3/5]'`, `'[3/7]'`, or `'[3/9]'`.
- Fourth order: `'[4/4]'`.
- Fifth order: `'[5/5]'`.
- Sixth order: `'[6/8]'`.

Dependencies

This property applies when you set the `Filter` property to `Biorthogonal` or `ReverseBiorthogonal`.

Data Types: `char`

NumLevels — Number of filter bank levels

2 (default) | integer greater than or equal to 1

Specify the number of filter bank levels as a scalar integer. An N -level asymmetric structure has $N + 1$ input subbands, and an N -level symmetric structure has 2^N input subbands.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

TreeStructure — Structure of filter bank

`Asymmetric` (default) | `Symmetric`

Specify the structure of the filter bank as `Asymmetric` or `Symmetric`. In the asymmetric structure, the low-frequency subband input to each level is the output of the previous level, while the high-frequency subband input to each level is an input to the filter bank. In the symmetric structure, both the low- and high-frequency subband inputs to each level are outputs from the previous level.

Usage

Syntax

```
y = dydsyn(x)
```

Description

`y = dydsyn(x)` reconstructs the concatenated subband input `x` to output `y`. Each column of input `x` contains the subbands for an independent signal. Upper rows contain the high-frequency subbands, and lower rows contain the low-frequency subbands.

Input Arguments

x — Data input

column vector | matrix

Data input, specified as a column vector or a matrix. Each column of input `x` contains the subbands for an independent signal. Upper rows contain the high-frequency subbands, and lower rows contain the low-frequency subbands. The number of rows of `x` must be a multiple of 2^N , where N is the value of the `NumLevels` property.

Data Types: `single` | `double`

Output Arguments

y — Reconstructed signal

column vector | matrix

Reconstructed signal, returned as a column vector or a matrix.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the `System` object as the first input argument. For example, to release system resources of a `System` object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Filter Square Wave Using Dyadic Filter Banks

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Denoise square wave input using dyadic analysis and synthesis filter banks.

```
t = 0:.0001:.0511;
x= square(2*pi*30*t);
xn = x' + 0.08*randn(length(x),1);
dydanl = dsp.DyadicAnalysisFilterBank;
```

The filter coefficients correspond to a haar wavelet.

```
dydanl.CustomLowpassFilter = [1/sqrt(2) 1/sqrt(2)];
dydanl.CustomHighpassFilter = [-1/sqrt(2) 1/sqrt(2)];
dydsyn = dsp.DyadicSynthesisFilterBank;
dydsyn.CustomLowpassFilter = [1/sqrt(2) 1/sqrt(2)];
dydsyn.CustomHighpassFilter = [1/sqrt(2) -1/sqrt(2)];
C = dydanl(xn);
```

Subband outputs.

```
C1 = C(1:256); C2 = C(257:384); C3 = C(385:512);
```

Set higher frequency coefficients to zero to remove the noise.

```
x_den = dydsyn([zeros(length(C1),1);...
    zeros(length(C2),1);C3]);
```

Plot the original and denoised signals.

```
subplot(2,1,1), plot(xn); title('Original noisy Signal');
subplot(2,1,2), plot(x_den); title('Denoised Signal');
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Dyadic Synthesis Filter Bank block reference page. The object properties correspond to the block parameters, except: The object only receives data as a vector or matrix of concatenated subbands.

dsp.FarrowRateConverter

Package: dsp

Polynomial sample rate converter with arbitrary conversion factor

Description

The `dsp.FarrowRateConverter` System object implements a polynomial-fit sample rate conversion filter using a Farrow structure. You can use this object to convert the sample rate of a signal up or down by an arbitrary factor. This object supports fixed-point operations.

To convert the sample rate of a signal:

- 1 Create the `dsp.FarrowRateConverter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
frc = dsp.FarrowRateConverter
frc = dsp.FarrowRateConverter(Name,Value)
frc = dsp.FarrowRateConverter(fsIn,fsOut,tol,np)
```

Description

`frc = dsp.FarrowRateConverter` creates a polynomial filter-based sample rate converter System object, `frc`. For each channel of an input signal, `frc` converts the input sample rate to the output sample rate.

`frc = dsp.FarrowRateConverter(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes.

Example: `frc = dsp.FarrowRateConverter('Specification','Coefficients','Coefficients',[1 2; 3 4])` returns a filter that converts from 44.1 kHz to 48 kHz using custom coefficients that implement a 2nd-order polynomial filter.

`frc = dsp.FarrowRateConverter(fsIn,fsOut,tol,np)` returns a sample rate converter System object, `frc`, with `InputSampleRate` property set to `fsIn`, `OutputSampleRate` property set to `fsOut`, `OutputRateTolerance` property set to `tol`, and `PolynomialOrder` property set to `np`.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Filter Properties

InputSampleRate — Sample rate of input signal

44100 (default) | positive scalar in Hz

Sample rate of the input signal, specified as a positive scalar in Hz. The input sample rate must be greater than the bandwidth of interest.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

OutputSampleRate — Sample rate of output signal

48000 (default) | positive scalar in Hz

Sample rate of the output signal, specified as a positive scalar in Hz. The output sample rate can represent an upsample or downsample of the input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

OutputRateTolerance — Maximum tolerance for output sample rate

0 (default) | positive scalar

Maximum tolerance for the output sample rate, specified as a positive scalar from 0 through 0.5, inclusive.

The actual output sample rate varies but is within the specified range. For example, if `OutputRateTolerance` is specified as `0.01`, then the actual output sample rate is in the range `OutputSampleRate ± 1%`. This flexibility often enables a simpler filter design.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Specification — Method for specifying filter coefficients

'Polynomial order' (default) | 'Coefficients'

Method for specifying filter coefficients for the interpolator filter, specified as one of the following:

- 'Polynomial order' — Use the `PolynomialOrder` property to specify the order of the Lagrange-interpolation-filter polynomial. The object calculates coefficients that meet the rate and tolerance properties.
- 'Coefficients' — Use the `Coefficients` property to specify the polynomial coefficients directly.

PolynomialOrder — Order of Lagrange-interpolation-filter polynomial

3 (default) | positive integer less than or equal to 4

Order of the Lagrange-interpolation-filter polynomial, specified as a positive integer less than or equal to 4. The object calculates coefficients that meet the rate and tolerance properties.

Dependencies

This property applies only when you set Specification to 'Polynomial order'.

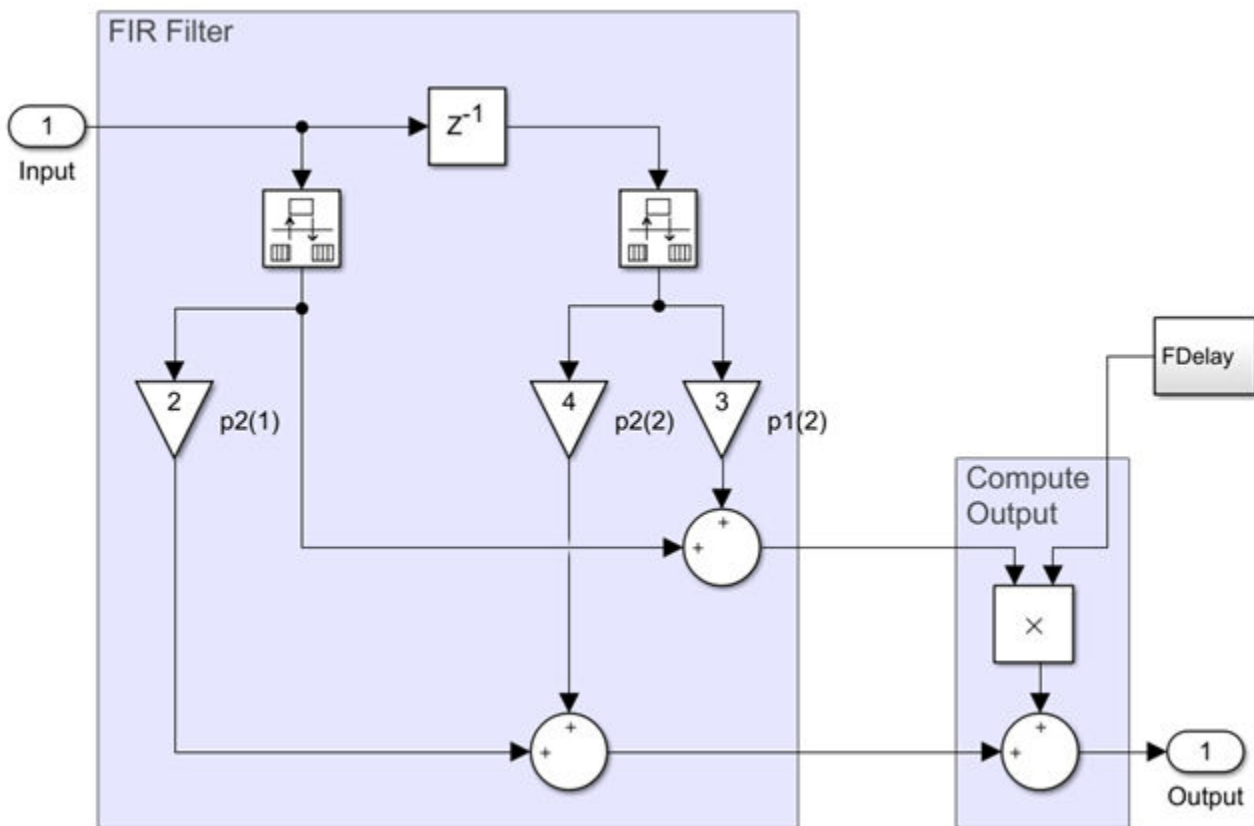

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Coefficients — Filter polynomial coefficients

[-1 1; 1 0] (default) | real-valued square matrix

Filter polynomial coefficients, specified as a real-valued M -by- M matrix, where M is the polynomial order.

The diagram shows the signal flow graph for a dsp.FarrowRateConverter object with coefficients set to [1 2; 3 4].

Each branch of the FIR filter corresponds to a row of the coefficient matrix.

Dependencies

This property applies only when you set Specification to 'Coefficients'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Fixed-Point Properties**RoundingMethod — Rounding method for fixed-point operations**

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Zero'

Rounding method for fixed-point operations, specified as a character vector. For more information on the rounding methods see “Rounding Modes”.

OverflowAction — Overflow action for fixed-point operations

'Wrap' (default) | 'Saturate'

Overflow action for fixed-point operations, specified as either 'Wrap' or 'Saturate'. For more details on the overflow actions, see “Overflow Handling”.

CoefficientsDataType — Data type of filter coefficients

numericType(1,16) (default) | numericType object

Data type of the filter coefficients, specified as a signed numericType object. The default data type is a signed, 16-bit numericType object. You must specify a numericType object without specific binary-point scaling. To maximize precision, the object determines the fraction length of this data type based on the coefficient values.

FractionalDelayDataType — Data type of fractional delay

numericType(0,8) (default) | numericType object

Data type of the fractional delay, specified as an unsigned numericType object. The default data type is an unsigned, 8-bit numericType object. You must specify a numericType object without specific binary-point scaling. To maximize precision, the object determines the fraction length of this data type based on the fractional delay values.

MultiplicandDataType — Data type of multiplicand

numericType(1,16,13) (default) | numericType object

Data type of the multiplicand, specified as a signed numericType object. The default data type is a signed 16-bit numericType object with 13-bit fraction length. You must specify a numericType object that has a specific binary point scaling.

OutputDataType — Data type of output

'Same word length as input' (default) | 'Same as accumulator' | numericType object

Data type of the output, specified as one of the following:

- 'Same word length as input' — Output word length and fraction length are the same as the input.
- 'Same as accumulator' — Output word length and fraction length are the same as the accumulator.
- numericType object — Signed fixed-point output data type. If you do not specify a fraction length, the object computes the fraction length based on the input range. The object preserves the dynamic range of the input.

Usage

Syntax

```
y = frc(x)
```

Description

`y = frc(x)` resamples input `x` to create output `y` according to the rate conversion defined by `frc`.

Input Arguments

x — Input signal

vector | matrix

Input signal, specified as a vector or a matrix. Each column of the input is treated as a separate channel.

Output Arguments

y — Resampled signal

vector | matrix

Resampled signal, returned as a vector or matrix.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.FarrowRateConverter`

<code>getPolynomialCoefficients</code>	Get polynomial coefficients of farrow rate conversion filter
<code>getActualOutputRate</code>	Get actual output rate
<code>getRateChangeFactors</code>	Get overall interpolation and decimation factors
<code>generatehdl</code>	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)

Filter Analysis

<code>freqz</code>	Frequency response of discrete-time filter System object
<code>fvtool</code>	Visualize frequency response of DSP filters
<code>info</code>	Information about filter System object
<code>cost</code>	Estimate cost of implementing filter System object

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Upsample an Audio Signal Using dsp.FarrowRateConverter

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Note: The `dsp.AudioFileWriter` System object™ is not supported in MATLAB Online.

Create a `dsp.FarrowRateConverter` System object™ to convert an audio signal from 44.1 kHz to 96 kHz. Set the polynomial order for the filter.

```
FsIn = 44.1e3;
FsOut = 96e3;
LagrangeOrder = 2; % 1 = linear interpolation
frc = dsp.FarrowRateConverter('InputSampleRate',FsIn,...
                             'OutputSampleRate',FsOut,...
                             'PolynomialOrder',LagrangeOrder);
ar = dsp.AudioFileReader('guitar10min.ogg','SamplesPerFrame',14700);
aw = dsp.AudioFileWriter('guitar10min_96kHz.wav','SampleRate',FsOut);
```

Check the resulting interpolation and decimation factors.

```
[interp,decim] = getRateChangeFactors(frc)
```

```
interp = 320
```

```
decim = 147
```

Display the polynomial that the object uses to fit the input samples.

```
coeffs = getPolynomialCoefficients(frc)
```

```
coeffs = 3x3
```

```
    0.5000    -0.5000         0
   -1.0000         0     1.0000
    0.5000     0.5000         0
```

Convert 100 frames of the audio signal. Write the result to a file.

```
for n = 1:1:100
    x = ar();
    y = frc(x);
    aw(y);
end
```

Release the `dsp.AudioFileWriter` System object™ to complete creation of the output file.

```
release(aw)
release(ar)
```

Plot the input and output signals. The latency of the Farrow rate converter introduces a delay in the output signal.

```
tx = (0:length(x)-1)./FsIn;
ty = (0:length(y)-1)./FsOut;
```

figure

```
subplot(2,1,1)
plot(tx,x(:,1),'.')
hold on
plot(ty,y(:,1),'--')
xlim([0 0.005])
xlabel('Time (s)')
legend('Input samples','Output samples','Location','best')
title('Channel 1')
subplot(2,1,2)
plot(tx,x(:,2),'.')
hold on
plot(ty,y(:,2),'--')
xlim([0 0.005])
xlabel('Time (s)')
legend('Input samples','Output samples','Location','best')
title('Channel 2')
```

Use the `outputDelay` function to determine this delay value. To account for this delay, shift the output by this delay value.

```
[delay,~,~] = outputDelay(frc,Fc=0)
```

```
delay = 4.5351e-05
```

```
tx = (0:length(x)-1)/FsIn;
ty = (0:length(y)-1)/FsOut;
```

```
figure
```

```
subplot(2,1,1)
plot(tx,x(:,1),'.')
hold on
plot(ty-delay,y(:,1),'--')
xlim([0 0.005])
xlabel('Time (s)')
legend('Input samples','Output samples','Location','best')
title('Channel 1')
subplot(2,1,2)
plot(tx,x(:,2),'.')
hold on
plot(ty-delay,y(:,2),'--')
xlim([0 0.005])
xlabel('Time (s)')
legend('Input samples','Output samples','Location','best')
title('Channel 2')
```

Zoom in to see the difference in sample rates.

```
figure
subplot(2,1,1)
plot(tx,x(:,1),Color=[0.6 0.6 0.6])
hold on
```

```

plot(tx,x(:,1),'ro')
plot(ty-delay,y(:,1),'b.')
xlim([0.0105 0.0107])
legend('Interpolated input','Input samples','Output samples')
title('Channel 1')
subplot(2,1,2)
plot(tx,x(:,2),Color=[0.6 0.6 0.6])
hold on
plot(tx,x(:,2),'ro')
plot(ty-delay,y(:,2),'b.')
xlim([0.0105 0.0107])
legend('Interpolated input','Input samples','Output samples')
title('Channel 2')

```

Reduce Input Size Restriction by Adjusting Tolerance

Create a `dsp.FarrowRateConverter` System object™ with 0% tolerance. The output rate is equal to the `OutputSampleRate` property. The input size must be a multiple of the decimation factor, M . In this case M is 320.

```

frc = dsp.FarrowRateConverter('InputSampleRate',96e3,...
    'OutputSampleRate',44.1e3);
FsOut = getActualOutputRate(frc)

FsOut = 44100

```

```
[L,M] = getRateChangeFactors(frc)
```

```
L = 147
```

```
M = 320
```

Allow a 1% tolerance on the output rate and observe the difference in decimation factor.

```
frc.OutputRateTolerance = 0.01;  
FsOut2 = getActualOutputRate(frc)
```

```
FsOut2 = 4.4308e+04
```

```
[L2,M2] = getRateChangeFactors(frc)
```

```
L2 = 6
```

```
M2 = 13
```

The decimation factor is now only 13. The lower the decimation factor, the more flexibility in input size. The output rate is within the range `OutputSampleRate ± 1%`.

Frequency Response of dsp.FarrowRateConverter

Create a `dsp.FarrowRateConverter` System object™ with default properties. Compute and display the frequency response.

```
frc = dsp.FarrowRateConverter;  
[h,f] = freqz(frc);  
plot(f,20*log10(abs(h)))  
ylabel('Filter Response')  
xlabel('Frequency (rad/s)')
```

Determine Computational Cost of `dsp.FarrowRateConverter`

Create a `dsp.FarrowRateConverter` System object™ with default values. Determine its computational cost: the number of coefficients, number of states, multiplications per input sample, and additions per input sample.

```
frc = dsp.FarrowRateConverter;
cst = cost(frc)

cst = struct with fields:
    NumCoefficients: 16
    NumStates: 3
    MultiplicationsPerInputSample: 13.0612
    AdditionsPerInputSample: 11.9728
```

Repeat the computation, allowing for a 10% tolerance in the output sample rate.

```
frc.OutputRateTolerance = 0.1;
ctl = cost(frc)

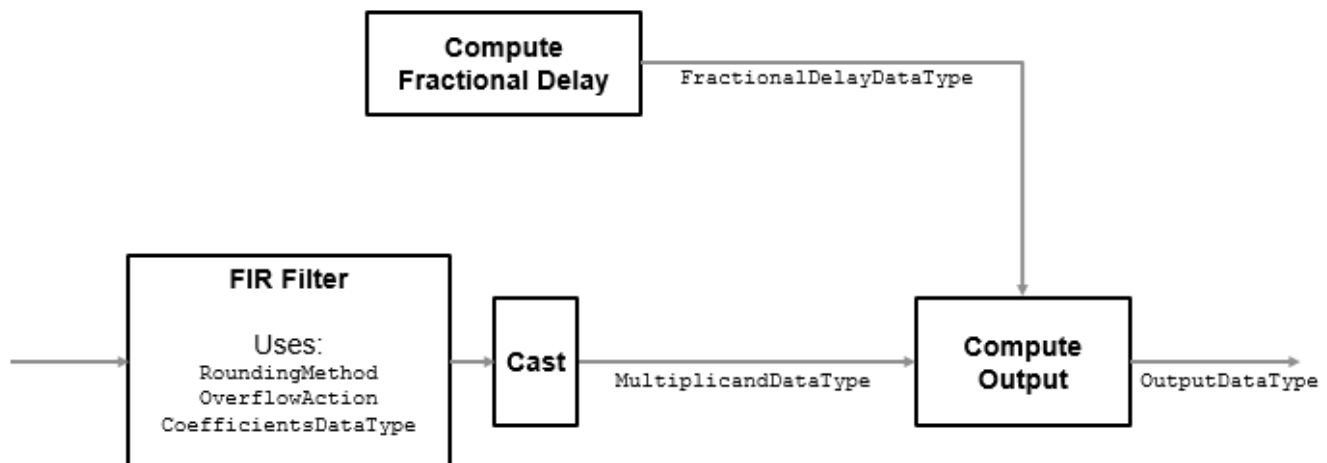

ctl = struct with fields:
    NumCoefficients: 16
    NumStates: 3
    MultiplicationsPerInputSample: 12
    AdditionsPerInputSample: 11
```

More About

Fixed Point

If the input is fixed point, it must be a signed integer or signed fixed point with a power-of-two slope and zero bias.

The diagram shows the data types that the `dsp.FarrowRateConverter` object uses for fixed-point signals and floating-point signals. You can specify these data types using the properties of the object, see “Fixed-Point Properties” on page 4-0 . If the input is floating point, all data types in filter are the same as the input data type, `single` or `double`.

If the input is fixed point, the FIR filter defines internal data types using the `RoundingMode`, `OverflowMode`, and `CoefficientsDataType` properties. The accumulators and products within the FIR filter use full precision data types. The object casts the output of the FIR filter to `MultiplicandDataType`.

Algorithms

Farrow filters implement piecewise polynomial interpolation using Horner’s rule to compute samples from the polynomial. The polynomial coefficients used to fit the input samples correspond to the Lagrange interpolation coefficients.

Once a polynomial is fitted to the input data, the value of the polynomial can be calculated at any point. Therefore, a polynomial filter enables interpolation at arbitrary locations between input samples.

You can use a polynomial of any order to fit to the existing samples. However, since large-order polynomials frequently oscillate, polynomials of order 1, 2, 3, or 4 are used in practice.

The algorithm computes interpolated values at the desired locations by varying only the fractional delay μ . This value is the interval between the previous input sample and the current output sample. All filter coefficients remain constant.

- The input samples are filtered using $M + 1$ FIR filters, where M is the polynomial order.
- The outputs of these filters are multiplied by the fractional delay, μ .
- The output is the sum of the multiplication results.

dsp.FastTransversalFilter

Package: dsp

Fast transversal least-squares FIR adaptive filter

Description

The `dsp.FastTransversalFilter` computes output, error and coefficients using a fast transversal least-squares FIR adaptive filter.

To implement the adaptive FIR filter object:

- 1 Create the `dsp.FastTransversalFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
ftf = dsp.FastTransversalFilter
ftf = dsp.FastTransversalFilter(len)
ftf = dsp.FastTransversalFilter(Name,Value)
```

Description

`ftf = dsp.FastTransversalFilter` returns a System object, `ftf`, which is a fast transversal, least-squares FIR adaptive filter. This System object computes the filtered output and the filter error for a given input and desired signal.

`ftf = dsp.FastTransversalFilter(len)` returns a `dsp.FastTrasversalFilter` System object with the `Length` property set to `len`.

`ftf = dsp.FastTransversalFilter(Name,Value)` returns a `dsp.FastTransversalFilter` System object with each specified property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Method — Method to calculate filter coefficients

'Fast transversal least-squares' (default) | 'Sliding-window fast transversal least-squares'

Specify the method used to calculate filter coefficients as either 'Fast transversal least-squares' or 'Sliding-window fast transversal least-squares'. For algorithms used to implement these two different methods, refer to [1]. This property is nontunable.

Length — Length of filter coefficients vector

32 (default) | positive integer

Specify the length of the FIR filter coefficients vector as a positive integer value.

Data Types: double

SlidingWindowBlockLength — Width of sliding window

32 (default) | positive integer

Specify the width of the sliding window as a positive integer value greater than or equal to the Length property value. The default value is the value of the Length property.

Dependencies

This property applies only if the Method property is set to 'Sliding-window fast transversal least-squares'.

Data Types: double

ForgettingFactor — Fast transversal filter forgetting factor

1 (default) | positive scalar

Specify the fast transversal filter forgetting factor as a positive scalar in the range (0,1]. Setting this value to 1 denotes infinite memory while filter adaptation. Setting this property value to 1 denotes infinite memory while adapting to find the new filter. For best results, set this property to a value that lies in the range $[1 - 0.5/L, 1]$, where L is the Length property value.

Tunable: Yes

Dependencies

This property applies only if the Method property is set to 'Fast transversal least-squares'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

InitialPredictionErrorPower — Initial prediction error power

10 (default) | positive scalar

Specify the initial value of the forward and backward prediction error vectors as a positive numeric scalar. This scalar should be sufficiently large to maintain stability and prevent an excessive number of Kalman gain rescues.

Tunable: Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

InitialConversionFactor — Initial conversion factor (gamma)

1 (default) | scalar | 2-element row vector

Specify the initial value of the conversion factor of the fast transversal filter.

The value of this property depends on the `Method` property. If `Method` is set to:

- 'Fast transversal least-squares' -- This property must be a positive numeric value less than or equal to 1
- 'Sliding-window fast transversal least-squares' -- This property must be a two-element numeric vector. The first element of this vector must lie within the range $[0, 1]$, and the second element must be less than or equal to -1. In this case, the default value is $[1, -1]$.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

InitialCoefficients — Initial coefficients of filter

0 (default) | `scalar` | `vector`

Specify the initial values of the FIR adaptive filter coefficients as a scalar or a vector of length equal to the value of the `Length` property.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

LockCoefficients — Locked status of coefficient updates

`false` (default) | `true`

Specify whether to lock the filter coefficient values. By default, the value of this property is `false`, and the object continuously updates the filter coefficients. If this property is set to `true`, the filter coefficients do not update, and their values remain the same.

Tunable: Yes

Usage

Syntax

```
[y,err] = ftf(x,d)
```

Description

`[y,err] = ftf(x,d)` filters the input `x`, using `d` as the desired signal, and returns the filtered output in `y` and the filter error in `err`. The System object estimates the filter weights needed to minimize the error between the output signal and the desired signal.

Input Arguments

x — Data input

`scalar` | `column vector`

The signal to be filtered by the fast transversal filter. The input, `x`, and the desired signal, `d` must have the same size and data type.

The data input can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double`

d — Desired signal

scalar | column vector

The fast transversal filter adapts its filter weights, `wts`, to minimize the error, `err`, and converge the input signal `x` to the desired signal `d` as closely as possible. You can access the current filter weights by calling `ftf.Coefficients`, where `ftf` is the fast transversal filter object.

The input and the desired signal must have the same size and data type.

The desired signal can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double`

Output Arguments

y — Filtered output

scalar | column vector

Filtered output, returned as a scalar or a column vector. The object adapts its filter weights to converge the input signal `x` to match the desired signal `d`. The filter outputs the converged signal.

Data Types: `single` | `double`

err — Difference between output and desired signal

scalar | column vector

Difference between the output signal `y` and the desired signal `d`, returned as a scalar or a column vector. The data type of `err` matches the data type of `y`. The objective of the adaptive filter is to minimize this error. The object adapts its weights to converge toward optimal filter weights that produce an output signal that matches closely with the desired signal.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.FastTransversalFilter`

`mseSim` Estimated mean squared error for adaptive filters

Common to All System Objects

`step` Run System object algorithm

release Release resources and allow changes to System object property values and input characteristics
 reset Reset internal states of System object

Examples

System Identification of FIR Filter Using Fast Transversal Filter

System identification is the process of identifying the coefficients of an unknown system using an adaptive filter. The general overview of the process is shown in “System Identification -- Using an Adaptive Filter to Identify an Unknown System”. The main components involved are:

- The adaptive filter algorithm.
- An unknown system or process to adapt to. In this example, the filter designed by `fir1` is the unknown system.
- Appropriate input data to exercise the adaptation process. In a generic system identification model, the desired signal $d(k)$ and the input signal $x(k)$ are used to exercise the adaptation process.

The objective of the adaptive filter is to minimize the error signal between the output of the adaptive filter $y(k)$ and the output of the unknown system (or the system to be identified) $d(k)$. Once the error signal is minimized, the adapted filter resembles the unknown system. The coefficients of both the filters match closely.

Note: If you are using R2016a or earlier, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Unknown System

Create a `dsp.FIRFilter` object that represents the system to be identified. Use the `fir1` function to design the filter coefficients. The designed filter is a 10th order lowpass digital filter with a cutoff frequency of 0.25.

```
filt = dsp.FIRFilter;
filt.Numerator = fir1(10,.25)

filt =
  dsp.FIRFilter with properties:
      Structure: 'Direct form'
  NumeratorSource: 'Property'
      Numerator: [-0.0039 1.7585e-18 0.0321 0.1167 0.2207 0.2687 ... ]
  InitialConditions: 0

  Show all properties
```

Pass the signal x to the FIR filter. The desired signal d is the sum of the output of the unknown system (FIR filter) and an additive noise signal n .

```
x = randn(1000,1);
d = filt(x) + 0.01*randn(1000,1);
```

Adaptive Filter

With the unknown filter designed and the desired signal in place, create and apply the fast transversal filter object to identify the unknown filter.

Create a `dsp.FastTransversalFilter` object to represent an adaptive filter. Set the length of the adaptive filter to 11 taps and a forgetting factor of 0.99.

```
ftf1 = dsp.FastTransversalFilter(11,...
    'ForgettingFactor',0.99)

ftf1 =
    dsp.FastTransversalFilter with properties:

                Method: 'Fast transversal least-squares'
                Length: 11
    ForgettingFactor: 0.9900
InitialPredictionErrorPower: 10
    InitialCoefficients: 0
    InitialConversionFactor: 1
    LockCoefficients: false
```

Pass the primary input signal `x` and the desired signal `d` to the fast transversal filter. Run the adaptive filter to determine the unknown system. The output `y` of the adaptive filter is the signal converged to the desired signal `d`, thereby minimizing the error `e` between the two signals.

```
[y,e] = ftf1(x,d);
w = ftf1.Coefficients

w = 1×11

    -0.0043    0.0016    0.0308    0.1171    0.2204    0.2677    0.2210    0.1181    0.0323    0.0000
```

Plot the results. The output signal matches the desired signal very closely making the error between the two close to zero.

```
subplot(2,1,1);
plot(1:1000,[d,y,e])
title('System Identification of an FIR filter');
legend('Desired','Output','Error');
xlabel('time index');
ylabel('signal value');
```

The coefficients of the FIR filter match very closely with the coefficients of the adapted filter, thereby confirming the convergence.

```
subplot(2,1,2);
stem([filt.Numerator; w].');
legend('Actual','Estimated');
xlabel('coefficient #');
ylabel('coefficient value');
```

dsp.FFT

Package: dsp

Discrete Fourier transform

Description

The `dsp.FFT` System object computes the discrete Fourier transform (DFT) of an input using fast Fourier transform (FFT). The object uses one or more of the following fast Fourier transform (FFT) algorithms depending on the complexity of the input and whether the output is in linear or bit-reversed order:

- Double-signal algorithm
- Half-length algorithm
- Radix-2 decimation-in-time (DIT) algorithm
- Radix-2 decimation-in-frequency (DIF) algorithm
- An algorithm chosen from FFTW [1], [2]

To compute the DFT of an input:

- 1** Create the `dsp.FFT` object and set its properties.
- 2** Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
ft = dsp.FFT  
ft = dsp.FFT(Name, Value)
```

Description

`ft = dsp.FFT` returns a FFT object that computes the discrete Fourier transform (DFT) of a real or complex N -D array input along the first dimension using fast Fourier transform (FFT).

`ft = dsp.FFT(Name, Value)` returns a FFT object with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

FFTImplementation — FFT implementation

Auto (default) | Radix-2 | FFTW

Specify the implementation used for the FFT as one of Auto, Radix-2, or FFTW. When you set this property to Radix-2, the FFT length must be a power of two.

BitReversedOutput — Order of output elements relative to input elements

false (default) | true

Designate order of output channel elements relative to order of input elements. Set this property to true to output the frequency indices in bit-reversed order. The default is false, which corresponds to a linear ordering of frequency indices.

Normalize — Divide butterfly outputs by two

false (default) | true

Set this property to true if the output of the FFT should be divided by the FFT length. This option is useful when you want the output of the FFT to stay in the same amplitude range as its input. This is particularly useful when working with fixed-point data types.

The default value of this property is false with no scaling.

FFTLengthSource — Source of FFT length

Auto (default) | Property

Specify how to determine the FFT length as Auto or Property. When you set this property to Auto, the FFT length equals the number of rows of the input signal.

FFTLength — FFT length

64 (default) | integer

FFT length, specified as an integer greater than or equal to 2.

This property must be a power of two if any of these conditions apply:

- The input is a fixed-point data type.
- The BitReversedOutput property is true.
- The FFTImplementation property is Radix-2.

Dependencies

This property applies when you set the FFTLengthSource property to Property.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

WrapInput — Boolean value of wrapping or truncating input

true (default) | false

Wrap input data when FFT length is shorter than input length. If this property is set to true, modulo-length data wrapping occurs before the FFT operation, given FFT length is shorter than the input length. If this property is set to false, truncation of the input data to the FFT length occurs before the FFT operation.

Fixed-Point Properties

RoundingMethod — Rounding method for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding method.

OverflowAction — Overflow action for fixed-point operations

Wrap (default) | Saturate

Specify the overflow action as Wrap or Saturate.

SineTableDataType — Sine table word and fraction lengths

Same word length as input (default) | Custom

Specify the sine table data type as Same word length as input or Custom.

CustomSineTableDataType — Sine table word and fraction lengths

numerictype([],16) (default) | numerictype

Specify the sine table fixed-point type as an unscaled numerictype object with a Signedness of Auto.

Dependencies

This property applies when you set the SineTableDataType property to Custom.

ProductDataType — Product word and fraction lengths

Full precision (default) | Same as input | Custom

Specify the product data type as Full precision, Same as input, or Custom.

CustomProductDataType — Product word and fraction lengths

numerictype([],32,30) (default) | numerictype

Specify the product fixed-point type as a scaled numerictype object with a Signedness of Auto.

Dependencies

This property applies when you set the ProductDataType property to Custom.

AccumulatorDataType — Accumulator word and fraction lengths

Full precision (default) | Same as input | Same as product | Custom

Specify the accumulator data type as Full precision, Same as input, Same as product, or Custom.

CustomAccumulatorDataType — Accumulator word and fraction lengths

numerictype([],32,30) (default) | numerictype

Specify the accumulator fixed-point type as a scaled numerictype object with a Signedness of Auto.

Dependencies

This property applies when you set the AccumulatorDataType property to Custom.

OutputDataType — Output word and fraction lengths

Full precision (default) | Same as input | Custom

Specify the output data type as one of Full precision, Same as input, Custom.

CustomOutputDataType — Output word and fraction lengths

numericType([],16,15) (default) | numericType

Specify the output fixed-point type as a scaled numericType object with a Signedness of Auto.

Dependencies

This property applies when you set the “OutputDataType” on page 4-0 property to Custom.

Usage**Syntax**

$$y = ft(x)$$
Description

$y = ft(x)$ computes the DFT, y , of the input x along the first dimension of x .

Input Arguments**x — Time-domain input signal**vector | matrix | N -D array

Time-domain input signal, specified as a vector, matrix, or N -D array.

When the FFTLengthSource property is set to 'Auto', the length of x along the first dimension must be a positive integer power of two. This length is also the FFT length. When the FFTLengthSource property is 'Property', the value you specify in FFTLength property must be a positive integer power of two.

Variable-size input signals are only supported when the FFTLengthSource property is set to 'Auto'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

Output Arguments**y — Discrete Fourier transform of input signal**vector | matrix | N -D array

Discrete Fourier transform of input signal, returned as a vector, matrix, or an N -D array. When FFTLengthSource property is set to 'Auto', the FFT length is same as the number of rows in the input signal. When FFTLengthSource property is set to 'Property', the FFT length is specified through the FFTLength property.

To support non-power-of-two transform lengths with variable-size data, set the FFTImplementation property to 'FFTW'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Single-Sided Amplitude Spectrum of Signal

Find frequency components of a signal in additive noise.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
Fs = 800; L = 1000;  
t = (0:L-1)/Fs;  
x = sin(2*pi*250*t) + 0.75*cos(2*pi*340*t);  
y = x + .5*randn(size(x)); % noisy signal  
ft = dsp.FFT('FFTLengthSource','Property', ...  
            'FFTLength',1024);  
Y = ft(y);
```

Plot the single-sided amplitude spectrum

```
plot(Fs/2*linspace(0,1,512), 2*abs(Y(1:512))/1024)  
title('Single-sided amplitude spectrum of noisy signal y(t)')  
xlabel('Frequency (Hz)'); ylabel('|Y(f)|')
```

Construct a Sinusoidal Signal Using High Energy FFT Coefficients

Compute the FFT of a noisy sinusoidal input signal. The energy of the signal is stored as the magnitude square of the FFT coefficients. Determine the FFT coefficients which occupy 99.99% of the signal energy and reconstruct the time-domain signal by taking the IFFT of these coefficients. Compare the reconstructed signal with the original signal.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj(x))`.

Consider a time-domain signal $x[n]$, which is defined over the finite time interval $0 \leq n \leq N - 1$. The energy of the signal $x[n]$ is given by the following equation:

$$E_N = \sum_{n=0}^{N-1} |x[n]|^2$$

FFT coefficients, $X[k]$, are considered signal values in the frequency domain. The energy of the signal $x[n]$ in the frequency-domain is therefore the sum of the squares of the magnitude of the FFT coefficients:

$$E_N = \frac{1}{N} \sum_{k=0}^{N-1} |X[k]|^2$$

According to Parseval's theorem, the total energy of the signal in time or frequency-domain is the same.

$$E_N = \sum_{n=0}^{N-1} |x[n]|^2 = \frac{1}{N} \sum_{k=0}^{N-1} |X[k]|^2$$

Initialization

Initialize a `dsp.SineWave` System object to generate a sine wave sampled at 44.1 kHz and has a frequency of 1000 Hz. Construct a `dsp.FFT` and `dsp.IFFT` objects to compute the FFT and the IFFT of the input signal.

The `'FFTLengthSource'` property of each of these transform objects is set to `'Auto'`. The FFT length is hence considered as the input frame size. The input frame size in this example is 1020, which is not a power of 2, so select the `'FFTImplementation'` as `'FFTW'`.

```
L = 1020;
Sineobject = dsp.SineWave('SamplesPerFrame',L,...
    'PhaseOffset',10,...
    'SampleRate',44100,...
    'Frequency',1000);
ft = dsp.FFT('FFTImplementation','FFTW');
ift = dsp.IFFT('FFTImplementation','FFTW',...
    'ConjugateSymmetricInput',true);
rng(1);
```

Streaming

Stream in the noisy input signal. Compute the FFT of each frame and determine the coefficients that constitute 99.99% energy of the signal. Take IFFT of these coefficients to reconstruct the time-domain signal.

```
numIter = 1000;
for Iter = 1:numIter
    Sinewave1 = Sineobject();
    Input = Sinewave1 + 0.01*randn(size(Sinewave1));
    FFTCoeff = ft(Input);
    FFTCoeffMagSq = abs(FFTCoeff).^2;

    EnergyFreqDomain = (1/L)*sum(FFTCoeffMagSq);
    [FFTCoeffSorted, ind] = sort((1/L)*FFTCoeffMagSq), ...
        1, 'descend');

    CumFFTCoeffs = cumsum(FFTCoeffSorted);
    EnergyPercent = (CumFFTCoeffs/EnergyFreqDomain)*100;
    Vec = find(EnergyPercent > 99.99);
    FFTCoeffsModified = zeros(L,1);
    FFTCoeffsModified(ind(1:Vec(1))) = FFTCoeff(ind(1:Vec(1)));
    ReonstrSignal = ift(FFTCoeffsModified);
end
```

99.99% of the signal energy can be represented by the number of FFT coefficients given by `Vec(1)`:

```
Vec(1)
ans = 296
```

The signal is reconstructed efficiently using these coefficients. If you compare the last frame of the reconstructed signal with the original time-domain signal, you can see that the difference is very small and the plots match closely.

```
max(abs(Input-ReconstrSignal))
```

```
ans = 0.0431
```

```
plot(Input, '*');
hold on;
plot(ReconstrSignal, 'o');
hold off;
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the FFT block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- "System Objects in MATLAB Code Generation" (MATLAB Coder).
- When the following conditions apply, the executable generated from this System object relies on prebuilt dynamic library files (.dll files) included with MATLAB:
 - `FFTImplementation` is set to 'FFTW'.
 - `FFTImplementation` is set to 'Auto', `FFTLengthSource` is set to 'Property', and `FFTLength` is not a power of two.

Use the `packNGo` function to package the code generated from this System object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see "How To Run a Generated Executable Outside MATLAB".

- When the FFT length is a power of two, you can generate standalone C and C++ code from this System object.

Objects

`dsp.IFFT`

dsp.FilterCascade

Package: dsp

Create cascade of filter System objects

Description

The `dsp.FilterCascade` object creates a multistage System object that enables cascading of filter System objects, delays, and scalar gains. This object operates similar to the `cascade` function. However, the `cascade` function does not support delay as a filter stage.

You can pass the `dsp.FilterCascade` System object as a stage to another `dsp.FilterCascade` System object. You can also pass `dsp.FilterCascade` System object as an input to the `cascade` function.

When you call the object, the size, data type, and complexity of the input signal must be supported by all of the stages in the filter cascade. This object supports variable-size signals if the filter stages within the object support variable-size signals.

To filter a signal with a cascade of filters:

- 1 Create the `dsp.FilterCascade` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Alternatively, you can generate a MATLAB function from the filter cascade object, and call that function to filter a signal. The generated function supports C/C++ code generation. For more details, see the `generateFilteringCode` function.

Creation

Syntax

```
FC = dsp.FilterCascade
FC = dsp.FilterCascade(filt1, filt2, ..., filtn)
```

Description

`FC = dsp.FilterCascade` returns a System object, `FC` that has a single stage, a `dsp.FIRFilter` System object with default properties.

`FC = dsp.FilterCascade(filt1, filt2, ..., filtn)` returns a multistage System object, `FC`, with the first stage set to `filt1`, the second stage set to `filt2`, and so on. Each stage can be a filter System object, a `dsp.FilterCascade` System object, a `dsp.Delay` System object, or a scalar gain value.

For example, create a filter cascade that includes a lowpass filter, a highpass filter, and a gain stage.

```
lpFilt = dsp.LowpassFilter('StopbandFrequency',15000,...
                           'PassbandFrequency',12000);
hpFilt = dsp.HighpassFilter('StopbandFrequency',5000,...
                            'PassbandFrequency',8000);
gain = 2;
bpFilt = dsp.FilterCascade(lpFilt, hpFilt, 2);
```

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Stage*i* — Filter stage

`dsp.FIRFilter` System object with default properties (default) | filter System object | delay System object | scalar gain value

Filter stage, specified as a filter System object, delay System object, or a scalar gain value. To see which System objects you can add to a filter cascade, use:

```
dsp.FilterCascade.helpSupportedSystemObjects
```

You can modify an existing stage by modifying the associated property. For example:

```
FC = dsp.FilterCascade(dsp.FIRFilter,5)
```

```
FC =
```

```
    dsp.FilterCascade with properties:
```

```
    Stage1: [1×1 dsp.FIRFilter]
    Stage2: 5
```

```
K>> FC.Stage2 = dsp.FIRDecimator
```

```
FC =
```

```
    dsp.FilterCascade with properties:
```

```
    Stage1: [1×1 dsp.FIRFilter]
    Stage2: [1×1 dsp.FIRDecimator]
```

To change the number of stages in a cascade, use the `addStage` and `removeStage` functions.

Usage

Syntax

```
y = FC(x)
```

Description

$y = FC(x)$ filters input signal x by using the filter cascade defined in FC and returns filtered output y . The size, data type, and complexity of the input signal must be supported by all of the stages in the filter cascade. This object supports variable-size signals if the filter stages within the object support variable-size signals.

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix. When the input is a matrix, each column of the matrix represents an independent data channel.

Data Types: `single` | `double`

Output Arguments

y — Filtered output data

vector | matrix

Filtered output data, returned as a vector or a matrix. The size, data type, and complexity of the output signal matches that of the input signal.

Data Types: `double` | `single`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.FilterCascade

<code>addStage</code>	Add filter stage to cascade
<code>generateFilteringCode</code>	Generate MATLAB code for a filter cascade
<code>getNumStages</code>	Get number of stages in filter cascade
<code>releaseStages</code>	Release locked state of all stages in cascade
<code>removeStage</code>	Remove stage from filter cascade

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Filter Signal Using Cascaded Lowpass and Highpass Filters

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Design a bandpass filter by cascading:

- A highpass filter with a stopband frequency of 5000 Hz and a passband frequency of 8000 Hz
- A lowpass filter with a passband frequency of 12,000 Hz and a stopband frequency of 15,000 Hz

Visualize the frequency response using `fvtool`.

```
lpFilt = dsp.LowpassFilter('StopbandFrequency',15000,...
    'PassbandFrequency',12000);
hpFilt = dsp.HighpassFilter('StopbandFrequency',5000,...
    'PassbandFrequency',8000);

bpFilt = dsp.FilterCascade(lpFilt,hpFilt);

hvft = fvtool(bpFilt);
legend(hvft,'Bandpass filter');
```

Pass a noisy sine wave as the input to the bandpass filter. The input is a sum of three sine waves with frequencies at 3 kHz, 10 kHz, and 15 kHz. The sampling frequency is 48 kHz. View the input and the filtered output on a spectrum analyzer.

The tones at 3 kHz and 15 kHz are attenuated, and the tone at 10 kHz is preserved by the bandpass filter.

```
Sine1 = dsp.SineWave('Frequency',3e3,...
    'SampleRate',48e3,...
    'SamplesPerFrame',6000);
Sine2 = dsp.SineWave('Frequency',10e3,...
    'SampleRate',48e3,...
    'SamplesPerFrame',6000);
Sine3 = dsp.SineWave('Frequency',15e3,...
    'SampleRate',48e3,...
    'SamplesPerFrame',6000);

SpecAna = spectrumAnalyzer(...
    'PlotAsTwoSidedSpectrum',false,...
    'SampleRate',Sine1.SampleRate, ...
    'ShowLegend',true, ...
    'YLimits',[-160,60]);

SpecAna.ChannelNames = {'Original noisy signal','Filtered signal'};

for i = 1:1000
    x = Sine1()+Sine2()+Sine3()+0.1.*randn(Sine1.SamplesPerFrame,1);
    y = bpFilt(x);
    SpecAna(x,y);
end
release(SpecAna)
```

Design Compensation Decimator for CIC Decimator

Create a CIC decimator. Cascade the decimator with a gain.

```
cicdecim = dsp.CICDecimator(...
    'DecimationFactor',6,...
    'NumSections',6);
decimcasc = dsp.FilterCascade(cicdecim,...
    1/gain(cicdecim));
```

Design a compensation decimator and cascade it with the filter cascade, `decimcasc`. This operation nests a `dsp.FilterCascade` object as a stage in another filter cascade. The CIC compensation decimator has an inherent gain, `gain(cicdecim)`. The factor of `1/gain(cicdecim)` from the decimation filter cascade, `decimcasc`, compensates for the compensation filter gain.

```
% Sample rate of input of compensation decimator
fs = 16e3;
% Passband frequency
fPass = 4e3;
% Stopband frequency
fStop = 4.5e3;
ciccomp = dsp.CICCompensationDecimator(cicdecim,...
    'DecimationFactor',2, ...
    'PassbandFrequency',fPass, ...
```

```

    'StopbandFrequency', fStop, ...
    'SampleRate', fs);
filtchain = dsp.FilterCascade(decimcasc, ciccomp);

```

Visualize the frequency response of the cascade of cascades.

```

f = fvtool(decimcasc, ciccomp, ...
    filtchain, 'Fs', [fs*6, fs, fs*6], ...
    'Arithmetic', 'fixed');
legend(f, 'CIC Decimator', ...
    'CIC Compensation Decimator', ...
    'Overall Response');

```

Generate Code to Filter Using Cascade

Design a two-stage decimator with a 100-Hz transition width, a 2-kHz sampling frequency, and 60-dB attenuation in the stopband. The decimator needs to downsample by a factor of 4.

```

filtCasc = designMultistageDecimator(4,2000,100,60)

```

```

filtCasc =
    dsp.FilterCascade with properties:
        Stage1: [1x1 dsp.FIRDecimator]
        Stage2: [1x1 dsp.FIRDecimator]

```

```
CloneStages: false
```

Verify your design by using `fvtool`.

```
info(filtCasc)
```

```
ans =

```

Generate code to filter data using this design. You cannot generate C/C++ code from the `dsp.FilterCascade` object directly, but you can generate C/C++ code from the generated function. The function defines the filter stages and calls them in sequence. The function is saved in a file called `myDecimator.m` in the current directory.

```
generateFilteringCode(filtCasc, 'myDecimator');
```

The `myDecimator` function creates a filter cascade and calls each stage object in turn.

```
type myDecimator
```

```
function y = myDecimator(x)
%MYDECIMATOR Construct filter cascade and process each stage

% MATLAB Code
% Generated by MATLAB(R) 9.13 and DSP System Toolbox 9.15.
% Generated on: 31-Aug-2022 04:44:53

% To generate C/C++ code from this function use the codegen command.
% Type 'help codegen' for more information.
%#codegen

%% Process  
y1 = filter1( x );  
y  = filter2( y1);
```

Version History

Introduced in R2014b

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- You cannot generate code directly from `dsp.FilterCascade`. If the filters in each stage support code generation, you can generate C/C++ code from the function returned by `generateFilteringCode`.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This object supports HDL code generation with the Filter Design HDL Coder product. For workflows and limitations, see “Generate HDL Code for Filter System Objects” (Filter Design HDL Coder).

Functions

`cascade`

addStage

Package: dsp

Add filter stage to cascade

Syntax

```
addStage(FC,newFilt)
addStage(FC,newFilt,stageId)
```

Description

`addStage(FC,newFilt)` adds a filter stage represented by the `newFilt` System object as the final stage of the `dsp.FilterCascade` System object, `FC`. To see which System objects you can add to a filter cascade, use:

```
dsp.FilterCascade.helpSupportedSystemObjects
```

`addStage(FC,newFilt,stageId)` adds `newFilt` at stage position `stageId` of the filter cascade `FC`. All existing filters from `stageId` to the end of the cascade are shifted up in the cascade when `newFilt` is added.

Examples

Add Filter Stage to Filter Cascade

Call `addStage` with only the System object™ arguments,. The function adds the new filter stage as the final stage in the filter cascade.

```
FC = dsp.FilterCascade
```

```
FC =
  dsp.FilterCascade with properties:
      Stage1: [1x1 dsp.FIRFilter]
      CloneStages: true
```

```
addStage(FC,dsp.IIRFilter)
FC
```

```
FC =
  dsp.FilterCascade with properties:
      Stage1: [1x1 dsp.FIRFilter]
      Stage2: [1x1 dsp.IIRFilter]
      CloneStages: true
```

Call `addStage` with an index argument. The function adds the new filter stage at the specified index. This example creates a filter cascade with three stages, and then adds a filter as the second stage of the cascade.

```
FC = dsp.FilterCascade(dsp.CICDecimator,dsp.FIRDecimator,dsp.FIRFilter)
```

```
FC =  
  dsp.FilterCascade with properties:  
      Stage1: [1x1 dsp.CICDecimator]  
      Stage2: [1x1 dsp.FIRDecimator]  
      Stage3: [1x1 dsp.FIRFilter]  
  CloneStages: true
```

```
addStage(FC,dsp.IIRFilter,2)
```

```
FC
```

```
FC =  
  dsp.FilterCascade with properties:  
      Stage1: [1x1 dsp.CICDecimator]  
      Stage2: [1x1 dsp.IIRFilter]  
      Stage3: [1x1 dsp.FIRDecimator]  
      Stage4: [1x1 dsp.FIRFilter]  
  CloneStages: true
```

Input Arguments

FC — Filter cascade

`dsp.FilterCascade` System object

Filter cascade, specified as a `dsp.FilterCascade` System object.

newFilt — Filter stage to add

filter System object | delay System object | scalar gain value

Filter stage to add, specified as one of the supported System objects or a scalar gain value. Each stage can be a filter or delay object, or a scalar gain value. To see which System objects you can add to a filter cascade, use:

```
dsp.FilterCascade.helpSupportedSystemObjects
```

stageId — Index of filter stage to be added

positive integer

Index of filter stage to be added, specified as a positive integer. The object adds this stage to the filter cascade. All existing filters from `stageId` to the end of the cascade are shifted up in the cascade when the new filter is added.

Functions

addStage | generateFilteringCode | getNumStages | releaseStages | removeStage

generateFilteringCode

Package: dsp

Generate MATLAB code for a filter cascade

Syntax

```
generateFilteringCode(FC)
generateFilteringCode(FC, fileName)
```

Description

`generateFilteringCode(FC)` creates a MATLAB function that contains code to create the stages of a filter cascade, `FC`, and calls each stage in sequence. If the filters in each stage support code generation, you can generate C/C++ code from the function returned by `generateFilteringCode`.

`generateFilteringCode(FC, fileName)` generates code and saves the resulting function to the file specified in `fileName`.

Examples

Generate Code to Filter Using Cascade

Design a two-stage decimator with a 100-Hz transition width, a 2-kHz sampling frequency, and 60-dB attenuation in the stopband. The decimator needs to downsample by a factor of 4.

```
filtCasc = designMultistageDecimator(4,2000,100,60)
```

```
filtCasc =

Functions

`addStage` | `generateFilteringCode` | `getNumStages` | `releaseStages` | `removeStage`

getNumStages

Package: dsp

Get number of stages in filter cascade

Syntax

```
getNumStages(FC)
```

Description

getNumStages(FC) returns the number of stages in the dsp.FilterCascade object, FC.

Examples

Find Number of Stages

This example shows how to query the number of stages in a filter cascade.

Create a filter cascade with two stages and call getNumStages on the cascade object.

```
FC = cascade(dsp.FIRFilter,dsp.IIRFilter)

FC =
dsp.FilterCascade with properties:
    Stage1: [1x1 dsp.FIRFilter]
    Stage2: [1x1 dsp.IIRFilter]
    CloneStages: true

FCstages = getNumStages(FC)

FCstages = 2
```

Input Arguments

FC — Filter cascade

dsp.FilterCascade System object

Filter cascade, specified as a dsp.FilterCascade System object.

Version History

Introduced in R2014b

Objects

`dsp.FilterCascade`

Functions

`addStage` | `generateFilteringCode` | `getNumStages` | `releaseStages` | `removeStage`

releaseStages

Package: dsp

Release locked state of all stages in cascade

Syntax

```
releaseStages(FC)
```

Description

`releaseStages(FC)` calls the `release` function of each individual stage in the `dsp.FilterCascade` System object `FC`.

For instance, if a `dsp.FilterCascade` object consists of a `dsp.FIRFilter` and a `dsp.FIRInterpolator` object, the `releaseStages` function calls the:

- `release` function of the `dsp.FIRFilter` object
- `release` function of the `dsp.FIRInterpolator` object

Examples

Release Stages of a Filter Cascade

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Create and release stages of a filter cascade.

```
firfilt = dsp.FIRFilter;  
y = firfilt(randn);  
FC = dsp.FilterCascade(dsp.FIRInterpolator, firfilt);  
isLocked(FC.Stage2)
```

```
ans = logical  
     1
```

```
releaseStages(FC);  
isLocked(FC.Stage2)
```

```
ans = logical  
     0
```

Input Arguments

FC — Filter cascade

`dsp.FilterCascade` System object

Filter cascade, specified as a `dsp.FilterCascade` System object.

Version History

Introduced in R2014b

See Also

Objects

`dsp.FilterCascade`

Functions

`addStage` | `generateFilteringCode` | `getNumStages` | `releaseStages` | `removeStage`

removeStage

Package: dsp

Remove stage from filter cascade

Syntax

```
removeStage(FC)
removeStage(FC, stageId)
```

Description

`removeStage(FC)` removes the final stage of the `dsp.FilterCascade` System object `FC`.

`removeStage(FC, stageId)` removes the stage from stage position `stageId` of the filter cascade `FC`. All existing filter stages from `stageId` to the end of the cascade are shifted down in the cascade when the stage is removed.

Examples

Remove Filter Stage

Call `removeStage` with no arguments other than the filter cascade System object™. The function removes the last stage in the filter cascade.

```
FC2= dsp.FilterCascade(dsp.FIRFilter,...
    dsp.IIRFilter)
```

```
FC2 =
    dsp.FilterCascade with properties:
```

```
    Stage1: [1x1 dsp.FIRFilter]
    Stage2: [1x1 dsp.IIRFilter]
    CloneStages: true
```

```
removeStage(FC2);
FC2
```

```
FC2 =
    dsp.FilterCascade with properties:
```

```
    Stage1: [1x1 dsp.FIRFilter]
    CloneStages: true
```

To remove a specific stage of the cascade, specify the index for that stage as an input argument. This example creates a filter cascade that has four stages, and then removes the third stage.

```
FC4 = cascade(dsp.FIRInterpolator,...
    dsp.FIRInterpolator,...
```

```

    dsp.FIRDecimator, ...
    dsp.FIRDecimator)

FC4 =
    dsp.FilterCascade with properties:

        Stage1: [1x1 dsp.FIRInterpolator]
        Stage2: [1x1 dsp.FIRInterpolator]
        Stage3: [1x1 dsp.FIRDecimator]
        Stage4: [1x1 dsp.FIRDecimator]
    CloneStages: true

removeStage(FC4,3);
FC4

FC4 =
    dsp.FilterCascade with properties:

        Stage1: [1x1 dsp.FIRInterpolator]
        Stage2: [1x1 dsp.FIRInterpolator]
        Stage3: [1x1 dsp.FIRDecimator]
    CloneStages: true

```

Input Arguments

FC — Filter cascade

`dsp.FilterCascade` System object

Filter cascade, specified as a `dsp.FilterCascade` System object.

stageId — Index of filter stage to be removed

positive integer

Index of filter stage to be removed, specified as a positive integer. The function removes this stage from the filter cascade. All existing filters from `stageId` to the end of the cascade are shifted up in the cascade when the filter is removed.

dsp.FilteredXLMSFilter

Package: dsp

Filtered XLMS filter

Description

The `dsp.FilteredXLMSFilter` System object computes output, error and coefficients using filtered-x least mean square FIR adaptive filter.

To implement the adaptive FIR filter object:

- 1 Create the `dsp.FilteredXLMSFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
fxlms = dsp.FilteredXLMSFilter  
fxlms = dsp.FilteredXLMSFilter(len)  
fxlms = dsp.FilteredXLMSFilter(Name,Value)
```

Description

`fxlms = dsp.FilteredXLMSFilter` returns a filtered-x least mean square FIR adaptive filter System object, `fxlms`. This System object is used to compute the filtered output and the filter error for a given input and desired signal.

`fxlms = dsp.FilteredXLMSFilter(len)` returns a `FilteredXLMSFilter` System object, `fxlms`, with the `Length` property set to `len`.

`fxlms = dsp.FilteredXLMSFilter(Name,Value)` returns a `FilteredXLMSFilter` System object, `fxlms`, with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Length — Length of filter coefficients vector

10 (default) | positive integer

Specify the length of the FIR filter coefficients vector as a positive integer value. This property is nontunable.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

StepSize — Adaptation step size

0.1 (default) | positive scalar

Specify the adaptation step size factor as a positive numeric scalar.

Tunable: Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

LeakageFactor — Adaptation leakage factor

1 (default) | scalar

Specify the leakage factor used in a leaky adaptive filter as a numeric value between 0 and 1, both inclusive. When the value is less than 1, the System object implements a leaky adaptive algorithm. The default value is 1, providing no leakage in the adapting method.

Tunable: Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

SecondaryPathCoefficients — Coefficients of the secondary path filter model

[0.0051 -3.2506e-18 -0.0419 1.3210e-17 0.2885 0.4968 0.2885 1.3210e-17 -0.0419 -3.2506e-18 0.0051] (default) | vector

Specify the coefficients of the secondary path filter model as a numeric vector. The secondary path connects the output actuator and the error sensor. The default value is a vector that represents the coefficients of a 10th-order FIR lowpass filter.

Tunable: Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

SecondaryPathEstimate — Estimate of secondary path filter model

[0.0051 -3.2506e-18 -0.0419 1.3210e-17 0.2885 0.4968 0.2885 1.3210e-17 -0.0419 -3.2506e-18 0.0051] (default) | vector

Specify the estimate of the secondary path filter model as a numeric vector. The secondary path connects the output actuator and the error sensor. The default value equals to the SecondaryPathCoefficients property value. This property is not tunable.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

InitialCoefficients — Initial coefficients of filter

0 (default) | scalar | vector

Specify the initial values of the FIR adaptive filter coefficients as a scalar or a vector of length equal to the value of the Length property.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

LockCoefficients — Locked status of coefficient updates

`false` (default) | `true`

Specify whether to lock the filter coefficient values. By default, the value of this property is `false`, and the object continuously updates the filter coefficients. If this property is set to `true`, the filter coefficients do not update and their values remain the same.

Tunable: Yes

Usage

Syntax

```
[y,err] = fxlms(x,d)
```

Description

`[y,err] = fxlms(x,d)` filters the input `x`, using `d` as the desired signal, and returns the filtered output `y` and the filter error `err`. The System object estimates the filter weights needed to minimize the error between the output signal and the desired signal. You can access these coefficients by accessing the `Coefficients` property of the object. This can be done only after calling the object. For example, to access the optimized coefficients of the `fxlms` filter, call `fxlms.Coefficients` after you pass the input and desired signal to the object.

Input Arguments

x — Data input

scalar | column vector

The signal to be filtered by the filtered XLMS filter. The input, `x`, and the desired signal, `d`, must have the same size and data type.

The input, `x` can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double`

d — Desired signal

scalar | column vector

The filtered XLMS filter adapts its coefficients to minimize the error, `err`, and converge the input signal `x` to the desired signal `d` as closely as possible.

The input, `x`, and the desired signal, `d`, must have the same size and data type.

The desired signal, `d`, can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double`

Complex Number Support: Yes

Output Arguments

y — Filtered output

scalar | column vector

Filtered output, returned as a scalar or a column vector. The object adapts its filter coefficients to converge the input signal x to match the desired signal d . The filter outputs the converged signal.

Data Types: `single` | `double`

err — Difference between output and desired signal

scalar | column vector

Difference between the output signal y and the desired signal d , returned as a scalar or a column vector. The objective of the filtered XLMS filter is to minimize this error. The object adapts its coefficients to converge towards optimal filter coefficients that produce an output signal that matches closely with the desired signal. To access the filtered XLMS filter coefficients, call `fxlms.Coefficients` after you pass the input and desired signal to the object.

Data Types: `single` | `double`

Complex Number Support: Yes

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.FilteredXLMSFilter`

`msesim` Estimated mean squared error for adaptive filters

Common to All System Objects

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

Examples

Active Noise Control of Random Noise Signal

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Generate noise, create FIR primary path system model, generate observation noise, filter the primary path system model output with added noise, and create FIR secondary path system model.

```
x = randn(1000,1);
g = fir1(47,0.4);
n = 0.1*randn(1000,1);
d = filter(g,1,x) + n;
b = fir1(31,0.5);
```

Use the `dsp.FilteredXLMSFilter` System object™ to compute the filtered output and the filter error for the input and the signal to be canceled.

```
mu = 0.008;
fxlms = dsp.FilteredXLMSFilter(32, 'StepSize', mu, 'LeakageFactor', ...
    1, 'SecondaryPathCoefficients', b);
[y,e] = fxlms(x,d);
```

Plot the results.

```
plot(1:1000,d,'b',1:1000,e,'r');
title('Active Noise Control of a Random Noise Signal');
legend('Original','Attenuated');
xlabel('Time Index'); ylabel('Signal Value'); grid on;
```

System Identification of FIR Filter Using Filtered XLMS Filter

Identify an unknown system by performing active noise control using a filtered-x LMS algorithm. The objective of the adaptive filter is to minimize the error signal between the output of the adaptive filter and the output of the unknown system (or the system to be identified). Once the error signal is minimal, the unknown system converges to the adaptive filter.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Initialization

Create a `dsp.FIRFilter` System object that represents the system to be identified. Pass the signal, `x`, to the FIR filter. The output of the unknown system is the desired signal, `d`, which is the sum of the output of the unknown system (FIR filter) and an additive noise signal, `n`.

```
num = fir1(31,0.5);
fir = dsp.FIRFilter('Numerator',num);
```

```
iir = dsp.IIRFilter('Numerator',sqrt(0.75),...
    'Denominator',[1 -0.5]);
x = iir(sign(randn(2000,25)));
n = 0.1*randn(size(x));
d = fir(x) + n;
```

Adaptive Filter

Create a `dsp.FilteredXLMSFilter` System object to create an adaptive filter that uses the filtered-x LMS algorithm. Set the length of the adaptive filter to 32 taps, step size to 0.008, and the decimation factor for analysis and simulation to 5. The variable `simmse` represents the error between the output of the unknown system, `d`, and the output of the adaptive filter.

```
l = 32;
mu = 0.008;
m = 5;
fxlms = dsp.FilteredXLMSFilter(l,'StepSize',mu);
[simmse,meanWsim,Wsim,traceKsim] = msesim(fxlms,x,d,m);
plot(m*(1:length(simmse)),10*log10(simmse))
xlabel('Iteration')
ylabel('MSE (dB)')
% Plot the learning curve for filtered-x LMS filter
% used in system identification
title('Learning curve')
```

With each iteration of adaptation, the value of `simmse` decreases to a minimal value, indicating that the unknown system has converged to the adaptive filter.

Version History

Introduced in R2013b

dsp.FIRDecimator

Package: dsp

Polyphase FIR decimator

Description

The `dsp.FIRDecimator` System object resamples vector or matrix inputs along the first dimension. The FIR decimator (as shown in the schematic) conceptually consists of an anti-aliasing FIR filter followed by a downsampler.

The FIR filter filters the data in each channel of the input using a direct-form FIR filter. The FIR filter coefficients can be specified through the `Numerator` property, or can be automatically designed by the object using the `designMultirateFIR` function. The `designMultirateFIR` function designs an anti-aliasing FIR filter. The downsampler that follows the FIR filter downsamples each channel of filtered data by taking every M -th sample and discarding the $M - 1$ samples that follow. M is the value of the decimation factor that you specify. The resulting discrete-time signal has a sample rate that is $1/M$ times the original sample rate.

Note that the actual object algorithm implements a direct-form FIR polyphase structure, an efficient equivalent of the combined system depicted in the diagram. For more details, see "Algorithms" on page 4-501.

To resample vector or matrix inputs along the first dimension:

- 1 Create the `dsp.FIRDecimator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Under specific conditions, this System object also supports SIMD code generation. For details, see "Code Generation" on page 4-504.

Creation

Syntax

```
firdecim = dsp.FIRDecimator
firdecim = dsp.FIRDecimator(M)
firdecim = dsp.FIRDecimator(M, 'Auto')
firdecim = dsp.FIRDecimator(M, num)
firdecim = dsp.FIRDecimator( ___, Name, Value)
firdecim = dsp.FIRDecimator(M, 'legacy')
```

Description

`firdecim = dsp.FIRDecimator` returns an FIR decimator object with a decimation factor of 2. The object designs the FIR filter coefficients using the `designMultirateFIR(1,2)` function.

`firdecim = dsp.FIRDecimator(M)` returns an FIR decimator with the integer-valued `DecimationFactor` property set to `M`. The object designs its filter coefficients based on the decimation factor `M` that you specify while creating the object, using the `designMultirateFIR(1,M)` function. The designed filter corresponds to a lowpass with a cutoff at π/M in radial frequency units.

`firdecim = dsp.FIRDecimator(M, 'Auto')` returns an FIR decimator with the `NumeratorSource` property set to `'Auto'`. In this mode, every time there is an update in the decimation factor, the object redesigns the filter using `designMultirateFIR(1,M)`.

`firdecim = dsp.FIRDecimator(M, num)` returns an FIR decimator with the `DecimationFactor` property set to `M` and the `Numerator` property set to `num`.

`firdecim = dsp.FIRDecimator(___, Name, Value)` returns an FIR decimator object with each specified property set to the specified value. Enclose each property name in quotes. You can use this syntax with any previous input argument combinations.

`firdecim = dsp.FIRDecimator(M, 'legacy')` returns an FIR decimator where the filter coefficients are designed using `fir1(35,0.4)`. The designed filter has a cutoff frequency of 0.4π radians/sample.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Main Properties

DecimationFactor — Decimation factor

2 (default) | positive integer

Decimation factor M , specified as a positive integer. The FIR decimator reduces the sampling rate of the input by this factor. The number of input rows must be a multiple of the decimation factor.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

NumeratorSource — FIR filter coefficient source

'Property' (default) | 'Input port' | 'Auto'

FIR filter coefficient source, specified as one of the following:

- 'Property' -- The numerator coefficients are specified through the `Numerator` property.
- 'Input port' -- The numerator coefficients are specified as an input to the object algorithm.
- 'Auto' -- The numerator coefficients are designed automatically using the `designMultirateFIR(1,M)` function.

Numerator — FIR filter coefficients

`designMultirateFIR(1,M)` (default) | row vector

Numerator coefficients of the FIR filter, specified as a row vector in powers of z^{-1} . The following equation defines the system function for a filter of length $N+1$:

$$H(z) = \sum_{l=0}^N b_l z^{-l}$$

The vector $\mathbf{b} = [b_0, b_1, \dots, b_N]$ represents the vector of filter coefficients.

To prevent aliasing as a result of downsampling, the filter transfer function should have a normalized cutoff frequency no greater than $1/M$. To design an effective anti-aliasing filter, use the `designMultirateFIR` function. For an example, see "Decimate Sum of Sine Waves" on page 4-494.

Dependencies

This property is visible only when you set `NumeratorSource` to 'Property'.

When `NumeratorSource` is set to 'Auto', the numerator coefficients are automatically redesigned using `designMultirateFIR(1,M)`. To access the filter coefficients in the automatic design mode, type `objName.Numerator` in the MATLAB command prompt.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Structure — Filter structure

'Direct form' (default) | 'Direct form transposed'

Specify the implementation of the FIR filter as either `Direct form` or `Direct form transposed`.

Code Generation Properties

AllowArbitraryInputLength — Allow arbitrary input length in generated code

`false` (default) | `true`

Allow arbitrary frame length for fixed-size input signals in the generated code, specified as `true` or `false`. When you specify:

- `true` -- The input frame length does not have to be a multiple of the decimation factor. The output of the object in the generated code is a variable-size array.

- `false` -- The input frame length must be a multiple of the decimation factor.

When you specify variable-size signals, the input frame length can be arbitrary and the object ignores this property in the generated code. When you run this object in MATLAB, the object supports arbitrary input frame lengths for fixed-size and variable-size signals and this property does not affect the object behavior.

Data Types: `logical`

Fixed-Point Properties

FullPrecisionOverride — Full-precision override for fixed-point arithmetic

`true` (default) | `false`

Flag to use full-precision rules for fixed-point arithmetic, specified as one of the following:

- `true` -- The object computes all internal arithmetic and output data types using the full-precision rules. These rules provide the most accurate fixed-point numerics. In this mode, other fixed-point properties do not apply. No quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- `false` -- Fixed-point data types are controlled through individual fixed-point property settings.

For more information, see “Full Precision for Fixed-Point System Objects” and “Set System Object Fixed-Point Properties”.

RoundingMethod — Rounding method for fixed-point operations

`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Rounding method for fixed-point operations. For more details, see rounding mode.

Dependencies

This property is not visible and has no effect on the numerical results when the following conditions are met:

- `FullPrecisionOverride` set to `true`.
- `FullPrecisionOverride` set to `false`, `ProductDataType` set to `'Full precision'`, `AccumulatorDataType` set to `'Full precision'`, and `OutputDataType` set to `'Same as accumulator'`.

Under these conditions, the object operates in full precision mode.

OverflowAction — Overflow action for fixed-point operations

`'Wrap'` (default) | `'Saturate'`

Overflow action for fixed-point operations, specified as one of the following:

- `'Wrap'` -- The object wraps the result of its fixed-point operations.
- `'Saturate'` -- The object saturates the result of its fixed-point operations.

For more details on overflow actions, see overflow mode for fixed-point operations.

Dependencies

This property is not visible and has no effect on the numerical results when the following conditions are met:

- FullPrecisionOverride set to true.
- FullPrecisionOverride set to false, OutputDataType set to 'Same as accumulator', ProductDataType set to 'Full precision', and AccumulatorDataType set to 'Full precision'

Under these conditions, the object operates in full precision mode.

CoefficientsDataType — Data type of FIR filter coefficients

Same word length as input (default) | Custom

Data type of the FIR filter coefficients, specified as:

- Same word length as input -- The word length of the coefficients is the same as that of the input. The fraction length is computed to give the best possible precision.
- Custom -- The coefficients data type is specified as a custom numeric type through the CustomCoefficientsDataType property.

CustomCoefficientsDataType — Word and fraction lengths of coefficients data type

numericType([],16,15) (default) | custom numeric type

Word and fraction lengths of the coefficients data type, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Dependencies

This property applies when you set the CoefficientsDataType property to Custom.

ProductDataType — Data type of product output

'Full precision' (default) | 'Custom' | 'Same as input'

Data type of the product output in this object, specified as one of the following:

- 'Full precision' -- The product output data type has full precision.
- 'Same as input' -- The object specifies the product output data type to be the same as that of the input data type.
- 'Custom' -- The product output data type is specified as a custom numeric type through the CustomProductDataType property.

For more information on the product output data type, see “Multiplication Data Types”.

Dependencies

This property applies when you set FullPrecisionOverride to false.

CustomProductDataType — Word and fraction lengths of product data type

numericType([],32,30) (default) | custom numeric type

Word and fraction lengths of the product data type, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set FullPrecisionOverride to false and ProductDataType to 'Custom'.

AccumulatorDataType — Data type of accumulation operation`'Full precision' (default) | 'Same as input' | 'Same as product' | 'Custom'`

Data type of an accumulation operation in this object, specified as one of the following:

- `'Full precision'` -- The accumulation operation has full precision.
- `'Same as product'` -- The object specifies the accumulator data type to be the same as that of the product output data type.
- `'Same as input'` -- The object specifies the accumulator data type to be the same as that of the input data type.
- `'Custom'` -- The accumulator data type is specified as a custom numeric type through the `CustomAccumulatorDataType` property.

Dependencies

This property applies when you set `FullPrecisionOverride` to `false`.

CustomAccumulatorDataType — Word and fraction lengths of accumulator data type`numerictype([],32,30) (default) | custom numeric type`

Word and fraction lengths of the accumulator data type, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set `FullPrecisionOverride` to `false` and `AccumulatorDataType` to `'Custom'`.

OutputDataType — Data type of object output`'Same as accumulator' (default) | 'Same as input' | 'Same as product' | 'Custom'`

Data type of the object output, specified as one of the following:

- `'Same as accumulator'` -- The output data type is the same as that of the accumulator output data type.
- `'Same as input'` -- The output data type is the same as that of the input data type.
- `'Same as product'` -- The output data type is the same as that of the product output data type.
- `'Custom'` -- The output data type is specified as a custom numeric type through the `CustomOutputDataType` property.

Dependencies

This property applies when you set `FullPrecisionOverride` to `false`.

CustomOutputDataType — Word and fraction lengths of output data type`numerictype([],16,15) (default) | custom numeric type`

Word and fraction lengths of the output data type, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Dependencies

This property applies only when you set `FullPrecisionOverride` to `false` and `OutputDataType` to `'Custom'`.

Usage

Syntax

```
y = firdecim(x)
y = firdecim(x,num)
```

Description

`y = firdecim(x)` outputs the filtered and downsampled values, `y`, of the input signal, `x`.

`y = firdecim(x,num)` uses the FIR filter, `num`, to decimate the input signal. This configuration is valid only when the 'NumeratorSource' property is set to 'Input port'.

Input Arguments

x — Data input

column vector | matrix

Data input, specified as a column vector or a matrix of size P -by- Q . The columns in the input signal represent Q independent channels.

Under most conditions, the number of inputs rows P can be arbitrary and does not have to be a multiple of the `DecimationFactor` property. See this table for details.

Input Signal	When you Run Object in MATLAB	When you Generate Code Using MATLAB Coder
Fixed-size	Object supports arbitrary input frame length	Object supports arbitrary input frame length when you set <code>AllowArbitraryInputLength</code> to <code>true</code> while generating code
Variable-size	Object supports arbitrary input frame length	Object supports arbitrary input frame length

Variable-size signals change in frame length once you lock the object while the fixed-size signals remain constant. When the object does not support arbitrary frame length, the input frame length must be a multiple of the `DecimationFactor` property.

This object does not support complex unsigned fixed-point inputs.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

num — FIR filter coefficients

row vector

FIR filter coefficients, specified as a row vector.

Dependencies

This input is accepted only when the 'NumeratorSource' property is set to 'Input port'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Output Arguments

y — FIR decimator output

column vector | matrix

FIR decimator output, returned as a column vector or a matrix. When the input is of size P -by- Q , and P is not a multiple of the decimation factor M , the output signal has an upper bound size of $\text{ceil}(P/M)$ -by- Q . If P is a multiple of the decimation factor, then the output is of size (P/M) -by- Q .

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.FIRDecimator

<code>freqz</code>	Frequency response of discrete-time filter System object
<code>fvtool</code>	Visualize frequency response of DSP filters
<code>info</code>	Information about filter System object
<code>cost</code>	Estimate cost of implementing filter System object
<code>polyphase</code>	Polyphase decomposition of multirate filter
<code>generatehdl</code>	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)
<code>impz</code>	Impulse response of discrete-time filter System object
<code>coeffs</code>	Returns the filter System object coefficients in a structure

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Decimate Sum of Sine Waves

Decimate a sum of sine waves by a factor of 2 and by a factor of 4.

Start with a cosine wave that has an angular frequency of $\frac{\pi}{4}$ radians/sample.

```
x = cos(pi/4*(0:95)');
```

Design Default Filter

Create a `dsp.FIRDecimator` object. To prevent aliasing, the object uses an anti-aliasing lowpass filter before downsampling. By default, the anti-aliasing lowpass filter is designed using the `designMultirateFIR` function. The function designs the filter based on the decimation factor that

you specify, and stores the coefficients in the Numerator property. For a decimation factor of 2, the object designs the coefficients using `designMultirateFIR(1,2)`.

```
firdecim = dsp.FIRDecimator(2)
```

```
firdecim =
  dsp.FIRDecimator with properties:

  Main
  DecimationFactor: 2
  NumeratorSource: 'Property'
    Numerator: [0 -1.0054e-04 0 3.8704e-04 0 -0.0010 0 0.0022 0 ... ]
    Structure: 'Direct form'
```

Show all properties

Visualize the filter response using `fvtool`. The designed filter meets the ideal filter constraints that are marked in red. The cutoff frequency is approximately half the spectrum.

```
fvtool(firdecim)
```

Decimate by 2

Decimate the cosine signal by a factor of 2.

```
y = firdecim(x);
```

Plot the original and the decimated signals. In order to plot the two signals on the same plot, you must account for the output delay of the FIR decimator and the scaling introduced by the filter. Use the `outputDelay` function to compute the `delay` value introduced by the decimator. Shift the output by this delay value.

Visualize the input and the resampled signals. After a short transition, the output converges to a cosine of frequency $\frac{\pi}{2}$ as expected, which is twice the frequency of the input signal $\frac{\pi}{4}$. Due to the decimation factor of 2, the output samples coincide with every other input sample.

```
[delay,FsOut] = outputDelay(firdecim);
nx = (0:length(x)-1);
ty = (0:length(y)-1)/FsOut-delay;
stem(ty,y,'filled',MarkerSize=4); hold on;
stem(nx,x); hold off;
xlim([-10,22])
ylim([-2.5 2.5])
legend('Decimated by 2 (y)','Input signal (x)');
```

Add a High Frequency Component to Input and Decimate

Add another frequency component to the input signal, a sine with an angular frequency of $\frac{2\pi}{3}$ radians/sample. Since $\omega = \frac{2\pi}{3}$ is above the FIR lowpass cutoff, $\frac{\pi}{2}$, the frequency $\frac{2\pi}{3}$ radians/sample is filtered out from the signal.

```
xhigh = x + 0.2*sin(2*pi/3*(0:95));
release(firdecim)
yhigh = firdecim(xhigh);
```

Plot the input signal, decimated signal, and the output of the low frequency component. The decimated signal `yhigh` has the high frequency component filtered out. `yhigh` is almost identical to the output of the low frequency component `y`.

```
stem(ty,yhigh,'filled',MarkerSize=4); hold on;
stem(nx,xhigh);
stem(ty,y,'m',MarkerSize=7);
hold off;
xlim([-10,22])
ylim([-2.5 2.5])
legend('Decimated by 2 (yhigh)',...
       'Input signal with the high tone added (xhigh)',...
       'Decimated by 2 - low tone only (y)');
```

Decimate by 4 in Automatic Filter Design Mode

Now decimate by a factor of 4. In order for the filter design to be updated automatically based on the new decimation factor, set the `NumeratorSource` property to `'Auto'`. Alternately, you can pass `'Auto'` as the keyword while creating the object. The object then operates in the automatic filter design mode. Every time there is a change in the decimation factor, the object updates the filter design.

```

release(firdecim)
firdecim.NumeratorSource = 'Auto';
firdecim.DecimationFactor = 4

firdecim =
    dsp.FIRDecimator with properties:

    Main
    DecimationFactor: 4
    NumeratorSource: 'Auto'
    Structure: 'Direct form'

    Show all properties

```

To access the filter coefficients in the automatic mode, type `firdecim.Numerator` in the MATLAB command prompt.

The designed filter occupies a narrower passband that is approximately a quarter of the spectrum.

```
fvtool(firdecim)
```

Decimate the cosine signal by a factor of 4. After a short transition, the output converges to a cosine of frequency π as expected, which is four times the lower frequency component of the input signal $\frac{\pi}{4}$. This time, the amplitude of the output is half the amplitude of the input since the gain of the FIR at

$\omega = \frac{\pi}{4}$ is exactly $\frac{1}{2}$. The high frequency component $\frac{2\pi}{3}$ diminishes by the lowpass FIR whose cutoff frequency is $\frac{\pi}{4}$.

```
yAuto = firdecim(xhigh);
```

Plot the input signal with the high frequency component added, low frequency component scaled by 1/2, and the decimated signal. Recalculate the output delay and the output sample rate since the decimation factor has changed.

```
[delay,FsOut] = outputDelay(firdecim);
```

```
tyAuto = (0:length(yAuto)-1)/FsOut-delay;
stem(tyAuto,yAuto,'filled',MarkerSize=4); hold on;
stem(nx,xhigh);
stem(nx,x/2,'m:',MarkerSize=7); hold off;
```

```
xlim([-20,36])
```

```
ylim([-2.5 2.5])
```

```
legend('Decimated by 4 (yAuto)',...
```

```
'Input signal with the high frequency component added (xhigh)',...
```

```
'Low tone input scaled by 1/2');
```

Reduce Sample Rate of Audio Signal

Reduce the sample rate of an audio signal by a factor of 2 and play the decimated signal using the `audioDeviceWriter` object.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Note: The `audioDeviceWriter` System object™ is not supported in MATLAB Online.

Create a `dsp.AudioFileReader` object. The default audio file read by the object has a sample rate of 22050 Hz.

```
afr = dsp.AudioFileReader('OutputDataType',...  
    'single');
```

Create a `dsp.FIRDecimator` object and specify the decimation factor to be 2. The object designs the filter using `designMultirateFIR(1,2)` and stores the coefficients in the `Numerator` property of the object.

```
firdecim = dsp.FIRDecimator(2)
```

```
firdecim =  
dsp.FIRDecimator with properties:
```

```
    Main  
    DecimationFactor: 2  
    NumeratorSource: 'Property'  
        Numerator: [0 -1.0054e-04 0 3.8704e-04 0 -0.0010 0 0.0022 0 ... ]  
        Structure: 'Direct form'
```

```
Show all properties
```

Create an `audioDeviceWriter` object. Specify the sample rate to be 22050/2.

```
adw = audioDeviceWriter(22050/2)
```

```
adw =  
audioDeviceWriter with properties:
```

```
    Driver: 'DirectSound'  
    Device: 'Default'  
    SampleRate: 11025
```

```
Show all properties
```

Read the audio signal using the file reader object, decimate the signal by a factor of 2, and play the decimated signal.

```
while ~isDone(afr)  
    frame = afr();  
    y = firdecim(frame);  
    adw(y);  
end
```

```
release(afr);
```

```
pause(0.5);
release(adw);
```

More About

Polyphase Subfilters

A polyphase implementation of an FIR decimator *splits* the lowpass FIR filter impulse response into M different subfilters, where M is the downsampling or decimation factor. For more details on the polyphase implementation, see “Algorithms” on page 4-501.

Let $h(n)$ denote the FIR filter impulse response of length $N+1$ and $x(n)$ the input signal. Decimating the filter output by a factor of M is equivalent to the downsampled convolution:

$$y(n) = \sum_{l=0}^N h(l)x(nM - l)$$

The key to the efficiency of polyphase filtering is that specific input values are only multiplied by select values of the impulse response in the downsampled convolution. For example, letting $M = 2$, the input values $x(0), x(2), x(4), \dots$ are combined only with the filter coefficients $h(0), h(2), h(4), \dots$, and the input values $x(1), x(3), x(5), \dots$ are combined only with the filter coefficients $h(1), h(3), h(5), \dots$. By splitting the filter coefficients into two polyphase subfilters, no unnecessary computations are performed in the convolution. The outputs of the convolutions with the polyphase subfilters are interleaved and summed to yield the filter output.

The following code demonstrates how to construct the two polyphase subfilters for the default order 35 filter.

```
M = 2;
Num = fir1(35,0.4);
FiltLength = length(Num);
Num = flipud(Num(:));

if (rem(FiltLength, M) ~= 0)
    nzeros = M - rem(FiltLength, M);
    Num = [zeros(nzeros,1); Num]; % Appending zeros
end

len = length(Num);
nrows = len / M;
PolyphaseFilt = flipud(reshape(Num, M, nrows).');
```

The columns of `PolyphaseFilt` are subfilters containing the two *phases* of the filter in `Num`. For a general downsampling factor of M , there are M phases and therefore M subfilters.

Algorithms

The FIR decimation filter is implemented efficiently using a polyphase structure. For more details on polyphase filters, see Polyphase Subfilters on page 4-501.

To derive the polyphase structure, start with the transfer function of the FIR filter:

$$H(z) = b_0 + b_1z^{-1} + \dots + b_Nz^{-N}$$

$N+1$ is the length of the FIR filter.

You can rearrange this equation as follows:

$$H(z) = (b_0 + b_M z^{-M} + b_{2M} z^{-2M} + \dots + b_{N-M+1} z^{-(N-M+1)}) + z^{-1}(b_1 + b_{M+1} z^{-M} + b_{2M+1} z^{-2M} + \dots + b_{N-M+2} z^{-(N-M+1)}) + \dots + z^{-(M-1)}(b_{M-1} + b_{2M-1} z^{-M} + b_{3M-1} z^{-2M} + \dots + b_N z^{-(N-M+1)})$$

M is the number of polyphase components, and its value equals the decimation factor that you specify.

You can write this equation as:

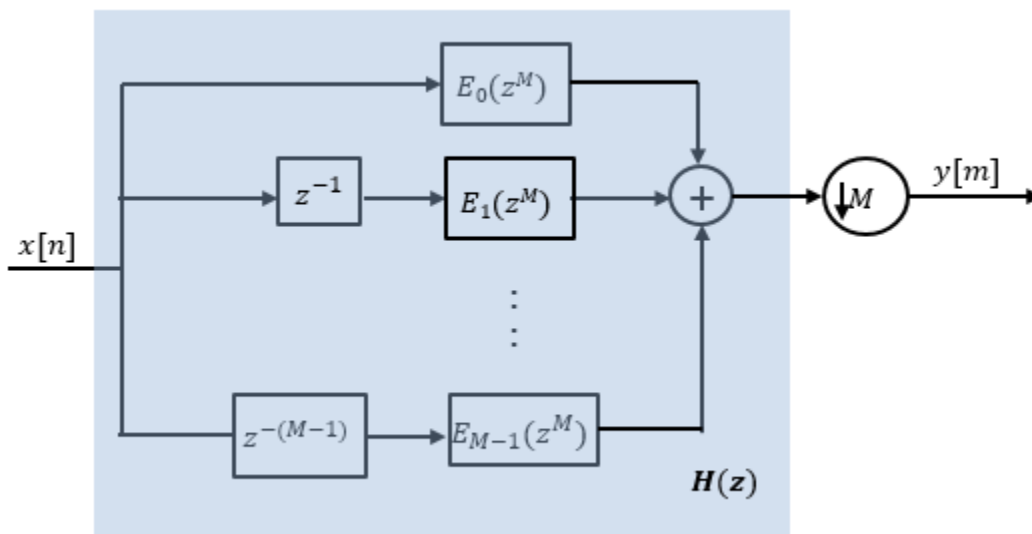

$$H(z) = E_0(z^M) + z^{-1}E_1(z^M) + \dots + z^{-(M-1)}E_{M-1}(z^M)$$

$E_0(z^M), E_1(z^M), \dots, E_{M-1}(z^M)$ are the polyphase components of the FIR filter $H(z)$.

Conceptually, the FIR decimation filter contains a lowpass FIR filter followed by a downsampler.

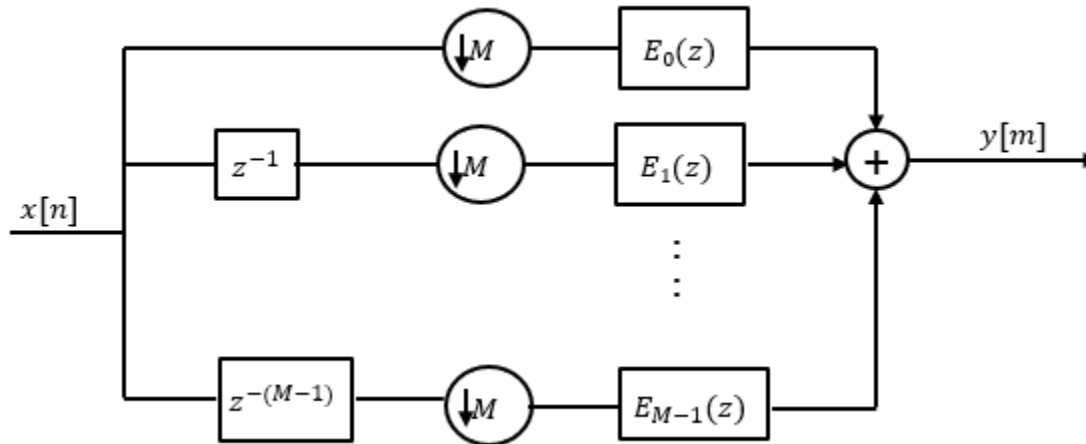

Replace $H(z)$ with its polyphase representation.

Here is the multirate noble identity for decimation.

Applying the noble identity for decimation moves the downsampling operation to before the filtering operation. This move enables you to filter the signal at a lower rate.

You can replace the delays and the decimation factor at the input with a commutator switch. The switch starts on the first branch 0 and moves in the counterclockwise direction as shown in this diagram. The accumulator at the output receives the processed input samples from each branch of the polyphase structure and accumulates these processed samples until the switch goes to branch 0. When the switch goes to branch 0, the accumulator outputs the accumulated value.

When the first input sample is delivered, the switch feeds this input to the branch 0 and the decimator computes the first output value. As more input samples come in, the switch moves in the counter clockwise direction through branches $M-1$, $M-2$, and all the way up to branch 0, delivering one sample at a time to each branch. When the switch comes to branch 0, the decimator outputs the next set of output values. This process continues as data keeps coming in. Every time the switch

comes to the branch 0, the decimator outputs $y[m]$. The decimator effectively outputs one sample for every M samples it receives. Hence the sample rate at the output of the FIR decimation filter is fs/M .

Version History

Introduced in R2012a

Support for arbitrary input frame length

Starting in R2022b, this object supports an input signal with an arbitrary frame length. That is, the input frame length does not have to be a multiple of the decimation factor.

When you generate code, to support arbitrary frame length for fixed-size signals, you must set the `AllowArbitraryInputLength` property to `true` while generating code.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

The `dsp.FIRDecimator` System object supports SIMD code generation using Intel AVX2 technology under these conditions:

- Filter structure is set to 'Direct form'.
- Input signal is real-valued with real filter coefficients.
- Input signal is complex-valued with real or complex filter coefficients.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This object supports HDL code generation with the Filter Design HDL Coder product. For workflows and limitations, see “Generate HDL Code for Filter System Objects” (Filter Design HDL Coder).

dsp.FIRFilter

Package: dsp

Static or time-varying FIR filter

Description

The `dsp.FIRFilter` System object filters each channel of the input using static or time-varying FIR filter implementations.

To filter each channel of the input:

- 1** Create the `dsp.FIRFilter` object and set its properties.
- 2** Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Under specific conditions, this System object also supports SIMD code generation. For details, see “Code Generation” on page 4-516.

Creation

Syntax

```
fir = dsp.FIRFilter
fir = dsp.FIRFilter(num)
fir = dsp.FIRFilter(Name,Value)
```

Description

`fir = dsp.FIRFilter` returns a finite impulse response (FIR) filter object, `fir`, which independently filters each channel of the input over time using a specified FIR filter implementation.

`fir = dsp.FIRFilter(num)` returns an FIR filter System object, `fir`, with the `Numerator` property set to `num`.

`fir = dsp.FIRFilter(Name,Value)` returns an FIR filter System object, `fir`, with each property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Structure – Filter structure

Direct form (default) | Direct form symmetric | Direct form antisymmetric | Direct form transposed | Lattice MA

Specify the filter structure. You can specify the filter structure as one of Direct form | Direct form symmetric | Direct form antisymmetric | Direct form transposed | Lattice MA.

NumeratorSource – Source of filter coefficients

Property (default) | Input port

Specify the source of the filter coefficients as Property or Input port. When you specify Input port, the filter object updates the time-varying filter once every frame.

Dependencies

This applies when you set the Structure to Direct form | Direct form symmetric | Direct form antisymmetric | Direct form transposed.

ReflectionCoefficientsSource – Source of filter coefficients

Property (default) | Input port

Specify the source of the Lattice filter coefficients as Property or Input port. When you specify Input port, the filter object updates the time-varying filter once every frame.

Dependencies

This applies when you set the Structure to Lattice MA.

Numerator – Numerator coefficients

[0.5 0.5] (default) | row vector

Specify the filter coefficients as a real or complex numeric row vector.

Tunable: Yes

Dependencies

This property applies when you set the NumeratorSource property to Property, and the “Structure” on page 4-0 property is set to Direct form, Direct form symmetric, Direct form antisymmetric, or Direct form transposed.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

ReflectionCoefficients – Reflection coefficients of lattice filter structure

[0.5 0.5] (default) | row vector

Specify the reflection coefficients of a lattice filter as a real or complex numeric row vector.

Tunable: Yes

Dependencies

This property applies when you set the “Structure” on page 4-0 property to Lattice MA, and the ReflectionCoefficientsSource property to Property.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

InitialConditions — Initial conditions for the FIR filter`0 (default) | scalar | vector | matrix`

Specify the initial conditions of the filter states. The number of states or delay elements equals the number of reflection coefficients for the lattice structure, or the number of filter coefficients-1 for the other direct form structures.

You can specify the initial conditions as a scalar, vector, or matrix. If you specify a scalar value, the FIR filter object initializes all delay elements in the filter to that value. If you specify a vector whose length equals the number of delay elements in the filter, each vector element specifies a unique initial condition for the corresponding delay element. The object applies the same vector of initial conditions to each channel of the input signal.

If you specify a vector whose length equals the product of the number of input channels and the number of delay elements in the filter, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel.

If you specify a matrix with the same number of rows as the number of delay elements in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel.

Tunable: Yes

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

Fixed-Point Properties**FullPrecisionOverride — Full precision override for fixed-point arithmetic**`true (default) | false`

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

RoundingMethod — Rounding method for fixed-point operations`Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero`

Specify the rounding method.

Dependencies

This property applies only if the object is not in full precision mode.

OverflowAction — Overflow action for fixed-point operations`Wrap (default) | Saturate`

Specify the overflow action as `Wrap` or `Saturate`.

Dependencies

This property applies only if the object is not in full precision mode.

CoefficientsDataType — Coefficients word and fraction lengths

Same word length as input (default) | Custom

Specify the coefficients fixed-point data type as Same word length as input or Custom.

Dependencies

This property applies when you set the NumeratorSource property to Property.

CustomCoefficientsDataType — Custom coefficients word and fraction lengths

numerictype(true,16,15) (default) | numerictype

Specify the coefficients fixed-point type as a signed or unsigned numerictype object.

Dependencies

This property applies when you set the CoefficientsDataType property to Custom.

ReflectionCoefficientsDataType — Reflection coefficients word and fraction lengths

Same word length as input (default) | Custom

Specify the reflection coefficients fixed-point data type as Same word length as input or Custom.

Dependencies

This property applies when you set the ReflectionCoefficientsSource property to Property.

CustomReflectionCoefficientsDataType — Custom reflection coefficients word and fraction lengths

numerictype(true,16,15) (default) | numerictype

Specify the reflection coefficients fixed-point type as a signed or unsigned numerictype object.

Dependencies

This property applies when you set the ReflectionCoefficientsDataType property to Custom.

ProductDataType — Product word and fraction lengths

Full precision (default) | Same as input | Custom

Specify the product fixed-point data type as Full precision, Same as input, or Custom.

CustomProductDataType — Custom product word and fraction lengths

numerictype(true,32,30) (default) | numerictype

Specify the product fixed-point type as a signed or unsigned scaled numerictype object.

Dependencies

This property applies when you set the ProductDataType property to Custom.

AccumulatorDataType — Accumulator word and fraction lengths

Full precision (default) | Same as input | Same as product | Custom

Specify the accumulator fixed-point data type to Full precision, Same as input, Same as product, or Custom.

CustomAccumulatorDataType — Custom accumulator word and fraction lengths`numerictype(true,32,30)` (default) | `numerictype`

Specify the accumulator fixed-point type as a signed or unsigned scaled `numerictype` object.

Dependencies

This property applies when you set the `AccumulatorDataType` property to `Custom`.

StateDataType — State word and fraction lengths`Same as accumulator` (default) | `Same as input` | `Custom`

Specify the state fixed-point data type as one of `Same as input`, `Same as accumulator`, or `Custom`.

Dependencies

This property does not apply to any of the direct form or direct form I filter structures.

CustomStateDataType — Custom state word and fraction lengths`numerictype(true,16,15)` (default) | `numerictype`

Specify the state fixed-point type as a signed or unsigned scaled `numerictype` object.

Dependencies

This property applies when you set the `StateDataType` property to `Custom`.

OutputDataType — Output word and fraction lengths`Same as accumulator` (default) | `Same as input` | `Custom`

Specify the output fixed-point data type as one of `Same as input`, `Same as accumulator`, or `Custom`.

CustomOutputDataType — Custom output word and fraction lengths`numerictype(true,16,15)` (default) | `numerictype`

Specify the output fixed-point type as a signed or unsigned scaled `numerictype` object.

Dependencies

This property applies when you set the “`OutputDataType`” on page 4-0 property to `Custom`.

Usage**Syntax**

```
y = fir(x)
y = fir(x,coeff)
```

Description

`y = fir(x)` applies an FIR filter to the real or complex input signal `x` to produce the output `y`.

$y = \text{fir}(x, \text{coeff})$ uses the time-varying coefficients, `coeff`, to filter the input signal `x` and produce the output `y`. You can use this option when you set the `NumeratorSource` or `ReflectionCoefficientsSource` property to `Input port`.

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix. When the input data is of a fixed-point type, it must be signed when the structure is set to `Direct form symmetric` or `Direct form antisymmetric`. The FIR filter object operates on each channel of the input signal independently over successive calls to the object.

This System object supports variable-size input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

coeff — Filter coefficients

row vector

Time-varying filter coefficients, specified as a row vector. The data and coefficient inputs must have the same data type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

Complex Number Support: Yes

Output Arguments

y — Filtered output

vector | matrix

Filtered output, returned as a vector or a matrix. The output has the same size and data type as the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.FIRFilter`

<code>freqz</code>	Frequency response of discrete-time filter System object
<code>fvtool</code>	Visualize frequency response of DSP filters
<code>impz</code>	Impulse response of discrete-time filter System object
<code>info</code>	Information about filter System object
<code>coeffs</code>	Returns the filter System object coefficients in a structure
<code>cost</code>	Estimate cost of implementing filter System object
<code>grpdelay</code>	Group delay response of discrete-time filter System object
<code>generatehdl</code>	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)

Common to All System Objects

`step` Run System object algorithm
`release` Release resources and allow changes to System object property values and input characteristics
`reset` Reset internal states of System object

Examples

Lowpass Filter a Sinusoid Signal Using FIRFilter object

Use an FIR filter to apply a low pass filter to a waveform with two sinusoidal components.

```
t = (0:1000)'/8e3;  
xin = sin(2*pi*0.3e3*t)+sin(2*pi*3e3*t);  
  
sr = dsp.SignalSource;  
sr.Signal = xin;  
sink = dsp.SignalSink;  
  
fir = dsp.FIRFilter(fir1(10,0.5));  
  
sa = spectrumAnalyzer(...  
    'SampleRate',8e3,...  
    'Method','welch',...  
    'PlotAsTwoSidedSpectrum',false,...  
    'OverlapPercent',80,...  
    'SpectrumUnits','dBW',...  
    'YLimits',[-150 -10]);  
  
while ~isDone(sr)  
    input = sr();  
    filteredOutput = fir(input);  
    sink(filteredOutput);  
    sa(filteredOutput)  
end
```

```
filteredResult = sink.Buffer;  
fvtool(fir,'Fs',8000)
```

Design an FIR filter as a System object.

```
N = 10;  
Fc = 0.4;  
B = fir1(N,Fc);  
fir1 = dsp.FIRFilter(B);  
fvtool(fir1)
```

This can also be achieved by using `fdesign` as a constructor and `design` to design the filter.

```
N = 10;
Fc = 0.4;
specLowpass = fdesign.lowpass('N,Fc',...
    N,Fc);
fir2 = design(specLowpass,...
    'systemobject',true)

fir2 =
    dsp.FIRFilter with properties:
        Structure: 'Direct form'
        NumeratorSource: 'Property'
        Numerator: [-1.2414e-18 -0.0126 -0.0247 0.0635 0.2748 0.3981 ... ]
        InitialConditions: 0

    Show all properties

fvtool(fir2);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Discrete FIR Filter block reference page. The object properties correspond to the block parameters.

dsp.FIRHalfbandDecimator

Package: dsp

Halfband decimator

Description

The `dsp.FIRHalfbandDecimator` System object performs an efficient polyphase decimation of the input signal by a factor of two. You can use `dsp.FIRHalfbandDecimator` to implement the analysis portion of a two-band filter bank to filter a signal into lowpass and highpass subbands.

`dsp.FIRHalfbandDecimator` uses an FIR equiripple design or a Kaiser window design to construct the halfband filters and a polyphase implementation to filter the input.

To filter and downsample your data:

- 1 Create the `dsp.FIRHalfbandDecimator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
firhalfbanddecim = dsp.FIRHalfbandDecimator  
firhalfbanddecim = dsp.FIRHalfbandDecimator(Name=Value)
```

Description

`firhalfbanddecim = dsp.FIRHalfbandDecimator` returns a halfband decimator, `firhalfbanddecim`, with the default settings. Under the default settings, the System object filters and downsamples the input data with a halfband frequency of 11025 Hz, a transition width of 4.1 kHz, and a stopband attenuation of 80 dB. The design method is set to "Auto".

`firhalfbanddecim = dsp.FIRHalfbandDecimator(Name=Value)` returns a halfband decimator, with additional properties specified by one or more `Name=Value` pair arguments.

Example: `firhalfbanddecim = dsp.FIRHalfbandDecimator(Specification="Filter order and stopband attenuation")` creates an FIR halfband decimator object with filter order set to 52 and stopband attenuation set to 80 dB.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Specification — Filter design parameters

"Transition width and stopband attenuation" (default) | "Filter order and stopband attenuation" | "Filter order and transition width" | "Coefficients"

Filter design parameters, specified as a character vector. When you set `Specification` to one of the following, you choose two of the three available design parameters to design the FIR Halfband filter.

- "Transition width and stopband attenuation" -- Transition width and stopband attenuation are the design parameters.
- "Filter order and stopband attenuation" -- Filter order and stopband attenuation are the design parameters.
- "Filter order and transition width" -- Filter order and transition width are the design parameters.

The filter is designed using the optimal equiripple filter design method or the kaiser-window-based design method.

When you set `Specification` to "Coefficients", you specify the halfband filter coefficients directly through the `Numerator` property.

FilterOrder — Filter order

52 (default) | even positive integer

Filter order, specified as an even positive integer.

Dependencies

This property applies when you set `Specification` to either "Filter order and stopband attenuation" or "Filter order and transition width".

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

StopbandAttenuation — Stopband attenuation

80 (default) | positive real scalar

Stopband attenuation in dB, specified as a positive real scalar.

Dependencies

This property applies when you set `Specification` to either "Filter order and stopband attenuation" or "Transition width and stopband attenuation".

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

TransitionWidth — Transition width

4100 (default) | positive real scalar

Transition width in Hz, specified as a positive real scalar. The value of the transition width in Hz must be less than 1/2 the input sample rate.

Dependencies

This property applies when you set `Specification` to either "Transition width and stopband attenuation" or "Filter order and transition width".

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Numerator — FIR halfband filter coefficients

`firhalfband('minororder',0.407,1e-4)` (default) | row vector

FIR halfband filter coefficients, specified as a row vector. The coefficients must comply with the FIR halfband impulse response format. For details on this format, see “Halfband Filters” on page 4-530 and “FIR Halfband Filter Design”. If half the order of the filter, $(\text{length}(\text{Numerator}) - 1)/2$, is even, every other coefficient starting from the first coefficient must be a zero except for the center coefficient which must be a 0.5. If half the order of the filter is odd, the sequence of alternating zeros with a 0.5 at the center starts at the second coefficient.

Dependencies

This property applies when you set `Specification` to “Coefficients”.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

DesignMethod — Filter design method

“Auto” (default) | “Equiripple” | “Kaiser”

Specify the filter design method as one of the following:

- “Auto” -- The algorithm automatically chooses the filter design method depending on the filter design parameters. The algorithm uses the equiripple or the Kaiser window method to design the filter.

If the design constraints are very tight, such as very high stopband attenuation or very narrow transition width, then the algorithm automatically chooses the Kaiser method, as this method is optimal for designing filters with very tight specifications. However, if the design constraints are not tight, then the algorithm chooses the equiripple method.

When you set the `DesignMethod` property to “Auto”, you can determine the method used by the algorithm by examining the passband and stopband ripple characteristics of the designed filter. If the object used the equiripple method, the passband and stopband ripples of the designed filter have a constant amplitude in the frequency response. If the filter design method the object chooses in the “Auto” mode is not suitable for your application, manually specify the `DesignMethod` as “Equiripple” or “Kaiser”.

- “Equiripple” -- The algorithm uses the equiripple method.
- “Kaiser” -- The algorithm uses the Kaiser window method.

For more details on these two methods, see “Algorithms” on page 4-531.

Dependencies

To enable this property, set `Specification` to “Transition width and stopband attenuation”, “Filter order and stopband attenuation”, or “Filter order and transition width”.

Data Types: `char` | `string`

SampleRate — Input sample rate

44100 (default) | positive real scalar

Input sample rate in Hz, specified as a positive real scalar. The input sample rate defaults to 44100 Hz. If you specify transition width as one of your filter design parameters, the transition width cannot exceed 1/2 the input sample rate.

Data Types: `single` | `double`

Fixed-Point Properties

CoefficientsDataType — Word and fraction lengths of coefficients

`numericity(1,16)` (default) | `numericity` object

Word and fraction lengths of coefficients, specified as a signed or unsigned `numericity` object. The default, `numericity(1,16)` corresponds to a signed numeric type object with 16-bit coefficients and a fraction length determined based on the coefficient values, to give the best possible precision.

This property is not tunable.

Word length of the output is same as the word length of the input. Fraction length of the output is computed such that the entire dynamic range of the output can be represented without overflow. For details on how the fraction length of the output is computed, see “Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters”.

RoundingMethod — Rounding method for output fixed-point operations

"Floor" (default) | "Ceiling" | "Convergent" | "Nearest" | "Round" | "Simplest" | "Zero"

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see “Precision and Range”.

Usage

Syntax

```
y_low = firhalfbanddecim(x)
[y_low,y_high] = firhalfbanddecim(x)
```

Description

`y_low = firhalfbanddecim(x)` filters the input signal `x` using the FIR halfband filter, `firhalfbanddecim`, and downsamples the output by a factor of 2.

`[y_low,y_high] = firhalfbanddecim(x)` computes the `y_low` and `y_high`, of the analysis filter bank, `firhalfbanddecim` for input `x`. A K_i -by- N input matrix is treated as N independent channels. The System object generates two power-complementary output signals by adding and subtracting the two polyphase branch outputs respectively. `y_low` and `y_high` are of the same size (K_o -by- N) and data type. $K_o = K_i/2$, where 2 is the decimation factor.

Input Arguments

x — Data input

column vector | matrix

Data input, specified as a column vector or a matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel. The number of rows in the input signal must be a multiple of 2.

This object supports variable-size input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Output Arguments

y_{low} — Lowpass subband of decimator output

column vector | matrix

Lowpass subband of decimator output, returned as a column vector or a matrix. The output, `ylow` is a lowpass halfband filtered and downsampled version of the input `x`. Due to the halfband nature of the filter, the downsampling factor is always 2.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

y_{high} — Highpass subband of decimator output

column vector | matrix

Highpass subband of decimator output, returned as a column vector or a matrix. The output, `yhigh` is a highpass halfband filtered and downsampled version of the input `x`. Due to the halfband nature of the filter, the downsampling factor is always 2.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.FIRHalfbandDecimator`

<code>freqz</code>	Frequency response of discrete-time filter System object
<code>fvtool</code>	Visualize frequency response of DSP filters
<code>info</code>	Information about filter System object
<code>cost</code>	Estimate cost of implementing filter System object
<code>coeffs</code>	Returns the filter System object coefficients in a structure
<code>polyphase</code>	Polyphase decomposition of multirate filter

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Impulse and Frequency Response of Halfband Decimation Filter

Create two lowpass halfband decimation filters for data sampled at 44.1 kHz. The design method in the first filter is set to "Equiripple" and in the second filter is set to "Kaiser".

The output data rate is 1/2 the input sample rate, or 22.05 kHz. Specify the filter order to be 52 with a transition width of 4.1 kHz.

```
Fs = 44.1e3;
filterspec = "Filter order and transition width";
Order = 52;
TW = 4.1e3;
firhalfbanddecimEquiripple = dsp.FIRHalfbandDecimator(...
    Specification=filterspec,...
    FilterOrder=Order,...
    TransitionWidth=TW,...
    DesignMethod="Equiripple",...
    SampleRate=Fs);
firhalfbanddecimKaiser = dsp.FIRHalfbandDecimator(...
    Specification=filterspec,...
    FilterOrder=Order,...
    TransitionWidth=TW,...
    DesignMethod="Kaiser",...
    SampleRate=Fs);
```

Plot the impulse response of both the filters. The zeroth-order coefficient is delayed 26 samples, which is equal to the group delay of the filter. This yields a causal halfband filter.

```
hfvt = fvtool(firhalfbanddecimEquiripple,firhalfbanddecimKaiser,...
    Analysis="impulse");
legend(hfvt,{'Equiripple','Kaiser'})
```

Plot the magnitude and phase response.

If the filter specifications are tight, say a very high filter order with a very narrow transition width, the filter designed using the "Kaiser" method converges more effectively.

```

hvftMag = fvtool(firhalfbanddecimEquiripple, firhalfbanddecimKaiser, ...
    Analysis="Magnitude");
legend(hvftMag, {'Equiripple', 'Kaiser'})

```

```
hvftPhase = fvtool(firhalfbanddecimEqui, firhalfbanddecimKaiser, ...  
    Analysis="Phase");  
legend(hvftPhase, {'Equiripple', 'Kaiser'})
```

Extract Low Frequency Subband From Speech

Use a halfband analysis filter bank and interpolation filter to extract the low frequency subband from a speech signal.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Note: The `audioDeviceWriter` System object™ is not supported in MATLAB Online.

Set up the audio file reader, the analysis filter bank, audio device writer, and interpolation filter. The sample rate of the audio data is 22050 Hz. The order of the halfband filter is 52, with a transition width of 2 kHz.

Set the design method to "Auto". This mode chooses one of the filter design methods, equiripple or Kaiser, based on the design parameters of the filter.

```
afr = dsp.AudioFileReader(...
    "speech_dft.mp3",...
    SamplesPerFrame=1024);

filtSpec = "Filter order and transition width";
Order = 52;
TW = 2000;
```

```

firhalfbanddecim = dsp.FIRHalfbandDecimator(...
    Specification=filtSpec,...
    FilterOrder=Order,...
    TransitionWidth=TW,...
    DesignMethod="Auto",...
    SampleRate=afr.SampleRate);

firhalfbandinterp = dsp.FIRHalfbandInterpolator(...
    Specification=filtSpec,...
    FilterOrder=Order,...
    TransitionWidth=TW,...
    DesignMethod="Auto",...
    SampleRate=afr.SampleRate/2);

adw = audioDeviceWriter(SampleRate=afr.SampleRate);

```

View the magnitude response of the halfband filter.

```
fvtool(firhalfbanddecim)
```

Read the speech signal from the audio file in frames of 1024 samples. Filter the speech signal into lowpass and highpass subbands with a halfband frequency of 5512.5 Hz. Reconstruct a lowpass approximation of the speech signal by interpolating the lowpass subband. Play the filtered output.

```

while ~isDone(afr)
    audioframe = afr();
    xlo = firhalfbanddecim(audioframe);

```

```
    ylow = firhalfbandinterp(xlo);  
    adw(ylow);  
end
```

Wait until the audio file is played to the end, then close the input file and release the audio output resource.

```
release(afr);  
release(adw);
```

Two-Channel Filter Bank

Use a halfband decimator and interpolator to implement a two-channel filter bank. This example uses an audio file input and shows that the power spectrum of the filter bank output does not differ significantly from the input.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Note: The `audioDeviceWriter` System object™ is not supported in MATLAB Online.

Set up the audio file reader and device writer. Construct the FIR halfband decimator and interpolator. Finally, set up the spectrum analyzer to display the power spectra of the filter-bank input and output.

```
AF = dsp.AudioFileReader("speech_dft.mp3",SamplesPerFrame=1024);  
AP = audioDeviceWriter(SampleRate=AF.SampleRate);
```

```
filterspec = "Filter order and transition width";  
Order = 52;  
TW = 2000;
```

```
firhalfbanddecim = dsp.FIRHalfbandDecimator(...  
    Specification=filterspec,FilterOrder=Order,...  
    TransitionWidth=TW,DesignMethod="Auto",...  
    SampleRate=AF.SampleRate);
```

```
firhalfbandinterp = dsp.FIRHalfbandInterpolator(...  
    Specification=filterspec,FilterOrder=Order,...  
    TransitionWidth=TW,SampleRate=AF.SampleRate/2,...  
    DesignMethod="Auto",...  
    FilterBankInputPort=true);
```

```
SpecAna = spectrumAnalyzer(SampleRate=AF.SampleRate,...  
    PlotAsTwoSidedSpectrum=false,...  
    ShowLegend=true,...  
    ChannelNames={'Input signal','Filtered output signal'});
```

Read the audio 1024 samples at a time. Filter the input to obtain the lowpass and highpass subband signals decimated by a factor of two. This is the analysis filter bank. Use the halfband interpolator as the synthesis filter bank. Display the running power spectrum of the audio input and the output of the synthesis filter bank. Play the output.

```
while ~isDone(AF)  
    audioInput = AF();  
    [xlo,xhigh] = firhalfbanddecim(audioInput);
```

```

    audioOutput = firhalfbandinterp(xlo,xhigh);
    spectrumInput = [audioInput audioOutput];
    SpecAna(spectrumInput);
    AP(audioOutput);
end

release(AF);
release(AP);
release(SpecAna);

```

Filter Input into Lowpass and Highpass Subbands Using FIR Halfband Decimator

Create a halfband decimator for data sampled at 44.1 kHz. Use a minimum-order design with a transition width of 2 kHz and a stopband attenuation of 60 dB.

Set the design method to "Auto". This mode chooses one of the filter design methods, equiripple or Kaiser, based on the specified filter design parameters.

```

hfirhalfbanddecim = dsp.FIRHalfbandDecimator(...
    Specification="Transition width and stopband attenuation",...
    TransitionWidth=2000,...
    StopbandAttenuation=60,...
    DesignMethod="Auto",...
    SampleRate=44.1e3);

```

Filter a two-channel input into low and highpass subbands.

```
x = randn(1024,2);
[ylow,yhigh] = hfirhalfbanddecim(x);
```

More About

Halfband Filters

The ideal lowpass halfband filter is given by

$$h(n) = \frac{1}{2\pi} \int_{-\pi/2}^{\pi/2} e^{j\omega n} d\omega = \frac{\sin(\frac{\pi}{2}n)}{\pi n}.$$

The ideal filter is not realizable because the impulse response is noncausal and not absolutely summable. However, the impulse response of the ideal lowpass filter possesses some important properties that are required of a realizable approximation. Specifically, the ideal lowpass halfband filter's impulse response is:

- equal to 0 for all even-indexed samples
- equal to 1/2 at $n=0$. You can see this by using L'Hopital's rule on the continuous-valued equivalent of the discrete-time impulse response.

The ideal highpass halfband filter is given by

$$g(n) = \frac{1}{2\pi} \int_{-\pi}^{-\pi/2} e^{j\omega n} d\omega + \frac{1}{2\pi} \int_{\pi/2}^{\pi} e^{j\omega n} d\omega.$$

Evaluating the preceding integral gives the following impulse response

$$g(n) = \frac{\sin(\pi n)}{\pi n} - \frac{\sin(\frac{\pi}{2}n)}{\pi n}.$$

The ideal highpass halfband filter's impulse is:

- equal to 0 for all even-indexed samples
- equal to 1/2 at $n=0$.

The FIR halfband decimator uses a causal FIR approximation to the ideal halfband response, which is based on minimizing the ℓ^∞ norm of the error (minimax). See "Algorithms" on page 4-531 for more details.

Kaiser Window

The coefficients of a Kaiser window are computed from this equation:

$$w(n) = \frac{I_0\left(\beta\sqrt{1 - \left(\frac{n - N/2}{N/2}\right)^2}\right)}{I_0(\beta)}, \quad 0 \leq n \leq N,$$

where I_0 is the zeroth-order modified Bessel function of the first kind.

To obtain a Kaiser window that represents an FIR filter with stopband attenuation of α dB, use this β .

$$\beta = \begin{cases} 0.1102(\alpha - 8.7), & \alpha > 50 \\ 0.5842(\alpha - 21)^{0.4} + 0.07886(\alpha - 21), & 50 \geq \alpha \geq 21 \\ 0, & \alpha < 21 \end{cases}$$

The filter order n is given by:

$$n = \frac{\alpha - 7.95}{2.285(\Delta\omega)}$$

where $\Delta\omega$ is the transition width.

Algorithms

Filter Design Method

The FIR halfband decimator algorithm uses the equiripple or the Kaiser window method to design the FIR halfband filter. When the design constraints are tight, such as very high stopband attenuation or very narrow transition width, use the Kaiser window method. When the design constraints are not tight, use the equiripple method. If you are not sure of which method to use, set the design method to **Auto**. In this mode, the algorithm automatically chooses a design method from the two methods that optimally meets the specified filter constraints.

Halfband Equiripple Design

In the equiripple method, the algorithm uses a minimax (minimize the maximum error) FIR design to design a fullband linear phase filter with the desired specifications. The algorithm upsamples a fullband filter to replace the even-indexed samples of the filter with zeros and creates a halfband filter. It then sets the filter tap corresponding to the group delay of the filter in samples to 1/2. This yields a causal linear-phase FIR filter approximation to the ideal halfband filter defined in “Halfband Filters” on page 4-530. See [1] for a description of this filter design method using the Remez exchange algorithm. Since you can design a filter using this approximation method with a constant ripple both in the passband and stopband, the filter is also known as the equiripple filter.

Kaiser Window Design

In the Kaiser window method, the algorithm first truncates the ideal halfband filter defined in “Halfband Filters” on page 4-530, then it applies a Kaiser window defined in “Kaiser Window” on page 4-530. This yields a causal linear-phase FIR filter approximation to the ideal halfband filter.

For more information on designing FIR halfband filters, see “FIR Halfband Filter Design”.

Polyphase Implementation with Halfband Filters

The FIR halfband decimator uses an efficient polyphase implementation for halfband filters when you filter the input signal. The chief advantage of the polyphase implementation is that you can downsample the signal prior to filtering. This allows you to filter at the lower sampling rate.

Splitting a filter’s impulse response, $h(n)$, into two polyphase components results in an even polyphase component with z -transform

$$H_0(z) = \sum_n h(2n)z^{-n}.$$

and an odd polyphase component with z -transform

$$H_1(z) = \sum_n h(2n + 1)z^{-n}.$$

The z -transform of the filter can be written in terms of the even and odd polyphase components as

$$H(z) = H_0(z^2) + z^{-1}H_1(z^2).$$

Graphically, you can represent filtering and input followed by downsampling by two with the following figure

Using the multirate noble identity for downsampling, you can move the downsampling operation before filtering. This allows you to filter at the lower rate.

For a halfband filter, the only nonzero coefficient in the even polyphase component is the coefficient corresponding to z^0 . Implementing the halfband filter as a causal FIR filter shifts the nonzero coefficient to approximately $z^{-N/4}$ where N is the number of filter taps. This process is illustrated in the following figure.

The top plot shows a halfband filter of order 52. The bottom plot shows the even polyphase component. Both of these filters are noncausal. Delaying the even polyphase component by 13 samples creates a causal FIR filter.

To efficiently implement the halfband decimator, the algorithm replaces the delay block and downsampling operator with a commutator switch. This is illustrated in the following figure where one polyphase component is replaced by a gain and delay.

The commutator switch takes input samples from a single branch and supplies every other sample to one of the two polyphase components for filtering. This halves the sampling rate of the input signal. Which polyphase component reduces to a simple delay depends on whether the half order of the filter is even or odd. This is because the delay required to make the even polyphase component causal can be odd or even depending on the filter half order.

To confirm this behavior, run the following code in the MATLAB command prompt and inspect the polyphase components of the following filters:

```
filterspec = "Filter order and stopband attenuation";
halfOrderEven = dsp.FIRHalfbandDecimator(Specification=filterspec,...
    FilterOrder=64,StopbandAttenuation=80,DesignMethod="Auto");
halfOrderOdd = dsp.FIRHalfbandDecimator(Specification=filterspec,...
    FilterOrder=54,StopbandAttenuation=80,DesignMethod="Auto");
polyphase(halfOrderEven)
polyphase(halfOrderOdd)
```

To summarize, the FIR halfband decimator:

- Decimates the input prior to filtering and filters the even and odd polyphase components of the input separately with the even and odd polyphase components of the filter.
- Exploits the fact that one filter polyphase component is a simple delay for a halfband filter.

dsp.FIRHalfbandInterpolator

Package: dsp

Halfband interpolator

Description

The `dsp.FIRHalfbandInterpolator` System object performs efficient polyphase interpolation of the input signal using an upsampling factor of two. You can use `dsp.FIRHalfbandInterpolator` to implement the synthesis portion of a two-band filter bank to synthesize a signal from lowpass and highpass subbands. `dsp.FIRHalfbandInterpolator` uses an FIR equiripple design or a Kaiser window design to construct the halfband filters and a polyphase implementation to filter the input. For more details, see “Algorithms” on page 4-549.

To upsample and interpolate your data:

- 1 Create the `dsp.FIRHalfbandInterpolator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
firhalfbandinterp = dsp.FIRHalfbandInterpolator  
firhalfbandinterp = dsp.FIRHalfbandInterpolator(Name=Value)
```

Description

`firhalfbandinterp = dsp.FIRHalfbandInterpolator` returns a FIR halfband interpolation filter, `firhalfbandinterp`, with the default settings. Under the default settings, the System object upsamples and interpolates the input data using a halfband frequency of 11025 Hz, a transition width of 4.1 kHz, and a stopband attenuation of 80 dB. The design method is set to "Auto".

`firhalfbandinterp = dsp.FIRHalfbandInterpolator(Name=Value)` returns a halfband interpolator, with additional properties specified by one or more `Name=Value` pair arguments.

Example: `firhalfbandinterp = dsp.FIRHalfbandInterpolator(Specification="Filter order and stopband attenuation")` creates an FIR halfband interpolator object with filter order set to 52 and stopband attenuation set to 80 dB.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

Specification — Filter design parameters

"Transition width and stopband attenuation" (default) | "Filter order and stopband attenuation" | "Filter order and transition width" | "Coefficients"

Filter design parameters, specified as a character vector. When you set `Specification` to one of the following, you choose two of the three available design parameters to design the FIR Halfband filter.

- "Transition width and stopband attenuation" -- Transition width and stopband attenuation are the design parameters.
- "Filter order and stopband attenuation" -- Filter order and stopband attenuation are the design parameters.
- "Filter order and transition width" -- Filter order and transition width are the design parameters.

The filter is designed using optimal equiripple filter design method.

When you set `Specification` to "Coefficients", you specify the halfband filter coefficients directly through the `Numerator` property.

FilterOrder — Filter order

52 (default) | even positive integer

Filter order, specified as an even positive integer.

Dependencies

This property applies when you set `Specification` to either "Filter order and stopband attenuation" or "Filter order and transition width".

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

StopbandAttenuation — Stopband attenuation

80 (default) | positive real scalar

Stopband attenuation in dB, specified as a positive real scalar.

Dependencies

This property applies when you set `Specification` to either "Filter order and stopband attenuation" or "Transition width and stopband attenuation".

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

TransitionWidth — Transition width

4100 (default) | positive real scalar

Transition width in Hz, specified as a positive real scalar. The value of the transition width in Hz must be less than 1/2 the input sample rate.

Dependencies

This property applies when you set `Specification` to either "Transition width and stopband attenuation" or "Filter order and transition width".

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Numerator — FIR halfband filter coefficients

`2*firhalfband("minorder",0.407,1e-4)` (default) | row vector

FIR halfband filter coefficients, specified as a row vector. The coefficients must comply with the FIR halfband impulse response format. For details on this format, see “Halfband Filters” on page 4-548 and “FIR Halfband Filter Design”. If half the order of the filter, $(\text{length}(\text{Numerator}) - 1)/2$ is even, every other coefficient starting from the first coefficient must be a zero except for the center coefficient which must be a 1.0. If half the order of the filter is odd, the sequence of alternating zeros with a 1.0 at the center starts at the second coefficient.

Dependencies

This property applies when you set `Specification` to “Coefficients”.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

DesignMethod — Filter design method

“Auto” (default) | “Equiripple” | “Kaiser”

Specify the filter design method as one of the following:

- “Auto” -- The algorithm automatically chooses the filter design method depending on the filter design parameters. The algorithm uses the equiripple or the Kaiser window method to design the filter.

If the design constraints are very tight, such as very high stopband attenuation or very narrow transition width, then the algorithm automatically chooses the Kaiser method, as this method is optimal for designing filters with very tight specifications. However, if the design constraints are not tight, then the algorithm chooses the equiripple method.

When you set the `DesignMethod` property to “Auto”, you can determine the method used by the algorithm by examining the passband and stopband ripple characteristics of the designed filter. If the object used the equiripple method, the passband and stopband ripples of the designed filter have a constant amplitude in the frequency response. If the filter design method the object chooses in the “Auto” mode is not suitable for your application, manually specify the `DesignMethod` as “Equiripple” or “Kaiser”.

- “Equiripple” -- The algorithm uses the equiripple method.
- “Kaiser” -- The algorithm uses the Kaiser window method.

For more details on these two methods, see “Algorithms” on page 4-549.

Dependencies

To enable this property, set `Specification` to “Transition width and stopband attenuation”, “Filter order and stopband attenuation”, or “Filter order and transition width”.

Data Types: `char` | `string`

SampleRate — Input sample rate

44100 (default) | positive real scalar

Input sample rate in Hz, specified as a positive real scalar. The input sample rate defaults to 44100 Hz. If you specify a transition width as one of your filter design parameters, the transition width cannot exceed 1/2 the input sample rate.

Data Types: `single` | `double`

FilterBankInputPort — Synthesis filter bank

`false` (default) | `true`

Synthesis filter bank, specified as either `false` or `true`. If this property is `false`, `dsp.FIRHalfbandInterpolator` is an interpolation filter for a single vector- or matrix-valued input when you call the algorithm. If this property is `true`, `dsp.FIRHalfbandInterpolator` is a synthesis filter bank and the algorithm accepts two inputs, the lowpass and highpass subbands to synthesize.

Fixed-Point Properties

CoefficientsDataType — Word and fraction lengths of coefficients

`numericType(1,16)` (default) | `numericType` object

Word and fraction lengths of coefficients, specified as a signed or unsigned `numericType` object. The default, `numericType(1,16)` corresponds to a signed numeric type object with 16-bit coefficients and a fraction length determined based on the coefficient values, to give the best possible precision.

This property is not tunable.

Word length of the output is same as the word length of the input. Fraction length of the output is computed such that the entire dynamic range of the output can be represented without overflow. For details on how the fraction length of the output is computed, see “Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters”.

RoundingMethod — Rounding method for output fixed-point operations

`"Floor"` (default) | `"Ceiling"` | `"Convergent"` | `"Nearest"` | `"Round"` | `"Simplest"` | `"Zero"`

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see “Precision and Range”.

Usage

Syntax

```
y = firhalfbandinterp(x1)
y = firhalfbandinterp(x1,x2)
```

Description

`y = firhalfbandinterp(x1)` upsamples by two and interpolates the input signal `x1` using the FIR halfband interpolator, `firhalfbandinterp`.

`y = firhalfbandinterp(x1,x2)` implements a halfband synthesis filter bank for the inputs `x1` and `x2`. `x1` is the lowpass output of a halfband analysis filter bank and `x2` is the highpass output of a halfband analysis filter bank. `dsp.FIRHalfbandInterpolator` implements a synthesis filter bank only when the `FilterBankInputPort` property is set to `true`.

Input Arguments

x1 — Data input

column vector | matrix

Data input to the FIR halfband interpolator, specified as a column vector or a matrix. This signal is the lowpass output of a halfband analysis filter bank. If the input signal is a matrix, each column of the matrix is treated as an independent channel.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

x2 — Second data input

column vector | matrix

Second data input to the synthesis filter bank, specified as a column vector or a matrix. This signal is the highpass output of a halfband analysis filter bank. If the input signal is a matrix, each column of the matrix is treated as an independent channel.

The size, data type, and complexity of both the inputs must be the same.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

Output Arguments

y — Output of interpolator

column vector | matrix

Output of the interpolator, returned as a column vector or a matrix. The number of rows in the interpolator output is twice the number of rows in the input signal.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.FIRHalfbandInterpolator`

<code>freqz</code>	Frequency response of discrete-time filter System object

Examples

Impulse and Frequency Response of Halfband Interpolation Filter

Create two lowpass halfband interpolation filters for upsampling data to 44.1 kHz. The design method in the first filter is set to "Equiripple" and in the second filter is set to "Kaiser".

Specify a filter order of 52 and a transition width of 4.1 kHz.

```
Fs = 44.1e3;
InputSampleRate = Fs/2;
Order = 52;
TW = 4.1e3;
filterspec = "Filter order and transition width";

firhalfbandinterpEqui = dsp.FIRHalfbandInterpolator(...
    Specification=filterspec,FilterOrder=Order,...
    TransitionWidth=TW,DesignMethod="Equiripple",...
    SampleRate=InputSampleRate);

firhalfbandinterpKaiser = dsp.FIRHalfbandInterpolator(...
    Specification=filterspec,FilterOrder=Order,...
    TransitionWidth=TW,DesignMethod="Kaiser",...
    SampleRate=InputSampleRate);
```

Plot the impulse response of both the filters. The zeroth-order coefficient is delayed 26 samples, which is equal to the group delay of the filter. This yields a causal halfband filter.

```
hfvt = fvtool(firhalfbandinterpEqui,firhalfbandinterpKaiser,...
    Analysis="Impulse");
legend(hfvt,{'Equiripple','Kaiser'})
```

Plot the magnitude and phase response.

If the filter specifications are tight, say a very high filter order with a very narrow transition width, the filter designed using the "Kaiser" method converges more effectively.

```
hvftMag = fvtool(firhalfbandinterpEqui,firhalfbandinterpKaiser,...  
    Analysis="Magnitude");  
legend(hvftMag,{'Equiripple','Kaiser'})
```

```
hvftPhase = fvtool(firhalfbandinterpEqui, firhalfbandinterpKaiser, ...  
    Analysis="Phase");  
legend(hvftPhase, {'Equiripple', 'Kaiser'})
```

Extract Low Frequency Subband From Speech

Use a halfband analysis filter bank and interpolation filter to extract the low frequency subband from a speech signal.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Note: The `audioDeviceWriter` System object™ is not supported in MATLAB Online.

Set up the audio file reader, the analysis filter bank, audio device writer, and interpolation filter. The sample rate of the audio data is 22050 Hz. The order of the halfband filter is 52, with a transition width of 2 kHz.

Set the design method to "Auto". This mode chooses one of the filter design methods, equiripple or Kaiser, based on the design parameters of the filter.

```
afr = dsp.AudioFileReader(...
    "speech_dft.mp3",...
    SamplesPerFrame=1024);

filtSpec = "Filter order and transition width";
Order = 52;
TW = 2000;
```

```

firhalfbanddecim = dsp.FIRHalfbandDecimator(...
    Specification=filtSpec,...
    FilterOrder=Order,...
    TransitionWidth=TW,...
    DesignMethod="Auto",...
    SampleRate=afr.SampleRate);

firhalfbandinterp = dsp.FIRHalfbandInterpolator(...
    Specification=filtSpec,...
    FilterOrder=Order,...
    TransitionWidth=TW,...
    DesignMethod="Auto",...
    SampleRate=afr.SampleRate/2);

adw = audioDeviceWriter(SampleRate=afr.SampleRate);

```

View the magnitude response of the halfband filter.

```
fvtool(firhalfbanddecim)
```

Read the speech signal from the audio file in frames of 1024 samples. Filter the speech signal into lowpass and highpass subbands with a halfband frequency of 5512.5 Hz. Reconstruct a lowpass approximation of the speech signal by interpolating the lowpass subband. Play the filtered output.

```

while ~isDone(afr)
    audioframe = afr();
    xlo = firhalfbanddecim(audioframe);

```

```
    ylow = firhalfbandinterp(xlo);  
    adw(ylow);  
end
```

Wait until the audio file is played to the end, then close the input file and release the audio output resource.

```
release(afr);  
release(adw);
```

Two-Channel Filter Bank

Use a halfband decimator and interpolator to implement a two-channel filter bank. This example uses an audio file input and shows that the power spectrum of the filter bank output does not differ significantly from the input.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Note: The `audioDeviceWriter` System object™ is not supported in MATLAB Online.

Set up the audio file reader and device writer. Construct the FIR halfband decimator and interpolator. Finally, set up the spectrum analyzer to display the power spectra of the filter-bank input and output.

```
AF = dsp.AudioFileReader("speech_dft.mp3",SamplesPerFrame=1024);  
AP = audioDeviceWriter(SampleRate=AF.SampleRate);
```

```
filterspec = "Filter order and transition width";  
Order = 52;  
TW = 2000;
```

```
firhalfbanddecim = dsp.FIRHalfbandDecimator(...  
    Specification=filterspec,FilterOrder=Order,...  
    TransitionWidth=TW,DesignMethod="Auto",...  
    SampleRate=AF.SampleRate);  
  
firhalfbandinterp = dsp.FIRHalfbandInterpolator(...  
    Specification=filterspec,FilterOrder=Order,...  
    TransitionWidth=TW,SampleRate=AF.SampleRate/2,...  
    DesignMethod="Auto",...  
    FilterBankInputPort=true);
```

```
SpecAna = spectrumAnalyzer(SampleRate=AF.SampleRate,...  
    PlotAsTwoSidedSpectrum=false,...  
    ShowLegend=true,...  
    ChannelNames={'Input signal','Filtered output signal'});
```

Read the audio 1024 samples at a time. Filter the input to obtain the lowpass and highpass subband signals decimated by a factor of two. This is the analysis filter bank. Use the halfband interpolator as the synthesis filter bank. Display the running power spectrum of the audio input and the output of the synthesis filter bank. Play the output.

```
while ~isDone(AF)  
    audioInput = AF();  
    [xlo,xhigh] = firhalfbanddecim(audioInput);
```

```

    audioOutput = firhalfbandinterp(xlo,xhigh);
    spectrumInput = [audioInput audioOutput];
    SpecAna(spectrumInput);
    AP(audioOutput);
end

release(AF);
release(AP);
release(SpecAna);

```

Upsample and Interpolate Multichannel Input Using FIR Halfband Interpolator

Create a half-band interpolation filter for data sampled at 44.1 kHz. The filter order is 52 with a transition width of 4.1 kHz. Use the filter to upsample and interpolate a multichannel input.

Set the design method to "Auto". This mode chooses one of the filter design methods, equiripple or Kaiser, based on the specified filter design parameters.

```

Fs = 44.1e3;
filterspec = "Filter order and transition width";
Order = 52;
TW = 4.1e3;
firhalfbandinterp = dsp.FIRHalfbandInterpolator(...
    Specification=filterspec,...

```

```

FilterOrder=Order,...
TransitionWidth=TW,...
DesignMethod="Auto",...
SampleRate=Fs);

x = randn(1024,4);
y = firhalfbandinterp(x);

```

More About

Halfband Filters

The ideal lowpass halfband filter is given by

$$h(n) = \frac{1}{2\pi} \int_{-\pi/2}^{\pi/2} e^{j\omega n} d\omega = \frac{\sin(\frac{\pi}{2}n)}{\pi n}.$$

The ideal filter is not realizable because the impulse response is noncausal and not absolutely summable. However, the impulse response of the ideal lowpass filter possesses some important properties that are required of a realizable approximation. Specifically, the ideal lowpass halfband filter's impulse response is:

- equal to 0 for all even-indexed samples
- equal to 1/2 at $n=0$. You can see this by using L'Hopital's rule on the continuous-valued equivalent of the discrete-time impulse response.

The ideal highpass halfband filter is given by

$$g(n) = \frac{1}{2\pi} \int_{-\pi}^{-\pi/2} e^{j\omega n} d\omega + \frac{1}{2\pi} \int_{\pi/2}^{\pi} e^{j\omega n} d\omega.$$

Evaluating the preceding integral gives the following impulse response

$$g(n) = \frac{\sin(\pi n)}{\pi n} - \frac{\sin(\frac{\pi}{2}n)}{\pi n}.$$

The ideal highpass halfband filter's impulse is:

- Equal to 0 for all even-indexed samples
- Equal to 1/2 at $n=0$.

The FIR halfband interpolator uses a causal FIR approximation to the ideal halfband response, which is based on minimizing the ℓ^∞ norm of the error (minimax). See "Algorithms" on page 4-549 for more details.

Kaiser Window

The coefficients of a Kaiser window are computed from this equation:

$$w(n) = \frac{I_0\left(\beta\sqrt{1 - \left(\frac{n - N/2}{N/2}\right)^2}\right)}{I_0(\beta)}, \quad 0 \leq n \leq N,$$

where I_0 is the zeroth-order modified Bessel function of the first kind.

To obtain a Kaiser window that represents an FIR filter with stopband attenuation of α dB, use this β .

$$\beta = \begin{cases} 0.1102(\alpha - 8.7), & \alpha > 50 \\ 0.5842(\alpha - 21)^{0.4} + 0.07886(\alpha - 21), & 50 \geq \alpha \geq 21 \\ 0, & \alpha < 21 \end{cases}$$

The filter order n is given by:

$$n = \frac{\alpha - 7.95}{2.285(\Delta\omega)}$$

where $\Delta\omega$ is the transition width.

Algorithms

Filter Design Method

The FIR halfband interpolator algorithm uses the equiripple or the Kaiser window method to design the FIR halfband filter. When the design constraints are tight, such as very high stopband attenuation or very narrow transition width, use the Kaiser window method. When the design constraints are not tight, use the equiripple method. If you are not sure of which method to use, set the design method to **Auto**. In this mode, the algorithm automatically chooses a design method from the two methods that optimally meets the specified filter constraints.

Halfband Equiripple Design

In the equiripple method, the algorithm uses a minimax (minimize the maximum error) FIR design to design a fullband linear phase filter with the desired specifications. The algorithm upsamples a fullband filter to replace the even-indexed samples of the filter with zeros and creates a halfband filter. It then sets the filter tap corresponding to the group delay of the filter in samples to 1/2. This yields a causal linear-phase FIR filter approximation to the ideal halfband filter defined in “Halfband Filters” on page 4-548. See [1] for a description of this filter design method using the Remez exchange algorithm. Since you can design a filter using this approximation method with a constant ripple both in the passband and stopband, the filter is also known as the equiripple filter.

Kaiser Window Design

In the Kaiser window method, the algorithm first truncates the ideal halfband filter defined in “Halfband Filters” on page 4-548, then it applies a Kaiser window defined in “Kaiser Window” on page 4-548. This yields a causal linear-phase FIR filter approximation to the ideal halfband filter.

The coefficients of the designed halfband interpolation filter are scaled by the interpolation factor, two, to preserve the output power of the signal.

For more information on designing FIR halfband filters, see “FIR Halfband Filter Design”.

Polyphase Implementation with Halfband Filters

The FIR halfband interpolator uses an efficient polyphase implementation for halfband filters when you filter the input signal. You can use a polyphase implementation to move the upsampling operation after filtering. This allows you to filter at the lower sampling rate.

Splitting a filter's impulse response, $h(n)$, into two polyphase components results in an even polyphase component with z -transform

$$H_0(z) = \sum_n h(2n)z^{-n}.$$

and an odd polyphase component with z -transform

$$H_1(z) = \sum_n h(2n + 1)z^{-n}.$$

The z -transform of the filter can be written in terms of the even and odd polyphase components as

$$H(z) = H_0(z^2) + z^{-1}H_1(z^2).$$

Graphically, you can represent upsampling by two followed by filtering with the following figure

Using the multirate noble identity for upsampling, you can move the upsampling operation after filtering. This enables you to filter at the lower rate.

For a halfband filter, the only nonzero coefficient in the even polyphase component is the coefficient corresponding to z^0 . Implementing the halfband filter as a causal FIR filter shifts the nonzero coefficient to approximately $z^{-N/4}$, where N is the number of filter taps. This process is shown in the following figure.

The top plot shows a halfband filter of order 52. The bottom plot shows the even polyphase component. Both of these filters are noncausal. Delaying the even polyphase component by 13 samples creates a causal FIR filter.

To efficiently implement the halfband interpolator, the algorithm replaces the upsampling operator, delay block, and adder with a commutator switch. This is shown in the following figure, where one polyphase component is replaced by a delay.

The commutator switch takes input samples from the two branches alternately, one sample at a time. This doubles the sampling rate of the input signal. The polyphase component that reduces to a simple delay depends on whether the half order of the filter is even or odd. This is because the delay required to make the even polyphase component causal can be odd or even, depending on the filter half order.

To confirm this behavior, run the following code in the MATLAB command prompt and inspect the polyphase components of the following filters:

```
filterspec = "Filter order and stopband attenuation";
halfOrderEven = dsp.FIRHalfbandInterpolator(Specification=filterspec,...
    FilterOrder=64,StopbandAttenuation=80);
halfOrderOdd = dsp.FIRHalfbandInterpolator(Specification=filterspec,...
    FilterOrder=54,StopbandAttenuation=80);
polyphase(halfOrderEven)
polyphase(halfOrderOdd)
```

One of the polyphase components has a single nonzero coefficient indicating that it is a simple delay. To preserve the output power of the signal, the coefficients are scaled by the interpolation factor, two. To see this scaling, compare the polyphase components of a halfband interpolator with the coefficients of a halfband decimator.

```
hfirinterp = dsp.FIRHalfbandInterpolator;
hfirdecim = dsp.FIRHalfbandDecimator;
polyphase(hfirdecim)
polyphase(hfirinterp)
```

To summarize, the FIR halfband interpolator:

- Filters the input before upsampling with the even and odd polyphase components of the filter.
- Exploits the fact that one filter polyphase component is a simple delay for a halfband filter.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

This object supports code generation for ARM Cortex-M and ARM Cortex-A processors. To learn more about ARM Cortex code generation, see “Code Generation for ARM Cortex-M and ARM Cortex-A Processors”.

This object also supports SIMD code generation using Intel AVX2 technology when the input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

dsp.FIRInterpolator

Package: dsp

Polyphase FIR interpolator

Description

The `dsp.FIRInterpolator` System object upsamples an input by the integer upsampling factor L along the first dimension. The FIR interpolator (as shown in the schematic) conceptually consists of an upsampler followed by an FIR anti-imaging filter, which is usually an approximation of an ideal band-limited interpolation filter. The coefficients of the anti-imaging filter can be specified through the `Numerator` property, or can be automatically designed by the object using the `designMultirateFIR` function.

The upsampler upsamples each channel of the input to a higher rate by inserting $L-1$ zeros between samples. The FIR filter that follows filters each channel of the upsampled data. The resulting discrete-time signal has a sample rate that is L times the original sample rate.

Note that the actual object algorithm implements a direct-form FIR polyphase structure, an efficient equivalent of the combined system depicted in the diagram. For more details, see “Algorithms” on page 4-569.

To upsample an input:

- 1 Create the `dsp.FIRInterpolator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Under specific conditions, this System object also supports SIMD code generation. For details, see “Code Generation” on page 4-571.

Creation

Syntax

```
firinterp = dsp.FIRInterpolator
firinterp = dsp.FIRInterpolator(L)
firinterp = dsp.FIRInterpolator(L, 'Auto')
```

```

firinterp = dsp.FIRInterpolator(L,num)
firinterp = dsp.FIRInterpolator(L,method)
firinterp = dsp.FIRInterpolator( ____,Name,Value)
firinterp = dsp.FIRInterpolator(L,'legacy')

```

Description

`firinterp = dsp.FIRInterpolator` returns an FIR interpolator with an interpolation factor of 3. The object designs the FIR filter coefficients using the `designMultirateFIR(3,1)` function.

`firinterp = dsp.FIRInterpolator(L)` returns an FIR interpolator with the integer-valued `InterpolationFactor` property set to L . The object designs its filter coefficients based on the interpolation factor L that you specify while creating the object using the `designMultirateFIR(L,1)` function. The designed filter corresponds to a lowpass with a cutoff at π/L in radial frequency units.

`firinterp = dsp.FIRInterpolator(L,'Auto')` returns an FIR interpolator with the `NumeratorSource` property set to 'Auto'. In this mode, every time there is an update in the interpolation factor, the object redesigns the filter using the design method specified in `DesignMethod`.

`firinterp = dsp.FIRInterpolator(L,num)` returns an FIR interpolator with the `InterpolationFactor` property set to L and the `Numerator` property set to `num`.

`firinterp = dsp.FIRInterpolator(L,method)` returns an FIR interpolator with the `InterpolationFactor` property set to L and the `DesignMethod` property set to `method`. When you pass the design method as an input, the `NumeratorSource` property is automatically set to 'Auto'.

`firinterp = dsp.FIRInterpolator(____,Name,Value)` returns an FIR interpolator object with each specified property set to the specified value. Enclose each property name in quotes. You can use this syntax with any previous input argument combinations.

`firinterp = dsp.FIRInterpolator(L,'legacy')` returns an FIR interpolator where the filter coefficients are designed using `fir1(15,0.25)`. The designed filter has a cutoff frequency of 0.25π radians/sample.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

InterpolationFactor — Interpolation factor

3 (default) | positive integer

Specify the integer factor, L , by which to increase the sampling rate of the input signal. The polyphase implementation uses L polyphase subfilters to compute convolutions at the lower sample rate. The FIR interpolator delays and interleaves these lower-rate convolutions to obtain the higher-rate output.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

NumeratorSource — FIR filter coefficient source

'Property' (default) | 'Input port' | 'Auto'

FIR filter coefficient source, specified as either:

- 'Property' -- The numerator coefficients are specified through the `Numerator` property.
- 'Input port' -- The numerator coefficients are specified as an input to the object algorithm.
- 'Auto' -- The numerator coefficients are designed automatically using the design method specified in `DesignMethod`.

Numerator — FIR filter coefficients`designMultirateFIR(L,1)` (default) | row vector

Numerator coefficients of the anti-imaging FIR filter, specified as a row vector in powers of z^{-1} . The following equation defines the system function for a filter of length $N+1$:

$$H(z) = \sum_{n=0}^N b(n)z^{-n}$$

The vector $\mathbf{b} = [b(0), b(1), \dots, b(N)]$ represents the vector of filter coefficients.

To act as an effective anti-imaging filter, the coefficients usually correspond to a lowpass filter with a normalized cutoff frequency no greater than the reciprocal of the `InterpolationFactor`. Use `designMultirateFIR` to design such a filter. More generally, any complex bandpass filter can be used. For an example, see “Double the Sample Rate Using FIR Interpolator” on page 4-567.

The filter coefficients are scaled by the value of the `InterpolationFactor` property before filtering the signal. To form the L polyphase subfilters, `Numerator` is appended with zeros if necessary.

Dependencies

This property is visible only when you set `NumeratorSource` to 'Property'.

When `NumeratorSource` is set to 'Auto', the numerator coefficients are automatically redesigned using the design method specified in `DesignMethod`. To access the filter coefficients in the automatic design mode, type `objName.Numerator` in the MATLAB command prompt.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

DesignMethod — Auto design method

'Kaiser' (default) | 'ZOH' | 'Linear'

Design method of the FIR filter coefficients, specified as one of the following:

- 'Kaiser' -- Kaiser method. Approximate anti-imaging lowpass filter using the `designMultirateFIR` function.
- 'ZOH' -- Zero order hold method. Hold the input sequence values.
- 'Linear' -- Linear interpolation method.

Dependencies

This property is visible only when you set the `NumeratorSource` property to 'Auto', or if you pass the 'auto' keyword as an input while creating the object.

Fixed-Point Properties

FullPrecisionOverride — Full-precision override for fixed-point arithmetic

true (default) | false

Flag to use full-precision rules for fixed-point arithmetic, specified as one of the following:

- `true` -- The object computes all internal arithmetic and output data types using the full-precision rules. These rules provide the most accurate fixed-point numerics. In this mode, other fixed-point properties do not apply. No quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- `false` -- Fixed-point data types are controlled through individual fixed-point property settings.

For more information, see “Full Precision for Fixed-Point System Objects” and “Set System Object Fixed-Point Properties”.

RoundingMethod — Rounding method for fixed-point operations

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Rounding method for fixed-point operations. For more details, see rounding mode.

Dependencies

This property is not visible and has no effect on the numerical results when the following conditions are met:

- FullPrecisionOverride set to `true`.
- FullPrecisionOverride set to `false`, ProductDataType set to 'Full precision', AccumulatorDataType set to 'Full precision', and OutputDataType set to 'Same as accumulator'.

Under these conditions, the object operates in full precision mode.

OverflowAction — Overflow action for fixed-point operations

'Wrap' (default) | 'Saturate'

Overflow action for fixed-point operations, specified as one of the following:

- `'Wrap'` -- The object wraps the result of its fixed-point operations.
- `'Saturate'` -- The object saturates the result of its fixed-point operations.

For more details on overflow actions, see overflow mode for fixed-point operations.

Dependencies

This property is not visible and has no effect on the numerical results when the following conditions are met:

- FullPrecisionOverride set to `true`.
- FullPrecisionOverride set to `false`, OutputDataType set to 'Same as accumulator', ProductDataType set to 'Full precision', and AccumulatorDataType set to 'Full precision'

Under these conditions, the object operates in full precision mode.

CoefficientsDataType — Data type of FIR filter coefficients`Same word length as input (default) | Custom`

Data type of the FIR filter coefficients, specified as:

- `Same word length as input` -- The word length of the coefficients is the same as that of the input. The fraction length is computed to give the best possible precision.
- `Custom` -- The coefficients data type is specified as a custom numeric type through the `CustomCoefficientsDataType` property.

CustomCoefficientsDataType — Word and fraction lengths of coefficients data type`numerictype([],16,15) (default) | custom numeric type`

Word and fraction lengths of the coefficients data type, specified as an autosigned `numerictype` with a word length of 16 and a fraction length of 15.

Dependencies

This property applies when you set the `CoefficientsDataType` property to `Custom`.

ProductDataType — Data type of product output`'Full precision' (default) | 'Custom' | 'Same as input'`

Data type of the product output in this object, specified as one of the following:

- `'Full precision'` -- The product output data type has full precision.
- `'Same as input'` -- The object specifies the product output data type to be the same as that of the input data type.
- `'Custom'` -- The product output data type is specified as a custom numeric type through the `CustomProductDataType` property.

For more information on the product output data type, see “Multiplication Data Types”.

Dependencies

This property applies when you set `FullPrecisionOverride` to `false`.

CustomProductDataType — Word and fraction lengths of product data type`numerictype([],32,30) (default) | custom numeric type`

Word and fraction lengths of the product data type, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set `FullPrecisionOverride` to `false` and `ProductDataType` to `'Custom'`.

AccumulatorDataType — Data type of accumulation operation`'Full precision' (default) | 'Same as input' | 'Same as product' | 'Custom'`

Data type of an accumulation operation in this object, specified as one of the following:

- `'Full precision'` -- The accumulation operation has full precision.
- `'Same as product'` -- The object specifies the accumulator data type to be the same as that of the product output data type.

- 'Same as input' -- The object specifies the accumulator data type to be the same as that of the input data type.
- 'Custom' -- The accumulator data type is specified as a custom numeric type through the CustomAccumulatorDataType property.

Dependencies

This property applies when you set FullPrecisionOverride to false.

CustomAccumulatorDataType — Word and fraction lengths of accumulator data type

numericType([],32,30) (default) | custom numeric type

Word and fraction lengths of the accumulator data type, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set FullPrecisionOverride to false and AccumulatorDataType to 'Custom'.

OutputDataType — Data type of object output

'Same as accumulator' (default) | 'Same as input' | 'Same as product' | 'Custom'

Data type of the object output, specified as one of the following:

- 'Same as accumulator' -- The output data type is the same as that of the accumulator output data type.
- 'Same as input' -- The output data type is the same as that of the input data type.
- 'Same as product' -- The output data type is the same as that of the product output data type.
- 'Custom' -- The output data type is specified as a custom numeric type through the CustomOutputDataType property.

Dependencies

This property applies when you set FullPrecisionOverride to false.

CustomOutputDataType — Word and fraction lengths of output data type

numericType([],16,15) (default) | custom numeric type

Word and fraction lengths of the output data type, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Dependencies

This property applies only when you set FullPrecisionOverride to false and OutputDataType to 'Custom'.

Usage

Syntax

```
y = firinterp(x)
y = firinterp(x,num)
```

Description

`y = firinterp(x)` interpolates the input signal `x` along the first dimension, and outputs the upsampled and filtered values, `y`.

`y = firinterp(x,num)` uses the FIR filter, `num`, to interpolate the input signal. This configuration is valid only when the 'NumeratorSource' property is set to 'Input port'.

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix. A P -by- Q input matrix is treated as Q independent channels, and the System object interpolates each channel over the first dimension and generates a $P*L$ -by- Q output matrix, where L is the interpolation factor.

This object supports variable-size input and does not support complex unsigned fixed-point inputs.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

num — FIR filter coefficients

row vector

FIR filter coefficients, specified as a row vector.

Dependencies

This input is accepted only when the 'NumeratorSource' property is set to 'Input port'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

Output Arguments

y — FIR interpolator output

vector | matrix

FIR interpolator output, returned as a vector or a matrix of size $P*L$ -by- Q , where L is the interpolation factor.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.FIRInterpolator

`freqz` Frequency response of discrete-time filter System object
`fvtool` Visualize frequency response of DSP filters

info	Information about filter System object
cost	Estimate cost of implementing filter System object
polyphase	Polyphase decomposition of multirate filter
generatehdl	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)
impz	Impulse response of discrete-time filter System object
coeffs	Returns the filter System object coefficients in a structure

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Interpolate a Cosine Wave

Interpolate a cosine wave by a factor of 2. In the automatic filter design mode, change the underlying D/A signal interpolation model to 'linear' and interpolate the signal by a factor of 4, change the underlying D/A signal interpolation model to 'ZOH' and interpolate the signal by a factor of 5.

The cosine wave has an angular frequency of $\frac{\pi}{4}$ radians/sample.

```
x = cos(pi/4*(0:39)');
```

Design Default Filter

Create a `dsp.FIRInterpolator` object. The object uses an anti-imaging lowpass filter after upsampling. By default, the anti-imaging lowpass filter is designed using the `designMultirateFIR` function. The function designs the filter based on the interpolation factor that you specify, and stores the coefficients in the `Numerator` property. For an interpolation factor of 2, the object designs the coefficients using `designMultirateFIR(2,1)`.

```
firinterp = dsp.FIRInterpolator(2)
```

```
firinterp =
  dsp.FIRInterpolator with properties:
    InterpolationFactor: 2
    NumeratorSource: 'Property'
    Numerator: [0 -2.0108e-04 0 7.7408e-04 0 -0.0020 0 0.0045 ... ]
```

```
Show all properties
```

Visualize the filter response using `fvtool`. The designed filter meets the ideal filter constraints that are marked in red. The cutoff frequency is approximately half the spectrum.

```
fvtool(firinterp)
```

Interpolate by 2

Interpolate the cosine signal by a factor of 2.

```
y = firinterp(x);
```

Plot the original and interpolated signals. In order to plot the two signals on the same plot, you must account for the output delay of the FIR interpolator and the scaling introduced by the filter. Use the `outputDelay` function to compute the delay value introduced by the interpolator. Shift the output by this delay value.

Visualize the input and the resampled signals. The input and output values coincide every other sample, due to the interpolation factor of 2.

```
[delay,FsOut] = outputDelay(firinterp)
```

```
delay = 12
```

```
FsOut = 2
```

```
nx = (0:length(x)-1);
ty = (0:length(y)-1)/FsOut-delay;
stem(ty,y,'filled',MarkerSize=4); hold on;
stem(nx,x); hold off;
xlim([-5,20])
ylim([-2.5 2.5])
legend('Interpolated by 2','Input signal','Location','best');
```

Interpolate by 4 in Automatic Filter Design Mode

Now interpolate by a factor of 4. In order for the filter design to be updated automatically based on the new interpolation factor, set the `NumeratorSource` property to `'Auto'`. Alternately, you can pass the keyword `'Auto'` as an input while creating the object. The object then operates in the automatic filter design mode. Every time there is a change in the interpolation factor, the object updates the filter design.

```
release(firinterp)
firinterp.NumeratorSource = 'Auto';
firinterp.InterpolationFactor = 4

firinterp =
  dsp.FIRInterpolator with properties:

    InterpolationFactor: 4
    NumeratorSource: 'Auto'
    DesignMethod: 'Kaiser'

Show all properties
```

To access the filter coefficients in the automatic filter design mode, type `firinterp.Numerator` in the MATLAB command prompt.

The designed filter occupies a narrower passband that is approximately a quarter of the spectrum.

```
fvtool(firinterp)
```

Interpolate the cosine signal by a factor of 4.

```
yAuto = firinterp(x);
```

Plot the original and resampled signals. Recalculate the delay and the output sample rate values since the interpolation factor has changed. The input and output values coincide every 4 output samples, owing to the interpolation factor of 4.

```
[delay,FsOut] = outputDelay(firinterp);
```

```
nx = (0:length(x)-1);
tyAuto = (0:length(yAuto)-1)/FsOut-delay;
stem(tyAuto,yAuto,'filled',MarkerSize=4); hold on;
stem(nx,x); hold off;
xlim([-5,10])
ylim([-2.5 2.5])
legend('Interpolated by 4','Input signal');
```

Specify Signal Interpolation Model

In the automatic design mode, you can also specify the underlying D/A signal interpolation model through the `DesignMethod` property.

Set `DesignMethod` to 'linear'

If you set the `DesignMethod` to 'linear', the object uses the linear interpolation model.

```
release(firinterp)
firinterp.DesignMethod = 'linear'

firinterp =
  dsp.FIRInterpolator with properties:

    InterpolationFactor: 4
    NumeratorSource: 'Auto'
    DesignMethod: 'Linear'

Show all properties
```

Interpolate the signal using the linear interpolation model.

```
ylinear = firinterp(x);
```

Plot the original and the linearly interpolated signal.

```

[delay,FsOut] = outputDelay(firinterp);
nx = (0:length(x)-1);

% Calculate output times for vector ylinear in input units
tylinear = (0:length(ylinear)-1)/FsOut-delay;

stem(tylinear,ylinear,'filled',MarkerSize=4); hold on;
stem(nx,x);
hold off;
xlim([0,10])
ylim([-2.5 2.5])
legend('Linear Interpolation by 4','Input signal');

```

Set DesignMethod to 'ZOH' and Change InterpolationFactor to 5

If you set the DesignMethod to 'ZOH', the object uses the zero order hold method. Change the interpolation factor to 5.

```

release(firinterp)
firinterp.DesignMethod = 'ZOH';
firinterp.InterpolationFactor = 5

firinterp =
    dsp.FIRInterpolator with properties:

        InterpolationFactor: 5
        NumeratorSource: 'Auto'
        DesignMethod: 'ZOH'

```

Show all properties

Interpolate the signal using the zero order hold method.

```
yzoh = firinterp(x);
```

Plot the original and ZOH interpolated signal.

```
[delay,FsOut] = outputDelay(firinterp);
nx = (0:length(x)-1);
```

```
% Calculate output times for vector yzoh in input units
tyzoh = (0:length(yzoh)-1)/FsOut-delay;
```

```
stem(tyzoh,yzoh,'filled',MarkerSize=4); hold on;
stem(nx,x); hold off;
xlim([0,10])
ylim([-1.5 1.5])
legend('ZOH Interpolation by 4','Input signal');
```

Double the Sample Rate Using FIR Interpolator

Double the sample rate of an audio signal and play the interpolated signal using the `audioDeviceWriter` object.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Note: The `audioDeviceWriter` System object™ is not supported in MATLAB Online.

Create a `dsp.AudioFileReader` object. The default audio file ready by the object has a sample rate of 22050 Hz.

```
afr = dsp.AudioFileReader('OutputDataType',...  
    'single');
```

Create a `dsp.FIRInterpolator` object and specify the interpolation factor to be 2. The object designs the filter using the `designMultirateFIR(2,1)` function and stores the coefficients in the `Numerator` property of the object.

```
firInterp = dsp.FIRInterpolator(2)  
  
firInterp =  
    dsp.FIRInterpolator with properties:  
  
        InterpolationFactor: 2  
        NumeratorSource: 'Property'  
        Numerator: [0 -2.0108e-04 0 7.7408e-04 0 -0.0020 0 0.0045 ... ]  
  
    Show all properties
```

Create an `audioDeviceWriter` object. Specify the sample rate to be 22050×2 , which equals 44100 Hz.

```
adw = audioDeviceWriter(44100)  
  
adw =  
    audioDeviceWriter with properties:  
  
        Driver: 'DirectSound'  
        Device: 'Default'  
        SampleRate: 44100  
  
    Show all properties
```

Read the audio signal using the file reader object, double the sample rate of the signal from 22050 Hz to 44100 Hz and play the interpolated signal.

```
while ~isDone(afr)  
    frame = afr();  
    y = firInterp(frame);  
    adw(y);  
end  
  
pause(1);  
release(afr);  
release(adw);
```

Algorithms

The FIR interpolation filter is implemented efficiently using a polyphase structure.

To derive the polyphase structure, start with the transfer function of the FIR filter:

$$H(z) = b_0 + b_1z^{-1} + \dots + b_Nz^{-N}$$

$N+1$ is the length of the FIR filter.

You can rearrange this equation as follows:

$$H(z) = \begin{aligned} & (b_0 + b_Lz^{-L} + b_{2L}z^{-2L} + \dots + b_{N-L+1}z^{-(N-L+1)}) + \\ & z^{-1}(b_1 + b_{L+1}z^{-L} + b_{2L+1}z^{-2L} + \dots + b_{N-L+2}z^{-(N-L+1)}) + \\ & \quad \vdots \\ & z^{-(L-1)}(b_{L-1} + b_{2L-1}z^{-L} + b_{3L-1}z^{-2L} + \dots + b_Nz^{-(N-L+1)}) \end{aligned}$$

L is the number of polyphase components, and its value equals the interpolation factor that you specify.

You can write this equation as:

$$H(z) = E_0(z^L) + z^{-1}E_1(z^L) + \dots + z^{-(L-1)}E_{L-1}(z^L)$$

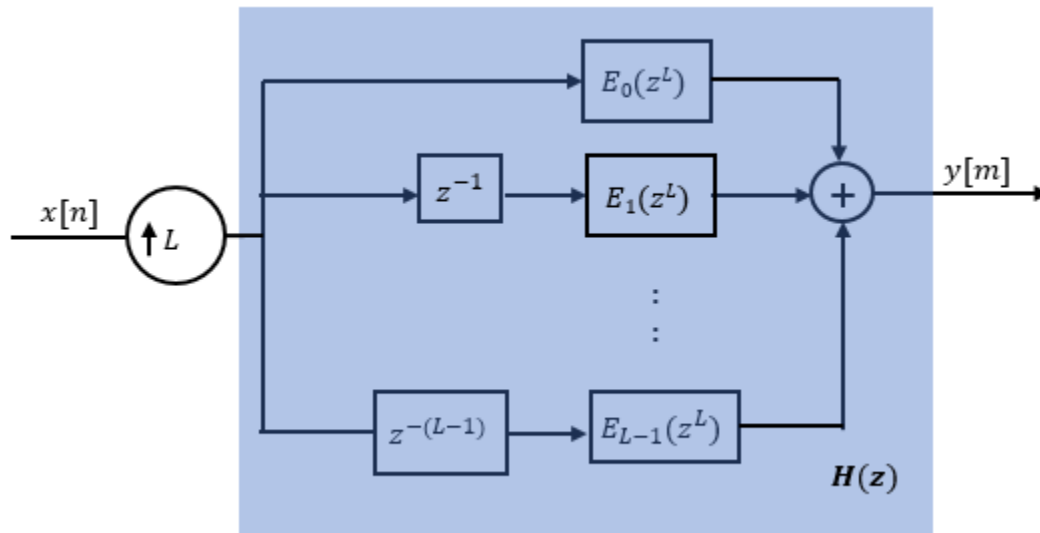

$E_0(z^L), E_1(z^L), \dots, E_{L-1}(z^L)$ are polyphase components of the FIR filter $H(z)$.

Conceptually, the FIR interpolation filter contains an upsampler followed by an FIR lowpass filter $H(z)$.

**Conceptual Operation
of FIR Interpolator**

Replace $H(z)$ with its polyphase representation.

Here is the multirate noble identity for interpolation.

Applying the noble identity for interpolation moves the upsampling operation to after the filtering operation. This move enables you to filter the signal at a lower rate.

You can replace the upsampling operator, delay block, and adder with a commutator switch. The switch starts on the first branch 0 and moves in the counterclockwise direction, each time receiving one sample from each branch. The interpolator effectively outputs L samples for every one input sample it receives. Hence the sample rate at the output of the FIR interpolation filter is Lfs .

Version History

Introduced in R2012a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

The dsp.FIRInterpolator System object supports SIMD code generation using Intel AVX2 technology under these conditions:

- Input signal is real-valued with real filter coefficients.
- Input signal is complex-valued with real or complex filter coefficients.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This object supports HDL code generation with the Filter Design HDL Coder product. For workflows and limitations, see “Generate HDL Code for Filter System Objects” (Filter Design HDL Coder).

dsp.FIRRateConverter

Package: dsp

Sample rate converter

Description

The `dsp.FIRRateConverter` System object performs sampling rate conversion by a rational factor on a vector or matrix input. The FIR rate converter cascades an interpolator with a decimator. The rate converter (as shown in the schematic) conceptually consists of an upsampler, followed by a combined anti-imaging and anti-aliasing FIR filter, followed by a downsampler. The coefficients of the anti-imaging and anti-aliasing FIR filter can be specified through the `Numerator` property, or can be automatically designed by the object using the `designMultirateFIR` function. For an example, see “Resample Signal Using FIR Rate Converter” on page 4-579.

The upsampler increases the sample rate of the signal by a factor L and the downsampler reduces the sample rate of the signal by a factor M . Use upsampling and downsampling factors that are relatively prime or coprime. The resulting discrete-time signal has a sample rate that is L/M times the original sample rate.

Note that the actual object algorithm implements a polyphase structure, an efficient equivalent of the combined system depicted in the diagram. For more details, see “Algorithms” on page 4-584.

To perform sampling rate conversion:

- 1 Create the `dsp.FIRRateConverter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
firrc = dsp.FIRRateConverter
firrc = dsp.FIRRateConverter(L,M)
firrc = dsp.FIRRateConverter(L,M,'Auto')
firrc = dsp.FIRRateConverter(L,M,num)
firrc = dsp.FIRRateConverter(L,M,method)
```

```
firrc = dsp.FIRRateConverter( ____,Name,Value)
firrc = dsp.FIRRateConverter(L,M,'legacy')
```

Description

`firrc = dsp.FIRRateConverter` returns an FIR sample rate converter object with an interpolation factor of 3 and a decimation factor of 2. The object designs the FIR filter coefficients using the `designMultirateFIR(3,2)` function.

`firrc = dsp.FIRRateConverter(L,M)` returns an FIR sample rate converter with the integer-valued `InterpolationFactor` property set to `L` and the `DecimationFactor` property set to `M`. The object designs its filter coefficients based on the rate conversion factors that you specify while creating the object, using the `designMultirateFIR(L,M)` function. The designed filter corresponds to a lowpass filter with normalized cutoff frequency no greater than $\min(\pi/L, \pi/M)$ in radial frequency units.

`firrc = dsp.FIRRateConverter(L,M,'Auto')` returns an FIR sample rate converter where the `NumeratorSource` property is set to `'Auto'`. In this mode, every time there is an update in the rate conversion factors, the object redesigns the filter using the design method specified in `DesignMethod`.

`firrc = dsp.FIRRateConverter(L,M,num)` returns an FIR sample rate converter with the `Numerator` property set to `num`.

`firrc = dsp.FIRRateConverter(L,M,method)` returns an FIR sample rate converter with the `DesignMethod` property set to `method`. When you pass the design method as an input, the `NumeratorSource` property is automatically set to `'Auto'`.

`firrc = dsp.FIRRateConverter(____,Name,Value)` returns an FIR sample rate converter with each specified property set to the specified value. Enclose each property name in quotes. You can use this syntax with any previous input argument combinations.

Example: `firrc = dsp.FIRRateConverter('FullPrecisionOverride','false')` enables the fixed-point data types to be controlled through the individual fixed-point property settings.

`firrc = dsp.FIRRateConverter(L,M,'legacy')` returns an FIR sample rate converter where the filter coefficients are designed using `firpm(70,[0 0.28 0.32 1],[1 1 0 0])`. The designed filter has a cutoff frequency of $\pi/3$ radians/sample.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Main Properties

InterpolationFactor — Interpolation factor

3 (default) | positive integer

Interpolation factor L , specified as a positive integer.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

DecimationFactor — Decimation factor

2 (default) | positive integer

Decimation factor M , specified as a positive integer.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

NumeratorSource — FIR filter coefficient source

'Property' (default) | 'Auto'

FIR filter coefficient source, specified as one of the following:

- 'Property' -- The numerator coefficients are specified through the Numerator property.
- 'Auto' -- The numerator coefficients are designed automatically using the design method specified in `DesignMethod`.

Numerator — FIR filter coefficients

`designMultirateFIR(L,M)` (default) | row vector

Numerator coefficients of the FIR filter, specified as a row vector in powers of z^{-1} .

The following equation defines the transfer function of the filter:

$$H(z) = \sum_{n=0}^N b(n)z^{-n}$$

The vector $\mathbf{b} = [b(0), b(1), \dots, b(N)]$ represents the vector of filter coefficients.

Use a lowpass filter with normalized cutoff frequency no greater than $\min(1/L, 1/M)$, where L is the interpolation factor and M is the decimation factor. The gain of the lowpass filter should equal L , the interpolation factor. Choose the length of the filter to be a multiple of the interpolation factor. To design such a filter, use the `designMultirateFIR` function. For an example, see “Resample Signal Using FIR Rate Converter” on page 4-579. All initial filter states are zero.

Dependencies

This property is visible only when you set `NumeratorSource` to 'Property'.

When `NumeratorSource` is set to 'Auto', the numerator coefficients are automatically redesigned using the design method specified in `DesignMethod`. To access the filter coefficients in the automatic design mode, type `objName.Numerator` in the MATLAB command prompt.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

DesignMethod — Auto design method

'Kaiser' (default) | 'ZOH' | 'Linear'

Design method of the FIR filter coefficients, specified as one of the following:

- 'Kaiser' -- Kaiser method. Approximate combined anti-aliasing and anti-imaging lowpass filter using the `designMultirateFIR` function.
- 'ZOH' -- Zero order hold method. Hold the input sequence values.
- 'Linear' -- Linear interpolation method.

Dependencies

This property is visible only when you set the `NumeratorSource` property to 'Auto', or if you pass the 'auto' keyword as an input while creating the object.

Code Generation Properties**AllowArbitraryInputLength — Allow arbitrary input length in generated code**`false (default) | true`

Allow arbitrary frame length for fixed-size input signals in the generated code, specified as `true` or `false`. When you specify:

- `true` -- The input frame length does not have to be a multiple of the decimation factor. The output of the object in the generated code is a variable-size array.
- `false` -- The input frame length must be a multiple of the decimation factor.

When you specify variable-size signals, the input frame length can be arbitrary and the object ignores this property in the generated code. When you run this object in MATLAB, the object supports arbitrary input frame lengths for fixed-size and variable-size signals and this property does not affect the object behavior.

Data Types: `logical`

Fixed-Point Properties**FullPrecisionOverride — Full precision override for fixed-point arithmetic**`true (default) | false`

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

RoundingMethod — Rounding method for fixed-point operations`Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero`

Specify the rounding method as one of | `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |.

Dependencies

This property applies only if the object is not in full precision mode.

OverflowAction — Overflow action for fixed-point operations`Wrap (default) | Saturate`

Specify the overflow action as one of | `Wrap` | `Saturate` |.

Dependencies

This property applies only if the object is not in full precision mode.

CoefficientsDataType — Word and fraction lengths of filter coefficients

Same word length as input (default) | Custom

Specify the filter coefficient fixed-point data type as one of | Same word length as input | Custom |.

CustomCoefficientsDataType — Word and fraction lengths of filter coefficients

numericitytype([],16,15) (default) | numericitytype

Specify the filter coefficient fixed-point type as a numericitytype object with a Signedness of Auto.

Dependencies

This property applies only when the CoefficientsDataType property is Custom.

ProductDataType — Product word and fraction lengths

Full precision (default) | Same as input | Custom

Specify the product fixed-point data type as one of | Full precision | Same as input | Custom |.

CustomProductDataType — Product word and fraction lengths

numericitytype([],32,30) (default) | numericitytype

Specify the product fixed-point type as a scaled numericitytype object with a Signedness of Auto.

Dependencies

This property applies only when the ProductDataType property is Custom.

AccumulatorDataType — Accumulator word and fraction lengths

Full precision (default) | Same as product | Same as input | Custom

Specify the accumulator fixed-point data type as one of | Full precision | Same as product | Same as input | Custom |.

CustomAccumulatorDataType — Accumulator word and fraction lengths

numericitytype([],32,30) (default) | numericitytype

Specify the accumulator fixed-point type as a scaled numericitytype object with a Signedness of Auto.

Dependencies

This property applies only when the AccumulatorDataType property is Custom.

OutputDataType — Output word and fraction lengths

Same as accumulator (default) | Same as product | Same as input | Custom

Specify the output fixed-point data type as one of | Same as accumulator | Same as product | Same as input | Custom |.

CustomOutputDataType — Output word and fraction lengths

numericitytype([],16,15) (default) | numericitytype

Specify the output fixed-point type as a scaled numericitytype object with a Signedness of Auto.

Dependencies

This property applies only when the `OutputDataType` property is `Custom`.

Usage**Syntax**

```
y = firrc(x)
```

Description

`y = firrc(x)` resamples the input `x` and returns the resampled signal `y`.

Input Arguments**x — Data input**

column vector | matrix

Data input, specified as a column vector or a matrix of size P -by- Q . The columns in the input signal represent Q independent channels.

Under most conditions, the number of inputs rows P can be arbitrary and does not have to be a multiple of the `DecimationFactor` property. See this table for details.

Input Signal	When you Run Object in MATLAB	When you Generate Code Using MATLAB Coder
Fixed-size	Object supports arbitrary input frame length	Object supports arbitrary input frame length when you set <code>AllowArbitraryInputLength</code> to <code>true</code> while generating code
Variable-size	Object supports arbitrary input frame length	Object supports arbitrary input frame length

Variable-size signals change in frame length once you lock the object while the fixed-size signals remain constant. When the object does not support arbitrary frame length, the input frame length must be a multiple of the `DecimationFactor` property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Output Arguments**y — Resampled output**

column vector | matrix

Resampled output, returned as a column vector or a matrix. When the input is of size P -by- Q , and P is not a multiple of the decimation factor M , the output signal has an upper bound size of $\text{ceil}(LP/M)$ -by- Q . If P is a multiple of the decimation factor, then the output is of size (LP/M) -by- Q .

The number of rows in the output signal is given by LP/M , where P is the number of input rows, L is the interpolation factor, and M is the decimation factor.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.FIRRateConverter`

<code>freqz</code>	Frequency response of discrete-time filter System object
<code>fvtool</code>	Visualize frequency response of DSP filters
<code>info</code>	Information about filter System object
<code>cost</code>	Estimate cost of implementing filter System object
<code>coeffs</code>	Returns the filter System object coefficients in a structure
<code>polyphase</code>	Polyphase decomposition of multirate filter
<code>generatehdl</code>	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Resample Signal Using FIR Rate Converter

Resample a 100 Hz sine wave signal by a factor of 3/2.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Create a `dsp.SineWave` object which generates a sinusoidal signal with 54 samples per frame, contains a tone at 100 Hz, and has a sample rate of 1250 Hz.

```
sine = dsp.SineWave(1,100, 'SampleRate',1250, 'SamplesPerFrame',54);

% Grab a frame
x = sine();

% Calculate input time vector
tx = (0:length(x)-1)/sine.SampleRate;
```

Design Default Filter

Create a `dsp.FIRRateConverter` object. The object uses a combined anti-imaging and anti-aliasing FIR filter. By default, this filter is designed using the `designMultirateFIR` function. The function designs the filter based on the rate conversion factors that you specify, and stores the coefficients in the `Numerator` property. For an interpolation factor of 3 and a decimation factor of 2, the object designs the coefficients using `designMultirateFIR(3,2)`.

```
firrc = dsp.FIRRateConverter(3,2);
```

Resample by a Factor of 3/2

Resample the signal by a factor of 3/2.

```
y = firrc(x);
```

Plot the original and resampled signals. In order to plot the two signals on the same plot, you must account for the output delay of the FIR rate converter and the scaling introduced by the filter. Use the `outputDelay` function to compute the delay value introduced by the rate converter. Shift the output by this delay value.

Visualize the input and the resampled signals. The input and output values coincide every 3 output samples, and every other input sample, owing to the conversion rate of 3/2.

```
FsIn = sine.SampleRate;
[delay,FsOut] = outputDelay(firrc,FsIn=FsIn);
% Calculate output times for vector y in input units
ty = (0:length(y)-1)/FsOut-delay;

stem(tx,x,'filled',MarkerSize=4)
hold on
stem(ty,y)
hold off
xlim([0.0 0.0145])
ylim([-1.5 1.5])
legend('Original input','Resampled')
```

Resample by a Factor of 5/3 in Automatic Filter Design Mode

Now change the interpolation factor to 5 and the decimation factor to 3. In order for the filter design to be updated automatically based on the new rate conversion factors, set the `NumeratorSource` property to `'Auto'`. Alternately, you can pass the keyword `'auto'` as an input while creating the object. The object then operates in the automatic filter design mode. Every time there is a change in the rate conversion factors, the object updates the filter design accordingly.

```
release(firrc)
firrc.NumeratorSource = 'Auto';
firrc.InterpolationFactor = 5;
firrc.DecimationFactor = 3

firrc =
    dsp.FIRRateConverter with properties:

    Main
        InterpolationFactor: 5
        DecimationFactor: 3
        NumeratorSource: 'Auto'
        DesignMethod: 'Kaiser'

    Show all properties
```

To access the filter coefficients in the automatic filter design mode, type `firrc.Numerator` in the MATLAB command prompt.

Resample the signal with the updated rate conversion values.

```
yAuto = firrc(x);
```

Plot the original and resampled signals. Recalculate the output delay and the output sample rate since the rate conversion factors have changed. Note that the input and output coincide every 3 input samples, and every 5 output samples, owing to the 5/3 conversion factor.

```
[delay,FsOut] = outputDelay(firrc,FsIn=FsIn);
% Calculate output times for vector yAuto in input units
tyAuto = (0:length(yAuto)-1)/FsOut-delay;

stem(tx,x,'filled',MarkerSize=4)
hold on
stem(tyAuto,yAuto,'r')
hold off
xlim([0.0 0.015])
ylim([-1.5 1.5])
legend('Original input','Resampled')
```

Specify Signal Interpolation Model

In the automatic design mode, you can also specify the underlying D/A signal interpolation model through the `DesignMethod` property.

Set `DesignMethod` to `'linear'` and change the interpolation factor to 11.

```
release(firrc)
firrc.DesignMethod = 'linear';
firrc.InterpolationFactor = 11;
```

Resample the signal using the linear interpolation model.

```
yLinear = firrc(x);
```

Plot the original and resampled signals. The output samples lie on a piecewise-linear curve. Note that the input and output coincide every three input samples and every 11 output samples as expected from the ratio 11/3.

```
[delay,FsOut] = outputDelay(firrc,FsIn=FsIn);
% Calculate output times for vector yLinear in input units
tyLinear = (0:length(yLinear)-1)/FsOut-delay;
```

```
stem(tx,x,'filled',MarkerSize=4)
hold on
stem(tyLinear,yLinear)
plot(tyLinear,yLinear,Color=[1 0 0 0.3])
hold off
```

```
xlim([0.0 0.009])
ylim([-1.5 1.5])
legend('Original input','Resampled')
```

Resample and Play Audio Signal

Resample an audio signal from 48 kHz to 44 kHz and play the resampled signal using the `audioDeviceWriter` object.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Note: The `audioDeviceWriter` System object™ is not supported in MATLAB Online.

Create a `dsp.AudioFileReader` object. The object reads an audio file that has a sample rate of 48 kHz.

```
L = 11;
M = 12;
afr = dsp.AudioFileReader('audio48kHz.wav', ...
    'OutputDataType','single', ...
    'SamplesPerFrame',4*M);
```

Create a `dsp.FIRRateConverter` object with an interpolation factor of $L = 11$ and a decimation factor of $M = 12$ (the co-prime representation of the ratio $44k/48k$), a reasonable approximation of

the standard 44.1 kHz rate. The object designs the filter using `designMultirateFIR(11,12)` and stores the coefficients in the `Numerator` property of the object.

```
firrc = dsp.FIRRateConverter(L,M)

firrc =
  dsp.FIRRateConverter with properties:

  Main
  InterpolationFactor: 11
  DecimationFactor: 12
  NumeratorSource: 'Property'
  Numerator: [0 2.3076e-05 5.4790e-05 9.3620e-05 1.3665e-04 ... ]

  Show all properties
```

Create an `audioDeviceWriter` object. Specify the sample rate to be 44100 Hz.

```
adw = audioDeviceWriter(44100);
```

Read the audio file, convert the sample rate of the audio signal, and play the resampled audio.

```
while ~isDone(afr)
    audio1 = afr();
    audio2 = firrc(audio1);
    adw(audio2);
end
release(afr)
release(adw)
```

Algorithms

The FIR rate converter is implemented efficiently using a polyphase structure.

To derive the polyphase structure, start with the transfer function of the FIR filter: This FIR filter is a combined anti-imaging and anti-aliasing filter.

$$H(z) = b_0 + b_1z^{-1} + \dots + b_Nz^{-N}$$

$N+1$ is the length of the FIR filter.

You can rearrange this equation as follows:

$$H(z) = \begin{aligned} & (b_0 + b_Lz^{-L} + b_{2L}z^{-2L} + \dots + b_{N-L+1}z^{-(N-L+1)}) + \\ & z^{-1}(b_1 + b_{L+1}z^{-L} + b_{2L+1}z^{-2L} + \dots + b_{N-L+2}z^{-(N-L+1)}) + \\ & \quad \vdots \\ & z^{-(L-1)}(b_{L-1} + b_{2L-1}z^{-L} + b_{3L-1}z^{-2L} + \dots + b_Nz^{-(N-L+1)}) \end{aligned}$$

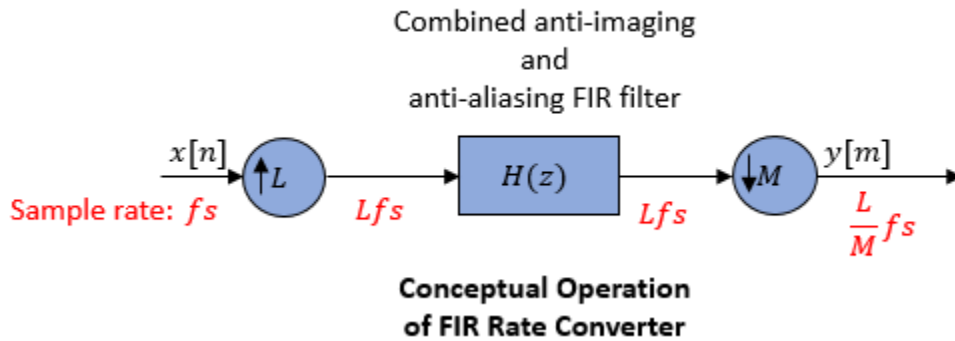

L is the number of polyphase components, and its value equals the interpolation factor that you specify.

You can write this equation as:

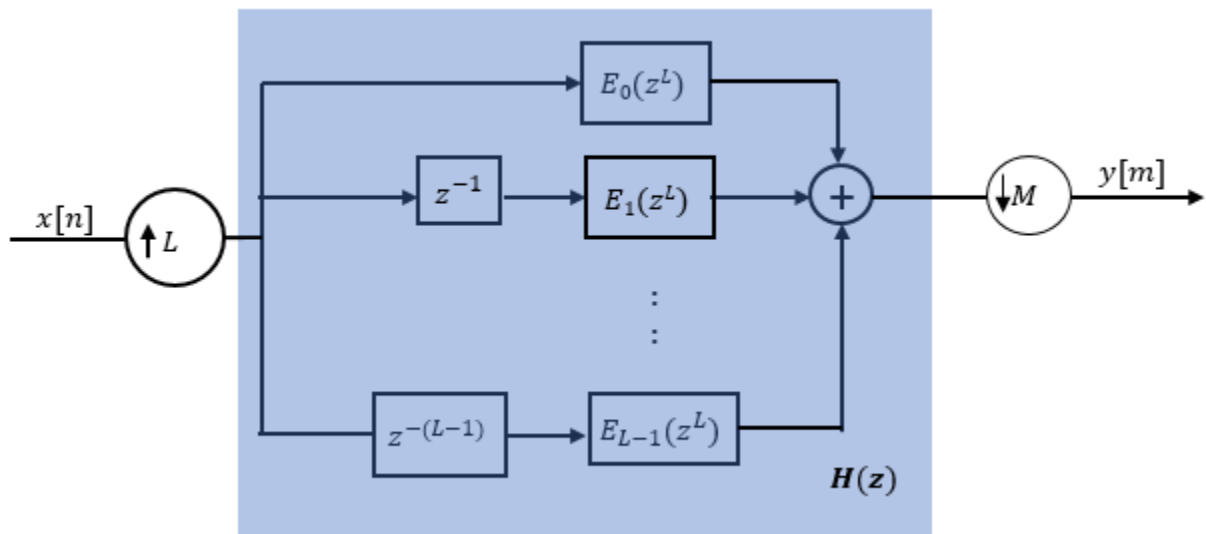

$$H(z) = E_0(z^L) + z^{-1}E_1(z^L) + \dots + z^{-(L-1)}E_{L-1}(z^L)$$

$E_0(z^L), E_1(z^L), \dots, E_{L-1}(z^L)$ are polyphase components of the FIR filter $H(z)$.

Conceptually, the FIR rate converter contains an upsampler, followed by a combined anti-imaging, anti-aliasing FIR filter $H(z)$, which is followed by a downsampler.

Replace $H(z)$ with its polyphase representation.

Here is the multirate noble identity for interpolation.

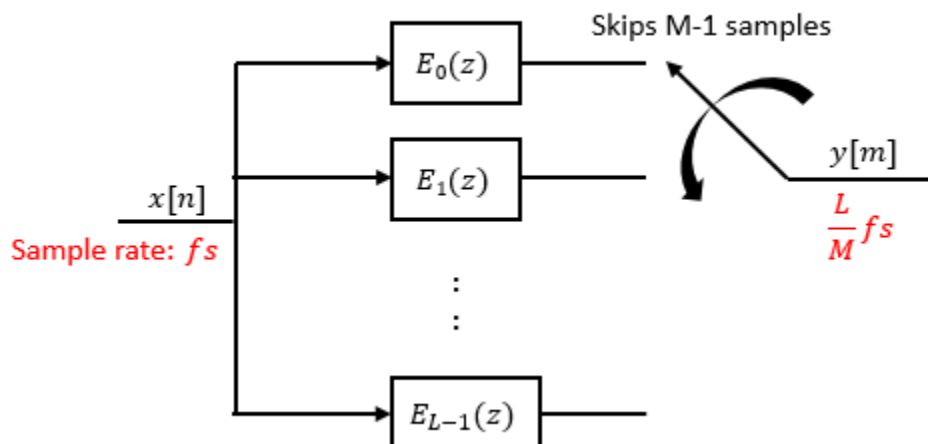

Applying the noble identity for interpolation moves the upsampling operation to after the filtering operation. This move enables you to filter the signal at a lower rate.

You can replace the upsampling operator, delay block, and the adder with a commutator switch. To account for the downsampler that follows, the switch moves in steps of size M . The switch receives the first sample from branch 0 and moves in the counter clockwise direction, each time skipping $M-1$ branches.

As an example, consider a rate converter with L set to 5 and M set to 3. The polyphase components are $E_0(z)$, $E_1(z)$, $E_2(z)$, $E_3(z)$, and $E_4(z)$. The switch starts on the first branch 0, skips branches 1 and 2, receives the next sample from branch 3, then skips branches 4 and 0, receives the next sample from branch 2, and so on. The sequence of branches from which the switch receives the data sample is [0, 3, 1, 4, 2, 0, 3, 1, ...].

The rate converter implements the L/M conversion by first applying the interpolation factor L to the incoming data, and using the commutator switch at the end to receive only 1 in M samples, effectively accounting for the downsampling factor M . Hence, the sample rate at the output of the FIR rate converter is Lfs/M .

Version History

Introduced in R2012a

Support for arbitrary input frame length

Starting in R2022b, this object supports an input signal with an arbitrary frame length. That is, the input frame length does not have to be a multiple of the decimation factor.

When you generate code, to support arbitrary frame length for fixed-size signals, you must set the `AllowArbitraryInputLength` property to `true` while generating code.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This object supports HDL code generation with the Filter Design HDL Coder product. For workflows and limitations, see “Generate HDL Code for Filter System Objects” (Filter Design HDL Coder).

dsp.FrequencyDomainAdaptiveFilter

Package: dsp

Compute output, error, and coefficients using frequency-domain FIR adaptive filter

Description

The `dsp.FrequencyDomainAdaptiveFilter` System object implements an adaptive finite impulse response (FIR) filter in the frequency domain using the fast block least mean squares (LMS) algorithm. The “Length” on page 4-0 and the “BlockLength” on page 4-0 properties specify the filter length and the block length values the algorithm uses. The “FFTCoefficients” on page 4-0 property contains the discrete Fourier transform of the current filter coefficients. The object offers the constrained and unconstrained versions of the algorithm with partitioned and non-partitioned modes. For details, see “Algorithms” on page 4-601.

To filter a signal using frequency-domain FIR adaptive filter:

- 1 Create the `dsp.FrequencyDomainAdaptiveFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
fdaf = dsp.FrequencyDomainAdaptiveFilter
fdaf = dsp.FrequencyDomainAdaptiveFilter(len)
fdaf = dsp.FrequencyDomainAdaptiveFilter( ____,Name,Value)
```

Description

`fdaf = dsp.FrequencyDomainAdaptiveFilter` returns a frequency domain FIR adaptive filter System object, `fdaf`. This System object is used to compute the filtered output and the filter error for a given input and desired signal.

`fdaf = dsp.FrequencyDomainAdaptiveFilter(len)` returns a frequency domain FIR adaptive filter object with the `Length` property set to `len`.

`fdaf = dsp.FrequencyDomainAdaptiveFilter(____,Name,Value)` returns a frequency domain FIR adaptive filter object with each specified property set to the specified value. Enclose each property name in quotes. You can use this syntax with any previous input argument combinations.

Example: `fdaf = dsp.FrequencyDomainAdaptiveFilter('Length',32,'StepSize',0.1)` models a frequency-domain adaptive filter with a length of 32 taps and a step size of 0.1.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

Method — Method to calculate filter coefficients

'Constrained FDAF' (default) | 'Unconstrained FDAF' | 'Partitioned constrained FDAF' | 'Partitioned unconstrained FDAF'

Method used to calculate the filter coefficients, specified as:

- 'Constrained FDAF' -- Imposes a gradient constraint on the filter tap weights.
- 'Unconstrained FDAF' -- No gradient constraint is imposed on the filter tap weights.
- 'Partitioned constrained FDAF' -- Partitions the impulse response of the filter to reduce latency.
- 'Partitioned unconstrained FDAF' -- Partitions the impulse response of the filter to reduce latency. No gradient constraint is imposed on the filter tap weights.

For more details, see “Algorithms” on page 4-601.

Length — Length of filter coefficients vector

32 (default) | positive, integer-valued scalar

Length of the FIR filter coefficients vector, specified as a positive, integer-valued scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

BlockLength — Block length for coefficient updates

32 (default) | positive, integer-valued scalar

Block length for the coefficient updates, specified as a positive, integer-valued scalar. The adaptive filter processes the input data and the desired signal as a block of samples of length set by this property. For details on how this data is processed by the filter, see “Algorithms” on page 4-601. The length of the input vector must be divisible by the `BlockLength` property value. The default value of the `BlockLength` property is set to the value of the `Length` property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

StepSize — Adaptation step size

1 (default) | real scalar in the range (0,1]

Adaptation step size factor, specified as a real scalar in the range (0,1]. Using a small step size ensures a small steady-state error. However, a small step size decreases the resulting convergence speed of the adaptive filter. Increasing the step size improves the convergence speed, at the cost of increased steady-state mean squared error. When the step size value is 1, the algorithm provides the optimal tradeoff between the convergence speed and the steady-state mean squared error.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

LeakageFactor — Adaptation leakage factor

1 (default) | scalar in the range [0,1]

Leakage factor used when implementing a leaky adaptive filter, specified as a scalar numeric value in the range [0,1]. When the value is less than 1, the System object implements a leaky adaptive algorithm. When the value is 1, the object provides no leakage in the adapting method.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

AveragingFactor — Averaging factor for signal power

0.9 (default) | real scalar in the range (0,1]

Averaging factor used to compute the exponentially windowed FFT input signal powers for the coefficient updates, specified as a real scalar in the range (0,1].

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

Offset — Offset for normalization terms

0 (default) | nonnegative real scalar

Offset for the normalization terms in the coefficient updates, specified as a nonnegative real scalar value. This property value is used to avoid division by zero or division by very small numbers if any of the FFT input signal powers become very small.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

InitialPower — Initial FFT input signal power

1 (default) | positive numeric scalar

Initial common value of all of the FFT input signal powers, specified as a positive numeric scalar.

If you change this value once the object is locked, the change takes effect only after you reset the object.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

InitialCoefficients — Initial time-domain coefficients of filter

0 (default) | scalar | vector

Initial time-domain coefficients of the adaptive filter, specified as a scalar or a vector of length equal to the `Length` property value. The adaptive filter object uses these coefficients to compute the initial frequency-domain filter coefficients.

If you change this value once the object is locked, the change takes effect only after you reset the object.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

LockCoefficients — Locked status of coefficient updates

`false` (default) | `true`

Locked status of the coefficient updates, specified as:

- `false` -- The object continuously updates the filter coefficients.
- `true` -- The filter coefficients do not get updated and their values remain at the current value.

Tunable: Yes

Data Types: `logical`

FFTCoefficients — Current FFT coefficients of filter

`[]` (default) | row vector

This property is read-only.

Current discrete Fourier transform of the filter coefficients, returned as a row vector. For 'Constrained FDAF' and 'Unconstrained FDAF' algorithms, the length of this vector is equal to the sum of the `Length` value and the `BlockLength` value. This property is initialized to the FFT values of the `InitialCoefficients` property. To get the discrete Fourier transform of the filter coefficients, call the object, and access the `FFTCoefficients` property of the object.

Data Types: `single` | `double`

Complex Number Support: Yes

Usage

Syntax

`[y,err] = fdaf(x,d)`

Description

`[y,err] = fdaf(x,d)` filters the input signal, `x`, using `d` as the desired signal, and returns the filtered output in `y` and the filter error in `err`. The System object estimates the filter weights needed to minimize the error between the output signal and the desired signal. The FFT of these filter weights can be obtained by accessing the `FFTCoefficients` property after calling the object algorithm.

Input Arguments

x — Data input

column vector

The signal to be filtered by the frequency-domain FIR adaptive filter. The input, `x`, and the desired signal, `d`, must have the same size and data type. The length of the input vector must be divisible by the "BlockLength" on page 4-0 property value.

The input, x , can be a variable-size signal as long as the frame length is a multiple of the `BlockLength`. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double`

d — Desired signal

column vector

The frequency domain adaptive filter adapts its filter weights to minimize the error, `err`, and converge the input signal, x , to the desired signal, d , as closely as possible.

The input signal and the desired signal must have the same size and data type. The length of the desired signal vector must be divisible by the `BlockLength` property value.

The input signal can be a variable-size signal as long as the frame length is a multiple of the `BlockLength`. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double`

Output Arguments

y — Filtered output

column vector

Filtered output, returned as a column vector. The object adapts its filter weights to converge the input signal, x , to match the desired signal, d . The filter outputs the converged signal.

Data Types: `single` | `double`

err — Difference between output and desired signal

column vector

Difference between the output signal and the desired signal, returned as a column vector. The objective of the adaptive filter is to minimize this error. The object adapts its weights to converge towards optimal filter weights which produce an output signal that matches the desired signal as closely as possible. For more details on how `err` is computed, see [2].

Data Types: `single` | `double`

Complex Number Support: Yes

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

QPSK Adaptive Equalization With FIR Filter

Transmit a quadrature phase shift keying (QPSK) signal across a noisy transmission channel. Minimize the noise in the received signal using a frequency-domain adaptive filter.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

The QPSK signal, s , is transmitted across a noisy channel. The numerator and the denominator coefficients of the channel are contained in the vectors b and a , respectively. The received signal, r , obtained at the end of the transmission channel contains the transmitted QPSK signal and the noise added to the channel, n . The adaptive filter is used to extract the QPSK signal from the received noisy input. The desired signal, d , is the delayed version of the QPSK signal.

```
D = 16;
b = exp(1i*pi/4)*[-0.7 1];
a = [1 -0.7];
ntr = 1024;
s = sign(randn(1,ntr+D)) + 1i*sign(randn(1,ntr+D));
n = 0.1*(randn(1,ntr+D) + 1i*randn(1,ntr+D));
r = filter(b,a,s) + n;
x = r(1+D:ntr+D);
d = s(1:ntr);
```

Create a `dsp.FrequencyDomainAdaptiveFilter` object to model a frequency-domain adaptive filter of length 32 taps and a step size of 0.1. The adaptive filter accepts the delayed version of the received signal and the desired signal as inputs. The output of the adaptive filter is compared to the desired signal. The error between the two signals represents the noise added to the transmission channel. The adaptive filter updates its coefficients until this error becomes minimal. To get the discrete Fourier transform of the filter coefficients, call the `fdaf` object, and access the `FFTCoefficients` property of this object.

```
mu = 0.1;
fdaf = dsp.FrequencyDomainAdaptiveFilter('Length',32,'StepSize',mu);
[y,e] = fdaf(x,d);
fftCoeffs = fdaf.FFTCoefficients

fftCoeffs = 1x64 complex

    0.6802 - 0.6847i  -0.2485 - 0.9427i  -0.9675 - 0.2123i  -0.5605 + 0.8002i   0.5748 + 0.7593i
```

Plot the In-Phase and the Quadrature components of the desired, output, and the error signals.

```
plot(1:ntr,real([d;y;e]))
legend('Desired','Output','Error')
title('In-Phase Components')
xlabel('Time Index'); ylabel('signal value')
```

```
plot(1:ntr,imag([d;y;e]))  
legend('Desired','Output','Error')  
title('Quadrature Components')  
xlabel('Time Index')  
ylabel('signal value')
```

Create scatter plots of the received signal and the desired signal.

```
plot(x(ntr-100:ntr),'.')  
axis([-3 3 -3 3])  
title('Received Signal Scatter Plot')  
axis('square')  
xlabel('Real[x]')  
ylabel('Imag[x]')  
grid on
```

```
plot(d(ntr-100:ntr),'.')
axis([-3 3 -3 3])
title('Desired Signal Scatter Plot')
axis('square')
xlabel('Real[y]')
ylabel('Imag[y]')
grid on
```

The adaptive filter equalizes the received signal to eliminate noise. Plot the scatter plot of the equalized signal.

```
plot(y(ntr-100:ntr),'.')  
axis([-3 3 -3 3])  
title('Equalized Signal Scatter Plot')  
axis('square')  
xlabel('Real[y]')  
ylabel('Imag[y]')  
grid on
```

Estimate Coefficients of long FIR Filter using Frequency-Domain Adaptive Filter

Use a frequency-domain adaptive filter to estimate the coefficients of a long FIR filter. The FIR filter models the impulse response of a room. Use the partitioned mode in the frequency-domain adaptive filter to reduce filter latency.

Note: This example runs only in R2018a or later.

Initialization

Generate a long FIR impulse response of 8192 samples and assign the impulse response to a `dsp.FIRFilter` object, `room`. This object models the impulse response of a room. Create a `dsp.FrequencyDomainAdaptiveFilter` filter, `lmsfilt`, in partitioned constrained mode. Set the length of the filter to one-fourth the length of the impulse response of the room. Set the block length of the filter to 128 samples. Set the step size to 0.025, initial power to 0.01, averaging factor to 0.98, offset to 1, and the leakage factor to 1. Initialize a `dsp.ArrayPlot` object to view the filter coefficients. Initialize a `timescope` object to show the mean-squared error between the filter output and the desired signal.

```
fs = 16e3;
m = 8192;
[b,a] = cheby2(4,20,[0.1 0.7]);
impulseResponseGenerator = dsp.IIRFilter(...
    'Numerator', [zeros(1,6) b], ...
```

```

    'Denominator', a);
roomImpulseResponse = impulseResponseGenerator( ...
    (log(0.99*rand(1,m)+0.01).*sign(randn(1,m)).*exp(-0.002*(1:m)))');
roomImpulseResponse = roomImpulseResponse/norm(roomImpulseResponse);
room = dsp.FIRFilter('Numerator',roomImpulseResponse');

lmsfilt = dsp.FrequencyDomainAdaptiveFilter(...
    'Method','Partitioned constrained FDAF',...
    'Length',m/4, ...
    'BlockLength',128,...
    'StepSize',0.025, ...
    'InitialPower',0.01, ...
    'AveragingFactor',0.98,...
    'Offset',1,...
    'LeakageFactor',1);

FrameSize = lmsfilt.BlockLength; NIter = 2000;

AP = dsp.ArrayPlot('YLimits',[-0.2 .2],'ShowLegend',true, ...
    'Position',[0 0 560 420],'ChannelNames', ...
    {'Actual Coefficients','Estimated Coefficients'});

TS = timescope('SampleRate',fs,'TimeSpanSource','property',...
    'TimeSpan',FrameSize*NIter/fs,...
    'TimeUnits','Seconds',...
    'YLimits',[-50 0],'Title','Learning curve',...
    'YLabel','dB', ...
    'BufferLength',FrameSize*NIter,...
    'ShowGrid',true);

signalmean = dsp.MovingAverage('SpecifyWindowLength',false);

```

Streaming

Generate a random input signal using the `randn` function. The frame size of the input matches the block length of the adaptive filter. The desired signal is the sum of the output of the FIR filter (`room`) and a white Gaussian noise signal. Pass the input signal and the desired signal to the adaptive filter. Compute the adaptive filter output and the error between the output and the desired signal.

Estimate the time-domain coefficients of the adaptive filter by taking the IFFT of the frequency-domain coefficients vector returned by the `lmsfilt.FFTCoefficients` property. Compare the estimated coefficients with the actual coefficients assigned to the FIR filter (`room`). Once the adaptive filter has converged its output to the desired signal, and minimized the error signal, the estimated coefficients match closely with the actual coefficients. This means that the adaptive filter has successfully adapted itself to model the impulse response of the FIR filter (`room`).

```

for k = 1:NIter
    x = randn(FrameSize,1);
    d = room(x) + 0.01*randn(FrameSize,1);
    [y,e] = lmsfilt(x,d);
    FFTCoeffs = lmsfilt.FFTCoefficients;
    w = ifft(FFTCoeffs,[],2,'symmetric');
    w = w(:,1:FrameSize) + w(:,FrameSize+1:end);
    w = reshape(w.',1,m/4);
    AP([roomImpulseResponse(1:m/4),w.']);
    TS(10*log10(signalmean(abs(e).^2)));
end

```

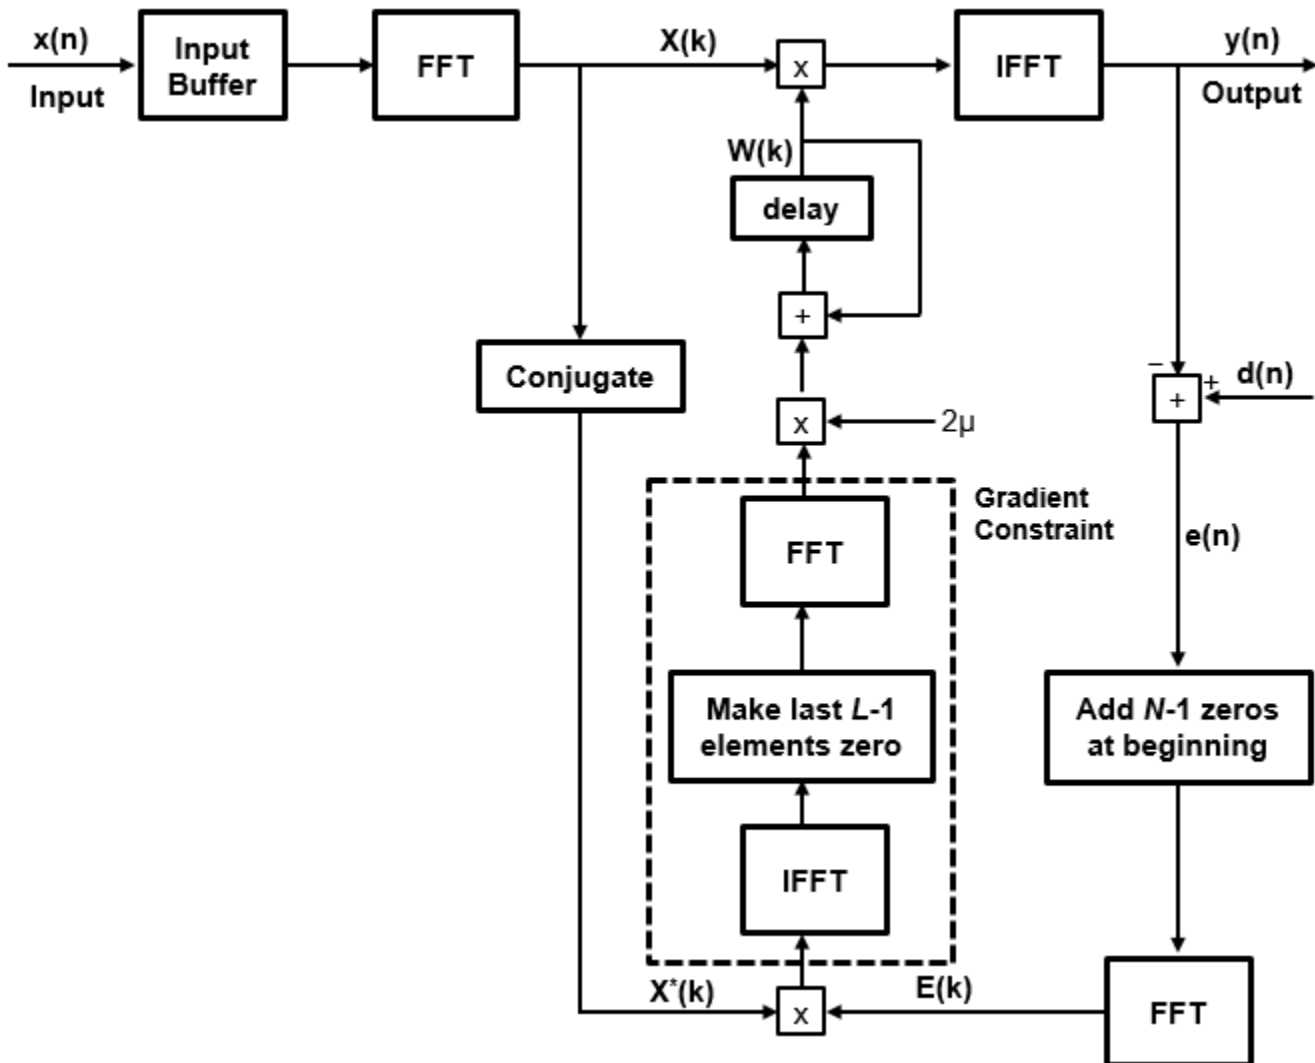

As the filter adapts with time, you can see in the time scope that the mean-squared error becomes minimal. Simultaneously, the estimated coefficients match the actual coefficients closely in the array plot.

Algorithms

Frequency-domain adaptive filtering consists of three steps - filtering, error estimation, and tap-weight adaptation. This algorithm implements FIR filtering in the frequency domain using the overlap-save or overlap-add method. For more implementation details of these two methods, see the "Algorithms" on page 4-614 section in the `dsp.FrequencyDomainFIRFilter` object page. The error estimation and the tap-weight adaptation are implemented using the fast block LMS algorithm (FBLMS).

Fast Block LMS Algorithm

The frequency-domain adaptive filter processes input data and the desired signal data as a block of samples using the fast block LMS (FBLMS) algorithm. Here is the block diagram of the frequency-domain adaptive filter using the FBLMS algorithm. The frequency-domain FIR filter in this diagram uses the overlap-save method.

where:

- N -- Filter length
- L -- Block length
- μ -- Step size parameter
- $x(n)$ -- Input signal
- $X(k)$ -- Transformed input signal in the frequency domain
- $d(n)$ -- Desired signal
- $e(n)$ -- Error between the desired signal and the filter output
- $E(k)$ -- Transformed error signal in the frequency domain
- $W(k)$ -- Tap-weights vector in the frequency domain

For more details on how the error is estimated and the tap-weights are adapted, see [2].

Constrained and Unconstrained FBLMS Algorithms

The previous diagram is the constrained version. If you remove the gradient constraint portion of the algorithm, you have the unconstrained FBLMS implementation. For details on the convergence behavior of both constrained and unconstrained variations, see [2].

Partitioned FBLMS Algorithm

The latency of the filter roughly equals the length of the FIR numerator. If the impulse response of the filter is very long, the latency becomes significantly large. The partitioned FBLMS algorithm reduces latency by partitioning the impulse response. The nonpartitioned frequency-domain FIR filtering is faster than the time-domain filtering for long impulse responses, at the cost of increased latency. To mitigate the latency and make the frequency domain filtering even more efficient, the algorithm partitions the impulse response into multiple short blocks and performs overlap-save or overlap-add on each block. The results of the different blocks are then combined to obtain the final output. The latency of this approach is of the order of the block length, rather than the entire impulse response length. This reduced latency comes at the cost of additional computation. For more details on the implementation, see [2].

Package: dsp

Filter input signal in frequency domain

Description

The `dsp.FrequencyDomainFIRFilter` System object implements frequency-domain, fast Fourier transform (FFT)-based filtering to filter a streaming input signal. In the time domain, the filtering operation involves a convolution between the input and the impulse response of the finite impulse response (FIR) filter. In the frequency domain, the filtering operation involves the multiplication of the Fourier transform of the input and the Fourier transform of the impulse response. The frequency-domain filtering is efficient when the impulse response is very long. You can specify the filter coefficients directly in the frequency domain by setting `NumeratorDomain` to 'Frequency'.

This object uses the overlap-save and overlap-add methods to perform the frequency-domain filtering. For filters with a long impulse response length, the latency inherent to these two methods can be significant. To mitigate this latency, the `dsp.FrequencyDomainFIRFilter` object partitions the impulse response into shorter blocks and implements the overlap-save and overlap-add methods on these shorter blocks. To partition the impulse response, set the "PartitionForReducedLatency" on page 4-0 property to `true`. For more details on these two methods and on reducing latency through impulse response partitioning, see "Algorithms" on page 4-614.

To filter the input signal in the frequency domain:

- 1 Create the `dsp.FrequencyDomainFIRFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
fdf = dsp.FrequencyDomainFIRFilter
fdf = dsp.FrequencyDomainFIRFilter(num)
fdf = dsp.FrequencyDomainFIRFilter(Name,Value)
```

Description

`fdf = dsp.FrequencyDomainFIRFilter` creates a frequency domain FIR filter System object that filters each channel of the input signal independently over time in the frequency domain using the overlap-save or overlap-add method.

`fdf = dsp.FrequencyDomainFIRFilter(num)` creates a frequency domain FIR filter object with the "Numerator" on page 4-0 property set to `num`.

Example: `dsp.FrequencyDomainFIRFilter(fir1(400,2 * 2000 / 8000));`

`fdf = dsp.FrequencyDomainFIRFilter(Name,Value)` creates a frequency domain FIR filter System object with each specified property set to the specified value. Enclose each property name in single quotes. You can use this syntax with any previous input argument combinations.

Example: `dsp.FrequencyDomainFIRFilter('Method','Overlap-add');`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Method — Frequency-domain filter method

'Overlap-save' (default) | 'Overlap-add'

Frequency-domain filter method, specified as either 'Overlap-save' or 'Overlap-add'. For more details on these two methods, see “Algorithms” on page 4-614.

NumeratorDomain — Numerator domain

'Time' (default) | 'Frequency'

Domain of the filter coefficients, specified as one of the following:

- 'Time' -- Specify the time-domain filter numerator in the Numerator property.
- 'Frequency' -- Specify the filter's frequency response in the FrequencyResponse property.

Numerator — FIR filter coefficients

`fir1(100,0.3)` (default) | row vector

FIR filter coefficients, specified as a row vector.

Tunable: Yes

Dependencies

This property applies when NumeratorDomain is set to 'Time'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`
Complex Number Support: Yes

FrequencyResponse — Filter frequency response

`fft(fir1(100,0.3),202)` (default) | row vector | matrix

Frequency response of the filter, specified as a row vector or a matrix. When `PartitionForReducedLatency` is `false`, `FrequencyResponse` must be a row vector. The FFT length is equal to the length of the `FrequencyResponse` vector. When `PartitionForReducedLatency` is `true`, `FrequencyResponse` must be a $2P$ -by- N matrix, where P is the partition size, and N is the number of partitions.

Tunable: Yes

Dependencies

This property applies when `NumeratorDomain` is set to 'Frequency'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`
 Complex Number Support: Yes

NumeratorLength — Time-domain numerator length

101 (default) | positive integer-valued scalar

Time-domain numerator length, specified as a positive integer-valued scalar.

Dependencies

This property applies when `NumeratorDomain` is set to 'Frequency' and `PartitionForReducedLatency` is set to `false`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

FilterIsReal — Flag to specify if filter is real

`true` (default) | `false`

Flag to specify if the filter coefficients are all real, specified as `true` or `false`.

Dependencies

This property applies when `NumeratorDomain` is set to 'Frequency'.

PartitionForReducedLatency — Flag to partition numerator to reduce latency

`false` (default) | `true`

Flag to partition numerator to reduce latency, specified as one of the following:

- `false` -- The filter uses the traditional overlap-save or overlap-add method. The latency in this case is “`FFTLength`” on page 4-0 - length(“`Numerator`” on page 4-0) + 1.
- `true` -- In this mode, the object partitions the numerator into segments of length specified by the “`PartitionLength`” on page 4-0 property. The filter performs overlap-save or overlap-add on each partition, and combines the partial results to form the overall output. The latency is now reduced to the partition length.

FFTLength — FFT length

[] (default) | positive integer

FFT length, specified as a positive integer. The default value of this property, [], indicates that the FFT length is equal to twice the numerator length. The FFT length must be greater than or equal to the numerator length.

Example: 64

Dependencies

This property applies when you set `NumeratorDomain` property to 'Time' and “`PartitionForReducedLatency`” on page 4-0 property to `false`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

PartitionLength — Numerator partition length

32 (default) | positive integer

Numerator partition length, specified as a positive integer less than or equal to the length of the numerator.

Example: 40

Example: 60

Dependencies

This property applies when you set the `NumeratorDomain` property to 'Time' and "PartitionForReducedLatency" on page 4-0 property to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Latency — Filter latency

102 (default) | positive integer

This property is read-only.

Filter latency in samples, returned as an integer greater than 0. When "PartitionForReducedLatency" on page 4-0 is `false`, the latency is equal to "FFTLength" on page 4-0 - length("Numerator" on page 4-0) + 1. When `PartitionForReducedLatency` is `true`, the latency is equal to the partition length.

Data Types: `uint32`

Usage

Syntax

```
fdfOut = fdf(input)
```

Description

`fdfOut = fdf(input)` filters the input signal and outputs the filtered signal. The object filters each channel of the input signal independently over time in the frequency domain.

Input Arguments

input — Data input

vector | matrix

Data input, specified as a vector or a matrix. This object supports variable-size input signals. That is, you can change the input frame size (number of rows) even after calling the algorithm. However, the number of channels (number of columns) must remain constant.

Example: `randn(164,4)`

Data Types: `single` | `double`

Output Arguments

fdfOut — Filtered output

vector | matrix

Filtered output, returned as a vector or matrix. The size, data type, and complexity of the output match those of the input.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.FrequencyDomainFIRFilter

`fvtool` Visualize frequency response of DSP filters

Common to All System Objects

`step` Run System object algorithm
`release` Release resources and allow changes to System object property values and input characteristics
`reset` Reset internal states of System object

Examples

Frequency Domain Filtering Using Overlap-Add and Overlap-Save

Filter input signal using overlap-add and overlap-save methods, and compare the outputs to the output of a FIR filter.

Initialization

Design the FIR lowpass filter coefficients using the `fir1` function. The sampling frequency is 8 kHz, and the cutoff frequency of the filter is 2 kHz. The impulse response has a length of 400.

```
impL = 400;
Fs = 8000;
Fcutoff = 2000;
imp = fir1(impL,2*Fcutoff/Fs);
```

Create two `dsp.FrequencyDomainFIRFilter` objects and a `dsp.FIRFilter` object. Set the numerator of all the three filters to `imp`. Delay the FIR output by the latency of the frequency-domain filter.

```
fdf0A = dsp.FrequencyDomainFIRFilter(imp, 'Method', 'overlap-add');
fdf0S = dsp.FrequencyDomainFIRFilter(imp, 'Method', 'overlap-save');
fir = dsp.FIRFilter('Numerator', imp);
dly = dsp.Delay('Length', fdf0A.Latency);
```

Create two `dsp.SineWave` objects. The sine waves generated have a sample rate of 8000 Hz, frame size of 256, and frequencies of 100 Hz and 3 kHz, respectively. Create a `timescope` object to view the filtered outputs.

```
frameLen = 256;
sin_100Hz = dsp.SineWave('Frequency', 100, 'SampleRate', Fs, ...
    'SamplesPerFrame', frameLen);
```

```

sin_3KHz = dsp.SineWave('Frequency',3e3,'SampleRate',Fs,...
    'SamplesPerFrame',frameLen);
ts = timescope('TimeSpanOvverrunAction','Scroll',...
    'ShowGrid',true,'TimeSpanSource','Property','TimeSpan',5 * frameLen/Fs,...
    'YLimits',[-1.1 1.1],...
    'ShowLegend',true,...
    'SampleRate',Fs,...
    'ChannelNames',{'Overlap-add','Overlap-save','Direct-form FIR'});

```

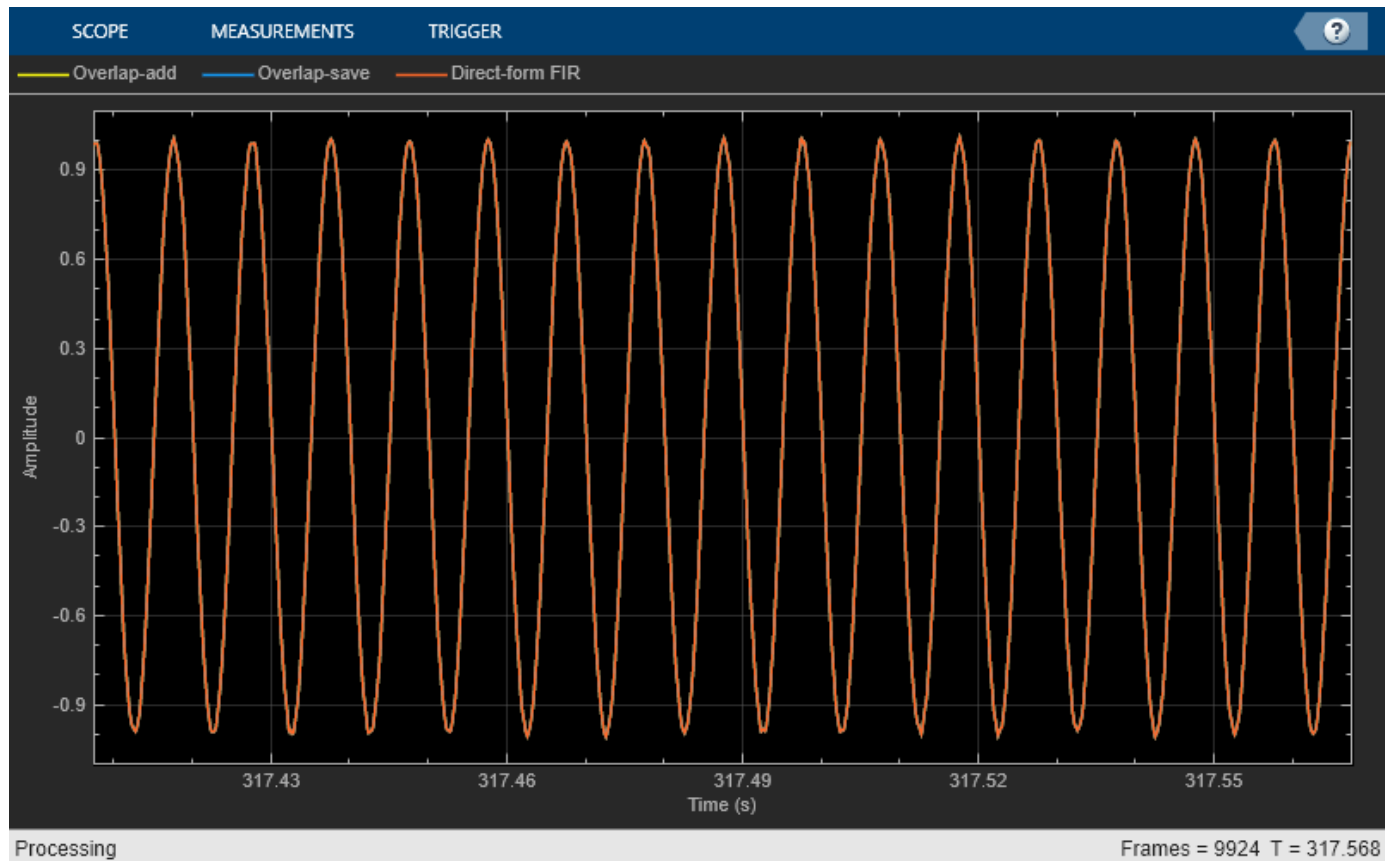

Streaming

Stream 1e4 frames of noisy input data. Pass this data through the frequency domain filters and the FIR filter. View the filtered outputs in the time scope.

```

numFrames = 1e4;
for idx = 1:numFrames
    x = sin_100Hz() + sin_3KHz() + 0.01*randn(frameLen,1);
    y0A = fdf0A(x);
    y0S = fdf0S(x);
    yFIR = fir(dly(x));
    ts([y0A,y0S,yFIR]);
end

```

The outputs of all the three filters match exactly.

Reduce Latency Through Partitioned Numerator

Partition the impulse response length of a frequency domain FIR filter. Compare the outputs of the partitioned filter and the original filter.

Design the FIR lowpass filter coefficients using the `fir1` function. The sampling frequency is 8 kHz and the cutoff frequency of the filter is 2 kHz. The impulse response is of length 4000.

```
impL    = 4000;
Fs      = 8000;
Fcutoff = 2000;
imp     = fir1(impL,2 * Fcutoff / Fs);
```

Create a `dsp.FrequencyDomainFIRFilter` with coefficients set to the `imp` vector. The latency of this filter is given by $FFTLength - Length(Numerator) + 1$, which is equal to 4002. By default, FFT length is equal to twice the numerator length. This makes the latency proportional to the impulse response length.

```
fdf0S = dsp.FrequencyDomainFIRFilter(imp,'Method','overlap-save');
fprintf('Frequency domain filter latency is %d samples\n',fdf0S.Latency);
```

```
Frequency domain filter latency is 4002 samples
```

Partition the impulse response to blocks of length 256. The latency after partitioning is proportional to the block length.

```
fdfRL = dsp.FrequencyDomainFIRFilter(imp,'Method','overlap-save',...
    'PartitionForReducedLatency',true,...
    'PartitionLength',256);
fprintf('Frequency domain filter latency is %d samples\n',fdfRL.Latency);
```

```
Frequency domain filter latency is 256 samples
```

Compare the outputs of the two frequency domain filters. The latency of `fdf0S` is 4002, and the latency of `fdfRL` is 256. To compare the two outputs, delay the input to `fdfRL` by 4002 - 256 samples.

```
dly = dsp.Delay('Length',(fdf0S.Latency-fdfRL.Latency));
```

Create two `dsp.SineWave` objects. The sine waves have a sample rate of 8000 Hz, frame size of 256, and frequencies of 100 Hz and 3 kHz, respectively. Create a `timescope` object to view the filtered outputs.

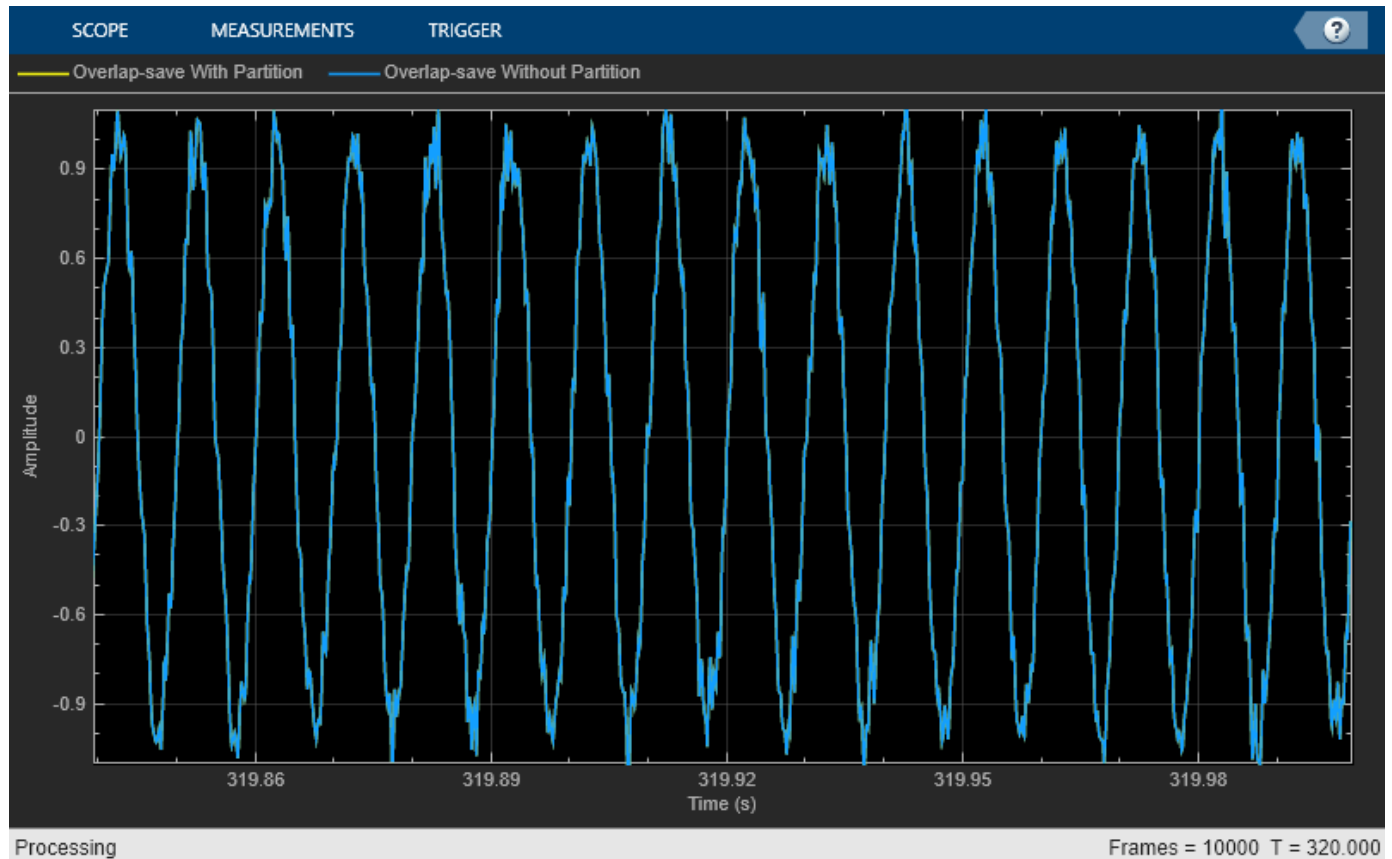

```
frameLen = 256;
sin_100Hz = dsp.SineWave('Frequency',100,'SampleRate',Fs,...
    'SamplesPerFrame',frameLen);
sin_3KHz = dsp.SineWave('Frequency',3e3,'SampleRate',Fs,...
    'SamplesPerFrame',frameLen);
ts = timescope('TimeSpanOvverrunAction','Scroll','ShowGrid',true,...
    'TimeSpanSource','Property','TimeSpan',5 * frameLen/Fs,...
    'YLimits',[-1.1 1.1],...
    'ShowLegend',true,...
    'SampleRate',Fs,...
    'ChannelNames',{'Overlap-save With Partition','Overlap-save Without Partition'});
```

Stream 1e4 frames of noisy input data. Pass this data through the two frequency domain filters. View the filtered outputs in the time scope.

```

numFrames = 1e4;
for idx = 1:numFrames
    x = sin_100Hz() + sin_3KHz() + .1 * randn(frameLen,1);
    yRL = fdfRL(dly(x));
    yOS = fdfOS(x);
    ts([yRL,yOS]);
end

```

The outputs match exactly.

Specify Frequency Response of the Frequency-Domain FIR Filter

Specify the numerator coefficients of the frequency-domain FIR filter in the frequency domain. Filter the input signal using the overlap-add method. Compare the frequency-domain FIR filter output to the corresponding time-domain FIR filter output.

Initialization

Design the FIR lowpass filter coefficients using the `fir1` function. The sampling frequency is 8 kHz, and the cutoff frequency of the filter is 2 kHz. The time-domain impulse response has a length of 400. Compute the FFT of this impulse response and specify this response as the frequency response of the frequency-domain FIR filter. Set the time-domain numerator length, specified by the `NumeratorLength` property, to the number of elements in the time-domain impulse response.

```

impL    = 400;
Fs      = 8000;
Fcutoff = 2000;
imp     = fir1(impL,2 * Fcutoff / Fs);
H      = fft(imp , 2 * numel(imp));
oa     = dsp.FrequencyDomainFIRFilter('NumeratorDomain','Frequency',...
    'FrequencyResponse', H,...
    'NumeratorLength',numel(imp),...
    'Method','overlap-add');
fprintf('Frequency domain filter latency is %d samples\n',oa.Latency);

```

```
Frequency domain filter latency is 402 samples
```

Create a `dsp.FIRFilter` System object? and specify the numerator as the time-domain coefficients computed using the `fir1` function, `imp`. Delay the FIR output by the latency of the frequency-domain FIR filter.

```

fir = dsp.FIRFilter('Numerator',imp);
dly = dsp.Delay('Length',oa.Latency);

```

Create two `dsp.SineWave` objects. The sine waves generated have a sample rate of 8000 Hz, frame size of 256, and frequencies of 100 Hz and 3 kHz, respectively. Create a `timescope` object to view the filtered outputs.

```

frameLen = 256;

sin_100Hz = dsp.SineWave('Frequency',100,'SampleRate',Fs,...
    'SamplesPerFrame',frameLen);
sin_3KHz  = dsp.SineWave('Frequency',3e3,'SampleRate',Fs,...
    'SamplesPerFrame',frameLen);

ts = timescope('TimeSpanOvrrunAction','Scroll',...
    'ShowGrid',true,'YLimits',[-1.1 1.1],...
    'TimeSpanSource','Property','TimeSpan',5 * frameLen/Fs,...
    'ShowLegend',true,...
    'SampleRate',Fs,...
    'ChannelNames',{'Overlap-add','Direct-form FIR'});

```

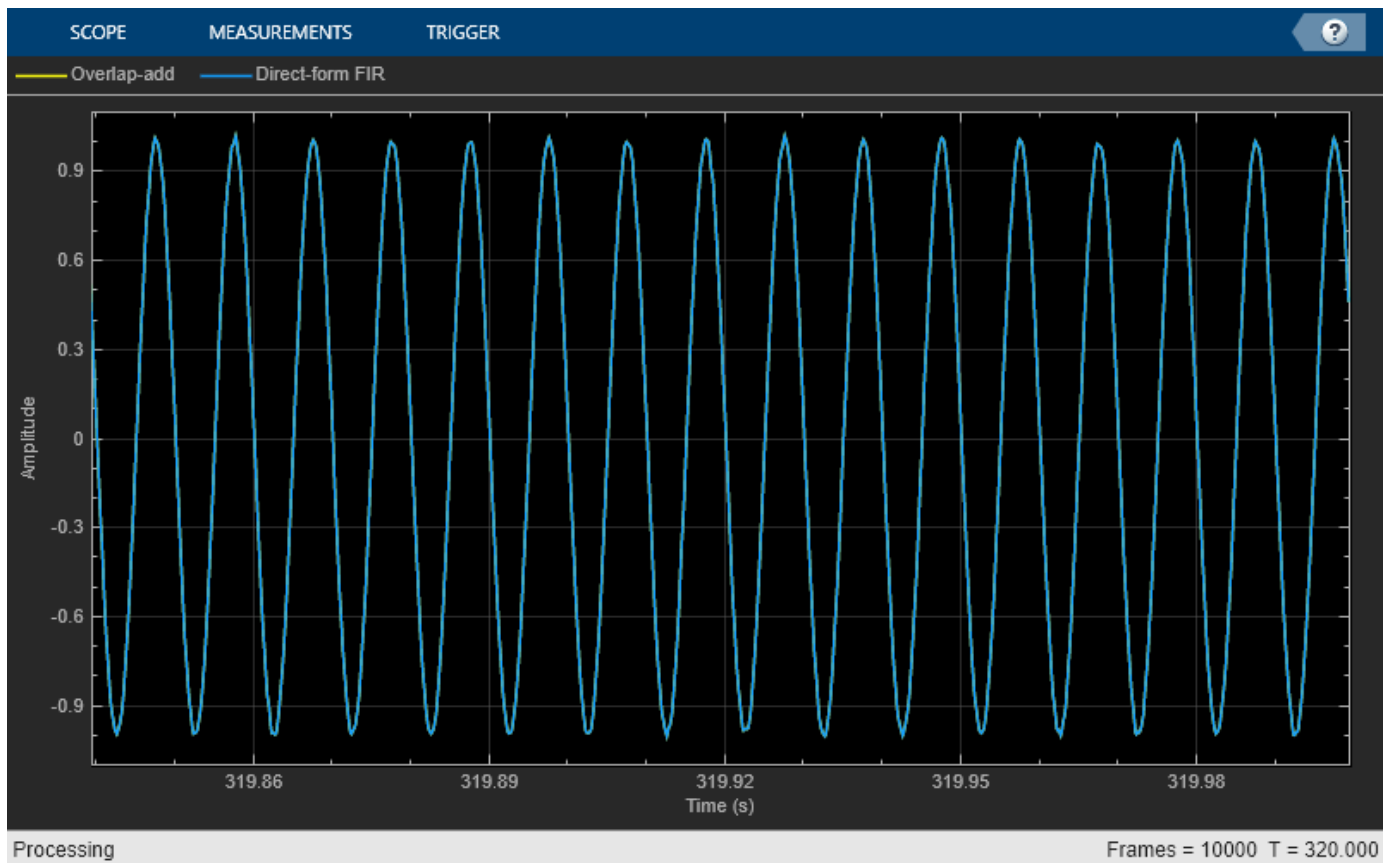

Streaming

Stream 1e4 frames of noisy input data. Pass this data through the frequency-domain FIR filter and the time-domain FIR filter. View the filtered outputs in the time scope.

```

numFrames = 1e4;
for idx = 1:numFrames
    x = sin_100Hz() + sin_3KHz() + 0.01 * randn(frameLen,1);
    y1 = oa(x);
    y2 = fir(dly(x));
    ts([y1,y2]);
end

```

The outputs of both the filters match exactly.

Algorithms

Overlap-save and overlap-add are the two frequency-domain FFT-based filtering methods this algorithm uses.

Overlap-Save

The overlap-save method is implemented using the following approach:

The input stream is partitioned into overlapping blocks of size $FFTLen$, with an overlap factor of $NumLen - 1$ samples. $FFTLen$ is the FFT length and $NumLen$ is the length of the FIR filter numerator. The FFT of each block of input samples is computed and multiplied with the length- $FFTLen$ FFT of

the FIR numerator. The inverse fast Fourier transform (IFFT) of the result is performed, and the last $FFTLen - NumLen + 1$ samples are saved. The remaining samples are dropped.

The latency of overlap-save is $FFTLen - NumLen + 1$. The first $FFTLen - NumLen + 1$ samples are equal to zero. The filtered value of the first input sample appears as the $FFTLen - NumLen + 2$ output sample.

Note that the FFT length must be larger than the numerator length, and is typically set to a value much greater than $NumLen$.

Overlap-Add

The overlap-add method is implemented using the following approach:

The input stream is partitioned into blocks of length $FFLen - NumLen + 1$, with no overlap between consecutive blocks. Similar to overlap-save, the FFT of the block is computed, and multiplied by the FFT of the FIR numerator. The IFFT of the result is then computed. The first $NumLen + 1$ samples are modified by adding the values of the last $NumLen + 1$ samples from the previous computed IFFT.

The latency of overlap-add is $FFTLen - NumLen + 1$. The first $FFTLen - NumLen + 1$ samples are equal to zero. The filtered value of the first input sample appears as the $FFTLen - NumLen + 2$ output sample.

Reduce Latency Through Impulse Response Partitioning

With an FFT length that is twice the length of the FIR numerator, the latency roughly equals the length of the FIR numerator. If the impulse response is very long, the latency becomes significantly large. However, frequency domain FIR filtering is still faster than the time-domain filtering. To mitigate the latency and make the frequency domain filtering even more efficient, the algorithm partitions the impulse response into multiple short blocks and performs overlap-save or overlap-add on each block. The results of the different blocks are then combined to obtain the final output. The latency of this approach is of the order of the block length, rather than the entire impulse response length. This reduced latency comes at the cost of additional computation. For more details, see [1].

dsp.HampelFilter

Package: dsp

Filter outliers using Hampel identifier

Description

The `dsp.HampelFilter` System object detects and removes the outliers of the input signal by using the Hampel identifier. The Hampel identifier is a variation of the three-sigma rule of statistics that is robust against outliers. For each sample of the input signal, the object computes the median of a window composed of the current sample and $\frac{Len-1}{2}$ adjacent samples on each side of current sample. *Len* is the window length you specify through the `WindowLength` property. The object also estimates the standard deviation of each sample about its window median by using the median absolute deviation. If a sample differs from the median by more than the threshold multiplied by the standard deviation, the filter replaces the sample with the median. For more information, see “Algorithms” on page 4-624.

To filter the input signal using a Hampel identifier:

- 1 Create the `dsp.HampelFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
hampFilt = dsp.HampelFilter
hampFilt = dsp.HampelFilter(Len)
hampFilt = dsp.HampelFilter(Len, Lim)
hampFilt = dsp.HampelFilter(Name,Value)
```

Description

`hampFilt = dsp.HampelFilter` returns a Hampel filter object, `hampFilt`, using the default properties.

`hampFilt = dsp.HampelFilter(Len)` sets the `WindowLength` property to `Len`.

`hampFilt = dsp.HampelFilter(Len, Lim)` sets the `WindowLength` property to `Len` and the `Threshold` property to `Lim`.

Example: `hampFilt = dsp.HampelFilter(11,2);`

`hampFilt = dsp.HampelFilter(Name,Value)` specifies properties using `Name,Value` pairs. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

If a property is listed as *tunable*, then you can change its value even when the object is locked.

WindowLength — Length of the sliding window

11 (default) | positive odd scalar integer

Length of the sliding window, specified as a positive odd scalar integer. The window of finite length slides over the data, and the object computes the median and median absolute deviation of the data in the window.

Data Types: `single` | `double`

Threshold — Threshold for outlier detection

3 (default) | positive real scalar

Threshold for outlier detection, specified as a positive real scalar. For information on how this property is used to detect the outlier, see “Algorithms” on page 4-624.

Tunable: Yes

Data Types: `single` | `double`

Usage

Syntax

```
y = hampFilt(x)
[y,isOutlier] = hampFilt(x)
```

Description

`y = hampFilt(x)` detects and removes the outliers of each channel of the input signal, `x`, independently over time using the Hampel filter.

`[y,isOutlier] = hampFilt(x)` returns a logical array, `isOutlier`, in which each true element indicates that the corresponding element in the input is an outlier. `isOutlier` is the same size as the input and output vectors.

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix. The object accepts multichannel inputs, that is, m -by- n size inputs, where $m \geq 1$, and $n > 1$. m is the number of samples in each frame (channel), and n is the

number of channels. The object also accepts variable-size inputs. After the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

Data Types: `single` | `double`

Output Arguments

y — Filtered data

vector | matrix

Filtered data, returned as a vector or a matrix.

Data Types: `single` | `double`

isOutlier — Indicate outlier

`true` | `false`

Logical array whose elements indicate if the corresponding element in the input array is an outlier. If an element in `isOutlier` is `true`, the corresponding element in the input array is an outlier.

Data Types: `logical`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Remove High-Frequency Noise Using Hampel Filter

Filter high-frequency noise from a noisy sine wave signal using a Hampel filter. Compare the performance of the Hampel filter with a median filter.

Initialization

Set up a `dsp.HampelFilter` and a `dsp.MedianFilter` object. These objects use the sliding window method with a window length of 7. Create a time scope for viewing the output.

```
Fs = 1000;
hampFilt = dsp.HampelFilter(7);
medFilt = dsp.MedianFilter(7);
scope = timescope('SampleRate',Fs, ...
    'TimeSpanOvverrunAction','Scroll', ...
    'TimeSpanSource','Property',...
    'TimeSpan',1,'ShowGrid',true, ...
```

```
        'LayoutDimensions',[3 1], ...
        'NumInputPorts',3);
scope.ActiveDisplay = 1;
scope.Title = 'Signal + Noise';
scope.YLimits = [-1 3];
scope.ActiveDisplay = 2;
scope.Title = 'Hampel Filter Output (Window Length = 7)';
scope.YLimits = [-1 1];
scope.ActiveDisplay = 3;
scope.Title = 'Median Filter Output (Window Length = 7)';
scope.YLimits = [-1 1];
```

Filter the Noisy Sine Wave Using a Window of Length 7

Generate a noisy sine wave signal with a frequency of 10 Hz. Apply the Hampel filter and the median filter object to the signal. View the output on the time scope.

```
FrameLength = 256;
sine = dsp.SineWave('SampleRate',Fs,'Frequency',10,...
    'SamplesPerFrame',FrameLength);

for i = 1:500
    hfn = 3 * (rand(FrameLength,1) < 0.02);
    x = sine() + 1e-2 * randn(FrameLength,1) + hfn;
    y1 = hampFilt(x);
    y2 = medFilt(x);
    scope(x,y1,y2);
end
release(scope)
```

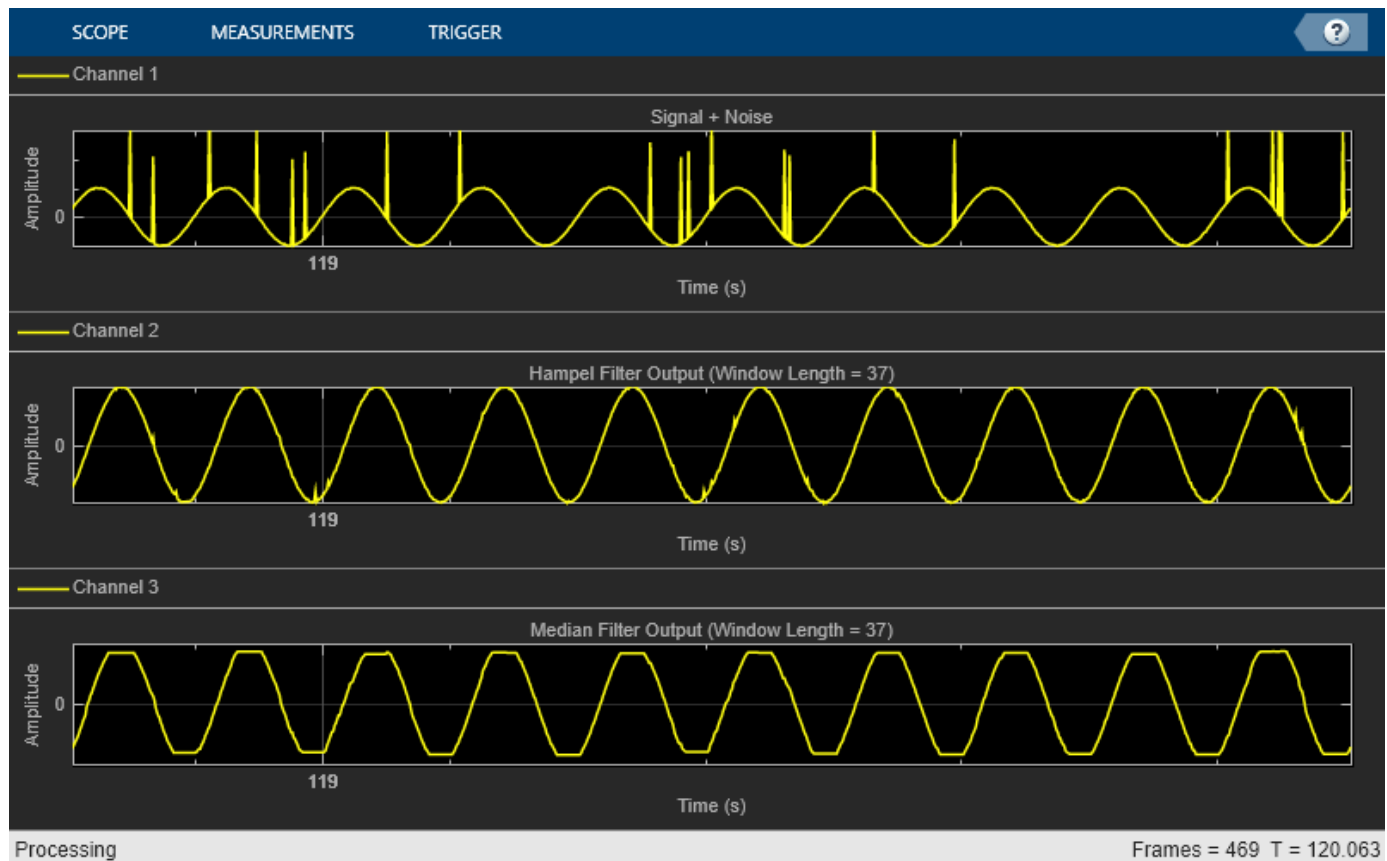

Both filters remove the high-frequency noise. However, when you increase the window length, the Hampel filter is preferred. Unlike the median filter, the Hampel filter preserves the shape of the sine wave even with large window lengths.

Filter the Noisy Sine Wave Using a Window of Length 37

Increase the window length of both the filters to 37. Filter the noisy sine wave and view the filtered output on the time scope. To change the window length of the filters, you must release the filter objects at the start of the processing loop.

```
release(hampFilt);
release(medFilt);
hampFilt.WindowLength = 37;
medFilt.WindowLength = 37;
scope.ActiveDisplay = 1;
scope.Title = 'Signal + Noise';
scope.ActiveDisplay = 2;
scope.Title = 'Hampel Filter Output (Window Length = 37)';
scope.ActiveDisplay = 3;
scope.Title = 'Median Filter Output (Window Length = 37)';
for i = 1:500
    hfn = 3 * (rand(FrameLength,1) < 0.02);
    x = sine() + 1e-2 * randn(FrameLength,1) + hfn;
    y1 = hampFilt(x);
    y2 = medFilt(x);
    scope(x,y1,y2);
end
```

```
end
release(scope)
```

The median filter flattens the crests and troughs of the sine wave due to the median operation over a large window of data. The Hampel filter preserves the shape of the signal, in addition to removing the outliers.

Remove High-Frequency Noise from Gyroscope Data Using Hampel Filter

Remove the high-frequency outliers from a streaming signal using the `dsp.HampelFilter` System object™.

Use the `dsp.MatFileReader` System object to read the gyroscope MAT file. The file contains three columns of data, with each column containing 7140 samples. The three columns represent the x-axis, y-axis, and z-axis data from the gyroscope motion sensor. Choose a frame size of 714 samples so that each column of the data contains 10 frames. The `dsp.HampelFilter` System object uses a window length of 11. Create a `timescope` object to view the filtered output.

```
reader = dsp.MatFileReader('SamplesPerFrame',714,'Filename','LSM9DSHampelgyroData73.mat', ...
    'VariableName','data');
hampFilt = dsp.HampelFilter(11);
scope = timescope('NumInputPorts',1,'SampleRate',119,'YLimits',[-300 300], ...
    'ChannelNames',{'Input','Filtered Output'},...
    'TimeSpanSource','Property','TimeSpan',60,'ShowLegend',true);
```

Filter the gyroscope data using the `dsp.HampFilter` System object. View the filtered z-axis data in the Time Scope.

```
for i = 1:10
    gyroData = reader();
    filteredData = hampFilt(gyroData);
    scope([gyroData(:,3), filteredData(:,3)]);
end
```

The Hampel filter removes all the outliers and preserves the shape of the signal.

More About

Hampel Identifier

The Hampel identifier is a variation of the three-sigma rule of statistics that is robust against outliers.

Given a sequence $x_1, x_2, x_3, \dots, x_n$ and a sliding window of length k , define point-to-point median and standard-deviation estimates using:

- Local median — $m_i = \text{median}(x_{i-k}, x_{i-k+1}, x_{i-k+2}, \dots, x_i, \dots, x_{i+k-2}, x_{i+k-1}, x_{i+k})$
- Standard deviation — $\sigma_i = \kappa \text{median}(|x_{i-k} - m_i|, \dots, |x_{i+k} - m_i|)$, where $\kappa = \frac{1}{\sqrt{2} \text{erfc}^{-1}(1/2)} \approx 1.4826$

The quantity σ_i / κ is known as the median absolute deviation (MAD).

If a sample x_i is such that

$$|x_i - m_i| > n_\sigma \sigma_i$$

for a given threshold n_σ , then the Hampel identifier declares x_i an outlier and replaces it with m_i . If n_σ is 0, then the Hampel filter behaves as a regular median filter.

Algorithms

For a given sample of data, x_s , the algorithm:

- Centers the window of odd length at the current sample.
- Computes the local median, m_i , and standard deviation, σ_i , over the current window of data.
- Compares the current sample with $n_\sigma \times \sigma_i$, where n_σ is the threshold value. If $|x_s - m_i| > n_\sigma \times \sigma_i$, the filter identifies the current sample, x_s , as an outlier and replaces it with the median value, m_i .

Consider a frame of data that is passed into the Hampel filter.

1	2	4	9	23	8	12	4	2
---	---	---	---	----	---	----	---	---

In this example, the Hampel filter slides a window of length 5 (Len) over the data. The filter has a threshold value of 2 (n_σ). To have a complete window at the beginning of the frame, the filter algorithm prepends the frame with $Len - 1$ zeros. To compute the first sample of the output, the window centers on the $\left[\frac{Len - 1}{2} + 1\right]^{\text{th}}$ sample in the appended frame, the third zero in this case. The filter computes the median, median absolute deviation, and the standard deviation over the data in the local window.

- Current sample: $x_s = 0$.
- Window of data: $win = [0\ 0\ 0\ 0\ 1]$.

- Local median: $m_i = \text{median}([0\ 0\ 0\ 0\ 1]) = 0$.
- Median absolute deviation: $mad_i = \text{median}(|x_{i-k} - m_i|, \dots, |x_{i+k} - m_i|)$. For this window of data, $mad = \text{median}(|0 - 0|, \dots, |1 - 0|) = 0$.
- Standard deviation: $\sigma_i = \kappa \times mad_i = 0$, where $\kappa = \frac{1}{\sqrt{2}\text{erfc}^{-1}(1/2)} \approx 1.4826$.
- The current sample, $x_s = 0$, does not obey the relation for outlier detection.
 $[|x_s - m_i| = 0] > [(n_\sigma \times \sigma_i) = 0]$

Therefore, the Hampel filter outputs the current input sample, $x_s = 0$.

Repeat this procedure for every succeeding sample until the algorithm centers the window on the $\left[\text{End} - \frac{\text{Len} - 1}{2} \right]^{\text{th}}$ sample, marked as End. Because the window centered on the last $\frac{\text{Len} - 1}{2}$ samples cannot be full, these samples are processed with the next frame of input data.

Here is the first output frame the Hampel filter generates:

The seventh sample of the appended input frame, 23, is an outlier. The Hampel filter replaces this sample with the median over the local window [4 9 23 8 12].

dsp.HighpassFilter

Package: dsp

FIR or IIR highpass filter

Description

The `dsp.HighpassFilter` System object independently filters each channel of the input over time using the given design specifications. You can set the `FilterType` property of `dsp.HighpassFilter` to 'FIR' or 'IIR' to implement the object as an FIR or IIR highpass filter.

To filter each channel of your input:

- 1 Create the `dsp.HighpassFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
HPF = dsp.HighpassFilter
HPF = dsp.HighpassFilter(Name,Value)
```

Description

`HPF = dsp.HighpassFilter` returns a minimum order FIR highpass filter, `HPF`, with the default filter settings. Calling the object with the default property settings filters the input data with a stopband frequency of 8 kHz, a passband frequency of 12 kHz, a stopband attenuation of 80 dB, and a passband ripple of 0.1 dB.

`HPF = dsp.HighpassFilter(Name,Value)` returns a highpass filter, with additional properties specified by one or more `Name,Value` pair arguments. `Name` is the property name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

SampleRate — Input sample rate

44100 (default) | positive real scalar

Input sample rate in Hz, specified as the comma-separated pair consisting of 'SampleRate' and a positive real scalar.

Data Types: `single` | `double`

FilterType – Filter type

'FIR' (default) | 'IIR'

Filter type, specified as one of the following options:

- 'FIR' — The object designs an FIR highpass filter.
- 'IIR' — The object designs an IIR highpass (biquad) filter.

DesignForMinimumOrder – Minimum order filter design

`true` (default) | `false`

Minimum order filter design, specified as the comma-separated pair consisting of 'DesignForMinimumOrder' and a logical value. If this property is `true`, then `dsp.HighpassFilter` designs filters with the minimum order that meets the passband frequency, stopband frequency, passband ripple, and stopband attenuation specifications. Set these specifications using the corresponding properties. If this property is `false`, then the object designs filters with the order that you specify in the `FilterOrder` property. This filter design meets the passband frequency, passband ripple, and stopband attenuation specifications that you set using the respective properties.

FilterOrder – Order of the FIR or IIR filter

50 (default) | positive integer scalar

Order of the FIR or IIR filter, specified as the comma-separated pair consisting of 'FilterOrder' and a positive integer scalar.

Dependencies

Specifying a filter order is only valid when the value of 'DesignForMinimumOrder' is `false`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

StopbandFrequency – Filter stopband edge frequency

8000 (default) | real positive scalar

Filter stopband edge frequency in Hz, specified as the comma-separated pair consisting of 'StopbandFrequency' and a real positive scalar. The value of the stopband edge frequency in Hz must be less than the passband frequency.

Dependencies

You can specify the stopband edge frequency only when 'DesignForMinimumOrder' is `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

PassbandFrequency – Filter passband edge frequency

12000 (default) | real positive scalar

Filter passband edge frequency in Hz, specified as the comma-separated pair consisting of 'PassbandFrequency' and a real positive scalar. The value of the passband edge frequency in Hz must be less than half the `SampleRate` and greater than `StopbandFrequency`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

StopbandAttenuation — Minimum attenuation in the stopband

80 (default) | real positive scalar

Minimum attenuation in the stopband in dB, specified as the comma-separated pair consisting of 'StopbandAttenuation' and a real positive scalar. Minimum attenuation in the stopband defaults to 80 dB.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

PassbandRipple — Maximum ripple of filter response in the passband

0.1 (default) | real positive scalar

Maximum ripple of filter response in the passband, in dB, specified as the comma-separated pair consisting of 'PassbandRipple' and a real positive scalar. Maximum ripple of filter response defaults to 0.1 dB.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Fixed-Point Properties

RoundingMethod — Rounding method for output fixed-point operations

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see “Precision and Range”.

CoefficientsDataType — Word and fraction lengths of coefficients

`numericType([],16)` (default) | `numericType` object

Word and fraction lengths of coefficients, specified as a `numericType` object. The default, `numericType(1,16)` corresponds to a signed numeric type object with 16-bit coefficients and a fraction length determined based on the coefficient values, to give the best possible precision.

This property is not tunable.

Word length of the output is same as the word length of the input. Fraction length of the output is computed such that the entire dynamic range of the output can be represented without overflow. For details on how the fraction length of the output is computed, see “Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters”.

Usage

Syntax

$y = \text{HPF}(x)$

Description

$y = \text{HPF}(x)$ highpass filters the input signal, x . y is a highpass-filtered version of x .

Input Arguments

x — Noisy data input

vector | matrix

Noisy data input, specified as a vector or a matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel. The number of rows in the input signal denote the channel length. This object accepts variable-size inputs. After the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Output Arguments

y — Filtered output

vector | matrix

Filtered output, returned as a vector or a matrix. The output has the same size, data type, and complexity characteristics as the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.HighpassFilter`

<code>freqz</code>	Frequency response of discrete-time filter System object
<code>fvtool</code>	Visualize frequency response of DSP filters
<code>impz</code>	Impulse response of discrete-time filter System object
<code>info</code>	Information about filter System object
<code>coeffs</code>	Returns the filter System object coefficients in a structure
<code>cost</code>	Estimate cost of implementing filter System object
<code>grpdelay</code>	Group delay response of discrete-time filter System object
<code>generatehdl</code>	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)
<code>measure</code>	Measure frequency response characteristics of filter System object

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Impulse and Frequency Response of FIR and IIR Highpass Filters

Create a minimum order FIR highpass filter for data sampled at 44.1 kHz. Specify a passband frequency of 12 kHz, a stopband frequency of 8 kHz, a passband ripple of 0.1 dB, and a stopband attenuation of 80 dB.

```
Fs = 44.1e3;
filtertype = 'FIR';
Fpass = 12e3;
Fstop = 8e3;
Rp = 0.1;
Astop = 80;
FIRHPF = dsp.HighpassFilter('SampleRate',Fs,...
                             'FilterType',filtertype,...
                             'PassbandFrequency',Fpass,...
                             'StopbandFrequency',Fstop,...
                             'PassbandRipple',Rp,...
                             'StopbandAttenuation',Astop);
```

Design a minimum order IIR highpass filter with the same properties as the FIR highpass filter. Use `clone` to create a system object with the same properties as the FIR Highpass filter. Change the `FilterType` property of the cloned filter to IIR.

```
IIRHPF = clone(FIRHPF);
IIRHPF.FilterType = 'IIR';
```

Plot the impulse response of the FIR highpass filter. The zeroth order coefficient is delayed by 19 samples, which is equal to the group delay of the filter. The FIR highpass filter is a causal FIR filter

```
fvtool(FIRHPF,'Analysis','impulse')
```

Plot the impulse response of the IIR highpass filter.

```
fvtool(IIRHPF, 'Analysis', 'impulse')
```

Plot the magnitude and phase response of the FIR highpass filter.

```
fvtool(FIRHPF, 'Analysis', 'freq')
```

Plot the magnitude and phase response of the IIR highpass filter.

```
fvtool(IIRHPF, 'Analysis', 'freq')
```

Calculate the cost of implementing the FIR highpass filter.

```
cost(FIRHPF)
```

```
ans = struct with fields:
    NumCoefficients: 39
    NumStates: 38
    MultiplicationsPerInputSample: 39
    AdditionsPerInputSample: 38
```

Calculate the cost of implementing the IIR highpass filter. The IIR filter is more efficient to implement than its FIR counterpart.

```
cost(IIRHPF)
```

```
ans = struct with fields:
    NumCoefficients: 18
    NumStates: 14
    MultiplicationsPerInputSample: 18
    AdditionsPerInputSample: 14
```

Calculate the group delay of the FIR highpass filter.

```
grpdelay(FIRHPF)
```

Calculate the group delay of the IIR highpass filter. The FIR filter has a constant group delay (linear phase) while its IIR counterpart does not.

```
grpdelay(IIRHPF)
```

Filter White Gaussian Noise with an IIR Highpass filter

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Set up the IIR highpass filter. The sampling rate of the white Gaussian noise is 44,100 Hz. The passband frequency of the filter is 12 kHz, the stopband frequency is 8 kHz, the passband ripple is 0.1 dB, and the stopband attenuation is 80 dB.

```
Fs = 44.1e3;
filtertype = 'IIR';
Fpass = 12e3;
Fstop = 8e3;
Rp = 0.1;
Astop = 80;
hpf = dsp.HighpassFilter('SampleRate',Fs,...
                        'FilterType',filtertype,...
                        'PassbandFrequency',Fpass,...
                        'StopbandFrequency',Fstop,...
                        'PassbandRipple',Rp,...
                        'StopbandAttenuation',Astop);
```

View the magnitude response of the highpass filter.

```
fvtool(hpf)
```

Create a spectrum analyzer object.

```
sa = spectrumAnalyzer('SampleRate',44.1e3,...
    'PlotAsTwoSidedSpectrum',false,'ShowLegend',true,'YLimits',...
    [-150 30],...
    'Title',...
    'Input Signal and Output Signal of IIR Highpass Filter');
sa.ChannelNames = {'Input','Output'};
```

Filter the white Gaussian noisy input signal. View the input and output signals using the spectrum analyzer.

```
for k = 1:100
    Input = randn(1024,1);
    Output = hpf(Input);
    sa([Input,Output]);
end
```

Measure Frequency Response Characteristics of Highpass Filter

Measure the frequency response characteristics of a highpass filter. Create a `dsp.HighpassFilter` System object with default properties. Measure the frequency response characteristics of the filter.

```
HPF = dsp.HighpassFilter
```

```
HPF =  
    dsp.HighpassFilter with properties:
```

```
        FilterType: 'FIR'  
    DesignForMinimumOrder: true  
        StopbandFrequency: 8000  
        PassbandFrequency: 12000  
    StopbandAttenuation: 80  
        PassbandRipple: 0.1000  
        SampleRate: 44100
```

```
Show all properties
```

```
HPFMeas = measure(HPF)
```

```
HPFMeas =  
Sample Rate      : 44.1 kHz
```

Stopband Edge : 8 kHz
6-dB Point : 10.418 kHz
3-dB Point : 10.8594 kHz
Passband Edge : 12 kHz
Stopband Atten. : 81.8558 dB
Passband Ripple : 0.08066 dB
Transition Width : 4 kHz

Algorithms

FIR Highpass Filter

When the `FilterType` property is set to 'FIR', the `dsp.HighpassFilter` object acts as a FIR highpass filter. In this configuration, `dsp.HighpassFilter` is an alternative to using `firceqrip` and `firgr` with `dsp.FIRFilter`. This object condenses the two-step process into one. For the minimum order design, the object uses generalized Remez FIR filter design algorithm. For the specified order design, the object uses constrained equiripple FIR filter design algorithm. The designed filter is then implemented as a linear phase Type-1 filter with a `Direct` form structure. You can use `measure` to verify that the design meets the prescribed specifications.

IIR Highpass Filter

When the `FilterType` property is set to 'IIR', the `dsp.HighpassFilter` object acts as an IIR highpass filter. In this configuration, this object uses the elliptic design method to compute the SOS and scale values required to meet the filter design specifications. The object uses the SOS and scale values to set up a `Direct` form I biquadratic IIR filter, which forms the basis of the IIR version of the `dsp.HighpassFilter` System object. You can use `measure` to verify that the design meets the prescribed specifications.

Version History

Introduced in R2015a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See "System Objects in MATLAB Code Generation" (MATLAB Coder).

This object supports code generation for ARM Cortex-M and ARM Cortex-A processors. To learn more about ARM Cortex code generation, see “Code Generation for ARM Cortex-M and ARM Cortex-A Processors”.

This object also supports SIMD code generation using Intel AVX2 technology under these conditions:

- `FilterType` is set to 'FIR'.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This object supports HDL code generation with the Filter Design HDL Coder product. For workflows and limitations, see “Generate HDL Code for Filter System Objects” (Filter Design HDL Coder).

dsp.IFFT

Package: dsp

Inverse discrete Fourier transform (IDFT)

Description

The `dsp.IFFT` System object computes the inverse discrete Fourier transform (IDFT) of the input. The object uses one or more of the following fast Fourier transform (FFT) algorithms depending on the complexity of the input and whether the output is in linear or bit-reversed order:

- Double-signal algorithm
- Half-length algorithm
- Radix-2 decimation-in-time (DIT) algorithm
- Radix-2 decimation-in-frequency (DIF) algorithm
- An algorithm chosen from FFTW [1], [2]

To compute the IFFT of the input:

- 1 Create the `dsp.IFFT` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
ift = dsp.IFFT  
ift = dsp.IFFT(Name,Value)
```

Description

`ift = dsp.IFFT` returns an IFFT object, `ift`, that computes the IDFT of a column vector or N -D array. For column vectors or N -D arrays, the IFFT object computes the IDFT along the first dimension of the array. If the input is a row vector, the IFFT object computes a row of single-sample IDFTs and issues a warning.

`ift = dsp.IFFT(Name,Value)` returns an IFFT object, `ift`, with each property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

FFTImplementation — FFT implementation

Auto (default) | Radix-2 | FFTW

Specify the implementation used for the FFT as `Auto`, `Radix-2`, or `FFTW`. When you set this property to `Radix-2`, the FFT length must be a power of two.

BitReversedInput — Enable bit-reversed order interpretation of input elements

false (default) | true

Set this property to `true` if the order of Fourier transformed input elements to the IFFT object are in bit-reversed order. The default is `false`, which denotes linear ordering.

Dependencies

This property applies only when the `FFTLengthSource` property is `Auto`.

ConjugateSymmetricInput — Enable conjugate symmetric interpretation of input

false (default) | true

Set this property to `true` if the input is conjugate symmetric to yield real-valued outputs. The discrete Fourier transform of a real valued sequence is conjugate symmetric, and setting this property to `true` optimizes the IDFT computation method. Setting this property to `false` for conjugate symmetric inputs may result in complex output values with nonzero imaginary parts. This occurs due to rounding errors. Setting this property to `true` for nonconjugate symmetric inputs results in invalid outputs.

Dependencies

This property applies only when the `FFTLengthSource` property is `Auto`.

Normalize — Enable dividing output by FFT length

true (default) | false

Specify whether to divide the IFFT output by the FFT length. The default is `true` and each element of the output is divided by the FFT length.

FFTLengthSource — Source of FFT length

Auto (default) | Property

Specify how to determine the FFT length as `Auto` or `Property`. When you set this property to `Auto`, the FFT length equals the number of rows of the input signal.

Dependencies

This property applies only when both the `BitReversedInput` and `ConjugateSymmetricInput` properties are `false`.

FFTLength — FFT length

64 (default) | integer

Specify the FFT length as an integer greater than or equal to 2.

This property must be a power of two if any of these conditions apply:

- The input is a fixed-point data type.
- The FFTImplementation property is Radix-2.

Dependencies

This property applies when you set the BitReversedInput and ConjugateSymmetricInput properties to false, and the FFTLengthSource property to 'Property'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

WrapInput — Boolean value of wrapping or truncating input

true (default) | false

Wrap input data when FFTLength is shorter than input length. If this property is set to true, modulo-length data wrapping occurs before the FFT operation, given FFTLength is shorter than the input length. If this property is set to false, truncation of the input data to the FFTLength occurs before the FFT operation.

Fixed-Point Properties**RoundingMethod — Rounding method for fixed-point operations**

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding method.

OverflowAction — Overflow action for fixed-point operations

Wrap (default) | Saturate

Specify the overflow action as Wrap or Saturate.

SineTableDataType — Sine table word and fraction lengths

Same word length as input (default) | Custom

Specify the sine table data type as Same word length as input or Custom.

CustomSineTableDataType — Sine table word and fraction lengths

numerictype([],16) (default) | numerictype

Specify the sine table fixed-point type as an unscaled numerictype object with a Signedness of Auto.

Dependencies

This property applies when you set the SineTableDataType property to Custom.

ProductDataType — Product word and fraction lengths

Full precision (default) | Same as input | Custom

Specify the product data type as Full precision, Same as input, or Custom.

CustomProductDataType — Product word and fraction lengths

numerictype([],32,30) (default) | numerictype

Specify the product fixed-point type as a scaled numerictype object with a Signedness of Auto.

Dependencies

This property applies when you set the `ProductDataType` property to `Custom`.

AccumulatorDataType — Accumulator word and fraction lengths

`Full precision (default) | Same as input | Same as product | Custom`

Specify the accumulator data type as `Full precision`, `Same as input`, `Same as product`, or `Custom`.

CustomAccumulatorDataType — Accumulator word and fraction lengths

`numerictype([],32,30) (default) | numerictype`

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies when you set the `AccumulatorDataType` property to `Custom`.

OutputDataType — Output word and fraction lengths

`Full precision (default) | Same as input | Custom`

Specify the output data type as `Full precision`, `Same as input`, or `Custom`.

CustomOutputDataType — Output word and fraction lengths

`numerictype([],16,15) (default) | numerictype`

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies when you set the `OutputDataType` property to `Custom`.

Usage**Syntax**

`y = ift(x)`

Description

`y = ift(x)` computes the inverse discrete Fourier transform (IDFT) , `y`, of the input `x` along the first dimension of `x`.

Input Arguments**x — Data input**

`vector | matrix | N-D array`

Data input, specified as a vector, matrix, or *N*-D array.

When the `FFTLengthSource` property is `Auto`, the length of `x` along the first dimension must be a positive integer power of two. When the `FFTLengthSource` property is `'Property'`, the length of `x` along the first dimension can be any positive integer and the `FFTLength` property must be a positive integer power of two.

Variable-size input signals are only supported when the `FFTLengthSource` property is set to `'Auto'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Output Arguments

y — Inverse discrete Fourier transform of input signal

vector | matrix | *N*-D array

Inverse discrete Fourier transform of input signal, returned as a vector, matrix, or *N*-D array.

When `FFTLengthSource` property is set to `'Auto'`, the FFT length is same as the number of rows in the input signal. When `FFTLengthSource` property is set to `'Property'`, the FFT length is specified through the `FFTLength` property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Construct a Sinusoidal Signal Using High Energy FFT Coefficients

Compute the FFT of a noisy sinusoidal input signal. The energy of the signal is stored as the magnitude square of the FFT coefficients. Determine the FFT coefficients which occupy 99.99% of the signal energy and reconstruct the time-domain signal by taking the IFFT of these coefficients. Compare the reconstructed signal with the original signal.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj(x))`.

Consider a time-domain signal $x[n]$, which is defined over the finite time interval $0 \leq n \leq N - 1$. The energy of the signal $x[n]$ is given by the following equation:

$$E_N = \sum_{n=0}^{N-1} |x[n]|^2$$

FFT coefficients, $X[k]$, are considered signal values in the frequency domain. The energy of the signal $x[n]$ in the frequency-domain is therefore the sum of the squares of the magnitude of the FFT coefficients:

$$E_N = \frac{1}{N} \sum_{k=0}^{N-1} |X[k]|^2$$

According to Parseval's theorem, the total energy of the signal in time or frequency-domain is the same.

$$E_N = \sum_{n=0}^{N-1} |x[n]|^2 = \frac{1}{N} \sum_{k=0}^{N-1} |X[k]|^2$$

Initialization

Initialize a `dsp.SineWave` System object to generate a sine wave sampled at 44.1 kHz and has a frequency of 1000 Hz. Construct a `dsp.FFT` and `dsp.IFFT` objects to compute the FFT and the IFFT of the input signal.

The `'FFTLengthSource'` property of each of these transform objects is set to `'Auto'`. The FFT length is hence considered as the input frame size. The input frame size in this example is 1020, which is not a power of 2, so select the `'FFTImplementation'` as `'FFTW'`.

```
L = 1020;
Sineobject = dsp.SineWave('SamplesPerFrame',L,...
    'PhaseOffset',10,...
    'SampleRate',44100,...
    'Frequency',1000);
ft = dsp.FFT('FFTImplementation','FFTW');
ift = dsp.IFFT('FFTImplementation','FFTW',...
    'ConjugateSymmetricInput',true);
rng(1);
```

Streaming

Stream in the noisy input signal. Compute the FFT of each frame and determine the coefficients that constitute 99.99% energy of the signal. Take IFFT of these coefficients to reconstruct the time-domain signal.

```
numIter = 1000;
for Iter = 1:numIter
    Sinewave1 = Sineobject();
    Input = Sinewave1 + 0.01*randn(size(Sinewave1));
    FFTCoeff = ft(Input);
    FFTCoeffMagSq = abs(FFTCoeff).^2;

    EnergyFreqDomain = (1/L)*sum(FFTCoeffMagSq);
    [FFTCoeffSorted, ind] = sort((1/L)*FFTCoeffMagSq), ...
        1, 'descend');

    CumFFTCoeffs = cumsum(FFTCoeffSorted);
    EnergyPercent = (CumFFTCoeffs/EnergyFreqDomain)*100;
    Vec = find(EnergyPercent > 99.99);
    FFTCoeffsModified = zeros(L,1);
    FFTCoeffsModified(ind(1:Vec(1))) = FFTCoeff(ind(1:Vec(1)));
    ReconstrSignal = ift(FFTCoeffsModified);
end
```

99.99% of the signal energy can be represented by the number of FFT coefficients given by `Vec(1)`:

```
Vec(1)
```

```
ans = 296
```

The signal is reconstructed efficiently using these coefficients. If you compare the last frame of the reconstructed signal with the original time-domain signal, you can see that the difference is very small and the plots match closely.

```
max(abs(Input-ReconstrSignal))
```

```
ans = 0.0431
```

```
plot(Input, '*');
hold on;
plot(ReconstrSignal, 'o');
hold off;
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the IFFT block reference page. The object properties correspond to the block parameters, except the **Output sampling mode** parameter is not supported by `dsp.IFFT`.

Version History

Introduced in R2012a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- See "System Objects in MATLAB Code Generation" (MATLAB Coder).
- When the following conditions apply, the executable generated from this System object relies on prebuilt dynamic library files (.dll files) included with MATLAB:
 - `FFTImplementation` is set to 'FFTW'.
 - `FFTImplementation` is set to 'Auto', `FFTLengthSource` is set to 'Property', and `FFTLength` is not a power of two.

Use the `packNGo` function to package the code generated from this System object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see "How To Run a Generated Executable Outside MATLAB".

- When the FFT length is a power of two, you can generate standalone C and C++ code from this System object.

`dsp.FFT`

dsp.IIRFilter

Package: dsp

Infinite impulse response (IIR) filter

Description

The `dsp.IIRFilter` System object filters each channel of the input using the specified filter. You can specify the filter to have a 'Direct form I', 'Direct form I transposed', 'Direct form II', or a 'Direct form II transposed' structure.

Use the “Numerator” on page 4-0 and “Denominator” on page 4-0 properties to specify the coefficients of the filter numerator and denominator coefficients. In addition to these coefficients, you can also specify nonzero initial filter states through the “InitialConditions” on page 4-0 property.

To filter a signal using an IIR filter:

- 1 Create the `dsp.IIRFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
iir = dsp.IIRFilter  
iir = dsp.IIRFilter(Name,Value)
```

Description

`iir = dsp.IIRFilter` creates an infinite impulse response (IIR) filter System object that independently filters each channel of the input over time using a specified IIR filter implementation.

`iir = dsp.IIRFilter(Name,Value)` creates an IIR filter object with each specified property set to the specified value. Enclose each property name in single quotes.

Example: `iir = dsp.IIRFilter('Structure','Direct form I');`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Structure — IIR filter structure

'Direct form II transposed' (default) | 'Direct form I' | 'Direct form I transposed' | 'Direct form II'

IIR filter structure, specified as 'Direct form I', 'Direct form I transposed', 'Direct form II', or 'Direct form II transposed'.

Numerator — Numerator coefficients

[1 1] (default) | row vector

Numerator coefficients, specified as a row vector.

Example: [0.0296 0.1775 0.4438 0.5918 0.4438 0.1775 0.0296]

Tunable: Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64
Complex Number Support: Yes

Denominator — Denominator coefficients

[1 0.1] (default) | row vector

Denominator coefficients, specified as a row vector. The leading denominator coefficient must equal 1.

Example: [1.0000 -0.0000 0.7777 -0.0000 0.1142 -0.0000 0.0018]

Tunable: Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64
Complex Number Support: Yes

InitialConditions — Initial conditions

0 (default) | scalar | vector | matrix

Initial conditions of the filter states, specified as one of the following:

- scalar -- The object initializes all delay elements in the filter to the scalar value.
- vector -- The length of the vector equals the number of delay elements in the filter. Each vector element specifies a unique initial condition for the corresponding delay element. The object applies the same vector to each channel of the input signal.
- matrix -- The number of rows in the matrix must equal the number of delay elements in the filter. The number of columns in the matrix must equal the number of channels in the input. Each element specifies a unique initial condition for the corresponding delay element in the corresponding channel.

The number of filter states equals $\max(N,M) - 1$, where N is the number of poles, and M is the number of zeros.

Tunable: Yes

Dependencies

This property applies only when you set the "Structure" on page 4-0 property to 'Direct form II' or 'Direct form II transposed'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Complex Number Support: Yes

NumeratorInitialConditions — Initial conditions on zeros side

0 (default) | scalar | vector | matrix

Initial conditions of the filter states on the side of the filter structure with the zeros, specified as one of the following:

- scalar -- The object initializes all delay elements on the zeros side in the filter to the scalar value.
- vector -- The length of the vector equals the number of delay elements on the zeros side in the filter. Each vector element specifies a unique initial condition for the corresponding delay element on the zeros side. The object applies the same vector of initial conditions to each channel of the input signal.
- matrix -- The number of rows in the matrix must equal the number of delay elements on the zeros side in the filter. The number of columns in the matrix must equal the number of channels in the input signal. Each element specifies a unique initial condition for the corresponding delay element on the zeros side in the corresponding channel.

The number of filter states equals $\max(N,M) - 1$, where N is the number of poles, and M is the number of zeros, respectively.

Tunable: Yes

Dependencies

This property applies only when you set the “Structure” on page 4-0 property to 'Direct form I' or 'Direct form I transposed'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64
Complex Number Support: Yes

DenominatorInitialConditions — Initial conditions on poles side

0 (default) | scalar | vector | matrix

Initial conditions of the filter states on the side of the filter structure with the poles, specified as one of the following:

- scalar -- The object initializes all delay elements on the poles side in the filter to the scalar value.
- vector -- The length of the vector equals the number of delay elements on the poles side in the filter. Each vector element specifies a unique initial condition for the corresponding delay element on the poles side. The object applies the same vector of initial conditions to each channel of the input signal.
- matrix -- The number of rows in the matrix must equal the number of delay elements on the poles side in the filter. The number of columns in the matrix must equal the number of channels in the input signal. Each element specifies a unique initial condition for the corresponding delay element on the poles side in the corresponding channel.

The number of filter states equals $\max(N,M) - 1$, where N is the number of poles, and M is the number of zeros, respectively.

Tunable: Yes

Dependencies

This property applies only when you set the “Structure” on page 4-0 property to 'Direct form I' or 'Direct form I transposed'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64
Complex Number Support: Yes

Fixed-Point Properties**RoundingMethod — Rounding method**

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Select the rounding mode for fixed-point operations.

OverflowAction — Overflow action

'Wrap' (default) | 'Saturate'

Overflow action for fixed-point operations, specified as one of the following:

- 'Wrap' -- The object wraps the result of its fixed-point operations.
- 'Saturate' -- The object saturates the result of its fixed-point operations.

For more details on overflow actions, see overflow mode for fixed-point operations.

StateDataType — State data type

'Same as input' (default) | 'Custom'

State data type, specified as one of the following:

- 'Same as input' -- The state data type is same as the input data type.
- 'Custom' -- The state output data type is an autosigned numeric type through the “CustomStateDataType” on page 4-0 property.

CustomStateDataType — State word and fraction lengths

numericType([],16,15) (default)

State word and fraction lengths, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Dependencies

This property applies only when you set “StateDataType” on page 4-0 to 'Custom'.

NumeratorCoefficientsDataType — Data type of numerator coefficients

'Same word length as input' (default) | 'Custom'

Data type of numerator coefficients, specified as one of the following:

- 'Same word length as input' -- The word length of the numerator coefficients is the same as the input word length. The fraction length is chosen to give the best possible precision.
- 'Custom' -- The data type of the numerator coefficients is the autosigned numeric type specified by the “CustomNumeratorCoefficientsDataType” on page 4-0 property.

CustomNumeratorCoefficientsDataType — Word and fraction lengths of the numerator coefficients`numerictype([],16,15)` (default)

Word and fraction lengths of the numerator coefficients, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Dependencies

This property applies only when you set “NumeratorCoefficientsDataType” on page 4-0 to 'Custom'.

DenominatorCoefficientsDataType — Data type of the denominator coefficients`'Same word length as input'` (default) | 'Custom'

Data type of the denominator coefficients, specified as one of the following:

- 'Same word length as input' -- The word length of the denominator coefficients is the same as that of the input word length. The fraction length is chosen to give the best possible precision.
- 'Custom' -- The data type of the denominator coefficients is the autosigned numeric type specified by the “CustomDenominatorCoefficientsDataType” on page 4-0 property.

CustomDenominatorCoefficientsDataType — Word and fraction lengths of denominator coefficients`numerictype([],16,15)` (default)

Word and fraction lengths of denominator coefficients, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Dependencies

This property applies only when you set “DenominatorCoefficientsDataType” on page 4-0 to 'Custom'.

NumeratorProductDataType — Numerator product data type`'Full precision'` (default) | 'Same as input' | 'Custom'

Data type of the output of a product operation in the numerator polynomial of the IIR filter, specified as one of the following:

- 'Full precision' -- The object computes the numerator product output data type using the full-precision rules. These rules provide the most accurate fixed-point numerics. No quantization occurs. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- 'Same as input' -- The product output data type is the same as the input data type.
- 'Custom' -- The product output data type is the custom numeric type specified by the “CustomNumeratorProductDataType” on page 4-0 property. The rounding method and the overflow action are specified by the “RoundingMethod” on page 4-0 and “OverflowAction” on page 4-0 properties.

CustomNumeratorProductDataType — Numerator product word and fraction lengths`numerictype([],32,30)` (default)

Numerator product word and fraction lengths, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set “NumeratorProductDataType” on page 4-0 to 'Custom'.

DenominatorProductDataType — Denominator product data type

'Full precision' (default) | 'Same as input' | 'Custom'

Data type of the output of a product operation in the denominator polynomial of the IIR filter, specified as one of the following:

- 'Full precision' -- The object computes the denominator product output data type using the full-precision rules. These rules provide the most accurate fixed-point numerics. No quantization occurs. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- 'Same as input' -- The product output data type is the same as the input data type.
- 'Custom' -- The product output data type is custom numeric type specified by the “CustomDenominatorProductDataType” on page 4-0 property. The rounding method and the overflow action are specified by the “RoundingMethod” on page 4-0 and “OverflowAction” on page 4-0 properties.

CustomDenominatorProductDataType — Denominator product word and fraction lengths

numericity([],32,30) (default)

Denominator product word and fraction lengths, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set “DenominatorProductDataType” on page 4-0 to 'Custom'.

NumeratorAccumulatorDataType — Numerator accumulator data type

'Full precision' (default) | 'Same as input' | 'Same as product' | 'Custom'

Data type of the output of an accumulation operation in the numerator polynomial of the IIR filter, specified as one of the following:

- 'Full precision' -- The object computes the numerator accumulator data type using the full-precision rules. These rules provide the most accurate fixed-point numerics. No quantization occurs. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- 'Same as input' -- The accumulator data type is the same as the input data type.
- 'Same as product' -- The accumulator data type is the same as the product output data type.
- 'Custom' -- The accumulator data type is the custom numeric type specified by the “CustomNumeratorAccumulatorDataType” on page 4-0 property. The rounding method and the overflow action are specified by the “RoundingMethod” on page 4-0 and “OverflowAction” on page 4-0 properties.

CustomNumeratorAccumulatorDataType — Numerator accumulator word and fraction lengths

numericity([],32,30) (default)

Numerator accumulator word and fraction lengths, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set “NumeratorAccumulatorDataType” on page 4-0 to 'Custom'.

DenominatorAccumulatorDataType — Denominator accumulator data type

'Full precision' (default) | 'Same as input' | 'Same as product' | 'Custom'

Data type of the output of an accumulation operation in the denominator polynomial of the IIR filter, specified as one of the following:

- 'Full precision' -- The object computes the denominator accumulator data type using the full-precision rules. These rules provide the most accurate fixed-point numerics. No quantization occurs. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- 'Same as input' -- The accumulator data type is the same as the input data type.
- 'Same as product' -- The accumulator data type is the same as the product output data type.
- 'Custom' -- The accumulator data type is the custom numeric type specified by the “CustomDenominatorAccumulatorDataType” on page 4-0 property. The rounding method and the overflow action are specified by the “RoundingMethod” on page 4-0 and “OverflowAction” on page 4-0 properties.

CustomDenominatorAccumulatorDataType — Denominator accumulator word and fraction lengths

numericType([],32,30) (default)

Denominator accumulator word and fraction lengths, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set “DenominatorAccumulatorDataType” on page 4-0 to 'Custom'.

OutputDataType — Output data type

'Same as input' (default) | 'Full precision' | 'Custom'

Data type of the output of the dsp.IIRFilter object, specified as one of the following:

- 'Same as input' -- The output data type is the same as the input data type.
- 'Full precision' -- The object computes the output data type using the full-precision rules. These rules provide the most accurate fixed-point numerics. No quantization occurs. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- 'Custom' -- The output data type is the custom numeric type specified by the “CustomOutputDataType” on page 4-0 property. The rounding method and the overflow action are specified by the “RoundingMethod” on page 4-0 and “OverflowAction” on page 4-0 properties.

CustomOutputDataType — Output word and fraction lengths

numericType([],16,15) (default)

Output word and fraction lengths, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Dependencies

This property applies only when you set “OutputDataType” on page 4-0 to 'Custom'.

MultiplicandDataType — Multiplicand data type

'Same as input' (default) | 'Custom'

Multiplicand data type, specified as one of the following:

- 'Same as input' -- The multiplicand data type is the same as the input data type.
- 'Custom' -- The multiplicand data type is the autosigned numeric type specifies by the “CustomMultiplicandDataType” on page 4-0 property.

CustomMultiplicandDataType — Multiplicand output word and fraction lengths

numericType([],16,15) (default)

Multiplicand output word and fraction lengths, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Dependencies

This property applies only when you set “MultiplicandDataType” on page 4-0 to 'Custom'.

Usage

Syntax

```
iirOut = iir(input)
```

Description

`iirOut = iir(input)` filters the input signal using the specified filter to produce the filtered output. The System object filters each column of the input signal independently over time.

Input Arguments

input — Data input

vector | matrix

Data input that is filtered, specified as a vector or matrix.

Example: `randn(34,24)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

Output Arguments

iirOut — Filtered output

vector | matrix

Filtered output, returned as a vector or a matrix. The size, data type, and complexity of the output match that of the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.IIRFilter`

<code>freqz</code>	Frequency response of discrete-time filter System object
<code>fvtool</code>	Visualize frequency response of DSP filters
<code>impz</code>	Impulse response of discrete-time filter System object
<code>phasez</code>	Phase response of discrete-time filter System object (unwrapped)
<code>sos</code>	Convert to second order sections

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

For a list of filter analysis methods this object supports, type `dsp.IIRFilter.helpFilterAnalysis` in the MATLAB command prompt. For the corresponding function reference pages, see “Analysis Methods for Filter System Objects” on page 3-2.

Examples

Filter Noisy Signal Using IIR Filter

Filter a noisy sinusoidal signal using a lowpass butterworth IIR filter.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Input Signal

The input signal has three tones, 1 kHz, 5 kHz, and 12 kHz.

```
Sine1 = dsp.SineWave('Frequency',1e3,...  
    'SampleRate',44.1e3);  
Sine2 = dsp.SineWave('Frequency',5e3,...  
    'SampleRate',44.1e3);  
Sine3 = dsp.SineWave('Frequency',12e3,...  
    'SampleRate',44.1e3);
```

Filter Design

Use the `butter` function to design a 10th order lowpass Butterworth filter.

```
N = 10;  
Fc = 0.4;  
[b,a] = butter(N,Fc);
```

Create a `dsp.IIRFilter` object and assign the designed coefficients to the `Numerator` and the `Denominator` properties.

```
iir = dsp.IIRFilter('Numerator',b,...
    'Denominator',a);
```

View the magnitude response of the filter. The cutoff frequency is at 0.4π rad/sample, which, with a sample rate of 44.1 kHz, translates to $0.4 \times 44100/2$ or 8.82 kHz.

```
fvtool(iir,'Fs',Sine1.SampleRate)
```

View the power spectrum of the input and output signal using the Spectrum Analyzer.

```
sa = spectrumAnalyzer('SampleRate',Sine1.SampleRate,...
    'Method','welch',...
    'PlotAsTwoSidedSpectrum',false,...
    'OverlapPercent',80,...
    'SpectrumUnits','dBW',...
    'YLimits',[-220 -10]);
```

Streaming

Add zero-mean white Gaussian noise with a standard deviation of 0.01 to the sum of sine waves. Filter the signal using the IIR filter.

The tones at 1 kHz and 5 kHz are unaffected since they fall in the passband. The frequency at 12 kHz is attenuated since it falls in the transition band of the filter.

```

for i = 1:1000
    input = Sine1()+Sine2()+Sine3()+...
           0.01*randn(Sine1.SamplesPerFrame,1);
    output = iir(input);
    sa(input,output)
end

```

Design an IIR Filter

Design a notching comb filter with 8 notches, and a notch bandwidth of 0.02 referenced to a -3 dB level.

Create a comb filter design specification object using the `fdesign.comb` function and specify these design parameters.

```
combSpecs = fdesign.comb('notch','N,BW',8,0.02);
```

Design the notching comb filter using the `design` function. The resulting filter is a `dsp.IIRFilter` System object™. For details on how to apply this filter on streaming data, refer to `dsp.IIRFilter`.

```
iirFilt = design(combSpecs,'Systemobject',true)
```

```
iirFilt =
    dsp.IIRFilter with properties:
```

```

Structure: 'Direct form II'
Numerator: [0.8878 0 0 0 0 0 0 0 -0.8878]
Denominator: [1 0 0 0 0 0 0 0 -0.7757]
InitialConditions: 0

```

Show all properties

View magnitude response of the designed filter using `fvtool`.

```
fvtool(iirFilt)
```

More About

Fixed Point

The `dsp.IIRFilter` System object supports the following filter structures. The diagrams in each section show the data types used in the filter structures for fixed-point signals. You can set the data types using the fixed-point properties of the object.

Direct form I

The following constraints apply when the Structure property is set to 'Direct form I':

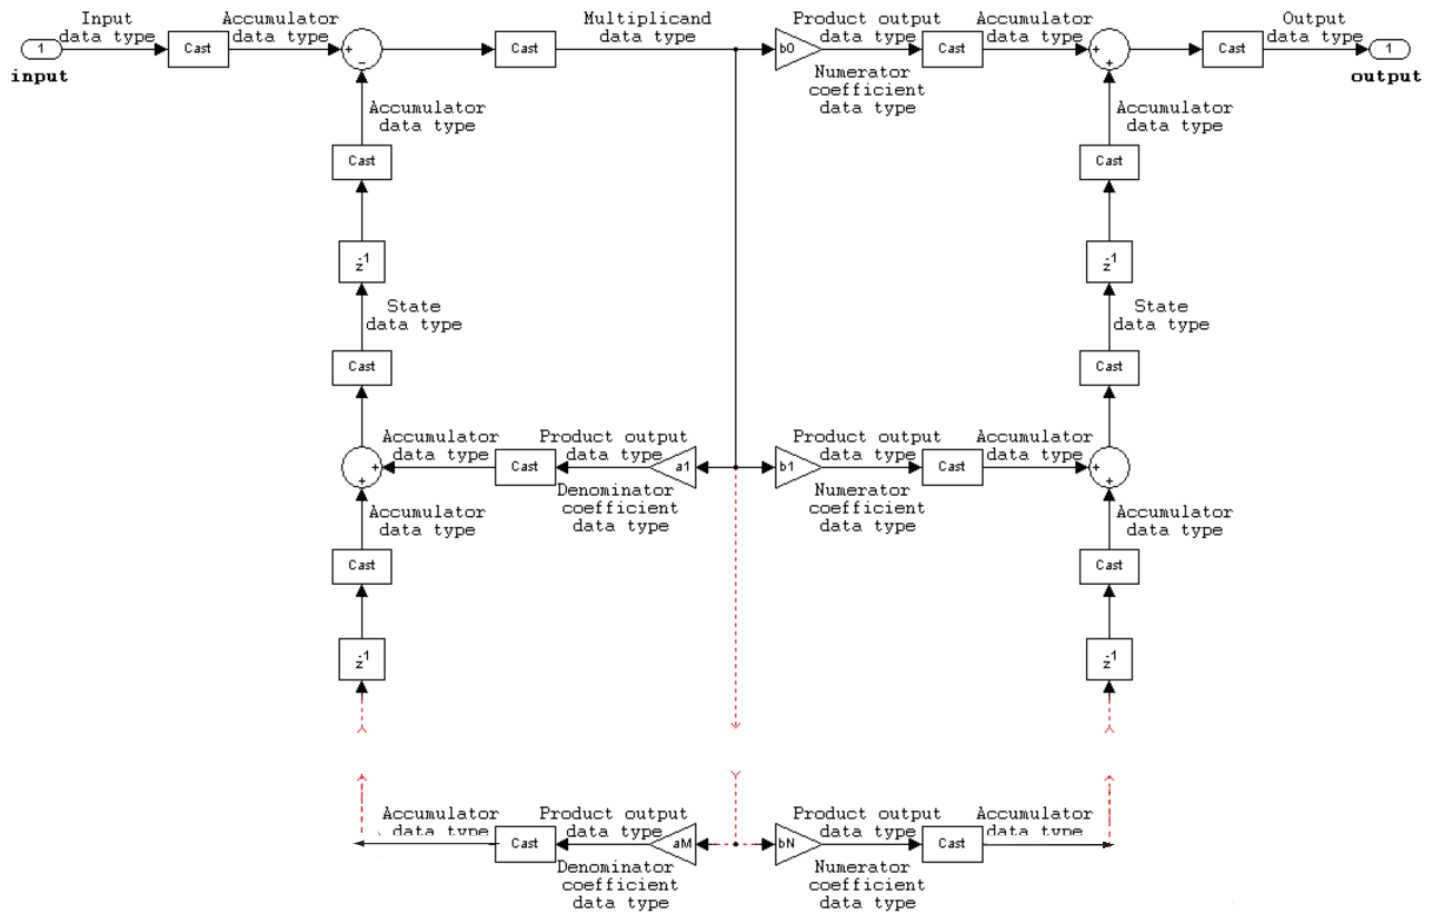

- Inputs can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Numerator and denominator coefficients must have the same complexity characteristics. When the numerator and denominator coefficients have different complexities from each other, the object processes the filter as if two sets of complex coefficients are provided. The real-valued coefficient set is treated as if it is a complex vector with zero-valued imaginary parts.
- The State data type cannot be specified for this structure. Doing so is not possible because the input and output states have the same data types as the input and output buffers.

Direct form I transposed

The following constraints apply when the Structure property is set to 'Direct form I transposed':

- Inputs can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Numerator and denominator coefficients must have the same complexity characteristics. When the numerator and denominator coefficients have different complexities from each other, the object processes the filter as if two sets of complex coefficients are provided. The real-valued coefficient set is treated as if it is a complex vector with zero-valued imaginary parts.
- States are complex when either the input or the coefficients are complex.

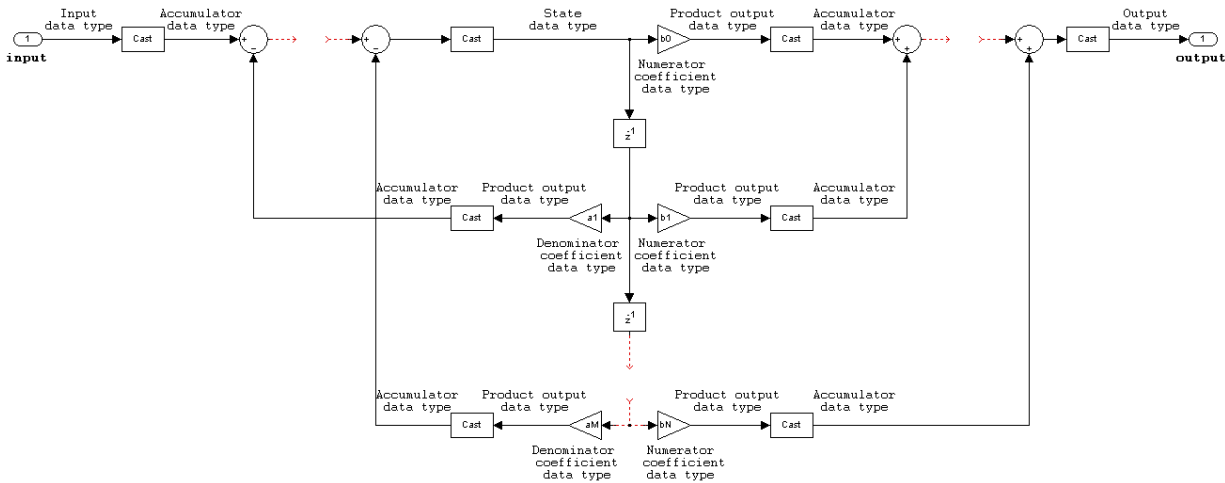

Direct form II

The following constraints apply when the Structure property is set to 'Direct form II':

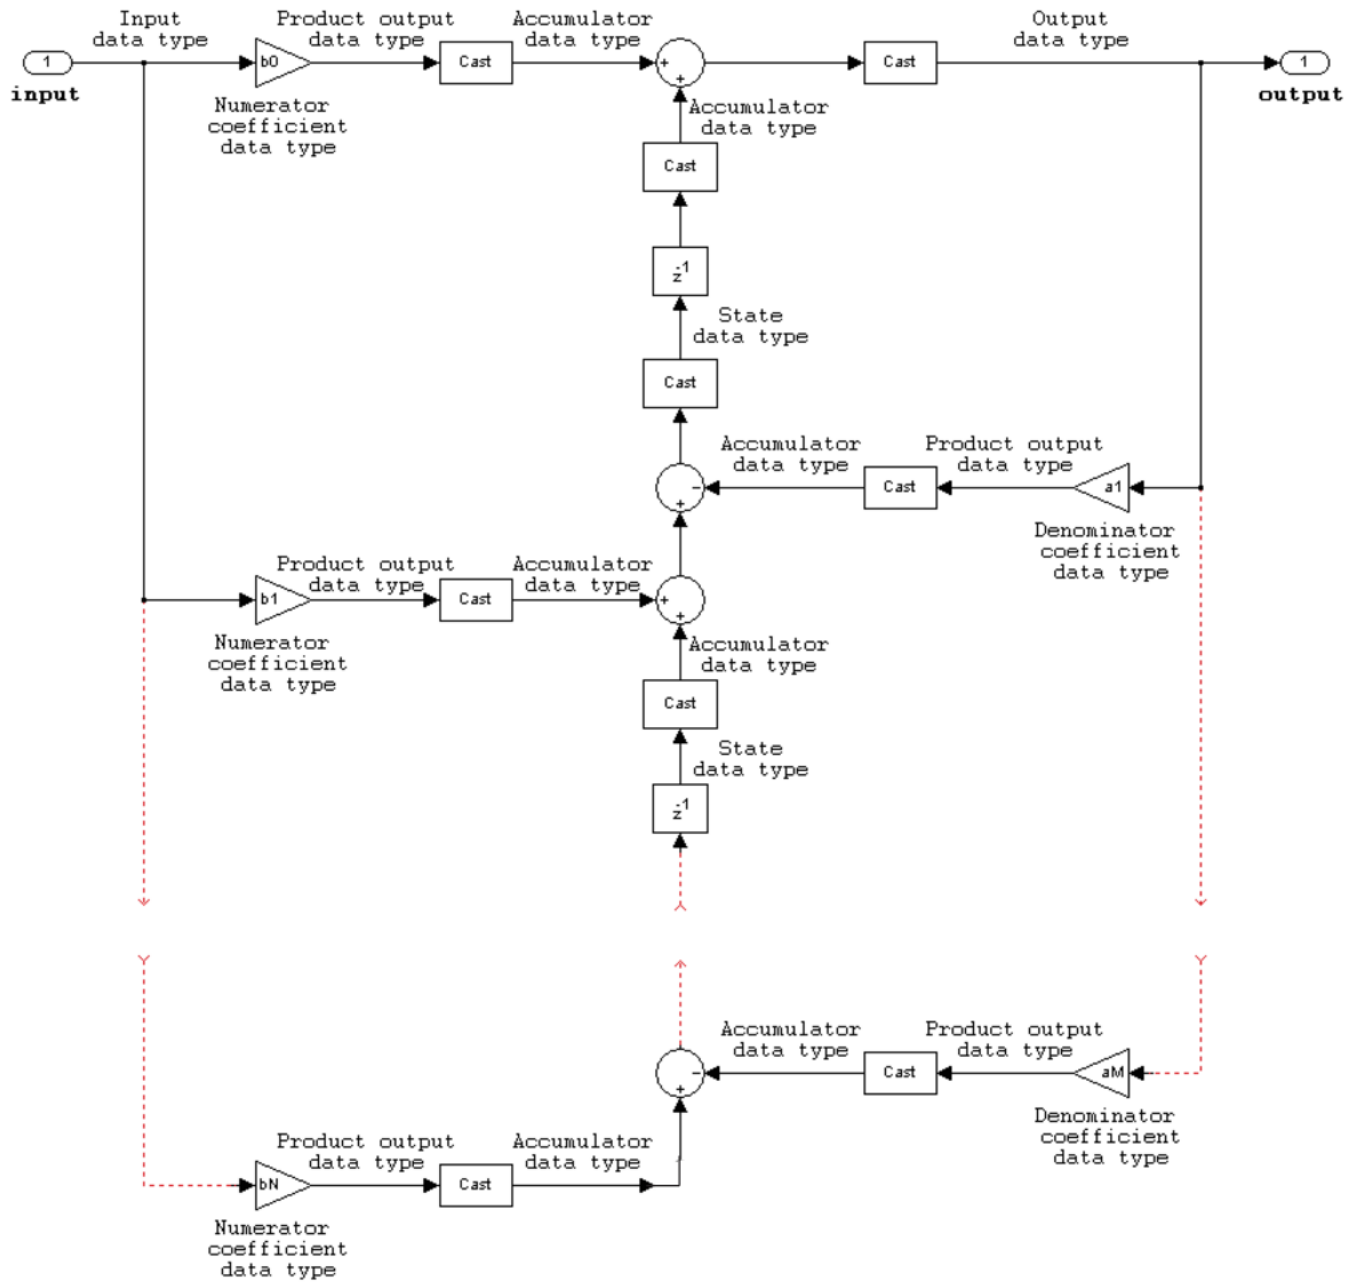

- Inputs can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Numerator and denominator coefficients must have the same complexity characteristics. When the numerator and denominator coefficients have different complexities from each other, the object processes the filter as if two sets of complex coefficients are provided. The real-valued coefficient set is treated as if it is a complex vector with zero-valued imaginary parts.
- States are complex when either the inputs or the coefficients are complex.

Direct form II transposed

The following constraints apply when the Structure property is set to 'Direct form II transposed':

- Inputs can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Numerator and denominator coefficients must have the same complexity characteristics. When the numerator and denominator coefficients have different complexities from each other, the object processes the filter as if two sets of complex coefficients are provided. The real-valued coefficient set is treated as if it is a complex vector with zero-valued imaginary parts.
- States are complex when either the inputs or the coefficients are complex.

dsp.IIRHalfbandDecimator

Package: dsp

Decimate by factor of two using polyphase IIR

Description

The `dsp.IIRHalfbandDecimator` System object performs efficient polyphase decimation of the input signal by a factor of two. To design the halfband filter, you can specify the object to use an elliptic design or a quasi-linear phase design. The object uses these design methods to compute the filter coefficients. To filter the inputs, the object uses a polyphase structure. The allpass filters in the polyphase structure are in a minimum multiplier form.

Elliptic design introduces nonlinear phase and creates the filter using fewer coefficients than quasi linear design. Quasi-linear phase design overcomes phase nonlinearity at the cost of additional coefficients.

Alternatively, instead of designing the halfband filter using a design method, you can specify the filter coefficients directly. When you choose this option, the allpass filters in the two branches of the polyphase implementation can be in a minimum multiplier form or in a wave digital form.

You can also use the `dsp.IIRHalfbandDecimator` object to implement the analysis portion of a two-band filter bank to filter a signal into lowpass and highpass subbands.

To filter and downsample your data:

- 1 Create the `dsp.IIRHalfbandDecimator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
iirhalfbanddecim = dsp.IIRHalfbandDecimator  
iirhalfbanddecim = dsp.IIRHalfbandDecimator(Name,Value)
```

Description

`iirhalfbanddecim = dsp.IIRHalfbandDecimator` returns a halfband decimator, `iirhalfbanddecim`, with the default settings. Under the default settings, the System object filters and downsamples the input data with a halfband frequency of 22050 Hz, a transition width of 4100 Hz, and a stopband attenuation of 80 dB.

`iirhalfbanddecim = dsp.IIRHalfbandDecimator(Name,Value)` returns an IIR halfband decimator, with additional properties specified by one or more `Name,Value` pair arguments.

Example: `iirhalfbanddecim = dsp.IIRHalfbandDecimator('Specification','Filter order and stopband attenuation')` creates an IIR halfband decimator object with filter order set to 9 and stopband attenuation set to 80 dB.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

Specification — Filter design parameters

'Transition width and stopband attenuation' (default) | 'Filter order and stopband attenuation' | 'Filter order and transition width' | 'Coefficients'

Filter design parameters, specified as a character vector. When you set `Specification` to one of the filter design options, you can specify the filter design parameters using the corresponding `FilterOrder`, `StopbandAttenuation`, and `TransitionWidth` properties. Also, you can specify the design method using `DesignMethod`. When you set `Specification` to 'Coefficients', you can specify the coefficients directly.

FilterOrder — Order of the IIR halfband filter

9 (default) | positive scalar integer

Order of the IIR halfband filter, specified as a positive scalar integer. If you set `DesignMethod` to 'Elliptic', then `FilterOrder` must be an odd integer greater than one. If you set `DesignMethod` to 'Quasi-linear phase', then `FilterOrder` must be a multiple of four.

Dependencies

This property applies when you set `Specification` to 'Filter order and stopband attenuation' or 'Filter order and transition width'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

StopbandAttenuation — Minimum attenuation needed in stopband

80 (default) | positive real scalar

Minimum attenuation needed in the stopband of the IIR halfband filter, specified as a positive real scalar. Units are in dB.

Dependencies

This property applies only when you set `Specification` to 'Filter order and stopband attenuation' or 'Transition width and stopband attenuation'.

Data Types: `single` | `double`

TransitionWidth — Transition width

4100 (default) | positive real scalar

Transition width of the IIR halfband filter, specified as a positive real scalar. Units are in Hz. The value of the transition width must be less than half the input sample rate.

Dependencies

This property applies only when you set `Specification` to 'Transition width and stopband attenuation' or 'Filter order and transition width'.

Data Types: `single` | `double`

DesignMethod — Design method

'Elliptic' (default) | 'Quasi-linear phase'

Design method for the IIR halfband filter, specified as 'Elliptic' or 'Quasi-linear phase'. When the property is set to 'Quasi-linear phase', the first branch of the polyphase structure is a pure delay, which results in an approximately linear phase response.

Dependencies

This property applies only when you set `Specification` to any accepted value except 'Coefficients'.

SampleRate — Input sample rate

44100 (default) | positive real scalar

Input sample rate, specified as a positive real scalar. Units are in Hz.

Dependencies

This property applies only when you set `Specification` to any accepted value except 'Coefficients'.

Data Types: `single` | `double`

Structure — Internal allpass filter implementation structure

'Minimum multiplier' (default) | 'Wave Digital Filter'

Internal allpass filter implementation structure, specified as 'Minimum multiplier' or 'Wave Digital Filter'.

This property is not tunable.

Dependencies

This property applies only when you set 'Specification' to 'Coefficients'. Each structure uses a different coefficients set, independently stored in the corresponding object property.

AllpassCoefficients1 — Allpass polynomial filter coefficients of first branch

[0.1284563; 0.7906755] (default) | [0.1284563 0.1534; 0.7906755 0.6745]

Allpass polynomial filter coefficients of the first branch, specified as an N -by-1 or N -by-2 matrix. N is the number of first-order or second-order allpass sections.

Tunable: Yes

Dependencies

This property applies only when you set `Specification` to 'Coefficients' and `Structure` to 'Minimum multiplier'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

AllpassCoefficients2 — Allpass polynomial filter coefficients of second branch

[0.4295667] (default) | [0.7906755 0.1534]

Allpass polynomial filter coefficients of the second branch, specified as an N -by-1 or N -by-2 matrix. N is the number of first-order or second-order allpass sections.

Tunable: Yes

Dependencies

This property applies only when you set Specification to 'Coefficients' and Structure to 'Minimum multiplier'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

WDFCoefficients1 — Allpass filter coefficients of first branch in Wave Digital Filter form

[0.1284563; 0.7906755] (default) | [0.1284563 0.1534; 0.7906755 0.6745]

Allpass filter coefficients of the first branch in Wave Digital Filter form, specified as an N -by-1 or N -by-2 matrix. N is the number of first-order or second-order allpass sections. Each element must have an absolute value less than or equal to 1.

This property is not tunable.

Dependencies

This property applies only when you set Specification to 'Coefficients' and Structure to 'Wave Digital Filter'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

WDFCoefficients2 — Allpass filter coefficients of second branch in Wave Digital Filter form

[0.4295667] (default) | [0.7906755 0.1534]

Allpass filter coefficients of the second branch in Wave Digital Filter form, specified as the comma-separated pair consisting of 'WDFCoefficients2' and a N -by-1 or N -by-2 matrix. N is the number of first-order or second-order allpass sections. Each element must have an absolute value less than or equal to 1.

This property is not tunable.

Dependencies

This property applies only when you set 'Specification' to 'Coefficients' and 'Structure' to 'Wave Digital Filter'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

HasPureDelayBranch — Make first branch a pure delay

false (default) | true

Flag to make the first allpass branch a delay, specified as a logical scalar. When this property is true, the first branch is treated as a pure delay and the properties AllpassCoefficients1 and WDFCoefficients1 do not apply.

This property is not tunable.

Dependencies

This property applies only when you set `Specification` to `'Coefficients'`.

Delay — Length of delay

1 (default) | finite positive scalar

Length of the first branch delay, specified as a finite positive scalar. The value of this property specifies the number of samples by which you can delay the input to the first branch.

This property is not tunable.

Dependencies

This property applies only when you set `Specification` to `'Coefficients'` and `HasPureDelayBranch` to 1.

Data Types: `single` | `double`

HasTrailingFirstOrderSection — Treat the last section of the second branch as first order

false (default) | true

Option to treat the last section of the second branch as first order, specified as a logical scalar. When this property is 1 and the coefficients of the second branch are in an N -by-2 matrix, the object ignores the second element of the last row of the matrix. The last section of the second branch then becomes a first-order section. When this property is set to 0, the last section of the second branch is a second-order section. When the coefficients of the second branch are in an N -by-1 matrix, this property is ignored.

This property is not tunable.

Dependencies

This property applies only when you set `Specification` to `'Coefficients'`.

Usage**Syntax**

```
y_low = iirhalfbanddecim(x)  
[y_low,y_high] = iirhalfbanddecim(x)
```

Description

`y_low = iirhalfbanddecim(x)` filters the input signal, `x`, using the IIR halfband filter, `iirhalfbanddecim`, and downsamples the output by a factor of 2.

`[y_low,y_high] = iirhalfbanddecim(x)` computes the `y_low` and `y_high`, of the analysis filter bank, `iirhalfbanddecim` for input `x`. A K_i -by- N input matrix is treated as N independent channels. The System object generates two power-complementary output signals by adding and subtracting the two polyphase branch outputs respectively. `y_low` and `y_high` are of the same size (K_o -by- N) and data type. $K_o = K_i/2$, where 2 is the decimation factor.

Input Arguments

x — Data input

column vector | matrix

Data input, specified as a column vector or a matrix. The number of rows in the input signal must be even since the decimation factor is always 2 for this object. If the input is a matrix, each column is treated as an independent channel.

Data Types: `single` | `double`

Output Arguments

y_{low} — Lowpass subband of decimator output

column vector | matrix

Lowpass subband of decimator output, returned as a column vector or a matrix. The output, `ylow` is a lowpass halfband filtered and downsampled version of the input `x`. Due to the halfband nature of the filter, the downsampling factor is always 2.

Data Types: `single` | `double`

y_{high} — Highpass subband of decimator output

column vector | matrix

Highpass subband of decimator output, returned as a column vector or a matrix. The output, `yhigh` is a highpass halfband filtered and downsampled version of the input `x`. Due to the halfband nature of the filter, the downsampling factor is always 2.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.IIRHalfbandDecimator

<code>freqz</code>	Frequency response of discrete-time filter System object
<code>fvtool</code>	Visualize frequency response of DSP filters
<code>info</code>	Information about filter System object
<code>cost</code>	Estimate cost of implementing filter System object
<code>polyphase</code>	Polyphase decomposition of multirate filter

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Frequency Response of Quasi-Linear Phase IIR Halfband Decimator

Create a minimum-order lowpass IIR halfband decimation filter for data sampled at 44.1 kHz. The filter has a transition width of 4.1 kHz, and a stopband attenuation of 80 dB.

```
IIRHalfbandDecim = dsp.IIRHalfbandDecimator(...
    'DesignMethod', 'Quasi-linear phase');
```

Obtain the filter coefficients.

```
c = coeffs(IIRHalfbandDecim);
```

Plot the magnitude and phase response.

```
fvtool(IIRHalfbandDecim, 'Analysis', 'freq')
```

Extract Low Frequency Subband from Speech

Use a halfband analysis filter bank and interpolation filter to extract the low frequency subband from a speech signal.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Note: The `audioDeviceWriter` System object™ is not supported in MATLAB Online.

Set up the audio file reader, the analysis filter bank, the audio device writer, and the interpolation filter. The sampling rate of the audio data is 22050 Hz. The halfband filter has an order of 21 and a transition width of 2 kHz.

```
afr = dsp.AudioFileReader('speech_dft.mp3','SamplesPerFrame',1024);
```

```
filterspec = 'Filter order and transition width';
Order = 21;
TW = 2000;
```

```
IIRHalfbandDecim = dsp.IIRHalfbandDecimator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',afr.SampleRate);
```

```
IIRHalfbandInterp = dsp.IIRHalfbandInterpolator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',afr.SampleRate/2);
```

```
ap = audioDeviceWriter('SampleRate',afr.SampleRate);
```

View the magnitude response of the halfband filter.

```
fvtool(IIRHalfbandDecim)
```

Read the speech signal from the audio file in frames of 1024 samples. Filter the speech signal into lowpass and highpass subbands with a halfband frequency of 5512.5 Hz. Reconstruct a lowpass approximation of the speech signal by interpolating the lowpass subband. Play the filtered output.

```
while ~isDone(afr)
    audioframe = afr();
    xlo = IIRHalfbandDecim(audioframe);
    ylow = IIRHalfbandInterp(xlo);
    ap(ylow);
end
```

Wait until the audio file ends, and then close the input file and release the audio output resource.

```
release(afr);
release(ap);
```

Two-Channel Filter Bank

Use a halfband decimator and interpolator to implement a two-channel filter bank. This example uses an audio file input and shows that the power spectrum of the filter bank output does not differ significantly from the input.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Note: The `audioDeviceWriter` System object™ is not supported in MATLAB Online.

Set up the audio file reader and audio device writer. Construct the IIR halfband decimator and interpolator. Finally, set up the spectrum analyzer to display the power spectra of the filter-bank input and output.

```
AF = dsp.AudioFileReader('speech_dft.mp3','SamplesPerFrame',1024);
AP = audioDeviceWriter('SampleRate',AF.SampleRate);
```

```
filterspec = 'Filter order and transition width';
Order = 51;
TW = 2000;
```

```
IIRHalfbandDecim = dsp.IIRHalfbandDecimator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',AF.SampleRate);
```

```
IIRHalfbandInterp = dsp.IIRHalfbandInterpolator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',AF.SampleRate/2,...
    'FilterBankInputPort',true);
```

```
SpecAna = spectrumAnalyzer('SampleRate',AF.SampleRate,...
    'PlotAsTwoSidedSpectrum',false,...
    'ShowLegend',true,...
    'ChannelNames',{'Input signal','Filtered output signal'});
```

Read the audio 1024 samples at a time. Filter the input to obtain the lowpass and highpass subband signals decimated by a factor of two. This is the analysis filter bank. Use the halfband interpolator as the synthesis filter bank. Display the running power spectrum of the audio input and the output of the synthesis filter bank. Play the output.

```
while ~isDone(AF)
    audioInput = AF();
```

```

[xlo,xhigh] = IIRHalfbandDecim(audioInput);
audioOutput = IIRHalfbandInterp(xlo,xhigh);
spectrumInput = [audioInput audioOutput];
SpecAna(spectrumInput);
AP(audioOutput);
end

release(AF);
release(AP);
release(SpecAna);

```

Filter Input into Lowpass and Highpass Subbands

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Create a halfband decimator for data sampled at 44.1 kHz. Use a minimum-order design with a transition width of 2 kHz and a stopband attenuation of 60 dB.

```

IIRHalfbanddecim = dsp.IIRHalfbandDecimator(...
    'Specification','Transition width and stopband attenuation',...
    'TransitionWidth',2000,'StopbandAttenuation',60,'SampleRate',44.1e3);

```

Filter a two-channel input into lowpass and highpass subbands.

```
x = randn(1024,2);
[y_low,y_high] = IIRHalfbanddecim(x);
```

Algorithms

Polyphase Implementation with Halfband Filters

When you filter your signal, `dsp.IIRHalfbandDecimator` uses an efficient polyphase implementation for halfband filters. You can use the polyphase implementation to move the downsample operation before filtering. This change enables you to filter at the lower sampling rate.

IIR halfband filters are generally modeled using two parallel allpass filter branches.

$$H(z) = 0.5 * [A_1(z^2) + z^{-1}A_2(z^2)]$$

Elliptic Design

The allpass filters for elliptic IIR halfband filter are given as

$$A_1(z) = \prod_{k=1}^{K_1} \frac{a_k^{(1)} + z^{-1}}{1 + a_k^{(1)}z^{-1}}$$

$$A_2(z) = \prod_{k=1}^{K_2} \frac{a_k^{(2)} + z^{-1}}{1 + a_k^{(2)}z^{-1}}$$

Quasi-Linear Phase Design

To achieve a near-linear phase response for IIR halfband filters, make one of the branches a pure delay. In this design, the cost of the filter increases.

The allpass filters for the quasi-linear phase IIR halfband filter are

$$A_1(z) = z^{-k}$$

where k is the length of the delay.

$$A_2(z) = \prod_{k=1}^{K_2^{(1)}} \frac{a_k + z^{-1}}{1 + a_k z^{-1}} \prod_{k=1}^{K_2^{(2)}} \frac{c_k + b_k z^{-1} + z^{-2}}{1 + b_k z^{-1} + c_k z^{-2}}$$

where N is the order of the IIR halfband filter.

This figure represents filtering and downsampling the input by two.

Using the multirate noble identity for downsampling, you can move the downsampling operation before filtering. This change enables you to filter at the lower rate.

To implement the halfband decimator efficiently, `dsp.IIRHalfbandDecimator` replaces the delay block and downsampling operator with a commutator switch.

Analysis Filter Bank

The transfer function of the complementary highpass filter branch of the analysis filter bank is given by

$$G(z) = 0.5 * [A_1(z^2) - z^{-1}A_2(z^2)]$$

Graphically, you can represent the analysis filter bank as follows.

`dsp.IIRHalfbandDecimator` generates two power-complementary output signals by adding and subtracting the two polyphase branch outputs respectively.

To summarize, `dsp.IIRHalfbandDecimator`

- Decimates the input prior to filtering.
- Acts as an analysis filter bank.
- Has non-linear phase response and uses few coefficients with elliptic design method.

- Has near-linear phase response at the cost of additional coefficients with quasi-linear phase design method. One of the branches in this design is a pure delay.

dsp.IIRHalfbandInterpolator

Package: dsp

Interpolate by a factor of two using polyphase IIR

Description

The `dsp.IIRHalfbandInterpolator` System object performs efficient polyphase interpolation of the input signal by a factor of two. To design the halfband filter, you can specify the object to use an elliptic design or a quasi-linear phase design. The object uses these design methods to compute the filter coefficients. To filter the inputs, the object uses a polyphase structure. The allpass filters in the polyphase structure are in a minimum multiplier form.

Elliptic design introduces nonlinear phase and creates the filter using fewer coefficients than quasi linear design. Quasi-linear phase design overcomes phase nonlinearity at the cost of additional coefficients.

Alternatively, instead of designing the halfband filter using a design method, you can specify the filter coefficients directly. When you choose this option, the allpass filters in the two branches of the polyphase implementation can be in a minimum multiplier form or in a wave digital form.

You can also use `dsp.IIRHalfbandInterpolator` object to implement the synthesis portion of a two-band filter bank to synthesize a signal from lowpass and highpass subbands.

To upsample and interpolate your data:

- 1 Create the `dsp.IIRHalfbandInterpolator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

Creation

Syntax

```
iirhalfbandinterp = dsp.IIRHalfbandInterpolator
iirhalfbandinterp = dsp.IIRHalfbandInterpolator(Name,Value)
```

Description

`iirhalfbandinterp = dsp.IIRHalfbandInterpolator` returns an IIR halfband interpolation filter, `iirhalfbandinterp`, with the default settings. Under the default settings, the System object upsamples and interpolates the input data using a halfband frequency of 22050 Hz, a transition width of 4100 Hz, and a stopband attenuation of 80 dB.

`iirhalfbandinterp = dsp.IIRHalfbandInterpolator(Name,Value)` returns an IIR halfband interpolator, with additional properties specified by one or more `Name, Value` pair arguments.

Example: `iirhalfbandinterp = dsp.IIRHalfbandInterpolator('Specification','Filter order and stopband`

`attenuation'`) creates an IIR halfband interpolator object with filter order set to 9 and stopband attenuation set to 80 dB.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Specification — Filter design parameters

'Transition width and stopband attenuation' (default) | 'Filter order and stopband attenuation' | 'Filter order and transition width' | 'Coefficients'

Filter design parameters, specified as a character vector. When you set `Specification` to one of the filter design options, you can specify the filter design parameters using the corresponding `FilterOrder`, `StopbandAttenuation`, and `TransitionWidth` properties. Also, you can specify the design method using `DesignMethod`. When you set `Specification` to 'Coefficients', you can specify the coefficients directly.

FilterOrder — Order of the IIR halfband filter

9 (default) | positive scalar integer

Order of the IIR halfband filter, specified as a positive scalar integer. If you set `DesignMethod` to 'Elliptic', then `FilterOrder` must be an odd integer greater than one. If you set `DesignMethod` to 'Quasi-linear phase', then `FilterOrder` must be a multiple of four.

Dependencies

This property applies when you set `Specification` to 'Filter order and stopband attenuation' or 'Filter order and transition width'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

StopbandAttenuation — Minimum attenuation needed in stopband

80 (default) | positive real scalar

Minimum attenuation needed in the stopband of the IIR halfband filter, specified as a positive real scalar. Units are in dB.

Dependencies

This property applies only when you set `Specification` to 'Filter order and stopband attenuation' or 'Transition width and stopband attenuation'.

Data Types: `single` | `double`

TransitionWidth — Transition width

4100 (default) | positive real scalar

Transition width of the IIR halfband filter, specified as a positive real scalar. Units are in Hz. The value of the transition width must be less than half the input sample rate.

Dependencies

This property applies only when you set `Specification` to 'Transition width and stopband attenuation' or 'Filter order and transition width'.

Data Types: `single` | `double`

DesignMethod — Design method

'Elliptic' (default) | 'Quasi-linear phase'

Design method for the IIR halfband filter, specified as 'Elliptic' or 'Quasi-linear phase'. When the property is set to 'Quasi-linear phase', the first branch of the polyphase structure is a pure delay, which results in an approximately linear phase response.

Dependencies

This property applies only when you set `Specification` to any accepted value except 'Coefficients'.

SampleRate — Input sample rate

44100 (default) | positive real scalar

Input sample rate, specified as a positive real scalar. Units are in Hz.

Dependencies

This property applies only when you set `Specification` to any accepted value except 'Coefficients'.

Data Types: `single` | `double`

FilterBankInputPort — Option to use object as synthesis filter bank

false (default) | true

Option to use object as synthesis filter bank, specified as a logical value. If this property is false, `dsp.IIRHalfbandInterpolator` acts as an interpolator. If this property is true, then `dsp.IIRHalfbandInterpolator` acts as a synthesis filter bank and the algorithm accepts two inputs: the lowpass and highpass subbands.

Dependencies

This property applies only when you set `Specification` to any accepted value except 'Coefficients'.

Structure — Filter structure used in coefficient mode

'Minimum multiplier' (default) | 'Wave Digital Filter'

Internal allpass filter implementation structure, specified as 'Minimum multiplier' or 'Wave Digital Filter'. Each structure uses a different coefficients set, independently stored in the corresponding object property.

This property is not tunable.

Dependencies

This property applies only when you set 'Specification' to 'Coefficients'.

AllpassCoefficients1 — Allpass polynomial filter coefficients of first branch

[0.1284563; 0.7906755] (default) | [0.1284563 0.1534; 0.7906755 0.6745]

Allpass polynomial filter coefficients of the first branch, specified as an N -by-1 or N -by-2 matrix. N is the number of first-order or second-order allpass sections.

Tunable: Yes

Dependencies

This property applies only when you set Specification to 'Coefficients' and Structure to 'Minimum multiplier'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

AllpassCoefficients2 — Allpass polynomial filter coefficients of second branch

[0.4295667] (default) | [0.7906755 0.1534]

Allpass polynomial filter coefficients of the second branch, specified as an N -by-1 or N -by-2 matrix. N is the number of first-order or second-order allpass sections.

Tunable: Yes

Dependencies

This property applies only when you set Specification to 'Coefficients' and Structure to 'Minimum multiplier'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

WDFCoefficients1 — Allpass filter coefficients of first branch in Wave Digital Filter form

[0.1284563; 0.7906755] (default) | [0.1284563 0.1534; 0.7906755 0.6745]

Allpass filter coefficients of the first branch in Wave Digital Filter form, specified as an N -by-1 or N -by-2 matrix. N is the number of first-order or second-order allpass sections. All elements must have an absolute value less than or equal to 1.

This property is not tunable.

Dependencies

This property applies only when you set Specification to 'Coefficients' and Structure to 'Wave Digital Filter'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

WDFCoefficients2 — Allpass filter coefficients of second branch in Wave Digital Filter form

[0.4295667] (default) | [0.7906755 0.1534]

Allpass filter coefficients of the second branch in Wave Digital Filter form, specified as an N -by-1 or N -by-2 matrix. N is the number of first-order or second-order allpass sections. All elements must have an absolute value less than or equal to 1.

This property is not tunable.

Dependencies

This property applies only when you set Specification to 'Coefficients' and Structure to 'Wave Digital Filter'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

HasPureDelayBranch — Make the first branch a pure delay

`false` (default) | `true`

Flag to make the first allpass branch a delay, specified as a logical scalar. When this property is true, the first branch is treated as a pure delay and the properties `AllpassCoefficients1` and `WDFCoefficients1` do not apply.

This property is not tunable.

Dependencies

This property applies only when you set `Specification` to `'Coefficients'`.

Delay — Length of the delay

1 (default) | finite positive scalar

Length of the first branch delay, specified as a finite positive scalar. The value of this property specifies the number of samples by which you can delay the input to the first branch.

This property is not tunable.

Dependencies

This property is applicable only when you set `'Specification'` to `'Coefficients'` and `HasPureDelayBranch` to 1.

Data Types: `single` | `double`

HasTrailingFirstOrderSection — Make the last section of the second branch as first order

`false` (default) | `true`

Option to treat the last section of the second branch as first order, specified as a logical scalar. When this property is 1 and the coefficients of the second branch are in an N -by-2 matrix, the object ignores the second element of the last row of the matrix. The last section of the second branch then becomes a first-order section. When this property is set to 0, the last section of the second branch is a second-order section. When the coefficients of the second branch are in an N -by-1 matrix, this property is ignored.

This property is not tunable.

Dependencies

This property applies only when you set `Specification` to `'Coefficients'`.

Usage

Syntax

```
y = iirhalfbandinterp(x1)
y = iirhalfbandinterp(x1,x2)
```

Description

`y = iirhalfbandinterp(x1)` upsamples by two and interpolates the input signal `x1` using the IIR halfband interpolator, `iirhalfbandinterp`.

`y = iirhalfbandinterp(x1,x2)` implements a halfband synthesis filter bank for the inputs `x1` and `x2`. `x1` is the lowpass output of a halfband analysis filter bank and `x2` is the highpass output of a halfband analysis filter bank. `dsp.IIRHalfbandInterpolator` implements a synthesis filter bank only when the `FilterBankInputPort` property is `true`.

Input Arguments

x1 — Data input

column vector | matrix

Data input to the IIR halfband interpolator, specified as a column vector or a matrix. This signal is the lowpass output of a halfband analysis filter bank. If the input signal is a matrix, each column of the matrix is treated as an independent channel.

Data Types: `single` | `double`

x2 — Second data input

column vector | matrix

Second data input to the synthesis filter bank, specified as a column vector or a matrix. This signal is the highpass output of a halfband analysis filter bank. If the input signal is a matrix, each column of the matrix is treated as an independent channel.

The size, data type, and complexity of both the inputs must be the same.

Data Types: `single` | `double`

Output Arguments

y — Output of interpolator

column vector | matrix

Output of the interpolator, returned as a column vector or a matrix. The number of rows in the interpolator output is twice the number of rows in the input signal.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.IIRHalfbandInterpolator`

<code>freqz</code>	Frequency response of discrete-time filter System object
<code>fvtool</code>	Visualize frequency response of DSP filters
<code>info</code>	Information about filter System object
<code>cost</code>	Estimate cost of implementing filter System object

polyphase Polyphase decomposition of multirate filter

Common to All System Objects

step Run System object algorithm
 release Release resources and allow changes to System object property values and input characteristics
 reset Reset internal states of System object

Examples

Frequency response of Quasi-linear Phase IIR Halfband Interpolator

Create a minimum order lowpass IIR half-band interpolation filter for data sampled at 44.1 kHz. The filter has a transition width of 4.1 kHz, and a stopband attenuation of 80 dB.

```
IIRHalfbandInterp = dsp.IIRHalfbandInterpolator(...
    'DesignMethod', 'Quasi-linear phase');
```

Obtain filter coefficients

```
c = coeffs(IIRHalfbandInterp);
```

Plot the Magnitude and Phase response

```
fvtool(IIRHalfbandInterp, 'Analysis', 'freq')
```

Extract Low Frequency Subband from Speech

Use a halfband analysis filter bank and interpolation filter to extract the low frequency subband from a speech signal.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Note: The `audioDeviceWriter` System object™ is not supported in MATLAB Online.

Set up the audio file reader, the analysis filter bank, the audio device writer, and the interpolation filter. The sampling rate of the audio data is 22050 Hz. The halfband filter has an order of 21 and a transition width of 2 kHz.

```
afr = dsp.AudioFileReader('speech_dft.mp3','SamplesPerFrame',1024);
```

```
filterspec = 'Filter order and transition width';  
Order = 21;  
TW = 2000;
```

```
IIRHalfbandDecim = dsp.IIRHalfbandDecimator(...  
    'Specification',filterspec,'FilterOrder',Order,...  
    'TransitionWidth',TW,'SampleRate',afr.SampleRate);
```

```
IIRHalfbandInterp = dsp.IIRHalfbandInterpolator(...  
    'Specification',filterspec,'FilterOrder',Order,...  
    'TransitionWidth',TW,'SampleRate',afr.SampleRate/2);
```

```
ap = audioDeviceWriter('SampleRate',afr.SampleRate);
```

View the magnitude response of the halfband filter.

```
fvtool(IIRHalfbandDecim)
```

Read the speech signal from the audio file in frames of 1024 samples. Filter the speech signal into lowpass and highpass subbands with a halfband frequency of 5512.5 Hz. Reconstruct a lowpass approximation of the speech signal by interpolating the lowpass subband. Play the filtered output.

```
while ~isDone(afr)
    audioframe = afr();
    xlo = IIRHalfbandDecim(audioframe);
    ylow = IIRHalfbandInterp(xlo);
    ap(ylow);
end
```

Wait until the audio file ends, and then close the input file and release the audio output resource.

```
release(afr);
release(ap);
```

Two-Channel Filter Bank

Use a halfband decimator and interpolator to implement a two-channel filter bank. This example uses an audio file input and shows that the power spectrum of the filter bank output does not differ significantly from the input.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Note: The `audioDeviceWriter` System object™ is not supported in MATLAB Online.

Set up the audio file reader and audio device writer. Construct the IIR halfband decimator and interpolator. Finally, set up the spectrum analyzer to display the power spectra of the filter-bank input and output.

```
AF = dsp.AudioFileReader('speech_dft.mp3','SamplesPerFrame',1024);
AP = audioDeviceWriter('SampleRate',AF.SampleRate);
```

```
filterspec = 'Filter order and transition width';
Order = 51;
TW = 2000;
```

```
IIRHalfbandDecim = dsp.IIRHalfbandDecimator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',AF.SampleRate);
```

```
IIRHalfbandInterp = dsp.IIRHalfbandInterpolator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',AF.SampleRate/2,...
    'FilterBankInputPort',true);
```

```
SpecAna = spectrumAnalyzer('SampleRate',AF.SampleRate,...
    'PlotAsTwoSidedSpectrum',false,...
    'ShowLegend',true,...
    'ChannelNames',{'Input signal','Filtered output signal'});
```

Read the audio 1024 samples at a time. Filter the input to obtain the lowpass and highpass subband signals decimated by a factor of two. This is the analysis filter bank. Use the halfband interpolator as the synthesis filter bank. Display the running power spectrum of the audio input and the output of the synthesis filter bank. Play the output.

```
while ~isDone(AF)
    audioInput = AF();
    [xlo,xhigh] = IIRHalfbandDecim(audioInput);
    audioOutput = IIRHalfbandInterp(xlo,xhigh);
    spectrumInput = [audioInput audioOutput];
    SpecAna(spectrumInput);
    AP(audioOutput);
end
```

```
release(AF);
release(AP);
release(SpecAna);
```

Upsample and Interpolate Multichannel Input with IIR Halfband Interpolator

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Create a half-band interpolation filter for data sampled at 44.1 kHz. The filter order is 51 with a transition width of 4.1 kHz. Use the filter to upsample and interpolate a multichannel input.

```
Fs = 44.1e3;
filterspec = 'Filter order and transition width';
Order = 51;
TW = 4.1e3;
iirhalfbandinterp = dsp.IIRHalfbandInterpolator(...
    'Specification',filterspec,...
    'FilterOrder',Order,...
    'TransitionWidth',TW,...
    'SampleRate',Fs);

x = randn(1024,4);
y = iirhalfbandinterp(x);
```

Algorithms

Polyphase Implementation with Halfband Filters

When you filter your signal, `dsp.IIRHalfbandInterpolator` uses an efficient polyphase implementation for halfband filters. You can use a polyphase implementation to move the upsampling operation after filtering. This change enables you to filter at the lower sampling rate.

IIR halfband filters are generally modeled using two parallel allpass filter branches.

$$H(z) = 0.5 * [A_1(z^2) + z^{-1}A_2(z^2)]$$

Elliptic Design

The allpass filters for elliptic IIR halfband filter are given as

$$A_1(z) = \prod_{k=1}^{K_1} \frac{a_k^{(1)} + z^{-1}}{1 + a_k^{(1)}z^{-1}}$$

$$A_2(z) = \prod_{k=1}^{K_2} \frac{a_k^{(2)} + z^{-1}}{1 + a_k^{(2)}z^{-1}}$$

Quasi-Linear Phase Design

A near-linear phase response for IIR halfband filters is achieved by making one of the branches a pure delay. In this design, the cost of the filter increases.

The allpass filters for quasi-linear phase IIR halfband filter are

$$A_1(z) = z^{-k}$$

where, k is the length of the delay.

$$A_2(z) = \prod_{K=1}^{K_2^{(1)}} \frac{a_k + z^{-1}}{1 + a_k z^{-1}} \prod_{K=1}^{K_2^{(2)}} \frac{c_k + b_k z^{-1} + z^{-2}}{1 + b_k z^{-1} + c_k z^{-2}}$$

where N is the order of the IIR halfband filter.

Graphically, you can represent upsampling by two followed by filtering with the following figure

Using the multirate noble identity for upsampling, you can move the upsampling operation after filtering. This enables you to filter at the lower rate.

To efficiently implement the halfband interpolator, `dsp.IIRHalfbandInterpolator` replaces the upsampling operator, delay block, and adder with a commutator switch. This is shown in the following figure:

The commutator switch takes input samples from the two branches alternately, one sample at a time. This doubles the sampling rate of the input signal.

Synthesis Filter Bank

Transfer function of the complementary high-pass filter branch of the synthesis filter bank is given by

$$G(z) = 0.5 * [A_1(z^2) - z^{-1}A_2(z^2)]$$

Graphically, you can represent the synthesis filter bank as

`dsp.IIRHalfbandInterpolator` to implement the synthesis portion of a two-band filter bank to synthesize a signal from lowpass and highpass subbands.

To summarize, `dsp.IIRHalfbandInterpolator`

- Filters the input before upsampling
- acts as a synthesis filter bank
- has non-linear phase response and uses few coefficients with elliptic design method

- has near-linear phase response at the cost of additional coefficients with quasi-linear phase design method. One of the branches in this design is a pure delay.

dsp.Interpolator

Package: dsp

(To be removed) Linear or polyphase FIR interpolation

Note dsp.Interpolator will be removed in a future release. Use dsp.FIRInterpolator, interp1 instead. For more information, see “Compatibility Considerations”.

Description

The dsp.Interpolator System object interpolates values between real-valued input samples using linear or polyphase FIR interpolation. Specify which values to interpolate by providing a vector of interpolation points. An interpolation point of 1 refers to the first sample in the input. To interpolate the value halfway between the second and third sample in the input, specify an interpolation point of 2.5. Interpolation points that are not within the valid range are replaced with the closest value in the valid range.

To interpolate a real-valued input signal:

- 1 Create the dsp.Interpolator object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
interp = dsp.Interpolator  
interp = dsp.Interpolator(Name, Value)
```

Description

interp = dsp.Interpolator creates an interpolation System object, interp, to interpolate values between real-valued input samples using linear interpolation.

interp = dsp.Interpolator(Name, Value) creates an interpolation System object, interp, with each specified property set to the specified value. Enclose each property name in single quotes.

Example: `interp = dsp.Interpolator('InterpolationPointsSource', 'Input port')`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

InterpolationPointsSource — Source of interpolation points

'Property' (default) | 'Input port'

Method to specify the interpolation points, specified as one of the following:

- 'Property' — Specify the interpolation points through the “InterpolationPoints” on page 4-0 property.
- 'Input port' — Pass the interpolation points as an input to the System object algorithm.

InterpolationPoints — Interpolation points

[1.1;4.8;2.67;1.6;3.2] (default) | vector | matrix | N -D array

Interpolation points, specified as a vector, matrix, or an N -D array. The valid range of the values in the interpolation vector is from 1 to the number of samples in each channel of the input. If you specify interpolation points outside the valid range, the object *clips* the point to the nearest point in the valid range. For example, if the input is [2;3.1;-2.1], the valid range of interpolation points is from 1 to 3. If you specify a [-1;1.5;2;2.5;3;3.5] vector of interpolation points, the interpolator object clips -1 to 1 and 3.5 to 3. This clipping results in the interpolation points [1 1.5 2 2.5 3 3].

For details on the dimension of the interpolation points array and how that influences the dimension of the output, see the tables in the “*ipts*” on page 4-0 input of the System object.

Tunable: Yes

Dependencies

This property applies only when you set the “InterpolationPointsSource” on page 4-0 property to 'Property'.

Method — Interpolation method

'Linear' (default) | 'FIR'

Interpolation method, specified as one of the following:

- 'Linear' -- The object interpolates data values by assuming that the data varies linearly between samples taken at adjacent sample times.
- 'FIR' -- The object uses polyphase interpolation to replace filtering (convolution) at the upsampled rate with a series of convolutions at the lower rate. If the input has insufficient low-rate samples to perform FIR interpolation, the interpolator object performs linear interpolation. For more details, see the “FilterHalfLength” on page 4-0 property.

FilterHalfLength — Half-length of interpolation filter

3 (default) | integer scalar greater than 0

For a filter half-length of P , the polyphase FIR subfilters have length $2P$. FIR interpolation always requires $2P$ low-rate samples for every interpolation point.

- If the interpolation point does not correspond to a low-rate sample, FIR interpolation requires P low-rate samples below and P low-rate samples above the interpolation point.
- If the interpolation point corresponds to a low-rate sample, the $2P$ -sample requirement includes the low-rate sample.

- If the input has less than $2P$ neighboring low-rate samples, the interpolator object uses linear interpolation.

For example, for an input [1 4 1 4 1 4 1 4], upsampling by a factor of 4 results in equally spaced interpolation points, `InterP = [1:0.25:8]`. The points `InterP(9:12)` are [3.0 3.25 3.5 3.75]. If you set `FilterHalfLength` to 2, interpolating at these points uses the 4 low-rate samples from the input with indices (2,3,4,5). If you set `FilterHalfLength` to 4, the interpolator object uses linear interpolation, because the input does not have enough low-rate samples to perform FIR interpolation.

The longer the `FilterHalfLength` property, the better the quality of the interpolation. However, increasing the filter half-length increases computation time and requires more low-rate samples below and above the interpolation point. In general, setting the `FilterHalfLength` property between 4 and 6 provides a reasonably accurate interpolation.

Dependencies

This property applies only when you set the “Method” on page 4-0 property to 'FIR'.

InterpolationPointsPerSample — Upsampling factor

3 (default) | integer scalar greater than 0

Upsampling factor, specified as an integer scalar greater than 0. An upsampling factor of L inserts $L - 1$ zeros between low-rate samples. Interpolation results from filtering the upsampled sequence with a lowpass anti-imaging filter. The interpolator object uses a polyphase FIR implementation with `InterpolationPointsPerSample` subfilters of length $2P$, where P is the value you specify in the “FilterHalfLength” on page 4-0 property. For nL low-rate samples in the upsampled input, where $n=1,2,\dots$, the interpolator object uses exactly one of the `InterpolationPointsPerSample` subfilters to interpolate at the points $nL+i/L$, where $i = 0, 1, 2, \dots, L - 1$.

If you specify interpolation points that do not correspond to a polyphase subfilter, the object rounds the point down to the nearest interpolation point associated with a polyphase subfilter. Suppose you set the `InterpolationPointsPerSample` property to 4 and interpolate at the points [3 3.2 3.4 3.6 3.8]. The interpolator object uses the first polyphase subfilter for the points [3.0 3.2], the second subfilter for the point 3.4, the third subfilter for the point 3.6, and the fourth subfilter for the point 3.8.

Dependencies

This property applies only when you set the “Method” on page 4-0 property to 'FIR'.

Bandwidth — Normalized input bandwidth

0.5 (default) | real scalar greater than 0 and less than or equal to 1

Bandwidth to which the interpolated output samples must be constrained, specified as a real scalar greater than 0 and less than or equal to 1. A value of 1 equals the Nyquist frequency, or half the sampling frequency, F_s . Use this property to take advantage of the bandlimited frequency content of the input. For example, if the input signal does not have frequency content above $F_s/4$, you can specify a value of 0.5 for the `Bandwidth` property.

Dependencies

This property applies only when you set the “Method” on page 4-0 property to 'FIR'.

Usage

Syntax

```
interpOut = interp(input)  
interpOut = interp(input, ipts)
```

Description

`interpOut = interp(input)` outputs the interpolated sequence, `interpOut`, of the input vector or matrix `input`, as specified in the “InterpolationPoints” on page 4-0 property. Each column of `input` is treated as an independent channel of the input.

`interpOut = interp(input, ipts)` outputs the interpolated sequence as specified by `ipts`.

To specify the interpolation points, set the “InterpolationPointsSource” on page 4-0 property to ‘Input port’.

```
t = 0:.0001:.0511;  
x = sin(2*pi*20*t);  
x1 = x(1:50:end);  
ipts = 1:0.1:length(x1);  
interp = dsp.Interpolator('InterpolationPointsSource', 'Input port');  
interpOut = interp(x1', ipts');
```

Input Arguments

input — Data input

vector | matrix | *N*-D array

Input that is interpolated by the object, specified as a vector, matrix, or *N*-D array.

Example: `t = 0:0.0001:0.0511; input = sin(2*pi*20*t);`

Data Types: `single` | `double`

ipts — Interpolation points

vector | matrix | *N*-D array

Interpolation array I_{pts} , specified as a vector, matrix, or *N*-D array. The interpolation array represents the points in time at which to interpolate values of the input signal. An entry of 1 in I_{pts} refers to the first sample of the input, an entry of 2.5 refers to the sample halfway between the second and third input sample, and so on. In most cases, when I_{pts} is a vector, it can be of any length.

Valid values in the interpolation array I_{pts} range from 1 to the number of samples in each channel of the input. For instance, given a length-5 input vector D , all entries of I_{pts} must range from 1 to 5. I_{pts} cannot contain entries such as 7 or -9, because D does not have a seventh or ninth entry.

The algorithm replaces any out-of-range values in I_{pts} with the closest value in the valid range (from 1 to the number of input samples). Then it performs the interpolation using the clipped version of I_{pts} .

Consider the following input data and interpolation points vector:

- `D = [11 22 33 44]'`

- $I_{pts} = [10 \ 2.6 \ -3]'$

Because D has four samples, valid interpolation points range from 1 to 4. The algorithm clips interpolation point 10 down to 4 and the point -3 up to 1. The result is the clipped interpolation vector $I_{ptsClipped} = [4 \ 2.6 \ 1]'$.

Depending on the dimension of the input and the dimension of I_{pts} , the algorithm applies I_{pts} to the input in one of the following ways:

- If I_{pts} is an array, the object applies I_{pts} across the first dimension of an N -D array, resulting in an N -D array output.
- If I_{pts} is a vector, the object applies I_{pts} to each input vector (as if the input vector were a single channel), resulting in a vector output with the same orientation as the input (row or column).

The following tables summarize how the object applies the interpolation array I_{pts} to all the possible types of inputs. The table also shows the resulting output dimensions.

This table describes the behavior when `InterpolationPointsSource` is set to 'Property'.

Input Dimensions	Valid Dimensions of Interpolation Array I_{pts}	How Object Applies I_{pts} to Input	Output Dimensions
M -by- N -by- K matrix	P -by-1 column	Applies I_{pts} to the first dimension of the input	P -by- N -by- K array
	P -by- N -by- K matrix	Applies each column element of I_{pts} to the corresponding column of the input matrix	P -by- N -by- K array
M -by- N matrix	1-by- N row	Applies each column element of I_{pts} to the corresponding column of the input matrix	1-by- N row
	P -by-1 column	Applies I_{pts} to each input column	P -by- N matrix
	P -by- N matrix	Applies the columns of I_{pts} to the corresponding columns of the input matrix	
M -by-1 column	1-by- P row (the algorithm treats I_{pts} as a column)	Applies I_{pts} to the input column	P -by-1 column
	P -by-1 column		
1-by- N row (not recommended)	1-by- N row	Not applicable. Object copies input vector.	1-by- N row, a copy of the input vector
	P -by-1 column		P -by- N matrix, where each row is a copy of the input vector
	P -by- N matrix		

This table describes the behavior when `InterpolationPointsSource` is set to 'Input port'.

Input Dimensions	Valid Dimensions of Interpolation Array I_{pts}	How Object Applies I_{pts} to Input	Output Dimensions
M -by- N -by- K matrix	Column vector of length P	Applies I_{pts} to the first dimension of the input	P -by- N -by- K array
	P -by- N -by- K matrix	Applies each column element of I_{pts} to the corresponding column of the input matrix	P -by- N -by- K array
M -by- N matrix	1-by- N row	Applies each column element of I_{pts} to the corresponding column of the input matrix	1-by- N row
	P -by-1 column	Applies I_{pts} to each input column	P -by- N matrix
	P -by- N matrix	Applies the columns of I_{pts} to the corresponding columns of the input matrix	
M -by-1 column	1-by- P row	Applies I_{pts} to the input column	P -by-1 column
	P -by-1 column		
1-by- N row (not recommended)	1-by- N row	Not applicable. Object copies input vector.	1-by- N row, a copy of the input vector
	P -by-1 column		P -by- N matrix, where each row is a copy of the input vector
	P -by- N matrix		

Example: `ipts = [1:10];`

Data Types: `single` | `double`

Output Arguments

interpOut – Interpolated sequence

vector | matrix | N -D array

Interpolated sequence, returned as a vector, matrix, or N -D array. The dimension of the output depends on the dimensions of the input and the interpolation points array. For more details on the dimensions, see the tables in “`ipts`” on page 4-0 .

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Interpolate a Sum of Sinusoids

Note If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Interpolate a sum of sinusoids with FIR interpolation, and with 'Input port' as the source of interpolation points.

```

Fs = 1000;
t = 0:(1/Fs):0.1-(1/Fs);
x = cos(2*pi*50*t)+0.5*sin(2*pi*100*t);
x1 = x(1:4:end);
I = 1:(1/4):length(x1);
interp = dsp.Interpolator('Method','FIR',...
'FilterHalfLength',3,'InterpolationPointsSource','Input Port');
y = interp(x1,I);
stem(I,y,'r');
hold on;
axis([0 25 -2 2]);
stem(x1,'b','linewidth',2);
legend('Interpolated Signal','Original',...
'Location','Northeast');

```

Algorithms

Linear Interpolation Mode

In the linear interpolation mode, the algorithm interpolates data values by assuming that the data varies linearly between samples taken at adjacent sample times.

Suppose the input signal is $D = [1 \ 2 \ 1.5 \ 3 \ 0.25]'$. The left plot shows the samples in D and the right plot shows the linearly interpolated values between the samples in D .

When the interpolation points are out of range, the algorithm clips the invalid interpolation points. Consider an input signal, $D = [1 \ 2 \ 1.5 \ 3 \ 0.25]'$, and an interpolation vector, $I_{pts} = [-4 \ 2.7 \ 4.3 \ 10]'$. The interpolated output is given by $[1 \ 1.65 \ 2.175 \ 0.25]'$.

Interpolated Values of D at Clipped Interpolation Points

FIR Interpolation Mode

In the FIR interpolation mode, the algorithm interpolates data values using an FIR interpolation filter. The FIR filter is implemented using a polyphase structure. A polyphase implementation *splits* the lowpass FIR filter impulse response into a number of different subfilters.

Let L represent the number of interpolation points per sample, or the upsampling factor. Let P represent the half length of the polyphase subfilters. Indexing from zero, if $h(n)$ is the impulse response of the FIR filter, the k th subfilter is:

$$h_k(n) = h(k + nL) \quad k = 0, 1, \dots, L - 1 \quad n = 0, 1, \dots, 2P - 1$$

The table describes the decomposition of an 18-coefficient FIR filter into 3 polyphase subfilters of length 6, the defaults for the FIR interpolator object.

Coefficients	Polyphase Subfilter
$h(0), h(3), h(6), \dots, h(15)$	$h_0(n)$
$h(1), h(4), h(7), \dots, h(16)$	$h_1(n)$
$h(2), h(5), h(8), \dots, h(17)$	$h_2(n)$

An upsampling factor of L inserts $L - 1$ zeros between low-rate samples. Interpolation results from filtering the upsampled sequence with a lowpass anti-imaging filter.

dsp.KalmanFilter

Package: dsp

(To be removed) Estimate system measurements and states using Kalman filter

Note `dsp.KalmanFilter` will be removed in a future release. Use the Kalman filter functionality in Sensor Fusion and Tracking Toolbox™ instead.

Description

The `dsp.KalmanFilter` System object is an estimator used to recursively obtain a solution for linear optimal filtering. This estimation is made without precise knowledge of the underlying dynamic system. The Kalman filter implements the following linear discrete-time process with state, x , at the k^{th} time-step: $x(k) = Ax(k-1) + Bu(k-1) + w(k-1)$ (state equation). This measurement, z , is given as: $z(k) = Hx(k) + v(k)$ (measurement equation).

The Kalman filter algorithm computes the following two steps recursively:

- Prediction: Process parameters x (state) and P (state error covariance) are estimated using the previous state.
- Correction: The state and error covariance are corrected using the current measurement.

To filter each channel of the input:

- 1 Create the `dsp.KalmanFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
kalman = dsp.KalmanFilter
kalman = dsp.KalmanFilter(STMatrix, MMatrix, PNCovariance, MNCovariance,
CIMatrix)
kalman = dsp.KalmanFilter(Name,Value)
```

Description

`kalman = dsp.KalmanFilter` returns the Kalman filter System object, `kalman`, with default values for the parameters.

`kalman = dsp.KalmanFilter(STMatrix, MMatrix, PNCovariance, MNCovariance, CIMatrix)` returns a Kalman filter System object, `kalman`. The `StateTransitionMatrix` property is set to `STMatrix`, the `MeasurementMatrix` property is set to `MMatrix`, the `ProcessNoiseCovariance` property is set to `PNCovariance`, the

MeasurementNoiseCovariance property is set to MNCovariance, and the ControlInputMatrix property is set to CIMatrix.

`kalman = dsp.KalmanFilter(Name, Value)` returns an Kalman filter System object, `kalman`, with each property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

StateTransitionMatrix — Model of state transition

1 (default) | scalar | square matrix

Specify A in the state equation that relates the state at the previous time step to the state at current time step. A is a square matrix with each dimension equal to the number of states.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

ControlInputMatrix — Model of relation between control input and states

1 (default) | column vector

Specify B in the state equation that relates the control input to the state. B is a column vector with a number of rows equal to the number of states.

Dependencies

This property is activated only when the `ControlInputPort` property value is `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

MeasurementMatrix — Model of relation between states and measurement output

1 (default) | row vector

Specify H in the measurement equation that relates the states to the measurements. H is a row vector with a number of columns equal to the number of measurements.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

ProcessNoiseCovariance — Covariance of process noise

0.1 (default) | scalar | square matrix

Specify Q as a square matrix with each dimension equal to the number of states. Q is the covariance of the white Gaussian process noise, w , in the state equation.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

MeasurementNoiseCovariance — Covariance of measurement noise

0.1 (default) | scalar | square matrix

Specify R as a square matrix with each dimension equal to the number of states. R is the covariance of the white Gaussian process noise, v , in the measurement equation.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

InitialStateEstimate — Initial value for states

`0` (default) | `scalar` | `column vector`

Specify an initial estimate of the states of the model as a column vector with length equal to the number of states.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

InitialErrorCovarianceEstimate — Initial value for state error covariance

`0.1` (default) | `scalar` | `square matrix`

Specify an initial estimate for covariance of the state error, as a square matrix with each dimension equal to the number of states.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

DisableCorrection — Disable port for filters

`false` (default) | `true`

Specify as a scalar logical value, disabling System object filters from performing the correction step after the prediction step in the Kalman filter algorithm.

ControlInputPort — Presence of a control input

`true` (default) | `false`

Specify if the control input is present, using a scalar logical value. The default value is `true`.

Usage

Syntax

```
[zEst, xEst, MSE_Est, zPred, xPred, MSE_Pred] = kalman(z,u)
```

Description

`[zEst, xEst, MSE_Est, zPred, xPred, MSE_Pred] = kalman(z,u)` carries out the iterative Kalman filter algorithm over measurements z and control inputs u . The columns in z and u are treated as inputs to separate parallel filters, whose correction (or update) step can be disabled by the `DisableCorrection` property. The values returned are estimated measurements `zEst`, estimated states `xEst`, MSE of estimated states `MSE_Est`, predicted measurements `zPred`, predicted states `xPred`, and MSE of predicted states `MSE_Pred`.

Input Arguments

z — Measurement input

`vector` | `matrix`

Measurement input, specified as a vector or a matrix.

The ratio of the number of rows of the measurement input to the number of rows of the `MeasurementMatrix` property must be equal to the ratio of the number of rows of the control input to the number of columns of the `ControlInputMatrix` property.

The measurement signal can be a variable-size input. Once the object is locked, you can change the size of each input channel, but the number of channels cannot change.

Data Types: `single` | `double`

u — Control input

vector | matrix

Control input, specified as a vector or a matrix.

The ratio of the number of rows of the control input to the number of columns of the `ControlInputMatrix` property must be equal to the ratio of the number of rows of the measurement input to the number of rows of the `MeasurementMatrix` property.

The control signal can be a variable-size input. Once the object is locked, you can change the size of each input channel, but the number of channels cannot change.

Data Types: `single` | `double`

Output Arguments

zEst — Estimated measurements

vector | matrix

Estimated measurements, returned as a vector or matrix.

Data Types: `single` | `double`

xEst — Estimated state

vector | matrix

Estimated state, returned as a vector or matrix.

Data Types: `single` | `double`

MSE_Est — MSE of estimated states

scalar | column vector

Mean-squared error of estimated states, returned as a scalar or column vector. If the input is a row vector, the MSE of the estimated states is a scalar.

Data Types: `single` | `double`

zPred — Predicted measurements

vector | matrix

Predicted measurements, returned as a vector or a matrix.

Data Types: `single` | `double`

xPred — Predicted states

vector | matrix

Predicted states, returned as a vector or a matrix.

Data Types: `single` | `double`

MSE_Pred — MSE of predicted states

scalar | column vector

Mean-squared error of predicted states, returned as a scalar or a column vector. If the input is a row vector, the MSE of the estimated states is a scalar.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Estimate Changing Scalar

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Create the System objects for the changing scalar input, the Kalman filter, and the scope (for plotting).

```
numSamples = 4000;
R = 0.02;
src = dsp.SignalSource;
src.Signal = [ones(numSamples/4,1); -3*ones(numSamples/4,1); ...
    4*ones(numSamples/4,1); -0.5*ones(numSamples/4,1)];
tScope = timescope('NumInputPorts',3,...
    'TimeSpanSource','Property','TimeSpan',numSamples, ...
    'TimeUnits','Seconds','YLimits',[-5 5], ...
    'ShowLegend',true); % Create the Time Scope
kalman = dsp.KalmanFilter('ProcessNoiseCovariance', 0.0001,...
    'MeasurementNoiseCovariance',R,...
    'InitialStateEstimate',5,...
    'InitialErrorCovarianceEstimate',1,...
    'ControlInputPort',false); %Create Kalman filter
```

Add noise to the scalar, and pass the result to the Kalman filter. Stream the data, and plot the filtered signal.

```
while(~isDone(src))
    trueVal = src();
    noisyVal = trueVal + sqrt(R)*randn;
```

```
    estVal = kalman(noisyVal);  
    tScope(noisyVal,trueVal,estVal);  
end
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Kalman Filter block reference page. The object properties correspond to the block parameters.

Version History

dsp.LDLFactor

Package: dsp

(To be removed) Factor square Hermitian positive definite matrices into components

Note dsp.LDLFactor will be removed in a future release. Use `ldl` instead. For more information, see “Compatibility Considerations”.

Description

The `LDLFactor` object factors square Hermitian positive definite matrices into lower, upper, and diagonal components. The object uses only the lower triangle of S .

To factor these matrices into lower, upper, and diagonal components:

- 1 Define and set up your LDL factor object. See “Construction” on page 4-714.
- 2 Call `step` to factor the matrices according to the properties of `dsp.LDLFactor`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Construction

`ldl = dsp.LDLFactor` returns an LDL factor System object, `ldl`, that computes unit lower triangular L and diagonal D such that $S = LDL$ for square, symmetric/Hermitian, positive definite input matrix S .

`ldl = dsp.LDLFactor('PropertyName', PropertyValue, ...)` returns an LDL factor System object, `ldl`, with each specified property set to the specified value.

Properties

Fixed-Point Properties

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as `Full precision`, `Same as input`, `Same as product` or `Custom`. The default is `Full precision`

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

CustomIntermediateProductDataType

Intermediate product word and fraction lengths

Specify the intermediate product fixed-point type as a signed, scaled `numericType` object. This property applies when you set the `IntermediateProductDataType` property to `Custom`. The default is `numericType(true, 16, 15)`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numericType([], 16, 15)`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

IntermediateProductDataType

Intermediate product word and fraction lengths

Specify the intermediate product fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. The default is `Wrap`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as `Full precision`, `Same as input` or `Custom`. The default is `Full precision`.

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as: `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest` or `Zero`. The default is `Floor`.

Methods

`step` Decompose matrix into components

Common to All System Objects	
<code>release</code>	Allow System object property value changes

Examples

Decompose a Matrix

Note If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Decompose a square Hermitian positive definite matrix using LDL factor.

```
A = gallery('randcorr',5);
ldl = dsp.LDLFactor;
y = ldl(A)
```

```
y = 5x5
 1.0000  -0.3884   0.0296  -0.6152  -0.3903
-0.3884   0.8491  -0.6386  -0.4901   0.3137
 0.0296  -0.6386   0.6529   0.3611   0.5770
-0.6152  -0.4901   0.3611   0.3324   0.5660
-0.3903   0.3137   0.5770   0.5660   0.4403
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the LDL Factorization block reference page. The object properties correspond to the block parameters, except: No object property that corresponds to the **Non-positive definite input** block parameter. The object does not issue any alerts for nonpositive definite inputs. The output is not a valid factorization. A partial factorization is in the upper left corner of the output.

`ldl`

step

System object: dsp.LDLFactor

Package: dsp

Decompose matrix into components

Syntax

```
Y = step(ldl,S)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(ldl,S)` decomposes the matrix `S` into lower, upper, and diagonal components. The output `Y` is a composite matrix with the `L` as its lower triangular part and `D` as the diagonal and `L'` as its upper triangular part. If `S` is not positive definite the output `Y` is not a valid factorization.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.LevinsonSolver

Package: dsp

(To be removed) Solve linear system of equations using Levinson-Durbin recursion

Note dsp.LevinsonSolver will be removed in a future release. Use levinson instead. For more information, see “Compatibility Considerations”.

Description

The LevinsonSolver object solves linear systems of equations using Levinson-Durbin recursion.

To solve linear systems of equations using Levinson-Durbin recursion:

- 1 Define and set up your System object. See “Construction” on page 4-719.
- 2 Call `step` to solve the system of equations according to the properties of `dsp.LevinsonSolver`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`levinson = dsp.LevinsonSolver` returns a System object, `levinson`, that solves a Hermitian Toeplitz system of equations using the Levinson-Durbin recursion.

`levinson = dsp.LevinsonSolver('PropertyName',PropertyValue,...)` returns a Levinson-Durbin object, `levinson`, with each specified property set to the specified value.

Properties

AOutputPort

Enable polynomial coefficients output

Set this property to `true` to output the polynomial coefficients *A*. Both `AOutputPort` and `KOutputPort` properties cannot be `false` at the same time. For scalar inputs, set the `AOutputPort` property to `true`. The default is `false`.

KOutputPort

Enable reflection coefficients output

Set this property to `true` to output the reflection coefficients K . You cannot set both the `AOutputPort` and `KOutputPort` properties to `false` at the same time. For scalar inputs, you must set the `KOutputPort` property to `false`. The default is `true`.

PredictionErrorOutputPort

Enable prediction error output

Set this property to `true` to output the prediction error. The default is `false`.

ZerothLagZeroAction

Action when value of lag zero is zero

Specify the output for an input with the first coefficient as zero. Select `Ignore` or `Use zeros`. The default is `Use zeros`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap`, `Saturate`. The default is `Wrap`.

ACoefficientDataType

A coefficient word and fraction lengths

This constant property has a value of `Custom`.

CustomACoefficientDataType

A coefficient word and fraction lengths

Specify the A coefficient fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. The default is `numericType([], 16, 15)`.

KCoefficientDataType

K coefficient word and fraction lengths

This constant property has a value of Custom.

CustomKCoefficientDataType

K coefficient word and fraction lengths

Specify the K coefficient fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. The default is `numericType([], 16, 15)`.

PredictionErrorDataType

Prediction error power word and fraction lengths

Specify the prediction error power fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

CustomPredictionErrorDataType

Prediction error power word and fraction lengths

Specify the prediction error power fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when the `PredictionErrorDataType` property is `Custom`. The default is `numericType([], 16, 15)`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as `Same as input` or `Custom`. The default is `Custom`

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when the `ProductDataType` property is `Custom`. The default is `numericType([], 32, 30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the Accumulator fixed-point data type as `Same as input`, `Same as product`, or `Custom`. The default is `Custom`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when the `AccumulatorDataType` property is `Custom`. The default is `numericType([], 32, 30)`.

Methods

`step` Reflection coefficients corresponding to columns of input

Common to All System Objects

<code>release</code>	Allow System object property value changes
----------------------	--

Examples

Compute Polynomial Coefficients

Note If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj, x)`.

Use the Levinson solver to compute polynomial coefficients from autocorrelation coefficients.

```
lev = dsp.LevinsonSolver;
lev.AOutputPort = true;
lev.KOutputPort = false;
x = (1:100)';
a = xcorr(x,10);
% Consider the autocorrelation computed over nonnegative lags [0 10].
c = lev(a(11:end)); % Compute polynomial coefficients
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Levinson-Durbin block reference page. The object properties correspond to the block parameters, except: **Output(s)** block parameter corresponds to the `AOutputPort` and the `KOutputPort` object properties.

Version History

Introduced in R2012a

`dsp.LevinsonSolver` System object will be removed

Warns starting in R2021b

`dsp.LevinsonSolver` System object will be removed in a future release. Use the `levinson` function instead.

Update Code

This table shows how the System object is typically used and explains how to update existing code to use the `levinson` function.

Discouraged Usage	Recommended Replacement
<pre>lev = dsp.LevinsonSolver; lev.AOutputPort = true; lev.KOutputPort = false; x = (1:100)';</pre> <p>Autocorrelation is computed over the lags [-10 10].</p> <pre>a = xcorr(x,10);</pre> <p>Consider the autocorrelation computed over nonnegative lags [0 10].</p> <pre>c = lev(a(11:end));</pre> <pre>c = 10x1 1.0000 -0.9920 0.0001 0.0001 0.0001 0.0001 0.0001 0.0001 0.0001 0.0001 0.0001 0.0070</pre> <p>If you are using a release prior to R2016b, replace <code>lev(x)</code> with <code>step(lev,x)</code>.</p>	<p>Polynomial coefficients returned by the function are in the form of a row vector.</p> <pre>cfn = levinson(a(11:end))</pre> <pre>cfn = 1x10 1.0000 -0.9920 0.0001 0.0001 0.0001 0.0001 0.0001... 0.0001 0.0001 0.0001 0.0001 0.0070</pre>

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

See Also

levinson

step

System object: dsp.LevinsonSolver

Package: dsp

Reflection coefficients corresponding to columns of input

Syntax

```
K = step(levinson,X)
A = step(levinson,X)
[A, K] = step(levinson,X)
[... , P] = step(levinson,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`K = step(levinson,X)` returns reflection coefficients `K` corresponding to the columns of input `X`. `X` is typically a column or matrix of autocorrelation coefficients with lag θ as the first element.

`A = step(levinson,X)` returns polynomial coefficients `A` when the `AOutputPort` property is `true` and the `KOutputPort` property is `false`.

`[A, K] = step(levinson,X)` returns polynomial coefficients `A` and reflection coefficients `K` when both the `AOutputPort` and `KOutputPort` properties are `true`.

`[... , P] = step(levinson,X)` also returns the error power `P` when the `PredictionErrorOutputPort` property is `true`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.LMSFilter

Package: dsp

Compute output, error, and weights of LMS adaptive filter

Description

The `dsp.LMSFilter` System object implements an adaptive finite impulse response (FIR) filter that converges an input signal to the desired signal using one of the following algorithms:

- LMS
- Normalized LMS
- Sign-Data LMS
- Sign-Error LMS
- Sign-Sign LMS

For more details on each of these methods, see “Algorithms” on page 4-768.

The filter adapts its weights until the error between the primary input signal and the desired signal is minimal. The mean square of this error (MSE) is computed using the `mseSim` function. The predicted version of the MSE is determined using a Wiener filter in the `msepred` function. The `maxstep` function computes the maximum adaptation step size, which controls the speed of convergence.

For an overview of the adaptive filter methodology, and the most common applications the adaptive filters are used in, see “Overview of Adaptive Filters and Applications”.

To filter a signal using an adaptive FIR filter:

- 1 Create the `dsp.LMSFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Under specific conditions, this System object also supports SIMD code generation. For details, see “Code Generation” on page 4-769.

Creation

Syntax

```
lms = dsp.LMSFilter
lms = dsp.LMSFilter(L)
lms = dsp.LMSFilter(Name, Value)
```

Description

`lms = dsp.LMSFilter` returns an LMS filter object, `lms`, that computes the filtered output, filter error, and the filter weights for a given input and a desired signal using the least mean squares (LMS) algorithm.

`lms = dsp.LMSFilter(L)` returns an LMS filter object with the “Length” on page 4-0 property set to `L`.

`lms = dsp.LMSFilter(Name, Value)` returns an LMS filter object with each specified property set to the specified value. Enclose each property name in single quotes. You can use this syntax with the previous input argument.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Method — Method to calculate filter weights

'LMS' (default) | 'Normalized LMS' | 'Sign-Data LMS' | 'Sign-Error LMS' | 'Sign-Sign LMS'

Method to calculate filter weights, specified as one of the following:

- 'LMS' -- Solves the Wiener-Hopf equation and finds the filter coefficients for an adaptive filter.
- 'Normalized LMS' -- Normalized variation of the LMS algorithm.
- 'Sign-Data LMS' -- Correction to the filter weights at each iteration depends on the sign of the input `x`.
- 'Sign-Error LMS' -- Correction applied to the current filter weights for each successive iteration depends on the sign of the error, `err`.
- 'Sign-Sign LMS' -- Correction applied to the current filter weights for each successive iteration depends on both the sign of `x` and the sign of `err`.

For more details on the algorithms, see “Algorithms” on page 4-768.

Length — Length of FIR filter weights vector

32 (default) | positive integer

Length of the FIR filter weights vector, specified as a positive integer.

Example: 64

Example: 16

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

StepSizeSource — Method to specify adaptation step size

'Property' (default) | 'Input port'

Method to specify the adaptation step size, specified as one of the following:

- 'Property' -- The property "StepSize" on page 4-0 specifies the size of each adaptation step.
- 'Input port' -- Specify the adaptation step size as one of the inputs to the object.

StepSize — Adaptation step size

0.1 (default) | non-negative scalar

Adaptation step size factor, specified as a non-negative scalar. For convergence of the normalized LMS method, the step size must be greater than 0 and less than 2.

A small step size ensures a small steady state error between the output "y" on page 4-0 and the desired signal "d" on page 4-0. If the step size is small, the convergence speed of the filter decreases. To improve the convergence speed, increase the step size. Note that if the step size is large, the filter can become unstable. To compute the maximum step size the filter can accept without becoming unstable, use the `maxstep` function.

Tunable: Yes

Dependencies

This property applies when you set "StepSizeSource" on page 4-0 to 'Property'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

LeakageFactor — Leakage factor used in leaky LMS method

1 (default) | [0 1]

Leakage factor used when implementing the leaky LMS method, specified as a scalar in the range [0 1]. When the value equals 1, there is no leakage in the adapting method. When the value is less than 1, the filter implements a leaky LMS method.

Example: 0.5

Tunable: Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

InitialConditions — Initial conditions of filter weights

0 (default) | scalar | vector

Initial conditions of filter weights, specified as a scalar or a vector of length equal to the value of the "Length" on page 4-0 property. When the input is real, the value of this property must be real.

Example: 0

Example: [1 3 1 2 7 8 9 0 2 2 8 2]

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Complex Number Support: Yes

AdaptInputPort — Flag to adapt filter weights

false (default) | true

Flag to adapt filter weights, specified as one of the following:

- false -- The object continuously updates the filter weights.

- `true` -- An adaptation control input is provided to the object when you call its algorithm. If the value of this input is non-zero, the object continuously updates the filter weights. If the value of this input is zero, the filter weights remain at their current value.

WeightsResetInputPort — Flag to reset filter weights

`false` (default) | `true`

Flag to reset filter weights, specified as one of the following:

- `false` -- The object does not reset weights.
- `true` -- A reset control input is provided to the object when you call its algorithm. This setting enables the “WeightsResetCondition” on page 4-0 property. The object resets the filter weights based on the values of the `WeightsResetCondition` property and the reset input provided to the object algorithm.

WeightsResetCondition — Event to reset filter weights

`'Non-zero'` (default) | `'Rising edge'` | `'Falling edge'` | `'Either edge'`

Event that triggers the reset of the filter weights, specified as one of the following. The object resets the filter weights whenever a reset event is detected in its reset input.

- `'Non-zero'` -- Triggers a reset operation at each sample, when the reset input is not zero.
- `'Rising edge'` -- Triggers a reset operation when the reset input does one of the following:
 - Rises from a negative value to either a positive value or zero.
 - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.

- `'Falling edge'` -- Triggers a reset operation when the reset input does one of the following:
 - Falls from a positive value to a negative value or zero.
 - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.

- 'Either edge' -- Triggers a reset operation when the reset input is a rising edge or a falling edge.

The object resets the filter weights based on the value of this property and the reset input `r` provided to the object algorithm.

Dependencies

This property applies when you set the “WeightsResetInputPort” on page 4-0 property to `true`.

WeightsOutput — Method to output adapted filter weights

'Last' (default) | 'None' | 'All'

Method to output adapted filter weights, specified as one of the following:

- 'Last' (default) — The object returns a column vector of weights corresponding to the last sample of the data frame. The length of the weights vector is the value given by the “Length” on page 4-0 property.
- 'All' — The object returns a *FrameLength*-by-*Length* matrix of weights. The matrix corresponds to the full sample-by-sample history of weights for all *FrameLength* samples of the input values. Each row in the matrix corresponds to a set of LMS filter weights calculated for the corresponding input sample.
- 'None' — This setting disables the weights output.

Fixed-Point Properties

RoundingMethod — Rounding method for fixed-point operations

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Specify the rounding mode for fixed-point operations. For more details, see rounding mode.

OverflowAction — Overflow action for fixed-point operations

'Wrap' (default) | 'Saturate'

Overflow action for fixed-point operations, specified as one of the following:

- 'Wrap' -- The object wraps the result of its fixed-point operations.
- 'Saturate' -- The object saturates the result of its fixed-point operations.

For more details on overflow actions, see overflow mode for fixed-point operations.

StepSizeDataType — Step size word length and fraction length settings

'Same word length as first input' (default) | 'Custom'

Step size word length and fraction length settings, specified as one of the following:

- 'Same word length as first input' -- The object specifies the word length of step size to be the same as that of the first input. The fraction length is computed to get the best possible precision.
- 'Custom' -- The step size data type is specified as a custom numeric type through the "CustomStepSizeDataType" on page 4-0 property.

For more information on the step size data type this object uses, see the "Fixed Point" on page 4-765 section.

CustomStepSizeDataType — Word and fraction lengths of step size

`numericType([],16,15)` (default)

Word and fraction lengths of the step size, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Example: `numericType([],32)`

Dependencies

This property applies under the following conditions:

- "StepSizeSource" on page 4-0 property set to 'Property' and "StepSizeDataType" on page 4-0 set to 'Custom'.
- StepSizeSource property set to 'Input port'.

LeakageFactorDataType — Leakage factor word length and fraction length settings

'Same word length as first input' (default) | 'Custom'

Leakage factor word length and fraction length settings, specified as one of the following:

- 'Same word length as first input' -- The object specifies the word length of leakage factor to be the same as that of the first input. The fraction length is computed to get the best possible precision.
- 'Custom' -- The leakage factor data type is specified as a custom numeric type through the "CustomLeakageFactorDataType" on page 4-0 property.

For more information on the leakage factor data type this object uses, see the "Fixed Point" on page 4-765 section.

CustomLeakageFactorDataType — Word and fraction lengths of the leakage factor

`numericType([],16,15)` (default)

Word and fraction lengths of the leakage factor, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Example: `numericType([],32)`

Dependencies

This property applies when you set the "LeakageFactorDataType" on page 4-0 property to 'Custom'.

WeightsDataType — Weights word length and fraction length settings

'Same as first input' (default) | 'Custom'

Weights word length and fraction length settings, specified as one of the following:

- 'Same as first input' -- The object specifies the data type of the filter weights to be the same as that of the first input.
- 'Custom' -- The data type of filter weights is specified as a custom numeric type through the "CustomWeightsDataType" on page 4-0 property.

For more information on the filter weights data type this object uses, see the "Fixed Point" on page 4-765 section.

CustomWeightsDataType — Word and fraction lengths of filter weights

`numericType([],16,15)` (default)

Word and fraction lengths of the filter weights, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Example: `numericType([],32,20)`

Dependencies

This property applies when you set the "WeightsDataType" on page 4-0 property to 'Custom'.

EnergyProductDataType — Energy product word length and fraction length settings

'Same as first input' (default) | 'Custom'

Energy product word length and fraction length settings, specified as one of the following:

- 'Same as first input' -- The object specifies the data type of the energy product to be the same as that of the first input.
- 'Custom' -- The data type of the energy product is specified as a custom numeric type through the "CustomEnergyProductDataType" on page 4-0 property.

For more information on the energy product data type this object uses, see the "Fixed Point" on page 4-765 section.

Dependencies

This property applies when you set the "Method" on page 4-0 property to 'Normalized LMS'.

CustomEnergyProductDataType — Word and fraction lengths of energy product

`numericType([],32,20)` (default)

Word and fraction lengths of the energy product, specified as an autosigned numeric type with a word length of 32 and a fraction length of 20.

Dependencies

This property applies when you set the "Method" on page 4-0 property to 'Normalized LMS' and "EnergyProductDataType" on page 4-0 property to 'Custom'.

EnergyAccumulatorDataType — Energy accumulator word length and fraction length settings

'Same as first input' (default) | 'Custom'

Energy accumulator word length and fraction length settings, specified as one of the following:

- 'Same as first input' -- The object specifies the data type of the energy accumulator to be the same as that of the first input.
- 'Custom' -- The data type of the energy accumulator is specified as a custom numeric type through the “CustomEnergyAccumulatorDataType” on page 4-0 property.

For more information on the energy accumulator data type this object uses, see the “Fixed Point” on page 4-765 section.

Dependencies

This property applies when you set the “Method” on page 4-0 property to 'Normalized LMS'.

CustomEnergyAccumulatorDataType — Word and fraction lengths of energy accumulator

numericity([],32,20) (default)

Word and fraction lengths of the energy accumulator, specified as an autosigned numeric type with a word length of 32 and a fraction length of 20.

Dependencies

This property applies when you set the “Method” on page 4-0 property to 'Normalized LMS' and “EnergyAccumulatorDataType” on page 4-0 property to 'Custom'.

ConvolutionProductDataType — Convolution product word length and fraction length settings

'Same as first input' (default) | 'Custom'

Convolution product word length and fraction length settings, specified as one of the following:

- 'Same as first input' -- The object specifies the data type of the convolution product to be the same as that of the first input.
- 'Custom' -- The data type of the convolution product is specified as a custom numeric type through the “CustomConvolutionProductDataType” on page 4-0 property.

For more information on the convolution product data type this object uses, see the “Fixed Point” on page 4-765 section.

CustomConvolutionProductDataType — Word and fraction lengths of convolution product

numericity([],32,20) (default)

Word and fraction lengths of the convolution product, specified as an autosigned numeric type with a word length of 32 and a fraction length of 20.

Dependencies

This property applies when you set the “ConvolutionProductDataType” on page 4-0 property to 'Custom'.

ConvolutionAccumulatorDataType — Convolution accumulator word length and fraction length settings

'Same as first input' (default) | 'Custom'

Convolution accumulator word length and fraction length settings, specified as one of the following:

- 'Same as first input' -- The object specifies the data type of the convolution accumulator to be the same as that of the first input.

- 'Custom' -- The data type of the convolution accumulator is specified as a custom numeric type through the “CustomConvolutionAccumulatorDataType” on page 4-0 property.

For more information on the convolution accumulator data type this object uses, see the “Fixed Point” on page 4-765 section.

CustomConvolutionAccumulatorDataType — Word and fraction lengths of convolution accumulator

`numericType([],32,20)` (default)

Word and fraction lengths of the convolution accumulator, specified as an autosigned numeric type with a word length of 32 and a fraction length of 20.

Dependencies

This property applies when you set the “ConvolutionAccumulatorDataType” on page 4-0 property to 'Custom'.

StepSizeErrorProductDataType — Step size error product word length and fraction length settings

`'Same as first input'` (default) | `'Custom'`

Step size error product word length and fraction length settings, specified as one of the following:

- 'Same as first input' -- The object specifies the data type of the step size error product to be the same as that of the first input.
- 'Custom' -- The data type of the step size error product is specified as a custom numeric type through the “CustomStepSizeErrorProductDataType” on page 4-0 property.

For more information on the step size error product data type this object uses, see the “Fixed Point” on page 4-765 section.

CustomStepSizeErrorProductDataType — Word and fraction lengths of step size error product

`numericType([],32,20)` (default)

Word and fraction lengths of the step size error product, specified as an autosigned numeric type with a word length of 32 and a fraction length of 20.

Dependencies

This property applies when you set the “StepSizeErrorProductDataType” on page 4-0 property to 'Custom'.

WeightsUpdateProductDataType — Filter weights update product word length and fraction length settings

`'Same as first input'` (default) | `'Custom'`

Word and fraction length settings of the filter weights update product, specified as one of the following:

- 'Same as first input' -- The object specifies the data type of the filter weights update product to be the same as that of the first input.
- 'Custom' -- The data type of the filter weights update product is specified as a custom numeric type through the “CustomWeightsUpdateProductDataType” on page 4-0 property.

For more information on the filter weights update product data type this object uses, see the “Fixed Point” on page 4-765 section.

CustomWeightsUpdateProductDataType — Word and fraction lengths of filter weights update product

`numericType([],32,20)` (default)

Word and fraction lengths of the filter weights update product, specified as an autosigned numeric type with a word length of 32 and a fraction length of 20.

Dependencies

This property applies when you set the “WeightsUpdateProductDataType” on page 4-0 property to 'Custom'.

QuotientDataType — Quotient word length and fraction length settings

'Same as first input' (default) | 'Custom'

Quotient word length and fraction length settings, specified as one of the following:

- 'Same as first input' -- The object specifies the quotient data type to be the same as that of the first input.
- 'Custom' -- The quotient data type is specified as a custom numeric type through the “CustomQuotientDataType” on page 4-0 property.

For more information on the quotient data type this object uses, see the “Fixed Point” on page 4-765 section.

Dependencies

This property applies when you set the “Method” on page 4-0 property to 'Normalized LMS'.

CustomQuotientDataType — Word and fraction lengths of quotient

`numericType([],32,20)` (default)

Word and fraction lengths of the filter weights update product, specified as an autosigned numeric type with a word length of 32 and a fraction length of 20.

Dependencies

This property applies when you set the “Method” on page 4-0 property to 'Normalized LMS' and “QuotientDataType” on page 4-0 property to 'Custom'.

Usage

Syntax

```
[y,err,wts] = lms(x,d)
[y,err] = lms(x,d)
[___] = lms(x,d,mu)
[___] = lms(x,d,a)
[___] = lms(x,d,r)
[y,err,wts] = lms(x,d,mu,a,r)
```

Description

`[y,err,wts] = lms(x,d)` filters the input signal, `x`, using `d` as the desired signal, and returns the filtered output in `y`, the filter error in `err`, and the estimated filter weights in `wts`. The LMS filter object estimates the filter weights needed to minimize the error between the output signal and the desired signal.

`[y,err] = lms(x,d)` filters the input signal, `x`, using `d` as the desired signal, and returns the filtered output in `y` and the filter error in `err` when the “WeightsOutput” on page 4-0 property is set to 'None'.

`[___] = lms(x,d,mu)` filters the input signal, `x`, using `d` as the desired signal and `mu` as the step size, when the “StepSizeSource” on page 4-0 property is set to 'Input port'. These inputs can be used with either of the previous sets of outputs.

`[___] = lms(x,d,a)` filters the input signal, `x`, using `d` as the desired signal and `a` as the adaptation control when the “AdaptInputPort” on page 4-0 property is set to `true`. When `a` is nonzero, the System object continuously updates the filter weights. When `a` is zero, the filter weights remain constant.

`[___] = lms(x,d,r)` filters the input signal, `x`, using `d` as the desired signal and `r` as a reset signal when the “WeightsResetInputPort” on page 4-0 property is set to `true`. The “WeightsResetCondition” on page 4-0 property can be used to set the reset trigger condition. If a reset event occurs, the System object resets the filter weights to their initial values.

`[y,err,wts] = lms(x,d,mu,a,r)` filters the input signal, `x`, using `d` as the desired signal, `mu` as the step size, `a` as the adaptation control, and `r` as the reset signal, and returns the filtered output in `y`, the filter error in `err`, and the adapted filter weights in `wts`.

Input Arguments

x — Data input

scalar | column vector

The signal to be filtered by the LMS filter. The input, `x`, and the desired signal, `d` must have the same size, data type, and complexity. If the input is fixed-point, the data type must be signed and must have the same word length as the desired signal.

The input, `x` can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

d — Desired signal

scalar | column vector

The LMS filter adapts its filter weights, `wts`, to minimize the error, `err`, and converge the input signal `x` to the desired signal `d` as closely as possible.

The input, `x`, and the desired signal, `d`, must have the same size, data type, and complexity. If the desired signal is fixed-point, the data type must be signed and must have the same word length as the data input.

The input, *d* can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

mu — Step size

nonnegative scalar

Adaptation step size factor, specified as a scalar, nonnegative numeric value. For convergence of the normalized LMS method, the step size should be greater than 0 and less than 2. The data type of the step size input must match the data type of *x* and *d*. If the data type is fixed-point, the data type must be signed.

A small step size ensures a small steady state error between the output *y* and the desired signal *d*. If the step size is small, the convergence speed of the filter decreases. To improve the convergence speed, increase the step size. Note that if the step size is large, the filter can become unstable. To compute the maximum step size the filter can accept without becoming unstable, use the `maxstep` function.

Dependencies

This input is required when the “StepSizeSource” on page 4-0 property is set to `'Input port'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

a — Adaptation control

scalar

Adaptation control input that controls how the filter weights are updated. If the value of this input is non-zero, the object continuously updates the filter weights. If the value of this input is zero, the filter weights remain at their current value.

Dependencies

This input is required when the “AdaptInputPort” on page 4-0 property is set to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

r — Reset signal

scalar

Reset signal that resets the filter weights based on the values of the “WeightsResetCondition” on page 4-0 property.

Dependencies

This input is required when the “WeightsResetInputPort” on page 4-0 property is set to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

Output Arguments**y — Filtered output**

scalar | column vector

Filtered output, returned as a scalar or a column vector. The object adapts its filter weights to converge the input signal *x* to match the desired signal *d*. The filter outputs the converged signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

err — Difference between output and desired signal

scalar | column vector

Difference between the output signal `y` and the desired signal `d`, returned as a scalar or a column vector. The data type of `err` matches the data type of `y`. The objective of the adaptive filter is to minimize this error. The object adapts its weights to converge towards optimal filter weights that produce an output signal that matches closely with the desired signal. For more details on how `err` is computed, see “Algorithms” on page 4-768.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

wts — Adaptive filter weights

scalar | column vector

Adaptive filter weights, returned as a scalar or a column vector of length specified by the value in “Length” on page 4-0 .

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.LMSFilter

`maxstep` Maximum step size for LMS adaptive filter convergence
`msepred` Predicted mean squared error for LMS adaptive filter
`msesim` Estimated mean squared error for adaptive filters

Common to All System Objects

`step` Run System object algorithm
`release` Release resources and allow changes to System object property values and input characteristics
`reset` Reset internal states of System object

Examples

Predict Mean Squared Error for LMS Filter

The mean squared error (MSE) measures the average of the squares of the errors between the desired signal and the primary signal input to the adaptive filter. Reducing this error converges the primary input to the desired signal. Determine the predicted value of MSE and the simulated value of MSE at each time instant using the `msepred` and `msesim` functions. Compare these MSE values with each other and with respect to the minimum MSE and steady-state MSE values. In addition, compute the sum of the squares of the coefficient errors given by the trace of the coefficient covariance matrix.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Initialization

Create a `dsp.FIRFilter` System object™ that represents the unknown system. Pass the signal, `x`, to the FIR filter. The output of the unknown system is the desired signal, `d`, which is the sum of the output of the unknown system (FIR filter) and an additive noise signal, `n`.

```
num = fir1(31,0.5);
fir = dsp.FIRFilter('Numerator',num);
iir = dsp.IIRFilter('Numerator',sqrt(0.75),...
    'Denominator',[1 -0.5]);
x = iir(sign(randn(2000,25)));
n = 0.1*randn(size(x));
d = fir(x) + n;
```

LMS Filter

Create a `dsp.LMSFilter` System object to create a filter that adapts to output the desired signal. Set the length of the adaptive filter to 32 taps, step size to 0.008, and the decimation factor for analysis and simulation to 5. The variable `simmse` represents the simulated MSE between the output of the unknown system, `d`, and the output of the adaptive filter. The variable `mse` gives the corresponding predicted value.

```
l = 32;
mu = 0.008;
m = 5;

lms = dsp.LMSFilter('Length',l,'StepSize',mu);
[mmse,emse,meanW,mse,traceK] = msepred(lms,x,d,m);
[simmse,meanWsim,Wsim,traceKsim] = msesim(lms,x,d,m);
```

Plot the MSE Results

Compare the values of simulated MSE, predicted MSE, minimum MSE, and the final MSE. The final MSE value is given by the sum of minimum MSE and excess MSE.

```
nn = m:m:size(x,1);
semilogy(nn,simmse,[0 size(x,1)],[(emse+mmse)...
    (emse+mmse)],nn,mse,[0 size(x,1)],[mmse mmse])
title('Mean Squared Error Performance')
axis([0 size(x,1) 0.001 10])
legend('MSE (Sim.)','Final MSE','MSE','Min. MSE')
xlabel('Time Index')
ylabel('Squared Error Value')
```

The predicted MSE follows the same trajectory as the simulated MSE. Both these trajectories converge with the steady-state (final) MSE.

Plot the Coefficient Trajectories

meanWsim is the mean value of the simulated coefficients given by msesim. meanW is the mean value of the predicted coefficients given by msepred.

Compare the simulated and predicted mean values of LMS filter coefficients 12,13,14, and 15.

```
plot(nn,meanWsim(:,12),'b',nn,meanW(:,12),'r',nn,...
meanWsim(:,13:15),'b',nn,meanW(:,13:15),'r')
PlotTitle ={'Average Coefficient Trajectories for';...
            'W(12), W(13), W(14), and W(15)'};
```

```
PlotTitle = 2x1 cell
            {'Average Coefficient Trajectories for'}
            {'W(12), W(13), W(14), and W(15)'}      }
```

```
title(PlotTitle)
legend('Simulation','Theory')
xlabel('Time Index')
ylabel('Coefficient Value')
```

In steady state, both the trajectories converge.

Sum of Squared Coefficient Errors

Compare the sum of the squared coefficient errors given by `msepred` and `msesim`. These values are given by the trace of the coefficient covariance matrix.

```
semilogy(nn,traceKsim,nn,traceK,'r')
title('Sum-of-Squared Coefficient Errors')
axis([0 size(x,1) 0.0001 1])
legend('Simulation','Theory')
xlabel('Time Index')
ylabel('Squared Error Value')
```

Compute Maximum Step of LMS Adaptive Filter

The `maxstep` function computes the maximum step size of the adaptive filter. This step size keeps the filter stable at the maximum possible speed of convergence. Create the primary input signal, `x`, by passing a signed random signal to an IIR filter. Signal `x` contains 50 frames of 2000 samples each frame. Create an LMS filter with 32 taps and a step size of 0.1.

```
x = zeros(2000,50);
IIRFilter = dsp.IIRFilter('Numerator',sqrt(0.75),...
    'Denominator',[1 -0.5]);
for k = 1:size(x,2)
    x(:,k) = IIRFilter(sign(randn(size(x,1),1)));
end
mu = 0.1;
LMSFilter = dsp.LMSFilter('Length',32,...
    'StepSize',mu);
```

Compute the maximum adaptation step size and the maximum step size in mean-squared sense using the `maxstep` function.

```
[mumax,mumaxmse] = maxstep(LMSFilter,x)

mumax = 0.0625
mumaxmse = 0.0536
```

System Identification of FIR Filter Using LMS Algorithm

System identification is the process of identifying the coefficients of an unknown system using an adaptive filter. The general overview of the process is shown in “System Identification -- Using an Adaptive Filter to Identify an Unknown System”. The main components involved are:

- The adaptive filter algorithm. In this example, set the `Method` property of `dsp.LMSFilter` to 'LMS' to choose the LMS adaptive filter algorithm.
- An unknown system or process to adapt to. In this example, the filter designed by `firband` is the unknown system.
- Appropriate input data to exercise the adaptation process. For the generic LMS model, these are the desired signal $d(k)$ and the input signal $x(k)$.

The objective of the adaptive filter is to minimize the error signal between the output of the adaptive filter $y(k)$ and the output of the unknown system (or the system to be identified) $d(k)$. Once the error signal is minimized, the adapted filter resembles the unknown system. The coefficients of both the filters match closely.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Unknown System

Create a `dsp.FIRFilter` object that represents the system to be identified. Use the `firband` function to design the filter coefficients. The designed filter is a lowpass filter constrained to 0.2 ripple in the stopband.

```
filt = dsp.FIRFilter;
filt.Numerator = firband(12,[0 0.4 0.5 1],[1 1 0 0],[1 0.2],...
{'w' 'c'});
```

Pass the signal x to the FIR filter. The desired signal d is the sum of the output of the unknown system (FIR filter) and an additive noise signal n .

```
x = 0.1*randn(250,1);
n = 0.01*randn(250,1);
d = filt(x) + n;
```

Adaptive Filter

With the unknown filter designed and the desired signal in place, create and apply the adaptive LMS filter object to identify the unknown filter.

Preparing the adaptive filter object requires starting values for estimates of the filter coefficients and the LMS step size (μ). You can start with some set of nonzero values as estimates for the filter coefficients. This example uses zeros for the 13 initial filter weights. Set the `InitialConditions` property of `dsp.LMSFilter` to the desired initial values of the filter weights. For the step size, 0.8 is a good compromise between being large enough to converge well within 250 iterations (250 input sample points) and small enough to create an accurate estimate of the unknown filter.

Create a `dsp.LMSFilter` object to represent an adaptive filter that uses the LMS adaptive algorithm. Set the length of the adaptive filter to 13 taps and the step size to 0.8.

```
mu = 0.8;  
lms = dsp.LMSFilter(13, 'StepSize', mu)
```

```
lms =  
  dsp.LMSFilter with properties:  
        Method: 'LMS'  
        Length: 13  
    StepSizeSource: 'Property'  
        StepSize: 0.8000  
    LeakageFactor: 1  
  InitialConditions: 0  
    AdaptInputPort: false  
WeightsResetInputPort: false  
        WeightsOutput: 'Last'
```

Show all properties

Pass the primary input signal x and the desired signal d to the LMS filter. Run the adaptive filter to determine the unknown system. The output y of the adaptive filter is the signal converged to the desired signal d thereby minimizing the error e between the two signals.

Plot the results. The output signal does not match the desired signal as expected, making the error between the two nontrivial.

```
[y,e,w] = lms(x,d);  
plot(1:250, [d,y,e])  
title('System Identification of an FIR filter')  
legend('Desired', 'Output', 'Error')  
xlabel('Time index')  
ylabel('Signal value')
```

Compare the Weights

The weights vector w represents the coefficients of the LMS filter that is adapted to resemble the unknown system (FIR filter). To confirm the convergence, compare the numerator of the FIR filter and the estimated weights of the adaptive filter.

The estimated filter weights do not closely match the actual filter weights, confirming the results seen in the previous signal plot.

```
stem([(filt.Numerator). ' w'])
title('System Identification by Adaptive LMS Algorithm')
legend('Actual filter weights', 'Estimated filter weights', ...
       'Location', 'NorthEast')
```

Changing the Step Size

As an experiment, change the step size to 0.2. Repeating the example with $\mu = 0.2$ results in the following stem plot. The filters do not converge, and the estimated weights are not good approximations of the actual weights.

```
mu = 0.2;
lms = dsp.LMSFilter(13, 'StepSize', mu);
[~,~,w] = lms(x,d);
stem([(filt.Numerator).' w])
title('System Identification by Adaptive LMS Algorithm')
legend('Actual filter weights', 'Estimated filter weights', ...
       'Location', 'NorthEast')
```

Increase the Number of Data Samples

Increase the frame size of the desired signal. Even though this increases the computation involved, the LMS algorithm now has more data that can be used for adaptation. With 1000 samples of signal data and a step size of 0.2, the coefficients are aligned closer than before, indicating an improved convergence.

```
release(filt);
x = 0.1*randn(1000,1);
n = 0.01*randn(1000,1);
d = filt(x) + n;
[y,e,w] = lms(x,d);
stem([filt.Numerator.' w])
title('System Identification by Adaptive LMS Algorithm')
legend('Actual filter weights','Estimated filter weights',...
'Location','NorthEast')
```

Increase the number of data samples further by inputting the data through iterations. Run the algorithm on 4000 samples of data, passed to the LMS algorithm in batches of 1000 samples over 4 iterations.

Compare the filter weights. The weights of the LMS filter match the weights of the FIR filter very closely, indicating a good convergence.

```

release(filt);
n = 0.01*randn(1000,1);
for index = 1:4
    x = 0.1*randn(1000,1);
    d = filt(x) + n;
    [y,e,w] = lms(x,d);
end
stem([(filt.Numerator).' w])
title('System Identification by Adaptive LMS Algorithm')
legend('Actual filter weights','Estimated filter weights',...
       'Location','NorthEast')

```

The output signal matches the desired signal very closely, making the error between the two close to zero.

```
plot(1:1000, [d,y,e])
title('System Identification of an FIR filter')
legend('Desired', 'Output', 'Error')
xlabel('Time index')
ylabel('Signal value')
```

System Identification of FIR Filter Using Normalized LMS Algorithm

To improve the convergence performance of the LMS algorithm, the normalized variant (NLMS) uses an adaptive step size based on the signal power. As the input signal power changes, the algorithm calculates the input power and adjusts the step size to maintain an appropriate value. The step size changes with time, and as a result, the normalized algorithm converges faster with fewer samples in many cases. For input signals that change slowly over time, the normalized LMS algorithm can be a more efficient LMS approach.

For an example using the LMS approach, see “System Identification of FIR Filter Using LMS Algorithm”.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Unknown System

Create a `dsp.FIRFilter` object that represents the system to be identified. Use the `firband` function to design the filter coefficients. The designed filter is a lowpass filter constrained to 0.2 ripple in the stopband.

```
filt = dsp.FIRFilter;
filt.Numerator = firband(12,[0 0.4 0.5 1],[1 1 0 0],[1 0.2],...
{'w' 'c'});
```

Pass the signal x to the FIR filter. The desired signal d is the sum of the output of the unknown system (FIR filter) and an additive noise signal n .

```
x = 0.1*randn(1000,1);
n = 0.001*randn(1000,1);
d = filt(x) + n;
```

Adaptive Filter

To use the normalized LMS algorithm variation, set the `Method` property on the `dsp.LMSFilter` to 'Normalized LMS'. Set the length of the adaptive filter to 13 taps and the step size to 0.2.

```
mu = 0.2;
lms = dsp.LMSFilter(13, 'StepSize', mu, 'Method', ...
    'Normalized LMS');
```

Pass the primary input signal x and the desired signal d to the LMS filter.

```
[y,e,w] = lms(x,d);
```

The output y of the adaptive filter is the signal converged to the desired signal d thereby minimizing the error e between the two signals.

```
plot(1:1000, [d,y,e])
title('System Identification by Normalized LMS Algorithm')
legend('Desired', 'Output', 'Error')
xlabel('Time index')
ylabel('Signal value')
```

Compare the Adapted Filter to the Unknown System

The weights vector w represents the coefficients of the LMS filter that is adapted to resemble the unknown system (FIR filter). To confirm the convergence, compare the numerator of the FIR filter and the estimated weights of the adaptive filter.

```
stem([filt.Numerator.' w])
title('System Identification by Normalized LMS Algorithm')
legend('Actual filter weights', 'Estimated filter weights', ...
       'Location', 'NorthEast')
```

Compare Convergence Performance Between LMS Algorithm and Normalized LMS Algorithm

An adaptive filter adapts its filter coefficients to match the coefficients of an unknown system. The objective is to minimize the error signal between the output of the unknown system and the output of the adaptive filter. When these two outputs converge and match closely for the same input, the coefficients are said to match closely. The adaptive filter at this state resembles the unknown system. This example compares the rate at which this convergence happens for the normalized LMS (NLMS) algorithm and the LMS algorithm with no normalization.

Unknown System

Create a `dsp.FIRFilter` that represents the unknown system. Pass the signal x as an input to the unknown system. The desired signal d is the sum of the output of the unknown system (FIR filter) and an additive noise signal n .

```
filt = dsp.FIRFilter;
filt.Numerator = fircband(12,[0 0.4 0.5 1],[1 1 0 0],[1 0.2],...
{'w' 'c'});
x = 0.1*randn(1000,1);
n = 0.001*randn(1000,1);
d = filt(x) + n;
```

Adaptive Filter

Create two `dsp.LMSFilter` objects, with one set to the LMS algorithm, and the other set to the normalized LMS algorithm. Choose an adaptation step size of 0.2 and set the length of the adaptive filter to 13 taps.

```
mu = 0.2;
lms_nonnormalized = dsp.LMSFilter(13,'StepSize',mu,...
'Method','LMS');
lms_normalized = dsp.LMSFilter(13,'StepSize',mu,...
'Method','Normalized LMS');
```

Pass the primary input signal `x` and the desired signal `d` to both the variations of the LMS algorithm. The variables `e1` and `e2` represent the error between the desired signal and the output of the normalized and nonnormalized filters, respectively.

```
[~,e1,~] = lms_normalized(x,d);
[~,e2,~] = lms_nonnormalized(x,d);
```

Plot the error signals for both variations. The error signal for the NLMS variant converges to zero much faster than the error signal for the LMS variant. The normalized version adapts in far fewer iterations to a result almost as good as the nonnormalized version.

```
plot([e1,e2]);
title('Comparing the LMS and NLMS Conversion Performance');
legend('NLMS derived filter weights', ...
'LMS derived filter weights','Location','NorthEast');
xlabel('Time index')
ylabel('Signal value')
```

Cancel Noise Using LMS Filter

Cancel additive noise, n , added to an unknown system using an LMS adaptive filter. The LMS filter adapts its coefficients until its transfer function matches the transfer function of the unknown system as closely as possible. The difference between the output of the adaptive filter and the output of the unknown system represents the error signal, e . Minimizing this error signal is the objective of the adaptive filter.

The unknown system and the LMS filter process the same input signal, x , and produce outputs d and y , respectively. If the coefficients of the adaptive filter match the coefficients of the unknown system, the error, e , in effect represents the additive noise.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Create a `dsp.FIRFilter` System object to represent the unknown system. Create a `dsp.LMSFilter` object and set the length to 11 taps and the step size to 0.05. Create a sine wave to represent the noise added to the unknown system. View the signals in a time scope.

```
FrameSize = 100;
NIter = 10;
lmsfilt2 = dsp.LMSFilter('Length',11,'Method','Normalized LMS', ...
    'StepSize',0.05);
firfilt2 = dsp.FIRFilter('Numerator', fir1(10,[.5, .75]));
```

```

sinewave = dsp.SineWave('Frequency',0.01, ...
    'SampleRate',1,'SamplesPerFrame',FrameSize);
scope = timescope('TimeUnits','Seconds',...
    'YLimits',[-3 3],'BufferLength',2*FrameSize*Niter, ...
    'ShowLegend',true,'ChannelNames', ...
    {'Noisy signal', 'Error signal'});

```

Create a random input signal, x and pass the signal to the FIR filter. Add a sine wave to the output of the FIR filter to generate the noisy signal, d . The signal, d is the output of the unknown system. Pass the noisy signal and the primary input signal to the LMS filter. View the noisy signal and the error signal in the time scope.

```

for k = 1:Niter
    x = randn(FrameSize,1);
    d = firfilt2(x) + sinewave();
    [y,e,w] = lmsfilt2(x,d);
    scope([d,e])
end
release(scope)

```

The error signal, e , is the sinusoidal noise added to the unknown system. Minimizing the error signal minimizes the noise added to the system.

Noise Cancellation Using Sign-Data LMS Algorithm

When the amount of computation required to derive an adaptive filter drives your development process, the sign-data variant of the LMS (SDLMS) algorithm might be a very good choice, as demonstrated in this example.

In the standard and normalized variations of the LMS adaptive filter, coefficients for the adapting filter arise from the mean square error between the desired signal and the output signal from the unknown system. The sign-data algorithm changes the mean square error calculation by using the sign of the input data to change the filter coefficients.

When the error is positive, the new coefficients are the previous coefficients plus the error multiplied by the step size μ . If the error is negative, the new coefficients are again the previous coefficients minus the error multiplied by μ — note the sign change.

When the input is zero, the new coefficients are the same as the previous set.

In vector form, the sign-data LMS algorithm is:

$$w(k+1) = w(k) + \mu e(k) \text{sgn}(x(k)),$$

where

$$\text{sgn}(x(k)) = \begin{cases} 1, & x(k) > 0 \\ 0, & x(k) = 0 \\ -1, & x(k) < 0 \end{cases}$$

with vector w containing the weights applied to the filter coefficients and vector x containing the input data. The vector e is the error between the desired signal and the filtered signal. The objective of the SDLMS algorithm is to minimize this error. Step size is represented by μ .

With a smaller μ , the correction to the filter weights gets smaller for each sample, and the SDLMS error falls more slowly. A larger μ changes the weights more for each step, so the error falls more rapidly, but the resulting error does not approach the ideal solution as closely. To ensure a good convergence rate and stability, select μ within the following practical bounds.

$$0 < \mu < \frac{1}{N\{\text{InputSignalPower}\}},$$

where N is the number of samples in the signal. Also, define μ as a power of two for efficient computing.

Note: How you set the initial conditions of the sign-data algorithm profoundly influences the effectiveness of the adaptation process. Because the algorithm essentially quantizes the input signal, the algorithm can become unstable easily.

A series of large input values, coupled with the quantization process might result in the error growing beyond all bounds. Restrain the tendency of the sign-data algorithm to get out of control by choosing a small step size ($\mu \ll 1$) and setting the initial conditions for the algorithm to nonzero positive and negative values.

In this noise cancellation example, set the Method property of `dsp.LMSFilter` to 'Sign-Data LMS'. This example requires two input data sets:

- Data containing a signal corrupted by noise. In the block diagram under “Noise or Interference Cancellation -- Using an Adaptive Filter to Remove Noise from an Unknown System”, this is the desired signal $d(k)$. The noise cancellation process removes the noise from the signal.
- Data containing random noise. In the block diagram under “Noise or Interference Cancellation -- Using an Adaptive Filter to Remove Noise from an Unknown System”, this is $x(k)$. The signal $x(k)$ is correlated with the noise that corrupts the signal data. Without the correlation between the noise data, the adapting algorithm cannot remove the noise from the signal.

For the signal, use a sine wave. Note that `signal` is a column vector of 1000 elements.

```
signal = sin(2*pi*0.055*(0:1000-1)');
```

Now, add correlated white noise to `signal`. To ensure that the noise is correlated, pass the noise through a lowpass FIR filter and then add the filtered noise to the signal.

```
noise = randn(1000,1);
filt = dsp.FIRFilter;
filt.Numerator = fir1(11,0.4);
fnoise = filt(noise);
d = signal + fnoise;
```

`fnoise` is the correlated noise and `d` is now the desired input to the sign-data algorithm.

To prepare the `dsp.LMSFilter` object for processing, set the initial conditions of the filter weights and `mu` (`StepSize`). As noted earlier in this section, the values you set for `coeffs` and `mu` determine whether the adaptive filter can remove the noise from the signal path.

In “System Identification of FIR Filter Using LMS Algorithm” on page 4-742, you constructed a default filter that sets the filter coefficients to zeros. In most cases that approach does not work for the sign-data algorithm. The closer you set your initial filter coefficients to the expected values, the more likely it is that the algorithm remains well behaved and converges to a filter solution that removes the noise effectively.

For this example, start with the coefficients used in the noise filter (`filt.Numerator`), and modify them slightly so the algorithm has to adapt.

```
coeffs = (filt.Numerator).'-0.01; % Set the filter initial conditions.
mu = 0.05; % Set the step size for algorithm updating.
```

With the required input arguments for `dsp.LMSFilter` prepared, construct the LMS filter object, run the adaptation, and view the results.

```
lms = dsp.LMSFilter(12,'Method','Sign-Data LMS',...
    'StepSize',mu,'InitialConditions',coeffs);
[~,e] = lms(noise,d);
L = 200;
plot(0:L-1,signal(1:L),0:L-1,e(1:L));
title('Noise Cancellation by the Sign-Data Algorithm');
legend('Actual signal','Result of noise cancellation',...
    'Location','NorthEast');
xlabel('Time index')
ylabel('Signal values')
```

When `dsp.LMSFilter` runs, it uses far fewer multiplication operations than either of the standard LMS algorithms. Also, performing the sign-data adaptation requires only multiplication by bit shifting when the step size is a power of two.

Although the performance of the sign-data algorithm as shown in this plot is quite good, the sign-data algorithm is much less stable than the standard LMS variations. In this noise cancellation example, the processed signal is a very good match to the input signal, but the algorithm could very easily grow without bound rather than achieve good performance.

Changing the weight initial conditions (`InitialConditions`) and μ (`StepSize`), or even the lowpass filter you used to create the correlated noise, can cause noise cancellation to fail.

Noise Cancellation Using Sign-Error LMS Algorithm

In the standard and normalized variations of the LMS adaptive filter, the coefficients for the adapting filter arise from calculating the mean square error between the desired signal and the output signal from the unknown system, and applying the result to the current filter coefficients. The sign-error LMS (SELMS) algorithm replaces the mean square error calculation by using the sign of the error to modify the filter coefficients.

When the error is positive, the new coefficients are the previous coefficients plus the error multiplied by the step size μ . If the error is negative, the new coefficients are the previous coefficients minus the error multiplied by μ — note the sign change. When the input is zero, the new coefficients are the same as the previous set.

In vector form, the sign-error LMS algorithm is:

$$w(k+1) = w(k) + \mu \text{sgn}(e(k))x(k),$$

where

$$\text{sgn}(e(k)) = \begin{cases} 1, & e(k) > 0 \\ 0, & e(k) = 0 \\ -1, & e(k) < 0 \end{cases}$$

with vector w containing the weights applied to the filter coefficients and vector x containing the input data. The vector e is the error between the desired signal and the filtered signal. The objective of the SELMS algorithm is to minimize this error.

With a smaller μ , the correction to the filter weights gets smaller for each sample and the SELMS error falls more slowly. A larger μ changes the weights more for each step so the error falls more rapidly, but the resulting error does not approach the ideal solution as closely. To ensure a good convergence rate and stability, select μ within the following practical bounds.

$$0 < \mu < \frac{1}{N\{\text{InputSignalPower}\}}$$

where N is the number of samples in the signal. Also, define μ as a power of two for efficient computation.

Note: How you set the initial conditions of the sign-error algorithm profoundly influences the effectiveness of the adaptation process. Because the algorithm essentially quantizes the error signal, the algorithm can become unstable easily.

A series of large error values, coupled with the quantization process might result in the error growing beyond all bounds. Restrain the tendency of the sign-error algorithm to become unstable by choosing a small step size ($\mu \ll 1$) and setting the initial conditions for the algorithm to nonzero positive and negative values.

In this noise cancellation example, set the Method property of `dsp.LMSFilter` to 'Sign-Error LMS'. This example requires two input data sets:

- Data containing a signal corrupted by noise. In the block diagram under “Noise or Interference Cancellation -- Using an Adaptive Filter to Remove Noise from an Unknown System”, this is the desired signal $d(k)$. The noise cancellation process removes the noise from the signal.
- Data containing random noise. In the block diagram under “Noise or Interference Cancellation -- Using an Adaptive Filter to Remove Noise from an Unknown System”, this is $x(k)$. The signal $x(k)$ is correlated with the noise that corrupts the signal data. Without the correlation between the noise data, the adapting algorithm cannot remove the noise from the signal.

For the signal, use a sine wave. Note that `signal` is a column vector of 1000 elements.

```
signal = sin(2*pi*0.055*(0:1000-1)');
```

Now, add correlated white noise to `signal`. To ensure that the noise is correlated, pass the noise through a lowpass FIR filter and then add the filtered noise to the signal.

```
noise = randn(1000,1);
filt = dsp.FIRFilter;
```

```
filt.Numerator = fir1(11,0.4);
fnoise = filt(noise);
d = signal + fnoise;
```

fnoise is the correlated noise and d is now the desired input to the sign-error algorithm.

To prepare the dsp.LMSFilter object for processing, set the initial conditions of the filter weights (InitialConditions) and mu (StepSize). As noted earlier in this section, the values you set for coeffs and mu determine whether the adaptive filter can remove the noise from the signal path.

In “System Identification of FIR Filter Using LMS Algorithm” on page 4-742, you constructed a default filter that sets the filter coefficients to zeros. In most cases that approach does not work for the sign-error algorithm. The closer you set your initial filter coefficients to the expected values, the more likely it is that the algorithm remains well behaved and converges to a filter solution that removes the noise effectively.

For this example, start with the coefficients used in the noise filter (filt.Numerator) and modify them slightly so the algorithm has to adapt.

```
coeffs = (filt.Numerator).'-0.01; % Set the filter initial conditions.
mu = 0.05; % Set the step size for algorithm updating.
```

With the required input arguments for dsp.LMSFilter prepared, run the adaptation and view the results.

```
lms = dsp.LMSFilter(12,'Method','Sign-Error LMS',...
    'StepSize',mu,'InitialConditions',coeffs);
[~,e] = lms(noise,d);
L = 200;
plot(0:199,signal(1:200),0:199,e(1:200));
title('Noise cancellation performance by the sign-error LMS algorithm');
legend('Actual signal','Error after noise reduction',...
    'Location','NorthEast')
xlabel('Time index')
ylabel('Signal value')
```

When the sign-error LMS algorithm runs, it uses far fewer multiplication operations than either of the standard LMS algorithms. Also, performing the sign-error adaptation requires only bit shifting multiples when the step size is a power of two.

Although the performance of the sign-error algorithm as shown in this plot is quite good, the sign-error algorithm is much less stable than the standard LMS variations. In this noise cancellation example, the adapted signal is a very good match to the input signal, but the algorithm could very easily become unstable rather than achieve good performance.

Changing the weight initial conditions (`InitialConditions`) and μ (`StepSize`), or even the lowpass filter you used to create the correlated noise, can cause noise cancellation to fail and the algorithm to become useless.

Noise Cancellation Using Sign-Sign LMS Algorithm

The sign-sign LMS algorithm (SSLMS) replaces the mean square error calculation by using the sign of the input data to change the filter coefficients. When the error is positive, the new coefficients are the previous coefficients plus the error multiplied by the step size μ . If the error is negative, the new coefficients are the previous coefficients minus the error multiplied by μ — note the sign change. When the input is zero, the new coefficients are the same as the previous set.

In essence, the algorithm quantizes both the error and the input by applying the sign operator to them.

In vector form, the sign-sign LMS algorithm is:

$$w(k+1) = w(k) + \mu \text{sgn}(e(k)) \text{sgn}(x(k)),$$

where

$$\text{sgn}(z(k)) = \begin{cases} 1, & z(k) > 0 \\ 0, & z(k) = 0 \\ -1, & z(k) < 0 \end{cases}$$

$$z(k) = e(k) \text{sgn}(x(k))$$

Vector w contains the weights applied to the filter coefficients and vector x contains the input data. The vector e is the error between the desired signal and the filtered signal. The objective of the SSLMS algorithm is to minimize this error.

With a smaller μ , the correction to the filter weights gets smaller for each sample and the SSLMS error falls more slowly. A larger μ changes the weights more for each step, so the error falls more rapidly, but the resulting error does not approach the ideal solution as closely. To ensure a good convergence rate and stability, select μ within the following practical bounds.

$$0 < \mu < \frac{1}{N\{\text{InputSignalPower}\}}$$

where N is the number of samples in the signal. Also, define μ as a power of two for efficient computation

Note:

How you set the initial conditions of the sign-sign algorithm profoundly influences the effectiveness of the adaptation process. Because the algorithm essentially quantizes the input signal and the error signal, the algorithm can become unstable easily.

A series of large error values, coupled with the quantization process might result in the error growing beyond all bounds. Restrain the tendency of the sign-sign algorithm to become unstable by choosing a small step size ($\mu \ll 1$) and setting the initial conditions for the algorithm to nonzero positive and negative values.

In this noise cancellation example, set the `Method` property of `dsp.LMSFilter` to 'Sign-Sign LMS'. This example requires two input data sets:

- Data containing a signal corrupted by noise. In the block diagram under "Noise or Interference Cancellation -- Using an Adaptive Filter to Remove Noise from an Unknown System", this is the desired signal $d(k)$. The noise cancellation process removes the noise from the signal.
- Data containing random noise. In the block diagram under "Noise or Interference Cancellation -- Using an Adaptive Filter to Remove Noise from an Unknown System", this is $x(k)$. The signal $x(k)$ is correlated with the noise that corrupts the signal data. Without the correlation between the noise data, the adapting algorithm cannot remove the noise from the signal.

For the signal, use a sine wave. Note that `signal` is a column vector of 1000 elements.

```
signal = sin(2*pi*0.055*(0:1000-1)');
```

Now, add correlated white noise to `signal`. To ensure that the noise is correlated, pass the noise through a lowpass FIR filter, then add the filtered noise to the signal.

```
noise = randn(1000,1);
filt = dsp.FIRFilter;
filt.Numerator = fir1(11,0.4);
fnoise = filt(noise);
d = signal + fnoise;
```

`fnoise` is the correlated noise and `d` is now the desired input to the sign-sign algorithm.

To prepare the `dsp.LMSFilter` object for processing, set the initial conditions of the filter weights (`InitialConditions`) and `mu` (`StepSize`). As noted earlier in this section, the values you set for `coeffs` and `mu` determine whether the adaptive filter can remove the noise from the signal path. In “System Identification of FIR Filter Using LMS Algorithm” on page 4-742, you constructed a default filter that sets the filter coefficients to zeros. Usually that approach does not work for the sign-sign algorithm.

The closer you set your initial filter coefficients to the expected values, the more likely it is that the algorithm remains well behaved and converges to a filter solution that removes the noise effectively. For this example, you start with the coefficients used in the noise filter (`filt.Numerator`), and modify them slightly so the algorithm has to adapt.

```
coeffs = (filt.Numerator).' -0.01; % Set the filter initial conditions.
mu = 0.05;
```

With the required input arguments for `dsp.LMSFilter` prepared, run the adaptation and view the results.

```
lms = dsp.LMSFilter(12,'Method','Sign-Sign LMS',...
    'StepSize',mu,'InitialConditions',coeffs);
[~,e] = lms(noise,d);
L = 200;
plot(0:199,signal(1:200),0:199,e(1:200));
title('Noise cancellation performance by the sign-sign LMS algorithm');
legend('Actual signal','Error after noise reduction',...
    'Location','NorthEast')
xlabel('Time index')
ylabel('Signal value')
```

When `dsp.LMSFilter` runs, it uses far fewer multiplication operations than either of the standard LMS algorithms. Also, performing the sign-sign adaptation requires only bit shifting multiples when the step size is a power of two.

Although the performance of the sign-sign algorithm as shown in this plot is quite good, the sign-sign algorithm is much less stable than the standard LMS variations. In this noise cancellation example, the adapted signal is a very good match to the input signal, but the algorithm could very easily become unstable rather than achieve good performance.

Changing the weight initial conditions (`InitialConditions`) and μ (`StepSize`), or even the lowpass filter you used to create the correlated noise, can cause noise cancellation to fail and the algorithm to become useless.

Access Full History of LMS Filter Weights

Note: This example runs only in R2017a or later. If you are using a release earlier than R2017a, the object does not output a full sample-by-sample history of filter weights. If you are using a release earlier than R2016b, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Initialize the `dsp.LMSFilter` System object and set the `WeightsOutput` property to `'All'`. This setting enables the LMS filter to output a matrix of weights with dimensions `[FrameLength Length]`, corresponding to the full sample-by-sample history of weights for all `FrameLength` samples of input values.

```
FrameSize = 15000;
lmsfilt3 = dsp.LMSFilter('Length',63,'Method','LMS', ...
    'StepSize',0.001,'LeakageFactor',0.99999, ...
    'WeightsOutput','All'); % full Weights history

w_actual = fir1(64,[0.5 0.75]);
firfilt3 = dsp.FIRFilter('Numerator',w_actual);
sinewave = dsp.SineWave('Frequency',0.01, ...
    'SampleRate',1,'SamplesPerFrame',FrameSize);

scope = timescope('TimeUnits','Seconds', ...
    'YLimits',[-0.25 0.75],'BufferLength',2*FrameSize, ...
    'ShowLegend',true,'ChannelNames', ...
    {'Coeff 33 Estimate','Coeff 34 Estimate','Coeff 35 Estimate', ...
    'Coeff 33 Actual','Coeff 34 Actual','Coeff 35 Actual'});
```

Run one frame and output the full adaptive weights history, w.

```
x = randn(FrameSize,1); % Input signal
d = firfilt3(x) + sinewave(); % Noise + Signal
[~,~,w] = lmsfilt3(x,d);
```

Each row in w is a set of weights estimated for the respective input sample. Each column in w gives the complete history of a specific weight. Plot the actual weight and the entire history of the 33rd, 34th, and 35th weight. In the plot, you can see that the estimated weight output eventually converges with the actual weight as the adaptive filter receives input samples and continues to adapt.

```
idxBeg = 33;
idxEnd = 35;
scope([w(:,idxBeg:idxEnd), repmat(w_actual(idxBeg:idxEnd),FrameSize,1)])
```

More About

Fixed Point

The following diagrams show the data types used within the `dsp.LMSFilter` object for fixed-point signals. The table summarizes the definitions of the variables used in the diagrams:

Variable	Definition
\mathbf{u}	Input vector
\mathbf{W}	Vector of filter weights
μ	Step size
e	Error
Q	Quotient, $Q = \frac{\mu \cdot e}{\mathbf{u}'\mathbf{u}}$
Product $\mathbf{u}'\mathbf{u}$	Product data type in Energy calculation diagram
Accumulator $\mathbf{u}'\mathbf{u}$	Accumulator data type in Energy calculation diagram
Product $\mathbf{W}'\mathbf{u}$	Product data type in Convolution diagram
Accumulator $\mathbf{W}'\mathbf{u}$	Accumulator data type in Convolution diagram
Product $\mu \cdot e$	Product data type in Product of step size and error diagram

Variable	Definition
Product $Q \cdot u$	Product and accumulator data type in Weight update diagram. ¹

¹The accumulator data type for this quantity is automatically set to be the same as the product data type. The minimum, maximum, and overflow information for this accumulator is logged as part of the product information. Autoscaling treats this product and accumulator as one data type.

Energy calculation (for normalized LMS algorithm only)

Convolution

Output error signal

Product of step size and error (for LMS and Sign-Data LMS algorithms only)**Quotient (for normalized LMS only)****Weight update**

You can set the data type of the properties, weights, products, quotient, and accumulators in the System object properties. Fixed-point inputs, outputs, and System object properties must have the following characteristics:

- The input signal and the desired signal must have the same word length, but their fraction lengths can differ.
- The step size and leakage factor must have the same word length, but their fraction lengths can differ.
- The output signal and the error signal have the same word length and the same fraction length as the desired signal.
- The quotient and the product output of the $\mathbf{u}'\mathbf{u}$, $\mathbf{W}'\mathbf{u}$, $\mu \cdot e$, and $Q \cdot \mathbf{u}$ operations must have the same word length, but their fraction lengths can differ.
- The accumulator data type of the $\mathbf{u}'\mathbf{u}$ and $\mathbf{W}'\mathbf{u}$ operations must have the same word length, but their fraction lengths can differ.

The output of the multiplier is in the product output data type if at least one of the inputs to the multiplier is real. If both of the inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”.

Algorithms

The LMS filter algorithm is defined by the following equations.

$$\begin{aligned}y(n) &= \mathbf{w}^T(n-1)\mathbf{u}(n) \\e(n) &= d(n) - y(n) \\ \mathbf{w}(n) &= \alpha\mathbf{w}(n-1) + f(\mathbf{u}(n), e(n), \mu)\end{aligned}$$

The various LMS adaptive filter algorithms available in this System object are defined as:

- LMS -- Solves the Wiener-Hopf equation and finds the filter coefficients for an adaptive filter.

$$f(\mathbf{u}(n), e(n), \mu) = \mu e(n)\mathbf{u}^*(n)$$

- Normalized LMS -- Normalized variation of the LMS algorithm.

$$f(\mathbf{u}(n), e(n), \mu) = \mu e(n) \frac{\mathbf{u}^*(n)}{\varepsilon + \mathbf{u}^H(n)\mathbf{u}(n)}$$

In Normalized LMS, to overcome potential numerical instability in the update of the weights, a small positive constant, ε , has been added in the denominator. For double-precision floating-point input, ε is the output of the `eps` function. For single-precision floating-point input, ε is the output of `eps('single')`. For fixed-point input, ε is 0.

- Sign-Data LMS -- Correction to the filter weights at each iteration depends on the sign of the input $\mathbf{u}(n)$.

$$f(\mathbf{u}(n), e(n), \mu) = \mu e(n)\text{sign}(\mathbf{u}(n))$$

where $\mathbf{u}(n)$ is real.

- Sign-Error LMS -- Correction applied to the current filter weights for each successive iteration depends on the sign of the error, $e(n)$.

$$f(\mathbf{u}(n), e(n), \mu) = \mu \text{sign}(e(n))\mathbf{u}^*(n)$$

- Sign-Sign LMS -- Correction applied to the current filter weights for each successive iteration depends on both the sign of $\mathbf{u}(n)$ and the sign of $e(n)$.

$$f(\mathbf{u}(n), e(n), \mu) = \mu \text{sign}(e(n))\text{sign}(\mathbf{u}(n))$$

where $\mathbf{u}(n)$ is real.

The variables are as follows:

Variable	Description
n	The current time index
$\mathbf{u}(n)$	The vector of buffered input samples at step n
$\mathbf{u}^*(n)$	The complex conjugate of the vector of buffered input samples at step n
$\mathbf{w}(n)$	The vector of filter weight estimates at step n
$y(n)$	The filtered output at step n
$e(n)$	The estimation error at step n
$d(n)$	The desired response at step n

Variable	Description
μ	The adaptation step size
α	The leakage factor ($0 < \alpha \leq 1$)
ε	A constant that corrects any potential numerical instability that occurs during the update of weights.

Version History

Introduced in R2012a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

The dsp.LMSFilter System object supports SIMD code generation using Intel AVX2 technology under these conditions:

- Method is set to 'LMS' or 'Normalized LMS'.
- WeightsOutput is set to 'None' or 'Last'.
- Input signal is real-valued.
- Input signal has a data type of single or double.

The SIMD technology significantly improves the performance of the generated code.

dsp.LogicAnalyzer

Package: dsp

Visualize, measure, and analyze transitions and states over time

Description

The Logic Analyzer System object displays the transitions in time-domain signals. Using `dsp.LogicAnalyzer`, you can:

- Debug and analyze models
- Trace and correlate 96 signals simultaneously
- Detect and analyze timing violations
- Trace system execution
- Detect signal changes using triggers

To display the transitions of signals in the Logic Analyzer:

- 1** Create the `dsp.LogicAnalyzer` object and set its properties.
- 2** Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

For more information about how to configure and customize the Logic Analyzer, see **Logic Analyzer**.

Creation

Syntax

```
scope = dsp.LogicAnalyzer
scope = dsp.LogicAnalyzer(Name,Value)
```

Description

`scope = dsp.LogicAnalyzer` creates a Logic Analyzer System object, `scope`.

`scope = dsp.LogicAnalyzer(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes. For example, `scope = dsp.LogicAnalyzer('BackgroundColor','White','NumInputPorts',4)`.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

BackgroundColor — Background color for display

'Black' (default) | 'White'

Background color of the display, specified as 'Black' or 'White'.

Tunable: Yes

Data Types: char | string

DisplayChannelColor — Color for channels in display

[0.0588 1 1] (default) | RGB triplet

Color for channels in the display, specified as an RGB triplet.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0,1]; for example, [0.4 0.6 0.7].

Tunable: Yes

Data Types: double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

DisplayChannelFontSize — Font size for channels in display

10 (default) | nonnegative scalar integer

Font size for channels in the display, in points, specified as a nonnegative integer.

Tunable: Yes

Data Types: double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

DisplayChannelFormat — Format for channels in display

'Automatic' (default) | 'Analog' | 'Digital'

Format for channels in the display, specified as one of the following:

- 'Automatic' — Displays floating-point signals in `Analog` format and integer and fixed-point signals in `Digital` format. Boolean signals are displayed as zero or one.
- 'Analog' — Shows values as an analog plot.
- 'Digital' — Shows values as digital transitions.

Tunable: Yes

Data Types: char | string

DisplayChannelHeight — Channel height in display

12 (default) | positive real scalar

Channel height in the display, in pixels, specified as a positive real scalar in the range [8, 200].

Tunable: Yes

Data Types: double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

DisplayChannelRadix — Base used to display values

'Hexadecimal' (default) | 'Binary' | 'Octal' | 'Signed decimal' | 'Unsigned decimal'

This property applies only to fixed-point (fi) values.

Tunable: Yes

Data Types: char | string

DisplayChannelSpacing — Spacing between channels in display (pixels)

4 (default) | positive integer

Spacing between channels in the display, in pixels, specified as a positive scalar integer.

Tunable: Yes

Data Types: double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

Name — Caption to display on scope window

'Logic Analyzer' (default) | character vector | string scalar

Caption to display on the scope window, specified as a character vector or string.

Tunable: Yes

Data Types: char | string

NumInputPorts — Number of input ports

1 (default) | integer between [1, 96]

Number of input ports, specified as a positive integer. Each signal coming through a separate input becomes a separate channel in the scope. You must invoke the scope with the same number of inputs as the value of this property.

Position — Scope window position

[left bottom width height] vector

Position of the scope window on your screen, in pixels, specified as a [left bottom width height] vector. The default position depends on your screen resolution. By default, the scope window appears in the center of your screen, with a width of 800 pixels and height of 600 pixels.

Tunable: Yes

Data Types: double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

SampleTime — Input sample time

1 (default) | scalar

Sample time of inputs in seconds, specified as a finite numeric scalar. The same sample time is used for all inputs.

Data Types: double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

TimeDisplayOffset — Time display offset

0 (default) | nonnegative scalar

Time display offset in seconds, specified as a nonnegative scalar.

Tunable: Yes

Data Types: double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

TimeSpan — Time span

10 | positive scalar

Time span in seconds, specified as a positive scalar. The x-axis limits are calculated as follows:

- Minimum x-axis limit = `min(TimeDisplayOffset)`
- Maximum x-axis limit = `max(TimeDisplayOffset) + TimeSpan`

`TimeDisplayOffset` and `TimeSpan` are the values of their respective properties.

Tunable: Yes

Data Types: double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

Usage

Syntax

```
scope(signal)
scope(signal1,signal2,...signalN)
```

Description

`scope(signal)` displays the signal `signal` in the Logic Analyzer scope.

`scope(signal1,signal2,...signalN)` displays multiple signals in the Logic Analyzer when you set the `NumInputPorts` property to `N`. Each signal can have different data types and dimensions.

Input Arguments

signal — Input signal or signals to visualize

scalar | vector | matrix

Specify one or more input signals to visualize in the `dsp.LogicAnalyzer`. Signals can have different data types and dimensions.

Integers are supported up to 64 bits and fixed-point signals are supported up to 128 bits.

Example: `scope(signal1,signal2)`

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | logical | struct | table | cell

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.LogicAnalyzer

addCursor	Add cursor to Logic Analyzer
addDivider	Add divider to Logic Analyzer
addWave	Add wave to Logic Analyzer
deleteCursor	Delete Logic Analyzer cursor
deleteDisplayChannel	Delete Logic Analyzer channel
getCursorInfo	Return settings for Logic Analyzer cursor
getCursorTags	Return all Logic Analyzer cursor tags
getDisplayChannelInfo	Return settings for Logic Analyzer display channel
getDisplayChannelTags	Return all Logic Analyzer display channel tags
modifyCursor	Modify properties of Logic Analyzer cursor
modifyDisplayChannel	Modify properties of Logic Analyzer display channel
moveDisplayChannel	Move position of Logic Analyzer display channel

Specific to Scopes

show	Display scope window
hide	Hide scope window
isVisible	Determine visibility of scope

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Display Simple Ramp Signals

Create a dsp.LogicAnalyzer object. Call the scope in a loop to display the signals.

```
scope = dsp.LogicAnalyzer('NumInputPorts',3);  
for ii = 1:20  
    scope(ii,10*ii,20*ii);  
end
```

Display Fixed-Point Signals

Create a `dsp.LogicAnalyzer` object with four channels. Call `modifyDisplayChannel` to set the radix of each of the channels. Run the scope in a loop to display the waves.

```
scope = dsp.LogicAnalyzer('NumInputPorts',4,'DisplayChannelFormat','Digital');
scope.TimeSpan = 12;
```

```
modifyDisplayChannel(scope,1,'Name','Index','Radix','Unsigned decimal');
modifyDisplayChannel(scope,2,'Name','Fi_hex','Radix','Hexadecimal');
modifyDisplayChannel(scope,3,'Name','Fi_bin','Radix','Binary');
modifyDisplayChannel(scope,4,'Name','Fi_actual','Radix','Signed decimal');
```

```
for ii = 1:20
    fival = fi((ii-1)/16,0,4,4);
    scope(ii,fival,fival,fival);
end
```

Display Vector, Complex, and Enumerated Signals

Define a `WeekDaysInt` class to hold an enumerated list of weekday values. Create and save the following class definition file.

```
classdef WeekDaysInt < int32
    enumeration
        Monday(1), Tuesday(2), Wednesday(3), Thursday(4), Friday(5)
    end
end
```

Create a `dsp.LogicAnalyzer` object and configure the vector, complex, and enumerated data signals.

```
scope = dsp.LogicAnalyzer('NumInputPorts',6);
waves = getDisplayChannelTags(scope);

modifyDisplayChannel(scope,waves{1},'InputChannel',1,'Name','Vector Digital');
```

```

modifyDisplayChannel(scope,waves{2},'InputChannel',2,'Name','Vector Analog',...
    'Format','Analog','Height',80);
modifyDisplayChannel(scope,waves{3},'InputChannel',3,'Name','Complex Digital');
modifyDisplayChannel(scope,waves{4},'InputChannel',4,'Name','Complex Analog',...
    'Format','Analog','Height',80,'Color','Green');
modifyDisplayChannel(scope,waves{5},'InputChannel',5,'Name','Enum Digital');
modifyDisplayChannel(scope,waves{6},'InputChannel',6,'Name','Enum Analog',...
    'Format','Analog','Height',80);

```

Call the scope object in a loop to display the signals.

```

stop = 30;
for count = 1:stop
    sinValVec      = sin(count/stop*2*pi);
    cosValVec      = cos(count/stop*2*pi);
    cosValVecOffset = cos((count+10)/stop*2*pi);
    sinValReal     = sin((count+2)/stop*2*pi);
    cosValImag     = cos((count+2)/stop*2*pi);

    % Create a weekday enumerated value by wrapping the index
    day = WeekDaysInt(1+mod(count-1,5));

    scope(...
        [count (count-(stop/2))],...           % digital vector
        [sinValVec cosValVec cosValVecOffset],... % analog vector
        complex((count-(stop/2)),count),...   % digital complex
        complex(sinValReal, cosValImag),...   % analog complex
        day,...                               % digital enum
        day...                               % analog enum
    )
end

```

Tips

To close the logic analyzer window and clear its associated data, use the MATLAB `clear` function.

dsp.LowerTriangularSolver

Package: dsp

(To be removed) Solve lower-triangular matrix equation

Note `dsp.LowerTriangularSolver` will be removed in a future release. Use the `mldivide` function or the `\` operator instead. For more information, see “Compatibility Considerations”.

Description

The `LowerTriangularSolver` object solves $LX = B$ for X when L is a square, lower-triangular matrix with the same number of rows as B .

To solve $LX = B$ for X :

- 1 Create the `dsp.LowerTriangularSolver` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
lowtriang = dsp.LowerTriangularSolver  
lowtriang = dsp.LowerTriangularSolver(Name,Value)
```

Description

`lowtriang = dsp.LowerTriangularSolver` returns a linear system solver, `lowtriang`, used to solve the linear system $LX = B$, where L is a lower (or unit-lower) triangular matrix.

`lowtriang = dsp.LowerTriangularSolver(Name,Value)` returns a linear system solver, `lowtriang`, with each specified property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

OverwriteDiagonal — Replace diagonal elements of input with ones

false (default) | true

When you set this property to `true`, the linear system solver replaces the elements on the diagonal of the input, L , with ones. This property is useful when matrix L is the result of another operation, such as an LDL decomposition, that uses the diagonal elements to represent the D matrix.

RealDiagonalElements — Indicate that diagonal of complex input is real

`false` (default) | `true`

When you set this property to `true`, the linear system solver optimizes computation speed if the input L is complex, but its diagonal elements are real. Set this property to either `true` or `false`.

Dependencies

This property applies only when you set the `OverwriteDiagonal` property to `false`.

Fixed-Point Properties

RoundingMethod — Rounding method for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`.

OverflowAction — Overflow action for fixed-point operations

`Wrap` (default) | `Saturate`

Specify the overflow action as `Wrap` or `Saturate`.

ProductDataType — Data type of product

`Full precision` (default) | `Same as input` | `Custom`

Specify the product data type as `Full precision`, `Same as input`, or `Custom`.

CustomProductDataType — Product word and fraction lengths

`numerictype([],32,30)` (default) | `numerictype`

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies only when you set the `ProductDataType` property to `Custom`.

AccumulatorDataType — Data type of accumulator

`Full precision` (default) | `Same as first input` | `Same as product` | `Custom`

Specify the accumulator data type as `Full precision`, `Same as first input`, `Same as product`, or `Custom`.

CustomAccumulatorDataType — Accumulator word and fraction lengths

`numerictype([],32,30)` (default) | `numerictype`

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies only when you set the `AccumulatorDataType` property to `Custom`.

OutputDataType — Data type of output

Same as first input (default) | Custom

Specify the output data type as Same as first input or Custom.

CustomOutputDataType — Output word and fraction lengths

numericType([],16,15) (default) | numericType

Specify the output fixed-point type as a scaled numericType object with a Signedness of Auto.

Dependencies

This property applies only when you set the OutputDataType property to Custom.

Usage**Syntax**`X = lowtriang(L,B)`**Description**

`X = lowtriang(L,B)` computes the solution, X , of the matrix equation $LX = B$, where L is a square, lower-triangular matrix with the same number of rows as the matrix B .

Input Arguments**L — Lower-triangular matrix**

matrix

Lower-triangular square matrix of size M -by- M .

If the matrix is of fixed-point data type, it must be signed fixed point.

Data Types: single | double | int8 | int16 | int32 | int64 | fi

B — Input B

vector | matrix

Input B in the equation $LX = B$, where B is an M -by- N matrix.

If the matrix is of fixed-point data type, it must be signed fixed point.

Data Types: single | double | int8 | int16 | int32 | int64 | fi

Output Arguments**X — Solution of the equation**

vector | matrix

Solution of the $LX = B$ equation, returned as an M -by- N output matrix. The object uses only the elements in the lower triangle of input L and ignores the upper elements. When you set `OverwriteDiagonal` to `true`, the object replaces the elements on the diagonal of the input, L , with ones.

If the matrix is of fixed-point data type, it must be signed fixed point.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Solve a Lower Triangular Matrix

Note If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

```
rng(1);
lowtriang = dsp.LowerTriangularSolver;
u = tril(rand(4,4));
b = rand(4,1);
```

Check that result is the solution to the linear equations.

```
x1 = u\b
```

```
x1 = 4×1
```

```
    1.0007
   -1.7557
    1.1148
   -0.3901
```

```
x = lowtriang(u,b)
```

```
x = 4×1
```

```
    1.0007
   -1.7557
    1.1148
   -0.3901
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Forward Substitution block reference page. The object properties correspond to the block parameters.

Version History

Introduced in R2012a

dsp.LowerTriangularSolver System object will be removed

Warns starting in R2021b

`dsp.LowerTriangularSolver` System object will be removed in a future release. Use the `mldivide` function or the `\` operator instead.

Update Code

This table shows how the System object is typically used and explains how to update existing code to use the `mldivide` function or the `\` operator.

Discouraged Usage	Recommended Replacement
<pre>rng(1); lowtriang = dsp.LowerTriangularSolver; u = tril(rand(4,4)); b = rand(4,1); x = lowtriang(u,b) x = 4x1 1.0007 -1.7557 1.1148 -0.3901</pre> <p>If you are using a release prior to R2016b, replace <code>lowtriang(x)</code> with <code>step(lowtriang,x)</code>.</p>	<pre>x1 = u\b x1 = 4x1 1.0007 -1.7557 1.1148 -0.3901</pre> <p>Alternatively, you can also use the <code>mldivide</code> function.</p> <pre>x1 = mldivide(u,b) x1 = 4x1 1.0007 -1.7557 1.1148 -0.3901</pre>

dsp.LowpassFilter

Package: dsp

FIR or IIR lowpass filter

Description

The `dsp.LowpassFilter` object independently filters each channel of the input over time using the given design specifications. You can set the `FilterType` property of `dsp.LowpassFilter` to 'FIR' or 'IIR' to implement the object as a FIR or IIR lowpass filter.

To filter each channel of your input:

- 1 Create the `dsp.LowpassFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
LPF = dsp.LowpassFilter
LPF = dsp.LowpassFilter(Name,Value)
```

Description

`LPF = dsp.LowpassFilter` returns a minimum order FIR lowpass filter, `LPF`, with the default filter settings. Calling the object with the default property settings filters the input data with a passband frequency of 8 kHz, a stopband frequency of 12 kHz, a passband ripple of 0.1 dB, and a stopband attenuation of 80 dB.

`LPF = dsp.LowpassFilter(Name,Value)` returns a lowpass filter, with additional properties specified by one, or more `Name,Value` pair arguments. `Name` is the property name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

SampleRate — Input sample rate
44100 (default) | real positive scalar

Input sample rate in Hz, specified as the comma-separated pair consisting of 'SampleRate' and a real positive scalar.

Data Types: `single` | `double`

FilterType – Filter type

'FIR' (default) | 'IIR'

Filter type, specified as one of the following options:

- 'FIR' — The object designs an FIR lowpass filter.
- 'IIR' — The object designs an IIR lowpass (biquad) filter.

DesignForMinimumOrder – Minimum order filter design

`true` (default) | `false`

Minimum order filter design, specified as the comma-separated pair consisting of 'DesignForMinimumOrder' and a logical value. If this property is `true`, then `dsp.LowpassFilter` designs filters with the minimum order that meets the passband frequency, stopband frequency, passband ripple, and stopband attenuation specifications. Set these specifications using the corresponding properties. If this property is `false`, then the object designs filters with the order that you specify in the `FilterOrder` property. This filter design meets the passband frequency, passband ripple, and stopband attenuation specifications that you set using the respective properties.

FilterOrder – Order of the FIR or IIR filter

50 (default) | positive integer scalar

Order of the FIR or IIR filter, specified as the comma-separated pair consisting of 'FilterOrder' and a positive integer scalar.

Dependencies

Specifying a filter order is only valid when the value of 'DesignForMinimumOrder' is `false`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

PassbandFrequency – Filter passband edge frequency

8000 (default) | real positive scalar

Filter passband edge frequency in Hz, specified as the comma-separated pair of 'PassbandFrequency' and a real positive scalar. The value of the passband edge frequency in Hz must be less than half the `SampleRate`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

StopbandFrequency – Filter stopband edge frequency

12000 (default) | real positive scalar

Filter stopband edge frequency in Hz, specified as the comma-separated pair consisting of 'StopbandFrequency' and a real positive scalar. The value of the stopband edge frequency in Hz must be less than half the `SampleRate`.

Dependencies

You can specify the stopband edge frequency only when 'DesignForMinimumOrder' is `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

PassbandRipple — Maximum ripple of filter response in the passband

0.1 (default) | real positive scalar

Maximum ripple of filter response in the passband, in dB, specified as the comma-separated pair consisting of 'PassbandRipple' and a real positive scalar. Maximum ripple of filter response defaults to 0.1 dB.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

StopbandAttenuation — Minimum attenuation in the stopband

80 (default) | real positive scalar

Minimum attenuation in the stopband in dB, specified as the comma-separated pair consisting of 'StopbandAttenuation' and a real positive scalar. Minimum attenuation in the stopband defaults to 80 dB.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Fixed-Point Properties

RoundingMethod — Rounding method for output fixed-point operations

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see "Precision and Range".

CoefficientsDataType — Word and fraction lengths of coefficients

`numericType(1,16)` (default) | `numericType` object

Word and fraction lengths of coefficients, specified as a `numericType` object. The default, `numericType(1,16)` corresponds to a signed numeric type object with 16-bit coefficients and a fraction length determined based on the coefficient values, to give the best possible precision.

This property is not tunable.

Word length of the output is same as the word length of the input. Fraction length of the output is computed such that the entire dynamic range of the output can be represented without overflow. For details on how the fraction length of the output is computed, see "Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters".

Usage

Syntax

$y = \text{LPF}(x)$

Description

$y = \text{LPF}(x)$ lowpass filters the input signal, x . y is a lowpass-filtered version of x .

Input Arguments

x — Noisy data input

vector | matrix

Noisy data input, specified as a vector or a matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel. The number of rows in the input signal denote the channel length. This object accepts variable-size inputs. After the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Output Arguments

y — Filtered output

vector | matrix

Filtered output, returned as a vector or a matrix. The output has the same size, data type, and complexity characteristics as the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.LowpassFilter`

<code>freqz</code>	Frequency response of discrete-time filter System object
<code>fvtool</code>	Visualize frequency response of DSP filters
<code>impz</code>	Impulse response of discrete-time filter System object
<code>info</code>	Information about filter System object
<code>coeffs</code>	Returns the filter System object coefficients in a structure
<code>cost</code>	Estimate cost of implementing filter System object
<code>grpdelay</code>	Group delay response of discrete-time filter System object
<code>generatehdl</code>	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)
<code>measure</code>	Measure frequency response characteristics of filter System object

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Impulse and Frequency Response of FIR and IIR Lowpass Filters

Create a minimum-order FIR lowpass filter for data sampled at 44.1 kHz. Specify a passband frequency of 8 kHz, a stopband frequency of 12 kHz, a passband ripple of 0.1 dB, and a stopband attenuation of 80 dB.

```
Fs = 44.1e3;
filtertype = 'FIR';
Fpass = 8e3;
Fstop = 12e3;
Rp = 0.1;
Astop = 80;
FIRLPF = dsp.LowpassFilter('SampleRate',Fs, ...
                           'FilterType',filtertype, ...
                           'PassbandFrequency',Fpass, ...
                           'StopbandFrequency',Fstop, ...
                           'PassbandRipple',Rp, ...
                           'StopbandAttenuation',Astop);
```

Design a minimum-order IIR lowpass filter with the same properties as the FIR lowpass filter. Change the `FilterType` property of the cloned filter to IIR.

```
IIRLPF = clone(FIRLPF);
IIRLPF.FilterType = 'IIR';
```

Plot the impulse response of the FIR lowpass filter. The zeroth-order coefficient is delayed by 19 samples, which is equal to the group delay of the filter. The FIR lowpass filter is a causal FIR filter.

```
fvtool(FIRLPF,'Analysis','impulse')
```

Plot the impulse response of the IIR lowpass filter.

```
fvtool(IIRLPF, 'Analysis', 'impulse')
```

Plot the magnitude and phase response of the FIR lowpass filter.

```
fvtool(FIRLPF, 'Analysis', 'freq')
```

Plot the magnitude and phase response of the IIR lowpass filter.

```
fvtool(IIRLPF, 'Analysis', 'freq')
```

Calculate the cost of implementing the FIR lowpass filter.

```
cost(FIRLPF)
```

```
ans = struct with fields:
    NumCoefficients: 39
    NumStates: 38
    MultiplicationsPerInputSample: 39
    AdditionsPerInputSample: 38
```

Calculate the cost of implementing the IIR lowpass filter. The IIR filter is more efficient to implement than the FIR filter.

```
cost(IIRLPF)
```

```
ans = struct with fields:
    NumCoefficients: 18
    NumStates: 14
    MultiplicationsPerInputSample: 18
    AdditionsPerInputSample: 14
```

Calculate the group delay of the FIR lowpass filter.

```
grpdelay(FIRLPF)
```

Calculate the group delay of the IIR lowpass filter. The FIR filter has a constant group delay (linear phase), while its IIR counterpart does not.

```
grpdelay(IIRLPF)
```

Filter White Gaussian Noise Signal With Lowpass Filter

Create a lowpass filter with default properties.

```
LPF = dsp.LowpassFilter;
```

Create a spectrumAnalyzer object.

```
SA = spectrumAnalyzer('SampleRate',44.1e3,...
    'PlotAsTwoSidedSpectrum',false,'ShowLegend',true,'YLimits',...
    [-150 30],...
    'Title',...
    'Input Signal and Output Signal of Lowpass Filter');
SA.ChannelNames = {'Input','Output'};
```

Run the lowpass filter algorithm to filter the white Gaussian noisy input signal. View the input and output signals using the spectrum analyzer.

```
for k = 1:100
    Input = randn(1024,1);

    Output = LPF(Input);

    SA([Input,Output]);
end
```

Filter White Gaussian Noise

Set up the IIR lowpass filter. The sampling rate of the white Gaussian noise is 44,100 Hz. The passband frequency of the filter is 8 kHz, the stopband frequency is 12 kHz, the passband ripple is 0.1 dB, and the stopband attenuation is 80 dB.

```

Fs = 44.1e3;
filtertype = 'IIR';
Fpass = 8e3;
Fstop = 12e3;
Rp = 0.1;
Astop = 80;
LPF = dsp.LowpassFilter('SampleRate',Fs,...
    'FilterType',filtertype,...
    'PassbandFrequency',Fpass,...
    'StopbandFrequency',Fstop,...
    'PassbandRipple',Rp,...
    'StopbandAttenuation',Astop);

```

View the magnitude response of the lowpass filter.

```
fvtool(LPf)
```

Create a spectrum analyzer object.

```
SA = spectrumAnalyzer('SampleRate',44.1e3,...
    'PlotAsTwoSidedSpectrum',false,...
    'ShowLegend',true,'YLimits',[-150 30],...
    'Title','Input Signal and Output Signal of IIR Lowpass Filter');
SA.ChannelNames = {'Input','Output'};
```

Filter the white Gaussian noisy input signal. View the input and output signals using the spectrum analyzer.

```
for k = 1:100
    Input = randn(1024,1);

    Output = LPF(Input);

    SA([Input,Output]);
end
```

Measure Frequency Response Characteristics of Lowpass Filter

Measure the frequency response characteristics of a lowpass filter. Create a `dsp.LowpassFilter` System object with default properties. Measure the frequency response characteristics of the filter.

```
LPF = dsp.LowpassFilter
```

```
LPF =  
  dsp.LowpassFilter with properties:
```

```
      FilterType: 'FIR'  
  DesignForMinimumOrder: true  
    PassbandFrequency: 8000  
    StopbandFrequency: 12000  
      PassbandRipple: 0.1000  
    StopbandAttenuation: 80  
      SampleRate: 44100
```

```
Show all properties
```

```
LPFMeas = measure(LPF)
```

```
LPFMeas =  
Sample Rate      : 44.1 kHz
```

Passband Edge : 8 kHz
3-dB Point : 9.1311 kHz
6-dB Point : 9.5723 kHz
Stopband Edge : 12 kHz
Passband Ripple : 0.08289 dB
Stopband Atten. : 81.6141 dB
Transition Width : 4 kHz

Algorithms

FIR Lowpass Filter

When the `FilterType` property is set to 'FIR', the `dsp.LowpassFilter` object acts as a FIR lowpass filter.

In this configuration, `dsp.LowpassFilter` is an alternative to using `firceqrip` and `firgr` with `dsp.FIRFilter`. This object condenses the two-step process into one. For the minimum order design, the object uses generalized Remez FIR filter design algorithm. For the specified order design, the object uses the constrained equiripple FIR filter design algorithm. The designed filter is then implemented as a linear phase Type-1 filter with a `Direct` form structure. You can use `measure` to verify that the design meets the prescribed specifications.

IIR Lowpass Filter

When the `FilterType` property is set to 'IIR', the `dsp.LowpassFilter` object acts as an IIR lowpass filter. In this configuration, the object uses the elliptic design method to compute the SOS and scale values required to meet the filter design specifications. The object uses the SOS and scale values to setup a `Direct` form I biquadratic IIR filter, which forms the basis of the IIR version of the `dsp.LowpassFilter` System object. You can use `measure` to verify that the design meets the prescribed specifications.

Version History

Introduced in R2015a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

This object supports code generation for ARM Cortex-M and ARM Cortex-A processors. To learn more about ARM Cortex code generation, see “Code Generation for ARM Cortex-M and ARM Cortex-A Processors”.

This object also supports SIMD code generation using Intel AVX2 technology under these conditions:

- `FilterType` is set to 'FIR'.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This object supports HDL code generation with the Filter Design HDL Coder product. For workflows and limitations, see “Generate HDL Code for Filter System Objects” (Filter Design HDL Coder).

“Analysis Methods for Filter System Objects” on page 3-2

dsp.LPCToLSF

Package: dsp

(Removed) Convert linear prediction coefficients to line spectral frequencies

Note dsp.LPCToLSF has been removed. Use `poly2lsf` from Signal Processing Toolbox™ instead. For more information, see “Compatibility Considerations”.

Description

The LPCToLSF object converts linear prediction coefficients to line spectral frequencies.

To convert LPC to LSF:

- 1 Define and set up your LPC to LSF converter. See “Construction” on page 4-803.
- 2 Call `step` to convert LPC according to the properties of `dsp.LPCToLSF`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Construction

`lpc2lsf = dsp.LPCToLSF` returns a System object, `lpc2lsf`, that converts linear prediction coefficients (LPCs) to line spectral frequencies (LSFs).

`lpc2lsf = dsp.LPCToLSF('PropertyName', PropertyValue, ...)` returns an LPC to LSF System object, `lpc2lsf`, with each specified property set to the specified value.

Properties

NumCoarseGridPoints

Number of coarse subintervals used for finding roots (LSP values)

Specify the number of coarse subintervals, n , used for finding line spectral pairs (LSP) values as a positive scalar integer. LSPs, which are the roots of two particular polynomials related to the input LPC polynomial, always lie in the range $(-1, 1)$. The System object finds these roots using the Chebyshev polynomial root finding method. To compute LSF outputs, the object computes the arc cosine of the LSPs, outputting values ranging from 0 to π radians. The object divides the interval $(-1, 1)$ into n subintervals and looks for roots in each subinterval. If you set n too small in relation to the LPC polynomial order, the object can fail to find some of the roots. The default is 64. This property is tunable.

NumBisects

Value of bisection refinement used for finding roots

Specify the root bisection refinement value, k , used in the Chebyshev polynomial root finding method, where each line spectral pair (LSP) output is within

$$\frac{1}{(n \cdot 2^k)}$$

of the actual LSP value. Here n is the value of the `NumCoarseGridPoints` property, and the object searches a maximum of $k \cdot (n - 1)$ points for finding the roots. You must set the `NumBisects` property value k , to a positive scalar integer. The default is 4. This property is tunable.

ExceptionOutputPort

Produces output with validity status of LSF output

Set this property to `true` to return a second output that indicates whether the computed LSF values are valid. The output is a vector with a length equal to the number of channels. A logical value of 1 indicates valid output. A logical value of 0 indicates invalid output. The LSF outputs are invalid when the object fails to find all the LSF values or when the input LPCs are unstable. The default is `false`.

OverwriteInvalidOutput

Enable overwriting invalid output with previous output

Specify the action that the System object should take for invalid LSF outputs. When you set this property to `true`, the object overwrites the invalid output with the previous output. When you set this property to `false`, the object does not take any action on invalid outputs and ignores the outputs.

FirstOutputValuesSource

Source of values for first output when output is invalid

Specify the source of values for the first output when the output is invalid as `Auto` or `Property`. This property applies when you set the `OverwriteInvalidOutput` property to `true`. The default is `Auto`. When you set this property to `Auto`, the object uses a default value for the first output. The default value corresponds to the LSF representation of an allpass filter.

FirstOutputValues

Value of the first output

Specify a numeric vector of LSF values for overwriting an invalid first output. The length of this vector must be one less than the length of the input LPC vector. For multichannel inputs, you can set this property to a matrix with the same number of channels as the input, or one vector that is applied to every channel. The default is an empty vector. This property applies when you set the `OverwriteInvalidOutput` property to `true` and the `FirstOutputValuesSource` property to `Property`.

NonUnityFirstCoefficientAction

Action to take when first LPC coefficient is not 1

Specify the action the object takes when the first coefficient of each channel of the LPC input is not 1 as `Replace with 1` or `Normalize`. The default is `Replace with 1`.

Methods

`reset` Reset values for overwriting invalid outputs to their initial values
`step` Convert LPC coefficients to line spectral frequencies

Common to All System Objects

<code>release</code>	Allow System object property value changes
----------------------	--

Examples

Convert LPC Coefficients To LSF Coefficients

Note This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Convert LPC to LSF coefficients

```
a = [1.0000 0.6149 0.9899 0.0000 0.0031 -0.0082]';
lpc2lsf = dsp.LPCToLSF;
y = lpc2lsf(a);
display(y);
```

```
y = 5×1
```

```
0.7842
1.5605
1.8776
1.8984
2.3593
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the [LPC to LSF/LSP Conversion block reference page](#). The object properties correspond to the block parameters, except: There is no object property that corresponds to the **Output** block parameter. The object only supports LSF outputs in the range $(0, \infty)$

Version History

Introduced in R2012a

dsp.LPCToLSF System object has been removed

Errors starting in R2022b

dsp.LPCToLSF System object has been removed. Use poly2lsf instead.

Update Code

This table shows typical usage of the System object and explains how to update existing code to use the equivalent function.

Discouraged Usage	Recommended Replacement
<pre>a = [1.0000 0.6149 0.9899 0.0000 0.0031]; lpc2lsf = dsp.LPCToLSF lsfObj = lpc2lsf(a)</pre> <p>If you are using a release prior to R2016b, replace lpc2lsf(a) with step(lpc2lsf,a).</p>	<pre>a = [1.0000 0.6149 0.9899 0.0000 0.0031 -0.0082]; lsfFn = poly2lsf(a)</pre>

Functions

poly2lsf

reset

Reset values for overwriting invalid outputs to their initial values

Syntax

```
reset(lpc2lsf)
```

Description

`reset(lpc2lsf)` resets the values for overwriting the invalid outputs to their initial values.

step

System object: dsp.LPCToLSF

Package: dsp

Convert LPC coefficients to line spectral frequencies

Syntax

```
LSF = step(lpc2lsf,A)  
[..., STATUS] = step(lpc2lsf,A)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`LSF = step(lpc2lsf,A)` converts the LPC coefficients, `A`, to line spectral frequencies, `LSF`, in the range (0 pi) . The System object operates along the columns of the input `A`.

`[..., STATUS] = step(lpc2lsf,A)` also returns the status flag, `STATUS`, indicating if the current output is valid when the `ExceptionOutputPort` property is `true`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.LUFactor

Package: dsp

(To be removed) Factor square matrix into lower and upper triangular matrices

Note dsp.LUFactor will be removed in a future release. Use `lu` instead. For more information, see “Compatibility Considerations”.

Description

The LUFactor object factors a square matrix into lower and upper triangular matrices.

To factor a square matrix into lower and upper triangular matrices:

- 1 Define and set up your System object. See “Construction” on page 4-809.
- 2 Call `step` to factor the square matrix according to the properties of dsp.LUFactor. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`lu = dsp.LUFactor` returns an LUFactor System object, `lu`, which factors a row permutation of a square input matrix A as $A_p = L \cdot U$, where L is the unit-lower triangular matrix, and U is the upper triangular matrix. The row-pivoted matrix A_p contains the rows of A permuted as indicated by the permutation index vector P . The equivalent MATLAB code is `Ap = A(P, :)`.

`lu = dsp.LUFactor('PropertyName', PropertyValue, ...)` returns an LUFactor object, `lu`, with each specified property set to the specified value.

Properties

ExceptionOutputPort

Set to `true` to output singularity of input

Set this property to `true` to output the singularity of the input as logical data type values of `true` or `false`. An output of `true` indicates that the current input is singular, and an output of `false` indicates the current input is nonsingular.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `|Ceiling|Convergent|Floor|Nearest |Round | Simplest | Zero|`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as `Full precision`, `Same as input` or `Custom`. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as `Full precision`, `Same as input`, `Same as product` or `Custom`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the “`OutputDataType`” on page 4-0 property to `Custom`. The default is `numericType([],16,15)`.

Methods

`step` Decompose matrix into lower and upper triangular matrices

Common to All System Objects

<code>release</code>	Allow System object property value changes
----------------------	--

Examples

Decompose a Square Matrix

Note If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Decompose a square matrix into the lower and upper components.

```
lu = dsp.LUFactor;
x = rand(4)

x = 4x4

    0.8147    0.6324    0.9575    0.9572
    0.9058    0.0975    0.9649    0.4854
    0.1270    0.2785    0.1576    0.8003
    0.9134    0.5469    0.9706    0.1419

[LU, P] = lu(x);
L = tril(LU, -1)+diag(ones(size(LU,1),1));
U = triu(LU);
y = L*U

y = 4x4

    0.9134    0.5469    0.9706    0.1419
    0.9058    0.0975    0.9649    0.4854
    0.8147    0.6324    0.9575    0.9572
    0.1270    0.2785    0.1576    0.8003
```

Check back whether `y` equals the permuted `x`

```
xp = x(P, :)

xp = 4x4
```

```

0.9134    0.5469    0.9706    0.1419
0.9058    0.0975    0.9649    0.4854
0.8147    0.6324    0.9575    0.9572
0.1270    0.2785    0.1576    0.8003
    
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the LU Factorization block reference page. The object properties correspond to the block parameters.

Version History

Introduced in R2012a

dsp.LUFactor System object will be removed

Warns starting in R2021b

dsp.LUFactor System object will be removed in a future release. Use the `lu` function instead.

Update Code

This table shows how the System object is typically used and explains how to update existing code to use the `lu` function.

Discouraged Usage	Recommended Replacement
<pre> rng(1) lu = dsp.LUFactor; x = rand(4) x = 4x4 0.4170 0.1468 0.3968 0.2045 0.7203 0.0923 0.5388 0.8781 0.0001 0.1863 0.4192 0.0274 0.3023 0.3456 0.6852 0.6705 [LU,P] = lu(x) LU = 4x4 0.7203 0.0923 0.5388 0.8781 0.4197 0.3068 0.4591 0.3019 0.0002 0.6070 0.1404 -0.1560 0.5789 0.3041 -0.3900 -0.4566 P = 4x1 2 4 3 1 </pre>	<pre> [LUfn,Pfn] = lu(x) LUfn = 4x4 0.7203 0.0923 0.5388 0.8781 0.4197 0.3068 0.4591 0.3019 0.0002 0.6070 0.1404 -0.1560 0.5789 0.3041 -0.3900 -0.4566 Pfn = 4x1 2 4 3 1 </pre>
<p>If you are using a release prior to R2016b, replace <code>lu(x)</code> with <code>step(lu,x)</code>.</p>

lu

step

System object: dsp.LUFactor

Package: dsp

Decompose matrix into lower and upper triangular matrices

Syntax

```
[LU,P] = step(lu,A)  
[LU,P,S] = step(lu,A)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[LU,P] = step(lu,A)` decomposes the matrix `A` into lower and upper triangular matrices. The output `LU` is a composite matrix with lower triangle elements from `L` and upper triangle elements from `U`. The permutation vector `P` is the second output.

`[LU,P,S] = step(lu,A)` returns an additional output `S` indicating if the input is singular when the `ExceptionOutputPort` property is set to `true`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.MatFileReader

Package: dsp

Read MAT file

Description

The `dsp.MatFileReader` System object reads V7.3 MAT files.

To read V7.3 MAT files:

- 1 Create the `dsp.MatFileReader` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
mfr = dsp.MatFileReader
mfr = dsp.MatFileReader(fname,vname,framesize)
mfr = dsp.MatFileReader( ___,Name,Value)
```

Description

`mfr = dsp.MatFileReader` returns a System object, `mfr`, to read a stream of scalar data from a V7.3 MAT file.

`mfr = dsp.MatFileReader(fname,vname,framesize)` reads frames of MAT file data, using the specified file name, variable name, and frame size.

`mfr = dsp.MatFileReader(___,Name,Value)` reads MAT file data with each specified property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Filename — Name of MAT file

'Untitled.mat' (default) | character vector | string scalar

Name of the MAT file from which to read, specified as a character vector or a string scalar. Specify the full path for the file only if the file is not on the MATLAB path.

VariableName — Name of variable to read

'x' (default) | character vector | string scalar

Name of the variable to read from the MAT file, specified as a character vector or a string scalar.

SamplesPerFrame — Number of samples per output frame

1 (default) | scalar

Number of samples per output frame to read from the MAT file on each call to the object algorithm, specified as a positive, integer-valued scalar.

Usage

Syntax

```
data = mfr()
```

Description

`data = mfr()` reads data from a specified variable stored in a MAT-file. The variable is assumed to be N -dimensional and a MATLAB built-in data type. The data is read into MATLAB by reading along the first dimension.

Output Arguments**data — Data read from MAT file**

scalar | vector | matrix

Data read from the MAT file, returned as a scalar, vector, or a matrix. The data can be an N -dimensional array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.MatFileReader`

`isDone` End-of-data status

Common to All System Objects

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

Examples

Read MAT File

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Read a MAT file using the `MatFileReader` object.

```
filename = [tempname '.mat']; % Create variable name
originalData = rand(40,2);
save(filename,'originalData','-v7.3'); % Write to MAT file

mfr = dsp.MatFileReader(filename,'VariableName',...
    'originalData','SamplesPerFrame', 4);
while ~isDone(mfr) % Stream data into MATLAB
    finalData = mfr();
end
```

Version History

Introduced in R2012b

“Outlier Removal Techniques with ECG Signals”

“Measure Statistics of Streaming Signals”

dsp.MatFileWriter

Package: dsp

Write MAT file

Description

The `dsp.MatFileWriter` System object writes data to a V7.3 MAT file.

To write data to a V7.3 MAT file:

- 1 Create the `dsp.MatFileWriter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
mfw = dsp.MatFileWriter  
mfw = dsp.MatFileWriter(fname,vname)  
mfw = dsp.MatFileWriter(Name,Value)
```

Description

`mfw = dsp.MatFileWriter` returns a MAT file writer System object, `mfw`, that writes data to a V7.3 MAT file.

`mfw = dsp.MatFileWriter(fname,vname)` returns a MAT file writer System object with the `Filename` property set to `fname` and the `VariableName` property set to `vname`.

`mfw = dsp.MatFileWriter(Name,Value)` returns a MAT file writer System object with each specified property set to the specified value. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Filename — Name of MAT file to write

'Untitled.mat' (default) | character vector | string scalar

Specify the name of a MAT file as a character vector or a string scalar. Specify the full path for the file only if the file is not on the MATLAB path.

VariableName — Name of variable to write

'x' (default) | character vector | string scalar

Name of the variable to which to write, returned as a character vector or a string scalar. This variable is stored in the MAT file. You cannot overwrite a variable that is already in an existing MAT file.

Usage

Syntax

```
mfw(data)
```

Description

`mfw(data)` writes one frame of data to the variable stored in the MAT file. The variable is assumed to be N -dimensional and a MATLAB built-in data type. The data is written to the file by concatenating along the first dimension.

Input Arguments

data — Data to be written to MAT file

scalar | vector | matrix

Data to be written to the MAT file, specified as a scalar, vector, or a matrix. The data can be an N -dimensional array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Write Data Into a MAT File

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

First, create a variable name.

```
filename = [tempname '.mat'];
```

Next, write that variable to a MAT-file.

```
mfw = dsp.MatFileWriter(filename, 'VariableName', 'originalData');  
for i = 1:10  
    originalData = rand(4,2);  
    mfw(originalData);  
end  
release(mfw); % This will close the MAT file
```

Finally, load the variable back into MATLAB.

```
data = load(filename, 'originalData');
```

Plot the data.

```
plot(data.originalData);
```

Objects

dsp.MatFileReader

dsp.MatrixViewer

Package: dsp

Visualize matrix data

Description

The `dsp.MatrixViewer` visualizes matrix data by mapping the matrix elements to a specified range of colors.

To visualize matrix data in the Matrix Viewer:

- 1 Create the `dsp.MatrixViewer` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Zoom and Pan

To scale the plot axes, you can use the scroll button on your mouse to zoom in/out of the plot and **CTRL+Click** and drag to pan around the plot. Additionally, you can use the buttons that appear when you hover over the upper right corner of the plot window.

-  — Autoscale the axes to fit the data.
-  — Zoom in to the plot.
-  — Pan around the axes.

Cursor Measurements

Activate cursor measurements by hovering over the matrix viewer and selecting the cursor button

Two horizontal and two vertical cursors appear on the plot. A dialog box shows the difference between the two intersection points. Hovering over an intersection point shows the value at that intersection point. Move the cursors by clicking and dragging the cursor lines or the intersection points to your desired location. Additionally, you can **Alt+Click** and drag the cursor dialog box to move the cursors while keeping the distance between the cursor lines constant.

Creation

Syntax

```
scope = dsp.MatrixViewer
scope = dsp.MatrixViewer(Name, Value)
```

Description

`scope = dsp.MatrixViewer` creates a Matrix Viewer System object, `scope`.

`scope = dsp.MatrixViewer(Name, Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes. For example, `scope = dsp.MatrixViewer("AxisOrigin", "Lower left corner")`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

Matrix Information

XDataMode — x-axis numbering mode

"Offset and resolution" (default) | "Custom"

Specify the x-axis numbering mode.

- "Offset and resolution" - Compute the x-axis data points from the XResolution and XOffset properties.
- "Custom" - Compute the x-axis data points using the CustomXData property.

Data Types: char | string

YDataMode — y-axis numbering mode

"Offset and resolution" (default) | "Span and resolution" | "Custom"

Specify the y-axis numbering mode:

- "Span and resolution" - Compute the y-axis data points from the YSpan and YResolution properties.
- "Offset and resolution" - Compute the y-axis data points from the YResolution and YOffset properties.
- "Custom" - Compute the y-axis data points using the CustomYData property.

Data Types: char | string

CustomXData — Custom data values for x-axis

[1 numberOfColumns] (default) | [min max] | monotonically increasing numeric vector

Specify custom values for the x-axis using a two-element numeric vector or a numeric vector with a finite number of elements.

If you specify a two-element vector, the numbers are used as the min and max values of the x-axis. If you specify a vector with more than two elements, the values must be monotonically increasing and the scope uses the first and last values of the vector as the minimum and maximum values, respectively. If you do not specify x-axis data limits, the scope uses the number of input columns as the maximum x-axis value.

Example: [5 156]

Tunable: Yes

Dependency

To enable this property, you must set XDataMode to "Custom".

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

CustomYData — Custom data values for y-axis

[1 numberOfRows] (default) | [min max] | monotonically increasing numeric vector

Specify custom values for the y-axis using a two-element numeric vector or a numeric vector with a finite number of elements.

If you specify a two-element vector, the numbers are used as the min and max values of the y-axis. If you specify a vector with more than two elements, the values must be monotonically increasing and the scope uses the first and last values of the vector as minimum and maximum values, respectively. If you do not specify y-axis data limits, the scope uses the number of input rows as the maximum y-axis value.

Example: [-130 10]

Tunable: Yes

Dependency

To enable this property, you must set `YDataMode` to "Custom".

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

XOffset — Display offset of x-axis

0 (default) | scalar

Specify the offset to display on the x-axis as a scalar.

Tunable: Yes

Dependency

To enable this property, you must set `XDataMode` to "Offset and resolution".

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

XResolution — Spacing of x-axis

1 (default) | scalar

Specify the spacing of values along the x-axis as a scalar.

Tunable: Yes

Dependency

To enable this property, you must set `XDataMode` to "Offset and resolution".

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

YOffset — Display offset of y-axis

0 (default) | scalar

Specify the offset to display on the y-axis as a scalar.

Tunable: No

Dependency

To enable this property, you must set `YDataMode` to "Offset and resolution".

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

YResolution — Spacing of y-axis

1 (default) | scalar

Specify the spacing of values along the y-axis as a scalar.

Tunable: No

Dependency

To enable this property, you must set `YDataMode` to "Offset and resolution" or "Span and resolution".

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

YSpan — Span of y-axis

100 (default) | positive scalar

Specify the span of values along the y-axis as a scalar.

Tunable: No

Dependency

To enable this property, you must set `YDataMode` to "Span and resolution".

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Visualization

Name — Window name

"Matrix Viewer" (default) | character vector | string scalar

Specify the name of the scope. This name appears as the title of the scope's figure window. To specify the title of plot, use the `Title` property.

Data Types: `char` | `string`

AxisOrigin — Starting location of plot

"Upper left corner" (default) | "Lower left corner"

Specify the starting location of the plot. If you specify "Upper left corner", the plot starts in the top left corner of the axes and continues down.

Data Types: `char` | `string`

Position — Scope window position in pixels

screen center (default) | [`left` `bottom` `width` `height`]

Specify, in pixels, the size and location of the scope window as a four-element vector of the form [`left` `bottom` `width` `height`]. By default, the scope window appears in the center of your screen with a width of 410 pixels and height of 300 pixels. The default values for this property may change depending on your screen resolution.

Title — Display title

"" (default) | character vector | string scalar

Specify the title of the plot as a character vector or string. By default, there is no title.

Tunable: Yes

Data Types: char | string

XLabel — x-axis label

"" (default) | character vector | string

Specify the text for the scope to display below the x-axis. By default, the axes is unlabeled.

Tunable: Yes

Data Types: char | string

YLabel — y-axis label

"" (default) | character vector | string

Specify the text for the scope to display to the left of the y-axis. By default, the axes is unlabeled.

Tunable: Yes

Data Types: char | string

ColorBarLabel — Color bar label

"" (default) | character vector | string

Specify the text for the scope to display next to the color bar. By default, the color bar is unlabeled.

Tunable: Yes

Data Types: char | string

Colormap — Color scheme

"parula" (default) | colormap name | three-column matrix of RGB triplets

Color scheme for the colormap, specified as a predefined colormap name or a three-column matrix of RGB triplets.

For a list of acceptable colormap names, see `map`.

To use a custom colormap, specify a three-column matrix of RGB triplets. You can create the RGB matrix yourself, or you can call a predefined colormap function, such as `colormap`, to create the matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | char | string

ColorLimits — Color bar limits

minimum and maximum matrix values (default) | two-element numeric vector [min max]

Specify the color bar limits as a two-element numeric vector [min max]. By default, limits are set as the minimum and maximum values of the input matrix.

Example: [1 80]

Tunable: Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

ColorBarLocation — Color bar location

"eastoutside" (default) | "northoutside" | "southoutside" | "westoutside"

Location of the color bar relative to the axes.

Tunable: Yes

Data Types: char | string

ShowColorBar — Color bar visibility

true (default) | false

Set this property to false to hide the color bar on the plot.

ShowGrid — Grid visibility

true (default) | false

Set this property to false to hide grid lines on the plot.

Tunable: Yes

ShowTicks — Axes tick visibility

true (default) | false

Set this property to false to hide the ticks on the x-axis and y-axis.

Usage**Syntax**

scope(matrix)

Description

scope(matrix) displays the matrix by mapping matrix element values to a range of colors.

Input Arguments**matrix — Matrix to visualize**

n-by-*m* numeric matrix

Specify an *n*-by-*m* numeric matrix to visualize.

Example: scope(rand(3,5))

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:

release(obj)

Specific to `dsp.MatrixViewer`

`setCursorDataLabels` Customize data labels for cursor measurements

Specific to Scopes

`show` Display scope window
`hide` Hide scope window
`isVisible` Determine visibility of scope

Common to All System Objects

`step` Run System object algorithm
`release` Release resources and allow changes to System object property values and input characteristics
`reset` Reset internal states of System object

Examples

Generate Spectrogram with `dsp.MatrixViewer`

This example shows how to create a spectrogram of a quadratic chirp with the `dsp.MatrixViewer` System object.

Set up the sample rate and a chirp signal.

```
Fs = 233e3;  
frameSize = 20e3;  
chirp = dsp.Chirp("SampleRate",Fs,"SamplesPerFrame",frameSize,...  
    "InitialFrequency",11e3,"TargetFrequency",11e3+55e3,...  
    "Type","Quadratic");
```

Create a `dsp.MatrixViewer` scope. Set the axis labels, select a colormap, and set the limits of the colormap.

```
scope = dsp.MatrixViewer(...  
    "ColorBarLabel","Power/Frequency (dB/Hz)",...  
    "XLabel","Frequency (Hz)",...  
    "YLabel","Time (secs)",...  
    "Colormap","hsv",...  
    "ColorLimits",[-100,-30]);
```

Visualize the spectrogram of the chirp signal in the scope.

```
for idx = 1:50  
    y = chirp() + 0.05*randn(frameSize,1);  
    [~,~,~,Ps] = spectrogram(y,128,120,128,1e3);  
    val = 10*log10(abs(Ps)'+eps);  
    scope(val);  
end
```

Version History

Introduced in R2019a

dsp.MedianFilter

Package: dsp

Median filter

Description

The `dsp.MedianFilter` System object computes the moving median of the input signal along each channel, independently over time. The object uses the sliding window method to compute the moving median. In this method, a window of specified length is moved over each channel, sample by sample, and the object computes the median of the data in the window. For more details, see “Algorithms” on page 4-836.

To compute the moving median of the input:

- 1 Create the `dsp.MedianFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
medFilt = dsp.MedianFilter
medFilt = dsp.MedianFilter(Len)
medFilt = dsp.MedianFilter(Name,Value)
```

Description

`medFilt = dsp.MedianFilter` returns a median filter object, `medFilt`, using the default properties.

`medFilt = dsp.MedianFilter(Len)` sets the `WindowLength` property to `Len`.

`medFilt = dsp.MedianFilter(Name,Value)` specifies the `WindowLength` property using a `Name,Value` pair.

Example:

```
movMin = dsp.MedianFilter('WindowLength',5);
```

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

WindowLength — Length of sliding window

5 (default) | positive scalar integer

Length of the sliding window in samples, specified as a positive scalar integer.

Usage

Syntax

```
y = medFilt(x)
```

Description

`y = medFilt(x)` computes the moving median of the input signal, `x`, using the sliding window method.

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix. If `x` is a matrix, each column is treated as an independent channel. The moving median is computed along each channel. The object accepts multichannel inputs, that is, m -by- n size inputs, where $m \geq 1$, and $n > 1$. m is the number of samples in each frame (or channel), and n is the number of channels.

The object also accepts variable-size inputs. Once the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

Data Types: `single` | `double`

Output Arguments

y — Filtered signal

vector | matrix

Filtered signal, returned as a vector or a matrix. The size and data type of the output matches the size and data type of the input.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

`step` Run System object algorithm

- release Release resources and allow changes to System object property values and input characteristics
- reset Reset internal states of System object

Examples

Remove High-Frequency Noise Using Median Filter

Filter high-frequency noise from a noisy sine wave signal using a median filter. Compare the performance of the median filter with an averaging filter.

Initialization

Set up a `dsp.MedianFilter` object, `medFilt`, and a `dsp.MovingAverage` object, `movavgWin`. These objects use the sliding window method with a window length of 7. Create a time scope for viewing the output.

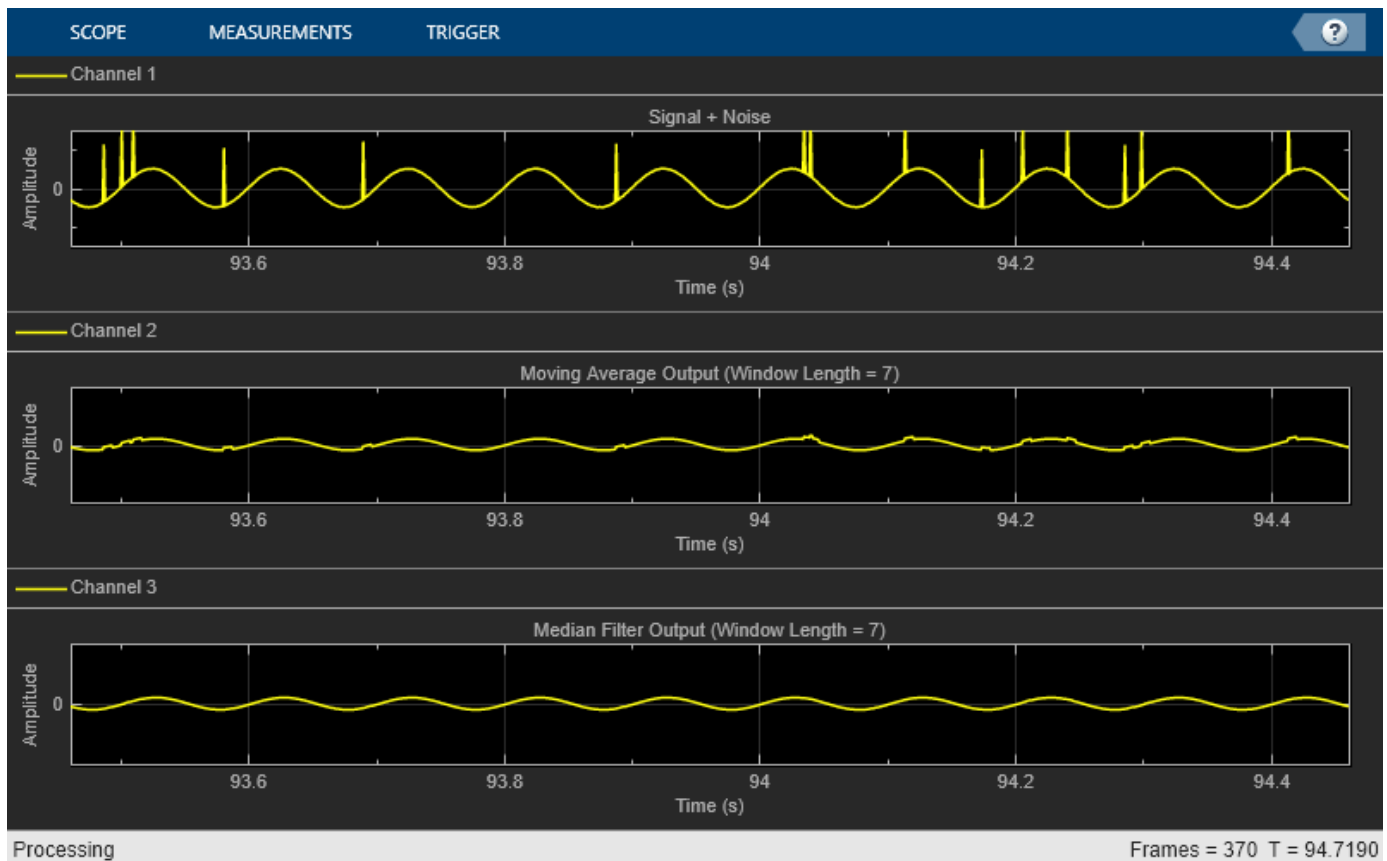

```
Fs = 1000;
medFilt = dsp.MedianFilter(7);
movavgWin = dsp.MovingAverage(7);
scope = timescope('SampleRate',Fs,...
    'TimeSpanSource','Property',...
    'TimeSpanOverrunAction','Scroll',...
    'TimeSpan',1,'ShowGrid',true,...
    'YLimits',[-3 3],...
    'LayoutDimensions',[3 1],...
    'NumInputPorts',3);
scope.ActiveDisplay = 1;
scope.Title = 'Signal + Noise';
scope.ActiveDisplay = 2;
scope.Title = 'Moving Average Output (Window Length = 7)';
scope.ActiveDisplay = 3;
scope.Title = 'Median Filter Output (Window Length = 7)';

FrameLength = 256;
count = 1;
sine = dsp.SineWave('SampleRate',Fs,'Frequency',10,...
    'SamplesPerFrame',FrameLength);
```

Filter the Noisy Sine Wave

Generate a noisy sine wave signal with a frequency of 10 Hz. Apply the median filter and the moving average object to the signal. View the output on the time scope.

```
for i = 1:500
    hfn = 3 * (rand(FrameLength,1) < 0.02);
    x = sine() + 1e-2 * randn(FrameLength,1) + hfn;
    y1 = movavgWin(x);
    y2 = medFilt(x);
    scope(x,y1,y2);
end
```

The median filter removes the high-frequency noise more effectively than the moving average object does.

Remove High-Frequency Noise from Gyroscope Data

This example shows how to remove the high-frequency outliers from a streaming signal using the `dsp.MedianFilter` System object?

Use the `dsp.MatFileReader` System object to read the gyroscope MAT file. The gyroscope MAT file contains 3 columns of data, with each column containing 7140 samples. The three columns represent the X-axis, Y-axis, and Z-axis data from the gyroscope motion sensor. Choose a frame size of 714 samples so that each column of the data contains 10 frames. The `dsp.MedianFilter` System object uses a window length of 10. Create a `timescope` object to view the filtered output.

```
reader = dsp.MatFileReader('SamplesPerFrame',714,...
    'Filename','LSM9DS1gyroData73.mat',...
    'VariableName','data');
medFilt = dsp.MedianFilter(10);
scope = timescope('NumInputPorts',1,...
    'SampleRate',119,...
    'YLimits',[-300 300],...
    'ChannelNames',{'Input','Filtered Output'},...
    'TimeSpanSource','Property',...
    'TimeSpan',60,'ShowLegend',true);
```

Filter the gyroscope data using the `dsp.MedianFilter` System object. View the filtered Z-axis data in the time scope.

```
for i = 1:10
    gyroData = reader();
    filteredData = medFilt(gyroData);
    scope([gyroData(:,3),filteredData(:,3)]);
end
```

The original data contains several outliers. Zoom in on the data to confirm that the median filter removes all the outliers.

Algorithms

Sliding Window Method

In the sliding window method, the output for each input sample is the median of the current sample and the $Len - 1$ previous samples. Len is the length of the window in samples. To compute the first $Len - 1$ outputs, when the window does not have enough data yet, the algorithm fills the window with zeros. As an example, to compute the median value when the second input sample comes in, the algorithm fills the window with $Len - 2$ zeros. The data vector, x , is then the two data samples followed by $Len - 2$ zeros. This object performs median filtering on the input data over time.

Consider an example of computing the moving median of a streaming input data using the sliding window method. The algorithm uses a window length of 4. With each input sample that comes in, the window of length 4 moves along the data.

dsp.MovingAverage

Package: dsp

Moving average

Description

The `dsp.MovingAverage` System object computes the moving average of the input signal along each channel, independently over time. The object uses either the sliding window method or the exponential weighting method to compute the moving average. In the sliding window method, a window of specified length is moved over the data, sample by sample, and the average is computed over the data in the window. In the exponential weighting method, the object multiplies the data samples with a set of weighting factors. The average is computed by summing the weighted data. For more details on these methods, see “Algorithms” on page 4-843.

To compute the moving average of the input:

- 1 Create the `dsp.MovingAverage` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
movAvg = dsp.MovingAverage
movAvg = dsp.MovingAverage(Len)
movAvg = dsp.MovingAverage(Len,Overlap)
movAvg = dsp.MovingAverage(Name,Value)
```

Description

`movAvg = dsp.MovingAverage` returns a moving average object, `movAvg`, using the default properties.

`movAvg = dsp.MovingAverage(Len)` sets the `WindowLength` property to `Len`.

`movAvg = dsp.MovingAverage(Len,Overlap)` sets the `WindowLength` property to `Len` and the `OverlapLength` property to `Overlap`.

`movAvg = dsp.MovingAverage(Name,Value)` specifies additional properties using `Name,Value` pairs. Unspecified properties have default values.

```
Example: movAvg = dsp.MovingAverage('Method','Exponential
weighting','ForgettingFactor',0.9);
```

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

Method — Averaging method

'Sliding window' (default) | 'Exponential weighting'

Averaging method, specified as 'Sliding window' or 'Exponential weighting'.

- 'Sliding window' — A window of length specified by `SpecifyWindowLength` is moved over the input data along each channel. For every sample the window moves by, the object computes the average over the data in the window.
- 'Exponential weighting' — The object multiplies the samples with a set of weighting factors. The magnitude of the weighting factors decreases exponentially as the age of the data increases, never reaching zero. To compute the average, the algorithm sums the weighted data.

For more details on these methods, see “Algorithms” on page 4-843.

SpecifyWindowLength — Specify window length

true (default) | false

Flag to specify a window length, specified as a scalar boolean.

- true — The length of the sliding window is equal to the value you specify in the `WindowLength` property.
- false — The length of the sliding window is infinite. In this mode, the average is computed using the current sample and all the past samples.

Dependencies

This property applies when you set `Method` to 'Sliding window'.

WindowLength — Length of the sliding window

4 (default) | positive scalar integer

Length of the sliding window in samples, specified as a positive scalar integer.

Dependencies

This property applies when you set `Method` to 'Sliding window' and `SpecifyWindowLength` to true.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

OverlapLength — Overlap length between windows

WindowLength - 1 (default) | nonnegative integer

Overlap length between sliding windows, specified as a nonnegative integer. The value of overlap length varies in the range $[0, \text{WindowLength} - 1]$. If not specified, the overlap length is `WindowLength - 1`.

Dependencies

This property applies when you set `Method` to 'Sliding window' and `SpecifyWindowLength` to true.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

ForgettingFactor — Exponential weighting factor

0.9 (default) | positive real scalar in the range (0,1]

Exponential weighting factor, specified as a positive real scalar in the range (0,1]. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All the past samples are given an equal weight.

Since this property is tunable, you can change its value even when the object is locked.

Tunable: Yes

Dependencies

This property applies when you set `Method` to 'Exponential weighting'.

Data Types: `single` | `double`

Usage**Syntax**

$$y = \text{movAve}(x)$$
Description

$y = \text{movAve}(x)$ computes the moving average of the input signal, x , using either the sliding window method or exponential weighting method.

Input Arguments**x — Data input**

vector | matrix

Data input, specified as a vector or a matrix. If x is a matrix, each column is treated as an independent channel. The moving average is computed along each channel.

The object accepts variable-size inputs. Once the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

Data Types: `single` | `double`

Output Arguments**y — Moving average**

vector | matrix

Moving average of the input signal, returned as a vector or a matrix.

When you input a signal of size m -by- n to the object, and if you set `Method` to 'Sliding window' and `SpecifyWindowLength` to `true`, the output has an upper bound size of $\text{ceil}(m/\text{hop size})$ -by- n . Hop size is window length – overlap length. In other cases, the output has a size of m -by- n .

When you generate code from this object, the variable-size behavior of the output in the generated code depends on the input frame length and whether the size of the input signal is fixed or variable. For more details, see “Code Generation” on page 4-845.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

`step` Run System object algorithm
`release` Release resources and allow changes to System object property values and input characteristics
`reset` Reset internal states of System object

Examples

Moving Average of Noisy Ramp Signal

Compute the moving average of a noisy ramp signal using the `dsp.MovingAverage` object.

Initialization

Set up `movavgWindow`, `movavgWindow_overlap`, and `movavgExp` objects. `movavgWindow` uses the sliding window method with a window length of 50 samples and a default overlap length of 49 samples, which is one sample less than the specified window length. `movavgWindow_overlap` uses a window length of 50 samples and an overlap length of 45 samples. `movavgExp` uses the exponentially weighting method with a forgetting factor of 0.95.

Create a time scope for viewing the output.

```
FrameLength = 1001;  
Fs = 1000;  
movavgWindow = dsp.MovingAverage(50);  
movavgWindow_overlap = dsp.MovingAverage(50,45);  
movavgExp = dsp.MovingAverage('Method','Exponential weighting',...  
    'ForgettingFactor',0.95);  
scope = timescope('SampleRate',[Fs, Fs, Fs/(50-45), Fs],...  
    'TimeSpanOvrrunAction','Scroll',...  
    'ShowGrid',true,...  
    'YLimits',[-0.5 1.5]);  
title = 'Moving Average';  
scope.Title = title;  
scope.ChannelNames = {'Original Signal',...  
    'Sliding window of 50 samples with default overlap',...}
```

```
'Sliding window of 50 samples with an overlap of 45 samples',...
'Exponential weighting with forgetting factor of 0.95'};
```

Compute the Average

Generate a ramp signal with an amplitude of 1 and a time span of 2 seconds. Apply the sliding window average and exponentially weighted average to the ramp. View the output in the time scope.

```
for i = 1:500
    t = (0:0.001:1)';
    unitstep = t>=0;
    ramp = t.*unitstep;
    x = ramp + 0.1 * randn(FrameLength,1);
    y1 = movavgWindow(x);
    y2 = movavgWindow_overlap(x);
    y3 = movavgExp(x);
    scope(x,y1,y2,y3);
end
```

Algorithms

Sliding Window Method

In the sliding window method, the output for each input sample is the average of the current sample and $Len - 1$ previous samples. Len is the length of the window in samples. To compute the first output sample, the algorithm waits until it receives the hop size number of input samples. Hop size is defined

as window length - overlap length. Remaining samples in the window are considered to be zero. As an example, if the window length is 5 and the overlap length is 2, then the algorithm waits until it receives 3 samples of input to compute the first sample of the output. After generating the first output, it generates the subsequent output samples for every hop size number of input samples.

When you do not specify the window length, the algorithm chooses an infinite window length. In this mode, the output is the moving average of the current sample and all the previous samples in the channel.

For an example, see “Sliding Window Method and Exponential Weighting Method”.

Exponential Weighting Method

In the exponential weighting method, the moving average is computed recursively using these formulas:

$$w_{N,\lambda} = \lambda w_{N-1,\lambda} + 1$$
$$\bar{x}_{N,\lambda} = \left(1 - \frac{1}{w_{N,\lambda}}\right) \bar{x}_{N-1,\lambda} + \left(\frac{1}{w_{N,\lambda}}\right) x_N$$

- $\bar{x}_{N,\lambda}$ — Moving average at the current sample
- x_N — Current data input sample
- $\bar{x}_{N-1,\lambda}$ — Moving average at the previous sample
- λ — Forgetting factor
- $w_{N,\lambda}$ — Weighting factor applied to the current data sample
- $\left(1 - \frac{1}{w_{N,\lambda}}\right) \bar{x}_{N-1,\lambda}$ — Effect of the previous data on the average

For the first sample, where $N = 1$, the algorithm chooses $w_{N,\lambda} = 1$. For the next sample, the weighting factor is updated and used to compute the average, as per the recursive equation. As the age of the data increases, the magnitude of the weighting factor decreases exponentially and never reaches zero. In other words, the recent data has more influence on the current average than the older data.

The value of the forgetting factor determines the rate of change of the weighting factors. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All the previous samples are given an equal weight.

For an example, see “Sliding Window Method and Exponential Weighting Method”.

Version History

Introduced in R2016b

Change in variable-size behavior for output signal in generated code

Starting in R2022b, if you generate code from this object with the `Method` property set to 'Sliding window' and the `SpecifyWindowLength` property set to `true`, and if you input a signal with a frame length that is a multiple of the hop size (window length - overlap length), this object generates

a fixed-size output signal in the generated code . For more details, see “Code Generation” on page 4-845.

References

- [1] Bodenham, Dean. “Adaptive Filtering and Change Detection for Streaming Data.” PH.D. Thesis. Imperial College, London, 2012.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- See “System Objects in MATLAB Code Generation” (MATLAB Coder).
- When you set `Method` to 'Sliding window' and `SpecifyWindowLength` to `true`, and generate code from this object, the variable-size behavior of the output depends on the input frame length and whether the size of the input signal is fixed or variable.

See this table for more details.

Input signal	Input size	Output signal
Fixed-size	m -by- n	When the input frame length is a multiple of the hop size, the output signal has a fixed-size of $(m/\text{hop size})$ -by- n . When input frame length is not a multiple of the hop size, the output signal is variable-sized and has an upper bound of $\text{ceil}(m/\text{hop size})$ -by- n .
Variable-size	m -by- n	Output is a variable-size signal. Output has an upper bound size of $\text{ceil}(m/\text{hop size})$ -by- n .

dsp.MovingMaximum

Package: dsp

Moving maximum

Description

The `dsp.MovingMaximum` System object determines the moving maximum of the input signal along each channel, independently over time. The object uses the sliding window method to determine the moving maximum. In this method, a window of specified length is moved over each channel, sample by sample, and the object determines the maximum of the data in the window. For more details, see “Algorithms” on page 4-850.

To determine the moving maximum of the input:

- 1 Create the `dsp.MovingMaximum` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
movMax = dsp.MovingMaximum
movMax = dsp.MovingMaximum(Len)
movMax = dsp.MovingMaximum(Name,Value)
```

Description

`movMax = dsp.MovingMaximum` returns a moving maximum object, `movMax`, using the default properties.

`movMax = dsp.MovingMaximum(Len)` sets the `WindowLength` property to `Len`.

`movMax = dsp.MovingMaximum(Name,Value)` specifies additional properties using `Name,Value` pairs. Unspecified properties have default values.

Example: `movMax = dsp.MovingMaximum('SpecifyWindowLength',1,'WindowLength',10);`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

SpecifyWindowLength — Specify window length`true (default) | false`

Flag to specify a window length, specified as a scalar boolean.

- `true` — The length of the sliding window is equal to the value you specify in the `WindowLength` property.
- `false` — The length of the sliding window is infinite. In this mode, the object determines the maximum of the current sample and all the past samples.

WindowLength — Length of the sliding window`4 (default) | positive scalar integer`

Length of the sliding window in samples, specified as a positive scalar integer.

Dependencies

This property applies when you set `SpecifyWindowLength` to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Usage**Syntax**

```
y = movMax(x)
```

Description

`y = movMax(x)` determines the moving maximum of the input signal, `x`, using the sliding window method.

Input Arguments**x — Data input**`vector | matrix`

Data input, specified as a vector or a matrix. If `x` is a matrix, each column is treated as an independent channel. The moving maximum is determined along each channel. The object also accepts variable-size inputs. Once the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Output Arguments**y — Moving maximum output**`vector | matrix`

Moving maximum of the input signal, returned as a vector or a matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Moving Maximum of Sine Wave Signal

Compute the moving maximum of a sum of three sine waves with varying amplitude. Use a sliding window of length 30.

Initialization

Set up an input signal that is a sum of three sine waves with frequencies at 2 Hz, 5 Hz, and 10 Hz. The sampling frequency is 100 Hz. Create a `dsp.MovingMaximum` object with a window length of 30. Create a time scope for viewing the output.

```
sin = dsp.SineWave('SampleRate',100,...
    'Frequency',[2 5 10],...
    'SamplesPerFrame',100);
movMax = dsp.MovingMaximum(30);
scope = timescope('SampleRate',100,...
    'TimeSpanOvrrunAction','Scroll',...
    'TimeSpanSource','Property',...
    'TimeSpan',10,'ShowGrid',true,...
    'YLimits',[-4.5 4.5]);
```

Compute the Moving Maximum

Each sine wave component of the input signal has a different amplitude that varies with the iteration. Use the `movMax` object to determine the maximum value of the current sample and the past 29 samples of the input signal.

```
for index = 1:100
    sin.Amplitude = rand(1,3);
    x = sum(sin(),2);
    xmax = movMax(x);
    scope([x,xmax])
end
```

Algorithms

Sliding Window Method

In the sliding window method, the output for each input sample is the maximum of the current sample and the $Len - 1$ previous samples. Len is the length of the window in samples. When the algorithm computes the first $Len - 1$ outputs, the length of the window is the length of the data that is available.

When you do not specify the window length, the algorithm chooses an infinite window length. In this mode, the output is the maximum of the current sample and all the previous samples in the channel.

Consider an example of computing the moving maximum of a streaming input data using the sliding window method. The algorithm uses a window length of 4. With each input sample that comes in, the window of length 4 moves along the data.

dsp.MovingMinimum

Package: dsp

Moving minimum

Description

The `dsp.MovingMinimum` System object determines the moving minimum of the input signal along each channel, independently over time. The object uses the sliding window method to determine the moving minimum. In this method, a window of specified length is moved over each channel, sample by sample, and the object determines the minimum of the data in the window. For more details, see “Algorithms” on page 4-856.

To determine the moving minimum of the input:

- 1 Create the `dsp.MovingMinimum` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
movMin = dsp.MovingMinimum
movMin = dsp.MovingMinimum(Len)
movMin = dsp.MovingMinimum(Name,Value)
```

Description

`movMin = dsp.MovingMinimum` returns a moving minimum object, `movMin`, using the default properties.

`movMin = dsp.MovingMinimum(Len)` sets the `WindowLength` property to `Len`.

`movMin = dsp.MovingMinimum(Name,Value)` specifies additional properties using `Name,Value` pairs. Unspecified properties have default values.

Example: `movMin = dsp.MovingMinimum('SpecifyWindowLength',1,'WindowLength',10);`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

SpecifyWindowLength — Specify window length`true (default) | false`

Flag to specify a window length, specified as a scalar boolean.

- `true` — The length of the sliding window is equal to the value you specify in the `WindowLength` property.
- `false` — The length of the sliding window is infinite. In this mode, the object determines the minimum of the current sample and all the past samples.

WindowLength — Length of the sliding window`4 (default) | positive scalar integer`

Length of the sliding window in samples, specified as a positive scalar integer.

Dependencies

This property applies when you set `SpecifyWindowLength` to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Usage**Syntax**

```
y = movMin(x)
```

Description

`y = movMin(x)` determines the moving minimum of the input signal, `x`, using the sliding window method.

Input Arguments**x — Data input**`vector | matrix`

Data input, specified as a vector or a matrix. If `x` is a matrix, each column is treated as an independent channel. The moving minimum is determined along each channel. The object also accepts variable-size inputs. Once the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Output Arguments**y — Moving minimum output**`vector | matrix`

Moving minimum output, returned as a vector or a matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Moving Minimum of Sine Wave Signal

Compute the moving minimum of a sum of three sine waves with varying amplitude. Use a sliding window of length 30.

Initialization

Set up an input signal that is a sum of three sine waves with frequencies at 2 Hz, 5 Hz, and 10 Hz. The sampling frequency is 100 Hz. Create a `dsp.MovingMinimum` object with a window length of 30. Create a time scope for viewing the output.

```
sin = dsp.SineWave('SampleRate',100,...
    'Frequency',[2 5 10],...
    'SamplesPerFrame',100);
movMin = dsp.MovingMinimum(30);
scope = timescope('SampleRate',100,...
    'TimeSpanSource','property','TimeSpan',10,...
    'TimeSpanOvverrunAction','Scroll',...
    'ShowGrid',true,'YLimits',[-4.5 4.5]);
```

Compute the Moving Minimum

Each sine wave component of the input signal has a different amplitude that varies with the iteration. Use the `movMin` object to determine the minimum value of the current sample and the past 29 samples of the input signal.

```
for index = 1:100
    sin.Amplitude = rand(1,3);
    x = sum(sin(),2);
    xmin = movMin(x);
    scope([x,xmin])
end
scope.AxesScaling = 'onceatstop';
```

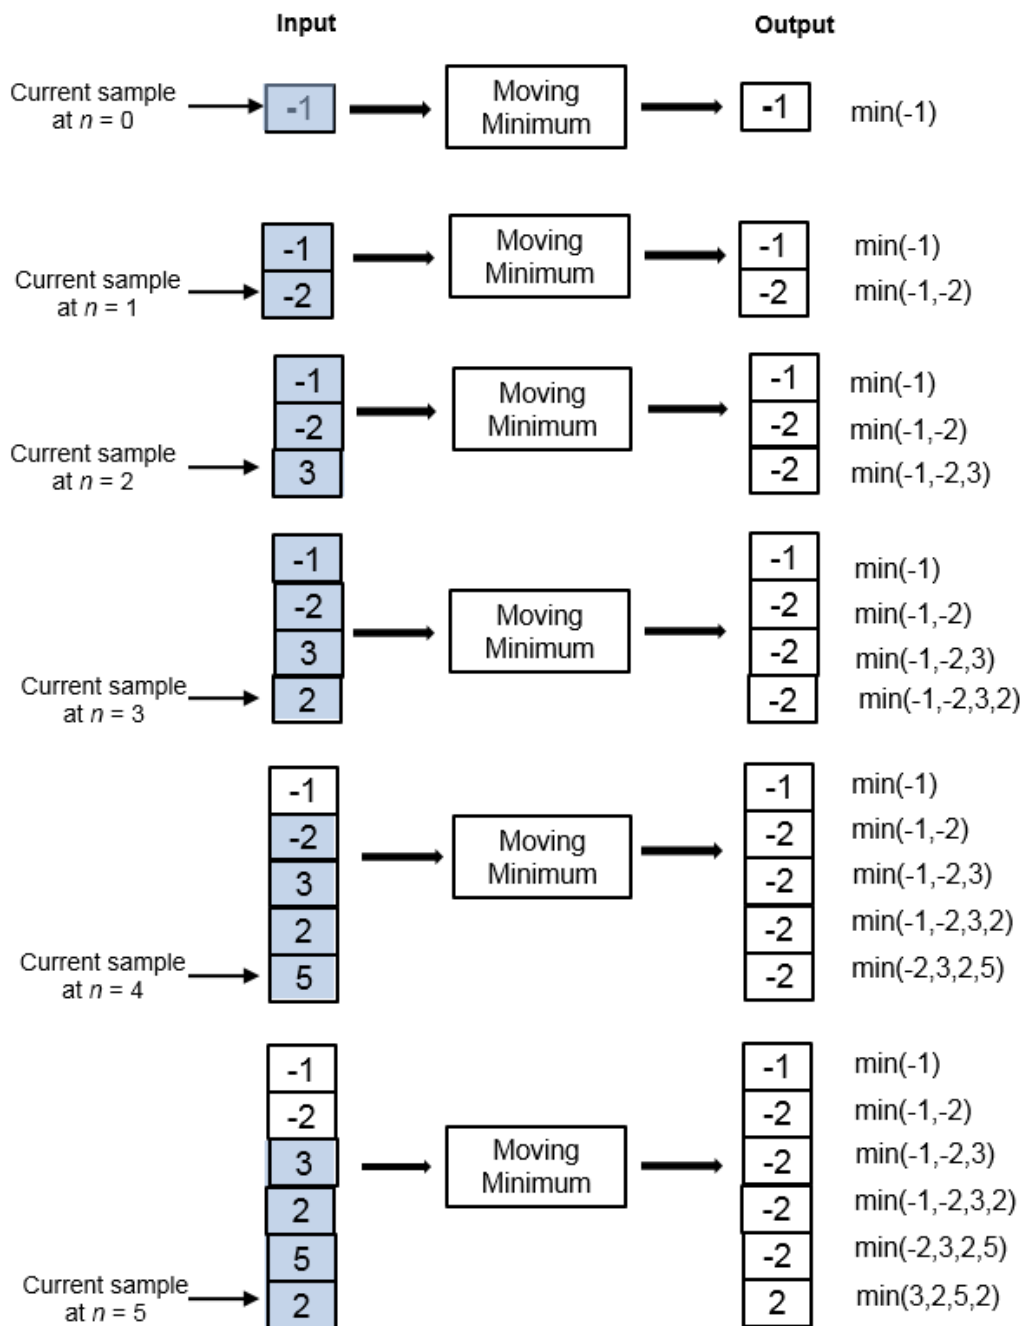

Algorithms

dsp.MovingRMS

Package: dsp

Moving root mean square

Description

The `dsp.MovingRMS` System object computes the moving root mean square (RMS) of the input signal along each channel, independently over time. The object uses either the sliding window method or the exponential weighting method to compute the moving RMS. In the sliding window method, a window of specified length is moved over the data, sample by sample, and the RMS is computed over the data in the window. In the exponential weighting method, the object squares the data samples, multiplies them with a set of weighting factors, and sums the weighed data. The object then computes the RMS by taking the square root of the sum. For more details on these methods, see “Algorithms” on page 4-864.

To compute the moving RMS of the input:

- 1 Create the `dsp.MovingRMS` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
movRMS = dsp.MovingRMS
movRMS = dsp.MovingRMS(Len)
MovRMS = dsp.MovingRMS(Len,Overlap)
movRMS = dsp.MovingRMS(Name,Value)
```

Description

`movRMS = dsp.MovingRMS` returns a moving RMS object, `movRMS`, using the default properties.

`movRMS = dsp.MovingRMS(Len)` sets the `WindowLength` property to `Len`.

`MovRMS = dsp.MovingRMS(Len,Overlap)` sets the `WindowLength` property to `Len` and the `OverlapLength` property to `Overlap`.

`movRMS = dsp.MovingRMS(Name,Value)` specifies additional properties using `Name, Value` pairs. Unspecified properties have default values.

```
Example: movRMS = dsp.MovingRMS('Method','Exponential
weighting','ForgettingFactor',0.9);
```

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Method — Moving RMS method

'Sliding window' (default) | 'Exponential weighting'

Moving RMS method, specified as 'Sliding window' or 'Exponential weighting'.

- 'Sliding window' — A window of length specified by `SpecifyWindowLength` is moved over the input data along each channel. For every sample the window moves by, the object computes the RMS over the data in the window.
- 'Exponential weighting' — The object multiplies the squares of the samples with a set of weighting factors. The magnitude of the weighting factors decreases exponentially as the age of the data increases, never reaching zero. To compute the RMS, the algorithm sums the weighted data, and takes a square root of the sum.

For more details on these methods, see “Algorithms” on page 4-864.

SpecifyWindowLength — Specify window length

true (default) | false

Flag to specify a window length, specified as a scalar Boolean.

- `true` — The length of the sliding window is equal to the value you specify in the `WindowLength` property.
- `false` — The length of the sliding window is infinite. In this mode, the RMS is computed using the current sample and all past samples.

Dependencies

This property applies when you set `Method` to 'Sliding window'.

WindowLength — Length of the sliding window

4 (default) | positive scalar integer

Length of the sliding window in samples, specified as a positive scalar integer.

Dependencies

This property applies when you set `Method` to 'Sliding window' and `SpecifyWindowLength` to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

OverlapLength — Overlap length between windows

`WindowLength - 1` (default) | nonnegative integer

Overlap length between sliding windows, specified as a nonnegative integer. The value of overlap length varies in the range $[0, \text{WindowLength} - 1]$. If not specified, the overlap length is $\text{WindowLength} - 1$.

Dependencies

This property applies when you set `Method` to 'Sliding window' and `SpecifyWindowLength` to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

ForgettingFactor — Exponential weighting factor

0.9 (default) | positive real scalar in the range (0,1]

Exponential weighting factor, specified as a positive real scalar in the range (0,1].

A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All the past samples are given an equal weight.

Since this property is tunable, you can change its value even when the object is locked.

Tunable: Yes

Dependencies

This property applies when you set `Method` to 'Exponential weighting'.

Data Types: `single` | `double`

Usage

Syntax

`y = movRMS(x)`

Description

`y = movRMS(x)` computes the moving RMS of the input signal, `x`, using either the sliding window method or exponential weighting method.

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix. If `x` is a matrix, each column is treated as an independent channel. The moving RMS is computed along each channel.

The object accepts variable-size inputs. Once the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

Data Types: `single` | `double`

Output Arguments

y — Moving RMS

vector | matrix

Moving RMS of the input signal, returned as a vector or a matrix.

When you input a signal of size m -by- n to the object, and if you set `Method` to 'Sliding window' and `SpecifyWindowLength` to `true`, the output has an upper bound size of `ceil(m/hop size)`-by- n . Hop size is window length – overlap length. In other cases, the output has a size of m -by- n .

When you generate code from this object, the variable-size behavior of the output in the generated code depends on the input frame length and whether the size of the input signal is fixed or variable. For more details, see “Code Generation” on page 4-867.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Moving RMS of Noisy Square Wave Signal

Compute the moving RMS of a noisy square wave signal with varying amplitude using the `dsp.MovingRMS` object.

Initialization

Set up `movrmsWin`, `movrmsWin_overlap`, and `movrmsExp` objects. `movrmsWin` uses the sliding window method with a window length of 20 samples and a default overlap length of 19 samples, which is one sample less than the specified window length. `movrmsWin_overlap` uses a window length of 20 samples and an overlap length of 15 samples. `movrmsExp` uses the exponentially weighting method with a forgetting factor of 0.995.

Create a time scope for viewing the output.

```
FrameLength = 10;  
Fs = 100;  
movrmsWin = dsp.MovingRMS(20);  
movrmsWin_overlap = dsp.MovingRMS(20,15);  
movrmsExp = dsp.MovingRMS('Method','Exponential weighting',...  
    'ForgettingFactor',0.995);
```

```

scope = timescope('SampleRate',[Fs,Fs,Fs/(20-15),Fs],...
    'TimeSpanOvverrunAction','Scroll',...
    'TimeSpanSource','Property',...
    'TimeSpan',100,...
    'ShowGrid',true,...
    'YLimits',[-1.0 5.5]);
title = 'Moving RMS';
scope.Title = title;
scope.ChannelNames = {'Original Signal',...
    'Sliding window of 20 samples with default overlap',...
    'Sliding window of 20 samples with an overlap of 15 samples',...
    'Exponential weighting with forgetting factor of 0.995'};

```

Compute the RMS

Generate a noisy square wave signal. Vary the amplitude of the square wave after a given number of frames. Apply the sliding window method and the exponential weighting method to this signal. View the output in the time scope.

```

count = 1;
Vect = [1/8 1/2 1 2 3 4];
for index = 1:length(Vect)
    V = Vect(index);
    for i = 1:160
        x = V + 0.1 * randn(FrameLength,1);
        y1 = movrmsWin(x);
        y2 = movrmsWin_overlap(x);
        y3 = movrmsExp(x);
        scope(x,y1,y2,y3);
    end
end

```

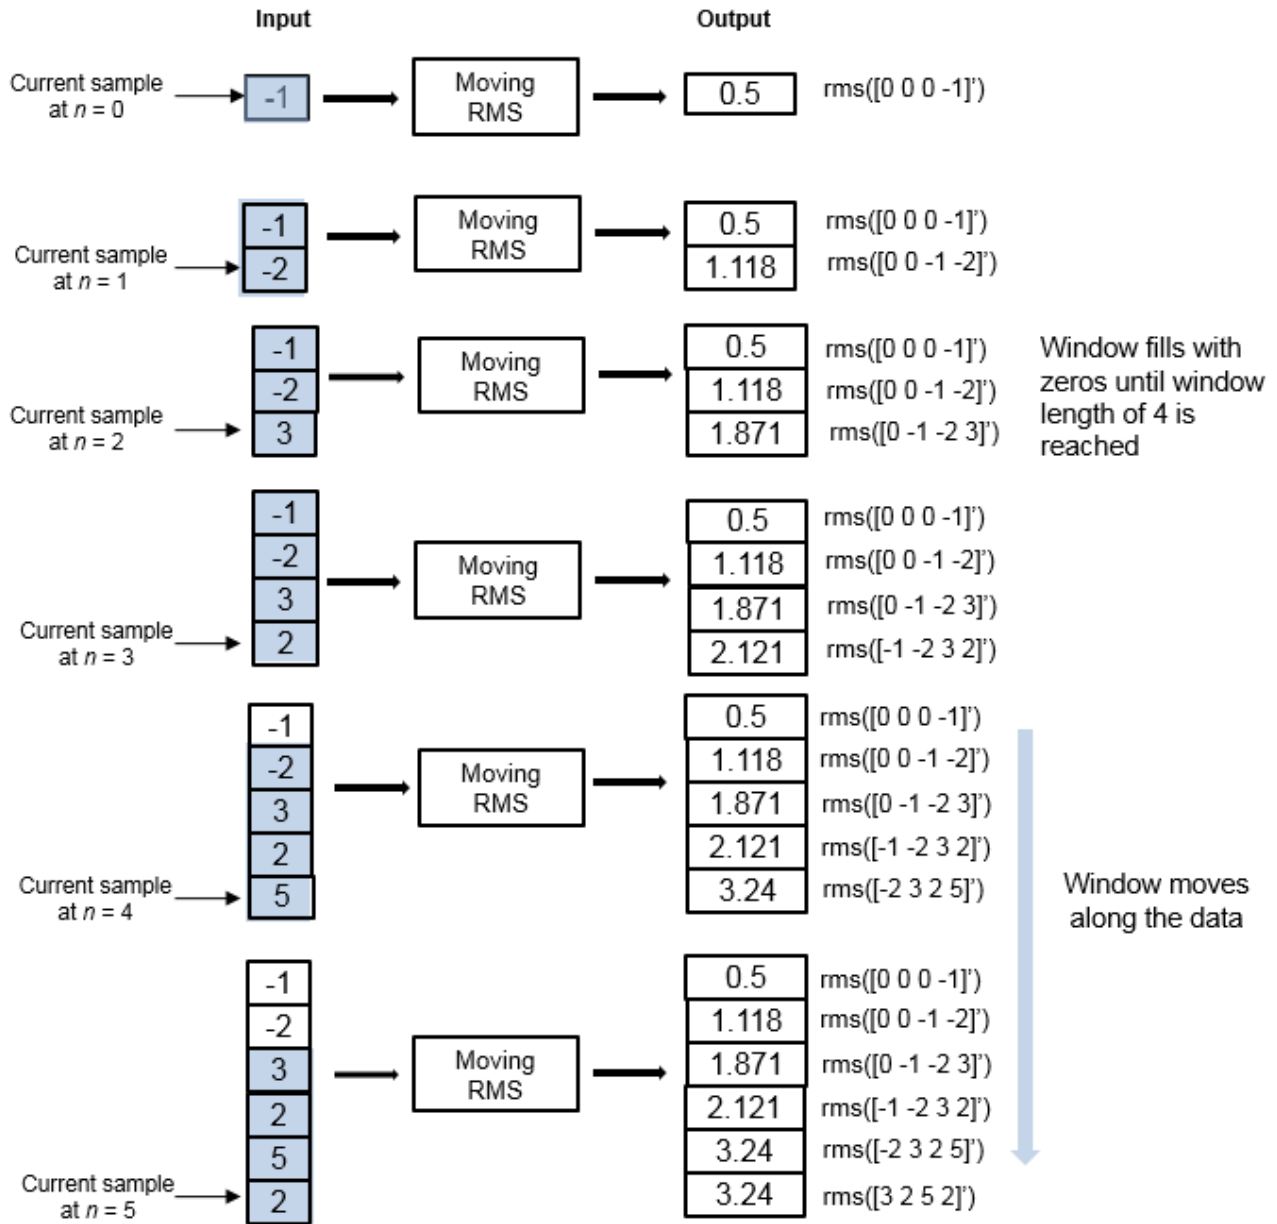

Algorithms

Sliding Window Method

In the sliding window method, the output for each input sample is the RMS of the current sample and $Len - 1$ previous samples. Len is the length of the window in samples. To compute the first output sample, the algorithm waits until it receives the hop size number of input samples. Hop size is defined as window length - overlap length. Remaining samples in the window are considered to be zero. As an example, if the window length is 5 and the overlap length is 2, then the algorithm waits until it receives 3 samples of input to compute the first sample of the output. After generating the first output, it generates the subsequent output samples for every hop size number of input samples.

When you do not specify the window length, the algorithm chooses an infinite window length. In this mode, the output is the moving RMS of the current sample and all the previous samples in the channel.

Consider an example of computing the moving RMS of a streaming input data using the sliding window method. The algorithm uses a window length of 4 and an overlap length of 3. With each input sample that comes in, the window of length 4 moves along the data.

Exponential Weighting Method

In the exponential weighting method, the moving RMS is computed recursively using these formulas:

$$w_{N,\lambda} = \lambda w_{N-1,\lambda} + 1$$

$$x_{rmsN,\lambda} = \sqrt{\left(1 - \frac{1}{w_{N,\lambda}}\right)x_{rmsN-1,\lambda} + \left(\frac{1}{w_{N,\lambda}}\right)x_N^2}$$

- $x_{rmsN,\lambda}$ – Moving RMS at the current sample
- x_N^2 – Square of the current input data sample

- $x_{rms_{N-1,\lambda}}$ — Moving RMS at the previous sample
- λ — Forgetting factor
- $w_{N,\lambda}$ — Weighting factor applied to the current data sample
- $\left(1 - \frac{1}{w_{N,\lambda}}\right)x_{rms_{N-1,\lambda}}$ — Effect of the previous data on the RMS

For the first sample, where $N = 1$, the algorithm chooses $w_{N,\lambda} = 1$. For the next sample, the weighting factor is updated and used to compute the RMS, as per the recursive equation. As the age of the data increases, the magnitude of the weighting factor decreases exponentially and never reaches zero. In other words, the recent data has more influence on the current RMS than the older data.

The value of the forgetting factor determines the rate of change of the weighting factors. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All the previous samples are given an equal weight.

Here is an example of computing the moving RMS using the exponential weighting method. The forgetting factor is 0.9.

Version History

Introduced in R2016b

Change in variable-size behavior for output signal in generated code

Starting in R2022b, if you generate code from this object with the `Method` property set to 'Sliding window' and the `SpecifyWindowLength` property set to `true`, and if you input a signal with a frame length that is a multiple of the hop size (window length – overlap length), this object generates a fixed-size output signal in the generated code. For more details, see “Code Generation” on page 4-867.

References

[1] Bodenham, Dean. “Adaptive Filtering and Change Detection for Streaming Data.” PH.D. Thesis. Imperial College, London, 2012.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- See “System Objects in MATLAB Code Generation” (MATLAB Coder).
- When you set `Method` to 'Sliding window' and `SpecifyWindowLength` to `true`, and generate code from this object, the variable-size behavior of the output depends on the input frame length and whether the size of the input signal is fixed or variable.

See this table for more details.

Input signal	Input size	Output signal
Fixed-size	m -by- n	When the input frame length is a multiple of the hop size, the output signal has a fixed-size of $(m/\text{hop size})$ -by- n . When input frame length is not a multiple of the hop size, the output signal is variable-sized and has an upper bound of $\text{ceil}(m/\text{hop size})$ -by- n .
Variable-size	m -by- n	Output is a variable-size signal. Output has an upper bound size of $\text{ceil}(m/\text{hop size})$ -by- n .

dsp.MovingStandardDeviation

Package: dsp

Moving standard deviation

Description

The `dsp.MovingStandardDeviation` System object computes the moving standard deviation of the input signal along each channel, independently over time. The object uses either the sliding window method or the exponential weighting method to compute the moving standard deviation. In the sliding window method, a window of specified length is moved over the data, sample by sample, and the object computes the standard deviation over the data in the window. In the exponential weighting method, the object computes the exponentially weighted moving variance, and takes the square root. For more details on these methods, see “Algorithms” on page 4-874.

To compute the moving standard deviation of the input:

- 1 Create the `dsp.MovingStandardDeviation` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
MovStd = dsp.MovingStandardDeviation
MovStd = dsp.MovingStandardDeviation(Len)
MovStd = dsp.MovingStandardDeviation(Len,Overlap)
MovStd = dsp.MovingStandardDeviation(Name,Value)
```

Description

`MovStd = dsp.MovingStandardDeviation` returns a moving standard deviation object, `MovStd`, using the default properties.

`MovStd = dsp.MovingStandardDeviation(Len)` sets the `WindowLength` property to `Len`.

`MovStd = dsp.MovingStandardDeviation(Len,Overlap)` sets the `WindowLength` property to `Len` and the `OverlapLength` property to `Overlap`.

`MovStd = dsp.MovingStandardDeviation(Name,Value)` specifies additional properties using `Name,Value` pairs. Unspecified properties have default values.

Example: `MovStd = dsp.MovingStandardDeviation('Method','Exponential weighting','ForgettingFactor',0.999);`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

Method — Moving standard deviation method

'Sliding window' (default) | 'Exponential weighting'

- 'Sliding window' — A window of length specified by `SpecifyWindowLength` is moved over the input data along each channel. For every sample the window moves by, the object computes the standard deviation over the data in the window.
- 'Exponential weighting' — The object computes the exponentially weighted moving variance, and takes the square root.

For more details on these methods, see “Algorithms” on page 4-874.

SpecifyWindowLength — Specify window length

true (default) | false

Flag to specify a window length, specified as a scalar boolean.

- true — The length of the sliding window is equal to the value you specify in the `WindowLength` property.
- false — The length of the sliding window is infinite. In this mode, the standard deviation is computed using the current sample and all the past samples.

Dependencies

This property applies when you set `Method` to 'Sliding window'.

WindowLength — Length of the sliding window

4 (default) | positive scalar integer

Length of the sliding window in samples, specified as a positive scalar integer.

Dependencies

This property applies when you set `Method` to 'Sliding window' and `SpecifyWindowLength` to true.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

OverlapLength — Overlap length between windows

WindowLength - 1 (default) | nonnegative integer

Overlap length between sliding windows, specified as a nonnegative integer. The value of overlap length varies in the range $[0, \text{WindowLength} - 1]$. If not specified, the overlap length is `WindowLength - 1`.

Dependencies

This property applies when you set `Method` to 'Sliding window' and `SpecifyWindowLength` to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

ForgettingFactor — Exponential weighting factor

0.9 (default) | positive real scalar in the range (0,1]

Exponential weighting factor, specified as a positive real scalar in the range (0,1].

Since this property is tunable, you can change its value even when the object is locked.

Tunable: Yes

Dependencies

This property applies when you set `Method` to 'Exponential weighting'.

Data Types: `single` | `double`

Usage**Syntax**

```
y = movStd(x)
```

Description

`y = movStd(x)` computes the moving standard deviation of the input signal, `x`, using either the sliding window method or exponential weighting method.

Input Arguments**x — Data input**

vector | matrix

Data input, specified as a vector or a matrix. If `x` is a matrix, each column is treated as an independent channel. The moving standard deviation is computed along each channel.

The object accepts variable-size inputs. Once the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

Data Types: `single` | `double`

Output Arguments**y — Moving standard deviation**

vector | matrix

Moving standard deviation of the input signal, returned as a vector or a matrix.

When you input a signal of size m -by- n to the object, and if you set `Method` to 'Sliding window' and `SpecifyWindowLength` to `true`, the output has an upper bound size of $\text{ceil}(m/\text{hop size})$ -by- n . Hop size is window length – overlap length. In other cases, the output has a size of m -by- n .

When you generate code from this object, the variable-size behavior of the output in the generated code depends on the input frame length and whether the size of the input signal is fixed or variable. For more details, see “Code Generation” on page 4-877.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Moving Standard Deviation of Noisy Square Wave Signal

Compute the moving standard deviation of a noisy square wave signal with varying amplitude using the `dsp.MovingStandardDeviation` object.

Initialization

Set up `movstdWindow`, `movstdWindow_overlap`, and `movstdExp` objects. `movstdWindow` uses the sliding window method with a window length of 800 samples and a default overlap length of 799 samples, which is one sample less than the specified window length. `movstdWindow_overlap` uses a window length of 800 samples and an overlap length of 700 samples. `movstdExp` uses the exponentially weighting method with a forgetting factor of 0.999.

Create a time scope for viewing the output.

```
FrameLength = 100;
Fs = 100;
movstdWindow = dsp.MovingStandardDeviation(800);
movstdWindow_overlap = dsp.MovingStandardDeviation(800,700);
movstdExp = dsp.MovingStandardDeviation(...
    'Method','Exponential weighting',...
    'ForgettingFactor',0.999);
scope = timescope('SampleRate',[Fs,Fs,Fs/(800-700),Fs],...
    'TimeSpanOverrunAction','Scroll',...
    'TimeSpanSource','Property',...
    'TimeSpan',1000,...
    'ShowGrid',true,...
    'BufferLength',1e7,...
    'YLimits',[0 3e-2]);
title = 'Moving Standard Deviation';
scope.Title = title;
scope.ChannelNames = {'Original Signal',...}
```

```
'Sliding window of 800 samples with default overlap',...
'Sliding window of 800 samples with an overlap of 700 samples',...
'Exponential weighting with forgetting factor of 0.999'}];
```

Compute the Standard Deviation

Generate a noisy square wave signal. Vary the amplitude of the square wave after a given number of frames. Apply the sliding window method and the exponential weighting method to this signal. The actual standard deviation is \sqrt{np} . The object uses this value while adding noise to the data. Compare the actual standard deviation with the computed standard deviation in the time scope.

```
count = 1;
noisepower = 1e-4 * [1 2 3 4];
for index = 1:length(noisepower)
    np = noisepower(index);
    yexp = sqrt(np)*ones(FrameLength,1);
    for i = 1:250
        x = sqrt(np) * randn(FrameLength,1);
        y1 = movstdWindow(x);
        y2 = movstdWindow_overlap(x);
        y3 = movstdExp(x);
        scope(yexp,y1,y2,y3);
    end
end
```

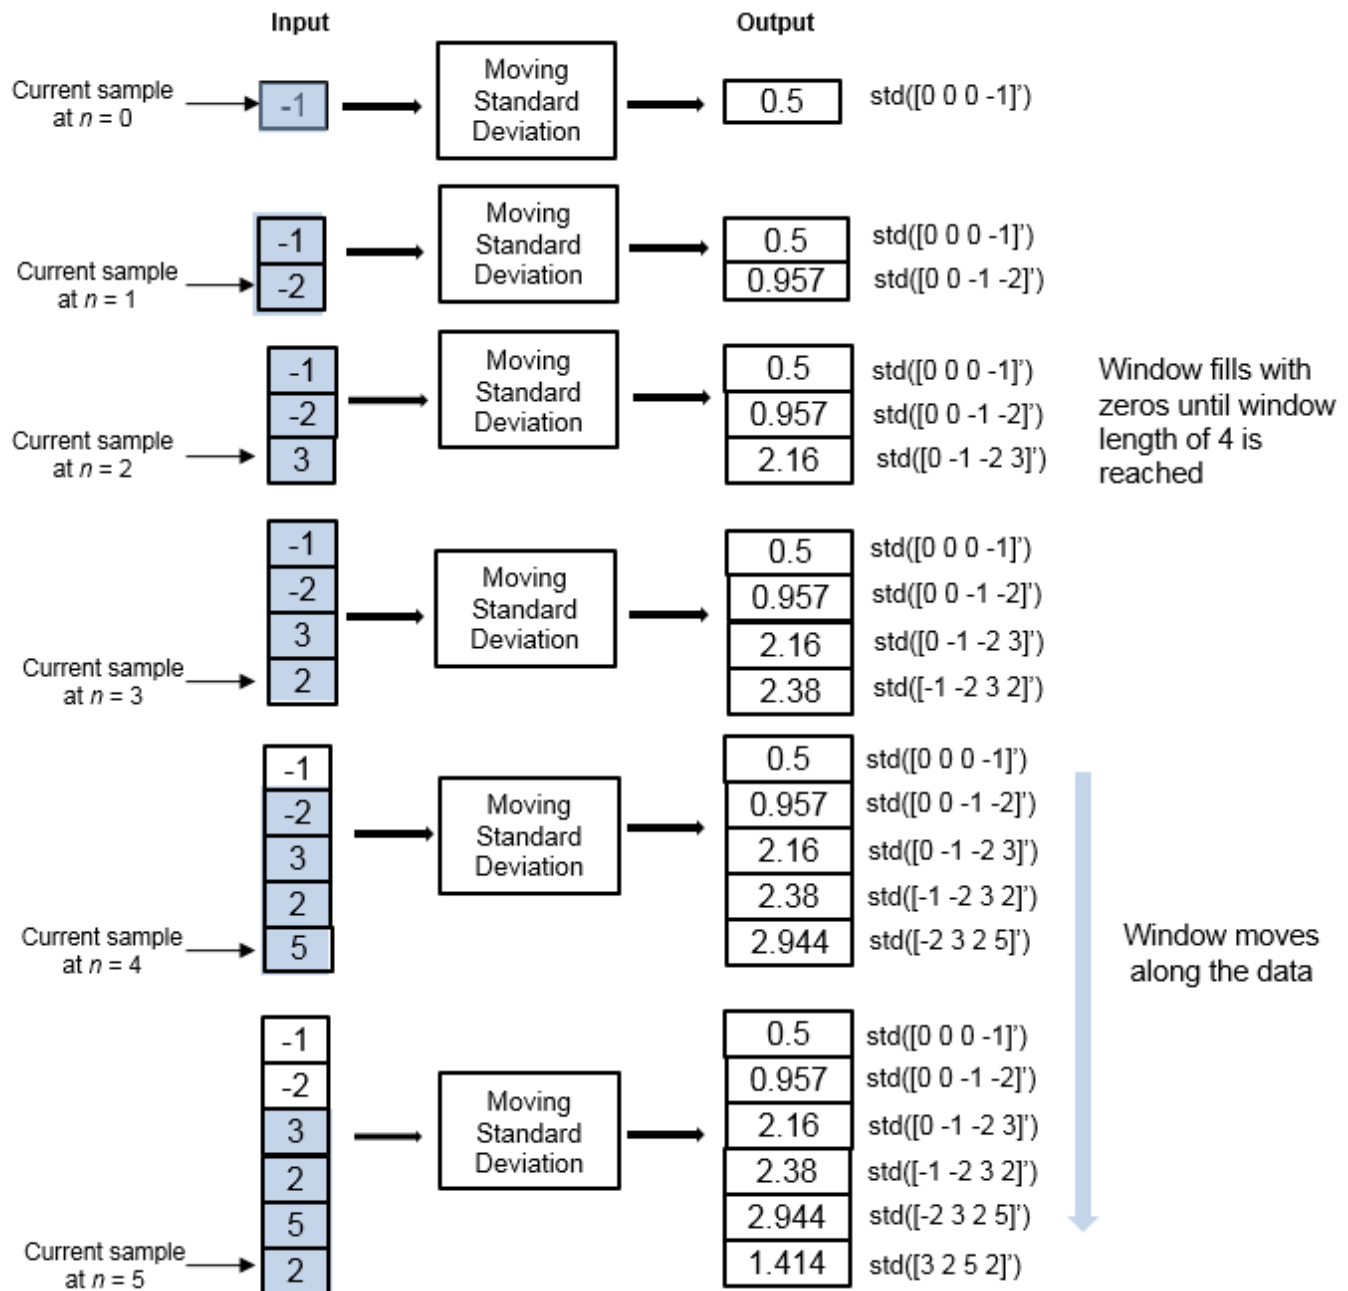

Algorithms

Sliding Window Method

In the sliding window method, the output at the current sample is the standard deviation of the current sample with respect to the data in the window. To compute the first output sample, the algorithm waits until it receives the hop size number of input samples. Hop size is defined as window length - overlap length. Remaining samples in the window are considered to be zero. As an example, if the window length is 5 and the overlap length is 2, then the algorithm waits until it receives 3 samples of input to compute the first sample of the output. After generating the first output, it generates the subsequent output samples for every hop size number of input samples.

When you do not specify the window length, the algorithm chooses an infinite window length. In this mode, the output is the moving standard deviation of the current sample with respect to all the previous samples in the channel.

Consider an example of computing the moving standard deviation of a streaming input data using the sliding window method. The algorithm uses a window length of 4 and an overlap length of 3. With each input sample that comes in, the window of length 4 moves along the data.

Exponential Weighting Method

In the exponential weighting method, the moving standard deviation is computed recursively using these formulas:

$$s_{N,\lambda} = \sqrt{\frac{1}{v_{N,\lambda}} \sum_{k=1}^N \lambda^{N-k} [x_k - \bar{x}_{N,\lambda}]^2}$$

$$v_{N,\lambda} = \frac{2\lambda(1 - \lambda^{N-1})}{(1 - \lambda)(1 + \lambda)}$$

- $s_{N,\lambda}$ — Moving standard deviation of the current data sample with respect to the rest of the data.
- $[x_k - \bar{x}_{N,\lambda}]^2$ — Difference between each data sample and the average of the data, squared.
- $\sum_{k=1}^N \lambda^{N-k} [x_k - \bar{x}_{N,\lambda}]^2$ — Difference between each data sample and the average of the data, squared and multiplied with the forgetting factor. All the squared terms are added.
- $\frac{1}{v_{N,\lambda}}$ — Weighting factor applied to the sum.
- λ — Forgetting factor.

As the age of the data increases, the magnitude of the weighting factor decreases exponentially and never reaches zero. In other words, the recent data has more influence on the current standard deviation than the older data.

The value of the forgetting factor determines the rate of change of the weighting factors. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All previous samples are given an equal weight.

Consider an example of computing the moving standard deviation using the exponential weighting method. The forgetting factor is 0.9.

Version History

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- See “System Objects in MATLAB Code Generation” (MATLAB Coder).
- When you set `Method` to 'Sliding window' and `SpecifyWindowLength` to `true`, and generate code from this object, the variable-size behavior of the output depends on the input frame length and whether the size of the input signal is fixed or variable.

See this table for more details.

Input signal	Input size	Output signal
Fixed-size	m -by- n	When the input frame length is a multiple of the hop size, the output signal has a fixed-size of $(m/\text{hop size})$ -by- n . When input frame length is not a multiple of the hop size, the output signal is variable-sized and has an upper bound of $\text{ceil}(m/\text{hop size})$ -by- n .
Variable-size	m -by- n	Output is a variable-size signal. Output has an upper bound size of $\text{ceil}(m/\text{hop size})$ -by- n .

dsp.MovingVariance

Package: dsp

Moving variance

Description

The `dsp.MovingVariance` System object computes the moving variance of the input signal along each channel, independently over time. The object uses either the sliding window method or the exponential weighting method to compute the moving variance. In the sliding window method, a window of specified length is moved over the data, sample by sample, and the variance is computed over the data in the window. In the exponential weighting method, the object subtracts each sample of the data from the average, squares the difference, and multiplies the squared result with a weighting factor. The object then computes the variance by adding all the weighted data. For more details on these methods, see “Algorithms” on page 4-884.

To compute the moving variance of the input:

- 1 Create the `dsp.MovingVariance` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
MovVar = dsp.MovingVariance
MovVar = dsp.MovingVariance(Len)
MovVar = dsp.MovingVariance(Len,Overlap)
MovVar = dsp.MovingVariance(Name,Value)
```

Description

`MovVar = dsp.MovingVariance` returns a moving variance object, `MovVar`, using the default properties.

`MovVar = dsp.MovingVariance(Len)` sets the `WindowLength` property to `Len`.

`MovVar = dsp.MovingVariance(Len,Overlap)` sets the `WindowLength` property to `Len` and the `OverlapLength` property to `Overlap`.

`MovVar = dsp.MovingVariance(Name,Value)` specifies additional properties using `Name, Value` pairs. Unspecified properties have default values.

```
Example: MovVar = dsp.MovingVariance('Method','Exponential
weighting','ForgettingFactor',0.9);
```

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Method — Method to compute the variance

'Sliding window' (default) | 'Exponential weighting'

- 'Sliding window' — A window of length specified by `SpecifyWindowLength` is moved over the input data along each channel. For every sample the window moves by, the object computes the variance over the data in the window.
- 'Exponential weighting' — The object subtracts each sample of the data from the average, squares the difference, and multiplies the squared result with a weighting factor. The object then computes the variance by adding all the weighted data. The magnitude of the weighting factors decreases exponentially as the age of the data increases, never reaching zero.

For more details on these methods, see “Algorithms” on page 4-884.

SpecifyWindowLength — Specify window length

true (default) | false

Flag to specify a window length, specified as a scalar Boolean.

- true — The length of the sliding window is equal to the value you specify in the `WindowLength` property.
- false — The length of the sliding window is infinite. In this mode, the variance is computed using the current sample and all past samples.

Dependencies

This property applies when you set `Method` to 'Sliding window'.

WindowLength — Length of the sliding window

4 (default) | positive scalar integer

Length of the sliding window in samples, specified as a positive scalar integer.

Dependencies

This property applies when you set `Method` to 'Sliding window' and `SpecifyWindowLength` to true.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

OverlapLength — Overlap length between windows

WindowLength - 1 (default) | nonnegative integer

Overlap length between sliding windows, specified as a nonnegative integer. The value of overlap length varies in the range $[0, \text{WindowLength} - 1]$. If not specified, the overlap length is set to `WindowLength - 1`.

Dependencies

This property applies when you set `Method` to 'Sliding window' and `SpecifyWindowLength` to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

ForgettingFactor — Exponential weighting factor

0.9 (default) | positive real scalar in the range (0,1]

Exponential weighting factor, specified as a positive real scalar in the range (0,1].

A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All the past samples are given an equal weight.

Since this property is tunable, you can change its value even when the object is locked.

Tunable: Yes

Dependencies

This property applies when you set `Method` to 'Exponential weighting'.

Data Types: `single` | `double`

Usage**Syntax**

```
y = movVar(x)
```

Description

`y = movVar(x)` computes the moving variance of the input signal, `x`, using either the sliding window method or exponential weighting method.

Input Arguments**x — Data input**

vector | matrix

Data input, specified as a vector or a matrix. If `x` is a matrix, each column is treated as an independent channel. The moving variance is computed along each channel.

The object accepts variable-size inputs. Once the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

Data Types: `single` | `double`

Output Arguments**y — Moving variance**

vector | matrix

Moving variance of the input signal, returned as a vector or a matrix.

When you input a signal of size m -by- n to the object, and if you set `Method` to 'Sliding window' and `SpecifyWindowLength` to `true`, the output has an upper bound size of $\text{ceil}(m/\text{hop size})$ -by- n . Hop size is window length – overlap length. In other cases, the output has a size of m -by- n .

When you generate code from this object, the variable-size behavior of the output in the generated code depends on the input frame length and whether the size of the input signal is fixed or variable. For more details, see “Code Generation” on page 4-888.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

`step` Run System object algorithm
`release` Release resources and allow changes to System object property values and input characteristics
`reset` Reset internal states of System object

Examples

Moving Variance of Noisy Square Wave Signal

Compute the moving variance of a noisy square wave signal with varying amplitude using the `dsp.MovingVariance` object.

Initialization

Set up `movvarWindow`, `movvarWindow_overlap`, and `movvarExp` objects. `movvarWindow` uses the sliding window method with a window length of 800 samples and a default overlap length of 799 samples, which is 1 sample less than the specified window length. `movvarWindow_overlap` uses a window length of 800 samples and an overlap length of 700 samples. `movvarExp` uses the exponentially weighting method with a forgetting factor of 0.999.

Create a time scope for viewing the output.

```
FrameLength = 100;
Fs = 100;
movvarWindow = dsp.MovingVariance(800);
movvarWindow_overlap = dsp.MovingVariance(800,700);
movvarExp = dsp.MovingVariance('Method','Exponential weighting',...
    'ForgettingFactor',0.999);
scope = timescope('SampleRate',[Fs,Fs,Fs/(800-700),Fs],...
    'TimeSpanOverrunAction','Scroll',...
    'TimeSpanSource','Property',...
    'TimeSpan',1000,...
    'ShowGrid',true,...
    'BufferLength',1e7,...
    'YLimits',[0 7e-4]);
```

```

title = 'Moving Variance';
scope.Title = title;
scope.ChannelNames = {'Original Signal',...
    'Sliding window of 800 samples with default overlap',...
    'Sliding window of 800 samples with an overlap of 700 samples',...
    'Exponential weighting with forgetting factor of 0.999'};

```

Compute the Variance

Generate a noisy square wave signal. Vary the amplitude of the square wave after a given number of frames. Apply the sliding window method and the exponentially weighting method on this signal. The actual variance is np . This value is used while adding noise to the data. Compare the actual variance with the computed variances on the time scope.

```

count = 1;
noisepower = 1e-4 * [1 2 3 4];
for index = 1:length(noisepower)
    np = noisepower(index);
    yexp = np*ones(FrameLength,1);
    for i = 1:250
        x = 1 + sqrt(np) * randn(FrameLength,1);
        y1 = movvarWindow(x);
        y2 = movvarWindow_overlap(x);
        y3 = movvarExp(x);
        scope(yexp,y1,y2,y3);
    end
end
end

```

Algorithms

Sliding Window Method

In the sliding window method, the output at the current sample is the variance of the current sample with respect to the data in the window. To compute the first output sample, the algorithm waits until it receives the hop size number of input samples. Hop size is defined as window length - overlap length. Remaining samples in the window are considered to be zero. As an example, if the window length is 5 and the overlap length is 2, then the algorithm waits until it receives 3 samples of input to compute the first sample of the output. After generating the first output, it generates the subsequent output samples for every hop size number of input samples.

When you do not specify the window length, the algorithm chooses an infinite window length. In this mode, the output is the moving variance of the current sample with respect to all previous samples in the channel.

Consider an example of computing the moving variance of a streaming input data using the sliding window method. The algorithm uses a window length of 4 and an overlap length of 3. With each input sample that comes in, the window of length 4 moves along the data.

Exponential Weighting Method

In the exponential weighting method, the moving variance is computed recursively using these formulas:

$$s^2_{N,\lambda} = \frac{1}{v_{N,\lambda}} \sum_{k=1}^N \lambda^{N-k} [x_k - \bar{x}_{N,\lambda}]^2$$

$$v_{N,\lambda} = \frac{2\lambda(1 - \lambda^{N-1})}{(1 - \lambda)(1 + \lambda)}$$

To compute the moving variance, the algorithm implements these equations recursively.

- $s_{N,\lambda}^2$ — Moving variance of the current data sample with respect to the rest of the data in the channel.
- $\bar{x}_{N,\lambda}$ — Moving average at the current sample. For details on computing the moving average, see `dsp.MovingAverage`.
- $[x_k - \bar{x}_{N,\lambda}]^2$ — Difference between each data sample and the average of the data, squared.
- $\sum_{k=1}^N \lambda^{N-k} [x_k - \bar{x}_{N,\lambda}]^2$ — Difference between each data sample and the average of the data, squared and multiplied with the forgetting factor. All the squared terms are added.
- $\frac{1}{v_{N,\lambda}}$ — Weighting factor applied to the sum.
- λ — Forgetting factor you can specify through the `ForgettingFactor` property.

As the age of the data increases, the magnitude of the weighting factor decreases exponentially, and never reaches zero. In other words, the recent data has more influence on the current variance, than the older data.

The value of the forgetting factor determines the rate of change of the weighting factors. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All the past samples are given an equal weight.

Consider an example of computing the moving variance using the exponential weighting method. The forgetting factor is 0.9.

dsp.NCO

Package: dsp

Generate real or complex sinusoidal signals

Description

The numerically controlled oscillator, or NCO object generates real or complex sinusoidal signals. The amplitude of the generated signal is always 1.

To generate real or complex sinusoidal signals:

- 1 Create the `dsp.NCO` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
nco = dsp.NCO
nco = dsp.NCO(Name, Value)
```

Description

`nco = dsp.NCO` returns an NCO System object, `nco`, that generates a multichannel real or complex sinusoidal signal, with independent frequency and phase in each output channel.

`nco = dsp.NCO(Name, Value)` returns an NCO System object, `nco`, with each specified property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

PhaseIncrementSource — Source of phase increment

'Input port' (default) | 'Property'

Specify the source of the phase increment as 'Property' or 'Input port'.

PhaseIncrement — Phase increment

100 (default) | scalar | vector

Specify the phase increment as an integer-valued scalar or vector.

Dependencies

This property applies only when you set the “PhaseIncrementSource” on page 4-0 property to 'Property'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

PhaseOffsetSource — Source of phase offset

'Property' (default) | 'Input port'

Specify the source of the phase offset as 'Property' or 'Input port'.

PhaseOffset — Phase offset

0 (default) | scalar | vector

Specify the phase offset as an integer-valued scalar or vector.

Dependencies

This property applies only when you set the “PhaseOffsetSource” on page 4-0 property to 'Property'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Dither — Enable adding internal dithering to NCO algorithm

`true` (default) | `false`

Set this property to `true` to add internal dithering to the NCO algorithm. Dithering is added using the PN Sequence Generator.

NumDitherBits — Number of dither bits

4 (default) | positive integer

Specify the number of dither bits as a positive integer.

Dependencies

This property applies only when you set the `Dither` property to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

PhaseQuantization — Enable quantization of accumulated phase

`true` (default) | `false`

Set this property to `true` to enable quantization of the accumulated phase.

NumQuantizerAccumulatorBits — Number of quantizer accumulator bits

12 (default) | integer

Specify the number of quantizer accumulator bits as an integer scalar greater than 2 and less than the accumulator word length (“CustomAccumulatorDataType” on page 4-0). This property determines the number of entries in the lookup table of sine values.

Dependencies

This property applies only when you set the “PhaseQuantization” on page 4-0 property to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

PhaseQuantizationErrorOutputPort — Enable output of phase quantization error

`false` (default) | `true`

Set this property to `true` to output the phase quantization error.

Dependencies

This property applies only when you set the “PhaseQuantization” on page 4-0 property to `true`.

Waveform — Type of output signal

`'Sine'` (default) | `'Cosine'` | `'Complex exponential'` | `'Sine and cosine'`

Specify the type of the output signal.

SamplesPerFrame — Number of output samples per frame

`1` (default) | positive integer

Specify the number of samples per frame of the output signal. When the `PhaseOffsetSource` property is `'Input port'`, and the “PhaseIncrementSource” on page 4-0 property is `'Property'`, the number of rows or frame size of the phase offset input determines the number of samples per frame of the output signal. When you set both the “PhaseOffsetSource” on page 4-0 and “PhaseIncrementSource” on page 4-0 properties to `'Input port'`, the number of rows in the inputs must be 1, and the samples per frame of the output signal is 1.

Dependencies

This property applies only when you set the “PhaseOffsetSource” on page 4-0 property to `'Property'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

OutputDataType — Output data type

`'Custom'` (default) | `'double'` | `'single'`

Specify the output data type as `'double'`, `'single'` or `'Custom'`. When you select `'Custom'`, you must also set the “CustomOutputDataType” on page 4-0 property.

Fixed-Point Properties

RoundingMethod — Rounding method for fixed-point operations

`'Floor'` (default)

This constant property has a value `'Floor'`.

OverflowAction — Overflow action for fixed-point operations

`'Wrap'` (default)

This constant property has a value `'Wrap'`.

AccumulatorDataType — Accumulator word and fraction lengths

`'Custom'` (default)

This constant property has a value `'Custom'`.

CustomAccumulatorDataType — Accumulator word and fraction lengths

numericitytype([],16) (default) | numericitytype

Specify the accumulator fixed-point type as an unscaled numericitytype object with a Signedness of Auto.

CustomOutputDataType — Output word and fraction lengths

numericitytype([],16,14) (default) | numericitytype

Specify the output fixed-point type as a scaled numericitytype object with a Signedness of Auto.

Dependencies

This property applies only when you set the “OutputDataType” on page 4-0 property to Custom.

Usage**Syntax**

```
Y = nco()  
Y = nco(phInc)  
Y = nco(OFFSET)  
Y = nco(phInc,OFFSET)  
[Y,cosine] = nco(____)  
[Y,qErr] = nco(____)
```

Description

`Y = nco()` returns a sinusoidal signal when the `PhaseIncrementSource` and the `PhaseOffsetSource` properties are both set to 'Property'.

`Y = nco(phInc)` returns a sinusoidal signal, `Y`, generated by the NCO with the specified phase increment, `phInc`.

`Y = nco(OFFSET)` returns a sinusoidal signal, `Y`, with phase offset, `OFFSET`, when the `PhaseOffsetSource` property is set to 'Input port'.

`Y = nco(phInc,OFFSET)` returns a sinusoidal signal, `Y`, with phase increment, `phInc`, and phase offset, `OFFSET`, when the `PhaseIncrementSource` and the `PhaseOffsetSource` properties are both 'Input port'. `phInc` and `OFFSET` must both be row vectors of the same length, where the length determines the number of channels in the output signal.

`[Y,cosine] = nco(____)` returns a sinusoidal signal, `Y`, and a cosinusoidal signal, `cosine`, when the `Waveform` property is set to 'Sine and cosine'. This syntax can include any of the input arguments in previous syntaxes.

`[Y,qErr] = nco(____)` returns a sinusoidal signal, `Y`, and output quantization error, `qErr`, when the `PhaseQuantization` and the `PhaseQuantizationErrorOutputPort` properties are both true.

Input Arguments**phInc — Phase increment**

scalar | row vector

Phase increment, specified as a scalar or a row vector, where each element corresponds to a separate channel.

When both `PhaseIncrementSource` and `PhaseOffsetSource` properties are set to 'Input port', the two inputs, `phInc` and `OFFSET` must have the same number of channels.

Dependencies

This property applies only when the `PhaseIncrementSource` property is set to 'Input port'.

Data Types: `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

OFFSET — Phase offset

row vector | matrix

Phase offset, specified as a row vector or a matrix. The number of rows of `OFFSET` determines the number of samples per frame of the output signal. The number of columns of `OFFSET` determines the number of channels of the output signal.

When both `PhaseIncrementSource` and `PhaseOffsetSource` properties are set to 'Input port', `phInc` and `OFFSET` must have the same number of channels.

Dependencies

This property applies only when the `PhaseOffsetSource` property is set to 'Input port'.

Data Types: `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Output Arguments

Y — NCO output

vector | matrix

NCO output, returned as a vector or a matrix. The number of rows in the output signal is determined by:

- `SamplesPerFrame` property -- When `PhaseOffsetSource` is set to 'Property'
- `OFFSET` input argument -- When `PhaseOffsetSource` is set to 'Input port'

The number of channels in the output signal is determined by the number of channels in the phase offset and the phase increment signals, which must be equal.

The data type of the output is determined by the `OutputDataType` property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

cosine — Cosinusoidal signal

vector | matrix

Cosinusoidal signal, returned as a vector or a matrix. The `cosine` output signal has the same size and data type as the sinusoidal signal, `Y`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

qErr — Output quantization error

vector | matrix

Output quantization error, returned as a vector or a matrix. The `qErr` output signal has the same size as the sinusoidal signal, `Y`.

Dependencies

This output is only available when both the `PhaseQuantization` and the `PhaseQuantizationErrorOutputPort` properties are set to `true`.

Data Types: `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.NCO`

`info` Characteristic information about generated signal

Common to All System Objects

`step` Run System object algorithm
`release` Release resources and allow changes to System object property values and input characteristics
`reset` Reset internal states of System object

Examples

Design NCO Source

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject()` becomes `step(myObject)`.

Design an NCO source according to given specifications.

```
df = 0.05; % Frequency resolution = 0.05 Hz  
minSFDR = 96; % Spurious free dynamic range >= 96 dB  
Ts = 1/8000; % Sample period = 1/8000 sec  
dphi = pi/2; % Desired phase offset = pi/2;
```

Calculate number of accumulator bits required for the given frequency resolution.

```
Nacc = ceil(log2(1/(df*Ts)));
```

Actual frequency resolution achieved.

```
actdf = 1/(Ts*2^Nacc);
```

Calculate number of quantized accumulator bits required from the SFDR requirement

```
Nqacc = ceil((minSFDR-12)/6);
```

Calculate the phase offset

```
phOffset = 2^Nacc*dphi/(2*pi);
```

Design the NCO source.

```
nco = dsp.NCO('PhaseOffset', phOffset,...
    'NumDitherBits', 4, ...
    'NumQuantizerAccumulatorBits', Nqacc,...
    'SamplesPerFrame', 1/Ts, ...
    'CustomAccumulatorDataType', numerictype([],Nacc));
san = spectrumAnalyzer('SampleRate', 1/Ts,...
    'Method', 'welch', 'AveragingMethod', 'exponential',...
    'ForgettingFactor', 0.3,...
    'PlotAsTwoSidedSpectrum', false);
```

View the output of the NCO source on a spectrum analyzer. Change the output frequency in the middle of the simulation from 510 Hz to 1520 Hz.

```
tic;
while toc < 10
    if toc < 5
        F0 = 510;
    else
        F0 = 1520;
    end
    % Calculate the phase increment
    phIncr = int32(round(F0*Ts*2^Nacc));
    y = nco(phIncr);
    san(y)
end
release(san)
```

Obtain the Characteristic Information of the NCO Object

The characteristic information of the NCO object is defined by the following fields:

- NumPointsLUT — Number of data points in the lookup table.
- SineLUTSize — Quarter-wave sine lookup table size in bytes.
- TheoreticalSFDR — Theoretical spurious free dynamic range (SFDR) in dBc.
- FrequencyResolution — Frequency resolution of the NCO.

To obtain the above characteristics for a specific NCO object, call the `info` function on the object.

```
nco = dsp.NCO
```

```
nco =  
    dsp.NCO with properties:
```

```
        PhaseIncrementSource: 'Input port'  
        PhaseOffsetSource: 'Property'  
        PhaseOffset: 0  
        Dither: true  
        NumDitherBits: 4  
        PhaseQuantization: true  
        NumQuantizerAccumulatorBits: 12  
        PhaseQuantizationErrorOutputPort: false
```

```

        Waveform: 'Sine'
    SamplesPerFrame: 1
    OutputDataType: 'Custom'

```

Show all properties

```
info(nco)
```

```
ans = struct with fields:
    NumPointsLUT: 1025
    SineLUTSize: 2050
    TheoreticalSFDR: 84
    FrequencyResolution: 1.5259e-05

```

The fields and their corresponding values change depending on the settings of the object. For instance, if the `PhaseQuantization` property is set to `false`, the `TheoreticalSFDR` field does not appear.

```
nco.PhaseQuantization = false;
info(nco)
```

```
ans = struct with fields:
    NumPointsLUT: 16385
    SineLUTSize: 32770
    FrequencyResolution: 1.5259e-05

```

Algorithms

This object implements the algorithm, inputs, and outputs described on the NCO block reference page. The object properties correspond to the block properties, except there is no object property that corresponds to the **Sample time** block parameter. The objects assumes a sample time of one second.

Version History

Objects

dsp.SineWave

dsp.NotchPeakFilter

Package: dsp

Second-order tunable notching and peaking IIR filter

Description

The `NotchPeakFilter` object filters each channel of the input using IIR filter implementation.

To filter each channel of the input:

- 1 Create the `dsp.NotchPeakFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
npFilter = dsp.NotchPeakFilter
npFilter = dsp.NotchPeakFilter('Specification','Quality factor and center
frequency')
npFilter = dsp.NotchPeakFilter('Specification','Coefficients')
npFilter = dsp.NotchPeakFilter(Name,Value)
```

Description

`npFilter = dsp.NotchPeakFilter` returns a second-order notching and peaking IIR filter that independently filters each channel of the input over time, using a specified center frequency and 3 dB bandwidth.

`npFilter = dsp.NotchPeakFilter('Specification','Quality factor and center frequency')` specifies the quality factor (Q factor) of the notch or peak filter instead of the 3 dB bandwidth.

`npFilter = dsp.NotchPeakFilter('Specification','Coefficients')` specifies the coefficient values that affect bandwidth and center frequency directly, rather than specifying the design parameters in Hz. This removes the trigonometry calculations involved when the properties are tuned.

`npFilter = dsp.NotchPeakFilter(Name,Value)` returns a notch filter with each specified property name set to the specified value. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Specification — Filter specification

'Bandwidth and center frequency' (default) | 'Quality factor and center frequency' | 'Coefficients'

Set the specification as 'Bandwidth and center frequency', 'Quality factor and center frequency', or 'Coefficients'.

Bandwidth — 3 dB bandwidth

2205 (default) | positive scalar

Specify the filter's 3 dB bandwidth as a finite positive numeric scalar in Hz. The value must be a scalar between 0 and half the sample rate.

Tunable: Yes

Dependencies

This property is applicable only if Specification is 'Bandwidth and center frequency'.

Data Types: single | double

CenterFrequency — Notch or peak center frequency

11025 (default) | positive scalar

Specify the filter's center frequency (for both the notch and the peak) as a finite positive numeric scalar in Hz. The value must be a scalar between 0 and half the sample rate.

Tunable: Yes

Dependencies

This property is applicable only if Specification is set to 'Bandwidth and center frequency' or 'Quality factor and center frequency'.

Data Types: single | double

QualityFactor — Quality factor for notch or peak filter

5 (default) | positive scalar

Specify the quality factor (Q factor) for both the notch and the peak filters. The Q factor is defined as the center frequency divided by the bandwidth. A higher Q factor corresponds to a narrower notch or peak. The Q factor should be a scalar value greater than 0.

Tunable: Yes

Dependencies

This property is applicable only if Specification is set to 'Quality factor and center frequency'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

SampleRate — Sample rate of input

44100 (default) | positive scalar

Specify the sample rate of the input in Hz as a finite numeric scalar.

Data Types: `single` | `double`

BandwidthCoefficient — Bandwidth coefficient

0.72654 (default) | real scalar in the range [-1 1]

Specify the value that determines the filter's 3 dB bandwidth as a finite numeric scalar in the range [-1 1]. The value -1 corresponds to the maximum 3 dB bandwidth ($\text{SampleRate}/4$), and 1 corresponds to the minimum 3 dB bandwidth (0 Hz, an allpass filter).

Tunable: Yes

Dependencies

This property is only applicable if `Specification` is set to `'Coefficients'`.

Data Types: `single` | `double`

CenterFrequencyCoefficient — Center frequency coefficient

0 (default) | real scalar in the range [-1 1]

Specify the coefficient that determines the filter's center frequency as a finite numeric scalar in the range [-1 1]. The value -1 corresponds to the minimum center frequency (0 Hz), and 1 corresponds to the maximum center frequency ($\text{SampleRate}/2$ Hz). The default is 0, which corresponds to $\text{SampleRate}/4$ Hz.

Tunable: Yes

Dependencies

This property is only applicable if `Specification` is set to `'Coefficients'`.

Data Types: `single` | `double`

Usage**Syntax**

```
Y = npFilter(x)
[Yn,Yp] = npFilter(x)
```

Description

`Y = npFilter(x)` filters each channel (column) of the input signal, `x`, to produce the notch filter output, `Y`.

`[Yn,Yp] = npFilter(x)` filters each channel of the input signal, `x`, to produce the notch filter output, `Yn`, and peak filter output, `Yp`.

Input Arguments**x — Input signal**

vector | matrix

Input signal, specified as a vector or a matrix.

Data Types: `single` | `double`

Output Arguments

Yn — Notch filter output

vector | matrix

Notch filter output, returned as a vector or a matrix.

Data Types: `single` | `double`

Yp — Peak filter output

vector | matrix

Peak filter output, returned as a vector or a matrix.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.NotchPeakFilter`

<code>getBandwidth</code>	Get 3 dB bandwidth
<code>getCenterFrequency</code>	Get center frequency
<code>getOctaveBandwidth</code>	Bandwidth in number of octaves
<code>getQualityFactor</code>	Get quality factor
<code>tf</code>	Transfer function

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Notch Filter

This example shows how to use `dsp.NotchPeakFilter` as a notch filter with center frequency of 5000 Hz and a 3 dB bandwidth of 500 Hz.

```
npFilter = dsp.NotchPeakFilter('CenterFrequency',5000,'Bandwidth',500);
sa = spectrumAnalyzer('SampleRate',44100,'AveragingMethod','exponential',...
    'ForgettingFactor',0.96,'PlotAsTwoSidedSpectrum',false);
for i=1:5000
    y = npFilter(randn(1024,1));
    sa(y);
end
```

```

if (i==2500)
    % Tune center frequency to 10000
    npFilter.CenterFrequency = 10000;
end
end
release(npFilter)
release(sa)

```

Get 3 dB Bandwidth of Notch Peak Filter

Create a `dsp.NotchPeakFilter` object with the `Specification` property set to 'Quality factor and center frequency'. The default quality factor Q is 5, and the center frequency F_c is 11,025 Hz.

```

np = dsp.NotchPeakFilter('Specification',...
    'Quality factor and center frequency')

```

```

np =
    dsp.NotchPeakFilter with properties:

```

```

    Specification: 'Quality factor and center frequency'
    QualityFactor: 5
    CenterFrequency: 11025
    SampleRate: 44100

```

Compute the 3 dB bandwidth of the notch peak filter using the `getBandwidth` function. The bandwidth is computed as the ratio of the center frequency and the quality factor, $\frac{F_c}{Q}$.

```
getBandwidth(np)
```

```
ans = 2205
```

Visualize the filter response using `fvtool`.

```
fvtool(np)
```

Get Center Frequency of Notch Peak Filter

Create a `dsp.NotchPeakFilter` object with the `Specification` property set to `'Coefficients'`.

```
np = dsp.NotchPeakFilter('Specification','Coefficients')
```

```
np =
  dsp.NotchPeakFilter with properties:
      Specification: 'Coefficients'
  BandwidthCoefficient: 0.7265
  CenterFrequencyCoefficient: 0
```

SampleRate: 44100

Determine the center frequency of the notch peak filter using the `getCenterFrequency` function. When the `Specification` is set to `'Coefficients'`, the center frequency is determined from the `CenterFrequencyCoefficient` value and the sample rate.

```
getCenterFrequency(np)
```

```
ans = 11025
```

Visualize the filter response using `fvtool`.

```
fvtool(np)
```

Get Octave Bandwidth of Notch Peak Filter

Create a `dsp.NotchPeakFilter` object in the default configuration.

```
np = dsp.NotchPeakFilter
```

```
np =  
dsp.NotchPeakFilter with properties:
```

```
Specification: 'Bandwidth and center frequency'
```

```
Bandwidth: 2205  
CenterFrequency: 11025  
SampleRate: 44100
```

Determine the octave bandwidth of the filter using the `getOctaveBandwidth` function.

```
getOctaveBandwidth(np)
```

```
ans = 0.2881
```

Visualize the filter response using `fvtool`.

```
fvtool(np)
```

Compute Quality Factor of Notch Peak Filter

Create a `dsp.NotchPeakFilter` object in the default configuration, where the `Specification` property is set to 'Bandwidth and center frequency'.

```
np = dsp.NotchPeakFilter
```

```
np =  
    dsp.NotchPeakFilter with properties:
```

```

Specification: 'Bandwidth and center frequency'
Bandwidth: 2205
CenterFrequency: 11025
SampleRate: 44100

```

Determine the quality factor of the filter using the `getQualityFactor` function. The quality factor is given by the ratio of the center frequency to the bandwidth.

```
getQualityFactor(np)
```

```
ans = 5
```

Visualize the filter response using `fvtool`.

```
fvtool(np)
```

Determine Transfer Function of Notch Peak Filter

Create a `dsp.NotchPeakFilter` System object™. Obtain the coefficients of the transfer function corresponding to the notch and peak filters.

```

notchpeak = dsp.NotchPeakFilter;
[Bnotch,Anotch,Bpeak,Apeak] = tf(notchpeak)

```

Bnotch = 1×3

0.8633 -0.0000 0.8633

Anotch = 1×3

1.0000 -0.0000 0.7265

Bpeak = 1×3

0.1367 0 -0.1367

Apeak = 1×3

1.0000 -0.0000 0.7265

Bnotch and Anotch are the vectors of numerator and denominator coefficients for the equivalent transfer function corresponding to the notch filter. Bpeak and Apeak are the vectors of numerator and denominator coefficients for the equivalent transfer function corresponding to the peak filter.

Algorithms

The design equation for the peak filter is:

$$H(z) = (1 - b) \frac{1 - z^{-2}}{1 - 2b \cos \omega_0 z^{-1} + (2b - 1)z^{-2}}$$

The design equation for the notch filter is:

$$H(z) = b \frac{1 - 2 \cos \omega_0 z^{-1} + z^{-2}}{1 - 2b \cos \omega_0 z^{-1} + (2b - 1)z^{-2}}$$

with

$$b = \frac{1}{1 + \tan(\Delta\omega/2)}$$

where $\omega_0 = 2\pi f_0/f_s$ is the center frequency in radians/sample (f_0 is the center frequency in Hz and f_s is the sampling frequency in Hz). $\Delta\omega = 2\pi\Delta f/f_s$ is the 3 dB bandwidth in radians/sample (Δf is the 3 dB bandwidth in Hz). Note that the two filters are complementary:

$$H_{\text{notch}}(z) + H_{\text{peak}}(z) = 1$$

they can be written as:

$$H_{\text{peak}}(z) = \frac{1}{2}[1 - A(z)]$$

$$H_{\text{notch}}(z) = \frac{1}{2}[1 + A(z)]$$

where $A(z)$ is a 2nd order allpass filter.

$$A(z) = \frac{a_2 + a_1z^{-1} + z^{-2}}{1 + a_1z^{-1} + a_2z^{-2}}$$

and

$$a_1 = -2b\cos\omega_0$$

$$a_2 = 2b - 1$$

The filter is implemented as follows:

where

$$G_{3dB} = a_2 = 2b - 1$$

$$G_{cf} = \frac{a_1 - a_1a_2}{1 - a_2^2} = -\cos\omega_0$$

Notice that G_{cf} depends only on the center frequency, and G_{3dB} depends only on the 3 dB bandwidth.

Notch-Peak Filter

dsp.PeakFinder

Package: dsp

(To be removed) Identify peak values in input signal

Note The `dsp.PeakFinder` System object™ will be removed in a future release. To determine the local maxima, use the `findpeaks` function. To determine the local minima, use the `islocalmin` function and find the signal values corresponding to the local minima indices that the function determines. For more details, see “Compatibility Considerations”.

Description

The `dsp.PeakFinder` System object counts the number of peak values (maxima, minima, or both) in each column of the real-valued input signal. To qualify as a peak, a point has to be larger (or smaller) than both of its neighboring points. The end points are not considered as peak values. The object can also output the indices and values of the peaks, and a binary array that indicates whether a peak is a maxima or a minima.

To output the peak indices and peak values, set “PeakIndicesOutputPort” on page 4-0 and “PeakValuesOutputPort” on page 4-0 to `true`, respectively. In addition, you can determine which of the peak values is a maxima or a minima using the polarity matrix. The polarity matrix is a logical array in which a 1 indicates a maxima, and a 0 indicates a minima. To view the polarity matrix, set “PeakType” on page 4-0 to 'Maxima and Minima' and access the fourth output.

Use the “MaximumPeakCount” on page 4-0 property to specify how many peak values to look for in each input signal. The object stops searching the input signal once this maximum number of peak values has been found.

If you set “IgnoreSmallPeaks” on page 4-0 to `true`, the object no longer detects low amplitude peaks and ignores noise within a threshold value that you define. In this mode, the current value is a maximum if $(current - previous) > threshold$ and $(current - next) > threshold$. The current value is a minimum if $(current - previous) < -threshold$ and $(current - next) < -threshold$.

To determine the peak values in an input signal:

- 1 Create the `dsp.PeakFinder` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
pkFind = dsp.PeakFinder
pkFind = dsp.PeakFinder(Name,Value)
```

Description

`pkFind = dsp.PeakFinder` creates a peak finder System object that identifies the peak values (maxima, minima, or both) in an input signal.

`pkFind = dsp.PeakFinder(Name, Value)` creates a peak finder System object with each specified property set to the specified value. Enclose each property name in single quotes.

Example: `delay = dsp.PeakFinder('PeakType','Maxima');`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

PeakType — Type of peaks to identify

'Maxima and Minima' (default) | 'Maxima' | 'Minima'

Type of peaks to identify, specified as one of the following:

- 'Maxima' -- If "IgnoreSmallPeaks" on page 4-0 is set to `true`, the current value is identified as a maximum if $(current - previous) > threshold$ and $(current - next) > threshold$. Specify *threshold* in "PeakThreshold" on page 4-0 property. If `IgnoreSmallPeaks` is set to `false`, the current value must be larger than both its neighboring points.
- 'Minima' -- If `IgnoreSmallPeaks` is set to `true`, the current value is identified as a minimum if $(current - previous) < -threshold$ and $(current - next) < -threshold$. If `IgnoreSmallPeaks` is set to `false`, the current value must be smaller than both its neighboring points.
- 'Maxima and Minima' -- The object identifies both the maxima and the minima points.

PeakIndicesOutputPort — Enable output of peak indices

`false` (default) | `true`

Enable output of the peak indices, specified as either:

- `true` -- The object returns the indices of the input signal peak values.
- `false` -- The object does not return the indices of the input signal peak values.

PeakValuesOutputPort — Enable output of peak values

`false` (default) | `true`

Enable output of the peak values, specified as either:

- `true` -- The object returns the peak values of the input signal.
- `false` -- The object does not return the peak values of the input signal.

MaximumPeakCount — Maximum number of peak values to identify

10 (default) | integer greater than or equal to 1

Maximum number of peak values to identify in each input signal, specified as an integer greater than or equal to 1. The object stops searching the input signal for peaks once it identifies the maximum number.

Example: 5

Example: 50

IgnoreSmallPeaks — Ignore peaks below a threshold

false (default) | true

Ignore peaks below a threshold, specified as either:

- **false** -- The object identifies the current value as a peak, if the current value is larger (or smaller) than both of its neighboring points.
- **true** -- The object identifies the current value as a maximum if $(current - previous) > threshold$ and $(current - next) > threshold$. The object identifies the current value as a minimum if $(current - previous) < -threshold$ and $(current - next) < -threshold$.

PeakThreshold — Threshold below which peaks are ignored

0 (default) | positive real scalar | vector

Threshold below which peaks are ignored, specified as a real scalar greater than or equal to 0 or a vector with all elements greater than or equal to 0. The length of the vector must be equal to the number of channels.

This property identifies the current input value to be a maximum if $(current\ input\ value - previous\ input\ value) > threshold$ and $(current\ input\ value - next\ input\ value) > threshold$. The current value is a minimum if $(current\ input\ value - previous\ input\ value) < -threshold$ and $(current\ input\ value - next\ input\ value) < -threshold$.

Example: 0.2

Example: [0.3 2.4]

Example: [3; 0.4]

Dependencies

This property applies only when you set IgnoreSmallPeaks to true.

Fixed-Point Properties

RoundingMethod — Rounding method

'Floor' (default)

Rounding method, specified as 'Floor', which is equivalent to truncation. The setting rounds the result of a calculation to the closest representable number in the direction of negative infinity.

OverflowAction — Overflow action

'Wrap' (default) | 'Saturate'

The overflow action for fixed-point operations, specified as one of the following:

- **'Wrap'** -- The object wraps the result of its fixed-point operations.
- **'Saturate'** -- The object saturates the result of its fixed-point operations.

For more details on overflow actions, see overflow mode for fixed-point operations.

Usage

Syntax

```
cnt = pkFind(input)
[cnt,idx] = pkFind(input)
[ ___,val] = pkFind(input)
[ ___,pol] = pkFind(input)
```

Description

`cnt = pkFind(input)` returns the number of peak values (minima, maxima, or both) in the input signal. Each column of the input is treated as a separate channel.

`[cnt,idx] = pkFind(input)` returns the number of peak values, `cnt`, and peak indices, `idx`, in the input signal.

To access the peak indices output, set the `PeakIndicesOutputPort` property to `true`.

```
pkFind = dsp.PeakFinder('PeakType','Maxima', ...
'PeakIndicesOutputPort',true);
...
[cnt,idx] = pkFind(input);
```

`[___,val] = pkFind(input)` returns the peak values `val` in the input signal.

To access the peak values output, set the `PeakValuesOutputPort` property to `true`.

```
pkFind = dsp.PeakFinder('PeakType','Maxima', ...
'PeakValuesOutputPort',true);
...
[cnt,idx,val] = pkFind(input);
```

`[___,pol] = pkFind(input)` returns the peak value polarity `pol` in input signal. The polarity is 1 for maxima and 0 for minima.

To access the polarity output, set the `PeakType` property to `'Maxima and Minima'`, and the `PeakIndicesOutputPort` property to `true`.

```
pkFind = dsp.PeakFinder('PeakType','Maxima and Minima', ...
'PeakIndicesOutputPort',true);
...
[cnt,idx,val,pol] = pkFind(input);
```

Input Arguments

input — Data input

column vector of at least three rows | matrix with at least three rows

Data input whose peak values are detected by the object, specified as a vector or matrix containing at least three rows.

Example: `[9 6 10 3 5 5 0 12; 9 6 1 13 4 1 0 12]'`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Output Arguments

cnt — Number of peak values

scalar | row vector

Number of peak values, returned as a scalar or a row vector of length equal to the number of channels in the data input.

Example: [4 3]

Data Types: uint32

idx — Indices of the peak values

column vector | matrix

Indices of the peak values in the input signal, returned as a column vector or matrix. The size of the peak indices output is the same as that of the input. All nonzero elements represent peak indices.

Example: [1 2 3 6 0 0 0 0 0 0; 2 3 6 0 0 0 0 0 0]'

Dependencies

To enable this output, set the `PeakIndicesOutputPort` property to `true`.

Data Types: uint32

val — Peak values

column vector | matrix

Peak values in the input signal, returned as a column vector or matrix.

Example: [6 10 3 0 0 0 0 0 0 0; 1 13 0 0 0 0 0 0 0 0]'

Dependencies

To access the peak values output, set the `PeakValuesOutputPort` property to `true`.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

pol — Peak value polarity

column vector | matrix

Peak value polarity in input signal, returned as a column vector or matrix of logical 1s and 0s. The polarity is 1 for maxima and 0 for minima.

Example: [0 1 0 0 0 0 0 0 0 0; 0 1 0 0 0 0 0 0 0 0]'

Data Types: logical

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

`step` Run System object algorithm
`release` Release resources and allow changes to System object property values and input characteristics
`reset` Reset internal states of System object

Examples

Determine Local Maxima and Minima

Note If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Determine whether each value of an input signal is a local maximum or minimum.

```
pkFind = dsp.PeakFinder;  
pkFind.PeakIndicesOutputPort = true;  
pkFind.PeakValuesOutputPort = true;
```

```
x1 = [9 6 10 3 4 5 0 12]';
```

Find the peaks of each input [prev;cur;next]: {[9;6;10],[6;10;3],...}

```
[cnt1, idx1, val1, pol1] = pkFind(x1)
```

```
cnt1 = uint32
```

```
5
```

```
idx1 = 10x1 uint32 column vector
```

```

dsp.PeakFinder System object will be removed

Errors starting in R2021b

The dsp.PeakFinder System object will be removed in a future release. To determine the local maxima, use the findpeaks function. To determine the local minima, use the islocalmin function and find the signal values corresponding to the local minima indices that the function determines. For more details, see the **Update Code** section.

Update Code

This table shows typical usage of the System object and explains how to update existing code to use the equivalent function.

Discouraged Usage	Recommended Replacement
<p>Find Local Maxima</p> <pre>x = [9 6 10 3 4 5 0 12]'; pf = dsp.PeakFinder('PeakType','Maxima', .. 'PeakValuesOutputPort', true); [cnt,val] = pf(x)</pre> <p>Find Local Minima</p> <pre>x = [9 6 10 3 4 5 0 12]'; pf = dsp.PeakFinder('PeakType','Minima', .. 'PeakValuesOutputPort', true); [cnt,val] = pf(x)</pre> <p>If you are using a release prior to R2016b, replace pf(x) with step(pf,x).</p>	<p>Find Local Maxima</p> <pre>x = [9 6 10 3 4 5 0 12]'; val = findpeaks(x) cnt = numel(val)</pre> <p>Find Local Minima</p> <pre>x = [9 6 10 3 4 5 0 12]'; tf = islocalmin(x); val = x(tf) cnt = sum(tf)</pre>

dsp.PeakToPeak

Package: dsp

(To be removed) Peak-to-peak value

Note dsp.PeakToPeak will be removed in a future release. Use the `peak2peak` function instead. For more information, see “Compatibility Considerations”.

Description

The `dsp.PeakToPeak` System object computes the peak-to-peak value of an input.

To obtain the peak-to-peak value:

- 1 Create the `dsp.PeakToPeak` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
ptp = dsp.PeakToPeak
ptp = dsp.PeakToPeak(Name, Value)
```

Description

`ptp = dsp.PeakToPeak` creates a peak-to-peak System object, `ptp`, that computes the difference between the maximum and minimum value in an input or a sequence of inputs.

`ptp = dsp.PeakToPeak(Name, Value)` returns a peak-to-peak System object with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

RunningPeakToPeak — Calculation over successive calls to object algorithm

false (default) | true

Set this property to `true` to enable the calculation of the peak-to-peak difference over successive calls to the algorithm.

Dimension — Dimension to operate along

'Column' (default) | 'All' | 'Row' | 'Custom'

Specify the dimension along which to calculate the peak-to-peak ratio as 'All', 'Row', 'Column', or 'Custom'. If you set this property to 'Custom', specify the dimension using the `CustomDimension` property.

Dependencies

This property applies when the `RunningPeakToPeak` property is `false`.

CustomDimension — Dimension to operate along

1 (default) | positive integer

Specify the dimension as a positive integer along which the peak-to-peak difference is computed. The value of this property cannot exceed the number of dimensions in the input signal.

Dependencies

This property applies when the `Dimension` property is 'Custom'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

ResetInputPort — Enables resetting in running peak-to-peak mode

`false` (default) | `true`

Set this property to `true` to enable resetting the running peak-to-peak. When the property is set to `true`, a reset input must be specified to the call of object algorithm to reset the running peak-to-peak difference.

Dependencies

This property applies when the `RunningPeakToPeak` property is `true`.

ResetCondition — Reset condition for running peak-to-peak mode

'Non-zero' (default) | 'Rising edge' | 'Falling edge' | 'Either edge'

Specify the event to reset the running peak-to-peak as one of 'Rising edge', 'Falling edge', 'Either edge', or 'Non-zero'.

Dependencies

This property applies when the `ResetInputPort` property is `true`.

Usage

Syntax

```
y = ptp(x)
y = ptp(x,r)
```

Description

`y = ptp(x)` computes the peak-to-peak value, `y`, of the floating-point input vector `x`.

$y = \text{ptp}(x, r)$ computes the peak-to-peak value of the input elements over successive calls to the object algorithm. The object optionally resets its state based on the reset input signal, r , and the value of the `ResetCondition` property. To enable reset, set both the `RunningPeakToPeak` and the `ResetInputPort` properties to `true`.

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix. If x is a matrix, each column is treated as an independent channel. The peak-to-peak value is computed along each channel.

Data Types: `single` | `double`

r — Reset signal

scalar

Reset signal, specified as a scalar value. The reset signal resets the object state based on the reset input signal and the value of the `ResetCondition` property.

Dependencies

To enable this signal, set both the `RunningPeakToPeak` and the `ResetInputPort` properties to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

Output Arguments

y — Peak-to-peak value

scalar | vector | matrix

Peak-to-peak value of the input signal, returned as a scalar, vector, or matrix. If `RunningPeakToPeak` is set to:

- `false` -- The object computes the peak-to-peak value of each input channel. If the input is a column vector, the output is a scalar. If the input is a multichannel signal, the output signal is a 1-by- N vector, where N is the number of input channels.
- `true` -- The object computes the running peak-to-peak value of the signal. The size of the output signal matches the size of the input signal.

When the `RunningPeakToPeak` property is `true`, y corresponds to the peak-to-peak value of the input elements over successive calls to the object algorithm.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Peak-to-Peak Value of Vector

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Determine the peak-to-peak value for a vector input.

```
in = (1:10)';  
ptp = dsp.PeakToPeak;  
y = ptp(in)  
  
y = 9
```

Version History

Introduced in R2012a

dsp.PeakToPeak System object will be removed

Warns starting in R2021b

`dsp.PeakToPeak` System object will be removed in a future release. Use the `peak2peak` function instead.

Update Code

This table shows how the System object is typically used and explains how to update existing code to use the `peak2peak` function.

Discouraged Usage	Recommended Replacement

dsp.PeakToRMS

dsp.PeakToRMS

Package: dsp

Peak-to-root-mean-square value of vector

Description

The `dsp.PeakToRMS` System object calculates the peak-to-root-mean-square ratio of a vector.

To compute the peak-to-root-mean-square ratio:

- 1 Create the `dsp.PeakToRMS` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
ptr = dsp.PeakToRMS  
ptr = dsp.PeakToRMS(Name, Value)
```

Description

`ptr = dsp.PeakToRMS` creates a peak-to-root-mean-square System object, `ptr`, that returns the ratio of the maximum magnitude (peak) to the root-mean-square (RMS) value in an input or a sequence of inputs.

`ptr = dsp.PeakToRMS(Name, Value)` returns an peak-to-root-mean-square System object, `ptr`, with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

RunningPeakToRMS — Calculation over successive calls to object algorithm

`false` (default) | `true`

Set this property to `true` to enable the calculation of the peak-to-RMS ratio over successive calls to the object algorithm.

Dimension — Dimension to operate along

'Column' (default) | 'All' | 'Row' | 'Custom'

Specify the dimension along which to calculate the peak-to-RMS ratio as one of 'All', 'Row', 'Column', or 'Custom'. If you set this property to 'Custom', specify the dimension using the CustomDimension property.

Dependencies

This property applies when the RunningPeakToRMS property is false.

CustomDimension — Numerical dimension to operate along

1 (default) | positive integer

Specify the dimension as a positive integer along which the peak-to-RMS ratio is computed. The value of this property cannot exceed the number of dimensions in the input signal.

Dependencies

This property applies when the Dimension property is 'Custom'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

DecibelScaledOutput — Report output in decibels (dB)

true (default) | false

Set this property to true to enable output in dB. Set this property to false to report output as a ratio.

ResetInputPort — Enables resetting in running peak-to-RMS mode

false (default) | true

Set this property to true to enable resetting. When the property is set to true, a reset input must be specified in the call of object algorithm to reset the running peak-to-RMS ratio.

Dependencies

This property applies when the RunningPeakToRMS property is true.

ResetCondition — Reset condition for running peak-to-RMS mode

'Non-zero' (default) | 'Rising edge' | 'Falling edge' | 'Either edge'

Specify the event to reset the running peak-to-RMS as 'Rising edge', 'Falling edge', 'Either edge', or 'Non-zero'.

Dependencies

This property applies when the ResetInputPort property is true.

Usage**Syntax**

```
y = ptr(x)
y = ptr(x,r)
```

Description

`y = ptr(x)` computes the peak-to-RMS ratio, `y`, of the floating-point input vector `x`.

`y = ptr(x,r)` computes the peak-to-RMS ratio of the input elements over successive calls to the object algorithm. The object optionally resets its state based on the reset input signal, `r`, and the value of the `ResetCondition` property. To enable reset, set both the `RunningPeakToRMS` and the `ResetInputPort` properties to `true`.

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix. If `x` is a matrix, each column is treated as an independent channel. The peak-to-RMS value is computed along each channel.

Data Types: `single` | `double`

r — Reset signal

scalar

Reset signal, specified as a scalar value. The reset signal resets the object state based on the reset input signal and the value of the `ResetCondition` property.

Dependencies

To enable this signal, set both the `RunningPeakToRMS` and the `ResetInputPort` properties to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

Output Arguments

y — Peak-to-RMS value

scalar | vector | matrix

Peak-to-RMS value of the input signal, returned as a scalar, vector, or matrix. If `RunningPeakToRMS` is set to:

- `false` -- The object computes the peak-to-RMS value of each input channel. If the input is a column vector, the output is a scalar. If the input is a multichannel signal, the output signal is a 1-by-*N* vector, where *N* is the number of input channels.
- `true` -- The object computes the running peak-to-RMS value of the signal. The size of the output signal matches the size of the input signal.

When the `RunningPeakToRMS` property is `true`, `y` corresponds to the peak-to-RMS ratio of the input elements over successive calls to the object algorithm.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

```
step    Run System object algorithm
release Release resources and allow changes to System object property values and input
        characteristics
reset   Reset internal states of System object
```

Examples

Peak-to-RMS Ratio of Vector Input

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Determine the peak-to-RMS ratio of a vector input.

```
in = (1:10)';
ptr = dsp.PeakToRMS;
y = ptr(in)

y = 1.6116
```

Peak-to-RMS Ratio of Matrix Input

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Determine the peak-to-RMS ratio of a matrix input.

```
in = magic(4);
ptr = dsp.PeakToRMS;
ptr.Dimension = 'All';
y = ptr(in)

y = 1.6547
```

More About

Peak-magnitude-to-RMS Level

The peak-magnitude-to-RMS level is

$$\frac{\|X\|_{\infty}}{\sqrt{\frac{1}{N} \sum_{n=1}^N |X_n|^2}}$$

where the l -infinity norm and RMS values are computed along the specified dimension.

Version History

dsp.PhaseExtractor

Package: dsp

Extract the unwrapped phase of a complex input

Description

The `dsp.PhaseExtractor` System object extracts the unwrapped phase of a real or a complex input.

To extract the unwrapped phase of a signal input:

- 1 Create the `dsp.PhaseExtractor` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
phase = dsp.PhaseExtractor
phase = dsp.PhaseExtractor(Name, Value)
```

Description

`phase = dsp.PhaseExtractor` returns a phase extractor System object that extracts the unwrapped phase of an input signal.

`phase = dsp.PhaseExtractor(Name, Value)` returns a phase extractor System object with the specified property name set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

TreatFramesIndependently — Unwrap phase only within the frame

`false` (default) | `true`

Specify if the phase is to be unwrapped only within the frame, as a logical scalar.

When you set this property to:

- `false` -- The object returns the unwrapped phase while ignoring boundaries between input frames.
- `true` -- The object treats each frame of input data independently, and resets the initial cumulative unwrapped phase value to zero each time a new input frame is received.

Usage

Syntax

```
p = phase(input)
```

Description

`p = phase(input)` extracts the unwrapped phase, `p`, of the input signal. Each column of the input signal is treated as a separate channel. The System object unwraps the phase of each channel of the input signal independently over time.

Input Arguments

input — Data input

vector | matrix

Data input, specified as a vector or a matrix. This object supports variable-size input signals. That is, you can change the input frame size (number of rows) even after calling the algorithm. However, the number of channels (number of columns) must remain constant.

Data Types: `single` | `double`

Output Arguments

p — Unwrapped phase

vector | matrix

Unwrapped phase of the input, returned as a vector or a matrix. The size and data type of the unwrapped phase output match the size and data type of the input signal.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Plot Unwrapped Phase Of a Sine Wave

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Create a `dsp.SineWave` System object™. Specify that the object generates an exponential output with a complex exponent.

```
sine = dsp.SineWave('Frequency',10,...
    'ComplexOutput',true,'SamplesPerFrame',128);
```

Create a `dsp.PhaseExtractor` System object?. Specify that the object ignores frame boundaries when returning the unwrapped phase.

```
phase = dsp.PhaseExtractor('TreatFramesIndependently',false);
```

Extract the unwrapped phase of a sine wave. Plot the phase versus time using a `timescope` System object.

```
timeplot = timescope('PlotType','Line','SampleRate',1000,...
    'TimeSpanSource','Property','TimeSpan',1.5,'YLimits',[0 80],...
    'ShowGrid',true,...
    'YLabel','Unwrapped Phase (rad)');
for ii = 1:10
    sineOutput = sine();
    phaseOutput = phase(sineOutput);
    timeplot(phaseOutput)
end
```

Plot Phase Response of Third-Order IIR Filter

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Create a `dsp.TransferFunctionEstimator` System object™.

```
tfe = dsp.TransferFunctionEstimator('FrequencyRange','centered');
```

Create a `dsp.PhaseExtractor` System object™. Specify that the object must treat each frame of data independently.

```
phase = dsp.PhaseExtractor('TreatFramesIndependently',true);
```

Create a `dsp.IIRFilter` System object™. Compute the transfer function of a third-order IIR filter. Use the `butter` function to generate coefficients for the filter.

```
[b,a] = butter(3,.3);
iir = dsp.IIRFilter('Numerator',b,'Denominator',a);
```

Extract the phase response of the transfer function. Plot using a `dsp.ArrayPlot` System object™.

```
sampleRate = 1e3;
phaseplot = dsp.ArrayPlot('PlotType','Line','XOffset',-sampleRate/2,...
    'YLimits',[-15 0],...);
```

```

        'YLabel','Phase Response (rad)',...
        'XLabel','Frequency (Hz)',...
        'Title','System Phase response');
    for ii = 1:100
        % Generate input
        input = 0.05*randn(1000,1);
        % Pass through IIR filter
        filterOutput = iir(input);
        % Estimate transfer function
        transferFunction = tfe(input,filterOutput);
        % Plot transfer function phase
        phaseOutput = phase(transferFunction);
        phaseplot(phaseOutput);
    end

```

Algorithms

Consider an input frame of length N :

$$\begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_N \end{pmatrix}$$

The object acts on this frame and produces this output:

$$\begin{pmatrix} \Phi_1 \\ \Phi_2 \\ \vdots \\ \Phi_N \end{pmatrix}$$

where:

$$\Phi_i = \Phi_{i-1} + \text{angle}(x_{i-1}^* x_i)$$

Here, i runs from 1 to N . The `angle` function returns the phase angle in radians.

If the input signal consists of multiple frames:

- If you set `TreatFramesIndependently` to `true`, the object treats each frame independently. Therefore, in each frame, the object calculates the phase using the preceding formula where:
 - Φ_0 is 0.
 - x_0 is 1.
- If you set `TreatFramesIndependently` to `false`, the object ignores boundaries between frames. Therefore, in each frame, the `step` method calculates the phase using the preceding formula where:
 - Φ_0 is the last unwrapped phase from the previous frame.
 - x_0 is the last sample from the previous frame.

phUnwrap = dsp.PhaseUnwrapper(Name, Value)
```

Description

`phUnwrap = dsp.PhaseUnwrapper` returns a phase unwrapper System object that adds or subtracts appropriate multiples of 2π to each input element to remove phase discontinuities (unwrap).

`phUnwrap = dsp.PhaseUnwrapper(Name, Value)` returns a phase unwrapper System object with each specified property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

InterFrameUnwrap — Enable unwrapping of phase discontinuities between successive frames

`true` (default) | `false`

Set this property to `false` to unwrap phase discontinuities only within the frame. Set this property to `true` to also unwrap phase discontinuities between successive frames.

Tolerance — Jump size as true phase discontinuity

3.1416 (default) | real scalar

Specify the jump size that the phase unwrapper recognizes as a true phase discontinuity. The default is set to π (rather than a smaller value) to avoid altering legitimate signal features. To increase the phase wrapper sensitivity, set the **Tolerance** property to a value slightly less than π .

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Usage**Syntax**

```
output = phUnwrap(input)
```

Description

`output = phUnwrap(input)` unwraps the phase of the input signal. This is done by adding or subtracting appropriate multiples of 2π to each input element to remove phase discontinuities (unwrap). Each column of the input signal is treated as a separate channel.

Input Arguments**input — Data input**

vector | matrix

Data input, specified as a vector or a matrix. The phase of the input signal should be in radians.

Data Types: single | double

Output Arguments**output — Unwrapped phase**

vector | matrix

Unwrapped phase of the input, returned as a vector or a matrix. The size and data type of the unwrapped phase output match the size and data type of the input signal.

Data Types: single | double

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Unwrap input phase data

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
phUnwrap = dsp.PhaseUnwrapper;
p = [0 2/5 4/5 -4/5 -2/5 0 2/5 4/5 -4/5 -2/5 0 2/5 ...
     4/5 -4/5, -2/5]*pi;
y = phUnwrap(p');
figure,stem(p); hold
```

Current plot held

```
stem(y, 'r');
legend('Input (blue)', 'Unwrapped data (red)');
hold off;
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Unwrap block reference page. The object properties correspond to the Simulink block parameters.

Version History

Introduced in R2012a

unwrap

dsp.PulseMetrics

Package: dsp

(To be removed) Pulse metrics of bilevel waveforms

Note `dsp.PulseMetrics` will be removed in a future release. Use functions from “Pulse and Transition Metrics” instead. Functions in this set include `dutycycle`, `midcross`, `pulseperiod`, `pulsesep`, and `pulsewidth` among others. For more information, see “Compatibility Considerations”.

Description

The `dsp.PulseMetrics` object computes rise times, fall times, pulse widths, and cycle metrics including pulse period, pulse separation, and duty cycle for bilevel waveforms.

To obtain pulse metrics for a bilevel waveform:

- 1 Create the `dsp.PulseMetrics` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
pm = dsp.PulseMetrics
pm = dsp.PulseMetrics(Name,Value)
```

Description

`pm = dsp.PulseMetrics` creates a pulse metrics System object, `pm`. The object computes the rise time, fall time, and width of a pulse. `dsp.PulseMetrics` also computes cycle metrics such as pulse separations, periods, and duty cycles. Because a pulse contains two transitions, the object contains a superset of the capability defined in `dsp.TransitionMetrics`.

`pm = dsp.PulseMetrics(Name,Value)` returns a `PulseMetrics` System object, `pm`, with each specified property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

CycleOutputPort — Enable cycle metrics

false (default) | true

If CycleOutputPort is true, cycle metrics are reported for each pulse period.

MaximumRecordLength — Maximum samples to preserve

1000 (default) | positive integer

Maximum samples to preserve between calls to the algorithm. This property requires a positive integer that specifies the maximum number of samples to save between calls to the algorithm. When the number of samples to be saved exceeds this length, the oldest excess samples are discarded.

Tunable: Yes

Dependencies

This property applies when the RunningMetrics property is true.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

PercentReferenceLevels — Percent reference levels

[10 50 90] (default) | three-element row vector

Lower-, middle-, and upper-percent reference levels. This property contains a three-element numeric row vector that contains the lower-, middle-, and upper-percent reference levels. These reference levels are used as an offset between the lower and upper states of the waveform when computing the duration of each transition.

Data Types: double

PercentStateLevelTolerance — Tolerance of state level

2 (default) | positive scalar

Tolerance of the state level (in percent). This property requires a scalar that specifies the maximum deviation from either the low or high state before it is considered to be outside that state. The tolerance is expressed as a percentage of the waveform amplitude.

Data Types: double

Polarity — Polarity of pulse to extract

'positive' (default) | 'negative'

Polarity of pulse to extract. This property specifies the type of pulse to extract by the polarity of the leading transition. Valid values for this property are 'positive' or 'negative'.

PostshootOutputPort — Enable posttransition aberration metrics

false (default) | true

Enable posttransition aberration metrics. If this property is set to true, overshoot and undershoot metrics are reported for a region defined immediately after each transition. The posttransition aberration region is defined as the waveform interval that begins at the end of each transition and whose duration is the value of PostshootSeekFactor times the computed transition duration. If a complete subsequent transition is detected before the interval is over, the region is truncated at the

start of the subsequent transition. The metrics are computed for each transition that has a complete posttransition aberration region.

PostshootSeekFactor — Postshoot seek factor

3 (default) | positive scalar

Corresponds to the duration of time to search for the overshoot and undershoot metrics immediately following each transition. The duration is expressed as a factor of the duration of the transition.

Tunable: Yes

Dependencies

This property is enabled only when the `PostshootOutputPort` property is set to `true`.

Data Types: `double`

PreshootOutputPort — Enable pretransition aberration metrics

false (default) | true

Enable pretransition aberration metrics. If `PreshootOutputPort` is set to `true`, overshoot and undershoot metrics are reported for a region defined immediately before each transition. The pretransition aberration region is defined as the waveform interval that ends at the start of each transition and whose duration is `PreshootSeekFactor` times the computed transition duration.

PreshootSeekFactor — Preshoot seek factor

3 (default) | positive scalar

Corresponds to the duration of time to search for the overshoot and undershoot metrics immediately preceding each transition. The duration is expressed as a factor of the duration of the transition.

Tunable: Yes

Dependencies

This property is enabled only when the `PreshootOutputPort` property is set to `true`.

Data Types: `double`

RunningMetrics — Enable metrics

false (default) | true

Enable metrics over all calls to the algorithm. If `RunningMetrics` is set to `false`, metrics are computed for each call to the algorithm independently. If `RunningMetrics` is set to `true`, metrics are computed across subsequent calls to the algorithm. If there are not enough samples to compute metrics associated with the last transition, posttransition aberration region, or settling seek duration in the current record, the object defers reporting all transition, aberration, and settling metrics associated with the last transition until a subsequent call to the algorithm is made with enough data to compute all enabled metrics for that transition.

SampleRate — Sampling rate

1 (default) | positive scalar

Sampling rate of uniformly-sampled signal. Specify the sample rate in hertz as a positive scalar. This property is used to construct the internal time values that correspond to the input sample values. Time values start with zero.

Dependencies

This property applies when the `TimeInputPort` property is set to `false`.

Data Types: `double`

SettlingOutputPort — Enable settling metrics

`false` (default) | `true`

Enable settling metrics. If the `SettlingOutputPort` property is set to `true`, settling metrics are reported for each transition. The region used to compute the settling metrics starts at the midcrossing and lasts until the `SettlingSeekDuration` has elapsed. If an intervening transition occurs, or the signal has not settled within the `PercentStateLevelTolerance` of the final level, `NaN` is returned for each metric. If there are not enough samples after the last transition to complete the `SettlingSeekDuration`, no metrics are reported for the last transition. The metrics are reported for the transition the next time the object algorithm is called if the `RunningMetrics` property is set to `true`.

SettlingSeekDuration — Duration of time

`0.02` (default) | positive scalar

Duration of time over which to search for settling. This property value is a scalar that specifies the amount of time to inspect from the mid-reference level crossing (in seconds). If the transition has not yet settled, or a subsequent complete transition is detected within this duration, the object reports `NaN` for all settling metrics.

Tunable: Yes

Dependencies

This property applies only when you set the `SettlingOutputPort` property to `true`.

Data Types: `double`

StateLevels — State levels

`[0 2.3]` (default) | two-element row vector

Low- and high-state levels. This property is a two-element numeric row vector that contains the low- and high-state levels. These state levels correspond to the nominal logic low and high levels of the pulse waveform.

Tunable: Yes

Data Types: `double`

StateLevelsSource — State-level computation

`'Property'` (default) | `'Auto'`

Auto or manual state-level computation. If `StateLevelsSource` is set to `'Auto'`, the first record sent to the object is sent to `dsp.StateLevels` with the default settings to determine the state levels of the incoming waveform. If this property is set to `'Property'`, the object uses the values the user specifies in the `StateLevels` property.

TimeInputPort — Specify sample instants

`false` (default) | `true`

Add input to specify sample instants. Set `TimeInputPort` to `true` to enable an additional real input column vector to the object algorithm to specify the sample instants that correspond to the sample

values. If this property is `false`, the sample instants are built internally. The sample instants start at zero and increment by the reciprocal of the `SampleRate` property for subsequent samples. The sample instants continue to increment if the `RunningMetrics` property is set to `true` and no intervening calls to the `reset` or `release` methods are encountered.

TransitionOutputPort — Enable transition metrics

`false` (default) | `true`

Enable transition metrics. If the `TransitionOutputPort` property is set to `true`, transition metrics are reported for the initial and final transitions of each pulse.

Usage

Syntax

```
pulse = pm(x)
[pulse,cycle] = pm(x)
[pulse,transition] = pm(x)
[pulse,preshoot] = pm(x)
[pulse,postshoot] = pm(x)
[pulse,settling] = pm(x)
[pulse,cycle,transition,preshoot,postshoot,settling] = pm(x)
[___] = pm(x,T)
```

Description

`pulse = pm(x)` returns a structure array, `pulse`, whose fields contain real-valued column vectors. The number of rows of each field corresponds to the number of complete pulses found in the real-valued column vector input, `x`.

`[pulse,cycle] = pm(x)` returns a structure array, `cycle`, whose fields contain real-valued column vectors when you set the `CycleOutputPort` property to `true`. The number of rows of each field corresponds to the number of complete pulse periods found in the real-valued column vector input, `x`.

`[pulse,transition] = pm(x)` returns a structure array, `transition`, when you set the `TransitionOutputPort` property to `true`. The fields of `transition` contain real-valued matrices with two columns that correspond to the metrics of the first and second transitions. The number of rows corresponds to the number of pulses found in the input waveform.

`[pulse,preshoot] = pm(x)` returns a structure array, `preshoot`, when you set the `PreshootOutputPort` property to `true`. The fields of `preshoot` contain real-valued two-column matrices whose row length corresponds to the number of transitions found in the input waveform. The field names are identical to those of the `postshoot` structure array.

`[pulse,postshoot] = pm(x)` returns a structure, `postshoot`, when you set the `PostshootOutputPort` property to `true`. The fields of `postshoot` contain real-valued two-column matrices whose row length corresponds to the number of transitions found in the input waveform.

`[pulse,settling] = pm(x)` returns a structure array, `settling`, when you set the `SettlingOutputPort` property to `true`. The fields of `settling` correspond to the settling metrics for each transition. Each field is a column vector whose elements correspond to the individual settling durations, levels, and instants.

[pulse,cycle,transition,preshoot,postshoot,settling] = pm(x) which returns the pulse, cycle, transition, preshoot, postshoot, and settling structures when the CycleOutputPort, PreshootOutputPort, PostshootPort, and SettlingOutputPort properties are true. You may enable or disable any combination of output ports. However, the output arguments are defined in the order shown here.

[___] = pm(x, T) calculates the above metrics with respect to a sampled signal, whose sample values, x, and sample instants, T, are real-valued column vectors of the same length. The additional input T applies only when you set the TimeInputPort property to true.

Input Arguments

x — Input signal

column vector

Input signal, specified as a real-valued column vector.

Data Types: double

T — Sampling instants

column vector

Sampling instants, specified as a real-valued column vector. Set TimeInputPort to true to enable an additional real input column vector to the object algorithm to specify the sample instants that correspond to the sample values. If TimeInputPort is false, the sample instants are built internally. The sample instants start at zero and increment by the reciprocal of the SampleRate property for subsequent samples. The sample instants continue to increment if the RunningMetrics property is set to true and no intervening calls to the reset or release methods are encountered.

Dependencies

This input is applicable when you set the TimeInputPort property to true.

Data Types: double

Output Arguments

puLse — Complete pulses

structure

Complete pulses, returned as a structure whose fields contain real-valued column vectors. The number of rows of each field corresponds to the number of complete pulses found in the real-valued column vector input, x. Each pulse starts with a transition of the polarity specified by the Polarity property and ends with a transition of the opposite polarity.

The pulse output contains the following fields:

- **PositiveCross** — Instants where the positive-going transitions cross the mid-reference level of each pulse
- **NegativeCross** — Instants where the negative-going transitions cross the mid-reference level of each pulse
- **Width** — Absolute difference between PositiveCross and NegativeCross of each pulse
- **RiseTime** — Duration between the linearly interpolated instants when the positive-going (rising) transition of each pulse crosses the lower- and upper-reference levels

- **FallTime** — Duration between the linearly interpolated instants when the negative-going (falling) transition of each pulse crosses the upper- and lower-reference levels

Data Types: `struct`

cycle — Complete pulse periods

structure

Complete pulse periods, returned as a structure whose fields contain real-valued column vectors. This structure can only be returned when you set the `CycleOutputPort` property to `true`. The number of rows of each field corresponds to the number of complete pulse periods found in the real-valued column vector input, `x`. You need at least three consecutive alternating polarity transitions that start and end with the same polarity as the value of the `Polarity` property if you want to compute cycle metrics. If the last transition found in the input `x` does not match the polarity of the `Polarity` property, the pulse separation, period, frequency, and duty cycle are not reported for the last pulse. If the `RunningMetrics` property is set to `true` when this occurs, all pulse, cycle, transition, preshoot, postshoot, and settling metrics associated with the last pulse are deferred until a subsequent call to the algorithm detects the next transition.

The cycle output contains the following fields:

- **Period** — Duration between the first transition of the current pulse and the first transition of the next pulse.
- **Frequency** — Reciprocal of the period.
- **Separation** — Durations between the mid-reference level crossings of the second transition of each pulse and the first transition of the next pulse.
- **Width** — Durations between the mid-reference level crossings of the first and second transitions of each pulse. This is equivalent to the width parameter of the `pulse` structure.
- **DutyCycle** — Ratio of the width to the period for each pulse.

Data Types: `struct`

transition — Transition metrics

structure

Transition metrics, returned as a structure array. This structure can only be returned when you set the `TransitionOutputPort` property to `true`. The fields of `transition` contain real-valued matrices with two columns, which correspond to the metrics of the first and second transitions. The number of rows corresponds to the number of pulses found in the input waveform.

The transition output contains the following fields:

- **Duration** — Amount of time between the interpolated instants where the transition crosses the lower- and upper-reference levels
- **SlewRate** — Ratio of absolute difference between the upper and lower reference levels to the transition duration
- **MiddleCross** — Linearly interpolated instant in time where the transition first crosses the mid-reference level
- **LowerCross** — Linearly interpolated instant where the signal crosses the lower-reference level
- **UpperCross** — Linearly interpolated instant where the signal crosses the upper-reference level

Data Types: `struct`

preshoot — Preshoot metrics

structure

Preshoot metrics, returned as a structure array. This structure can only be returned when you set the `PreshootOutputPort` property to `true`. The fields of `preshoot` contain real-valued two-column matrices whose row length corresponds to the number of transitions found in the input waveform.

The `preshoot` output contains the following fields:

- `Overshoot` — Overshoot of the region of interest expressed as a percentage of the waveform amplitude
- `Undershoot` — Undershoot of the region of interest expressed as a percentage of the waveform amplitude
- `OvershootLevel` — Level of the overshoot
- `UndershootLevel` — Level of the undershoot
- `OvershootInstant` — Instant that corresponds to the overshoot
- `UndershootInstant` — Instant that corresponds to the undershoot

Data Types: `struct`

postshoot — Postshoot metrics

structure

Postshoot metrics, returned as a structure array. This structure can only be returned when you set the `PostshootOutputPort` property to `true`. The fields of `postshoot` contain real-valued two-column matrices whose row length corresponds to the number of transitions found in the input waveform.

The `postshoot` output contains the following fields:

- `Overshoot` — Overshoot of the region of interest expressed as a percentage of the waveform amplitude
- `Undershoot` — Undershoot of the region of interest expressed as a percentage of the waveform amplitude
- `OvershootLevel` — Level of the overshoot
- `UndershootLevel` — Level of the undershoot
- `OvershootInstant` — Instant that corresponds to the overshoot
- `UndershootInstant` — Instant that corresponds to the undershoot

Data Types: `struct`

settling — Settling metrics

structure

Settling metrics for each transition, returned as a structure array. This structure can only be returned when you set the `SettlingOutputPort` property to `true`. The fields of `settling` correspond to the settling metrics for each transition. Each field is a column vector whose elements correspond to the individual settling durations, levels, and instants.

The `settling` output contains the following fields:

- **Duration** — Amount of time from when the signal crosses the mid-reference level to the time where the signal enters and remains within the specified `PercentStateLevelTolerance` of the waveform amplitude over the specified settling seek duration
- **Instant** — Instant in time where the signal enters and remains within the specified tolerance
- **Level** — Level of the waveform where it enters and remains within the specified tolerance

Data Types: `struct`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.PulseMetrics

`plot` (To be removed) Plot pulse signal and metrics

Common to All System Objects

`step` Run System object algorithm
`release` Release resources and allow changes to System object property values and input characteristics
`reset` Reset internal states of System object

Examples

Width, Period, and Duty Cycle

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Determine the width, period, and duty cycle of a 5 V pulse sampled at 4 MHz.

```
load('pulseex.mat','x','t');
```

Construct the `dsp.PulseMetrics` object. Set the `TimeInputPort` property to `true` to specify the sampling instants as an input. Set the `CycleOutputPort` property to `true` to obtain metrics for each pulse. Because the input is a 5 V pulse, set the `StateLevels` property to `[0 5]`.

```
pm = dsp.PulseMetrics('TimeInputPort',true, ...
                    'CycleOutputPort', true, ...
                    'StateLevels',[0 5])
```

```
pm =
dsp.PulseMetrics with properties:
```

```

                    Polarity: 'Positive'
        StateLevelsSource: 'Property'
           StateLevels: [0 5]
PercentStateLevelTolerance: 2
    PercentReferenceLevels: [10 50 90]
           RunningMetrics: false
```

```
TimeInputPort: true
CycleOutputPort: true
TransitionOutputPort: false
PreshootOutputPort: false
PostshootOutputPort: false
SettlingOutputPort: false
```

Call the object to compute the cycle metrics and plot the result.

```
[pulse,cycle] = pm(x,t);
plot(pm)
text(t(2),-0.5,['Duty Cycle: ',num2str(cycle.DutyCycle)]);
```

Version History

Introduced in R2012a

dsp.PulseMetrics System object will be removed

Warns starting in R2021b

`dsp.PulseMetrics` System object will be removed in a future release. Use functions from “Pulse and Transition Metrics” instead. Functions in this set include `dutycycle`, `midcross`, `pulseperiod`, `pulsesep`, and `pulsewidth` among others.

Update Code

This table shows how the System object is typically used and explains how to update existing code to use these functions.

Discouraged Usage	Recommended Replacement
<pre>load('clockx.mat','x','t'); pm = dsp.PulseMetrics('SampleRate',4e6,... 'TransitionOutputPort',true,... 'StateLevelsSource','Auto',... “Pulse and Transition Metrics”

dsp.RLSFilter

Package: dsp

Compute output, error and coefficients using recursive least squares (RLS) algorithm

Description

The `dsp.RLSFilter` System object filters each channel of the input using RLS filter implementations.

To filter each channel of the input:

- 1 Create the `dsp.RLSFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
rlsFilt = dsp.RLSFilter
rlsFilt = dsp.RLSFilter(len)
rlsFilt = dsp.RLSFilter(Name,Value)
```

Description

`rlsFilt = dsp.RLSFilter` returns an adaptive RLS filter System object, `rlsFilt`. This System object computes the filtered output, filter error, and the filter weights for a given input and desired signal using the RLS algorithm.

`rlsFilt = dsp.RLSFilter(len)` returns an RLS filter System object, `rlsFilt`. This System object has the `Length` property set to `len`.

`rlsFilt = dsp.RLSFilter(Name,Value)` returns an RLS filter System object with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Method — Method to calculate filter coefficients

Conventional RLS (default) | Householder RLS | Sliding-window RLS | Householder sliding-window RLS | QR decomposition

You can specify the method used to calculate filter coefficients as Conventional RLS [1] [2], Householder RLS [3] [4], Sliding-window RLS [5][1][2], Householder sliding-window RLS [4], or QR decomposition [1] [2]. This property is nontunable.

Length — Length of filter coefficients vector

32 (default) | positive integer

Specify the length of the RLS filter coefficients vector as a scalar positive integer value. This property is nontunable.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

SlidingWindowBlockLength — Width of sliding window

48 (default) | positive integer

Specify the width of the sliding window as a scalar positive integer value greater than or equal to the Length property value. This property is nontunable.

Dependencies

This property applies only when the Method property is set to Sliding-window RLS or Householder sliding-window RLS.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

ForgettingFactor — RLS forgetting factor

1 (default) | positive scalar

Specify the RLS forgetting factor as a scalar positive numeric value less than or equal to 1. Setting this property value to 1 denotes infinite memory, while adapting to find the new filter.

Tunable: Yes

Data Types: single | double

InitialCoefficients — Initial coefficients of filter

0 (default) | scalar | vector

Specify the initial values of the FIR adaptive filter coefficients as a scalar or a vector of length equal to the Length property value.

Tunable: Yes

Data Types: single | double

InitialInverseCovariance — Initial inverse covariance

1000 (default) | scalar | square matrix

Specify the initial values of the inverse covariance matrix of the input signal. This property must be either a scalar or a square matrix, with each dimension equal to the Length property value. If you set a scalar value, the InverseCovariance property is initialized to a diagonal matrix with diagonal elements equal to that scalar value.

Tunable: Yes

Dependencies

This property applies only when the `Method` property is set to `Conventional RLS` or `Sliding-window RLS`.

Data Types: `single` | `double`

InitialSquareRootInverseCovariance — Initial square root inverse covariance

`sqrt(1000)` (default) | `scalar` | `square matrix`

Specify the initial values of the square root inverse covariance matrix of the input signal. This property must be either a scalar or a square matrix with each dimension equal to the `Length` property value. If you set a scalar value, the `SquareRootInverseCovariance` property is initialized to a diagonal matrix with diagonal elements equal to that scalar value.

Tunable: Yes

Dependencies

This property applies only when the `Method` property is set to `Householder RLS` or `Householder sliding-window RLS`.

Data Types: `single` | `double`

InitialSquareRootCovariance — Initial square root covariance

`sqrt(1/1000)` (default) | `scalar` | `square matrix`

Specify the initial values of the square root covariance matrix of the input signal. This property must be either a scalar or a square matrix with each dimension equal to the `Length` property value. If you set a scalar value, the `SquareRootCovariance` property is initialized to a diagonal matrix with diagonal elements equal to the scalar value.

Tunable: Yes

Dependencies

This property applies only when the `Method` property is set to `QR-decomposition RLS`.

Data Types: `single` | `double`

LockCoefficients — Lock coefficient updates

`false` (default) | `true`

Specify whether the filter coefficient values should be locked. When you set this property to `true`, the filter coefficients are not updated and their values remain the same. The default value is `false` (filter coefficients continuously updated).

Tunable: Yes

Usage**Syntax**

```
y = rlsFilt(x,d)
[y,e] = rlsFilt(x,d)
```

Description

$y = \text{rlsFilt}(x, d)$ recursively adapts the reference input, x , to match the desired signal, d , using the System object, `rlsFilt`. The desired signal, d , is the signal desired plus some undesired noise.

$[y, e] = \text{rlsFilt}(x, d)$ shows the output of the RLS filter along with the error, e , between the reference input and the desired signal. The filter adapts its coefficients until the error e is minimized. You can access these coefficients by accessing the `Coefficients` property of the object. This can be done only after calling the object. For example, to access the optimized coefficients of the `rlsFilt` filter, call `rlsFilt.Coefficients` after you pass the input and desired signal to the object.

Input Arguments

x — Data input

scalar | column vector

The signal to be filtered by the RLS filter. The input, x , and the desired signal, d , must have the same size and data type.

The input can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double`
Complex Number Support: Yes

d — Desired signal

scalar | column vector

The RLS filter adapts its coefficients to minimize the error, e , and converge the input signal x to the desired signal d as closely as possible.

The input, x , and the desired signal, d , must have the same size and data type.

The desired signal, d , can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double`
Complex Number Support: Yes

Output Arguments

y — Filtered output

scalar | column vector

Filtered output, returned as a scalar or a column vector. The object adapts its filter coefficients to converge the input signal x to match the desired signal d . The filter outputs the converged signal.

Data Types: `single` | `double`

e — Difference between output and desired signal

scalar | column vector

Difference between the output signal y and the desired signal d , returned as a scalar or a column vector. The objective of the RLS filter is to minimize this error. The object adapts its coefficients to

converge toward optimal filter coefficients that produce an output signal that matches closely with the desired signal. For more details on how e is computed, see “Algorithms” on page 4-964. To access the RLS filter coefficients, call `rlsFilt.Coefficients` after you pass the input and desired signal to the object.

Data Types: `single` | `double`
Complex Number Support: Yes

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.RLSFilter`

`mseSim` Estimated mean squared error for adaptive filters

Common to All System Objects

`step` Run System object algorithm
`release` Release resources and allow changes to System object property values and input characteristics
`reset` Reset internal states of System object

Examples

System Identification of FIR Filter Using RLS Filter

Use a recursive least squares (RLS) filter to identify an unknown system modeled with a lowpass FIR filter. Compare the frequency responses of the unknown and estimated systems.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Initialization

Create a `dsp.FIRFilter` object that represents the system to be identified. Pass the signal `x` to the FIR filter. The output of the unknown system is the desired signal `d`, which is the sum of the output of the unknown system (FIR filter) and an additive noise signal `n`.

```
filt = dsp.FIRFilter('Numerator',fir1(10,.25));  
x = randn(1000,1);  
n = 0.01*randn(1000,1);  
d = filt(x) + n;
```

Adaptive Filter

Create a `dsp.RLSFilter` object to create an RLS filter. Set the length of the filter to 11 taps and the forgetting factor to 0.98. Pass the primary input signal `x` and the desired signal `d` to the RLS filter. The output `y` of the adaptive filter is the signal converged to the desired signal `d` thereby minimizing the error `e` between the two signals.

```
rls = dsp.RLSFilter(11, 'ForgettingFactor', 0.98);
[y,e] = rls(x,d);
w = rls.Coefficients;
```

Plot the results

The output signal matches the desired signal, making the error between the two close to zero.

```
plot(1:1000, [d,y,e]);
title('System Identification of an FIR filter');
legend('Desired', 'Output', 'Error');
xlabel('time index');
ylabel('signal value');
```

Compare the weights

The weights vector w represents the coefficients of the RLS filter that is adapted to resemble the unknown system (FIR filter). To confirm the convergence, compare the numerator of the FIR filter and the estimated weights of the RLS filter.

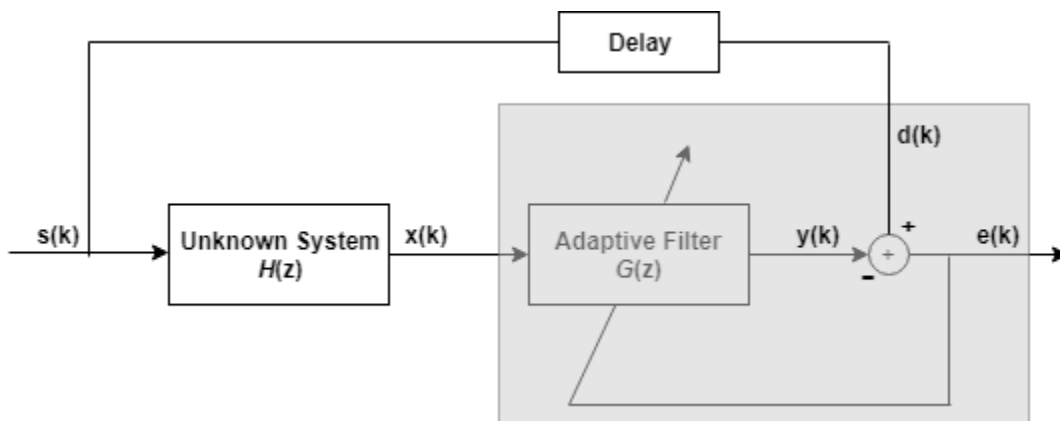

The estimated filter weights closely match the actual filter weights, confirming the results seen in the previous signal plot.

```
stem([filt.Numerator; w].');
legend('Actual', 'Estimated');
xlabel('coefficient #');
ylabel('coefficient value');
```

Inverse System Identification Using RLS Algorithm

This example demonstrates the RLS adaptive algorithm using the inverse system identification model shown here.

Cascading the adaptive filter with an unknown filter causes the adaptive filter to converge to a solution that is the inverse of the unknown system.

If the transfer function of the unknown system and the adaptive filter are $H(z)$ and $G(z)$, respectively, the error measured between the desired signal and the signal from the cascaded system reaches its

minimum when $G(z) \times H(z) = 1$. For this relation to be true, $G(z)$ must equal $1/H(z)$, the inverse of the transfer function of the unknown system.

To demonstrate that this is true, create a signal s to input to the cascaded filter pair.

```
s = randn(3000,1);
```

In the cascaded filters case, the unknown filter results in a delay in the signal arriving at the summation point after both filters. To prevent the adaptive filter from trying to adapt to a signal it has not yet seen (equivalent to predicting the future), delay the desired signal by 12 samples, which is the order of the unknown system.

Generally, you do not know the order of the system you are trying to identify. In that case, delay the desired signal by number of samples equal to half the order of the adaptive filter. Delaying the input requires prepending 12 zero-value samples to the input s .

```
delay = zeros(12,1);
d = [delay; s(1:2988)]; % Concatenate the delay and the signal.
```

You have to keep the desired signal vector d the same length as x , so adjust the signal element count to allow for the delay samples.

Although not generally the case, for this example you know the order of the unknown filter, so add a delay equal to the order of the unknown filter.

For the unknown system, use a lowpass, 12th-order FIR filter.

```
filt = dsp.FIRFilter;
filt.Numerator = fir1(12,0.55,'low');
```

Filtering s provides the input data signal for the adaptive algorithm function.

```
x = filt(s);
```

To use the RLS algorithm, create a `dsp.RLSFilter` object and set its `Length`, `ForgettingFactor`, and `InitialInverseCovariance` properties.

For more information about the input conditions to prepare the RLS algorithm object, refer to `dsp.RLSFilter`.

```
p0 = 2 * eye(13);
lambda = 0.99;
rls = dsp.RLSFilter(13,'ForgettingFactor',lambda,...
    'InitialInverseCovariance',p0);
```

This example seeks to develop an inverse solution, you need to be careful about which signal carries the data and which is the desired signal.

Earlier examples of adaptive filters use the filtered noise as the desired signal. In this case, the filtered noise (x) carries the unknown system's information. With Gaussian distribution and variance of 1, the unfiltered noise d is the desired signal. The code to run this adaptive filter is:

```
[y,e] = rls(x,d);
```

where y returns the filtered output and e contains the error signal as the filter adapts to find the inverse of the unknown system.

Obtain the estimated coefficients of the RLS filter.

```
b = rls.Coefficients;
```

View the frequency response of the adapted RLS filter (inverse system, $G(z)$) using `freqz`. The inverse system looks like a highpass filter with linear phase.

```
freqz(b,1)
```

View the frequency response of the unknown system, $H(z)$. The response is that of a lowpass filter with a cutoff frequency of 0.55.

```
freqz(filt.Numerator,1)
```

The result of the cascade of the unknown system and the adapted filter is a compensated system with an extended cutoff frequency of 0.8.

```
overallCoeffs = conv(filt.Numerator,b);  
freqz(overallCoeffs,1)
```

Cancel Noise Using RLS Filter

Cancel additive noise n added to an unknown system using an RLS filter. The RLS filter adapts its coefficients until its transfer function matches the transfer function of the unknown system as closely as possible. The difference between the output of the adaptive filter and the output of the unknown system is the error signal e , which represents the additive white noise. Minimizing this error signal is the objective of the adaptive filter.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Initialization

Create a `dsp.FIRFilter` System object™ to represent the unknown system. Create a `dsp.RLSFilter` object and set the length to 11 taps. Set the method to 'Householder RLS'. Create a sine wave to represent the noise added to the unknown system. View the signals in a time scope.

```
FrameSize = 100;
NIter = 10;
```

```
rls = dsp.RLSFilter('Length',11,...
    'Method','Householder RLS');
filt = dsp.FIRFilter('Numerator',...
```

```
    fir1(10,[.5,.75]));

sinewave = dsp.SineWave('Frequency',0.01,...
    'SampleRate',1,...
    'SamplesPerFrame',FrameSize);
scope = timescope('LayoutDimensions',[2 1],...
    'NumInputPorts',2, ...
    'TimeUnits','Seconds',...
    'YLimits',[-2.5 2.5], ...
    'BufferLength',2*FrameSize*NIter,...
    'ActiveDisplay',1,...
    'ShowLegend',true,...
    'ChannelNames',{'Noisy signal'},...
    'ActiveDisplay',2,...
    'ShowLegend',true,...
    'ChannelNames',{'Error signal'});

for k = 1:NIter
    x = randn(FrameSize,1);
    d = filt(x) + sinewave();
    [y,e] = rls(x,d);
    w = rls.Coefficients;
    scope(d,e)
end
release(scope)
```

Algorithms

The `dsp.RLSFilter` System object, when `Conventional` RLS is selected, recursively computes the least squares estimate (RLS) of the FIR filter weights. The System object estimates the filter weights or coefficients, needed to convert the input signal into the desired signal. The input signal can be a scalar or a column vector. The desired signal must have the same data type, complexity, and dimensions as the input signal. The corresponding RLS filter is expressed in matrix form as $\mathbf{P}(n)$:

$$\mathbf{k}(n) = \frac{\lambda^{-1}\mathbf{P}(n-1)\mathbf{u}(n)}{1 + \lambda^{-1}\mathbf{u}^H(n)\mathbf{P}(n-1)\mathbf{u}(n)}$$

$$y(n) = \mathbf{w}^T(n-1)\mathbf{u}(n)$$

$$e(n) = d(n) - y(n)$$

$$\mathbf{w}(n) = \mathbf{w}(n-1) + \mathbf{k}^*(n)e(n)$$

$$\mathbf{P}(n) = \lambda^{-1}\mathbf{P}(n-1) - \lambda^{-1}\mathbf{k}(n)\mathbf{u}^H(n)\mathbf{P}(n-1)$$

where λ^{-1} denotes the reciprocal of the exponential weighting factor. The variables are as follows:

Variable	Description
n	The current time index
$\mathbf{u}(n)$	The vector of buffered input samples at step n

Variable	Description
$\mathbf{P}(n)$	The conjugate of the inverse correlation matrix at step n
$\mathbf{k}(n)$	The gain vector at step n
$\mathbf{k}^*(n)$	Complex conjugate of \mathbf{k}
$\mathbf{w}(n)$	The vector of filter tap estimates at step n
$y(n)$	The filtered output at step n
$e(n)$	The estimation error at step n
$d(n)$	The desired response at step n
λ	The forgetting factor

\mathbf{u} , \mathbf{w} , and \mathbf{k} are all column vectors.

Version History

Introduced in R2013a

dsp.SampleRateConverter

Package: dsp

Multistage sample rate converter

Description

The `SampleRateConverter` System object converts the sample rate of an incoming signal.

To convert the sample rate of a signal:

- 1 Create the `dsp.SampleRateConverter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
src = dsp.SampleRateConverter  
src = dsp.SampleRateConverter(Name, Value)
```

Description

`src = dsp.SampleRateConverter` creates a multistage FIR sample rate converter System object, `src`, that converts the sample rate of each channel of an input signal.

`src = dsp.SampleRateConverter(Name, Value)` returns a multistage FIR sample rate converter System object, `src`, with properties and options specified by one or more `Name, Value` pair arguments.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Bandwidth — Two-sided bandwidth of interest

40000 (default) | positive scalar

Specify the two-sided bandwidth of interest (after rate conversion) as a positive scalar expressed in Hz. This property sets the two-sided bandwidth of the information-carrying portion of the signal that you wish to retain.

InputSampleRate — Sample rate of input signal

192000 (default) | positive scalar

Specify the sample rate of the input signal as a positive scalar expressed in Hz. The input sample rate must be greater than the bandwidth of interest.

OutputRateTolerance — Maximum allowed tolerance for output sample rate

0 (default) | positive scalar

Specify the maximum allowed tolerance for the sample rate of the output signal as a positive scalar between 0 and 1.

The output rate tolerance allows for a simpler design in many cases. The actual output sample rate varies but is within the specified range. For example, if `OutputRateTolerance` is specified as `0.01`, then the actual output sample rate is in the range given by `OutputSampleRate ± 1%`.

OutputSampleRate — Sample rate of output signal

44100 (default) | positive scalar

Specify the sample rate of the output signal as a positive scalar expressed in Hz. The output sample rate must be greater than the bandwidth of interest.

StopbandAttenuation — Minimum dB attenuation for aliased components

80 (default) | positive scalar

Specify the stopband attenuation as a positive scalar expressed in dB. This property is the minimum amount by which any aliasing involved in the process is attenuated.

Usage**Syntax**

$$y = \text{src}(x)$$
Description

`y = src(x)` designs one or more multirate FIR filters and then uses the filters to convert the rate of each channel (column) of the real or complex input signal `x` to the output sampling rate.

Input Arguments**x — Input signal**

vector | matrix

Input signal, specified as a vector or a matrix. The row length of `x` must be a multiple of the overall decimation factor. The decimation factor is determined from the `getRateChangeFactors` function. Each column of `x` is treated as a separate channel.

Data Types: `single` | `double`

Output Arguments**y — Resampled signal**

vector | matrix

Resampled signal, returned as a vector or matrix.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.SampleRateConverter`

<code>getActualOutputRate</code>	Get actual output rate
<code>getFilters</code>	Obtain single-stage filters
<code>getRateChangeFactors</code>	Get overall interpolation and decimation factors
<code>visualizeFilterStages</code>	Visualize filter stages

Filter Analysis

<code>cost</code>	Implementation cost of the sample rate converter
<code>freqz</code>	Frequency response of the multirate multistage filter
<code>info</code>	Display information about sample rate converter

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Convert Sample Rate of Audio Signal

Convert the sample rate of an audio signal from 44.1 kHz (CD quality) to 96 kHz (DVD quality).

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Note: The `dsp.AudioFileWriter` System object™ is not supported in MATLAB Online.

```
FsIn = 44.1e3;  
FsOut = 96e3;  
  
SRC = dsp.SampleRateConverter('Bandwidth',40e3,...  
    'InputSampleRate',FsIn,'OutputSampleRate',FsOut);  
  
[L,M] = getRateChangeFactors(SRC);  
FrameSize = 10*M;  
  
AR = dsp.AudioFileReader('guitar10min.ogg', ...  
    'SamplesPerFrame',FrameSize);  
AW = dsp.AudioFileWriter('guitar10min_96k.wav', ...  
    'SampleRate',FsOut);
```

Convert 100 frames of audio signal. Release all objects.

```
for n = 1:100
    x = AR();
    y = SRC(x);
    AW(y);
end

release(AR);
release(AW);
release(SRC);
```

Plot the input and output signals. The latency of the sample rate converter introduces a delay in the output signal.

```
tx = (0:length(x)-1)./FsIn;
ty = (0:length(y)-1)./FsOut;
figure
subplot(2,1,1)
plot(tx,x(:,1),'.')
hold on
plot(ty,y(:,1),'--')
ylim([-0.25 0.25]);
xlim([0 0.005])
xlabel('Time (s)')
legend('Input samples','Output samples','Location','best')
title('Channel 1')
subplot(2,1,2)
plot(tx,x(:,2),'.')
hold on
plot(ty,y(:,2),'--')
ylim([-0.25 0.25]);
xlim([0 0.005])
xlabel('Time (s)')
legend('Input samples','Output samples','Location','best')
title('Channel 2')
```

Use the `outputDelay` function to determine this delay value. To account for this delay, shift the output by this delay value.

```
[delay,~,~] = outputDelay(SRC,Fc=0)

delay = 0.0012

tx = (0:length(x)-1)./FsIn;
ty = (0:length(y)-1)./FsOut;
figure
subplot(2,1,1)
plot(tx,x(:,1),'.')
hold on
plot(ty-delay,y(:,1),'--')
xlim([0 0.005])
xlabel('Time (s)')
legend('Input samples','Output samples','Location','best')
title('Channel 1')
subplot(2,1,2)
plot(tx,x(:,2),'.')
hold on
plot(ty-delay,y(:,2),'--')
xlim([0 0.005])
xlabel('Time (s)')
legend('Input samples','Output samples','Location','best')
title('Channel 2')
```

Zoom in to see the difference in sample rates.

```
figure
subplot(2,1,1)
plot(tx,x(:,1),Color=[0.6 0.6 0.6])
hold on
plot(tx,x(:,1),'ro')
plot(ty-delay,y(:,1),'b.')
xlim([0.0105 0.0107])
legend('Interpolated input','Input samples','Output samples')
title('Channel 1')
subplot(2,1,2)
plot(tx,x(:,2),Color=[0.6 0.6 0.6])
hold on
plot(tx,x(:,2),'ro')
plot(ty-delay,y(:,2),'b.')
xlim([0.0105 0.0107])
legend('Interpolated input','Input samples','Output samples')
title('Channel 2')
```

Convert Sample Rate of Sinusoid

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Create a multistage sample rate converter with default properties. The converter converts from 192 kHz to 44.1 kHz in three stages.

```
src = dsp.SampleRateConverter;
```

Use `src` to convert the sample rate of a noisy sinusoid. The sinusoid has a frequency of 20 kHz and is sampled for 0.1 s.

```
f = 20e3;
```

```
FsIn = src.InputSampleRate;  
FsOut = src.OutputSampleRate;
```

```
t1 = (0:1/FsIn:0.1-1/FsIn)';
```

```
sIn = sin(2*pi*f*t1) + randn(size(t1));
```

Estimate the power spectral density of the input.

```
hsa = spectrumAnalyzer('SampleRate',FsIn,...  
    'Method','welch','YLimits',[-40 40]);
```

```
hsa(sIn)
release(hsa)
```

Convert the sample rate of the signal. Estimate the power spectral density of the output.

```
s0out = src(sIn);

hsb = spectrumAnalyzer('SampleRate',FsOut,...
    'Method','welch','YLimits',[-40 40]);
hsb(s0out)
release(hsb)
```

Tolerance Cost in Sample Rate Conversion

A signal output from an A/D converter is sampled at 98.304 MHz. The signal has a bandwidth of 20 MHz. Reduce the sample rate of the signal to 22 MHz, which is the bandwidth of 802.11 channels. Make the conversion exactly and then redo it with an output rate tolerance of 1%.

```
SRC1 = dsp.SampleRateConverter('Bandwidth',20e6, ...
    'InputSampleRate',98.304e6,'OutputSampleRate',22e6, ...
    'OutputRateTolerance',0);
SRC2 = dsp.SampleRateConverter('Bandwidth',20e6, ...
    'InputSampleRate',98.304e6,'OutputSampleRate',22e6, ...
    'OutputRateTolerance',0.01);
```

Use the `cost` method to determine the cost of each sample rate conversion. The zero-tolerance process requires more than 500 times as many coefficients as the 1% process.

```
c1 = cost(SRC1)

c1 = struct with fields:
    NumCoefficients: 84779
    NumStates: 133
    MultiplicationsPerInputSample: 27.0422
    AdditionsPerInputSample: 26.0684
```

```

c2 = cost(SRC2)
c2 = struct with fields:
    NumCoefficients: 150
    NumStates: 127
    MultiplicationsPerInputSample: 22.6667
    AdditionsPerInputSample: 22.1111

```

Find the integer upsampling and downsampling factors used in each conversion.

```

[L1,M1] = getRateChangeFactors(SRC1)
L1 = 1375
M1 = 6144
[L2,M2] = getRateChangeFactors(SRC2)
L2 = 2
M2 = 9

```

Compute the actual sample rate of the output signal when the sample rate conversion has a tolerance of 1%.

```

getActualOutputRate(SRC2)
ans = 2.1845e+07

```

Reset a Sample Rate Converter

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Create a multistage sample rate converter with default properties, corresponding to the combined three filter stages used to convert from 192 kHz to 44.1 kHz. Determine its overall decimation and interpolation factors.

```

src = dsp.SampleRateConverter;
[L,M] = getRateChangeFactors(src);

```

Create a two-channel random signal. Specify a number of samples equal to the decimation factor. Call the object twice on the signal.

```

x = randn(M,2);
y1 = src(x);
y2 = src(x);
no = all(y2==y1)
no = 1x2 logical array
    0    0

```

The output is different because the internal states of `src` have changed. Use `reset` to reset the converter and call the converter again. Verify that the output is unchanged.

```
reset(src)
y3 = src(x);
yes = all(y3==y1)
yes = 1x2 logical array
     1     1
```

Frequency Response of Default Converter

Create a multistage sample rate converter with default properties, corresponding to the combined three filter stages used to convert from 192 kHz to 44.1 kHz. Compute and display the frequency response.

```
src = dsp.SampleRateConverter;
[H,f] = freqz(src);
plot(f,20*log10(abs(H)))
```

Compute and display the frequency response over the range between 20 Hz and 44.1 kHz.

```
f = 20:10:44.1e3;
[H,f] = freqz(src,f);
plot(f,20*log10(abs(H)))
```

Single-Stage Filters

Create `src`, a multistage sample rate converter with default properties. `src` converts between 192 kHz and 44.1 kHz. Find the individual filters that are cascaded together to perform the conversion.

```
src = dsp.SampleRateConverter;
c = getFilters(src);
```

Visualize the frequency response of the decimator used in the first stage of the process.

```
m = c.Stage1;

[h,w] = freqz(m);
plot(w/pi,20*log10(abs(h)))
xlabel('\omega / \pi')
ylabel('Magnitude (dB)')
```

Default Multistage Sample Rate Converter

Create a multistage sample rate converter with default properties, corresponding to the combined three filter stages used to convert from 192 kHz to 44.1 kHz.

```
src = dsp.SampleRateConverter
```

```
src =  
  dsp.SampleRateConverter with properties:
```

```
    InputSampleRate: 192000  
    OutputSampleRate: 44100  
    OutputRateTolerance: 0  
        Bandwidth: 40000  
    StopbandAttenuation: 80
```

Display information about the design.

```
info(src)
```

```
ans =  
  'Overall Interpolation Factor    : 147  
  Overall Decimation Factor      : 640  
  Number of Filters              : 3
```

```

Multiplications per Input Sample: 27.667188
Number of Coefficients           : 8631
Filters:
  Filter 1:
    dsp.FIRDecimator      - Decimation Factor   : 2
  Filter 2:
    dsp.FIRDecimator      - Decimation Factor   : 2
  Filter 3:
    dsp.FIRRateConverter  - Interpolation Factor: 147
                        - Decimation Factor    : 160

```

Output Sample Rate with Given Tolerance

Get the actual output sample rate for conversion between 192 kHz and 44.1 kHz when given a tolerance of 1%.

```

src = dsp.SampleRateConverter;
src.OutputRateTolerance = 0.01;
FsOut = getActualOutputRate(src)

```

```

FsOut = 4.4308e+04

```

Default Resampling Factors

Create `src`, a multistage sample rate converter with default properties. `src` combines three filter stages to convert from 192 kHz to 44.1 kHz. Determine its overall interpolation and decimation factors.

```

src = dsp.SampleRateConverter;
[L,M] = getRateChangeFactors(src)

```

```

L = 147

```

```

M = 640

```

Sample Rate Converter Stages

Create a multistage sample rate converter with default properties, corresponding to the combined three filter stages used to convert from 192 kHz to 44.1 kHz. Visualize the stages.

```

src = dsp.SampleRateConverter;
visualizeFilterStages(src)

```

Algorithms

- The general multistage sample rate converter performs a multistage decimation, a single-stage sample rate conversion, and a multistage interpolation. Actual designs include at most two of these steps.
- The procedure automatically determines the optimal number of decimation or interpolation stages. In special cases, the algorithm can perform a decimation or interpolation in a single stage.
- The algorithm always attempts to start by reducing the sample rate. This decreases the amount of computation required. The decimation step ensures that the intermediate sample rate does not go below the bandwidth of interest and that the block does not filter out any information.
- Each individual stage uses halfband or Nyquist filters to minimize the number of nonzero coefficients.
- The algorithm allows transition-band aliasing because it decreases the implementation cost. It keeps the signal within the bandwidth of interest alias free up to the value specified by the `StopbandAttenuation` property.

Version History

Introduced in R2014b

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

The `getRateChangeFactors` function supports C and C++ code generation.

This object supports SIMD code generation using Intel AVX2 technology under these conditions:

- For upsampling, the ratio of output sample rate to input sample rate must be an integer.
- For downsampling, the ratio of input sample rate to output sample rate must be an integer.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

dsp.ScalarQuantizerDecoder

Package: dsp

(To be removed) Convert each index value into quantized output value

Note dsp.ScalarQuantizerDecoder will be removed in a future release.

Description

The dsp.ScalarQuantizerDecoder object converts each index value into a quantized output value. The specified codebook defines the set of all possible quantized output values or codewords. Input index values less than 0 are set to 0 and index values greater $N - 1$ are set to $N - 1$. N is the length of the codebook vector.

To convert an index value into a quantized output value:

- 1 Create the dsp.ScalarQuantizerDecoder object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
sqdec = dsp.ScalarQuantizerDecoder  
sqdec = dsp.ScalarQuantizerDecoder(Name, Value)
```

Description

sqdec = dsp.ScalarQuantizerDecoder returns a scalar quantizer decoder System object, sqdec, that transforms zero-based input index values into quantized output values.

sqdec = dsp.ScalarQuantizerDecoder(Name, Value) returns a scalar quantizer decoder object, sqdec, with each specified property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

CodebookSource — How to specify codebook values

'Property' (default) | 'Input port'

Specify how to determine the codebook values as 'Property' or 'Input port'.

Codebook — Codebook

1:10 (default) | vector

Specify the codebook as a vector of quantized output values that correspond to each index value.

Tunable: Yes

Dependencies

This property applies when you set CodebookSource to 'Property'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

OutputDataType — Data type of codebook and quantized output

'double' | 'single' | 'Custom' | 'Same as input'

Specify the data type of the codebook and quantized output values as 'Same as input', 'double', 'single', or 'Custom'.

Dependencies

This property applies when you set CodebookSource to 'Property'.

Fixed-Point Properties

CustomOutputDataType — Output word and fraction lengths

numerictype(true,16) (default) | numerictype

Specify the output fixed-point type as a signed or unsigned numerictype object.

Dependencies

This property applies only when you set the OutputDataType property to Custom.

Usage

Syntax

```
Q = sqdec(I)
Q = sqdec(I,C)
```

Description

$Q = \text{sqdec}(I)$ returns the quantized output values Q corresponding to the input indices I .

$Q = \text{sqdec}(I,C)$ uses input C as the codebook values when you set the CodebookSource property to Input port. The data type of C can be double, single, or fixed-point. The output Q has the same data type as the codebook input C .

Input Arguments

I — Input indices

vector | matrix

Input indices, specified as a vector or a matrix.

Data Types: `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

C — Codebook values

vector

Codebook, specified as a vector of quantized output values that correspond to each index value.

Dependencies

This property applies when you set `CodebookSource` to `'Input port'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Output Arguments

Q — Quantized output values

vector | matrix

Quantized output values, returned as a vector or a matrix of the same size as the input, `I`. When codebook is specified as a property, the output data type is determined by the `OutputDataType` property. When the codebook is specified as an input, the output data type is same as the data type of the codebook input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Quantize Signal

Note: If you are using R2016a or earlier, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Given a codebook and index values as inputs, determine the corresponding output quantized values.

```
codebook = single([-2.1655 -1.3238 -0.7365 -0.2249 0.2726, ...  
    0.7844 1.3610 2.1599]);  
indices = uint8([1 3 5 7 6 4 2 0]);  
sqdec = dsp.ScalarQuantizerDecoder;  
sqdec.CodebookSource = 'Input port';  
qout = sqdec(indices,codebook)
```

qout = 1x8 single row vector

-1.3238 -0.2249 0.7844 2.1599 1.3610 0.2726 -0.7365 -2.1655

Algorithms

This object implements the algorithm, inputs, and outputs described on the Scalar Quantizer Decoder block reference page. The object properties correspond to the block parameters, except there is no object property that directly corresponds to the **Action for out of range index value** block parameter. The object sets any index values less than 0 to 0 and any index values greater than or equal to N to $N - 1$.

dsp.ScalarQuantizerEncoder

Package: dsp

(To be removed) Associate input value with index value of quantization region

Note dsp.ScalarQuantizerEncoder will be removed in a future release.

Description

The dsp.ScalarQuantizerEncoder object encodes each input value by associating that value with the index value of the quantization region. Then, the object outputs the index of the associated region.

To encode an input value by associating it with an index value of the quantization region:

- 1 Create the dsp.ScalarQuantizerEncoder object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
sqenc = dsp.ScalarQuantizerEncoder  
sqenc = dsp.ScalarQuantizerEncoder(Name,Value)
```

Description

sqenc = dsp.ScalarQuantizerEncoder returns a scalar quantizer encoder System object, sqenc. This object maps each input value to a quantization region by comparing the input value to the user-specified boundary points.

sqenc = dsp.ScalarQuantizerEncoder(Name,Value) returns a scalar quantizer encoder object, sqenc, with each specified property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

BoundaryPointsSource — Source of boundary points

'Property' (default) | 'Input port'

Specify how to determine the boundary points and codebook values as 'Property' or 'Input port'.

Partitioning — Quantizer is bounded or unbounded

'Bounded' (default) | 'Unbounded'

Specify the quantizer as 'Bounded' or 'Unbounded'.

BoundaryPoints — Boundary points of quantizer regions

1:10 (default) | vector

Specify the boundary points of quantizer regions as a vector. The vector values must be in ascending order. Let $[p_0 \ p_1 \ p_2 \ p_3 \ \dots \ p_N]$ denote the boundary points property in the quantizer. If the quantizer is bounded, the object uses this property to specify $[p_0 \ p_1 \ p_2 \ p_3 \ \dots \ p_N]$. If the quantizer is unbounded, the object uses this property to specify $[p_1 \ p_2 \ p_3 \ \dots \ p_{(N-1)}]$ and sets $p_0 = -\text{Inf}$ and $p_N = +\text{Inf}$.

Tunable: Yes

Dependencies

This property applies when you set the BoundaryPointsSource property to Property.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

SearchMethod — Find quantizer index by linear or binary search

'Linear' (default) | 'Binary'

Specify whether to find the appropriate quantizer index using a linear search or a binary search as one of 'Linear' or 'Binary'. The computational cost of the linear search method is of the order P and the computational cost of the binary search method is of the order

$$\log_2(P)$$

where P is the number of boundary points.

TiebreakerRule — Behavior when input equals boundary point

'Choose the lower index' (default) | 'Choose the higher index'

Specify whether the input value is assigned to the lower indexed region or higher indexed region when the input value equals boundary point by selecting 'Choose the lower index' or 'Choose the higher index'.

CodewordOutputPort — Enable output of codeword value

false (default) | true

Set this property to true to output the codeword values that correspond to each index value.

QuantizationErrorOutputPort — Enable output of quantization error

false (default) | true

Set this property to true to output the quantization error for each input value. The quantization error is the difference between the input value and the quantized output value.

Codebook — Codebook

1.5:9.5 (default) | vector

Specify the codebook as a vector of quantized output values that correspond to each region. If the `Partitioning` property is 'Bounded' and the boundary points vector has length `N`, you must set this property to a vector of length `N-1`. If the `Partitioning` property is 'Unbounded' and the boundary points vector has length `N`, you must set this property to a vector of length `N+1`.

Tunable: Yes

Dependencies

This property applies when you set the `BoundaryPointsSource` property to 'Property' and either the `CodewordOutputPort` property or the `QuantizationErrorOutputPort` property is true.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

ClippingStatusOutputPort — Enable output of clipping status

`false` (default) | `true`

Set this property to `true` to output the clipping status. The output is a 1 when an input value is outside the range defined by the `BoundaryPoints` property. When the value is inside the range, the exception output is a 0.

Dependencies

This property applies when you set the `Partitioning` property to 'Bounded'.

OutputIndexDataType — Data type of the index output

`int32` (default) | `int8` | `int16` | `uint8` | `uint16` | `uint32`

Specify the data type of the index output from the object as: `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`.

Fixed-Point Properties

RoundingMethod — Rounding method for fixed-point operations

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Specify the rounding method.

OverflowAction — Overflow action for fixed-point operations

'Wrap' (default) | 'Saturate'

Specify the overflow action.

Usage

Syntax

```
index = sqenc(input)
[index] = sqenc(input,bpoints)
[index] = sqenc(input,bpoints,cBook)
[index,codeword] = sqenc(____)
[____,qerr] = sqenc(____)
[____,cStatus] = sqenc(____)
```

Description

`index = sqenc(input)` returns the index of the quantization region to which the input belongs. The input data, boundary points, codebook values, quantized output values, and the quantization error must have the same data type whenever they are present.

`[index] = sqenc(input,bpoints)` uses input `bpoints` as the boundary points when the `BoundaryPointsSource` property is `Input port`.

`[index] = sqenc(input,bpoints,cBook)` uses input `bpoints` as the boundary points and input `cBook` as the codebook when the `BoundaryPointsSource` property is `'Input port'` and either the `CodewordOutputPort` property or the `QuantizationErrorOutputPort` property is `true`.

`[index,codeword] = sqenc(____)` outputs the codeword values that corresponds to each index value when the `CodewordOutputPort` property is `true`.

`[____,qerr] = sqenc(____)` outputs the quantization error `qerr` for each input value when the `QuantizationErrorOutputPort` property is `true`.

`[____,cStatus] = sqenc(____)` also returns output `cStatus` as the clipping status output port for each input value when the `Partitioning` property is `'Bounded'` and the `ClippingStatusOutputPort` property is `true`. If an input value is outside the range defined by the `BoundaryPoints` property, `cStatus` is `true`. If an input value is inside the range, `cStatus` is `false`.

Input Arguments

input — Input data

vector | matrix

Input data, specified as a vector or a matrix. If the input is fixed point, it must be signed fixed point with power-of-two slope and zero bias.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

bpoints — Boundary points

vector

Boundary points of the quantizer regions, specified as a vector. The vector values must be in ascending order. Let `[p0 p1 p2 p3 ... pN]` denote the boundary points in the quantizer. If the quantizer is bounded, the object uses this input to specify `[p0 p1 p2 p3 ... pN]`. If the quantizer is unbounded, the object uses this input to specify `[p1 p2 p3 ... p(N-1)]` and sets `p0 = -Inf` and `pN = +Inf`.

Dependencies

This input applies when you set the `BoundaryPointsSource` property to `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

cBook — Code book

vector

Codebook, specified as a vector of quantized output values that correspond to each region. If the `Partitioning` property is `'Bounded'` and the boundary points vector has length N , this input must be a vector of length $N-1$. If the `Partitioning` property is `'Unbounded'` and the boundary points vector has length N , this input must be a vector of length $N+1$.

Dependencies

This input applies when you set the `BoundaryPointsSource` property is 'Input port' and either the `CodewordOutputPort` property or the `QuantizationErrorOutputPort` property is true.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Output Arguments**index — Index of quantization region**

vector | matrix

Index of the quantization region to which the input belongs, returned as a vector or a matrix of the same size as the input.

Data Types: `int32`

codeword — Codeword values

vector | matrix

Codeword values that correspond to each index value, returned as a vector or a matrix of the same size as the input.

Dependencies

This output is available when the `CodewordOutputPort` property is set to true.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

qerr — Quantization error

vector | matrix

Quantization error for each input value, returned as a vector or a matrix of the same size as the input.

Dependencies

This output is available when the `QuantizationErrorOutputPort` property is set to true.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

cStatus — Clipping status

vector | matrix

Clipping status for each input value, returned as a vector or a matrix. If an input value is outside the range defined by the `BoundaryPoints` property, `cStatus` is true. If an input value is inside the range, `cStatus` is false.

Dependencies

This output is available when the `Partitioning` property is 'Bounded' and the `ClippingStatusOutputPort` property is set to true.

Data Types: `logical`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step Run System object algorithm
 release Release resources and allow changes to System object property values and input characteristics
 reset Reset internal states of System object

Examples

Quantize Varying Fractional Inputs

Note: If you are using R2016a or earlier, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Quantize the varying fractional inputs between zero and five to the closest integers, and then plot the results.

```
sqenc = dsp.ScalarQuantizerEncoder;
sqenc.BoundaryPoints = [-.001 .499 1.499 ...
    2.499 3.499 4.499 5.001];
sqenc.CodewordOutputPort = true;
sqenc.Codebook = [0 1 2 3 4 5];
input = (0:0.02:5)';
[index, quantizedValue] = sqenc(input);
plot(1:length(input), [input quantizedValue]);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Scalar Quantizer Encoder block reference page. The object properties correspond to the block parameters.

dsp.SignalSink

Package: dsp

Log simulation data in buffer

Description

The `dsp.SignalSink` System object logs MATLAB simulation data. This object accepts any numeric data type.

To log MATLAB simulation data :

- 1 Create the `dsp.SignalSink` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
ss = dsp.SignalSink
ss = dsp.SignalSink(Name,Value)
```

Description

`ss = dsp.SignalSink` returns a signal sink, `ss`, that logs 2-D input data in the object.

`ss = dsp.SignalSink(Name,Value)` returns a signal sink, `ss`, with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

BufferLength — Maximum number of input frames to log

`inf` (default) | positive integer

Specify the maximum number of frames to log. The object always preserves the most recent data in the buffer. When you specify a buffer length that is greater than the input length, the object pads the end of the logged data with zeros. To capture all input data without extra padding, set the `BufferLength` property to `inf`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Decimation — Decimation factor

1 (default) | positive integer

Setting this property to any positive integer d causes the signal sink to write data at every d th sample.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

FrameHandlingMode — Output dimensionality for frame-based inputs

2-D array (concatenate) (default) | 3-D array (separate)

Set the dimension of the output array for frame-based inputs as 2-D array (concatenate) or 3-D array (separate). Concatenation occurs along the first dimension for 2-D array (concatenate).

Buffer — Logged data (read only)

matrix

This property is read-only.

The signal sink writes simulation data into a buffer. Specify the maximum length of the buffer with the `BufferLength` property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Usage**Syntax**

`ss(x)`

Description

`ss(x)` buffers the signal `x`. The buffer may be accessed at any time from the `Buffer` property of `ss`.

Input Arguments**x — Data input**

vector | matrix

Data input, specified as a vector or a matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

`release(obj)`

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Log Input Data

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

```
hlog = dsp.SignalSink;
for i=1:10
    y = sin(i);
    hlog(y);
end
log = hlog.Buffer;
display(log)
```

```
log = 10x1
```

```
    0.8415
    0.9093
    0.1411
   -0.7568
   -0.9589
   -0.2794
    0.6570
    0.9894
    0.4121
   -0.5440
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the To Workspace block reference page. The object properties correspond to the block properties, except the object always generates fixed-point output for fixed-point input.

Version History

Introduced in R2012b

See Also

Objects

`dsp.SignalSource`

dsp.SignalSource

Package: dsp

Import variable from workspace

Description

The `SignalSource` object imports a variable from the MATLAB workspace.

To import a variable from the MATLAB workspace:

- 1 Create the `dsp.SignalSource` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
src = dsp.SignalSource
src = dsp.SignalSource(signal,spf)
src = dsp.SignalSource(Name,Value)
```

Description

`src = dsp.SignalSource` returns a signal source System object, `src`, that outputs the variable, specified by the `Signal` property, one sample or frame at a time.

`src = dsp.SignalSource(signal,spf)` returns a signal source object, `src`, with the `Signal` property set to `signal` and the “SamplesPerFrame” on page 4-0 property set to `spf`.

`src = dsp.SignalSource(Name,Value)` returns a signal source object, `src`, with each specified property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Signal — Variable or expression containing the signal

[1:10]' (default) | vector | matrix

Specify the name of the workspace variable from which to import the signal, or a valid expression specifying the signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `fi`

SamplesPerFrame — Number of samples per output frame

1 (default) | positive scalar

Specify the number of samples to buffer into each output frame. This property must be 1 when you specify a 3-D array in the `Signal` property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

SignalEndAction — Action after final signal values are generated

'Set to zero' (default) | 'Hold final value' | 'Cyclic repetition'

Specify the output after all of the specified signal samples have been generated as one of 'Set to zero', 'Hold final value', or 'Cyclic repetition'.

Usage

Syntax

`Y = src()`

Description

`Y = src()` outputs one sample or frame of data from each column of the imported signal. The imported signal is the variable or expression you specify for the `Signal` property of the `SignalSource` System object, `src`.

Output Arguments

Y — Output data

scalar | vector | matrix

One sample or one frame of data from each column of the imported signal, returned as a scalar, vector, or matrix. The number of columns in the output signal matches the number of columns in the imported signal, `Signal`. The number of rows in the output signal matches the value specified in the `SamplesPerFrame` property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

`release(obj)`

Specific to `dsp.SignalSource`

`isDone` End-of-file status for signal reader object

Common to All System Objects

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

Examples

Create Signal Source

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject()` becomes `step(myObject)`.

Create a signal source to output one sample at a time.

```
src1 = dsp.SignalSource;
src1.Signal = randn(1024,1);
y1 = zeros(1024,1);
idx = 1;
while(~isDone(src1))
    y1(idx) = src1();
    idx = idx + 1;
end
```

Create a signal source to output vectors.

```
src2 = dsp.SignalSource(randn(1024,1),128);
y2 = src2(); % y2 is a 128-by-1 frame of samples
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Signal From Workspace block reference page. The object properties correspond to the block parameters, except the System object does not have properties that correspond to the **Sample time** or **Warn when frame size does not evenly divide input length** block parameters.

Objects

dsp.SignalSink

dsp.SineWave

Package: dsp

Generate discrete sine wave

Description

The `dsp.SineWave` System object generates a real or complex, multichannel sinusoidal signal with independent amplitude, frequency, and phase in each output channel.

For both real and complex sinusoids, the “Amplitude” on page 4-0 , “Frequency” on page 4-0 , and “PhaseOffset” on page 4-0 properties can be scalars or length- N vectors, where N is the number of channels in the output. When you specify at least one of these properties as a length- N vector, scalar values specified for the other properties are applied to each of the N channels.

To generate a discrete-time sinusoidal signal:

- 1 Create the `dsp.SineWave` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
sine = dsp.SineWave
sine = dsp.SineWave(Name,Value)
sine = dsp.SineWave(amp,freq,phase,Name,Value)
```

Description

`sine = dsp.SineWave` creates a sine wave object that generates a real-valued sinusoid with an amplitude of 1, a frequency of 100 Hz, and a phase offset of 0. By default, the sine wave object generates only one sample.

`sine = dsp.SineWave(Name,Value)` creates a sine wave object with each specified property set to the specified value. Enclose each property name in single quotes.

Example: `sine = dsp.SineWave('Amplitude',2);`

`sine = dsp.SineWave(amp,freq,phase,Name,Value)` creates a sine wave object with the “Amplitude” on page 4-0 property set to `amp`, “Frequency” on page 4-0 property set to `freq`, “PhaseOffset” on page 4-0 property set to `phase`, and any other specified properties set to the specified values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

Amplitude — Amplitude of sine wave

1 (default) | scalar | vector

Amplitude of the sine wave, specified as one of the following:

- scalar -- A scalar applies to all channels.
- vector -- A length- N vector contains the amplitudes of the sine waves in each of the N output channels. The vector length must be the same as that specified for the “Frequency” on page 4-0 and “PhaseOffset” on page 4-0 properties.

Tunable: Yes

Dependencies

This property is tunable only when you set “Method” on page 4-0 to either 'Trigonometric function' or 'Differential'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Frequency — Frequency of sine wave

100 (default) | scalar | vector

Frequency of the sine wave in Hz, specified as one of the following:

- scalar -- A scalar applies to all channels.
- vector -- A length- N vector contains the frequencies of the sine waves in each of the N output channels. The vector length must be the same as that specified for the “Amplitude” on page 4-0 and “PhaseOffset” on page 4-0 properties.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

PhaseOffset — Phase offset of sine wave

0 (default) | scalar | vector

Phase offset of the sine wave in radians, specified as one of the following:

- scalar -- A scalar applies to all channels.
- vector -- A length- N vector contains the phase offsets of the sine waves in each of the N output channels. The vector length must be the same as that specified for the “Amplitude” on page 4-0 and “Frequency” on page 4-0 properties.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

ComplexOutput — Flag that indicates whether waveform is real or complex

false (default) | true

Flag that indicates whether the waveform is real or complex, specified as either:

- `false` -- The waveform output is real.
- `true` -- The waveform output is complex.

Method — Method used to generate sinusoids

'Trigonometric function' (default) | 'Table lookup' | 'Differential'

Method used to generate sinusoids, specified as one of the following:

- 'Trigonometric function' -- The object computes the sinusoid by sampling the continuous-time function.
- 'Table lookup' -- The object precomputes the unique samples of every output sinusoid at the start of the simulation, and recalls the samples from memory as needed.
- 'Differential' -- The object uses an incremental algorithm. This algorithm computes the output samples based on the output values computed at the previous sample time and precomputed update terms.

TableOptimization — Optimize table of sine values for speed or memory

'Speed' (default) | 'Memory'

Optimize table of sine values for speed or memory, specified as either:

- 'Speed' -- The table contains k elements, where k is the number of input samples in one full period of the sine wave. The period of each sinusoid must be an integer multiple of $1/F_s$, where F_s is the value of the "SampleRate" on page 4-0 property value. That is, each element of the "Frequency" on page 4-0 property must be of the form F_s/m , where m is an integer greater than 1.
- 'Memory' -- The table contains $k/4$ elements.

Dependencies

This property applies only when you set the Method property to 'Table lookup'.

SampleRate — Sample rate of output signal

1000 (default) | positive scalar

Sample rate of output signal in Hz, specified as a positive scalar.

Example: 44100

Example: 22050

SamplesPerFrame — Number of samples per frame

1 (default) | positive integer

Number of consecutive samples from each sinusoid to buffer into the output frame, specified as a positive integer.

Example: 1000

Example: 5000

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

OutputDataType — Data type of the sine wave output

'double' (default) | 'single' | 'Custom'

Data type of the sine wave output, specified as 'double', 'single', or 'Custom'.

Fixed-Point Properties

CustomOutputDataType — Output word and fraction lengths

numericType([],16) (default) | numericType([],32,30)

Output word and fraction lengths, specified as an autosigned numeric type with a word length of 16.

Example: numericType([],32,30)

Example: numericType([],16,15)

Dependencies

This property applies only when you set the “Method” on page 4-0 property to 'Table lookup' and the “OutputDataType” on page 4-0 property to 'Custom'.

Usage

Syntax

```
sineOut = sine()
```

Description

sineOut = sine() creates the sine wave output, sineOut.

Output Arguments

sineOut — Sine wave output

vector | matrix

Sine wave output, returned as a vector or matrix. The “SamplesPerFrame” on page 4-0 property determines the number of rows in the output matrix. If the “Frequency” on page 4-0 or the “PhaseOffset” on page 4-0 property is a vector, the length of the vector determines the number of columns (channels) in the output matrix. If the Frequency or the PhaseOffset properties is a scalar, then the number of channels in the output matrix is 1.

The “OutputDataType” on page 4-0 property sets the data type of the output.

Data Types: single | double | fi

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:

```
release(obj)
```

Common to All System Objects

step Run System object algorithm

release Release resources and allow changes to System object property values and input characteristics

reset Reset internal states of System object

Examples

Generate a Sine Wave Signal

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Generate a sine wave with an amplitude of 2, frequency of 10 Hz, and an initial phase of 0.

```
sine1 = dsp.SinWave(2,10);  
sine1.SamplesPerFrame = 1000;  
y = sine1();  
plot(y)
```

Generate two sine waves offset by a phase of $\pi/2$ radians.

```
sine2 = dsp.SinWave;  
sine2.Frequency = 10;  
sine2.PhaseOffset = [0 pi/2];  
sine2.SamplesPerFrame = 1000;  
y = sine2();  
plot(y)
```

Filter Frames of a Noisy Sine Wave Signal in MATLAB

This example shows how to lowpass filter a noisy signal in MATLAB® and visualize the original and filtered signals using a spectrum analyzer. For a Simulink® version of this example, see “Filter Frames of a Noisy Sine Wave Signal in Simulink”.

Specify Signal Source

The input signal is the sum of two sine waves with frequencies of 1 kHz and 10 kHz. The sampling frequency is 44.1 kHz.

```
Sine1 = dsp.SineWave('Frequency',1e3,'SampleRate',44.1e3);  
Sine2 = dsp.SineWave('Frequency',10e3,'SampleRate',44.1e3);
```

Create Lowpass Filter

The lowpass FIR filter, `dsp.LowpassFilter`, designs a minimum-order FIR lowpass filter using the generalized Remez FIR filter design algorithm. Set the passband frequency to 5000 Hz and the stopband frequency to 8000 Hz. The passband ripple is 0.1 dB and the stopband attenuation is 80 dB.

```
FIRLowPass = dsp.LowpassFilter('PassbandFrequency',5000,...  
    'StopbandFrequency',8000);
```

Create Spectrum Analyzer

Set up the spectrum analyzer to compare the power spectra of the original and filtered signals. The spectrum units are dBm.

```
SpecAna = spectrumAnalyzer('PlotAsTwoSidedSpectrum',false,...  
    'SampleRate',Sine1.SampleRate,...  
    'ShowLegend',true, ...  
    'YLimits',[-145,45]);  
  
SpecAna.ChannelNames = {'Original noisy signal',...  
    'Lowpass filtered signal'};
```

Specify Samples per Frame

This example uses frame-based processing, where data is processed one frame at a time. Each frame of data contains sequential samples from an independent channel. Frame-based processing is advantageous for many signal processing applications because you can process multiple samples at once. By buffering your data into frames and processing multisample frames of data, you can improve the computational time of your signal processing algorithms. Set the number of samples per frame to 4000.

```
Sine1.SamplesPerFrame = 4000;  
Sine2.SamplesPerFrame = 4000;
```

Filter the Noisy Sine Wave Signal

Add zero-mean white Gaussian noise with a standard deviation of 0.1 to the sum of sine waves. Filter the result using the FIR filter. While running the simulation, the spectrum analyzer shows that frequencies above 8000 Hz in the source signal are attenuated. The resulting signal maintains the peak at 1 kHz because it falls in the passband of the lowpass filter.

```
for i = 1 : 1000  
    x = Sine1()+Sine2()+0.1.*randn(Sine1.SamplesPerFrame,1);  
    y = FIRLowPass(x);  
    SpecAna(x,y);  
end  
release(SpecAna)
```

Bandpass Filtering of Sinusoids

Bandpass filter a discrete-time sine wave signal which consists of three sinusoids at frequencies, 1 kHz, 10 kHz, and 15 kHz.

Design an FIR Equiripple bandpass filter by first creating a bandpass filter design specifications object, and then designing a filter using these specifications.

Design Bandpass Filter

Create a bandpass filter design specifications object using `fdesign.bandpass`.

```
bandpassSpecs = fdesign.bandpass('Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2', ...
    1/4,3/8,5/8,6/8,60,1,60);
```

List the available design methods for this object.

```
designmethods(bandpassSpecs)
```

Design Methods for class `fdesign.bandpass (Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2)`:

```
butter
cheby1
cheby2
```

```
ellip  
equiripple  
kaiserwin
```

To design an Equiripple filter, pick 'equiripple'.

```
bpFilter = design(bandpassSpecs, 'equiripple', 'Systemobject', true)
```

```
bpFilter =  
  dsp.FIRFilter with properties:  
  
    Structure: 'Direct form'  
    NumeratorSource: 'Property'  
    Numerator: [-0.0043 -3.0812e-15 0.0136 3.7820e-15 -0.0180 ... ]  
    InitialConditions: 0
```

Show all properties

Visualize the frequency response of the designed filter.

```
fvtool(bpFilter, 'Fs', 44100)
```

Create Sinusoidal Signal

Create a signal that is a sum of three sinusoids with frequencies at 1 kHz, 10 kHz, and 15 kHz. Initialize Spectrum Analyzer to view the original signal and the filtered signal.

```
Sine1 = dsp.SineWave('Frequency',1e3,'SampleRate',44.1e3,'SamplesPerFrame',4000);
Sine2 = dsp.SineWave('Frequency',10e3,'SampleRate',44.1e3,'SamplesPerFrame',4000);
Sine3 = dsp.SineWave('Frequency',15e3,'SampleRate',44.1e3,'SamplesPerFrame',4000);

SpecAna = spectrumAnalyzer('PlotAsTwoSidedSpectrum',false, ...
    'SampleRate',Sine1.SampleRate, ...
    'ShowLegend',true, ...
    'YLimits',[-240,45]);

SpecAna.ChannelNames = {'Original noisy signal','Bandpass filtered signal'};
```

Filter Sinusoidal Signal

Filter the sinusoidal signal using the bandpass filter that has been designed. View the original signal and the filtered signal in the Spectrum Analyzer. The tone at 1 kHz is filtered out and attenuated. The tone at 10 kHz is unaffected, and the tone at 15 kHz is mildly attenuated because it appears in the transition band of the filter.

```
for i = 1 : 1000
    x = Sine1()+Sine2()+Sine3();
    y = bpFilter(x);
    SpecAna(x,y);
end
release(SpecAna)
```

More About

Sinusoid

A real-valued, discrete-time sinusoid is defined as:

$$y(n) = A \sin(2\pi f n + \phi)$$

where A is the amplitude, f is the frequency in Hz, and ϕ is the initial phase, or phase offset, in radians.

A complex sinusoid is defined as:

$$y(n) = A e^{j(2\pi f n + \phi)}$$

Algorithms

Trigonometric Function

The trigonometric function method computes the sinusoid in the i th channel, y_i , by sampling the continuous function

$$y_i = A_i \sin(2\pi f_i t + \phi_i) \text{ (real)}$$

or

$$y_i = A_i e^{j(2\pi f_i t + \phi_i)} \text{ (complex)}$$

with a period of T_s , where you specify T_s in the sample time.

At each sample time, the algorithm evaluates the sine function at the appropriate time value *within the first cycle* of the sinusoid. By constraining trigonometric evaluations to the first cycle of each sinusoid, the algorithm avoids the imprecision of computing the sine of very large numbers. This constraint also eliminates the possibility of discontinuity during extended operations, when an absolute time variable might overflow. This method therefore avoids the memory demands of the table lookup method at the expense of many more floating-point operations.

Table Lookup

The table lookup method precomputes the *unique* samples of every output sinusoid at the start of the simulation, and recalls the samples from memory as needed. Because a table of finite length can only be constructed when all output sequences repeat, the method requires that the period of every sinusoid in the output be evenly divisible by the sample period. That is, $1/(f_i T_s) = k_i$ must be an integer value for every channel $i = 1, 2, \dots, N$.

When the algorithm optimizes the table of sine values for **Speed**, the table constructed for each channel contains k_i elements. When the optimization is for **Memory**, the table constructed for each channel contains $k_i/4$ elements.

For long output sequences, the table lookup method requires far fewer floating-point operations than any of the other methods. However, the method can demand considerably more memory, especially for high sample rates (long tables). This method is recommended for models that are intended to emulate or generate code for DSP hardware, which need to be optimized for execution speed.

Note The lookup table for this object is constructed from double-precision floating-point values. When you use the **Table Lookup** computation mode, the maximum amount of precision you can achieve in your output is 53 bits. Setting the word length of the output data type to values greater than 53 bits does not improve the precision of your output.

Differential

The differential method uses an incremental algorithm. This algorithm computes the output samples based on the output values computed at the previous sample time (and precomputed update terms) by making use of the following identities.

$$\sin(t + T_s) = \sin(t)\cos(T_s) + \cos(t)\sin(T_s)$$

$$\cos(t + T_s) = \cos(t)\cos(T_s) - \sin(t)\sin(T_s)$$

The update equations for the sinusoid in the i th channel, y_i , can therefore be written in matrix form as

$$\begin{bmatrix} \sin\{2\pi f_i(t + T_s) + \phi_i\} \\ \cos\{2\pi f_i(t + T_s) + \phi_i\} \end{bmatrix} = \begin{bmatrix} \cos(2\pi f_i T_s) & \sin(2\pi f_i T_s) \\ -\sin(2\pi f_i T_s) & \cos(2\pi f_i T_s) \end{bmatrix} \begin{bmatrix} \sin(2\pi f_i t + \phi_i) \\ \cos(2\pi f_i t + \phi_i) \end{bmatrix}$$

where you specify T_s in the sample time. Since T_s is constant, the right-hand matrix is a constant and can be computed once at the start of the simulation. The value of $A_i \sin[2\pi f_i(t + T_s) + \phi_i]$ is then

computed from the values of $\sin(2\pi f_i t + \phi_i)$ and $\cos(2\pi f_i t + \phi_i)$ by a simple matrix multiplication at each time step.

This mode offers reduced computational load, but is subject to drift over time due to cumulative quantization error. Because the method is not contingent on an absolute time value, there is no danger of discontinuity during extended operations, when an absolute time variable might overflow.

Version History

dsp.SOSFilter

Package: dsp

Second-order section biquadratic IIR filter structures

Description

The `dsp.SOSFilter` System object implements an IIR filter structure using second-order sections (SOS).

To implement an IIR filter structure using SOS:

- 1 Create the `dsp.SOSFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
sos = dsp.SOSFilter
sos = dsp.SOSFilter(num,den)
sos = dsp.SOSFilter(Name,Value)
```

Description

`sos = dsp.SOSFilter` returns a biquadratic IIR filter System object, `sos`, which independently filters each channel (column) of the input over time using a specified biquadratic structure.

`sos = dsp.SOSFilter(num,den)` returns a biquadratic filter object with the `Numerator` property set to `num` and the `Denominator` property set to `den`.

`sos = dsp.SOSFilter(Name,Value)` returns a biquadratic filter object with each property set to the specified value. Enclose each property name in single quotes.

Example: `sos = dsp.SOSFilter('CoefficientSource','Input port')`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Structure – Filter structure

'Direct form II transposed' (default) | 'Direct form I' | 'Direct form I transposed' | 'Direct form II'

Filter structure, specified as one of 'Direct form I', 'Direct form I transposed', 'Direct form II', or 'Direct form II transposed'.

CoefficientSource – Source of filter coefficients

'Property' (default) | 'Input port'

Source of the filter coefficients, specified as one of the following:

- 'Property' -- The filter coefficients are specified through the `Numerator`, `Denominator`, and `ScaleValues` properties.
- 'Input port' -- The numerator coefficients, denominator coefficients, and the scale values are specified as inputs to the object while running the algorithm. For more details, see “Usage” on page 4-1017.

Numerator – Numerator coefficients of filter

[0.0975 0.195 0.0975] (default) | *N*-by-3 matrix

Numerator coefficients of the filter, specified as an *N*-by-3 matrix, where *N* is the number of biquadratic sections.

The size of this property cannot be modified once you have run the System object algorithm. However, the coefficient values can change as the property is tunable.

Tunable: Yes

Dependencies

To enable this property, set the `CoefficientSource` property to 'Property'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Denominator – Denominator coefficients of filter

[1 -0.9428 0.3333] (default) | *N*-by-3 matrix

Denominator coefficients of the filter, specified as an *N*-by-3 matrix, where *N* is the number of biquadratic sections.

The leading denominator coefficient is always assumed to be 1. If any other value is specified in the first column, the object ignores this value and treats it as 1.

The size of this property cannot be modified once you step through the algorithm. However, the denominator values can be modified as the property is tunable.

Tunable: Yes

Dependencies

To enable this property, set `CoefficientSource` property to 'Property'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

HasScaleValues – Specify if filter has scale values for each section

false (default) | true

Specify if the filter has scale values for each section. When set to `true`, using the `ScaleValues` property, you can specify the scale values to be applied before and after each section of the biquadratic filter.

ScaleValues — Scale values for each biquad second-order section

[1 1] (default) | vector

Scale values to apply before and after each section of a biquadratic filter, specified as a vector. The length of the `ScaleValues` vector must be $N + 1$, where N is the number of biquadratic sections. If you set this property to a scalar value, the scalar value is used as the gain value only before the first filter section. The remaining gain values are set to 1. If you set this property to a vector of $N + 1$ values, each value is used for a separate section of the filter.

Tunable: Yes

Dependencies

This property applies only when you set the `CoefficientSource` property to `'Property'` and `HasScaleValues` property to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Fixed-Point Properties

RoundingMethod — Rounding method for fixed-point operations

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Rounding method for fixed-point operations, specified as one of the following:

- 'Floor'
- 'Ceiling'
- 'Convergent'
- 'Nearest'
- 'Round'
- 'Simplest'
- 'Zero'

For more details, see Rounding Modes.

OverflowAction — Overflow action for fixed-point operations

Wrap (default) | Saturate

Overflow action for fixed-point operations, specified as one of the following:

- 'Wrap' -- The object wraps the result of its fixed-point operations.
- 'Saturate' -- The object saturates the result of its fixed-point operations.

For more details on overflow actions, see Overflow Handling for fixed-point operations.

SectionInputDataType — Section input word- and fraction-length designations

'Same as input' (default) | `numericType` object

Section input word- and fraction-length designations, specified as either `'Same as input'` or a `numericType` object.

When specified as a `numericType` object, the data type must be signed fixed point with a power-of-two slope and zero bias.

Dependencies

This property applies only when you set the `HasScaleValues` property to `true`.

SectionOutputDataType — Section output word- and fraction-length designations

'Same as section input' (default) | `numericType` object

Section output word- and fraction-length designations, specified as either 'Same as section input' or a `numericType` object.

When specified as a `numericType` object, the data type must be signed fixed point with a power-of-two slope and zero bias.

Dependencies

This property applies only when you set the `HasScaleValues` property to `true`.

NumeratorDataType — Numerator coefficients word- and fraction-length designations

'Same word length as input' (default) | `numericType` object

Numerator coefficients word- and fraction-length designations, specified as either 'Same word length as input' or as a `numericType` object.

When specified as a `numericType` object, the data type must be signed fixed point with a power-of-two slope and zero bias. If not specified, the fraction length is determined based on the numerator coefficient values to give the best possible precision.

Dependencies

This property applies only when you set the `CoefficientSource` property to 'Property'.

DenominatorDataType — Denominator coefficients word- and fraction-length designations

'Same word length as input' (default) | `numericType` object

Denominator coefficients word- and fraction-length designations, specified as either 'Same word length as input' or as a `numericType` object.

When specified as a `numericType` object, the data type must be signed fixed point with a power-of-two slope and zero bias. If not specified, the fraction length is determined based on the denominator coefficient values to give the best possible precision.

Dependencies

This property applies only when you set the `CoefficientSource` property to 'Property'.

ScaleValuesDataType — Scale values word- and fraction-length designations

'Same word length as input' (default) | `numericType` object

Scale values word- and fraction-length designations, specified as either 'Same word length as input' or as a `numericType` object.

When specified as a `numericType` object, the data type must be signed fixed point with a power-of-two slope and zero bias. If not specified, the fraction length is determined based on the scale values to give the best possible precision.

Dependencies

This property applies only when you set the `CoefficientSource` property to 'Property' and `HasScaleValues` property to `true`.

MultiplicandDataType — Multiplicand word- and fraction-length designations

'Same as output' (default) | `numericType` object

Multiplicand word- and fraction-length designations, specified as either 'Same as output' or as a `numericType` object.

When specified as a `numericType` object, the data type must be signed fixed point with a power-of-two slope and zero bias.

Dependencies

This property applies only when you set the `Structure` property to 'Direct form I transposed'.

StateDataType — State word- and fraction-length designations

'Full precision' (default) | `numericType` object

State word- and fraction-length designations, specified as either 'Full precision' or as a `numericType` object.

When specified as a `numericType` object, the data type must be signed fixed point with a power-of-two slope and zero bias.

Dependencies

This property applies only when you set the `Structure` property to 'Direct form II'.

DenominatorAccumulatorDataType — Denominator accumulator word- and fraction-length designations

`numericType(1,64,48)` (default) | `numericType` object

Denominator accumulator word- and fraction-length designations, specified as a `numericType` object.

OutputDataType — Output word- and fraction-length designations

'Full precision' (default) | `numericType` object

Output word- and fraction-length designations, specified as either 'Full precision' or as a `numericType` object.

When specified as a `numericType` object, the data type must be signed fixed point with a power-of-two slope and zero bias.

Usage**Syntax**

```
y = sos(x)
y = sos(x, num, den)
y = sos(x, num, den, g)
```

Description

$y = \text{sos}(x)$ filters the input signal x and outputs the filtered values y . The sos filter object filters each channel (column) of the input signal independently over successive calls to the algorithm.

This syntax is valid only when the `CoefficientSource` property is set to 'Property'.

$y = \text{sos}(x, \text{num}, \text{den})$ filters the input using `num` as the numerator coefficients and `den` as the denominator coefficients of the sos filter.

This syntax is valid only when the `CoefficientSource` property is set to 'Input port' and `HasScaleValues` property is set to `false`.

$y = \text{sos}(x, \text{num}, \text{den}, g)$ specifies the scale values `g` of the sos filter.

This syntax is valid only when the `CoefficientSource` property is set to 'Input port' and `HasScaleValues` property is set to `true`.

Input Arguments **x — Data input**

vector | matrix

Data input, specified as a vector or a matrix.

This object also accepts variable-size inputs. Once you have run the System object algorithm, you can change the size of each input channel, but you cannot change the number of channels.

If the input is fixed-point, it must be signed fixed point with a power-of-two slope and zero bias. When the fraction length is not specified, the object determines the fraction length based on the input data to give the best possible precision.

The data type of all inputs must be the same.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

 num — Numerator coefficients

N -by-3 matrix

Numerator coefficients, specified as an N -by-3 matrix, where N is the number of biquadratic sections.

Once you step through the algorithm, the size of this input cannot be modified. However, the numerator coefficient values can be modified as the input is tunable.

If `num` is fixed-point, it must be signed fixed point with a power-of-two slope and zero bias. When the fraction length is not specified, the object determines the fraction length based on the numerator coefficient values to give the best possible precision.

The data type of all inputs must be the same.

The size and complexity of the `num` and `den` inputs must be the same.

Tunable: Yes

Dependencies

This input applies only when you set the `CoefficientSource` property to 'Input port'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

den — Denominator coefficients

N -by-3 matrix

Denominator coefficients of the filter, specified as an N -by-3 matrix, where N is the number of biquadratic sections.

The leading denominator coefficient is always assumed to be 1. If any other value is specified in the first column, the object ignores this value and treats it as 1.

The size of this input cannot be modified once you step through the algorithm. However, the denominator values can be modified as the input is tunable.

If `den` is fixed-point, it must be signed fixed point with a power-of-two slope and zero bias. When the fraction length is not specified, the object determines the fraction length based on the denominator coefficient values to give the best possible precision.

The data type of all inputs must be the same.

The size and complexity of the `num` and `den` inputs must be the same.

Tunable: Yes

Dependencies

This input applies only when you set the `CoefficientSource` property to `'Input port'`.
