Apps

Filter Builder

Design filters starting with frequency and magnitude specifications (`filterBuilder`)

Description

The **Filter Builder** app provides a graphical user interface to design filters using the `fdesign` object. The first step is to choose the filter response. Based on the response you choose, the algorithm, constraints, and the design parameter settings appear on the **Main** tab of the user interface. You can further specify the precision and data types in the **Data Types** tab. The **Code Generation** tab contains options for various implementations of the completed filter design. Once you specify all the filter parameters and the design algorithm, you can visualize the filter response by clicking on the **View Filter Response** button. When you click on this button, **FVTool** opens to display the magnitude response of the filter. When you have achieved the desired filter response through iterations of design and analysis, click **OK**. When you click **OK**, the app exports the filter object to the base workspace. If you select the **Use a System object to implement filter** check box in the user interface, the app exports a filter System object™. For more information on the design process using the **Filter Builder** app, see “Filter Builder Design Process”. For details on each of the response methods and settings of all the associated parameters, see `filterBuilder`.

Open the Filter Builder App

- MATLAB® Toolstrip: On the **Apps** tab, under **Signal Processing and Communications**, click the  app icon.
- MATLAB command prompt: Enter `filterBuilder`.

- MATLAB command prompt: Enter `filterBuilder(obj)`, where `obj` is an existing filter object. For example, if `obj` is a bandpass filter, `filterBuilder(obj)` opens the bandpass filter design dialog. The `obj` object must have been created using `filterBuilder` or using `fdesign`.
- MATLAB command prompt: Enter `filterBuilder('response')` to replace *response* with a supported response method. MATLAB opens a filter design dialog that corresponds to the specified response. For details on the supported response methods, see `filterBuilder`.

Logic Analyzer

Visualize, measure, and analyze transitions and states over time

Description

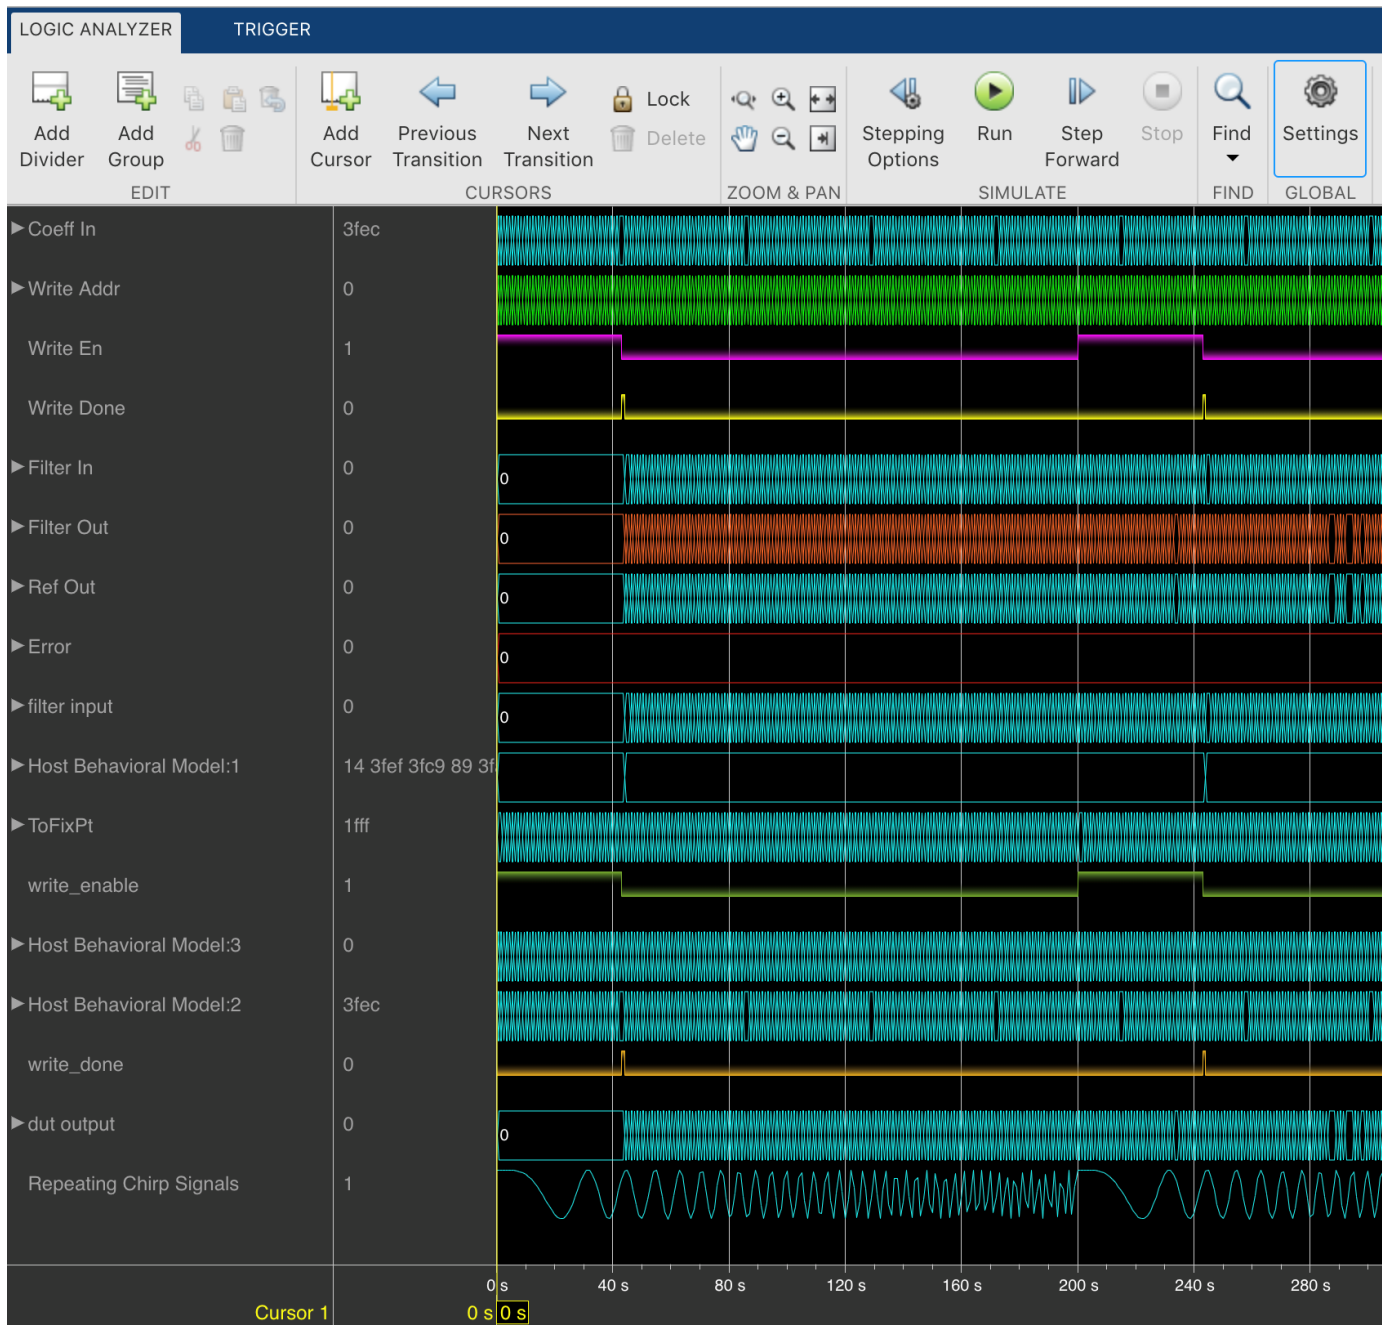

The **Logic Analyzer** is a tool for visualizing and inspecting signals and states in your Simulink® model. Using the **Logic Analyzer**, you can:

- Debug and analyze models
- Trace and correlate many signals simultaneously
- Detect and analyze timing violations
- Trace system execution
- Detect signal changes using triggers

For keyboard shortcuts, click [More](#).

Keyboard Shortcuts

Actions	Description	Applicable When
Ctrl+X	Cut	Wave is selected
Ctrl+C	Copy	Wave is selected
Ctrl+V	Paste	Wave is selected
Delete	Delete	Wave is selected
Ctrl+-	Zoom out	Always
Shift+Ctrl+-	Zoom out around active cursor	Always
Ctrl++	Zoom in	Always
Shift+Ctrl++	Zoom in around active cursor	Always
Shift+Ctrl+C	Move display to active cursor	When cursor is not in the display range
Space	Zoom out full	Always
Tab, Right Arrow	Next transition	Digital format wave is selected
Shift+Tab, Left Arrow	Previous transition	Digital format wave is selected
Ctrl+A	Select all waves	Always
Up Arrow	Select wave above selected	Wave is selected
Down Arrow	Select wave below selection	Wave is selected
Ctrl+Up Arrow	Move selected waves up	Wave is selected
Ctrl+Down Arrow	Move selected waves down	Wave is selected
Escape	Unselect all signals	Wave is selected
Page Up	Scroll up	Always
Page Down	Scroll down	Always

Open the Logic Analyzer App

On the Simulink toolstrip Simulation tab, click the **Logic Analyzer** app button. If the button is not displayed, expand the review results app gallery. Your most recent choice for data visualization is saved across Simulink sessions.

To visualize referenced models, you must open the Logic Analyzer from the referenced model. You should see the name of the referenced model in the Logic Analyzer toolbar.

Examples

Select Signals to Analyze

The **Logic Analyzer** supports several methods for selecting data to visualize.

- Select a signal in your model. When you select a signal, an ellipsis appears above the signal line. Hover over the ellipsis to view options and then select the **Enable Data Logging** option.

- Right-click a signal in your model to open an options dialog box. Select the **Log Selected Signals** option.

- Use any method to select multiple signal lines in your model. For example, use **Shift**+click to select multiple lines individually or **CTRL+A** to select all lines at once. Then, on the **Signal** tab, select the **Log Signals** button.

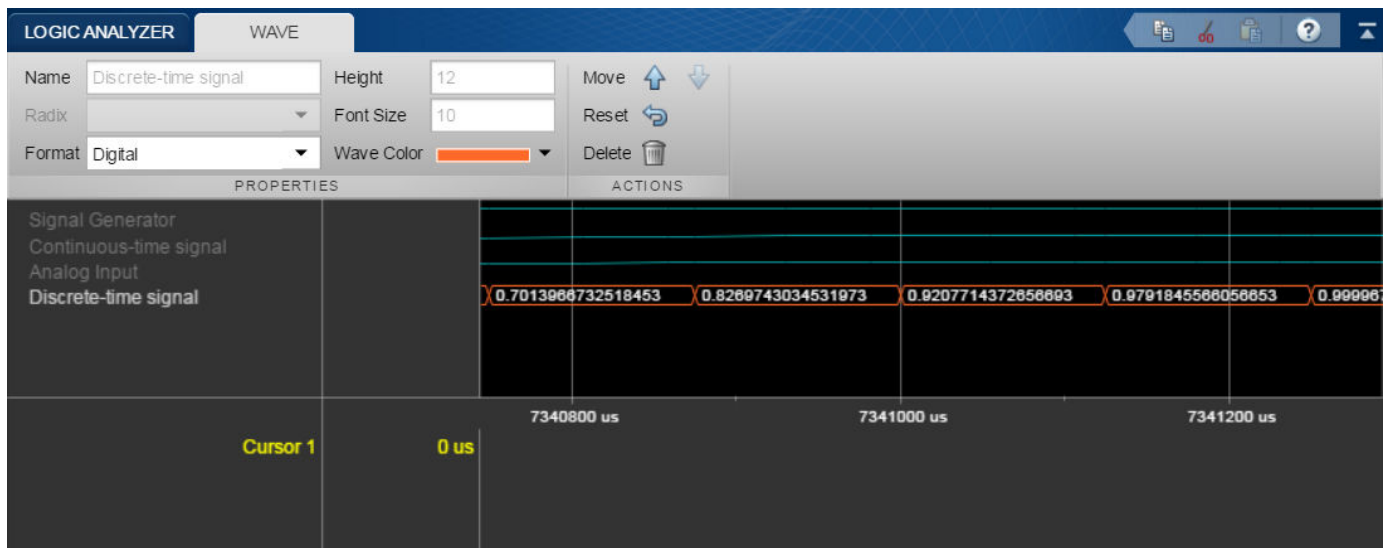

To visualize data in the Logic Analyzer, you must enable signal logging for the model. (Logging is on by default.) To enable signal logging, open **Model Settings** from the toolstrip, navigate to the **Data Import/Export** pane, and select **Signal logging**.

When you open the **Logic Analyzer**, all signals marked for logging are listed. You can add and delete waves from your **Logic Analyzer** while it is open. Adding and deleting signals does not disable logging, only removes the signal from the Logic Analyzer.

Modify Individual Wave Settings

Open the **Logic Analyzer** and select a wave by double-clicking the wave name. Then from the **Wave** tab, set parameters specific to the individual wave you selected. Any setting made on individual signals supersedes the global setting. To return individual wave parameters to the global settings, click **Reset**.

Delete and Restore Waves

- 1 Open the **Logic Analyzer** and select a wave by clicking the wave name.

- 2 From the **Logic Analyzer** toolbar, click . The wave is removed from the **Logic Analyzer**.
- 3 To restore the wave, from the **Logic Analyzer** toolbar, click .

A divider named **Restored Waves** is added to the bottom of your channels, with all deleted waves placed below it.

Add Trigger

- 1 Open the **Logic Analyzer** and select the **Trigger** tab.

- 2 To attach a signal to the trigger, select **Attach Signals**, then select the signal you want to trigger on. You can attach up to 20 signals to the trigger. Each signal can have only one triggering condition.
- 3 By default, the trigger looks for rising edges in the attached signals. You can set the trigger to look for rising or falling edges, bit sequences, or a comparison value. To change the triggering conditions, select **Set Conditions**.

If you add multiple signals to the trigger, control the trigger logic using the **Operator** option:

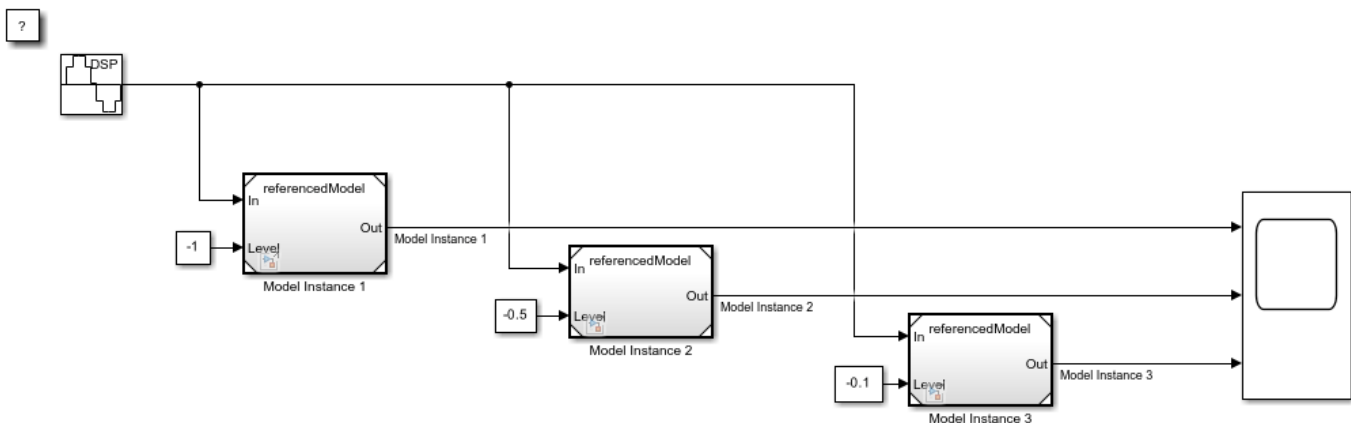

- AND - match all conditions.
 - OR - match any condition.
- 4 To control how many samples you see before triggering, set the **Display Samples** option. For example, if you set this option to 500, the **Logic Analyzer** tries to give you 500 samples before the trigger. Depending on the simulation, the **Logic Analyzer** may show more or fewer than 500 samples before the trigger. However, if the trigger is found before the 500th sample, the Logic Analyzer still shows the trigger.
 - 5 Control the trigger mode using **Display Mode**.
 - Once - The **Logic Analyzer** marks only the first location matching the trigger conditions and stops showing updates to the Logic Analyzer. If you want to reset the trigger, select **Rearm Trigger**. Relative to the current simulation time, the **Logic Analyzer** shows the next matching trigger event.
 - Auto - The **Logic Analyzer** marks every location matching the trigger conditions.
 - 6 Before running the simulation, select **Enable Trigger**. A blue cursor appears as time 0. Then, run the simulation. When a trigger is found, the **Logic Analyzer** marks the location with a locked blue cursor.

Choose Visible Instance of Multi-Reference Model Block

The **Logic Analyzer** can stream only a single instance of a multi-instance Model block. If the same model is opened across different windows, those models will share the same Logic Analyzer. This example shows how to select an instance of a multi-instance Model block for logging on the **Logic Analyzer**.

Open the `multipleModelInstances` model.

```
open_system('multipleModelInstances')
```

Copyright 2016 The MathWorks, Inc.

The model contains three instances of the `referencedModel` model.

Double-click any of the Model blocks to open the model referenced by all three Model blocks.

```
open_system('referencedModel')
```

Copyright 2016 The MathWorks, Inc.

Open the Logic Analyzer in the referenced model by double-clicking the logging symbol next to the MovingAverage block. You should see `referencedModel - [multipleModelInstances]` in the toolbar of the Logic Analyzer.

From the Logic Analyzer window, run the model. By running the simulation from a referenced version of `referencedModel`, Simulink runs the top model (`multipleModelInstances`) and referenced models (`referencedModel`). The **Logic Analyzer** displays a single instance of a multi-instance Model block.

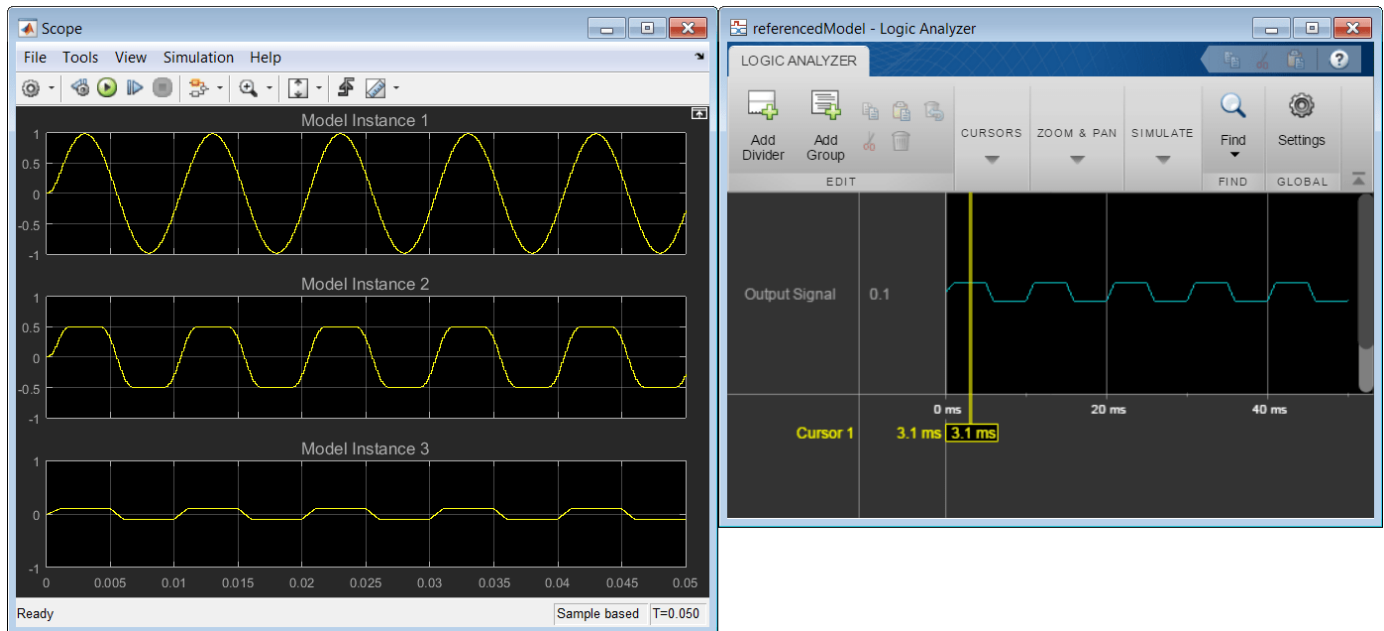

When you run a simulation, the logic analyzer runs the model listed in the Logic Analyzer toolbar. If this model is a referenced model, the toolbar also lists the top model and you will see results from

running the top model. To view results from the referenced model in isolation, you must open the referenced model as a top model.

To switch between instances, from the Simulink Editor menu, on the Simulation tab open the Prepare gallery and select **Normal Mode Diagram > Subsystem & Model Reference > Model Block Normal Mode Visibility**. Select **Model Instance 3** and then click **OK**.

Run the `multipleModelInstances` model again. The **Logic Analyzer** displays Model Instance 3 data.

View Bit-Expanded Wave and Reverse Display Order of Bits

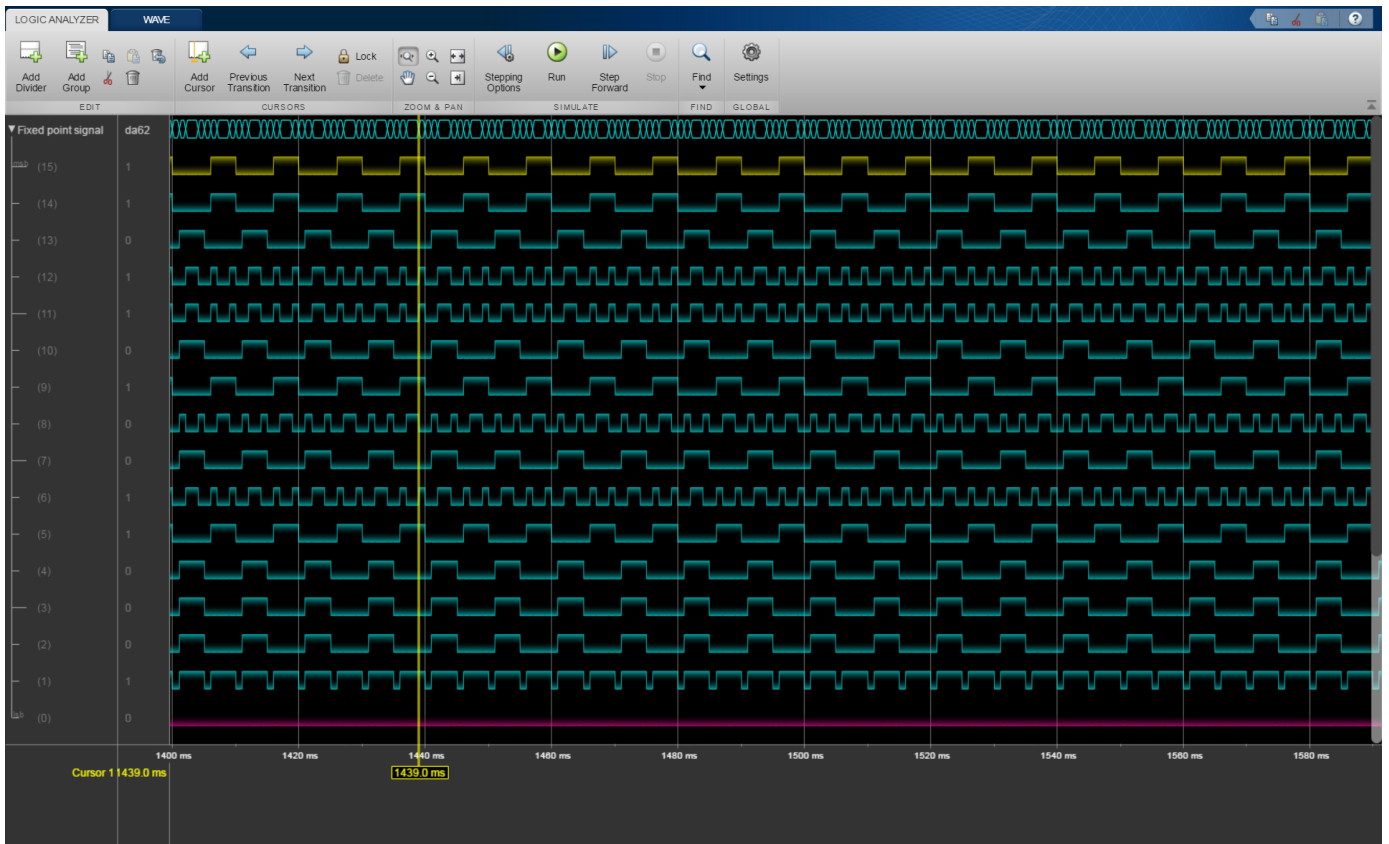

The **Logic Analyzer** enables you to bit-expand fixed-point and integer waves.

- 1 In the **Logic Analyzer**, click the arrow next to a fixed-point or integer wave to view the bits.

The least significant bit and the most significant bit are marked with **lsb** and **msb** next to the wave names.

1 Apps

- 2 Click Settings, and then select **Display Least Significant bit first** to reverse the order of the displayed bits.

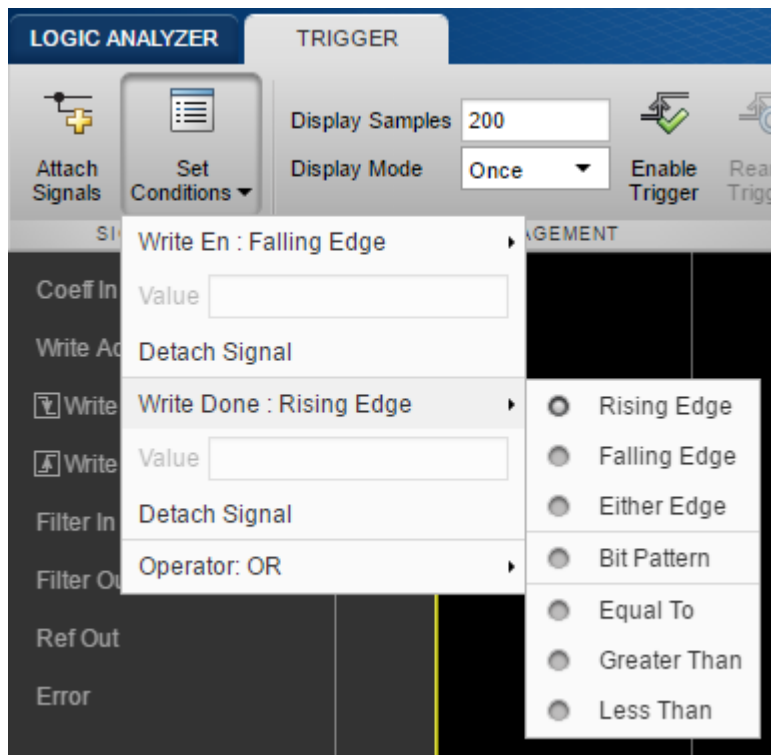

Add Triggers to Verify Write Operation

- 1 Open the Programmable FIR Filter model (dspprogfirhdl).

- 2 Open the **Logic Analyzer** and select the **Trigger** tab.
- 3 To add a trigger, in the toolstrip, select **Attach Signals** and attach the write enable `Write En` signal. An icon appears in front of the signal name to indicate it is attached to a trigger. The icon changes depending on the type of trigger.
- 4 Select **Set Conditions** and change the trigger condition for the `Write En` signal to **Falling Edge**. The trigger will show when the write enable signal was sent.
- 5 Attach the `Write Done` signal to the trigger. Keep the trigger condition for this signal as the default, **Rising Edge**. Now, the trigger will also show when the write was completed.

If you open the **Set Conditions** drop down, you see an **Operator** field. This field appears when multiple signals are attached to the trigger. Change the operator to **OR** so that the trigger will show instances where a write was started or completed.

- 6 Set the **Display Mode** to Auto. With this setting, the **Logic Analyzer** marks all locations where the trigger conditions are met.
- 7 Select **Enable Trigger** and run the simulation.

Each time the trigger conditions are met, the **Logic Analyzer** marks the time with a locked blue cursor. At each marked location, `Write En` is 0 and `Write Done` is 1. If you examine each location marked by a trigger, you can verify that each time a write is sent, it is also completed.

Limitations

Logging Settings

- If you enable the configuration parameter **Log Dataset data to file**, you cannot stream logged data to the **Logic Analyzer**.
- Signals marked for logging using `Simulink.sdi.markSignalForStreaming` or visualized with a Dashboard Scope do not appear on the **Logic Analyzer**.
- You cannot visualize Data Store Memory block signals in the **Logic Analyzer** if you set the **Log data store data** parameter to on.

Input Signal Limitations

- Signals marked for logging for the **Logic Analyzer** must have fewer than 8000 samples per simulation step.
- The **Logic Analyzer** does not support frame-based processing.
- For 64-bit integers and fixed-point numbers greater than 53 bits, if the numbers are greater than the maximum value of double precision, the transitions between numbers might not display correctly.
- You may see performance degradation in the **Logic Analyzer** for large matrices (greater than 500 elements) and buses with more than 1000 signals.
- The **Logic Analyzer** does not support Stateflow data output.

Graphical Settings

- While the simulation is running, you cannot zoom, pan, or modify the trigger.
- To visualize constant signals, in the settings, you must set the **Format** to **Digital**. Constants marked for logging are visualized as a continuous transition.

Supported Simulation Modes

Mode	Supported	Notes and Limitations
Normal	Yes	
Accelerator	Yes	You cannot use the Logic Analyzer to visualize signals in Model blocks with Simulation mode set to Accelerator.
Rapid Accelerator	Yes	Data is not available in the Logic Analyzer during simulation. If you simulate a model with the simulation mode set to rapid accelerator, after simulation the following signals cannot be visualized in the Logic Analyzer : <ul style="list-style-type: none"> • Multi-instance model reference signals • Nonvirtual bus signals
Processor-in-the-loop (PIL)	No	
Software-in-the-loop (SIL)	No	
External	No	

For more information about these modes, see “How Acceleration Modes Work” (Simulink).

Blocks

Allpass Filter

Single-section or multiple-section allpass filter

Library: DSP System Toolbox / Filtering / Filter Implementations

Description

The Allpass Filter block filters each channel of the input signal independently using a single-section or multiple-section (cascaded) allpass filter. You can implement the allpass filter using a minimum multiplier, wave digital filter, or a lattice structure.

In minimum multiplier form, the block uses the minimum number of required multipliers, n , with $2n$ delay units and $2n$ adders. In wave digital filter form, the block uses only n multipliers and n delay units, at the expense of $3n$ adders. The lattice structure uses $2n$ multipliers, n delay units, and $2n$ adders. For more details on these structures, see “Algorithms” on page 2-7.

Input/Output Ports

Input

x — Input data

column vector | row vector | matrix

Input data that is passed into the allpass filter. The block accepts real-valued or complex-valued multichannel inputs, that is, m -by- n size inputs, where $m \geq 1$ and $n \geq 1$. The block also accepts variable-size inputs. That is, you can change the size of each input channel during simulation. However, the number of channels cannot change.

This port is unnamed until you set **Internal allpass structure** to Minimum multiplier or Lattice, and select the **Specify coefficients from input port** parameter.

Data Types: single | double

coeffs — Allpass filter coefficients

column vector | row vector | matrix

This port inputs the coefficients of the allpass filter. When you set **Internal allpass structure** to Minimum multiplier, the **coeffs** port accepts matrices of size N -by-1 or N -by-2. When you set **Internal allpass structure** to Lattice, the **coeffs** port accepts an N -by-1 column vector or an 1-by- N row vector.

Dependencies

This port appears when you set **Internal allpass structure** to Minimum multiplier or Lattice, and select the **Specify coefficients from input port** parameter.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32

Output

Port_1 — Output of the allpass filter

column vector | row vector | matrix

The size of the filtered output matches the size of the input.

Data Types: single | double

Parameters

If a parameter is listed as tunable, then you can change its value during simulation.

Internal allpass structure — Filter structure

Minimum multiplier (default) | Wave Digital Filter | Lattice

- **Minimum multiplier** — This structure uses the minimum number of required multipliers, n , with $2n$ delay units and $2n$ adders. The coefficients to this structure are specified through the **Allpass polynomial coefficients** parameter.
- **Wave Digital Filter** — The structure uses n multipliers and n delay units, at the expense of $3n$ adders. The coefficients to this structure are specified through the **Wave Digital Filter allpass coefficients** parameter.
- **Lattice** — The structure uses $2n$ multipliers, n delay units, and $2n$ adders. The coefficients to this structure are specified through the **Lattice allpass coefficients** parameter.

For more details on these structures, see “Algorithms” on page 2-7.

Specify coefficients from input port — Flag to specify allpass polynomial coefficients

off (default) | on

When you select this check box and set **Internal allpass structure** to **Minimum multiplier**, the allpass polynomial coefficients are input through the **coeffs** port. When you clear this check box, the allpass polynomial coefficients are specified on the block dialog through the **Allpass polynomial coefficients** parameter.

When you select this check box and set **Internal allpass structure** to **Lattice**, the lattice allpass coefficients are input through the **coeffs** port. When you clear this check box, the lattice allpass coefficients are specified on the block dialog through the **Lattice allpass coefficients** parameter.

Dependencies

This parameter applies when you set **Internal allpass structure** to **Minimum multiplier** or **Lattice**.

Allpass polynomial coefficients — Coefficients in minimum multiplier form

$[-2^{(-1/2)}, 1/2]$ (default) | N -by-1 matrix | N -by-2 matrix

Specify the real allpass polynomial filter coefficients in minimum multiplier form as an N -by-1 matrix or an N -by-2 matrix.

- N -by-1 matrix — The block realizes N first-order allpass sections.

- N -by-2 matrix — The block realizes N second-order allpass sections.

The default value, $[-2^{(-1/2)}, 1/2]$, defines a stable second-order allpass filter with poles and zeros at $\pm\pi/3$ in the z -plane.

Tunable: Yes

Dependencies

To enable this parameter, set **Internal allpass structure** to Minimum multiplier and clear the **Specify coefficients from input port** parameter.

Wave Digital Filter allpass coefficients — Coefficients in wave digital filter form

$[1/2, -2^{(1/2)}/3]$ (default) | N -by-1 matrix | N -by-2 matrix

Specify the real allpass filter coefficients in wave digital filter form. The coefficients can be N -by-1 matrix for N first-order allpass sections and N -by-2 matrix for N second-order allpass sections. The default value, $[1/2, -2^{(1/2)}/3]$, is a transformed version of the default value of allpass polynomial coefficients. This value is computed using `allpass2wdf(Allpass polynomial coefficients)`. These coefficients define the same stable second-order allpass filter as when the allpass structure is set to Minimum multiplier.

Tunable: Yes

Dependencies

To enable this parameter, set **Internal allpass structure** to Wave Digital Filter.

Indicate if last section is first order — Is last section first order

off (default) | on

- on — When you set select this check box, the last section is considered first order. Also, the second element of the last row of the N -by-2 matrix is ignored.
- off — When you do not select this check box, the last section is considered second-order.

Dependencies

To enable this parameter, set **Internal allpass structure** to Minimum multiplier or Wave Digital Filter.

Lattice allpass coefficients — Coefficients in lattice form

$[-2^{(1/2)}/3, 1/2]$ (default) | N -by-1 column vector | 1-by- N row vector

Specify the real or complex allpass coefficients as lattice reflection coefficients. The default value, $[-2^{(1/2)}/3, 1/2]$, is a transformed and transposed version of the default value of the allpass polynomial coefficients. This value is computed using `transpose(tf2latc(1, [1 A]))`, where A is the value specified in **Allpass polynomial coefficients**.

Tunable: Yes

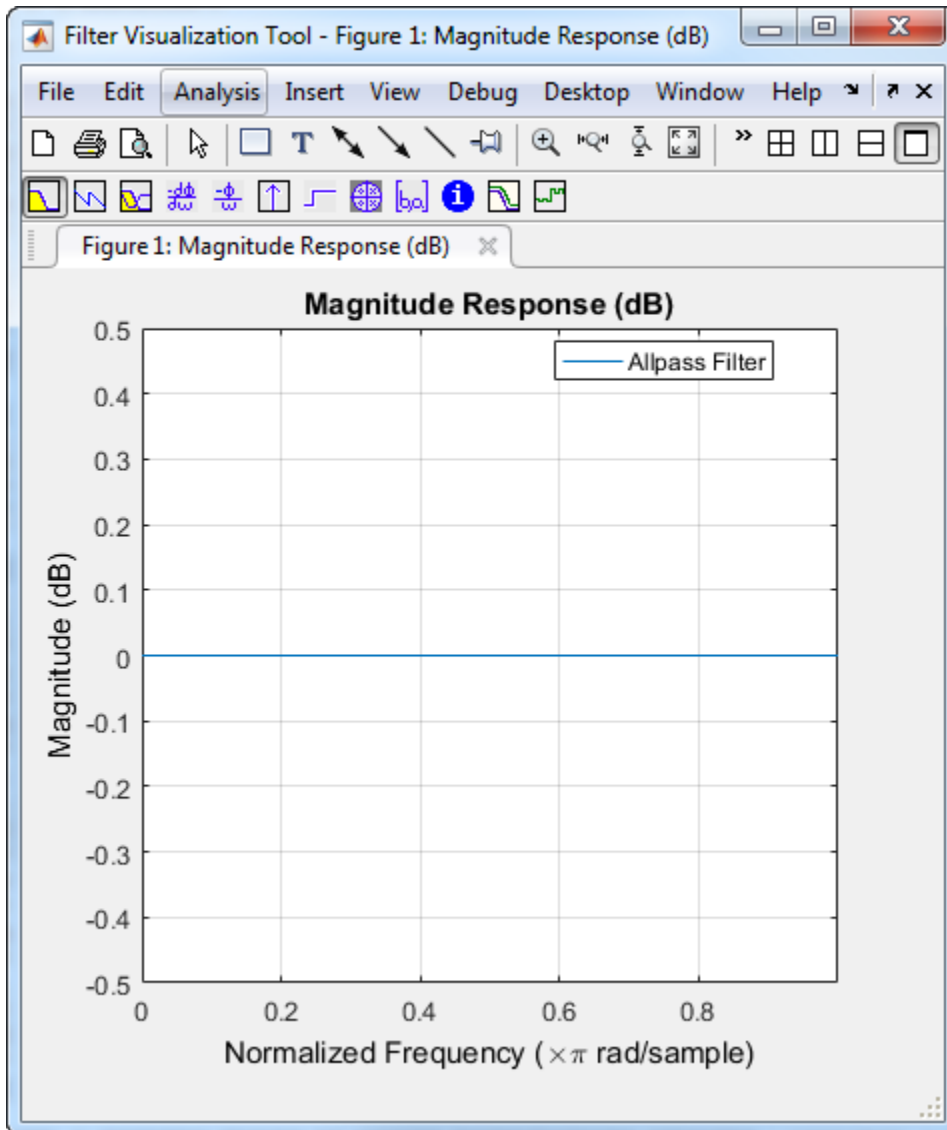

Dependencies

To enable this parameter, set **Internal allpass structure** to Lattice and clear the **Specify coefficients from input port** parameter.

View Filter Response — Visualize filter response

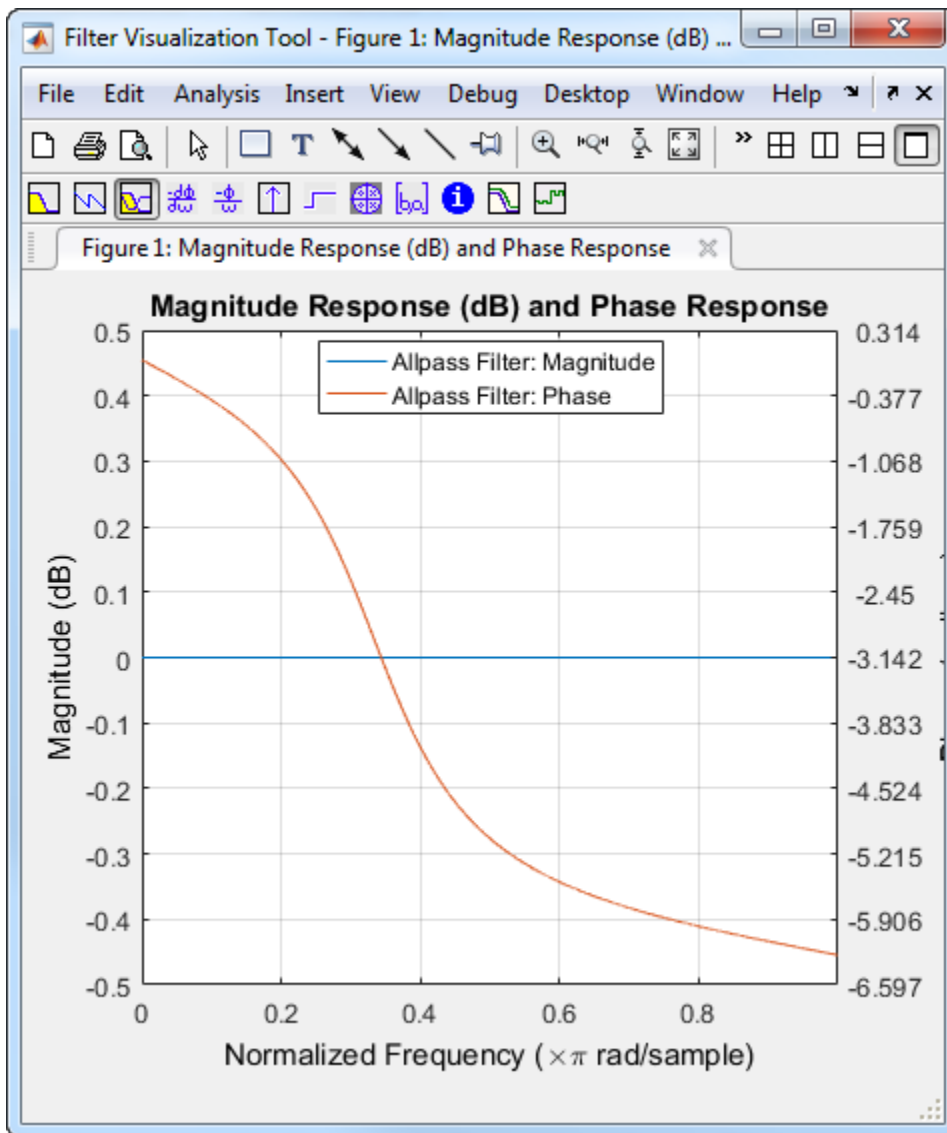

button

Opens the Filter Visualization Tool, `fvtool`, and displays the magnitude response of the allpass filter. The response is based on the parameters. Changes made to these parameters update `fvtool`.

To update the magnitude response while `fvtool` is running, modify the block parameters and click **Apply**.

To view the magnitude response and phase response simultaneously, click the **Magnitude and Phase responses** button on the toolbar.

In this example, the magnitude response is flat and the phase response varies with frequencies. This varying phase response has applications in phase equalization, notch filtering, and multirate filtering. You can realize a lowpass filter using a parallel combination of two allpass filters that have 180 degrees of phase shift with respect to each other.

Simulate using – Type of simulation to run

Code generation (default) | Interpreted execution

Specify the type of simulation to run as one of the following:

- **Code generation** -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.

- **Interpreted execution** -- Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

Block Characteristics

Data Types	double single
Multidimensional Signals	No
Variable-Size Signals	Yes

Algorithms

The transfer function of an allpass filter is given by

$$H(z) = \frac{c(n) + c(n-1)z^{-1} + \dots + z^{-n}}{1 + c(1)z^{-1} + \dots + c(n)z^{-n}}$$

c is allpass polynomial coefficients vector. The order, n , of the transfer function is the length of vector c .

In the minimum multiplier form and wave digital form, the allpass filter is implemented as a cascade of either second-order (biquad) sections or first-order sections. When the coefficients are specified as an N -by-2 matrix, each row of the matrix specifies the coefficients of a second-order filter. The last element of the last row can be ignored based on the trailing first-order setting. When the coefficients are specified as an N -by-1 matrix, each element in the matrix specifies the coefficient of a first-order filter. The cascade of all the filter sections forms the allpass filter.

In the lattice form, the coefficients are specified as a vector.

These structures are computationally more economical and structurally more stable compared to the generic IIR filters, such as df1, df1t, df2, df2t. For all structures, the allpass filter can be a single-section or a multiple-section (cascaded) filter. The different sections can have different orders, but they are all implemented according to the same structure.

Minimum Multiplier

This structure realizes the allpass filter with the minimum number of required multipliers, equal to the order n . It also uses $2n$ delay units and $2n$ adders. The multipliers uses the specified coefficients, which are equal to the polynomial vector c in the allpass transfer function. In this second-order section of the minimum multiplier structure, the coefficients vector, c , is equal to $[0.1 \ -0.7]$.

Wave Digital Filter

This structure uses n multipliers, but only n delay units, at the expense of requiring $3n$ adders. To use this structure, specify the coefficients in wave digital filter (WDF) form. Obtain the WDF equivalent of the conventional allpass coefficients using `allpass2wdf(allpass_coefficients)`. To convert WDF coefficients into the equivalent allpass polynomial form, use `wdf2allpass(WDF_coefficients)`. In this second-order section of the WDF structure, the coefficients vector w is equal to `allpass2wdf([0.1 -0.7])`.

Allpole Filter

Model allpole filters

Library

Filtering / Filter Implementations

dsparch4

Description

The Allpole Filter block independently filters each channel of the input signal with the specified allpole filter. The block can implement static filters with fixed coefficients, as well as time-varying filters with coefficients that change over time. You can tune the coefficients of a static filter during simulation.

This block filters each channel of the input signal independently over time. The **Input processing** parameter allows you to specify whether the block treats each element of the input as an independent channel (sample-based processing), or each column of the input as an independent channel (frame-based processing).

This block supports the Simulink state logging feature. See “State” (Simulink) in the *Simulink User's Guide* for more information.

Filter Structure Support

You can change the filter structure implemented with the Allpole Filter block by selecting one of the following from the **Filter structure** parameter:

- Direct form
- Direct form transposed
- Lattice AR

Specifying Initial States

The Allpole Filter block initializes the internal filter states to zero by default, which has the same effect as assuming that past inputs and outputs are zero. You can optionally use the **Initial states** parameter to specify nonzero initial conditions for the filter delays.

To determine the number of initial states you must specify and how to specify them, see the table on valid initial states. The **Initial states** parameter can take one of the forms described in the next table.

Valid Initial States

Initial Condition	Description
Scalar	The block initializes all delay elements in the filter to the scalar value.
Vector or matrix (for applying different delay elements to each channel)	<p>Each vector or matrix element specifies a unique initial condition for a corresponding delay element in a corresponding channel:</p> <ul style="list-style-type: none"> • The vector length equals the product of the number of input channels and the number of delay elements in the filter, <code>#_of_filter_coeffs-1</code> (or <code>#_of_reflection_coeffs</code> for Lattice AR). • The matrix must have the same number of rows as the number of delay elements in the filter, <code>#_of_filter_coeffs-1</code> (<code>#_of_reflection_coeffs</code> for Lattice AR), and must have one column for each channel of the input signal.

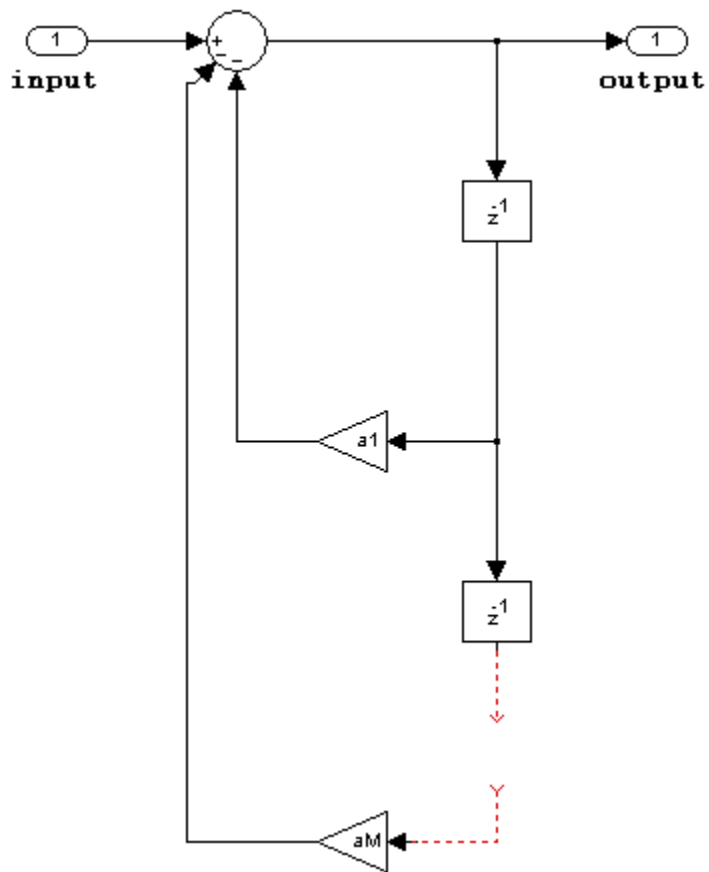

Data Type Support

The Allpole Filter block accepts and outputs real and complex signals of any numeric data type supported by Simulink. The block supports the same types for the coefficients.

The following diagrams show the filter structure and the data types used within the Allpole Filter block for fixed-point signals.

Direct Form

You cannot specify the state data type on the block mask for this structure because the output states have the same data types as the output.

Direct Form Transposed

States are complex when either the inputs or the coefficients are complex.

Lattice AR

Dialog Box

The **Main** pane of the Allpole Filter block dialog box appears as follows.

Coefficient source

Select whether you want to specify the filter coefficients on the block mask or through an input port.

Filter structure

Select the filter structure you want the block to implement. You can select `Direct form`, `Direct form transposed`, or `Lattice AR`.

Coefficients

Specify the row vector of coefficients of the filter's transfer function.

This parameter is visible only when you set the **Coefficient source** to `Dialog parameters`.

Input processing

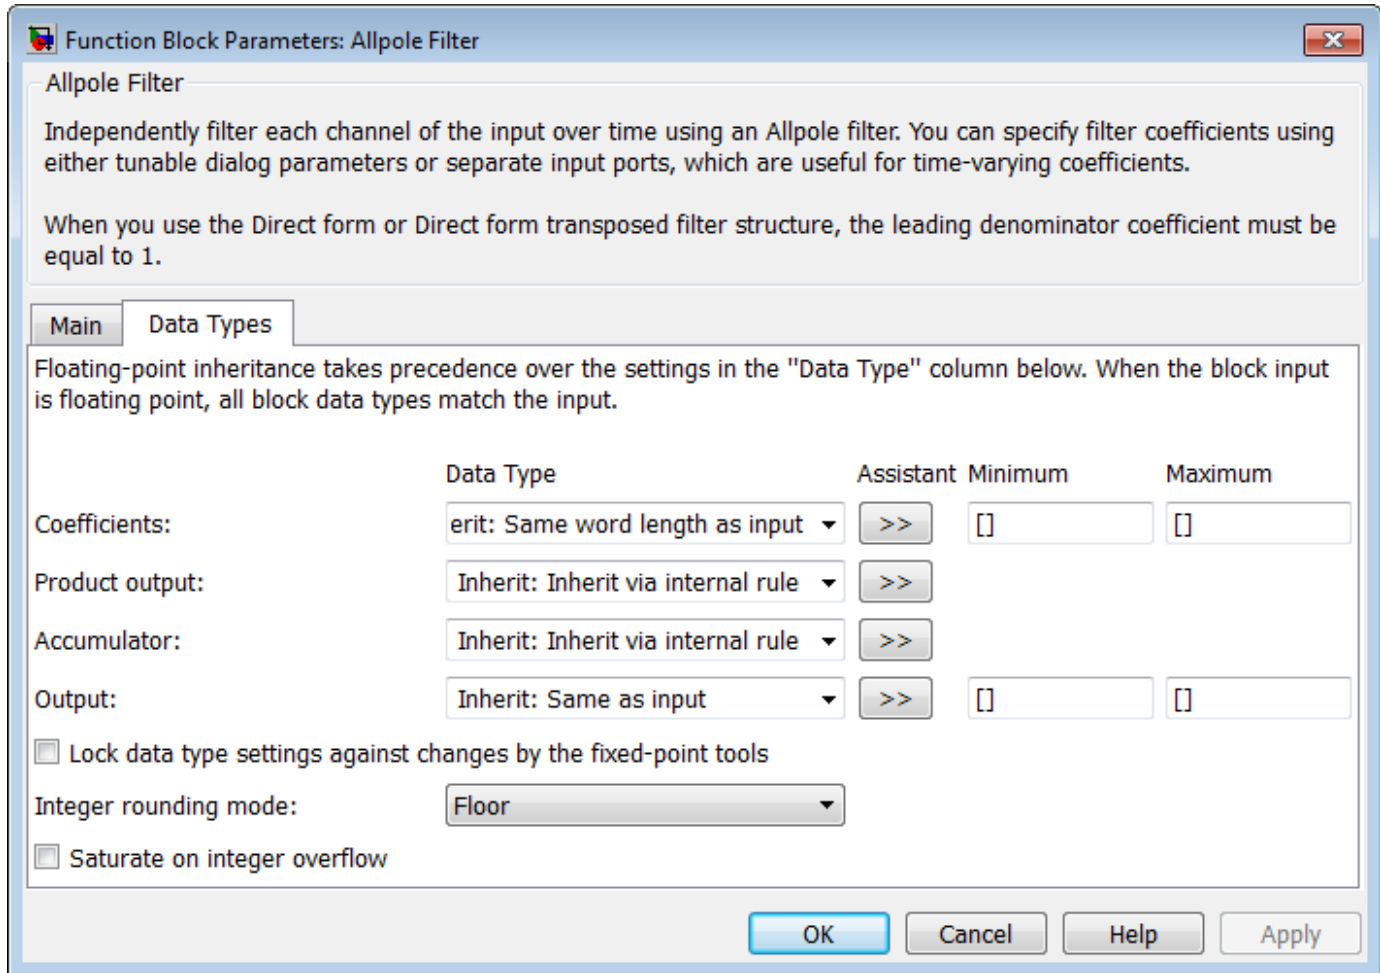

Specify whether the block performs sample- or frame-based processing. You can select one of the following options:

- `Elements as channels (sample based)` — Treat each element of the input as an independent channel (sample-based processing).
- `Columns as channels (frame based)` — Treat each column of the input as an independent channel (frame-based processing).

Initial states

Specify the initial conditions of the filter states. To learn how to specify initial states, see “Specifying Initial States” on page 2-11.

The **Data Types** pane of the Allpole Filter block dialog box appears as follows.

Coefficients

Specify the coefficient data type. You can set it to:

- A rule that inherits a data type, for example, Inherit: Same word length as input
- A built-in integer, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Coefficient** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) for more information.

Coefficients minimum

Specify the minimum value that a filter coefficient should have. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters” (Simulink))
- Automatic scaling of fixed-point data types

Coefficients maximum

Specify the maximum value that a filter coefficient should have. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters” (Simulink))
- Automatic scaling of fixed-point data types

Product output

Specify the product output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) for more information.

Accumulator

Specify the accumulator data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) for more information.

State

Specify the state data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- A built-in integer, for example, `int8`

- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

This parameter is only visible when the selected filter structure is `Lattice MA`.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **State** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) for more information.

Output

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Data Types of Signals” (Simulink) in the *Simulink User's Guide* (Simulink) for more information.

Output minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Output maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Integer rounding mode

Specify the rounding mode for fixed-point operations.

Saturate on integer overflow

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	An overflow associated with a signed 8-bit integer can saturate to -128 or 127.
Do not select this check box.	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see "Troubleshoot Signal Range Errors" (Simulink).	Overflows wrap to the appropriate value that is representable by the data type.	The number 130 does not fit in a signed 8-bit integer and wraps to -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Signed fixed point
- 8-, 16-, and 32-bit signed integers

Version History

Introduced in R2011b

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

If the input is fixed point, it must be a signed integer or signed fixed point with a power-of-two slope and zero bias.

Analog Filter Design

Design and implement analog filters

Library: DSP System Toolbox / Filtering / Filter Implementations

Description

The Analog Filter Design block designs and implements a Butterworth, Chebyshev type I, Chebyshev type II, elliptic, or bessel filter in a highpass, lowpass, bandpass, or bandstop configuration.

You select the design and band configuration of the filter from the **Design method** and **Filter type** drop-down lists in the dialog box. For each combination of design method and band configuration, an appropriate set of secondary parameters is displayed. For more details, see “Design/Band Combination Table” on page 2-28.

The Analog Filter Design block uses a state-space filter representation, and applies the filter using the State-Space block in the Simulink Continuous library. All of the design methods use Signal Processing Toolbox™ functions to design the filter.

The Analog Filter Design block is built on the filter design capabilities of Signal Processing Toolbox software.

Note The Analog Filter Design block does not work with the Simulink discrete solver, which is enabled when you set the **Solver** list to **Discrete (no continuous states)** in the **Solver** pane of the **Model Configuration Parameters** dialog box. Select one of the continuous solvers (such as ode4) instead.

Ports

Input

Port_1 — Input signal

scalar

Input signal to filter, specified as a sample-based, continuous-time, real-valued scalar value.

Data Types: double

Output

Port_1 — Output signal

scalar

Filtered signal, returned as a real double scalar value.

Data Types: double

Parameters

Design method — Filter design

Butterworth (default) | Chebyshev I | Chebyshev II | Elliptic | Bessel

The filter design methods are:

- **Butterworth** — The magnitude response of a Butterworth filter is maximally flat in the passband and monotonic overall. The Butterworth design uses the toolbox function `butter`.
- **Chebyshev I** — The magnitude response of a Chebyshev I filter is equiripple in the passband and monotonic in the stopband. The Chebyshev I design uses the toolbox function `cheby1`.
- **Chebyshev II** — The magnitude response of a Chebyshev II filter is monotonic in the passband and equiripple in the stopband. The Chebyshev II design uses the toolbox function `cheby2`.
- **Elliptic** — The magnitude response of an elliptic filter is equiripple in both the passband and the stopband. The elliptic design uses the toolbox function `ellip`.
- **Bessel** — The magnitude response of a Bessel filter is maximally flat in the passband and monotonic overall. The filter has a maximally flat linear phase response. The Bessel design uses the function `bessel`.

Tunable: Yes

Filter type — Filter type

Lowpass (default) | Highpass | Bandpass | Bandstop

The type of filter to design:

- Lowpass
- Highpass
- Bandpass
- Bandstop

Tunable: Yes

Filter order — Filter order

8 (default) | scalar value

The order of the filter when **Filter type** is set to:

- Lowpass
- Highpass

The order of the final filter is *twice* the value of **Filter order** when **Filter type** is set to:

- Bandpass
- Bandstop

Passband edge frequency (rad/s) – Passband edge frequency

30 (default) | scalar value

The passband edge frequency, in rad/s.

Tunable: Yes**Dependencies**This parameter appears only when `Design method` is set to:

- Butterworth
- Chebyshev I
- Elliptic
- Bessel

and `Filter type` is set to:

- Lowpass
- Highpass

Lower passband edge frequency (rad/s) – Lower passband edge frequency

30 (default) | scalar value

The lower passband edge frequency, specified in rad/s.

Tunable: Yes**Dependencies**This parameter appears only when `Design method` is set to:

- Butterworth
- Chebyshev I
- Elliptic
- Bessel

and `Filter type` is set to:

- Bandpass
- Bandstop

Upper passband edge frequency (rad/s) – Upper passband edge frequency

80 (default) | scalar value

The upper passband edge frequency, specified in rad/s.

Tunable: Yes**Dependencies**This parameter appears only when `Design method` is set to:

- Butterworth
- Chebyshev I
- Elliptic
- Bessel

and `Filter type` is set to:

- Bandpass
- Bandstop

Stopband edge frequency (rad/s) — Stopband edge frequency

30 (default) | scalar value

The stopband edge frequency, specified in rad/s.

Tunable: Yes

Dependencies

This parameter appears only when `Design method` is set to:

- Chebyshev II

and `Filter type` is set to:

- Lowpass
- Highpass

Lower stopband edge frequency (rad/s) — Lower stopband edge frequency

30 (default) | scalar value

The lower stopband edge frequency, in rad/s.

Tunable: Yes

Dependencies

This parameter appears only when `Design method` is set to:

- Chebyshev II

and `Filter type` is set to:

- Bandpass
- Bandstop

Upper stopband edge frequency (rad/s) — Upper stopband edge frequency

80 (default) | scalar value

The upper stopband edge frequency, specified in rad/s.

Tunable: Yes

Dependencies

This parameter appears only when `Design` method is set to:

- Chebyshev II

and `Filter` type is set to:

- Bandpass
- Bandstop

Passband ripple in dB — Passband ripple

2 (default) | scalar value

The passband ripple, specified in dB.

Tunable: Yes

Dependencies

This parameter appears only when `Design` method is set to:

- Chebyshev I
- Elliptic

Stopband attenuation in dB — Stopband attenuation

40 (default) | scalar value

The stopband attenuation, in dB.

Tunable: Yes

Dependencies

This parameter appears only when `Design` method is set to:

- Chebyshev II
- Elliptic

Block Characteristics

Data Types	double
Multidimensional Signals	No
Variable-Size Signals	No

More About**Design/Band Combination Table**

This table lists the available parameters for each design/band combination. For lowpass and highpass band configurations, these parameters include:

- The passband edge frequency Ω_p .
- The stopband edge frequency Ω_s
- The passband ripple R_p
- The stopband attenuation R_s

For bandpass and bandstop configurations, the parameters include:

- The lower and upper passband edge frequencies, Ω_{p1} and Ω_{p2}
- The lower and upper stopband edge frequencies, Ω_{s1} and Ω_{s2}
- The passband ripple R_p
- The stopband attenuation R_s

Frequency values are in rad/s, and ripple and attenuation values are in dB.

Filter Design Type	Lowpass	Highpass	Bandpass	Bandstop
Butterworth	Order, Ω_p	Order, Ω_p	Order, Ω_{p1}, Ω_{p2}	Order, Ω_{p1}, Ω_{p2}
Chebyshev Type I	Order, Ω_p, R_p	Order, Ω_p, R_p	Order, $\Omega_{p1}, \Omega_{p2}, R_p$	Order, $\Omega_{p1}, \Omega_{p2}, R_p$
Chebyshev Type II	Order, Ω_s, R_s	Order, Ω_s, R_s	Order, $\Omega_{s1}, \Omega_{s2}, R_s$	Order, $\Omega_{s1}, \Omega_{s2}, R_s$
Elliptic	Order, Ω_p, R_p, R_s	Order, Ω_p, R_p, R_s	Order, $\Omega_{p1}, \Omega_{p2}, R_p, R_s$	Order, $\Omega_{p1}, \Omega_{p2}, R_p, R_s$
Bessel	Order, Ω_p	Order, Ω_p	Order, Ω_{p1}, Ω_{p2}	Order, Ω_{p1}, Ω_{p2}

Version History

Introduced before R2006a

Blocks

Digital Filter Design

Topics

“Filter Design”

“Filter Analysis”

Analytic Signal

Compute analytic signals of discrete-time inputs

Library

Transforms

`dspxfm3`

Description

The Analytic Signal block computes the complex analytic signal corresponding to each channel of the real M -by- N input, u

$$y = u + jH\{u\}$$

where $j = \sqrt{-1}$ and $H\{ \}$ denotes the Hilbert transform. The real part of the output in each channel is a replica of the real input in that channel; the imaginary part is the Hilbert transform of the input. In the frequency domain, the Fourier transform of the analytic signal doubles the positive frequency content of the original signal while zeroing-out negative frequencies and retaining the DC component.

The block computes the Hilbert transform using an equiripple FIR filter with the order specified by the **Filter order** parameter, n . The linear phase filter is designed using the Remez exchange algorithm, and imposes a delay of $n/2$ on the input samples.

The output has the same dimensions as the input.

This block supports SIMD code generation. For details, see “Code Generation” on page 2-32.

Frame-Based Processing

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block performs frame-based processing. In this mode, the block treats an M -by- N matrix input as N independent channels containing M sequential time samples. The block computes the analytic signal for each channel over time.

Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block performs sample-based processing. In this mode, the block treats an M -by- N matrix input as $M*N$ independent channels and computes the analytic signal for each channel (matrix element) over time.

Parameters

Filter order

The length of the FIR filter used to compute the Hilbert transform.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` (default) — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Supported Data Types

- Double-precision floating point
- Single-precision floating point

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.

The Analytic Signal block supports SIMD code generation using Intel AVX2 technology under these conditions:

- **Input processing** is set to `Columns as channels (frame based)`.
- Input signal has to be real-valued.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

Arbitrary Response Filter

Design arbitrary response filter

Library

Filtering / Filter Designs

dspfdesign

Description

This block brings the filter design capabilities of the `filterBuilder` function to the Simulink environment.

This block supports SIMD code generation. For details, see “Code Generation” on page 2-37.

Dialog Box

See “Arbitrary Response Filter Design — Main Pane” on page 5-594 for more information about the parameters of this block. The **Data Types** and **Code Generation** panes are not available for blocks in the DSP System Toolbox Filter Designs library.

View filter response

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

In this group, you specify your filter format, such as the impulse response and the filter order.

Impulse response

Select either FIR or IIR from the drop down list, where FIR is the default. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

Order mode

Select Minimum or Specify from the drop-down list. Selecting Specify enables the **Order** option so you can enter the filter order. When you set the **Impulse response** to IIR, you can

specify different numerator and denominator orders. To specify a different denominator order, you must select the **Denominator order** check box.

Order

Enter the order for FIR filter, or the order of the numerator for the IIR filter.

Denominator order

Select the check box and enter the denominator order. This option is enabled only if IIR is selected for **Impulse response**.

Filter type

This option is available for FIR filters only. Select **Single-rate**, **Decimator**, **Interpolator**, or **Sample-rate converter**. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, the block specifies a single-rate filter.

- Selecting **Decimator** or **Interpolator** activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting **Sample-rate converter** activates both factors.

Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to **Decimator** or **Sample-rate converter**. The default value is 2.

Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to **Interpolator** or **Sample-rate converter**. The default value is 2.

Response Specification**Number of Bands**

Select the number of bands in the filter. Multiband design is available for both FIR and IIR filters.

Specify response as

Specify the response as **Amplitudes**, **Magnitudes and phases**, **Frequency response**, or **Group delay**. **Group delay** is only available for IIR designs.

Frequency units

Specify frequency units as either **Normalized**, which means normalized by the input sampling frequency, or select from **Hz**, **kHz**, **MHz**, or **GHz**.

Input sample rate

Enter the input sampling frequency in the units specified in the **Frequency units** drop-down list. When you select the frequency units, this option is available.

Band Properties

These properties are modified automatically depending on the response chosen in the **Specify response as** drop-down list. Two or three columns are presented for input. The first column is always **Frequencies**. The other columns are **Amplitudes**, **Magnitudes**, **Phases**, or **Frequency Response**. Enter the corresponding vectors of values for each column.

- **Frequencies** and **Amplitudes** — These columns are presented for input if the response chosen in the **Specify response as** drop-down list is **Amplitudes**.

- **Frequencies, Magnitudes, and Phases** — These columns are presented for input if the response chosen in the **Specify response as** drop-down list is **Magnitudes and phases**.
- **Frequencies and Frequency response** — These columns are presented for input if the response chosen in the **Specify response as** drop-down list is **Frequency response**.

Algorithm

Design Method

Select the design method for the filter. Different methods are enabled depending on the defining parameters entered in the previous sections.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications.

- **Window** — Replace the square brackets with the name of a window function or function handle. For example, `hamming` or `@hamming`. If the window function takes parameters other than the length, use a cell array. For example, `{'kaiser', 3.5}` or `{@chebwin, 60}`.
- **Density factor** — Valid when the **Design method** is **Equiripple**. Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade-off between the accurate approximation to the ideal filter and the time to design the filter.

- **Phase constraint** — Valid when the **Design method** is **Equiripple**, you have the DSP System Toolbox installed, and **Specify response as** is set to **Amplitudes**. Choose one of **Linear**, **Minimum**, or **Maximum**.
- **Weights** — Valid when the **Design method** is **Equiripple**. Uses the weights in **Weights** to weight the error for a single-band design. If you have multiple frequency bands, the **Weights** design option changes to **B1 Weights**, **B2 Weights** to designate the separate bands.

Filter Implementation

Structure

Select the structure for the filter, available for the corresponding design method.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.

- **Optimize for delay chains** — Substitute delay chains made up of n unit delays with a single delay by n .
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

Input processing

Specify how the block should process the input. The available options may vary depending on the settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- **Enforce single-rate processing** — When you select this option, the block maintains the sample rate of the input.
- **Allow multirate processing** — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to **Elements as channels (sample based)**.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point

Version History

Introduced in R2009b

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The Arbitrary Response Filter block supports SIMD code generation using Intel AVX2 technology under these conditions:

- **Filter type** is set to Single-rate, Decimator, or Interpolator.
- For **Filter type** that is set to Single-rate, **Structure** is set to Direct-form FIR or Direct-form FIR transposed.
- For **Filter type** that is set to Decimator, **Structure** is set to Direct-form FIR polyphase decimator and **Rate options** is set to Enforce single-rate processing.
- For **Filter type** that is set to Interpolator, **Rate options** is set to Enforce single-rate processing.
- **Input processing** is set to Columns as channels (frame based).
- Input signal has a data type of single or double.

The SIMD technology significantly improves the performance of the generated code.

Array Plot

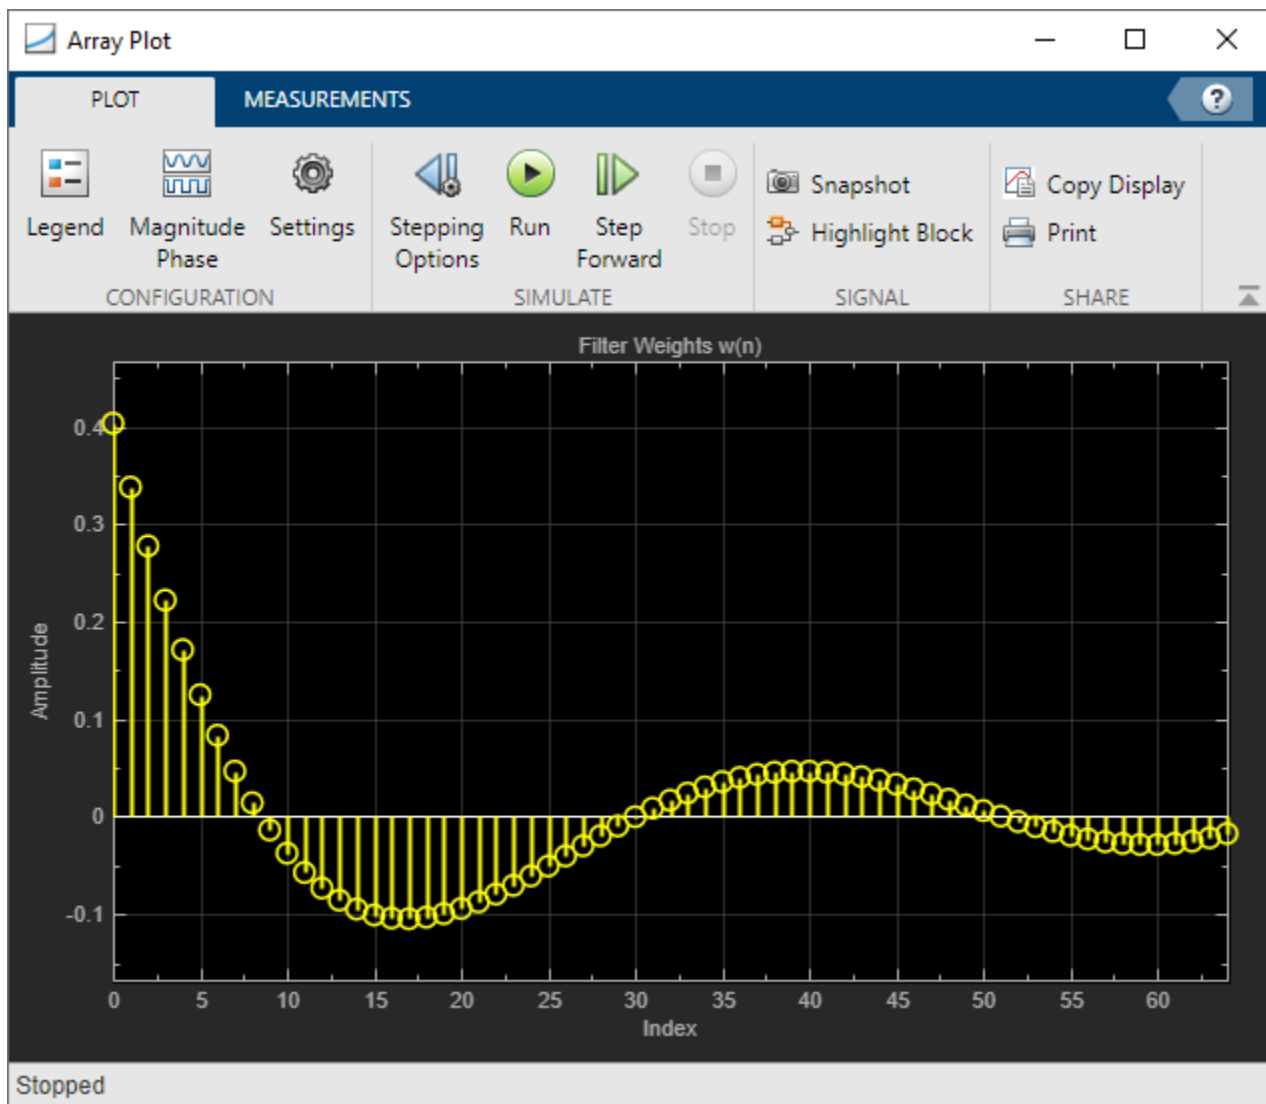

Display vectors or arrays

Library: DSP System Toolbox / Sinks

Description

The Array Plot block plots vectors or arrays of data.

The Array Plot is a vector plot where data is uniformly spaced along the x-axis. To modify the spacing, change the Sample Increment property.

Measurements available:

- Data Cursors — Measure signal values using vertical and horizontal cursors.
- Signal Statistics — Display the maximum, minimum, peak-to-peak difference, mean, median, and RMS values of a selected signal.
- Peak Finder — Find maxima, showing the x-axis values at which they occur.

Ports

Input

Port_1 — Signal or signals to visualize

scalar | vector | matrix | array

Connect the signals you want to visualize. You can have up to 96 input ports. Input signals must have these characteristics:

- Fixed number of channels, but size can be variable
- Discrete, continuous, or constant sample time
- Real or complex values
- Floating- or fixed-point data type
- 2-D and nonscalar

The Array Plot block supports inputs with different frame lengths.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Properties

For information about how to configure the Array Plot and use the toolstrip, see “Configure Array Plot”.

Plot

Legend — Display signal legend

`off` (default) | `on`

Select this option to show the legend on the plot. The names listed in the legend are taken from the `Channel Names` property.

From the legend, you can control which signals are visible. This control is equivalent to changing the visibility in the **Style** properties. In the scope legend, click a signal name to hide the signal in the scope. To show the signal, click the signal name again. To show only one signal, right-click the signal name, which hides all other signals. To show all signals, press **Esc**.

Note The legend only shows the first 20 signals. Any additional signals cannot be controlled from the legend.

Tunable: Yes

Programmatic Use

Block Parameter: `ShowLegend`

Type: logical

Magnitude and Phase — Split display into magnitude and phase plots

`off` (default) | `on`

- **On** — Display magnitude and phase plots. If the signal is real, the scope plots the absolute value of the signal for the magnitude. The phase is 0 degrees for positive values and 180 degrees for negative values. This feature is useful for complex-valued input signals. If the input is a real-valued signal, selecting this check box returns the absolute value of the signal for the magnitude.
- **Off** — Display signal plot. If the signal is complex, the scope plots the real and imaginary parts on the same y-axis.

Tunable: Yes

Programmatic Use

Block Parameter: `PlotAsMagnitudePhase`

Type: logical

Measurements

For more information about the measurements, see “Use Array Plot Measurements”.

Settings

Data and Axes

X-Data Mode — Type of x-axis spacing

Sample increment and X-offset (default) | Custom

Select the type of spacing to use between x-axis data values.

- **Sample increment and X-offset** — Use the “Sample Increment” on page 2-0 and “X-Offset” on page 2-0 values to specify x-axis data.
- **Custom** — Specify a custom spacing between data values using the “Custom X-data” on page 2-0 property.

Programmatic Use

Block Parameter: XDataMode

Type: character vector or string scalar

Values: 'Sample increment and X-offset' | 'Custom'

Sample Increment — x-axis spacing

1 (default) | finite scalar

Specify the spacing between samples along the x-axis as a finite numeric scalar. The input signal is only y-axis data. x-axis data is set automatically based on both the **Sample Increment** and “X-Offset” on page 2-0 values.

Example: When **X-Offset** is 0 and **Sample Increment** is 1, the x-axis values are set to 0, 1, 2, 3, 4,

Example: When **X-Offset** is -1 and **Sample Increment** is 0.25, the x-axis values are set to -1, -0.75, -0.5, -0.25, 0,

Tunable: Yes

Dependency

To use this property, set “X-Data Mode” on page 2-0 to **Sample increment and X-offset**.

Programmatic Use

Block Parameter: SampleIncrement

Type: character vector or string scalar

Values: scalar

X-Offset — x-axis offset

0 (default) | scalar

Specify the offset to apply to the x-axis, as a numeric scalar. x-axis data is set automatically based on both the “Sample Increment” on page 2-0 and **X-Offset** values. The x-offset represents the first value on the x-axis.

Example: When **X-Offset** is 0 and **Sample Increment** is 1, the x-axis values are set to 0, 1, 2, 3, 4,

Example: When **X-Offset** is -1 and **Sample Increment** is 0.25, the x-axis values are set to -1, -0.75, -0.5, -0.25, 0,

Tunable: Yes

Dependency

To use this property, set “X-Data Mode” on page 2-0 to Sample increment and X-offset.

Programmatic Use

Block Parameter: XOffset

Type: character vector or string scalar

Values: scalar

Custom X-data — x-axis data values

empty vector (default) | vector with length equal to the input frame length

Specify the x-axis data values as a vector equal in length to the frame length of the inputs. If you use the default (empty vector) value, the x-axis data is uniformly spaced over the interval (0:L-1), where L is the frame length.

Example: A custom logarithmic x-axis data scaling is `[0:log10(44100/2):1024]`

Tunable: Yes

Dependency

To use this property, set “X-Data Mode” on page 2-0 to Custom

Programmatic Use

Block Parameter: CustomXData

Type: character vector or string scalar

Values: scalar

Default: ' [] '

X-Axis Scale — x-axis scale

Linear (default) | Log

Select Linear or Log as the x-axis scale.

Tunable: Yes

Dependency

If **X-Offset** is a negative value, you cannot set this parameter to Log.

Programmatic Use

Block Parameter: XScale

Type: character vector or string scalar

Y-Axis Scale — y-axis scale

Linear (default) | Log

Select Linear or Log as the y-axis scale.

Tunable: Yes

Programmatic Use

Block Parameter: YScale

Type: character vector or string scalar

Y-limits — y-axis limits

`[-10,10]` (default) | `[ymin, ymax]`

Specify the y-axis limits as a two-element numeric vector, `[ymin, ymax]`.

If **Magnitude and Phase** is off, the default is `[-10,10]`. If the magnitude/phase plot is on, the default is `[0,10]`.

Tunable: Yes

Dependencies

When `PlotAsMagnitudePhase` is `true`, this property specifies the y-axis limits of only the magnitude plot. The y-axis limits of the phase plot are always `[-180,180]`.

Programmatic Use

Block Parameter: YLimits

Type: character vector or string scalar

Value: two-element numeric vector

Plot Type — Type of plot

`Stem` (default) | `Stairs` | `Line`

- `Stem` — Stem graph displayed as circles at the input value with vertical lines to the x-axis.
- `Line` — Line graph
- `Stairs` — Stair-step graph. A stair-step graph is made up of only horizontal and vertical lines. Each horizontal line represents the signal value for a discrete sample period and is connected to two vertical lines. Each vertical line represents the change in the signal value occurring at a specific sample time.

Tunable: Yes

Programmatic Use

Block Parameter: PlotType

Type: character vector or string scalar

Grid — Show internal grid lines

`on` (default) | `off`

Select this option to show grid lines on the plot.

Tunable: Yes

Programmatic Use

Block Parameter: ShowGrid

Type: logical

Display and Labels

Title — Display name

`none` (default) | string

Specify a title for display. To use the input signal name for the title, enter %<SignalLabel>.

Tunable: Yes

Programmatic Use

Block Parameter: Title

Type: character vector or string scalar

Default: ''

X-Label — x-axis label

none (default) | string

Specify the text for the scope to display below the x-axis.

Tunable: Yes

Programmatic Use

Block Parameter: XLabel

Type: character vector or string scalar

Default: ''

Y-Label — Y-axis label

none (default) | string

Specify the text to display on the y-axis. To display signal units, add (%<SignalUnits>) to the label. At the beginning of a simulation, Simulink replaces (%<SignalUnits>) with the units associated with the signals.

Example: For a velocity signal with units of m/s, enter Velocity (%<SignalUnits>).

Tunable: Yes

Dependency

If you click on **Magnitude and Phase**, this property does not apply. The y-axes are labeled Magnitude and Phase.

Programmatic Use

Block Parameter: YLabel

Type: character vector or string scalar

Default: ''

Property Inspector Only

Number of input ports — Number of input ports

1 (default) | integer between 1 and 96

The number of input ports to the block, specified as an integer between 1 and 96. To change the number of input ports, drag a new input signal line to the block and the block will auto-create new ports.

Programmatic Use

Block Parameter: NumInputPorts

Type: character vector or string scalar

Values: scalar between 1 and 96

Open at start of simulation — Automatically open scope at start

on (default) | off

Select this parameter to automatically open the Array Plot window when you run the simulation.

This parameter is only available from the Property Inspector.

Programmatic Use

Block Parameter: OpenAtSimulationStart

Type: logical

Channel Names — Input channel names

[] (default) | character vector | string | array of strings or character vectors.

Input channel names, specified as a character vector, string, or array of either. The names appear in the legend, **Settings**, and **Measurements** panels. If you do not specify names, the channels are labeled as Channel 1, Channel 2, etc.

Example: ["A","B"]

Dependency

To see channel names, set “Legend” on page 2-0 to true.

Programmatic Use

Block Parameter: ChannelNames

Type: cell array of character vectors or string array

Maximize axes — Maximize size of plots

Auto (default) | Off | On

- Auto — If “Title” on page 2-0 and “Y-Label” on page 2-0 properties are not specified, maximize all plots.
- On — Maximize all plots. Values in **Title** and **Y-label** are hidden.
- Off — Do not maximize plots.

Hover over the array plot to see the maximize axes button .

Tunable: Yes

Programmatic Use

Block Parameter: MaximizeAxes

Type: character vector or string scalar

Axes scaling — Y-axis scaling mode

OnceAtStop (default) | Manual | Auto | Updates

- OnceAtStop — Scale y-axis after the simulation is finished.
- Manual — Manually scale y-axis range with the **Scale Y-axis Limits** toolbar button.

- **Auto** — Scale y-axis range during and after simulation.
- **Updates** — Scale y-axis after the number of time steps specified in the “Number of updates” on page 2-0 text box (100 by default). Scaling occurs only once during each run.

Tunable: Yes

Programmatic Use

Block Parameter: AxesScaling

Type: character vector or string scalar

Number of updates — Number of updates before scaling

10 (default) | integer

Set this property to delay auto scaling the y-axis.

Tunable: Yes

Dependency

To enable this property, set “Axes scaling” on page 2-0 to AfterNUpdates.

Programmatic Use

Block Parameter: AxesScalingNumUpdates

Type: character vector or string scalar

Values: scalar

Block Characteristics

Data Types	Boolean double enumerated fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Array-Vector Add

Add vector to array along specified dimension

Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

dspmtx3

Description

The Array-Vector Add block adds the values in the specified dimension of the N -dimensional input array A to the values in the input vector V .

The length of the input V must be the same as the length of the specified dimension of A . The Array-Vector Add block adds each element of V to the corresponding element along that dimension of A .

Consider a 3-dimensional M -by- N -by- P input array $A(i,j,k)$ and an N -by-1 input vector V . When the **Add along dimension** parameter is set to 2, the output of the block $Y(i,j,k)$ is

$$Y(i, j, k) = A(i, j, k) + V(j)$$

where

$$1 \leq i \leq M$$

$$1 \leq j \leq N$$

$$1 \leq k \leq P$$

The output of the Array-Vector Add block is the same size as the input array, A . This block accepts real and complex floating-point and fixed-point inputs.

Fixed-Point Data Types

The following diagram shows the data types used within the Array-Vector Add block for fixed-point signals.

When you specify the vector V on the **Main** pane of the block mask, you must specify the data type and scaling properties of its elements in the **Vector (V)** parameter on the **Data Types** tab. When the

vector comes in through the block port, its elements inherit their data type and scaling from the driving block.

You can set the vector, accumulator, and output data types in the block dialog as discussed below.

Parameters

Main Tab

Add along dimension

Specify the dimension along which to add the input array A to the elements of vector V .

Vector (V) source

Specify the source of the vector, V . The vector can come from the `Input` port or from a `Dialog` parameter.

Vector (V)

Specify the vector, V . This parameter is visible only when you select `Dialog` parameter for the **Vector (V) source** parameter.

Data Types Tab

Note Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

Rounding mode

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

If **Accumulator** data type is `Inherit: Inherit via internal rule` and **Output** data type is `Inherit: Same as accumulator`, the value of **Rounding mode** does not affect the numerical results.

Note The **Rounding mode** and **Saturate on integer overflow** settings have no effect on numerical results when both of these conditions are met:

- **Accumulator** is `Inherit: Inherit via internal rule`
- **Output** is `Inherit: Same as accumulator`

With these data type settings, the block is effectively operating in full precision mode.

Saturate on integer overflow

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see `overflow mode for fixed-point operations`.

Vector (V)

Use this parameter to specify the word and fraction lengths for the elements of the vector, *V*. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Note The **Vector (V)** parameter on the **Data Types** pane is only visible when you select **Dialog** parameter for the **Vector (V) source** parameter on the **Main** pane of the block mask. When the vector comes in through the block's input port, the data type and scaling of its elements are inherited from the driving block.

Accumulator

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-48 for a diagram showing the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- A rule that inherits a data type, for example, `Inherit: Same as first input`.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Output

Specify the output data type. See “Fixed-Point Data Types” on page 2-48 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- A rule that inherits a data type, for example, `Inherit: Same as first input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Data Types of Signals” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Minimum

Specify the minimum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Maximum

Specify the maximum value that the block should output. The default value is [] (unspecified). Simulink uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
A	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
V	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers

Version History

Introduced in R2007b

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

If the input is fixed point, it must be a signed integer or signed fixed point with a power-of-two slope and zero bias.

Array-Vector Divide

Divide array by vector along specified dimension

Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

dspmtrx3

Description

The Array-Vector Divide block divides the values in the specified dimension of the N -dimensional input array A by the values in the input vector V .

The length of the input V must be the same as the length of the specified dimension of A . The Array-Vector Divide block divides each element of V by the corresponding element along that dimension of A .

Consider a 3-dimensional M -by- N -by- P input array $A(i,j,k)$ and an N -by-1 input vector V . When the **Divide along dimension** parameter is set to 2, the output of the block $Y(i,j,k)$ is

$$Y(i, j, k) = \frac{A(i, j, k)}{V(j)}$$

where

$$1 \leq i \leq M$$

$$1 \leq j \leq N$$

$$1 \leq k \leq P$$

The output of the Array-Vector Divide block is the same size as the input array, A . This block accepts real and complex floating-point and fixed-point input arrays, and real floating-point and fixed-point input vectors.

Fixed-Point Data Types

The following diagram shows the data types used within the Array-Vector Divide block for fixed-point signals.

When you specify the vector V on the **Main** pane of the block mask, you must specify the data type and scaling properties of its elements in the **Vector (V)** parameter on the **Data Types** tab. When the vector comes in through the block port, its elements inherit their data type and scaling from the driving block.

You can set the vector and output data types in the block dialog.

Parameters

Main Tab

Divide along dimension

Specify the dimension along which to divide the input array A by the elements of vector V .

Vector (V) source

Specify the source of the vector, V . The vector can come from the `Input` port or from a `Dialog` parameter.

Vector (V)

Specify the vector, V . This parameter is visible only when you select `Dialog` parameter for the **Vector (V) source** parameter.

Data Types Tab

Note Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

Rounding mode

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

Saturate on integer overflow

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

Vector (V)

Use this parameter to specify the word and fraction lengths for the elements of the vector, V . You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Vector (V)** data type parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Note The **Vector (V)** parameter on the **Data Types** pane is only visible when you select **Dialog** parameter for the **Vector (V) source** parameter on the **Main** pane of the block mask. When the vector comes in through the block's input port, the data type and scaling of its elements are inherited from the driving block.

Output

Specify the output data type. See “Fixed-Point Data Types” on page 2-53 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as first input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Data Types of Signals” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
A	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
V	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers

Blocks

Array-Vector Add | Array-Vector Multiply | Array-Vector Subtract

Array-Vector Multiply

Multiply array by vector along specified dimension

Library: DSP System Toolbox / Math Functions / Matrices and Linear Algebra / Matrix Operations

Description

The Array-Vector Multiply block multiplies the values in the specified dimension of the N -dimensional input array A by the values in the input vector V .

The length of the input V must be the same as the length of the specified dimension of A . The Array-Vector Multiply block multiplies each element of V by the corresponding element along that dimension of A .

Consider a 3-dimensional M -by- N -by- P input array $A(i,j,k)$ and an N -by-1 input vector V . When the **Multiply along dimension** parameter is set to 2, the output of the block $Y(i,j,k)$ is

$$Y(i, j, k) = A(i, j, k) * V(j)$$

where

$$1 \leq i \leq M$$

$$1 \leq j \leq N$$

$$1 \leq k \leq P$$

The output of the Array-Vector Multiply block is the same size as the input array A . This block accepts real and complex floating-point and fixed-point inputs.

Ports

Input

A — Array input

vector | matrix

Specify the array input as a vector or a matrix.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

V — Vector input

vector

Specify the vector input as a vector.

Dependencies

This port appears only when you set the **Vector (V) source** parameter to Input port.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

Port_1 — Multiplied output

`vector` | `matrix`

Output of the Array-Vector Multiply block, returned as a vector or a matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Parameters

Main Tab

Multiply along dimension — Dimension along which to multiply input array

2 (default) | positive integer

Specify the dimension along which to multiply the input array *A* by the elements of vector *V* as a positive integer.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Vector (V) source — Source of vector

`Input port` (default) | `Dialog parameter`

Set the source of the vector *V* to one of these options.

- `Input port` — Vector comes from the input port.
- `Dialog parameter` — Vector comes from the dialog parameter **Vector (V)**.

Vector (V) — Vector parameter

[0.5 0.25] (default) | vector

Specify the vector *V*.

Dependencies

This parameter appears only when you set the **Vector (V) source** parameter to `Dialog parameter`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Data Types Tab

Note Floating-point inheritance takes precedence over the data type settings defined on the **Data Types** tab. When inputs are floating point, the block ignores these settings and all internal data types are floating point.

Rounding mode — Method of rounding operation

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Set the rounding mode for fixed-point operations to one of these options.

- Ceiling
- Convergent
- Floor
- Nearest
- Round
- Simplest
- Zero

For details, see rounding mode.

Saturate on integer overflow — Method of overflow action

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operations. When you clear this parameter, the block wraps the result of its fixed-point operations. For details on `saturate` and `wrap`, see overflow mode for fixed-point operations.

Vector (V) — Word and fraction lengths for elements of vector

Inherit: Same word length as input (default) | `fixdt(1,16,0)` | <data type expression>

Use this parameter to specify the word and fraction lengths for the elements of the vector, *V*. Select this parameter as one of these options.

- `Inherit: Same word length as input` — Inherits the data type so it is the same as that of the input array *A*.
- `fixdt(1,16,0)` — Specifies a signed, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.
- <data type expression> — Lets you specify an expression that evaluates to a valid data type.

Alternatively, you can set the **Vector (V)** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink).

Note When the vector comes in through the input port of the block, the data type and scaling of its elements are inherited from the driving block.

Dependencies

This parameter appears only when you set the **Vector (V) source** parameter on the **Main** tab to **Dialog** parameter.

Vector (V) Minimum — Minimum value for elements of vector

[] (unspecified) (default) | scalar

Specify the minimum value for the elements of vector V . The default value is [] (unspecified). Simulink uses this value to perform:

- Parameter range checking. For more information, see “Specify Minimum and Maximum Values for Block Parameters” (Simulink).
- Automatic scaling of fixed-point data types.

Dependencies

This parameter appears only when you set the **Vector (V) source** parameter on the **Main** tab to Dialog parameter.

Vector (V) Maximum — Maximum value for elements of vector

[] (unspecified) (default) | scalar

Specify the maximum value for the element of vector V . The default value is [] (unspecified). Simulink uses this value to perform:

- Parameter range checking. For more information, see “Specify Minimum and Maximum Values for Block Parameters” (Simulink).
- Automatic scaling of fixed-point data types.

Dependencies

This parameter appears only when you set the **Vector (V) source** parameter on the **Main** tab to Dialog parameter.

Product output — Product output data type

Inherit: Inherit via internal rule (default) | Inherit: Same as first input | fixdt([],16,0) | <data type expression>

Specify the data type of the output of a product operation in the Array-Vector Multiply block. For illustrations depicting the use of the product output data type in this block, see “Fixed Point” on page 2-62 and “Multiplication Data Types”. Set this parameter to one of these options.

- **Inherit: Inherit via internal rule** — Inherits the data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- **Inherit: Same as first input** — Inherits the data type so it is the same as that of the input array A .
- **fixdt([],16,0)** — Lets you specify the fixed-point attributes of the data type.
- **<data type expression>** — Lets you specify an expression that evaluates to a valid data type.

Alternatively, you can set the **Product output** data type by using the **Data Type Assistant**. To use

the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink).

Accumulator — Accumulator data type

Inherit: Inherit via internal rule (default) | Inherit: Same as first input | Inherit: Same as product output | fixdt([],16,0) | <data type expression>

Specify the data type of the output of an accumulation operation in the Array-Vector Multiply block. For illustrations depicting the use of the accumulator data type in this block, see “Fixed Point” on page 2-62. Set this parameter to one of these options.

- `Inherit: Inherit via internal rule` — Inherits the data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- `Inherit: Same as first input` — Inherits the data type so it is the same as that of the input array *A*.
- `Inherit: Same as product output` — Inherits the data type so it is the same as the product output data type.
- `fixdt([],16,0)` — Lets you specify the fixed-point attributes of the data type.
- `<data type expression>` — Lets you specify an expression that evaluates to a valid data type.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink).

Output — Output data type

`Inherit: Same as product output (default) | Inherit: Same as first input | Inherit: Same as first input | fixdt([],16,0) | <data type expression>`

Specify the output data type. For illustrations depicting the use of the output data type in this block, see “Fixed Point” on page 2-62. Set this parameter to one of these options.

- `Inherit: Same as first input` — Inherits the data type so it is the same as that of the input array *A*.
- `Inherit: Same as product output` — Inherits the data type so it is the same as the product output data type.
- `fixdt([],16,0)` — Lets you specify the fixed-point attributes of the data type.
- `<data type expression>` — Lets you specify an expression that evaluates to a valid data type.

For more information, see “Control Data Types of Signals” (Simulink).

Alternatively, you can set the **Output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink).

Output Minimum — Minimum value of block output

`[] (unspecified) (default) | scalar`

Specify the minimum value that the block outputs. The default value is `[]` (unspecified). Simulink uses this value to perform:

- Simulation range checking. For more information, see “Specify Signal Ranges” (Simulink).

- Automatic scaling of fixed-point data types.

Output Maximum — Maximum value of block output

[] (unspecified) (default) | scalar

Specify the maximum value that the block should output. The default value is [] (unspecified). Simulink uses this value to perform:

- Simulation range checking. For more information, see “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

Version History

Introduced in R2007b

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

If the input is fixed point, it must be a signed integer or signed fixed point with a power-of-two slope and zero bias.

The following diagram shows the data types used within the Array-Vector Multiply block for fixed-point signals.

When you specify the vector V on the **Main** tab of the block mask, you must specify the data type and scaling properties of its elements in the **Vector (V)** parameter on the **Data Types** tab. When the vector comes in through the block port, its elements inherit their data type and scaling from the driving block.

The output of the multiplier is in the product output data type when at least one of the inputs to the multiplier is real. When both of the inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”.

You can set the vector, accumulator, product output, and output data types in the block dialog.

Array-Vector Add | Array-Vector Divide | Array-Vector Subtract

Array-Vector Subtract

Subtract vector from array along specified dimension

Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

dspmtrx3

Description

The Array-Vector Subtract block subtracts the values in the input vector V from the values in the specified dimension of the N -dimensional input array A .

The length of the input V must be the same as the length of the specified dimension of A . The Array-Vector Subtract block subtracts each element of V from the corresponding element along that dimension of A .

Consider a 3-dimensional M -by- N -by- P input array $A(i,j,k)$ and an N -by-1 input vector V . When the **Subtract along dimension** parameter is set to 2, the output of the block $Y(i,j,k)$ is

$$Y(i, j, k) = A(i, j, k) - V(j)$$

where

$$1 \leq i \leq M$$

$$1 \leq j \leq N$$

$$1 \leq k \leq P$$

The output of the Array-Vector Subtract block is the same size as the input array, A . This block accepts real and complex floating-point and fixed-point inputs.

Fixed-Point Data Types

The following diagram shows the data types used within the Array-Vector Subtract block for fixed-point signals.

When you specify the vector V on the **Main** pane of the block mask, you must specify the data type and scaling properties of its elements in the **Vector (V)** parameter on the **Data Types** tab. When the

vector comes in through the block port, its elements inherit their data type and scaling from the driving block.

The output of the subtractor is in the accumulator data type.

You can set the vector, accumulator, and output data types in the block dialog as discussed below.

Parameters

Main Tab

Subtract along dimension

Specify the dimension along which to subtract the elements of vector V from the input array A .

Vector (V) source

Specify the source of the vector, V . The vector can come from the `Input` port or from a `Dialog` parameter.

Vector (V)

Specify the vector, V . This parameter is visible only when you select `Dialog` parameter for the **Vector (V) source** parameter.

Data Types

Note Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

Rounding mode

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

Note The **Rounding mode** and **Saturate on integer overflow** settings have no effect on numerical results when both of these conditions are met:

- **Accumulator** is `Inherit`: Inherit via internal rule
- **Output** is `Inherit`: Same as accumulator

With these data type settings, the block is effectively operating in full precision mode.

Saturate on integer overflow

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

Vector (V)

Use this parameter to specify the word and fraction lengths for the elements of the vector, V. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Note The **Vector (V)** parameter on the **Data Types** pane is only visible when you select **Dialog** parameter for the **Vector (V) source** parameter on the **Main** pane of the block mask. When the vector comes in through the block's input port, the data type and scaling of its elements are inherited from the driving block.

Accumulator

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-64 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- A rule that inherits a data type, for example, `Inherit: Same as first input`.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Output

Specify the output data type. See “Fixed-Point Data Types” on page 2-64 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- A rule that inherits a data type, for example, `Inherit: Same as first input`.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Data Types of Signals” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Minimum

Specify the minimum value that the block should output. The default value is [] (unspecified). Simulink uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Maximum

Specify the maximum value that the block should output. The default value is [] (unspecified). Simulink uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
A	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
V	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers

[Array-Vector Add](#) | [Array-Vector Divide](#) | [Array-Vector Multiply](#)

Audio Device Writer

Play to sound card

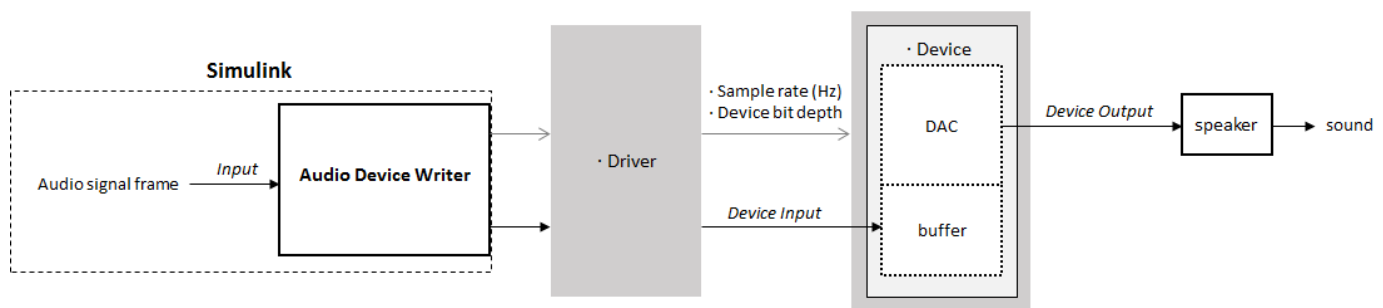

Library: Audio Toolbox / Sinks
DSP System Toolbox / Sinks

Description

The Audio Device Writer block writes audio samples to an audio output device.

Parameters of the Audio Device Writer block specify the driver, the device, and device attributes such as sample rate and bit depth.

Data Flow of Audio Device Writer Block

- An audio signal frame is input to the Audio Device Writer block.
- The Audio Device Writer block uses the specified driver to pass the frame (device input) to your specified audio device buffer.
- The audio device performs digital-to-analog conversion at the specified sample rate and bit depth.
- The audio device outputs an analog chunk to your speaker.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

If input to the Audio Device Writer block is of data type `double` or `single`, the block clips values outside the range $[-1, 1]$. For other data types, the allowed input range is $[\text{min}, \text{max}]$ of the specified data type.

Data Types: `single` | `double` | `int16` | `int32` | `uint8`

Output

Port_1 — Number of samples underrun

scalar

This port outputs the number of samples underrun while writing a frame of data (one input matrix).

Dependencies

To enable this port, select the **Output number of samples underrun** parameter.

Data Types: uint32

Parameters

Main Tab

Driver — Driver used to access your audio device

DirectSound (default) | ASIO | WASAPI

- ASIO drivers do not come pre-installed on Windows machines. To use the ASIO driver option, install an ASIO driver outside of MATLAB.

Note If **Driver** is set to ASIO, open the ASIO UI outside of MATLAB to set the sound card buffer size to the frame size (number of rows) input to the Audio Device Writer block. See the documentation of your ASIO driver for more information.

- WASAPI drivers are supported for exclusive-mode only.

ASIO and WASAPI drivers do not provide sample rate conversion. For ASIO and WASAPI drivers, supply an audio stream with a sample rate supported by your audio device.

This parameter applies only on Windows machines. Linux machines always use the ALSA driver. Mac machines always use the CoreAudio driver.

To specify nondefault **Driver** values, you must install Audio Toolbox™. If the toolbox is not installed, specifying nondefault **Driver** values returns an error.

Device — Device used to play audio samples

default audio device (default)

The device list is populated with devices available on your computer.

Info — View information about your audio output configuration

button

This button opens a dialog box that lists your selected audio driver, the full name of your audio device, and the maximum output channels for your configuration. For example:

Inherit sample rate from input – Specify source of input sample rate

on (default) | off

When you select this parameter, the block inherits its sample rate from the input signal. When you clear this parameter, you specify the sample rate in **Sample rate (Hz)**.

Sample rate (Hz) – Sample rate used by device to play audio data

44100 (default) | positive scalar

The possible range of **Sample rate (Hz)** depends on your audio hardware.

Dependencies

To enable this parameter, clear the **Inherit sample rate from input** parameter.

Advanced Tab

Device bit depth – Data type used by device to perform digital-to-analog conversion

16-bit integer (default) | 8-bit integer | 24-bit integer | 32-bit float

Before performing digital-to-analog conversion, the input data is cast to a data type specified by this parameter.

Note To specify a nondefault **Device bit depth**, you must install Audio Toolbox. If the toolbox is not installed, specifying a nondefault **Device bit depth** returns an error.

Use default channel mapping – Toggle channel mapping source

on (default) | off

When you select this parameter, the block uses the default mapping between columns of the matrix input to this block and the channels of your device. When you clear this parameter, you specify the mapping in **Device output channels**.

Device output channels – Specify nondefault channel mapping

[1:MaximumOutputChannels] (default) | scalar | vector

Nondefault mapping between columns of matrix input to the Audio Device Writer block and channels of output device, specified as a scalar or vector. For example:

If **Device output channels** is specified as 1:3, then:

- The first column of the input matrix maps to channel 1.
- The second column of the input matrix maps to channel 2.
- The third column of the input matrix maps to channel 3.

If **Device output channels** is specified as [3, 1, 2], then:

- The first column of the input matrix maps to channel 3.
- The second column of the input matrix maps to channel 1.
- The third column of the input matrix maps to channel 2.

Note To selectively map between columns of the input matrix and your sound card's output channels, you must install Audio Toolbox. If the toolbox is not installed, specifying nondefault values for **Device output channels** returns an error.

Dependencies

To enable this parameter, clear the **Use default mapping between columns of input of this block and sound card's output channels** parameter.

Output number of samples underrun — Specify output port for number of samples underrun

off (default) | on

When you select this parameter, an output port is added to the block. The port outputs the number of samples underrun while writing a frame of data (one input matrix).

Block Characteristics

Data Types	double integer ^a single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

^a Supports 16- and 32-bit signed and 8-bit unsigned integers.

Version History

Introduced in R2016a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The following code generation limitations apply:

- Host computer only. Excludes Simulink Desktop Real-Time™ code generation.
- The executable generated from this block relies on prebuilt dynamic library files (.dll files) included with MATLAB. Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

Audio Weighting Filter

Design audio weighting filter

Compatibility

Note The Audio Weighting Filter block will be removed from DSP System Toolbox in a future release. Existing instances of the block continue to run. For new code, use the Weighting Filter block from Audio Toolbox instead.

Library

Filtering / Filter Designs

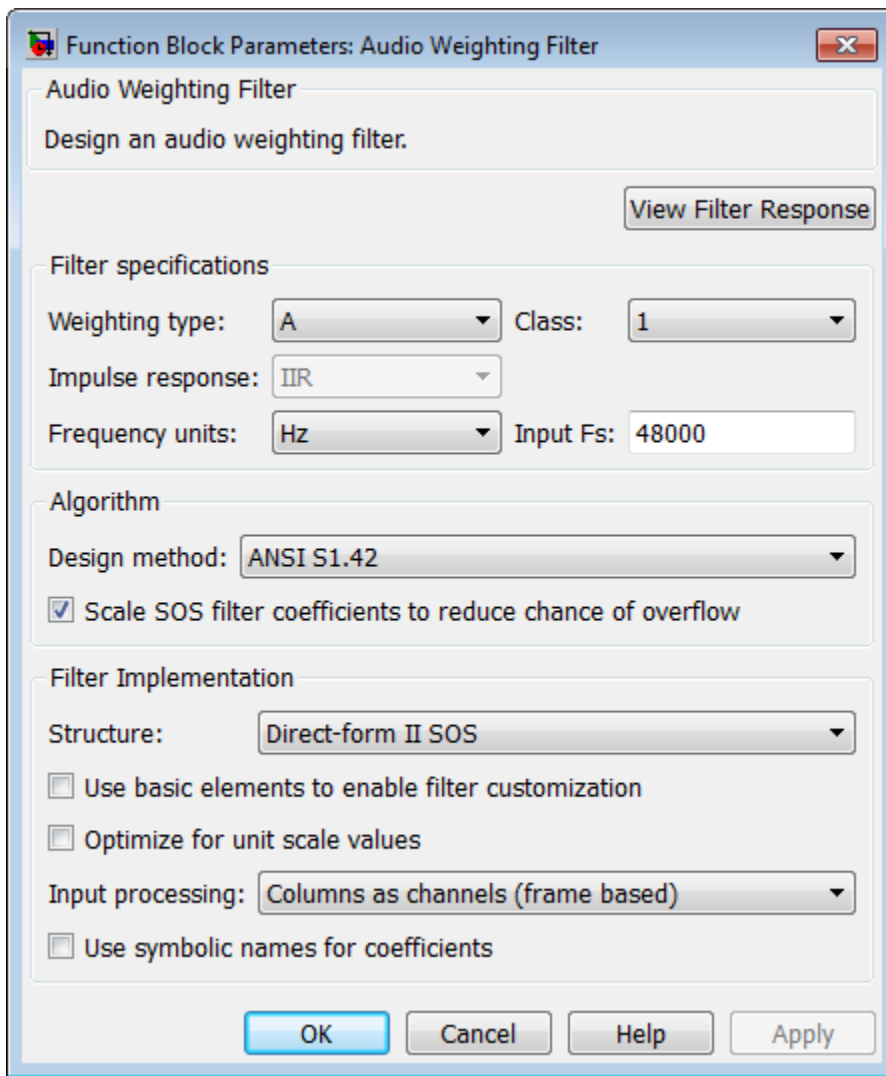

dspfdesign

Description

This block brings the filter design capabilities of the `filterBuilder` function to the Simulink environment.

Dialog Box

See “Audio Weighting Filter Design — Main Pane” on page 5-597 for more information about the parameters of this block. The **Data Types** and **Code** panes are not available for blocks in the DSP System Toolbox Filter Designs library.

View Filter Response

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

In this group, you specify your filter format, such as the impulse response and the filter order.

Weighting type

The weighting type defines the frequency response of the filter. The valid weighting types for this filter are A, C, C-message, ITU-R 468-4, and ITU-T 0.41.

Class

The filter class describes the frequency-dependent tolerances specified in the relevant standards [1], [2]. There are two possible class values: 1 and 2. Class 1 weighting filters have stricter tolerances than class 2 filters. The filter class value does not affect the design. The class value is only used to provide a specification mask in **FVTool** for the analysis of the filter design. The default value of this parameter is 1.

The filter class is only applicable for A weighting and C weighting filters.

Impulse response

Specify the impulse response type as one of IIR or FIR. For A, C, C-message, and ITU-R 468-4 filter, IIR is the only option. For a ITU-T 0.41 weighting filter, FIR is the only option.

Frequency units

Specify the frequency units as Hertz (Hz), kilohertz (kHz), megahertz (MHz), or gigahertz (GHz). Normalized frequency designs are not supported for audio weighting filters. The default value of this parameter is Hz.

Input sample rate

Specify the input sampling frequency. The units correspond to the setting of the **Frequency units** parameter.

Algorithm**Design Method**

Valid design methods depend on the weighting type. For type A and C weighting filters, the only valid design type is ANSI S1.42. This is an IIR design method that follows ANSI standard S1.42-2001. For a C message filter, the only valid design method is Bell 41009, which is an IIR design method following the Bell System Technical Reference PUB 41009. For a ITU-R 468-4 weighting filter, you can design an IIR or FIR filter. If you choose an IIR design, the design method is IIR least p-norm. If you choose an FIR design, the design method choices are Equiripple or Frequency Sampling. For an ITU-T 0.41 weighting filter, the available FIR design methods are Equiripple or Frequency Sampling.

Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Filter Implementation**Structure**

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. For audio weighting IIR filter designs, you can choose direct form I or II biquad (SOS). You can also choose to implement these structures in transposed form.

For FIR designs, you can choose a direct form, direct-form transposed, direct-form symmetric, or direct-form asymmetric structure.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of n unit delays with a single delay by n .
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

Input processing

Specify how the block should process the input. The available options may vary depending on the settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

For more information about sample- and frame-based processing, see “Sample- and Frame-Based Concepts”.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point

Autocorrelation

Autocorrelation of N -D array

Library: DSP System Toolbox / Statistics

Description

The Autocorrelation block computes the autocorrelation along the first dimension of an N -D input array. The computation can be done in the time domain or frequency domain. You can specify the domain through the **Computation domain** parameter. In the time domain, the input signal is convolved with its time-reversed complex conjugate. In the frequency domain, the block computes the autocorrelation by taking the Fourier transform of the input signal, multiplying the Fourier transform with its conjugate, and computing the inverse Fourier transform of the product. In this domain, depending on the input length, the block can require fewer computations. For information on these two computation methods, see “Algorithms” on page 2-84.

You can specify the maximum lag for autocorrelation using the **Compute all non-negative lags** and **Maximum non-negative lag (less than input length)** parameters.

The block accepts fixed-point signals when you set the **Computation domain** to Time.

Ports

Input

Port_1 — Data input

vector | matrix | N -D array

Data input. The block accepts real-valued or complex-valued multichannel and multidimensional inputs. The input can be a fixed-point signal when you set the **Computation domain** to Time.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 — Autocorrelated output

vector | matrix | N -D array

Autocorrelated output of the data input.

- When the input is an M -by- N matrix, u , the output, y , is an $(l+1)$ -by- N matrix. l is the maximum positive lag for autocorrelation.
- When the input is an N -D array, the block outputs an N -D array. The size of the first dimension is $l+1$, and the sizes of all other dimensions match those of the input array. For example, when the input is an M -by- N -by- P array, the block outputs an $(l+1)$ -by- N -by- P array.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Main Tab

Compute all non-negative lags — Compute autocorrelation over all nonnegative lags
on (default) | off

When you select this parameter, the Autocorrelation block computes the autocorrelation over all nonnegative lags in the range $[0, \text{length}(\text{input}) - 1]$. When you clear this parameter, the block computes the autocorrelation using the lags in the range $[0, l]$, where l is the value you specify in **Maximum non-negative lag (less than input length)**.

Maximum non-negative lag (less than input length) — Maximum positive lag
1 (default) | integer greater than or equal to 0 and less than input length

Maximum positive lag for autocorrelation, specified as an integer that is greater than or equal to 0 and less than the input length.

Dependencies

To enable this parameter, clear the **Compute all non-negative lags** parameter.

Scaling — Scaling of the output

None (default) | Biased | Unbiased | Unity at zero-lag

Scaling applied to the output.

- **None** — Generates the raw autocorrelation $y_{i,j}$ without normalization.
- **Biased** — Generates the biased estimate of the autocorrelation.

$$y_{i,j}^{biased} = \frac{y_{i,j}}{M}$$

- **Unbiased** — Generates the unbiased estimate of the autocorrelation.

$$y_{i,j}^{unbiased} = \frac{y_{i,j}}{M-i}$$

- **Unity at zero-lag** — Normalizes the estimate of the autocorrelation for each channel so that the zero-lag sum, the first element in each column, is identically 1.

$$y_{0,j} = 1$$

Computation domain — Domain in which the block computes the autocorrelation

Time (default) | Frequency

- **Time** — Computes the convolutions in the time domain, which minimizes the memory usage.
- **Frequency** — Computes the autocorrelation in frequency domain. For more information, see “Algorithms” on page 2-84.

To autocorrelate fixed-point signals, set this parameter to **Time**.

Data Types Tab

Note Fixed-point signals are supported for the time domain only. To use these parameters, on the **Main** tab, set **Computation domain** to Time.

Rounding mode — Method of rounding operation

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

Note The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numerical results when all these conditions are met:

- **Product output** data type is Inherit: Inherit via internal rule.
- **Accumulator** data type is Inherit: Inherit via internal rule.
- **Output** data type is Inherit: Same as accumulator.

With these data type settings, the block operates in full-precision mode.

Saturate on integer overflow — Method of overflow action

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

Note The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numeric results when all these conditions are met:

- **Product output** data type is Inherit: Inherit via internal rule.
- **Accumulator** data type is Inherit: Inherit via internal rule.

With these data type settings, the block operates in full-precision mode.

Product output — Product output data type

Inherit: `Inherit via internal rule (default)` | Inherit: `Same as input` |
`fixdt([],16,0)`

Product output specifies the data type of the output of a product operation in the Autocorrelation block. For more information on the product output data type, see “Multiplication Data Types” and the ‘Fixed-Point Conversion’ section in “Extended Capabilities” on page 2-0 .

- **Inherit: Inherit via internal rule** — The block inherits the product output data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- **Inherit: Same as input** — The block specifies the product output data type to be the same as the input data type.
- **`fixdt([],16,0)`** — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Product output** data type by using the **Data Type Assistant**. To use

the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

Accumulator — Accumulator data type

Inherit: `Inherit via internal rule (default)` | Inherit: `Same as input` | Inherit:
`Same as product output` | `fixdt([],16,0)`

Accumulator specifies the data type of the output of an accumulation operation in the Autocorrelation block. For illustrations on how to use the accumulator data type in this block, see the ‘Fixed-Point Conversion’ section in “Extended Capabilities” on page 2-0 .

- **Inherit: Inherit via internal rule** — The block inherits the accumulator data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- **Inherit: Same as input** — The block specifies the accumulator data type to be the same as the input data type.
- **Inherit: Same as product output** — The block specifies the accumulator data type to be the same as the product output data type.
- **`fixdt([],16,0)`** — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the

assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

Output — Output data type

Inherit: `Same as accumulator (default)` | Inherit: `Same as input` | Inherit: `Same as product output` | `fixdt([],16,0)`

Output specifies the data type of the output of the Autocorrelation block. For more information on the output data type, see the 'Fixed-Point Conversion' section in “Extended Capabilities” on page 2-0 .

- **Inherit: Same as input** — The block specifies the output data type to be the same as the input data type.
- **Inherit: Same as product output** — The block specifies the output data type to be the same as the product output data type.
- **Inherit: Same as accumulator** — The block specifies the output data type to be the same as the accumulator data type.
- **fixdt([], 16, 0)** — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

Output Minimum — Minimum value the block can output

[] (default) | scalar

Specify the minimum value the block can output. Simulink software uses this minimum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

Output Maximum — Maximum value block can output

[] (default) | scalar

Specify the maximum value the block can output. Simulink software uses this maximum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

Block Characteristics

Data Types	double single base integer fixed point
Multidimensional Signals	No

Variable-Size Signals	No
------------------------------	----

More About

Autocorrelation

Autocorrelation is the correlation of a signal with itself at different points in time.

For a deterministic discrete-time sequence, $x(n)$, the autocorrelation is computed using the following relationship:

$$r_x(h) = \sum_{n=0}^{N-h-1} x^*(n)x(n+h) \quad h = 0, 1, \dots, N-1$$

where h is the lag and $*$ denotes the complex conjugate. If the input is a length N realization of a WSS stationary random process, $r_x(h)$ is an estimate of the theoretical autocorrelation:

$$\rho_x(h) = E\{x^*(n)x(n+h)\}$$

where $E\{\}$ is the expectation operator. The Unity at zero-lag normalization divides each sequence value by the autocorrelation or autocorrelation estimate at zero lag.

$$\frac{\rho_x(h)}{\rho_x(0)} = \frac{E\{x^*(n)x(n+h)\}}{E\{|x(0)|^2\}}$$

The most commonly used estimate of the theoretical autocorrelation of a WSS random process is the biased estimate:

$$\hat{\rho}_x(h) = \frac{1}{N} \sum_{k=0}^{N-h-1} x^*(k)x(k+h)$$

Algorithms

Time-Domain Computation

When you set the computation domain to time, the algorithm computes the autocorrelation of the input signal in the time domain. The input signal can be a fixed-point signal in this domain.

The autocorrelation sequence, y , is computed using this equation:

$$y_{i,j} = \sum_{k=0}^{M-l-1} u_{k,j}^* u_{(k+i),j} \quad 0 \leq i \leq l$$

- $y_{0,j}$ is the zero-lag element in the j th column of the input.
- i is the index of the lag.
- j is the index of the input data column.
- $*$ denotes the complex conjugate.
- M is the number of elements in each column.

- l is the maximum positive lag for autocorrelation. When you choose to compute the autocorrelation with all nonnegative lags, $l=M-1$. Otherwise, l is the maximum nonnegative integer lag value specified.
- u is an M -by- N input matrix.

Frequency-Domain Computation

When you set the computation domain to frequency, the algorithm computes the autocorrelation in the frequency domain.

In this domain, the algorithm computes the autocorrelation sequence by taking the Fourier transform of the input signal, multiplying the Fourier transform with its complex conjugate, and taking the inverse Fourier transform of the product. In this domain, depending on the input length, the algorithm can require fewer computations.

Correlation

Autocorrelation LPC

Determine coefficients of Nth-order forward linear predictors

Library: DSP System Toolbox / Estimation / Linear Prediction

Description

The Autocorrelation LPC block determines the coefficients of an *N-step forward linear predictor* for the time-series in each length-*M* input channel, *u*, by minimizing the prediction error in the least squares sense. A linear predictor is an FIR filter that predicts the next value in a sequence from the present and past inputs. This technique has applications in filter design, speech coding, spectral analysis, and system identification.

The Autocorrelation LPC block can output the prediction error for each channel as polynomial coefficients, reflection coefficients, or both. The block can also output the prediction error power for each channel.

Ports

Input

Input 1 — Input array

unoriented vector | column vector | matrix

Specify the input *u* as an unoriented vector, column vector, or a matrix. Row vectors are not valid inputs. The block treats all *M*-by-*N* matrix inputs as *N* channels of length *M*.

Data Types: single | double

Output

A — Polynomial coefficients

column vector | matrix

Polynomial coefficients generated when you set the **Output(s)** parameter to A or A and K. For each input channel, port A outputs an (*N*+1)-by-1 column vector $a = [1 \ a_2 \ a_3 \ \dots \ a_{N+1}]^T$, containing the coefficients of an *N*th-order moving average (MA) linear process that predicts the next value, \hat{u}_{M+1} , in the input time-series.

$$\hat{u}_{M+1} = -(a_2 u_M) - (a_3 u_{M-1}) - \dots - (a_{N+1} u_{M-N+1})$$

Dependencies

To enable port A, set **Output(s)** to A or A and K.

Data Types: single | double

K — Reflection coefficients

column vector | matrix

Reflection coefficients generated when **Output(s)** is set to K or A and K. For each input channel, port K outputs a length- N column vector whose elements are the prediction error reflection coefficients.

Dependencies

To enable port K, set **Output(s)** to A or A and K.

Data Types: single | double

P — Prediction error power

vector

Prediction error power output at port P as a vector whose length is the number of input channels.

Dependencies

To enable port P, select the **Output prediction error power (P)** parameter.

Data Types: single | double

Parameters**Output(s) — Type of prediction coefficients**

A (default) | A and K | K

Specify the type of prediction coefficients output by the block. The block can output polynomial coefficients (A), reflection coefficients (K), or both (A and K).

When you set **Output(s)** to A and K, the block enables port A and K and each port outputs its respective set of prediction coefficients for each channel.

Output prediction error power (P) — Output prediction error power

off (default) | on

Select this parameter to enable the output port P, which outputs the output prediction error power.

Inherit prediction order from input dimensions — Inherit prediction order from input dimensions

off (default) | on

Select this parameter to inherit the prediction order N from the input dimensions.

Prediction order (N) — Prediction order

1 (default) | scalar

Specify the prediction order N . Note that N must be a scalar with a value less than the length of the input channels or the block produces an error.

Dependencies

This parameter appears only when you do not select the **Inherit prediction order from input dimensions** parameter.

Block Characteristics

Data Types	double single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Algorithms

The Autocorrelation LPC block computes the least squares solution to

$$\min_{i \in \mathfrak{R}^n} \|U\tilde{a} - b\|$$

where $\|\cdot\|$ indicates the 2-norm and

$$U = \begin{bmatrix} u_1 & 0 & \cdots & 0 \\ u_2 & u_1 & \ddots & \vdots \\ \vdots & u_2 & \ddots & 0 \\ \vdots & \vdots & \ddots & u_1 \\ \vdots & \vdots & \vdots & u_2 \\ \vdots & \vdots & \vdots & \vdots \\ u_M & \vdots & \vdots & \vdots \\ 0 & \ddots & \vdots & \vdots \\ \vdots & \ddots & \ddots & \vdots \\ 0 & \cdots & 0 & u_M \end{bmatrix}, \quad \tilde{a} = \begin{bmatrix} a_2 \\ \vdots \\ a_{n+1} \end{bmatrix}, \quad b = \begin{bmatrix} u_2 \\ u_3 \\ \vdots \\ u_M \\ 0 \\ \vdots \\ 0 \end{bmatrix}$$

Solving the least squares problem via the normal equations

$$U^*U\tilde{a} = U^*b$$

leads to the system of equations

$$\begin{bmatrix} r_1 & r_2^* & \cdots & r_n^* \\ r_2 & r_1 & \ddots & \vdots \\ \vdots & \ddots & \ddots & r_2^* \\ r_n & \cdots & r_2 & r_1 \end{bmatrix} \begin{bmatrix} a_2 \\ a_3 \\ \vdots \\ a_{n+1} \end{bmatrix} = \begin{bmatrix} -r_2 \\ -r_3 \\ \vdots \\ -r_{n+1} \end{bmatrix}$$

where $r = [r_1 r_2 r_3 \dots r_{n+1}]^T$ is an autocorrelation estimate for u computed using the Autocorrelation block, and $*$ indicates the complex conjugate transpose. The normal equations are solved in $O(n^2)$ operations by the Levinson-Durbin block.

Note that the solution to the LPC problem is very closely related to the Yule-Walker AR method of spectral estimation. In that context, the normal equations above are referred to as the Yule-Walker AR equations.

Blocks

Autocorrelation | Levinson-Durbin | Yule-Walker Method

Backward Substitution

Solve $UX = B$ for X when U is upper triangular matrix

Library: DSP System Toolbox / Math Functions / Matrices and Linear Algebra / Linear System Solvers

Description

The Backward Substitution block solves the linear system $UX = B$ by simple backward substitution of variables, where:

- U is the upper triangular M -by- M matrix input to the **U** port.
- B is the M -by- N matrix input to the **B** port.
- X is the M -by- N output matrix and is the solution of the system of equations.

The block does not check the rank of the inputs. The block uses only the elements in the *upper triangle* of input U and ignores the lower elements. When you select the **Input U is unit-upper triangular** check box, the block assumes the elements on the diagonal of U are 1s. This is useful when matrix U is the result of another operation, such as an LDL decomposition, that uses the diagonal elements to represent the D matrix.

Ports

Input

U — Input upper triangular matrix

M -by- M matrix

Specify the input upper triangular M -by- M matrix U through this port. Inputs U and B must have the same number of rows.

When the input U is fixed-point, it is signed only.

Data Types: single | double | int8 | int16 | int32 | fixed point

B — B matrix

M -by- N matrix | M -by-1 vector

Specify the B matrix in the $UX = B$ equation as an M -by- N matrix or an M -by-1 vector.

When you specify an M -by-1 vector, the block treats the length- M vector input at port **B** as an M -by-1 matrix. Inputs U and B must have the same number of rows.

When the input B is fixed-point, it is signed only.

Data Types: single | double | int8 | int16 | int32 | fixed point

Output

X — Solution of system of equations

M-by-*N* matrix | *M*-by-1 matrix

The block returns the output as an *M*-by-*N* matrix or an *M*-by-1 vector. The size of the *X* matrix is same as the size of the *B* matrix.

When the inputs are fixed-point, the output matrix *X* is signed only fixed-point.

Data Types: single | double | int8 | int16 | int32 | fixed point

Parameters

Main Tab

Input U is unit-upper triangular — Diagonal elements of input matrix have a value of 1

off (default) | on

Select this check box only when all elements on the diagonal of *U* have a value of 1. When you do so, the block optimizes its behavior by skipping an unnecessary division operation.

Do not select this check box if any elements on the diagonal of *U* do not have a value of 1. When you clear the **Input U is unit-upper triangular** check box, the block always performs the division operation.

Diagonal of complex input U is real — Diagonal elements of complex input are real

off (default) | on

Select to optimize simulation speed when the diagonal elements of complex input *U* are real.

Note When *U* is a complex fixed-point signal, you must select either **Input U is unit-upper triangular** or **Diagonal of complex input U is real**. When either of these options are selected, the block ignores any imaginary part of the diagonal of *U*.

Dependencies

This parameter is visible only when **Input U is unit-upper triangular** is not selected.

Data Types Tab

Note Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

Rounding mode — Method of rounding operation

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

Saturate on integer overflow — Method of overflow action

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

Product output — Product output data type

Inherit: Inherit via internal rule (default) | Inherit: Same as first input | fixdt(1,16,0)

Product output specifies the data type of the output of a product operation in the Backward Substitution block. For more information on the product output data type, see “Fixed Point” on page 2-95 and “Multiplication Data Types”.

- **Inherit: Inherit via internal rule** — The block inherits the product output data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- **Inherit: Same as first input** — The block specifies the product output data type to be the same as the first input data type.
- **fixdt(1,16,0)** — The block specifies a signed, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Product output** data type by using the **Data Type Assistant**. To use

the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

Accumulator — Accumulator data type

Inherit: Inherit via internal rule (default) | Inherit: Same as product output | Inherit: Same as first input | fixdt(1,16,0)

Accumulator specifies the data type of the output of an accumulation operation in the Backward Substitution block. For illustrations on how to use the accumulator data type in this block, see the “Fixed Point” on page 2-95 section.

- **Inherit: Inherit via internal rule** — The block inherits the accumulator data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- **Inherit: Same as product output** — The block specifies the accumulator data type to be the same as the product output data type.
- **Inherit: Same as first input** — The block specifies the accumulator data type to be the same as the first input data type.
- **fixdt(1,16,0)** — The block specifies a signed, binary-point scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

Output — Output data type

Inherit: Same as first input (default) | fixdt(1,16,0)

Output specifies the data type of the output of the Backward Substitution block. For more information on the output data type, see the “Fixed Point” on page 2-95 section.

- **Inherit: Same as first input** — The block specifies the output data type to be the same as the first input data type.
- **fixdt(1,16,0)** — The block specifies a signed, binary-point scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

Output Minimum — Minimum value the block can output

[] (default) | scalar

Specify the minimum value the block can output. Simulink software uses this minimum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

Output Maximum — Maximum value block can output

[] (default) | scalar

Specify the maximum value the block can output. Simulink software uses this maximum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

Lock data type settings against changes by the fixed-point tools – Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

Bandpass Filter

Design bandpass filter

Library: DSP System Toolbox / Filtering / Filter Designs

Description

This block brings the filter design capabilities of the `filterBuilder` function to the Simulink environment.

This block supports SIMD code generation. For details, see “Code Generation” on page 2-106.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Input signal to filter, specified as a scalar, vector, or matrix.

Data Types: `single` | `double`

Output

Port_1 — Filtered output signal

scalar | vector | matrix

Filtered output signal, specified as a scalar, vector, or matrix.

Data Types: `single` | `double`

Parameters

View Filter Response — Open Filter Visualization Tool

button

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Impulse response — FIR or IIR filter

FIR (default) | IIR

Choose to implement an FIR or IIR filter.

Note The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Order mode — Mode of specifying filter order

Minimum (default) | Specify

Select Minimum to have the block implement a filter with minimum order. When you select Specify, you must enter the filter order using the **Order** parameter.

Tip When you set the **Impulse response** to IIR, you can specify different numerator and denominator orders. To specify a different denominator order, select the **Denominator order** check box.

Order — Filter order

20 (default) | positive integer

Specify the filter order as a positive integer.

Dependencies

To enable this parameter, set **Order mode** to Specify.

Denominator order — Specify denominator order

off (default) | on

Select this check box to specify a different denominator order. When you select this check box, you can specify the denominator order as a positive integer in the resulting text box.

Dependencies

To enable this parameter, set the **Impulse response** to IIR and the **Order mode** to Specify.

Filter type — Type of filter

Single-rate (default) | Decimator | Interpolator | Sample-rate converter

Select the type of filter to implement. Your choice determines the type of filter and the design methods and structures that are available to implement your filter.

Dependencies

- Selecting Decimator or Interpolator activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting Sample-rate converter activates both factors.

Decimation Factor — Decimation factor

2 (default) | positive integer

Specify the decimation factor as a positive integer.

Dependencies

To enable this parameter, set the **Filter type** to Decimator or Sample-rate converter.

Interpolation Factor — Interpolation factor

2 (default) | positive integer

Specify the interpolation factor as a positive integer.

Dependencies

To enable this parameter, set the **Filter type** to Interpolator or Sample-rate converter.

Frequency constraints — Frequency response constraints

Passband and stopband edges (default) | Passband edges | Half power (3dB) frequencies | Half power (3dB) frequencies and passband width | Half power (3dB) frequencies and stopband width | Cutoff (6dB) frequencies

When you set the **Order mode** to Specify, this parameter allows you to choose the filter features that the block uses to define the frequency response characteristics. Depending on the **Impulse response** you choose, you can set the **Frequency constraints** to one of:

- **Passband and stopband edges** — Specify the frequencies for the edges for the stop- and passbands.
- **Passband edges** — For IIR filters, define the filter by specifying frequencies for the edges of the passband.
- **Stopband edges** — For IIR filters, define the filter by specifying frequencies for the edges of the stopbands.
- **Half power (3dB) frequencies** — For IIR filters, define the filter response by specifying the locations of the 3 dB points. The 3 dB point is the frequency for the point three decibels below the passband value.
- **Half power (3dB) frequencies and passband width** — For IIR filters, define the filter by specifying frequencies for the 3 dB points in the filter response and the width of the passband.
- **Half power (3dB) frequencies and stopband width** — For IIR filters, define the filter by specifying frequencies for the 3 dB points in the filter response and the width of the stopband.
- **Cutoff (6dB) frequencies** — For FIR filters, define the filter response by specifying the locations of the 6 dB points. The 6 dB point is the frequency for the point 6 dB below the passband value.

Dependencies

To enable this parameter, set the **Order mode** to Specify. The available **Frequency constraints** will depend on whether the **Impulse response** is FIR or IIR.

Frequency units — Frequency units

Normalized (0 to 1) (default) | Hz | kHz | MHz | GHz

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0 to 1)** to enter frequencies in normalized form. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz.

Input sample rate — Input sample rate

2 (default) | positive scalar

F_s , specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well.

Dependencies

To enable this parameter, set **Filter type** to Single-rate, Decimator, or Sample-rate converter and **Frequency units** to one of the unit options (Hz, kHz, MHz, or GHz).

Output sample rate — Output sample rate

2 (default) | positive scalar

When you design an interpolator, F_s represents the sampling frequency at the filter output.

Dependencies

To enable this parameter, set **Filter type** to Interpolator and **Frequency units** to one of the unit options (Hz, kHz, MHz, or GHz).

Stopband frequency 1 — Frequency at edge of end of first stopband

0.35 (default) | positive scalar

Enter the frequency at the edge of the end of the first stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Passband frequency 1 — Frequency at edge of start of passband

0.45 (default) | positive scalar

Enter the frequency at the edge of the start of the passband. Specify the value in either normalized frequency units or the absolute units you selected for **Frequency units**.

Passband frequency 2 — Frequency at edge of end of passband

.55 (default) | positive scalar

Enter the frequency at the edge of the end of the passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Stopband frequency 2 — Frequency at edge of start of second stopband

.65 (default) | positive scalar

Enter the frequency at the edge of the start of the second stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Half power (3dB) frequency 1 — Lower frequency 3 dB point

.4 (default) | positive scalar

Specify the lower frequency 3 dB point as a positive scalar between zero and one.

Dependencies

To enable this parameter, set **Impulse response** to IIR, **Order mode** to Specify, and **Frequency constraints** to Half power (3dB) frequencies, Half power (3dB) frequencies and passband width, or Half power (3dB) frequencies and stopband width.

Half power (3dB) frequency 2 — Higher frequency 3 dB point

.6 (default) | positive scalar

Specify the higher frequency 3 dB point as a positive scalar between zero and one.

Dependencies

To enable this parameter, set **Impulse response** to IIR, **Order mode** to Specify, and **Frequency constraints** to Half power (3dB) frequencies, Half power (3dB) frequencies and passband width, or Half power (3dB) frequencies and stopband width.

Cutoff (6dB) frequency 1 — Lower frequency 6 dB point

.4 (default) | positive scalar

Specify the lower frequency 6 dB point as a positive scalar between zero and one.

Dependencies

To enable this parameter, set **Frequency constraints** to Cutoff (6dB) frequencies.

Cutoff (6dB) frequency 2 — Higher frequency 6 dB point

.6 (default) | positive scalar

Specify the higher frequency 6 dB point as a positive scalar between zero and one.

Dependencies

To enable this parameter, set **Frequency constraints** to Cutoff (6dB) frequencies.

Passband width — Passband width

.15 (default) | positive scalar

Specify the width of the passband as a positive scalar, in units corresponding to the **Frequency units** parameter.

Dependencies

To enable this parameter, set **Frequency constraints** to Half power (3dB) frequencies and passband width.

Stopband width — Width of stopband

.25 (default) | positive scalar

Specify the width of the stopband as a positive scalar, in units corresponding to the **Frequency units** parameter.

Dependencies

To enable this parameter, set **Frequency constraints** to Half power (3dB) frequencies and stopband width.

Magnitude constraints — Magnitude constraints

Unconstrained (default) | Constrained bands | Passband ripple | Passband ripple and stopband attenuation | Stopband attenuation

Specify the magnitude constraints for the filter design.

Dependencies

To enable this parameter, set **Order mode** to Specify. The available options depend on the value of the **Frequency constraints** parameters.

Magnitude units — Units for magnitude specifications

dB (default) | Linear | Squared

Specify the units for any parameter you provide in magnitude specifications:

- Linear — Specify the magnitude in linear units.
- dB — Specify the magnitude in decibels (default).
- Squared — Specify the magnitude in squared units.

Dependencies

To enable this parameter, set **Order mode** to Minimum.

Stopband attenuation 1 — Filter attenuation in first stopband

60 (default) | real-valued positive scalar

Enter the filter attenuation in the first stopband in the units you choose for **Magnitude units**. Values must be real, positive scalars. If you are specifying values in linear units, they must be smaller than 1.

Dependencies

To enable this parameter, set the **Order mode** to Minimum.

Passband ripple — Allowable filter ripple in passband

1 (default) | real-valued positive scalar

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**. Values must be real, positive scalars. If you are specifying values in linear units, they must be smaller than 1.

Dependencies

To enable this parameter, set the **Order mode** to Minimum.

Stopband attenuation 2 — Filter attenuation in second stopband

60 (default) | real-valued positive scalar

Enter the filter attenuation in the second stopband in the units you choose for **Magnitude units**. Values must be real, positive scalars. If you are specifying values in linear units, they must be smaller than 1.

Dependencies

To enable this parameter, set the **Order mode** to Minimum.

Design method — Filter design method

Equiripple (default) | Kaiser window | Butterworth | Chebyshev type I | Chebyshev type II | Elliptic

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is Equiripple.

Scale SOS filter coefficients to reduce chance of overflow — Scale filter coefficients

on (default) | off

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling.

Dependencies

To enable this parameter, set **Impulse response** to IIR.

Density factor — Density factor

16 (default) | positive scalar

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times `filter_order + 1`.

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable balance between the accurate approximation to the ideal filter and the time to design the filter.

Dependencies

To enable this parameter, set **Impulse response** to FIR and **Design method** to Equiripple.

Phase constraint — Phase constraint

Linear (default) | Maximum | Minimum

Specify the phase constraint of the filter as Linear, Maximum, or Minimum.

Dependencies

To enable this parameter, set **Impulse response** to FIR and **Design method** to Equiripple.

Match exactly — Match passband, stopband, or both

Stopband (default) | Passband | Both

Specifies that the resulting filter design matches either the passband, stopband, or both bands.

Dependencies

To enable this parameter, set **Impulse response** to IIR.

Minimum order — Minimum filter order

Any (default) | Even | Odd

When you select this parameter, the design method determines and designs a minimum order filter to meet your specifications.

Dependencies

To enable this parameter, set **Impulse response** to FIR and **Order mode** to Minimum.

Structure — Filter structure

Direct-form FIR (default) | Direct-form FIR transposed | Direct-form symmetric FIR | Cascade minimum-multiplier allpass | Cascade wave digital filter allpass |

Direct-form I SOS | Direct-form I transposed SOS | Direct-form II SOS | Direct-form II transposed SOS

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use basic elements to enable filter customization — Implement filter with basic Simulink blocks

off (default) | on

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements.

Dependencies

When you select this check box, the block enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of n unit delays with a single delay by n .
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Optimize for unit-scale values — Optimize unit scale values

off (default) | on

Select this check box to scale unit gains between sections in SOS filters.

Dependencies

To enable this parameter, set **Impulse response** to IIR.

Rate options — Enforce single-rate or allow multirate processing

Enforce single-rate processing (default) | Allow multirate processing

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block:

- **Enforce single-rate processing** — When you select this option, the block maintains the sample rate of the input.
- **Allow multirate processing** — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples.

Dependencies

To enable this parameter, set the **Impulse response** to FIR and set **Filter type** to a multirate filter.

Use symbolic names for coefficients — Specify coefficients with MATLAB variables

off (default) | on

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code.

Block Characteristics

Data Types	double single
Multidimensional Signals	No
Variable-Size Signals	No

Version History

Introduced in R2006b

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The Bandpass Filter block supports SIMD code generation using Intel AVX2 technology under these conditions:

- **Impulse response** is set to FIR.
- **Filter type** is set to Single-rate.
- **Structure** is set to Direct-form FIR or Direct-form FIR transposed.
- **Use basic elements to enable filter customization** parameter is not selected.
- **Input processing** is set to Columns as channels (frame based).
- Input signal has a data type of single or double.

The SIMD technology significantly improves the performance of the generated code.

Bandstop Filter

Design bandstop filter

Library: DSP System Toolbox / Filtering / Filter Designs

Description

This block brings the filter design capabilities of the `filterBuilder` function to the Simulink environment.

This block supports SIMD code generation. For details, see “Code Generation” on page 2-115.

Ports

Input

Port_1 – Input signal

scalar | vector | matrix

Input signal to filter, specified as a scalar, vector, or matrix.

Data Types: `single` | `double`

Output

Port_1 – Filtered output signal

scalar | vector | matrix

Filtered output signal, specified as a scalar, vector, or matrix.

Data Types: `single` | `double`

Parameters

View Filter Response – Open Filter Visualization Tool

button

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Impulse response — FIR or IIR filter

FIR (default) | IIR

Specify whether the block implements an FIR or IIR filter.

Note The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Order mode — Mode of specifying filter order

Minimum (default) | Specify

Select Minimum to have the block implement a filter with minimum order. When you select Specify, you must enter the filter order using the **Order** parameter.

Tip When you set the **Impulse response** to IIR, you can specify different numerator and denominator orders. To specify a different denominator order, select the **Denominator order** check box.

Order — Filter order

20 (default) | positive integer

Specify the filter order as a positive integer.

Dependencies

To enable this parameter, set **Order mode** to Specify.

Denominator order — Specify denominator order

off (default) | on

Select this check box to specify a different denominator order. When you select this check box, you can specify the denominator order as a positive integer in the resulting text box.

Dependencies

To enable this parameter, set the **Impulse response** to IIR and the **Order mode** to Specify.

Filter type — Type of filter

Single-rate (default) | Decimator | Interpolator | Sample-rate converter

Select the type of filter to implement. Your choice determines the type of filter and the design methods and structures that are available to implement your filter.

Dependencies

- This parameter applies only when you set **Impulse response** to FIR.
- Selecting Decimator or Interpolator activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting Sample-rate converter activates both factors.

Decimation Factor — Decimation factor

2 (default) | positive integer

Specify the decimation factor as a positive integer.

Dependencies

To enable this parameter, set the **Filter type** to Decimator or Sample-rate converter.

Interpolation Factor — Interpolation factor

2 (default) | positive integer

Specify the interpolation factor as a positive integer.

Dependencies

To enable this parameter, set the **Filter type** to Interpolator or Sample-rate converter.

Frequency constraints — Frequency response constraints

Passband and stopband edges (default) | Passband edges | Half power (3dB) frequencies | Half power (3dB) frequencies and passband width | Half power (3dB) frequencies and stopband width | Cutoff (6dB) frequencies

When you set the **Order mode** to Specify, this parameter allows you to choose the filter features that the block uses to define the frequency response characteristics. Depending on the **Impulse response** you choose, you can set the **Frequency constraints** to one of:

- **Passband and stopband edges** — Specify the frequencies for the edges for the stop- and passbands.
- **Passband edges** — For IIR filters, define the filter by specifying frequencies for the edges of the passband.
- **Stopband edges** — For IIR filters, define the filter by specifying frequencies for the edges of the stopbands.
- **Half power (3dB) frequencies** — For IIR filters, define the filter response by specifying the locations of the 3 dB points. The 3 dB point is the frequency for the point three decibels below the passband value.
- **Half power (3dB) frequencies and passband width** — For IIR filters, define the filter by specifying frequencies for the 3 dB points in the filter response and the width of the passband.
- **Half power (3dB) frequencies and stopband width** — For IIR filters, define the filter by specifying frequencies for the 3 dB points in the filter response and the width of the stopband.
- **Cutoff (6dB) frequencies** — For FIR filters, define the filter response by specifying the locations of the 6 dB points. The 6 dB point is the frequency for the point 6 dB below the passband value.

Dependencies

To enable this parameter, set the **Order mode** to Specify. The available **Frequency constraints** will depend on whether the **Impulse response** is FIR or IIR.

Frequency units — Frequency units

Normalized (0 to 1) (default) | Hz | kHz | MHz | GHz

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0 to 1)** to enter frequencies in normalized form. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz.

Input sample rate — Input sample rate

2 (default) | positive scalar

F_s , specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well.

Dependencies

To enable this parameter, set **Filter type** to Single-rate, Decimator, or Sample-rate converter and **Frequency units** to one of the unit options (Hz, kHz, MHz, or GHz).

Output sample rate — Output sample rate

2 (default) | positive scalar

When you design an interpolator, F_s represents the sampling frequency at the filter output rather than the filter input.

Dependencies

To enable this parameter, set **Filter type** to Interpolator and **Frequency units** to one of the unit options (Hz, kHz, MHz, or GHz).

Passband frequency 1 — Frequency at edge of end of first passband

0.35 (default) | positive scalar

Enter the frequency at the edge of the end of the first passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Stopband frequency 1 — Frequency at edge of start of stopband

0.45 (default) | positive scalar

Enter the frequency at the edge of the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Stopband frequency 2 — Frequency at edge of end of stopband

0.55 (default) | positive scalar

Enter the frequency at the edge of the end of the stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Passband frequency 2 — Frequency at edge of start of second passband

0.65 (default) | positive scalar

Enter the frequency at the edge of the start of the second passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Half power (3dB) frequency 1 — Lower frequency 3 dB point

0.4 (default) | positive scalar

Specify the lower frequency 3 dB point as a positive scalar between zero and one.

Dependencies

To enable this parameter, set **Impulse response** to IIR, **Order mode** to Specify, and **Frequency constraints** to Half power (3dB) frequencies, Half power (3dB) frequencies and passband width, or Half power (3dB) frequencies and stopband width.

Half power (3dB) frequency 2 — Higher frequency 3 dB point

0.6 (default) | positive scalar

Specify the higher frequency 3 dB point as a positive scalar between zero and one.

Dependencies

To enable this parameter, set **Impulse response** to IIR, **Order mode** to Specify, and **Frequency constraints** to Half power (3dB) frequencies, Half power (3dB) frequencies and passband width, or Half power (3dB) frequencies and stopband width.

Cutoff (6dB) frequency 1 — Lower frequency 6 dB point

0.4 (default) | positive scalar

Specify the lower frequency 6 dB point as a positive scalar between zero and one.

Dependencies

To enable this parameter, set **Frequency constraints** to Cutoff (6dB) frequencies.

Cutoff (6dB) frequency 2 — Higher frequency 6 dB point

0.6 (default) | positive scalar

Specify the higher frequency 6 dB point as a positive scalar between zero and one.

Dependencies

To enable this parameter, set **Frequency constraints** to Cutoff (6dB) frequencies.

Passband width — Passband width

0.25 (default) | positive scalar

Specify the width of the passband as a positive scalar, in units corresponding to the **Frequency units** parameter.

Dependencies

To enable this parameter, set **Frequency constraints** to Half power (3dB) frequencies and passband width.

Stopband width — Width of stopband

0.15 (default) | positive scalar

Specify the width of the stopband as a positive scalar, in units corresponding to the **Frequency units** parameter.

Dependencies

To enable this parameter, set **Frequency constraints** to Half power (3dB) frequencies and stopband width.

Magnitude constraints — Magnitude constraints

Unconstrained (default) | Constrained bands | Passband ripples and stopband attenuation

Specify the magnitude constraints for the filter design.

Dependencies

To enable this parameter, set **Order mode** to Specify. The available options depend on the value of the **Frequency constraints** parameter.

Magnitude units — Units for magnitude specifications

dB (default) | Linear | Squared

Specify the units for any parameter you provide in magnitude specifications:

- Linear — Specify the magnitude in linear units.
- dB — Specify the magnitude in decibels (default).
- Squared — Specify the magnitude in squared units.

Dependencies

To enable this parameter, set **Order mode** to Minimum.

Passband ripple 1 — Allowable filter ripple in first passband

1 (default) | real-valued positive scalar

Specify the filter ripple allowed in the first passband in the units you choose for **Magnitude units**. Values must be real, positive scalars. If you are specifying values in linear units, they must be smaller than 1.

Dependencies

To enable this parameter, set the **Order mode** to Minimum.

Stopband attenuation — Stopband attenuation

60 (default) | real-valued positive scalar

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**. Values must be real, positive scalars. If you are specifying values in linear units, they must be smaller than 1.

Dependencies

To enable this parameter, set the **Order mode** to Minimum.

Passband ripple 2 — Allowable filter ripple in second passband

1 (default) | real-valued positive scalar

Enter the filter ripple allowed in the second passband in the units you choose for **Magnitude units**. Values must be real, positive scalars. If you are specifying values in linear units, they must be smaller than 1.

Dependencies

To enable this parameter, set the **Order mode** to Minimum.

Design method — Filter design method

Equiripple (default) | Kaiser window | Butterworth | Chebyshev type I | Chebyshev type II | Elliptic

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods

available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is Equiripple.

Scale SOS filter coefficients to reduce chance of overflow — Scale filter coefficients

on (default) | off

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling.

Dependencies

To enable this parameter, set **Impulse response** to IIR.

Density factor — Density factor

16 (default) | positive scalar

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable balance between the accurate approximation to the ideal filter and the time to design the filter.

Dependencies

To enable this parameter, set **Impulse response** to FIR and **Design method** to Equiripple.

Phase constraint — Phase constraint

Linear (default) | Maximum | Minimum

Specify the phase constraint of the filter as Linear, Maximum, or Minimum.

Dependencies

To enable this parameter, set **Impulse response** to FIR and **Design method** to Equiripple.

Minimum order — Minimum filter order

Any (default) | Even

When you select this parameter, the design method determines and designs a minimum order filter to meet your specifications.

Dependencies

To enable this parameter, set **Impulse response** to FIR, **Order mode** to Minimum, and **Design method** to Kaiser window.

Match exactly — Match passband, stopband, or both

Stopband (default) | Passband | Both

Specifies that the resulting filter design matches either the passband, stopband, or both bands.

Dependencies

To enable this parameter, set **Impulse response** to IIR.

Structure – Filter structure

Direct-form FIR (default) | Direct-form FIR transposed | Direct-form symmetric FIR | Cascade minimum-multiplier allpass | Cascade wave digital filter allpass | Direct-form I SOS | Direct-form I transposed SOS | Direct-form II SOS | Direct-form II transposed SOS

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use basic elements to enable filter customization – Implement filter with basic Simulink blocks

off (default) | on

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements.

Dependencies

When you select this check box, the block enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of n unit delays with a single delay of n .
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Optimize for unit scale values – Optimize unit scale values

off (default) | on

Select this check box to scale unit gains between sections in SOS filters.

Dependencies

To enable this parameter, set **Impulse response** to IIR.

Rate options – Enforce single-rate or allow multirate processing

Enforce single-rate processing (default) | Allow multirate processing

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block:

- **Enforce single-rate processing** — When you select this option, the block maintains the sample rate of the input.
- **Allow multirate processing** — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples.

Dependencies

To enable this parameter, set the **Impulse response** to FIR and set **Filter type** to a multirate filter.

Use symbolic names for coefficients – Specify coefficients with MATLAB variables

off (default) | on

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code.

Bandpass Filter

Functions

filterBuilder | fdesign.bandpass

Binary File Reader

Read data from binary files

Library: DSP System Toolbox / Sources

Description

The Binary File Reader block reads multichannel signal data from a binary file. The block reads the header that precedes the data. The **File header** parameter specifies the structure of the header. You can specify the type, size, and complexity of the data through the block parameters. You can also export the header to the base workspace by clicking on the **Export header to base workspace** button.

The first time you read the file, the reader reads the header, followed by the data. On subsequent calls, the reader reads the remaining data. Once the end of the file is reached, the reader returns zeros of the specified data type, size, and complexity. The reader can read signal data from a binary file that is not created by the Binary File Writer block.

Output Ports

Output

data — Binary file data

column vector | row vector | matrix

The reader block reads the binary data from the file specified in the **File name** parameter. The data output from the block has dimensions **Samples per frame-by-Number of channels**. The block can read floating-point data and integer data. The input data can be real or complex. When the data is complex, the block reads the data as interleaved real and imaginary components. The reader assumes the default endianness of the host machine.

This port is unnamed until you select the **Output end-of-file indicator** parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

EOF — End-of-file indicator

boolean scalar

When the block reaches the end of the file, the port outputs a 1. Otherwise, the port outputs a 0.

This port is unnamed until you select the **Output end-of-file indicator** parameter.

Data Types: Boolean

Parameters

File name — Name of the file

'Untitled.bin' (default) | character vector

Name of the file from which the block reads the data. If the file is not on the MATLAB path, then specify the full path for the file.

File header — Size of the header

`struct([])` (default) | structure

The structure specifies the prototype of the file header, that is, the size of the header and the data type of the field values. The structure can have an arbitrary number of fields. Each field of the structure must be a real matrix of a built-in type. For example, if **File header** is set to `struct('field1',1:10,'field2',single(1))`, the block assumes that the header is formed by 10 real double-precision values followed by 1 single-precision value. If the file contains no header, you can set this parameter to an empty structure, `struct([])`.

Export header to base workspace — Retrieve the header

button

To retrieve the file header, click **Export header to base workspace**. The block exports the file header to the base workspace.

Storage data type — Storage class of data in file

'double' (default) | 'single' | 'int8' | 'int16' | 'int32' | 'int64' | 'uint8' | 'uint16' | 'uint32' | 'uint64'

Storage class of data in file, specified as a character vector. This parameter defines the data type of the matrix the block outputs.

Samples per frame — Number of samples per output frame

1024 (default) | positive integer

Samples per frame specifies the number of rows of the output matrix that the block outputs. The output matrix has dimensions **Samples per frame**-by-**Number of channels**. Once the end of the file is reached, the block returns zeros of the specified data type, size, and complexity.

Data is complex — Specify data complexity

off (default) | on

When you select this parameter, the reader treats the data as complex data. The block reads the data as interleaved real and imaginary components. Configure the block to read the data as a 2-by-2 matrix. The block reads [1 5 2 6 3 7 4 8] as [1 2; 3 4]+1j*[5 6; 7 8]. When you do not select this parameter, the block reads the data as [1 5; 2 6].

Number of channels — Number of channels

1 (default) | positive integer

Number of channels specifies the number of columns of the output matrix that the block outputs. This parameter defines the number of consecutive interleaved data samples stored in the file for each

time instant. The size of the data is **Samples per frame-by-Number of channels**. Once the end of the file is reached, if the output matrix is not full, the block fills the matrix with zeros to make it a full-sized matrix.

Output end-of-file indicator — End-of-file indicator

off (default) | on

When you select this parameter, an additional output port named **EOF** appears on the block. When the block reaches the end of the file, the port outputs a 1. Otherwise, the port outputs a 0.

Sample time (s) — Sample time

1 (default) | nonnegative scalar

Sample time (s) controls the sample time at the output port of the block. This value represents $1/F_s$, where F_s is the sampling rate of the signal data. The Simulink sample time at the output port is **Samples per frame × Sample time (s)**.

Simulate using — Type of simulation to run

Code generation (default) | Interpreted execution

Specify the type of simulation to run as one of the following:

- **Code generation** -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than **Interpreted execution**.
- **Interpreted execution** -- Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than **Code generation**.

Block Characteristics

Blocks

Binary File Writer | Audio Device Writer

Objects

`dsp.BinaryFileWriter` | `dsp.BinaryFileReader` | `dsp.MatFileWriter`

Binary File Writer

Write data to binary files

Library: DSP System Toolbox / Sinks

Description

The Binary File Writer block writes multichannel signal data to a binary file. The block specifies the name of the file and the structure of the header that precedes the signal data. If there is no header to write, the block specifies an empty structure, `struct([])`. The first time you write to the file, the block writes the header, followed by the data. On subsequent calls, the block writes the remaining data. If the header is empty, then no header is written.

The block writes the data in a row-major format. For example, if the input array is `[1 2 4 5; 8 7 9 2]`, the block writes the data as `[1 2 4 5 8 7 9 2]`.

Input Ports

Input

Port_1 — Data to write

column vector | row vector | matrix

The writer block writes the data to the file specified in the **File name** parameter. If the **File header** structure is not empty, then the writer writes the header before writing the data. The block can write floating-point data and integer data. The input data can be real or complex. When the data is complex, the block writes the data as interleaved real and imaginary components. The writer assumes the default endianness of the host machine.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Parameters

File name — Name of the file

'Untitled.bin' (default) | character vector

Name of the file to which the block writes the data.

File header — Size of the header

`struct([])` (default) | structure

The structure can have an arbitrary number of fields. Each field of the structure must be a real matrix of a built-in type. For example, if **File header** is set to `struct('field1',1:10,'field2',single(1))`, the block writes a header formed by 10 double-

precision values, (1:10), followed by 1 single precision value, `single(1)`. If there is no header to write, set this parameter to an empty structure, `struct([])`.

Simulate using – Type of simulation to run

Code generation (default) | Interpreted execution

Specify the type of simulation to run as one of the following:

- `Code generation` -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.
- `Interpreted execution` -- Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

Biquad Filter

Model biquadratic IIR (SOS) filters

Library: DSP System Toolbox / Filtering / Filter Implementations
 DSP System Toolbox HDL Support / Filtering

Description

The Biquad Filter block independently filters each channel of the input signal with the specified biquadratic infinite impulse response (IIR) filter. When you specify the filter coefficients in the dialog box, the block implements static filters with fixed coefficients. When you provide the filter coefficients through an input port, you can tune the coefficients during simulation.

The Biquad Filter block supports the Simulink state logging feature. See “State” (Simulink) for more information.

Ports

Input

In — Data input

vector | matrix

Data input to the block, specified as a vector or a matrix. This block supports variable-size input signals, enabling you to change the input frame size (number of rows) during simulation. However, the number of channels (number of columns) must remain constant.

If the input is fixed-point, it must be signed fixed-point with binary point scaling.

This port is unnamed unless you set the **Coefficient source** to `Input port(s)`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fixed point`

Num — Numerator coefficients

matrix

Numerator coefficients of the biquad filter, specified as a 3-by- N matrix, where N is the number of biquad filter sections.

If **Num** is fixed-point, it must be signed fixed-point with binary point scaling.

Dependencies

This port appears only when you set the **Coefficient source** to `Input port(s)`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fixed point`

Den — Denominator coefficients

matrix

Denominator coefficients of the biquad filter, specified as a 2-by- N matrix, where N is the number of biquad filter sections.

If **Den** is fixed-point, it must be signed fixed-point with binary point scaling.

Dependencies

This port appears only when you set the **Coefficient source** to `Input port(s)`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fixed point`

g — Scale values

row vector

Scale values of the biquad filter, specified as a 1-by- $(N+1)$ vector, where N is the number of biquad filter sections.

If **g** is fixed-point, it must be signed fixed-point with binary point scaling.

Dependencies

This port appears only when you set the **Coefficient source** to `Input port(s)`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fixed point`

Output

Out — Filtered output

vector | matrix

Filtered output, returned as a vector or a matrix.

The output dimensions always equal the dimensions of the input signal. The output of this block numerically matches the outputs of the `dsp.BiquadFilter` System object.

If **Out** is fixed-point, it must be signed fixed-point with binary point scaling.

This port is unnamed unless you set the **Coefficient source** to `Input port(s)`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fixed point`

Parameters

Main Tab

Coefficient source — Mode of operation

Dialog parameters (default) | `Input port(s)` | `Filter object`

The Biquad Filter block can operate in three different modes:

- `Dialog parameters` — Enter information about the filter, such as structure and coefficients, in the block mask.
- `Input port(s)` — Enter information about the filter structure in the block mask using the **Filter structure** parameter. The filter coefficients come into the block through additional input ports that appear on the block icon:

- **Num** — Specify numerator coefficients.
- **Den** — Specify denominator coefficients.
- **g** — Specify scale values.

The block assumes the first denominator coefficients and of each section to be 1. This configuration is applicable when the `SOSMatrixSource` property is `'Input port'` and the `ScaleValuesInputPort` property is `true`. The reason you would need to specify `Num` and `Den` instead of the `SOSMatrix`, is that in Fixed-Point operation, the numerators, and denominators can have different fraction lengths. Therefore, there is a need to be able to pass the data of the numerator with a fixed-point type different from that of the denominator.

- **Filter object** — Specify the filter using a `dsp.BiquadFilter` System object.

Filter — Name of filter object

BQF (default) | `dsp.BiquadFilter` System object name

Specify the name of the discrete-time filter that you want the block to implement. You must specify the filter as a `dsp.BiquadFilter` System object.

You can define the System object in the block mask or in a MATLAB workspace variable.

For information on creating System objects, see “Define Basic System Objects”.

Dependencies

This parameter is visible only when **Coefficient source** is set to `Filter object`.

Filter structure — Filter structure

Direct form II transposed (default) | Direct form I | Direct form I transposed | Direct form II

Specify the filter structure.

Dependencies

This parameter is visible only when **Coefficient source** is set to `Dialog parameters` or `Input port(s)`.

SOS Matrix (Mx6) — SOS matrix

[1 0.3 0.4 1 0.1 0.2] (default) | M -by-6 matrix

Specify an M -by-6 matrix, where M is the number of sections in the second-order section filter. Each row of the SOS matrix contains the numerator and denominator coefficients (b_{ik} and a_{ik}) of the corresponding section in the filter.

$$\begin{bmatrix} b_{01} & b_{11} & b_{21} & a_{01} & a_{11} & a_{21} \\ b_{02} & b_{12} & b_{22} & a_{02} & a_{12} & a_{22} \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ b_{0M} & b_{1M} & b_{2M} & a_{0M} & a_{1M} & a_{2M} \end{bmatrix}$$

The leading denominator coefficients [a_{01} a_{02} ... a_{0N}] are treated as 1s, regardless of their actual values. No scaling is applied to the SOS matrix when **a0** is not 1.

The `ss2sos` and `tf2sos` functions convert a state-space or transfer function description of your filter into the second-order section description used by this block.

Dependencies

This parameter is visible only when **Coefficient source** is set to Dialog parameters.

Scale values — Scale values

1 (default) | scalar | vector

Specify scale values to be used between SOS sections. You can specify a real-valued scalar or a vector of length $M+1$:

- When you enter a scalar, the value specifies the gain value before the first section of the second-order filter. The rest of the gain values default to 1.
- When you enter a vector of $M+1$ values, each value specifies a separate section of the filter. For example, the first element is the first gain value, the second element is the second gain value, and so on.

Select the **Optimize unity scale values** check box to optimize your simulation when one or more scale values equal 1. Selecting this option removes the unity gains so that the values are treated like Simulink lines or wires. In some fixed-point cases when there are unity scale values, selecting this parameter also omits certain casts. Refer to the **Fixed-Point Conversion** section under **Extended Capabilities** for more information.

Dependencies

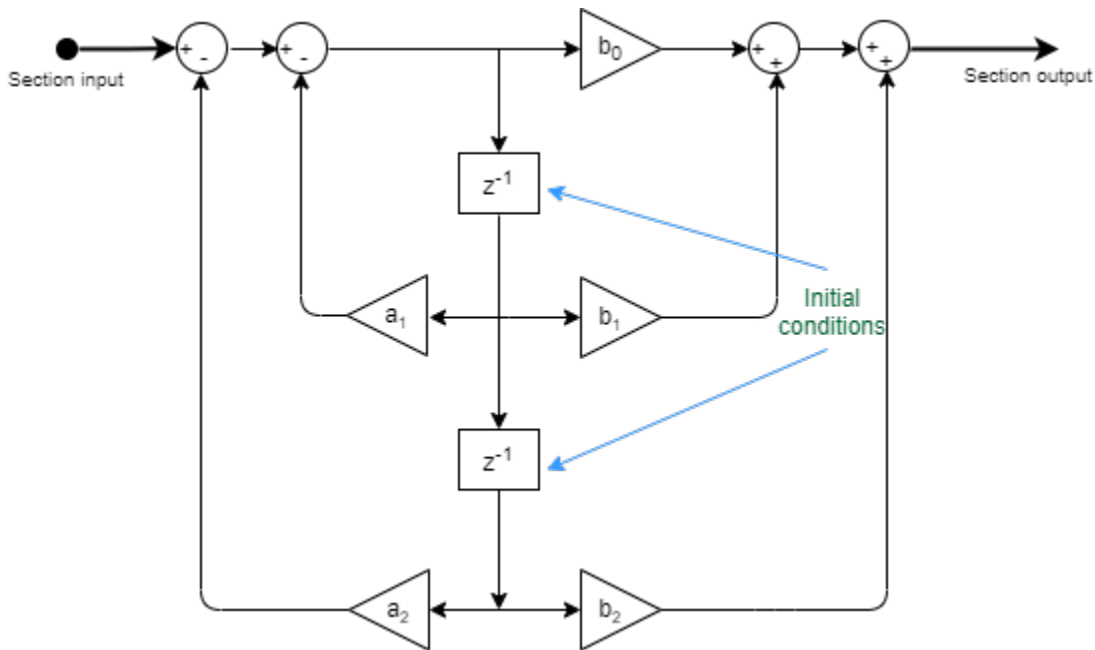

This parameter is visible only when **Coefficient source** is set to Dialog parameters.

Initial conditions — Initial conditions

0 (default) | scalar | vector

Specify the initial conditions of the filter states when **Filter structure** is set to Direct form II or Direct form II transposed.

Direct form II

Direct form II transposed

The Biquad Filter block initializes the internal filter states to zero by default. To specify nonzero initial states for the filter delays, use the **Initial conditions** parameter.

To determine the number of initial conditions you must specify and how to specify them, see the following table on valid initial conditions.

Valid Initial Conditions

Initial Condition	Description
Scalar	The block initializes all delay elements in the filter to the scalar value.
Vector or matrix (for applying different delay elements to each channel)	<p>Each vector or matrix element specifies a unique initial condition for a corresponding delay element in a corresponding channel. M is the number of sections, and N is the number of input channels:</p> <ul style="list-style-type: none"> The vector length must equal the number of delay elements in the filter, $2M$. The matrix must have the same number of rows as the number of delay elements in the filter $2MN$. The matrix must also have one column for each channel of the input signal.

Dependencies

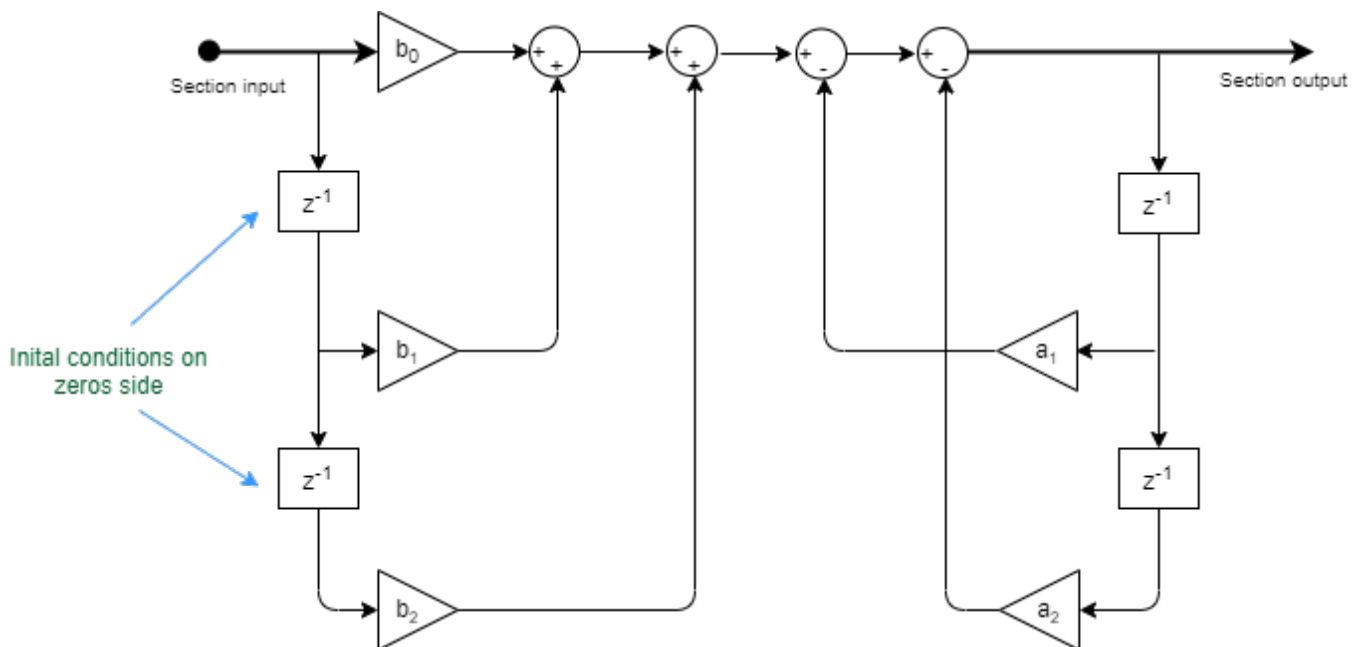

This parameter is only visible when **Coefficient source** is set to Dialog parameters or Input port(s) and the **Filter structure** is set to Direct form II or Direct form II transposed.

Initial conditions on zeros side – Initial conditions on zeros side

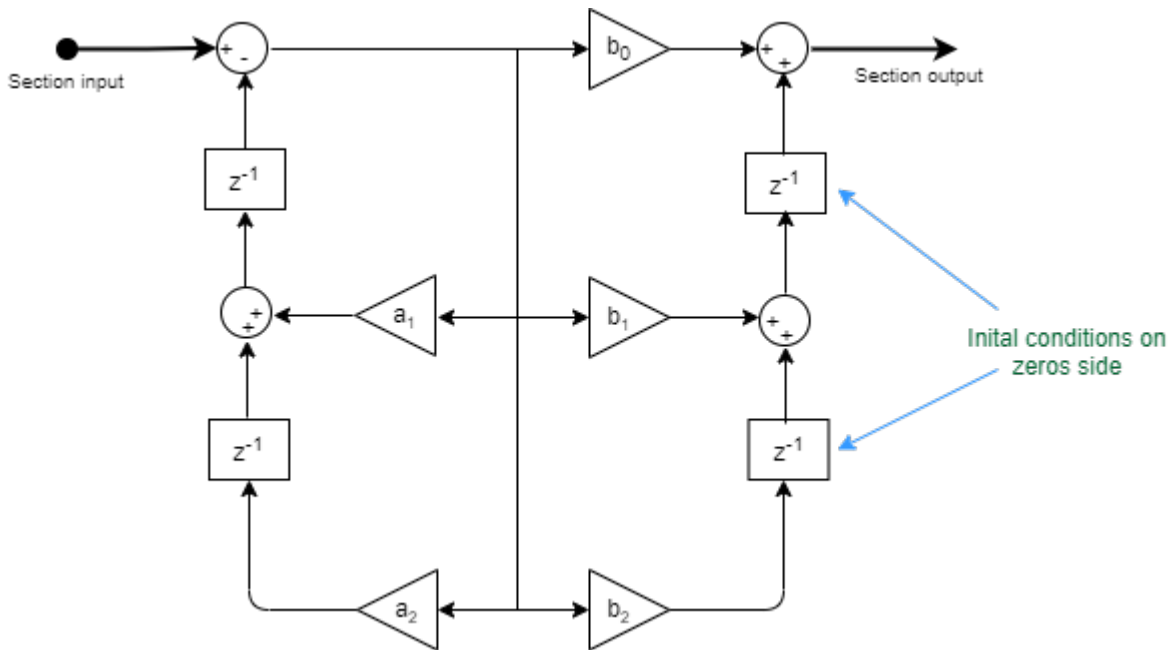

0 (default) | scalar | vector

Specify the initial conditions for the filter states on the side of the filter structure with the zeros (b_0, b_1, b_2, \dots). This parameter applies only when **Filter structure** is set to Direct form I or Direct form I transposed.

Direct form I

Direct form I transposed

The Biquad Filter block initializes the internal filter states to zero by default. To specify nonzero initial states for the filter delays, use the **Initial conditions on zeros side** parameter.

For an example model, type the following model name in the MATLAB command prompt.

```
ex_biquad_filter_ref
```

To determine the number of initial conditions you must specify and how to specify them, see the following table on valid initial conditions.

Valid Initial Conditions

Initial Condition	Description
Scalar	The block initializes all delay elements in the filter to the scalar value.
Vector or matrix (for applying different delay elements to each channel)	Each vector or matrix element specifies a unique initial condition for a corresponding delay element in a corresponding channel. Where M is the number of sections and N is the number of input channels: <ul style="list-style-type: none"> The vector length must equal the number of delay elements in the filter, $2M$. The matrix must have the same number of rows as the number of delay elements in the filter $2MN$. The matrix must also have one column for each channel of the input signal.

Dependencies

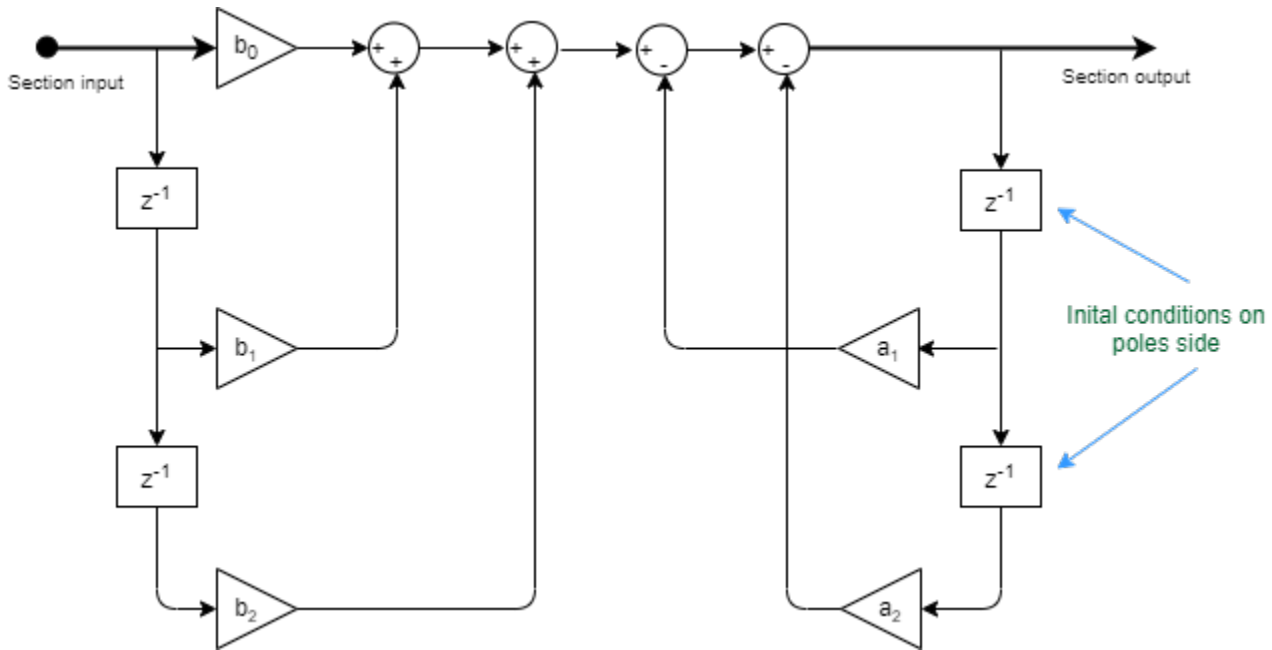

This parameter is visible only when **Coefficient source** is set to Dialog parameters or Input port(s) and the **Filter structure** is set to Direct form I or Direct form I transposed.

Initial conditions on poles side – Initial conditions on poles side

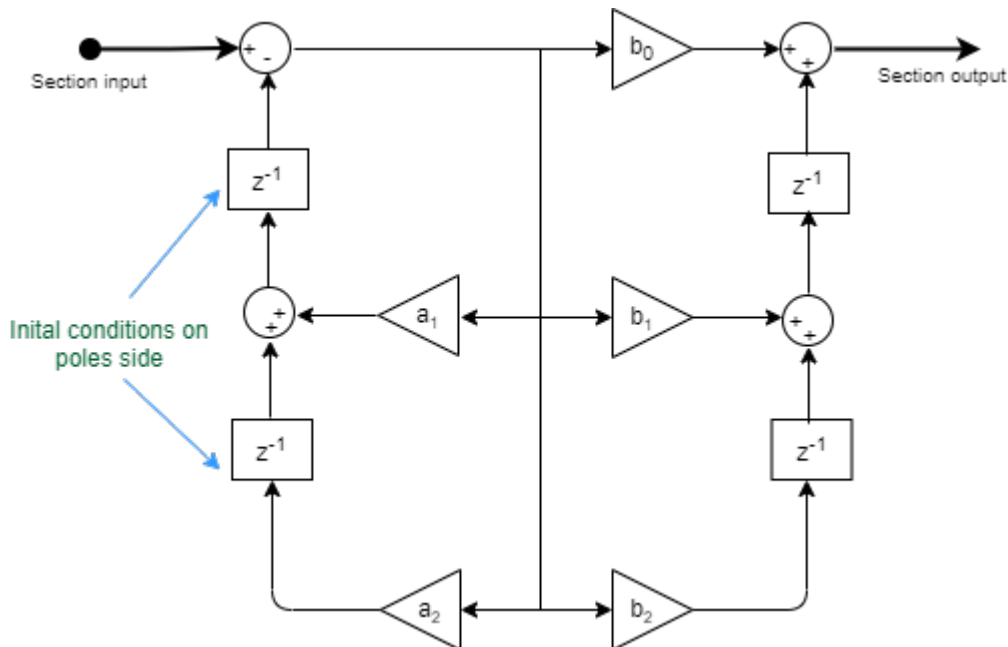

0 (default) | scalar | vector

Specify the initial conditions for the filter states on the side of the filter structure with the poles (a_1 , a_2 , ...). This parameter applies only when **Filter structure** is set to Direct form I or Direct form I transposed.

Direct form I

Direct form I transposed

The Biquad Filter block initializes the internal filter states to zero by default. To specify nonzero initial states for the filter delays, use the **Initial conditions on poles side** parameter.

For an example model, type the following model name in the MATLAB command prompt.

```
ex_biquad_filter_ref
```

To determine the number of initial conditions you must specify and how to specify them, see the following table on valid initial conditions.

Valid Initial Conditions

Initial Condition	Description
Scalar	The block initializes all delay elements in the filter to the scalar value.
Vector or matrix (for applying different delay elements to each channel)	<p>Each vector or matrix element specifies a unique initial condition for a corresponding delay element in a corresponding channel. Where M is the number of sections and N is the number of input channels:</p> <ul style="list-style-type: none"> The vector length must equal the number of delay elements in the filter, $2M$. The matrix must have the same number of rows as the number of delay elements in the filter $2MN$. The matrix must also have one column for each channel of the input signal.

Dependencies

This parameter is visible only when **Coefficient source** is set to `Dialog parameters` or `Input port(s)` and the **Filter structure** is set to `Direct form I` or `Direct form I transposed`.

Scale values mode — Mode to specify scale values

`Specify via input port (g)` (default) | `Assume all are unity and optimize`

Choose how to specify the scale values to use between filter sections. When you select `Specify via input port (g)`, you enter the scale values as a 2-D vector at port **g**. When you select `Assume all are unity and optimize`, all scale values are removed and treated like Simulink lines or wires.

Dependencies

This parameter is visible only when **Coefficient source** is set to `Input port(s)`.

Action when the a0 values of the SOS matrix are not one — Action when a0 values of SOS matrix are not one

`Warning` (default) | `None` | `Error`

Specify the action the block should perform when the SOS matrix a_{0j} values do not equal one. The action can be `Warning`, `Error`, or `None`.

When you choose `None`, the leading coefficients a_{0j} are treated as 1's, regardless of their actual values. No scaling is applied on the SOS matrix when **a0** is not 1.

Dependencies

This parameter is visible only when **Coefficient source** is set to `Dialog parameters`.

Optimize unity scale values — Optimize unity scale values

`on` (default) | `off`

Select this check box to optimize your simulation when one or more scale values equal 1. Selecting this option removes the unity gains so that the values are treated like Simulink lines or wires. In some fixed-point cases when there are unity scale values, selecting this parameter also omits certain casts. See the **Fixed Point** section under “Extended Capabilities” on page 2-0 for more information.

Dependencies

This parameter is visible only when **Coefficient source** is set to Dialog parameters.

Input processing — Input processing

Columns as channels (frame based) (default) | Elements as channels (sample based)

Specify how the block should process the input. If the input is an M -by- N matrix, you can set this parameter to:

- **Columns as channels (frame based) (default)** — The block treats each column as a separate channel. In this mode, the block creates M instances of the same filter, each with its own independent state buffer. Each of the M filters process N input samples at every Simulink time step.
- **Elements as channels (sample based)** — The block treats each element as a separate channel. In this mode, the block creates MN instances of the same filter, each with its own independent state buffer. Each filter processes one input sample at every Simulink time step.

View Filter Response — View filter response

button

This button opens the Filter Visualization Tool (**FVTool**) and displays the filter response of the filter specified in the dialog.

Note When you make changes to the filter parameters on the block dialog, you must click the **Apply** button before using the **View Filter Response** button.

Data Types Tab

Note This tab appears only when you set **Coefficient source** to either Dialog parameters or Input port(s). When the **Coefficient source** is set to Filter object, the data types specified in the filter object properties are used by the block.

Rounding mode — Rounding mode

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations.

For more details, see rounding mode. The filter coefficients do not obey this parameter; instead, they always round to Nearest.

Saturate on integer overflow — Method of overflow action

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see `overflow mode for fixed-point operations`.

The filter coefficients are always saturated and do not obey this parameter.

Section input — Section input data type

Same as `input (default)` | `Binary point scaling`

Choose how you specify the word and fraction lengths of the fixed-point data type going into each section of a biquadratic filter. See the **Fixed-Point Conversion** section under “**Extended Capabilities**” on page 2-0 for illustrations depicting the use of the section input data type in this block. When you select:

- `Same as input` — Word length and fraction length characteristics of the **Section input** data type match those of the input to the block.
- `Binary point scaling` — Enter the word and fraction lengths of the section input, in bits.

Section output — Section output data type

Same as `section input (default)` | `Binary point scaling`

Choose how you specify the word and fraction lengths of the fixed-point data type coming out of each section of a biquadratic filter. See the **Fixed-Point Conversion** section under **Extended Capabilities** for illustrations depicting the use of the section output data type in this block. When you select:

- `Same as section input` — Word length and fraction length characteristics of the **Section output** data type match with those of the input to the block.
- `Binary point scaling` — Enter the word and fraction lengths of the section output, in bits.

Multiplicand — Multiplicand data type

Same as `output (default)` | `Binary point scaling`

Choose how you specify the word and fraction lengths of the multiplicand data type of a `Direct form I transposed` filter structure. See the **Fixed-Point Conversion** section under **Extended Capabilities** for illustrations depicting the use of the multiplicand data type in this block.

When you select:

- `Same as output` — Word length and fraction length characteristics of the **Multiplicand** data type match with those of the output of the block.
- `Binary point scaling` — Enter the word length and the fraction length of the multiplicand, in bits.

Dependencies

This parameter is visible only when the **Filter structure** parameter is set to `Direct form I transposed`.

Coefficients — Coefficients data type

Same word length as `input (default)` | `Specify word length` | `Binary point scaling`

Choose how you specify the word and fraction lengths of the filter coefficients (numerator, denominator, and scale value) when **Coefficient source** is set to **Dialog** parameters. See the **Fixed-Point Conversion** section under **Extended Capabilities** for illustrations depicting the use of the coefficient data types in this block. When you select:

- **Same word length as input** — Word length of the filter coefficients matches that of the input to the block. In this mode, the block automatically sets the fraction length of the coefficients to the binary point-only scaling that provides the best precision possible given the value and word length of the coefficients.
- **Specify word length** — Enter the word length of the coefficients, in bits. In this mode, the block automatically sets the fraction length of the coefficients to the binary point-only scaling that provides the best precision possible given the value and word length of the coefficients.
- **Binary point scaling** — Enter the word length and the fraction length of the coefficients, in bits. If applicable, enter separate fraction lengths for the numerator and denominator coefficients.

The filter coefficients do not obey the **Rounding mode** and the **Overflow mode** parameters; instead, they are always saturated and rounded to Nearest.

Dependencies

This parameter is visible only when **Coefficient source** is set to **Dialog** parameters.

Product output — Product output data type

Same as input (default) | Inherit via internal rule | Binary point scaling

Specify how to designate the product output word and fraction lengths. See “Multiplication Data Types” and the **Fixed-Point Conversion** section under **Extended Capabilities** for illustrations depicting the use of the product output data type in this block. When you select:

- **Same as input** — Product output word length and fraction length characteristics match those of the input to the block.
- **Inherit via internal rule** — Product output word length and fraction lengths are computed based on full-precision rules. These rules prevent quantization from occurring within the block. Bits are added, as needed, so that no roundoff or overflow occurs. For more details, see “Inherit via Internal Rule”.
- **Binary point scaling** — Enter the word length and the fraction length of the product output, in bits. If applicable, enter separate fraction lengths for the numerator and denominator product output data type.

Accumulator — Accumulator data type

Same as product output (default) | Same as input | Binary point scaling

Specify how to designate the accumulator word and fraction lengths. See “Multiplication Data Types” and the **Fixed-Point Conversion** section under **Extended Capabilities** for illustrations depicting the use of the accumulator data type in this block. When you select:

- **Same as input** — Accumulator word and fraction length characteristics match those of the input to the block.
- **Same as product output** — Accumulator word and fraction length characteristics match those of the product output.
- **Binary point scaling** — Enter the word length and the fraction length of the accumulator, in bits. If applicable, enter separate fraction lengths for the numerator and denominator accumulator data type.

States — States data type

Same as accumulator (default) | Same as input | Binary point scaling

Specify how to designate the state word and fraction lengths when **Coefficient source** is set to **Dialog** parameters. See the **Fixed-Point Conversion** section under **Extended Capabilities** for illustrations depicting the use of the state data type in this block.

When you select:

- **Same as input** — State word and fraction length characteristics match those of the input to the block.
- **Same as accumulator** — State word and fraction length characteristics match those of the accumulator.
- **Binary point scaling** — Enter the word length and the fraction length of the state, in bits. If applicable, enter separate fraction lengths for the numerator and denominator state data type.

Dependencies

This parameter is visible only when **Filter structure** is set to **Direct form II** or **Direct form II transposed**.

Output — Output data type

Same as accumulator (default) | Same as input | Binary point scaling

Choose how you specify the output word length and fraction length. See the **Fixed-Point Conversion** section under **Extended Capabilities** for illustrations depicting the use of the output data type in this block. When you select:

- **Same as input** — Output word and fraction length characteristics match those of the input to the block.
- **Same as accumulator** — Output word and fraction length characteristics match those of the accumulator.
- **Binary point scaling** — Enter the word length and the fraction length of the output, in bits.

Lock data type settings against changes by the fixed-point tools — Lock data type settings

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	yes

Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder™ provides additional configuration options that affect HDL implementation and synthesized logic.

For an HDL-optimized biquad filter architecture with hardware-friendly control signals, use the Biquad Filter block. The DSP HDL Toolbox™ block generates a direct form II or direct form II transposed pipelined add-multiply operation that fits into the DSP block on an FPGA. It provides an optional pipelined feedback architecture that uses more multipliers but reduces the critical path and achieves higher clock rates. The DSP HDL Toolbox block does not support programmable coefficients. To perform multichannel filtering, put the DSP HDL Toolbox Biquad Filter block into a For Each subsystem.

Programmable Filter Support

HDL Coder supports programmable filters for Biquad Filter blocks.

- 1 On the filter block mask, set **Coefficient source** to **Input port(s)**.
- 2 Connect vector signals to the **Num** and **Den** coefficient ports. Matrix input signals are not supported for HDL code generation. You must use one Biquad Filter block for each second-order section in your filter. For a filter with M second-order sections, use a series of M Biquad Filter blocks, each with an input **Num** that is a 3-by-1 vector and an input **Den** that is a 2-by-1 vector.

The following limitations apply to the HDL optimizations for a programmable Biquad Filter block:

- Fully serial and partly serial architectures are not supported. **Architecture** must be set to **Fully parallel**.
- Canonical signed digit (CSD) multiplier optimization is not supported. **CoeffMultipliers** must be set to **multiplier**.

Multichannel Filter Support

HDL Coder supports the use of vector inputs to Biquad Filter blocks.

- 1 Connect a vector signal to the Biquad Filter block input port.
- 2 Specify **Input processing** as **Elements as channels (sample based)**.
- 3 To reduce area by sharing the filter kernel between channels, set the **StreamingFactor** parameter of the subsystem to the number of channels. See the Streaming section of “Subsystem Optimizations for Filters” (HDL Coder).

Serial Architectures

To use block-level optimizations to reduce hardware resources, select a serial **Architecture**. Then set either `NumMultipliers` or `Folding Factor`. See “HDL Filter Properties” on page 2-136.

When you select a serial architecture, set **Filter structure** to `Direct form I` or `Direct form II`. The direct form transposed structures are not supported with serial architectures.

AddPipelineRegisters Support

When you use **AddPipelineRegisters**, registers are placed based on the filter structure. The pipeline register placement determines the latency.

Filter Structure	Pipeline Register Placement	Latency (Clock Cycles)
Any	Pipeline registers are added between the filter sections.	NS - 1, where NS is number of sections.

Subsystem Optimizations

This block can participate in subsystem-level optimizations such as sharing, streaming, and pipelining. For the block to participate in subsystem-level optimizations, set **Architecture** to `Fully parallel`. See “Subsystem Optimizations for Filters” (HDL Coder).

HDL Filter Properties

AddPipelineRegisters	Insert a pipeline register between stages of computation in a filter. See also <code>AddPipelineRegisters</code> (HDL Coder).
CoeffMultipliers	Specify the use of canonical signed digit (CSD) optimization to decrease filter area by replacing coefficient multipliers with shift-and-add logic. When you choose a fully parallel filter implementation, you can set CoeffMultipliers to <code>csd</code> or <code>factored-csd</code> . The default is <code>multipliers</code> , which retains multipliers in the HDL. See also <code>CoeffMultipliers</code> (HDL Coder).
FoldingFactor	Specify a serial implementation of an IIR SOS filter by the number of cycles it takes to generate the result. See also <code>FoldingFactor</code> (HDL Coder).
NumMultipliers	Specify a serial implementation of an IIR SOS filter by the number of hardware multipliers that are generated. See also <code>NumMultipliers</code> (HDL Coder).

For more details about HDL filter properties, see “HDL Filter Block Properties” (HDL Coder).

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ <code>ConstrainedOutputPipeline</code> ” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “ <code>InputPipeline</code> ” (HDL Coder).

OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "OutputPipeline" (HDL Coder).
-----------------------	--

Restrictions

- Frame input is not supported for HDL code generation. For frame-based input, use the Biquad Filter block.
- You must set **Initial conditions** to 0. HDL code generation is not supported for nonzero initial states.
- You must select **Optimize unity scale values**.
- You cannot generate HDL for this block inside a Resettable Synchronous Subsystem.

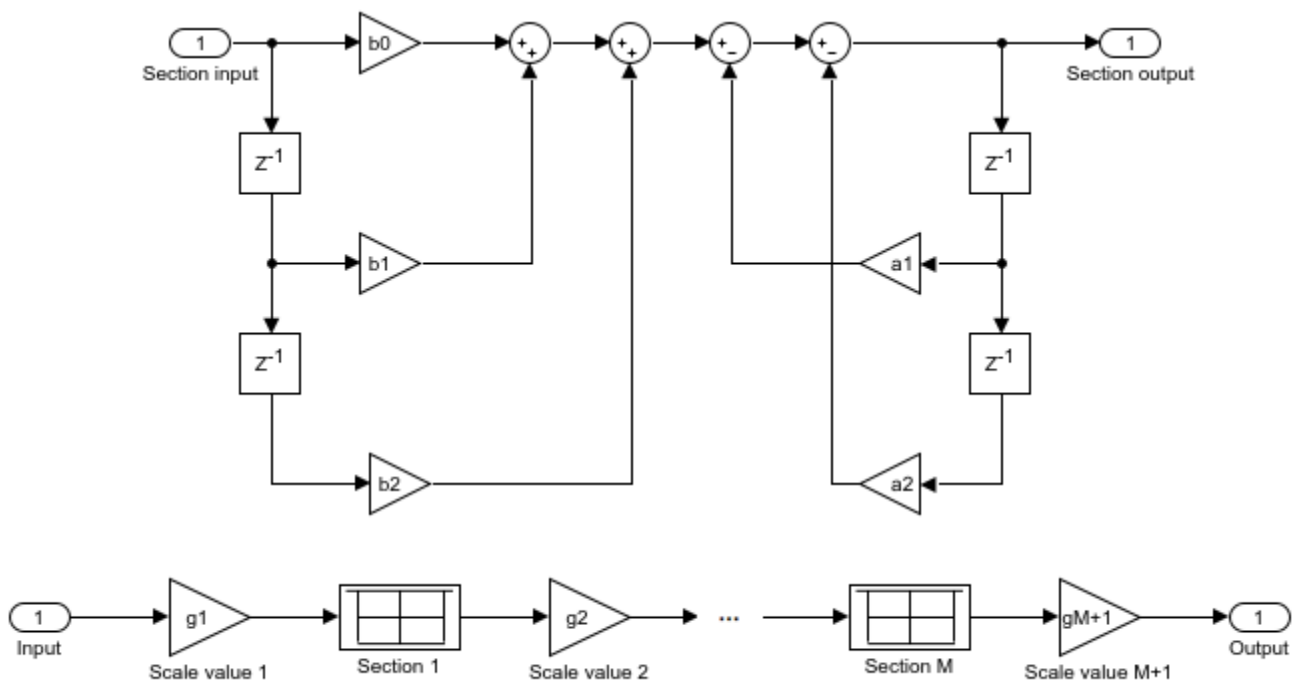

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

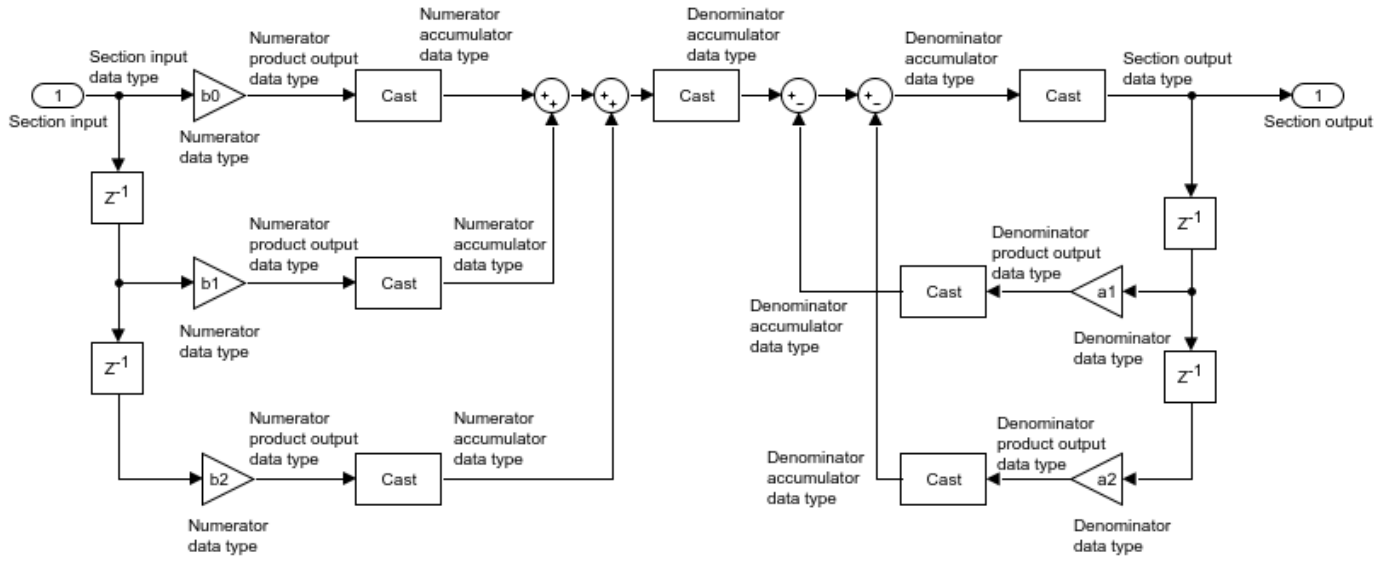

If the input is fixed point, it must be a signed integer or signed fixed point with a power-of-two slope and zero bias.

The diagrams in the following sections show the filter structures supported by the Biquad Filter block. They also show the data types used in the filter structures for fixed-point signals. You can set the data types shown in these diagrams in the block dialog box.

Direct Form I

The following diagram shows the data types for one section of the filter for fixed-point signals.

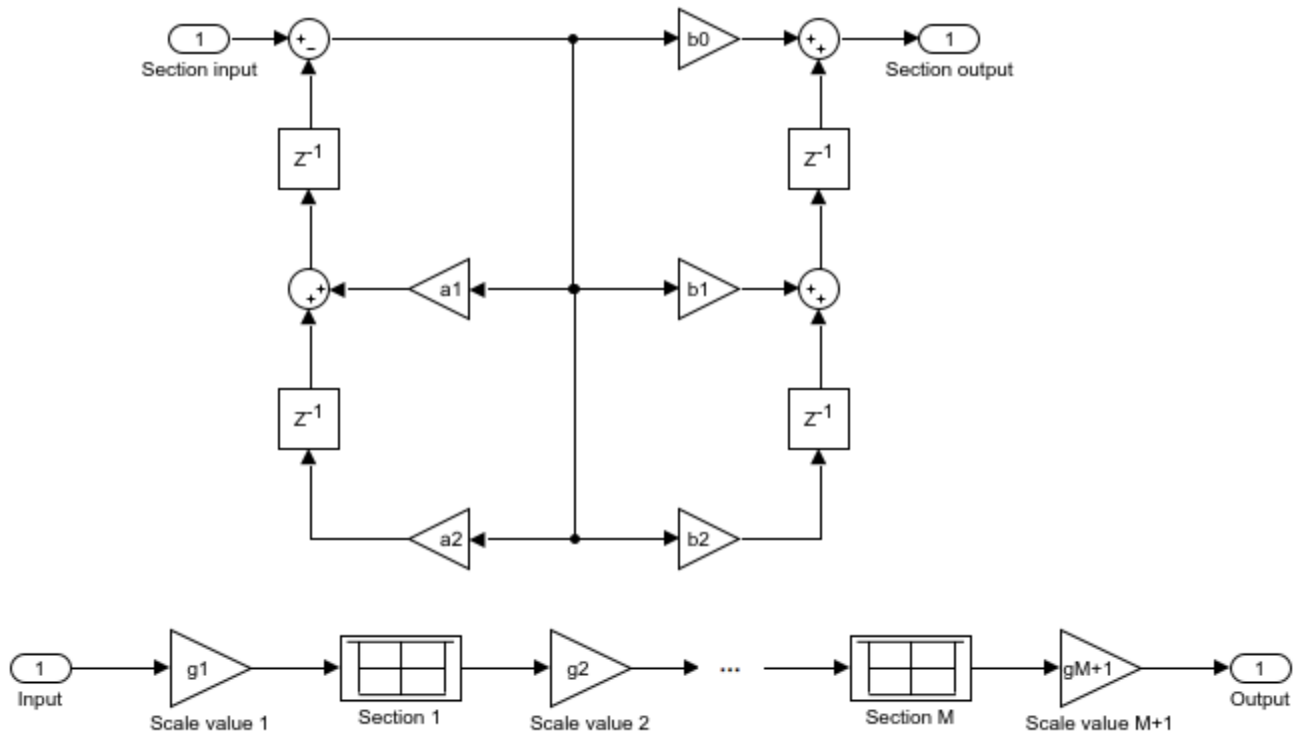

The following diagrams show the fixed-point data types between filter sections.

When the data is not optimized:

When you select **Optimize unity scale values** and scale values equal 1:

Direct Form I Transposed

The following diagram shows the data types for one section of the filter for fixed-point signals.

The dashed casts are omitted when **Optimize unity scale values** is selected and scale values equal one.

`dsp.BiquadFilter`

Blocks

Discrete FIR Filter | Variable Bandwidth FIR Filter | Variable Bandwidth IIR Filter

Block LMS Filter

Compute output, error, and weights using LMS adaptive algorithm

Library

Filtering / Adaptive Filters

dspadpt3

Description

The Block LMS Filter block implements an adaptive least mean-square (LMS) filter, where the adaptation of filter weights occurs once for every block of samples. The block estimates the filter weights, or coefficients, needed to minimize the error, $e(n)$, between the output signal, $y(n)$, and the desired signal, $d(n)$. Connect the signal you want to filter to the **Input** port. The input signal can be a scalar or a column vector. Connect the signal you want to model to the **Desired** port. The desired signal must have the same data type, complexity, and dimensions as the input signal. The **Output** port outputs the filtered input signal. The **Error** port outputs the result of subtracting the output signal from the desired signal.

The block calculates the filter weights using the Block LMS adaptive filter algorithm. This algorithm is defined by the following equations.

$$\begin{aligned}
 n &= kN + i \\
 y(n) &= \mathbf{w}^T(k-1)\mathbf{u}(n) \\
 e(n) &= d(n) - y(n) \\
 \mathbf{w}(k) &= \mathbf{w}(k-1) + f(\mathbf{u}(n), e(n), \mu)
 \end{aligned}$$

The weight update function for the Block LMS adaptive filter algorithm is defined as

$$f(\mathbf{u}(n), e(n), \mu) = \mu \sum_{i=0}^{N-1} \mathbf{u}^*(kN + i)e(kN + i)$$

The variables are as follows.

Variable	Description
n	The current time index
i	The iteration variable in each block, $0 \leq i \leq N - 1$
k	The block number

Variable	Description
N	The block size
$\mathbf{u}(n)$	The vector of buffered input samples at step n
$\mathbf{w}(n)$	The vector of filter-tap estimates at step n
$y(n)$	The filtered output at step n
$e(n)$	The estimation error at time n
$d(n)$	The desired response at time n
μ	The adaptation step size

Use the **Filter length** parameter to specify the length of the filter weights vector.

The **Block size** parameter determines how many samples of the input signal are acquired before the filter weights are updated. The number of rows in the input must be an integer multiple of the **Block size** parameter.

The adaptation **Step-size (mu)** parameter corresponds to μ in the equations. You can either specify a step-size using the input port, Step-size, or enter a value in the Block Parameters: Block LMS Filter dialog box.

Use the **Leakage factor (0 to 1)** parameter to specify the leakage factor, $0 < 1 - \mu\alpha \leq 1$, in the leaky LMS algorithm shown below.

$$\mathbf{w}(k) = (1 - \mu\alpha)\mathbf{w}(k - 1) + f(\mathbf{u}(n), e(n), \mu)$$

Enter the initial filter weights as a vector or a scalar in the **Initial value of filter weights** text box. When you enter a scalar, the block uses the scalar value to create a vector of filter weights. This vector has length equal to the filter length and all of its values are equal to the scalar value

When you select the **Adapt port** check box, an **Adapt** port appears on the block. When the input to this port is greater than zero, the block continuously updates the filter weights. When the input to this port is zero, the filter weights remain at their current values.

When you want to reset the value of the filter weights to their initial values, use the **Reset input** parameter. The block resets the filter weights whenever a reset event is detected at the Reset port. The reset signal rate must be the same rate as the data signal input.

From the **Reset input** list, select **None** to disable the Reset port. To enable the Reset port, select one of the following from the **Reset input** list:

- **Rising edge** — Triggers a reset operation when the Reset input does one of the following:
 - Rises from a negative value to a positive value or zero
 - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure).

- **Falling edge** — Triggers a reset operation when the Reset input does one of the following:
 - Falls from a positive value to a negative value or zero
 - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)

- **Either edge** — Triggers a reset operation when the Reset input is a **Rising edge** or **Falling edge** (as described above)
- **Non-zero sample** — Triggers a reset operation at each sample time that the Reset input is not zero

Select the **Output filter weights** check box to create a **Wts** port on the block. For each iteration, the block outputs the current updated filter weights from this port.

Parameters

Filter length

Enter the length of the FIR filter weights vector.

Block size

Enter the number of samples to acquire before the filter weights are updated. The number of rows in the input must be an integer multiple of the **Block size**.

Specify step-size via

Select **Dialog** to enter a value for μ in the Block parameters: LMS Filter dialog box. Select **Input port** to specify μ using the Step-size input port.

Step-size (μ)

Enter the step-size. Tunable (Simulink).

Leakage factor (0 to 1)

Enter the leakage factor, $0 < 1 - \mu\alpha \leq 1$. Tunable (Simulink).

Initial value of filter weights

Specify the initial values of the FIR filter weights.

Adapt port

Select this check box to enable the Adapt input port.

Reset port

Select this check box to enable the Reset input port.

Output filter weights

Select this check box to export the filter weights from the Wts port.

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.

Buffer

Buffer input sequence to smaller or larger frame size

Library: DSP System Toolbox / Signal Management / Buffers

Description

The Buffer block always performs frame-based processing. The block redistributes the data in each column of the input to produce an output with a different frame size. Buffering a signal to a larger frame size yields an output with a *slower* frame rate than the input. For example, consider this illustration for a scalar input.

Buffering a signal to a smaller frame size yields an output with a *faster* frame rate than the input. For example, consider this illustration of a scalar output.

The block coordinates the output *frame size* and *frame rate* of nonoverlapping buffers such that the sample period of the signal is the same at both the input and output: $T_{so} = T_{si}$.

This block supports triggered subsystems when the block input and output rates are the same.

Ports

Input

Port_1 – Input signal

scalar | vector | matrix

To buffer single-channel signals, input a scalar or column vector. To buffer multichannel signals, input a row vector or matrix. To buffer single-channel signals, input a scalar or column vector of the size M_i -by-1, where M_i is the input frame size.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point

Complex Number Support: Yes

Output

Port_1 — Output signal

vector | matrix

The buffered input signal returned as a vector or a matrix.

When the input is a single-channel signal:

- 1-by-1 (scalar) — Output is an M_o -by-1 vector.
- M_i -by-1 (column vector) — Output is an M_o -by-1 vector.

where

- M_i — Input frame size
- M_o — Value of the **Output buffer size** parameter

The input frame period is $M_i \cdot T_{si}$, where T_{si} is the input sample period. The output frame period is $(M_o - L)T_{si}$, where L is the value of the **Buffer overlap** parameter and T_{si} is the input sample period. When you set the **Buffer overlap** parameter to $M_o - 1$, the output frame period equals the input sample period.

When the input is a multichannel signal:

- 1-by- N — Output is an M_o -by- N matrix.
- M_i -by- N — Output is an M_o -by- N matrix.

where

- N — Number of channels in the signal
- M_i — Input frame period
- M_o is the value of the **Output buffer size** parameter and can be greater or less than the input frame size, M_i . The block buffers each of the N input channels independently.

The input frame period is $M_i \cdot T_{si}$. The output frame period is $(M_o - L)T_{si}$, which equals the sequence sample period when the **Buffer overlap** is $M_o - 1$. Thus, the output sample period T_{so} is related to the input sample period T_{si} by

$$T_{so} = \frac{(M_o - L)T_{si}}{M_i}$$

The output has the same data type and complexity as the input

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point

Complex Number Support: Yes

Parameters

Output buffer size (per channel) — Buffer size

64 (default) | positive integer

Specify the number of consecutive samples, M_o , from each channel to buffer into the output frame.

Data Types: double | int8 | int16 | int32 | uint8 | uint16 | uint32

Buffer overlap – Buffer overlap

0 (default) | integer

Specify the number of samples, L , which specifies the amount of overlap or underlap in each successive output frame.

To overlap the data in the buffer, specify a value of L in the range $0 \leq L < M_o$, where M_o is the value of the **Output buffer size** parameter. The block takes L samples (rows) from the current output and repeats them in the next output. In cases of overlap, the block acquires $M_o - L$ new input samples before propagating the buffered data to the output.

When $L < 0$, you are buffering the signal with underlap. The block discards L input samples after the buffer fills and outputs the buffer with period $(M_o - L)T_{si}$, which is longer than in the zero-overlap case.

The output frame period is $(M_o - L)T_{si}$, which equals the input sequence sample period, T_{si} , when the **Buffer overlap** is $M_o - 1$.

Data Types: double | int8 | int16 | int32 | uint8 | uint16 | uint32

Initial conditions – Initial output

0 (default) | scalar | vector | matrix

Specify the value of the block's initial output, in cases of nonzero latency, as a scalar, vector, or matrix.

For all cases of single-tasking operation (Simulink Coder) other than those listed in “Zero-Tasking Latency” on page 2-153, the Buffer block's buffer is initialized to the value(s) specified by the **Initial conditions** parameter. The block reads from this buffer to generate the first D output samples, where

$$D = \begin{cases} M_o + L & (L \geq 0) \\ M_o & (L < 0) \end{cases}$$

The dimensions of the **Initial conditions** parameter depend on the **Buffer overlap**, L , and whether the input is single-channel or multichannel:

- When $L \neq 0$, the **Initial conditions** parameter must be a scalar.
- When $L = 0$, the **Initial conditions** parameter can be a scalar, or it can be a vector with either of these constraints:
 - For single-channel inputs, the **Initial conditions** parameter can be a vector of length M_o if M_i is 1, or a vector of length M_i if M_o is 1.
 - For multichannel inputs, the **Initial conditions** parameter can be a vector of length $M_o * N$ if M_i is 1, or a vector of length $M_i * N$ if M_o is 1.

For all multitasking operations (Simulink Coder), use the `rebuffer_delay` function to compute the exact delay in samples that the Buffer block introduces for a given combination of buffer size and buffer overlap.

For general buffering between arbitrary frame sizes, the **Initial conditions** parameter must be a scalar, which is then repeated across all elements of the initial output(s). However, in the special case where the input is a 1-by- N row vector, and the output of the block is an M_o -by- N matrix, **Initial conditions** can be:

- An M_o -by- N matrix
- A length- M_o vector to be repeated across all columns of the initial output(s)
- A scalar to be repeated across all elements of the initial output(s)

In the special case where the output is a 1-by- N row vector, which is the result of unbuffering an M_i -by- N matrix, the **Initial conditions** can be:

- A vector containing M_i samples to output sequentially for each channel during the first M_i sample times
- A scalar to be repeated across all elements of the initial output(s)

For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Complex Number Support: Yes

Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

More About

Zero-Tasking Latency

Zero-tasking latency means that the first input sample, received at $t = 0$, appears as the first output sample. In the Simulink single-tasking mode (Simulink Coder), the Buffer block has zero-tasking latency for these special cases:

- Scalar input and output ($M_o = M_i = 1$) with zero or negative **Buffer overlap** ($L \leq 0$)
- Input frame size is an integer multiple of the output frame size

$$M_i = kM_o$$

where k is an integer with zero **Buffer overlap** ($L = 0$); notable cases of this include:

- Any input frame size M_i with scalar output ($M_o = 1$) and zero **Buffer overlap** ($L = 0$)
- Equal input and output frame sizes ($M_o = M_i$) with zero **Buffer overlap** ($L = 0$)

Overflow and Underflow

The Buffer block cannot be used in an enabled subsystem under the following conditions:

- In a multirate, multitasking environment
- When the **Buffer overlap** parameter is set to a negative value

The Buffer block has an internal reservoir that temporarily stores data. When the Buffer block is used in an enabled subsystem, there is the possibility that the reservoir can overflow or underflow. The block implements safeguards against these occurrences.

Overflow occurs when more data enters the buffer than what it can hold. For example, consider buffering a scalar input to a frame of size three with a buffer that accepts an input every second and outputs every three seconds. If you place this buffer inside an enabled subsystem that is disabled every three seconds at $t = 3s$, $t = 6s$, and so on, the buffer accumulates data in its internal reservoir without being able to empty it. This condition results in an overflow.

Underflow occurs when the buffer runs out of data to output. For example, again consider buffering a scalar input to a frame size of three with a buffer that accepts an input every second and outputs every three seconds. If you place this buffer inside an enabled subsystem that is disabled at $t = 10s$, $t = 11s$, $t = 13s$, $t = 14s$, $t = 16s$, and $t = 17s$, its internal reservoir becomes drained, and there is no data to output at $t = 18s$. This condition results in an underflow.

To protect from an overflow or an underflow, the Buffer block keeps a record of the amount of data in its internal reservoir. When the Buffer block reads data, the amount of data in its reservoir goes up. When the Buffer block outputs the data, the amount of data in its reservoir goes down. To protect from overflow, the oldest samples in the reservoir are discarded whenever the amount of data in the reservoir is larger than the actual buffer size. To protect from underflow, the most recent samples are repeated whenever an output is due and there is no data in the reservoir.

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The Buffer block supports code generation for Simulink Real-Time™. The code generated for this target is executed concurrently. To generate this code, set the system target file of the model to `slrealtime.tlc`. The Buffer block also needs to satisfy certain conditions.

To set the system target file:

- 1 In the Simulink model window, in the **Modeling** tab, click **Model Settings**.
- 2 In the Model Settings > **Code Generation** pane, set the **System target file** to `slrealtime.tlc`.

In addition, the Buffer block must satisfy the following conditions:

- Ratio between output and input buffer size must be a pure integer, that is $1/N$ or $N/1$. Ratios such as $3/12$, $1/7$, $7/1$, or $2/4$ are all valid ratios. In the Buffer block, you can specify the appropriate output buffer size using the **Output buffer size (per channel)** parameter.
- There should be no overlap between frames. In the Buffer block, set the **Buffer overlap** parameter to 0.

Burg AR Estimator

Compute estimate of autoregressive (AR) model parameters using Burg method

Library

Estimation / Parametric Estimation

dspparest3

Description

The Burg AR Estimator block uses the Burg method to fit an autoregressive (AR) model to the input data by minimizing (least squares) the forward and backward prediction errors while constraining the AR parameters to satisfy the Levinson-Durbin recursion.

The input must be a column vector or an unoriented vector, which is assumed to be the output of an AR system driven by white noise. This input represents a frame of consecutive time samples from a single-channel signal. The block computes the normalized estimate of the AR system parameters, $A(z)$, independently for each successive input frame.

$$H(z) = \frac{G}{A(z)} = \frac{G}{1 + a(2)z^{-1} + \dots + a(p+1)z^{-p}}$$

When you select the **Inherit estimation order from input dimensions** parameter, the order, p , of the all-pole model is one less than the length of the input vector. Otherwise, the order is the value specified by the **Estimation order** parameter.

The **Output(s)** parameter allows you to select between two realizations of the AR process:

- **A** — The top output, A , is a column vector of length $p+1$ with the same frame status as the input, and contains the normalized estimate of the AR model polynomial coefficients in descending powers of z .
 $[1 \ a(2) \ \dots \ a(p+1)]$
- **K** — The top output, K , is a column vector of length p with the same frame status as the input, and contains the reflection coefficients (which are a secondary result of the Levinson recursion).
- **A and K** — The block outputs both realizations.

The scalar gain, G , is provided at the bottom output (G).

The following table compares the features of the Burg AR Estimator block to the Covariance AR Estimator, Modified Covariance AR Estimator, and Yule-Walker AR Estimator blocks.

	Burg AR Estimator	Covariance AR Estimator	Modified Covariance AR Estimator	Yule-Walker AR Estimator
Characteristics	Does not apply window to data	Does not apply window to data	Does not apply window to data	Applies window to data
	Minimizes the forward and backward prediction errors in the least squares sense, with the AR coefficients constrained to satisfy the L-D recursion	Minimizes the forward prediction error in the least squares sense	Minimizes the forward and backward prediction errors in the least squares sense	Minimizes the forward prediction error in the least squares sense (also called "autocorrelation method")
Advantages	Always produces a stable model			Always produces a stable model
Disadvantages		May produce unstable models	May produce unstable models	Performs relatively poorly for short data records
Conditions for Nonsingularity		Order must be less than or equal to half the input frame size	Order must be less than or equal to 2/3 the input frame size	Because of the biased estimate, the autocorrelation matrix is guaranteed to positive-definite, hence nonsingular

Parameters

Output(s)

The realization to output, model coefficients, reflection coefficients, or both.

Inherit estimation order from input dimensions

When selected, sets the estimation order p to one less than the length of the input vector.

Estimation order

The order of the AR model, p . This parameter is enabled when you do not select **Inherit estimation order from input dimensions**.

Burg Method

Power spectral density estimate using Burg method

Library

Estimation / Power Spectrum Estimation

dspspect3

Description

The Burg Method block estimates the power spectral density (PSD) of the input frame using the Burg method. This method fits an autoregressive (AR) model to the signal by minimizing (least squares) the forward and backward prediction errors. Such minimization occurs with the AR parameters constrained to satisfy the Levinson-Durbin recursion.

The input must be a column vector or an unoriented vector. This input represents a frame of consecutive time samples from a single-channel signal. The block outputs a column vector containing the estimate of the power spectral density of the signal at N_{fft} equally spaced frequency points. The frequency points are in the range $[0, F_s)$, where F_s is the sampling frequency of the signal.

When you select the **Inherit estimation order from input dimensions** parameter, the order of the all-pole model is one less than the input frame size. Otherwise, the **Estimation order** parameter specifies the order. The block computes the spectrum from the FFT of the estimated AR model parameters.

Selecting the **Inherit FFT length from estimation order** parameter specifies that N_{fft} is one greater than the estimation order. Clearing the **Inherit FFT length from estimation order** check box, allows you to use the **FFT length** parameter to specify N_{fft} as a power of 2. The block zero-pads or wraps the input to N_{fft} before computing the FFT. The output is always sample based.

When you select the **Inherit sample time from input** check box, the block computes the frequency data from the sample period of the input signal. For the block to produce valid output, the following conditions must hold:

- The input to the block is the original signal, with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** check box. You can then specify a sample time using the **Sample time of original time series** parameter.

The Burg Method and Yule-Walker Method blocks return similar results for large frame sizes. The following table compares the features of the Burg Method block to the Covariance Method, Modified Covariance Method, and Yule-Walker Method blocks.

	Burg	Covariance	Modified Covariance	Yule-Walker
Characteristics	Does not apply window to data	Does not apply window to data	Does not apply window to data	Applies window to data
	Minimizes the forward and backward prediction errors in the least squares sense, with the AR coefficients constrained to satisfy the L-D recursion	Minimizes the forward prediction error in the least squares sense	Minimizes the forward and backward prediction errors in the least squares sense	Minimizes the forward prediction error in the least squares sense (also called autocorrelation method)
Advantages	High resolution for short data records	Better resolution than Y-W for short data records (more accurate estimates)	High resolution for short data records	Performs as well as other methods for large data records
	Always produces a stable model	Able to extract frequencies from data consisting of p or more pure sinusoids	Able to extract frequencies from data consisting of p or more pure sinusoids Does not suffer spectral line-splitting	Always produces a stable model
Disadvantages	Peak locations highly dependent on initial phase	May produce unstable models	May produce unstable models	Performs relatively poorly for short data records
	May suffer spectral line-splitting for sinusoids in noise, or when order is very large	Frequency bias for estimates of sinusoids in noise	Peak locations slightly dependent on initial phase	Frequency bias for estimates of sinusoids in noise
	Frequency bias for estimates of sinusoids in noise		Minor frequency bias for estimates of sinusoids in noise	
Conditions for Nonsingularity		Order must be less than or equal to half the input frame size	Order must be less than or equal to 2/3 the input frame size	Because of the biased estimate, the autocorrelation matrix is guaranteed to be positive-definite, hence nonsingular

Parameters

Inherit estimation order from input dimensions

Selecting this check box sets the estimation order to one less than the length of the input vector.

Estimation order

The order of the AR model. This parameter becomes visible only when you clear the **Inherit estimation order from input dimensions** check box.

Inherit FFT length from estimation order

When selected, the FFT length is one greater than the estimation order. To specify the number of points on which to perform the FFT, clear the **Inherit FFT length from estimation order** check box. You can then specify a power-of-two FFT length using the **FFT length** parameter.

FFT length

Enter the number of data points on which to perform the FFT, N_{fft} . When N_{fft} is larger than the input frame size, the block zero-pads each frame as needed. When N_{fft} is smaller than the input frame size, the block wraps each frame as needed. This parameter becomes visible only when you clear the **Inherit FFT length from input dimensions** check box.

Inherit sample time from input

If you select the **Inherit sample time from input** check box, the block computes the frequency data from the sample period of the input signal. For the block to produce valid output, the following conditions must hold:

- The input to the block is the original signal, with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** check box. You can then specify a sample time using the **Sample time of original time series** parameter.

Sample time of original time series

Specify the sample time of the original time-domain signal. This parameter becomes visible only when you clear the **Inherit sample time from input** check box.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point

Channelizer

Polyphase FFT analysis filter bank

Library: DSP System Toolbox / Filtering / Multirate Filters

Description

The Channelizer block separates a broadband input signal into multiple narrow subbands using an FFT-based analysis filter bank. The filter bank uses a prototype lowpass filter and is implemented using a polyphase structure. You can specify the filter coefficients directly or through design parameters. When you specify the design parameters, the filter is designed using the `designMultirateFIR` function.

This block accepts variable-size inputs. That is, during the simulation, you can change the size of each input channel. The number of channels cannot change.

Input/Output Ports

Input

x — Broadband signal

L-by-1 column vector | *L*-by-*N* matrix

Specify the input broadband signal that the channelizer splits into multiple narrow bands.

- When you input a variable-size signal (frame length changes during simulation), the frame length of the signal can be arbitrary. That is, the input frame length does not have to be a multiple of the decimation factor.
- When you input a fixed-size signal (frame length does not change during simulation), the frame length can be arbitrary only when you select the **Allow arbitrary frame length for fixed-size input signals** parameter.

This port is unnamed until you set **Polyphase filter specification** to `Coefficients` and select the **Specify coefficients from input port** parameter.

Data Types: `single` | `double`

coeffs — Prototype lowpass filter coefficients

row vector

Coefficients of the prototype lowpass filter. There must be at least one coefficient per frequency band. If the length of the lowpass filter is less than the number of frequency bands, the block zero-pads the coefficients.

If you specify complex coefficients, the block designs a prototype filter that is centered at a nonzero frequency, also known as a bandpass filter. The modulated versions of the prototype bandpass filter appear with respect to the prototype filter and are wrapped around the frequency range $[-F_s, F_s]$.

Dependencies

This port appears when you set **Polyphase filter specification** to `Coefficients` and select the **Specify coefficients from input port** parameter.

Data Types: `single` | `double`

Output

Port_1 — Multiple narrowband signals

L/M -by- M | L/M -by- M -by- N array

Multiple narrow subbands of the input broadband signal. Each narrow band signal forms a column in the output.

The dimensions of the output signal depend on the dimensions of the input signal and whether you select the **Allow arbitrary frame length for fixed-size input signals** parameter.

This table provides more details on the dimensions of the output signal when you input a fixed-size input signal.

Fixed-Size Input Signal

Input Signal	Output Signal Dimensions
L -by-1 column vector, where L is a multiple of M	(L/M) -by- M
L -by-1 column vector, where L is not a multiple of M	$\text{ceil}(L/M)$ -by- M when you select Allow arbitrary frame length for fixed-size input signals . If you do not select Allow arbitrary frame length for fixed-size input signals , the block errors.
L -by- N matrix, where L is a multiple of M	(L/M) -by- M -by- N
L -by- N matrix, where L is not a multiple of M	$\text{ceil}(L/M)$ -by- M -by- N when you select Allow arbitrary frame length for fixed-size input signals . If you do not select Allow arbitrary frame length for fixed-size input signals , the block errors.

This table provides more details on the dimensions of the output signal when you input a variable-size input signal.

Variable-Size Input Signal

Input Signal	Output Signal Dimensions
L -by-1 column vector, where L is a multiple of M	(L/M) -by- M
L -by-1 column vector, where L is not a multiple of M	$\text{ceil}(L/M)$ -by- M Allow arbitrary frame length for fixed-size input signals parameter setting is ignored.
L -by- N matrix, where L is a multiple of M	(L/M) -by- M -by- N
L -by- N matrix, where L is not a multiple of M	$\text{ceil}(L/M)$ -by- M -by- N Allow arbitrary frame length for fixed-size input signals parameter setting is ignored.

Data Types: single | double

Parameters

If a parameter is listed as tunable, then you can change its value during simulation.

Number of frequency bands — Number of frequency bands

8 (default) | positive integer greater than 1

Number of frequency bands M into which the block separates the input broadband signal. This parameter indicates the FFT length and the decimation factor used by the algorithm.

Polyphase filter specification — Filter design parameters or coefficients

Number of taps per band and stopband attenuation (default) | Coefficients

- Number of taps per band and stopband attenuation — Specify the filter design parameters through the **Number of filter taps per frequency band** and **Stopband attenuation (dB)** parameters. When you specify the design parameters, the filter is designed using the `designMultirateFIR` function.
- Coefficients — Specify the filter coefficients directly using the **Prototype lowpass filter coefficients** parameter or input them through the **coeffs** port.

DecimationFactor — Decimation factor

8 (default) | positive integer

Decimation factor D specified as a positive integer less than or equal to the number of frequency bands M .

If the decimation factor D equals the number of frequency bands M , then the M/D ratio equals 1, and the channelizer is known as the maximally decimated channelizer.

If the M/D ratio is greater than 1, the output sample rate is different from the channel spacing, and the channelizer is known as the non-maximally decimated channelizer. If the ratio is an integer, the channelizer is known as the integer-oversampled channelizer. If the ratio is not an integer, say $4/3$,

the channelizer is known as the rationally oversampled channelizer. For more details, see “Algorithm” on page 4-200.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Number of filter taps per frequency band — Number of filter coefficients per frequency band

12 (default) | positive integer

Number of filter coefficients that each polyphase branch uses. The number of polyphase branches matches the number of frequency bands. The total number of filter coefficients for the prototype lowpass filter is given by **Number of frequency bands** × **Number of filter taps per frequency band**. For a given stopband attenuation, increasing the number of taps per band narrows the transition width of the filter. As a result, there is more usable bandwidth for each frequency band, at the expense of increased computation.

Dependencies

To enable this parameter, set **Polyphase filter specification** to Number of taps per band and stopband attenuation.

Stopband attenuation (dB) — Stopband attenuation

80 (default) | positive real scalar

Stopband attenuation of the lowpass filter, in dB. This value controls the maximum amount of aliasing from one frequency band to the next. As the stopband attenuation increases, the passband ripple decreases.

Dependencies

To enable this parameter, set **Polyphase filter specification** to Number of taps per band and stopband attenuation.

Specify coefficients from input port — Flag to specify lowpass filter coefficients

off (default) | on

When you select this parameter, the lowpass filter coefficients are input through the **coeffs** port. When you clear this parameter, the coefficients are specified on the block dialog through the **Prototype lowpass filter coefficients** parameter.

Dependencies

To enable this parameter, set **Polyphase filter specification** to Coefficients.

Prototype lowpass filter coefficients — Coefficients of prototype lowpass filter

`rcosdesign(0.25,6,8,'sqrt')` (default) | row vector

Coefficients of the prototype lowpass filter. The default value is the coefficients vector that `rcosdesign(0.25,6,8,'sqrt')` returns. There must be at least one coefficient per frequency band. If the length of the lowpass filter is less than the number of frequency bands, the block zero-pads the coefficients.

If you specify complex coefficients, the block designs a prototype filter that is centered at a nonzero frequency, also known as a bandpass filter. The modulated versions of the prototype bandpass filter appear with respect to the prototype filter and are wrapped around the frequency range $[-F_s, F_s]$.

Tunable: Yes

Dependencies

To enable this parameter, set **Polyphase filter specification** to `Coefficients` and clear the **Specify coefficients from input port** parameter.

Allow arbitrary frame length for fixed-size input signals – Allow arbitrary frame length for fixed-size input signals

off (default) | on

Specify whether fixed-size input signals (whose size does not change during simulation) can have an arbitrary frame length, where the frame length does not have to be a multiple of the decimation factor. The block uses this parameter setting only for fixed-size input signals and ignores this parameter if the input has a variable-size.

When the input signal is a variable-size signal, the signal can have arbitrary frame length, that is, the frame length does not have to be a multiple of the decimation factor.

For fixed-size input signals, if you:

- Select the **Allow arbitrary frame length for fixed-size input signals** parameter, the frame length of the signal does not have to be a multiple of the decimation factor. If the input is not a multiple of the decimation factor, then the output is generally a variable-size signal. Therefore, to support arbitrary input size, the block must also support variable-size operations, which you can enable by selecting the **Allow arbitrary frame length for fixed-size input signals** parameter.
- Clear the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length must be a multiple of the decimation factor.

Simulate using – Type of simulation to run

Interpreted execution (default) | Code generation

Type of simulation to run. You can set this parameter to:

- **Interpreted execution:** Simulate model using the MATLAB interpreter. This option shortens startup time.
- **Code generation:** Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations as long as the model does not change. This option requires additional startup time but provides faster subsequent simulations.

More About

Analysis Filter Bank

The generic analysis filter bank consists of a series of parallel bandpass filters that split an input broadband signal, $x[n]$, into a series of narrow subbands. Each bandpass filter retains a different portion of the input signal. After the bandwidth is reduced by one of the bandpass filters, the signal is downsampled to a lower sampling rate commensurate with the new bandwidth.

Prototype Lowpass Filter

To implement the analysis filter bank efficiently, the channelizer uses a prototype lowpass filter.

The prototype lowpass filter has an impulse response of $h[n]$, a normalized two-sided bandwidth of $2\pi/M$, and a cutoff frequency of π/M . M is the number of frequency bands, that is, the branches of the analysis filter bank. This value corresponds to the FFT length that the filter bank uses. M can be high on the order of 2048 or more. The stopband attenuation determines the minimum level of interference (aliasing) from one frequency band to another. The passband ripple must be small so that the input signal is not distorted in the passband.

The prototype lowpass filter corresponds to $H_0(z)$ in the filter bank. The first branch of the filter bank contains $H_0(z)$ followed by the decimator. The other $M - 1$ branches contain filters that are modulated versions of the prototype filter. The modulation factor is given by the following equation:

$$e^{-jw_k n}, \quad w_k = 2\pi k/M, \quad k = 0, 1, \dots, M - 1$$

Using the Prototype Lowpass Filter

The transfer function of the modulated k th bandpass filter is given by:

$$H_k(z) = H_0(z e^{-jw_k}), \quad w_k = 2\pi k/M, \quad k = 1, 2, \dots, M - 1$$

This figure shows the frequency response of M filters.

To obtain the frequency response characteristics of the filter $H_k(z)$, where $k = 1, \dots, M-1$, uniformly shift the frequency response of the prototype filter, $H_0(z)$, by multiples of $2\pi/M$. Each subband filter, $H_k(z)$, $\{k = 1, \dots, M-1\}$, is derived from the prototype filter.

Following is an equivalent representation of the frequency response diagram with ω ranging from $[-\pi, \pi]$.

Shift Narrow Subbands to Baseband

The frequency components in the input signal, $x[n]$, are translated in frequency to baseband by multiplying $x[n]$ with the complex exponentials, $e^{-jw_k n}$, $w_k = 2\pi k/M$, $k = 1, 2, \dots, M-1$, where $w_k = 2\pi k/M$, and $k = 1, 2, \dots, M-1$. The resulting product signals are passed through the lowpass filters, $H_0(z)$. The output of the lowpass filter is relatively narrow in bandwidth. Downsample the signal commensurate with the new bandwidth. Choose a decimation factor, $D \leq M$, where M is the number of branches of the analysis filter bank. When $D < M$, the channelizer is known as oversampled or non-maximally decimated channelizer.

The figure shows an analysis filter bank that uses the prototype lowpass filter.

Conceptual Diagram

$y_1[m], y_2[m], \dots, y_{M-1}[m]$ are narrow subband signals translated into baseband.

Algorithms

Polyphase Implementation

The analysis filter bank can be implemented efficiently using the polyphase structure. For more details on the analysis filter bank, see Analysis Filter Bank on page 2-168.

To derive the polyphase structure, start with the transfer function of the prototype lowpass filter:

$$H_0(z) = b_0 + b_1z^{-1} + \dots + b_Nz^{-N}$$

$N + 1$ is the length of the prototype filter.

You can rearrange this equation as follows:

$$\begin{aligned}
 H_0(z) = & (b_0 + b_Mz^{-M} + b_{2M}z^{-2M} + \dots + b_{N-M+1}z^{-(N-M+1)}) + \\
 & z^{-1}(b_1 + b_{M+1}z^{-M} + b_{2M+1}z^{-2M} + \dots + b_{N-M+2}z^{-(N-M+1)}) + \\
 & \vdots \\
 & z^{-(M-1)}(b_{M-1} + b_{2M-1}z^{-M} + b_{3M-1}z^{-2M} + \dots + b_Nz^{-(N-M+1)})
 \end{aligned}$$

M is the number of polyphase components.

You can write this equation as:

$$H_0(z) = E_0(z^M) + z^{-1}E_1(z^M) + \dots + z^{-(M-1)}E_{M-1}(z^M)$$

$E_0(z^M), E_1(z^M), \dots, E_{M-1}(z^M)$ are polyphase components of the prototype lowpass filter $H_0(z)$.

The other filters in the filter bank, $H_k(z)$, where $k = 1, \dots, M-1$, are modulated versions of this prototype filter.

You can write the transfer function of the k^{th} modulated bandpass filter as $H_k(z) = H_0(ze^{-jw_k})$.

Replacing z with ze^{jw_k} ,

$$H_k(z) = h_0 + h_1 e^{-jw_k} z^{-1} + h_2 e^{-j2w_k} z^{-2} \dots + h_N e^{-jNw_k} z^{-N}$$

$N + 1$ is the length of the k^{th} filter.

In polyphase form, the equation is as follows:

$$H_k(z) = \begin{bmatrix} 1 & e^{-jw_k} & e^{-j2w_k} & \dots & e^{-j(M-1)w_k} \end{bmatrix} \begin{bmatrix} E_0(z^M) \\ z^{-1}E_1(z^M) \\ \vdots \\ z^{-(M-1)}E_{M-1}(z^M) \end{bmatrix}$$

For all M channels in the filter bank, the transfer function $H(z)$ is given by:

$$H(z) = \begin{bmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & e^{-jw_1} & e^{-j2w_1} & \dots & e^{-j(M-1)w_1} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & e^{-jw_{M-1}} & e^{-j2w_{M-1}} & \dots & e^{-j(M-1)w_{M-1}} \end{bmatrix} \begin{bmatrix} E_0(z^M) \\ z^{-1}E_1(z^M) \\ \vdots \\ z^{-(M-1)}E_{M-1}(z^M) \end{bmatrix}$$

Maximally decimated channelizer

When $D = M$, the channelizer is known as the maximally decimated channelizer or critically sampled channelizer.

Here is the multirate noble identity for decimation, assuming that $D = M$.

For example, consider the first branch of the filter bank that contains the lowpass filter.

Replace $H_0(z)$ with its polyphase representation on page 2-170.

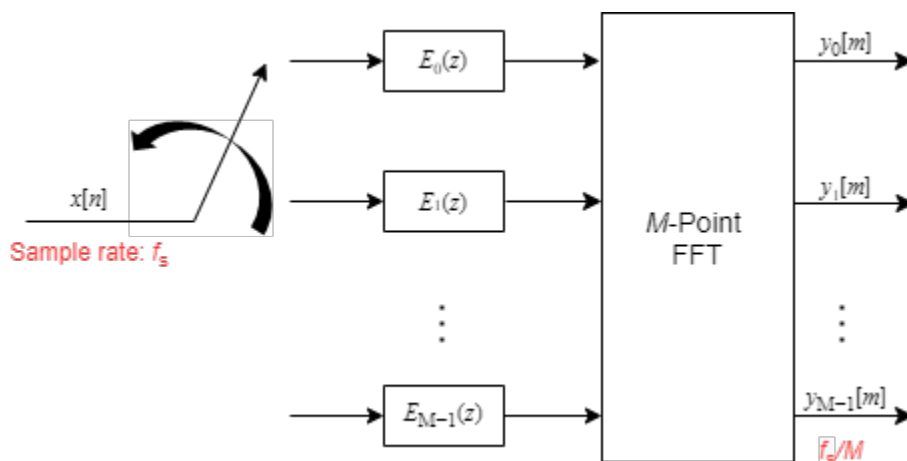

After applying the noble identity for decimation, you can replace the delays and the decimation factor with a commutator switch. The switch starts on the first branch 0 and moves in the counterclockwise direction as shown in the following diagram. The accumulator at the output receives the processed input samples from each branch of the polyphase structure and accumulates these processed samples until the switch goes to branch 0. When the switch goes to branch 0, the accumulator outputs the accumulated value.

For all M channels in the filter bank, the transfer function $H(z)$ is given by:

$$H(z) = \begin{bmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & e^{-jw_1} & e^{-j2w_1} & \dots & e^{-j(M-1)w_1} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & e^{-jw_{M-1}} & e^{-j2w_{M-1}} & \dots & e^{-j(M-1)w_{M-1}} \end{bmatrix} \begin{bmatrix} E_0(z) \\ E_1(z) \\ \vdots \\ E_{M-1}(z) \end{bmatrix}$$

The matrix on the left is a discrete Fourier transform (DFT) matrix. With the DFT matrix, the efficient implementation of the lowpass prototype-based filter bank looks like this.

When the first input sample is delivered, the switch feeds this input to the branch 0 and the channelizer computes the first set of output values. As more input samples come in, the switch moves in the counterclockwise direction through branches $M-1, M-2$, all the way up to branch 0, delivering one sample at a time to each branch. When the switch comes to branch 0, the channelizer outputs the next set of output values. This process continues as the data keeps coming in. Every time the switch comes to the first branch 0, the channelizer outputs $y_0[m], y_1[m], \dots, y_{M-1}[m]$. Each branch in the channelizer effectively outputs one sample for every M samples it receives. Hence, the sample rate at the output of the channelizer is f_s/M .

Non-maximally decimated or oversampled channelizer

When $D < M$, the channelizer is known as the non-maximally decimated channelizer or oversampled channelizer. In this configuration, the output sample rate is different from the channel spacing. The non-maximally decimated channelizers offer increased design freedom, but at the expense of increasing computational cost.

If the ratio M/D equals an integer that is greater than 1 and is less than or equal to $M-1$, the channelizer is known as integer-oversampled channelizer. If the ratio M/D is not an integer, then the channelizer is known as rationally-oversampled channelizer.

In this configuration, when the first input sample is delivered, the switch feeds this input to branch 0 and the channelizer computes the first set of output values. As more input samples come in, the switch moves in the counterclockwise direction through branches $D-1, D-2$, all the way up to branch 0, delivering one sample at a time to each branch. When the switch comes to branch 0, the channelizer outputs the next set of output values. This process continues as the data keeps coming in. Every time the switch comes to the first branch 0, the channelizer outputs $y_0[m], y_1[m], \dots, y_{M-1}[m]$.

As more data keeps coming in and the switch feeds these samples to the first D addresses, the formal contents of these addresses are shifted to the next set of D addresses, and this process of data shift continues every time there is a new set of D input samples.

For every D input samples that are fed to the polyphase structure, the channelizer outputs M samples, $y_0[m], y_1[m], \dots, y_{M-1}[m]$. This process increases the output sample rate from f_s/M in the case of a maximally decimated channelizer, to f_s/D in the case of a non-maximally decimated channelizer.

For more details, see [2].

After each D -point data sequence is delivered to the partitioned M -stage polyphase filter, the outputs of the M stages are computed and conditioned for delivery to the M -point FFT. The data shifting

through the filter introduces frequency-dependent phase shift. To correct for this phase shift and alias all bands to DC, a circular shift buffer is inserted after the polyphase filters and before the M -point FFT.

With the commutator switch followed by M -stage polyphase filter, circular shift buffer, and a DFT matrix, the efficient implementation of the lowpass prototype-based filter bank looks like this.

Introduced in R2017a

Support for arbitrary input frame length

Channelizer block supports input signals with arbitrary frame lengths when the:

- Input signal is a fixed-size signal (frame length does not change during simulation) and you select the **Allow arbitrary frame length for fixed-size input signals** parameter
- Input signal is a variable-size signal (frame length changes during simulation)

The frame length is arbitrary when it is not a multiple of the decimation factor.

Channel Synthesizer

Polyphase FFT synthesis filter bank

Library: DSP System Toolbox / Filtering / Multirate Filters

Description

The Channel Synthesizer block merges multiple narrowband signals into a broadband signal by using an FFT-based synthesis filter bank. The filter bank uses a prototype lowpass filter and is implemented using a polyphase structure. You can specify the filter coefficients directly or through design parameters. When you specify the design parameters, the filter is designed using the `designMultirateFIR` function.

This block also accepts variable-size inputs. That is, during the simulation, you can change the size of each input channel. The number of channels cannot change.

Input/Output Ports

Input

x — Input narrowband signals

L-by-*M* matrix | *L*-by-*M*-by-*N* array

Input narrowband signals, which the channel synthesizer merges to form the broadband signal. Each narrowband signal forms a column in the input signal. The number of columns in the input correspond to the number of frequency bands of the filter bank. If the input is three-dimensional, each matrix corresponds to a separate channel.

This port is unnamed until you set **Polyphase filter specification** to `Coefficients` and select the **Specify coefficients from input port** parameter.

Data Types: `single` | `double`

coeffs — Prototype lowpass filter coefficients

row vector

Coefficients of the prototype lowpass filter. There must be at least one coefficient per frequency band. If the length of the lowpass filter is less than the number of frequency bands, the block zero-pads the coefficients.

If you specify complex coefficients, the block designs a prototype filter that is centered at a nonzero frequency, also known as a bandpass filter. The modulated versions of the prototype bandpass filter appear with respect to the prototype filter and are wrapped around the frequency range $[-F_s, F_s]$.

Dependencies

This port appears when you set **Polyphase filter specification** to `Coefficients` and select the **Specify coefficients from input port** parameter.

Data Types: `single` | `double`

Output

Port_1 — Broadband signal

$L \times M$ -by-1 vector | $L \times M$ -by- N matrix

Broadband signal the channel synthesizer forms from the multiple input narrow subbands.

If the input is one of the following:

- L -by- M matrix — The output is a $L \times M$ -by-1 vector. M is the number of frequency bands.
- L -by- M -by- N matrix — The output is a $L \times M$ -by- N matrix.

Data Types: `single` | `double`

Parameters

If a parameter is listed as tunable, then you can change its value during simulation.

Polyphase filter specification — Filter design parameters or coefficients

Number of taps per band and stopband attenuation (default) | Coefficients

- Number of taps per band and stopband attenuation — Specify the filter design parameters through the **Number of filter taps per frequency band** and **Stopband attenuation (dB)** parameters. When you specify the design parameters, the filter is designed using the `designMultirateFIR` function.
- Coefficients — Specify the filter coefficients directly using the **Prototype lowpass filter coefficients** parameter or input them through the **coeffs** port.

Number of filter taps per frequency band — Number of filter coefficients per frequency band

12 (default) | positive integer

Number of filter coefficients that each polyphase branch uses. The number of polyphase branches matches the number of frequency bands. The total number of filter coefficients for the prototype lowpass filter is given by the product of the number of frequency bands and the number of filter taps per frequency band. The number of frequency bands equals the number of columns in the input. For a given stopband attenuation, increasing the number of taps per band narrows the transition width of the filter. As a result, there is more usable bandwidth for each frequency band, at the expense of increased computation.

Dependencies

To enable this parameter, set **Polyphase filter specification** to Number of taps per band and stopband attenuation.

Stopband attenuation (dB) — Stopband attenuation

80 (default) | positive real scalar

Stopband attenuation of the lowpass filter, in dB. This value controls the maximum amount of aliasing from one frequency band to the next. As the stopband attenuation increases, the passband ripple decreases.

Dependencies

To enable this parameter, set **Polyphase filter specification** to Number of taps per band and stopband attenuation.

Specify coefficients from input port — Flag to specify lowpass filter coefficients

off (default) | on

When you select this check box, the lowpass filter coefficients are input through the **coeffs** port. When you clear this check box, the coefficients are specified on the block dialog through the **Prototype lowpass filter coefficients** parameter.

Dependencies

To enable this parameter, set **Polyspace filter specification** to Coefficients.

Prototype lowpass filter coefficients — Coefficients of prototype lowpass filter

`rcosdesign(0.25,6,8,'sqrt')` (default) | row vector

This parameter specifies the coefficients of the prototype lowpass filter. The default value is the coefficients vector that `rcosdesign(0.25,6,8,'sqrt')` returns. There must be at least one coefficient per frequency band. If the length of the lowpass filter is less than the number of frequency bands, the block zero-pads the coefficients.

If you specify complex coefficients, the block designs a prototype filter that is centered at a nonzero frequency, also known as a bandpass filter. The modulated versions of the prototype bandpass filter appear with respect to the prototype filter and are wrapped around the frequency range $[-F_s/2, F_s/2]$.

Tunable: Yes

Dependencies

To enable this parameter, set **Polyphase filter specification** to Coefficients and clear the **Specify coefficients from input port** parameter.

Simulate using — Type of simulation to run

Interpreted execution (default) | Code generation

Type of simulation to run. You can set this parameter to:

- **Interpreted execution:** Simulate model using the MATLAB interpreter. This option shortens startup time.
- **Code generation:** Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations as long as the model does not change. This option requires additional startup time but provides faster subsequent simulations.

More About

Synthesis Filter Bank

The synthesis filter bank consists of a set of parallel bandpass filters that merge multiple input narrowband signals, $y_0[m]$, $y_1[m]$, ..., $y_{M-1}[m]$ into a single broadband signal, $v[n]$. The input narrowband signals are in the baseband. Each narrowband signal is interpolated to a higher sampling rate by using the upsampler, and then filtered by the lowpass filter. A complex exponential that follows the lowpass filter centers the baseband signal around w_k .

Conceptual Diagram

Prototype Lowpass Filter

To implement the synthesis filter bank efficiently, the synthesizer uses a prototype lowpass filter. This filter has an impulse response of $h[n]$, a normalized two-sided bandwidth of $2\pi/M$, and a cutoff frequency of π/M . M is the number of frequency bands, that is, the branches of the synthesis filter bank. This value corresponds to the FFT length that the filter bank uses. M can be high, in the order of 2048 or more. The stopband attenuation determines the minimum level of interference (aliasing) from one frequency band to another. The passband ripple must be small so that the input signal is not distorted in the passband.

The prototype lowpass filter models the first branch of the filter bank. The other $M - 1$ branches are modeled by filters that are modulated versions of the prototype filter. The modulation factor is given by $e^{jw_k n}$, $w_k = 2\pi k/M$, $k = 0, 1, \dots, M - 1$.

The output of each bandpass filter forms a specific portion of the broadband signal. The output of all the branches are added to form the broadband signal, $v[n]$.

Algorithms

Polyphase Implementation

The synthesis filter bank can be implemented efficiently using the polyphase structure.

To derive the polyphase structure, start with the transfer function of the prototype lowpass filter.

$$H_0(z) = b_0 + b_1z^{-1} + \dots + b_Nz^{-N}$$

$N + 1$ is the length of the prototype filter.

You can rearrange this equation as follows:

$$H_0(z) = \begin{aligned} & (b_0 + b_Mz^{-M} + b_{2M}z^{-2M} + \dots + b_{N-M+1}z^{-(N-M+1)}) + \\ & z^{-1}(b_1 + b_{M+1}z^{-M} + b_{2M+1}z^{-2M} + \dots + b_{N-M+2}z^{-(N-M+1)}) + \\ & \quad \vdots \\ & z^{-(M-1)}(b_{M-1} + b_{2M-1}z^{-M} + b_{3M-1}z^{-2M} + \dots + b_Nz^{-(N-M+1)}) \end{aligned}$$

M is the number of polyphase components.

You can write this equation as:

$$H_0(z) = E_0(z^M) + z^{-1}E_1(z^M) + \dots + z^{-(M-1)}E_{M-1}(z^M)$$

$E_0(z^M), E_1(z^M), \dots, E_{M-1}(z^M)$ are polyphase components of the prototype lowpass filter, $H_0(z)$.

The other filters in the filter bank, $H_k(z)$, where $k = 1, \dots, M - 1$, are modulated versions of this prototype filter.

You can write the transfer function of the k th modulated bandpass filter as $H_k(z) = H_0(ze^{jw_k})$.

Replacing z with ze^{jw_k} ,

$$H_k(z) = h_0 + h_1e^{jw_k}z^{-1} + h_2e^{j2w_k}z^{-2} \dots + h_Ne^{jNw_k}z^{-N}$$

$N + 1$ is the length of the k th filter.

In polyphase form, the equation is as follows:

$$H_k(z) = \begin{bmatrix} 1 & e^{jw_k} & e^{j2w_k} & \dots & e^{j(M-1)w_k} \end{bmatrix} \begin{bmatrix} E_0(z^M) \\ z^{-1}E_1(z^M) \\ \vdots \\ z^{-(M-1)}E_{M-1}(z^M) \end{bmatrix}$$

For all M channels in the filter bank, the MIMO transfer function, $H(z)$, is given by:

$$H(z) = \begin{bmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & e^{jw_1} & e^{j2w_1} & \dots & e^{j(M-1)w_1} \\ \vdots & & & & \\ 1 & e^{jw_{M-1}} & e^{j2w_{M-1}} & \dots & e^{j(M-1)w_{M-1}} \end{bmatrix} \begin{bmatrix} E_0(z^M) \\ z^{-1}E_1(z^M) \\ \vdots \\ z^{-(M-1)}E_{M-1}(z^M) \end{bmatrix}$$

Here is the multirate noble identity for interpolation, assuming that $D = M$:

For illustration, consider the first branch of the filter bank that contains the lowpass filter.

Replace $H_0(z)$ with its polyphase representation.

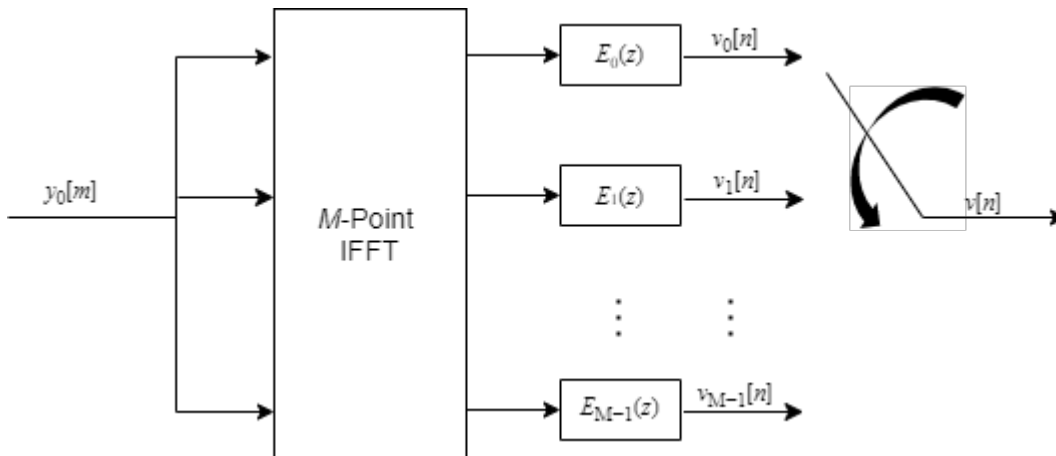

After applying the noble identity for interpolation, you can replace the delays, interpolation factor, and the adder with a commutator switch.

For all the M channels in the filter bank, the MIMO transfer function, $H(z)$, is given by:

$$H(z) = \begin{bmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & e^{jw_1} & e^{j2w_1} & \dots & e^{j(M-1)w_1} \\ & & & \vdots & \\ 1 & e^{jw_{M-1}} & e^{j2w_{M-1}} & \dots & e^{j(M-1)w_{M-1}} \end{bmatrix} \begin{bmatrix} E_0(z) \\ E_1(z) \\ \vdots \\ E_{M-1}(z) \end{bmatrix}$$

The matrix on the left is an IDFT matrix. With the IDFT matrix, the efficient implementation of the lowpass prototype based filter bank looks like the following.

Check Signal Attributes

Error when input signal does or does not match selected attributes exactly

Library

Signal Management / Signal Attributes

dspsigattribs

Description

The Check Signal Attributes block terminates the simulation with an error when the input characteristics differ from the characteristics you specify in the block parameters.

When you set **Error when input** to `Does not match attributes exactly`, the block generates an error when the input fails to match *any* of the specified attributes. Only signals that possess *all* of the specified attributes propagate to the output unaltered and do not cause the block to generate an error.

When you set **Error when input** to `Matches attributes exactly`, the block generates an error only when the input possesses *all* specified attributes. Signals that do not possess *all* of the specified attributes propagate to the output unaltered, and do not cause the block to generate an error.

Signal Attributes

The Check Signal Attributes block can test for up to five different signal attributes, as specified by the following parameters. When you select `Ignore` for any parameter, the block does not check the signal for the corresponding attribute. For example, when you set **Complexity** to `Ignore`, neither real nor complex inputs cause the block to generate an error. The attributes are:

- **Complexity**

Check whether the input is real or complex. You can display this information in a model by attaching a Probe block with **Probe complex signal** selected. Alternatively, in the **Debug** tab, select **Information Overlays > Port Data Type**.

- **Dimensionality**

Check the dimensionality of the input for compliance or noncompliance with the attributes in the subordinate **Dimension** menu. See the following table. *M* and *N* are positive integers unless otherwise indicated.

Dimensions	Is...	Is not...
1-D	1-D vector, 1-D scalar	M -by- N matrix, 1-by- N matrix (row vector), M -by-1 matrix (column vector), 1-by-1 matrix (2-D scalar)
2-D	M -by- N matrix, 1-by- N matrix (row vector), M -by-1 matrix (column vector), 1-by-1 matrix (2-D scalar)	1-D vector, 1-D scalar
Scalar (1-D or 2-D)	1-D scalar, 1-by-1 matrix (2-D scalar)	1-D vector with length >1 , M -by- N matrix with $M>1$ and/or $N>1$
Vector (1-D or 2-D)	1-D vector, 1-D scalar, 1-by- N matrix (row vector), M -by-1 matrix (column vector), 1-by-1 matrix (2-D scalar) Vector (1-D or 2-D) or scalar	M -by- N matrix with $M>1$ and $N>1$
Row Vector (2-D)	1-by- N matrix (row vector), 1-by-1 matrix (2-D scalar) Row vector (2-D) or scalar	1-D vector, 1-D scalar, M -by- N matrix with $M>1$
Column Vector (2-D)	M -by-1 matrix (column vector), 1-by-1 matrix (2-D scalar) Column vector (2-D) or scalar	1-D vector, 1-D scalar, M -by- N matrix with $N>1$
Full matrix	M -by- N matrix with $M>1$ and $N>1$	1-D vector, 1-D scalar, 1-by- N matrix (row vector), M -by-1 matrix (column vector), 1-by-1 matrix (2-D scalar)
Square matrix	M -by- N matrix with $M=N$, 1-D scalar, 1-by-1 matrix (2-D scalar)	M -by- N matrix with $M\neq N$, 1-D vector, 1-by- N matrix (row vector), M -by-1 matrix (column vector)

In the **Debug** tab, when you select **Information Overlays > Signal Dimensions**, Simulink displays the size of a 1-D vector signal as an unbracketed integer, and displays the dimension of a 2-D signal as a pair of bracketed integers, $[M\times N]$. Simulink *does not display* any size information for a 1-D or 2-D scalar signal. You can also display dimension information for a signal in a model by attaching a Probe block with **Probe signal dimensions** selected.

- **Data type**

Check the signal data type for compliance (Is...) or noncompliance (Is not...) with the attributes in the subordinate **General data type** menu. See the following table. You can individually select any of the specific data types listed in the (Is...) column from the subordinate **Specific data type** menu.

General Data Type	Is...	Is not...
Boolean	boolean	single, double, uint8, int8, uint16, int16, uint32, int32, fixed point, enumerated
Enumerated	A user-defined enumerated data type. See "Data Types" (Simulink).	boolean, single, double, uint8, int8, uint16, int16, uint32, int32, fixed point
Floating point	single, double	boolean, uint8, int8, uint16, int16, uint32, int32, fixed point, enumerated
Floating point or Boolean	single, double, boolean	uint8, int8, uint16, int16, uint32, int32, fixed point, enumerated
Fixed point	fixed point, uint8, int8, uint16, int16, uint32, int32	boolean, single, double, enumerated
Integer	Signed integer int8, int16, int32 Unsigned integer uint8, uint16, uint32	boolean, single, double, fixed point, enumerated

To display data type information, in the **Debug** tab, select **Information Overlays > Port Data Type**.

- **Sample time**

Check whether the signal is discrete time or continuous time. In the **Debug** tab, when you select **Information Overlays > Colors**, Simulink displays continuous-time signal lines in black or grey and discrete-time signal lines in colors corresponding to the relative rate.

When you attach a Probe block with **Probe sample time** enabled to a continuous-time signal, the block icon displays $T_s : [0 \ T_0]$, where T_0 is the sample time offset. Valid values of T_0 for continuous-time signals are 0 and 1. When T_0 is 0, updates occur at every major and minor time step. When T_0 is 1, updates occur only at major time steps and the sample time is *fixed in minor time step*.

When you attach a Probe block with **Probe sample time** enabled to a discrete-time signal, the block icon displays $T_s : [T_s \ T_0]$ for sample-based signals, and $T_f : [T_f \ T_0]$ for frame-based signals. T_s and T_f are the positive sample period and frame period, respectively. T_0 is the offset, such that $0 \leq \text{offset} < \text{period}$. Frame-based signals are almost always discrete time.

Parameters

Error when input

Specify whether the block generates an error when the input *does* or *does not* possess *all* of the required attributes.

Complexity

Specify the complexity for which you want to check the input, **Real** or **Complex**. When you select **Ignore** from the list, the block does not check the complexity of the input.

Dimensionality

Specify whether you want to check the input for compliance or noncompliance with the attributes in the subordinate **Dimensions** menu. When you select **Ignore** from the list, the block does not check the dimensionality of the input.

Dimensions

Specify the dimensions for which you want to check the input. This parameter is only visible when you set the **Dimensionality** parameter to **Is...** or **Is not...**

Data type

Specifies whether you want to check the input for compliance or noncompliance with the attributes in the subordinate **General data type** menu. When you select **Ignore** from the list, the block does not check the input data type.

General data type

Specify the general data type for which you want to check the input. This parameter is only visible when you set the **Data type** to **Is...** or **Is not...**

Specific floating-point

Specify the floating-point data type for which you want to check the input. This parameter is only visible when you set the **General data type** to **Floating-point** or **Floating-point or boolean**.

Specific fixed-point

Specify the fixed-point data type for which you want to check the input. This parameter is only visible when you set the **General data type** to **Fixed-point**.

Specific integer

Specify the integer data type for which you want to check the input. This parameter is only visible when you set the **General data type** to **Integer**.

Sample time

Specify the sample time for which you want to check the input, **Discrete** or **Continuous**. When you select **Ignore** from the list, the block does not check the sample time of the input.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8, 16, and 32-bit signed integers • 8, 16, and 32-bit unsigned integers • Enumerated

Port	Supported Data Types
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8, 16, and 32-bit signed integers • 8, 16, and 32-bit unsigned integers • Enumerated

Chirp

Generate swept-frequency cosine (chirp) signal

Library: DSP System Toolbox / Sources

Description

The Chirp block outputs a swept-frequency cosine (chirp) signal with unity amplitude and continuous phase. To specify the desired output chirp signal, you must define its instantaneous frequency function, also known as the output frequency sweep. The frequency sweep can be linear, quadratic, or logarithmic, and repeats once every **Sweep time** by default. For a description of the algorithms used by the Chirp block, see “Algorithms” on page 2-193.

Ports

Output

Port_1 — Swept-frequency cosine (chirp) signal

scalar | vector

Swept-frequency cosine (chirp) signal. In **Linear**, **Logarithmic**, and **Quadratic** modes (set by the **Frequency sweep** parameter), the block outputs a swept-frequency cosine with instantaneous frequency values specified by the frequency and time parameters. In **Swept cosine** mode, the block outputs a swept-frequency cosine with a linear instantaneous output frequency that may differ from the one specified by the frequency and time parameters.

For more information about how the block computes the output, see “Algorithms” on page 2-193.

Data Types: `single` | `double`

Parameters

Frequency sweep — Type of frequency sweep

`Linear` (default) | `Swept cosine` | `Logarithmic` | `Quadratic`

The type of output instantaneous frequency sweep, $f_i(t)$: **Linear**, **Logarithmic**, **Quadratic**, or **Swept cosine**. For more information, see “Shaping the Frequency Sweep” on page 2-192 and “Algorithms” on page 2-193.

Limitations

When you want a linearly swept chirp signal, we recommend that you use a **Linear** frequency sweep. Though a **Swept cosine** frequency sweep also yields a linearly swept chirp signal, the output might have unexpected frequency content.

- The swept cosine sweep value at the **Target time** is not necessarily the **Target frequency**. This is because the user-specified sweep is not the actual frequency sweep of the swept cosine output, as

noted in “Output Computation Method for Swept Cosine Frequency Sweep” on page 2-195. See the table Instantaneous Frequency Sweep Values for the actual value of the swept cosine sweep at the **Target time**.

- In **Swept cosine** mode, do not set the parameters so that $1/T_{sw}$ is much greater than the values of the **Initial frequency** and **Target frequency** parameters. In such cases, the actual frequency content of the swept cosine sweep might be closer to $1/T_{sw}$, far exceeding the **Initial frequency** and **Target frequency** parameter values.

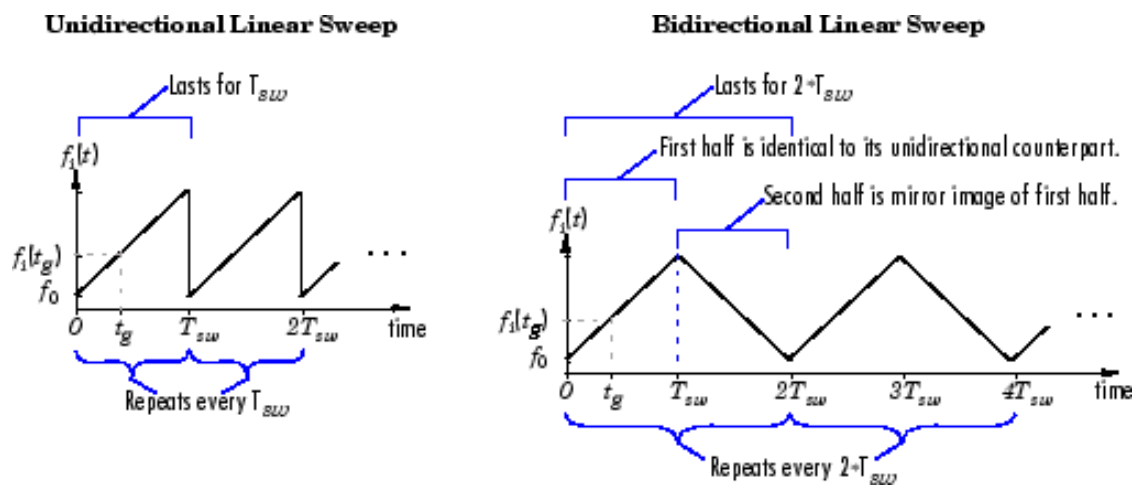

Sweep mode – Sweep mode

Unidirectional (default) | Bidirectional

The **Sweep mode** parameter determines whether your sweep is unidirectional or bidirectional, which affects the shape of your output frequency sweep (see “Shaping the Frequency Sweep” on page 2-192). The following table describes the characteristics of unidirectional and bidirectional sweeps.

Sweep Mode Parameter Settings	Sweep Characteristics
Unidirectional	<ul style="list-style-type: none"> • Lasts for one Sweep time, T_{sw} • Repeats once every T_{sw}
Bidirectional	<ul style="list-style-type: none"> • Lasts for twice the Sweep time, $2T_{sw}$ • Repeats once every $2T_{sw}$ • First half is identical to its unidirectional counterpart. • Second half is a mirror image of the first half.

The following diagram illustrates a linear sweep in both sweep modes. For information on setting the frequency values in your sweep, see “Setting Instantaneous Frequency Sweep Values” on page 2-193.

Initial frequency (Hz) – Initial frequency

1000 (default) | scalar

For Linear, Quadratic, and Swept cosine sweeps, the initial frequency, f_0 , of the output chirp signal. You can specify the **Initial frequency (Hz)** as a scalar, greater than or equal to zero. For Logarithmic sweeps, **Initial frequency** is one less than the actual initial frequency of the sweep.

Also, when the sweep is Logarithmic, you must set the **Initial frequency** to be less than the **Target frequency**.

For more information, see “Setting Instantaneous Frequency Sweep Values” on page 2-193.

Tunable: Yes

Target frequency (Hz) – Target frequency

4000 (default) | scalar

For Linear, Quadratic, and Logarithmic sweeps, the instantaneous frequency, $f_i(t_g)$, of the output at the **Target time**, t_g . You can specify the **Target frequency (Hz)** as a scalar, greater than or equal to zero. For a Swept cosine sweep, **Target frequency** is the instantaneous frequency of the output at half the **Target time**, $t_g/2$. When **Frequency sweep** is Logarithmic, you must set the **Target frequency** to be greater than the **Initial frequency**.

For more information, see “Setting Instantaneous Frequency Sweep Values” on page 2-193.

Tunable: Yes

Target time (s) – Target time of sweep

1 (default) | scalar

For Linear, Quadratic, and Logarithmic sweeps, the time, t_g , at which the sweep reaches the **Target frequency**, $f_i(t_g)$. For a Swept cosine sweep, **Target time** is the time at which the sweep reaches $2f_i(t_g) - f_0$. **Target time** must be a scalar that is greater than or equal to zero, and less than or equal to **Sweep time**, $T_{sw} \geq t_g$.

For more information, see “Setting Instantaneous Frequency Sweep Values” on page 2-193.

Tunable: Yes

Sweep time (s) – Sweep time

1 (default) | scalar

In Unidirectional **Sweep mode**, the **Sweep time**, T_{sw} , is the period of the output frequency sweep. In Bidirectional **Sweep mode**, the **Sweep time** is half the period of the output frequency sweep. **Sweep time** must be a scalar that is greater than or equal to **Target time**, $T_{sw} \geq t_g$.

Tunable: Yes

Initial phase (rad) – Initial phase of cosine output

0 (default) | scalar

The phase, ϕ_0 , of the cosine output at $t=0$; $y_{chirp}(t) = \cos(\phi_0)$. You can specify the **Initial phase (rad)** as a scalar that is greater than or equal to zero.

Tunable: Yes

Sample time – Output sample period

1/8000 (default) | positive scalar

The sample period, T_s , of the output. The output frame period is $M_o T_s$, where M_o is the number of samples per frame.

Samples per frame — Samples per frame

1 (default) | positive integer

The number of samples, M_o , to buffer into each output frame, specified as a positive integer scalar.

Output data type — Output data type

Double (default) | Single

The data type of the output, specified as single precision or double precision.

Block Characteristics

Data Types	double single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

More About

Shaping the Frequency Sweep

You control the basic shape of the output instantaneous frequency sweep, $f_i(t)$, using the **Frequency sweep** and **Sweep mode** parameters.

Parameters for Setting Sweep Shape	Possible Setting	Parameter Description
Frequency sweep	Linear Quadratic Logarithmic Swept cosine	Determines whether the sweep frequencies vary linearly, quadratically, or logarithmically. Linear and swept cosine sweeps both vary linearly.
Sweep mode	Unidirectional Bidirectional	Determines whether the sweep is unidirectional or bidirectional. For details, see “Sweep mode” on page 2-0

The following diagram illustrates the possible shapes of the frequency sweep that you can obtain by setting the **Frequency sweep** and **Sweep mode** parameters.

Possible Shapes of the Output Instantaneous Frequency Sweep

Swept Cosine and Linear Sweeps

Quadratic and Logarithmic Sweeps
 Logarithmic sweeps cannot be negative.

Unidirectional Sweeps

Positive Sweeps
 ($f_i(t_g) > f_0$)

Negative Sweeps
 ($f_i(t_g) < f_0$)

Positive Sweeps

These diagrams apply only to quadratic sweeps.

Negative Sweeps

Bidirectional Sweeps

For information on how to set the frequency values in your sweep, see “Setting Instantaneous Frequency Sweep Values” on page 2-193.

Setting Instantaneous Frequency Sweep Values

Set the following parameters to tune the frequency values of your output frequency sweep.

- **Initial frequency** (Hz), f_0
- **Target frequency** (Hz), $f_i(t_g)$
- **Target time** (seconds), t_g

The following table summarizes the sweep values at specific times for all **Frequency sweep** settings. For information on the formulas used to compute sweep values at other times, see “Algorithms” on page 2-193.

Instantaneous Frequency Sweep Values

Frequency Sweep	Sweep Value at $t = 0$	Sweep Value at $t = t_g$	Time When Sweep Value Is Target Frequency, $f_i(t_g)$
Linear	f_0	$f_i(t_g)$	t_g
Quadratic	f_0	$f_i(t_g)$	t_g
Logarithmic	f_0	$f_i(t_g)$	t_g
Swept cosine	f_0	$2f_i(t_g) - f_0$	$t_g/2$

Algorithms

The Chirp block uses one of two formulas to compute the block output, depending on the **Frequency Sweep** parameter setting. For details, see the following sections.

Equations for Output Computation

The following table shows the equations used by the block to compute the user-specified output frequency sweep, $f_i(t)$, the block output, $y_{chirp}(t)$, and the actual output frequency sweep, $f_{i(actual)}(t)$. The only time the user-specified sweep is not the actual output sweep is when the **Frequency sweep** parameter is set to Swept cosine.

Note The following equations apply only to unidirectional sweeps in which $f_i(0) < f_i(t_g)$. To derive equations for other cases, examine the following table and the diagram in “Shaping the Frequency Sweep” on page 2-192.

The table of equations used by the block contains the following variables:

- $f_i(t)$ — the user-specified frequency sweep
- $f_{i(actual)}(t)$ — the actual output frequency sweep, usually equal to $f_i(t)$
- $y(t)$ — the Chirp block output
- $\psi(t)$ — the phase of the chirp signal, where $\psi(0) = 0$, and $2\pi f_i(t)$ is the derivative of the phase

$$f_i(t) = \frac{1}{2\pi} \cdot \frac{d\psi(t)}{dt}$$

- ϕ_0 — the **Initial phase** parameter value, where $y_{chirp}(0) = \cos(\phi_0)$

Equations for Unidirectional Positive Sweeps

Frequency Sweep	Block Output Chirp Signal	User-Specified Frequency Sweep, $f_i(t)$	β	Actual Frequency Sweep, $f_{i(actual)}(t)$
Linear	$y(t) = \cos(\psi(t) + \phi_0)$	$f_i(t) = f_0 + \beta t$	$\beta = \frac{f_i(t_g) - f_0}{t_g}$	$f_{i(actual)}(t) = f_i(t)$
Quadratic	Same as Linear	$f_i(t) = f_0 + \beta t^2$	$\beta = \frac{f_i(t_g) - f_0}{t_g^2}$	$f_{i(actual)}(t) = f_i(t)$
Logarithmic	Same as Linear	$F_i(t) = f_0 \left(\frac{f_i(t_g)}{f_0} \right)^{\frac{t}{t_g}}$ Where $f_i(t_g) > f_0 > 0$	N/A	$f_{i(actual)}(t) = f_i(t)$
Swept cosine	$y(t) = \cos(2\pi f_i(t)t + \phi_0)$	Same as Linear	Same as Linear	$f_{i(actual)}(t) = f_i(t) + \beta t$

Output Computation Method for Linear, Quadratic, and Logarithmic Frequency Sweeps

The derivative of the phase of a chirp function gives the instantaneous frequency of the chirp function. The Chirp block uses this principle to calculate the chirp output when the **Frequency Sweep** parameter is set to Linear, Quadratic, or Logarithmic.

$$y_{chirp}(t) = \cos(\psi(t) + \phi_0)$$

Linear, quadratic, or logarithmic chirp signal with phase $\psi(t)$

$$f_i(t) = \frac{1}{2\pi} \cdot \frac{d\psi(t)}{dt}$$

Phase derivative is instantaneous frequency

For instance, if you want a chirp signal with a linear instantaneous frequency sweep, set the **Frequency Sweep** parameter to **Linear**, and tune the linear sweep values by setting other parameters appropriately. The block outputs a chirp signal, the phase derivative of which is the specified linear sweep. This ensures that the instantaneous frequency of the output is the linear sweep you desired. For equations describing the linear, quadratic, and logarithmic sweeps, see “Equations for Output Computation” on page 2-194.

Output Computation Method for Swept Cosine Frequency Sweep

To generate the swept cosine chirp signal, the block sets the swept cosine chirp output as follows.

$$y_{chirp}(t) = \cos(\psi(t) + \phi_0) = \cos(2\pi f_i(t)t + \phi_0)$$

Swept cosine chirp output
(Instantaneous frequency equation, does not hold.)

The instantaneous frequency equation, shown in “Output Computation Method for Linear, Quadratic, and Logarithmic Frequency Sweeps” on page 2-194, does not hold for the swept cosine chirp, so the user-defined frequency sweep, $f_i(t)$, is not the actual output frequency sweep, $f_{i(actual)}(t)$, of the swept cosine chirp. Thus, the swept cosine output might not behave as you expect. To learn more about swept cosine chirp behavior, see “Frequency sweep” on page 2-0 described for the **Frequency sweep** parameter and “Equations for Output Computation” on page 2-194.

Cholesky Factorization

Factor square Hermitian positive definite matrix into triangular components

Library

Math Functions / Matrices and Linear Algebra / Matrix Factorizations

dspfacto

Description

The Cholesky Factorization block uniquely factors the square Hermitian positive definite input matrix S as

$$S = LL^*$$

where L is a lower triangular square matrix with positive diagonal elements and L^* is the Hermitian (complex conjugate) transpose of L . The block outputs a matrix with lower triangle elements from L and upper triangle elements from L^* . The output is not in the same form as the output of the MATLAB `chol` function. In order to convert the output of the Cholesky Factorization block to the MATLAB form, use the following equation:

$$R = \text{triu}(LL');$$

In order to extract the L matrix exclusively, pass the output of the Cholesky Factorization block, LL' , to the Extract Triangular Matrix block. Setting the **Extract** parameter of the Extract Triangular Matrix to **Lower** extracts the L matrix. Setting the **Extract** parameter to **Upper** extracts the L' matrix.

Here, LL' is the output of the Cholesky Factorization block. Due to roundoff error, these equations do not produce a result that is exactly the same as the MATLAB result.

Block Output Composed of L and L^*

Input Requirements for Valid Output

The block output is valid only when its input has the following characteristics:

- Hermitian — The block does *not* check whether the input is Hermitian; it uses only the diagonal and upper triangle of the input to compute the output.
- Real-valued diagonal entries — The block disregards any imaginary component of the input's diagonal entries.
- Positive definite — Set the block to notify you when the input is not positive definite as described in “Response to Nonpositive Definite Input” on page 2-197.

Response to Nonpositive Definite Input

To generate a valid output, the block algorithm requires a positive definite input (see “Input Requirements for Valid Output” on page 2-197). Set the **Non-positive definite input** parameter to determine how the block responds to a nonpositive definite input:

- Ignore — Proceed with the computation and *do not* issue an alert. The output is *not* a valid factorization. A partial factorization will be present in the upper left corner of the output.
- Warning — Display a warning message in the MATLAB Command Window, and continue the simulation. The output is *not* a valid factorization. A partial factorization will be present in the upper left corner of the output.
- Error — Display an error dialog and terminate the simulation.

Note The **Non-positive definite input** parameter is a diagnostic parameter. Like all diagnostic parameters on the Configuration Parameters dialog box, it is set to **Ignore** in the code generated for this block by Simulink Coder™ code generation software.

Performance Comparisons with Other Blocks

Note that L and L^* share the same diagonal in the output matrix. Cholesky factorization requires half the computation of Gaussian elimination (LU decomposition), and is always stable.

Parameters

Non-positive definite input

Response to nonpositive definite matrix inputs: **Ignore**, **Warning**, or **Error**. See “Response to Nonpositive Definite Input” on page 2-197.

Cholesky Inverse

Compute inverse of Hermitian positive definite matrix using Cholesky factorization

Library

Math Functions / Matrices and Linear Algebra / Matrix Inverses

dspinverses

Description

The Cholesky Inverse block computes the inverse of the Hermitian positive definite input matrix S by performing Cholesky factorization.

$$S^{-1} = (LL^*)^{-1}$$

L is a lower triangular square matrix with positive diagonal elements and L^* is the Hermitian (complex conjugate) transpose of L . Only the diagonal and upper triangle of the input matrix are used, and any imaginary component of the diagonal entries is disregarded. Cholesky factorization requires half the computation of Gaussian elimination (LU decomposition), and is always stable.

Response to Nonpositive Definite Input

The algorithm requires that the input be Hermitian positive definite. When the input is not positive definite, the block reacts with the behavior specified by the **Non-positive definite input** parameter. The following options are available:

- **Ignore** — Proceed with the computation and *do not* issue an alert. The output is *not* a valid inverse.
- **Warning** — Display a warning message in the MATLAB Command Window, and continue the simulation. The output is *not* a valid inverse.
- **Error** — Display an error dialog box and terminate the simulation.

Note The **Non-positive definite input** parameter is a diagnostic parameter. Like all diagnostic parameters on the Configuration Parameters dialog box, it is set to **Ignore** in the code generated for this block by Simulink Coder code generation software.

Parameters

Non-positive definite input

Response to nonpositive definite matrix inputs: Ignore, Warning, or Error. See “Response to Nonpositive Definite Input” on page 2-199.

Cholesky Solver

Solve $SX = B$ for X when S is a square Hermitian positive definite matrix

Library: DSP System Toolbox / Math Functions / Matrices and Linear Algebra / Linear System Solvers

Description

The Cholesky Solver block solves the linear system $SX = B$ by applying the Cholesky factorization to the input matrix, where:

- S is an M -by- M square matrix input through the **S** port. The matrix must be Hermitian positive definite.
- B is an M -by- N matrix input through the **B** port.
- X is the M -by- N output matrix and is the unique solution to the equations.

Ports

Input

S — Input **S** matrix

M -by- M matrix

Specify the input M -by- M square matrix S through this port. The matrix must be Hermitian positive definite. The block uses only the diagonal and upper triangle of the matrix and disregards any imaginary component in the diagonal entries. Inputs S and B must have the same number of rows.

Data Types: single | double

B — **B** matrix

M -by- N matrix | M -by-1 vector

Specify the B matrix in the $SX = B$ equation as an M -by- N matrix or an M -by-1 vector.

When you specify an M -by-1 vector, the block treats the length- M unoriented vector input at port **B** as an M -by-1 matrix. Inputs S and B must have the same number of rows.

Data Types: single | double

Output

X — Solution to system of equations

M -by- N matrix | M -by-1 matrix

The block returns the output as an M -by- N matrix or an M -by-1 matrix. The size of the matrix X is same as the size of the matrix B .

Data Types: single | double

Parameters

Non-positive definite input — Response to nonpositive definite matrix input

Ignore (default) | Warning | Error

The input matrix S must be Hermitian positive definite.

When the input is not positive definite, the block reacts as per the behavior you specify in the **Non-positive definite input** parameter.

- **Ignore** — Proceed with the computation and do not issue an alert. The output is not a valid solution.
- **Warning** — Proceed with the computation and display a warning message in the MATLAB command window. The output is not a valid solution.
- **Error** — Display an error dialog box and terminate the simulation.

Note The **Non-positive definite input** parameter is a diagnostic parameter. Like all diagnostic parameters in the Configuration Parameters dialog box, it is set to **Ignore** in the code generated for this block by Simulink Coder code generation software.

Block Characteristics

Data Types	double single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Algorithms

Cholesky factorization uniquely factors the Hermitian positive definite input matrix S as

$$S = LL^*$$

where L is a lower triangular square matrix with positive diagonal elements.

The equation $SX = B$ then becomes

$$LL^*X = B,$$

which is solved for X by substituting $Y = L^*X$ and solving the following two triangular systems by forward and backward substitution, respectively.

$$LY = B$$

$$L^*X = Y$$

CIC Compensator (Obsolete)

(Removed) Design CIC compensator

Compatibility

Note The CIC Compensator block has been removed from the DSP System Toolbox block library. Existing instances of the CIC Compensator block will continue to operate. For new models, use the CIC Compensation Decimator and CIC Compensation Interpolator blocks. These blocks replace the functionality of the CIC Compensator block, when **FilterType** is set to **Decimator** and **Interpolator**, respectively.

Library

Filtering / Filter Designs

dspfdesign

Description

This block brings the filter design capabilities of the `filterBuilder` function to the Simulink environment.

Dialog Box

See “CIC Compensator Design — Main Pane” on page 5-608 for more information about the parameters of this block. The **Data Types** and **Code Generation** panes are not available for blocks in the DSP System Toolbox Filter Designs library.

Function Block Parameters: CIC Compensator

View filter response

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.

- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

In its normal mode of operation, the CIC Compensator block allows the adder's numbers to wrap around. The Fixed-Point infrastructure then causes warnings to appear on the command line.

Filter Specifications

In this group, you specify your filter format, such as the filter order mode and the filter type.

Filter order mode

Select either `Minimum` (the default) or `Specify` from the drop-down list. Selecting `Specify` enables the **Order** option (see the following sections) so you can enter the filter order.

Filter type

Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, the block specifies a single-rate filter.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

Order

Enter the filter order. This option is enabled only if `Specify` was selected for **Filter order mode**.

Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default value is 2.

Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default value is 2.

Number of CIC sections

Specify the number of sections in the CIC filter for which you are designing this compensator. Select the number of sections from the drop-down list or enter the number.

Differential Delay

Specify the differential delay of your target CIC filter. The default value is 1. Most CIC filters use 1 or 2.

Frequency Specifications

The parameters in this group allow you to specify your filter response curve.

Frequency Specifications

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0–1)` to enter frequencies in normalized form. This behavior is

the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Output Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter output. When you provide an output sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available only when you design interpolators.

Fpass

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Fstop

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Magnitude Specifications

Parameters in this group specify the filter response in the passbands and stopbands.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. From the drop-down list, select one of the following options:

- Linear — Specify the magnitude in linear units.
- dB — Specify the magnitude in decibels (default).
- Squared — Specify the magnitude in squared units.

Apass

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels

Algorithm

The parameters in this group allow you to specify the design method and structure of your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default method is Equiripple.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 20 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Phase constraint

Specify the phase constraint of the filter as **Linear**, **Maximum**, or **Minimum**.

Minimum order

When you select this parameter, the design method determines and design the minimum order filter to meet your specifications. Some filters do not provide this parameter. Select **Any**, **Even**, or **Odd** from the drop-down list to direct the design to be any minimum order, or minimum even order, or minimum odd order.

Match Exactly

Specifies that the resulting filter design matches either the passband or stopband or both bands when you select **passband** or **stopband** or **both** from the drop-down list.

Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- **Flat** — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- **Linear** — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- **1/f** — Specifies that the stopband attenuation changes exponentially as the frequency increases, where f is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to **Flat**, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to **Linear**, enter the slope of the stopband in units of dB/rad/s. The block applies that slope to the stopband.
- When you set **Stopband shape** to **1/f**, enter a value for the exponent n in the relation $(1/f)^n$ to define the stopband decay. The block applies the $(1/f)^n$ relation to the stopband to result in an exponentially decreasing stopband attenuation.

Filter Implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, the filter uses direct-form structure.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of n unit delays with a single delay by n .
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Input processing

Specify how the block should process the input. The available options may vary depending on the settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

Note The **Inherited** (this choice will be removed – see release notes) option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- **Enforce single-rate processing** — When you select this option, the block maintains the sample rate of the input.
- **Allow multirate processing** — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to **Elements as channels (sample based)**.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

CIC Compensation Interpolator

Compensate for CIC filter using FIR interpolator

Library

Filtering/Filter Designs

dspfdesign

Description

The CIC Compensation Interpolator block uses an FIR polyphase interpolator as the compensation filter. CIC compensation interpolators are multirate FIR filters that can be cascaded with CIC interpolators to mitigate the drawbacks of the CIC filters.

CIC interpolation filters are used in areas that require high interpolation. These filters are popular in ASICs and FPGAs, since they do not have any multipliers. CIC filters have two drawbacks:

- CIC filters have a magnitude response that causes a droop in the passband region. This magnitude response is:

$$abs\left(\frac{\sin\left(M\frac{\omega}{2}\right)}{\sin\left(\frac{\omega}{2}\right)}\right)^n$$

- M — Differential delay
- n — Number of stages
- ω — Normalized angular frequency
- CIC filters have a wide transition region.

The compensation interpolator filters have an inverse sinc passband response to correct for the CIC droop, and they have a narrow transition width.

This block brings the capabilities of the `dsp.CICCompensationInterpolator` System object to the Simulink environment.

Rate change factor

Rate change factor for the CIC filter to be compensated, specified as a positive scalar integer. The default is 2.

Number of sections

Number of integrator and comb sections of the CIC filter to be compensated, specified as a positive scalar integer. The default is 2.

Differential delay

Delay value used in each of the comb sections of the CIC filter to be compensated, specified as a positive scalar integer. The default is 1.

Filter parameters**Interpolation factor**

Interpolation factor of the compensator, specified as a positive scalar integer. The default value is 2.

Minimum order filter design

When you select this check box, the block designs filters with the minimum order that meets the specifications for passband frequency, stopband frequency, passband ripple, and stopband attenuation. When you clear this check box, the block designs filters with the order that you specify in **Filter order**.

By default, this check box is selected.

Filter order

Order of the compensation filter, specified as a positive scalar integer. The default is 12.

Passband edge frequency (Hz)

Passband edge frequency of the compensation filter, specified as a real positive scalar in Hz.

Passband edge frequency (Hz) must be less than $F_s/2$, where F_s is the output sample rate. The default is 100000.

Stopband edge frequency (Hz)

Stopband edge frequency of the compensation filter, specified as a real positive scalar in hertz.

Stopband edge frequency (Hz) must be less than $F_s/2$, where F_s is the output sample rate. The default is 400000.

Passband ripple (dB)

Passband ripple of compensation filter, specified as a real positive scalar in dB. The default is 0.1.

Stopband attenuation (dB)

Stopband attenuation of compensation filter, specified as a real positive scalar in dB. The default is 60.

Inherit sample rate from input

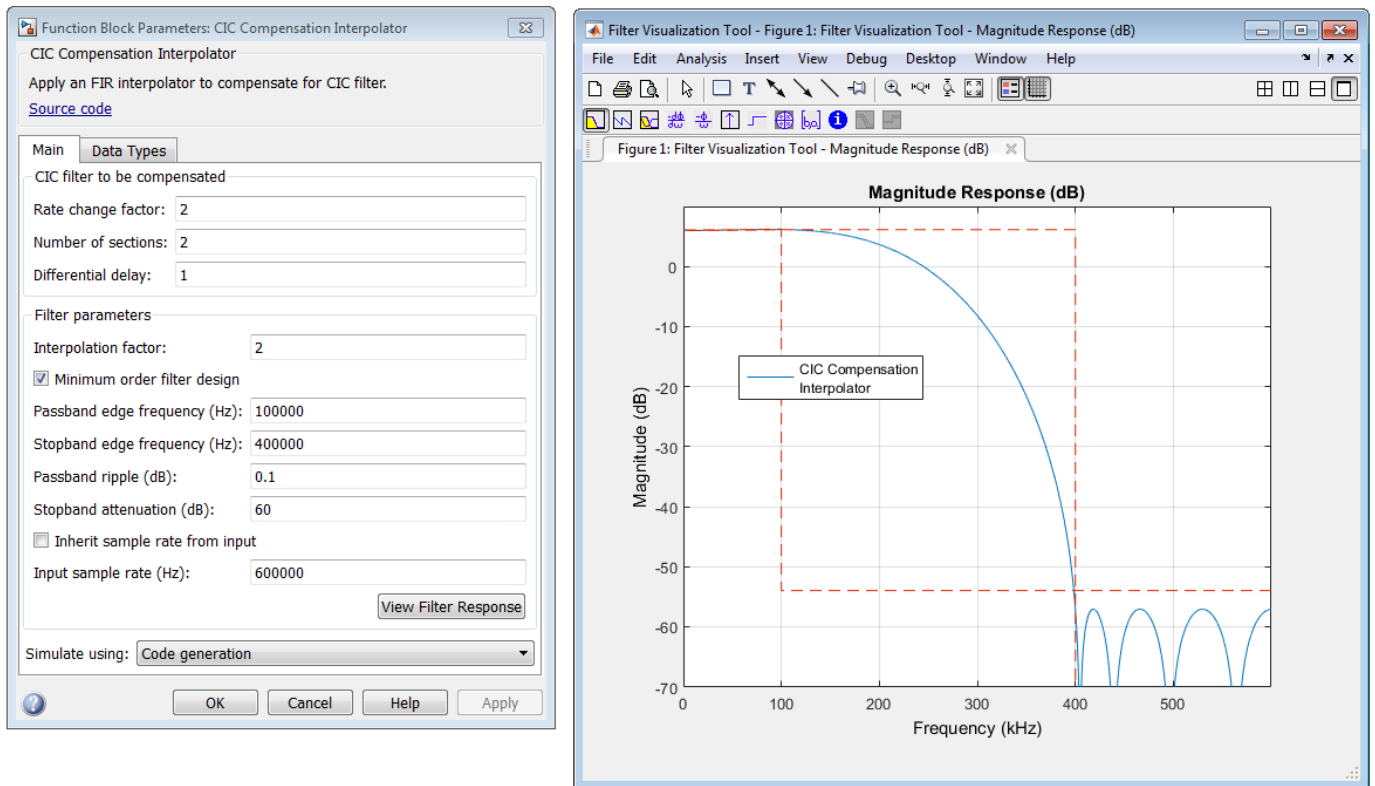

When you select this check box, the block inherits its sample rate from the input signal. When you clear this check box, you must specify the sample rate in **Input sample rate (Hz)**.

Input sample rate (Hz)

Input sample rate, specified as a scalar in Hz. The default is 600000.

View Filter Response

Opens the Filter Visualization Tool FVTool and displays the magnitude/phase response of the CIC Compensation Interpolator. The response is based on the block dialog box parameters. Changes made to these parameters update FVTool.

To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

Simulate using

Type of simulation to run. You can set this parameter to:

- Code generation (default)

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.

- Interpreted execution

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

Data Types Tab

Rounding mode

Rounding method for the output fixed-point operations. The rounding methods are Ceiling, Convergent, Floor, Nearest, Round, Simplest, and Zero. The default is Floor.

Coefficients

Fixed-point data type of the coefficients, specified as one of the following:

- `fixdt(1, 16)` (default) — Signed fixed-point data type of word length 16, with binary point scaling. The block determines the fraction length automatically from the coefficient values in such a way that the coefficients occupy maximum representable range without overflowing.

- `fixdt(1,16,0)` — Signed fixed-point data type of word length 16, fraction length 0. You can change the fraction length to any other integer value.
- `<data type expression>` — Specify the coefficients data type by using the expression that evaluates to a data type object, for example, numeric type (`fixdt([],16,15)`), to specify the coefficients data type. Specify the sign mode of this data type as `[]` or `true`.
- **Refresh Data Type** — Refreshes to the default data type.

Click the **Show data type assistant** button  to display the data type assistant, which helps you set the stage input parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Algorithms

The response of a CIC filter is given by:

$$H_{cic}(\omega) = \left[\frac{\sin\left(\frac{RD\omega}{2}\right)}{\sin\left(\frac{\omega}{2}\right)} \right]^N$$

R , D , and N are the rate change factor, the differential delay, and the number of sections of the CIC filter, respectively.

After decimation, the cic response has the form:okay

$$H_{cic}(\omega) = \left[\frac{\sin\left(\frac{D\omega}{2}\right)}{\sin\left(\frac{\omega}{2R}\right)} \right]^N$$

The normalized version of this last response is the one that the CIC compensator needs to compensate. Hence, the passband response of the CIC compensator should take the following form:

$$H_{ciccomp}(\omega) = \left[RD \frac{\sin\left(\frac{\omega}{2R}\right)}{\sin\left(\frac{D\omega}{2}\right)} \right]^N \text{ for } \omega \leq \omega_p < \pi$$

where ω_p is the passband frequency of the CIC compensation filter.

Notice that when $\omega/2R \ll \pi$, the previous equation for $H_{ciccomp}(\omega)$ can be simplified using the fact that $\sin(x) \cong x$:

$$H_{ciccomp}(\omega) \approx \left[\frac{\left(\frac{D\omega}{2}\right)}{\sin\left(\frac{D\omega}{2}\right)} \right]^N = \left[\text{sinc}\left(\frac{D\omega}{2}\right) \right]^{-N} \text{ for } \omega \leq \omega_p < \pi$$

This previous equation is the inverse sinc approximation to the true inverse passband response of the CIC filter.

Rate change factor

Rate change factor for the CIC filter to be compensated, specified as a positive scalar integer. The default is 2.

Number of sections

Number of decimator and comb sections of the CIC filter to be compensated, specified as a positive scalar integer. The default is 2.

Differential delay

Delay value used in each of the comb sections of the CIC filter to be compensated, specified as a positive scalar integer. The default is 1.

Decimation factor

Decimation factor of the compensator, specified as a positive scalar integer. The number of input rows must be a multiple of the decimation factor. The default is 2.

Minimum order filter design

When you select this check box, the block designs filters with the minimum order that meets the specifications passband frequency, stopband frequency, passband ripple, and stopband attenuation. When you clear this check box, the block designs filters with the order that you specify in **Filter order**.

By default, this check box is selected.

Filter order

Order of compensation filter, specified as a positive scalar integer. The default is 12.

Passband edge frequency (Hz)

Passband edge frequency of the compensation filter, specified as a real positive scalar in Hz.

Passband edge frequency (Hz) must be less than $F_s/2$, where F_s is the input sample rate. The default value is 100000.

Stopband edge frequency (Hz)

Stopband edge frequency of the compensation filter, specified as a real positive scalar in Hz.

Stopband edge frequency (Hz) must be less than $F_s/2$, where F_s is the input sample rate. This parameter applies when you select the **Minimum order filter design** check box. The default is 400000.

Passband ripple (dB)

Passband ripple of the compensation filter, specified as a real positive scalar in dB. The default is 0.1.

Stopband attenuation (dB)

Stopband attenuation of the compensation filter, specified as a real positive scalar in dB. The default is 60.

Inherit sample rate from input

When you select this check box, the block inherits its sample rate from the input signal. When you clear this check box, you must specify the sample rate in **Input sample rate (Hz)**.

Input sample rate (Hz)

Input sample rate, specified as a scalar in Hz. The default is 1200000.

To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

Simulate using

Type of simulation to run. You can set this parameter to:

- Code generation (default)

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.

- Interpreted execution

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

Data Types Tab

Rounding mode

Rounding method for the output fixed-point operations. The rounding methods are Ceiling, Convergent, Floor, Nearest, Round, Simplest, and Zero. The default is Floor.

Coefficients

Fixed-point data type of the coefficients, specified as one of the following:

- `fixdt(1,16)` (default) — Signed fixed-point data type of word length 16, with binary point scaling. The block determines the fraction length automatically from the coefficient values in such a way that the coefficients occupy maximum representable range without overflowing.

- `fixdt(1,16,0)` — Signed fixed-point data type of word length 16, fraction length 0. You can change the fraction length to any other integer value.
- `<data type expression>` — Specify the coefficients data type by using an expression that evaluates to a data type object, for example, numeric type (`fixdt([],16,15)`), to specify the coefficients data type. Specify the sign mode of this data type as `[]` or `true`.
- Refresh Data Type — Refresh to the default data type.

Click the **Show data type assistant** button  to display the data type assistant, which helps you set the stage input parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed or unsigned) • 8-, 16-, 32-, and 64-bit signed integers
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, 32-, and 64-bit signed integers

Algorithms

The response of a CIC filter is given by:

$$H_{cic}(\omega) = \left[\frac{\sin\left(\frac{RD\omega}{2}\right)}{\sin\left(\frac{\omega}{2}\right)} \right]^N$$

R , D , and N are the rate change factor, the differential delay, and the number of sections of the CIC filter, respectively.

After decimation, the cic response has the form:okay

$$H_{cic}(\omega) = \left[\frac{\sin\left(\frac{D\omega}{2}\right)}{\sin\left(\frac{\omega}{2R}\right)} \right]^N$$

The normalized version of this last response is the one that the CIC compensator needs to compensate. Hence, the passband response of the CIC compensator should take the following form:

$$H_{ciccomp}(\omega) = \left[RD \frac{\sin\left(\frac{\omega}{2R}\right)}{\sin\left(\frac{D\omega}{2}\right)} \right]^N \text{ for } \omega \leq \omega_p < \pi$$

where ω_p is the passband frequency of the CIC compensation filter.

Notice that when $\omega/2R \ll \pi$, the previous equation for $H_{ciccomp}(\omega)$ can be simplified using the fact that $\sin(x) \cong x$:

$$H_{ciccomp}(\omega) \approx \left[\frac{\left(\frac{D\omega}{2}\right)}{\sin\left(\frac{D\omega}{2}\right)} \right]^N = \left[\text{sinc}\left(\frac{D\omega}{2}\right) \right]^{-N} \text{ for } \omega \leq \omega_p < \pi$$

This previous equation is the inverse sinc approximation to the true inverse passband response of the CIC filter.

CIC Compensation Interpolator

CIC Decimation

Decimate signal using cascaded integrator-comb filter

Library: DSP System Toolbox / Filtering / Multirate Filters
 DSP System Toolbox HDL Support / Filtering

Description

The CIC Decimation block performs a sample rate decrease (decimation) on an input signal by an integer factor. Cascaded Integrator-Comb (CIC) filters are a class of linear phase FIR filters comprised of a comb part and an integrator part.

The block supports real and complex fixed-point inputs. In its normal mode of operation, the CIC Decimation block allows the adder's numeric values to overflow and wrap around [1] [3]. The Fixed-Point infrastructure then causes overflow warnings to appear on the command line. This overflow is of no consequence.

The CIC Decimation block requires a Fixed-Point Designer™ license.

Ports

Input

Port_1 — Input signal

vector | matrix

Data input, specified as a vector or matrix. The number of input rows must be a multiple of the decimation factor.

If the input is fixed-point, it must be signed integer or signed fixed point with power-of-two slope and zero bias.

Data Types: int8 | int16 | int32 | int64 | fixed point

Output

Port_1 — CIC decimated output

vector | matrix

CIC decimated output, returned as a vector or a matrix. The data type of the output is determined by the settings in the block dialog. The complexity of the output matches that of the input. The number of output rows is $(1/R) \times Num$, where R is the decimation factor and Num is the number of input rows.

Data Types: int8 | int16 | int32 | int64 | fixed point

Parameters

Coefficient source — Source of the filter information

Dialog parameters (default) | Filter object

Source of the filter information, specified as one of the following:

- **Dialog parameters** — Enter information about the filter, such as **Decimation factor (R)**, **Differential delay (M)** and **Number of sections (N)**, in the block dialog.
- **Filter object** — Specify the filter using a `dsp.CICDecimator` System object.

Different items appear on the CIC Decimation block dialog depending on whether you select **Dialog parameters** or **Filter object** in the **Coefficient source** parameter.

Decimation factor (R) — Decimation factor

2 (default) | integer

Decimation factor of the filter, specified as an integer greater than 1.

Dependencies

This parameter appears when you set **Coefficient source** to **Dialog parameters**.

Differential Delay (M) — Differential delay

1 (default) | positive integer

Specify the differential delay of the comb part of the filter, M , as a positive integer. For more details, see “CIC Decimation Filter” on page 4-252.

Dependencies

This parameter appears when you set **Coefficient source** to **Dialog parameters**.

Number of sections (N) — Number of filter sections

2 (default) | positive integer

Specify the number of filter sections. The number you specify determines the number of sections in either the comb part of the filter or the integrator part of the filter. This value does not represent the total number of sections in the comb and integrator parts combined.

Dependencies

This parameter appears when you set **Coefficient source** to **Dialog parameters**.

Data type specification mode — Specify word length and fraction length of filter sections and output

Full precision (default) | Minimum section word lengths | Specify word lengths | Binary point scaling

Choose how you specify the fixed-point word length and fraction length of the filter sections and/or output:

- **Full precision** — The word and fraction lengths of the filter sections and outputs are automatically selected for you. All word lengths (WL) are set to:

$$WL = \text{ceil}(N \times \log_2(M \times R)) + I$$

where,

- I -- Input word length
- M -- Differential delay
- N -- Number of sections
- R -- Decimation factor

All fraction lengths are set to the input fraction length.

- **Minimum section word lengths** — Specify the word length of the filter output in the **Output word length** parameter. The block automatically selects the word lengths of the filter sections and all fraction lengths such that each of the section word lengths is as small as possible. The precision of each filter section is less than in **Full precision** mode, but the range of each section is preserved.
- **Specify word lengths** — Specify the word lengths of the filter sections and output in the **Section word lengths** and **Output word length** parameters. The block automatically selects fraction lengths for the filter sections and output such that the range of each section is preserved when the least significant bits are discarded.
- **Binary point scaling** — Specify the word and fraction lengths of the filter sections and output in the **Section word lengths**, **Section fraction lengths**, **Output word length**, and **Output fraction length** parameters.

Dependencies

This parameter appears when you set **Coefficient source** to **Dialog** parameters.

Section word lengths — Word length of filter sections

[16 16 16 16] (default) | scalar | row vector

Word lengths of filter sections, specified as a scalar or a vector of length equal to $2N$, where N is the number of filter sections. The section word length must be in the range [2, 128].

Dependencies

This parameter appears when you set **Coefficient source** to **Dialog** parameters and **Data type specification mode** to either **Specify word lengths** or **Binary point scaling**.

Section fraction lengths — Fraction lengths of filter sections

0 (default) | integer

Fraction lengths of filter sections, specified as an integer.

Dependencies

This parameter appears when you set **Coefficient source** to **Dialog** parameters and **Data type specification mode** to **Binary point scaling**.

Output word length — Word length of filter output

32 (default) | integer

Word length of the filter output, specified as an integer in the range [2, 128].

Dependencies

This parameter appears when you set **Coefficient source** to Dialog parameters and **Data type specification mode** to any option other than Full precision.

Output fraction length — Fraction length of filter output

0 (default) | integer

Fraction length of the filter output, specified as an integer.

Dependencies

This parameter appears when you set **Coefficient source** to Dialog parameters and **Data type specification mode** to Binary point scaling.

Rate options — Rate processing rule

Enforce single-rate processing (default) | Allow multirate processing

Specify the rate processing rule for the block:

- **Enforce single-rate processing** — The block performs frame-based processing and produces an output that has the same sample rate as the input. To decimate the signal while maintaining the input sample rate, the block decreases the output frame size. In this mode, the input column size must be a multiple of **Decimation Factor (R)**.
- **Allow multirate processing** — In this mode, the block produces an output with a sample rate that is R times slower than the input sample rate.

Filter object — Multirate filter object

dsp.CICDecimator

Specify the name of the multirate filter object that you want the block to implement. You must specify the filter as a dsp.CICDecimator System object.

You can define the System object in the block dialog or in a MATLAB workspace variable.

For information on creating System objects, see “Define Basic System Objects”.

Dependencies

This parameter appears when you set **Coefficient source** to Filter object.

View Filter Response — View filter response

gui button

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product and displays the filter response of the filter defined in the block. For more information on FVTool, see the Signal Processing Toolbox documentation.

Note If you specify a filter in the **Filter object** parameter, you must apply the filter by clicking the **Apply** button before using the **View Filter Response** button.

Block Characteristics

More About

CIC Filter

CIC filters are an optimized class of linear phase FIR filters composed of a comb part and an integrator part.

The CIC decimation filter is conceptually given by a single rate CIC filter, $H(z)$ which is a lowpass anti-imaging filter, followed by a downsampler. The CIC decimation filter decreases the sample rate of an input signal by an integer factor using a cascaded integrator-comb (CIC) filter.

In a more efficient implementation, the single rate CIC filter $H(z)$ is factorized this way:

$$H(z) = \left[\sum_{k=0}^{RM-1} z^{-k} \right]^N = \frac{(1 - z^{-RM})^N}{(1 - z^{-1})^N} = \frac{1}{(1 - z^{-1})^N} \cdot \frac{(1 - z^{-RM})^N}{1} = H_I^N(z) \cdot H_C^N(z)$$

where,

- H_I is the transfer function of the integrator part of the filter containing N stages of integrators.
- H_C is the transfer function of the N sections of the cascaded comb filters, each with a width of RM .
- N is the number of sections. The number of sections in a CIC filter is defined as the number of sections in either the comb part or the integrator part of the filter. This value does not represent the total number of sections throughout the entire filter.

- R is the decimation factor.
- M is the differential delay.

In the overall multirate realization, the algorithm applies the noble identity for decimation and moves the rate change factor, R , to follow after the N sections of the cascaded integrators. The transfer function of the resulting filter is given by the following equation:

$$H(z) = \frac{(1 - z^{-M})^N}{(1 - z^{-1})^N}.$$

For a block diagram that shows the multirate implementation, see Algorithms on page 2-230.

Algorithms

CIC Decimation Filter

The CIC decimation filter in More About on page 2-229 is realized as a cascade of N sections of the integrators followed by a rate change factor of R , followed by N sections of comb filters.

This diagram shows two sections of cascaded integrators and two sections of cascaded comb filters. The unit delay in the integrator portion of the CIC filter can be located in either the feedforward or the feedback path. These two configurations yield identical filter frequency response. However, the numerical outputs from these two configurations are different due to the latency. This block puts the unit delay in the feedforward path of the integrator because it is a preferred configuration for HDL implementation.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the memcopy or memset function (`string.h`) under certain conditions.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Coder supports **Coefficient source** options **Dialog parameters** and **Filter object**.

AddPipelineRegisters Support

When you use **AddPipelineRegisters**, registers are placed based on the filter structure. The pipeline register placement determines the latency.

Pipeline Register Placement	Latency (clock cycles)
A pipeline register is added between the comb stages of the differentiators.	NS - 1, where NS is number of sections (at the output side).

HDL Filter Properties

AddPipelineRegisters	Insert a pipeline register between stages of computation in a filter. See also AddPipelineRegisters (HDL Coder).
-----------------------------	--

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see "ConstrainedOutputPipeline" (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "InputPipeline" (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "OutputPipeline" (HDL Coder).

Restrictions

- Vector and frame inputs are not supported for HDL code generation.
- When you select **Dialog parameters**, the **Filter Structure** option Zero-latency decimator is not supported for HDL code generation. From the **Filter Structure** drop-down list, select Decimator.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

If the input is fixed point, it must be a signed integer or signed fixed point with a power-of-two slope and zero bias.

CIC Filter

Design Cascaded Integrator-Comb (CIC) Filter

Library

Filtering / Filter Designs

dspfdesign

Description

This block brings the filter design capabilities of the `filterBuilder` function to the Simulink environment.

Dialog Box

Main Pane

See “CIC Filter Design — Main Pane” on page 5-607 for more information about the parameters of this block. The **Data Types** and **Code Generation** panes are not available for blocks in the DSP System Toolbox Filter Designs library.

View filter response

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

In its normal mode of operation, the CIC Filter block allows the adder’s numbers to wrap around. The Fixed-Point infrastructure then causes warnings to appear on the command line.

Filter Specifications

In this group, you specify your CIC filter format, such as the filter type and the differential delay.

Filter type

Select whether your filter will be a **decimator** or an **interpolator**. Your choice determines the type of filter and the design methods and structures that are available to implement your filter.

Selecting **decimator** or **interpolator** activates the **Factor** option. When you design an interpolator, you enable the **Output sample rate** parameter.

When you design either a decimator or interpolator, the resulting filter is a CIC filter that decimates or interpolates your input signal.

Differential delay

Specify the differential delay of your CIC filter as an integer value greater than or equal to 1. The default value is 1. The differential delay changes the shape, number, and location of nulls in the filter response. Increasing the differential delay increases the sharpness of the nulls and the response between the nulls. In practice, differential delay values of 1 or 2 are the most common.

Factor

Specify the decimation or interpolation factor for your filter as an integer value greater than or equal to 1. The default value is 2.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0–1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input sample rate** parameter.

Input sample rate

F_s, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Output sample rate

F_s, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter output. When you provide an output sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available only when you design interpolators.

Passband frequency

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. From the drop-down list, select one of the following options:

- **Linear** — Specify the magnitude in linear units.
- **dB** — Specify the magnitude in decibels (default).
- **Squared** — Specify the magnitude in squared units.

Stopband attenuation

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

Filter Implementation

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- **Enforce single-rate processing** — When you select this option, the block maintains the sample rate of the input.
- **Allow multirate processing** — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to **Elements as channels (sample based)**.

Data Types Pane

See the Data Types Pane subsection of the `filterBuilder` function reference page for more information about specifying data type parameters.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	<ul style="list-style-type: none"> • Fixed point

Version History

CIC Interpolation

Interpolate signal using cascaded integrator-comb filter

Library: DSP System Toolbox / Filtering / Multirate Filters
 DSP System Toolbox HDL Support / Filtering

Description

The CIC Interpolation block performs a sample rate increase (interpolation) on an input signal by an integer factor. cascaded integrator-comb (CIC) filters are a class of linear phase FIR filters that consist of a comb part and an integrator part.

The CIC Interpolation block requires a Fixed-Point Designer license.

Ports

Input

Port_1 — Input signal

vector | matrix

Data input, specified as a vector or matrix. If the input is fixed point, it must be signed integer or signed fixed point with power-of-two slope and zero bias.

Data Types: int8 | int16 | int32 | int64 | fixed point

Output

Port_1 — CIC interpolated output

vector | matrix

CIC interpolated output, returned as a vector or a matrix. The data type of the output is determined by the settings in the block dialog. The complexity of the output matches that of the input. The number of output rows is $R \times Num$, where R is the interpolation factor and Num is the number of input rows.

Data Types: int8 | int16 | int32 | int64 | fixed point

Parameters

Coefficient source — Source of filter information

Dialog parameters (default) | Filter object

Source of the filter information, specified as one of the following:

- Dialog parameters — Enter information about the filter, such as **Interpolation factor (R)**, **Differential delay (M)** and **Number of sections (N)**, in the block dialog.

- **Filter object** — Specify the filter using a `dsp.CICInterpolator` System object.

Interpolation factor (R) — Interpolation factor

2 (default) | integer

Interpolation factor of the filter, specified as an integer greater than 1.

Dependencies

This parameter appears when you set **Coefficient source** to `Dialog` parameters.

Differential Delay (M) — Differential delay

1 (default) | positive integer

Specify the differential delay of the comb part of the filter, M , as a positive integer. For more details, see “CIC Interpolation Filter” on page 4-267.

Dependencies

This parameter appears when you set **Coefficient source** to `Dialog` parameters.

Number of sections (N) — Number of filter sections

2 (default) | positive integer

Specify the number of filter sections. The number you specify determines the number of sections in either the comb part of the filter or the integrator part of the filter. This value does not represent the total number of sections in the comb and integrator parts combined.

Dependencies

This parameter appears when you set **Coefficient source** to `Dialog` parameters.

Data type specification mode — Specify word length and fraction length of filter sections and output

Full precision (default) | Minimum section word lengths | Specify word lengths | Binary point scaling

Choose how you specify the fixed-point word length and fraction length of the filter sections and/or output:

- **Full precision** — The word and fraction lengths of the filter sections and outputs are automatically selected for you. The output and last section word lengths (WL) are set to:

$$WL = \text{ceil} \left(\log_2 \left(\frac{(RM)^N}{R} \right) \right) + I$$

where,

- I -- Input word length
- M -- Differential delay
- N -- Number of sections

- R -- Interpolation factor

The other section word lengths are set to accommodate the bit growth, as described in Hogenauer's paper [1]. All fraction lengths are set to the input fraction length.

- **Minimum section word lengths** — Specify the word length of the filter output in the **Output word length** parameter. The word lengths of the filter sections are set in the same way as in Full precision mode.

The section fraction lengths are set to the input fraction length. The output fraction length is set to the input fraction length minus the difference between the last section word length and the output word length.

- **Specify word lengths** — Specify the word lengths of the filter sections and output in the **Section word lengths** and **Output word length** parameters. The fraction lengths of the filter sections are set such that the spread between word length and fraction length is the same as in full-precision mode. The output fraction length is set to the input fraction length minus the difference between the last section word length and the output word length.
- **Binary point scaling** — Specify the word and fraction lengths of the filter sections and output in the **Section word lengths**, **Section fraction lengths**, **Output word length**, and **Output fraction length** parameters.

Dependencies

This parameter appears when you set **Coefficient source** to Dialog parameters.

Section word lengths — Word length of filter sections

[16 16 16 16] (default) | scalar | row vector

Word lengths of filter sections, specified as a scalar or a vector of length equal to $2N$, where N is the number of filter sections. The section word length must be in the range [2, 128].

Dependencies

This parameter appears when you set **Coefficient source** to Dialog parameters and **Data type specification mode** to either Specify word lengths or Binary point scaling.

Section fraction lengths — Fraction length of filter sections

0 (default) | integer

Fraction lengths of filter sections, specified as an integer.

Dependencies

This parameter appears when you set **Coefficient source** to Dialog parameters and **Data type specification mode** to Binary point scaling.

Output word length — Word length of filter output

32 (default) | integer

Word length of the filter output, specified as an integer in the range [2, 128].

Dependencies

This parameter appears when you set **Coefficient source** to Dialog parameters and **Data type specification mode** to any option other than Full precision.

Output fraction length — Fraction length of filter output

0 (default) | integer

Fraction length of the filter output, specified as an integer.

Dependencies

This parameter appears when you set **Coefficient source** to Dialog parameters and **Data type specification mode** to Binary point scaling.

Input processing — Method of processing input

Columns as channels (frame based) (default) | Elements as channels (sample based)

Specify how the block should process the input. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — The block treats each column of the input as a separate channel. In this mode, the block always performs single-rate processing.
- **Elements as channels (sample based)** — The block treats each element of the input as a separate channel. In this mode, the input to the block must be a scalar or a vector. You can use the **Rate options** parameter to specify whether the block performs single-rate or multirate processing.

Rate options — Rate processing rule

Enforce single-rate processing (default) | Allow multirate processing

Specify the rate processing rule for the block. You can select one of the following options:

- **Enforce single-rate processing** — The block maintains the sample rate of the input.
- **Allow multirate processing** — The block produces an output with a sample rate that is R times faster than the input sample rate. To select this option, you must set the **Input processing** parameter to **Elements as channels (sample based)**.

Filter object — Multirate filter object

dsp.CICInterpolator System object

Specify the name of the multirate filter object that you want the block to implement. You must specify the filter as a dsp.CICInterpolator System object.

You can define the System object in the block dialog or in a MATLAB workspace variable.

For information on creating System objects, see “Define Basic System Objects”.

Dependencies

This parameter appears when you set **Coefficient source** to Filter object.

View Filter Response — View filter response

button

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product and displays the filter response of the filter defined in the block. For more information on FVTool, see the Signal Processing Toolbox documentation.

Note If you specify a filter in the **Filter object** parameter, you must apply the filter by clicking the **Apply** button before using the **View Filter Response** button.

Block Characteristics

Data Types	fixed point integer
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

More About**CIC Filter**

CIC filters are an optimized class of linear phase FIR filters composed of a comb part and an integrator part.

The CIC interpolation filter is conceptually given by an upsampler followed by a single rate CIC filter, $H(z)$, which is a lowpass anti-imaging filter. The CIC interpolation filter increases the sample rate of an input signal by an integer factor using a cascaded integrator-comb (CIC) filter.

In a more efficient implementation, the single rate CIC filter $H(z)$ is factorized this way:

$$H(z) = \left[\sum_{k=0}^{RM-1} z^{-k} \right]^N = \frac{(1 - z^{-RM})^N}{(1 - z^{-1})^N} = \frac{(1 - z^{-RM})^N}{1} \cdot \frac{1}{(1 - z^{-1})^N} = H_C^N(z) \cdot H_I^N(z)$$

where,

- H_C is the transfer function of the N sections of the cascaded comb filters, each with a width of RM .
- H_I is the transfer function of the integrator part of the filter containing N stages of integrators.

- N is the number of sections. The number of sections in a CIC filter is defined as the number of sections in either the comb part *or* the integrator part of the filter. This value does not represent the total number of sections throughout the entire filter.
- R is the interpolation factor.
- M is the differential delay.

In the overall multirate realization, the algorithm applies the noble identity for interpolation and moves the rate change factor, R , to follow after the N sections of the cascaded comb filters.

The transfer function of the resulting filter is given by the following equation:

$$H(z) = \frac{(1 - z^{-M})^N}{(1 - z^{-1})^N}.$$

For a block diagram that shows the multirate implementation, see Algorithms on page 2-241.

Algorithms

CIC Interpolation Filter

The CIC interpolation filter in More About on page 2-240 is realized as a cascade of N sections of comb filters followed by a rate change by a factor R , followed by N sections of cascaded integrators.

This diagram shows two sections of cascaded comb filters and two sections of cascaded integrators. The unit delay in the integrator portion of the CIC filter can be located in either the feedforward or the feedback path. These two configurations yield identical filter frequency response. However, the numerical outputs from these two configurations are different due to the latency. This algorithm puts the unit delay in the feedforward path of the integrator since it is a preferred configuration for HDL implementation.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the memcpy or memset function (`string.h`) under certain conditions.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Coder supports **Coefficient source** options **Dialog parameters** and **Filter object**.

AddPipelineRegisters Support

When you use **AddPipelineRegisters**, registers are placed based on the filter structure. The pipeline register placement determines the latency.

Pipeline Register Placement	Latency (clock cycles)
A pipeline register is added between the comb stages of the differentiators.	NS, the number of sections (at the input side).

HDL Filter Properties

AddPipelineRegisters	Insert a pipeline register between stages of computation in a filter. See also AddPipelineRegisters (HDL Coder).
-----------------------------	--

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Restrictions

- Vector and frame inputs are not supported for HDL code generation.
- When you select **Dialog parameters**, the **Filter Structure** option **Zero-latency interpolator** is not supported for HDL code generation. From the **Filter Structure** drop-down list, select **Interpolator**.
- When you use **AddPipelineRegisters**, delays in parallel paths are not automatically balanced. Manually add delays where required by your design.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

If the input is fixed point, it must be a signed integer or signed fixed point with a power-of-two slope and zero bias.

Colored Noise

Generate colored noise signal

Library: DSP System Toolbox / Sources

Description

The Colored Noise block generates a colored noise signal with a power spectral density of $1/|f|^\alpha$ over its entire frequency range. The inverse power spectral density component, α , can be any value in the interval $[-2 \ 2]$. The type of colored noise the block generates depends on the **Noise color** option you choose in the block dialog box. When you set **Noise color** to **custom**, you can specify the power density of the noise through the **Power of inverse frequency** parameter.

Ports

Output

Port_1 — Colored noise signal

scalar | vector | matrix

Colored noise output signal. The size and data type of the signal depend on the values of the **Number of output channels**, **Number of samples per output channel**, and **Output data type** parameters.

Data Types: single | double

Parameters

Noise color — Color of the generated noise

pink (default) | white | brown | blue | purple | custom

Color of the noise the block generates. You can set this parameter to:

- **pink** — Generates pink noise. This option is equivalent to setting **Power of inverse frequency** to 1.
- **white** — Generates white noise (flat power spectral density). This option is equivalent to setting **Power of inverse frequency** to 0.
- **brown** — Generates brown noise. Also known as red or Brownian noise. This option is equivalent to setting **Power of inverse frequency** to 2.
- **blue** — Generates blue noise. Also known as azure noise. This option is equivalent to setting **Power of inverse frequency** to -1.
- **purple** — Generates violet (purple) noise. This option is equivalent to setting **Power of inverse frequency** to -2.
- **custom** — Specify the power density of the noise using the **Power of inverse frequency** parameter.

Power of inverse frequency — Inverse power spectral density component

1 (default) | scalar in the range [-2 2]

Inverse power spectral density component, α , specified as a real-valued scalar in the interval [-2 2]. The inverse exponent defines the power spectral density of the random process by $1/|f|^\alpha$. The default value of this property is 1. When **Power of inverse frequency** is greater than 0, the block generates lowpass noise, with a singularity (pole) at $f=0$. These processes exhibit long memory. When **Power of inverse frequency** is less than 0, the block generates highpass noise with negatively correlated increments. These processes are referred to as antipersistent. In a log-log plot of power as a function of frequency, processes generated by the Colored Noise block exhibit an approximate linear relationship, with the slope equal to $-\alpha$.

Dependencies

To enable this parameter, set **Noise color** to custom.

Guarantee the output is bounded (+/-1) — Set output bounds to +1 and -1

off (default) | on

Select the parameter to make the output bounded between +1 and -1.

When you select the parameter, the internal random source that generates the noise is uniform. If **Noise color** is set to white, there is no color filter applied to the output of the random source. The output is uniform noise of amplitude between +1 and -1. If **Noise color** is set to any other option, then a coloring filter is applied to the output of the random source, followed by a gain that ensures the absolute maximum output never exceeds 1.

When you do not select the parameter, the internal random source is Gaussian. The output is not bounded.

Number of output channels — Number of output channels

1 (default) | positive integer

Number of output channels, specified as a positive integer scalar. This parameter defines the number of columns in the generated signal.

Output data type — Output data type

double (default) | single

Data type of the output specified as double or single.

Number of samples per output channel — Samples per frame of output

1024 (default) | positive integer

Number of samples in each frame of the output signal, specified as a positive integer scalar. This parameter defines the number of rows in the generated signal.

Output sample time (s) — Sample time of the output

1 (default) | positive scalar

Sample time of the output signal, specified as a positive scalar in seconds.

Initial seed — Initial seed of random number generator

67 (default) | positive integer

Initial seed of the random number generator algorithm, specified as a real-valued positive integer scalar.

Simulate using — Type of simulation to run

Interpreted execution (default) | Code generation

Type of simulation to run. You can set this parameter to:

- **Interpreted execution:** Simulate model using the MATLAB interpreter. This option shortens startup time.
- **Code generation:** Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations as long as the model does not change. This option requires additional startup time but provides faster subsequent simulations.

Block Characteristics

Data Types	double single
Multidimensional Signals	No
Variable-Size Signals	No

More About

Colored Noise Processes

Many phenomena in diverse fields, such as hydrology and finance, produce time series with PSD functions that follow a power law of the form

$$S(f) = \frac{L(f)}{|f|^\alpha}$$

where α is a real number in the interval $[-2,2]$ and $L(f)$ is a positive, slowly-varying or constant function. Plotting the PSD of such processes on a log-log plot displays an approximate linear relationship between the log frequency and log PSD with slope equal to $-\alpha$

$$\ln S(f) = -\alpha \ln |f| + \ln L(f).$$

It is often convenient to plot the PSD in dB as a function of the frequency on a base-2 logarithmic scale. The slope of the plot is then dB/octave. Rewriting the preceding equation, you obtain

$$10 \log S(f) = -10\alpha \frac{\ln(2) \log_2(f)}{\ln(10)} + 10 \frac{\ln(L(f))}{\ln(10)}$$

with the slope in dB/octave given by

$$-10\alpha \frac{\ln(2)\log_2(f)}{\ln(10)}$$

If $\alpha > 0$, $S(f)$ goes to infinity as the frequency, f , approaches 0. Stochastic processes with PSDs of this form exhibit long memory. Long-memory processes have autocorrelations that persist for a long time as opposed to decaying exponentially like many common time-series models. If $\alpha < 0$, the process is antipersistent and exhibits negative correlation between increments [1].

Special examples of $\frac{1}{|f|^\alpha}$ processes include:

- $\alpha = 0$ — White noise, where $L(f)$ is a constant proportional to the process variance.
- $\alpha = 1$ — Pink, or flicker noise. Pink noise has equal energy per octave. See “Measure Pink Noise Power in Octave Bands” on page 4-273 for a demonstration. The power spectral density of pink noise decreases 3 dB per octave.
- $\alpha = 2$ — brown noise, or Brownian motion. Brownian motion is a nonstationary process with stationary increments. You can think of Brownian motion as the integral of a white noise process. Even though Brownian motion is nonstationary, you can still define a generalized power spectrum, which behaves like $\frac{1}{|f|^2}$. Accordingly, power in a brown noise decreases 6 dB per octave.
- $\alpha = -1$ — blue noise. The power spectral density of blue noise increases 3 dB per octave.
- $\alpha = -2$ — violet, or purple noise. The power spectral density of violet noise increases 6 dB per octave. You can think of violet noise as the derivative of white noise process.

Algorithms

The figure shows the overall process of generating the colored noise.

The random stream generator produces a stream of white noise that is either Gaussian or uniform in distribution. A coloring filter applied to the white noise generates colored noise with a power spectral density (PSD) function given by:

$$S(f) = \frac{L(f)}{|f|^\alpha}$$

When α , the inverse frequency power, equals 0, no coloring filter is applied to the output of the random stream generator. If the bounded option is enabled, the output is uniform white noise with amplitude between +1 and -1. If the bounded output is not enabled, the output is a Gaussian white noise and the values are not bounded between +1 and -1. If α is set to any other value, then a coloring filter is applied to the output of the random stream generator. If the bounded output option is enabled, a gain g is applied to the output of the coloring filter to ensure that the absolute maximum output never exceeds 1.

For details on colored noise processes and how the value of α affects the PSD of the colored noise, see “Colored Noise Processes” on page 2-246.

When the inverse frequency power α is positive, the colored noise is generated using an autoregressive (AR) model of order 63. The AR coefficients are:

$$a_0 = 1,$$
$$a_k = (k - 1 - \frac{\alpha}{2}) \frac{a_{k-1}}{k}, \quad k = 1, 2, \dots, 63$$

Pink and brown noises are special cases, which are generated from specially tuned SOS filters of orders 12 and 10, respectively. These filters are optimized for better performance.

When the inverse frequency power α is negative, the colored noise is generated using a moving average (MA) model of order 255. The MA coefficients are:

$$b_0 = 1,$$
$$b_k = (k - 1 + \frac{\alpha}{2}) \frac{b_{k-1}}{k}, \quad k = 1, 2, \dots, 255$$

Purple noise is generated from a first order filter, $B = [1 \ -1]$.

The coloring filters applied (except pink, brown, and purple) are detailed on pp. 820-822 in [2].

Comb Filter

Design comb Filter

Library

Filtering / Filter Designs

dspfdesign

Description

This block brings the filter design capabilities of the `filterBuilder` function to the Simulink environment.

Dialog Box

See “Comb Filter Design —Main Pane” on page 5-611 for more information about the parameters of this block. The **Data Types** and **Code Generation** panes are not available for blocks in the DSP System Toolbox Filter Designs library.

View filter response

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

In this group, you specify the type of comb filter and the number of peaks or notches.

Comb Type

Select either **Notch** or **Peak** from the drop-down list. **Notch** creates a comb filter that attenuates a set of harmonically related frequencies. **Peak** creates a comb filter that amplifies a set of harmonically related frequencies.

Order mode

Select either **Order** or **Number of Peaks/Notches** from the drop-down menu.

Select **Order** to enter the desired filter order in the dialog box. The comb filter has notches or peaks at increments of $2/\text{Order}$ in normalized frequency units.

Select **Number of Peaks** or **Number of Notches** to specify the number of peaks or notches and the **Shelving filter order**

Shelving filter order

The **Shelving filter order** is a positive integer that determines the sharpness of the peaks or notches. Larger values result in sharper peaks or notches.

Frequency specifications

In this group, you specify the frequency constraints and frequency units.

Frequency specifications

Select either **Quality factor** or **Bandwidth**.

Quality factor is the ratio of the center frequency of the peak or notch to the bandwidth calculated at the -3 dB point.

Bandwidth specifies the bandwidth of the peak or notch. By default the bandwidth is measured at the -3 dB point. For example, setting the bandwidth equal to 0.1 results in 3 dB frequencies at normalized frequencies 0.05 above and below the center frequency of the peak or notch.

Frequency Units

Specify the frequency units. The default is normalized frequency. Choosing an option in Hz enables the **Input sample rate** dialog box.

Magnitude specifications

Specify the units for the magnitude specification and the gain at which the bandwidth is measured. This menu is disabled if you specify a filter order. Select one of the following magnitude units from the drop down list:

- dB — Specify the magnitude in decibels (default).
- Squared — Specify the magnitude in squared units.

Bandwidth gain — Specify the gain at which the bandwidth is measured. The default is -3 dB.

Algorithm

The parameters in this group allow you to specify the design method and structure of your filter.

Design Method

The IIR Butterworth design is the only option for peaking or notching comb filters.

Filter Implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of n unit delays with a single delay by n .
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

Input processing

Specify how the block should process the input. The available options may vary depending on the settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- **Enforce single-rate processing** — When you select this option, the block maintains the sample rate of the input.
- **Allow multirate processing** — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to **Elements as channels (sample based)**.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

Supported Data Types

Complex Bandpass Decimator

Extract a frequency subband using a one-sided (complex) bandpass decimator

Library: DSP System Toolbox / Filtering / Multirate Filters

Description

The Complex Bandpass Decimator block extracts a specific subband of frequencies using a one-sided, multistage, complex bandpass decimator. The block determines the bandwidth of interest using the specified center frequency, decimator factor, and bandwidth values.

This block supports SIMD code generation. For details, see “Code Generation” on page 2-259.

Ports

Input

x — Data input

vector | matrix

Data input, specified as a vector or a matrix. The number of rows in the input must be a multiple of the decimation factor.

This port is unnamed unless you select the **Specify center frequency from input port** parameter.

Data Types: single | double

Fc — Center frequency

real scalar

Center frequency of the desired band in Hz, specified as a real, finite numeric scalar in the range $[-Fs/2, Fs/2]$. The value of F_s depends on the setting of the **Inherit sample rate from input** parameter. When you select this parameter, F_s is the value the block inherits from the input signal. When you clear this parameter, F_s is the value you specify in the **Input sample rate (Hz)** parameter.

This port is only available if you select the **Specify center frequency from input port** parameter.

Data Types: single | double

Output

Port_1 — Filtered output

vector | matrix

Output of the complex bandpass decimator, returned as a vector or a matrix. The output contains the subband of frequencies specified by the parameters on the block dialog. The number of rows (frame size) in the output signal is $1/D$ times the number of rows in the input signal, where D is the decimation factor. The number of channels (columns) does not change.

The data type of the output is same as the data type of the input. The output signal is always complex.

Data Types: `single` | `double`

Parameters

Filter specification — Filter design parameters

`Decimation factor` (default) | `Bandwidth` | `Decimation factor and bandwidth`

Filter design parameters, specified as one of the following:

- **Decimation factor** -- The block specifies the decimation factor through the **Decimation factor** parameter. The bandwidth of interest (BW) is computed using the following equation:

$$BW = Fs/D$$

where

- Fs -- Sample rate specified through the **Input sample rate (Hz)** parameter.
- D -- Decimation factor.
- **Bandwidth** -- The block specifies the bandwidth through the **Bandwidth (Hz)** parameter. The decimation factor (D) is computed using the following equation:

$$D = \text{floor}\left(\frac{Fs}{BW + TW}\right)$$

where

- Fs -- Sample rate specified through the **Input sample rate (Hz)** parameter.
- BW -- Bandwidth of interest.
- TW -- Transition width specified through the **Transition width (Hz)** parameter.
- **Decimation factor and bandwidth** -- The decimation factor and the bandwidth of interest are specified through the **Decimation factor** and **Bandwidth (Hz)** parameters.

Decimation factor — Decimation factor

2 (default) | positive integer

Factor by which to reduce the bandwidth of the input signal, specified as a positive integer. The frame size (number of rows) of the input signal must be a multiple of the decimation factor.

Dependencies

This parameter applies when you set **Filter specification** to either `Decimation factor` or `Decimation factor and bandwidth`.

Bandwidth (Hz) — Bandwidth in Hz

5000 (default) | real positive scalar

Width of the frequency band of interest, specified as a real positive scalar in Hz.

Dependencies

This parameter applies when you set **Filter specification** to either Bandwidth or Decimation factor and bandwidth.

Data Types: single | double

Specify center frequency from input port — Flag to specify center frequency

off (default) | on

When you select this check box, the center frequency is input through the **Fc** port. When you clear this check box, the center frequency is specified on the block dialog through the **Center frequency (Hz)** parameter.

When you select this check box, the block does not compute the filter response. To view the filter response, clear this check box, specify the center frequency on the block dialog, and click **View Filter Response** button.

Center frequency (Hz) — Center frequency in Hz

0 (default) | real scalar

Center frequency of the desired band in Hz, specified as a real, finite numeric scalar in the range $[-Fs/2, Fs/2]$.

Tunable: Yes

Data Types: single | double

Stopband attenuation (dB) — Stopband attenuation in dB

80 (default) | positive scalar

Stopband attenuation of the filter in dB, specified as a finite positive scalar.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Passband ripple (dB) — Passband ripple in dB

1 (default) | positive scalar

Passband ripple of the filter, specified as a positive scalar in dB.

Dependencies

This parameter applies when you set **Filter specification** to either Bandwidth or Decimation factor and bandwidth.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Transition width (Hz) — Transition width in Hz

100 (default) | positive scalar

Transition width of the filter in Hz, specified as a positive scalar.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Reduce number of complex coefficients — Minimize number of complex coefficients

on (default) | off

Minimize the number of complex coefficients. When you select this parameter, the first stage of the multistage filter is bandpass (with complex coefficients) centered at the specified center frequency. The first stage is followed by a mixing stage that heterodynes the signal to DC. The remaining filter stages, all with real coefficients, follow.

When you clear the parameter, the input signal is first passed through the different stages of the multistage filter. All stages are bandpass (complex coefficients). The signal is then heterodyned to DC if **Mix signal to baseband** parameter is selected and the frequency offset resulting from the decimation is nonzero.

Mix signal to baseband — Mix signal to baseband

on (default) | off

Mix the signal to baseband. When you select this parameter, the block heterodynes the filtered, decimated signal to DC. This mixing stage runs at the output sample rate of the filter. When you clear this parameter, the block skips the mixing stage.

Dependencies

This parameter applies when you clear the **Reduce number of complex coefficients** parameter.

Inherit sample rate from input — Flag to specify input sample rate

off (default) | on

When you select this parameter, the block inherits its sample rate from the input signal. The block calculates the sample rate based on the sample time of the input port. When you clear this parameter, specify the sample rate in **Input sample rate (Hz)**.

Input sample rate (Hz) — Input sample rate in Hz

44100 (default) | real positive scalar

Sampling rate of the input signal in Hz, specified as a real positive scalar.

Dependencies

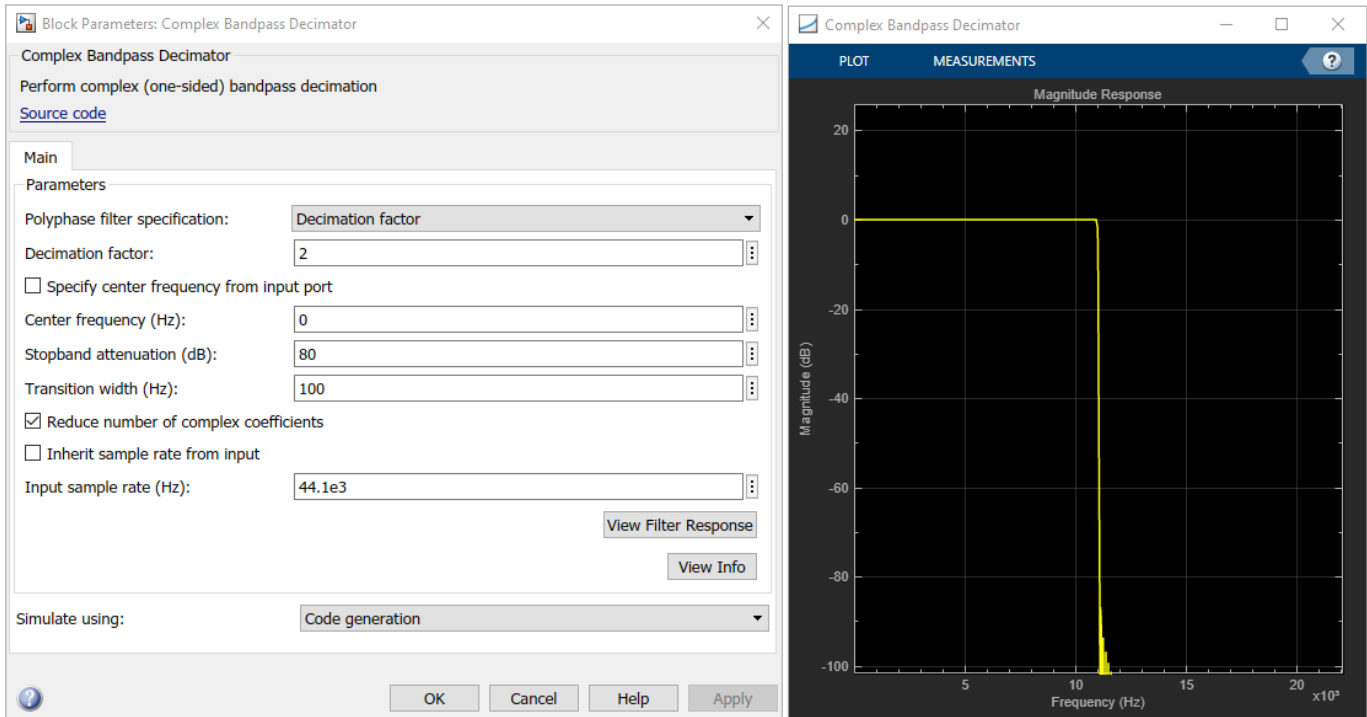

This parameter applies when you clear the **Inherit sample rate from input** parameter.

Data Types: single | double

View Filter Response — Visualize frequency response

button

Click this button to open the Dynamic Filter Visualizer window and display the magnitude and phase response of the complex bandpass decimator. The response is based on the parameters you select in the block dialog box. To update the response while the visualizer is running, modify the parameters in the dialog box and click **Apply**.

You can configure the plot settings and the frequency response measurements from the interface of the visualizer.

On the **Plot** tab, you can enable the legend, specify to plot both magnitude and phase responses of the filter, modify the plot settings, generate a script to re-create the plot, and even save or share the settings.

On the **Measurements** tab, you can enable data cursors, and display the peak values of the filter response.

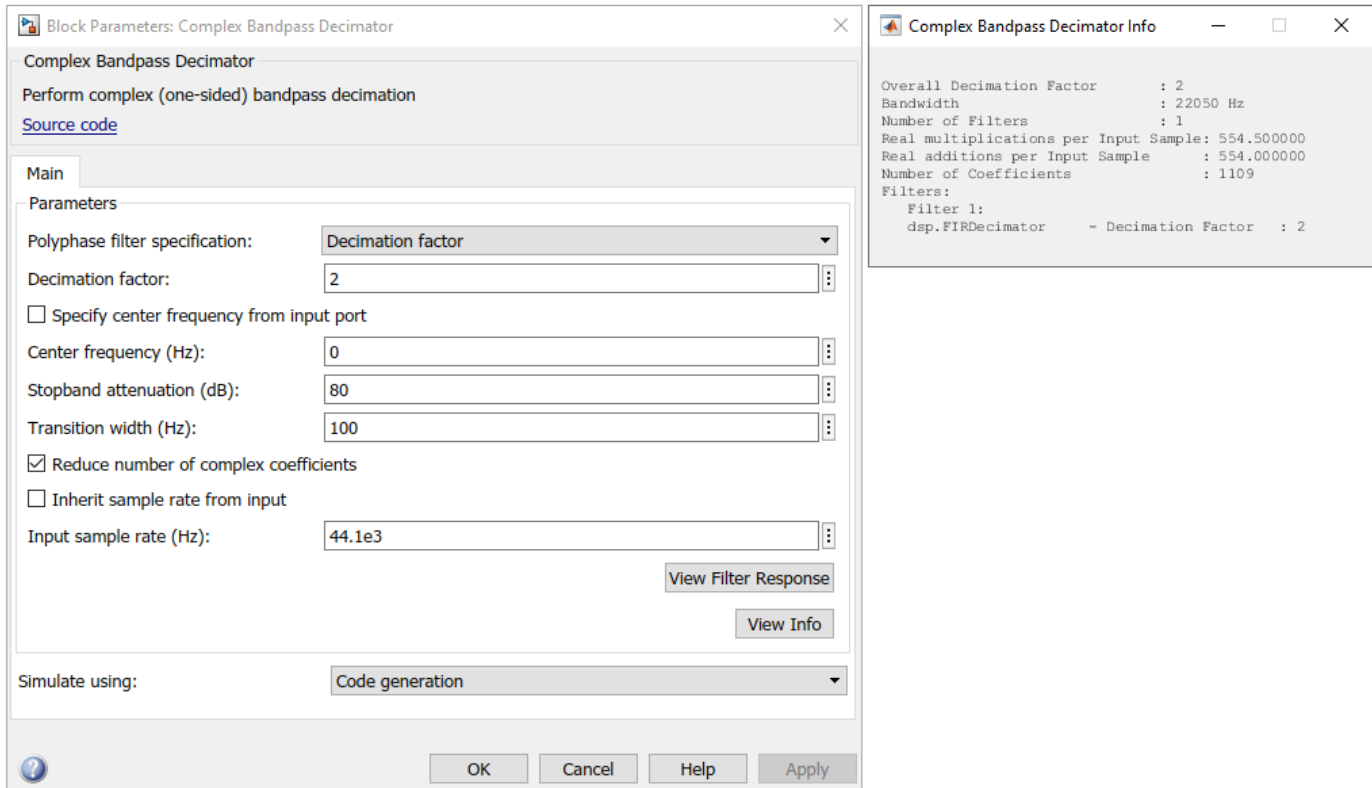

For more details on the Dynamic Filter Visualizer interface and its tools, see "Configure Dynamic Filter Visualizer".

View Info – View filter information

button

Display filter information of the Complex Bandpass Decimator block:

This button brings the functionality of the `info` analysis method into the Simulink environment.

Simulate using – Type of simulation to run

Code generation (default) | Interpreted execution

Specify the type of simulation to run as one of the following:

- **Code generation** -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than **Interpreted execution**.
- **Interpreted execution** -- Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than **Code generation**.

Block Characteristics

Data Types	double single
Multidimensional Signals	No

Variable-Size Signals	Yes
------------------------------	-----

Algorithms

The complex bandpass decimator is designed by applying a complex frequency shift transformation on a lowpass prototype filter. The lowpass prototype in this case is a multirate, multistage finite impulse response (FIR) filter. The desired frequency shift applies only to the first stage. Subsequent stages scale the desired frequency shift by their respective cumulative decimation factors. For details, see “Complex Bandpass Filter Design” and “Zoom FFT”.

Version History

Introduced in R2018a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The Complex Bandpass Decimator block supports SIMD code generation using Intel AVX2 technology under these conditions:

- Input signal is complex-valued.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

Complex Cepstrum

Compute complex cepstrum of input

Library

Transforms

dspxfm3

Description

The Complex Cepstrum block computes the complex cepstrum of each column in the real-valued M -by- N input matrix, u . The block treats each column of the input as an independent channel containing M consecutive samples. The block *always* processes unoriented vector inputs as a single channel, and returns the result as a length- M column vector. The block does not accept complex-valued inputs.

The input is altered by the application of a linear phase term so that there is no phase discontinuity at $\pm\pi$ radians. That is, each input channel is independently zero padded and circularly shifted to have zero phase at π radians.

The output is a real M_o -by- N matrix, where M_o is specified by the **FFT length** parameter. Each output column contains the length- M_o complex cepstrum of the corresponding input column.

```
y = cceps(u,Mo) % Equivalent MATLAB code
```

When you select the **Inherit FFT length from input port dimensions** check box, the output frame size matches the input frame size ($M_o = M$).

The output port rate is the same as the input port rate.

Parameters

Inherit FFT length from input port dimensions

When you select this check box, the output frame size matches the input frame size.

FFT length

The number of frequency points at which to compute the FFT, which is also the output frame size, M_o . This parameter is visible only when you clear the **Inherit FFT length from input port dimensions** check box.

Supported Data Types

- Double-precision floating point
- Single-precision floating point

Constant

Generate constant value

Library: Simulink / Commonly Used Blocks
 Simulink / Sources
 DSP System Toolbox / Sources
 HDL Coder / Commonly Used Blocks
 HDL Coder / Sources

Description

The Constant block generates a real or complex constant value signal. Use this block to provide a constant signal input. The block generates scalar, vector, or matrix output, depending on:

- The dimensionality of the **Constant value** parameter
- The setting of the **Interpret vector parameters as 1-D** parameter

The output of the block has the same dimensions and elements as the **Constant value** parameter. If you specify for this parameter a vector that you want the block to interpret as a vector, select the **Interpret vector parameters as 1-D** check box. Otherwise, if you specify a vector for the **Constant value** parameter, the block treats that vector as a matrix.

Tip To output a constant enumerated value, consider using the Enumerated Constant block instead. The Constant block provides block parameters that do not apply to enumerated types, such as **Output minimum** and **Output maximum**.

Using Bus Objects as the Output Data Type

The Constant block supports nonvirtual buses as the output data type. Using a bus object as the output data type can help simplify your model. If you use a bus object as the output data type, set the **Constant value** to \emptyset or to a MATLAB structure that matches the bus object.

Using Structures for the Constant Value of a Bus

The structure you specify must contain a value for every element of the bus represented by the bus object. The block output is a nonvirtual bus signal.

You can use the `Simulink.Bus.createMATLABStruct` to create a full structure that corresponds to a bus.

You can use `Simulink.Bus.createObject` to create a bus object from a MATLAB structure.

If the signal elements in the output bus use numeric data types other than `double`, you can specify the structure fields by using typed expressions such as `uint16(37)` or untyped expressions such as

37. To control the field data types, you can use the bus object as the data type of a `Simulink.Parameter` object. To decide whether to use typed or untyped expressions, see “Control Data Types of Initial Condition Structure Fields” (Simulink).

Setting Configuration Parameters to Support Using a Bus Object Data Type

To enable the use of a bus object as an output data type, before you start a simulation, set **Configuration Parameters > Diagnostics > Data Validity > Advanced parameters > Underspecified initialization detection** to `Simplified`. For more information, see “Underspecified initialization detection” (Simulink).

Ports

Output

Port_1 — Constant value

scalar | vector | matrix | N-D array

Constant value, specified as a real or complex valued scalar, vector, matrix, or N-D array. By default, the Constant block outputs a signal whose dimensions, data type, and complexity are the same as those of the **Constant value** parameter. However, you can specify the output to be any data type that Simulink supports, including fixed-point and enumerated data types.

Note If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For more information, see `Simulink.BusElement`.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Main

Constant value — Constant output value

1 (default) | scalar | vector | matrix | N-D array

Specify the constant value output of the block.

- You can enter any expression that MATLAB evaluates as a matrix, including the Boolean keywords `true` and `false`.
- If you set the **Output data type** to be a bus object, you can specify one of these options:
 - A full MATLAB structure corresponding to the bus object
 - `0` to indicate a structure corresponding to the ground value of the bus object

For details, see “Using Bus Objects as the Output Data Type” on page 2-262.

- For nonbus data types, Simulink converts this parameter from its value data type to the specified output data type offline, using a rounding method of nearest and overflow action of saturate.

Programmatic Use**Block Parameter:** Value**Type:** character vector**Value:** scalar | vector | matrix | N-D array**Default:** '1'**Interpret vector parameters as 1-D — Treat vectors as 1-D**

on (default) | off

Select this check box to output a vector of length N if the **Constant value** parameter evaluates to an N-element row or column vector.

- When you select this check box, the block outputs a vector of length N, provided the **Constant value** parameter evaluates to an N-element row or column vector.
- When you clear this check box, the block outputs a matrix of dimension 1-by-N or N-by-1, provided the **Constant value** parameter evaluates to an N-element row or column vector. For example, the block outputs a matrix of dimension 1-by-N or N-by-1.

Programmatic Use**Block Parameter:** VectorParams1D**Type:** character vector**Values:** 'on' | 'off'**Default:** 'on'**Sample time — Sampling interval**

inf (default) | scalar | vector

Specify the interval between times that the Constant block output can change during simulation (for example, due to tuning the **Constant value** parameter).

The default value of `inf` indicates that the block output can never change. This setting speeds simulation and generated code by avoiding the need to recompute the block output.

See “Specify Sample Time” (Simulink) for more information.

Programmatic Use**Block Parameter:** SampleTime**Type:** character vector**Values:** scalar | vector**Default:** 'inf'**Signal Attributes****Output minimum — Minimum output value for range checking**

[] (default) | scalar

Specify the lower value of the output range that Simulink checks as a finite, real, double, scalar value.

Note If you specify a bus object as the data type for this block, do not set the minimum value for bus data on the block. Simulink ignores this setting. Instead, set the minimum values for bus elements of

the bus object specified as the data type. For information on the Minimum parameter for a bus element, see `Simulink.BusElement`.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters” (Simulink)) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” (Simulink) and “Enable Simulation Range Checking” (Simulink)).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see Optimize using the specified minimum and maximum values (Embedded Coder).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: scalar

Default: '[]'

Output maximum — Maximum output value for range checking

[] (default) | scalar

Specify the upper value of the output range that Simulink checks as a finite, real, double, scalar value.

Note If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For information on the Maximum parameter for a bus element, see `Simulink.BusElement`.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters” (Simulink)) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” (Simulink) and “Enable Simulation Range Checking” (Simulink)).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see Optimize using the specified minimum and maximum values (Embedded Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use**Block Parameter:** OutMax**Type:** character vector**Values:** scalar**Default:** '[]'**Output data type – Output data type**

Inherit: Inherit from 'Constant value' (default) | Inherit: Inherit via back propagation | double | single | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | boolean | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | Enum: <class name> | Bus: <object name> | <data type expression>

Specify the output data type. The type can be inherited, specified directly, or expressed as a data type object such as Simulink.NumericType.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

Programmatic Use**Block Parameter:** OutDataTypeStr**Type:** character vector

Values: 'Inherit: Inherit from 'Constant value'' | 'Inherit: Inherit via back propagation' | 'double' | 'single' | 'half' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'boolean' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | 'Enum: <class name>' | 'Bus: <object name>'

Default: 'Inherit: Inherit from 'Constant value''**Lock output data type setting against changes by the fixed-point tools – Prevent fixed-point tools from overriding Output data type**

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use**Block Parameter:** LockScale**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

Tunable Parameters

You can use a tunable parameter in a Constant block intended for HDL code generation. For details, see “Generate DUT Ports for Tunable Parameters” (HDL Coder).

HDL Architecture

Architecture	Parameters	Description
default Constant	None	This implementation emits the value of the Constant block.
Logic Value	None	By default, this implementation emits the character 'Z' for each bit in the signal. For example, for a 4-bit signal, the implementation would emit 'ZZZZ'.
	{'Value', 'Z'}	If the signal is in a high-impedance state, use this parameter value. This implementation emits the character 'Z' for each bit in the signal. For example, for a 4-bit signal, the implementation would emit 'ZZZZ'.

Architecture	Parameters	Description
	{'Value', 'X'}	If the signal is in an unknown state, use this parameter value. This implementation emits the character 'X' for each bit in the signal. For example, for a 4-bit signal, the implementation would emit 'XXXX'.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Complex Data Support

This block supports code generation for complex signals.

Restrictions

- The Logic Value implementation does not support the `double` data type. If you specify this implementation for a constant value of type `double`, a code generation error occurs.
- For **Sample time**, enter -1. Delay balancing does not support an `inf` sample time.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Constant Ramp

Generate ramp signal with length based on input dimensions

Library: DSP System Toolbox / Signal Operations

Description

The Constant Ramp block generates the constant ramp signal

$$y = (0:L-1)*m + b$$

where m is the slope specified by the scalar **Slope** parameter, and b is the y -intercept specified by the scalar **Offset** parameter.

For an unoriented vector input, L is equal to the length of the input vector. For an N-D input array, the length L of the output ramp is equal to the length of the input in the dimension specified by the **Ramp length equals number of** or **Dimension** parameter. The output, y , is always an unoriented vector.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix | N-D array

Input signal used to generate ramp signal, specified as a scalar, vector, matrix, or N-D array.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 — Output signal

vector

Output signal, specified as an unoriented vector. The block determines the length of the output based on the length of the input signal, and the **Ramp length equals number of** or **Dimension** parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Parameters

Main

Ramp length equals number of — Dimension used to determine ramp length

Rows (default) | Columns | Elements in specified dimension

Specify whether the length of the output ramp is the number of rows, number of columns, or the length of the specified dimension of the input.

Dimension — Dimension that determines length of output ramp

1 (default) | positive integer

Specify the one-based dimension of the input array that determines the length of the output ramp as a positive integer scalar.

Dependencies

To enable this parameter, set **Ramp length equals number of** to **Elements in specified dimension**.

Slope — Slope of the ramp

1 (default) | scalar

Specify the slope of the ramp as a real-valued double-precision scalar.

Offset — y-intercept of the ramp

0 (default) | scalar

Specify the scalar y-intercept of the ramp as a real-valued double-precision scalar.

Data Types

Output data type — Output data type

Inherit: Same as input (default) | Inherit: Inherit via back propagation | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | boolean | fixdt(1,16) | fixdt(1,16,0) | <data type conversion>

Specify the output data type for this block. You can select one of the following:

- A rule that inherits a data type, for example, **Inherit: Same as input**.
- A built-in data type, such as **double**
- An expression that evaluates to a valid data type, for example, **fixdt(1,16)**

For help setting data type parameters, display the **Data Type Assistant** by clicking the **Show data type assistant** button .

See “Control Data Types of Signals” (Simulink) for more information.

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no

Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the memcpy or memset function (string.h) under certain conditions.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Blocks

Create Diagonal Matrix | Constant | Ramp | Identity Matrix

Contiguous Copy (Obsolete)

Create discontinuous input in contiguous block of memory

Library

dspobslib

Description

Note The Contiguous Copy block is still supported but is likely to be obsoleted in a future release.

The Contiguous Copy block copies the input to a contiguous block of memory, and passes this new copy to the output. The output is identical to the input, but is guaranteed to reside in a contiguous section of memory.

Because Simulink software employs an efficient copy-by-reference method for propagating data in a model, some operations produce outputs with discontinuous memory locations.

Although this does not present a problem during simulation, blocks linked to versions of DSP Blockset prior to 4.0 may require contiguous inputs for code generation with the Simulink Coder product. When such blocks are used in a model intended for code generation, they should be preceded by the Contiguous Copy block to ensure that their inputs are contiguous.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point
- Boolean
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

Version History

Introduced in R2008b

Convert 1-D to 2-D

Reshape 1-D or 2-D input to 2-D matrix with specified dimensions

Library: DSP System Toolbox / Signal Management / Signal Attributes
 DSP System Toolbox HDL Support / Signal Management

Description

The Convert 1-D to 2-D block reshapes a length- M_i 1-D vector or an M_i -by- N_i matrix to an M_o -by- N_o matrix, where M_o is specified by the **Number of output rows** parameter and N_o is specified by the **Number of output columns** parameter.

`y = reshape(u,Mo,No)` % Equivalent MATLAB code

The input is reshaped *column-wise*, as shown in the two cases below. The length-6 vector and the 2-by-3 matrix are both reshaped to the same 3-by-2 output matrix.

An error is generated when $(M_o * N_o) \neq (M_i * N_i)$. In other words, the total number of input elements must be conserved in the output.

The output is frame based when you select the **Frame-based output** check box; otherwise, the output is sample based.

Ports

Input

Port_1 — Input signal

vector | matrix

Input signal, specified as a 1-D vector or 2-D matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 — Output signal

matrix

Output signal, returned as a 2-D matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Parameters

Number of output rows — Number of rows in output matrix

1 (default) | positive integer

Number of rows M_o in the output matrix, specified as a positive integer.

Number of output columns — Number of columns in output matrix

1 (default) | positive integer

Number of columns N_o in the output matrix, specified as a positive integer.

Frame-based output — Option to enable frame-based output

`off` (default) | `on`

Select this parameter to create a frame-based output.

Convolution

Convolution of two inputs

Library: DSP System Toolbox / Signal Operations

Description

The Convolution block convolves the first dimension of an N -D input array u with the first dimension of an N -D input array v . The block can also convolve a column vector with the first-dimension of an N -D input array.

The general equation for convolution is:

$$y(k) = \sum_n u(n - k)v(k)$$

Two DSP System Toolbox blocks can be used for convolving two input signals:

- Convolution
- Discrete FIR Filter

The Convolution block assumes that all elements of u and v are available at each Simulink time step and computes the entire convolution at every step.

The Discrete FIR Filter block can be used for convolving signals in situations where all elements of v is available at each time step, but u is a sequence that comes in over the life of the simulation. When you use the Discrete FIR Filter block, the convolution is computed only once.

To determine which block best fits your needs, see “Selecting the Appropriate Convolution Block” on page 2-282.

Ports

Input

Port_1 — First input signal

scalar | vector | matrix | N -D array

First input u specified as a scalar, vector, matrix, or N -D array. When both inputs are real, the output is real. When one or both inputs are complex, the output is complex. All the input port dimensions for both the inputs, except the first dimension, must have the same value.

Inputs u and v are zero when indexed outside their valid ranges.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point
Complex Number Support: Yes

Port_2 — Second input signal

scalar | vector | matrix | N -D array

Second input v specified as a scalar, vector, matrix, or N -D array. When both inputs are real, the output is real. When one or both inputs are complex, the output is complex. All the input port dimensions for both the inputs, except the first dimension, must have the same value.

Inputs u and v are zero when indexed outside their valid ranges.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`
Complex Number Support: Yes

Output

Port_1 — Output signal

scalar | vector | matrix | N -D array

Convolved signal, returned as a scalar, vector, matrix, or N -D array depending on the input signals. When both inputs are real, the output is real. When one or both inputs are complex, the output is complex. Inputs u and v are zero when indexed outside of their valid ranges. For more details on how the convolved signal changes based on the inputs, see “More About” on page 2-282.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Parameters

Main Tab

Computation domain — Computation domain

Time (default) | Frequency | Fastest

Set the domain in which the block computes convolutions:

- **Time** — The block computes in the time domain, which minimizes memory use.
- **Frequency** — The block computes in the frequency domain, which might require fewer computations than computing in the time domain, depending on the input length.
- **Fastest** — The block computes in the domain that minimizes the number of computations.

Fixed-point signals are only supported in the time domain. When inputting fixed-point signals, make sure you set the **Computation domain** parameter to **Time**.

Data Types Tab

Rounding mode — Method of rounding operation

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round

- Simplest
- Zero

For more details, see Rounding Modes.

Note The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numerical results when all these conditions are met:

- **Product output** data type is Inherit: Inherit via internal rule.
- **Accumulator** data type is Inherit: Inherit via internal rule.
- **Output** data type is Inherit: Same as accumulator.

With these data-type settings, the block operates in a full-precision mode.

Saturate on integer overflow — Method of overflow action

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on *saturate* and *wrap*, see Overflow Handling for fixed-point operations.

Note The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numerical results when all these conditions are met:

- **Product output** data type is Inherit: Inherit via internal rule.
- **Accumulator** data type is Inherit: Inherit via internal rule.
- **Output** data type is Inherit: Same as accumulator.

With these data-type settings, the block operates in a full-precision mode.

Product output — Product output data type

Inherit: Inherit via internal rule (default) | Inherit: Same as first input |
fixdt([],16,0)

Product output specifies the data type of the output of a product operation in the Convolution block.

- **Inherit: Inherit via internal rule** — The block inherits the product output data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- **Inherit: Same as first input** — The block specifies the product output data type to be the same as the first input data type.
- **fixdt([],16,0)** — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Product output** data type by using the **Data Type Assistant**. To use

the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink).

For more information on the product output data type, see “Multiplication Data Types” and Fixed-Point Conversion in “Extended Capabilities” on page 2-0 .

Accumulator — Data type of accumulator

Inherit: `Inherit via internal rule (default)` | Inherit: Same as first input |

Inherit: Same as product output | `fixdt([],16,0)`

Accumulator specifies the data type of the output of an accumulation operation in the Convolution block.

- `Inherit: Inherit via internal rule` — The block inherits the accumulator data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- `Inherit: Same as first input` — The block specifies the accumulator data type to be the same as the first input data type.
- `Inherit: Same as product output` — The block specifies the accumulator data type to be the same as the product output data type.
- `fixdt([],16,0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink).

For a diagrammatic representation on how to use the accumulator data type in this block, see Fixed-Point Conversion in “Extended Capabilities” on page 2-0 .

Output — Data type of output

Inherit: Same as accumulator (default) | Inherit: Same as input | Inherit: Same as product output | `fixdt([],16,0)`

Output specifies the data type of the output of the Convolution block.

- `Inherit: Same as accumulator` — The block specifies the output data type to be the same as the accumulator data type.
- `Inherit: Same as first input` — The block specifies the output data type to be the same as the first input data type.
- `Inherit: Same as product output` — The block specifies the output data type to be the same as the product output data type.
- `fixdt([],16,0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information, see “Control Data Types of Signals” (Simulink).

For more information on the output data type, see Fixed-Point Conversion in “Extended Capabilities” on page 2-0 .

Output Minimum — Minimum value that block can output

[] (default) | scalar

Specify the minimum value the block can output. Simulink uses this minimum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

Output Maximum — Maximum value that block can output

[] (default) | scalar

Specify the maximum value the block can output. Simulink uses this maximum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

More About

Selecting the Appropriate Convolution Block

Question	Answer	Recommended Block(s)
How many convolutions do you intend to perform?	Many convolutions, one at each time step	<ul style="list-style-type: none"> • Convolution block
	One convolution over the life of the simulation	<ul style="list-style-type: none"> • Convolution block • Discrete FIR Filter block

Question	Answer	Recommended Block(s)
How long are your input sequences?	Both sequences have a finite length	<ul style="list-style-type: none"> Convolution block Discrete FIR Filter block
	One sequence has an infinite (not predetermined) length	<ul style="list-style-type: none"> Discrete FIR Filter block
How many of the inputs are scalar streams?	None	<ul style="list-style-type: none"> Convolution block Discrete FIR Filter block
	One or both	<ul style="list-style-type: none"> Buffer block followed by the Convolution block Discrete FIR Filter block

Convoluting Two N-D Arrays

The block always computes the convolution of two N-D input arrays along the first dimension. When both inputs are N-D arrays, the size of their first dimension can differ, but the size of all other dimensions must be equal. For example, when u is an M_u -by- N -by- P array and v is an M_v -by- N -by- P array, the output is an (M_u+M_v-1) -by- N -by- P array.

When u is a M_u -by- N matrix and v is an M_v -by- N matrix, the output y is a (M_u+M_v-1) -by- N matrix whose j th column has these elements

$$y_{i,j} = \sum_{k=0}^{\max(M_u, M_v) - 1} u_{k,j} v_{(i-k),j} \quad 0 \leq i \leq (M_u + M_v - 2)$$

Inputs u and v are zero when indexed outside their valid ranges. When both inputs are real, the output is real. When one or both inputs are complex, the output is complex.

Convoluting a Column Vector with an N-D Array

When one input is a column vector and the other is an N-D array, the block independently convolves the vector with the first dimension of the N-D input array. For example, when u is a M_u -by-1 column vector and v is an M_v -by- N matrix, the output is an (M_u+M_v-1) -by- N matrix whose j th column has these elements:

$$y_{i,j} = \sum_{k=0}^{\max(M_u, M_v) - 1} u_k v_{(i-k),j} \quad 0 \leq i \leq (M_u + M_v - 2)$$

Convoluting Two Column Vectors

The Convolution block also accepts two column vector inputs. When u and v are column vectors with lengths M_u and M_v , the Convolution block performs the vector convolution with lengths M_u and M_v such that:

$$y_i = \sum_{k=0}^{\max(M_u, M_v) - 1} u_k v_{(i-k)} \quad 0 \leq i \leq (M_u + M_v - 2)$$

The output is a (M_u+M_v-1) -by-1 column vector.

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

This diagram shows the data types used within the Convolution block for fixed-point signals (time domain only).

You can set the product output, accumulator, and output data types in the block dialog as discussed in “Parameters” on page 2-279.

The output of the multiplier is in the product output data type when the input is real. When the input is complex, the result of the multiplication is in the accumulator data type. For details on how the multiplication operation is performed, see “Multiplication Data Types”.

Note When one or both of the inputs are signed fixed-point signals, all internal block data types are signed fixed point. The internal block data types are unsigned fixed point only when *both* inputs are unsigned fixed-point signals.

Functions

conv

Blocks

Correlation | Discrete FIR Filter

Correlation

Cross-correlation of two inputs

Library: DSP System Toolbox / Statistics

Description

The Correlation block computes the cross-correlation of two N -D input arrays along the first-dimension. The computation can be done in the time domain or frequency domain. You can specify the domain through the **Computation domain** parameter. In the time domain, the block convolves the first input signal, u , with the time-reversed complex conjugate of the second input signal, v . In the frequency domain, to compute the cross-correlation, the block:

- 1 Takes the Fourier transform of both input signals, U and V .
- 2 Multiplies U and V^* , where $*$ denotes the complex conjugate.
- 3 Computes the inverse Fourier transform of the product.

If you set **Computation domain** to **Fastest**, the block chooses the domain that minimizes the number of computations. For information on these computation methods, see “Algorithms” on page 2-290.

Ports

Input

Port_1 — First data input signal

vector | matrix | N -D array

The block accepts real-valued or complex-valued multichannel and multidimensional inputs. The input can be a fixed-point signal when you set the **Computation domain** to **Time**. When one or both of the input signals are complex, the output signal is also complex.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Port_2 — Second data input signal

vector | matrix | N -D array

The block accepts real-valued or complex-valued multichannel and multidimensional inputs. The input can be a fixed-point signal when you set the **Computation domain** to **Time**. When one or both of the input signals are complex, the output signal is also complex.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 — Cross-correlated output

vector | matrix | N -D array

Cross-correlated output of the two input signals.

When the inputs are N -D arrays, the object outputs an N -D array, where all the dimensions, except for the first dimension, match with the input array. For example,

- When the inputs u and v have dimensions M_u -by- N -by- P and M_v -by- N -by- P , respectively, the Correlation block outputs an $(M_u + M_v - 1)$ -by- N -by- P array.
- When the inputs u and v have the dimensions M_u -by- N and M_v -by- N , the block outputs an $(M_u + M_v - 1)$ -by- N matrix.

If one input is a column vector and the other input is an N -D array, the Correlation block computes the cross-correlation of the vector with each column in the N -D array. For example,

- When the input u is an M_u -by-1 column vector and v is an M_v -by- N matrix, the block outputs an $(M_u + M_v - 1)$ -by- N matrix.
- Similarly, when u and v are column vectors with lengths M_u and M_v , respectively, the block performs the vector cross-correlation.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Main Tab

Computation domain — Domain in which the block computes the cross-correlation

Time (default) | Frequency | Fastest

- **Time** — Computes the cross-correlation in the time domain, which minimizes the memory usage.
- **Frequency** — Computes the cross-correlation in the frequency domain. For more information, see “Algorithms” on page 2-290.
- **Fastest** — Computes the cross-correlation in the domain that minimizes the number of computations.

To cross-correlate fixed-point signals, set this parameter to **Time**.

Data Types Tab

Note Fixed-point signals are supported for the time domain only. To use these parameters, on the **Main** tab, set **Computation domain** to **Time**.

Rounding mode — Method of rounding operation

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

Note The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numerical results when all these conditions are met:

- **Product output** data type is Inherit: Inherit via internal rule.
- **Accumulator** data type is Inherit: Inherit via internal rule.
- **Output** data type is Inherit: Same as accumulator.

With these data type settings, the block operates in full-precision mode.

Saturate on integer overflow – Method of overflow action

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

Note The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numeric results when all these conditions are met:

- **Product output** data type is Inherit: Inherit via internal rule.
- **Accumulator** data type is Inherit: Inherit via internal rule.

With these data type settings, the block operates in full-precision mode.

Product output – Product output data type

Inherit: Inherit via internal rule (default) | Inherit: Same as input |
fixdt([],16,0)

Product output specifies the data type of the output of a product operation in the Correlation block. For more information on the product output data type, see “Multiplication Data Types” and the ‘Fixed-Point Conversion’ section in “Extended Capabilities” on page 2-0 .

- **Inherit: Inherit via internal rule** — The block inherits the product output data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- **Inherit: Same as input** — The block specifies the product output data type to be the same as the input data type.

- `fixdt([],16,0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Product output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

Accumulator — Accumulator data type

Inherit: `Inherit via internal rule`(default) | Inherit: `Same as input` | Inherit: `Same as product output` | `fixdt([],16,0)`

Accumulator specifies the data type of output of an accumulation operation in the Correlation block. For illustrations on how to use the accumulator data type in this block, see the 'Fixed-Point Conversion' section in “Extended Capabilities” on page 2-0 .

- `Inherit: Inherit via internal rule` — The block inherits the accumulator data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- `Inherit: Same as input` — The block specifies the accumulator data type to be the same as the input data type.
- `Inherit: Same as product output` — The block specifies the accumulator data type to be the same as the product output data type.
- `fixdt([],16,0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

Output — Output data type

Inherit: `Same as accumulator`(default) | Inherit: `Same as input` | Inherit: `Same as product output` | `fixdt([],16,0)`

Output specifies the data type of the output of the Correlation block. For more information on the output data type, see the 'Fixed-Point Conversion' section in “Extended Capabilities” on page 2-0 .

- `Inherit: Same as input` — The block specifies the output data type to be the same as the input data type.
- `Inherit: Same as product output` — The block specifies the output data type to be the same as the product output data type.
- `Inherit: Same as accumulator` — The block specifies the output data type to be the same as the accumulator data type.
- `fixdt([],16,0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

Output Minimum — Minimum value block can output

[] (default) | scalar

Specify the minimum value the block can output. Simulink software uses this minimum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

Output Maximum — Maximum value the block can output

[] (default) | scalar

Specify the maximum value the block can output. Simulink software uses this maximum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

Block Characteristics

Data Types	double fixed point integer single

Variable-Size Signals	no
Zero-Crossing Detection	no

More About

Cross-Correlation

Cross-correlation is the measure of similarity of two discrete-time sequences as a function of the lag of one relative to the other.

For two length- N deterministic inputs or realizations of jointly wide-sense stationary (WSS) random processes, x and y , the cross-correlation is computed using the following relationship:

$$r_{xy}(h) = \begin{cases} \sum_{n=0}^{N-h-1} x(n+h)y^*(n) & 0 \leq h \leq N-1 \\ r_{yx}^*(h) & -(N-1) \leq h \leq 0 \end{cases}$$

where h is the lag and $*$ denotes the complex conjugate. If the inputs are realizations of jointly WSS stationary random processes, $r_{xy}(h)$ is an unnormalized estimate of the theoretical cross-correlation:

$$\rho_{xy}(h) = E\{x(n+h)y^*(n)\}$$

where $E\{ \}$ is the expectation operator.

Algorithms

Time-Domain Computation

When you set the computation domain to time, the algorithm computes the cross-correlation of two signals in the time domain. The input signals can be fixed-point signals in this domain.

Correlate Two 2-D Arrays

When the inputs are two 2-D arrays, the j th column of the output, y_{uv} , has these elements:

$$y_{uv}(i, j) = \sum_{k=0}^{\max(M_u, M_v) - 1} u_{k, j}^* v_{(k+i), j} \quad 0 \leq i < M_v$$

$$y_{uv}(i, j) = y_{vu}^*(-i, j) \quad -M_u < i < 0$$

where:

- $*$ denotes the complex conjugate.
- u is an M_u -by- N input matrix.
- v is an M_v -by- N input matrix.
- $y_{u,v}$ is an $(M_u + M_v - 1)$ -by- N matrix.

Inputs u and v are zero when indexed outside their valid ranges.

Correlate a Column Vector with a 2-D Array

When one input is a column vector and the other input is a 2-D array, the algorithm independently cross-correlates the input vector with each column of the 2-D array. The j th column of the output, $y_{u,v}$, has these elements:

$$y_{uv}(i, j) = \sum_{k=0}^{\max(M_u, M_v) - 1} u_k^* v_{(k+i), j} \quad 0 \leq i < M_v$$

$$y_{uv}(i, j) = y_{vu}^*(-i, j) \quad -M_u < i < 0$$

where:

- $*$ denotes the complex conjugate.
- u is an M_u -by-1 column vector.
- v is an M_v -by- N matrix.
- y_{uv} is an $(M_u + M_v - 1)$ -by- N matrix.

Inputs u and v are zero when indexed outside their valid ranges.

Correlate Two Column Vectors

When the inputs are two column vectors, the j th column of the output, y_{uv} , has these elements:

$$y_{uv}(i) = \sum_{k=0}^{\max(M_u, M_v) - 1} u_k^* v_{(k+i)} \quad 0 \leq i < M_v$$

$$y_{uv}(i) = y_{vu}^*(-i) \quad -M_u < i < 0$$

where:

- $*$ denotes the complex conjugate.
- u is an M_u -by-1 column vector.
- v is an M_v -by-1 column vector.
- y_{uv} is an $(M_u + M_v - 1)$ -by-1 column vector.

Inputs u and v are zero when indexed outside their valid ranges.

Frequency-Domain Computation

When you set the computation domain to frequency, the algorithm computes the cross-correlation in the frequency domain.

To compute the cross-correlation, the algorithm:

- 1 Takes the Fourier transform of both input signals, U and V .
- 2 Multiplies U and V^* , where $*$ denotes the complex conjugate.
- 3 Computes the inverse Fourier transform of the product.

In this domain, depending on the input length, the algorithm can require fewer computations.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

The following diagram shows the data types the Correlation block uses for fixed-point signals (time domain only).

You can set the product output, accumulator, and output data types on the **Data Types** tab of the block.

When the input is real, the output of the multiplier is in the product output data type. When the input is complex, the output of the multiplier is in the accumulator data type. For details on the complex multiplication performed, see "Multiplication Data Types".

Note When one or both of the inputs are signed fixed-point signals, all internal block data types are signed fixed point. The internal block data types are unsigned fixed point only when both inputs are unsigned fixed-point signals.

Autocorrelation

Counter

Count up or down through specified range of numbers

Library: DSP System Toolbox / Signal Management / Switches and Counters

Description

The Counter block counts up or down through a specified range of numbers. The block enables the **Inc** (increment) port when you set the **Count direction** parameter to Up. When you set the **Count direction** parameter to Down, the block enables the **Dec** (decrement) port. If you set the **Count event** parameter to Free running, the block disables the **Inc** or **Dec** port and counts at a constant time interval. For all other settings of the **Count event** parameter, the block increments or decrements the counter each time a trigger event occurs at the **Inc** or **Dec** input port. When a trigger event occurs at the optional **Rst** port, the block resets the counter to its initial state.

The Counter block accepts single-channel inputs. For more information about scalar input operation, vector input operation, and free-running operation, see “Algorithms” on page 2-299.

Ports

Input

Inc/Dec — Input signal to trigger count event

scalar | vector

Input signal used to determine when the block increments or decrements the counter, specified as a real-valued scalar or vector. If the input to the **Inc** or **Dec** port is a vector, the block treats the vector as a frame. Each time a triggering event occurs at the **Inc** or **Dec** input port, the block increments or decrements the counter, respectively. You control the type of triggering event using the **Count event** parameter.

Dependencies

The block enables the **Inc** (increment) port when you set the **Count direction** parameter to Up.

The block enables the **Dec** (decrement) port when you set the **Count direction** parameter to Down.

The block disables the **Inc/Dec** input port when you set the **Count event** parameter to Free running. In free running mode, the block counts at a constant time interval.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean

Rst — Reset signal

scalar

Input signal used to determine when the block resets the counter, specified as a real-valued scalar. The **Rst** port must have the same port sample time as the **Inc** or **Dec** input port. Each time a

triggering event occurs at the **Rst** port, the block resets the counter to its initial value. For more information about triggering events, see “Count event” on page 2-0 .

Dependencies

To enable this port, select the **Reset input** check box.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean

Max — Maximum counter size

scalar

Specify the maximum counter size as any unsigned integer that the **Count data type** can represent. The counter values range from 0 to the value you specify as an input to the **Max** port.

Dependencies

To enable this port, set the **Counter size** parameter to Specify via input port.

Data Types: uint8 | uint16 | uint32

Output

Cnt — Current value of counter

scalar | vector

Current value of the counter, specified as a scalar or vector. When you set the **Count event** parameter to Free running, the **Cnt** output is a M -by-1 vector containing the count value at each of M consecutive sample times, where M is the value you specify for the **Samples per output frame** parameter.

Dependencies

To enable this port, set the **Output** parameter to Count or Count and Hit.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean

Hit — Hit status

scalar | vector

Hit status of the integer values you specified in the **Hit values** parameter. When a value you specify occurs in the count, the block outputs a 1 at the **Hit** port.

Note The block might output Boolean values from the **Hit** output port depending on the setting of the **Hit data type** parameter.

Dependencies

To enable this port, set the **Output** parameter to Hit or Count and Hit.

Data Types: Boolean | Logical

Parameters

Count direction — Count up or down

Up (default) | Down

Specify whether to count **Up** or **Down**. The port label on the block icon changes to **Inc** (increment) or **Dec** (decrement) based on the value of this parameter.

- When you set the **Count direction** parameter to **Up** and the counter reaches the upper limit of the counter range, the block restarts the counter at zero the next time a trigger event occurs at the **Inc** port.
- When you set the **Count direction** parameter to **Down** and the counter reaches zero, the block restarts the counter at the upper limit of the counter range the next time a trigger event occurs at the **Dec** port.

This parameter is tunable (Simulink) in Simulink normal mode.

Tunable: Yes

Count event — Type of trigger event

Rising edge (default) | Falling edge | Either edge | Non-zero sample | Free running

Specify the type of event that triggers the block to increment, decrement, or reset the counter when received at the **Inc/Dec** or **Rst** ports. You can select:

- **Rising edge** — Triggers a count or reset operation when the input to the **Inc/Dec** or **Rst** port behaves in one of the following ways:
 - Rises from a negative value to a positive value or zero.
 - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure).

- **Falling edge** — Triggers a count or reset operation when the input to the **Inc/Dec** or **Rst** port behaves in one of the following ways:
 - Falls from a positive value to a negative value or zero.
 - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure).

- **Either edge** — Triggers a count or reset operation when the input to the **Inc/Dec** or **Rst** port is a Rising edge or Falling edge.
- **Non-zero sample** — Triggers a count or reset operation at each sample time when the input to the **Inc/Dec** or **Rst** port is not zero.
- **Free running** — Disables the **Inc/Dec** port and enables the **Samples per output frame** and **Sample time** block parameters. The block increments or decrements the counter at a constant interval, T_s , which you specify using the **Sample time** parameter. For more information, see “Free-Running Operation” on page 2-300. In this mode, the block resets the counter whenever it receives a non-zero sample at the **Rst** port.

Dependencies

When you set this parameter to **Free running**, the block disables the **Inc/Dec** port and counts at the constant interval specified by the **Sample time** parameter.

Counter size — Range of integer values to count through

8 bits (default) | 16 bits | 32 bits | User defined | Specify via input port

Specify the range of integer values the block counts through. When the block counts through the entire counter range, the next time a trigger event occurs at the **Inc/Dec** port, the block resets the counter as follows:

- When you set the **Count direction** parameter to **Up** and the counter reaches the upper limit of the counter range, the block restarts the counter at zero.
- When you set the **Count direction** parameter to **Down** and the counter reaches zero, the block restarts the counter at the upper limit of the counter range.

You can set the **Counter size** parameter to one of the following options:

- **8 bits** — Specifies a counter with a range of 0 to 255.
- **16 bits** — Specifies a counter with a range of 0 to 65535.
- **32 bits** — Specifies a counter with a range of 0 to $2^{32}-1$.
- **User defined** — Enables the **Maximum count** parameter, which allows you to specify the upper-count limit as any arbitrary unsigned integer that the **Count data type** can represent. The counter values range from 0 to the value of the **Maximum count** parameter.
- **Specify via input port** — Enables the **Max** input port, which allows you to specify the upper-count limit as any arbitrary unsigned integer that the **Count data type** can represent. The counter values range from 0 to the value you specify as an input to the **Max** port.

Maximum count — Maximum value of counter

255 (default) | positive integer

Specify the maximum value of the counter as any unsigned integer representable by the data type you specify for the **Counter data type** parameter. Tunable (Simulink) in Simulink normal mode.

Tunable: Yes**Dependencies**

To enable this parameter, set the **Counter size** to User defined.

Initial count — Initial value of counter0 (default) | integer ≥ 0

Specify the initial value of the counter as any unsigned integer in the range defined by the **Counter size** parameter. The block uses the initial value of the counter at the start of simulation and resets the counter back to that initial value each time a trigger event occurs at the **Rst** port.

Tunable: Yes**Output — Output count value, hit value, or both**

Count (default) | Hit | Count and Hit

Select the output ports to enable. You can choose to enable the Count, Hit, or Count and Hit ports.

Hit values — Count values to flag

32 (default) | scalar | vector

Specify an integer or vector of integers whose occurrence in the count should be flagged by a 1 at the (optional) **Hit** output port. This parameter appears only when you set the **Output** parameter to Hit or Count and Hit.

Tunable: Yes**Reset input — Enable Rst input port**

on (default) | off

Select this check box to enable the **Rst** input port. When you enable the **Rst** port, the block resets the counter to its initial value each time a trigger event occurs at the **Rst** port. To specify the type of event that triggers a reset of the counter, set the **Count event** parameter. When you clear the **Reset input** check box, you cannot reset the counter during simulation.

Samples per output frame — Number of samples in each output vector

1 (default) | positive integer

Specify the number of samples, M , in each output vector as a positive integer.

Dependencies

To enable this parameter, set the **Count event** to Free running.

Sample time — Sample time in Free Running mode

1 (default) | -1 | scalar ≥ 0

Specify the constant interval, T_s , at which the block increments or decrements the counter when in free-running mode. You can specify a scalar that is greater than or equal to zero, or specify a value of -1 to inherit the sample time.

For example, to have the block increment the counter every 5 seconds, set the **Count direction** parameter to Up, the **Count event** parameter to Free running, and specify a value of 5 for the **Sample time** parameter. In free running mode, the sample time of the output ports is always MT_s .

Dependencies

To enable this parameter, set the **Count event** to Free running.

Count data type — Data type of Cnt port

double (default) | single | int8 | uint8 | int16 | uint16 | int32 | uint32

Specify the data type of the output at the **Cnt** port.

Dependencies

To enable this parameter, set the **Output** parameter to Count or Count and Hit.

Hit data type — Data type of Hit port

Logical (default) | Boolean

Specify the data type of the output at the **Hit** port.

Dependencies

To enable this parameter, set the **Output** parameter to Hit or set it to Count and Hit with the **Count data type** parameter set to Double.

Block Characteristics

Data Types	Boolean double integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Algorithms

Scalar Input Operation

When you set the **Count direction** parameter to Up, a trigger event at the **Inc** (increment) input port causes the block to increase the counter by one. Assuming no reset events occur, the block continues increasing the counter value when triggered, until the counter value reaches the upper-count limit. The next time a trigger event occurs at the **Inc** port, the block restarts the counter at 0 and resumes increasing the counter by one for each subsequent trigger event at the **Inc** port.

When you set the **Count direction** parameter to Down, a trigger event at the **Dec** (decrement) input port causes the block to decrease the counter by one. Assuming no reset events occur, the block continues decreasing the counter value when triggered until the counter value reaches zero. The next time a trigger event occurs at the **Dec** port, the block restarts the counter at the upper-count limit and resumes decreasing the counter by one for each subsequent trigger event at the **Dec** port.

Between triggering events, the block holds the output at its most recent value. The block resets the counter to its initial state when the trigger event specified by the **Count event** parameter occurs at the optional **Rst** input port. When the **Inc/Dec** and **Rst** ports receive trigger events simultaneously, the block first resets the counter and then increments or decrements the counter appropriately. If you do not need to reset the counter during simulation, you can disable the **Rst** port by clearing the **Reset input** check box.

The **Output** parameter allows you to specify which values the block outputs:

- **Count** enables a **Cnt** output port on the block. The **Cnt** port provides the current value of the counter as a scalar value. The **Cnt** output port has the same port sample time as the **Inc/Dec** input port.
- **Hit** enables a **Hit** output port on the block. The **Hit** port produces zeros while the value of the counter does not equal any of the integers you specify for the **Hit values** parameter. You can specify an integer or a vector of integers for the **Hit values** parameter. When the counter value does equal one or more of the values you specify for the **Hit values** parameter, the block outputs a value of 1 at the **Hit** output port. The **Hit** output port has the same port sample time as the **Inc/Dec** input port.
- **Count** and **Hit** enables both the **Cnt** and **Hit** output ports.

Vector Input Operation

The block treats vector inputs to the **Inc/Dec** port as a frame. Vector operation is the same as scalar operation, except that the block increments or decrements the counter by the total number of trigger events contained in the **Inc/Dec** input vector. Thus, the counter may change multiple times during the processing of a single **Inc/Dec** input vector.

When the block has a **Hit** port, the block outputs a value of 1 if any of the **Hit values** match any of the counter values during the processing of the **Inc/Dec** input vector.

When a trigger event splits across two consecutive vectors, that event is counted in the vector that contains the conclusion of the event. When the **Rst** port receives a trigger event at the same time as the **Inc/Dec** port, the block first resets the counter. The block then increments or decrements the counter by the number of trigger events contained in the **Inc/Dec** input vector.

When the input to the **Inc/Dec** port is a length N vector, the port sample time of the **Inc/Dec** input port is equal to the frame period of the input, or N times the sample time of the input signal. The port sample time of the **Cnt** and **Hit** output ports equals that of the **Inc/Dec** input port.

Free-Running Operation

The block operates in free-running mode when you select **Free running** for the **Count event** parameter.

The **Inc/Dec** input port is disabled in this mode, and the block simply increments or decrements the counter at the constant interval, T_s , which you specify using the **Sample time** parameter.

In this mode, the **Rst** port always behaves as if the **Count event** parameter were set to **Non-zero sample**. Thus, the block triggers a reset event at each sample time that the **Rst** input is not zero.

In this mode, the **Cnt** output is an M -by-1 vector containing the count value at each of M consecutive sample times, where M is the value you specify for the **Samples per output frame** parameter. The **Hit** output is an M -by-1 vector containing the hit status (0 or 1) at each of those M consecutive sample times. Both the **Cnt** and **Hit** output ports have a port sample time of MT_s .

Covariance AR Estimator

Compute estimate of autoregressive (AR) model parameters using covariance method

Library

Estimation / Parametric Estimation

dspparest3

Description

The Covariance AR Estimator block uses the covariance method to fit an autoregressive (AR) model to the input data. This method minimizes the forward prediction error in the least squares sense.

The input must be a column vector or an unoriented vector, which is assumed to be the output of an AR system driven by white noise. This input represents a frame of consecutive time samples from a single-channel signal. The block computes the normalized estimate of the AR system parameters, $A(z)$, independently for each successive input frame.

$$H(z) = \frac{G}{A(z)} = \frac{G}{1 + a(2)z^{-1} + \dots + a(p+1)z^{-p}}$$

The order, p , of the all-pole model is specified by the **Estimation order** parameter. To guarantee a valid output, you must set the **Estimation order** parameter to be less than or equal to half the input vector length.

The top output, A , is a column vector of length $p+1$ with the same frame status as the input, and contains the normalized estimate of the AR model coefficients in descending powers of z .

$[1 \ a(2) \ \dots \ a(p+1)]$

The scalar gain, G , is provided at the bottom output (G).

See the Burg AR Estimator block reference page for a comparison of the Burg AR Estimator, Covariance AR Estimator, Modified Covariance AR Estimator, and Yule-Walker AR Estimator blocks.

Parameters

Estimation order

The order of the AR model, p . To guarantee a nonsingular output, you must set p to be less than or equal to half the input length. Otherwise, the output might be singular.

Covariance Method

Power spectral density estimate using covariance method

Library

Estimation / Power Spectrum Estimation

dspspect3

Description

The Covariance Method block estimates the power spectral density (PSD) of the input using the covariance method. This method fits an autoregressive (AR) model to the signal by minimizing the forward prediction error in the least squares sense. The **Estimation order** parameter specifies the order of the all-pole model. The block computes the spectrum from the FFT of the estimated AR model parameters. To guarantee a valid output, the **Estimation order** parameter must be less than or equal to half the input vector length.

The input must be a column vector or an unoriented vector. It represents a frame of consecutive time samples from a single-channel signal. The block outputs a column vector containing the estimate of the power spectral density of the signal at N_{fft} equally spaced frequency points. The frequency points are in the range $[0, F_s)$, where F_s is the sampling frequency of the signal.

Selecting **Inherit FFT length from estimation order**, specifies that N_{fft} is one greater than the estimation order. Clearing the **Inherit FFT length from estimation order** parameter allows you to use the **FFT length** parameter to specify N_{fft} as a power of 2. The block zero-pads or wraps the input to N_{fft} before computing the FFT.

When you select the **Inherit sample time from input** check box, the block computes the frequency data from the sample period of the input signal. For the block to produce valid output, the following conditions must hold:

- The input to the block is the original signal, with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** check box. You can then specify a sample time using the **Sample time of original time series** parameter.

See the Burg Method block reference for a comparison of the Burg Method, Covariance Method, Modified Covariance Method, and Yule-Walker Method blocks.

Parameters

Estimation order

The order of the AR model. To guarantee a nonsingular output, the value of this parameter must be less than or equal to half the input length.

Inherit FFT length from estimation order

When selected, this option specifies that the FFT length is one greater than the estimation order.

FFT length

Enter the number of data points on which to perform the FFT, N_{fft} . When N_{fft} is larger than the input frame size, the block zero-pads each frame as needed. When N_{fft} is smaller than the input frame size, the block wraps each frame as needed. This parameter becomes visible only when you clear the **Inherit FFT length from estimation order** check box.

Inherit sample time from input

When you select the **Inherit sample time from input** check box, the block computes the frequency data from the sample period of the input signal. For the block to produce valid output, the following conditions must hold:

- The input to the block is the original signal, with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** check box. You can then specify a sample time using the **Sample time of original time series** parameter.

Sample time of original time series

Specify the sample time of the original time-domain signal. This parameter becomes visible only when you clear the **Inherit sample time from input** check box.

Cross-Spectrum Estimator

Estimate cross-power spectrum density

Library

Estimation / Power Spectrum Estimation

dspsect3

Description

The Cross-Spectrum Estimator block outputs the frequency cross-power spectrum density of two real or complex input signals, x and y , via Welch's method of averaged modified periodograms. The input signals must be of the same size and data type.

The Cross-Spectrum Estimator block computes the current power spectrum estimate by averaging the last N power spectrum estimates, where N is the number of spectral averages defined in **Number of spectral averages**. The block buffers the input data into overlapping segments. You can set the length of the data segment and the amount of data overlap through the parameters set in the block dialog box. The block computes the power spectrum based on the parameters set in the block dialog box.

Each column of the input signal is treated as a separate channel. If the input is a two-dimensional signal, the first dimension represents the channel length (or frame size) and the second dimension represents the number of channels. If the input is a one-dimensional signal, then it is interpreted as a single channel.

Parameters

Window length source

Source of the window length value. You can set this parameter to:

- Same as input frame length (default) — Window length is set to the frame size of the input.
- Specify on dialog — Window length is the value specified in **Window length**.

This parameter is nontunable.

Window length

Length of the window, in samples, used to compute the spectrum estimate, specified as a positive integer scalar greater than 2. This parameter applies when you set **Window length source** to **Specify on dialog**. The default is 1024. This parameter is nontunable.

Window Overlap (%)

Percentage of overlap between successive data windows, specified as a scalar in the range [0, 100). The default is 0. This parameter is nontunable.

Averaging method

Specify the averaging method as `Running` or `Exponential`. In the running averaging method, the block computes an equally weighted average of a specified number of spectrum estimates defined by the **Number of spectral averages** parameter. In the exponential method, the block computes the average over samples weighted by an exponentially decaying forgetting factor.

Number of spectral averages

Number of spectral averages, specified as a positive integer scalar. The default is 1. The spectrum estimator computes the current power spectrum estimate by averaging the last N power spectrum estimates, where N is the number of spectral averages defined in **Number of spectral averages**. This parameter is nontunable.

This parameter applies when **Averaging method** is set to `Running`.

Specify forgetting factor from input port

Select this check box to specify the forgetting factor from an input port. When you do not select this check box, the forgetting factor is specified through the **Forgetting factor** parameter.

This parameter applies when **Averaging method** is set to `Exponential`.

Forgetting factor

Specify the exponential weighting forgetting factor as a scalar value greater than zero and smaller than or equal to one. The default is 0.9.

This parameter applies when you set **Averaging method** to `Exponential` and clear the **Specify forgetting factor from input port** parameter.

FFT length source

Source of the FFT length value. You can set this parameter to:

- Auto (default) — FFT length is set to the frame size of the input.
- Property — FFT length is the value specified in **FFT length**.

This parameter is nontunable.

FFT length

Length of the FFT used to compute the spectrum estimates, specified as a positive integer scalar. This parameter applies when you set **FFT length source** to `Property`. The default is 1024. This parameter is nontunable.

Window function

Window function for the cross-spectrum estimator, specified as one of `Chebyshev` | `Flat Top` | `Hamming` | `Hann` | `Kaiser` | `Rectangular`. The default is `Hann`. This parameter is nontunable.

Sidelobe attenuation of window (dB)

Side lobe attenuation of the window, specified as real positive scalar. This parameter applies when you set **Window function** to `Chebyshev` or `Kaiser`. The default is 60. This parameter is nontunable.

Frequency range

Frequency range of the cross-spectrum estimator. You can set this parameter to:

- **centered** (default) — The cross-spectrum estimator computes the centered two-sided spectrum of complex or real input signals, x and y . The length of the cross-spectrum estimate is equal to the FFT length. The spectrum estimate is computed over the frequency range $[-\text{SampleRate}/2 \text{ SampleRate}/2]$ when the FFT length is even and $[-\text{SampleRate}/2 \text{ SampleRate}/2]$ when FFT length is odd.
- **onesided** — The cross-spectrum estimator computes the one-sided spectrum of real input signals, x and y . When the FFT length, $NFFT$ is even, length of the cross-spectrum estimate is $(NFFT/2) + 1$, and is computed over the frequency range $[0 \text{ SampleRate}/2]$. When the FFT length, $NFFT$ is odd, length of the cross-spectrum estimate is $(NFFT + 1)/2$, and is computed over the frequency range $[0 \text{ SampleRate}/2]$.
- **twosided** — The cross-spectrum estimator computes the two-sided spectrum of complex or real input signals, x and y . The length of the cross-spectrum estimate is equal to the FFT length. The spectrum estimate is computed over the frequency range $[0 \text{ SampleRate}]$, where SampleRate is the sample rate of the input signal.

This parameter is nontunable.

Inherit sample rate from input

When you select this check box, the block's sample rate is computed as N/T_s , where N is the frame size of the input signal, and T_s is the sample time of the input signal. When you clear this check box, the block sample rate is the value specified in **Sample rate (Hz)**. By default, this check box is selected.

Sample rate (Hz)

Sample rate of the input signal, specified as a positive scalar value. The default is 44100. This parameter applies when you clear the **Inherit sample rate from input** check box. This parameter is nontunable.

Simulate using

Type of simulation to run. You can set this parameter to:

- **Code generation** (default)

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than **Interpreted execution**.

- **Interpreted execution**

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than **Code generation**.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point

Algorithms

Welch's Method of Averaged Modified Periodograms

Give two signal inputs, x and y :

- 1 Multiply the inputs by the window and scale the result by the window power.
- 2 Compute FFT of the signals, X and Y , and multiply X with $\text{conj}(Y)$ using $Z = X.\text{*conj}(Y)$.
- 3 Compute the current cross power spectrum estimate by taking the moving average of the last N number of Z 's and scaling the answer by the sample rate.

For further information on the algorithms, refer to the "Averaging Method" on page 2-1215 section in Spectrum Analyzer.

Cumulative Product

Cumulative product of channel, column, or row elements

Library

Math Functions / Math Operations

dspmathops

Description

The Cumulative Product block computes the cumulative product along the specified dimension of the input or across time (running product).

The input can be a vector or matrix.

Input and Output Characteristics

Valid Input

The Cumulative Product block accepts vector or matrix inputs containing real or complex values.

Valid Reset Signal

The optional reset port, `Rst`, accepts scalar values, which can be any built-in Simulink data type including `boolean`. The rate of the input to the `Rst` port must be the same or slower than that of the input data signal. The sample time of the input to the `Rst` port must be a positive integer multiple of the input sample time.

Computing the Running Product Along Channels of the Input

When you set the **Multiply input along** parameter to `Channels (running product)`, the block computes the cumulative product of the elements in each input channel. The running product of the current input takes into account the running product of all previous inputs. In this mode, you must also specify a value for the **Input processing** parameter. When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block computes the running product along each column of the current input. When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block computes a running product for each element of the input across time. See the following sections for more information:

- “Computing the Running Product for Each Column of the Input” on page 2-311
- “Computing the Running Product for Each Element of the Input” on page 2-311
- “Resetting the Running Product” on page 2-312

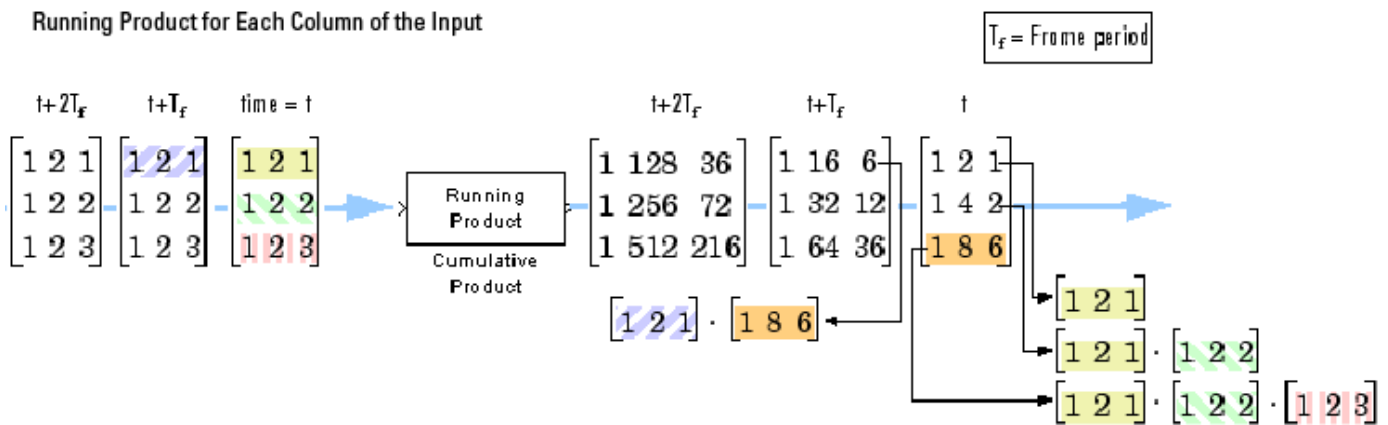

Computing the Running Product for Each Column of the Input

When you set the **Input processing** parameter to **Columns as channels (frame based)**, the block treats each input column as an independent channel. As the following figure and equation illustrate, the output has the following characteristics:

- The first row of the first output is the same as the first row of the first input.
- The first row of each subsequent output is the element-wise product of the first row of the current input (time t), and the last row of the previous output (time $t - T_f$, where T_f is the frame period).
- The output has the same size, dimension, data type, and complexity as the input.

Given an M -by- N matrix input, u , the output, y , is an M -by- N matrix whose first row has elements

$$y_{1,j}(t) = u_{1,j}(t) \cdot y_{M,j}(t - T_f)$$

Computing the Running Product for Each Element of the Input

When you set the **Input processing** parameter to **Elements as channels (sample based)**, the block treats each element of the input matrix as an independent channel. As the following figure and equation illustrate, the output has the following characteristics:

- The first output is the same as the first input.
- Each subsequent output is the element-wise product of the current input (time t) and the previous output (time $t - T_s$, where T_s is the sample period).
- The output has the same size, dimension, data type, and complexity as the input.

Given an M -by- N matrix input, u , the output, y , is an M -by- N matrix with the elements

$$y_{i,j}(t) = u_{i,j}(t) \cdot y_{i,j}(t - T_s) \quad \begin{matrix} 1 \leq i \leq M \\ 1 \leq j \leq N \end{matrix}$$

For convenience, the block treats length- M unoriented vector inputs as M -by-1 column vectors when multiplying along channels. In such cases, the output is a length- M unoriented vector.

Resetting the Running Product

When you are computing the running product, you can configure the block to reset the running product whenever it detects a reset event at the optional Rst port. The rate of the input to the Rst port must be the same or slower than that of the input data signal. The sample time of the input to the Rst port must be a positive integer multiple of the input sample time. The input to the Rst port can be of the Boolean data type.

If a reset event occurs while the block is performing sample-based processing, the block initializes the current output to the values of the current input. If a reset event occurs while the block is performing frame-based processing, the block initializes the first row of the current output to the values in the first row of the current input.

The **Reset port** parameter specifies the reset event, which can be one of the following:

- **None** disables the Rst port.
- **Rising edge** — Triggers a reset operation when the Rst input does one of the following:
 - Rises from a negative value to a positive value or zero
 - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)

- **Falling edge** — Triggers a reset operation when the Rst input does one of the following:

- Falls from a positive value to a negative value or zero
- Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)

- **Either edge** — Triggers a reset operation when the Rst input is a Rising edge or Falling edge (as described above)
- **Non-zero sample** — Triggers a reset operation at each sample time that the Rst input is not zero

Note When you run simulations in Simulink MultiTasking mode, reset signals have a one-sample latency. When the block detects a reset event, a one-sample delay occurs at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Multiplying Along Columns

When you set the **Multiply input along** parameter to **Columns**, the block computes the cumulative product of each column of the input. In this mode, the current cumulative product is independent of the cumulative products of previous inputs.

```
y = cumprod(u) % Equivalent MATLAB code
```

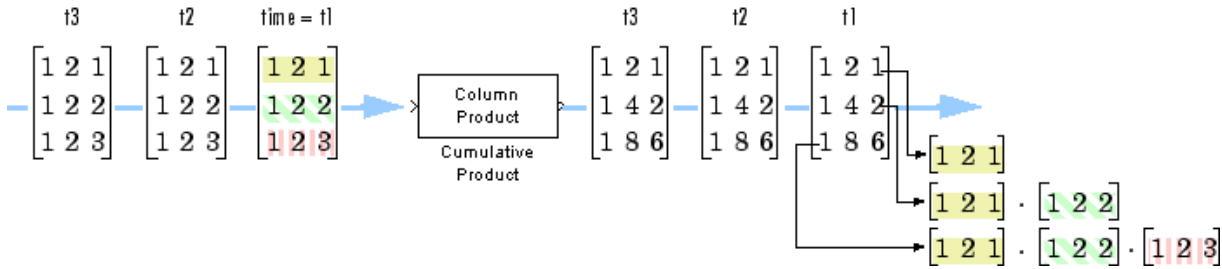

The output has the same size, dimension, data type, and complexity as the input. The m th output row is the element-wise product of the first m input rows.

Given an M -by- N input, u , the output, y , is an M -by- N matrix whose j th column has elements

$$y_{i,j} = \prod_{k=1}^i u_{k,j} \quad 1 \leq i \leq M$$

When multiplying along columns, the block treats length- M unoriented vector inputs as M -by-1 column vectors.

Product Along Columns

Multiplying Along Rows

When you set the **Multiply input along** parameter to Rows, the block computes the cumulative product of the row elements. In this mode, the current cumulative product is independent of the cumulative products of previous inputs.

```
y = cumprod(u,2) % Equivalent MATLAB code
```

The output has the same size, dimension, and data type as the input. The n th output column is the element-wise product of the first n input columns.

Given an M -by- N matrix input, u , the output, y , is an M -by- N matrix whose i th row has elements

$$y_{i,j} = \prod_{k=1}^j u_{i,k} \quad 1 \leq j \leq N$$

When you multiply along rows, the block treats length- N unoriented vector inputs as 1-by- N row vectors.

Product Along Rows

Fixed-Point Data Types

The following diagram shows the data types used within the Cumulative Product block for fixed-point signals.

The output of the multiplier is in the product output data type when at least one of the inputs to the multiplier is real. When both of the inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”. You can set the accumulator, product output, intermediate product, and output data types in the block dialog as discussed in “Parameters” on page 2-315.

Parameters

Main Tab

Multiply input along

Specify the dimension along which to compute the cumulative product. You can choose to multiply along Channels (running product), Columns, or Rows. For more information, see the following sections:

- “Computing the Running Product Along Channels of the Input” on page 2-310
- “Multiplying Along Columns” on page 2-313
- “Multiplying Along Rows” on page 2-314

Input processing

Specify how the block should process the input when computing the running product along the channels of the input. You can set this parameter to one of the following options:

- Columns as channels (frame based) — When you select this option, the block treats each column of the input as a separate channel.
- Elements as channels (sample based) — When you select this option, the block treats each element of the input as a separate channel.

This parameter is available only when you set the **Multiply input along** parameter to Channels (running product).

Reset port

Determines the reset event that causes the block to reset the product along channels. The rate of the input to the Rst port must be the same or slower than that of the input data signal. The sample time of the input to the Rst port must be a positive integer multiple of the input sample time. This parameter appears only when you set the **Multiply input along** parameter to Channels (running product). For more information, see “Resetting the Running Product” on page 2-312.

Data Types Tab

Note Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

Rounding mode

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

Saturate on integer overflow

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

Intermediate product

Specify the intermediate product data type. As shown in “Fixed-Point Data Types” on page 2-314, the output of the multiplier is cast to the intermediate product data type before the next element of the input is multiplied into it. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt([], 16, 0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Product output

Specify the product output data type. See “Fixed-Point Data Types” on page 2-314 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt([], 16, 0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Accumulator

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-314 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- A rule that inherits a data type, for example, `Inherit: Same as product output`
- An expression that evaluates to a valid data type, for example, `fixdt([], 16, 0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Output

Specify the output data type. See “Fixed-Point Data Types” on page 2-314 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- A rule that inherits a data type, for example, `Inherit: Same as product output`
- An expression that evaluates to a valid data type, for example, `fixdt([], 16, 0)`

If both inputs are unsigned, all data types including the output data type is unsigned. If one of the inputs is signed, internal and output data types are signed.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Data Types of Signals” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Minimum

Specify the minimum value that the block should output. The default value is [] (unspecified). Simulink uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Maximum

Specify the maximum value that the block should output. The default value is [] (unspecified). Simulink uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Blocks

Cumulative Sum | Matrix Product

Cumulative Sum

Cumulative sum of channel, column, or row elements

Library: DSP System Toolbox / Math Functions / Math Operations

Description

The Cumulative Sum block computes the cumulative sum along the specified dimension of the input or across time (running sum).

Ports

Input

In — Input signal

vector | matrix

Input, specified as a vector or as matrix inputs containing real or complex values.

This port is unnamed until you select a non-None value for the **Reset** port parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Rst — Reset port

scalar

The optional reset port, **Rst**, accepts scalar values, which can be any built-in Simulink data type including **boolean**. The rate of the input to the **Rst** port must be the same or slower than that of the input data signal. The sample time of the input to the **Rst** port must be a positive integer multiple of the input sample time.

This port is unnamed until you select a non-None value for the **Reset** port parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean

Output

Port_1 — Output signal

vector | matrix

Cumulative sum of input, specified as a vector or a matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Main

Sum input along — Dimension to sum along

Channels (running sum) (default) | Columns | Rows

Specify the dimension along which to compute the cumulative summations. You can choose to sum along Channels (running sum), Columns, or Rows. For more information, see these sections:

- “Computing the Running Sum Along Channels of the Input” on page 2-323
- “Summing Along Columns” on page 2-325
- “Summing Along Rows” on page 2-326

Input processing — Method to process the input

Columns as channels (frame based) (default) | Elements as channels (sample based)

Specify how the block processes the input when computing the running sum along the channels of the input. You can set this parameter to one of these options:

- Columns as channels (frame based) — The block treats each column of the input as a separate channel.
- Elements as channels (sample based) — The block treats each element of the input as a separate channel.

Dependencies

This parameter is available only when you set the Sum input along parameter to Channels (running sum).

Reset port — Reset type

None (default) | Rising edge | Falling edge | Either edge | Non-zero sample

Determines the reset event that causes the block to reset the sum along channels. The rate of the input to the **Rst** port must be the same or slower than that of the input data signal. The sample time of the input to the **Rst** port must be a positive integer multiple of the input sample time. For more information, see “Resetting the Running Sum” on page 2-324.

Dependencies

This parameter is available only when you set the Sum input along parameter to Channels (running sum).

Data Types

Note Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings. All internal data types are floating point.

Rounding mode — Rounding mode

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

Saturate on integer overflow — Saturate for fixed-point operation

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

Accumulator — Data type of accumulator

Inherit: Same as first input (default) | fixdt([],16,0)

Accumulator specifies the data type of the output of an accumulation operation in the Cumulative Sum block. For illustrations on how to use the accumulator data type in this block, see the 'Fixed-Point Conversion' section in “Extended Capabilities” on page 2-0 .

- **Inherit: Same as input** — The block specifies the accumulator data type to be the same as the input data type.
- **fixdt([],16,0)** — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. Click the

Show data type assistant button  .

For more information, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

Output — Data type of output

Inherit: Same as accumulator (default) | Inherit: Same as input | fixdt([],16,0)

Output specifies the data type of the output of the Cumulative Sum block. For more information on the output data type, see the 'Fixed-Point Conversion' section in “Extended Capabilities” on page 2-0 .

- **Inherit: Same as input** — The block specifies the output data type to be the same as the input data type.
- **Inherit: Same as accumulator** — The block specifies the output data type to be the same as the accumulator data type.
- **fixdt([], 16, 0)** — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Output** data type by using the **Data Type Assistant**. Click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

Output Minimum — Minimum value the block can output

[] (default) | scalar

Specify the minimum value the block can output. Simulink software uses this minimum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

Output Maximum — Maximum value block can output

[] (default) | scalar

Specify the maximum value the block can output. Simulink software uses this maximum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

More About

Computing the Running Sum Along Channels of the Input

When you set the `Sum input along` parameter to `Channels (running sum)`, the block computes the cumulative sum of the elements in each input channel. The running sum of the current input takes into account the running sum of all previous inputs. In this mode, you must also specify a value for the `Input processing` parameter.

When you set the **Input processing** parameter to:

- `Columns as channels (frame based)` -- The block computes the running sum along each column of the current input.
- `Elements as channels (sample based)` -- The block computes a running sum for each element of the input across time.

Computing the Running Sum for Each Column of the Input

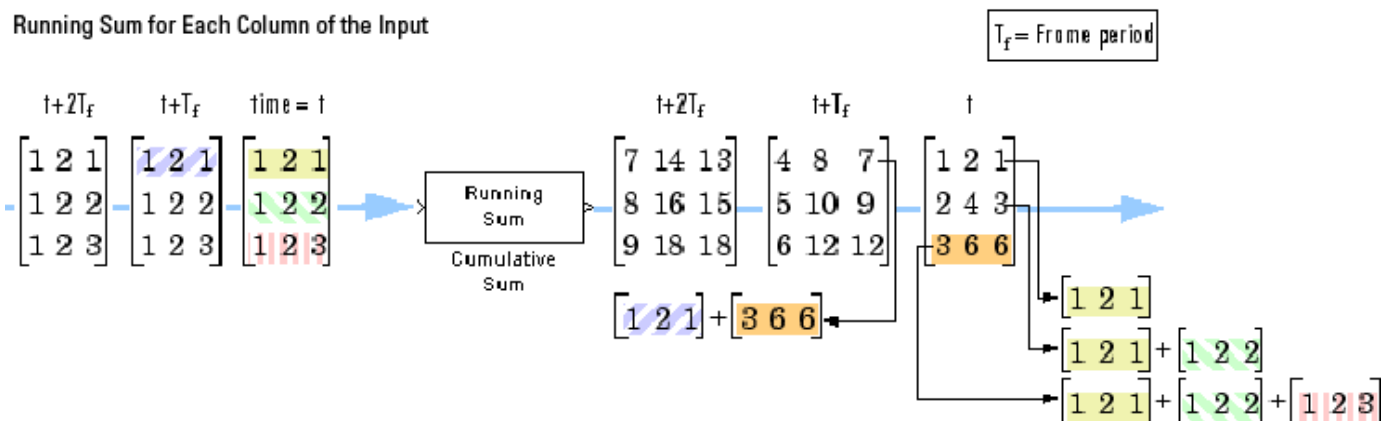

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block treats each input column as an independent channel. As the following figure and equation illustrate, the output has the following characteristics:

- The first row of the first output is the same as the first row of the first input.
- The first row of each subsequent output is the sum of the first row of the current input (time t), and the last row of the previous output (time $t - T_f$, where T_f is the frame period).
- The output has the same size, dimension, data type, and complexity as the input.

Given an M -by- N matrix input, u , the output, y , is an M -by- N matrix whose first row has elements

$$y_{1,j}(t) = u_{1,j}(t) + y_{M,j}(t - T_f)$$

Running Sum for Each Column of the Input

Computing the Running Sum for Each Element of the Input

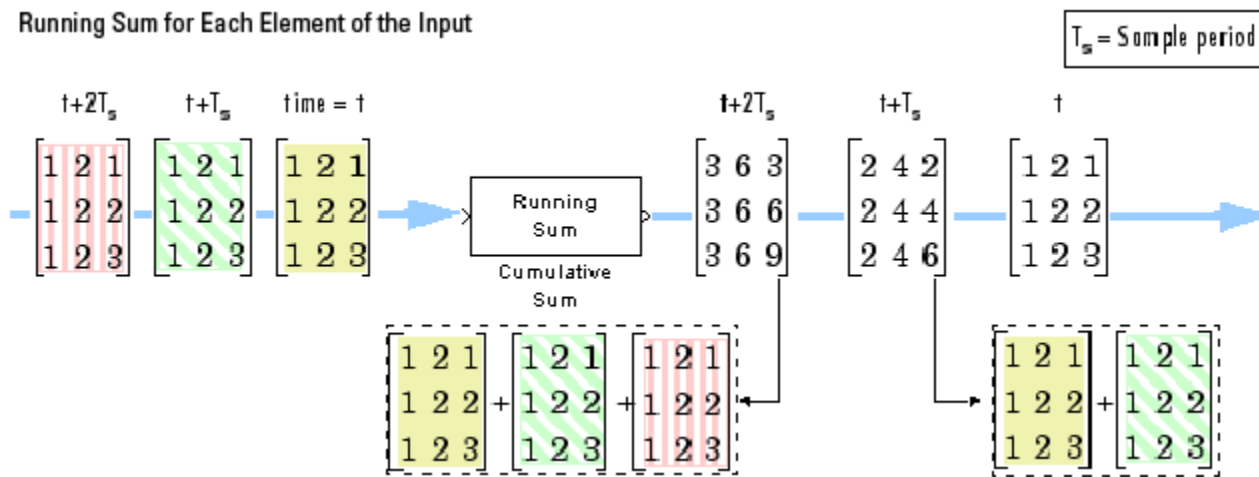

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats each element of the input matrix as an independent channel. As the following figure and equation illustrate, the output has these characteristics:

- The first output is the same as the first input.
- Each subsequent output is the sum of the current input (time t) and the previous output (time $t - T_s$, where T_s is the sample period).
- The output has the same size, dimension, data type, and complexity as the input.

Given an M -by- N matrix input, u , the output, y , is an M -by- N matrix with the elements

$$y_{i,j}(t) = u_{i,j}(t) + y_{i,j}(t - T_s) \quad \begin{array}{l} 1 \leq i \leq M \\ 1 \leq j \leq N \end{array}$$

Running Sum for Each Element of the Input

Resetting the Running Sum

When you are computing the running sum, you can configure the block to reset the running sum whenever it detects a reset event at the optional **Rst** port. The rate of the input to the **Rst** port must be the same or slower than that of the input data signal. The sample time of the input to the **Rst** port must be a positive integer multiple of the input sample time. The reset sample time must be a positive integer multiple of the input sample time. The input to the **Rst** port can be boolean.

If a reset event occurs while the block is performing sample-based processing, the block initializes the current output to the values of the current input. If a reset event occurs while the block is performing frame-based processing, the block initializes the first row of the current output to the values in the first row of the current input.

The **Reset** port parameter specifies the reset event, which can be one of the following:

- **None** disables the **Rst** port.
- **Rising edge** — Triggers a reset operation when the **Rst** input does one of the following:
 - Rises from a negative value to a positive value or zero
 - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero

- **Falling edge** — Triggers a reset operation when the **Rst** input does one of the following:
 - Falls from a positive value to a negative value or zero
 - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero

- **Either edge** — Triggers a reset operation when the **Rst** input is a **Rising edge** or **Falling edge**
- **Non-zero sample** — Triggers a reset operation at each sample time that the **Rst** input is not zero

Note When you run simulations in the Simulink **MultiTasking** mode, reset signals have a one-sample latency. When the block detects a reset event, a one-sample delay occurs at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Summing Along Columns

When you set the `Sum input` along parameter to `Columns`, the block computes the cumulative sum of each column of the input. In this mode, the current cumulative sum is independent of the cumulative sums of previous inputs.

```
y = cumsum(u) % Equivalent MATLAB code
```

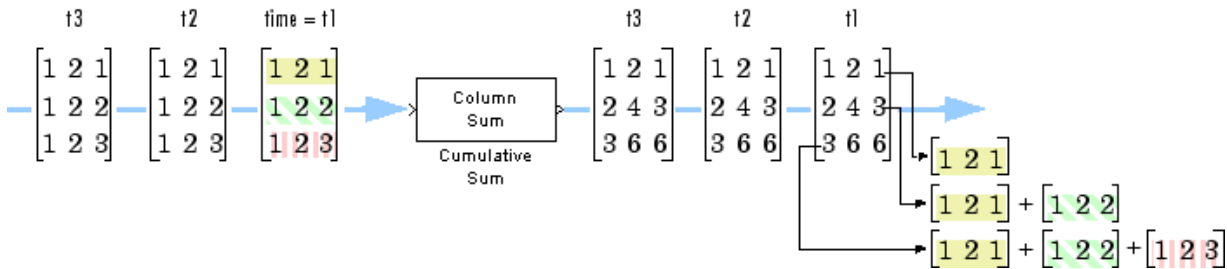

The output has the same size, dimension, data type, and complexity as the input. The m th output row is the sum of the first m input rows.

Given an M -by- N input, u , the output, y , is an M -by- N matrix whose j th column has elements

$$y_{i,j} = \sum_{k=1}^j u_{k,j} \quad 1 \leq i \leq M$$

The block treats length- M unoriented vector inputs as M -by-1 column vectors when summing along columns.

Sum Along Columns

Summing Along Rows

When you set the Sum input along parameter to Rows, the block computes the cumulative sum of the row elements. In this mode, the current cumulative sum is independent of the cumulative sums of previous inputs.

```
y = cumsum(u,2) % Equivalent MATLAB code
```

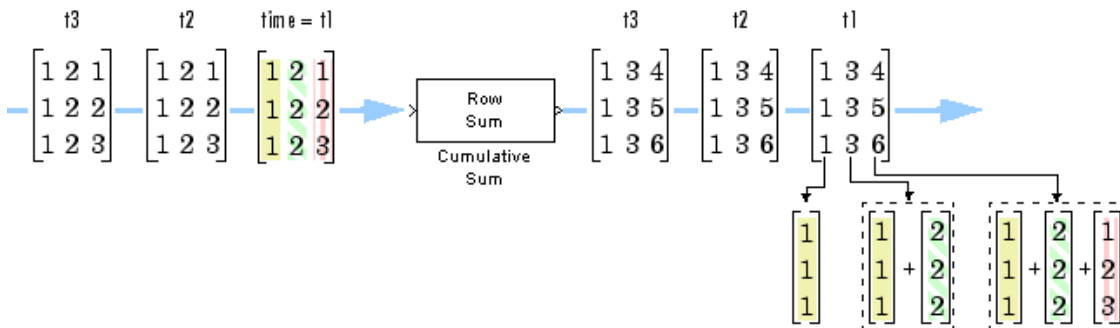

The output has the same size, dimension, and data type as the input. The n th output column is the sum of the first n input columns.

Given an M -by- N input, u , the output, y , is an M -by- N matrix whose i th row has elements

$$y_{i,j} = \sum_{k=1}^j u_{i,k} \quad 1 \leq j \leq N$$

When you sum along rows, the block treats length- N unoriented vector inputs as 1-by- N row vectors.

Sum Along Rows

Dataflow Subsystem

Subsystem whose execution domain is set to Dataflow

Library: DSP System Toolbox / Dataflow

Description

The Dataflow Subsystem block is a Subsystem block preconfigured with the execution domain set to dataflow. A Dataflow Subsystem uses synchronous dataflow as a model of computation, which is data-driven and statically scheduled.

Dataflow Subsystems help to

- Improve simulation throughput with multithreaded execution

Dataflow domains leverage the multicore CPU architecture of the host computer and can improve simulation speed significantly. It automatically partitions your model and simulates the system using multiple threads. By adding latency to your system, you can further increase concurrency and improve simulation throughput of your model.

- Automatically infer signal sizes for frame-based multirate models

See “Dataflow Domain” for more information.

Ports

Input

In — Signal input to dataflow subsystem

scalar | vector | matrix

Placing an Inport block in a subsystem adds an external input port to the block. The port label on the subsystem block is the name of the Inport block.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output

Out — Signal output from dataflow subsystem

scalar | vector | matrix

Placing an Outport block in a subsystem adds an output port from the block. The port label on the subsystem block is the name of the Outport block.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Parameters

The Dataflow Subsystem block uses the same parameters as the Subsystem block. For parameter descriptions and programmatic use information, see Subsystem, Atomic Subsystem, Nonvirtual Subsystem, CodeReuse Subsystem.

Note Dataflow subsystems cannot be atomic subsystems.

Latency — Latency of dataflow subsystem

0 (default) | scalar integer

To increase the throughput of a system, it can be advantageous to increase the latency of the system. Specify the **Latency** value in the **Execution** tab of the Property Inspector. The Dataflow Simulation Assistant can recommend a latency value for simulation. Click the **Dataflow assistant** button to open the Dataflow Simulation Assistant. For more information, see “Latency”

Programmatic Use

Block Parameter: Latency

Type: character vector

Values: scalar integer

Default: '0'

Automatic frame size calculation — Automatically calculate frame sizes and insert buffers

0 (default) | 1

When the **Automatic frame size calculation** parameter is enabled, dataflow domains automatically calculate frame sizes and insert buffers into your model, avoiding signal size propagation errors in multirate signal processing systems. For more information, see “Automatic Frame Size Calculation”.

Programmatic Use

Block Parameter: AutoFrameSizeCalculation

Type: character vector

Values: 'off'|'on'

Default: 'off'

Block Characteristics

Data Types	Boolean ^a bus ^a double ^a enumerated ^a fixed point ^a half ^a integer ^a single ^a string ^a
Direct Feedthrough	no
Multidimensional Signals	yes ^a
Variable-Size Signals	yes ^a
Zero-Crossing Detection	no

^a Actual data type or capability support depends on block implementation.

dB Conversion

Convert magnitude data to decibels (dB or dBm)

Library: DSP System Toolbox / Math Functions / Math Operations

Description

The dB Conversion block converts a linearly scaled power or amplitude input to dB or dBm. The reference power is 1 Watt for conversions to dB and 1 mWatt for conversions to dBm. The block's **Input signal** parameter specifies whether the input is a power signal or a voltage signal, and the **Convert to** parameter controls the scaling of the output. When selected, the **Add eps to input to protect against “log(0) = -inf”** parameter adds a value of `eps` to all power and voltage inputs. When this parameter is not selected, zero-valued inputs produce `-Inf` at the output.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Input signal to be converted, specified as a real scalar, vector, or matrix.

When the “Input signal” on page 2-0 parameter is set to:

- **Power** — The input is treated as a power signal, specified in Watts.
- **Amplitude** — The input is treated as a voltage signal, specified in Volts.

Data Types: `single` | `double`

Output

Port_1 — Output signal

scalar | vector | matrix

The converted output signal, returned as a scalar, vector, or matrix. The output is the same size, and data type as the input. The output `y` is calculated as follows.

When the “Input signal” on page 2-0 parameter is set to **Power** and **Convert to** parameter is set to:

- **dB** — The block performs this dB conversion:

$$y = 10 \cdot \log_{10}(u)$$
- **dBm** — The block performs this dBm conversion:

$$y = 10 \cdot \log_{10}(u) + 30$$

The dBm conversion is equivalent to performing the dB operation after converting the input to milliwatts.

Input u is a real, nonnegative, power signal, specified in Watts.

When the **Input signal** parameter is set to **Amplitude** and **Convert to** parameter is set to:

- dB — The block performs this dB conversion:

$$y = 10 \cdot \log_{10}(\text{abs}(u)^2/R)$$
- dBm — The block performs the following dBm conversion:

$$y = 10 \cdot \log_{10}(\text{abs}(u)^2/R) + 30$$

Input u is a real voltage signal, specified in Volts.

The dBm conversion is equivalent to performing the dB operation after converting the $(\text{abs}(u)^2/R)$ result to milliwatts. The scale factor, R , is specified in Ohms.

Data Types: `single` | `double`

Parameters

Convert to — Signal to convert

dB (default) | dBm

The logarithmic scaling to which the input is converted, dB or dBm. The reference power is 1 Watt for conversions to dB and 1 mW for conversions to dBm.

Amplitude conversions use the scale factor specified in ohms by the **Load resistance** parameter, R , to convert the voltage input to units of power (watts) before converting to dB or dBm.

When the “Input signal” on page 2-0 parameter is set to **Power** and **Convert to** parameter is set to:

- dB — The block performs this dB conversion:

$$y = 10 \cdot \log_{10}(u)$$
- dBm — The block performs this dBm conversion:

$$y = 10 \cdot \log_{10}(u) + 30$$

The dBm conversion is equivalent to performing the dB operation after converting the input to milliwatts.

Input u is a real, nonnegative, power signal, specified in Watts.

Input signal is set to **Amplitude** and **Convert to** parameter is set to:

- dB — The block performs this dB conversion:

$$y = 10 \cdot \log_{10}(\text{abs}(u)^2/R)$$
- dBm — The block performs this dBm conversion:

$$y = 10 \cdot \log_{10}(\text{abs}(u)^2/R) + 30$$

The dBm conversion is equivalent to performing the dB operation after converting the $(\text{abs}(u)^2/R)$ result to mW. The scale factor R is specified in Ohms.

Input u is a real voltage signal, specified in Volts.

Tunable: Yes

Input signal — Type of signal

Amplitude (default) | Power

The type of input signal, Power or Amplitude.

When **Input signal** is set to:

- Power -- Input u is a real, nonnegative, power signal (units of Watts).
- Amplitude -- Input u is a real voltage signal (units of Volts).

Load resistance (ohms) — Scale factor

1 (default) | positive scalar | positive integer

The scale factor R , specified in ohms. The block uses the scale factor to convert voltage input to units of power (watts) before converting to dB or dBm.

Tunable: Yes

Dependencies

To enable this parameter, set the "Input signal" on page 2-0 parameter to Amplitude.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point

Complex Number Support: Yes

Add eps to input to protect against " $\log(0) = -\text{inf}$ " — Add eps

off (default) | on

Select this parameter to add eps to all input values (power or voltage).

Tunable: Yes

dB Gain

dB Gain

Apply decibel gain

Library

Math Functions / Math Operations

dspmathops

Description

The dB Gain block multiplies the input by the decibel values specified in the **Gain** parameter. For an M -by- N input matrix u with elements u_{ij} , the **Gain** parameter can be a real M -by- N matrix with elements g_{ij} to be multiplied element-wise with the input, or a real scalar.

$$y_{ij} = u_{ij}10^{(g_{ij}/k)}$$

The value of k is 10 for power signals (select **Power** as the **Input signal** parameter) and 20 for voltage signals (select **Amplitude** as the **Input signal** parameter).

The value of the equivalent linear gain

$$g_{ij}^{lin} = 10^{(g_{ij}/k)}$$

is displayed in the block icon below the dB gain value. The output is the same size as the input.

The dB Gain block supports real and complex floating-point and fixed-point data types.

Fixed-Point Data Types

The following diagram shows the data types used within the dB Gain subsystem block for fixed-point signals.

The settings for the fixed-point parameters of the Gain block in the diagram above are as follows:

- Integer rounding mode: **Floor**
- Saturate on integer overflow — unselected
- Parameter data type mode — **Inherit via internal rule**
- Output data type mode — **Inherit via internal rule**

See the Gain reference page for more information.

Parameters

Gain

The dB gain to apply to the input, a scalar or a real M -by- N matrix. Tunable (Simulink).

Input signal

The type of input signal: Power or Amplitude. Tunable (Simulink).

Note This block does not support tunability in generated code.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed and unsigned)
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

DCT

Discrete cosine transform (DCT) of input

Library

Transforms

`dspxfm3`

Description

The DCT block computes the unitary discrete cosine transform (DCT) of each channel in the M -by- N input matrix, u .

```
y = dct(u) % Equivalent MATLAB code
```

For all N-D input arrays, the block computes the DCT across the first dimension. The size of the first dimension (frame size), must be a power of two. To work with other frame sizes, use the Pad block to pad or truncate the frame size to a power-of-two length.

When the input to the DCT block is an M -by- N matrix, the block treats each input column as an independent channel containing M consecutive samples. The block outputs an M -by- N matrix whose l th column contains the length- M DCT of the corresponding input column.

$$y(k, l) = w(k) \sum_{m=1}^M u(m, l) \cos \frac{\pi(2m-1)(k-1)}{2M}, \quad k = 1, \dots, M$$

where

$$w(k) = \begin{cases} \frac{1}{\sqrt{M}}, & k = 1 \\ \sqrt{\frac{2}{M}}, & 2 \leq k \leq M \end{cases}$$

The **Sine and cosine computation** parameter determines how the block computes the necessary sine and cosine values. This parameter has two settings, each with its advantages and disadvantages, as described in the following table.

Sine and Cosine Computation Parameter Setting	Sine and Cosine Computation Method	Effect on Block Performance
Table lookup	The block computes and stores the trigonometric values before the simulation starts, and retrieves them during the simulation. When you generate code from the block, the processor running the generated code stores the trigonometric values computed by the block in a speed-optimized table, and retrieves the values during code execution.	The block usually runs much more quickly, but requires extra memory for storing the precomputed trigonometric values.
Trigonometric fcn	The block computes sine and cosine values during the simulation. When you generate code from the block, the processor running the generated code computes the sine and cosine values while the code runs.	The block usually runs more slowly, but does not need extra data memory. For code generation, the block requires a support library to emulate the trigonometric functions, increasing the size of the generated code.

This block supports Simulink virtual buses.

Fixed-Point Data Types

The following diagrams show the data types used within the DCT block for fixed-point signals. You can set the sine table, accumulator, product output, and output data types displayed in the diagrams in the DCT block dialog as discussed in “Parameters” on page 2-339.

Inputs to the DCT block are first cast to the output data type and stored in the output buffer. Each butterfly stage processes signals in the accumulator data type, with the final output of the butterfly being cast back into the output data type.

Butterfly Stage Data Types

Twiddle Multiplication Data Types

The output of the multiplier is in the product output data type when at least one of the inputs to the multiplier is real. When both of the inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”.

Note When the block input is fixed point, all internal data types are signed fixed point.

Parameters

Main Tab

Sine and cosine computation

Sets the block to compute sines and cosines by either looking up sine and cosine values in a speed-optimized table (Table lookup), or by making sine and cosine function calls (Trigonometric fcn). See the table in the “Description” on page 2-337 section.

Data Types Tab

Rounding mode

Select the rounding mode for fixed-point operations. The sine table values do not obey this parameter; they always round to Nearest.

Saturate on integer overflow

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

Note The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numeric results when all these conditions are met:

- **Product output** data type is Inherit: Inherit via internal rule.
- **Accumulator** data type is Inherit: Inherit via internal rule.

With these data type settings, the block operates in full-precision mode.

Sine table

Choose how you specify the word length of the values of the sine table. The fraction length of the sine table values always equals the word length minus one. You can set this parameter to:

- A rule that inherits a data type, for example, Inherit: Same word length as input
- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

The sine table values do not obey the **Rounding mode** and **Saturate on integer overflow** parameters; instead, they are always saturated and rounded to Nearest.

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 2-338 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Accumulator

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-338 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule. For more information on this rule, see “Inherit via Internal Rule”.

- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Output

Specify the output data type. See “Fixed-Point Data Types” on page 2-338 for illustrations depicting the use of the output data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`.

When you select `Inherit: Inherit via internal rule`, the block calculates the output word length and fraction length automatically. The internal rule first calculates an ideal output word length and fraction length using the following equations:

$$WL_{idealoutput} = WL_{input} + \text{floor}(\log_2(DCTlength - 1)) + 1$$

$$FL_{idealoutput} = FL_{input}$$

Using these ideal results, the internal rule then selects word lengths and fraction lengths that are appropriate for your hardware. For more information on this rule, see “Inherit via Internal Rule”.

- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Data Types of Signals” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Output Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Output Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers

DC Blocker

Block DC component

Library: DSP System Toolbox / Signal Operations
 DSP System Toolbox HDL Support / Signal Operations

Description

The DC Blocker block removes the DC component of the input signal. This block supports SIMD code generation. For details, see “Code Generation” on page 2-347.

Ports

Input

Input — Input signal

scalar | vector | matrix

Specify the input signal that contains the DC component as a scalar, vector, or a matrix. When the input is fixed-point, it is signed only.

Data Types: single | double | int8 | int16 | int32 | fixed point

Output

Output — Output signal with no DC component

scalar | vector | matrix

Output signal with the DC component removed. When the output is fixed-point, it is signed only.

The size, data type, and complexity of the output signal are the same as that of the input signal.

Data Types: single | double | int8 | int16 | int32 | fixed point

Parameters

Algorithm for estimating DC offset — Algorithm for estimating DC offset

IIR (default) | FIR | CIC | Subtract mean

Specify the algorithm used for estimating the DC offset. Select from the following:

- IIR uses a recursive estimate based on a narrow, lowpass elliptic filter. This algorithm typically uses less memory than FIR and is more efficient.
- FIR uses a nonrecursive, moving-average estimate. This algorithm typically uses more memory than IIR and is less efficient.

- CIC uses a lowpass filter that does not employ any multipliers. If the algorithm is CIC, then fixed-point data must be input to the DC Blocker.
- `Subtract mean` computes the means of the columns of the input matrix and subtracts the means from the input. This method does not retain state between inputs. For example, if the input is $\begin{bmatrix} 1 & 2 & 3 & 4 \\ 3 & 4 & 5 & 6 \end{bmatrix}$, then the DC Blocker block in `Subtract mean` mode outputs $\begin{bmatrix} -1 & -1 & -1 \\ -1 & 1 & 1 & 1 \end{bmatrix}$.

Normalized bandwidth of lowpass IIR or CIC filter — Normalized bandwidth

0.001 (default) | real scalar in the range (0 1)

Specify the normalized filter bandwidth as a real scalar greater than 0 and less than 1.

Dependencies

The DC Blocker uses this parameter only when the estimation algorithm is set to IIR or CIC.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Order of lowpass IIR elliptic filter — Order of lowpass IIR elliptic filter

6 (default) | integer greater than 3

Specify the filter order of the lowpass IIR elliptic filter as an integer greater than 3.

Dependencies

The DC Blocker uses this parameter only when the estimation algorithm is set to IIR.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Number of past input samples for FIR algorithm — Number of past input samples for FIR algorithm

50 (default) | positive integer

Specify, as a positive integer, the number of samples to use when the estimation algorithm is set to FIR.

Dependencies

The DC Blocker uses this parameter only when the estimation algorithm is set to FIR.

Data Types: `single` | `double`

View Filter Response — Visualize frequency response

button

Opens the `fvtool` and displays the magnitude response of the DC Blocker. The response is based on the block parameters. Changes made to these parameters update `fvtool`.

To update the magnitude response while `fvtool` is running, modify the block parameters and click **Apply**.

Simulate using — Type of simulation to run

Code generation (default) | Interpreted execution

Specify the type of simulation to run as one of the following:

- **Code generation** -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than **Interpreted execution**.
- **Interpreted execution** -- Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than **Code generation**.

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	yes ^a
Zero-Crossing Detection	no

^a

Algorithms

The DC blocker subtracts the DC component from the input signal. You can estimate the DC component by using the IIR, FIR, CIC, or subtract mean algorithm.

IIR

Pass the input signal through an IIR lowpass elliptical filter.

The elliptical IIR filter has a passband ripple of 0.1 dB and a stopband attenuation of 60 dB. You specify the normalized bandwidth and the filter order.

FIR

Pass the input signal through an FIR filter that uses a nonrecursive moving average from a finite number of past input samples.

The FIR filter coefficients are given as $\text{ones}(1, \text{Length})/\text{Length}$, where Length is the number of past input samples for FIR algorithm. The FIR filter structure is a direct form I transposed structure.

CIC

Pass the input signal through a CIC filter. Because the CIC filter amplifies the signal, the filter gain is estimated and subtracted from the DC estimate.

The Cascaded Integrator-Comb (CIC) filter consists of two integrator-comb pairs. These pairs help to ensure that the peak of the first sidelobe of the filter response is attenuated by at least 25 dB relative to the peak of the main lobe. The normalized 3 dB bandwidth is used to calculate the differential delay. The delay is used to determine the gain of the CIC filter. The inverse of the filter gain is used as a multiplier, which is applied to the output of the CIC filter. This ensures that the aggregate gain of the DC estimate is 0 dB.

The following equation characterizes the aggregate magnitude response of the filter and the multiplier:

$$|H(e^{j\omega})| = \left| \frac{\sin(M\frac{\pi}{2}B_{norm})}{M\sin(\frac{\pi}{2}B_{norm})} \right|^N$$

- B_{norm} is the normalized bandwidth such that $0 < B_{norm} < 1$.
- M is the differential delay in samples.
- N is the number of sections, equal to 2.

Set the differential delay, M , to the smallest integer such that $|H(e^{j\omega})| < 1/\sqrt{2}$. Once M is known, the gain of the CIC filter is calculated as M^N . Therefore, to precisely compensate for the filter gain, the multiplier is set to $(1/M)^N$.

Subtract mean

Compute the mean value of each column of the input signal and subtract the mean from the input. For example, if the input is [1 2 3 4; 3 4 5 6], then a DC Blocker set to this mode outputs [-1 -1 -1 -1; 1 1 1 1].

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The DC Blocker block supports SIMD code generation using Intel AVX2 technology when the input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has one default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see "ConstrainedOutputPipeline" (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "InputPipeline" (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "OutputPipeline" (HDL Coder).

Complex Data Support

This block supports code generation for complex signals.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

If the input is fixed point, it must be a signed integer or signed fixed point with a power-of-two slope and zero bias.

Delay

Delay discrete-time input by specified number of samples or frames

Compatibility

Note The Delay block from the `dspsigops` library has been replaced by the Delay block from the Discrete library in Simulink. Existing instances of the `dspsigops` Delay block will be replaced with Simulink Delay block when there is an exact match in functionality between the two blocks. For new models, use the Delay block from the Discrete library in Simulink.

Library

Signal Operations

`dspsigops`

Description

The Delay block delays a discrete-time input by the number of samples or frames specified in the **Delay units** and **Delay** parameters. The **Delay** value must be an integer value greater than or equal to zero. When you enter a value of zero for the **Delay** parameter, any initial conditions you might have entered have no effect on the output.

The Delay block allows you to set the initial conditions of the signal that is being delayed. The initial conditions must be numeric.

Frame-Based Processing

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block treats each column of the M -by- N input matrix as an independent channel. The block delays each channel of the input as specified by the **Delay** parameter.

The **Delay** parameter can be a scalar integer by which the block equally delays all channels or a vector whose length is equal to the number of channels.

There are four different choices for initial conditions. The initial conditions can be the same or different for each channel. They can also be constant or varying along each channel. See the “Frame-Based Processing Examples” on page 2-351 section for more information.

Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats each element of the N -D input array as an independent channel. Thus, the total number

of channels in the input is equal to the product of the input dimensions. The dimension of the output is the same as that of the input.

The **Delay** parameter can be a scalar integer by which to equally delay all channels or an N-D array of the same dimensions as the input array, containing nonnegative integers that specify the number of sample intervals to delay each channel of the input.

There are four different choices for initial conditions. The initial conditions can be the same or different for each channel. They can also be the same or different within a channel. See the “Sample-Based Processing Examples” on page 2-354 section for more information.

Resetting the Delay

The Delay block resets the delay whenever it detects a reset event at the optional Rst port. The reset sample time must be a positive integer multiple of the input sample time.

The reset event is specified by the **Reset port** parameter, and can be one of the following:

- None disables the Rst port.
- Rising edge triggers a reset operation when the Rst input does one of the following:
 - Rises from a negative value to a positive value or zero
 - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)

- Falling edge triggers a reset operation when the Rst input does one of the following:
 - Falls from a positive value to a negative value or zero
 - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)

- Either edge triggers a reset operation when the Rst input is Rising edge or Falling edge (as described earlier).
- Non-zero sample triggers a reset operation at each sample time that the Rst input is not zero.

Note When running simulations in the Simulink MultiTasking mode, reset signals have a one-sample latency. Therefore, when the block detects a reset event, there is a one-sample delay at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

This block supports Simulink virtual buses.

Examples

Frame-Based Processing Examples

There are four different choices for initial conditions. The initial conditions can be the same or different for each channel. They can also be constant or varying along each channel. The next sections describe the behavior of the block for each of these four cases:

- “Case 1 — Use the Same Initial Conditions for Each Channel and Within a Channel” on page 2-351
- “Case 2 — Use Different Initial Conditions for Each Channel and the Same Initial Conditions Within a Channel” on page 2-352
- “Case 3 — Use the Same Initial Conditions for Each Channel and Different Initial Conditions Within a Channel” on page 2-352
- “Case 4 — Use Different Initial Conditions for Each Channel and Within a Channel” on page 2-353

Case 1 — Use the Same Initial Conditions for Each Channel and Within a Channel

Enter a scalar value for the initial conditions. This value is used as the constant initial condition value for each of the channels.

For example, suppose your input is a matrix and you set the **Input processing** parameter to Columns as channels (frame based).

$$\begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 & 4 \\ 5 & 5 & 5 \\ 6 & 6 & 6 \end{bmatrix}, \begin{bmatrix} 7 & 7 & 7 \\ 8 & 8 & 8 \\ 9 & 9 & 9 \end{bmatrix}, \dots$$

You want the initial conditions of your three-channel signal to be identical and zero for the first frame:

- 1 Set the **Delay (frames)** parameter to 1.
- 2 Clear the **Specify different initial conditions for each channel** and the **Specify different initial conditions within a channel** check boxes.
- 3 Set the **Initial conditions** parameter to a scalar value of 0.

The output of the delay block is

$$\begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 & 4 \\ 5 & 5 & 5 \\ 6 & 6 & 6 \end{bmatrix}, \begin{bmatrix} 7 & 7 & 7 \\ 8 & 8 & 8 \\ 9 & 9 & 9 \end{bmatrix}, \dots$$

0, the scalar initial condition value, is used across the channels and within the channels for the first frame. This frame is the output at sample time zero.

Case 2 — Use Different Initial Conditions for Each Channel and the Same Initial Conditions Within a Channel

The initial conditions must be a vector of length N , where $N \geq 1$. N is also equal to the number of channels in your signal. These initial condition values are used as the constant initial condition value for each of the channels.

For example, suppose your input is a matrix and you set the **Input processing** parameter to Columns as channels (frame based).

$$\begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 & 4 \\ 5 & 5 & 5 \\ 6 & 6 & 6 \end{bmatrix}, \begin{bmatrix} 7 & 7 & 7 \\ 8 & 8 & 8 \\ 9 & 9 & 9 \end{bmatrix}, \dots$$

You want the initial conditions of your three-channel signal to be [0 10 20] for the first frame:

- 1 Set the **Delay (frames)** parameter to 1.
- 2 Select the **Specify different initial conditions for each channel** check box.
- 3 Clear the **Specify different initial conditions within a channel** check box.
- 4 Set the **Initial conditions** parameter to [0 10 20].

The output of the delay block is

$$\begin{bmatrix} 0 & 10 & 20 \\ 0 & 10 & 20 \\ 0 & 10 & 20 \end{bmatrix}, \begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 & 4 \\ 5 & 5 & 5 \\ 6 & 6 & 6 \end{bmatrix}, \begin{bmatrix} 7 & 7 & 7 \\ 8 & 8 & 8 \\ 9 & 9 & 9 \end{bmatrix}, \dots$$

The initial condition vector expands to create the frame that is output at sample time zero. Different initial conditions are used for each channel, but the same initial condition value is used with a channel.

Case 3 — Use the Same Initial Conditions for Each Channel and Different Initial Conditions Within a Channel

In this case, the **Delay** parameter can be a scalar integer by which to equally delay all channels or a vector whose length is equal to the number of channels. All the values of this vector must be equal.

Enter the initial conditions as a vector. These values are used as the initial condition value along each of the channels to be delayed. The initial condition vector must have length equal to the value of the **Delay (frames)** parameter multiplied by the frame length. For example, if you want to delay your signal by two frames with frame length two and an initial condition value of 3, enter your initial condition vector as [3 3 3 3].

For example, suppose your input is a matrix and you set the **Input processing** parameter to Columns as channels (frame based).

$$\begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 & 4 \\ 5 & 5 & 5 \\ 6 & 6 & 6 \end{bmatrix}, \begin{bmatrix} 7 & 7 & 7 \\ 8 & 8 & 8 \\ 9 & 9 & 9 \end{bmatrix}, \dots$$

You want the initial conditions of your three-channel signal to be the same along each of the channels to be delayed:

- 1 Set the **Delay (frame)** parameter to 1.
- 2 Clear the **Specify different initial conditions for each channel** check box.
- 3 Select the **Specify different initial conditions within a channel** check box.
- 4 Set the **Initial conditions** parameter to [10 20 30].

The output of the delay block is

$$\begin{bmatrix} 10 & 10 & 10 \\ 20 & 20 & 20 \\ 30 & 30 & 30 \end{bmatrix}, \begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 & 4 \\ 5 & 5 & 5 \\ 6 & 6 & 6 \end{bmatrix}, \begin{bmatrix} 7 & 7 & 7 \\ 8 & 8 & 8 \\ 9 & 9 & 9 \end{bmatrix}, \dots$$

The initial condition vector defines the initial condition values within each of the three channels. The same initial conditions are used for each channel, but different initial condition values are used with a channel.

Case 4 – Use Different Initial Conditions for Each Channel and Within a Channel

Enter a cell array for your initial condition values. Or, when you have a scalar delay value, you can enter the initial conditions as a matrix.

For example, suppose your input is a matrix and you set the **Input processing** parameter to Columns as channels (frame based).

$$\begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 & 4 \\ 5 & 5 & 5 \\ 6 & 6 & 6 \end{bmatrix}, \begin{bmatrix} 7 & 7 & 7 \\ 8 & 8 & 8 \\ 9 & 9 & 9 \end{bmatrix}, \dots$$

You want the initial conditions of your three-channel signal to be different for each channel and along each channel.

- 1 Set the **Delay (frames)** parameter to 1.
- 2 Select the **Specify different initial conditions for each channel** and the **Specify different initial conditions within a channel** check boxes.
- 3 Set the **Initial conditions** parameter to either [10 20 30; 40 50 60; 70 80 90] or {[10 40 70]; [20 50 80]; [30 60 90]}. Each cell of the cell array represents the delay along one channel.

Regardless of whether you use a matrix or cell array, the output of the delay block is

$$\begin{bmatrix} 10 & 20 & 30 \\ 40 & 50 & 60 \\ 70 & 80 & 90 \end{bmatrix}, \begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 & 4 \\ 5 & 5 & 5 \\ 6 & 6 & 6 \end{bmatrix}, \begin{bmatrix} 7 & 7 & 7 \\ 8 & 8 & 8 \\ 9 & 9 & 9 \end{bmatrix} \dots$$

The initial condition matrix is the output at sample time zero. The elements of the initial condition cell array define the initial condition values within each channel. The first element, a

vector, represents the initial conditions within channel 1. The second element, a vector, represents the initial conditions within channel 2, and so on. Different initial conditions are used for each channel and within the channels.

Sample-Based Processing Examples

There are four different choices for initial conditions. The initial conditions can be the same or different for each channel. They can also be the same or different along each channel. The next sections describe the behavior of the block for each of these four cases:

- “Case 1 — Use the Same Initial Conditions for Each Channel and Within a Channel” on page 2-354
- “Case 2 — Use Different Initial Conditions for Each Channel and the Same Initial Conditions Within a Channel” on page 2-354
- “Case 3 — Use the Same Initial Conditions for Each Channel and Different Initial Conditions Within a Channel” on page 2-355
- “Case 4 — Use Different Initial Conditions for Each Channel and Within a Channel” on page 2-356

Case 1 — Use the Same Initial Conditions for Each Channel and Within a Channel

Enter a scalar value for the initial conditions. This value is used as the constant initial condition value for each of the channels.

For example, suppose your input is a matrix and you set the **Input processing** parameter to `Elements as channels (sample based)`.

$$\begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}, \begin{bmatrix} 2 & 2 \\ 2 & 2 \end{bmatrix}, \begin{bmatrix} 3 & 3 \\ 3 & 3 \end{bmatrix}, \dots$$

You want the initial conditions of your four-channel signal to be identical and zero for the first two samples:

- 1 Set the **Delay (samples)** parameter to 2.
- 2 Clear the **Specify different initial conditions for each channel** and **Specify different initial conditions within a channel** check boxes.
- 3 Set the **Initial conditions** parameter to a scalar value of 0.

The output of the delay block is

$$\begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}, \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}, \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}, \begin{bmatrix} 2 & 2 \\ 2 & 2 \end{bmatrix}, \begin{bmatrix} 3 & 3 \\ 3 & 3 \end{bmatrix}, \dots$$

0, the scalar initial condition value, is used for each channel and within the channels. It is the output at sample time zero and sample time one.

Case 2 — Use Different Initial Conditions for Each Channel and the Same Initial Conditions Within a Channel

The initial conditions must be an N-D array for N-D input. The initial conditions must have the same dimensions as the input data. These initial condition values are used as the constant initial condition value for each of the channels.

For example, suppose your input is a matrix and you set the **Input processing** parameter to `Elements as channels (sample based)`.

$$\begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}, \begin{bmatrix} 2 & 2 \\ 2 & 2 \end{bmatrix}, \begin{bmatrix} 3 & 3 \\ 3 & 3 \end{bmatrix}, \dots$$

You want the initial conditions of your four-channel signal to be

$$\begin{bmatrix} 7 & 9 \\ 11 & 13 \end{bmatrix}$$

for the first two samples:

- 1 Set the **Delay (samples)** parameter to 2.
- 2 Select the **Specify different initial conditions for each channel** check box.
- 3 Clear the **Specify different initial conditions within a channel** check box.
- 4 Set the **Initial conditions** parameter to [7 9; 11 13].

The output of the delay block is

$$\begin{bmatrix} 7 & 9 \\ 11 & 13 \end{bmatrix}, \begin{bmatrix} 7 & 9 \\ 11 & 13 \end{bmatrix}, \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}, \begin{bmatrix} 2 & 2 \\ 2 & 2 \end{bmatrix}, \begin{bmatrix} 3 & 3 \\ 3 & 3 \end{bmatrix}, \dots$$

The initial condition matrix is the output at sample time zero and sample time one. Different initial conditions are used for each channel; the same initial condition value is used within a channel.

Case 3 — Use the Same Initial Conditions for Each Channel and Different Initial Conditions Within a Channel

In this case, for N-D sample-based inputs, the initial conditions parameter must be a vector whose length is equal to the delay value, specified by the **Delay** parameter. The values in this vector are used as the initial condition values along each of the channels to be delayed.

For example, suppose your input is a matrix and you set the **Input processing** parameter to **Elements as channels (sample based)**.

$$\begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}, \begin{bmatrix} 2 & 2 \\ 2 & 2 \end{bmatrix}, \begin{bmatrix} 3 & 3 \\ 3 & 3 \end{bmatrix}, \dots$$

You want the initial conditions of your four channel signal to be the same along each of the channels to be delayed:

- 1 Set the **Delay (samples)** parameter to 2.
- 2 Clear the **Specify different initial conditions for each channel** check box.
- 3 Select the **Specify different initial conditions within a channel** check box.
- 4 Set the **Initial conditions** parameter to [10 20].

The output of the delay block is

$$\begin{bmatrix} 10 & 10 \\ 10 & 10 \end{bmatrix}, \begin{bmatrix} 20 & 20 \\ 20 & 20 \end{bmatrix}, \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}, \begin{bmatrix} 2 & 2 \\ 2 & 2 \end{bmatrix}, \begin{bmatrix} 3 & 3 \\ 3 & 3 \end{bmatrix}, \dots$$

The first element of the initial conditions vector is the output, for all channels, at sample time zero. The second element of the initial conditions vector is the output, for all channels, at sample

time one. The same initial conditions are used for each channel, but different initial condition values are used within a channel.

Case 4 — Use Different Initial Conditions for Each Channel and Within a Channel

Enter a cell array for your initial condition values. The cell array must be the same size as your input signal. Each cell of the cell array represents the delay values for one channel, and must be a vector of size equal to the delay value. If you have a vector or scalar input and a scalar delay value, you can enter the initial conditions as a matrix.

For example, suppose your input is a matrix and you set the **Input processing** parameter to **Elements as channels (sample based)**.

$$[1 \ 1], [2 \ 2], [3 \ 3], \dots$$

You want the initial conditions of your two channel signal to be different for each channel and along each channel:

- 1 Set the **Delay (samples)** parameter to 2.
- 2 Select the **Specify different initial conditions for each channel** and **Specify different initial conditions within a channel** check boxes.
- 3 Set the **Initial conditions** parameter to `[10 20; 30 40]`.

The output of the delay block is

$$[10 \ 20], [30 \ 40], [1 \ 1], [2 \ 2] \dots$$

The first row of the initial conditions vector is the output at sample time zero. The second row of the initial conditions vector is the output at sample time one. Different initial conditions are used for each channel and within the channels.

In addition, suppose your input is a matrix and you set the **Input processing** parameter to **Elements as channels (sample based)**.

$$\begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}, \begin{bmatrix} 2 & 2 \\ 2 & 2 \end{bmatrix}, \begin{bmatrix} 3 & 3 \\ 3 & 3 \end{bmatrix}, \dots$$

You want the initial conditions of your two-channel signal to be different for each channel and along each channel:

- 1 Set the **Delay (samples)** parameter to 2.
- 2 Select the **Specify different initial conditions for each channel** and the **Specify different initial conditions within a channel** check boxes.
- 3 Set the **Initial conditions** parameter to `{[11 15] [12 16]; [13 17] [14 18]}`. The dimensions of the cell array match the dimensions of the input. Also, each element of the cell array represents the initial conditions within one channel.

The output of the delay block is

$$\begin{bmatrix} 11 & 12 \\ 13 & 14 \end{bmatrix}, \begin{bmatrix} 15 & 16 \\ 17 & 18 \end{bmatrix}, \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}, \begin{bmatrix} 2 & 2 \\ 2 & 2 \end{bmatrix}, \dots$$

Each element of the cell array represents the initial conditions within a channel. The first element, a vector, represents the initial conditions within channel 1. The second element, a

vector, represents the initial conditions within channel 2, and so on. Different initial conditions are used for each channel and within the channels.

Parameters

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

Note The option **Inherit from input** (this choice will be removed - see release notes) will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

Delay units

Select whether you want to delay your input by a specified number of **Samples** or **Frames**. This parameter appears only when you set the **Input processing** parameter to **Columns as channels (frame based)**.

Delay (samples) or Delay (frames)

See “Sample-Based Processing” on page 2-349 and “Frame-Based Processing” on page 2-349 for a description of what format to use for each configuration of the block dialog.

Specify different initial conditions for each channel

Select this check box when you want the initial conditions to vary across the channels. When you do not select this check box, the initial conditions are the same across the channels.

Specify different initial conditions within a channel

Select this check box when you want the initial conditions to vary within the channels. When you do not select this check box, the initial conditions are the same within the channels.

Initial conditions

Enter a scalar, vector, matrix, or cell array of initial condition values, depending on your choice for the **Specify different initial conditions for each channel** and **Specify different initial conditions within a channel** check boxes. See “Sample-Based Processing” on page 2-349 and “Frame-Based Processing” on page 2-349 for a description of what format to use for each configuration of the block dialog.

Reset port

Determines the reset event that causes the block to reset the delay. For more information, see “Resetting the Delay” on page 2-350.

Supported Data Types

- Double-precision floating point
- Single-precision floating point

- Fixed point (signed and unsigned)
- Boolean
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

Delay Line

Rebuffer sequence of inputs

Library

Signal Management / Buffers

dspbuff3

Description

The Delay Line block rebuffers a sequence of M_i -by- N matrix inputs into a sequence of M_o -by- N matrix outputs, where M_o is the output frame size you specify in the **Delay line size** parameter. Depending on whether M_o is greater than, less than, or equal to the input frame size, M_i , the output frames can be underlapped or overlapped. The block always performs frame-based processing and rebuffers each of the N input channels independently.

When $M_o > M_i$, the output frame overlap is the difference between the output and input frame size, $M_o - M_i$. When $M_o < M_i$, the output is underlapped; the Delay Line block discards the first $M_i - M_o$ samples of each input frame so that only the last M_o samples are buffered into the corresponding output frame. When $M_o = M_i$, the output data is identical to the input data, but is delayed by the latency of the block. Due to the block's latency, the outputs are always delayed by one frame, the entries of which you specify in the **Initial conditions** parameter (see "Initial Conditions" on page 2-359).

The output frame period is equal to the input frame period ($T_{fo} = T_{fi}$). The output sample period, T_{so} , is therefore equal to T_{fi}/M_o , or equivalently, $T_{si}(M_i/M_o)$

In the most typical use, each output differs from the preceding output by only one sample, as illustrated below for scalar input.

Note that the first output of the block in the example above is all zeros; this is because the **Initial Conditions** parameter is set to zero.

Initial Conditions

The Delay Line block's buffer is initialized to the value specified by the **Initial conditions** parameter. The block outputs this buffer at the first simulation step ($t=0$). When the block's output is a vector, the **Initial conditions** can be a vector of the same size, or a scalar value to be repeated across all

elements of the initial output. When the block's output is a matrix, the **Initial conditions** can be a matrix of the same size, a vector (of length equal to the number of matrix rows) to be repeated across all columns of the initial output, or a scalar to be repeated across all elements of the initial output.

Examples

In the following `ex_delayline_ref2` model, the block rebuffers a two-channel input with a **Delay line size** of 3.

The first output frame in this example is due to the latency of the Delay Line block; it is all zeros because the **Initial conditions** parameter is set to zero. Because the input frame size of 4 is larger than the output frame size of 3, only the last three samples in each input frame are propagated to the corresponding output frame. The frame periods of the input and output are the same, and the output sample period is $T_{si}(M_i/M_o)$, or $4/3$ the input sample period.

Parameters

Delay line size

Specify the number of rows in output matrix, M_o .

Initial conditions

Specify the value of the block's initial output. When the block outputs a vector, the **Initial conditions** can be a vector of the same size, or a scalar value to be repeated across all elements of the initial output. When the block outputs a matrix, the **Initial conditions** can be a matrix of the same size, a vector (of length equal to the number of matrix rows) to be repeated across all columns of the initial output, or a scalar to be repeated across all elements of the initial output.

Allow direct feedthrough

When you select this check box, the input data is not delayed by an extra frame before it is available at the output buffer. Instead, the input data is available immediately at the output port of the block.

Show En_Out port for selectively enabling output

When you select this check box, the `En_Out` port appears on the block icon. This block uses a circular buffer internally even though the output is linear. This means that for valid output, data from the circular buffer has to be linearized. The `En_Out` port determines whether or not a valid output needs to be computed based on the value of its Boolean input. If the input value to the `En_Out` port is 1, the block output is linearized, and thus is valid. Otherwise, the output is not

linearized, and is invalid. This allows the block to be more efficient when the tapped Delay Line's output is not required at each sample time.

Note that when the input value to the En_Out port is 0, the block can give different results depending on the state of the model. The results can appear to match valid results or can be invalid, and they cannot be predicted. You should ignore the block output in all cases when the input to the En_Out port is 0.

Hold previous value when the output is disabled

This parameter only appears and applies when the **Show En_Out port for selectively enabling output** parameter is selected. Use this parameter to specify the block output at those time steps when the internal state buffer is not being linearized to output valid data.

When you do not select this check box, the block memory is free to be used by other parts of the model, and the signal on the output port is invalid. When you select this check box, the most recent valid value is held on the output port, and slightly more memory is used by the block.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Detrend

Remove linear trend from vectors

Library

Statistics

dspstat3

Description

The Detrend block removes a linear trend from the length- M input vector, u , by subtracting the straight line that best fits the data in the least squares sense.

The least squares line, $\hat{u} = ax + b$, is the line with parameters a and b that minimizes the quantity

$$\sum_{i=1}^M (u_i - \hat{u}_i)^2$$

for M evenly-spaced values of x , where u_i is the i th element in the input vector. The output, $y = u - \hat{u}$, is always an M -by-1 column vector.

Difference

Compute element-to-element difference along specified dimension of input

Library: DSP System Toolbox / Math Functions / Math Operations

Description

The Difference block computes the difference between adjacent elements in rows, columns, or a specified dimension of the input array u . You can configure the block to compute the difference only within the current input, or across consecutive inputs (running difference).

Ports

Input

Port_1 — Input signal

vector | matrix | N -D array

Input signal, specified as a vector, matrix, or an N -D array.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

Complex Number Support: Yes

Output

Port_1 — Output signal

vector | matrix | N -D array

The difference between adjacent rows, columns, or a specified dimension of the input, returned as a vector, matrix, or an N -D array.

The output is the same data type and complexity as the input, but the dimension that the difference was calculated on is one less. The length of the other dimensions is unchanged.

For more details on how the output is computed, see the “Difference along” on page 2-0 parameter.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

Complex Number Support: Yes

Parameters

Main Tab

Running difference — Running difference

No (default) | Yes

Specify whether the block computes a running difference.

- **No** -- The block computes the difference between adjacent elements in the specified dimension of the current input. In this mode, the block can compute the difference along the columns, rows, or a specified dimension of the input depending on the “Difference along” on page 2-0 parameter.
- **Yes** -- The block computes the running difference along the columns of the input. See “Running Operation” on page 2-369 for more information.

Difference along – Difference dimension

Columns (default) | Rows | Specified dimension

Specify whether the block computes the difference along the columns, rows, or a specified dimension of the input.

- **Columns** -- The block computes differences between adjacent elements in each column of the input. Equivalent MATLAB code is given by:

```
y = diff(u)
```

For M -by- N inputs, the output is an $(M - 1)$ -by- N matrix whose j th column has these elements:

$$y_{i,j} = u_{i+1,j} - u_{i,j} \quad 1 \leq i \leq (M - 1)$$

- **Rows** -- The block computes differences between adjacent elements in each row of the input. Equivalent MATLAB code is given by:

```
y = diff(u, [], 2)
```

The output is an M -by- $(N-1)$ matrix whose i th row has the following elements:

$$y_{i,j} = u_{i,j+1} - u_{i,j} \quad 1 \leq j \leq (N - 1)$$

- **Specified dimension** -- The behavior of the block is an extension of the row-wise differencing described earlier. The block computes differences between adjacent elements along the dimension you specify in the **Dimension** parameter. Equivalent MATLAB code is given by:

```
y = diff(u, [], d)
```

where d is the dimension.

The output is an array whose length in the specified dimension is one less than that of the input, and whose lengths in other dimensions are unchanged. For example, consider an M -by- N -by- P -by- R input array with elements $u(i,j,k,l)$ and assume that the value of the **Dimension** parameter is 3. The output of the block is an M -by- N -by- $(P-1)$ -by- R array with the following elements:

$$y_{i,j,k,l} = u_{i,j,k+1,l} - u_{i,j,k,l} \quad 1 \leq k \leq (P - 1)$$

Dimension – One-based dimension

1 (default) | 2 | 3

Specify the one-based dimension along which to compute element-to-element differences.

Dependencies

To enable this parameter, select **Specified dimension** for the **Difference along** parameter.

Data Types Tab

Rounding mode — Method of rounding operation

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see Rounding Modes.

Saturate on integer overflow — Method of overflow action

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see overflow mode for fixed-point operations.

Accumulator — Accumulator data type

Inherit: `Inherit via internal rule` (default) | `Inherit: Same as input` | `fixdt([],16,0)`

Accumulator specifies the data type of the output of an accumulation operation in the Difference block.

- `Inherit: Inherit via internal rule` — The block inherits the accumulator data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- `Inherit: Same as input` — The block specifies the accumulator data type to be the same as the input data type.
- `fixdt([],16,0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink).

For illustrations on how to use the accumulator data type in this block, see Fixed-Point Conversion in “Extended Capabilities” on page 2-0 .

Output — Output data type

Inherit: Same as accumulator (default) | Inherit: Same as input | fixdt([],16,0)

Output specifies the data type of the output of the Difference block.

- **Inherit: Same as input** — The block specifies the output data type to be the same as the input data type.
- **Inherit: Same as accumulator** — The block specifies the output data type to be the same as the accumulator data type.
- **fixdt([],16,0)** — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information, see “Control Data Types of Signals” (Simulink).

For more information on the output data type, see Fixed-Point Conversion in “Extended Capabilities” on page 2-0 .

Output Minimum — Minimum value that block can output

[] (default) | scalar

Specify the minimum value the block can output. Simulink uses this minimum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

Output Maximum — Maximum value that block can output

[] (default) | scalar

Specify the maximum value the block can output. Simulink uses this maximum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

Note Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

More About

Running Operation

When you set the **Running difference** parameter to Yes, the block computes the running difference along the columns of the input.

For an M -by- N input matrix, the output is an M -by- N matrix whose j th column has the following elements:

$$y_{i,j} = u_{i+1,j} - u_{i,j} \quad 2 \leq i \leq (M - 1)$$

In the **Running difference** mode, the first element of the output for each column is the first input element minus the last input element of the previous frame. For the first frame, the block subtracts zero from the first input element.

$$y_{1,j}(t) = u_{1,j}(t) - u_{M,j}(t - T_f)$$

Differentiator Filter

Direct form FIR fullband differentiator filter

Library

Filtering / Filter Designs

dspfdesign

Description

The Differentiator Filter block applies a fullband differentiator filter on the input signal to differentiate all its frequency components. The block uses an FIR equiripple filter design to design the differentiator filter. The ideal frequency response of the differentiator is $D(\omega) = j\omega$ for $-\pi \leq \omega \leq \pi$.

You can design the filter with minimum order or with a specifies order.

The input signal can be a real- or complex-valued column vector or matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel.

This block supports variable-size input, enabling you to change the channel length during simulation. The output port properties, such as data type, complexity, and dimension, are identical to the input port properties. The block supports fixed-point operations.

This block also supports SIMD code generation. For details, see “Code Generation” on page 2-376.

Examples

- “Group Delay Estimation in Simulink”

Dialog Box

Main Tab

Design minimum order filter

When you select this check box, the block designs a filter with the minimum order, with the passband ripple specified in **Maximum passband ripple (dB)**. When you clear this check box, specify the order of the filter in **Filter order**.

By default, this check box is selected.

Filter order

Filter order of the differentiator filter, specified as an odd positive scalar integer. You can specify the filter order only when **Design minimum order filter** check box is not selected. The default is 31.

Maximum passband ripple (dB)

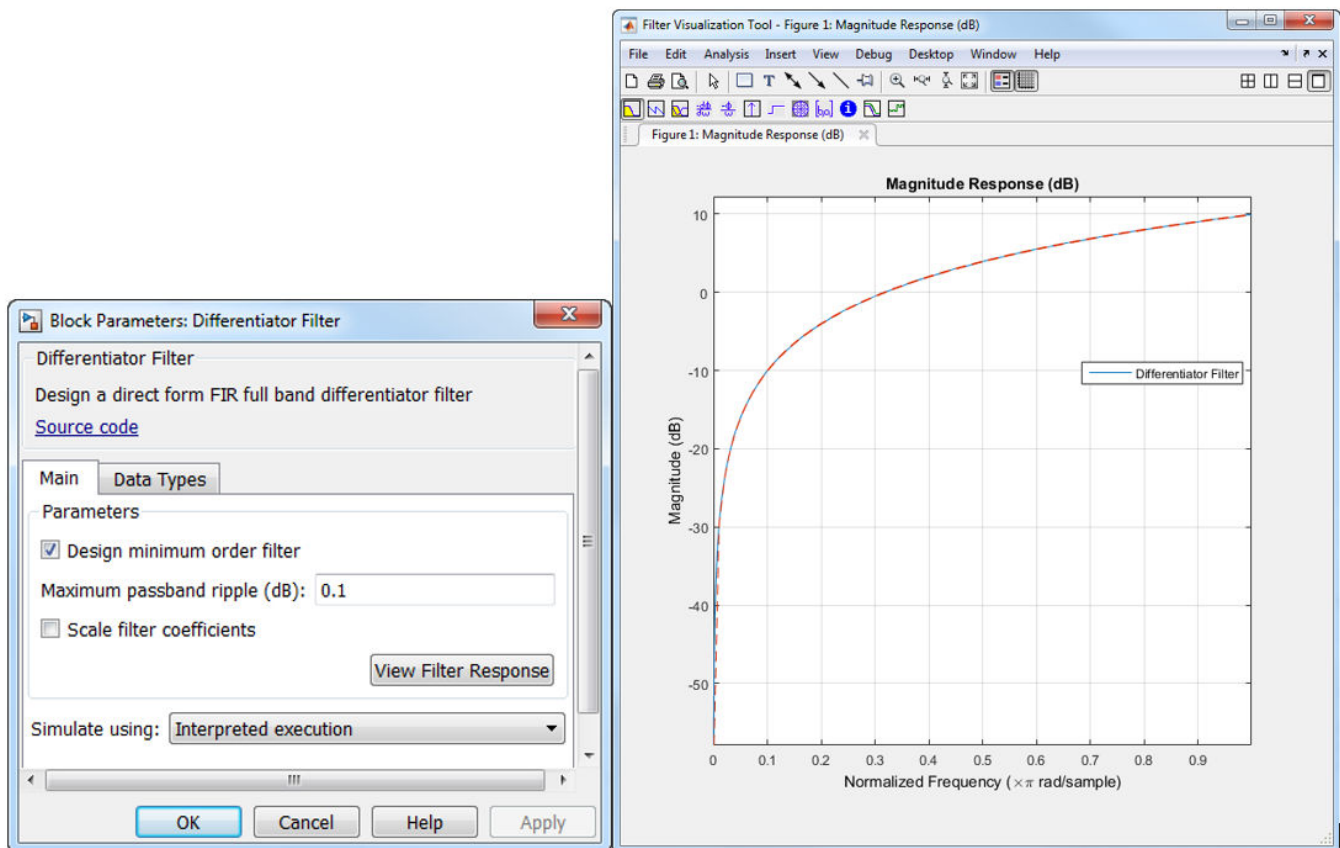

Maximum ripple of the filter response in the passband, specified as a real positive scalar in dB. The default is 0.1.

Scale filter coefficients

When you select this check box, the filter coefficients are scaled to preserve the input dynamic range. By default, this check box is not selected.

View Filter Response

Opens the Filter Visualization Tool (fvtool) and displays the magnitude and phase response of the Differentiator Filter block. The response is based on the block dialog box parameters. Changes made to these parameters update FVTool.

To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

Simulate using

Type of simulation to run. You can set this parameter to:

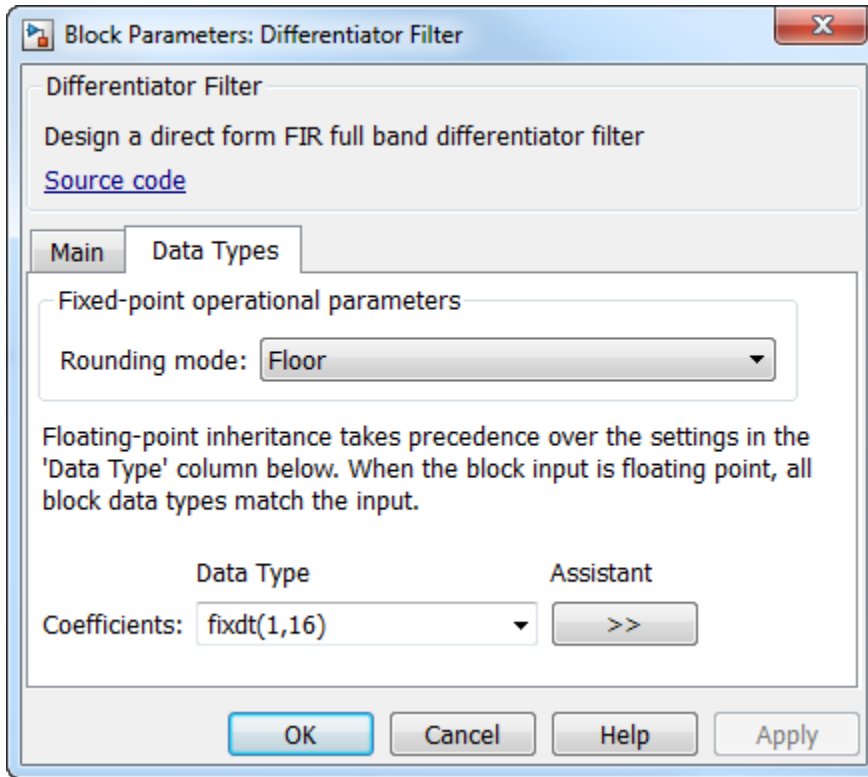

- Interpreted execution (default)

Simulate model using the MATLAB interpreter. This option shortens startup time and has faster simulation speed than Code generation.

- Code generation

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster subsequent simulations.

Data Types Tab

Rounding mode

Rounding method for the output fixed-point operations. The rounding methods are Ceiling, Convergent, Floor, Nearest, Round, Simplest, and Zero. The default is Floor.

Coefficients

Fixed-point data type of the coefficients, specified as one of the following:

- `fixdt(1,16)` (default) — Signed fixed-point data type of word length 16, with binary point scaling. The block determines the fraction length automatically from the coefficient values such that the coefficients occupy the maximum representable range without overflowing.
- `fixdt(1,16,0)` — Signed fixed-point data type of word length 16 and fraction length 0. You can change the fraction length to any other integer value.
- `<data type expression>` — Specify the data type using an expression that evaluates to a data type object, for example, numeric type (`fixdt([],16,15)`). Specify the sign mode of this data type as `[]` or `true`.
- Refresh Data Type — Refresh to the default data type.

Click the **Show data type assistant** button  to display the data type assistant, which helps you set the stage input parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

The word length of the output is same as the word length of the input. The fraction length of the output is computed such that the entire dynamic range of the output can be represented without

overflow. For details on how the block computes the fraction length, see “Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters”.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed or unsigned)
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed or unsigned)

Algorithms

Differentiator Filter

Differentiator computes the derivative of a signal. The frequency response of an ideal differentiator filter is given by $D(\omega) = j\omega$, defined over the Nyquist interval $-\pi \leq \omega \leq \pi$.

The frequency response is antisymmetric and is linearly proportional to the frequency.

`dsp.Differentiator` object acts as a differentiator filter. This object condenses the two-step process into one. For the minimum order design, the object uses generalized Remez FIR filter design algorithm. For the specified order design, the object uses the Parks-McClellan optimal equiripple FIR filter design algorithm. The filter is designed as a linear phase Type-IV FIR filter with a Direct form structure.

The ideal differentiator has an antisymmetric impulse response given by $d(n) = -d(-n)$. Hence $d(0) = 0$. The differentiator must have zero response at zero frequency.

Linear-Phase FIR Differentiator Filter

The impulse response of an antisymmetric linear-phase FIR filter is given by $h(n) = -h(M - 1 - n)$, where M is the length of the filter. Because the filter is antisymmetric, you can use this type of FIR filter to design the linear-phase FIR differentiators.

Consider the design of linear-phase FIR differentiators based on the Chebyshev approximation criterion.

If M is odd, the real-valued frequency response of the FIR filter, $H_r(\omega)$, has the characteristics that $H_r(0) = 0$ and $H_r(\pi) = 0$. This filter satisfies the condition of zero response at zero frequency. However, it is not fullband because $H_r(\pi) = 0$. This differentiator has a linear response over the limited frequency range $[0, 2\pi f_p]$, where f_p is the bandwidth of the differentiator. The absolute error between the desired response and the Chebyshev approximation increases as ω increases from 0 to $2\pi f_p$.

If M is even, the real-valued frequency response of the FIR filter, $H_r(\omega)$, has the characteristics that $H_r(0) = 0$ and $H_r(\pi) \neq 0$. This filter satisfies the condition of zero response at zero frequency. It is fullband and this design results in a significantly smaller approximation error than comparable odd-length differentiators. Hence, even-length (odd order) differentiators are preferred in practical systems.

Note The Differentiator Filter (Obsolete) block has been replaced by the Differentiator Filter block. Existing instances of the Differentiator Filter (Obsolete) block will continue to operate. For new models, use the Differentiator Filter block.

Library

Filtering / Filter Designs

dspfdesign

Description

This block brings the filter design capabilities of the `filterBuilder` function to the Simulink environment.

Dialog Box

See “Differentiator Filter Design — Main Pane” on page 5-613 for more information about the parameters of this block. The **Data Types** and **Code Generation** panes are not available for blocks in the DSP System Toolbox Filter Designs library.

View filter response

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

Order mode

Select either **Minimum** or **Specify** (the default). Selecting **Specify** enables the **Order** option so you can enter the filter order.

Order

Enter the filter order. This option is enabled only if you set the **Order mode** to **Specify**. The default order is 31.

Filter type

Select **Single-rate**, **Decimator**, **Interpolator**, or **Sample-rate converter**. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, the block specifies a single-rate filter.

- Selecting **Decimator** or **Interpolator** activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting **Sample-rate converter** activates both factors.

Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to **Decimator** or **Sample-rate converter**. The default value is 2.

Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to **Interpolator** or **Sample-rate converter**. The default value is 2.

Frequency Specifications

The parameters in this group allow you to specify your filter response curve.

Frequency constraints

This option is only available when you specify the order of the filter design. Supported options are **Unconstrained** and **Passband edge and stopband edge**.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0–1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—**Hz**, **KHz**, **MHz**, or **GHz**. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Fpass

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Fstop

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Magnitude Specifications

Parameters in this group specify the filter response in the passbands and stopbands. These parameters are only available for minimum-order designs.

Magnitude constraints

This option is only available when you specify the order of your filter design. The available **Magnitude constraints** depend on the value of the **Frequency constraints** parameter. When you set the **Frequency constraints** parameter to Unconstrained, the **Magnitude constraints** parameter must also be Unconstrained. When you set the **Frequency constraints** parameter to Passband edge and stopband edge, the **Magnitude constraints** parameter can be Unconstrained, Passband ripple, or Stopband attenuation.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. From the drop-down list, select one of the following options:

- Linear — Specify the magnitude in linear units.
- dB — Specify the magnitude in decibels (default).
- Squared — Specify the magnitude in squared units.

Apass

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

Astop2

Enter the filter attenuation in the second stopband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure of your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 20 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Wpass

Passband weight. This option is only available for a specified-order design when **Frequency constraints** is equal to Passband edge and stopband edge and the **Design method** is Equiripple.

Wstop

Stopband weight. This option is only available for a specified-order design when **Frequency constraints** is equal to Passband edge and stopband edge and the **Design method** is Equiripple.

Filter Implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of n unit delays with a single delay by n .
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Input processing

Specify how the block should process the input. The available options may vary depending on the settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

Note The Inherited (this choice will be removed – see release notes) option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- **Enforce single-rate processing** — When you select this option, the block maintains the sample rate of the input.
- **Allow multirate processing** — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to **Elements as channels (sample based)**.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

Supported Data Types

Digital Down-Converter

Translate digital signal from Intermediate Frequency (IF) band to baseband and decimate it

Library

Signal Operations

dsp.sigops

Description

The Digital Down-Converter (DDC) block converts a digitized real signal, centered at an intermediate frequency (IF) to a baseband complex signal centered at zero frequency. The DDC block downsamples the frequency down-converted signal using a cascade of three decimation filters. This block designs the decimation filters according to the filter parameters set in the block dialog box.

Structure

This block brings the capabilities of `dsp.DigitalDownConverter` System object to the Simulink environment.

The DDC block consists of a CIC decimator, a CIC compensator, and a FIR decimator. You can bypass the FIR Decimator, depending on how you set the DDC block parameters.

For more information on the structure that the DDC block uses, including the flow of fixed-point input, see the “Creation” on page 4-384 section in `dsp.DigitalDownConverter`.

Examples

Simulate using: Code generation

OK Cancel Help Apply

Decimation factor

Decimation factor, specified as a positive integer scalar, or as a 1-by-2 or 1-by-3 vector of positive integers. The default is 100.

When you set this parameter to a scalar, the block chooses the decimation factors for each of the three filtering stages.

When you set this parameter to a 1-by-2 vector, the block bypasses the third filter stage and sets the decimation factor of the first and second filtering stages to the values in the first and second vector elements, respectively. Both elements of **Decimation factor** must be greater than 1.

When you set this parameter to a 1-by-3 vector, the *i*th element of the vector specifies the decimation factor for the *i*th filtering stage. The first and second elements of **Decimation factor** must be greater than 1, and the third element must be 1 or 2.

Minimum order filter design

When you select this check box, the block designs filters with the minimum order that meets the requirements specified in these parameters:

- **Passband ripple of cascade response (dB)**
- **Stopband attenuation of cascade response (dB)**
- **Two sided bandwidth of input signal (Hz)**
- **Source of stopband frequency**
- **Stopband frequency (Hz)**

When you clear this check box, the block designs filters with orders that you specify in **Number of sections of CIC decimator**, **Order of CIC compensation filter stage**, and **Order of third filter stage**. The filter designs meet the passband and stopband frequency specifications that you set in **Two sided bandwidth of input signal (Hz)**, **Source of stopband frequency**, and **Stopband frequency (Hz)**. By default, this check box is selected.

Number of sections of CIC decimator

Number of sections in the CIC decimator, specified as a positive integer scalar. This parameter applies when you clear the **Minimum order filter design** check box. The default is 3.

Order of CIC compensation filter stage

Order of the CIC compensation filter stage, specified as a positive integer scalar. This parameter applies when you clear the **Minimum order filter design** check box. The default is 12.

Order of third filter stage

Order of the third filter stage, specified as an even positive integer scalar. When you specify **Decimation factor** as a 1-by-2 vector, the block ignores the value of **Order of third filter stage** because the block bypasses the third filter stage. This parameter applies when you clear the **Minimum order filter design** check box. The default is 10.

Two sided bandwidth of input signal (Hz)

Two sided bandwidth of the input signal, specified as a positive integer scalar. The block sets the passband frequency of the cascade of filters to half the value that you specify in this parameter. Set the value of this parameter to less than **Input sample rate/Decimation factor**. When you select the **Inherit sample rate from input** check box, then set this value to less than $((1/T_s) / \text{Decimation factor})$, where T_s is the sample time of the input signal. The default is 200 kHz.

Source of stopband frequency

Source of the stopband frequency, specified as Auto or Property. The default is Auto.

When you set this parameter to Auto, the block places the cutoff frequency of the cascade filter response at approximately $F_c = \text{SampleRate} / M/2$ Hz, where M is the total decimation factor specified in **Decimation factor**. SampleRate is computed as $1/T_s$, where T_s is the sample time of the input signal. The block computes the stopband frequency as $F_{stop} = F_c + (TW / 2)$. TW is the transition bandwidth of the cascade response, computed as $2 \times (F_c - F_p)$, where the passband frequency, F_p , equals $\text{Bandwidth}/2$.

When you set this parameter to Property, specify the source in **Stopband frequency (Hz)**.

Stopband frequency (Hz)

Stopband frequency, specified as a double-precision positive scalar. This parameter applies when you set the **Source of stopband frequency** to Property. The default is 150 kHz.

Passband ripple of cascade response (dB)

Passband ripple of the cascade response, specified as a double-precision positive scalar. When you select the **Minimum order filter design**, the block designs the filters so that the cascade response meets the passband ripple that you specify in **Passband ripple of cascade response (dB)**. This parameter applies when you select the **Minimum order filter design**. The default is 0.1 dB.

Stopband attenuation of cascade response (dB)

Stopband attenuation of the cascade response, specified as a double-precision positive scalar. When you select the **Minimum order filter design**, the block designs the filters so that the cascade response meets the stopband attenuation that you specify in **Stopband attenuation of cascade response (dB)**. This parameter applies when you select the **Minimum order filter design**. The default is 60.

Type of oscillator

Oscillator type, specified as one of the following:

- **Sine wave** (default) — The block performs frequency down conversion on input signal using a complex exponential obtained from samples of a sinusoidal trigonometric function.
- **NCO** — The block performs frequency down conversion on input signal with a complex exponential obtained using a numerically controlled oscillator (NCO).
- **Input port** — The block performs frequency down conversion on input signal using the complex signal that you provide through the input port of the block.
- **None** — The mixer stage in the block is not present and the block acts as three stage cascaded decimator.

Center frequency of input signal (Hz)

Center frequency of the input signal, specified as a double-precision positive scalar that is less than or equal to half the sample rate. The block downconverts the input signal from the passband center frequency, which you specify in **Center frequency of input signal (Hz)**, to 0 Hz. This parameter applies when you set **Type of oscillator** to Sine wave or NCO. The default is 14e6.

Number of NCO accumulator bits

Number of NCO accumulator bits, specified as an integer scalar in the range [1 128]. This parameter applies when you set **Type of oscillator** to NCO. The default is 16.

Number of NCO quantized accumulator

Number of NCO quantized accumulator bits, specified as an integer scalar in the range [1 128]. This value must be less than the value you specify in **Number of NCO accumulator bits**. This parameter applies when you set **Type of oscillator** to NCO. The default is 12.

Dither control for NCO

When you select this check box, a number of dither bits specified in **Number of NCO dither bits** applies dither to the NCO signal. This parameter applies when you set **Type of oscillator** to NCO. By default, this check box is selected.

Number of NCO dither bits

Number of NCO dither bits, specified as an integer scalar smaller than the number of accumulator bits that you specify in **Number of NCO accumulator bits**. This parameter applies when you set **Type of oscillator** to NCO and select the **Dither control for NCO**. The default is 4.

Inherit sample rate from input

When you select this check box, sample rate is computed as N/T_s , where N is the frame size of the input signal, and T_s is the sample time of the input signal. When you clear this check box, the block's sample rate is the value specified in **Input sample rate (Hz)**. By default, this check box is selected.

Input sample rate

Input sample rate, specified as a positive scalar value, greater than or equal to twice the value of the **Center frequency of input signal (Hz)**. The default is 30 MHz. This parameter applies when you clear the **Inherit sample rate from input** check box.

View Filter Response

Opens the Filter Visualization Tool FVTool and displays the magnitude/phase response of each stage as well as the cascade of stages in the Digital Down-Converter. The response is based on the block dialog box parameters. Changes made to these parameters update FVTool.

To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

Simulate using

Type of simulation to run. You can set this parameter to:

- Code generation (default)

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as

the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.

- Interpreted execution

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

Data Types tab

Stage input

Data type of the input of the first, second, and third filter stages. You can set this parameter to:

- `Inherit: Same as input` (default) — The block inherits the **Stage input** from the input signal.

- `fixdt([], 16, 0)` — Fixed-point data type with binary point scaling. Specify the sign mode of this data type as `[]` or `true`.
- An expression that evaluates to a data type, for example, `numerictype([], 16, 15)`. Specify the sign mode of this data type as `[]` or `true`.

Click the **Show data type assistant** button  to display the data type assistant, which helps you set the stage input parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Output

Data type of the block output. You can set this parameter to:

- `Inherit: Same as input` (default) — The block Inherits the output datatype from the input.
- `fixdt([], 16, 0)` — Fixed-point data type with binary point scaling. Specify the sign mode of this data type as `[]` or `true`.
- An expression that evaluates to a data type, for example, `numerictype([], 16, 15)`. Specify the sign mode of this data type as `[]` or `true`.

Click the **Show data type assistant** button  to display the data type assistant, which helps you set the **Output** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Minimum

Minimum value of the block output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Maximum

Maximum value of the block output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, 32- and 64-bit signed integers
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, 32- and 64-bit signed integers

Version History

Introduced in R2015a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

If the input is fixed point, it must be a signed integer or signed fixed point with a power-of-two slope and zero bias.

Blocks

Digital Up-Converter

Digital Up-Converter

Interpolate digital signal and translate it from baseband to Intermediate Frequency (IF) band

Library

Signal Operations

dspsigops

Description

The Digital Up-Converter (DUC) block converts a complex digital baseband signal to a real passband signal.

The DUC block upsamples the input signal using a cascade of three interpolation filters. The block frequency upconverts the upsampled signal by multiplying it by the specified center frequency of the output signal. This block designs the interpolation filters according to the filter parameters that you set in the block dialog.

Structure

This block brings the capabilities of `dsp.DigitalUpConverter` System object to the Simulink environment.

The DUC block consists of a FIR interpolator, a CIC compensator, and a CIC interpolator. You can bypass the FIR interpolator, depending on how you set the DUC block parameters.

For more information on the structure that the DUC block uses, including the flow of fixed-point input, see the Construction on page 4-399 section in `dsp.DigitalUpConverter`.

? OK Cancel Help Apply

Interpolation factor

Interpolation factor, specified as a positive integer scalar, or as a 1-by-2 or 1-by-3 vector of positive integers. The default is 100.

When you set this parameter to a scalar, the block chooses the interpolation factors for each of the three filtering stages.

When you set this parameter to a 1-by-2 vector, the block bypasses the first filter stage and sets the interpolation factor of the second and third filtering stages to the values in the first and

second vector elements, respectively. Both elements of the **Interpolation factor** must be greater than 1.

When you set this parameter to a 1-by-3 vector, the *i*th element of the vector specifies the interpolation factor for the *i*th filtering stage. The second and third elements of **Interpolation factor** must be greater than 1, and the first element must be 1 or 2.

Minimum order filter design

When you select this check box, the block designs filters with the minimum order that meets the requirements specified in these parameters:

- **Passband ripple of cascade response (dB)**
- **Stopband attenuation of cascade response (dB)**
- **Two sided bandwidth of input signal (Hz)**
- **Source of stopband frequency**
- **Stopband frequency (Hz)**

When you clear this check box, the block designs filters with orders that you specify in **Order of first filter stage**, **Order of CIC compensation filter stage**, and **Number of sections of CIC interpolator**. The filter designs meet the passband and stopband frequency specifications that you set in **Two sided bandwidth of input signal (Hz)**, **Source of stopband frequency**, and **Stopband frequency (Hz)**. By default, this check box is selected.

Order of first filter stage

Order of the first filter stage, specified as an even positive integer scalar. When you specify **Interpolation factor** as a 1-by-2 vector, the block ignores the value of **Order of first filter stage** because the block bypasses the first filter stage. This parameter applies when you clear the **Minimum order filter design** check box. The default is 10.

Order of CIC compensation filter stage

Order of the CIC compensation filter stage, specified as a positive integer scalar. This parameter applies when you clear the **Minimum order filter design** check box. The default is 12.

Number of sections of CIC interpolator

Number of sections in the CIC interpolator, specified as a positive integer scalar. This parameter applies when you clear the **Minimum order filter design** check box. The default is 3.

Two sided bandwidth of input signal (Hz)

Two sided bandwidth of the input signal, specified as a positive integer scalar. The block sets the passband frequency of the cascade of filters to half the value that you specify in this parameter. The default is 200 kHz.

Source of stopband frequency

Source of the stopband frequency, specified as Auto or Property. The default is Auto.

When you set this parameter to Auto, the block places the cutoff frequency of the cascade filter response at approximately $F_c = \text{SampleRate}/2$ Hz, and computes the stopband frequency as $F_{stop} = F_c + TW/2$. *SampleRate* is computed as $1/T_s$, where T_s is the sample time of the input signal. *TW* is the transition bandwidth of the cascade response, computed as $2 \times (F_c - F_p)$, and the passband frequency, F_p , equals *Bandwidth/2*.

When you set this parameter to Property, specify the source in **Stopband frequency (Hz)**.

Stopband frequency (Hz)

Stopband frequency, specified as a double-precision positive scalar. This parameter applies when you set the **Source of stopband frequency** to Property. The default is 150 kHz.

Passband ripple of cascade response (dB)

Passband ripple of the cascade response, specified as a double-precision positive scalar. When you select the **Minimum order filter design**, the block designs the filters so that the cascade response meets the passband ripple that you specify in **Passband ripple of cascade response (dB)**. This parameter applies when you select the **Minimum order filter design** check box. The default is 0.1 dB.

Stopband attenuation of cascade response (dB)

Stopband attenuation of the cascade response, specified as a double-precision positive scalar. When you select the **Minimum order filter design** check box, the block designs the filters so that the cascade response meets the stopband attenuation that you specify in **Stopband attenuation of cascade response (dB)**. This parameter applies when you select the **Minimum order filter design** check box. The default is 60 dB.

Type of oscillator

Oscillator type, specified as one of the following:

- Sine wave (default) — The block frequency upconverts the output of the interpolation filter cascade using a complex exponential signal obtained from samples of a sinusoidal trigonometric function.
- NCO — The block performs frequency up conversion with a complex exponential obtained using a numerically controlled oscillator (NCO).

Center frequency of output signal (Hz)

Center frequency of the output signal, specified as a double-precision positive scalar. The value of this parameter must be less than or equal to half the product of the *SampleRate* times the total interpolation factor. *SampleRate* is computed as $1/T_s$, where T_s is the sample time of the input signal. The block up converts the input signal so that the output spectrum centers at the frequency you specify in **Center frequency of output signal (Hz)**. The default is 14 MHz.

Number of NCO accumulator bits

Number of NCO accumulator bits, specified as an integer scalar in the range [1 128]. This parameter applies when you set **Type of oscillator** to NCO. The default is 16.

Number of NCO quantized accumulator

Number of NCO quantized accumulator bits, specified as an integer scalar in the range [1 128]. This value must be less than the value you specify in **Number of NCO accumulator bits**. This parameter applies when you set **Type of oscillator** to NCO. The default is 12.

Dither control for NCO

When you select this check box, a number of dither bits specified in **Number of NCO dither bits** applies dither to the NCO signal. This parameter applies when you set **Type of oscillator** to NCO. By default, this check box is selected.

Number of NCO dither bits

Number of NCO dither bits, specified as an integer scalar smaller than the number of accumulator bits that you specify in **Number of NCO accumulator bits**. This parameter applies when you set **Type of oscillator** to NCO and select the **Dither control for NCO**. The default is 4.

Inherit sample rate from input

When you select this check box, sample rate is computed as N/T_s , where N is the frame size of the input signal, and T_s is the sample time of the input signal. When you clear this check box, the

block's sample rate is the value specified in **Input sample rate (Hz)**. By default, this check box is selected.

Input sample rate

Input sample rate, specified as a positive scalar. The value of this parameter multiplied by the total interpolation factor must be greater than or equal to twice the value of the **Center frequency of output signal (Hz)**. The default is 30 MHz. This parameter applies when you clear the **Inherit sample rate from input** check box.

View Filter Response

Opens the Filter Visualization Tool FVTool and displays the magnitude/phase response of each stage as well as the cascade of stages in the Digital Up-Converter. The response is based on the block dialog box parameters. Changes made to these parameters update FVTool.

To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

Simulate using

Type of simulation to run. You can set this parameter to:

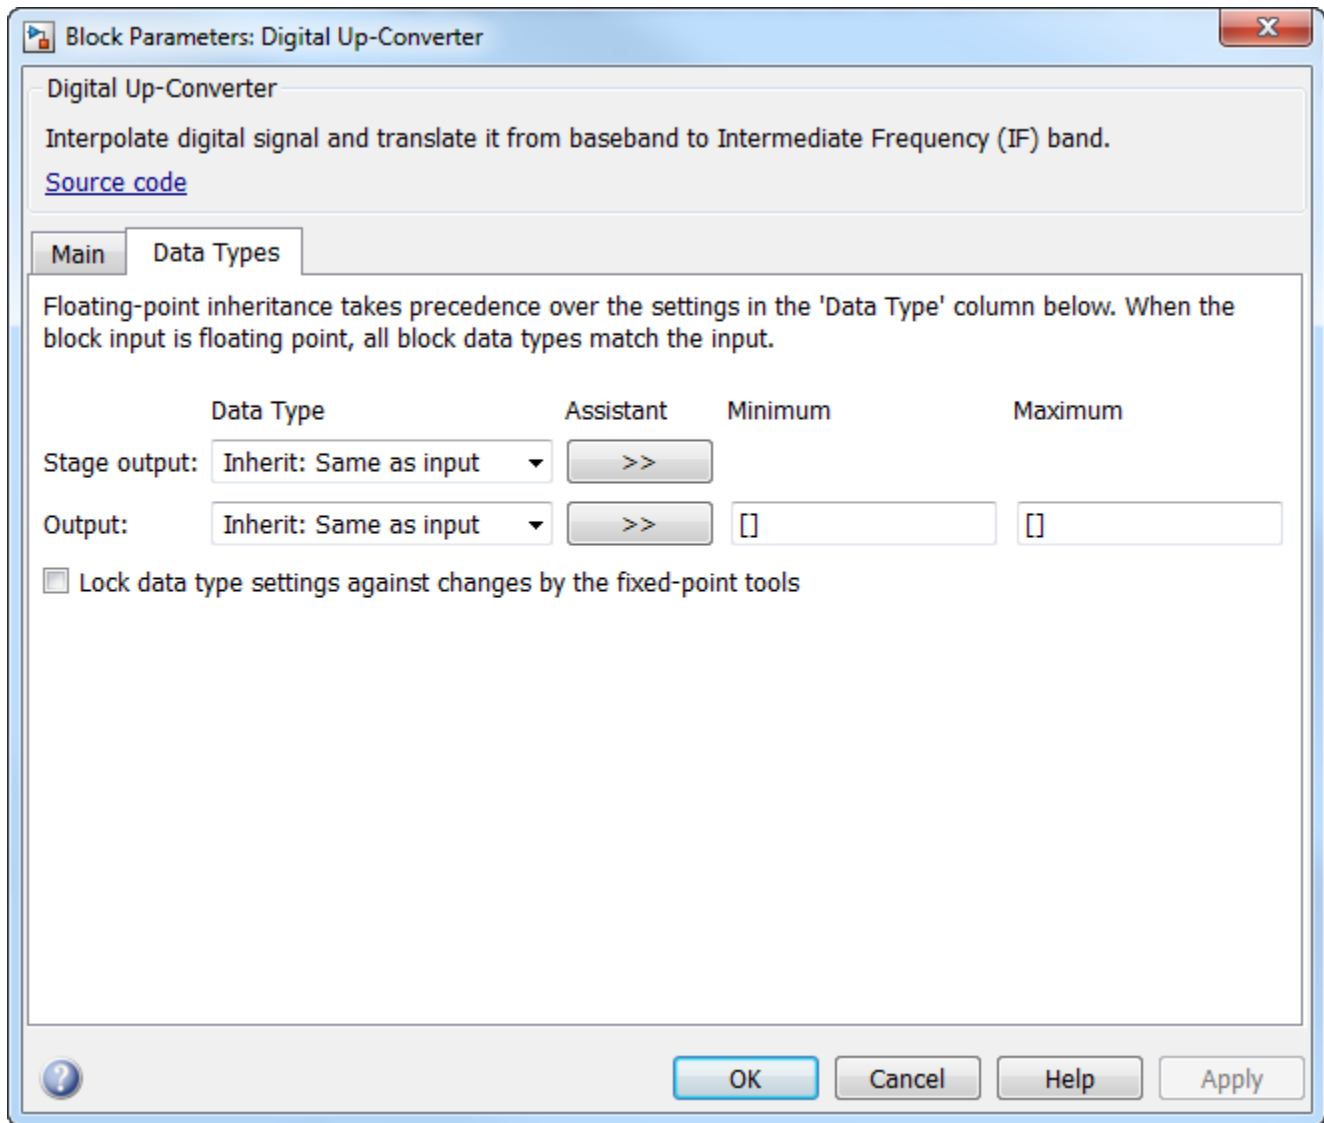

- Code generation (default)

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.

- Interpreted execution

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

Data Types Tab

Stage output

Data type of the output of the first, second, and third filter stages. You can set this parameter to:

- `Inherit: Same as input` (default) — The block inherits the **Stage output** from the input signal.
- `fixdt([], 16, 0)` — Fixed-point data type with binary point scaling. Specify the sign mode of this data type as `[]` or `true`.
- An expression that evaluates to a data type, for example, `numerictype([], 16, 15)`. Specify the sign mode of this data type as `[]` or `true`.

The block casts the data at the output of each filter stage according to the value you set in this parameter. For the CIC stage, the casting is done after the signal has been scaled by the normalization factor.

Click the **Show data type assistant** button  to display the data type assistant, which helps you set the stage output parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Output

Data type of the block output. You can set this parameter to:

- `Inherit`: Same as `input` (default) — The block Inherits the output datatype from the input.
- `fixdt([], 16, 0)` — Fixed-point data type with binary point scaling. Specify the sign mode of this data type as `[]` or `true`.
- An expression that evaluates to a data type, for example, `numerictype([], 16, 15)`. Specify the sign mode of this data type as `[]` or `true`.

Click the **Show data type assistant** button  to display the data type assistant, which helps you set the **Output** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Minimum

Minimum value of the block output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Maximum

Maximum value of the block output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, 32- and 64-bit signed integers

Digital Filter (Obsolete)

Filter each channel of input over time using static or time-varying digital filter implementations

Library

Filtering / Filter Implementations

dsparch4

Description

Note Use of Digital Filter block in future releases is not recommended. Existing instances will continue to operate, but certain functionality will be disabled. See “Functionality being removed or replaced for blocks and System objects”. We strongly recommend using one of Discrete FIR Filter, Discrete Filter, Biquad Filter, or Allpole Filter in new designs.

You can use the Digital Filter block to efficiently implement a floating-point or fixed-point filter for which you know the coefficients, or that is already defined in a `dfilt` object. The block independently filters each channel of the input signal with a specified digital IIR or FIR filter. The block can implement *static filters* with fixed coefficients, as well as *time-varying filters* with coefficients that change over time. You can tune the coefficients of a static filter during simulation.

This block filters each channel of the input signal independently over time. You must set the **Input processing** parameter to specify how the block interprets the input signal. You can select one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as an independent channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as an individual channel.

The output dimensions always match those of the input signal. The outputs of this block numerically match the outputs of the Digital Filter Design block and of the `dfilt` object.

Note The Digital Filter block has direct feedthrough, so if you connect the output of this block back to its input you get an algebraic loop. For more information on direct feedthrough and algebraic loops, see “Algebraic Loop Concepts” (Simulink).

Coefficient Source

The Digital Filter block can operate in three different modes. Select the mode in the **Coefficient source** group box.

- **Dialog parameters** Enter information about the filter such as structure and coefficients in the block mask.
- **Input port(s)** Enter the filter structure in the block mask, and the filter coefficients come in through one or more block ports. This mode is useful for specifying time-varying filters.
- **Discrete-time filter object (DFILT)** Specify the filter using a `dfilt` object.

Supported Filter Structures

When you select **Discrete-time filter object (DFILT)**, the following `dfilt` structures are supported:

- `dfilt.df1`
- `dfilt.df1t`
- `dfilt.df2`
- `dfilt.df2t`
- `dfilt.df1sos`
- `dfilt.df1tsos`
- `dfilt.df2sos`
- `dfilt.df2tsos`
- `dfilt.dffir`
- `dfilt.dffirt`
- `dfilt.dfsymfir`
- `dfilt.dfasymfir`
- `dfilt.latticear`
- `dfilt.latticemamin`

When you select **Dialog parameters** or **Input port(s)**, the list of filter structures offered in the **Filter structure** parameter depends on whether you set the **Transfer function type** to IIR (poles & zeros), IIR (all poles), or FIR (all zeros), as summarized in the following table.

Note Each structure listed in the table below supports both fixed-point and floating-point signals.

The table also shows the vector or matrix of filter coefficients you must provide for each filter structure.

Filter Structures and Filter Coefficients

Transfer Function Type	Supported Filter Structures	Filter Coefficient Specification
IIR (poles & zeros)	Direct form I	<ul style="list-style-type: none"> Numerator coefficients vector [b0, b1, b2, ..., bn] Denominator coefficients vector [a0, a1, a2, ..., am] See Special Consideration for the Leading Denominator Coefficient on page 2-401.
	Direct form I transposed	
	Direct form II	
	Direct form II transposed	
	Biquadratic direct form I (SOS)	<ul style="list-style-type: none"> M-by-6 second-order section (SOS) matrix. Scale values
	Biquadratic direct form I transposed (SOS)	
	Biquadratic direct form II (SOS)	
	Biquadratic direct form II transposed (SOS)	
IIR (all poles)	Direct form	Denominator coefficients vector [a0, a1, a2, ..., am]
	Direct form transposed	
	Lattice AR	Reflection coefficients vector [k1, k2, ..., kn]
FIR (all zeros)	Direct form	Numerator coefficients vector [b0, b1, b2, ..., bn]
	Direct form symmetric	
	Direct form antisymmetric	
	Direct form transposed	
	Lattice MA	Reflection coefficients vector [k1, k2, ..., kn]

Special Considerations for the Leading Denominator Coefficient

In some cases, the Digital Filter block requires the leading denominator coefficient (a_0) to be 1. This requirement applies under the following conditions:

- The Digital Filter block is operating in a fixed-point mode. The block operates in a fixed-point mode when at least one of the following statements is true:
 - The input to the Digital Filter block has a fixed-point or integer data type.

- The **Fixed-point instrumentation mode** parameter under **Analysis > Fixed Point Tool** has a setting of Minimums, maximums and overflows.
- The **Coefficient source** has a setting of Dialog or Input port(s).

Note If you are working in one of the fixed-point situations described in the previous bullet, and the **Coefficient source** is set to Input port(s), you must select the **First denominator coefficient = 1, remove a0 term in the structure** check box.

- The **Transfer function type** and **Filter structure** parameters are set to one of the combinations described in the following table.

Transfer function type	Filter structure
IIR (poles & zeros)	Direct form I
	Direct form I transposed
	Direct form II
	Direct form II transposed
IIR (all poles)	Direct form
	Direct form transposed

The Digital Filter block produces an error if you use it in one of these configurations and your leading denominator coefficient (a_0) does not equal 1. To resolve the error, set your leading denominator coefficient to 1 by scaling all numerator and denominator coefficients by a factor of a_0 .

Specifying Initial Conditions

In **Dialog parameters** and **Input port(s)** modes, the block initializes the internal filter states to zero by default, which is equivalent to assuming past inputs and outputs are zero. You can optionally use the **Initial conditions** parameter to specify nonzero initial conditions for the filter delays.

To determine the number of initial condition values you must specify, and how to specify them, see the following table on Valid Initial Conditions and Number of Delay Elements (Filter States). The **Initial conditions** parameter can take one of four forms as described in the following table.

Valid Initial Conditions

Initial Condition	Examples	Description
Scalar	5 Each delay element for each channel is set to 5.	The block initializes all delay elements in the filter to the scalar value.
Vector (for applying the same delay elements to each channel)	For a filter with two delay elements: $[d_1 \ d_2]$ The delay elements for all channels are d_1 and d_2 .	Each vector element specifies a unique initial condition for a corresponding delay element. The block applies the same vector of initial conditions to each channel of the input signal. The vector length must equal the number of delay elements in the filter (specified in the table Number of Delay Elements (Filter States)).
Vector or matrix (for applying different delay elements to each channel)	For a 3-channel input signal and a filter with two delay elements: $[d_1 \ d_2 \ D_1 \ D_2 \ d_1 \ d_2]$ or $\begin{bmatrix} d_1 & D_1 & d_1 \\ d_2 & D_2 & d_2 \end{bmatrix}$ <ul style="list-style-type: none"> The delay elements for channel 1 are d_1 and d_2. The delay elements for channel 2 are D_1 and D_2. The delay elements for channel 3 are d_1 and d_2. 	Each vector or matrix element specifies a unique initial condition for a corresponding delay element in a corresponding channel: <ul style="list-style-type: none"> The vector length must be equal to the product of the number of input channels and the number of delay elements in the filter (specified in the table Number of Delay Elements (Filter States)). The matrix must have the same number of rows as the number of delay elements in the filter (specified in the table Number of Delay Elements (Filter States)), and must have one column for each channel of the input signal.
Empty matrix	$[\]$ Each delay element for each channel is set to θ .	The empty matrix, $[\]$, is equivalent to setting the Initial conditions parameter to the scalar value θ .

The number of delay elements (filter states) per input channel depends on the filter structure, as indicated in the following table.

Number of Delay Elements (Filter States)

Filter Structure	Number of Delay Elements per Channel
Direct form Direct form transposed Direct form symmetric Direct form antisymmetric	$\#_of_filter_coeffs-1$
Direct form I Direct form I transposed	<ul style="list-style-type: none"> • $\#_of_zeros-1$ • $\#_of_poles-1$
Direct form II Direct form II transposed	$\max(\#_of_zeros, \#_of_poles)-1$
Biquadratic direct form I (SOS) Biquadratic direct form I transposed (SOS) Biquadratic direct form II (SOS) Biquadratic direct form II transposed (SOS)	$2 * \#_of_filter_sections$
Lattice AR Lattice MA	$\#_of_reflection_coeffs$

State Logging

Simulink enables you to log the states in your model to the MATLAB workspace. The following table indicates which filter structures of the Digital Filter block support the Simulink state logging feature. See “State” (Simulink) for more information.

Transfer Function Type	Filter Structure	State Logging Supported
IIR (poles & zeros)	Direct form I	No
	Direct form I transposed	Yes
	Direct form II	No
	Direct form II transposed	Yes
	Biquadratic direct form I (SOS)	Yes
	Biquadratic direct form I transposed (SOS)	Yes
	Biquadratic direct form II (SOS)	Yes
	Biquadratic direct form II transposed (SOS)	Yes
IIR (all poles)	Direct form	No
	Direct form transposed	Yes
	Lattice AR	Yes
FIR (all zeros)	Direct form	No
	Direct form symmetric	No
	Direct form antisymmetric	No
	Direct form transposed	Yes
	Lattice MA	Yes

Fixed-Point Data Types

All structures supported by the Digital Filter block support fixed-point data types. You can specify intermediate fixed-point data types for quantities such as the coefficients, accumulator, and product output for each filter structure. See “Filter Structure Diagrams” on page 2-415 for diagrams depicting the use of these intermediate fixed-point data types in each filter structure.

Dialog Box

Coefficient Source

The Digital Filter block can operate in three different modes. Select the mode in the **Coefficient source** group box.

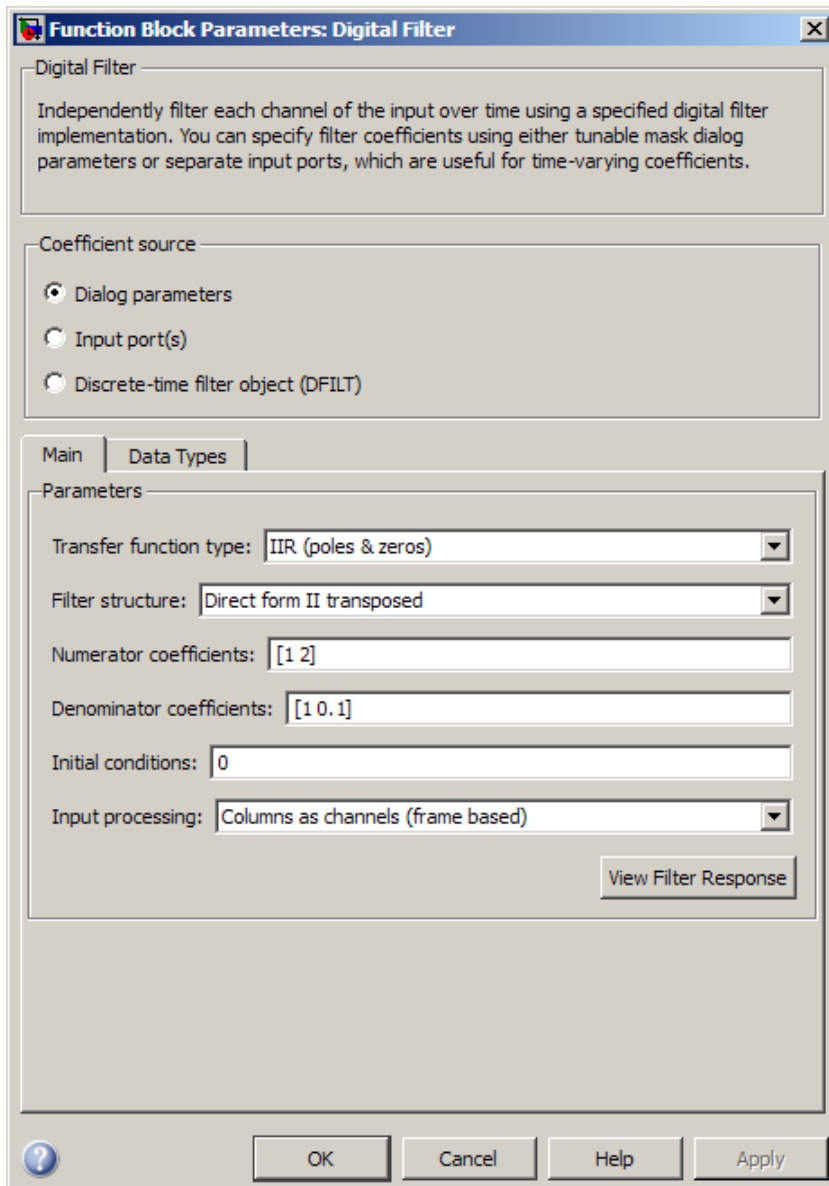

- **Dialog parameters** Enter information about the filter such as structure and coefficients in the block mask.
- **Input port(s)** Enter the filter structure in the block mask, and the filter coefficients come in through one or more block ports. This mode is useful for specifying time-varying filters.
- **Discrete-time filter object (DFILT)** Specify the filter using a `dfilt` object.

Different items appear on the Digital Filter block dialog depending on whether you select **Dialog parameters**, **Input port(s)**, or **Discrete-time filter object (DFILT)** in the **Coefficient source** group box. See the following sections for details:

- “Specify Filter Characteristics in Dialog and/or Through Input Ports” on page 2-405
- “Specify Discrete-Time Filter Object” on page 2-412

Specify Filter Characteristics in Dialog and/or Through Input Ports

The **Main** pane of the Digital Filter block dialog appears as follows when **Dialog parameters** is specified in the **Coefficient source** group box. The parameters below can appear when **Dialog parameters** or **Input port(s)** is selected, as noted.

Transfer function type

Select the type of transfer function of the filter; IIR (poles & zeros), IIR (all poles), or FIR (all zeros). See “Supported Filter Structures” on page 2-400 for more information.

Filter structure

Select the filter structure. The selection of available structures varies depending the setting of the **Transfer function type** parameter. See “Supported Filter Structures” on page 2-400 for more information.

Numerator coefficients

Specify the vector of numerator coefficients of the filter's transfer function.

This parameter is only visible when **Dialog parameters** is selected *and* when the selected filter structure lends itself to specification with numerator coefficients. Tunable (Simulink).

Denominator coefficients

Specify the vector of denominator coefficients of the filter's transfer function.

In some cases, the leading denominator coefficient (a_0) must be 1. See *Special Consideration for the Leading Denominator Coefficient* on page 2-401 for more information.

This parameter is only visible when **Dialog parameters** is selected *and* when the selected filter structure lends itself to specification with denominator coefficients. Tunable (Simulink).

Reflection coefficients

Specify the vector of reflection coefficients of the filter's transfer function.

This parameter is only visible when **Dialog parameters** is selected *and* when the selected filter structure lends itself to specification with reflection coefficients. Tunable (Simulink).

SOS matrix (Mx6)

Specify an M -by-6 *SOS matrix* containing coefficients of a second-order section (SOS) filter, where M is the number of sections. You can use the `ss2sos` and `tf2sos` functions from Signal Processing Toolbox software to check whether your SOS matrix is valid.

This parameter is only visible when **Dialog parameters** is selected *and* when the selected filter structure is biquadratic. Tunable (Simulink).

Scale values

Specify the scale values to be applied before and after each section of a biquadratic filter.

- If you specify a scalar, that value is applied before the first filter section. The rest of the scale values are set to 1.
- You can also specify a vector with $M + 1$ elements, assigning a different value to each scale. See “Filter Structure Diagrams” on page 2-415 for diagrams depicting the use of scale values in biquadratic filter structures.

This parameter is only visible when **Dialog parameters** is selected *and* when the selected filter structure is biquadratic. Tunable (Simulink).

First denominator coefficient = 1, remove a_0 term in the structure

Select this parameter to reduce the number of computations the block must make to produce the output by omitting the $1 / a_0$ term in the filter structure. The block output is invalid if you select this parameter when the first denominator filter coefficient is *not* always 1 for your time-varying filter.

This parameter is only enabled when the **Input port(s)** is selected *and* when the selected filter structure lends itself to this specification.

Coefficient update rate

Specify how often the block updates time-varying filters; once per sample or once per frame.

This parameter appears only when the following conditions are met:

- You specify **Input port(s)** in the Coefficient source group box.
- You set the **Input processing** parameter to `Columns as channels (frame based)`.

Initial conditions

Specify the initial conditions of the filter states. To learn how to specify initial conditions, see “Specifying Initial Conditions” on page 2-402.

Initial conditions on zeros side

(Not shown in dialog above.) Specify the initial conditions for the filter states on the side of the filter structure with the zeros (b_0, b_1, b_2, \dots); see the diagram below.

This parameter is enabled only when the filter has both poles and zeros, *and* when you select a structure such as direct form I, which has separate filter states corresponding to the poles (a_k) and zeros (b_k). To learn how to specify initial conditions, see “Specifying Initial Conditions” on page 2-402.

Initial conditions on poles side

(Not shown in dialog above.) Specify the initial conditions for the filter states on the side of the filter structure with the poles (a_0, a_1, a_2, \dots); see the diagram below.

This parameter is enabled only when the filter has both poles and zeros, *and* when you select a structure such as direct form I, which has separate filter states corresponding to the poles (a_k) and zeros (b_k). To learn how to specify initial conditions, see “Specifying Initial Conditions” on page 2-402.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- Columns as channels (frame based) — When you select this option, the block treats each column of the input as a separate channel.
- Elements as channels (sample based) — When you select this option, the block treats each element of the input as a separate channel.

Note The Inherited (this choice will be removed - see release notes) option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

View filter response

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product and displays the filter response of the filter defined by the block. For more information on FVTool, see the Signal Processing Toolbox documentation.

Note If you specify a filter in the **Filter** parameter, you must click the **Apply** button to apply the filter before using the **View filter response** button.

The **Data Types** pane of the Digital Filter block dialog appears as follows when **Dialog parameters** is specified in the **Coefficient source** group box. The parameters below can appear when **Dialog parameters** or **Input port(s)** is selected, depending on the filter structure and whether the coefficients are being entered via ports or on the block mask.

Rounding mode

Select the rounding mode for fixed-point operations. The filter coefficients do not obey this parameter; they always round to Nearest.

Overflow mode

Select the overflow mode for fixed-point operations. The filter coefficients do not obey this parameter; they are always saturated.

Section I/O

Choose how you specify the word length and the fraction length of the fixed-point data type going into and coming out of each section of a biquadratic filter. See “Filter Structure Diagrams” on page 2-415 for illustrations depicting the use of the section I/O data type in this block.

This parameter is only visible when the selected filter structure is biquadratic:

- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word and fraction lengths of the section input and output, in bits.
- When you select `Slope and bias scaling`, you can enter the word lengths, in bits, and the slopes of the section input and output. This block requires power-of-two slope and a bias of zero.

Tap sum

Choose how you specify the word length and the fraction length of the tap sum data type of a direct form symmetric or direct form antisymmetric filter. See “Filter Structure Diagrams” on page 2-415 for illustrations depicting the use of the tap sum data type in this block.

This parameter is only visible when the selected filter structure is either `Direct form symmetric` or `Direct form antisymmetric`:

- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the tap sum accumulator, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the tap sum accumulator. This block requires power-of-two slope and a bias of zero.

Multiplicand

Choose how you specify the word length and the fraction length of the multiplicand data type of a direct form I transposed or biquadratic direct form I transposed filter. See “Filter Structure Diagrams” on page 2-415 for illustrations depicting the use of the multiplicand data type in this block.

This parameter is only visible when the selected filter structure is either `Direct form I transposed` or `Biquad direct form I transposed (SOS)`:

- When you select `Same as output`, these characteristics match those of the output to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the multiplicand data type, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the multiplicand data type. This block requires power-of-two slope and a bias of zero.

Coefficients

Choose how you specify the word length and the fraction length of the filter coefficients (numerator and/or denominator). See “Filter Structure Diagrams” on page 2-415 for illustrations depicting the use of the coefficient data types in this block:

- When you select **Same word length as input**, the word length of the filter coefficients match that of the input to the block. In this mode, the fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- When you select **Specify word length**, you can enter the word length of the coefficients, in bits. In this mode, the fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- When you select **Binary point scaling**, you can enter the word length and the fraction length of the coefficients, in bits. If applicable, you can enter separate fraction lengths for the numerator and denominator coefficients.
- When you select **Slope and bias scaling**, you can enter the word length, in bits, and the slope of the coefficients. If applicable, you can enter separate slopes for the numerator and denominator coefficients. This block requires power-of-two slope and a bias of zero.
- The filter coefficients do not obey the **Rounding mode** and the **Overflow mode** parameters; they are always saturated and rounded to Nearest.

Product output

Use this parameter to specify how you would like to designate the product output word and fraction lengths. See “Filter Structure Diagrams” on page 2-415 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block:

- When you select **Same as input**, these characteristics match those of the input to the block.
- When you select **Binary point scaling**, you can enter the word length and the fraction length of the product output, in bits.
- When you select **Slope and bias scaling**, you can enter the word length, in bits, and the slope of the product output. This block requires power-of-two slope and a bias of zero.

Accumulator

Use this parameter to specify how you would like to designate the accumulator word and fraction lengths. See “Filter Structure Diagrams” on page 2-415 and “Multiplication Data Types” for illustrations depicting the use of the accumulator data type in this block:

- When you select **Same as input**, these characteristics match those of the input to the block.
- When you select **Same as product output**, these characteristics match those of the product output.
- When you select **Binary point scaling**, you can enter the word length and the fraction length of the accumulator, in bits.
- When you select **Slope and bias scaling**, you can enter the word length, in bits, and the slope of the accumulator. This block requires power-of-two slope and a bias of zero.

State

Use this parameter to specify how you would like to designate the state word and fraction lengths. See “Filter Structure Diagrams” on page 2-415 for illustrations depicting the use of the state data type in this block.

This parameter is not visible for direct form and direct form I filter structures.

- When you select **Same as input**, these characteristics match those of the input to the block.

- When you select `Same as accumulator`, these characteristics match those of the accumulator.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the accumulator, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the accumulator. This block requires power-of-two slope and a bias of zero.

Output

Choose how you specify the output word length and fraction length:

- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Same as accumulator`, these characteristics match those of the accumulator.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the output, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the output. This block requires power-of-two slope and a bias of zero.

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Specify Discrete-Time Filter Object

The **Main** pane of the Digital Filter block dialog appears as follows when **Discrete-time filter object (DFILT)** is specified in the **Coefficient source** group box.

Filter

Specify the discrete-time filter object (`dffilt`) that you would like the block to implement. You can do this in one of three ways:

- You can fully specify the `dffilt` object in the block mask, as shown in the default value.
- You can enter the variable name of a `dffilt` object that is defined in any workspace.
- You can enter a variable name for a `dffilt` object that is not yet defined.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

Note The Inherited (this choice will be removed - see release notes) option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

View filter response

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product and displays the filter response of the `dfilt` object specified in the **Filter** parameter. For more information on FVTool, see the Signal Processing Toolbox documentation.

Note If you specify a filter in the **Filter** parameter, you must click the **Apply** button to apply the filter before using the **View filter response** button.

The **Data Types** pane of the Digital Filter block dialog appears as follows when **Discrete-time filter object (DFILT)** is specified in the **Coefficient source** group box.

The fixed-point settings of the filter object specified on the **Main** pane are displayed on the **Data Types** pane. You cannot change these settings directly on the block mask. To change the fixed-point settings you must edit the filter object directly.

Filter Structure Diagrams

The diagrams in the following sections show the filter structures supported by the Digital Filter block. They also show the data types used in the filter structures for fixed-point signals. You can set the coefficient, output, accumulator, product output, and state data types shown in these diagrams in the block dialog. This is discussed in “Dialog Box” on page 2-405.

IIR direct form I

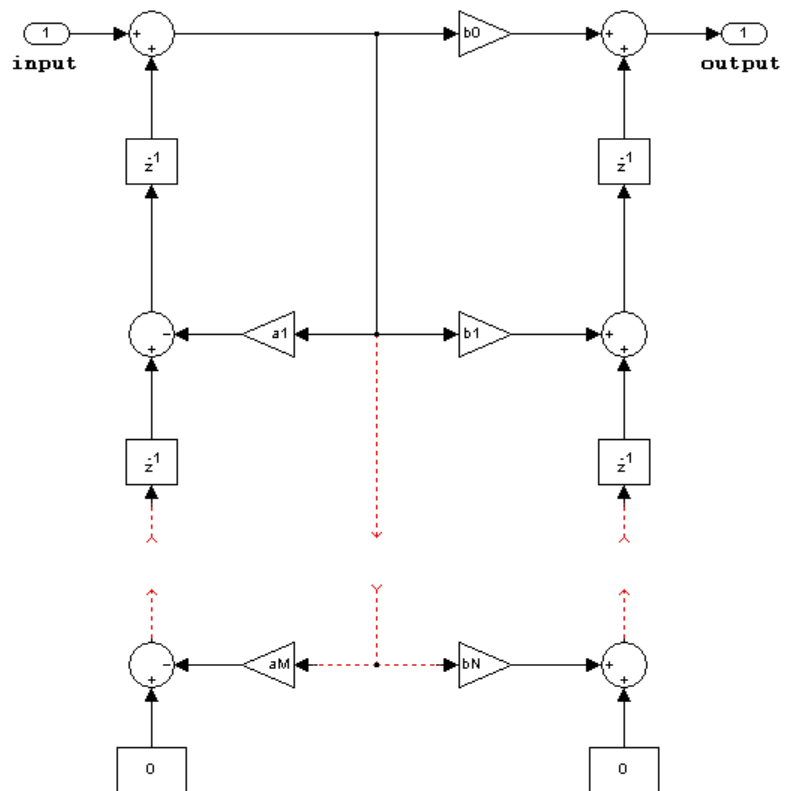

The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Numerator and denominator coefficients must be the same complexity as each other.
 - When the numerator and denominator coefficients are specified via input ports and have different complexities from each other, you get an error.
 - When the numerator and denominator coefficients are specified in the dialog and have different complexities from each other, the block does not error, but instead processes the filter as if two sets of complex coefficients are provided. The coefficient set that is real-valued is treated as if it is a complex vector with zero-valued imaginary parts.
- Numerator and denominator coefficients must have the same word length. They can have different fraction lengths.
- The State data type cannot be specified on the block mask for this structure, because the input and output states have the same data types as the input and output buffers.

IIR direct form I transposed

The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs can be real or complex.
- Numerator and denominator coefficients can be real or complex.

- Numerator and denominator coefficients must be the same complexity as each other.
- When the numerator and denominator coefficients are specified via input ports and have different complexities from each other, you get an error.
- When the numerator and denominator coefficients are specified in the dialog and have different complexities from each other, the block does not error, but instead processes the filter as if two sets of complex coefficients are provided. The coefficient set that is real-valued is treated as if it is a complex vector with zero-valued imaginary parts.
- States are complex when either the input or the coefficients are complex.
- Numerator and denominator coefficients must have the same word length. They can have different fraction lengths.

IIR direct form II

The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Numerator and denominator coefficients must be the same complexity as each other.
 - When the numerator and denominator coefficients are specified via input ports and have different complexities from each other, you get an error.
 - When the numerator and denominator coefficients are specified in the dialog and have different complexities from each other, the block does not error, but instead processes the filter as if two sets of complex coefficients are provided. The coefficient set that is real-valued is treated as if it is a complex vector with zero-valued imaginary parts.
- States are complex when either the inputs or the coefficients are complex.
- Numerator and denominator coefficients must have the same word length. They can have different fraction lengths.

IIR direct form II transposed

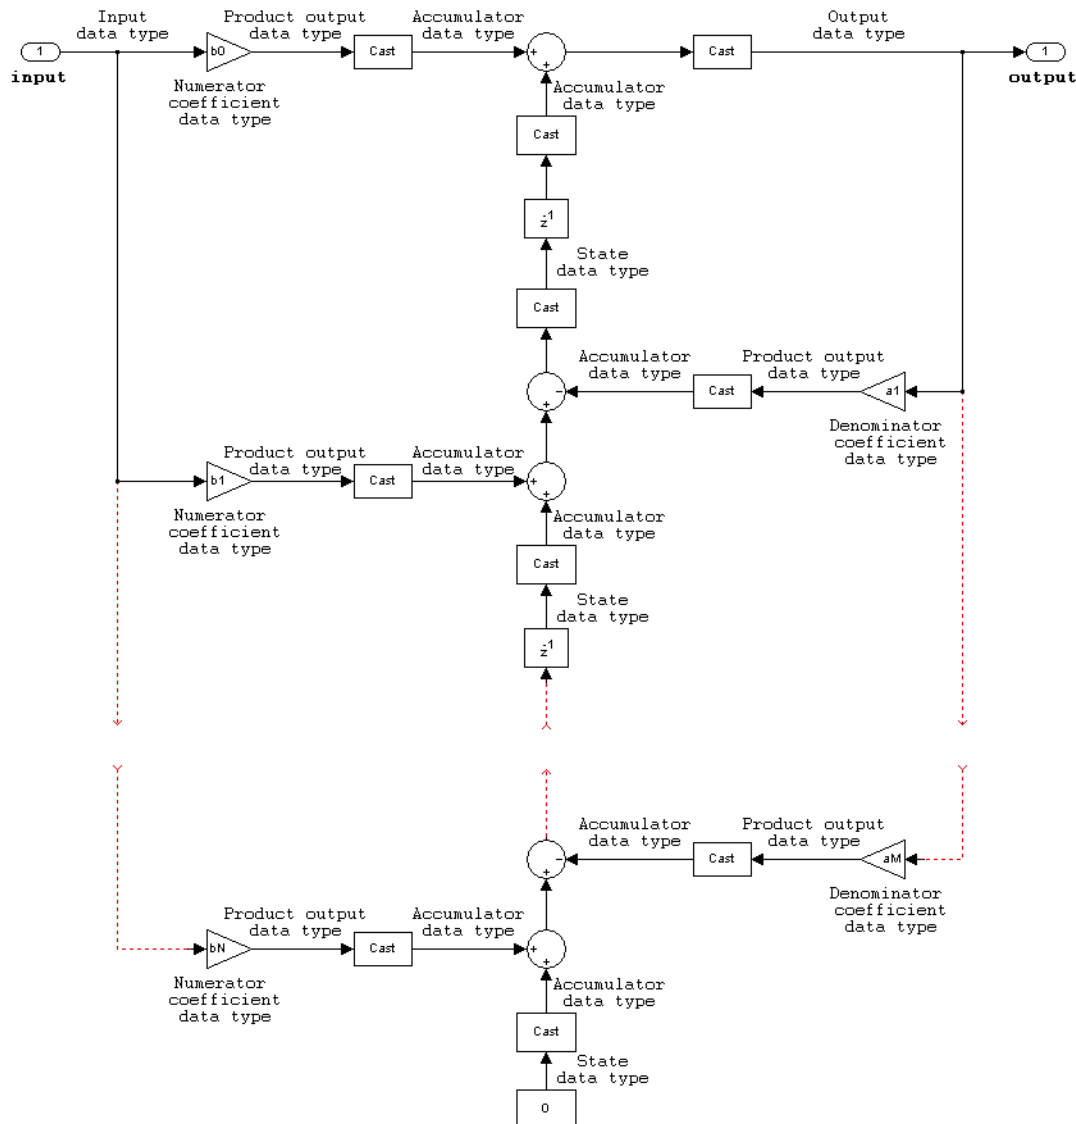

The following constraints are applicable when processing a fixed-point signal with this filter structure:

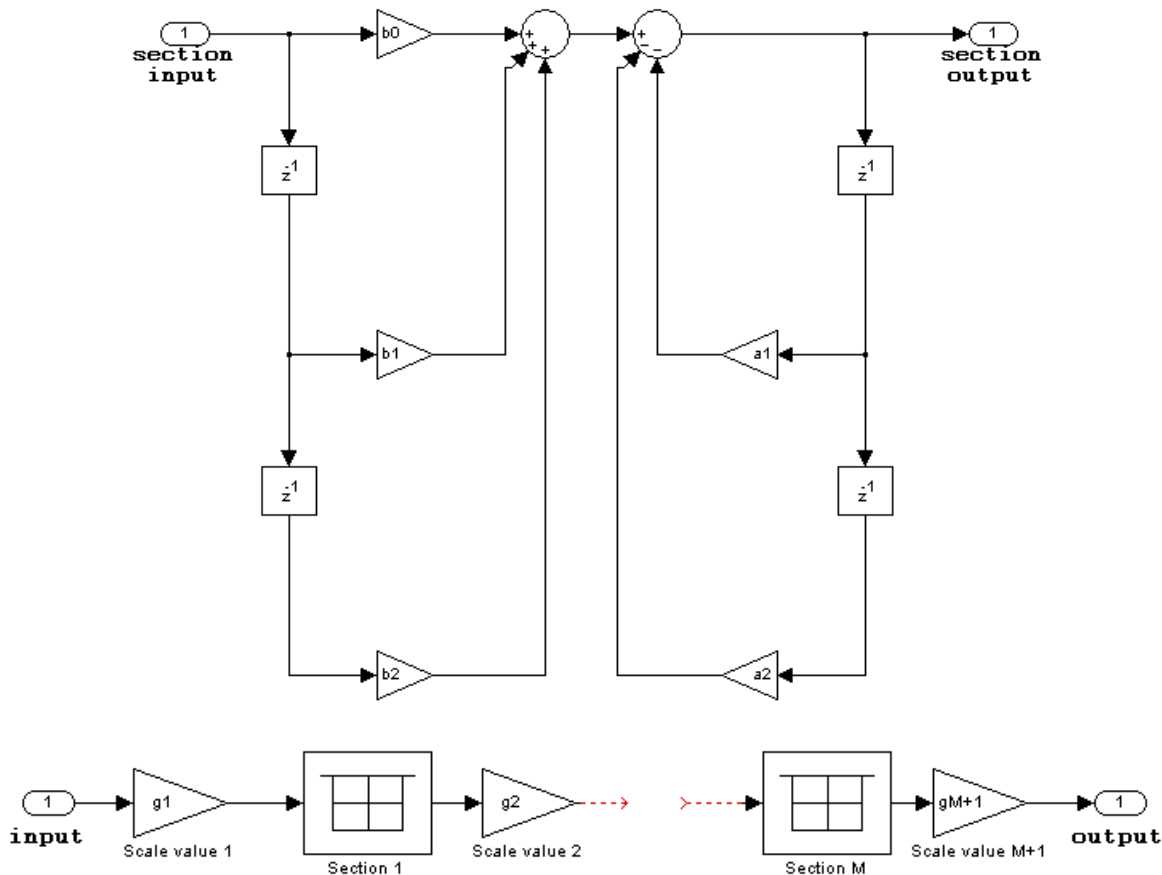

- Inputs can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Numerator and denominator coefficients must be the same complexity as each other.
 - When the numerator and denominator coefficients are specified via input ports and have different complexities from each other, you get an error.
 - When the numerator and denominator coefficients are specified in the dialog and have different complexities from each other, the block does not error, but instead processes the filter

as if two sets of complex coefficients are provided. The coefficient set that is real-valued is treated as if it is a complex vector with zero-valued imaginary parts.

- States are complex when either the inputs or the coefficients are complex.
- Numerator and denominator coefficients must have the same word length. They can have different fraction lengths.

IIR biquadratic direct form I

The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs and coefficients can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Specify the coefficients by a M -by-6 matrix in the block mask. You cannot specify coefficients by input ports for this filter structure.
- When the a_0 element of any row is not equal to one, that row is normalized by a_0 prior to filtering.
- States are complex when either the inputs or the coefficients are complex.
- You cannot specify the state data type on the block mask for this structure, because the input and output states have the same data types as the input.
- Scale values must have the same complexity as the coefficient SOS matrix.
- The scale value parameter must be a scalar or a vector of length $M+1$, where M is the number of sections.
- The **Section I/O** parameter determines the data type for the section input and output data types. The section input and stage output data type must have the same word length but can have different fraction lengths.

The following diagram shows the data types for one section of the filter.

The following diagram shows the data types between filter sections.

IIR biquadratic direct form I transposed

The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs and coefficients can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Specify the coefficients by a M -by-6 matrix in the block mask. You cannot specify coefficients by input ports for this filter structure.
- When the a_0 element of any row is not equal to one, that row is normalized by a_0 prior to filtering.
- States are complex when either the inputs or the coefficients are complex.
- Scale values must have the same complexity as the coefficient SOS matrix.
- The scale value parameter must be a scalar or a vector of length $M+1$, where M is the number of sections.
- The **Section I/O** parameter determines the data type for the section input and output data types. The section input and section output data type must have the same word length but can have different fraction lengths.

The following diagram shows the data types for one section of the filter.

The following diagram shows the data types between filter sections.

IIR biquadratic direct form II

The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs and coefficients can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Specify the coefficients by a M -by-6 matrix in the block mask. You cannot specify coefficients by input ports for this filter structure.
- When the a_0 element of any row is not equal to one, that row is normalized by a_0 prior to filtering.
- States are complex when either the inputs or the coefficients are complex.
- Scale values must have the same complexity as the coefficient SOS matrix.
- The scale value parameter must be a scalar or a vector of length $M+1$, where M is the number of sections.
- The **Section I/O** parameter determines the data type for the section input and output data types. The section input and section output data type must have the same word length but can have different fraction lengths.

The following diagram shows the data types for one section of the filter.

The following diagram shows the data types between filter sections.

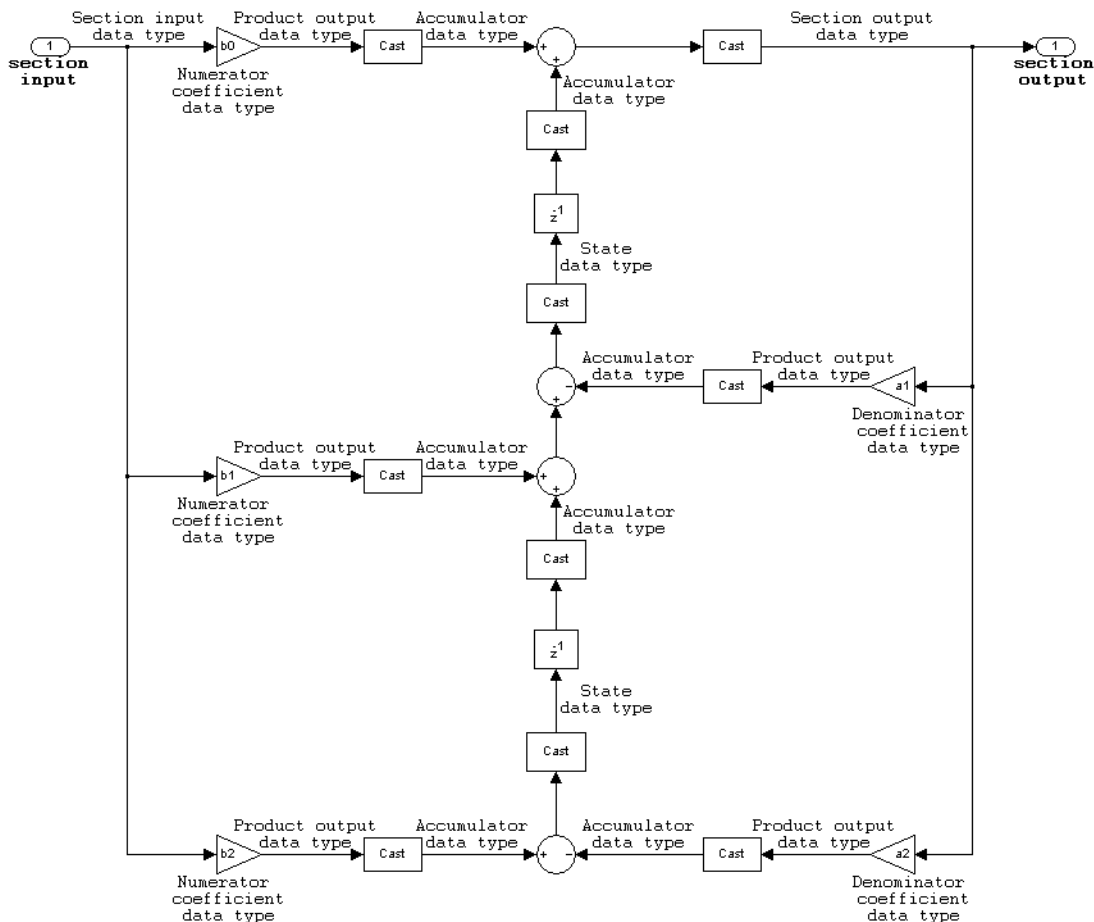

IIR biquadratic direct form II transposed

The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs and coefficients can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Specify the coefficients by a M -by-6 matrix in the block mask. You cannot specify coefficients by input ports for this filter structure.
- When the a_0 element of any row is not equal to one, that row is normalized by a_0 prior to filtering.
- States are complex when either the inputs or the coefficients are complex.
- Scale values must have the same complexity as the coefficient SOS matrix.
- The scale value parameter must be a scalar or a vector of length $M+1$, where M is the number of sections.
- The **Section I/O** parameter determines the data type for the section input and output data types. The section input and section output data type must have the same word length but can have different fraction lengths.

The following diagram shows the data types for one section of the filter.

The following diagram shows the data types between filter sections.

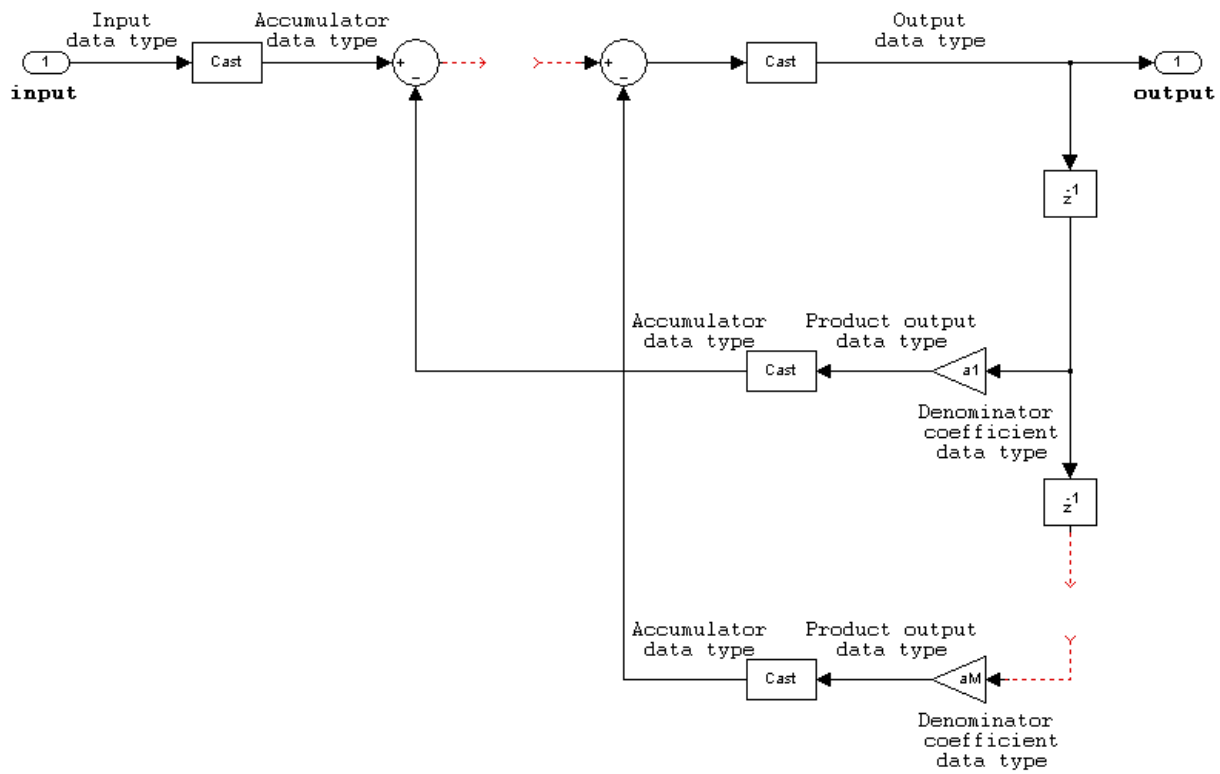

IIR (all poles) direct form

The following constraints are applicable when processing a fixed-point signal with this filter structure:

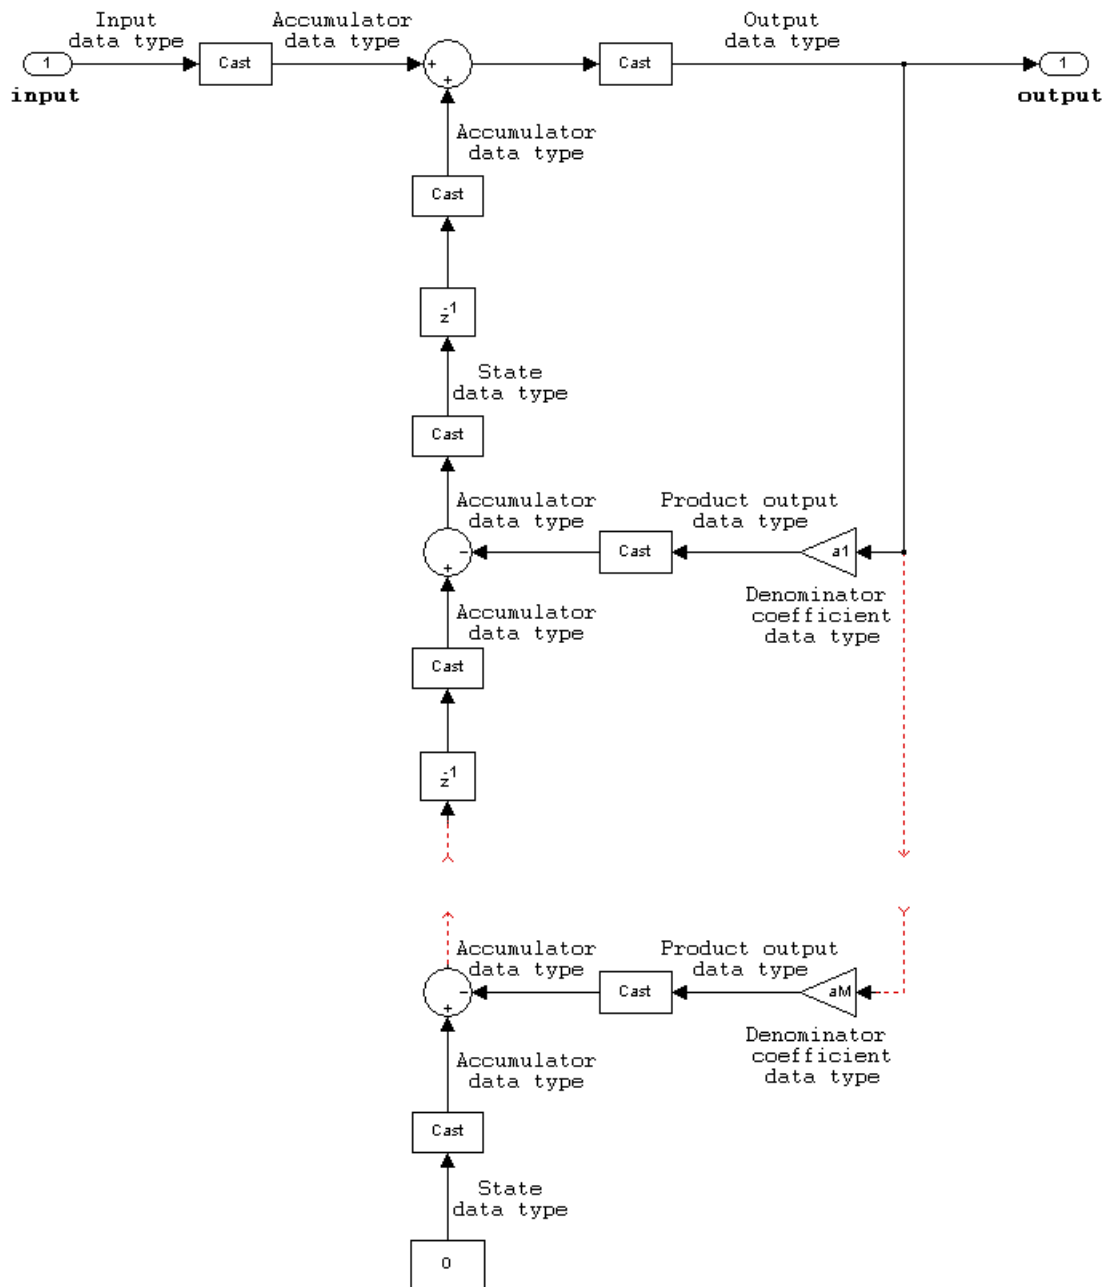

- Inputs and coefficients can be real or complex.
- Denominator coefficients can be real or complex.
- You cannot specify the state data type on the block mask for this structure, because the input and output states have the same data types as the input.

IIR (all poles) direct form transposed

The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs and coefficients can be real or complex.
- Denominator coefficients can be real or complex.

IIR (all poles) direct form lattice AR

The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs and coefficients can be real or complex.
- Coefficients can be real or complex.

FIR (all zeros) direct form

The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs can be real or complex.
- Numerator coefficients can be real or complex.
- You cannot specify the state data type on the block mask for this structure, because the input and output states have the same data types as the input.

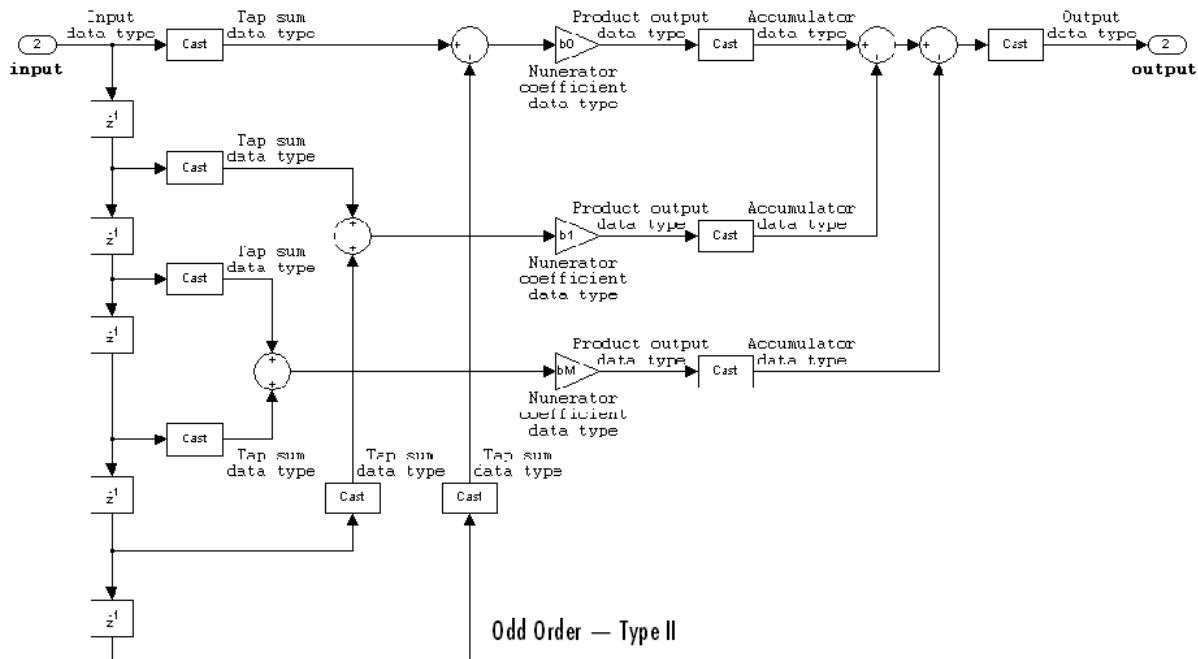

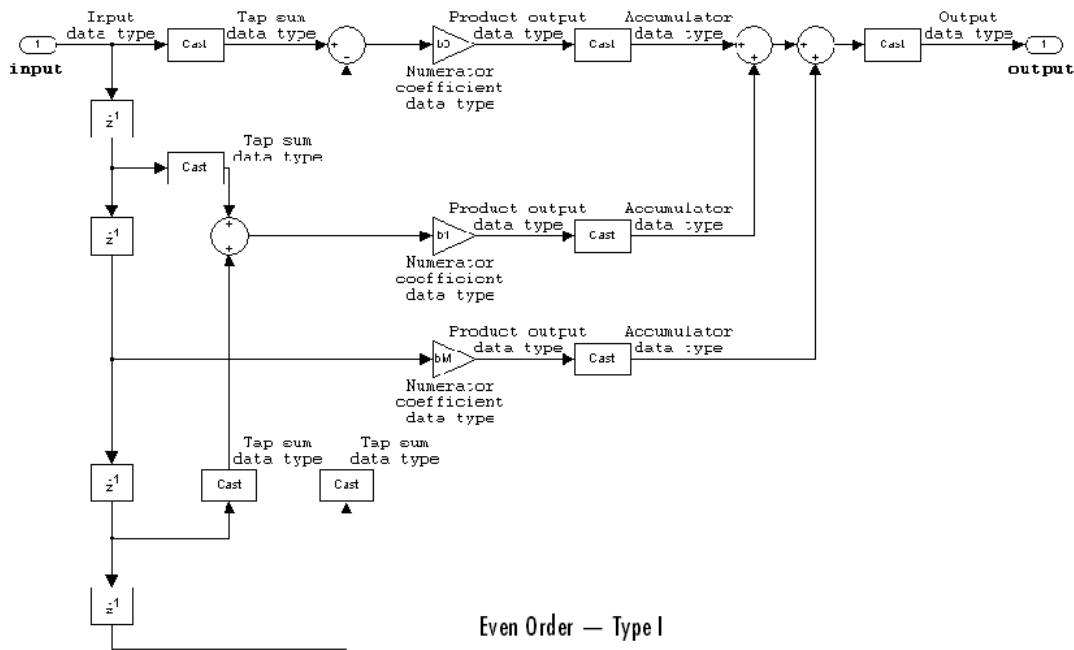

FIR (all zeros) direct form symmetric

The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs can be real or complex.
- Numerator coefficients can be real or complex.
- You cannot specify the state data type on the block mask for this structure, because the input and output states have the same data types as the input.
- It is assumed that the filter coefficients are symmetric. Only the first half of the coefficients are used for filtering.
- The **Tap Sum** parameter determines the data type the filter uses when it sums the inputs prior to multiplication by the coefficients.

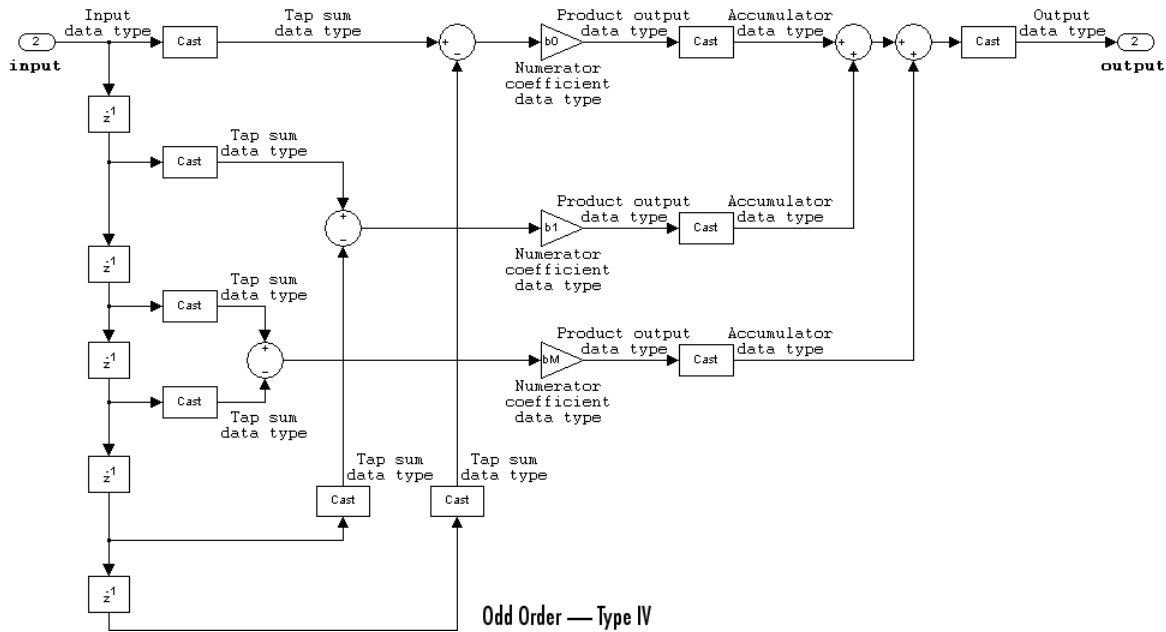

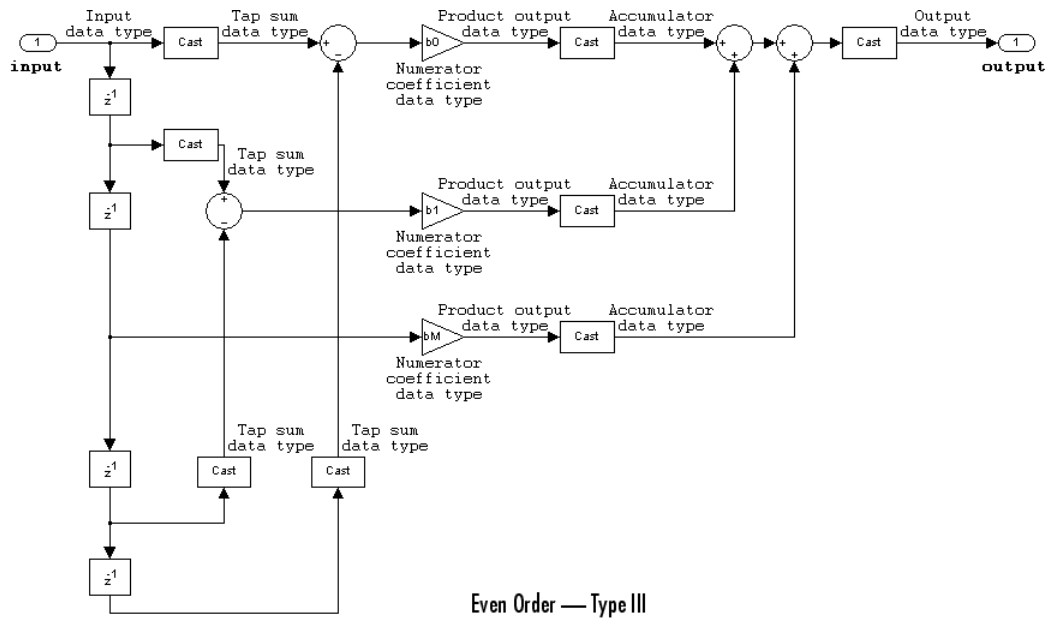

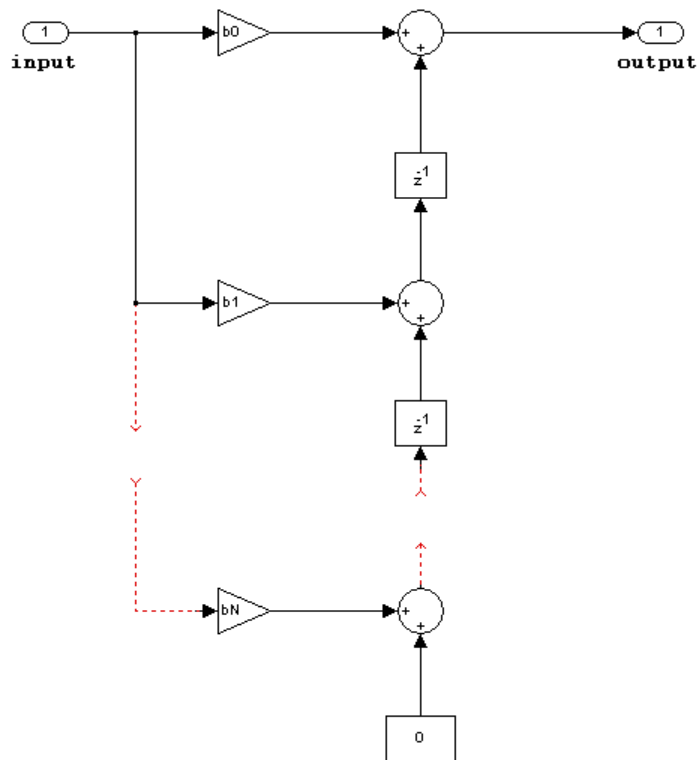

FIR (all zeros) direct form antisymmetric

The following constraints are applicable when processing a fixed-point signal with this filter structure:

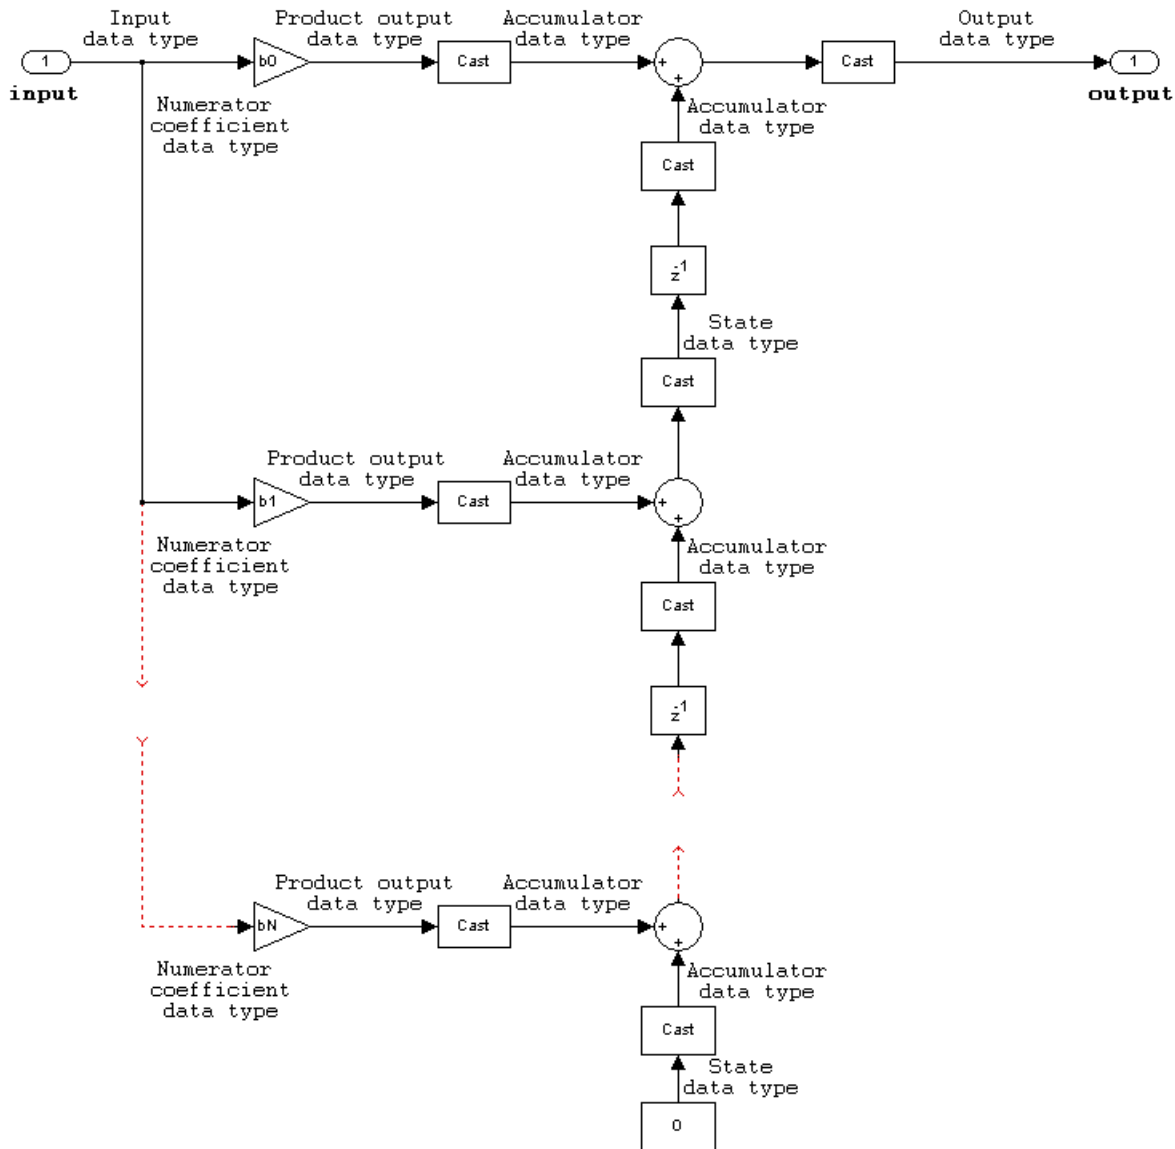

- Inputs can be real or complex.
- Numerator coefficients can be real or complex.
- You cannot specify the state data type on the block mask for this structure, because the input and output states have the same data types as the input.
- It is assumed that the filter coefficients are antisymmetric. Only the first half of the coefficients are used for filtering.
- The **Tap Sum** parameter determines the data type the filter uses when it sums the inputs prior to multiplication by the coefficients.

FIR (all zeros) direct form transposed

The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs can be real or complex.
- Coefficients can be real or complex.
- States are complex when either the inputs or the coefficients are complex.

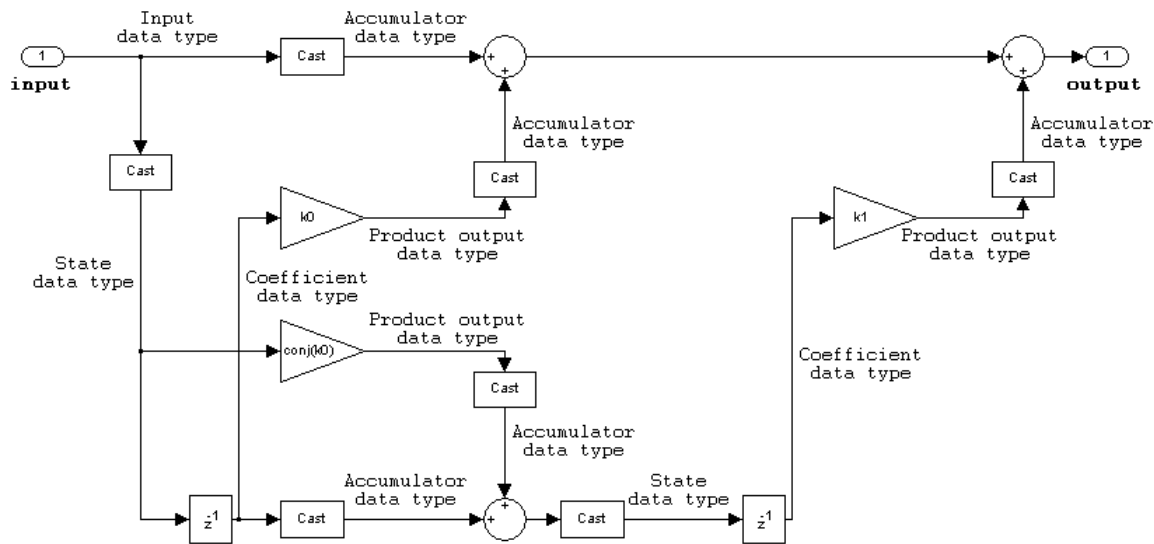

FIR (all zeros) lattice MA

The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs and coefficients can be real or complex.
- Coefficients can be real or complex.

HDL Code Generation

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

Note Use of Digital Filter block in future releases is not recommended. Existing instances will continue to operate, but certain functionality will be disabled. See “Functionality being removed or replaced for blocks and System objects”. We strongly recommend using Discrete FIR Filter or Biquad Filter in new designs.

HDL Architecture

When you specify `SerialPartition` and `ReuseAccum` for a Digital Filter block, observe the following constraints.

- If you specify **Dialog parameters** as the Coefficient source:
 - Set **Transfer function type** to FIR (all zeros).
 - Select **Filter structure** as one of: Direct form, Direct form symmetric, or Direct form asymmetric.

Distributed Arithmetic Support

Distributed Arithmetic properties **DALUTPartition** and **DARadix** are supported for the default architecture, with FIR, Asymmetric FIR, and Symmetric FIR filter structures.

AddPipelineRegisters Support

When you use **AddPipelineRegisters**, registers are placed based on the filter structure. The pipeline register placement determines the latency.

Architecture	Pipeline Register Placement	Latency (clock cycles)
FIR, Asymmetric FIR, and Symmetric FIR filters	A pipeline register is added between levels of a tree-based adder.	$\text{ceil}(\log_2(\text{FL}))$. FL is the filter length.
FIR Transposed	A pipeline register is added after the products.	1
IIR SOS	Pipeline registers are added between the filter sections.	NS - 1. NS is the number of sections.

HDL Filter Properties

AddPipelineRegisters	Insert a pipeline register between stages of computation in a filter. See also AddPipelineRegisters (HDL Coder).
CoeffMultipliers	Specify the use of canonical signed digit (CSD) optimization to decrease filter area by replacing coefficient multipliers with shift-and-add logic. When you choose a fully parallel filter implementation, you can set CoeffMultipliers to <code>csd</code> or <code>factored-csd</code> . The default is <code>multipliers</code> , which retains multipliers in the HDL. See also CoeffMultipliers (HDL Coder).
DALUTPartition	Specify distributed arithmetic partial-product LUT partitions as a vector of the sizes of each partition. The sum of all vector elements must be equal to the filter length. The maximum size for a partition is 12 taps. Set DALUTPartition to a scalar value equal to the filter length to generate DA code without LUT partitions. See also DALUTPartition (HDL Coder).
MultiplierInputPipeline	Specify the number of pipeline stages to add at filter multiplier inputs. See also MultiplierInputPipeline (HDL Coder).
MultiplierOutputPipeline	Specify the number of pipeline stages to add at filter multiplier outputs. See also MultiplierOutputPipeline (HDL Coder).
ReuseAccum	Enable or disable accumulator reuse in a serial filter implementation. Set ReuseAccum to <code>on</code> to use a cascade-serial implementation. See also ReuseAccum (HDL Coder).

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see "ConstrainedOutputPipeline" (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "InputPipeline" (HDL Coder).

OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
-----------------------	--

Complex Coefficients and Data Support

Except for decimator and interpolator filter structures, HDL Coder supports use of complex coefficients and complex input signals for all filter structures of the Digital Filter block.

Restrictions

- You must set **Initial conditions** to zero. HDL code generation is not supported for nonzero initial states.
- HDL Coder does not support the Digital Filter block **Input port(s)** option for HDL code generation.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed only)
- 8-, 16-, and 32-bit signed integers

Digital Filter Design

Design and implement digital FIR and IIR filters

Library: DSP System Toolbox / Filtering / Filter Implementations

Description

Use this block to design, analyze, and efficiently implement floating-point filters.

The Digital Filter Design block implements a digital Finite Impulse Response (FIR) or Infinite Impulse Response (IIR) filter that you design by using the **Filter Designer** (`filterDesigner`) app. This block provides the same filter implementation as the Discrete FIR Filter or Biquad Filter blocks.

You must specify whether the block performs frame-based or sample-based processing on the input by setting the **Input processing** parameter. The block applies the specified filter to each channel of a discrete-time input signal and outputs the result. The outputs of the block numerically match the outputs of the Discrete FIR Filter or Biquad Filter block and the MATLAB `filter` function. For more information, see “Getting Started with Filter Designer”.

These blocks also implement digital filters, but serve slightly different purposes:

- Discrete FIR Filter and Biquad Filter— Use to efficiently implement floating-point or fixed-point filters that you have already designed. These blocks provide the same exact filter implementation as the Digital Filter Design block.
- Filter Realization Wizard — Use to implement floating-point or fixed-point filters built from Sum, Gain, and Unit Delay blocks. You can either design the filter within this block, or import the coefficients of a filter that you designed elsewhere.

Ports

Input

Port_1 — Input signal

vector | matrix

Signal to filter, specified as a vector or matrix of real values. When given matrix input, the block treats each column as an independent channel.

The sample rate, F_s , that you specify in the filter designer app must be identical to the sample rate of the input to the Digital Filter Design block. When the sampling frequencies do not match, the Digital Filter Design block returns a warning message and inherits the sample rate of the input block.

Data Types: `single` | `double`

Output

Port_1 — Output signal

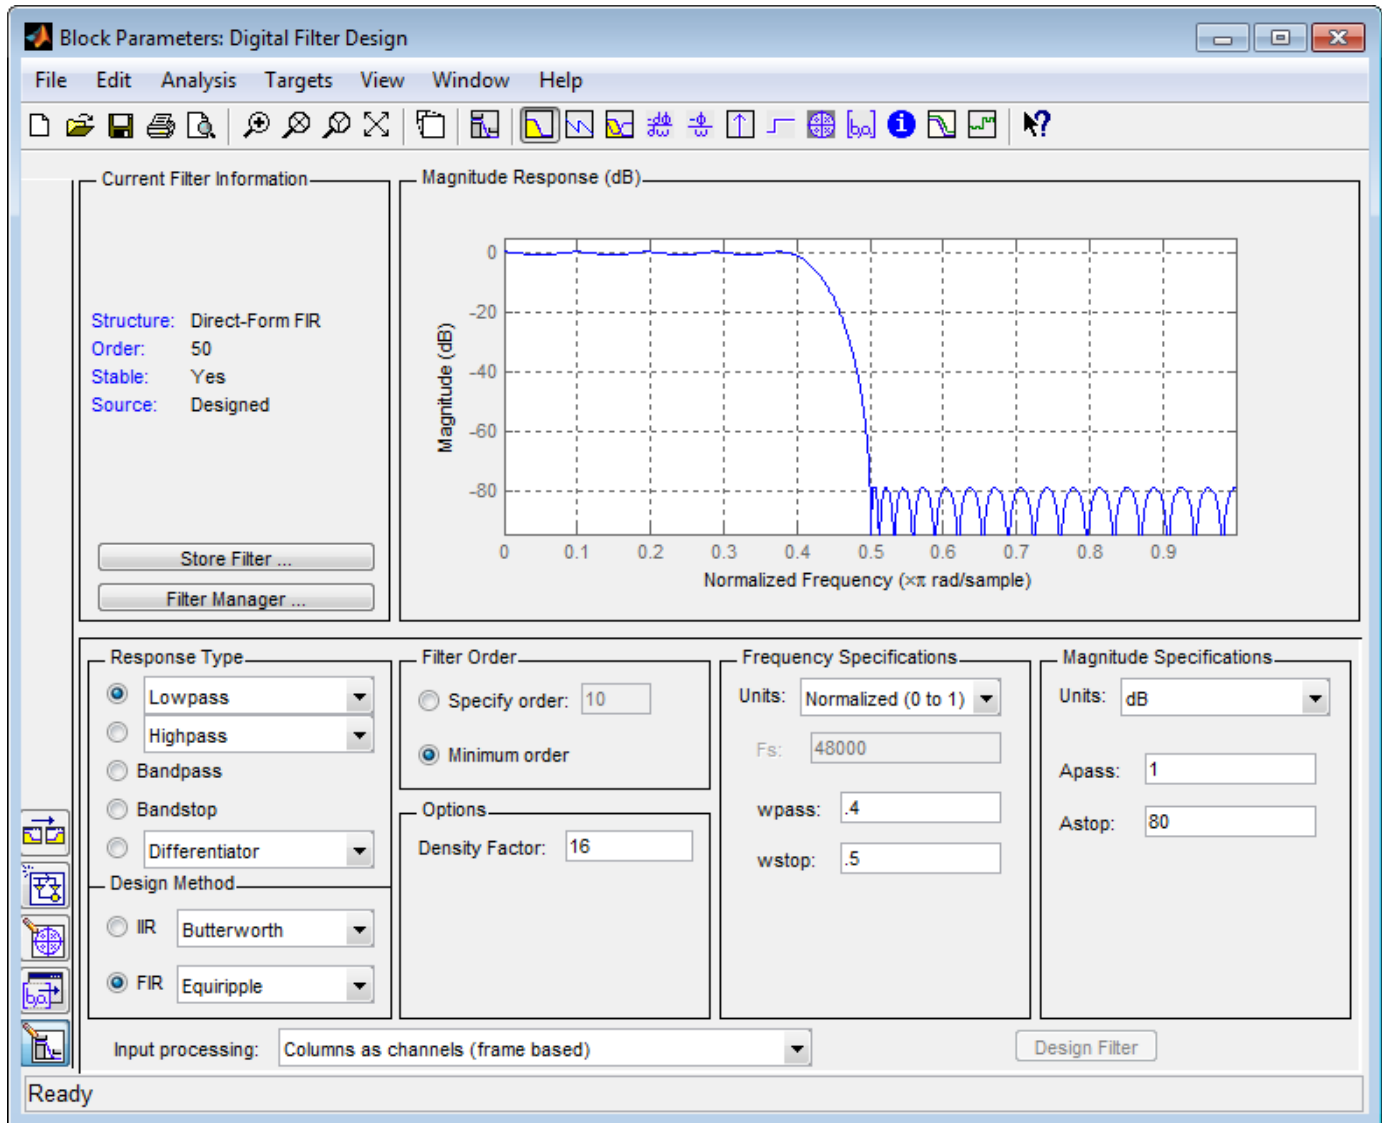

vector | matrix

Filtered signal, returned as a vector or a matrix of real values.

Data Types: `single` | `double`

Parameters

Dialog Box

For more information about the parameters in this dialog box, see “Getting Started with Filter Designer”.

Block Characteristics

Data Types	<code>double</code> <code>single</code>
-------------------	---

Multidimensional Signals	No
Variable-Size Signals	No

More About

Designing the Filter

To open filter designer, double-click the Digital Filter Design block. Use the filter designer to design or import a digital FIR or IIR filter. To learn how to design filters with this block and filter designer, see:

- “Using Digital Filter Design Block”
- **Filter Designer** app reference page. For details, see `filterDesigner`.

Tuning the Filter During Simulation

You can tune the filter specifications in filter designer during simulations if your changes do not modify the filter length or filter order. As you apply any filter changes in filter designer, the filter is updated.

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.

The Digital Filter Design block supports SIMD code generation using Intel AVX2 technology under these conditions:

- **Input processing** is set to `Columns as channels` (frame based).
- **Filter Structure** (in **Import Filter from Workspace** pane) is set to `Direct-Form FIR`. You can generate SIMD code even when the filter is a `Direct-Form FIR Transposed` filter. To create a `Direct-Form FIR Transposed` filter, select **Edit > Convert Structure**, and click **Direct-Form FIR Transposed**.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

Discrete Impulse

Generate discrete impulse

Library: DSP System Toolbox / Sources

Description

The Discrete Impulse block generates an impulse (the value 1) at output sample $D+1$, where you specify D using the **Delay** parameter ($D \geq 0$). All output samples preceding and following sample $D+1$ are zero.

When D is a length- N vector, the block generates an M -by- N matrix output representing N distinct channels, where you specify frame size M using the **Samples per frame** parameter. The impulse for the i th channel appears at sample $D(i)+1$.

The **Sample time** parameter value, T_s , specifies the output signal sample period. The resulting frame period is MT_s .

Ports

Output

Port_1 — Discrete impulse signal

scalar | vector | matrix

Output signal containing a discrete impulse at output sample $D(i)+1$, where D is a scalar or vector specified by the **Delay** parameter. For more information, see “Description” on page 2-447.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Parameters

Main

Delay (samples) — Number of zero-valued output samples

0 (default) | scalar | vector

The number of zero-valued output samples, D , preceding the impulse, specified as a scalar or vector of integer values, greater than or equal to zero. A length- N vector specifies an N -channel output.

Sample time — Output sample period

1 (default) | positive scalar

The sample period, T_s , of the output signal specified as a positive finite scalar. The output frame period is MT_s .

Samples per frame — Samples per frame

1 (default) | positive integer

The number of samples, M , in each output frame, specified as a positive integer scalar.

Data Types**Output data type — Output data type**

```
double (default) | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 |
boolean | fixdt(1,16) | fixdt(1,16,0) | Inherit: Inherit via back propagation |
<data type expression>
```

Specify the output data type for this block. You can select one of the following:

- A rule that inherits a data type, for example, **Inherit: Inherit via back propagation**. When you select this option, the output data type and scaling matches that of the next downstream block.
- A built-in data type, such as `double`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

For help setting data type parameters, display the **Data Type Assistant** by clicking the **Show data type assistant** button .

See “Control Data Types of Signals” (Simulink) for more information.

Block Characteristics

Data Types	Boolean double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Discrete Transfer Function Estimator

Compute estimate of frequency-domain transfer function of system

Library

Estimation / Power Spectrum Estimation

dspspect3

Description

The Discrete Transfer Function Estimator block estimates the frequency-domain transfer function of a system using the Welch's method of averaged modified periodograms.

The block takes two inputs, x and y . x is the system input signal and y is the system output signal. x and y must have the same dimensions. For 2D inputs, the block treats each column as an independent channel. The first dimension is the length of the channel. The second dimension is the number of channels. The block treats 1D inputs as one channel. The sample rate of the block is equal to $1/T$. T is the sample time of the inputs to the block.

The block buffers the input data into overlapping segments. You can set the length of the data segment and the amount of data overlap through the parameters set in the block dialog box.

The block first applies a window function to the two inputs, x and y , and then scales them by the window power. It takes the FFT of each signal, calling them X and Y . The block calculates P_{xx} which is the square magnitude of the FFT, X . The block then calculates P_{yx} which is X multiplied by the conjugate of Y . The output transfer function estimate, H , is calculated by dividing P_{yx} by P_{xx} .

Parameters

Window length source

Source of the window length value. You can set this parameter to:

- Same as input frame length (default) — Window length is set to the frame size of the input.
- Specify on dialog — Window length is the value specified in **Window length**.

This parameter is nontunable.

Window length

Length of the window, in samples, used to compute the spectrum estimate, specified as a positive integer scalar greater than 2. This parameter applies when you set **Window length source** to **Specify on dialog**. The default is 1024. This parameter is nontunable.

Window Overlap (%)

Percentage of overlap between successive data windows, specified as a scalar in the range $[0, 100]$. The default is 0. This parameter is nontunable.

Averaging method

Specify the averaging method as `Running` or `Exponential`. In the running averaging method, the block computes an equally weighted average of specified number of spectrum estimates defined by **Number of spectral averages** parameter. In the exponential method, the block computes the average over samples weighted by an exponentially decaying forgetting factor.

Number of spectral averages

Specify the number of spectral averages. The Transfer Function Estimator block computes the current estimate by averaging the last N estimates. N is the number of spectral averages. It can be any positive integer scalar, and the default is 1.

This parameter applies when **Averaging method** is set to `Running`.

Specify forgetting factor from input port

Select this check box to specify the forgetting factor from an input port. When you do not select this check box, the forgetting factor is specified through the **Forgetting factor** parameter.

This parameter applies when **Averaging method** is set to `Exponential`.

Forgetting factor

Specify the exponential weighting forgetting factor as a scalar value greater than zero and smaller than or equal to one. The default is 0.9.

This parameter applies when you set **Averaging method** to `Exponential` and clear the **Specify forgetting factor from input port** parameter.

FFT length source

Specify the source of the FFT length value. It can be one of `Auto` (default) or `Property`. When the source of the FFT length is set to `Auto`, the Transfer Function Estimator block sets the FFT length to the input frame size. When the source of the FFT length is set to `Property`, you specify the FFT length in the **FFT length** parameter.

FFT length

Specify the length of the FFT that the Transfer Function Estimator block uses to compute spectral estimates. It can be any positive integer scalar, and the default is 128.

Window function

Specify a window function for the Transfer Function Estimator block. Possible values are:

- Hann (default)
- Rectangular
- Chebyshev
- Flat Top
- Hamming
- Kaiser

Sidelobe attenuation of window (dB)

Specify the sidelobe attenuation of the window. It can be any real positive scalar value in decibels (dB). The default is 60.

Note This parameter is visible only when **Window function** is set to **Kaiser** or **Chebyshev**.

Frequency range

Specify the frequency range of the transfer function estimate.

- centered (default)

When you set the frequency range to **centered**, the Transfer Function Estimator block computes the centered two-sided transfer function of the real or complex input signals, x and y .

- onesided

When you set the frequency range to **onesided**, the Transfer Function Estimator block computes the one-sided transfer function of real input signals, x and y .

- twosided

When you set the frequency range to **twosided**, the Transfer Function Estimator block computes the two-sided transfer function of the real or complex input signals, x and y .

Output magnitude squared coherence estimate

Select this check box to compute and output the magnitude squared coherence estimate using Welch's averaged, modified periodogram method. The magnitude squared coherence estimate indicates how well two inputs correspond to each other at each frequency.

Simulate using

Type of simulation to run. You can set this parameter to:

- Code generation (default)

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.

- Interpreted execution

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

Supported Data Types

The Discrete Transfer Function Estimator block supports real and complex inputs.

Port	Supported Data Type
x	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point
y	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point
Output, H	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point

Examples

This example shows how to use the Discrete Transfer Function Estimator block to estimate the frequency-domain transfer function of a system.

The Random Source block represents the system input signal. The sample rate of the system input is 44.1 KHz. The Random Source input passes through a low-pass filter with a normalized cutoff frequency of 0.3. The filtered signal represents the system output signal. Because the Discrete Transfer Function Estimator block outputs complex values, take the magnitude of the output to see a plot of the transfer function estimate.

To view this example, execute `ex_discrete_transfer_function_estimator` in MATLAB Command prompt.

Copyright 2018 The MathWorks, Inc.

The transfer function plot displays the system transfer function, a low-pass filter that matches the frequency response of the Discrete FIR Filter block.

Algorithms

Welch's Method of Averaged Modified Periodograms

Give two signal inputs, x and y :

- 1 Multiply the inputs by the window and scale the result by the window power.
- 2 Take FFT of the signals, X and Y .
- 3 Compute the current power spectral density estimates, P_{xx} , P_{yy} , and the current cross power spectral density estimate, P_{yx} , by taking the moving average of last N number of Z_1 , Z_2 , and Z_3 vectors, respectively:
 - $Z_1 = X \cdot \text{conj}(X)$
 - $Z_2 = Y \cdot \text{conj}(Y)$
 - $Z_3 = Y \cdot \text{conj}(X)$

For details on the moving average methods, see “Averaging Method” on page 4-1135.

The transfer function estimate is calculated by dividing P_{yx} by P_{xx} .

The magnitude squared coherence, C_{xy} , is defined by the following equation:

$$C_{xy} = \frac{(\text{abs}(P_{xy}) \cdot \wedge 2)}{(P_{xx} \cdot * P_{yy})}$$

Downsample

Resample input at lower rate by deleting samples

Library: DSP System Toolbox / Signal Operations
 DSP System Toolbox HDL Support / Signal Operations

Description

The Downsample block decreases the sampling rate of the input by deleting samples. When the block performs frame-based processing, it resamples the data in each column of the P_r -by- Q input matrix independently. When the block performs sample-based processing, it treats each element of the input as a separate channel and resamples each channel of the input array across time. The resample rate is K times lower than the input sample rate, where K is the value of the **Downsample factor** parameter. The Downsample block resamples the input by discarding $K-1$ consecutive samples following each sample that is output.

This block supports triggered subsystems when you set the **Rate options** parameter to Enforce single-rate processing.

Ports

Input

Port_1 — Data input

column vector | matrix | N -D array

Data input whose sampling rate you want to decrease by using the block, specified as a column vector or a matrix.

When you set the **Input processing** parameter to Elements as channels (sample based), the input can be an N -D array.

The block supports variable-size input signals when you set **Input processing** to Columns as channels (frame based) and **Rate options** to Enforce single-rate processing. That is, the frame length (number of rows) and the number of channels (columns) can change during simulation. When the block accepts variable-size input signals, they can be of arbitrary frame length. That is, the input frame length does not have to be a multiple of the downsampling factor. When you specify fixed-size signals, the frame length can be arbitrary under certain conditions. For more details, see “Frame-Based Processing” on page 2-460 and “Sample-Based Processing” on page 2-461.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 — Downsampled output

column vector | matrix

Downsampled output with a sampling rate that is $1/K$ times the input sampling rate, returned as a column vector or a matrix.

When you set **Rate options** to:

- **Enforce single-rate processing** -- The block maintains the input sample rate and downsamples the signal by decreasing the output frame size by a factor of K .

The output has an upper bound size of $\text{ceil}(P/K)$ -by- Q for an input of size P -by- Q .

- **Allow multirate processing** -- The block downsamples the signal such that the output sample rate is K times slower than the input sample rate.

The output frame size is the same as the input frame size.

For more details, see “Frame-Based Processing” on page 2-460 and “Sample-Based Processing” on page 2-461.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Parameters

Downsample factor, K — Downsampling factor

2 (default) | positive integer

The integer factor, K , by which to decrease the input sample rate.

Sample offset (0 to $K-1$) — Sample offset

0 (default) | integer

The **Sample offset** parameter delays the output samples by an integer number of sample periods, D , where $0 \leq D \leq (K-1)$, so that any of the K possible output phases can be selected. For example, when you downsample the sequence 1, 2, 3, ... by a factor of 4, you can select from four phases.

Input Sequence	Sample Offset, D	Output Sequence ($K = 4$)
1, 2, 3, ...	0	1, 5, 9, 13, 17, 21, 25, 29, ...
1, 2, 3, ...	1	0, 2, 6, 10, 14, 18, 22, 26, ...
1, 2, 3, ...	2	0, 3, 7, 11, 15, 19, 23, 27, ...
1, 2, 3, ...	3	0, 4, 8, 12, 16, 20, 24, 28, ...

The initial zero in each of the latter three output sequences in the table is a result of the default zero **Initial conditions** parameter setting for this example. See “Latency” on page 2-462 for more information on the **Initial conditions** parameter.

Input processing — Method to process input

Columns as channels (frame based) (default) | Elements as channels (sample based)

Specify the method for input processing:

- **Columns as channels (frame based)** -- When you set the **Input processing** parameter to **Columns as channels (frame based)**, the block treats each of the Q input columns as an individual channel containing P_i sequential time samples. The block downsamples each channel independently by discarding $K-1$ rows of the input matrix following each row that it outputs.

For more information, see “What Is Frame-Based Processing?”.

- **Elements as channels (sample based)** -- When you set the **Input processing** parameter to **Elements as channels (sample based)**, the input can be an Q -D array. The Downsample block treats each element of the input as a separate channel, and resamples each channel of the input over time. The block downsamples the input array by discarding $K-1$ samples following each sample that it passes through to the output. The input and output sizes of the Downsample block are identical.

For more information, see “What Is Sample-Based Processing?”.

Rate options — Enforce single-rate or allow multirate processing

Enforce single-rate processing (default) | Allow multirate processing

Specify the method by which the block adjusts the rate at the output to accommodate the reduced number of samples. You can select one of the following options. The behavior of these options depends on whether the **Input processing** parameter is set to **Elements as channels (sample based)** (sample-based processing mode) or **Columns as channels (frame based)** (frame-based processing mode).

- **Elements as channels (sample based)**
 - **Enforce single-rate processing**

The block forces the output sample rate to match the input sample rate ($T_{so} = T_{si}$) by repeating every K th input sample K times at the output. In this mode, the behavior of the block is similar to the operation of a Sample and Hold block with a repeating trigger event of period KT_{si} .

- **Allow multirate processing**

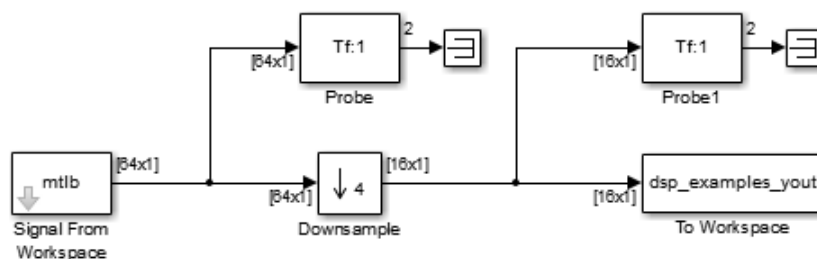

The sample period of the output is K times longer than the input sample period ($T_{so} = KT_{si}$).

For more details, see “Sample-Based Processing” on page 2-461

- **Columns as channels (frame based)**
 - **Enforce single rate processing**

The block generates the output at the slower (downsampled) rate using a proportionally smaller frame size than the input. The output has an upper bound size of $\text{ceil}(P/K)$, where P is the input frame length and K is the downsample factor specified in the **Downsample factor, K** parameter. The input and output frame rates are equal. For more details, see “Frame-Based Processing” on page 2-460.

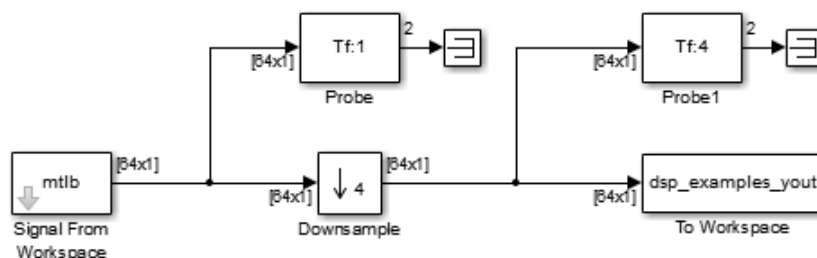

The `ex_downsample_ref2` model shows a single-channel input with a frame size of 64 being downsampled by a factor of 4 to a frame size of 16. The input and output frame rates are identical.

- Allow multirate processing

The block generates the output at the slower (downsampled) rate by using a proportionally longer frame *period* at the output port than at the input port. For downsampling by a factor of K , the output frame period is K times longer than the input frame period ($T_{fo} = KT_{fi}$), but the input and output frame sizes are equal. For more details, see “Frame-Based Processing” on page 2-460.

The `ex_downsample_ref1` model shows a single-channel input with a frame period of 1 second being downsampled by a factor of 4 to a frame period of 4 seconds. The input and output frame sizes are identical.

Allow arbitrary frame length for fixed-size input signals – Allow arbitrary frame length for fixed-size input signals

on (default) | off

Specify whether fixed-size input signals (whose size does not change during simulation) can have an arbitrary frame length, where the frame length does not have to be a multiple of the downsampling factor. The block uses this parameter setting only for fixed-size input signals and ignores this parameter if the input has a variable-size.

When the input signal is a variable-size signal, the signal can have arbitrary frame length, that is, the frame length does not have to be a multiple of the decimation factor.

For fixed-size input signals, if you:

- Select the **Allow arbitrary frame length for fixed-size input signals** parameter, the frame length of the signal does not have to be a multiple of the downsampling factor. If the input is not a multiple of the downsampling factor, then the output is generally a variable-size signal. Therefore, to support arbitrary input size, the block must also support variable-size operations, which you can enable by selecting the **Allow arbitrary frame length for fixed-size input signals** parameter.
- Clear the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length must be a multiple of the downsampling factor.

Dependency

To enable this parameter, set **Input processing** to Columns as channels (frame based) and **Rate options** to Enforce single-rate processing.

Initial conditions — Initial value

0 (default) | real scalar | array

The initial block value for cases of nonzero latency. You can specify a scalar or an array of the same size as the input.

Dependencies

This parameter does not appear when **Input processing** is set to Columns as channels (frame based) and **Rate options** is set to Enforce single-rate processing.

Block Characteristics

Data Types	Boolean double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

More About

Frame-Based Processing

When you set the **Input processing** parameter to Columns as channels (frame based) and use an input signal of size P -by- Q , the block treats each of the Q input columns as an individual channel containing P sequential time samples. The block downsamples each channel independently by discarding $K-1$ rows of the input matrix following each row that it outputs.

In this mode, the block can perform either single-rate or multirate processing. You can use the **Rate options** parameter to specify how the block adjusts the rate at the output to accommodate the reduced number of samples.

- When you set the **Rate options** parameter to Enforce single-rate processing, the block generates the output at the slower (downsampled) rate using a proportionally smaller frame size than the input.

The output has an upper bound size of $\text{ceil}(P/K)$, where P is the input frame length and K is the downsample factor specified in the **Downsample factor, K** parameter.

In this mode, if you input a fixed-size signal (signal dimensions do not change during simulation) and select the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length can be arbitrary and does not have to be a multiple of the downsampling factor. If you clear the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length must be a multiple of the downsampling factor.

In this mode, if you input a variable-size signal (signal dimensions change during simulation), the **Allow arbitrary frame length for fixed-size input signals** appears on the block dialog box but does not have any impact on the input frame size requirements. You can input a variable-size signal of any frame size even if you do not select the **Allow arbitrary frame length for fixed-size input signals** parameter.

This table summarizes the support for arbitrary input frame length when you set **Input processing** to Columns as channels (frame based) and **Rate options** to Enforce single-rate processing.

Input Signal	Block Support for this Signal	Support for Arbitrary Input Frame Length	Input Size	Output Size
Fixed-size input signal	Yes	When you select Allow arbitrary frame length for fixed-size input signals	P -by- Q	Upper bound size of $\text{ceil}(P/K)$ -by- Q
Variable-size input signal	Yes	Always	P -by- Q	Upper bound size of $\text{ceil}(P/K)$ -by- Q

- When you set the **Rate options** parameter to Allow multirate processing, the input and output of the Downsample block are of the same size, but the sample rate of the output is K times slower than that of the input. In this mode, the block treats a P -by- Q matrix input as Q independent channels.

In this mode, the block accepts only fixed-size signals and these signals can have an arbitrary frame length.

This table summarizes the support for arbitrary input frame length when you set **Input processing** to Columns as channels (frame based) and **Rate options** to Allow multirate processing.

Input Signal	Block Support for this Signal	Support for Arbitrary Input Frame Length	Input Size	Output Size
Fixed-size input signal	Yes	Always	P -by- Q	P -by- Q
Variable-size input signal	No	Not applicable	Not applicable	Not applicable

Sample-Based Processing

When you set the **Input processing** parameter to Elements as channels (sample based), the block treats a P -by- Q matrix input as $P*Q$ independent channels, and resamples each channel over time. The output sample period (T_{so}) is K times longer than the input sample period ($T_{so} = K*T_{si}$), and the input and output sizes are identical.

In this mode, the block accepts only fixed-size signals and these signals can have an arbitrary frame length.

This table summarizes the support for arbitrary input frame length when you set **Input processing** to Elements as channels (sample based).

Input Signal	Block Support for this Signal	Support for Arbitrary Input Frame Length	Input Size	Output Size
Fixed-size input signal	Yes	Always	P -by- Q	P -by- Q
Variable-size input signal	No	Not applicable	Not applicable	Not applicable

Latency

Latency is the delay, measured in samples or frames, between the input and the output of the block.

The Downsample block has *zero-tasking latency* in the following cases:

- The **Downsample factor** parameter, K , is 1.
- The **Input processing** parameter is set to `Columns as channels` (frame based), and the **Rate options** parameter is set to `Enforce single-rate processing`.
- The **Input processing** parameter is set to `Columns as channels` (frame based), the **Rate options** parameter is set to `Allow multirate processing`, the **Sample offset** parameter, D , is set to 0, and the input frame size is equal to 1.
- The **Input processing** parameter is set to `Elements as channels` (sample based), and the **Sample offset** parameter, D , is 0.

Zero-tasking latency means that the block propagates input sample $D+1$ (received at $t = 0$) as the first output sample, followed by input sample $D+1+K$, input sample $D+1+2K$, and so on. When there is zero-tasking latency, the block ignores the value of the **Initial conditions** parameter.

In all other cases, the latency is nonzero:

- When the **Input processing** parameter is set to `Elements as channels` (sample based), the latency is one sample.
- When the **Input processing** parameter is set to `Columns as channels` (frame based) and the input frame size is greater than one, the latency is one frame.

In all cases of *one-sample latency*, the initial condition for each channel appears as the first output sample. Input sample $D+1$ appears as the second output sample for each channel, followed by input sample $D+1+K$, input sample $D+1+2K$, and so on. The **Initial conditions** parameter can be an array of the same size as the input or a scalar to be applied to all signal channels.

In all cases of *one-frame latency*, the P_i rows of the initial condition matrix appear in sequence as the first P_i output rows. Input sample $D+1$ (row $D+1$ of the input matrix) appears in the output as sample P_i+1 , followed by input sample $D+1+K$, input sample $D+1+2K$, and so on. The **Initial conditions** value can be an P_i -by- Q matrix containing one value for each channel or a scalar to be repeated across all elements of the P_i -by- Q matrix.

Note For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Version History

Introduced before R2006a

Support for arbitrary input frame length and variable input frame sizes

Starting in R2022b, this block supports input signals with arbitrary frame lengths when the:

- Input signal is a fixed-size signal (signal dimensions do not change during simulation) and the block allows for multirate processing
- Input signal is a fixed-size signal, block enforces single-rate processing, and you select the **Allow arbitrary frame length for fixed-size input signals** parameter (if enabled)
- Input signal is a variable-size signal (signal dimensions change during simulation)

When this block supports an arbitrary frame length input signal, the input frame length does not have to be a multiple of the downsampling factor.

For more details, see “Frame-Based Processing” on page 2-460 and “Sample-Based Processing” on page 2-461.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

Best Practices

It is good practice to follow the Downsample block with a unit delay. Doing so prevents the code generator from inserting an extra bypass register in the HDL code.

See also “Multirate Model Requirements for HDL Code Generation” (HDL Coder).

HDL Architecture

This block has one default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).

OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
-----------------------	--

Complex Data Support

This block supports code generation for complex signals.

Restrictions

- **Input processing** set to Columns as channels (frame based) is not supported.
- For **Input processing** set to Elements as channels (sample based), select Allow multirate processing. With this setting, if **Sample offset** is set to 0, **Initial conditions** has no effect on generated code.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

DSP Constant (Obsolete)

Generate discrete- or continuous-time constant signal

Library

Sources

dspobslib

Description

Note The DSP Constant block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the Constant block.

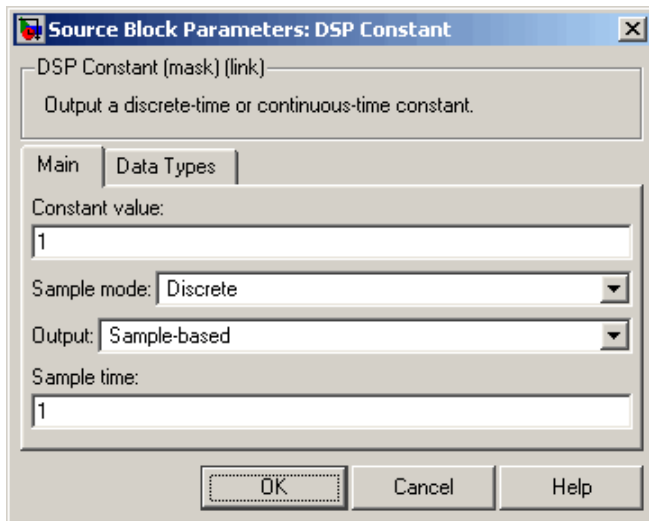

The DSP Constant block generates a signal whose value remains constant throughout the simulation. The **Constant value** parameter specifies the constant to output, and can be any valid MATLAB expression that evaluates to a scalar, vector, or matrix.

When **Sample mode** is set to **Continuous**, the output is a continuous-time signal. When **Sample mode** is set to **Discrete**, the **Sample time** parameter is visible, and the signal has the discrete output period specified by the **Sample time** parameter.

You can set the output signal to **Frame-based**, **Sample-based**, or **Sample-based** (interpret vectors as 1-D) with the **Output** parameter.

Dialog Box

The **Main** pane of the DSP Constant block dialog box appears as follows.

Constant value

Specify the constant to generate. This parameter is Tunable (Simulink); values entered here can be tuned, but their dimensions must remain fixed.

When you specify any data type information in this field, it is overridden by the value of the **Output data type** parameter in the **Data Types** pane, unless you select **Inherit** from 'Constant value'.

Sample mode

Specify the sample mode of the output, **Discrete** for a discrete-time signal or **Continuous** for a continuous-time signal.

Output

Specify whether the output is **Sample-based** (interpret vectors as 1-D), **Sample-based**, or **Frame-based**. When you select **Sample-based** and the output is a vector, its dimension is constrained to match the **Constant value** dimension (row or column). When you select **Sample-based** (interpret vectors as 1-D), however, the output has no specified dimensionality.

Sample time

Specify the discrete sample period for sample-based outputs. When you select **Frame-based** for the **Output** parameter, this parameter is named **Frame period**, and is the discrete frame period for the frame-based output. This parameter is only visible when you select **Discrete** for the **Sample mode** parameter.

The **Data Types** pane of the DSP Constant block dialog box appears as follows.

Output data type

Specify the output data type in one of the following ways:

- Choose one of the built-in data types from the list.
- Choose **Fixed-point** to specify the output data type and scaling in the **Signed**, **Word length**, **Set fraction length in output to**, and **Fraction length** parameters.
- Choose **User-defined** to specify the output data type and scaling in the **User-defined data type**, **Set fraction length in output to**, and **Fraction length** parameters.
- Choose **Inherit from 'Constant value'** to set the output data type and scaling to match the values of the **Constant value** parameter in the **Main** pane.
- Choose **Inherit via back propagation** to set the output data type and scaling to match the following block.

The value of this parameter overrides any data type information specified in the **Constant value** parameter in the **Main** pane, except when you select **Inherit from 'Constant value'**.

Signed

Select to output a signed fixed-point signal. Otherwise, the signal is unsigned. This parameter is only visible when you select **Fixed-point** for the **Output data type** parameter.

Word length

Specify the word length, in bits, of the fixed-point output data type. This parameter is only visible when you select **Fixed-point** for the **Output data type** parameter.

User-defined data type

Specify any built-in or fixed-point data type. You can specify fixed-point data types using the following `fixdt` function. This parameter is only visible when you select **User-defined** for the **Output data type** parameter.

Set fraction length in output to

Specify the scaling of the fixed-point output by either of the following two methods:

- Choose **Best precision** to have the output scaling automatically set such that the output signal has the best possible precision.

- Choose **User-defined** to specify the output scaling in the **Fraction length** parameter.

This parameter is only visible when you select **Fixed-point** for the **Output data type** parameter, or when you select **User-defined** and the specified output data type is a fixed-point data type.

Fraction length

For fixed-point output data types, specify the number of fractional bits, or bits to the right of the binary point. This parameter is only visible when you select **Fixed-point** or **User-defined** for the **Output data type** parameter and **User-defined** for the **Set fraction length in output to** parameter.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point
- Boolean
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

Decompose signals into subbands with smaller bandwidths and slower sample rates or compute discrete wavelet transform (DWT)

Library

Filtering / Multirate Filters

dspmlti4

Description

Note This block always interprets input signals as frames. The frame size of the input signal must be a multiple of 2^n , where n is the value of the **Number of levels** parameter. The block decomposes the input signal into either $n+1$ or 2^n subbands. To decompose signals with a frame size that is not a multiple of 2^n , use the Two-Channel Analysis Subband Filter block. (You can connect multiple copies of the Two-Channel Analysis Subband Filter block to create a multilevel dyadic analysis filter bank.)

You can configure this block to compute the Discrete Wavelet Transform (DWT) or decompose a broadband signal into a collection of subbands with smaller bandwidths and slower sample rates. The block uses a series of highpass and lowpass FIR filters to repeatedly divide the input frequency range, as illustrated in “Wavelet Filter Banks” on page 2-473 (the Asymmetric one).

You can specify the filter bank's highpass and lowpass filters by providing vectors of filter coefficients. You can do so directly on the block mask, or, if you have a Wavelet Toolbox™ license, you can specify wavelet-based filters by selecting a wavelet from the **Filter** parameter. You must set the filter bank structure to asymmetric or symmetric, and specify the number of levels in the filter bank.

For the same input, the DWT configuration of this block does not produce the same results as the Wavelet Toolbox `dwt` function. Because DSP System Toolbox is designed for real-time implementation and Wavelet Toolbox is designed for analysis, the products handle boundary conditions and filter states differently. To make the output of the `dwt` function match the DWT output of this block, complete the following steps:

- 1 Set the boundary condition of the `dwt` function to zero-padding. To do so, type `dwtmode('zpd')` at the MATLAB command line.
- 2 To match the latency of the block (implemented using FIR filters), add zeros to the input of the `dwt` function. The number of zeros you add must be equal to the half-length of the filter.

Input Requirements

- Input must be a vector or matrix.
- The input frame size must be a multiple of 2^n , where n is the number of filter bank levels. For example, a frame size of 16 would be appropriate for a three-level tree (16 is a multiple of 2^3).
- The block always treats input signals as frames and operates along the columns.

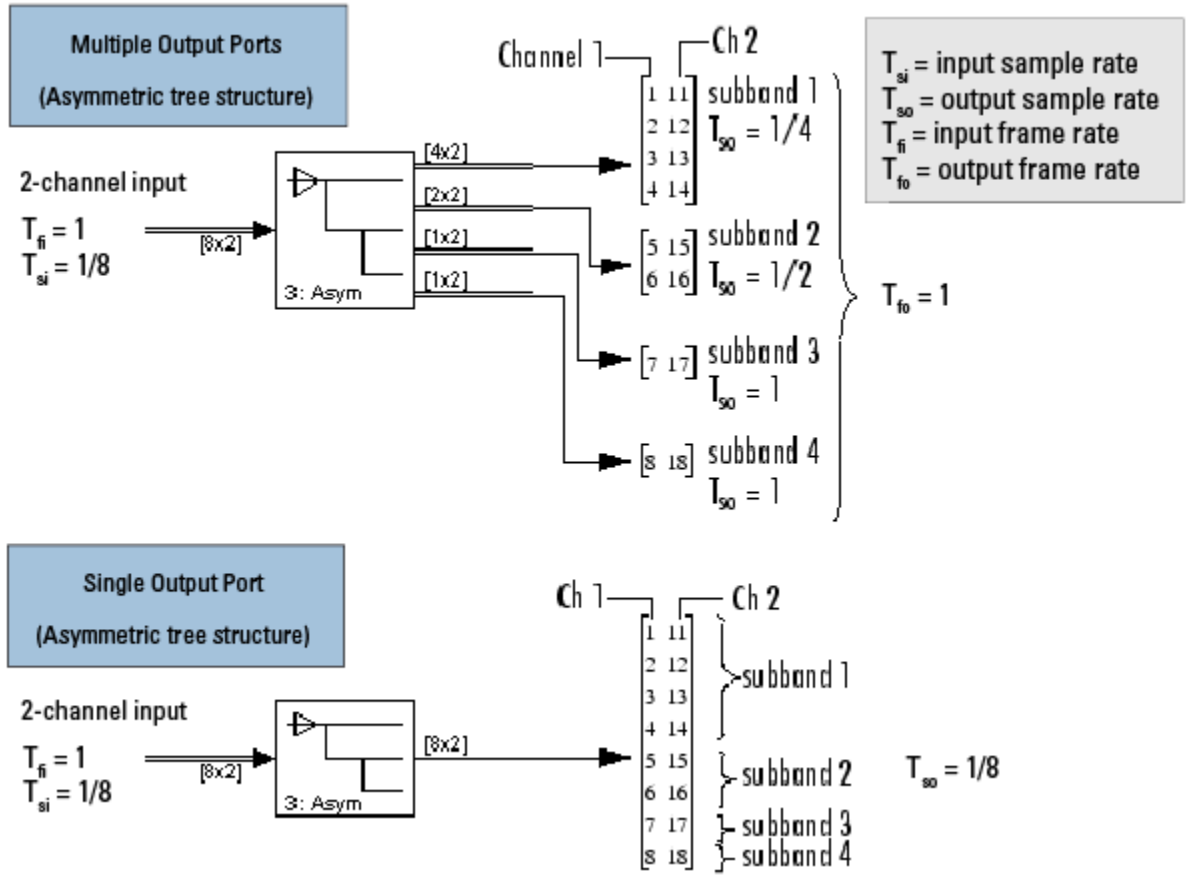

For an illustration of why the above input requirements exist, see the figure “Outputs of a 3-Level Asymmetric Dyadic Analysis Filter Bank” on page 2-472.

Output Characteristics

The output characteristics vary depending on the block's parameter settings, as summarized in the following list and figure:

- **Number of levels** parameter set to n
- **Tree structure** parameter setting:
 - **Asymmetric** — Block produces $n+1$ output subbands
 - **Symmetric** — Block produces 2^n output subbands
- **Output** parameter setting can be **Multiple ports** or **Single port**. When you set the **Output** parameter to **Single port**, the block outputs one vector or matrix of concatenated subbands. The following figure illustrates the difference between the two settings for a 3-level asymmetric dyadic analysis filter bank. For an explanation of the illustrated output characteristics, see the table Output Characteristics for an n-Level Dyadic Analysis Filter Bank.

For more information about the filter bank levels and structures, see “Dyadic Analysis Filter Banks”.

Outputs of a 3-Level Asymmetric Dyadic Analysis Filter Bank

The following table summarizes the different output characteristics of the block when it is set to output from single or multiple ports.

Output Characteristics for an n-Level Dyadic Analysis Filter Bank

	Single Output Port	Multiple Output Ports
Output Description	Block concatenates all the subbands into one vector or matrix, and outputs the concatenated subbands from a single output port. Each output column contains subbands of the corresponding input channel.	Block outputs each subband from a separate output port. The topmost port outputs the subband with the highest frequencies. Each output column contains a subband for the corresponding input channel.
Output Frame Rate	<i>Not applicable</i>	Same as input frame rate (However, the output frame sizes can vary, so the output sample rates can vary.)
Output Dimensions (Frame Size)	Same number of rows and columns as the input.	<p>The output has the same number of columns as the input. The number of output rows is the output frame size. For an input with frame size M_i output y_k has frame size $M_{o,k}$:</p> <ul style="list-style-type: none"> • Symmetric — All outputs have the frame size, $M_i / 2^n$. • Asymmetric — The frame size of each output (except the last) is half that of the output from the previous level. The outputs from the last two output ports have the same frame size since they originate from the same level in the filter bank. $M_{o,k} = \begin{cases} M_i/2^k & (1 \leq k \leq n) \\ M_i/2^n & (k = n + 1) \end{cases}$
Output Sample Rate	Same as input sample rate.	<p>Though the outputs have the same frame rate as the input, they have different frame sizes than the input. Thus, the output sample rates, $F_{so, k}$, are different from the input sample rate, F_{si}:</p> <ul style="list-style-type: none"> • Symmetric — All outputs have the sample rate $F_{si} / 2^n$. • Asymmetric — $F_{so,k} = \begin{cases} F_{si}/2^k & (1 \leq k \leq n) \\ F_{si}/2^n & (k = n + 1) \end{cases}$

Wavelet Filter Banks

- “Multilevel Filter Banks”

Filter Bank Filters

You must specify the highpass and lowpass filters in the filter bank by setting the **Filter** parameter to one of the following options:

- **User defined** — Allows you to explicitly specify the filters with two vectors of filter coefficients in the **Lowpass FIR filter coefficients** and **Highpass FIR filter coefficients** parameters. The block uses the same lowpass and highpass filters throughout the filter bank. The two filters should be halfband filters, where each filter passes the frequency band that the other filter stops.
- **Wavelet** such as **Biorthogonal** or **Daubechies** — The block uses the specified wavelet to construct the lowpass and highpass filters using the Wavelet Toolbox `wfilters` function. Depending on the wavelet, the block might enable either the **Wavelet order** or **Filter order [synthesis / analysis]** parameter. (The latter parameter allows you to specify different wavelet orders for the analysis and synthesis filter stages.) You must have a Wavelet Toolbox license to use wavelets.

Specifying Filters with the Filter Parameter and Related Parameters

Filter	Sample Setting for Related Filter Specification Parameters	Corresponding Wavelet Function Syntax
User-defined	Filters based on Daubechies wavelets with wavelet order 3: <ul style="list-style-type: none"> • Lowpass FIR filter coefficients = [0.0352 -0.0854 -0.1350 0.4599 0.8069 0.3327] • Highpass FIR filter coefficients = [-0.3327 0.8069 -0.4599 -0.1350 0.0854 0.0352] 	None
Haar	None	<code>wfilters('haar')</code>
Daubechies	Wavelet order = 4	<code>wfilters('db4')</code>
Symlets	Wavelet order = 3	<code>wfilters('sym3')</code>
Coiflets	Wavelet order = 1	<code>wfilters('coif1')</code>
Biorthogonal	Filter order [synthesis / analysis] = [3/1]	<code>wfilters('bior3.1')</code>
Reverse Biorthogonal	Filter order [synthesis / analysis] = [3/1]	<code>wfilters('rbio3.1')</code>
Discrete Meyer	None	<code>wfilters('dmey')</code>

Examples

Wavelets

The primary application for dyadic analysis filter banks and dyadic synthesis filter banks is coding for data compression using wavelets.

At the transmitting end, the output of the dyadic analysis filter bank is fed to a lossy compression scheme, which typically assigns the number of bits for each filter bank output in proportion to the relative energy in that frequency band. This represents the more powerful signal components by a greater number of bits than the less powerful signal components.

At the receiving end, the transmission is decoded and fed to a dyadic synthesis filter bank to reconstruct the original signal. The filter coefficients of the complementary analysis and synthesis stages are designed to cancel aliasing introduced by the filtering and resampling.

See “Calculate Channel Latencies Required for Wavelet Reconstruction” for an example using the Dyadic Analysis and Dyadic Synthesis Filter Bank blocks.

Examples

See the floating-point frame-based version of the DSP System Toolbox “Wavelet Reconstruction and Noise Reduction” example, which uses the Dyadic Analysis Filter Bank and Dyadic Synthesis Filter Bank blocks.

Parameters

The parameters displayed in the block dialog vary depending on the setting of the **Filter** parameter. Only some of the parameters described below are visible in the dialog box at any one time.

Filter

The type of filter used to determine the high- and low-pass FIR filters in the filter bank:

Select **User defined** to explicitly specify the filter coefficients in the **Lowpass FIR filter coefficients** and **Highpass FIR filter coefficients** parameters.

Select a wavelet such as **Biorthogonal** or **Daubechies** to specify a wavelet-based filter. The block uses the Wavelet Toolbox `wfilters` function to construct the filters. Extra parameters such as **Wavelet order** or **Filter order [synthesis / analysis]** might become enabled. For a list of the supported wavelets, see [Specifying Filters with the Filter Parameter and Related Parameters](#).

Lowpass FIR filter coefficients

A vector of filter coefficients (descending powers of z) that specifies coefficients used by all the lowpass filters in the filter bank. This parameter is enabled when you set **Filter** to **User defined**. The lowpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Highpass FIR filter coefficients** parameter. The default values of this parameter specify a filter based on a Daubechies wavelet with wavelet order 3.

Highpass FIR filter coefficients

A vector of filter coefficients (descending powers of z) that specifies coefficients used by all the highpass filters in the filter bank. This parameter is enabled when you set **Filter** to **User defined**. The highpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Lowpass FIR filter coefficients** parameter. The default values of this parameter specify a filter based on a Daubechies wavelet with wavelet order 3.

Wavelet order

The order of the wavelet selected in the **Filter** parameter. This parameter is enabled only when you set **Filter** to certain types of wavelets, as shown in the [Specifying Filters with the Filter Parameter and Related Parameters](#) table.

Filter order [synthesis / analysis]

The order of the wavelet for the synthesis and analysis filter stages. For example, when you set the **Filter** parameter to `Biorthogonal` and set the **Filter order [synthesis / analysis]** parameter to `[2 / 6]`, the block calls the `wfilters` function with input argument `'bior2.6'`. This parameter is enabled only when you set **Filter** to certain types of wavelets, as shown in [Specifying Filters with the Filter Parameter and Related Parameters](#).

Number of levels

The number of filter bank levels. An n -level asymmetric structure has $n+1$ outputs, and an n -level symmetric structure has 2^n outputs, as shown in [“Wavelet Filter Banks”](#) on page 2-473. The block's icon changes depending on the value of this parameter.

The default setting of this parameter is 2.

Tree structure

The structure of the filter bank: `Asymmetric`, or `Symmetric`. See [“Wavelet Filter Banks”](#) on page 2-473.

The default setting of this parameter is `Asymmetric` for the Dyadic Analysis Filter Bank block, and `Symmetric` for the DWT block.

Output

Set to `Multiple ports` to output each output subband on a separate port (the topmost port outputs the subband with the highest frequency band). Set to `Single port` to concatenate the subbands into one vector or matrix and output the concatenated subbands on a single port. For more information, see [“Output Characteristics”](#) on page 2-471.

The default setting of this parameter is `Multiple ports` for the Dyadic Analysis Filter Bank block, and `Single port` for the DWT block.

Dyadic Synthesis Filter Bank

Reconstruct signals from subbands with smaller bandwidths and slower sample rates or compute inverse discrete wavelet transform (IDWT)

Library

Filtering / Multirate Filters

dspmlti4

Description

Note This block always does frame-based processing, and its inputs must be of certain sizes. To use input subbands that do not fit the criteria of this block, use the Two-Channel Synthesis Subband Filter block. (You can connect multiple copies of the Two-Channel Synthesis Subband Filter block to create a multilevel dyadic synthesis filter bank.)

You can configure this block to compute the inverse discrete wavelet transform (IDWT) or reconstruct a signal from subbands with smaller bandwidths and slower sample rates. When the block computes the inverse discrete wavelet transform (IDWT) of the input, the output has the same dimensions as the input. Each column of the output is the IDWT of the corresponding input column. When reconstructing a signal, the block uses a series of highpass and lowpass FIR filters to reconstruct the signal from the input subbands, as illustrated in “Wavelet Filter Banks” on page 2-481 (the Asymmetric one). The reconstructed signal has a wider bandwidth and faster sample rate than the input subbands.

You can specify the filter bank's highpass and lowpass filters by providing vectors of filter coefficients. You can do so directly on the block mask, or, if you have a Wavelet Toolbox license, you can specify wavelet-based filters by selecting a wavelet from the **Filter** parameter. You must set the filter bank structure to asymmetric or symmetric, and specify the number of levels in the filter bank.

When you set the **Input** parameter to **Multiple ports**, you must provide each subband to the block through a different input port as a vector or matrix. You should input the highest frequency band through the topmost port. When you set the **Input** parameter to **Single port**, the block input must be a vector or matrix of concatenated subbands.

Note To use a dyadic synthesis filter bank to perfectly reconstruct the output of a dyadic analysis filter bank, the number of levels and tree structures of both filter banks *must* be the same. In addition, the filters in the synthesis filter bank *must* be designed to perfectly reconstruct the outputs of the analysis filter bank. Otherwise, the reconstruction is not perfect.

This block automatically computes wavelet-based perfect reconstruction filters when the wavelet selection in the **Filter** parameter of this block is the *same* as the **Filter** parameter setting of the corresponding Dyadic Analysis Filter Bank block. The use of wavelets requires a Wavelet Toolbox license. To learn how to design your own perfect reconstruction filters, see “References” on page 2-484.

Input Requirements

The inputs to this block are usually the outputs of a Dyadic Analysis Filter Bank block. Since the Dyadic Analysis Filter Bank block can output from either a single port or multiple ports, the Dyadic Synthesis Filter Bank block accepts inputs to either a single port or multiple ports.

The **Input** parameter sets whether the block accepts inputs from a single port or multiple ports, and thus determines the input requirements, as summarized in the following lists and figure.

Note Any output of a Dyadic Analysis Filter Bank block whose parameter settings match the corresponding settings of this block is a valid input to this block. For example, the setting of the Dyadic Analysis Filter Bank block parameter, **Output**, must be the same as this block's **Input** parameter (Single port or Multiple ports).

Valid Inputs for Input Set to Single Port

- Inputs must be vectors or matrices of concatenated subbands.
- Each input column contains the subbands for an independent signal.
- Upper input rows contain the high-frequency subbands, and the lower rows contain the low-frequency subbands.

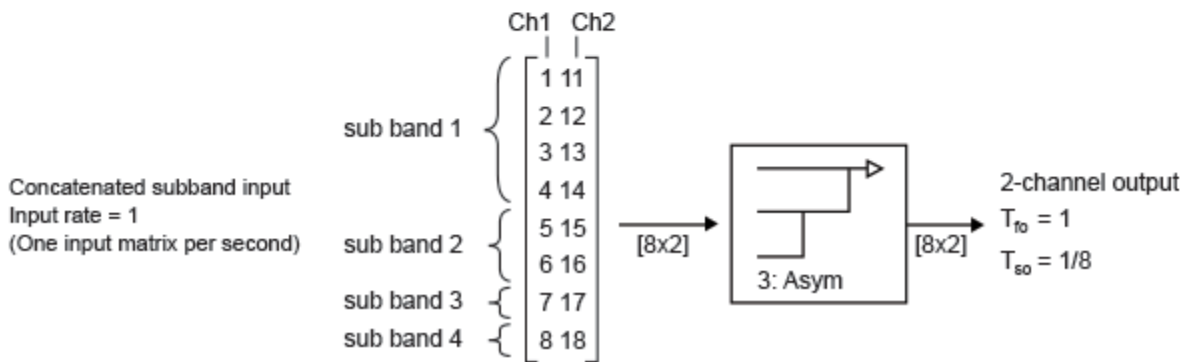

Valid Inputs for Input Set to Multiple Ports

- Each subband must be provided as a vector or matrix to separate block input ports.
- The columns of each input contains a subband for an independent signal.
- The input to the topmost input port is the subband containing the highest frequencies, and the input to the bottommost port is the subband containing the lowest frequencies.

Multiple Input Ports
(Asymmetric tree structure)

Single Input Ports
(Asymmetric tree structure)

Valid Inputs to a 3-Level Asymmetric Dyadic Synthesis Filter Bank

For general information about the filter banks, see “Dyadic Synthesis Filter Banks”.

Output Characteristics

The following table summarizes the output characteristics for both types of inputs. For an illustration of why the output characteristics exist, see the figure “Valid Inputs to a 3-Level Asymmetric Dyadic Synthesis Filter Bank” on page 2-480.

	Input = Multiple ports	Input = Single port (Concatenated Subband Inputs)
Output Frame Rate	Same as the input frame rate.	Same as the input rate (the rate of the concatenated subband inputs).
Output Frame Dimensions	<ul style="list-style-type: none"> The output has the same number of columns as the inputs. The number of output rows depends on the tree structure of the filter bank: <ul style="list-style-type: none"> Asymmetric — The number of output rows is twice the number of rows in the input to the topmost input port. Symmetric — The number of output rows is the product of the number of input ports and the number of rows in an input to any input port. 	The output has the same number of rows and columns as the input.

For general information about the filter banks, see “Dyadic Synthesis Filter Banks”.

Wavelet Filter Banks

- “Multilevel Filter Banks”

Filter Bank Filters

You must specify the highpass and lowpass filters in the filter bank by setting the **Filter** parameter to one of the following options:

- User defined** — Allows you to explicitly specify the filters with two vectors of filter coefficients in the **Lowpass FIR filter coefficients** and **Highpass FIR filter coefficients** parameters. The block uses the same lowpass and highpass filters throughout the filter bank. The two filters should be halfband filters, where each filter passes the frequency band that the other filter stops. To use this block to perfectly reconstruct a signal decomposed by a Dyadic Analysis Filter Bank block, the filters in this block *must* be designed to perfectly reconstruct the outputs of the analysis filter bank. To learn how to design your own perfect reconstruction filters, see “References” on page 2-484.
- Wavelet** such as `Biorthogonal` or `Daubechies` — The block uses the specified wavelet to construct the lowpass and highpass filters using the Wavelet Toolbox function `wfilters`. Depending on the wavelet, the block might enable either the **Wavelet order** or **Filter order [synthesis / analysis]** parameter. (The latter parameter allows you to specify different wavelet orders for the analysis and synthesis filter stages.) To use this block to reconstruct a signal decomposed by a Dyadic Analysis Filter Bank block, you must set both blocks to use the same wavelets with the same order. You must have a Wavelet Toolbox license to use wavelets.

Specifying Filters with the Filter Parameter and Related Parameters

Filter	Sample Setting for Related Filter Specification Parameters	Corresponding Wavelet Function Syntax
User-defined	Filters based on Daubechies wavelets with wavelet order 3: <ul style="list-style-type: none"> • Lowpass FIR filter coefficients = [0.0352 -0.0854 -0.1350 0.4599 0.8069 0.3327] • Highpass FIR filter coefficients = [-0.3327 0.8069 -0.4599 -0.1350 0.0854 0.0352] 	None
Haar	None	wfilters('haar')
Daubechies	Wavelet order = 4	wfilters('db4')
Symlets	Wavelet order = 3	wfilters('sym3')
Coiflets	Wavelet order = 1	wfilters('coif1')
Biorthogonal	Filter order [synthesis / analysis] = [3/1]	wfilters('bior3.1')
Reverse Biorthogonal	Filter order [synthesis / analysis] = [3/1]	wfilters('rbio3.1')
Discrete Meyer	None	wfilters('dmey')

Examples

See “Examples” on page 2-474 on the Dyadic Analysis Filter Bank block reference page.

Parameters

The parameters displayed in the block dialog vary depending on the setting of the **Filter** parameter. Only some of the parameters described below are visible in the dialog box at any one time.

Note To use this block to reconstruct a signal decomposed by a Dyadic Analysis Filter Bank block, all the parameters in this block must be the same as the corresponding parameters in the Dyadic Analysis Filter Bank block (except the **Lowpass FIR filter coefficients** and **Highpass FIR filter coefficients**; see the descriptions of these parameters).

Filter

The type of filter used to determine the high- and low-pass FIR filters in the filter bank:

- Select **User defined** to explicitly specify the filter coefficients in the **Lowpass FIR filter coefficients** and **Highpass FIR filter coefficients** parameters.
- Select a wavelet such as **Biorthogonal** or **Daubechies** to specify a wavelet-based filter. The block uses the Wavelet Toolbox `wfilters` function to construct the filters. Extra parameters such as **Wavelet order** or **Filter order [synthesis / analysis]** might become enabled. For a list of the supported wavelets, see the table Specifying Filters with the Filter Parameter and Related Parameters.

Lowpass FIR filter coefficients

A vector of filter coefficients (descending powers of z) that specifies coefficients used by all the lowpass filters in the filter bank. This parameter is enabled when you set **Filter** to **User defined**. The lowpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Highpass FIR filter coefficients** parameter. To perfectly reconstruct a signal decomposed by the Dyadic Analysis Filter Bank, the filters in this block *must* be designed to perfectly reconstruct the outputs of the analysis filter bank. Otherwise, the reconstruction is not perfect. The default values of this parameter specify a perfect reconstruction filter for the default settings of the Dyadic Analysis Filter Bank (based on a Daubechies wavelet with wavelet order 3).

Highpass FIR filter coefficients

A vector of filter coefficients (descending powers of z) that specifies coefficients used by all the highpass filters in the filter bank. This parameter is enabled when you set **Filter** to **User defined**. The highpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Lowpass FIR filter coefficients** parameter. To perfectly reconstruct a signal decomposed by the Dyadic Analysis Filter Bank, the filters in this block *must* be designed to perfectly reconstruct the outputs of the analysis filter bank. Otherwise, the reconstruction is not perfect. The default values of this parameter specify a perfect reconstruction filter for the default settings of the Dyadic Analysis Filter Bank (based on a Daubechies wavelet with wavelet order 3).

Wavelet order

The order of the wavelet selected in the **Filter** parameter. This parameter is enabled only when you set **Filter** to certain types of wavelets, as shown in the table Specifying Filters with the Filter Parameter and Related Parameters.

Filter order [synthesis / analysis]

The order of the wavelet for the synthesis and analysis filter stages. For example, when you set the **Filter** parameter to **Biorthogonal** and set the **Filter order [synthesis / analysis]** parameter to [2 / 6], the block calls the `wfilters` function with input argument 'bior2.6'. This parameter is enabled only when you set **Filter** to certain types of wavelets, as shown in Specifying Filters with the Filter Parameter and Related Parameters.

Number of levels

The number of filter bank levels. An n -level asymmetric structure has $n+1$ inputs, and an n -level symmetric structure has 2^n inputs, as shown in "Wavelet Filter Banks" on page 2-481.

The default setting of this parameter is 2.

Tree structure

The structure of the filter bank: **Asymmetric**, or **Symmetric**. See "Wavelet Filter Banks" on page 2-481.

The default setting of this parameter is **Asymmetric** for the Dyadic Synthesis Filter Bank block, and **Symmetric** for the IDWT block.

Input

Set to **Multiple ports** to accept each input subband at a separate port (the topmost port accepts the subband with the highest frequency band). Set to **Single port** to accept one vector or matrix of concatenated subbands at a single port. For more information, see "Input Requirements" on page 2-479.

The default setting of this parameter is **Multiple ports** for the Dyadic Synthesis Filter Bank block, and **Single port** for the IDWT block.

Edge Detector

Detect transition from zero to nonzero value

Library

Signal Management / Switches and Counters

dspswit3

Description

The Edge Detector block generates an impulse (the value 1) in a given output channel when the corresponding channel of the input transitions from zero to a nonzero value. When the input does not transition from zero to a nonzero value, the block generates a zero in the corresponding output channel.

This block supports only discrete-time fixed-step signals. Continuous signals are not supported.

The output has the same dimension and sample rate as the input. When you set the **Input processing** parameter to *Columns as channels (frame based)*, the block counts an edge that is split across two consecutive frames in the frame that contains the nonzero value. For example, if there is a zero at the bottom of the first frame and a nonzero value at the top of the second frame, the block counts the edge in the second frame.

Examples

In the `ex_edgedetector_ref` model, the **Input processing** parameter of the Edge Detector block is set to *Columns as channels (frame based)*. Thus, the block interprets the 3-by-2 input as a multichannel signal with a frame size of 3. The Matrix Concatenate block concatenates the two input channels of the original signal with the two output channels of the Edge Detector block to create the four-channel workspace variable `sp_examples_yout`.

As shown in the following figure, the block finds edges at sample 7 in channel 1, and at samples 2, 5, and 9 in channel 2.

Parameters

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- Columns as channels (frame based) (default) — When you select this option, the block treats each column of the input as a separate channel.
- Elements as channels (sample based) — When you select this option, the block treats each element of the input as a separate channel.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed and unsigned)
- Boolean — The block might output Boolean values depending on the input data type, and whether Boolean support is enabled or disabled.
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers
- Enumerated

Event-Count Comparator

Detect threshold crossing of accumulated nonzero inputs

Library

Signal Management / Switches and Counters

dspswit3

Description

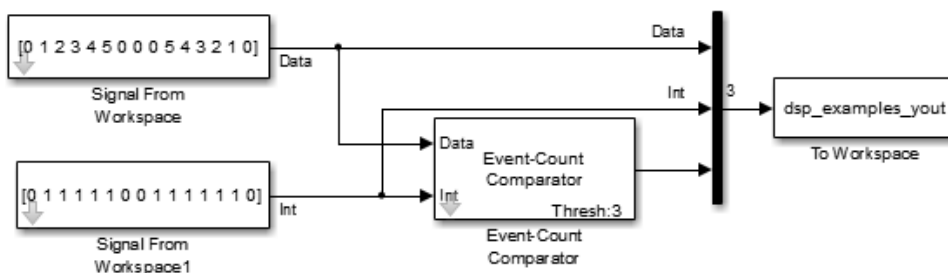

The Event-Count Comparator block records the number of nonzero inputs to the Data port during the period that the block is enabled by a high signal (the value 1) at the Int port. Both inputs must be scalars.

When the number of accumulated nonzero inputs first equals the **Event threshold** setting, the block waits one additional sample interval, and then sets the output high (1). The block holds the output high until recording is restarted by a low-to-high (0-to-1) transition at the Int port.

The Event-Count Comparator block accepts real and complex floating-point and fixed-point inputs. However, because the block has discrete state, it does not support constant or continuous sample times. Therefore, at least one input or output port of the Event-Count Comparator block must be connected to a block whose **Sample time** parameter is discrete. The Event-Count Comparator block inherits this non-infinite discrete sample time.

Examples

In the `ex_eventcountcomp_ref` model, the Event-Count Comparator block (**Event threshold = 3**) detects two threshold crossings in the input to the Data port, one at sample 4 and one at sample 12.

All inputs and outputs are multiplexed into the workspace variable `yout`, whose contents are shown in the figure below. The two left columns in the illustration show the inputs to the Data and Int ports, the center column shows the state of the block's internal counter, and the right column shows the block's output.

Parameters

Event threshold

Specify the value against which to compare the number of nonzero inputs. Tunable (Simulink).

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed and unsigned)
- Boolean
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers
- Enumerated

Extract Triangular Matrix

Extract lower or upper triangle from input matrices

Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

dspmtx3

Description

The Extract Triangular Matrix block creates a triangular matrix output from the upper or lower triangular elements of an M -by- N input matrix. The block treats length- M unoriented vector inputs as an M -by-1 matrix.

The **Extract** parameter selects between the two components of the input:

- **Upper** — Copies the elements on and above the main diagonal of the input matrix to an output matrix of the same size. The first *row* of the output matrix is therefore identical to the first *row* of the input matrix. The elements below the main diagonal of the output matrix are zero.
- **Lower** — Copies the elements on and below the main diagonal of the input matrix to an output matrix of the same size. The first *column* of the output matrix is therefore identical to the first *column* of the input matrix. The elements above the main diagonal of the output matrix are zero.

Examples

The `ex_extracttriang_ref` model below shows the extraction of upper and lower triangles from a 5-by-3 input matrix.

Parameters

Extract

The component of the matrix to copy to the output: upper triangle or lower triangle.

Simulate using

Code generation (default) — Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than **Interpreted execution**.

Interpreted execution — Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than **Code generation**.

Supported Data Types

Port	Supported Data Types
A	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
U	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
L	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Farrow Rate Converter

Polynomial sample-rate converter with arbitrary conversion factor

Library: DSP System Toolbox / Signal Operations

Description

The Farrow Rate Converter block converts the sample rate of an input signal using polynomial-fit sample-rate conversion. Polynomial-based filters are efficient at implementing fractional sample rate conversion. Farrow structures are implementations of polynomial-based filters. This block uses a Farrow structure to implement arbitrary rate-change factors efficiently. The rate-change factors can be irrational.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Specify the input signal as a real or a complex-valued scalar, vector, or a matrix signal.

The block treats each column of the input signal as a separate channel. If the input is a two-dimensional signal, the first dimension represents the channel length (or frame size) and the second dimension represents the number of channels. If the input is a one-dimensional signal, then the block interprets it as a single-channel signal.

When you input a variable-size signal (frame length changes during simulation), the frame length of the signal can be arbitrary. That is, the input frame length does not have to be a multiple of the decimation factor. When you input a fixed-size signal (frame length does not change during simulation), the frame length can be arbitrary only when you select the **Allow arbitrary frame length for fixed-size input signals** parameter.

To determine the decimation factor, click the **View Info** button.

Data Types: single | double | int8 | int16 | int32 | int64 | fixed point

Output

Port_1 — Rate converted signal

scalar | vector | matrix

The Farrow Rate Converter block outputs a signal that has the same data type and complexity as the input signal.

The output signal dimensions depend on the input signal dimensions, the overall interpolation and decimation factors of the Farrow Rate Converter block, and whether you select the **Allow arbitrary**

frame length for fixed-size input signals parameter. You can determine the overall interpolation factor L and the decimator factor M by clicking the **View Info** button in the block dialog box.

This table provides more details on the dimensions of the output signal when you input a fixed-size input signal.

Fixed-Size Input Signal

Input Signal	Output Signal Dimensions
P -by-1 column vector, where P is a multiple of the decimation factor M	(LP/M) -by-1, where L is the interpolation factor
P -by-1 column vector, where P is not a multiple of the decimation factor M	$\text{ceil}(LP/M)$ -by-1 when you select Allow arbitrary frame length for fixed-size input signals . If you do not select Allow arbitrary frame length for fixed-size input signals , the block errors.
P -by- Q matrix, where P is a multiple of the decimation factor M	(LP/M) -by- Q
P -by- Q matrix, where P is not a multiple of the decimation factor M	$\text{ceil}(LP/M)$ -by- Q when you select Allow arbitrary frame length for fixed-size input signals . If you do not select Allow arbitrary frame length for fixed-size input signals , the block errors.

This table gives more details on the dimensions of the output signal when you input a variable-size input signal. When you input a variable-size signal (frame length changes during simulation), the **Allow arbitrary frame length for fixed-size input signals** appears on the block dialog box but does not have any impact on the input frame length. You can input a variable-size signal of any frame length even if you do not select the **Allow arbitrary frame length for fixed-size input signals** parameter.

Variable-Size Input Signal

Input Signal	Output Signal Dimensions
P -by- Q	$\text{ceil}(LP/M)$ -by- Q

Data Types: single | double | int8 | int16 | int32 | int64 | fixed point

Parameters

Main Tab

Sample rate of input signal (Hz) — Sample rate of input signal in Hz

48e3 (default) | positive scalar

Specify the sample rate of the input signal as a positive scalar in Hz. The input sample rate must be greater than the bandwidth of interest.

Sample rate of output signal (Hz) — Sample rate of output signal in Hz

96e3 (default) | positive scalar in Hz

Specify the sample rate of the output signal as a positive scalar in Hz. The output sample rate must be higher or lower than the input sample rate.

Tolerance for output sample rate — Maximum tolerance for output sample rate

0 (default) | positive scalar

Specify the maximum tolerance for the output sample rate as a positive scalar in the range [00.5].

The actual output sample rate varies but is within the specified range. For example, if you set the **Tolerance for output sample rate** to 0.01, then the actual output sample rate is in the range given by sample rate of output signal $\pm 1\%$. This flexibility allows for a simpler filter design.

Filter Specification method — Method for specifying filter coefficients

Polynomial order (default) | Coefficients

Specify the method the block uses to determine the polynomial interpolator coefficients as one of the following:

- **Polynomial order** — Specify the order of the Lagrange interpolation filter polynomial through the **Polynomial order** parameter.
- **Coefficients** — Specify the polynomial coefficients directly through the **Coefficients** parameter.

Coefficients — Filter polynomial coefficients

[-1 1; 1 0] (default) | real-valued square matrix

Specify the filter polynomial coefficients as a real-valued square matrix.

Dependencies

To enable this parameter, set **Filter specification method** to **Coefficients**.

Polynomial order — Order of Lagrange-interpolation-filter polynomial

3 (default) | positive integer less than or equal to 4

Specify the order of the Lagrange-interpolation-filter polynomial as 1, 2, 3, or 4.

Dependencies

To enable this parameter, set **Filter specification method** to **Polynomial order**.

Allow arbitrary frame length for fixed-size input signals — Allow arbitrary frame length for fixed-size input signals

on (default) | off

Specify whether fixed-size input signals (whose size does not change during simulation) can have an arbitrary frame length, where the frame length does not have to be a multiple of the decimation

factor. The block uses this parameter setting only for fixed-size input signals and ignores this parameter if the input has a variable-size.

When the input signal is a variable-size signal, the signal can have arbitrary frame length, that is, the frame length does not have to be a multiple of the decimation factor.

For fixed-size input signals, if you:

- Select the **Allow arbitrary frame length for fixed-size input signals** parameter, the frame length of the signal does not have to be a multiple of the decimation factor. If the input is not a multiple of the decimation factor, then the output is generally a variable-size signal. Therefore, to support arbitrary input size, the block must also support variable-size operations, which you can enable by selecting the **Allow arbitrary frame length for fixed-size input signals** parameter.
- Clear the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length must be a multiple of the decimation factor.

View Filter Response — View filter response

button

Opens the FVTool and displays the magnitude/phase response of the Farrow Rate Converter. The response is based on the block parameters. FVTool updates when you change the parameters.

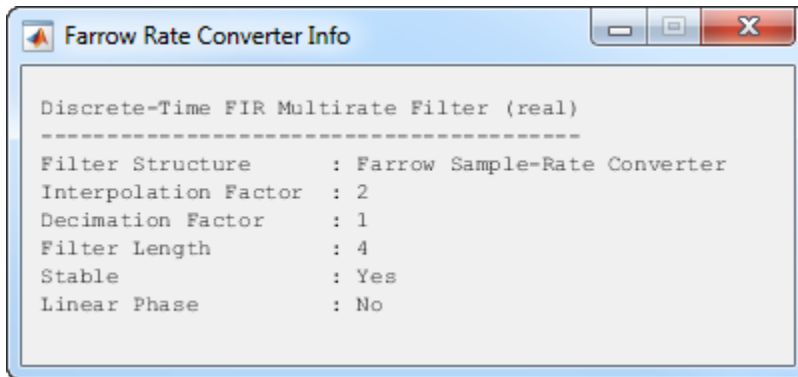

To update the magnitude response while FVTool is running, modify the parameters in the dialog box and click **Apply**.

View Info – View info
button

Click this button for the block to display the following information about the Farrow filter system:

- Filter Structure
- Interpolation Factor
- Decimation Factor
- Filter Length
- Stable
- Linear Phase

This button brings the functionality of the `info` method into the Simulink environment.

Simulate using — Type of simulation to run

Code generation (default) | Interpreted execution

Type of simulation to run. You can set this parameter to:

- **Code generation** -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than **Interpreted execution**.
- **Interpreted execution** -- Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than **Code generation**.

Data Types Tab

Rounding mode — Rounding mode

Floor (default) | Ceiling | Convergent | Nearest | Round | Zero

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

Saturate on integer overflow — Method of overflow action

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see `overflow mode for fixed-point operations`.

Coefficients — Data type of filter coefficients

`fixdt(1,16)` (default) | `fixdt(1,16,0)`

Specify the data type of the filter coefficients as a signed fixed-point object. The default `fixdt(1,16)` corresponds to a signed fixed-point type object with 16-bit coefficients. For maximum precision, the block determines the fraction length based on the coefficient values.

Fractional Delay — Data type of fractional delay

`fixdt(0,8)` (default) | `fixdt(0,16)`

Specify the data type of the fractional delay as an unsigned fixed-point object. The default `fixdt(0,8)` corresponds to an unsigned fixed-point data type object with 8-bit word length. For maximum precision, the block computes the fractional length based on the fractional delay values.

Multiplicand — Data type of multiplicand

`fixdt(1,16,13)` (default) | `fixdt(1,16,0)`

Specify the multiplicand data type as a signed fixed-point object. The default `fixdt(1,16,13)` corresponds to a signed fixed-point multiplicand data type with 16-bit word length and 13-bit fraction length.

Output — Data type of output

Inherit: Same word length as input (default) | Inherit: Same as accumulator | `fixdt(1,16)` | `fixdt(1,16,0)`

Specify the word length and fraction length of the output data type as one of the following:

- `Inherit: Same word length as input` (default) — Output word length and fraction lengths are the same as the input.
- `Inherit: Same as accumulator` — Output word length and fraction lengths are the same as the accumulator.
- `fixdt(1,16)` — Signed fixed-point data type with 16-bit word length. For maximum precision, the block computes the fraction length based on the input range and preserves the dynamic range of the input.
- `fixdt(1,16,0)` — Signed fixed-point data type with 16-bit word length and zero fraction length.

Output Minimum — Minimum value that the block can output

`[]` (default) | scalar

Specify the minimum value that the block can output. Simulink software uses this minimum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

Output Maximum — Maximum value that the block can output

[] (default) | scalar

Specify the maximum value that the block can output. Simulink software uses this maximum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

Algorithms

Farrow filters implement piecewise polynomial interpolation using Horner’s rule to compute samples from the polynomial. The polynomial coefficients used to fit the input samples correspond to the Lagrange interpolation coefficients.

Once a polynomial is fitted to the input data, the value of the polynomial can be calculated at any point. Therefore, a polynomial filter enables interpolation at arbitrary locations between input samples.

You can use a polynomial of any order to fit to the existing samples. However, since large-order polynomials frequently oscillate, polynomials of order 1, 2, 3, or 4 are used in practice.

The algorithm computes interpolated values at the desired locations by varying only the fractional delay μ . This value is the interval between the previous input sample and the current output sample. All filter coefficients remain constant.

- The input samples are filtered using $M + 1$ FIR filters, where M is the polynomial order.
- The outputs of these filters are multiplied by the fractional delay, μ .
- The output is the sum of the multiplication results.

Version History

Introduced in R2015b

Support for arbitrary input frame length

Starting in R2022b, this block supports input signals with arbitrary frame lengths when the:

- Input signal is a fixed-size signal (frame length does not change during simulation) and you select the **Allow arbitrary frame length for fixed-size input signals** parameter
- Input signal is a variable-size signal (frame length changes during simulation)

When this block supports an arbitrary frame length input signal, the input frame length does not have to be a multiple of the decimation factor.

Extended Capabilities

C/C++ Code Generation

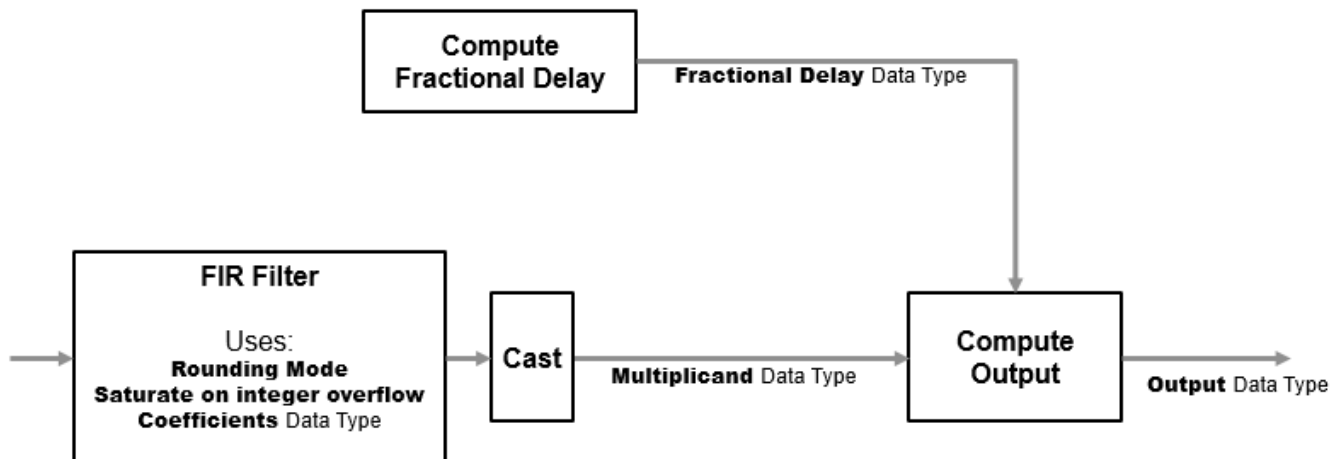

Generate C and C++ code using Simulink® Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

If the input is fixed point, it must be a signed integer or signed fixed point with a power-of-two slope and zero bias.

The diagram shows the data types that the Farrow Rate Converter block uses for fixed-point signals and floating-point signals. You can specify these data types using the parameters on the **Data Types** tab. If the input is floating point, all data types in the filter are the same as the input data type, single or double.

If the input is fixed point, the FIR filter defines internal data types using the **Rounding mode**, **Saturate on integer overflow**, and **Coefficients** parameters. The accumulators and products within the FIR filter use full-precision data types. The block casts the output of the FIR filter to the **Multiplicand** data type.

Fast Block LMS Filter

Compute output, error, and weights using LMS adaptive algorithm

Library

Filtering / Adaptive Filters

dspadpt3

Description

The Fast Block LMS Filter block implements an adaptive least mean-square (LMS) filter, where the adaptation of the filter weights occurs once for every block of data samples. The block estimates the filter weights, or coefficients, needed to convert the input signal into the desired signal. Connect the signal you want to filter to the Input port. The input signal can be a scalar or a column vector. Connect the signal you want to model to the Desired port. The desired signal must have the same data type, complexity, and dimensions as the input signal. The Output port outputs the filtered input signal. The Error port outputs the result of subtracting the output signal from the desired signal.

The block calculates the filter weights using the Block LMS Filter equations. For more information, see Block LMS Filter. The Fast Block LMS Filter block implements the convolution operation involved in the calculations of the filtered output, y , and the weight update function in the frequency domain using the FFT algorithm used in the Overlap-Save FFT Filter block. See Overlap-Save FFT Filter (Obsolete) for more information.

Use the **Filter length** parameter to specify the length of the filter weights vector.

The **Block size** parameter determines how many samples of the input signal are acquired before the filter weights are updated. The input frame length must be a multiple of the **Block size** parameter.

The **Step-size (μ)** parameter corresponds to μ in the equations. You can either specify a step-size using the input port, Step-size, or enter a value in the Block Parameters: Block LMS Filter dialog box.

Use the **Leakage factor (0 to 1)** parameter to specify the leakage factor, $0 < 1 - \mu\alpha \leq 1$, in the leaky LMS algorithm shown below.

$$\mathbf{w}(k) = (1 - \mu\alpha)\mathbf{w}(k - 1) - f(\mathbf{u}(n), e(n), \mu)$$

Enter the initial filter weights, $\mathbf{w}(0)$, as a vector or a scalar in the **Initial value of filter weights** text box. When you enter a scalar, the block uses the scalar value to create a vector of filter weights. This vector has length equal to the filter length and all of its values are equal to the scalar value.

When you select the **Adapt port** check box, an Adapt port appears on the block. When the input to this port is nonzero, the block continuously updates the filter weights. When the input to this port is zero, the filter weights remain at their current values.

When you want to reset the value of the filter weights to their initial values, use the **Reset input** parameter. The block resets the filter weights whenever a reset event is detected at the Reset port. The reset signal rate must be the same rate as the data signal input.

From the **Reset input** list, select **None** to disable the Reset port. To enable the Reset port, select one of the following from the **Reset input** list:

- **Rising edge** — Triggers a reset operation when the Reset input does one of the following:
 - Rises from a negative value to a positive value or zero
 - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)

- **Falling edge** — Triggers a reset operation when the Reset input does one of the following:
 - Falls from a positive value to a negative value or zero
 - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)

- **Either edge** — Triggers a reset operation when the Reset input is a Rising edge or Falling edge (as described above)
- **Non-zero sample** — Triggers a reset operation at each sample time that the Reset input is not zero

Select the **Output filter weights** check box to create a Wts port on the block. For each iteration, the block outputs the current updated filter weights from this port.

Parameters

Filter length

Enter the length of the FIR filter weights vector. The sum of the **Block size** and the **Filter length** must be a power of 2.

Block size

Enter the number of samples to acquire before the filter weights are updated. The number of rows in the input must be an integer multiple of the **Block size**. The sum of the **Block size** and the **Filter length** must be a power of 2.

Specify step-size via

Select Dialog to enter a value for mu, or select Input port to specify mu using the Step-size input port.

Step-size (mu)

Enter the step-size. Tunable (Simulink).

Leakage factor (0 to 1)

Enter the leakage factor, $0 < 1 - \mu\alpha \leq 1$. Tunable (Simulink).

Initial value of filter weights

Specify the initial values of the FIR filter weights.

Adapt port

Select this check box to enable the Adapt input port.

Reset input

Select this check box to enable the Reset input port.

Output filter weights

Select this check box to export the filter weights from the Wts port.

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the memcopy or memset function (string.h) under certain conditions.

FFT

Fast Fourier transform (FFT) of input

Library: DSP System Toolbox / Transforms

Description

The FFT block computes the fast Fourier transform (FFT) across the first dimension of an N -D input array, u . The block uses one of two possible FFT implementations. You can select an implementation based on the FFTW library or an implementation based on a collection of Radix-2 algorithms. To allow the block to choose the implementation, you can select **Auto**. For more information about the FFT implementations, see “Algorithms” on page 2-514.

For user-specified FFT lengths not equal to P , zero padding or truncating, or modulo-length data wrapping occurs before the FFT operation. For an FFT with $P \leq M$:

```
y = fft(u,M) % P ≤ M
```

Wrapping:

```
y(:,L) = fft(datawrap(u(:,L),M)) % P > M; L = 1, ..., N
```

Truncating:

```
y(:,L) = fft(u,M) % P > M; L = 1, ..., N
```

Tip When the input length, P , is greater than the FFT length, M , you may see magnitude increases in your FFT output. These magnitude increases occur because the FFT block uses modulo- M data wrapping to preserve all available input samples.

To avoid such magnitude increases, you can truncate the length of your input sample, P , to the FFT length, M . To do so, place a Pad block before the FFT block in your model.

Ports

Input

Port_1 — Input signal

vector | matrix | N -D array

Input signal for computing the FFT. The block computes the FFT along the first dimension of the N -D input signal.

For more information on how the block computes the FFT, see “Description” on page 2-508 and “Algorithms” on page 2-514.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 – FFT of input

vector | matrix | N -D array

The FFT, computed across the first dimension of an N -D input array. When the output of the block has an integer or fixed-point data type, it is always signed.

The k th entry of the L th output channel, $y(k,L)$, equals the k th point of the M -point discrete Fourier transform (DFT) of the L th input channel:

$$y(k, L) = \sum_{p=1}^P u(p, L) e^{-j2\pi(p-1)(k-1)/M} \quad k = 1, \dots, M$$

For more information on how the block computes the FFT, see “Description” on page 2-508 and “Algorithms” on page 2-514.

Data Types: single | double | int8 | int16 | int32 | fixed point

Parameters

Main

FFT implementation – FFT implementation

Auto (default) | Radix-2 | FFTW

Set this parameter to FFTW to support an arbitrary length input signal. The block restricts generated code with FFTW implementation to host computers capable of running MATLAB.

Set this parameter to Radix-2 for bit-reversed processing, fixed or floating-point data, or portable C-code generation using the Simulink Coder. The dimension M of the M -by- N input matrix, must be a power of two. To work with other input sizes, use the Pad block to pad or truncate these dimensions to powers of two, or if possible choose the FFTW implementation. For more information about the algorithms used by the Radix-2 mode, see “Radix-2 Implementation” on page 2-514.

Set this parameter to Auto to let the block choose the FFT implementation. For floating-point inputs with non-power-of-two transform lengths, the FFTW algorithm is automatically chosen. Otherwise a Radix-2 algorithm is automatically chosen. For non-power-of-two transform lengths, the block restricts generated code to MATLAB host computers.

Output in bit-reversed order – Output in bit-reversed order

off (default) | on

Designate the order of the output channel elements relative to the ordering of the input elements. When you select this check box, the output channel elements appear in bit-reversed order relative to the input ordering. If you clear this check box, the output channel elements appear in linear order relative to the input ordering.

Note The FFT block calculates its output in bit-reversed order. Linearly ordering the FFT block output requires an extra bit-reversal operation. In many situations, you can increase the speed of the FFT block by selecting the **Output in bit-reversed order** check box.

For more information ordering of the output, see “Linear and Bit-Reversed Output Order”.

Dependencies

To enable this parameter, set **FFT implementation** to Auto or Radix-2.

Divide output by FFT length — Divide output by FFT length

off (default) | on

When you select this parameter, the block divides the output of the FFT by the FFT length. This option is useful when you want the output of the FFT to stay in the same amplitude range as its input. This is particularly useful when working with fixed-point data types.

Inherit FFT length from input dimensions — Inherit FFT length from input dimensions

on (default) | off

Select to inherit the FFT length from the input dimensions. When you select this check box, the input length must be a power of two.

Dependencies

When you do not select this check box, the **FFT length** parameter becomes available to specify the length.

FFT length — FFT length

64 (default) | integer

Specify FFT length as an integer greater than or equal to two.

When you set the **FFT implementation** parameter to Radix-2, or when you check the **Output in bit-reversed order** check box, this value must be a power of two.

Dependencies

To enable this parameter, clear the **Inherit FFT length from input dimensions** check box.

Wrap input data when FFT length is shorter than input length — Wrap or truncate input

on (default) | off

Choose to wrap or truncate the input, depending on the FFT length. If you select this parameter, modulo-length data wrapping occurs before the FFT operation when the FFT length is shorter than the input length. If you clear this check box, truncation of the input data to the FFT length occurs before the FFT operation.

Dependencies

To enable this parameter, clear the **Inherit FFT length from input dimensions** check box.

Data Types

Rounding mode — Rounding method

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Select the rounding mode for fixed-point operations.

Limitations

The sine table values do not obey this parameter; instead, they always round to **Nearest**.

The **Rounding mode** parameter has no effect on numeric results when all these conditions are met:

- **Product output** data type is `Inherit: Inherit via internal rule`.
- **Accumulator** data type is `Inherit: Inherit via internal rule`.

With these data type settings, the block operates in full-precision mode.

Saturate on integer overflow — Saturate on integer overflow

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see `overflow mode for fixed-point operations`.

Limitations

The **Saturate on integer overflow** parameter has no effect on numeric results when all these conditions are met:

- **Product output** data type is `Inherit: Inherit via internal rule`.
- **Accumulator** data type is `Inherit: Inherit via internal rule`.

With these data type settings, the block operates in full-precision mode.

Sine table — Data type of sine table values

Inherit: Same word length as input (default) | `fixdt(1,16)`

Choose how to specify the word length of the values of the sine table. The fraction length of the sine table values always equals the word length minus one. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Sine table** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) for more information.

Limitations

The sine table values do not obey the **Rounding mode** and **Saturate on integer overflow** parameters; instead, they are always saturated and rounded to **Nearest**.

Product output — Product output data type

Inherit: Inherit via internal rule (default) | Inherit: Same as input |
fixdt(1,16,0)

Specify the product output data type. See “Fixed Point” on page 2-516 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) for more information.

Accumulator — Accumulator data type

Inherit: Inherit via internal rule (default) | Inherit: Same as input | Inherit:
Same as product output | fixdt(1,16,0)

Specify the accumulator data type. See “Fixed Point” on page 2-516 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) for more information.

Output — Output data type

Inherit: Inherit via internal rule (default) | Inherit: Same as input |
fixdt(1,16,0)

Specify the output data type. See “Fixed Point” on page 2-516 for illustrations depicting the use of the output data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`.

When you select `Inherit: Inherit via internal rule`, the block calculates the output word length and fraction length automatically. The equations that the block uses to calculate the ideal output word length and fraction length depend on the setting of the **Divide output by FFT length** check box.

- When you select the **Divide output by FFT length** check box, the ideal output word and fraction lengths are the same as the input word and fraction lengths.
- When you clear the **Divide output by FFT length** check box, the block computes the ideal output word and fraction lengths according to the following equations:

$$WL_{idealoutput} = WL_{input} + \text{floor}(\log_2(FFTlength - 1)) + 1$$

$$FL_{idealoutput} = FL_{input}$$

Using these ideal results, the internal rule then selects word lengths and fraction lengths that are appropriate for your hardware. For more information, see “Inherit via Internal Rule”.

- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Data Types of Signals” (Simulink) for more information.

Output Minimum — Minimum value block should output

[] (default) | scalar

Specify the minimum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Output Maximum — Maximum value block should output

[] (default) | scalar

Specify the maximum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	yes ^a
Zero-Crossing Detection	no

^a Variable-size signals are only supported when the Inherit FFT length from input dimensions checkbox is selected.

Algorithms

FFTW Implementation

The FFTW implementation provides an optimized FFT calculation including support for power-of-two and non-power-of-two transform lengths in both simulation and code generation. Generated code using the FFTW implementation can only run on computers capable of running MATLAB. The input data type must be floating-point.

Radix-2 Implementation

The Radix-2 implementation supports bit-reversed processing, fixed or floating-point data, and allows the block to provide portable C-code generation using the Simulink Coder. The dimension M of the M -by- N input matrix must be a power of two. To work with other input sizes, use the Pad block to pad or truncate these dimensions to powers of two, or if possible choose the FFTW implementation.

With Radix-2 selected, the block implements one or more of the following algorithms:

- Butterfly operation
- Double-signal algorithm
- Half-length algorithm
- Radix-2 decimation-in-time (DIT) algorithm
- Radix-2 decimation-in-frequency (DIF) algorithm

Radix-2 Algorithms for Real and Complex Signals

Complexity of Input	Output Ordering	Algorithms Used for FFT Computation
Complex	Linear	Bit-reversed operation and radix-2 DIT
Complex	Bit-reversed	Radix-2 DIF
Real	Linear	Bit-reversed operation and radix-2 DIT in conjunction with the half-length and double-signal algorithms
Real	Bit-reversed	Radix-2 DIF in conjunction with the half-length and double-signal algorithms

The efficiency of the FFT algorithm can be enhanced for real input signals by forming complex-valued sequences from the real-valued sequences prior to the computation of the DFT. When there are $2N+1$ real input channels, the FFT block forms these complex-valued sequences by applying the double-signal algorithm to the first $2N$ input channels, and the half-length algorithm to the last odd-numbered channel.

For real input signals with fixed-point data types, different numerical results might appear in the output of the last odd-numbered channel, even when all input channels are identical. This numerical difference results from differences in the double-signal algorithm and the half-length algorithm.

You can eliminate this numerical difference in two ways:

- Using full precision arithmetic for fixed-point input signals
- Changing the input data type to floating point

For more information on the double-signal algorithm, see [2], “Efficient Computation of the DFT of Two Real Sequences” on page 475. For more information on the half-length algorithm, see [2], “Efficient Computation of the DFT of a 2N-Point Real Sequence” on page 476.

Radix-2 Optimization for the Table of Trigonometric Values

In certain situations, the block’s Radix-2 algorithm computes all the possible trigonometric values of the twiddle factor

$$e^{j\frac{2\pi k}{K}}$$

where K is the greater value of either M or N and $k = 0, \dots, K - 1$. The block stores these values in a table and retrieves them during simulation. The number of table entries for fixed-point and floating-point is summarized in the following table:

Number of Table Entries for N-Point FFT	
floating-point	$3N/4$
fixed-point	N

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- When the following conditions apply, the executable generated from this block relies on prebuilt dynamic library files (.dll files) included with MATLAB:
 - **FFT implementation** is set to FFTW.
 - **Inherit FFT length from input dimensions** is cleared, and **FFT length** is set to a value that is not a power of two.

Use the packNGo function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

- When the FFT length is a power of two, you can generate standalone C and C++ code from this block.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

The following diagrams show the data types used in the FFT block for fixed-point signals. You can set the **Sine table**, **Accumulator**, **Product output**, and **Output** data types displayed in the diagrams in the FFT dialog box as discussed in “Parameters” on page 2-509.

Inputs to the FFT block are first cast to the output data type and stored in the output buffer. Each butterfly stage then processes signals in the accumulator data type, with the final output of the butterfly being cast back into the output data type. The block multiplies in a twiddle factor before each butterfly stage in a decimation-in-time FFT and after each butterfly stage in a decimation-in-frequency FFT.

Decimation-in-time IFFT

Decimation-in-frequency IFFT

Butterfly stage data types

Twiddle multiplication data types

The output of the multiplier appears in the accumulator data type because both of the inputs to the multiplier are complex. For details on the complex multiplication performed, see “Multiplication Data Types”.

Note When the block input is fixed point, all internal data types are signed fixed point.

Filter Realization Wizard

Construct filter realizations using digital filter blocks or Sum, Gain, and Delay blocks

Library

Filtering / Filter Implementations

dsparch4

Description

Note Use this block to implement fixed-point or floating-point digital filters using Sum, Gain, and Delay blocks or digital filter blocks from the DSP System Toolbox library. You can either design a filter by using the block parameters, or import the coefficients of a filter you have designed elsewhere.

The following blocks also implement digital filters, but serve slightly different purposes:

- Discrete FIR Filter and Biquad Filter— Use to implement floating-point or fixed-point filters that you have already designed
- Digital Filter Design — Use to design, analyze, and then implement floating-point filters.

The Filter Realization Wizard is a tool for automatically implementing a digital filter. You must specify a filter, its structure, and the data types for the inputs, outputs, and computations. The filter can support double-precision, single-precision, or fixed-point data types.

The Filter Realization Wizard can implement a digital filter in one of two ways. It can use digital filter blocks from the DSP System Toolbox library, or it can create a subsystem block that implements the specified filter using Sum, Gain, and Delay blocks. If the Filter Realization Wizard creates a block, double-click the block to open the dialog box. If it creates a subsystem, double-click the subsystem block to see the filter implementation as shown in the figure below.

For more information about filter implementation, see “Specify the Filter Implementation” on page 2-520.

The parameters of the Filter Realization Wizard are a part of a larger app, the Filter Designer (`filterDesigner`). You can use filter designer to design and analyze your filter, and then use the Filter Realization Wizard parameters to implement the filter in your models.

Specify the Filter and Data Types

To specify a purely double-precision filter, you can either design a filter using the **Design Filter** panel, or import a filter using the **Import Filter** panel. In the **Import Filter** panel, you can specify the coefficients directly or specify the workspace variables which store the coefficients.

You can also specify a fixed-point filter or a single-precision filter by using the **Set Quantization Parameters** panel.

Note *Running* a model containing implementations of fixed-point filters requires the Fixed-Point Designer product, but you can still edit models containing such filter implementations without it. See the Fixed-Point Designer documentation for more information.

See the following topics to learn how to use the panels to specify your filter:

- For more information on the **Design Filter** panel, see `filterDesigner`.
- For more information on the **Import Filter** panel, see “Importing a Filter Design”.
- For more information on the **Set Quantization Parameters** panel, see “Access the Quantization Features of Filter Designer”.

To open a panel, click the appropriate button in the lower-left corner of filter designer.

Supported Filter Structures

The Filter Realization Wizard supports the following structures:

- Direct form I

- Direct form I, second-order sections
- Direct form I transposed
- Direct form I transposed, second-order sections
- Direct form II
- Direct form II, second-order sections
- Direct form II transposed
- Direct form II transposed, second-order sections
- Direct form FIR
- Direct form FIR transposed
- Direct form symmetric FIR
- Direct form antisymmetric FIR
- Lattice all-pass
- Lattice AR
- Lattice ARMA
- Lattice MA for maximum phase
- Lattice MA for minimum phase
- Cascade
- Parallel

Specify the Filter Implementation

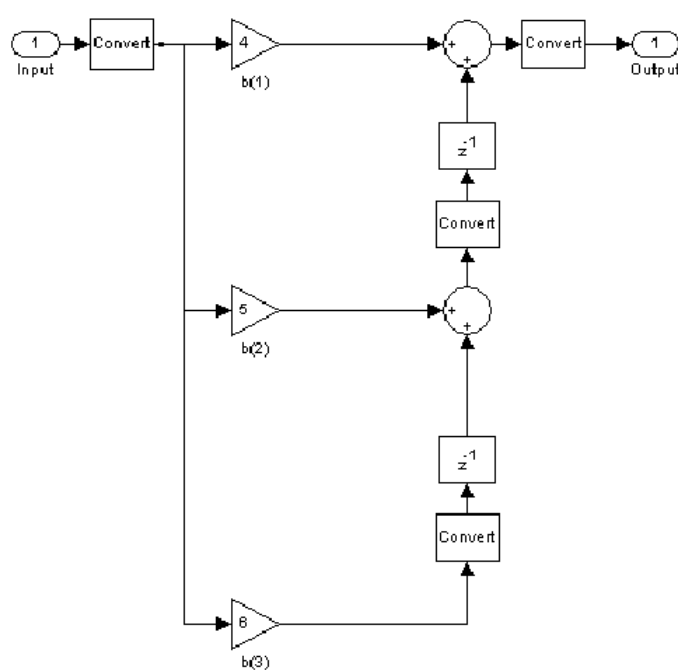

You can determine how the Filter Realization Wizard models the specified filter. In the **Realize Model** panel, select the **Build model using basic elements** check box. When you select this check box and click on the **Realize Model** button, the Filter Realization Wizard creates a subsystem block that implements your filter using Sum, Gain, and Delay blocks. When you clear this check box, the Filter Realization Wizard uses a digital filter block to implement your filter. The **Build model using basic elements** check box is available only when your filter can be implemented using a digital filter block available in the DSP System Toolbox library.

The Filter Realization Wizard can generate a subsystem that represents either a double-precision or fixed-point filter. You must install the Fixed-Point Designer product to simulate a fixed-point filter. You can still edit the blocks used to implement the filter without installing the Fixed-Point Designer product.

Double-precision filter implemented with Sum, Gain, and Delay blocks

Fixed-point filter implemented with Sum, Gain, Delay, and Conversion blocks

Implementations of Double-Precision and Fixed-Point Filters

Command Line Alternative to Realize Model Button

You can enter `realizemdl(sysobj)` in the MATLAB command prompt to generate an architectural model of the filter System object, *sysobj*, in a Simulink subsystem block using individual sum, gain, and delay blocks, according to user-defined specifications. For more information, see `realizemdl`.

Parameters

Note The following parameters for the Filter Realization Wizard are in the **Realize Model** pane of the filter designer app. To open different panels of filter designer, click the different buttons at the lower-left corner. For more information about relevant panels, see “Specify the Filter and Data Types” on page 2-519.

Block Name

Enter the name of the new filter block.

Destination

Specify where the new filter block should be created. This can be in a new model or in the current (most recently selected) model.

User Defined

Specify the name of the target subsystem in which the Filter Realization Wizard should create the new filter block.

Overwrite generated block “Filter” block

When selected, the block overwrites any filter block in the current model with the name specified in the **Block Name** parameter. This parameter is enabled when the **Destination** parameter is set to Current.

Build model using basic elements

Select this check box to implement your filter using Sum, Gain, and Delay blocks. Clear this check box to implement your filter using digital filter blocks from the DSP System Toolbox library. This parameter is available only when your filter can be modeled using an available digital filter block.

Optimize for zero gains

Select this check box to remove zero-gain paths from the filter structure. For an example, see “Optimize the Filter Structure”.

Optimize for unity gains

Select this check box to substitute gains equal to 1 with a wire (short circuit). For an example, see “Optimize the Filter Structure”.

Optimize for negative gains

Select this check box to substitute gains equal to -1 with a wire (short circuit), and change the corresponding sums to subtractions. For an example, see “Optimize the Filter Structure”.

Optimize delay chains

Select this check box to substitute any delay chains made up of n unit delays with a single delay by n . For an example, see “Optimize the Filter Structure”.

Optimize for unity scale values

Select this check box to remove all scale value multiplications by 1 from the filter structure.

Input processing

Specify how the generated filter block or subsystem block processes the input. Depending on the type of filter you are designing, one or both of the following options may be available:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

For more information about sample- and frame-based processing, see “Sample- and Frame-Based Concepts”.

Rate options

For multirate filters, specify how the block should process the input. You can set this parameter to one of the following options:

- **Enforce single-rate processing** — When you select this option, the block maintains the input sample rate.
- **Allow multirate processing** — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples.

Realize Model

Click to create a filter block according to the settings you’ve specified. When the **Build model using basic elements** check box is selected, the filter is implemented as a subsystem block consisting of Sum, Gain, and Delay blocks. To see the filter implementation, double-click the subsystem block in your model.

Note For more information about relevant parameters in other panels of filter designer, see “Specify the Filter and Data Types” on page 2-519.

Supported Data Types

- Double-precision floating point
- Single-precision floating point — Supported only when you install Fixed-Point Designer.
- Fixed point (signed and unsigned) — Supported only when you install Fixed-Point Designer and Fixed-Point Designer.

FIR Decimation

Filter and downsample input signals

Library: DSP System Toolbox / Filtering / Multirate Filters
 DSP System Toolbox HDL Support / Filtering

Description

The ChangeFIR Decimation block resamples vector or matrix inputs along the first dimension. The FIR decimator (as shown in the schematic) conceptually consists of an anti-aliasing FIR filter followed by a downsampler. To design an FIR anti-aliasing filter, use the `designMultirateFIR` function.

The FIR filter filters the data in each channel of the input using a direct-form FIR filter. The downsampler that follows downsamples each channel of filtered data by taking every M -th sample and discarding the $M - 1$ samples that follow. M is the value of the decimation factor that you specify. The resulting discrete-time signal has a sample rate that is $1/M$ times the original sample rate.

The actual block algorithm implements a direct-form FIR polyphase structure, an efficient equivalent of the combined system depicted in the diagram. For more details, see “Algorithms” on page 2-536.

Under specific conditions, this block also supports SIMD code generation. For details, see “Code Generation” on page 2-539.

Ports

Input

In — Data input

vector | matrix

Specify the data input as a vector or a matrix of size P -by- Q . The columns in the input signal represent Q independent channels.

The block supports variable-size input signals (frame length changes during simulation) when you set **Input processing** to Columns as channels (frame based) and **Rate options** to Enforce

single-rate processing. When the block accepts variable-size input signals, they can be of arbitrary frame length. That is, the input frame length does not have to be a multiple of the decimation factor. When you specify fixed-size signals, the frame length can be arbitrary under certain conditions. For more details, see “Frame-Based Processing” on page 2-533 and “Sample-Based Processing” on page 2-535.

This port is unnamed until you set **Coefficient source** to **Input port**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Num — Numerator coefficients

vector

Specify the numerator coefficients of the FIR filter as a vector.

The transfer function $H(z)$ of the FIR filter is given by:

You can generate the FIR filter coefficient vector, $\mathbf{b} = [b_0, b_1, \dots, b_N]$, using one of the DSP System Toolbox filter design functions such as `designMultirateFIR`, `firnyquist`, `firhalfband`, `firgr`, or `firceqrip`.

To act as an effective anti-aliasing filter, the coefficients usually correspond to a lowpass filter with a normalized cutoff frequency no greater than $1/M$, where M is the decimation factor. To design such a filter, use the `designMultirateFIR` function.

Coefficient values obtained through **Num** are tunable, that is, they can change during simulation, while their properties must remain constant.

The data type of the **Num** input must match the data type of the **In** input.

Dependencies

The **Num** input port appears when you set **Coefficient source** as **Input port**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

Out — Decimator output

vector | matrix

Output of the FIR Decimator block, returned as a vector or a matrix.

When you set **Rate options** to:

- **Enforce single-rate processing** -- The block maintains the input sample rate and decimates the signal by decreasing the output frame size by a factor of M .

The output has an upper bound size of $\text{ceil}(P/M)$ -by- Q for an input of size P -by- Q .

- **Allow multirate processing** -- The block decimates the signal such that the output sample rate is M times slower than the input sample rate.

The output frame size is the same as the input frame size.

For more details, see “Frame-Based Processing” on page 2-533 and “Sample-Based Processing” on page 2-535.

This port is unnamed until you set **Coefficient source** to **Input port**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Parameters

Coefficient source

Coefficient source — FIR filter coefficient source

Auto (default) | **Dialog parameters** | **Input port** | **Filter object**

Specify the FIR filter coefficient source as one of the following:

- **Dialog parameters** -- Specify the filter coefficients through the **FIR filter coefficients** parameter in the block dialog box.
- **Input port** -- Specify the filter coefficients through the **Num** input port.
- **Filter object** -- Specify the filter using a `dsp.FIRDecimator` System object.
- **Auto** -- When you select **Auto**, the block designs an FIR decimator using the decimation factor that you specify in **Decimation factor**. The `designMultirateFIR` function designs the filter and returns the coefficients used by the block.

For more information on the filter design, see Orfanidis [2].

Main Tab

FIR filter coefficients — Lowpass FIR filter coefficients

`designMultirateFIR(1,2)` (default) | `vector`

Specify the lowpass FIR filter coefficients, in descending powers of z , as a vector. By default, `designMultirateFIR(1,2)` computes the filter coefficients.

The transfer function $H(z)$ of the FIR filter is given by:

You can generate the FIR filter coefficient vector, $\mathbf{b} = [b_0, b_1, \dots, b_N]$, using one of the DSP System Toolbox filter design functions such as `designMultirateFIR`, `firnyquist`, `firhalfband`, `firgr`, or `firceqrip`.

To act as an effective anti-aliasing filter, the coefficients usually correspond to a lowpass filter with a normalized cutoff frequency no greater than $1/M$, where M is the decimation factor. To design such a filter, use the `designMultirateFIR` function.

The block internally initializes all filter states to zero.

Dependencies

This parameter appears only when you set the **Coefficient source** to **Dialog parameters**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Decimation factor — Decimation factor

2 (default) | positive scalar

Specify the integer factor M . The block decreases the sample rate of the input sequence by this factor.

Dependencies

This parameter appears only when you set the **Coefficient source** to **Dialog parameters**, **Input port**, or **Auto**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Filter structure — FIR filter structure

`Direct form (default)` | `Direct form transposed`

Specify the FIR filter structure as either `Direct form` or `Direct form transposed`.

Dependencies

This parameter appears only when you set the **Coefficient source** to **Dialog parameters**, **Input port**, or **Auto**.

Filter object — Filter object

`dsp.FIRDecimator`

Specify the name of the multirate filter object that you want the block to implement. You must specify the filter as a `dsp.FIRDecimator` System object.

You can define the System object directly in the block dialog box. Alternatively, you can define the object in a MATLAB workspace variable and specify the variable in the block dialog box.

For information on creating System objects, see “Define Basic System Objects”.

Dependencies

This parameter appears only when you set the **Coefficient source** to **Filter object**.

Input processing — Method to process input signals

`Columns as channels (frame based) (default)` | `Elements as channels (sample based)`

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Rate options — Method by which block decimates input

`Enforce single-rate processing (default)` | `Allow multirate processing`

Specify the method by which the block should decimate the input. You can select one of the following options:

- **Enforce single-rate processing** — When you select this option, the block maintains the input sample rate and decimates the signal by decreasing the output frame size by a factor of M . To select this option, you must set the **Input processing** parameter to `Columns as channels (frame based)`.

When you set the **Rate options** parameter to `Enforce single-rate processing`, you can use the FIR Decimation block inside triggered subsystems.

- **Allow multirate processing** — When you select this option, the block decimates the signal such that the output sample rate is M times slower than the input sample rate.

Allow arbitrary frame length for fixed-size input signals — Allow arbitrary frame length for fixed-size input signals

off (default) | on

Specify whether fixed-size input signals (whose size does not change during simulation) can have an arbitrary frame length, where the frame length does not have to be a multiple of the decimation factor. The block uses this parameter setting only for fixed-size input signals and ignores this parameter if the input has a variable-size.

When the input signal is a variable-size signal, the signal can have arbitrary frame length, that is, the frame length does not have to be a multiple of the decimation factor.

For fixed-size input signals, if you:

- Select the **Allow arbitrary frame length for fixed-size input signals** parameter, the frame length of the signal does not have to be a multiple of the decimation factor. If the input is not a multiple of the decimation factor, then the output is generally a variable-size signal. Therefore, to support arbitrary input size, the block must also support variable-size operations, which you can enable by selecting the **Allow arbitrary frame length for fixed-size input signals** parameter.
- Clear the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length must be a multiple of the decimation factor.

Dependency

To enable this parameter, set **Input processing** to `Columns as channels (frame based)` and **Rate options** to `Enforce single-rate processing`.

Output buffer initial conditions — Initial conditions

0 (default) | scalar | matrix

When you set the FIR Decimation block to the frame-based processing mode, the block can exhibit one-frame latency. In the case of one-frame latency, this parameter specifies the output of the block until the first filtered input sample is available. Specify this parameter as a scalar value to be applied to all signal channels, or as a matrix containing one value for each channel.

Cases of one-frame latency can occur when the input frame size is greater than one, and you set the **Input processing** and **Rate options** parameters of the FIR Decimation block as follows:

- **Input processing** set to `Columns as channels (frame based)`
- **Rate options** set to `Allow multirate processing`

For more information on latency in the FIR Decimation block, see “Latency” on page 2-535.

Dependencies

This parameter appears only when you configure the block to perform multirate processing by setting **Rate options** to Allow multirate processing.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

View Filter Response — View filter response

button

Click on this button to open the Filter Visualization Tool (fvtool) and display the filter response of the filter defined in the block dialog box.

Data Types Tab**Rounding mode — Rounding mode**

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Select the rounding mode for fixed-point operations. The default is Floor. The filter coefficients do not obey this parameter and always round to Nearest.

Note The **Rounding mode** and **Saturate on integer overflow** settings have no effect on numerical results when all the following conditions exist:

- **Product output** is Inherit: Inherit via internal rule
- **Accumulator** is Inherit: Inherit via internal rule
- **Output** is Inherit: Same as accumulator

With these data type settings, the block is effectively operating in the full-precision mode.

Saturate on integer overflow — Saturate on integer overflow

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

Note The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numeric results when all these conditions are met:

- **Product output** data type is Inherit: Inherit via internal rule.
- **Accumulator** data type is Inherit: Inherit via internal rule.

With these data type settings, the block operates in full-precision mode.

Coefficients Data Type — Coefficients data type

Inherit: Same word length as input (default) | fixdt(1,16) | fixdt(1,16,0)

Specify the coefficients data type. See “Fixed Point” on page 2-541 and “Multiplication Data Types” for illustrations depicting the use of the coefficients data type in this block.

You can set this parameter to one of the following:

- `Inherit`: Same word length as input
- `fixdt(1,16,0)` or `fixdt(1,16)` -- Specify a data type object.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Coefficients** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Dependencies

This parameter appears only when you set **Coefficient source** to `Dialog` parameters, `Filter` object, or `Auto`.

When **Coefficient source** is set to `Filter` object, **Coefficients** parameter is automatically set to `Same word length as input`.

Coefficients Minimum — Minimum value of filter coefficients

`[]` (default) | scalar

Specify the minimum value of the filter coefficients. The default value is `[]` (unspecified). Simulink software uses this value to perform automatic scaling of fixed-point data types.

Dependencies

This parameter appears only when you set **Coefficient source** to `Dialog` parameters or `Auto`.

Coefficients Maximum — Maximum value of filter coefficients

`[]` (default) | scalar

Specify the maximum value of the filter coefficients. The default value is `[]` (unspecified). Simulink software uses this value to perform automatic scaling of fixed-point data types.

Dependencies

This parameter appears only when you set **Coefficient source** to `Dialog` parameters or `Auto`.

Product output Data Type — Product output data type

`Inherit`: `Inherit via internal rule` (default) | `Inherit`: `Same as input` | `fixdt(1,16,0)`

Specify the product output data type. See “Fixed Point” on page 2-541 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block.

You can set this parameter to one of the following:

- `Inherit`: `Inherit via internal rule`
For more information on this rule, see “Inherit via Internal Rule”.
- `Inherit`: `Same as input`

- `fixdt(1,16,0)` -- Specify a data type object.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Dependencies

When **Coefficient source** is set to `Filter` object, **Product output** parameter is automatically set to `Full` precision.

Accumulator Data Type — Accumulator data type

Inherit: `Inherit via internal rule (default)` | Inherit: `Same as input` | Inherit: `Same as product output` | `fixdt(1,16,0)`

Specify the accumulator data type. See “Fixed Point” on page 2-541 for illustrations depicting the use of the accumulator data type in this block.

You can set this parameter to one of the following:

- `Inherit: Inherit via internal rule.`

For more information on this rule, see “Inherit via Internal Rule”.

- `Inherit: Same as input`
- `Inherit: Same as product output`
- `fixdt(1,16,0)` -- Specify a data type object.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Dependencies

When **Coefficient source** is set to `Filter` object, **Accumulator** parameter is automatically set to `Full` precision.

Output Data Type — Output data type

Inherit: `Same as accumulator (default)` | Inherit: `Same as input` | Inherit: `Same as product output` | `fixdt(1,16,0)`

Specify the output data type. See “Fixed Point” on page 2-541 for illustrations depicting the use of the output data type in this block.

You can set it to one of the following:

- `Inherit: Same as accumulator`
- `Inherit: Same as input`
- `Inherit: Same as product output`

- `fixdt(1,16,0)` -- Specify a data type object.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Data Types of Signals” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Dependencies

When **Coefficient source** is set to `Filter` object, **Output** parameter is automatically set to `Same as accumulator`.

Output Minimum — Minimum value of block output

`[]` (default) | scalar

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Dependencies

This parameter appears only when you set **Coefficient source** to `Dialog` parameters, `Input port`, or `Auto`.

Output Maximum — Maximum value of block output

`[]` (default) | scalar

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Dependencies

This parameter appears only when you set **Coefficient source** to `Dialog` parameters, `Input port`, or `Auto`.

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

Block Characteristics

Data Types	<code>double</code> <code>fixed point</code> <code>integer</code> <code>single</code>
Direct Feedthrough	<code>no</code>

Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

More About

Polyphase Subfilters

A polyphase implementation of an FIR decimator *splits* the lowpass FIR filter impulse response into M different subfilters, where M is the downsampling or decimation factor. For more details on the polyphase implementation, see “Algorithms” on page 2-536.

Let $h(n)$ denote the FIR filter impulse response of length $N+1$ and $x(n)$ the input signal. Decimating the filter output by a factor of M is equivalent to the downsampled convolution:

$$y(n) = \sum_{l=0}^N h(l)x(nM - l)$$

The key to the efficiency of polyphase filtering is that specific input values are only multiplied by select values of the impulse response in the downsampled convolution. For example, letting $M = 2$, the input values $x(0), x(2), x(4), \dots$ are combined only with the filter coefficients $h(0), h(2), h(4), \dots$, and the input values $x(1), x(3), x(5), \dots$ are combined only with the filter coefficients $h(1), h(3), h(5), \dots$. By splitting the filter coefficients into two polyphase subfilters, no unnecessary computations are performed in the convolution. The outputs of the convolutions with the polyphase subfilters are interleaved and summed to yield the filter output.

The following code demonstrates how to construct the two polyphase subfilters for the default order 35 filter.

```
M = 2;
Num = fir1(35,0.4);
FiltLength = length(Num);
Num = flipud(Num(:));

if (rem(FiltLength, M) ~= 0)
    nzeros = M - rem(FiltLength, M);
    Num = [zeros(nzeros,1); Num]; % Appending zeros
end

len = length(Num);
nrows = len / M;
PolyphaseFilt = flipud(reshape(Num, M, nrows).');
```

The columns of `PolyphaseFilt` are subfilters containing the two *phases* of the filter in `Num`. For a general downsampling factor of M , there are M phases and therefore M subfilters.

Frame-Based Processing

When you set the **Input processing** parameter to `Columns as channels` (frame based), the block resamples each column of the input over time. In this mode, the block can perform either single-rate or multirate processing. You can use the **Rate options** parameter to specify how the block resamples the input.

- When you set the **Rate options** parameter to Enforce single-rate processing, the input and output of the block have the same sample rate. To decimate the output while maintaining the input sample rate, the block resamples the data in each column of the input such that the frame length of the output has an upper bound size of $\text{ceil}(P/M)$, where P is the input frame length and M is the decimation factor specified in the **Decimation factor** parameter.

In this mode, if you input a fixed-size signal (frame length does not change during simulation) and select the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length can be arbitrary and does not have to be a multiple of the decimation factor. If you clear the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length must be a multiple of the decimation factor.

In this mode, if you input a variable-size signal (frame length changes during simulation), the **Allow arbitrary frame length for fixed-size input signals** appears on the block dialog box but does not have any impact on the input frame length. You can input a variable-size signal of any frame length even if you do not select the **Allow arbitrary frame length for fixed-size input signals** parameter.

This table summarizes the support for arbitrary input frame length when you set **Input processing** to Columns as channels (frame based) and **Rate options** to Enforce single-rate processing.

Input Signal	Block Support for this Signal	Support for Arbitrary Input Frame Length	Input Size	Output Size
Fixed-size input signal	Yes	When you select Allow arbitrary frame length for fixed-size input signals	P -by- Q	Upper bound size of $\text{ceil}(P/M)$ -by- Q
Variable-size input signal	Yes	Always	P -by- Q	Upper bound size of $\text{ceil}(P/M)$ -by- Q

For an example that shows single-rate FIR decimation, see “FIR Decimation Using Single-Rate Processing”.

- When you set the **Rate options** parameter to Allow multirate processing, the input and output of the FIR Decimation block are of the same size, but the sample rate of the output is M times slower than that of the input. In this mode, the block treats a P -by- Q matrix input as Q independent channels. The block decimates each column of the input over time by keeping the frame size constant, and making the output frame period (T_{fo}) M times longer than the input frame period ($T_{fo} = M \cdot T_{fi}$).

In this mode, the block accepts only fixed-size signals and these signals can have arbitrary frame length.

This table summarizes the support for arbitrary input frame length when you set **Input processing** to Columns as channels (frame based) and **Rate options** to Allow multirate processing.

Input Signal	Block Support for this Signal	Support for Arbitrary Input Frame Length	Input Size	Output Size
Fixed-size input signal	Yes	Always	P -by- Q	P -by- Q
Variable-size input signal	No	Not applicable	Not applicable	Not applicable

See “FIR Decimation Using Multirate Frame-Based Processing” for an example that uses the FIR Decimation block in this mode.

Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels` (sample based), the block treats a P -by- Q matrix input as $P*Q$ independent channels, and decimates each channel over time. The output sample period (T_{so}) is M times longer than the input sample period ($T_{so} = M*T_{si}$), and the input and output sizes are identical.

In this mode, the block accepts only fixed-size signals and these signals can have an arbitrary frame length.

This table summarizes the support for arbitrary input frame length when you set **Input processing** to `Elements as channels` (sample based). **Rate options** is automatically set to `Allow multirate processing`.

Input Signal	Block Support for this Signal	Support for Arbitrary Input Frame Length	Input Size	Output Size
Fixed-size input signal	Yes	Always	P -by- Q	P -by- Q
Variable-size input signal	No	Not applicable	Not applicable	Not applicable

Latency

When you use the FIR Decimation block in the sample-based processing mode, the block always has zero-tasking latency. Zero-tasking latency means that the block propagates the first filtered input sample (received at time $t=0$) as the first output sample. That first output sample is then followed by filtered input samples $M+1$, $2M+1$, and so on.

When you use the FIR Decimation block in the frame-based processing mode with a frame size greater than one, the block may exhibit *one-frame latency*. Cases of one-frame latency can occur when the input frame size is greater than one and you set the **Input processing** and **Rate options** parameters of the FIR Decimation block as follows:

- **Input processing** = `Columns as channels` (frame based)
- **Rate options** = `Allow multirate processing`

In cases of one-frame latency, you can define the value of the first P output rows by setting the **Output buffer initial conditions** parameter. The default value of the **Output buffer initial conditions** parameter is \emptyset . However, you can enter a matrix containing one value for each channel of the input, or a scalar value to be applied to all channels. The first filtered input sample (first filtered

row of the input matrix) appears in the output as sample $P+1$. That sample is then followed by filtered input samples $M+1$, $2M+1$, and so on.

Note For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Algorithms

The FIR decimation filter is implemented efficiently using a polyphase structure. For more details on polyphase filters, see Polyphase Subfilters on page 2-533.

To derive the polyphase structure, start with the transfer function of the FIR filter:

$$H(z) = b_0 + b_1z^{-1} + \dots + b_Nz^{-N}$$

$N+1$ is the length of the FIR filter.

You can rearrange this equation as follows:

$$H(z) = \begin{aligned} & (b_0 + b_Mz^{-M} + b_{2M}z^{-2M} + \dots + b_{N-M+1}z^{-(N-M+1)}) + \\ & z^{-1}(b_1 + b_{M+1}z^{-M} + b_{2M+1}z^{-2M} + \dots + b_{N-M+2}z^{-(N-M+1)}) + \\ & \quad \vdots \\ & z^{-(M-1)}(b_{M-1} + b_{2M-1}z^{-M} + b_{3M-1}z^{-2M} + \dots + b_Nz^{-(N-M+1)}) \end{aligned}$$

M is the number of polyphase components, and its value equals the decimation factor that you specify.

You can write this equation as:

$$H(z) = E_0(z^M) + z^{-1}E_1(z^M) + \dots + z^{-(M-1)}E_{M-1}(z^M)$$

$E_0(z^M)$, $E_1(z^M)$, ..., $E_{M-1}(z^M)$ are the polyphase components of the FIR filter $H(z)$.

Conceptually, the FIR decimation filter contains a lowpass FIR filter followed by a downsampler.

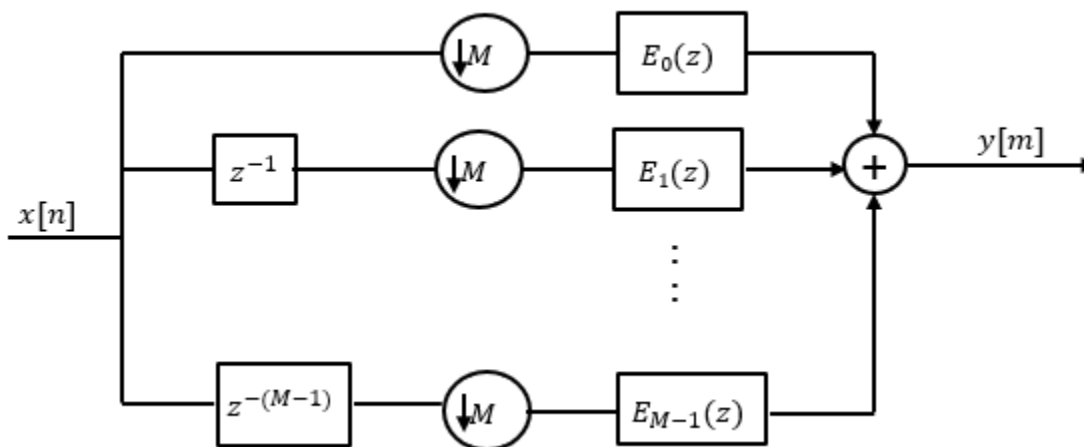

Replace $H(z)$ with its polyphase representation.

Here is the multirate noble identity for decimation.

Applying the noble identity for decimation moves the downsampling operation to before the filtering operation. This move enables you to filter the signal at a lower rate.

You can replace the delays and the decimation factor at the input with a commutator switch. The switch starts on the first branch 0 and moves in the counterclockwise direction as shown in this diagram. The accumulator at the output receives the processed input samples from each branch of the polyphase structure and accumulates these processed samples until the switch goes to branch 0. When the switch goes to branch 0, the accumulator outputs the accumulated value.

When the first input sample is delivered, the switch feeds this input to the branch 0 and the decimator computes the first output value. As more input samples come in, the switch moves in the counter clockwise direction through branches $M-1$, $M-2$, and all the way up to branch 0, delivering one sample at a time to each branch. When the switch comes to branch 0, the decimator outputs the next set of output values. This process continues as data keeps coming in. Every time the switch comes to the branch 0, the decimator outputs $y[m]$. The decimator effectively outputs one sample for every M samples it receives. Hence the sample rate at the output of the FIR decimation filter is f_s/M .

Version History

Introduced before R2006a

Support for arbitrary input frame length

Starting in R2022b, this block supports input signals with arbitrary frame lengths when the:

- Input signal is a fixed-size signal (frame length does not change during simulation) and the block allows for multirate processing
- Input signal is a fixed-size signal, the block enforces single-rate processing, and you select the **Allow arbitrary frame length for fixed-size input signals** parameter
- Input signal is a variable-size signal (frame length changes during simulation)

When this block supports an arbitrary frame length input signal, the input frame length does not have to be a multiple of the decimation factor.

For more details, see “Frame-Based Processing” on page 2-533 and “Sample-Based Processing” on page 2-535.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.

The FIR Decimation block supports SIMD code generation using Intel AVX2 technology under these conditions:

- **Filter structure** is set to `Direct` form.
- **Input processing** is set to `Columns as channels (frame based)`.
- **Rate options** is set to `Enforce single-rate processing`.
- Input signal is real-valued with real filter coefficients.
- Input signal is complex-valued with real or complex filter coefficients.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

For a FIR decimation filter with hardware-friendly control signals and simulation of HDL latency in Simulink, or for complex data with complex coefficients, use the FIR Decimation block instead of this block.

HDL Coder supports **Coefficient source** options **Dialog parameters**, **Filter object**, or **Auto**. Programmable coefficients are not supported.

Frame-Based Input Support

HDL Coder supports the use of vector inputs to FIR Decimation blocks, where each element of the vector represents a sample in time. You can use an input vector of up to 512 samples. The frame-based implementation supports fixed-point input and output data types, and uses full-precision internal data types. The output is a column vector of reduced size, corresponding to your decimation factor. You can use real input signals with real coefficients, complex input signals with real coefficients, or real input signals with complex coefficients.

- 1 Connect a column vector signal to the FIR Decimation block input port.
- 2 Specify **Input processing** as `Columns as channels (frame based)`.
- 3 Set **Rate options** to `Enforce single-rate processing`.
- 4 Right-click the block and open **HDL Code > HDL Block Properties**. Set the **Architecture** to `Frame Based`. The block implements a parallel HDL architecture. See “Frame-Based Architecture” (HDL Coder).

Block Optimizations

To reduce area or increase speed, the FIR Decimator block supports block-level optimizations.

Right-click on the block or the subsystem to open the corresponding **HDL Properties** dialog box and set optimization properties.

Serial Architectures	<p>To use block-level optimizations to reduce hardware resources, set Architecture to <code>Fully Serial</code> or <code>Partly Serial</code>. See “HDL Filter Architectures” (HDL Coder).</p> <p>When you specify SerialPartition for a FIR Decimator block, set Filter structure to <code>Direct</code> form. The <code>Direct</code> form transposed structure is not supported with serial architectures. Accumulator reuse is not supported for FIR Decimation filters.</p>
Distributed Arithmetic	<p>To minimize multipliers by replacing them with LUTs and shift registers, use a distributed arithmetic (DA) filter implementation. See “Distributed Arithmetic for HDL Filters” (HDL Coder).</p> <p>When you select the <code>Distributed Arithmetic (DA)</code> architecture and use the DALUTPartition and DARadix distributed arithmetic properties, set Filter structure to <code>Direct</code> form. The <code>Direct</code> form transposed structure is not supported with distributed arithmetic.</p>
Pipelining	<p>To improve clock speed, use AddPipelineRegisters to use a pipelined adder tree rather than the default linear adder. This option is supported for <code>Direct</code> form architecture. You can also specify the number of pipeline stages before and after the multipliers. See “HDL Filter Architectures” (HDL Coder).</p>

HDL Filter Properties

AddPipelineRegisters	Insert a pipeline register between stages of computation in a filter. See also <code>AddPipelineRegisters</code> (HDL Coder).
CoeffMultipliers	Specify the use of canonical signed digit (CSD) optimization to decrease filter area by replacing coefficient multipliers with shift-and-add logic. When you choose a fully parallel filter implementation, you can set CoeffMultipliers to <code>csd</code> or <code>factored-csd</code> . The default is <code>multipliers</code> , which retains multipliers in the HDL. See also <code>CoeffMultipliers</code> (HDL Coder).
DALUTPartition	Specify distributed arithmetic partial-product LUT partitions as a vector of the sizes of each partition. The sum of all vector elements must be equal to the filter length. The maximum size for a partition is 12 taps. Set DALUTPartition to a scalar value equal to the filter length to generate DA code without LUT partitions. See also <code>DALUTPartition</code> (HDL Coder).
DARadix	Specify how many distributed arithmetic bit sums are computed in parallel. A DA radix of 8 (2^3) generates a DA implementation that computes three sums at a time. The default value is 2^1 , which generates a fully serial DA implementation. See also <code>DARadix</code> (HDL Coder).
MultiplierInputPipeline	Specify the number of pipeline stages to add at filter multiplier inputs. See also <code>MultiplierInputPipeline</code> (HDL Coder).
MultiplierOutputPipeline	Specify the number of pipeline stages to add at filter multiplier outputs. See also <code>MultiplierOutputPipeline</code> (HDL Coder).

SerialPartition	Specify partitions for partly serial or cascade-serial filter implementations as a vector of the lengths of each partition. For a fully serial implementation, set this parameter to the length of the filter. See also SerialPartition (HDL Coder).
------------------------	--

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see "ConstrainedOutputPipeline" (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "InputPipeline" (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "OutputPipeline" (HDL Coder).

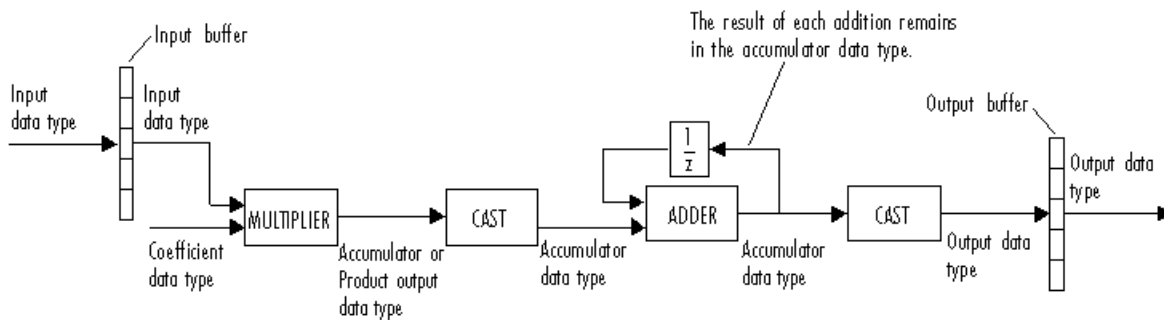

Restrictions

- You must set **Initial conditions** to zero. HDL code generation is not supported for nonzero initial states.
- When you select **Dialog parameters**, the following fixed-point options are not supported for HDL code generation:
 - Slope and Bias scaling
- **CoeffMultipliers** options are supported only when using a fully parallel architecture. When you select a serial architecture, **CoeffMultipliers** is hidden from the HDL Block Properties dialog box.
- Programmable coefficients are not supported.
- Frame-based input filters are not supported for:
 - Resettable and enabled subsystems
 - Complex input signals with complex coefficients. You can use either complex input signals and real coefficients, or complex coefficients and real input signals.
 - Sharing and streaming optimizations

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

The following diagram shows the data types used within the FIR Decimation block for fixed-point signals.

This diagram shows that data is stored in the input buffer with the same data type and scaling as the input. The block stores filtered data and any initial conditions in the output buffer using the output data type and scaling that you set in the block dialog box.

When at least one of the inputs to the multiplier is real, the output of the multiplier is in the product output data type. When both inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed by this block, see “Multiplication Data Types”.

Note When the block input is fixed point, all internal data types are signed fixed-point values.

FIR Interpolation

Upsample and filter input signals

Library: DSP System Toolbox / Filtering / Multirate Filters
 DSP System Toolbox HDL Support / Filtering

Description

The FIR Interpolation block upsamples an input by the integer upsampling factor L along the first dimension. The FIR interpolator (as shown in the schematic) conceptually consists of an upsampler followed by an FIR anti-imaging filter, which is usually an approximation of an ideal band-limited interpolation filter. To design an FIR anti-imaging filter, use the `designMultirateFIR` function.

The upsampler upsamples each channel of the input to a higher rate by inserting $L-1$ zeros between samples. The FIR filter that follows filters each channel of the upsampled data. The resulting discrete-time signal has a sample rate that is L times the original sample rate.

The actual block algorithm implements a direct-form FIR polyphase structure, an efficient equivalent of the combined system depicted in the diagram. For more details, see “Algorithms” on page 2-552.

You can use the FIR Interpolation block inside triggered subsystems when you set the **Rate options** parameter to `Enforce single-rate processing`.

Under specific conditions, this block also supports SIMD code generation. For more details, see “Code Generation” on page 2-555.

Ports

Input

In — Data input

vector | matrix

Specify the data input as a vector or a matrix.

When you set **Input processing** to `Columns as channels (frame based)` and **Rate options** to `Enforce single-rate processing`, the input can be a variable-size signal. That is, the frame size (number of rows) and the number of channels (columns) of the signal can change during simulation.

This port is unnamed until you set **Coefficient source** to **Input port**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Num — Numerator coefficients

vector

Specify the numerator coefficients of the FIR filter as a vector.

The transfer function $H(z)$ of the FIR filter is given by:

You can generate the FIR filter coefficient vector, $\mathbf{b} = [b_0, b_1, \dots, b_N]$, using one of the DSP System Toolbox filter design functions such as `designMultirateFIR`, `firnyquist`, `firhalfband`, `firgr` or `firceqrip`.

To act as an effective anti-imaging filter, the coefficients usually correspond to a lowpass filter with a normalized cutoff frequency no greater than the reciprocal of the interpolation factor. To design such a filter, use the `designMultirateFIR` function.

Coefficient values are tunable. That is, their values can change during simulation while their properties such as size, data type, and complexity cannot change.

The data type of the **Num** input must match the data type of the **In** input.

Dependencies

The **Num** input port appears when you set **Coefficient source** as **Input port**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

Out — Interpolator output

vector | matrix

Output of the FIR Interpolator block, returned as a vector or a matrix.

When **Rate options** is set to:

- `Enforce single-rate processing` — When you select this option, the block maintains the input sample rate, and interpolates the signal by increasing the output frame size by a factor of L .
- `Allow multirate processing` — When you select this option, the block interpolates the signal such that the output sample rate is L times faster than the input sample rate.

When the input is a variable-size signal, the output is also a variable-size signal.

This port is unnamed until you set **Coefficient source** to **Input port**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Parameters

Coefficient source

Coefficient source — FIR filter coefficient source

Auto (default) | **Dialog parameters** | **Input port** | **Filter object**

Specify the FIR filter coefficient source as one of the following:

- **Dialog parameters** -- Specify the filter coefficients through the **FIR filter coefficients** parameter in the block dialog box.
- **Input port** -- Specify the filter coefficients through the **Num** input port.
- **Filter object** -- Specify the filter using a `dsp.FIRInterpolator` System object.
- **Auto** -- When you select **Auto**, the block designs an FIR interpolator using the interpolation factor you specify in **Interpolation factor**. The `designMultirateFIR` function designs the filter and returns the coefficients used by the block.

For more information on the filter design, see Orfanidis [2].

Main Tab

FIR filter coefficients — Lowpass FIR filter coefficients

`designMultirateFIR(3,1)` (default) | vector

Specify the numerator coefficients of the FIR filter transfer function $H(z)$.

$$H(z) = b_0 + b_1z^{-1} + \dots + b_Nz^{-N}$$

You can generate the FIR filter coefficient vector, $\mathbf{b} = [b_0, b_1, \dots, b_N]$, using one of the DSP System Toolbox filter design functions such as `designMultirateFIR`, `firnyquist`, `firhalfband`, `firgr` or `firceqrip`.

To act as an effective anti-imaging filter, the coefficients usually correspond to a lowpass filter with a normalized cutoff frequency no greater than the reciprocal of the interpolation factor. To design such a filter, use the `designMultirateFIR` function.

The block internally initializes all filter states to zero.

Dependencies

This parameter appears only when you set the **Coefficient source** to **Dialog parameters**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Interpolation factor — Interpolation factor

3 (default) | positive scalar

Specify the integer factor L . The block increases the sample rate of the input sequence by this factor.

Dependencies

This parameter appears only when you set the **Coefficient source** to **Dialog parameters**, **Input port**, or **Auto**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Filter object — Filter object

`dsp.FIRInterpolator`

Specify the name of the multirate filter object that you want the block to implement. You must specify the filter as a `dsp.FIRInterpolator` System object.

You can define the System object directly in the block dialog box. Alternatively, you can define the object in a MATLAB workspace variable and specify the variable in the block dialog box.

For information on creating System objects, see “Define Basic System Objects”.

Dependencies

This parameter appears only when you set the **Coefficient source** to **Filter object**.

Input processing — Method to process input signals

`Columns as channels (frame based)` (default) | `Elements as channels (sample based)`

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Rate options — Method by which block interpolates input

`Enforce single-rate processing` (default) | `Allow multirate processing`

Specify the method by which the block should interpolate the input. You can select one of the following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the input sample rate, and interpolates the signal by increasing the output frame size by a factor of L . To select this option, you must set the **Input processing** parameter to `Columns as channels (frame based)`.
- `Allow multirate processing` — When you select this option, the block interpolates the signal such that the output sample rate is L times faster than the input sample rate.

Output buffer initial conditions — Initial conditions

`0` (default) | `scalar` | `matrix`

When you set the **Rate options** parameter to `Allow multirate processing` and run your models in Simulink `MultiTasking` mode, the block exhibits latency. The amount of latency for multirate, multitasking operation depends on how you set the **Input processing** parameter.

Input processing	Latency
Elements as channels (sample based)	L samples
Columns as channels (frame based)	L frames (K_i samples per frame)

When the block exhibits latency, the default initial condition is zero. Alternatively, you can use the **Output buffer initial conditions** parameter to specify a matrix of initial conditions containing one value for each channel or a scalar initial condition that the block applies to all channels. The block divides the **Output buffer initial conditions** by the **Interpolation factor** and outputs the scaled initial conditions until the first filtered input sample becomes available.

Output buffer initial conditions are stored in the output data type and scaling.

See “Latency” on page 2-552 for more information about latency in the FIR Interpolation block.

Dependencies

This parameter appears only when you configure the block to perform multirate processing by setting **Rate options** to Allow multirate processing.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

View Filter Response — View filter response button

Click on this button to open the Filter Visualization Tool (fvtool) and display the filter response of the filter defined in the block dialog box.

Rounding mode — Rounding mode

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Select the rounding mode for fixed-point operations. The default is Floor. The filter coefficients do not obey this parameter and always round to Nearest.

Note The **Rounding mode** and **Saturate on integer overflow** settings have no effect on numerical results when all the following conditions exist:

- **Product output** is Inherit: Inherit via internal rule
- **Accumulator** is Inherit: Inherit via internal rule
- **Output** is Inherit: Same as accumulator

With these data type settings, the block is effectively operating in the full-precision mode.

Saturate on integer overflow — Saturate on integer overflow off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see `overflow mode for fixed-point operations`.

Note The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numeric results when all these conditions are met:

- **Product output** data type is `Inherit`: `Inherit via internal rule`.
- **Accumulator** data type is `Inherit`: `Inherit via internal rule`.

With these data type settings, the block operates in the full-precision mode.

Coefficients Data Type — Coefficients data type

`Inherit`: Same word length as input (default) | `fixdt(1,16)` | `fixdt(1,16,0)`

Specify the coefficients data type. See “Fixed Point” on page 2-557 and “Multiplication Data Types” for illustrations depicting the use of the coefficients data type in this block.

You can set this parameter to one of the following:

- `Inherit`: Same word length as input
- `fixdt(1,16,0)` or `fixdt(1,16)` -- Specify a data type object.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Coefficients** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Dependencies

This parameter appears only when you set **Coefficient source** to `Dialog` parameters, `Filter` object, or `Auto`.

When **Coefficient source** is set to `Filter` object, **Coefficients** parameter is automatically set to `Same word length as input`.

Coefficients Minimum — Minimum value of filter coefficients

`[]` (default) | scalar

Specify the minimum value of the filter coefficients. The default value is `[]` (unspecified). Simulink software uses this value to perform automatic scaling of fixed-point data types.

Dependencies

This parameter appears only when you set **Coefficient source** to `Dialog` parameters or `Auto`.

Coefficients Maximum — Maximum value of filter coefficients

`[]` (default) | scalar

Specify the maximum value of the filter coefficients. The default value is `[]` (unspecified). Simulink software uses this value to perform automatic scaling of fixed-point data types.

Dependencies

This parameter appears only when you set **Coefficient source** to `Dialog` parameters or `Auto`.

Product output Data Type — Product output data type

Inherit: `Inherit via internal rule` (default) | Inherit: `Same as input` | `fixdt(1,16,0)`

Specify the product output data type. See “Fixed Point” on page 2-557 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block.

You can set this parameter to one of the following:

- `Inherit: Inherit via internal rule`

For more information on this rule, see “Inherit via Internal Rule”.

- `Inherit: Same as input`
- `fixdt(1,16,0)` -- Specify a data type object.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Dependencies

When **Coefficient source** is set to `Filter` object, **Product output** parameter is automatically set to `Full` precision.

Accumulator Data Type — Accumulator data type

Inherit: `Inherit via internal rule` (default) | Inherit: `Same as input` | Inherit: `Same as product output` | `fixdt(1,16,0)`

Specify the accumulator data type. See “Fixed Point” on page 2-557 for illustrations depicting the use of the accumulator data type in this block.

You can set this parameter to one of the following:

- `Inherit: Inherit via internal rule`.

For more information on this rule, see “Inherit via Internal Rule”.

- `Inherit: Same as input`
- `Inherit: Same as product output`
- `fixdt(1,16,0)` -- Specify a data type object.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Dependencies

When **Coefficient source** is set to `Filter` object, **Accumulator** parameter is automatically set to `Full` precision.

Output Data Type — Output data type

Inherit: Same as accumulator (default) | Inherit: Same as input | Inherit: Same as product output | `fixdt(1,16,0)`

Specify the output data type. See “Fixed Point” on page 2-557 for illustrations depicting the use of the output data type in this block.

You can set it to one of the following:

- Inherit: Same as accumulator
- Inherit: Same as input
- Inherit: Same as product output
- `fixdt(1,16,0)` -- Specify a data type object.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Data Types of Signals” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Dependencies

When **Coefficient source** is set to `Filter` object, **Output** parameter is automatically set to `Same as accumulator`.

Output Minimum — Minimum value of block output

[] (default) | scalar

Specify the minimum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Dependencies

This parameter appears only when you set **Coefficient source** to `Dialog` parameters, `Input port`, or `Auto`.

Output Maximum — Maximum value of block output

[] (default) | scalar

Specify the maximum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Dependencies

This parameter appears only when you set **Coefficient source** to Dialog parameters, Input port, or Auto.

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

More About

Frame-Based Processing

When you set the **Input processing** parameter to Columns as channels (frame based), the block resamples each column of the input over time. In this mode, the block can perform either single-rate or multirate processing. You can use the **Rate options** parameter to specify how the block resamples the input:

- When you set the **Rate options** parameter to Enforce single-rate processing, the input and output of the block have the same sample rate. To interpolate the output while maintaining the input sample rate, the block resamples the data in each column of the input such that the frame size of the output (K_o) is L times larger than that of the input ($K_o = K_i * L$).

For an example of single-rate FIR Interpolation, see “FIR Interpolation Using Single-Rate Processing”.

- When you set the **Rate options** parameter to Allow multirate processing, the input and output of the FIR Interpolation block are the same size. However, the sample rate of the output is L times faster than that of the input. In this mode, the block treats a K_i -by- N matrix input as N independent channels. The block interpolates each column of the input over time by keeping the frame size constant ($K_i = K_o$), while making the output frame period (T_{fo}) L times shorter than the input frame period ($T_{fi} = T_{fo} / L$).

See “FIR Interpolation Using Multirate Frame-Based Processing” for an example that uses the FIR Interpolation block in this mode.

Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats a P -by- Q matrix input as $P*Q$ independent channels, and interpolates each channel over time. The output sample period (T_{so}) is L times shorter than the input sample period ($T_{so} = T_{si}/L$), while the input and output sizes remain identical.

Latency

When you run your models in the Simulink `SingleTasking` mode or set the **Input processing** parameter to `Columns as channels (frame based)` and the **Rate options** parameter to `Enforce single-rate processing`, the FIR Interpolation block always has zero-tasking latency. Zero-tasking latency means that the block propagates the first filtered input sample (received at time $t=0$) as the first output sample. That first output sample is then followed by $L-1$ interpolated values, the second filtered input sample, and so on.

The only time the FIR Interpolation block exhibits latency is when you set the **Rate options** parameter set to `Allow multirate processing` and run your models in the Simulink `MultiTasking` mode. The amount of latency for a multirate, multitasking operation depends on how you set the **Input processing** parameter.

Input processing	Latency
Elements as channels (sample based)	L samples
Columns as channels (frame based)	L frames (K_i samples per frame)

When the block exhibits latency, the default initial condition is zero. Alternatively, you can use the **Output buffer initial conditions** parameter to specify a matrix of initial conditions containing one value for each channel or a scalar initial condition that the block applies to all channels. The block scales the **Output buffer initial conditions** by the **Interpolation factor** and outputs the scaled initial conditions until the first filtered input sample becomes available.

When the block is in the sample-based processing mode, the block outputs the scaled initial conditions at the start of each channel, followed immediately by the first filtered input sample, then $L-1$ interpolated values, and so on.

When the block is in the frame-based processing mode and using the default initial condition of zero, the first K_i*L output rows contain zeros, where K_i is the input frame size. The first filtered input sample (first filtered row of the input matrix) appears in the output as sample K_i*L+1 . That value is then followed by $L-1$ interpolated values, the second filtered input sample, and so on.

Note For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Algorithms

The FIR interpolation filter is implemented efficiently using a polyphase structure.

To derive the polyphase structure, start with the transfer function of the FIR filter:

$$H(z) = b_0 + b_1z^{-1} + \dots + b_Nz^{-N}$$

$N+1$ is the length of the FIR filter.

You can rearrange this equation as follows:

$$H(z) = (b_0 + b_L z^{-L} + b_{2L} z^{-2L} + \dots + b_{N-L+1} z^{-(N-L+1)}) + z^{-1}(b_1 + b_{L+1} z^{-L} + b_{2L+1} z^{-2L} + \dots + b_{N-L+2} z^{-(N-L+1)}) + \dots + z^{-(L-1)}(b_{L-1} + b_{2L-1} z^{-L} + b_{3L-1} z^{-2L} + \dots + b_N z^{-(N-L+1)})$$

L is the number of polyphase components, and its value equals the interpolation factor that you specify.

You can write this equation as:

$$H(z) = E_0(z^L) + z^{-1}E_1(z^L) + \dots + z^{-(L-1)}E_{L-1}(z^L)$$

$E_0(z^L), E_1(z^L), \dots, E_{L-1}(z^L)$ are polyphase components of the FIR filter $H(z)$.

Conceptually, the FIR interpolation filter contains an upsampler followed by an FIR lowpass filter $H(z)$.

Conceptual Operation of FIR Interpolator

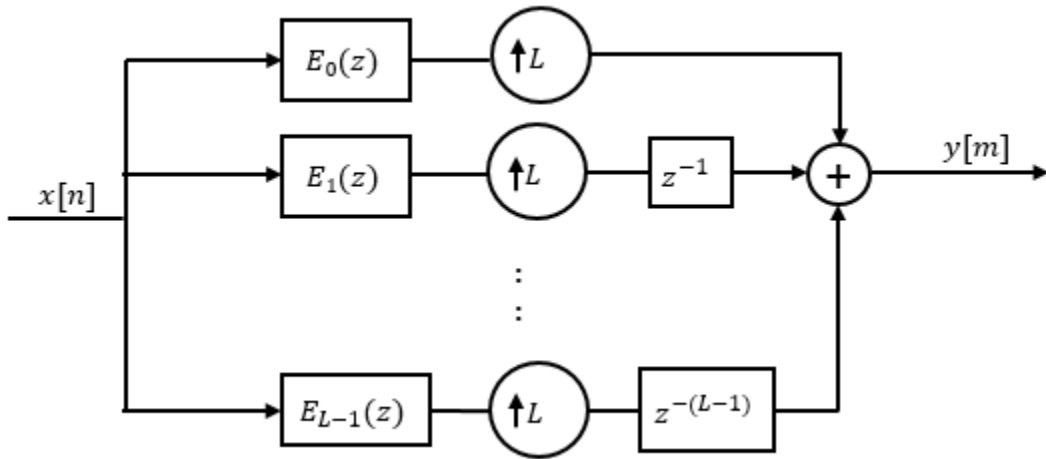

Replace $H(z)$ with its polyphase representation.

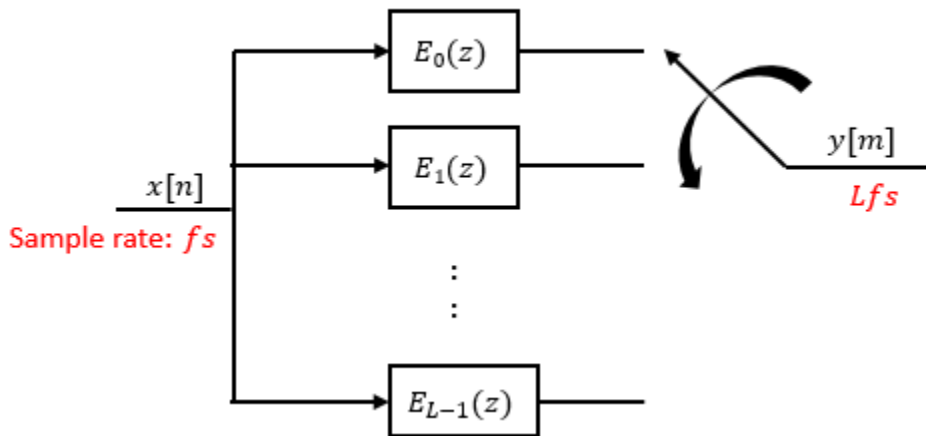

Here is the multirate noble identity for interpolation.

Applying the noble identity for interpolation moves the upsampling operation to after the filtering operation. This move enables you to filter the signal at a lower rate.

You can replace the upsampling operator, delay block, and adder with a commutator switch. The switch starts on the first branch 0 and moves in the counterclockwise direction, each time receiving one sample from each branch. The interpolator effectively outputs L samples for every one input sample it receives. Hence the sample rate at the output of the FIR interpolation filter is Lfs .

Version History
 Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.

The FIR Interpolation block supports SIMD code generation using Intel AVX2 technology under these conditions:

- **Input processing** is set to `Columns` as channels (`frame based`).
- **Rate options** is set to `Enforce single-rate processing`.
- Input signal is real-valued with real filter coefficients.
- Input signal is complex-valued with real or complex filter coefficients.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Coder supports **Coefficient source** options **Dialog parameters**, **Filter object**, or **Auto**.

Block Optimizations

To reduce area or increase speed, the FIR Decimator block supports block-level optimizations.

Right-click on the block or the subsystem to open the corresponding **HDL Properties** dialog box and set optimization properties.

Serial Architectures	When you select <code>Fully Serial</code> architecture, the <code>SerialPartition</code> property is set on the FIR Interpolation Block.
Distributed Arithmetic	Distributed Arithmetic properties DALUTPartition and DARadix are supported for the <code>Distributed Arithmetic (DA)</code> architecture with a default FIR filter structure. structures.

Pipelining	<p>When you use AddPipelineRegisters, registers are placed based on the filter structure. The pipeline register placement determines the latency.</p> <p>A pipeline register is added between levels of a tree-based adder, for a latency of $\text{ceil}(\log_2(PL)) - 1$, where PL is polyphase filter length.</p>
------------	--

HDL Filter Properties

AddPipelineRegisters	Insert a pipeline register between stages of computation in a filter. See also AddPipelineRegisters (HDL Coder).
CoeffMultipliers	Specify the use of canonical signed digit (CSD) optimization to decrease filter area by replacing coefficient multipliers with shift-and-add logic. When you choose a fully parallel filter implementation, you can set CoeffMultipliers to <code>csd</code> or <code>factored-csd</code> . The default is <code>multipliers</code> , which retains multipliers in the HDL. See also CoeffMultipliers (HDL Coder).
DALUTPartition	Specify distributed arithmetic partial-product LUT partitions as a vector of the sizes of each partition. The sum of all vector elements must be equal to the filter length. The maximum size for a partition is 12 taps. Set DALUTPartition to a scalar value equal to the filter length to generate DA code without LUT partitions. See also DALUTPartition (HDL Coder).
DARadix	Specify how many distributed arithmetic bit sums are computed in parallel. A DA radix of 8 (2^3) generates a DA implementation that computes three sums at a time. The default value is 2^1 , which generates a fully serial DA implementation. See also DARadix (HDL Coder).
MultiplierInputPipeline	Specify the number of pipeline stages to add at filter multiplier inputs. See also MultiplierInputPipeline (HDL Coder).
MultiplierOutputPipeline	Specify the number of pipeline stages to add at filter multiplier outputs. See also MultiplierOutputPipeline (HDL Coder).
SerialPartition	Specify partitions for partly serial or cascade-serial filter implementations as a vector of the lengths of each partition. For a fully serial implementation, set this parameter to the length of the filter. See also SerialPartition (HDL Coder).

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see "ConstrainedOutputPipeline" (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "InputPipeline" (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "OutputPipeline" (HDL Coder).

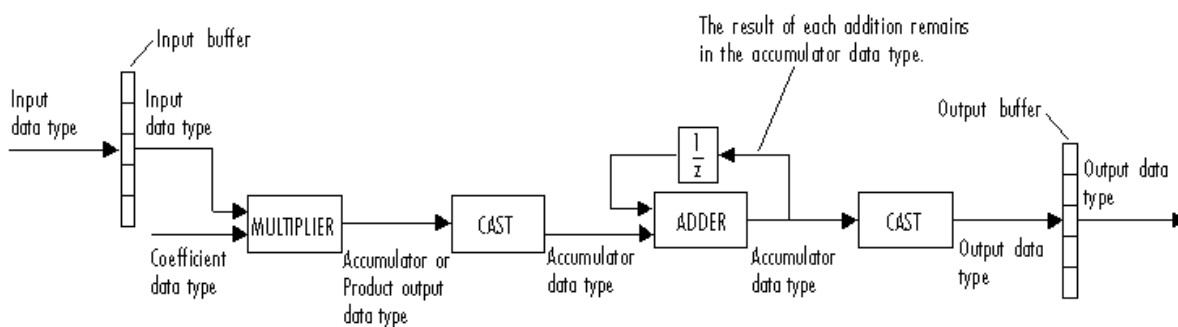

Restrictions

- You must set **Initial conditions** to zero. HDL code generation is not supported for nonzero initial states.
- Vector and frame inputs are not supported for HDL code generation.
- When you select **Dialog parameters**, the following fixed-point options are not supported for HDL code generation:
 - Coefficients:** Slope and Bias scaling
- CoeffMultipliers** options are supported only when using a fully parallel architecture. When you select a serial architecture, **CoeffMultipliers** is hidden from the HDL Block Properties dialog box.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

The following diagram shows the data types used within the FIR Interpolation block for fixed-point signals.

This diagram shows that input data is stored in the input buffer with the same data type and scaling as the input. The block stores filtered data and any initial conditions in the output buffer using the output data type and scaling that you set in the block dialog box.

When at least one of the inputs to the multiplier is real, the output of the multiplier is in the product output data type. When both inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed by this block, see “Multiplication Data Types”.

Note When the block input is fixed point, all internal data types are signed fixed point.

FIR Halfband Decimator

Decimate signal using polyphase FIR halfband filter

Library

Filtering/Filter Designs

dspfdesign

Description

The FIR Halfband Decimator block performs polyphase decimation of the input signal by a factor of two. The block uses an FIR equiripple design or a Kaiser window design to construct the halfband filters. The implementation takes advantage of the zero-valued coefficients of the FIR halfband filter, making one of the polyphase branches a delay. You can also use the block to implement the analysis portion of a two-band filter bank to separate a signal into lowpass and highpass subbands. For more information, see “Algorithms” on page 2-564.

The input signal can be a real- or complex-valued column vector or matrix. If the input signal is a matrix, the block treats each column of the matrix as an independent channel. The number of rows in the input signal must be a multiple of 2. The block supports fixed-point operations and ARM® Cortex® code generation. For more information on ARM Cortex code generation, see “Code Generation for ARM Cortex-M and ARM Cortex-A Processors”.

Dialog Box

Main Tab

Filter specification

Parameters used to design the FIR halfband filter.

- Transition width and stopband attenuation (default) — Design the filter using **Transition width (Hz)** and **Stopband attenuation (dB)**. This design is the minimum order design.
- Filter order and transition width — Design the filter using **Filter order** and **Transition width (Hz)**.
- Filter order and stopband attenuation — Design the filter using **Filter order** and **Stopband attenuation (dB)**.
- Coefficients — Specify the filter coefficients directly through the **Numerator** parameter.

Transition width (Hz)

Transition width, specified as a real positive scalar in Hz. The transition width must be less than half the input sample rate. You can specify the transition width when **Filter specification** is set

to **Filter order and transition width** or **Transition width and stopband attenuation**. The default is $4.1e3$.

Filter order

Filter order, specified as an even positive integer. You can specify the filter order when **Filter specification** is set to **Filter order and transition width** or **Filter order and stopband attenuation**. The default is 52.

Stopband attenuation (dB)

Stopband attenuation, specified as a real positive scalar in dB. You can specify the stopband attenuation when **Filter specification** is set to **Filter order and stopband attenuation** or **Transition width and stopband attenuation**. The default is 80.

Numerator

Specify the FIR halfband filter coefficients directly as a row vector. The coefficients must comply with the FIR halfband impulse response format. If half the order of the filter, $(\text{length}(\text{Numerator}) - 1)/2$, is even, every other coefficient starting from the first coefficient must be a zero except for the center coefficient which must be a 0.5. If half the order of the filter is odd, the sequence of alternating zeros with a 0.5 at the center starts at the second coefficient.

This parameter appears when **Filter specification** is set to **Coefficients**. The default is the coefficients vector returned by `firhalfband("minorder", 0.407, 1e-4)`.

Design method

Specify the filter design method as one of the following:

- **Auto** -- The algorithm automatically chooses the filter design method depending on the filter design parameters. The algorithm uses the equiripple or the Kaiser window method to design the filter.

If the design constraints are very tight, such as very high stopband attenuation or very narrow transition width, then the algorithm automatically chooses the Kaiser method, as this method is optimal for designing filters with very tight specifications. However, if the design constraints are not tight, then the algorithm chooses the equiripple method.

When you set the **Design method** parameter to **Auto**, you can determine the method used by the algorithm by examining the passband and stopband ripple characteristics of the designed filter. If the block used the equiripple method, the passband and stopband ripples of the designed filter have a constant amplitude in the frequency response. If the filter design method the block chooses in the **Auto** mode is not suitable for your application, manually specify the **Design method** as **Equiripple** or **Kaiser**.

- **Equiripple** -- The algorithm uses the equiripple method.
- **Kaiser** -- The algorithm uses the Kaiser window method.

This parameter appears when you set **Filter specification** to **Filter order and stopband attenuation**, **Filter order and transition width**, or **Transition width and stopband attenuation**.

Output highpass subband

When you select this check box, the block acts as a synthesis filter bank and synthesizes a signal from the highpass and lowpass subbands. When you clear this check box, the block acts as an FIR halfband decimator and accepts a single vector- or matrix-valued input.

Inherit sample rate from input

When you select this check box, the block inherits its sample rate from the input signal. When you clear this check box, you specify the sample rate in **Input sample rate (Hz)**. This parameter appears when you set **Filter specification** to any option other than **Coefficients**.

Input sample rate (Hz)

Input sample rate, specified as a scalar in Hz. The default is 44100. This parameter appears when you set **Filter specification** to any option other than **Coefficients** and clear the **Inherit sample rate from input** parameter.

View Filter Response

Opens the Filter Visualization Tool FVTool and displays the magnitude/phase response of the FIR Halfband Decimator. The response is based on the block dialog box parameters. Changes made to these parameters update FVTool.

To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

Simulate using

Type of simulation to run. You can set this parameter to:

- Code generation (default)

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.

- Interpreted execution

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

Data Types Tab

Rounding mode

Rounding method for the output fixed-point operations. The rounding methods are Ceiling, Convergent, Floor, Nearest, Round, Simplest, and Zero. The default is Floor.

Coefficients

Fixed-point data type of the coefficients, specified as one of the following:

- `fixdt(1,16)` (default) — Signed fixed-point data type of word length 16, with binary point scaling. The block determines the fraction length automatically from the coefficient values in such a way that the coefficients occupy maximum representable range without overflowing.
- `fixdt(1,16,0)` — Signed fixed-point data type of word length 16 and fraction length, 0. You can change the fraction length to any other integer value.
- `<data type expression>` — Specify the data type using an expression that evaluates to a data type object, for example, numeric type (`fixdt([],16,15)`). Specify the sign mode of this data type as `[]` or `true`.
- Refresh Data Type — Refreshes to the default data type.

Click the **Show data type assistant** button  to display the data type assistant, which helps you set the stage input parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed or unsigned) • 8-, 16-, 32-, and 64-bit signed integers • real and complex data
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, 32-, and 64-bit signed integers • real and complex data

More About

Halfband Filters

The ideal lowpass halfband filter is given by

$$h(n) = \frac{1}{2\pi} \int_{-\pi/2}^{\pi/2} e^{j\omega n} d\omega = \frac{\sin(\frac{\pi}{2}n)}{\pi n}.$$

The ideal filter is not realizable because the impulse response is noncausal and not absolutely summable. However, the impulse response of the ideal lowpass filter possesses some important properties that are required of a realizable approximation. Specifically, the ideal lowpass halfband filter's impulse response is:

- equal to 0 for all even-indexed samples
- equal to 1/2 at $n=0$. You can see this by using L'Hopital's rule on the continuous-valued equivalent of the discrete-time impulse response.

The ideal highpass halfband filter is given by

$$g(n) = \frac{1}{2\pi} \int_{-\pi}^{-\pi/2} e^{j\omega n} d\omega + \frac{1}{2\pi} \int_{\pi/2}^{\pi} e^{j\omega n} d\omega.$$

Evaluating the preceding integral gives the following impulse response

$$g(n) = \frac{\sin(\pi n)}{\pi n} - \frac{\sin(\frac{\pi}{2}n)}{\pi n}.$$

The ideal highpass halfband filter's impulse is:

- equal to 0 for all even-indexed samples
- equal to 1/2 at $n=0$.

The FIR halfband decimator uses a causal FIR approximation to the ideal halfband response, which is based on minimizing the ℓ^∞ norm of the error (minimax). See "Algorithms" on page 2-564 for more details.

Kaiser Window

The coefficients of a Kaiser window are computed from this equation:

$$w(n) = \frac{I_0\left(\beta \sqrt{1 - \left(\frac{n - N/2}{N/2}\right)^2}\right)}{I_0(\beta)}, \quad 0 \leq n \leq N,$$

where I_0 is the zeroth-order modified Bessel function of the first kind.

To obtain a Kaiser window that represents an FIR filter with stopband attenuation of α dB, use this β .

$$\beta = \begin{cases} 0.1102(\alpha - 8.7), & \alpha > 50 \\ 0.5842(\alpha - 21)^{0.4} + 0.07886(\alpha - 21), & 50 \geq \alpha \geq 21 \\ 0, & \alpha < 21 \end{cases}$$

The filter order n is given by:

$$n = \frac{\alpha - 7.95}{2.285(\Delta\omega)}$$

where $\Delta\omega$ is the transition width.

Algorithms

Filter Design Method

The FIR halfband decimator algorithm uses the equiripple or the Kaiser window method to design the FIR halfband filter. When the design constraints are tight, such as very high stopband attenuation or very narrow transition width, use the Kaiser window method. When the design constraints are not tight, use the equiripple method. If you are not sure of which method to use, set the design method to **Auto**. In this mode, the algorithm automatically chooses a design method from the two methods that optimally meets the specified filter constraints.

Halfband Equiripple Design

In the equiripple method, the algorithm uses a minimax (minimize the maximum error) FIR design to design a fullband linear phase filter with the desired specifications. The algorithm upsamples a fullband filter to replace the even-indexed samples of the filter with zeros and creates a halfband filter. It then sets the filter tap corresponding to the group delay of the filter in samples to 1/2. This yields a causal linear-phase FIR filter approximation to the ideal halfband filter defined in “Halfband Filters” on page 2-563. See [1] for a description of this filter design method using the Remez exchange algorithm. Since you can design a filter using this approximation method with a constant ripple both in the passband and stopband, the filter is also known as the equiripple filter.

Kaiser Window Design

In the Kaiser window method, the algorithm first truncates the ideal halfband filter defined in “Halfband Filters” on page 2-563, then it applies a Kaiser window defined in “Kaiser Window” on page 2-563. This yields a causal linear-phase FIR filter approximation to the ideal halfband filter.

For more information on designing FIR halfband filters, see “FIR Halfband Filter Design”.

Polyphase Implementation with Halfband Filters

The FIR halfband decimator uses an efficient polyphase implementation for halfband filters when you filter the input signal. The chief advantage of the polyphase implementation is that you can downsample the signal prior to filtering. This allows you to filter at the lower sampling rate.

Splitting a filter’s impulse response, $h(n)$, into two polyphase components results in an even polyphase component with z -transform

$$H_0(z) = \sum_n h(2n)z^{-n}.$$

and an odd polyphase component with z -transform

$$H_1(z) = \sum_n h(2n+1)z^{-n}.$$

The z -transform of the filter can be written in terms of the even and odd polyphase components as

$$H(z) = H_0(z^2) + z^{-1}H_1(z^2).$$

Graphically, you can represent filtering and input followed by downsampling by two with the following figure

Using the multirate noble identity for downsampling, you can move the downsampling operation before filtering. This allows you to filter at the lower rate.

For a halfband filter, the only nonzero coefficient in the even polyphase component is the coefficient corresponding to z^0 . Implementing the halfband filter as a causal FIR filter shifts the nonzero coefficient to approximately $z^{-N/4}$ where N is the number of filter taps. This process is illustrated in the following figure.

The top plot shows a halfband filter of order 52. The bottom plot shows the even polyphase component. Both of these filters are noncausal. Delaying the even polyphase component by 13 samples creates a causal FIR filter.

To efficiently implement the halfband decimator, the algorithm replaces the delay block and downsampling operator with a commutator switch. This is illustrated in the following figure where one polyphase component is replaced by a gain and delay.

The commutator switch takes input samples from a single branch and supplies every other sample to one of the two polyphase components for filtering. This halves the sampling rate of the input signal. Which polyphase component reduces to a simple delay depends on whether the half order of the filter is even or odd. This is because the delay required to make the even polyphase component causal can be odd or even depending on the filter half order.

To confirm this behavior, run the following code in the MATLAB command prompt and inspect the polyphase components of the following filters:

```
filterspec = "Filter order and stopband attenuation";
halfOrderEven = dsp.FIRHalfbandDecimator(Specification=filterspec,...
    FilterOrder=64,StopbandAttenuation=80,DesignMethod="Auto");
halfOrderOdd = dsp.FIRHalfbandDecimator(Specification=filterspec,...
    FilterOrder=54,StopbandAttenuation=80,DesignMethod="Auto");
polyphase(halfOrderEven)
polyphase(halfOrderOdd)
```

To summarize, the FIR halfband decimator:

- Decimates the input prior to filtering and filters the even and odd polyphase components of the input separately with the even and odd polyphase components of the filter.
- Exploits the fact that one filter polyphase component is a simple delay for a halfband filter.

FIR Halfband Interpolator

Interpolate signal using polyphase FIR half band filter

Library

Filtering / Filter Designs

dspfdesign

Description

The FIR Halfband Interpolator block performs interpolation of the input signal by a factor of two. The block uses an FIR equiripple design or a Kaiser window design to construct the halfband filters. The block uses an efficient polyphase implementation to filter the input. The implementation takes advantage of the zero-valued coefficients of the FIR halfband filter, making one of the polyphase branches a delay. For more information, see “Algorithms” on page 2-573. You can also use the block to implement the synthesis portion of a two-band filter bank to synthesize a signal from lowpass and highpass subbands.

The input signal can be a real- or complex-valued column vector or matrix. If the input signal is a matrix, the block treats each column of the matrix as an independent channel. The block supports fixed-point operations and ARM Cortex code generation. For more information on ARM Cortex code generation, see “Code Generation for ARM Cortex-M and ARM Cortex-A Processors”.

The block also supports SIMD code generation. For details, see “Code Generation” on page 2-576.

Dialog Box

Main Tab

Filter specification

Parameters used to design the FIR halfband filter.

- Transition width and stopband attenuation (default) — Design the filter using **Transition width (Hz)** and **Stopband attenuation (dB)**. This design is the minimum order design.
- Filter order and transition width — Design the filter using **Filter order** and **Transition width (Hz)**.
- Filter order and stopband attenuation — Design the filter using **Filter order** and **Stopband attenuation (dB)**.
- Coefficients — Specify the filter coefficients directly through the **Numerator** parameter.

Transition width (Hz)

Transition width, specified as a real positive scalar in Hz. The transition width must be less than half the input sample rate. You can specify the transition width only when **Filter specification** is

set to **Filter order and transition width** or **Transition width and stopband attenuation**. The default is $4.1e3$.

Filter order

Filter order, specified as an even positive integer. You can specify only when **Filter specification** is set to **Filter order and transition width** or **Filter order and stopband attenuation**. The default is 52.

Stopband attenuation (dB)

Stopband attenuation, specified as a real positive scalar in dB. You can specify the stopband attenuation only when **Filter specification** is set to **Filter order and stopband attenuation** or **Transition width and stopband attenuation**. The default is 80.

Numerator

Specify the FIR halfband filter coefficients directly as a row vector. The coefficients must comply with the FIR halfband impulse response format. If half the order of the filter, $(\text{length}(\text{Numerator}) - 1)/2$, is even, every other coefficient starting from the first coefficient must be a zero except for the center coefficient, which must be a 1.0. If half the order of the filter is odd, the sequence of alternating zeros with a 1.0 at the center starts at the second coefficient.

This parameter appears when **Filter specification** is set to **Coefficients**. The default is the coefficients vector returned by `2*firhalfband("minorder", 0.407, 1e-4)`.

Design method

Specify the filter design method as one of the following:

- **Auto** -- The algorithm automatically chooses the filter design method depending on the filter design parameters. The algorithm uses the equiripple or the Kaiser window method to design the filter.

If the design constraints are very tight, such as very high stopband attenuation or very narrow transition width, then the algorithm automatically chooses the Kaiser method, as this method is optimal for designing filters with very tight specifications. However, if the design constraints are not tight, then the algorithm chooses the equiripple method.

When you set the **Design method** parameter to **Auto**, you can determine the method used by the algorithm by examining the passband and stopband ripple characteristics of the designed filter. If the block used the equiripple method, the passband and stopband ripples of the designed filter have a constant amplitude in the frequency response. If the filter design method the block chooses in the **Auto** mode is not suitable for your application, manually specify the **Design method** as **Equiripple** or **Kaiser**.

- **Equiripple** -- The algorithm uses the equiripple method.
- **Kaiser** -- The algorithm uses the Kaiser window method.

This parameter appears when you set **Filter specification** to **Filter order and stopband attenuation**, **Filter order and transition width**, or **Transition width and stopband attenuation**.

Input highpass subband

When you select this check box, the block acts as a synthesis filter bank and synthesizes a signal from the highpass and lowpass subbands. When you clear this check box, the block acts as an FIR half band interpolator and accepts a single vector- or matrix-valued input.

Inherit sample rate from input

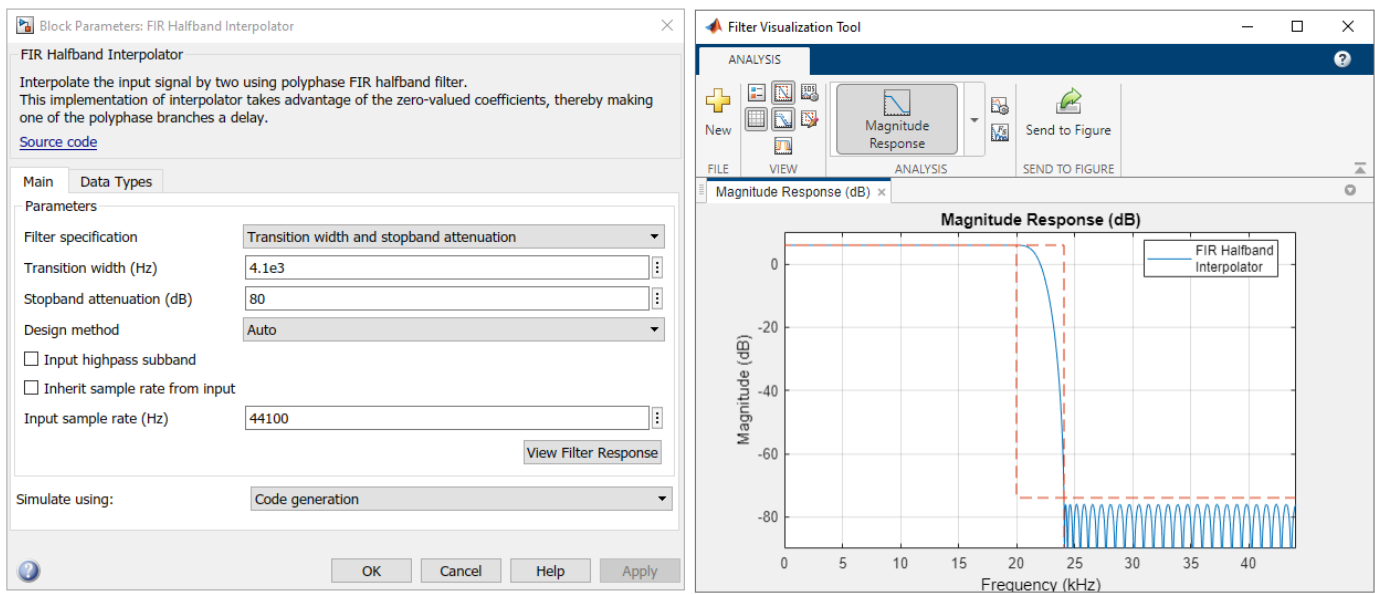

When you select this check box, the block inherits its sample rate from the input signal. When you clear this check box, you specify the sample rate in **Input Sample Rate (Hz)**. This parameter appears when you set **Filter specification** to any option other than Coefficients.

Input sample rate (Hz)

Input sample rate, specified as a scalar in Hz. The default value is 44100. This parameter appears when you set **Filter specification** to any option other than Coefficients and clear the **Inherit sample rate from input** parameter.

View Filter Response

Opens the Filter Visualization Tool FVTool and displays the magnitude/phase response of the FIR Halfband Interpolator. The response is based on the block dialog box parameters. Changes made to these parameters update FVTool.

To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

Simulate using

Type of simulation to run. You can set this parameter to:

- Code generation (default)

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.

- Interpreted execution

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

Data Types Tab

Rounding mode

Rounding method for the output fixed-point operations. The rounding methods are Ceiling, Convergent, Floor, Nearest, Round, Simplest, and Zero. The default is Floor.

Coefficients

Fixed-point data type of the coefficients, specified as one of the following:

- `fixdt(1,16)` (default) — Signed fixed-point data type of word length 16, with binary point scaling. The block determines the fraction length automatically from the coefficient values in such a way that the coefficients occupy maximum representable range without overflowing.
- `fixdt(1,16,0)` — Signed fixed-point data type of word length 16 and fraction length, 0. You can change the fraction length to any other integer value.
- `<data type expression>` — Specify the data type using an expression that evaluates to a data type object, for example, numeric type (`[]`, 16, 15). Specify the sign mode of this data type as `[]` or `true`.
- Refresh Data Type — Refreshes to the default data type.

Click the **Show data type assistant** button  to display the data type assistant, which helps you set the stage input parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed or unsigned) • 8-, 16-, 32-, and 64-bit signed integers • real and complex data
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, 32-, and 64-bit signed integers • real and complex data

More About

Halfband Filters

The ideal lowpass halfband filter is given by

$$h(n) = \frac{1}{2\pi} \int_{-\pi/2}^{\pi/2} e^{j\omega n} d\omega = \frac{\sin(\frac{\pi}{2}n)}{\pi n}.$$

The ideal filter is not realizable because the impulse response is noncausal and not absolutely summable. However, the impulse response of the ideal lowpass filter possesses some important properties that are required of a realizable approximation. Specifically, the ideal lowpass halfband filter's impulse response is:

- equal to 0 for all even-indexed samples
- equal to 1/2 at $n=0$. You can see this by using L'Hopital's rule on the continuous-valued equivalent of the discrete-time impulse response.

The ideal highpass halfband filter is given by

$$g(n) = \frac{1}{2\pi} \int_{-\pi}^{-\pi/2} e^{j\omega n} d\omega + \frac{1}{2\pi} \int_{\pi/2}^{\pi} e^{j\omega n} d\omega.$$

Evaluating the preceding integral gives the following impulse response

$$g(n) = \frac{\sin(\pi n)}{\pi n} - \frac{\sin(\frac{\pi}{2}n)}{\pi n}.$$

The ideal highpass halfband filter's impulse is:

- Equal to 0 for all even-indexed samples
- Equal to 1/2 at $n=0$.

The FIR halfband interpolator uses a causal FIR approximation to the ideal halfband response, which is based on minimizing the ℓ^∞ norm of the error (minimax). See "Algorithms" on page 2-573 for more details.

Kaiser Window

The coefficients of a Kaiser window are computed from this equation:

$$w(n) = \frac{I_0\left(\beta\sqrt{1 - \left(\frac{n - N/2}{N/2}\right)^2}\right)}{I_0(\beta)}, \quad 0 \leq n \leq N,$$

where I_0 is the zeroth-order modified Bessel function of the first kind.

To obtain a Kaiser window that represents an FIR filter with stopband attenuation of α dB, use this β .

$$\beta = \begin{cases} 0.1102(\alpha - 8.7), & \alpha > 50 \\ 0.5842(\alpha - 21)^{0.4} + 0.07886(\alpha - 21), & 50 \geq \alpha \geq 21 \\ 0, & \alpha < 21 \end{cases}$$

The filter order n is given by:

$$n = \frac{\alpha - 7.95}{2.285(\Delta\omega)}$$

where $\Delta\omega$ is the transition width.

Algorithms

Filter Design Method

The FIR halfband interpolator algorithm uses the equiripple or the Kaiser window method to design the FIR halfband filter. When the design constraints are tight, such as very high stopband attenuation or very narrow transition width, use the Kaiser window method. When the design constraints are not tight, use the equiripple method. If you are not sure of which method to use, set the design method to **Auto**. In this mode, the algorithm automatically chooses a design method from the two methods that optimally meets the specified filter constraints.

Halfband Equiripple Design

In the equiripple method, the algorithm uses a minimax (minimize the maximum error) FIR design to design a fullband linear phase filter with the desired specifications. The algorithm upsamples a fullband filter to replace the even-indexed samples of the filter with zeros and creates a halfband filter. It then sets the filter tap corresponding to the group delay of the filter in samples to 1/2. This yields a causal linear-phase FIR filter approximation to the ideal halfband filter defined in “Halfband Filters” on page 2-571. See [1] for a description of this filter design method using the Remez exchange algorithm. Since you can design a filter using this approximation method with a constant ripple both in the passband and stopband, the filter is also known as the equiripple filter.

Kaiser Window Design

In the Kaiser window method, the algorithm first truncates the ideal halfband filter defined in “Halfband Filters” on page 2-571, then it applies a Kaiser window defined in “Kaiser Window” on page 2-572. This yields a causal linear-phase FIR filter approximation to the ideal halfband filter.

The coefficients of the designed halfband interpolation filter are scaled by the interpolation factor, two, to preserve the output power of the signal.

For more information on designing FIR halfband filters, see “FIR Halfband Filter Design”.

Polyphase Implementation with Halfband Filters

The FIR halfband interpolator uses an efficient polyphase implementation for halfband filters when you filter the input signal. You can use a polyphase implementation to move the upsampling operation after filtering. This allows you to filter at the lower sampling rate.

Splitting a filter’s impulse response, $h(n)$, into two polyphase components results in an even polyphase component with z -transform

$$H_0(z) = \sum_n h(2n)z^{-n}.$$

and an odd polyphase component with z -transform

$$H_1(z) = \sum_n h(2n + 1)z^{-n}.$$

The z -transform of the filter can be written in terms of the even and odd polyphase components as

$$H(z) = H_0(z^2) + z^{-1}H_1(z^2).$$

Graphically, you can represent upsampling by two followed by filtering with the following figure

Using the multirate noble identity for upsampling, you can move the upsampling operation after filtering. This enables you to filter at the lower rate.

For a halfband filter, the only nonzero coefficient in the even polyphase component is the coefficient corresponding to z^0 . Implementing the halfband filter as a causal FIR filter shifts the nonzero coefficient to approximately $z^{-N/4}$, where N is the number of filter taps. This process is shown in the following figure.

The top plot shows a halfband filter of order 52. The bottom plot shows the even polyphase component. Both of these filters are noncausal. Delaying the even polyphase component by 13 samples creates a causal FIR filter.

To efficiently implement the halfband interpolator, the algorithm replaces the upsampling operator, delay block, and adder with a commutator switch. This is shown in the following figure, where one polyphase component is replaced by a delay.

The commutator switch takes input samples from the two branches alternately, one sample at a time. This doubles the sampling rate of the input signal. The polyphase component that reduces to a simple delay depends on whether the half order of the filter is even or odd. This is because the delay required to make the even polyphase component causal can be odd or even, depending on the filter half order.

To confirm this behavior, run the following code in the MATLAB command prompt and inspect the polyphase components of the following filters:

```
filterspec = "Filter order and stopband attenuation";
halfOrderEven = dsp.FIRHalfbandInterpolator(Specification=filterspec,...
    FilterOrder=64,StopbandAttenuation=80);
halfOrderOdd = dsp.FIRHalfbandInterpolator(Specification=filterspec,...
    FilterOrder=54,StopbandAttenuation=80);
polyphase(halfOrderEven)
polyphase(halfOrderOdd)
```

One of the polyphase components has a single nonzero coefficient indicating that it is a simple delay. To preserve the output power of the signal, the coefficients are scaled by the interpolation factor, two. To see this scaling, compare the polyphase components of a halfband interpolator with the coefficients of a halfband decimator.

```
hfirinterp = dsp.FIRHalfbandInterpolator;
hfirdecim = dsp.FIRHalfbandDecimator;
polyphase(hfirdecim)
polyphase(hfirinterp)
```

To summarize, the FIR halfband interpolator:

- Filters the input before upsampling with the even and odd polyphase components of the filter.
- Exploits the fact that one filter polyphase component is a simple delay for a halfband filter.

FIR Rate Conversion

Upsample, filter, and downsample input signals

Library: DSP System Toolbox / Filtering / Multirate Filters

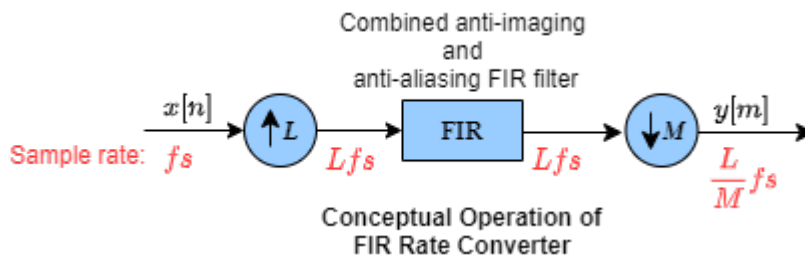

Description

The FIR Rate Conversion block resamples the discrete-time input such that its sample period is M/L times the input sample period (T_{si}). M is the integer value you specify for the **Decimation factor** parameter, and L is the integer value you specify for the **Interpolation factor** parameter. The block treats each column of the input as a separate channel and resamples the data in each channel independently over time.

Conceptually, the rate converter combines an FIR interpolator followed by an FIR decimator. The following schematic contains an upsampler, a combined anti-imaging and anti-aliasing FIR filter, and a downsampler. To design an FIR filter which acts as a combined anti-imaging and anti-aliasing FIR filter, use the `designMultirateFIR` function.

The rate converter does the following:

- 1 Upsamples the input to a higher rate by inserting $L-1$ zeros between input samples.
- 2 Passes the upsampled data through an FIR filter.
- 3 Downsamples the filtered data to a lower rate by discarding $M-1$ consecutive samples following each sample that the block retains.

Note that the actual block algorithm implements a polyphase structure, an efficient equivalent of the combined system depicted in the diagram. For more details, see “Algorithms” on page 2-590.

Ports

Input

Port_1(In1) — Input signal

vector | matrix

Specify the input signal as a vector or a matrix of size P -by- Q . The input columns represent the Q independent channels.

The block supports variable-size input signals (frame length changes during simulation) when you set **Rate options** to **Enforce single-rate processing**. When the block accepts variable-size input signals, they can be of arbitrary frame length. That is, the input frame length does not have to be a multiple of the decimation factor. For fixed-size signals, the frame length can be arbitrary under certain conditions. For more details, see “Frame-Based Processing” on page 2-589.

When the block input is fixed point, all internal data types are signed fixed point.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Output

Port_1(Out1) — Rate converted signal

`vector` | `matrix`

Rate converted signal, returned as a vector or a matrix.

When you set the **Rate options** parameter to:

- **Enforce single-rate processing** -- The block maintains the input sample rate and resamples the signal by changing the output frame size by a factor of L/M .

The output has an upper bound size of $\text{ceil}(LP/M)$ -by- Q for an input of size P -by- Q .

- **Allow multirate processing** -- The block decimates the signal such that the output signal sample rate is L/M times the input sample rate.

The output frame size is the same as the input frame size, $F_o = (L/M) \times F_i$

All blocks connected to the output operate at F_o , and all blocks connected to the input operate at F_i .

For more details, see “Frame-Based Processing” on page 2-589.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Parameters

Coefficient source — Mode of operation

Auto (default) | **Dialog parameters** | **Filter object**

The FIR Rate Conversion block can operate in three different modes. Select the mode in the **Coefficient source** group box.

- **Dialog parameters** — Enter information about the filter, such as FIR filter coefficients in the block dialog box.
- **Filter object** — Specify the filter using a `dsp.FIRRateConverter` System object.
- **Auto** (default) — The block determines the filter coefficients.

The settings in the FIR Rate Conversion block dialog box change based on the mode selected.

Main Tab**Interpolation factor — Interpolation factor**

3 (default) | positive integer

Specify the interpolation factor, L , as a positive integer. The block upsamples the signal by this value before filtering it.

Dependencies

To enable this parameter, set **Coefficient source** to either **Dialog parameters** or **Auto**.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

FIR filter coefficients — FIR filter coefficients

designMultirateFIR(3,2) (default) | vector

Specify the FIR filter coefficients in descending powers of z . By default, the block uses the designMultirateFIR(3,2) function to compute the filter coefficients.

Dependencies

To enable this parameter, set **Coefficient source** to **Dialog parameters**.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Decimation factor — Decimation factor

2 (default) | positive integer

Specify the decimation factor, M , as a positive integer. The block downsamples the signal by this value after filtering it.

Dependencies

To enable this parameter, set **Coefficient source** to either **Dialog parameters** or **Auto**.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Rate options — Enforce single-rate or allow multirate processing

Enforce single-rate processing (default) | Allow multirate processing

Specify whether to enforce single-rate processing or allow multirate processing.

- **Enforce single-rate processing** -- The output frame size P_o is L/M times the input frame size P_i , where L is the interpolation factor and M is the decimation factor.

$$P_o = (L/M) \times P_i$$

The output signal rate in Simulink equals the input signal rate.

$$F_o = F_i$$

- **Allow multirate processing** -- The output frame size equals the input frame size.

$$P_o = P_i$$

The output signal rate in Simulink is L/M times the input signal rate.

$$F_o = (L/M) \times F_i$$

All blocks connected to the output operate at F_o , and all blocks connected to the input operate at F_i .

Filter object – Filter object

FRC (default) | `dsp.FIRRateConverter` System object

Specify the multirate filter object that you want the block to implement. The specified filter object must be a `dsp.FIRRateConverter` System object.

You can define the System object in the block mask or in a MATLAB workspace variable.

For information on creating System objects, see “Define Basic System Objects”.

Dependencies

This parameter appears when **Coefficient source** is set to **Filter object**.

Allow arbitrary frame length for fixed-size input signals – Allow arbitrary frame length for fixed-size input signals

off (default) | on

Specify whether fixed-size input signals (whose size does not change during simulation) can have an arbitrary frame length, where the frame length does not have to be a multiple of the decimation factor. The block uses this parameter setting only for fixed-size input signals and ignores this parameter if the input has a variable-size.

When the input signal is a variable-size signal, the signal can have arbitrary frame length, that is, the frame length does not have to be a multiple of the decimation factor.

For fixed-size input signals, if you:

- Select the **Allow arbitrary frame length for fixed-size input signals** parameter, the frame length of the signal does not have to be a multiple of the decimation factor. If the input is not a multiple of the decimation factor, then the output is generally a variable-size signal. Therefore, to support arbitrary input size, the block must also support variable-size operations, which you can enable by selecting the **Allow arbitrary frame length for fixed-size input signals** parameter.
- Clear the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length must be a multiple of the decimation factor.

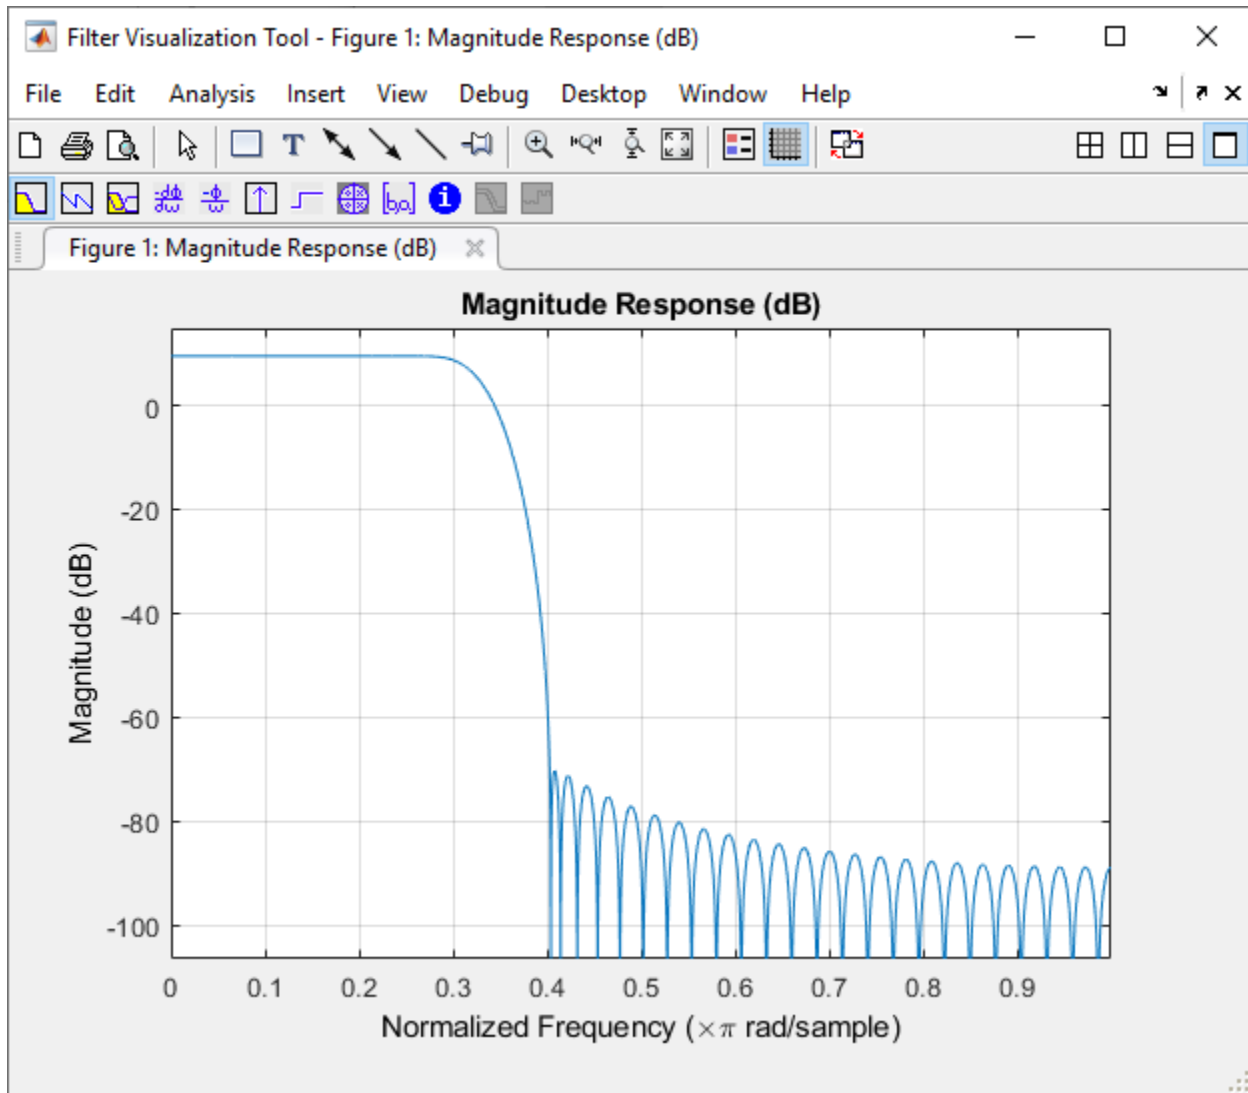

Dependency

To enable this parameter, set **Rate options** to `Enforce single-rate processing`.

View Filter Response – Visualize filter response

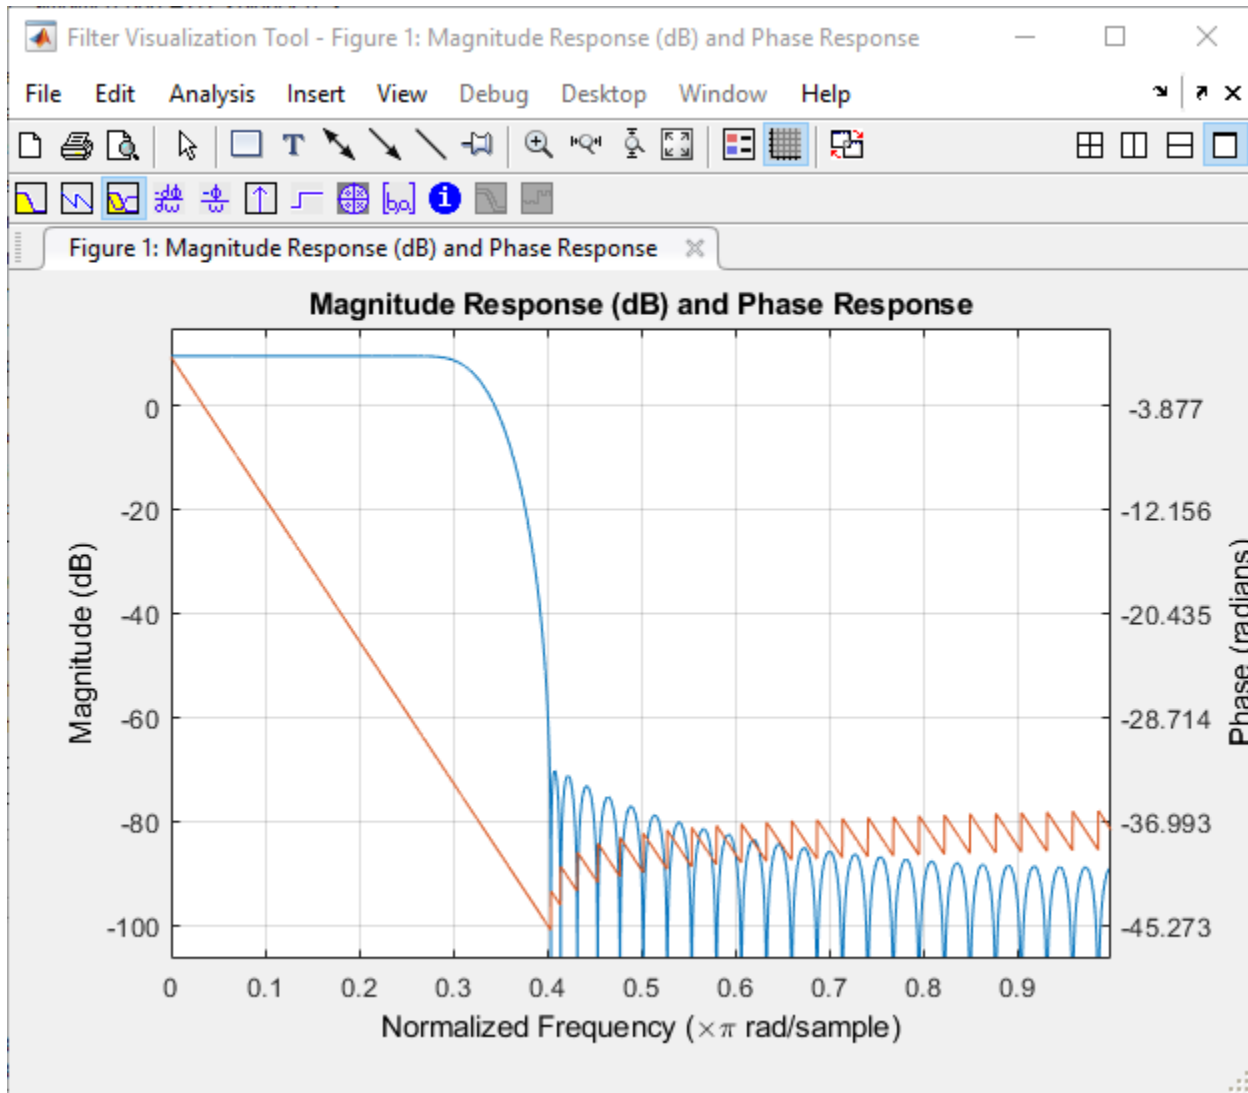

button

Select this parameter to open the Filter Visualization Tool, `fvtool`, and display the magnitude response of the FIR filter. The response is based on the parameters selected in the block dialog box. Changes made to these parameters update `fvtool`.

To update the magnitude response while `fvtool` is running, modify the block parameters and click **Apply**.

To view the magnitude response and phase response simultaneously, click the **Magnitude and Phase responses** button on the toolbar.

Data Types Tab

When **Coefficient source** is set to **Filter object**, the fixed-point settings of the filter object specified on the **Main tab** are displayed on the **Data Types tab**. You cannot change these settings directly on the block dialog box. To change the fixed-point settings, you must edit the filter object.

For more information on System objects, see the “What Are System Objects?”.

When **Coefficient source** is set to **Auto**, the block chooses the filter coefficients automatically. For more information on the filter design algorithm that the block uses, see “Specify FIR Filter Coefficients” on page 2-588.

Rounding mode — Rounding method

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations as:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see Rounding Modes.

The filter coefficients do not obey this parameter and always round to Nearest.

Note The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numerical results when all these conditions are met:

- **Product output** data type is Inherit: Inherit via internal rule.
- **Accumulator** data type is Inherit: Inherit via internal rule.
- **Output** data type is Inherit: Same as accumulator.

With these data-type settings, the block operates in a full-precision mode.

Dependencies

To enable this parameter, set **Coefficient source** to either **Dialog parameters** or **Auto**.

Saturate on integer overflow – Overflow handling method

off (default) | on

Select this parameter to saturate the result of the fixed-point operation. Clear this parameter to wrap the result of the fixed-point operation. For details on *saturate* and *wrap*, see Overflow Handling for fixed-point operations.

Note The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numeric results when all these conditions are met:

- **Product output** data type is Inherit: Inherit via internal rule.
- **Accumulator** data type is Inherit: Inherit via internal rule.

With these data-type settings, the block operates in a full-precision mode.

Dependencies

This parameter is editable only when **Coefficient source** is set to either **Dialog parameters** or **Auto**.

Coefficients – Coefficients data type

Inherit: Same word length as input (default) | fixdt(1,16) | fixdt(1,16,0)

Coefficients specifies the data type of the filter coefficients.

- **Inherit: Same word length as input** -- The block inherits the word length of the coefficients from the fixed-point input. The fraction length is determined based on the coefficient values in order to obtain the best possible precision.
- **fixdt(1,16)** -- The coefficients data type is a signed, binary-point, scaled, fixed-point data type with a word length of 16 bits.
- **fixdt(1,16,0)** -- The coefficients data type is a signed, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Coefficients** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink).

For a diagrammatic representation of how this block uses the filter coefficients data type, see “Fixed Point” on page 2-593.

Dependencies

This parameter is editable only when **Coefficient source** is set to either **Dialog parameters** or **Auto**.

Coefficients Minimum — Minimum value of filter coefficients

[] (default) | scalar

Specify the minimum value of the filter coefficients. Simulink uses this minimum value to perform automatic scaling of fixed-point data types.

Coefficients Maximum — Maximum value of filter coefficients

[] (default) | scalar

Specify the maximum value of the filter coefficients. Simulink uses this maximum value to perform automatic scaling of fixed-point data types.

Product output — Product output data type

Inherit: *Inherit via internal rule* (default) | Inherit: Same as input | **fixdt(1,16,0)**

Product output specifies the data type of the output of a product operation in the FIR Rate Conversion block.

- **Inherit: Inherit via internal rule** — The block inherits the product output data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- **Inherit: Same as input** — The block specifies the product output data type to be the same as the input data type.
- **fixdt(1,16,0)** — The block specifies a signed, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Product output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink).

For a diagrammatic representation of how this block uses the product output data type, see “Fixed Point” on page 2-593.

Dependencies

This parameter is editable only when **Coefficient source** is set to either **Dialog parameters** or **Auto**.

Accumulator — Accumulator data type

Inherit: `Inherit via internal rule (default)` | Inherit: `Same as input` | Inherit: `Same as product output` | `fixdt(1,16,0)`

Accumulator specifies the data type of the output of an accumulation operation in the FIR Rate Conversion block. For illustrations on how this block uses the accumulator data type, see “Fixed Point” on page 2-593.

- `Inherit: Inherit via internal rule` — The block inherits the accumulator data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- `Inherit: Same as input` — The block specifies the accumulator data type to be the same as the input data type.
- `Inherit: Same as product output` — The block specifies the accumulator data type to be the same as the product output data type.
- `fixdt(1,16,0)` — The block specifies a signed, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink).

Dependencies

This parameter is editable only when **Coefficient source** is set to either **Dialog parameters** or **Auto**.

Output — Output data type

Inherit: `Same as accumulator (default)` | Inherit: `Same as input` | Inherit: `Same as product output` | `fixdt(1,16,0)`

Output specifies the data type of the output of the FIR Rate Conversion block.

- `Inherit: Same as input` — The block specifies the output data type to be the same as the input data type.
- `Inherit: Same as product output` — The block specifies the output data type to be the same as the product output data type.
- `Inherit: Same as accumulator` — The block specifies the output data type to be the same as the accumulator data type.
- `fixdt(1,16,0)` — The block specifies a signed, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink).

For a diagrammatic representation of how this block uses the output data type, see “Fixed Point” on page 2-593.

Dependencies

This parameter is editable only when **Coefficient source** is set to either **Dialog parameters** or **Auto**.

Output Minimum — Minimum value the block can output

[] (default) | scalar

Specify the minimum value the block can output. Simulink uses this minimum value to perform:

- Simulation range checking. For more information, see “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

Output Maximum — Maximum value block can output

[] (default) | scalar

Specify the maximum value the block can output. Simulink uses this maximum value to perform:

- Simulation range checking. For more information, see “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block dialog box.

Dependencies

This parameter appears only when **Coefficient source** is set to either **Dialog parameters** or **Auto**.

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

More About

Specify FIR Filter Coefficients

When you select the **Dialog parameters** option, you use the **FIR filter coefficients** parameter to specify the numerator coefficients of the FIR filter transfer function $H(z)$.

$$H(z) = b_0 + b_1z^{-1} + \dots + b_Nz^{-N}$$

You can generate the FIR filter coefficient vector, $\mathbf{b} = [b_0, b_1, \dots, b_N]$, using one of the DSP System Toolbox filter design functions such as `designMultirateFIR`, `firnyquist`, `firhalfband`, `firgr`, or `firceqrip`.

The coefficient vector you specify must have a length greater than the interpolation factor ($N + 1 > L$). The FIR filter must be a lowpass filter with a normalized cutoff frequency no greater than $\min(1/L, 1/M)$. The block internally initializes all filter states to zero.

When you select the **Auto** mode, the block designs an FIR multirate filter with the decimation factor specified in **Decimation factor** and interpolation factor specified in **Interpolation factor**. The `designMultirateFIR` function designs the filter and returns the coefficients used by the block. For more information on the filter design algorithm, see Orfanidis [1].

Specify Resampling Rate

This section applies only to the single-rate processing mode when the **Rate options** parameter is set to **Enforce single-rate processing**.

You specify the resampling rate of the FIR Rate Conversion block using the **Decimation factor** and **Interpolation factor** parameters. For a P_i -by- Q matrix input, the **Decimation factor** M and the **Interpolation factor** L must satisfy these requirements:

- M and L must be relatively prime integers. That is, the ratio M/L cannot be reduced to a ratio of smaller integers.
- $\frac{M}{L} = \frac{P_i}{P_o}$, where P_i and P_o are the integer frame sizes of the input and output, respectively.

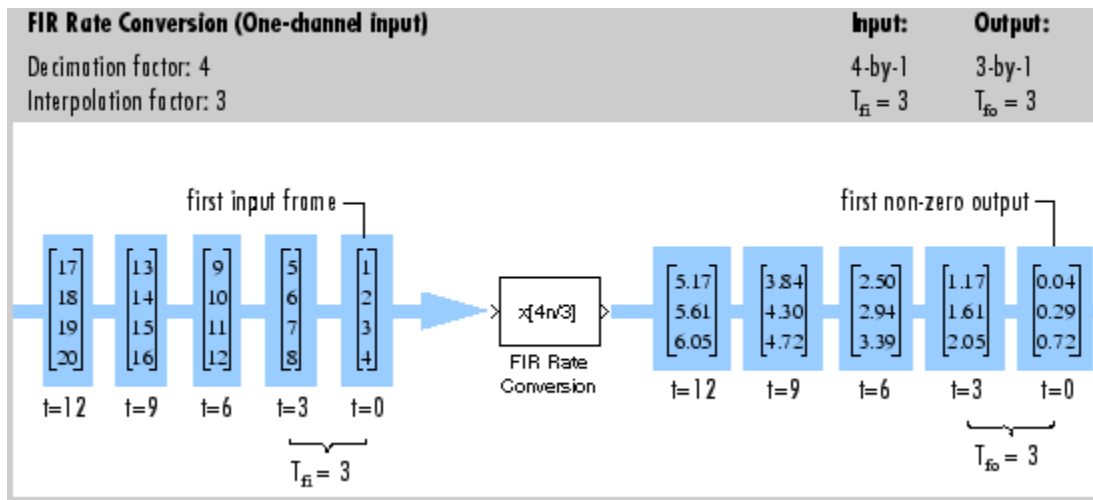

You can satisfy the second requirement by setting the **Decimation factor**, M , to equal the input frame size P_i . When you do so, the output frame size P_o equals the **Interpolation factor** L .

By changing the frame size in this way, the block is able to hold the frame period constant ($T_{\hat{f}} = T_{f_0}$) and achieve the desired conversion of the sample period, such that

$$T_{so} = \frac{M}{L} \times T_{si}$$

where T_{so} is the output sample period.

This figure shows how the FIR Rate Conversion block converts a 4-by-1 input with a sample period of $3/4$ to a 3-by-1 output with a sample period of 1. The frame period (T_f) of 3 remains constant.

Frame-Based Processing

The FIR Rate Conversion block resamples each column of the input over time. In this mode, the block can perform either single-rate or multirate processing. You can use the **Rate options** parameter to specify how the block resamples the input.

- When you set the **Rate options** parameter to Enforce single-rate processing, the input and output of the block have the same sample rate. To resample the output while maintaining the input sample rate, the block resamples the data in each column of the input such that the frame length of the output has an upper bound size of $\text{ceil}(LP/M)$, where L is the interpolation factor specified in the **Interpolation factor** parameter, P is the input frame length, and M is the decimation factor specified in the **Decimation factor** parameter.

In this mode, if you input a fixed-size signal (frame length does not change during simulation) and select the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length can be arbitrary and does not have to be a multiple of the decimation factor. If you clear the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length must be a multiple of the decimation factor.

In this mode, if you input a variable-size signal (frame length changes during simulation), the **Allow arbitrary frame length for fixed-size input signals** appears on the block dialog box but does not have any impact on the input frame length. You can input a variable-size signal of any frame length even if you do not select the **Allow arbitrary frame length for fixed-size input signals** parameter.

This table summarizes the support for arbitrary input frame length when you set **Rate options** to Enforce single-rate processing.

Input Signal	Block Support for this Signal	Support for Arbitrary Input Frame Length	Input Size	Output Size
Fixed-size input signal	Yes	When you select Allow arbitrary frame length for fixed-size input signals	P -by- Q	Upper bound size of $\text{ceil}(LP/M)$ -by- Q
Variable-size input signal	Yes	Always	P -by- Q	Upper bound size of $\text{ceil}(LP/M)$ -by- Q

- When you set the **Rate options** parameter to **Allow multirate processing**, the input and output of the FIR Rate Conversion block are of the same size, but the sample rate of the output is L/M times that of the input. In this mode, the block treats a P -by- Q matrix input as Q independent channels. The block decimates each column of the input over time by keeping the frame size constant, and making the output frame period (T_{fo}) M/L times the input frame period ($T_{fo} = (M/L)*T_{fi}$).

In this mode, the block accepts only fixed-size signals and these signals can have an arbitrary frame length.

This table summarizes the support for arbitrary input frame length when you set **Rate options** to **Allow multirate processing**.

Input Signal	Block Support for this Signal	Support for Arbitrary Input Frame Length	Input Size	Output Size
Fixed-size input signal	Yes	Always	P -by- Q	P -by- Q
Variable-size input signal	No	Not applicable	Not applicable	Not applicable

Algorithms

The FIR rate converter is implemented efficiently using a polyphase structure.

To derive the polyphase structure, start with the transfer function of the FIR filter: This FIR filter is a combined anti-imaging and anti-aliasing filter.

$$H(z) = b_0 + b_1z^{-1} + \dots + b_Nz^{-N}$$

$N+1$ is the length of the FIR filter.

You can rearrange this equation as follows:

$$\begin{aligned}
 H(z) = & (b_0 + b_Lz^{-L} + b_{2L}z^{-2L} + \dots + b_{N-L+1}z^{-(N-L+1)}) + \\
 & z^{-1}(b_1 + b_{L+1}z^{-L} + b_{2L+1}z^{-2L} + \dots + b_{N-L+2}z^{-(N-L+1)}) + \\
 & \vdots \\
 & z^{-(L-1)}(b_{L-1} + b_{2L-1}z^{-L} + b_{3L-1}z^{-2L} + \dots + b_{N-L}z^{-(N-L+1)})
 \end{aligned}$$

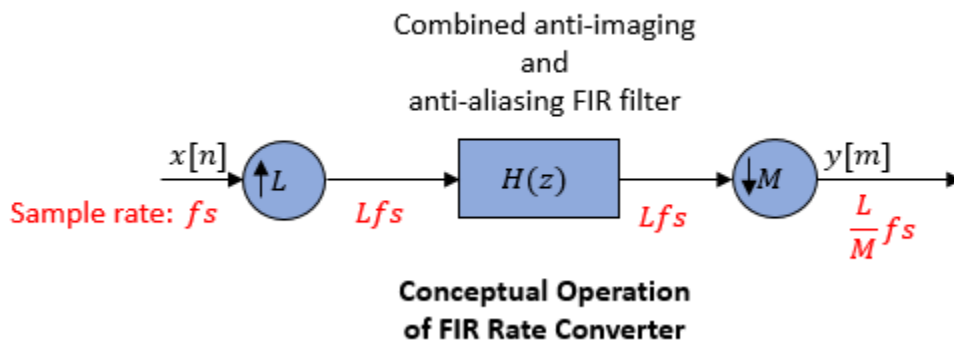

L is the number of polyphase components, and its value equals the interpolation factor that you specify.

You can write this equation as:

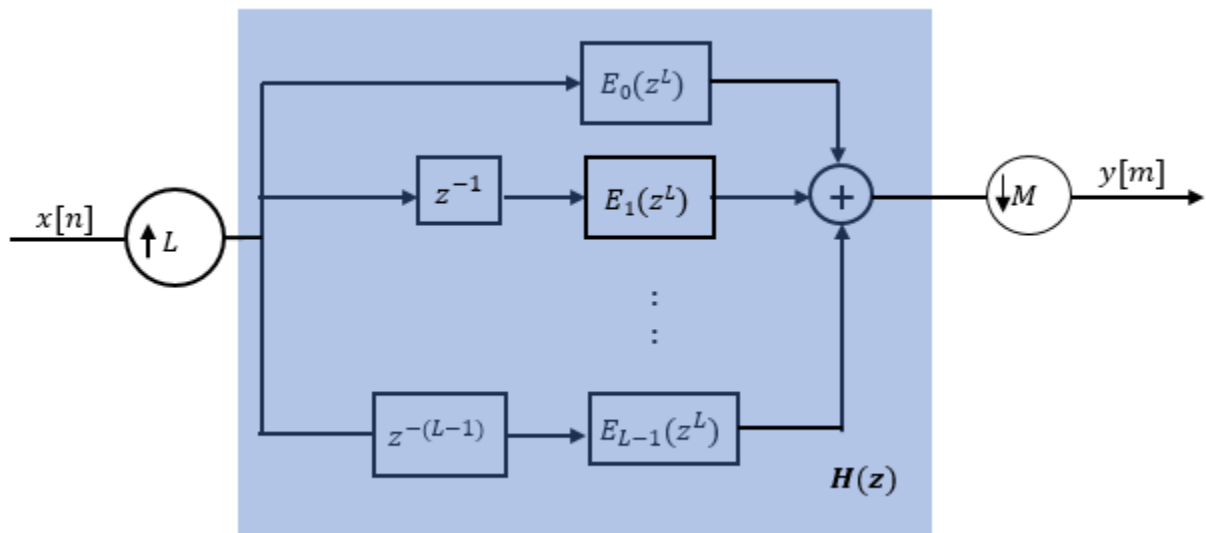

$$H(z) = E_0(z^L) + z^{-1}E_1(z^L) + \dots + z^{-(L-1)}E_{L-1}(z^L)$$

$E_0(z^L), E_1(z^L), \dots, E_{L-1}(z^L)$ are polyphase components of the FIR filter $H(z)$.

Conceptually, the FIR rate converter contains an upsampler, followed by a combined anti-imaging, anti-aliasing FIR filter $H(z)$, which is followed by a downsampler.

Replace $H(z)$ with its polyphase representation.

Here is the multirate noble identity for interpolation.

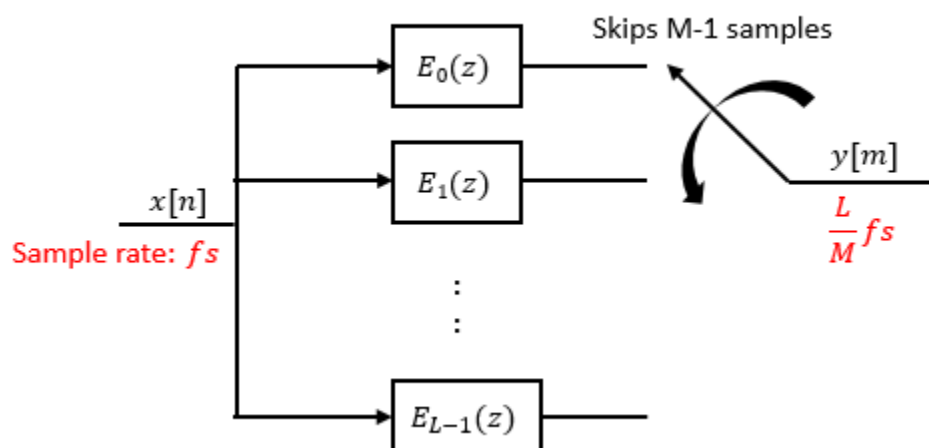

Applying the noble identity for interpolation moves the upsampling operation to after the filtering operation. This move enables you to filter the signal at a lower rate.

You can replace the upsampling operator, delay block, and the adder with a commutator switch. To account for the downsampler that follows, the switch moves in steps of size M . The switch receives the first sample from branch 0 and moves in the counter clockwise direction, each time skipping $M-1$ branches.

As an example, consider a rate converter with L set to 5 and M set to 3. The polyphase components are $E_0(z)$, $E_1(z)$, $E_2(z)$, $E_3(z)$, and $E_4(z)$. The switch starts on the first branch 0, skips branches 1 and 2, receives the next sample from branch 3, then skips branches 4 and 0, receives the next sample from branch 2, and so on. The sequence of branches from which the switch receives the data sample is [0, 3, 1, 4, 2, 0, 3, 1, ...].

The rate converter implements the L/M conversion by first applying the interpolation factor L to the incoming data, and using the commutator switch at the end to receive only 1 in M samples, effectively accounting for the downsampling factor M . Hence, the sample rate at the output of the FIR rate converter is Lfs/M .

Version History

Introduced before R2006a

Support for arbitrary input frame length

Starting in R2022b, this block supports input signals with arbitrary frame lengths when the:

- Input signal is a fixed-size signal (frame length does not change during simulation) and the block allows for multirate processing
- Input signal is a fixed-size signal, the block enforces single-rate processing, and you select the **Allow arbitrary frame length for fixed-size input signals** parameter
- Input signal is a variable-size signal (frame length changes during simulation)

When this block supports an arbitrary frame length input signal, the input frame length does not have to be a multiple of the decimation factor.

For more details, see “Frame-Based Processing” on page 2-589.

Extended Capabilities

C/C++ Code Generation

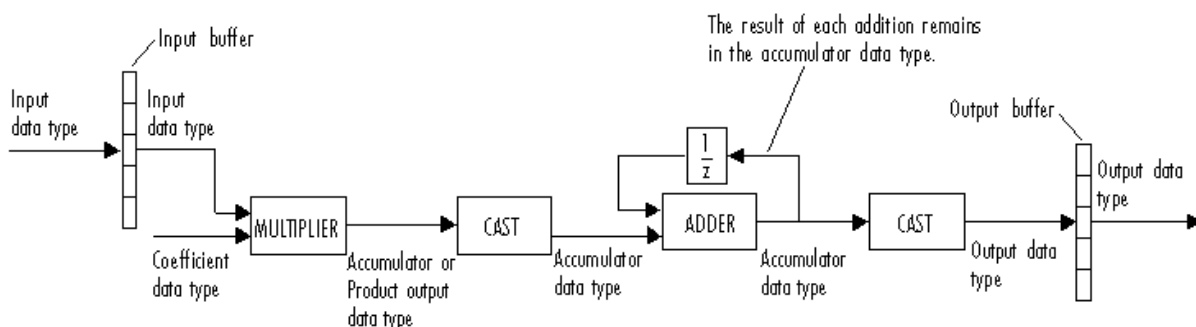

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the memcpy or memset function (string.h) under certain conditions.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

This diagram shows the data types used within the FIR Rate Conversion block for fixed-point signals.

You can set the coefficient, product output, accumulator, and output data types in the block dialog box. The diagram shows that input data is stored in the input buffer in the same data type and scaling as the input. Filtered data resides in the output buffer in the output data type and scaling that you set in the block dialog. The block stores any initial conditions in the output buffer using the output data type and scaling that you set in the block dialog box.

The output of the multiplier is in the product output data type when at least one of the inputs to the multiplier is real. When both the inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on how the complex multiplication is performed in the block, see “Multiplication Data Types”.

Note When the block input is fixed point, all internal data types are signed fixed point.

Flip

Flip input vertically or horizontally

Library

Signal Management / Indexing

dspindex

Description

The Flip block vertically or horizontally reverses the M -by- N input matrix, u . The output always has the same dimensionality as the input.

When you set the **Flip along** parameter to Columns, the block flips the input *vertically* so the first row of the input becomes the last row of the output.

```
y = flipud(u) % Equivalent MATLAB code
```

When flipping the input vertically, the block treats length- M unoriented vector inputs as M -by-1 column vectors.

When you set the **Flip along** parameter to Rows, the block flips the input *horizontally* so the first column of the input becomes the last column of the output.

```
y = fliplr(u) % Equivalent MATLAB code
```

When flipping the input horizontally, the block treats length- N unoriented vector inputs as 1-by- N row vectors.

This block supports Simulink virtual buses.

Parameters

Flip along

Specify the dimension along which to flip the input. When you set this parameter to Columns, the block flips the input vertically. When you set this parameter to Rows, the block flips the input horizontally.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers • Enumerated
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers • Enumerated

Forward Substitution

Solve $LX = B$ for X when L is lower triangular matrix

Library: DSP System Toolbox / Math Functions / Matrices and Linear Algebra / Linear System Solvers

Description

The Forward Substitution block solves the linear system $LX = B$ by simple forward substitution of variables, where:

- L is the lower triangular M -by- M matrix input to the **L** port.
- B is the M -by- N matrix input to the **B** port.
- X is the M -by- N output matrix and is the solution of the system of equations.

The block does not check the rank of the inputs. The block only uses the elements in the *lower triangle* of input L and ignores the upper elements. When you select **Input L is unit-lower triangular**, the block assumes the elements on the diagonal of L are 1s. This is useful when matrix L is the result of another operation, such as an LDL decomposition, that uses the diagonal elements to represent the D matrix.

Ports

Input

L — Input lower triangular matrix

M -by- M matrix

Specify the input lower triangular M -by- M matrix L through this port. Inputs L and B must have the same number of rows.

When the input L is fixed-point, it is signed only.

Data Types: single | double | int8 | int16 | int32 | fixed point

B — **B** matrix

M -by- N matrix | M -by-1 vector

Specify the B matrix in the $LX = B$ equation as an M -by- N matrix or a M -by-1 vector.

When you specify an M -by-1 vector, the block treats the length- M vector input at port **B** as an M -by-1 matrix. Inputs L and B must have the same number of rows.

When the input B is fixed-point, it is signed only.

Data Types: single | double | int8 | int16 | int32 | fixed point

Output

X — Solution of system of equations

M-by-*N* matrix | *M*-by-1 matrix

The block returns the output as an *M*-by-*N* matrix or an *M*-by-1 matrix. The size of *X* matrix is same as the size of the *B* matrix.

When the inputs are fixed-point, the output matrix *X* is signed only fixed-point.

Data Types: single | double | int8 | int16 | int32 | fixed point

Parameters

Main Tab

Input L is unit-lower triangular — Diagonal elements of input matrix have a value of 1

off (default) | on

Select this check box only when all elements on the diagonal of *L* have a value of 1. When you do so, the block optimizes its behavior by skipping an unnecessary division operation.

Do not select this check box if any elements on the diagonal of *L* do not have a value of 1. When you clear the **Input L is unit-lower triangular** check box, the block always performs the division operation.

Diagonal of complex input L is real — Diagonal elements of complex input are real

off (default) | on

Select to optimize simulation speed when the diagonal elements of complex input *L* are real.

Note When *L* is a complex fixed-point signal, you must select either **Input L is unit-lower triangular** or **Diagonal of complex input L is real**. In these cases, the block ignores any imaginary part of the diagonal of *L*.

Dependencies

This parameter is visible only when **Input L is unit-upper triangular** is not selected.

Data Types Tab

Note Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

Rounding mode — Method of rounding operation

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

Saturate on integer overflow — Method of overflow action

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

Product output — Product output data type

Inherit: Inherit via internal rule (default) | Inherit: Same as first input | fixdt(1,16,0)

Product output specifies the data type of the output of a product operation in the Backward Substitution block. For more information on the product output data type, see “Fixed Point” on page 2-601 and “Multiplication Data Types”.

- **Inherit: Inherit via internal rule** — The block inherits the product output data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- **Inherit: Same as first input** — The block specifies the product output data type to be the same as the first input data type.
- **fixdt(1,16,0)** — The block specifies a signed, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Product output** data type by using the **Data Type Assistant**. To use

the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

Accumulator — Accumulator data type

Inherit: Inherit via internal rule (default) | Inherit: Same as product output | Inherit: Same as first input | fixdt(1,16,0)

Accumulator specifies the data type of the output of an accumulation operation in the Backward Substitution block. For illustrations on how to use the accumulator data type in this block, see the “Fixed Point” on page 2-601 section.

- **Inherit: Inherit via internal rule** — The block inherits the accumulator data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- **Inherit: Same as product output** — The block specifies the accumulator data type to be the same as the product output data type.
- **Inherit: Same as first input** — The block specifies the accumulator data type to be the same as the first input data type.
- **fixdt(1,16,0)** — The block specifies a signed, binary-point scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

Output — Output data type

Inherit: Same as first input (default) | fixdt(1,16,0)

Output specifies the data type of the output of the Backward Substitution block. For more information on the output data type, see the “Fixed Point” on page 2-601 section.

- **Inherit: Same as first input** — The block specifies the output data type to be the same as the first input data type.
- **fixdt(1,16,0)** — The block specifies a signed, binary-point scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

Output Minimum — Minimum value the block can output

[] (default) | scalar

Specify the minimum value the block can output. Simulink software uses this minimum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

Output Maximum — Maximum value block can output

[] (default) | scalar

Specify the maximum value the block can output. Simulink software uses this maximum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

Lock data type settings against changes by the fixed-point tools – Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

Block Characteristics

Fourth-Order Section Filter

Implement cascade of fourth-order section filters

Library: DSP System Toolbox / Filtering / Filter Implementations

Description

The Fourth-Order Section Filter block implements a cascade of fourth-order section filters in Simulink. You can specify the numerator and denominator coefficients of the filter in the block parameters dialog box or through input ports.

Ports

Input

x — Input signal

vector | matrix

Input signal, specified as a vector or a matrix. The input can be a variable size signal. That is, the frame size of the signal can change during simulation but the number of channels cannot.

This port is unnamed until you set the **Coefficient source** parameter to `Input ports`.

Data Types: `single` | `double`

Num — Numerator coefficients

P -by-5 matrix

Specify the numerator coefficients of the fourth-order section filter as a P -by-5 matrix, where P is the number of filter sections. For more details on this input port, see **Numerator coefficients of filter**.

While the simulation is running, you can change the number of sections (rows) in the numerator coefficients. You can also change the coefficient values.

Dependencies

This port appears only when you set the **Coefficient source** parameter to `Input ports`.

Data Types: `single` | `double`

Den — Denominator coefficients

P -by-5 matrix | P -by-4 matrix

Specify the denominator coefficients of the fourth-order section filter as a P -by-5 matrix or a P -by-4 matrix, where P is the number of filter sections. For more details on this input port, see **Denominator coefficients of filter**.

While the simulation is running, you can change the number of sections (rows) in the denominator coefficients. You can also change the coefficient values.

Dependencies

This port appears only when you set the **Coefficient source** parameter to `Input ports`.

Data Types: `single` | `double`

Output**y — Filtered output**

vector | matrix

Filtered output, returned as a vector or a matrix. The output has the same size and data type as the input. The output signal is complex if either the input signal, numerator coefficients, or the denominator coefficients are complex.

This port is unnamed until you set the **Coefficient source** parameter to `Input ports`.

Data Types: `single` | `double`

Parameters**Coefficient source — Filter coefficient source**

Dialog parameters (default) | `Input ports` | `Filter object`

Specify the filter coefficient source as one of the following:

- `Dialog parameters` -- Specify the filter coefficients through the **Numerator coefficients of filter** and the **Denominator coefficients of filter** parameters in the block dialog box.
- `Input ports` -- Specify the filter coefficients through the **Num** and **Den** input ports.
- `Filter object` -- Specify the filter coefficients using a `dsp.FourthOrderSectionFilter` object.

To view the filter response, set this parameter to `Dialog parameters` or `Filter object`, and then click the **View Filter Response** button.

Numerator coefficients of filter — Numerator coefficients

[0.07795634 0 -0.15591268 0 0.07795634; 0.06188520 0 -0.12377039 0 0.06188520] (default) | P -by-5 matrix

Specify the numerator coefficients **b** of the fourth-order section filter as a P -by-5 matrix, where P is the number of filter sections.

$$\mathbf{b} = \begin{bmatrix} b_{01} & b_{11} & b_{21} & b_{31} & b_{41} \\ b_{02} & b_{12} & b_{22} & b_{32} & b_{42} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ b_{0P} & b_{1P} & b_{2P} & b_{3P} & b_{4P} \end{bmatrix}$$

In the transfer function form, the fourth-order section filter can be represented using the following equation:

$$H(z) = \prod_{k=1}^P H_k(z) = \prod_{k=1}^P \frac{b_{0k} + b_{1k}z^{-1} + b_{2k}z^{-2} + b_{3k}z^{-3} + b_{4k}z^{-4}}{a_{0k} + a_{1k}z^{-1} + a_{2k}z^{-2} + a_{3k}z^{-3} + a_{4k}z^{-4}}$$

where,

- **a** -- Denominator coefficients matrix. For more details on how to specify this matrix, see **Denominator coefficients of filter**.
- *k* -- Row index.

You cannot change the size of this parameter during simulation, but you can change its value.

Tunable: Yes

Dependencies

To enable this parameter, set **Coefficient source** to Dialog parameters.

Data Types: single | double

Denominator coefficients of filter — Denominator coefficients

[1 0 1.32091343 0 0.63273879; 1 0 1.04859957 0 0.29614035] (default) | *P*-by-5 matrix | *P*-by-4 matrix

Specify the denominator coefficients **a** of the fourth-order section filter as a *P*-by-5 matrix or a *P*-by-4 matrix, where *P* is the number of filter sections.

$$\mathbf{a} = \begin{bmatrix} a_{01} & a_{11} & a_{21} & a_{31} & a_{41} \\ a_{02} & a_{12} & a_{22} & a_{32} & a_{42} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{0P} & a_{1P} & a_{2P} & a_{3P} & a_{4P} \end{bmatrix}$$

The block algorithm assumes that the value of the leading coefficients is always 1. If the denominator is of size *P*-by-4, the block algorithm places 1s in the first column to make the denominator size *P*-by-5. If the denominator is of size *P*-by-5 and the elements in the first column do not equal 1, the algorithm ignores the values in the first column and appends them with 1s.

In the transfer function form, the fourth-order section filter can be represented using the following equation:

$$H(z) = \prod_{k=1}^P H_k(z) = \prod_{k=1}^P \frac{b_{0k} + b_{1k}z^{-1} + b_{2k}z^{-2} + b_{3k}z^{-3} + b_{4k}z^{-4}}{a_{0k} + a_{1k}z^{-1} + a_{2k}z^{-2} + a_{3k}z^{-3} + a_{4k}z^{-4}}$$

where,

- **b** -- Numerator coefficients matrix. For more details on how to specify this matrix, see **Numerator coefficients of filter**.
- *k* -- Row index.

You cannot change the size of this parameter during simulation, but you can change its value.

Tunable: Yes

Dependencies

To enable this parameter, set **Coefficient source** to Dialog parameters.

Data Types: single | double

Filter – Filter object

`dsp.FourthOrderSectionFilter` object

Specify the filter coefficients using a `dsp.FourthOrderSectionFilter` object. You can enter this object directly in the **Filter** parameter. Alternatively, you can create this object in the MATLAB workspace or model workspace and specify the filter variable in the **Filter** parameter. When you specify the filter as a variable and you simulate the model, you cannot change the complexity, data type, and size of the filter coefficients in the workspace between simulations.

Dependencies

To enable this parameter, set **Coefficient source** to `Filter` object.

View Filter Response – Visualize frequency response

`gui` button

Click this button to open the Dynamic Filter Visualizer window and display the magnitude and phase response of the fourth-order section filter. The response is based on the coefficients that you specify in the block dialog box. If you set **Coefficient source** to `Input ports` and click **Apply**, you cannot view the magnitude response using this button. To view the response in the visualizer, you must specify the filter coefficients directly in the block dialog box or through the `dsp.FourthOrderSectionFilter` object.

To update the filter response while the visualizer is running, modify the coefficients in the block dialog box and click **Apply**.

You can configure the plot settings and the frequency response measurements from the interface of the visualizer.

On the **Plot** tab, you can enable the legend, specify to plot both magnitude and phase responses of the filter, modify the plot settings, generate a script to re-create the plot, and even save or share the settings.

On the **Measurements** tab, you can enable data cursors, and display the peak values of the filter response.

For more details on the Dynamic Filter Visualizer interface and its tools, see “Configure Dynamic Filter Visualizer”.

Simulate using – Type of simulation to run

Interpreted execution (default) | Code generation

Type of simulation to run. You can set this parameter to:

- **Interpreted execution:** Simulate model using the MATLAB interpreter. This option shortens startup time.
- **Code generation:** Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations as long as the model does not change. This option requires additional startup time but provides faster subsequent simulations.

Block Characteristics

Data Types	double integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

Version History

Introduced in R2022a

Enhancements to Fourth-Order Section Filter block

Starting in R2022b, when you pass numerator and denominator coefficients through the input ports of the Fourth-Order Section Filter block, you can change the number of sections (rows) in the filter coefficients while the simulation is running.

You can also specify the coefficients in the block dialog box using a `dsp.FourthOrderSectionFilter` object. Set **Coefficient source** to `Filter` object and specify a `dsp.FourthOrderSectionFilter` object directly in the **Filter** parameter. Alternatively, you can create this object in the MATLAB workspace or model workspace and specify the filter variable in the **Filter** parameter.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Blocks

Biquad Filter

Frame Conversion

(Removed) Specify sampling mode of output signal

Note The Frame Conversion block has been removed.

Library

Signal Management / Signal Attributes

dspsigattribs

Description

The Frame Conversion block passes the input through to the output and sets the output sampling mode to the value of the **Sampling mode of output signal** parameter, which can be either **Frame-based** or **Sample-based**. The output sampling mode can also be inherited from the signal at the Ref (reference) input port, which you make visible by selecting the **Inherit output sampling mode from <Ref> input port** check box.

The Frame Conversion block does not make any changes to the input signal other than the sampling mode. In particular, the block does not rebuffer or resize 2-D inputs. Because 1-D vectors cannot be frame based, when the input is a length- M 1-D vector and the block is in **Frame-based** mode, the output is a frame-based M -by-1 matrix — that is, a single channel.

Parameters

Inherit output sampling mode from <Ref> input port

Select to enable the Ref port from which the block inherits the output sampling mode.

Sampling mode of output signal

Specify the sampling mode of the output signal, **Frame-based** or **Sample-based**.

Supported Data Types

Port	Supported Data Types
In	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed only) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers • Enumerated

Port	Supported Data Types
Ref	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed only) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers • Enumerated
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed only) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers • Enumerated

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has one default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see "ConstrainedOutputPipeline" (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "InputPipeline" (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "OutputPipeline" (HDL Coder).

Complex Data Support

This block supports code generation for complex signals.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Frame Status Conversion (Obsolete)

Specify frame status of output as sample based or frame based

Library

dspobslib

Description

Note The Frame Status Conversion block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the Frame Conversion block.

The Frame Status Conversion block passes the input through to the output, and sets the output frame status to the **Output signal** parameter, which can be either **Frame-based** or **Sample-based**. The output frame status can also be inherited from the signal at the Ref (reference) input port, which is made visible by selecting the **Inherit output frame status from Ref input port** check box.

When the **Output signal** parameter setting or the inherited signal's frame status differs from the input frame status, the block changes the input frame status accordingly, but does not otherwise alter the signal. In particular, the block does not rebuffer or resize 2-D inputs. Because 1-D vectors cannot be frame based, when the input is a length- M 1-D vector, and the **Output signal** parameter is set to **Frame-based**, the output is a frame-based M -by-1 matrix (that is, a single channel).

When the **Output signal** parameter or the inherited signal's frame status matches the input frame status, the block passes the input through to the output unaltered.

Parameters

Inherit output frame status from Ref input port

When selected, enables the Ref input port from which the block inherits the output frame status.

Output signal

The output frame status, **Frame-based** or **Sample-based**.

From Audio Device

Read audio data from computer's audio device

Compatibility

Note The From Audio Device block will be removed in a future release. Existing instances of the block continue to run. For new models, use the Audio Device Reader block from Audio Toolbox instead.

Library

Sources

dspsrcs4

Description

The From Audio Device block reads audio data from an audio device in real time. This block is not supported for use with the Simulink Model block.

Use the **Device** parameter to specify the device from which to acquire audio. This parameter is automatically populated based on the audio devices installed on your system. If you plug or unplug an audio device from your system, type `clear mex` at the MATLAB command prompt to update this list.

Use the **Number of channels** parameter to specify the number of audio channels in the signal. For example:

- Enter 2 if the audio source is two channels (stereo).
- Enter 1 if the audio source is single channel (mono).
- Enter 6 if you are working with a 5.1 speaker system.

The block's output is an M -by- N matrix, where M is the number of consecutive samples and N is the number of audio channels.

Use the **Sample rate (Hz)** parameter to specify the number of samples per second in the signal. If the audio data is processed in uncompressed pulse code modulation (PCM) format, it should typically be sampled at one of the standard audio device rates: 8000, 11025, 22050, 44100, or 48000 Hz.

The range of supported audio device sample rates and data type formats, depend on both the sound card and the API which is chosen for the sound card.

Use the **Device data type** parameter to specify the data type of the audio data that the device is placing in the buffer. You can choose:

- 8-bit integer
- 16-bit integer
- 24-bit integer
- 32-bit float
- Determine from output data type

If you choose `Determine from output data type`, the following table summarizes the block's behavior.

Output Data Type	Device Data Type
Double-precision floating point or single-precision floating point	32-bit floating point
32-bit integer	24-bit integer
16-bit integer	16-bit integer
8-bit integer	8-bit integer

If you choose `Determine from output data type` and the device does not support a data type, the block uses the next lowest precision data type supported by the device.

Use the **Frame size (samples)** parameter to specify the number of samples in the block's output. Use the **Output data type** parameter to specify the data type of audio data output by the block.

The generated code for this block relies on prebuilt .dll files. You can run this code outside the MATLAB environment, or redeploy it, but be sure to account for these extra .dll files when doing so. The `packNGo` function creates a single zip file containing all of the pieces required to run or rebuild this code. See `packNGo` for more information.

Buffering

The From Audio Device block buffers the data from the audio device using the process illustrated by the following figure.

From Audio Device Block

- 1 At the start of the simulation, the audio device begins writing the input data to a buffer. This data has the data type specified by the **Device data type** parameter.
- 2 When the buffer is full, the From Audio Device block writes the contents of the buffer to the queue. Specify the size of this queue using the **Queue duration (seconds)** parameter.

- 3 As the audio device appends audio data to the bottom of the queue, the From Audio Device block pulls data from the top of the queue to fill the Simulink frame. This data has the data type specified by the **Output data type** parameter.

Select the **Automatically determine buffer size** check box to allow the block to calculate a conservative buffer size using the following equation:

$$size = 2^{\lceil \log_2 \frac{sr}{10} \rceil}$$

In this equation, *size* is the buffer size, and *sr* is the sample rate. If you clear this check box, the **Buffer size (samples)** parameter appears on the block. Use this parameter to specify the buffer size in samples.

When the simulation throughput rate is lower than the hardware throughput rate, the queue, which is initially empty, fills up. If the queue is full, the block drops the incoming data from the audio device. You can monitor dropped samples using the optional **Overrun** output port. When the simulation throughput rate is higher than the hardware throughput rate, the From Audio Device block waits for new samples to become available.

Channel Mapping

The term Channel Mapping refers to a 1-to-1 mapping that associates channels on the selected audio device to channels of the data. When you record audio, channel mapping allows you to specify which channel of the audio data directs input to a specific channel of audio. You can specify channel mapping as a vector of audio channel indices corresponding to each channel of data being read. The default value in the **Device Input Channels** parameter is 1:MAXINPUTCHANNELS. If you do not select the default mapping, you must specify the **Device Input Channels** parameter in the dialog box.

Example: The selected input audio device contains 8 channels. You want to read data from only channels 2, 4, 6, and redirect the data as follows:

- Audio Device channel 2 to first data channel
- Audio Device channel 4 to second data channel
- Audio Device channel 6 to third data channel

Thus you would specify the **Device Input Channels** as [2 4 6].

Troubleshooting

Not Keeping Up in Real Time

When Simulink cannot keep up with an audio device that is operating in real time, the queue fills up and the block begins to lose audio data. Select the **Output number of samples by which the queue was overrun** check box to add an output port indicating when the queue was full. Here are several ways to deal with this situation:

- *Increase the queue duration.*

The **Queue duration (seconds)** parameter specifies the duration of the signal, in seconds, that can be buffered during the simulation. This is the maximum length of time that the block's data demand can lag behind the hardware's data supply.

- *Increase the buffer size.*

The size of the buffer processed in each interrupt from the audio device affects the performance of your model. If the buffer is too small, a large portion of hardware resources are used to write data to the queue. If the buffer is too big, Simulink must wait for the device to fill the buffer before it moves the data to the queue, which introduces latency.

- *Increase the simulation throughput rate.*

Two useful methods for improving simulation throughput rates are increasing the signal frame size and compiling the simulation into native code:

- Increase frame sizes and convert sample-based signals to frame-based signals throughout the model to reduce the amount of block-to-block communication overhead. This can increase throughput rates in many cases. However, larger frame sizes generally result in greater model latency due to initial buffering operations.
- Generate executable code with Simulink Coder code generation software. Native code runs much faster than Simulink and should provide rates adequate for real-time audio processing.

Other ways to improve throughput rates include simplifying the model and running the simulation on a faster PC processor. For other ideas on improving simulation performance, see “Delay and Latency” and “Optimize Performance” (Simulink).

Running an Executable Outside MATLAB

To run your generated standalone executable application in Shell, you need to set your environment to the following:

Platform	Command
Mac	<pre>setenv DYLD_LIBRARY_PATH \$LD_LIBRARY_PATH: \$MATLABROOT/bin/ maci64 (csh/tcsh) export DYLD_LIBRARY_PATH \$LD_LIBRARY_PATH: \$MATLABROOT/bin/ maci64 (Bash)</pre>
Linux	<pre>setenv LD_LIBRARY_PATH \$LD_LIBRARY_PATH: \$MATLABROOT/bin/ glnxa64 (csh/tcsh) export LD_LIBRARY_PATH \$LD_LIBRARY_PATH: \$MATLABROOT/bin/ glnxa64 (Bash)</pre>
Windows	<pre>set PATH = \$MATLABROOT\bin\win64;%PATH %</pre>

Audio Hardware API

In order to communicate with the audio hardware on a given computer, the To Audio Device and From Audio Device blocks use the open-source PortAudio library. The PortAudio library supports a range of APIs designed to communicate with the audio hardware on a given platform. The following API choices were made when building the PortAudio library for the DSP System Toolbox product:

- Windows®: DirectSound, WDM—KS, ASIO™
- Linux®: OSS, ALSA

- Mac: CoreAudio

For Windows, the default is DirectSound, for Linux, the default is ALSA, and for Mac there is only one choice.

To determine the audio hardware API currently selected, type the following command in the MATLAB command prompt.

```
getpref('dsp', 'portaudioHostApi')
```

The output is a scalar indicating the choice of the API.

- 1 — DirectSound
- 3 — ASIO
- 7 — OSS
- 8 — ALSA
- 11 — WDM-KS

To select a particular API, type the following command in the MATLAB command prompt.

```
setpref('dsp', 'portaudioHostApi', N)
```

where N is a scalar. Choose N based on the API choice above.

Parameters

Device

Specify the device from which to acquire audio data.

Use default mapping between Device Input Channels and Data

Select this check box to have the default mapping, where the data from the first channel of audio device is sent to the first channel of the input data, data from second channel of audio device is sent to second channel of data and so on. The maximum number of channels in the input data is determined by the **Number of channels** property.

Number of channels

Specify the number of audio channels. This parameter is visible when the **Use default mapping between Device Input Channels and Data** check box is enabled.

Device Input Channels

Specify the channel mapping. This parameter is visible when the **Use default mapping between Device Input Channels and Data** check box is disabled.

Sample rate (Hz)

Specify the number of samples per second in the signal.

Device data type

Specify the data type used by the device to acquire audio data.

Automatically determine buffer size

Select this check box to enable the block to use a conservative buffer size.

Buffer size (samples)

Specify the size of the buffer that the block uses to communicate with the audio device. This parameter is visible when the **Automatically determine buffer size** check box is cleared.

Queue duration (seconds)

Specify the size of the queue in seconds.

Output number of samples by which the queue was overrun

Select this check box to output the number of samples lost to queue overrun since the last transfer of a frame from the audio device. You can use this value to debug throughput problems and adjust the queues and buffers in your model. To learn how to improve throughput, see “Troubleshooting” on page 2-618.

Frame size (samples)

Specify the number of samples in the block's output signal.

Output data type

Select the data type of the block's output.

Supported Data Types

Port	Supported Data Types
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • 32-bit signed integers • 16-bit signed integers • 8-bit unsigned integers
Overrun	32-bit unsigned integer

Frequency-Domain Adaptive Filter

Compute output, error, and coefficients using frequency domain FIR adaptive filter

Library: DSP System Toolbox / Filtering / Adaptive Filters

Description

The Frequency-Domain Adaptive Filter block implements an adaptive finite impulse response (FIR) filter in the frequency domain using the fast block least mean squares (LMS) algorithm. The **Filter length** and the **Block length** parameters specify the filter length and the block length values the algorithm uses. When you select the **Output filter FFT coefficients** check box, the block outputs the discrete Fourier transform of the current filter coefficients. The block offers the constrained and unconstrained versions of the algorithm with partitioned and nonpartitioned modes. For details, see “Algorithms” on page 2-628.

Ports

Input

Input — Data input

column vector

The signal to be filtered by the frequency-domain FIR adaptive filter. The data input and the desired signal input must have the same size and data type. The length of the input vector must be divisible by the **Block length** parameter value.

The data input can be a variable-size signal as long as the frame length is a multiple of the **Block length**. You can change the number of elements in the column vector during the model simulation.

Data Types: `single` | `double`

Desired — Desired signal

column vector

The frequency-domain adaptive filter adapts its filter weights to minimize the error, **Error**, and converge the input signal to match the desired signal as closely as possible.

The data input and the desired signal must have the same size and data type. The length of the desired signal vector must be divisible by the **Block length** parameter value.

The desired signal can be a variable-size signal as long as the frame length is a multiple of the **Block length**. You can change the number of elements in the column vector during the model simulation.

Data Types: `single` | `double`

Mu — Step size input

real scalar in the range (0,1]

Adaptation step size factor, specified as a real scalar in the range (0,1]. Using a small step size ensures a small steady-state error. However, a small step size decreases the resulting convergence speed of the adaptive filter. Increasing the step size improves the convergence speed, at the cost of increased steady-state mean squared error. When the step size value is 1, the algorithm provides the optimal tradeoff between the convergence speed and the steady-state mean squared error.

Dependencies

This port appears when you select the **Specify step size from port** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Leak — Leakage factor input

real scalar in the range (0,1]

Leakage factor used in leaky adaptive filter, specified as a real scalar in the range (0,1]. When the value is less than 1, the block implements a leaky adaptive algorithm. When the value is 1, the block provides no leakage in the adapting method.

Dependencies

This port appears when you select the **Specify leakage factor from port** check box.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Avrg — Averaging factor input

real scalar in the range (0,1]

Averaging factor used to compute the exponentially windowed fast Fourier transform (FFT) input signal powers for the coefficient updates, specified as a real scalar in the range (0,1].

Dependencies

This port appears when you select the **Specify averaging factor from port** check box.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Offset — Offset for normalization terms

nonnegative real scalar

Offset for the normalization terms in the coefficient updates, specified as a nonnegative real scalar value. Use this value to avoid division by zero or division by very small numbers if any of the FFT input signal powers become very small.

Dependencies

This port appears when you select the **Specify offset from port** check box.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Adapt — Enable filter coefficient updates

nonnegative real scalar

If you input a nonzero scalar value through this port, the block continuously updates its filter coefficients. If you input a zero through this port, the filter coefficients do not update, and their values remain at the current value.

Dependencies

This port appears when you select the **Enable adapt port** check box.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Reset — Enable filter states reset

nonnegative real scalar

If you input a nonzero scalar value through this port, the block resets all internal states. If you input a zero through this port, the internal states are not reset.

Dependencies

This port appears when you select the **Enable reset port** check box.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Output**Output — Filtered output**

column vector

Filtered output, returned as a column vector. The block adapts its filter weights to converge the input signal to match the desired signal as closely as possible. The filter outputs the converged signal.

Data Types: `single` | `double`

Error — Difference between output and desired signal

column vector

Difference between the output signal and the desired signal, returned as a column vector. The objective of the adaptive filter is to minimize this error. The block adapts its weights to converge towards optimal filter weights which produce an output signal that matches the desired signal as closely as possible. For more details on how **Error** is computed, see “References” on page 2-630.

Data Types: `single` | `double`

Complex Number Support: Yes

FFTCoeffs — Current FFT coefficients of filter

row vector

Current discrete Fourier transform of the filter coefficients, returned as a row vector. For **Constrained FDAF** and **Unconstrained FDAF** algorithms, the length of this vector is equal to the sum of the **Filter length** value and the **Block length** value. This port initially outputs the FFT values of the **Initial time-domain coefficients** parameter. During the model simulation, this port outputs the FFT values of the current filter coefficients.

Dependencies

This port appears when you select the **Output filter FFT coefficients** check box.

Data Types: `single` | `double`

Complex Number Support: Yes

Parameters

Method — Method to calculate filter coefficients

Constrained FDAF (default) | Partitioned constrained FDAF | Unconstrained FDAF | Partitioned unconstrained FDAF

Method used to calculate the filter coefficients, specified as::

- **Constrained FDAF** -- Imposes a gradient constraint on the filter tap weights.
- **Partitioned constrained FDAF** -- Partitions the impulse response of the filter to reduce latency.
- **Unconstrained FDAF** -- No gradient constraint is imposed on the filter tap weights.
- **Partitioned unconstrained FDAF** -- Partitions the impulse response of the filter to reduce latency. No gradient constraint is imposed on the filter tap weights.

For more details, see “Algorithms” on page 2-628.

Filter length — Length of filter coefficients vector

32 (default) | positive, integer-valued scalar

Length of the FIR filter coefficients vector, specified as a positive, integer-valued scalar.

Block length — Block length for coefficient updates

32 (default) | positive, integer-valued scalar

Block length for the coefficients update, specified as a positive, integer-valued scalar. The adaptive filter processes the input data and the desired signal as a block of samples of length set by this parameter. For details on how this data is processed by the filter, see “Algorithms” on page 2-628. The length of the input vector must be divisible by the **Block length** parameter value. The default value of the **Block length** parameter is set to the value of the **Filter length** parameter.

Specify step size from port — Flag to specify step size

off (default) | on

When you select this check box, the adaptation step size is input through the **Mu** port. When you clear this check box, the step size is specified on the block dialog through the **Step size** parameter.

Step size — Adaptation step size

1 (default) | real scalar in the range (0,1]

Adaptation step size factor, specified as a real scalar in the range (0,1]. Setting the **Step size** parameter to 1 provides the fastest convergence during adaptation.

Tunable: Yes

Dependencies

This parameter appears when you clear the **Specify step size from port** check box.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32

Specify leakage factor from port — Flag to specify leakage factor

off (default) | on

When you select this check box, the leakage factor is input through the **Leak** port. When you clear this check box, the leakage factor is specified on the block dialog through the **Leakage factor** parameter.

LeakageFactor — Adaptation leakage factor

1 (default) | real scalar in the range (0,1]

Leakage factor used in leaky adaptive filter, specified as a real scalar in the range (0,1]. When the value is less than 1, the block implements a leaky adaptive algorithm. When the value is 1, the block provides no leakage in the adapting method.

Tunable: Yes**Dependencies**

This parameter appears when you clear the **Specify leakage factor from port** check box.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32

Specify averaging factor from port — Flag to specify averaging factor

off (default) | on

When you select this check box, the averaging factor for signal power is input through the **Avrg** port. When you clear this check box, the averaging factor is specified on the block dialog through the **Averaging factor** parameter.

Averaging factor — Averaging factor for signal power

0.9 (default) | real scalar in the range (0,1]

Averaging factor used to compute the exponentially windowed FFT input signal powers for the coefficient updates, specified as a real scalar in the range (0,1].

Tunable: Yes**Dependencies**

This parameter appears when you clear the **Specify averaging factor from port** check box.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32

Specify offset from port — Flag to specify offset

off (default) | on

When you select this check box, the offset for the normalization terms in the coefficient updates is input through the **Offset** port. When you clear this check box, the offset is specified on the block dialog through the **Offset** parameter.

Offset — Offset for normalization terms

0 (default) | nonnegative real scalar

Offset for the normalization terms in the coefficient updates, specified as a nonnegative real scalar value. Use this value to avoid division by zero or division by very small numbers if any of the FFT input signal powers become very small.

Tunable: Yes

Dependencies

This parameter appears when you clear the **Specify offset from port** check box.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Initial FFT input signal power — Initial FFT input signal power

1 (default) | positive numeric scalar

Initial common value of all of the FFT input signal powers, specified as a positive numeric scalar value.

If you change this value during the simulation, the change takes effect only after a reset event occurs.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Initial time-domain coefficients — Initial time-domain coefficients of filter

0 (default) | scalar | vector

Initial time-domain coefficients of the adaptive filter, specified as a scalar or a vector of length equal to the value you specify in the **Filter length** parameter. The adaptive filter block uses these coefficients to compute the initial frequency-domain filter coefficients.

If you change this value during the simulation, the change takes effect only after a reset event occurs.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Enable adapt port — Flag to enable coefficient update

off (default) | on

When you select this check box, the **Adapt** input port is enabled. If you input a nonzero scalar value through this port, the block continuously updates its filter coefficients. If you input a zero through this port, the filter coefficients do not update and their values remain at the current value.

Enable reset port — Flag to reset internal states

off (default) | on

When you select this check box, the **Reset** input port is enabled. If you input a nonzero scalar value through this port, the block resets all internal states. If you input a zero through this port, the internal states are not reset.

Output filter FFT coefficients – Flag to output the DFT of the filter coefficients

off (default) | on

When you select this check box, the **FFTCoeffs** output port is enabled. Through this port, the block outputs the discrete Fourier transform of the current filter coefficients.

Simulate using – Type of simulation to run

Code generation (default) | Interpreted execution

Specify the type of simulation to run as one of the following:

- **Code generation** -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than **Interpreted execution**.
- **Interpreted execution** -- Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than **Code generation**.

Block Characteristics

Data Types	double single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

Algorithms

Frequency-domain adaptive filtering consists of three steps - filtering, error estimation, and tap-weight adaptation. This algorithm implements FIR filtering in the frequency domain using the overlap-save or overlap-add method. For more implementation details of these two methods, see the “Algorithms” on page 4-614 section in the `dsp.FrequencyDomainFIRFilter` object page. The error estimation and the tap-weight adaptation are implemented using the fast block LMS algorithm (FBLMS).

Fast Block LMS Algorithm

The frequency-domain adaptive filter processes input data and the desired signal data as a block of samples using the fast block LMS (FBLMS) algorithm. Here is the block diagram of the frequency-domain adaptive filter using the FBLMS algorithm. The frequency-domain FIR filter in this diagram uses the overlap-save method.

where:

- N -- Filter length
- L -- Block length
- μ -- Step size parameter
- $x(n)$ -- Input signal
- $X(k)$ -- Transformed input signal in the frequency domain
- $d(n)$ -- Desired signal
- $e(n)$ -- Error between the desired signal and the filter output
- $E(k)$ -- Transformed error signal in the frequency domain
- $W(k)$ -- Tap-weights vector in the frequency domain

For more details on how the error is estimated and the tap-weights are adapted, see [2].

Constrained and Unconstrained FBLMS Algorithms

The previous diagram is the constrained version. If you remove the gradient constraint portion of the algorithm, you have the unconstrained FBLMS implementation. For details on the convergence behavior of both constrained and unconstrained variations, see [2].

Partitioned FBLMS Algorithm

The latency of the filter roughly equals the length of the FIR numerator. If the impulse response of the filter is very long, the latency becomes significantly large. The partitioned FBLMS algorithm reduces latency by partitioning the impulse response. The nonpartitioned frequency-domain FIR filtering is faster than the time-domain filtering for long impulse responses, at the cost of increased latency. To mitigate the latency and make the frequency domain filtering even more efficient, the algorithm partitions the impulse response into multiple short blocks and performs overlap-save or overlap-add on each block. The results of the different blocks are then combined to obtain the final output. The latency of this approach is of the order of the block length, rather than the entire impulse response length. This reduced latency comes at the cost of additional computation. For more details on the implementation, see [2].

Frequency-Domain FIR Filter

Filter input signal in the frequency domain

Library: DSP System Toolbox / Filtering / Filter Implementations

Description

The Frequency-Domain FIR Filter block implements frequency-domain, fast Fourier transform (FFT)-based filtering to filter a streaming input signal. In the time domain, the filtering operation involves a convolution between the input and the impulse response of the finite impulse response (FIR) filter. In the frequency domain, the filtering operation involves the multiplication of the Fourier transform of the input and the Fourier transform of the impulse response. The frequency-domain filtering becomes more efficient than time-domain filtering as the impulse response grows longer. You can specify the filter coefficients directly in the frequency domain by setting **Numerator domain** to Frequency.

This block uses the overlap-save and overlap-add methods to perform the frequency-domain filtering. For filters with a long impulse response length, the latency inherent to these two methods can be significant. To mitigate this latency, the Frequency-Domain FIR Filter block partitions the impulse response into shorter blocks and implements the overlap-save and overlap-add methods on these shorter blocks. To partition the impulse response, select the **Partition numerator to reduce latency** check box. For more details on these two methods and on reducing latency through impulse response partitioning, see “Algorithms” on page 2-638.

Ports

Input

x — Data Input

vector | matrix

Data input, specified as a vector or matrix. This block supports variable-size input signals. That is, you can change the input frame size (number of rows) even after calling the algorithm. However, the number of channels (number of columns) must remain constant.

This port is unnamed until you select the **Specify coefficients from input port** parameter.

Data Types: single | double

NUM — Time domain FIR filter coefficients

row vector

Time domain FIR filter coefficients, specified as a row vector.

Dependencies

This port appears when you set **Numerator domain** to Time and select the **Specify coefficients from input port** parameter.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32

NUMFFT — Frequency domain FIR filter coefficients

row vector

Frequency domain FIR filter coefficients, specified as a row vector or a matrix. When you clear the **Partition numerator to reduce latency** parameter, the coefficients input through this port must be a row vector. The FFT length is equal to the length of the vector input. When you select the **Partition numerator to reduce latency** parameter, **Frequency response** must be a $2P$ -by- N matrix, where P is the partition size, and N is the number of partitions.

Dependencies

This port appears when you set **Numerator domain** to Frequency and select the **Specify frequency response from input port** parameter.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32

Output Arguments

y — Filtered output

vector | matrix

Filtered output, returned as a vector or matrix. The size, data type, and complexity of the output match those of the input.

This port is unnamed until you select the **Output filter latency** parameter and click **Apply**.

Data Types: single | double

Latency — Filter latency

positive integer

Filter latency, returned as a scalar. This latency is inherent to overlap-add and overlap-save methods and does not include the group delay of the filter. This port appears only when you select the **Output filter latency** check box.

This port is unnamed until you select the **Output filter latency** check box and click **Apply**.

Data Types: uint32

Parameters

Frequency-domain filter method — Filtering method in frequency domain

Overlap-save (default) | Overlap-add

Filtering method in the frequency domain, specified as either Overlap-save or Overlap-add. For more details on these two methods, see “Algorithms” on page 2-638

Numerator domain — Numerator domain

Time (default) | Frequency

Domain of the filter coefficients, specified as one of the following:

- Time -- Specify the time-domain filter coefficients in the **Filter coefficients** parameter or through the **NUM** input port.
- Frequency -- Specify the filter's frequency response in the **Frequency response** parameter or through the **NUMFFT** input port.

Specify coefficients from input port — Flag to specify lowpass filter coefficients
off (default) | on

When you select this check box, the FIR filter coefficients are input through the port, **NUM**. When you clear this check box, the coefficients are specified on the block dialog through the **Filter coefficients** parameter.

To view the filter response, clear this check box, specify the coefficients on the block dialog, and click on the **View Filter Response** button.

Dependencies

To enable this parameter, set **Numerator domain** to Time.

Filter coefficients — filter coefficients
fir1(100,0.3) (default) | row vector

FIR filter coefficients, specified as a row vector.

Dependencies

To enable this parameter, set **Numerator domain** to Time and clear the **Specify coefficients from input port** parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64
Complex Number Support: Yes

Specify frequency response from input port — Flag to specify frequency-domain filter coefficients
off (default) | on

When you select this check box, the FIR filter coefficients in the frequency domain are input through the port, **NUMFFT**. When you clear this check box, the coefficients are specified on the block dialog through the **Frequency response** parameter.

To view the filter response, clear this check box, specify the frequency response on the block dialog, and click on the **View Filter Response** button.

Dependencies

To enable this parameter, set **Numerator domain** to Frequency.

Frequency response — Filter coefficients
fft(fir1(100,0.3),202) (default) | row vector | matrix

Frequency response of the filter, specified as a row vector or a matrix. When you clear the **Partition numerator to reduce latency** parameter, **Frequency response** must be a row vector. The FFT

length is equal to the length of the **Frequency response** vector. When you select the **Partition numerator to reduce latency** parameter, **Frequency response** must be a $2P$ -by- N matrix, where P is the partition size, and N is the number of partitions.

Dependencies

To enable this parameter, set **Numerator domain** to Frequency and clear the **Specify frequency response from input port** parameter.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32

Complex Number Support: Yes

Partition numerator to reduce latency — Flag to partition the numerator to reduce latency

off (default) | on

Flag to partition the numerator to reduce latency, specified as one of the following:

- off -- The filter uses the traditional overlap-save or overlap-add method. The latency in this case is FFT length - $NumLen + 1$. $NumLen$ is the length of the numerator vector you specify in the **Filter coefficients** parameter.
- on -- In this mode, the block partitions the numerator into segments of length specified by the **Numerator partition length** parameter. The filter performs overlap-save or overlap-add on each partition, and combines the partial results to form the overall output. The latency is now reduced to the partition length.

Numerator partition length — Partition length of numerator

32 (default) | positive integer

Partition length of the numerator, specified as a positive integer less than or equal to the length of the numerator.

Dependencies

This parameter applies only when you set **Numerator domain** to Time and select the **Partition numerator to reduce latency** parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Time-domain numerator length — Time-domain numerator length

101 (default) | positive integer-valued scalar

Time-domain numerator length, specified as a positive integer-valued scalar.

Dependencies

This parameter applies only when you set **Numerator domain** to Frequency and clear the **Partition numerator to reduce latency** check box.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32

Inherit FFT length from numerator length — Flag to inherit FFT length from the numerator length

on (default) | off

When you select this check box, the FFT length equals twice the numerator length. When you clear this check box, you specify the FFT length through the **FFT length** parameter.

Dependencies

This parameter applies only when you set **Numerator domain** to Time and clear the **Partition numerator to reduce latency** parameter.

FFT length – FFT length

1024 (default) | positive integer

The FFT length you specify must be greater than or equal to the length of the numerator vector you specify in the **Filter coefficients** parameter.

Dependencies

This parameter applies when you set **Numerator domain** to Time, clear the **Partition numerator to reduce latency** and the **Inherit FFT length from numerator length** parameters.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Filter is real – Flag to specify if filter is real

true (default) | false

Flag to specify if the filter is real, specified as true or false.

Dependencies

This parameter applies when **Numerator domain** to Frequency.

Output filter latency – Flag to output filter latency

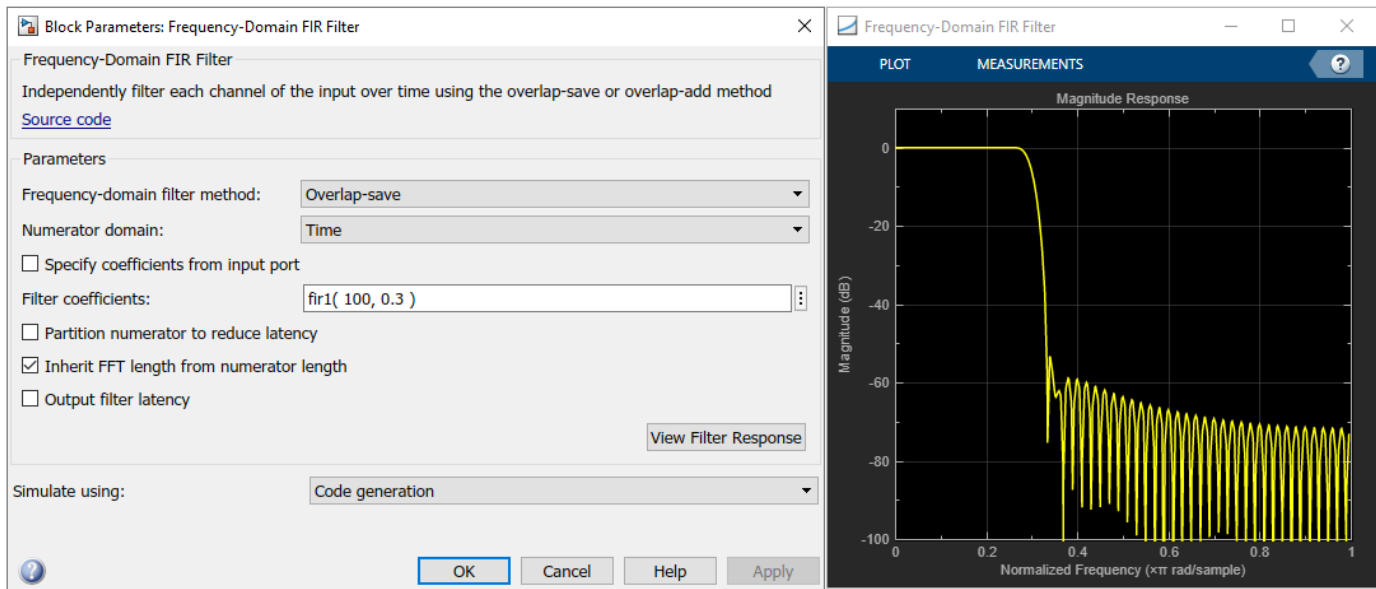

'off' (default) | 'on'

When you select this check box and click **Apply**, the block outputs the filter latency through the **latency** port.

View Filter Response – Visualize frequency response

button

Opens the Dynamic Filter Visualizer window and displays the magnitude and phase response of the frequency domain FIR filter. The response is based on the parameters you select in the block dialog box. To update the response while the visualizer is running, modify the parameters in the dialog box and click **Apply**.

You can configure the plot settings and the frequency response measurements from the interface of the visualizer.

On the **Plot** tab, you can enable the legend, specify to plot both magnitude and phase responses of the filter, modify the plot settings, generate a script to re-create the plot, and even save or share the settings.

On the **Measurements** tab, you can enable data cursors, and display the peak values of the filter response.

For more details on the Dynamic Filter Visualizer interface and its tools, see “Configure Dynamic Filter Visualizer”.

Simulate using — Type of simulation to run

Code generation (default) | Interpreted execution

Specify the type of simulation to run as one of the following:

- **Code generation** -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than **Interpreted execution**.
- **Interpreted execution** -- Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than **Code generation**.

Block Characteristics

Data Types	double single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

Algorithms

Overlap-save and overlap-add are the two frequency-domain FFT-based filtering methods this algorithm uses.

Overlap-Save

The overlap-save method is implemented using the following approach:

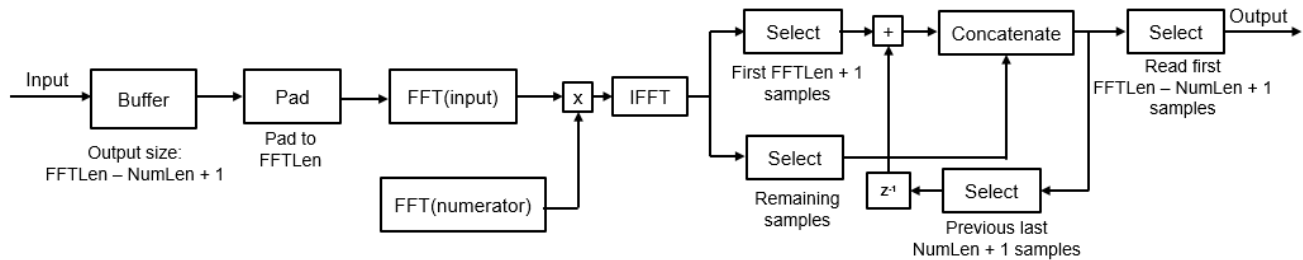

The input stream is partitioned into overlapping blocks of size $FFTLen$, with an overlap factor of $NumLen - 1$ samples. $FFTLen$ is the FFT length and $NumLen$ is the length of the FIR filter numerator. The FFT of each block of input samples is computed and multiplied with the length- $FFTLen$ FFT of the FIR numerator. The inverse fast Fourier transform (IFFT) of the result is performed, and the last $FFTLen - NumLen + 1$ samples are saved. The remaining samples are dropped.

The latency of overlap-save is $FFTLen - NumLen + 1$. The first $FFTLen - NumLen + 1$ samples are equal to zero. The filtered value of the first input sample appears as the $FFTLen - NumLen + 2$ output sample.

Note that the FFT length must be larger than the numerator length, and is typically set to a value much greater than $NumLen$.

Overlap-Add

The overlap-add method is implemented using the following approach:

The input stream is partitioned into blocks of length $FFLen - NumLen + 1$, with no overlap between consecutive blocks. Similar to overlap-save, the FFT of the block is computed, and multiplied by the FFT of the FIR numerator. The IFFT of the result is then computed. The first $NumLen + 1$ samples are modified by adding the values of the last $NumLen + 1$ samples from the previous computed IFFT.

The latency of overlap-add is $FFLen - NumLen + 1$. The first $FFLen - NumLen + 1$ samples are equal to zero. The filtered value of the first input sample appears as the $FFLen - NumLen + 2$ output sample.

Reduce Latency Through Impulse Response Partitioning

With an FFT length that is twice the length of the FIR numerator, the latency roughly equals the length of the FIR numerator. If the impulse response is very long, the latency becomes significantly large. However, frequency domain FIR filtering is still faster than the time-domain filtering. To mitigate the latency and make the frequency domain filtering even more efficient, the algorithm partitions the impulse response into multiple short blocks and performs overlap-save or overlap-add on each block. The results of the different blocks are then combined to obtain the final output. The latency of this approach is of the order of the block length, rather than the entire impulse response length. This reduced latency comes at the cost of additional computation. For more details, see [1].

From Multimedia File

Stream from multimedia file

Library: Audio Toolbox / Sources
DSP System Toolbox / Sources

Description

The From Multimedia File block reads audio samples, video frames, or both from a multimedia file and generates a signal with one of the following data types and amplitude ranges.

Output Data Type	Output Amplitude Range
double	± 1
single	± 1
int16	-32768 to 32767 (-2^{15} to $2^{15} - 1$)
uint8	0 to 255

The block imports data from the file into a Simulink model.

Note This block supports code generation for a host computer that has file I/O available. You cannot use this block with Simulink Desktop Real-Time software because that product does not support file I/O. The generated code for this block relies on prebuilt library files. For more details, see “Code Generation” on page 2-650.

Limitations

To support OPUS file format on a Linux machine, you must have `libsndfile 1.0.29` or a later version installed. On Windows and Mac, this file is shipped with MATLAB and is available under `$MATLABROOT/bin/<platform>`.

Ports

The output ports of the From Multimedia File block change according to the content of the multimedia file. If the file contains only video frames, the **Image** port, intensity **I** port, **R,G,B** ports, or **Y,Cb,Cr** ports appear based on the settings on the block dialog box. If the file contains only audio samples, the **Audio** port appears on the block. If the file contains both audio and video, you can select the data to emit. This section describes these ports in more detail.

Output

Image — Color image or video frame

array

Color image or video frame, returned as an M -by- N -by- P array. M and N are the number of rows and columns in each image. P is the number of color channels in each image.

Dependencies

To enable this port:

- Set the **File name** parameter to the name of a multimedia file that contains video or image data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to Video only or Video and audio.
- Set the **Output color format** parameter to RGB and **Image signal** parameter to One multidimensional signal.
- This port is named as **Simulink Image** if the **Output color format** parameter is set to RGB and the **Image signal** parameter is set to Simulink image signal.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Simulink.ImageType

I — Grayscale image or video frame

matrix

Grayscale image or video frame, returned as an M -by- N matrix. M and N are the number of rows and columns in the grayscale image.

Dependencies

To enable this port:

- Set the **File name** parameter to the name of a multimedia file that contains video or image data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to Video only or Video and audio.
- Set the **Output color format** parameter to Intensity.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32

R — Red color component of image or video frame

matrix

Red color component of the image or video frame, returned as an M -by- N matrix. M and N are the number of rows and columns in the image.

Outputs from the **R**, **G**, or **B** ports must have the same dimensions.

Dependencies

To enable this port:

- Set the **File name** parameter to the name of a multimedia file that contains video or image data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to Video only or Video and audio.
- Set the **Output color format** parameter to RGB and **Image signal** parameter to Separate color signals.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32

G — Green color component of image or video frame

matrix

Green color component of the image or video frame, returned as an M -by- N matrix. M and N are the number of rows and columns in the image.

Outputs from the **R**, **G**, or **B** ports must have the same dimensions.

Dependencies

To enable this port:

- Set the **File name** parameter to the name of a multimedia file that contains video or image data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to **Video only** or **Video and audio**.
- Set the **Output color format** parameter to **RGB** and **Image signal** parameter to **Separate color signals**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

B — Blue color component of image or video frame

matrix

Blue color component of the image or video frame, returned as an M -by- N matrix. M and N are the number of rows and columns in the image.

Outputs from the **R**, **G**, or **B** ports must have the same dimensions.

Dependencies

To enable this port:

- Set the **File name** parameter to the name of a multimedia file that contains video or image data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to **Video only** or **Video and audio**.
- Set the **Output color format** parameter to **RGB** and **Image signal** parameter to **Separate color signals**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Y — Luma component of image or video frame

matrix

Luma component of the image or video frame, returned as an M -by- N matrix. M and N are the number of rows and columns in the image.

Dependencies

To enable this port:

- Set the **File name** parameter to the name of a multimedia file that contains video or image data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to **Video only** or **Video and audio**.
- Set the **Output color format** parameter to **YCbCr 4:2:2**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Cb — Blue-difference chrominance component of image or video frame

matrix

Blue-difference chrominance component of the image or video frame, returned as an M -by- $N/2$ matrix. M and N are the number of rows and columns in the input image.

Dependencies

To enable this port:

- Set the **File name** parameter to the name of a multimedia file that contains video or image data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to `Video only` or `Video and audio`.
- Set the **Output color format** parameter to `YCbCr 4:2:2`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Cr — Red-difference chrominance component of image or video frame matrix

Red-difference chrominance component of the image or video frame, returned as an M -by- $N/2$ matrix. M and N are the number of rows and columns in each input image.

Dependencies

To enable this port:

- Set the **File name** parameter to the name of a multimedia file that contains video or image data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to `Video only` or `Video and audio`.
- Set the **Output color format** parameter to `YCbCr 4:2:2`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Audio — Audio signal vector | matrix

Audio signal, returned as an M -element vector or an M -by- N matrix. M is the number of samples in each channel and N is the number of channels.

Dependencies

To enable this port, set the **File name** parameter to the name of a multimedia file that contains audio data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to `Audio only` or `Video and audio`.

Data Types: `single` | `double` | `int16` | `uint8`

EOF — End-of-file indicator scalar

End-of-file indicator, returned as a logical scalar for each video frame or audio sample. The end-of-file indicator is 1 when the block outputs the final video frame or audio sample from the file, and is 0 otherwise.

Dependencies

To enable this port, select the **Output end-of-file indicator** parameter.

Data Types: `Boolean`

Parameters

Main Tab

File name — Name of multimedia file

speech_dft.mp3 (default) | character vector

Specify the name of the multimedia file for the block to read. The block determines the type of file (audio and video, audio only, or video only) and provides the associated parameters.

If the location of the file does not appear on the MATLAB path, use the **Browse** button to specify the full path. If the location of the file appears on the MATLAB path, enter only the file name.

On Windows platforms, this parameter supports URLs that point to MMS (Microsoft Media Server) streams.

Inherit sample time from file — Inherit sample time from file

on (default) | off

Specify whether the block inherits the sample time from the multimedia file or uses a specified sample time. When you select this parameter, the block inherits the sample time from the input multimedia file. When you clear this parameter, the block uses the sample time that you specify in the **Desired sample time** parameter.

Tip Select this parameter when you do not know the intended sample rate of the multimedia file.

Desired sample time — Block sample time

1/30 (default) | real positive scalar

Specify the block sample time.

Dependencies

To enable this parameter, clear the **Inherit sample time from file** parameter.

Number of times to play file — Number of times to play multimedia file

inf (default) | positive integer

Specify the number of times to play the input multimedia file. The default value of `inf` specifies that the block repeats playing the multimedia file until the simulation stop time.

Read range — Range of audio samples

[1 Inf] (default) | two-element vector

Specify the sample range from which to read as a two-element row vector in the form of `[StartSample EndSample]`, where `StartSample` is the sample at which file reading starts, and `EndSample` is the sample at which file reading stops.

Dependencies

To enable this parameter, set the **File name** parameter to the name of a multimedia file that contains audio data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to `Audio only`.

Output end-of-file indicator — End-of-file indicator

`off (default) | on`

Use this parameter to determine whether the output is the last video frame or audio sample in the multimedia file. When you select this parameter, a Boolean output port labeled **EOF** appears on the block. The output from the **EOF** port defaults to 1 when the last video frame or audio sample is output from the block. Otherwise, the output from the **EOF** port defaults to 0.

Multimedia outputs — Type of media

`Audio only (default) | Video and audio | Video only`

Specify the type of media to read from a file containing both video and audio data.

Dependencies

To enable this parameter, set the **File name** parameter to the name of a multimedia file that contains both audio and video data.

Samples per audio channel — Samples per audio channel

`1024 (default) | positive integer`

Specify number of samples per audio channel. This parameter becomes available for files containing audio.

Dependencies

To enable this parameter, set the **File name** parameter to the name of a multimedia file that contains audio data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to `Audio only`.

Output color format — Color format of video

`RGB (default) | Intensity | YCbCr 4:2:2`

Specify the output color format of the input video data. The block supports the RGB, Intensity, and YCbCr 4:2:2 color formats.

If you select RGB, use the **Image signal** parameter to specify how to output a color signal.

Dependencies

To enable this parameter, set the **File name** parameter to the name of a multimedia file that contains video data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to `Video only` or `Video and audio`.

Image signal — Output port configuration for RGB video

One multidimensional signal (default) | Separate color signals | Simulink image signal

Specify how the block outputs an RGB color video. If you select:

- **One multidimensional signal** -- The block outputs an M -by- N -by- P color video signal through the **Image** port, where P is the number of color planes.
- **Separate color signals** -- The block outputs the video data using three separate color channels, divided across the **R**, **G**, and **B** ports. Each port outputs one M -by- N plane of an RGB video stream.
- **Simulink image signal** -- The block outputs a video in `Simulink.ImageType` datatype.

Dependencies

To enable this parameter:

- Set the **File name** parameter to the name of a multimedia file that contains video data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to `Video only` or `Video and audio`.
- Set the **Output color format** parameter to `RGB`.

Data Types Tab

Audio output data type — Audio output data type

double (default) | single | int16 | uint8

Specify the data type for the audio samples output at the **Audio** port.

Dependencies

To enable this parameter, set the **File name** parameter to the name of a multimedia file that contains audio data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to `Audio only` or `Video and audio`.

Video output data type — Video output data type

single (default) | double | int8 | uint8 | int16 | uint16 | int32 | uint32 | Inherit from file

Specify the data type of the video frames output at the **R**, **G**, **B**, or **Image** ports..

Dependencies

To enable this parameter, set the **File name** parameter to the name of a multimedia file that contains video data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to `Video only` or `Video and audio`.

Block Characteristics

Data Types	double integer ^a single
Direct Feedthrough	no

Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

a Supports 16- and 32-bit signed and 8-bit unsigned integers.

More About

Supported Platforms and File Types

The supported file formats available to you depends on the codecs installed on your system.

Windows Platforms Supported File Formats

With the necessary Windows DirectShow codecs installed on your system, the From Multimedia File Block supports many video and audio file formats. This block performs best on platforms with Version 9.0 or later of DirectX® software.

The following table lists the most common file formats.

Multimedia Types	File Name Extensions
Image files	.jpg, .bmp, .png
Video files	.qt, .mov, .avi, .asf, .asx, .wmv, .mpg, .mpeg, .mp2, .mp4, .m4v
Audio files	.wav, .wma, .avi, .aif, .aifc, .aiff, .mp3, .au, .snd, .mp4, .m4a, .flac, .ogg, .opus

The default for image files is .png, for video files is .avi, and for audio files is .mp3.

Windows 7 and later versions of Windows ship with a limited set of 64-bit video and audio codecs. If the From Multimedia File block cannot work on a compressed multimedia file, save the multimedia file to a file format supported by the block.

If you use Windows, use Windows Media® Player Version 11 or later with this block for best results.

Non- Windows Platform Supported File Formats

The following table lists the most common file formats.

Multimedia Types	File Name Extensions
Video files	.avi, .mj2, .mov, .mp4, .m4v
Audio files	.avi, .mp3, .mp4, .m4a, .wav, .flac, .ogg, .aif, .aifc, .aiff, .au, .opus, .snd

The default for video files is .avi and for audio files is .mp3.

Sample Rates

The sample rate that the block uses depends on the audio and video sample rate. While the From Multimedia File block operates at a single rate in Simulink, the underlying audio and video streams can produce different rates. In some cases, when the block outputs both audio and video, it makes a small adjustment to the video rate.

Sample Time Calculations Used for Video and Audio Files

$$\text{Sample time} = \frac{\text{ceil}(\text{AudioSampleRate}/\text{FPS})}{\text{AudioSampleRate}}.$$

When the audio sample time $\frac{\text{AudioSampleRate}}{\text{FPS}}$ is noninteger, the equation cannot reduce to $\frac{1}{\text{FPS}}$.

In this case, to prevent synchronization problems, the block drops the corresponding video frame when the audio stream leads the video stream by more than $\frac{1}{\text{FPS}}$.

In summary, the block outputs one video frame at each Simulink time step. To calculate the number of audio samples to output at each time step, the block divides the audio sample rate by the video frame rate (fps). If the audio sample rate does not divide evenly by the number of video frames per second, the block rounds the number of audio samples up to the nearest whole number. If necessary, the block periodically drops a video frame to maintain synchronization for large files.

Running Executable Outside MATLAB

To run your generated standalone executable application in Shell, you need to set your environment to the following:

Platform	Command
Mac	<pre>setenv DYLD_LIBRARY_PATH "\$ {DYLD_LIBRARY_PATH}:\$MATLABROOT/bin/ maci64" (csh/tcsh) export DYLD_LIBRARY_PATH= \$DYLD_LIBRARY_PATH:\$MATLABROOT/bin/ maci64 (Bash)</pre> <p>For more information, see Append library path to "DYLD_LIBRARY_PATH" in MAC.</p>
Linux	<pre>setenv LD_LIBRARY_PATH \$ {LD_LIBRARY_PATH}:\$MATLABROOT/bin/ glnxa64 (csh/tcsh) export LD_LIBRARY_PATH= \$LD_LIBRARY_PATH:\$MATLABROOT/bin/ glnxa64 (Bash)</pre>
Windows	<pre>set PATH=%PATH%;%MATLABROOT%\bin\win64</pre>

Version History

Introduced before R2006a

Support for OPUS audio file format

The From Multimedia File block supports audio files in the OPUS file format (.opus).

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- Host computer only. Excludes Simulink Desktop Real-Time code generation.
- The executable generated from this block relies on prebuilt dynamic library files (.dll files) included with MATLAB. Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed ZIP file. Using this ZIP file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

From Wave Device (Obsolete)

Read audio data from standard audio device in real-time (32-bit Windows operating systems only)

Library

dspwin32

Description

Note The From Wave Device block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the From Audio Device block.

The From Wave Device block reads audio data from a standard Windows audio device in real-time. It is compatible with most popular Windows hardware, including Sound Blaster cards. (Models that contain both this block and the To Wave Device block require a *duplex-capable* sound card.)

The **Use default audio device** parameter allows the block to detect and use the system's default audio hardware. This option should be selected on systems that have a single sound device installed, or when the default sound device on a multiple-device system is the desired source. In cases when the default sound device is not the desired input source, clear **Use default audio device**, and select the desired device in the **Audio device menu** parameter.

When the audio source contains two channels (stereo), the **Stereo** check box should be selected. When the audio source contains a single channel (mono), the **Stereo** check box should be cleared. For stereo input, the block's output is an M -by-2 matrix containing one frame (M consecutive samples) of audio data from each of the two channels. For mono input, the block's output is an M -by-1 matrix containing one frame (M consecutive samples) of audio data from the mono input. The frame size, M , is specified by the **Samples per frame** parameter. For $M=1$, the output is sample based; otherwise, the output is frame based.

The audio data is processed in uncompressed pulse code modulation (PCM) format, and should typically be sampled at one of the standard Windows audio device rates: 8000, 11025, 22050, or 44100 Hz. You can select one of these rates from the **Sample rate** parameter. To specify a different rate, select the **User-defined** option and enter a value in the **User-defined sample rate** parameter.

The **Sample Width (bits)** parameter specifies the number of bits used to represent the signal samples read by the audio device. The following settings are available:

- 8 — allocates 8 bits to each sample, allowing a resolution of 256 levels
- 16 — allocates 16 bits to each sample, allowing a resolution of 65536 levels
- 24 — allocates 24 bits to each sample, allowing a resolution of 16777216 levels (only for use with 24-bit audio devices)

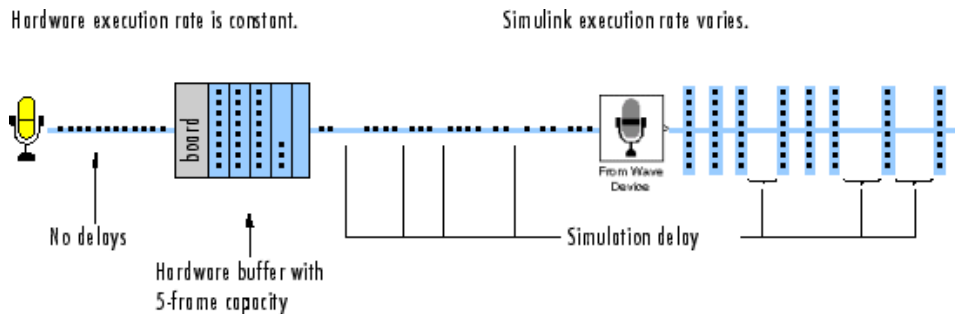

Higher sample width settings require more memory but yield better fidelity. The output from the block is independent of the **Sample width (bits)** setting. The output data type is determined by the **Data type** parameter setting.

Buffering

Since the audio device accepts real-time audio input, Simulink software must read a continuous stream of data from the device throughout the simulation. Delays in reading data from the audio hardware can result in hardware errors or distortion of the signal. This means that the From Wave Device block must read data from the audio hardware as quickly as the hardware itself acquires the signal. However, the block often *cannot* match the throughput rate of the audio hardware, especially when the simulation is running from within Simulink rather than as generated code. (Simulink operations are generally slower than comparable hardware operations, and execution speed routinely varies during the simulation as the host operating system services other processes.) The block must therefore rely on a buffering strategy to ensure that signal data can be read on schedule without losing samples.

At the start of the simulation, the audio device begins writing the input data to a (hardware) buffer with a capacity of T_b seconds. The From Wave Device block immediately begins pulling the earliest samples off the buffer (first in, first out) and collecting them in length- M frames for output. As the audio device continues to append inputs to the bottom of the buffer, the From Wave Device block continues to pull inputs off the top of the buffer at the best possible rate.

The following figure shows an audio signal being acquired and output with a frame size of 8 samples. The buffer of the sound board is approaching its five-frame capacity at the instant shown, which means that the hardware is adding samples to the buffer more rapidly than the block is pulling them off. (If the signal sample rate was 8 kHz, this small buffer could hold approximately 0.005 second of data.)

When the simulation throughput rate is higher than the hardware throughput rate, the buffer remains empty throughout the simulation. If necessary, the From Wave Device block simply waits for new samples to become available on the buffer (the block does not interpolate between samples). More typically, the simulation throughput rate is lower than the hardware throughput rate, and the buffer tends to fill over the duration of the simulation.

Troubleshooting

When the buffer size is too small in relation to the simulation throughput rate, the buffer might fill before the entire length of signal is processed. This usually results in a device error or undesired device output. When this problem occurs, you can choose to either increase the buffer size or the simulation throughput rate:

- *Increase the buffer size*

The **Queue duration** parameter specifies the duration of signal, T_b (in real-time seconds), that can be buffered in hardware during the simulation. Equivalently, this is the maximum length of time that the block's data acquisition can lag the hardware's data acquisition. The number of frames buffered is approximately

$$\frac{T_b F_s}{M}$$

where F_s is the sample rate of the signal and M is the number of samples per frame. The required buffer size for a given signal depends on the signal length, the frame size, and the speed of the simulation. Note that increasing the buffer size might increase model latency.

- *Increase the simulation throughput rate*

Two useful methods for improving simulation throughput rates are increasing the signal frame size and compiling the simulation into native code:

- Increase frame sizes (and convert sample-based signals to frame-based signals) throughout the model to reduce the amount of block-to-block communication overhead. This can drastically increase throughput rates in many cases. However, larger frame sizes generally result in greater model latency due to initial buffering operations.
- Generate executable code with Simulink Coder. Native code runs much faster than Simulink, and should provide rates adequate for real-time audio processing.

More general ways to improve throughput rates include simplifying the model, and running the simulation on a faster PC processor. See “Delay and Latency” and “Optimize Performance” (Simulink) for other ideas on improving simulation performance.

Parameters

Sample rate (Hz)

The sample rate of the audio data to be acquired. Select one of the standard Windows rates or the User-defined option.

User-defined sample rate (Hz)

The (nonstandard) sample rate of the audio data to be acquired.

Sample width (bits)

The number of bits used to represent each signal sample.

Stereo

Specifies stereo (two-channel) inputs when selected, mono (one-channel) inputs when cleared. Stereo output is M -by-2; mono output is M -by-1.

Samples per frame

The number of audio samples in each successive output frame, M . When the value of this parameter is 1, the block outputs a sample-based signal.

Queue duration (seconds)

The length of signal (in seconds) to buffer to the hardware at the start of the simulation.

Use default audio device

Reads audio input from the system's default audio device when selected. Clear to enable the **Audio device ID** parameter and select a device.

Audio device

The name of the audio device from which to read the audio output (lists the names of the installed audio device drivers). Select **Use default audio device** when the system has only a single audio card installed.

Data type

The data type of the output: double-precision, single-precision, signed 16-bit integer, or unsigned 8-bit integer.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- 16-bit signed integer
- 8-bit unsigned integer

From Wave File (Obsolete)

Read audio data from Microsoft Wave (.wav) file

Library

dspwin32

Description

Note The From Wave File block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the From Multimedia File block.

The From Wave File block streams audio data from a Microsoft® Wave (.wav) file and generates a signal with one of the data types and amplitude ranges in the following table.

Note AVI files are the only supported file type for non-Windows platforms.

Output Data Type	Output Amplitude Range
double	± 1
single	± 1
int16	-32768 to 32767 (-2^{15} to $2^{15} - 1$)
uint8	0 to 255

The audio data must be in uncompressed pulse code modulation (PCM) format.

```
y = wavread('filename') % Equivalent MATLAB code
```

The block supports 8-, 16-, 24-, and 32-bit Microsoft Wave (.wav) files.

The **File name** parameter can specify an absolute or relative path to the file. When the file is on the MATLAB path or in the current folder (the folder returned by typing `pwd` at the MATLAB command line), you need only specify the file name. You do not need to specify the .wav extension.

Note The From Wave File block does not support .wav file names that contain a + character. To read .wav files that have a + character in the file name, use the From Multimedia File block.

For an audio file containing C channels, the block's output is an M -by- C matrix containing one frame (M consecutive samples) of audio data from each channel. The frame size, M , is specified by the

Samples per output frame parameter. For $M=1$, the output is sample based; otherwise, the output is frame based.

The output frame period, T_{fo} , is

$$T_{fo} = \frac{M}{F_s}$$

where F_s is the data sample rate in Hz.

To reduce the required number of file accesses, the block acquires L consecutive samples from the file during each access, where L is specified by the **Minimum number of samples for each read from file** parameter ($L \geq M$). For $L < M$, the block instead acquires M consecutive samples during each access. Larger values of L result in fewer file accesses, which reduces run-time overhead.

Use the **Data type** parameter to specify the data type of the block's output. Your choices are `double`, `single`, `uint8`, or `int16`.

Select the **Loop** check box if you want to play the file more than once. Then, enter the number of times to play the file. The number you enter must be a positive integer or `inf`.

Use the **Number of times to play file** parameter to enter the number of times to play the file. The number you enter must be a positive integer or `inf`, to play the file until you stop the simulation.

The **Samples restart** parameter determines whether the samples from the audio file repeat immediately or repeat at the beginning of the next frame output from the output port. When you select `immediately after last sample`, the samples repeat immediately. When you select `at beginning of next frame`, the frame containing the last sample value from the audio file is zero padded until the frame is filled. The block then places the first sample of the audio file in the first position of the next output frame.

Use the **Output start-of-file indicator** parameter to determine when the first audio sample in the file is output from the block. When you select this check box, a Boolean output port labeled SOF appears on the block. The output from the SOF port is 1 when the first audio sample in the file is output from the block. Otherwise, the output from the SOF port is 0.

Use the **Output end-of-file indicator** parameter to determine when the last audio sample in the file is output from the block. When you select this check box, a Boolean output port labeled EOF appears on the block. The output from the EOF port is 1 when the last audio sample in the file is output from the block. Otherwise, the output from the EOF port is 0.

The block icon shows the name, sample rate (in Hz), number of channels (1 or 2), and sample width (in bits) of the data in the specified audio file. All sample rates are supported; the sample width must be either 8, 16, 24, or 32 bits.

Parameters

File name

Enter the path and name of the file to read. Paths can be relative or absolute.

Note The From Wave File block does not support .wav file names that contain a + character. To read .wav files that have a + character in the file name, use the From Multimedia File block.

Samples per output frame

Enter the number of samples in each output frame, M . When the value of this parameter is 1, the block outputs a sample-based signal.

Minimum number of samples for each read from file

Enter the number of consecutive samples to acquire from the file with each file access, L .

Data type

Select the output data type: double, single, uint8, or int16. The data type setting determines the output's amplitude range.

Loop

Select this check box if you want to play the file more than once.

Number of times to play file

Enter the number of times you want to play the file.

Samples restart

Select immediately after last sample to repeat the audio file immediately. Select at beginning of next frame to place the first sample of the audio file in the first position of the next output frame.

Output start-of-file indicator

Use this check box to determine whether the output contains the first audio sample in the file.

Output end-of-file indicator

Use this check box to determine whether the output contains the last audio sample in the file.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- 16-bit signed integer
- 8-bit unsigned integer

G711 Codec

Quantize narrowband speech input signals

Library

Quantizers

dspquant2

Description

The G711 Codec block is a logarithmic scalar quantizer designed for narrowband speech. Narrowband speech is defined as a voice signal with an analog bandwidth of 4 kHz and a Nyquist sampling frequency of 8 kHz. The block quantizes a narrowband speech input signal so that it can be transmitted using only 8-bits. The G711 Codec block has three modes of operation: encoding, decoding, and conversion. You can choose the block's mode of operation by setting the **Mode** parameter.

If, for the **Mode** parameter, you choose **Encode PCM to A-law**, the block assumes that the linear PCM input signal has a dynamic range of 13 bits. Because the block always operates in saturation mode, it assigns any input value above $2^{12} - 1$ to $2^{12} - 1$ and any input value below -2^{12} to -2^{12} . The block implements an A-law quantizer on the input signal and outputs A-law index values. When you choose **Encode PCM to mu-law**, the block assumes that the linear PCM input signal has a dynamic range of 14 bits. Because the block always operates in saturation mode, it assigns any input value above $2^{13} - 1$ to $2^{13} - 1$ and any input value below -2^{13} to -2^{13} . The block implements a mu-law quantizer on the input signal and outputs mu-law index values.

If, for the **Mode** parameter, you choose **Decode A-law to PCM**, the block decodes the input A-law index values into quantized output values using an A-law lookup table. When you choose **Decode mu-law to PCM**, the block decodes the input mu-law index values into quantized output values using a mu-law lookup table.

If, for the **Mode** parameter, you choose **Convert A-law to mu-law**, the block converts the input A-law index values to mu-law index values. When you choose **Convert mu-law to A-law**, the block converts the input mu-law index values to A-law index values.

Note Set the **Mode** parameter to **Convert A-law to mu-law** or **Convert mu-law to A-law** only when the input to the block is A-law or mu-law index values.

If, for the **Mode** parameter, you choose **Encode PCM to A-law** or **Encode PCM to mu-law**, the **Overflow diagnostic** parameter appears on the block parameters dialog box. Use this parameter to determine the behavior of the block when overflow occurs. The following options are available:

- **Ignore** — Proceed with the computation and do not issue a warning message.
- **Warning** — Display a warning message in the MATLAB Command Window, and continue the simulation.
- **Error** — Display an error dialog box and terminate the simulation.

Note Like all diagnostic parameters on the Configuration Parameters dialog box, **Overflow diagnostic** parameter is set to **Ignore** in the code generated for this block by Simulink Coder code generation software.

Parameters

Mode

- When you choose **Encode PCM to A-law**, the block implements an A-law encoder.
- When you choose **Encode PCM to mu-law**, the block implements a mu-law encoder.
- When you choose **Decode A-law to PCM**, the block decodes the input index values into quantized output values using an A-law lookup table.
- When you choose **Decode mu-law to PCM**, the block decodes the input index values into quantized output values using a mu-law lookup table.
- When you choose **Convert A-law to mu-law**, the block converts the input A-law index values to mu-law index values.
- When you choose **Convert mu-law to A-law**, the block converts the input mu-law index values to A-law index values.

Overflow diagnostic

Use this parameter to determine the behavior of the block when overflow occurs.

- Select **Ignore** to proceed with the computation without a warning message.
- Select **Warning** to display a warning message in the MATLAB Command Window and continue the simulation.
- Select **Error** to display an error dialog box and terminate the simulation.

This parameter is only visible if, for the **Mode** parameter, you select **Encode PCM to A-law** or **Encode PCM to mu-law**.

Halfband Filter (Obsolete)

(Removed) Design halfband filter

Compatibility

Note The Halfband Filter block has been removed from the DSP System Toolbox block library. Existing instances of the Halfband Filter block will continue to operate. To model FIR halfband decimators and interpolators, use the FIR Halfband Decimator and FIR Halfband Interpolator blocks. These blocks replace the functionality of the Halfband Filter block, when **Impulse response** is set to FIR, and **FilterType** is set to Decimator and Interpolator. To model IIR halfband decimators and interpolators, use the IIR Halfband Decimator and IIR Halfband Interpolator blocks. These blocks replace the functionality of the Halfband Filter block, when **Impulse response** is set to IIR, and **FilterType** is set to Decimator and Interpolator.

Library

Filtering / Filter Designs

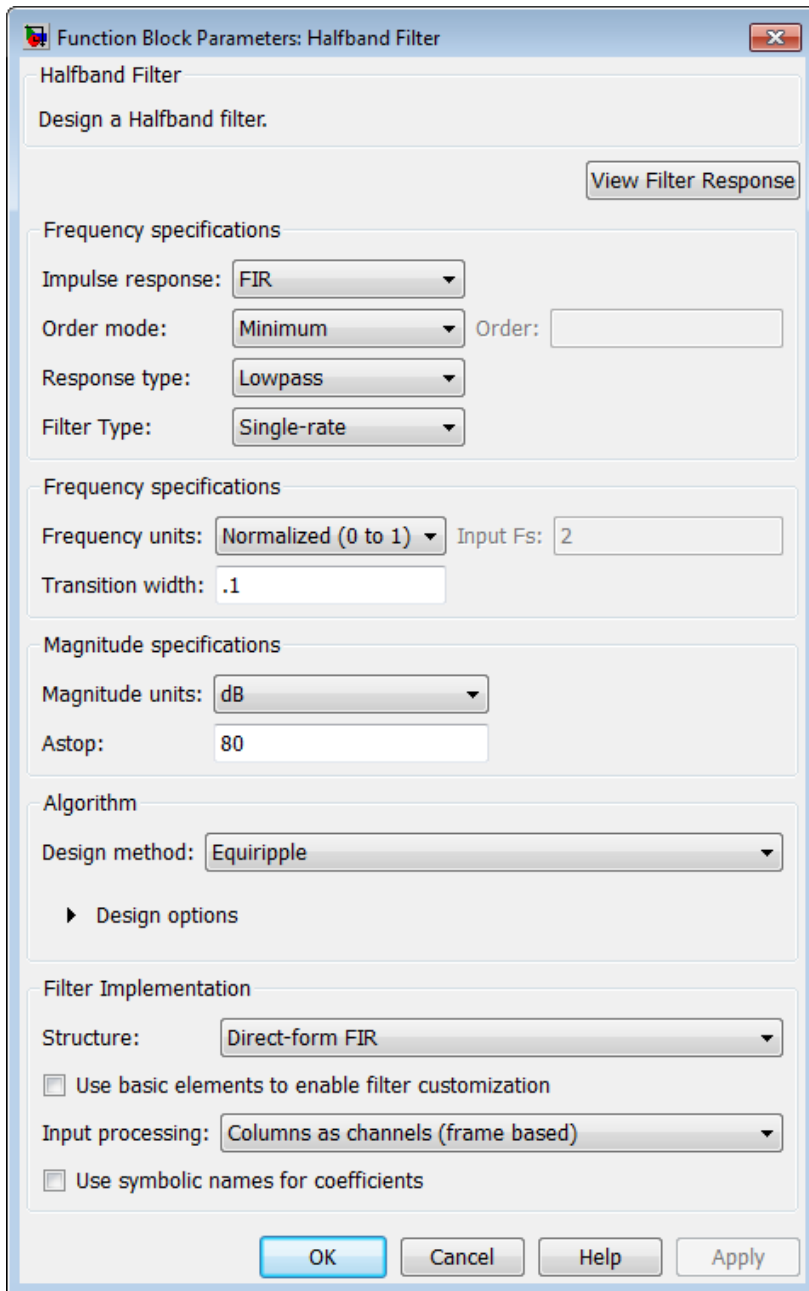

dspfdesign

Description

This block brings the filter design capabilities of the `filterBuilder` function to the Simulink environment.

Dialog Box

See “Halfband Filter Design — Main Pane” on page 5-616 for more information about the parameters of this block. The **Data Types** and **Code Generation** panes are not available for blocks in the DSP System Toolbox Filter Designs library.

View filter response

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

In this group, you specify your filter type and order.

Impulse response

Select either FIR or IIR from the drop-down list. FIR is the default. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

Note The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Order mode

Select either Minimum (the default) or Specify from the drop-down list. Selecting Specify enables the **Order** option (see the following sections) so you can enter the filter order.

Response type

Specify the filter response as Lowpass (the default) or Highpass.

Filter type

Select Single-rate, Decimator, or Interpolator. By default, the block specifies a single-rate filter.

Order

Enter the filter order. This option is enabled only when the **Filter order mode** is set to Specify.

Frequency Specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications for a halfband lowpass filter look similar to those shown in the following figure.

In the figure, the transition region lies between the end of the passband and the start of the stopband. The width is defined explicitly by the value of **Transition width**.

Frequency constraints

When **Order mode** is **Specify**, set this parameter to **Unconstrained** or **Transition width**.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0–1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Transition width

Specify the width of the transition between the end of the passband and the edge of the stopband. Specify the value in normalized frequency units or the absolute units you select in **Frequency units**.

Magnitude Specifications

Parameters in this group specify the filter response in the passbands and stopbands.

Magnitude constraints

Specify **Unconstrained** (the default), or select **Stopband attenuation** to constrain the response in the stopband explicitly.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. From the drop-down list, select one of the following options:

- **Linear** — Specify the magnitude in linear units.
- **dB** — Specify the magnitude in decibels (default).

Astop

When **Magnitude units** is **Stopband attenuation**, enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure of your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. For FIR halfband filters, the available design options are **equiripple**, and **Kaiser window**. For IIR halfband filters, the available design options are **Butterworth**, **elliptic**, and **IIR quasi-linear phase**.

Design Options

The following design options are available for FIR halfband filters when the user specifies an equiripple design:

Minimum phase

Select the checkbox to specify a minimum-phase design.

Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- **Flat** — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- **Linear** — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- **1/f** — Specifies that the stopband attenuation changes exponentially as the frequency increases, where f is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. The following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to **Flat**, **Stopband decay** has no effect on the stopband.
- When you set **Stopband shape** to **Linear**, enter the slope of the stopband in units of dB/rad/s. The block applies that slope to the stopband.
- When you set **Stopband shape** to **1/f**, enter a value for the exponent n in the relation $(1/f)^n$ to define the stopband decay. The block applies the $(1/f)^n$ relation to the stopband to result in an exponentially decreasing stopband attenuation.

Filter Implementation**Structure**

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of n unit delays with a single delay by n .
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

Input processing

Specify how the block should process the input. The available options may vary depending on the settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

Note The **Inherited** (this choice will be removed – see release notes) option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- **Enforce single-rate processing** — When you select this option, the block maintains the sample rate of the input.
- **Allow multirate processing** — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to **Elements as channels (sample based)**.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

Hampel Filter

Filter outliers using Hampel identifier

Library: DSP System Toolbox / Filtering / Filter Designs

Description

The Hampel Filter block detects and removes the outliers of the input signal by using the Hampel identifier. The Hampel identifier is a variation of the three-sigma rule of statistics, which is robust against outliers. For each sample of the input signal, the block computes the median of a window composed of the current sample and $\frac{Len - 1}{2}$ adjacent samples on each side of the current sample.

Len is the window length you specify through the **Window length** parameter. The block also estimates the standard deviation of each sample about its window median by using the median absolute deviation. If a sample differs from the median by more than the threshold multiplied by the standard deviation, the filter replaces the sample with the median. For more information, see “Algorithms” on page 2-671.

Ports

Input

x — Data input

vector | matrix

The block accepts multichannel inputs, that is, *m*-by-*n* size inputs, where $m \geq 1$, and $n \geq 1$. *m* is the number of samples in each frame (channel), and *n* is the number of channels. The block also accepts variable-size inputs. That is, you can change the size of each input channel during simulation. However, the number of channels cannot change.

This port is unnamed until you select the **Specify threshold from input port** parameter.

Data Types: single | double

T — Threshold

real scalar greater than or equal to 0

Threshold for outlier detection, specified as a real scalar greater than or equal to 0. For information on how this parameter is used to detect the outlier, see “Algorithms” on page 2-671.

Dependencies

This port appears when you select the **Specify threshold from input port** parameter.

Data Types: single | double

Output

y — Filtered output

vector | matrix

The size and data type of this output matches the size and data type of the input.

This port is unnamed until you select the **Output outlier status** check box.

Data Types: single | double

outlier — Output the outlier status

vector | matrix

A value of 1 in this output indicates that the corresponding element in the input is an outlier. This output has the same size as the input.

Dependencies

To enable this port, select the **Output outlier status** check box.

Data Types: Boolean

Parameters

If a parameter is listed as tunable, then you can change its value during simulation.

Window length — Length of sliding window

11 (default) | positive odd scalar integer

Length of the sliding window, specified as a positive odd scalar integer. The window of finite length slides over the data, and the block computes the median and median absolute deviation of the data in the window.

Specify threshold from input port — Flag to specify threshold

off (default) | on

When you select this check box, the threshold is input through the **T** port. When you clear this check box, the threshold is specified on the block dialog through the **Threshold for outlier detection (standard deviations)** parameter.

Threshold for outlier detection (standard deviations) — Threshold

3 (default) | real scalar greater than or equal to 0

Threshold for outlier detection, specified as a real scalar greater than or equal to 0. For information on how this parameter is used to detect the outlier, see “Algorithms” on page 2-671.

Tunable: Yes

Dependencies

This parameter appears when you clear the **Specify threshold from input port** check box.

Output outlier status — Flag to output the outlier status

off (default) | on

Select this parameter to output a matrix of `boolean` values that has the same size as the input. Each element in this matrix indicates whether the corresponding element in the input is an outlier. A value of 1 indicates an outlier.

Simulate using — Type of simulation to run

Interpreted execution (default) | Code generation

Type of simulation to run. You can set this parameter to:

- `Interpreted execution`: Simulate model using the MATLAB interpreter. This option shortens startup time.
- `Code generation`: Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations as long as the model does not change. This option requires additional startup time but provides faster subsequent simulations.

Block Characteristics

Data Types	double single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

More About**Hampel Identifier**

The Hampel identifier is a variation of the three-sigma rule of statistics that is robust against outliers.

Given a sequence $x_1, x_2, x_3, \dots, x_n$ and a sliding window of length k , define point-to-point median and standard-deviation estimates using:

- Local median — $m_i = \text{median}(x_{i-k}, x_{i-k+1}, x_{i-k+2}, \dots, x_i, \dots, x_{i+k-2}, x_{i+k-1}, x_{i+k})$
- Standard deviation — $\sigma_i = \kappa \text{median}(|x_{i-k} - m_i|, \dots, |x_{i+k} - m_i|)$, where $\kappa = \frac{1}{\sqrt{2} \text{erfc}^{-1}(1/2)} \approx 1.4826$

The quantity σ_i / κ is known as the median absolute deviation (MAD).

If a sample x_i is such that

$$|x_i - m_i| > n_\sigma \sigma_i$$

for a given threshold n_σ , then the Hampel identifier declares x_i an outlier and replaces it with m_i . If n_σ is 0, then the Hampel filter behaves as a regular median filter.

Algorithms

For a given sample of data, x_s , the algorithm:

- Centers the window of odd length at the current sample.
- Computes the local median, m_i , and standard deviation, σ_i , over the current window of data.
- Compares the current sample with $n_\sigma \times \sigma_i$, where n_σ is the threshold value. If $|x_s - m_i| > n_\sigma \times \sigma_i$, the filter identifies the current sample, x_s , as an outlier and replaces it with the median value, m_i .

Consider a frame of data that is passed into the Hampel filter.

1	2	4	9	23	8	12	4	2
---	---	---	---	----	---	----	---	---

In this example, the Hampel filter slides a window of length 5 (Len) over the data. The filter has a threshold value of 2 (n_σ). To have a complete window at the beginning of the frame, the filter algorithm prepends the frame with $Len - 1$ zeros. To compute the first sample of the output, the window centers on the $\left[\frac{Len - 1}{2} + 1\right]^{\text{th}}$ sample in the appended frame, the third zero in this case. The filter computes the median, median absolute deviation, and the standard deviation over the data in the local window.

- Current sample: $x_s = 0$.
- Window of data: $win = [0\ 0\ 0\ 0\ 1]$.
- Local median: $m_i = \text{median}([0\ 0\ 0\ 0\ 1]) = 0$.
- Median absolute deviation: $mad_i = \text{median}(|x_{i-k} - m_i|, \dots, |x_{i+k} - m_i|)$. For this window of data, $mad = \text{median}(|0 - 0|, \dots, |1 - 0|) = 0$.

- Standard deviation: $\sigma_i = \kappa \times mad_i = 0$, where $\kappa = \frac{1}{\sqrt{2}\text{erfc}^{-1}(1/2)} \approx 1.4826$.
- The current sample, $x_s = 0$, does not obey the relation for outlier detection.
 $[|x_s - m_i| = 0] > [(n_\sigma \times \sigma_i) = 0]$

Therefore, the Hampel filter outputs the current input sample, $x_s = 0$.

Repeat this procedure for every succeeding sample until the algorithm centers the window on the $\left[End - \frac{Len - 1}{2}\right]^{\text{th}}$ sample, marked as End. Because the window centered on the last $\frac{Len - 1}{2}$ samples cannot be full, these samples are processed with the next frame of input data.

Here is the first output frame the Hampel filter generates:

The seventh sample of the appended input frame, 23, is an outlier. The Hampel filter replaces this sample with the median over the local window [4 9 23 8 12].

Highpass Filter

Design FIR or IIR highpass filter

Library: DSP System Toolbox / Filtering / Filter Designs

Description

The Highpass Filter block independently filters each channel of the input signal over time using the given design specifications. You can control whether the block implements an IIR or FIR highpass filter using the **Filter type** parameter.

This block supports ARM Cortex code generation. Under specific conditions, this block also supports SIMD code generation. For details, see “Code Generation” on page 2-678.

Ports

Input

Port_1 — Input signal to filter

column vector | matrix

Input signal, specified as a real- or complex-valued column vector or matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel. The number of rows in the input signal denotes the channel length.

Data Types: `single` | `double` | `fixed point`

Output

Port_1 — Filtered signal

vector | matrix

Filtered signal, specified as a vector or matrix. The output has the same size and complexity characteristics as the input. If the output has a fixed-point data type, it is always signed.

Data Types: `single` | `double` | `fixed point`

Parameters

Main

Filter type — FIR or IIR filter

FIR (default) | IIR

Specify whether the block implements an FIR highpass filter or an IIR highpass filter.

Design minimum order filter — Design filter with minimum order

on (default) | off

When you select this check box, the block designs a filter with minimum order. When you clear this check box, you can specify the **Filter order** as a positive integer.

Filter order — Order of highpass filter

50 (default) | positive integer

Filter order of highpass filter, specified as a positive scalar integer.

Dependencies

To enable this parameter, clear the **Design minimum order filter** check box.

Stopband edge frequency (Hz) — Stopband edge frequency

8e3 (default) | real positive scalar

Stopband edge frequency of the highpass filter, specified as a real positive scalar in Hz. The value of the stopband edge frequency in Hz must be less than the passband frequency.

Dependencies

To enable this parameter, select the **Design minimum order filter** check box.

Passband edge frequency (Hz) — Passband edge frequency

12e3 (default) | real positive scalar

Passband edge frequency of the highpass filter, specified as a real positive scalar in Hz. The passband edge frequency must be less than half the value of the **Input sample rate (Hz)**.

Minimum stopband attenuation (dB) — Minimum stopband attenuation

80 (default) | real positive scalar

Minimum attenuation in the stopband, specified as a real positive scalar in dB.

Maximum passband ripple (dB) — Maximum passband ripple

0.1 (default) | real positive scalar

Maximum ripple of the filter response in the passband, specified as a real positive scalar in dB.

Inherit sample rate from input — Inherit sample rate from input

off (default) | on

When you select this check box, the block inherits its sample rate from the input signal. When you clear this check box, you specify the sample rate using the **Input sample rate (Hz)** parameter.

Input sample rate (Hz) — Input sample rate

44100 (default) | scalar

Input sample rate, specified as a scalar in Hz.

Simulate using — Type of simulation to run

Interpreted execution (default) | Code generation

Type of simulation to run:

- Interpreted execution (default)

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

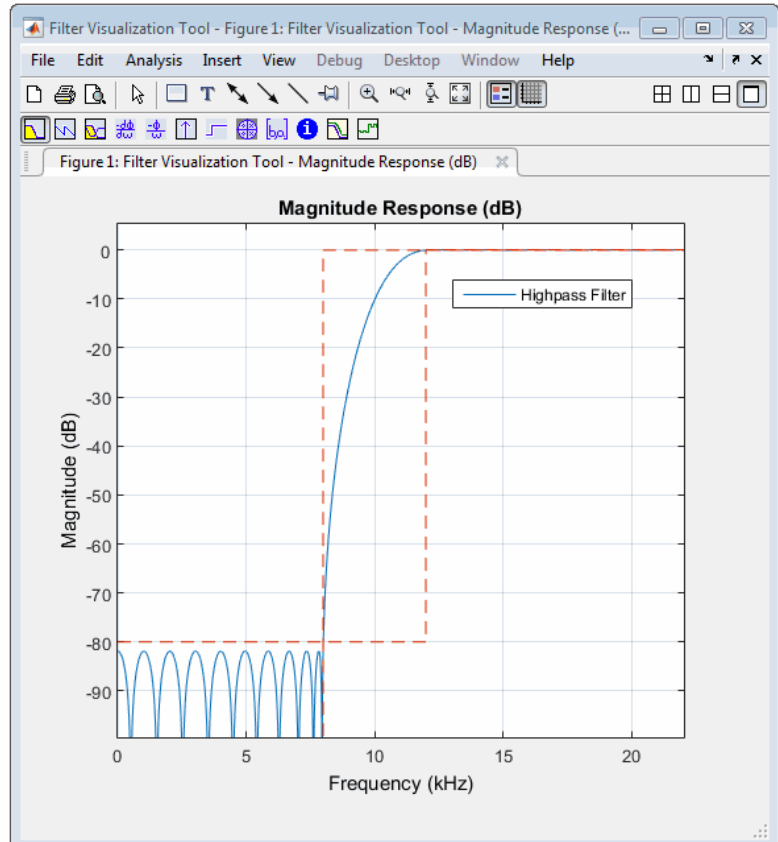

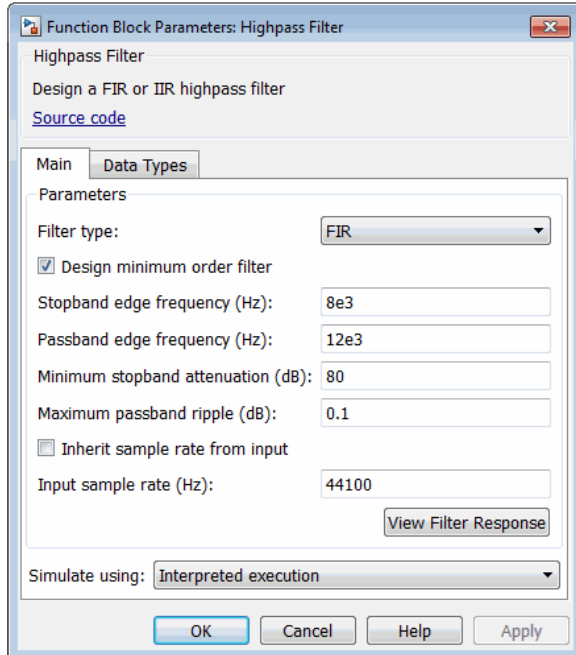

- Code generation

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.

View Filter Response — Open Filter Visualization Tool

button

Opens the Filter Visualization Tool (`fvtool`) and displays the magnitude/phase response of the highpass filter. The response is based on the block dialog box parameters. Changes made to these parameters update FVTool.

To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

Data Types

Rounding mode — Rounding method

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Rounding method for the output fixed-point operations.

Coefficients — Coefficient data type

fixdt(1,16) (default) | fixdt(1,16,0) | <data type expression>

Fixed-point data type of the coefficients, specified as one of the following:

- `fixdt(1,16)` — Signed fixed-point data type of word length 16, with binary point scaling. The block determines the fraction length automatically from the coefficient values in such a way that the coefficients occupy maximum representable range without overflowing.
- `fixdt(1,16,0)` — Signed fixed-point data type of word length 16 and fraction length 0. You can change the fraction length to any other integer value.
- `<data type expression>` — Specify the data type using an expression that evaluates to a data type object, for example, numeric type (`fixdt([],16,15)`). Specify the sign mode of this data type as `[]` or `true`.
- Refresh Data Type — Refresh to the default data type.

Click the **Show data type assistant** button  to display the data type assistant, which helps you set the data type. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no

Variable-Size Signals	yes
Zero-Crossing Detection	no

Algorithms

This block brings the capabilities of the `dsp.HighpassFilter` System object to the Simulink environment.

For information on the algorithms used by this block, see the Algorithms on page 4-640 section of `dsp.HighpassFilter`.

Version History

Introduced in R2015b

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The Highpass Filter block supports ARM Cortex code generation. To learn more about ARM Cortex code generation, see “Code Generation for ARM Cortex-M and ARM Cortex-A Processors”.

The Highpass Filter block also supports SIMD code generation using Intel AVX2 technology under these conditions:

- **Filter type** is set to FIR.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Description

This block brings the filter design capabilities of the `filterBuilder` function to the Simulink environment.

Dialog Box

See “Highpass Filter Design — Main Pane” on page 5-619 for more information about the parameters of this block. The **Data Types** and **Code Generation** panes are not available for blocks in the DSP System Toolbox Filter Designs library.

View filter response

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.

- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

In this group, you specify your filter format, such as the impulse response and the filter order.

Impulse response

Select either FIR or IIR from the drop-down list. FIR is the default. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

Note The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Order mode

Select **Minimum** (the default) or **Specify**. Selecting **Specify** enables the **Order** option so you can enter the filter order. When you set the **Impulse response** to IIR, you can specify different numerator and denominator orders. To specify a different denominator order, you must select the **Denominator order** check box.

Order

Enter the filter order. This option is enabled only if you set the **Order mode** to **Specify**.

Denominator order

Select this check box to specify a different denominator order. This option is enabled only if you set the **Impulse response** to IIR and the **Order mode** to **Specify**.

Filter type

Select **Single-rate**, **Decimator**, **Interpolator**, or **Sample-rate converter**. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, the block specifies a single-rate filter.

- Selecting **Decimator** or **Interpolator** activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting **Sample-rate converter** activates both factors.

Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to **Decimator** or **Sample-rate converter**. The default value is 2.

Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to **Interpolator** or **Sample-rate converter**. The default value is 2.

Frequency Specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.

In the figure, the region between specification values F_{stop} and F_{pass} represents the transition region where the filter response is not constrained.

Frequency constraints

When **Order mode** is **Specify**, select the filter features that the block uses to define the frequency response characteristics. The list contains the following options, when available for the filter specifications.

- **Stopband edge and passband edge** — Define the filter by specifying the frequencies for the edges for the stop- and passbands.
- **Passband edge** — Define the filter by specifying the edge of the passband.
- **Stopband edge** — Define the filter by specifying the edge of the stopband.
- **Stopband edge and 3 dB point** — For IIR filters, define the filter by specifying the frequency of the 3 dB point in the filter response and the edge of the stopband.
- **3 dB point** — Define the filter response by specifying the location of the 3 dB point. The 3 dB point is the frequency for the point three decibels below the passband value.
- **3 dB point and passband edge** — For IIR filters, define the filter by specifying the frequency of the 3 dB point in the filter response and the edge of the passband.
- **6 dB point** — For FIR filters, define the filter response by specifying the location of the 6 dB point. The 6 dB point is the frequency for the point six decibels below the passband value.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized** (0–1) to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

F_s , specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Fstop

Enter the frequency at the edge of the end of the stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Fpass

Enter the frequency at the edge of the start of the passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

F3dB

When **Frequency constraints** is 3 dB point, Stopband edge and 3 dB point, or 3 dB point and passband edge, specify the frequency of the 3 dB point. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

F6dB

When **Frequency constraints** is 6 dB point, specify the frequency of the 6 dB point. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Magnitude Specifications

Parameters in this group specify the filter response in the passbands and stopbands.

Magnitude constraints

This option is only available when you specify the order of your filter design. Depending on the setting of the **Frequency constraints** parameter, some combination of the following options will be available for the **Magnitude constraints** parameter: Unconstrained, Passband ripple, Passband ripple and stopband attenuation or Stopband attenuation.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. From the drop-down list, select one of the following options:

- Linear — Specify the magnitude in linear units.
- dB — Specify the magnitude in decibels (default).
- Squared — Specify the magnitude in squared units.

Astop

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

Apass

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure of your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is Equi ripple.

Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 20 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Phase constraint

Specify the phase constraint of the filter as **Linear**, **Maximum**, or **Minimum**.

Minimum order

When you select this parameter, the design method determines and design the minimum order filter to meet your specifications. Some filters do not provide this parameter. Select **Any**, **Even**, or **Odd** from the drop-down list to direct the design to be any minimum order, or minimum even order, or minimum odd order.

Match Exactly

Specifies that the resulting filter design matches either the passband or stopband or both bands when you select **passband** or **stopband** or **both** from the drop-down list.

Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- **Flat** — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- **Linear** — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- **1/f** — Specifies that the stopband attenuation changes exponentially as the frequency increases, where f is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to **Flat**, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to **Linear**, enter the slope of the stopband in units of dB/rad/s. `filterbuilder` applies that slope to the stopband.
- When you set **Stopband shape** to **1/f**, enter a value for the exponent n in the relation $(1/f)^n$ to define the stopband decay. `filterbuilder` applies the $(1/f)^n$ relation to the stopband to result in an exponentially decreasing stopband attenuation.

Filter Implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of n unit delays with a single delay by n .
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

Input processing

Specify how the block should process the input. The available options may vary depending on the settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

Note The Inherited (this choice will be removed – see release notes) option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- **Enforce single-rate processing** — When you select this option, the block maintains the sample rate of the input.
- **Allow multirate processing** — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to **Elements as channels (sample based)**.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

Filtering / Filter Designs

dspfdesign

Description

This block brings the filter design capabilities of the `filterBuilder` function to the Simulink environment.

This block supports SIMD code generation. For details, see “Code Generation” on page 2-691.

Dialog Box

See “Hilbert Filter Design — Main Pane” on page 5-623 for more information about the parameters of this block. The **Data Types** and **Code** panes are not available for blocks in the DSP System Toolbox Filter Designs library.

View filter response

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

In this group, you specify your filter format, such as the impulse response and the filter order.

Impulse response

Select either FIR or IIR from the drop-down list. FIR is the default. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

Note The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Filter order mode

Select either **Minimum** (the default) or **Specify** from the drop-down list. Selecting **Specify** enables the **Order** option (see the following sections) so you can enter the filter order.

Filter type

Select **Single-rate**, **Decimator**, **Interpolator**, or **Sample-rate converter**. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, the block specifies a single-rate filter.

- Selecting **Decimator** or **Interpolator** activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting **Sample-rate converter** activates both factors.

Order

Enter the filter order. This option is enabled only if **Specify** was selected for **Filter order mode**.

Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to **Decimator** or **Sample-rate converter**. The default value is 2.

Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to **Interpolator** or **Sample-rate converter**. The default value is 2.

Frequency Specifications

The parameters in this group allow you to specify your filter response curve.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0 to 1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—**Hz**, **kHz**, **MHz**, or **GHz**. Selecting one of the unit options enables the **Input sample rate** parameter.

Input sample rate

F_s , specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Transition width

Specify the width of the transitions at the ends of the passband. Specify the value in normalized frequency units or the absolute units you select in **Frequency units**.

Magnitude Specifications

Parameters in this group specify the filter response in the passbands and stopbands.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. From the drop-down list, select one of the following options:

- Linear — Specify the magnitude in linear units.
- dB — Specify the magnitude in decibels (default)
- Squared — Specify the magnitude in squared units.

Passband ripple

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure of your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default FIR method is `Equiripple`.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 20 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

FIR Type

Specify whether to design a type 3 or a type 4 FIR filter. The filter type is defined as follows:

- Type 3 — FIR filter with even order antisymmetric coefficients
- Type 4 — FIR filter with odd order antisymmetric coefficients

Select either 3 or 4 from the drop-down list.

Filter Implementation**Structure**

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use `Direct-form FIR`, and IIR filters use `Cascade minimum-multiplier allpass`.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of n unit delays with a single delay by n .
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Input processing

Specify how the block should process the input. The available options may vary depending on the settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- **Enforce single-rate processing** — When you select this option, the block maintains the sample rate of the input.
- **Allow multirate processing** — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to **Elements as channels (sample based)**.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point

Version History

Introduced in R2006b

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The Hilbert Filter block supports SIMD code generation using Intel AVX2 technology under these conditions:

- **Filter type** is set to Single-rate, Decimator, or Interpolator.
- For **Filter type** that is set to Single-rate, **Structure** is set to Direct-form FIR or Direct-form FIR transposed.
- For **Filter type** that is set to Decimator, **Structure** is set to Direct-form FIR polyphase decimator and **Rate options** is set to Enforce single-rate processing.
- For **Filter type** that is set to Interpolator:
 - **Interpolation Factor** cannot be equal to 1.
 - **Rate options** is set to Enforce single-rate processing.
- **Input processing** is set to Columns as channels (frame based).
- Input signal has a data type of single or double.
- Input port dimensions cannot be equal to [1 1].

The SIMD technology significantly improves the performance of the generated code.

Histogram

Histogram of input or sequence of inputs

Library: DSP System Toolbox / Statistics

Description

The Histogram block computes the frequency distribution of the input elements along each column or along the entire input. You can specify the dimension using the **Find the histogram over** parameter. The block distributes the input elements based on their value into a number of discrete bins specified by the **Number of bins** parameter. For more details, see “Algorithms” on page 2-697.

When the input data is real, the bin boundaries are cast into the double data type. When the input data is complex, bin boundaries for double-precision inputs are cast into double, and bin boundaries for integer inputs are cast into double and squared. For an example, see “Compute the Histogram of Real and Complex Data”.

To track the frequency distribution of inputs over a period of time, select the **Running histogram** parameter.

When the input is complex, the block sorts the elements by their magnitude.

Ports

Input

In — Data input

vector | matrix | N -D array

The block accepts real-valued or complex-valued multichannel and multidimensional inputs. The input data type must be double precision, single precision, integer, or fixed point, with power-of-two slope and zero bias.

This port is unnamed until you select the **Running histogram** parameter and set the **Reset port** parameter to any option other than **None**.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Rst — Reset port

scalar

Specify the reset event that causes the block to reset the running histogram. The reset signal and the input data signal must have the same rate.

Dependencies

To enable this port, select the **Running histogram** parameter, and set the **Reset port** parameter to any option other than **None**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

Output

Port_1 — Histogram output

vector | matrix | N -D array

Outputs the histogram data as a vector, matrix, or array. The output primarily depends on the settings of the **Running histogram** and **Find the histogram over** parameters.

For example, consider a two-dimensional input signal of size M -by- N .

When you clear the **Running histogram** parameter, the block computes the frequency distribution in each column of input or along the entire input. When you set **Find the histogram over** to:

- **Each column** — The block computes a histogram for each column of the input. The output is an n -by- N matrix, where n is the **Number of bins**. The j th column of the output matrix contains the histogram for the data in the j th column of the M -by- N input matrix.
- **Entire input** — The block computes a histogram for the entire input vector, matrix, or N -D array. The output is an n -by-1 vector, where n is the **Number of bins**.

When you select the **Running histogram** parameter, the block computes the frequency distribution of all inputs over a period of time. In this case, when you set **Find the histogram over** to:

- **Each column** — The block computes a running histogram for each column of the input. The output is an n -by- N matrix, where n is the **Number of bins**. The j th column of the output matrix contains the running histogram for the data in the j th column of the M -by- N matrix input.
- **Entire input** — The block computes the running histogram for the entire input vector, matrix, or N -D array. The output is an n -by-1 vector, where n is the **Number of bins**.

The output data type is `uint32` when the input has a data type other than `single` or `double`. The largest number that can be represented by `uint32` is $2^{32}-1$. If the range of any input exceeds this value, the block wraps the value back to 0.

Data Types: `single` | `double` | `uint32`

Parameters

Main Tab

Lower limit of histogram — Lower boundary of lowest-valued bin

scalar

Specify the lower boundary of the lowest-valued bin as a real scalar. This parameter does not accept NaN or Inf. If the input has a value less than **Lower limit of histogram**, the block places this element in the lowest-valued bin.

Upper limit of histogram — Upper boundary of highest-valued bin

scalar

Specify the upper boundary of the highest-valued bin as a real scalar. This parameter does not accept NaN or Inf. If the input has a value greater than **Upper limit of histogram**, the block places this element in the highest-valued bin.

Number of bins — Number of histogram bins

positive integer

Specify the number of histogram bins as a positive integer.

Find the histogram over — Compute histogram over each column or entire input

Each column (default) | Entire input

Specify whether the histogram is computed over each column or the entire input. The options for this parameter are affected by the setting of the **Running histogram** parameter.

When you clear the **Running histogram** parameter, and you set **Find the histogram over** parameter to:

- `Each column` — The block computes the histogram over each column.
- `Entire input` — The block outputs the histogram over the entire input.

When you select the **Running histogram** parameter, and you set **Find the histogram over** parameter to:

- `Each column` — The block computes the running histogram over each column.
- `Entire input` — The block outputs the running histogram over the entire input.

Normalized — Normalize output

off (default) | on

When you select this parameter, the block output, y , is normalized. In mathematical terms, $\text{sum}(y) = 1$. This parameter does not apply for fixed-point input signals.

Running histogram — Track frequency distribution over time

off (default) | on

When you select this parameter, the block tracks the frequency distribution of inputs over a period of time.

Reset port — Reset event

Non-zero sample (default) | None | Rising edge | Falling edge | Either edge

The block resets the running histogram and empties all the bins whenever a reset event is detected at the optional **Rst** port. The reset sample time must equal the input sample time.

Use this parameter to specify the reset event:

- `Non-zero sample` — Triggers a reset operation at each sample time when the **Rst** input is not zero.

- None — Disables the **Rst** port.
- Rising edge — Triggers a reset operation when the **Rst** input does one of the following:
 - Rises from a negative value to either a positive value or zero.
 - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.

- Falling edge — Triggers a reset operation when the **Rst** input does one of the following:
 - Falls from a positive value to a negative value or zero.
 - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.

- Either edge — Triggers a reset operation when the **Rst** input is a Rising edge or Falling edge.

Note When running simulations in the Simulink multitasking mode, reset signals have a one-sample latency. When the block detects a reset event, there is a one-sample delay at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Dependencies

To enable this parameter, select the **Running histogram** parameter.

Data Types Tab

Note To use these parameters, the data input must be complex and fixed point. For all other inputs, the parameters on the **Data Types** tab are ignored.

Rounding mode — Method of rounding operation

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more details, see rounding mode.

Saturate on integer overflow — Method of overflow action

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

Product output — Product output data type

Inherit: Same as input (default) | fixdt([],16,0)

The squares of the real and imaginary parts of the complex input are stored in the **Product output** data type.

You can set this parameter to:

- **Inherit: Same as input** — The product output data type is the same as the input data type.
- **fixdt([],16,0)** — The product output data type is an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Product output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

Accumulator — Accumulator data type

Inherit: Same as input (default) | Inherit: Same as product output | fixdt([],16,0)

The result of the sum of the squares of the real and imaginary parts of the complex input are stored in the **Accumulator** data type.

You can set this parameter to:

- **Inherit: Same as input** — The accumulator data type is the same as the input data type.
- **Inherit: Same as product output** — The accumulator data type is the same as the product output data type.
- **fixdt([],16,0)** — The accumulator data type is an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

Lock data type settings against changes by the fixed-point tools – Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block.

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Algorithms

Histogram

The histogram value for a given bin represents the frequency of occurrence of the input values bracketed by that bin. **Upper limit of histogram** specifies the upper boundary of the highest-valued bin, B_M . **Lower limit of histogram** specifies the lower boundary of the lowest-valued bin, B_m . The bins have equal width, given by:

$$\Delta = \frac{B_M - B_m}{n}.$$

The bins are centered at the following locations:

$$B_m + \left(k + \frac{1}{2}\right)\Delta \quad k = 0, 1, 2, \dots, n - 1.$$

n is the number of bins, specified by the **Number of bins** parameter.

Input values that fall on the border between two bins are placed into the lower-valued bin. Each bin includes its upper boundary. For example, a bin of width 4 centered on the value 5 contains the input value 7, but not 3. Input values greater than the **Upper limit of histogram** parameter are placed in the highest-valued bin. Similarly, values less than the **Lower limit of histogram** parameter are placed in the lowest-valued bin.

The block sorts the complex data into bins by magnitude. The magnitude is the sum of the squares of the real and imaginary components of the complex data.

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the memcpy or memset function (`string.h`) under certain conditions.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

The parameters on the **Data Types** tab are used only for complex fixed-point inputs. Complex inputs are sorted by magnitude, which is the sum of the squares of the real and imaginary components of the input. The results of the squares of the real and imaginary parts are stored in the **Product output** data type. The result of the sum of the squares is stored in the **Accumulator** data type. The parameters on the **Data Types** tab are ignored for all other inputs.

Blocks

Sort | Median | Maximum | Minimum

IDCT

Inverse discrete cosine transform (IDCT) of input

Library

Transforms

`dspxfm3`

Description

The IDCT block computes the inverse discrete cosine transform (IDCT) of each channel in the M -by- N input matrix, u .

```
y = idct(u) % Equivalent MATLAB code
```

For all N-D input arrays, the block computes the IDCT across the first dimension. The size of the first dimension (frame size), must be a power of two. To work with other frame sizes, use the Pad block to pad or truncate the frame size to a power-of-two length.

When the input is an M -by- N matrix, the block treats each input column as an independent channel containing M consecutive samples. The block outputs an M -by- N matrix whose l th column contains the length- M IDCT of the corresponding input column.

$$y(m, l) = \sum_{k=1}^M w(k)u(k, l)\cos\frac{\pi(2m-1)(k-1)}{2M}, \quad m = 1, \dots, M$$

where

$$w(k) = \begin{cases} \frac{1}{\sqrt{M}}, & k = 1 \\ \sqrt{\frac{2}{M}}, & 2 \leq k \leq M \end{cases}$$

The **Sine and cosine computation** parameter determines how the block computes the necessary sine and cosine values. This parameter has two settings, each with its advantages and disadvantages, as described in the following table.

Sine and Cosine Computation Parameter Setting	Sine and Cosine Computation Method	Effect on Block Performance
Table lookup	The block computes and stores the trigonometric values before the simulation starts, and retrieves them during the simulation. When you generate code from the block, the processor running the generated code stores the trigonometric values computed by the block in a speed-optimized table, and retrieves the values during code execution.	The block usually runs much more quickly, but requires extra memory for storing the precomputed trigonometric values.
Trigonometric fcn	The block computes sine and cosine values during the simulation. When you generate code from the block, the processor running the generated code computes the sine and cosine values while the code runs.	The block usually runs more slowly, but does not need extra data memory. For code generation, the block requires a support library to emulate the trigonometric functions, increasing the size of the generated code.

Fixed-Point Data Types

The following diagrams show the data types used within the IDCT block for fixed-point signals. You can set the sine table, accumulator, product output, and output data types displayed in the diagrams in the IDCT block dialog as discussed in “Parameters” on page 2-701.

Inputs to the IDCT block are first cast to the output data type and stored in the output buffer. Each butterfly stage processes signals in the accumulator data type, with the final output of the butterfly being cast back into the output data type.

Butterfly Stage Data Types

Twiddle Multiplication Data Types

The output of the multiplier is in the product output data type when at least one of the inputs to the multiplier is real. When both of the inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see "Multiplication Data Types".

Note When the block input is fixed point, all internal data types are signed fixed point.

Parameters

Main Tab

Sine and cosine computation

Sets the block to compute sines and cosines by either looking up sine and cosine values in a speed-optimized table (**Table lookup**), or by making sine and cosine function calls (**Trigonometric fcn**). See the table in the "Description" on page 2-699 section.

Data Types Tab

Rounding mode

Select the rounding mode for fixed-point operations. The sine table values do not obey this parameter; they always round to Nearest.

Saturate on integer overflow

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

Note The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numeric results when all these conditions are met:

- **Product output** data type is Inherit: Inherit via internal rule.
- **Accumulator** data type is Inherit: Inherit via internal rule.

With these data type settings, the block operates in full-precision mode.

Sine table

Choose how you specify the word length of the values of the sine table. The fraction length of the sine table values always equals the word length minus one. You can set this parameter to:

- A rule that inherits a data type, for example, Inherit: Same word length as input
- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

The sine table values do not obey the **Rounding mode** and **Saturate on integer overflow** parameters; instead, they are always saturated and rounded to Nearest.

Product output

Specify the product output data type. See “Fixed-Point Data Types” on page 2-700 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Accumulator

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-700 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule. For more information on this rule, see “Inherit via Internal Rule”.

- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Output

Specify the output data type. See “Fixed-Point Data Types” on page 2-700 for illustrations depicting the use of the output data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`.

When you select `Inherit: Inherit via internal rule`, the block calculates the output word length and fraction length automatically. The internal rule first calculates an ideal output word length and fraction length using the following equations:

$$WL_{idealoutput} = WL_{input} + \text{floor}(\log_2(DCTlength - 1)) + 1$$

$$FL_{idealoutput} = FL_{input}$$

Using these ideal results, the internal rule then selects word lengths and fraction lengths that are appropriate for your hardware. For more information, see “Inherit via Internal Rule”.

- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Data Types of Signals” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Output Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Output Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers

IFFT

Inverse fast Fourier transform (IFFT) of input

Library: DSP System Toolbox / Transforms

Description

The IFFT block computes the inverse fast Fourier transform (IFFT) across the first dimension of an N -D input array. The block uses one of two possible FFT implementations. You can select an implementation based on the FFTW library or an implementation based on a collection of Radix-2 algorithms. To allow the block to choose the implementation, you can select **Auto**. For more information about the FFT implementations, see “Algorithms” on page 2-712.

When you specify an FFT length not equal to the length of the input vector (or first dimension of the input array), the block implements zero-padding, truncating, or modulo- M (FFT length) data wrapping. This occurs before the IFFT operation. For an IFFT with $P \leq M$:

```
y = ifft(u,M) % P ≤ M
```

Wrapping:

```
y(:,L) = ifft(datawrap(u(:,L),M)) % P > M; L = 1,...,N
```

Truncating:

```
y(:,L) = ifft(u,M) % P > M; L = 1,...,N
```

Tip When the input length, P , is greater than the FFT length, M , you may see magnitude increases in your IFFT output. These magnitude increases occur because the IFFT block uses modulo- M data wrapping to preserve all available input samples.

To avoid such magnitude increases, you can truncate the length of your input sample, P , to the FFT length, M . To do so, place a Pad block before the IFFT block in your model.

Ports

Input

Port_1 — Input signal

vector | matrix | N -D array

Input signal for computing the IFFT. The block computes the IFFT along the first dimension of the N -D input signal. The input can be floating-point or fixed-point, real, or complex, and conjugate symmetric.

For more information on how the block computes the IFFT, see “Description” on page 2-706 and “Algorithms” on page 2-712.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Output

Port_1 – IFFT of input

`vector` | `matrix` | `N-D array`

The IFFT, computed across the first dimension of an N -D input array. For more information on how the block computes the IFFT, see “Description” on page 2-706 and “Algorithms” on page 2-712.

The k th entry of the L th output channel, $y(k,L)$, is equal to the k th point of the M -point inverse discrete Fourier transform (IDFT) of the L th input channel:

$$y(k, L) = \frac{1}{M} \sum_{p=1}^P u(p, L) e^{j2\pi(p-1)(k-1)/M} \quad k = 1, \dots, M$$

The output has the same dimensions as the input. If the input signal has a floating-point data type, the data type of the output signal uses the same floating-point data type. Otherwise, the output can be any signed fixed-point data type. The block computes scaled and unscaled versions of the IFFT.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

Parameters

Main

FFT implementation – FFT implementation

`Auto (default)` | `Radix-2` | `FFTW`

Set this parameter to `FFTW` to support an arbitrary length input signal. The block restricts generated code with `FFTW` implementation to MATLAB host computers.

Set this parameter to `Radix-2` for bit-reversed processing, fixed or floating-point data, or portable C-code generation using the Simulink Coder. The dimension M of the M -by- N input matrix, must be a power of two. To work with other input sizes, use the Pad block to pad or truncate these dimensions to powers of two, or if possible choose the `FFTW` implementation. For more information about the algorithms used by the `Radix-2` mode, see “Radix-2 Implementation” on page 2-712.

Set this parameter to `Auto` to let the block choose the FFT implementation. For floating-point inputs with non-power-of-two transform lengths, the `FFTW` algorithm is automatically chosen. Otherwise a `Radix-2` algorithm is automatically chosen. For non-power-of-two transform lengths, the block restricts generated code to MATLAB host computers.

Input is in bit-reversed order – Input is in bit-reversed order

`off (default)` | `on`

Select or clear this check box to designate the order of the input channel elements. Select this check box when the input is in bit-reversed order, and clear it when the input is in linear order. The block yields invalid outputs when you do not set this parameter correctly.

You cannot select this check box if you have cleared the **Inherit FFT length from input dimensions** check box, and you are specifying the FFT length using the **FFT length** parameter. Also, it cannot be selected when you set the **FFT implementation** parameter to FFTW.

For more information on ordering of the output, see “Linear and Bit-Reversed Output Order”.

Dependencies

To enable this parameter, set **FFT implementation** to Auto or Radix-2.

Input is conjugate symmetric — Input is conjugate symmetric

off (default) | on

Select this option when the block inputs conjugate symmetric data and you want real-valued outputs. Selecting this check box optimizes the block's computation method.

The FFT block yields conjugate symmetric output when you input real-valued data. Taking the IFFT of a conjugate symmetric input matrix produces real-valued output. Therefore, if the input to the block is both floating point and conjugate symmetric, and you select this check box, the block produces real-valued outputs.

You cannot select this check box if you have cleared the **Inherit FFT length from input dimensions** check box, and you are specifying the FFT length using the **FFT length** parameter.

If you input conjugate symmetric data to the IFFT block and do not select this check box, the IFFT block outputs a complex-valued signal with small imaginary parts. The block outputs invalid data if you select this option with non conjugate symmetric input data.

Divide output by FFT length — Divide output by FFT length

on (default) | off

When you select this check box, the block computes its output according to the IDFT equation, discussed in the Description on page 2-706 section.

When you clear this check box, the block computes the output using a modified version of the IDFT: $M \cdot y(k, l)$, which is defined by the following equation:

$$M \cdot y(k, l) = \sum_{p=1}^P u(p, l) e^{j2\pi(p-1)(k-1)/M} \quad k = 1, \dots, M$$

The modified IDFT equation does not include the multiplication factor of $1/M$.

Inherit FFT length from input dimensions — Inherit FFT length from input dimensions

on (default) | off

Select to inherit the FFT length from the input dimensions. If you do not select this parameter, the **FFT length** parameter becomes available to specify the length. You cannot clear this parameter when you select either the **Input is in bit-reversed order** or the **Input is conjugate symmetric** parameter.

FFT length — FFT length

64 (default) | integer

Specify FFT length as an integer greater than or equal to two.

When you set the **FFT implementation** parameter to Radix-2, or when you check the **Output in bit-reversed order** check box, this value must be a power of two.

Dependencies

To enable this parameter, clear the **Inherit FFT length from input dimensions** check box.

Wrap input data when FFT length is shorter than input length — Wrap or truncate the input

on (default) | off

Choose to wrap or truncate the input, depending on the FFT length. If you select this parameter, modulo-length data wrapping occurs before the FFT operation when the FFT length is shorter than the input length. If you clear this parameter, truncation of the input data to the FFT length occurs before the FFT operation.

Dependencies

To enable this parameter, clear the **Inherit FFT length from input dimensions** check box.

Data Types

Rounding mode — Rounding method

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Select the rounding mode for fixed-point operations.

Limitations

The sine table values do not obey this parameter; instead, they always round to **Nearest**.

The **Rounding mode** parameter has no effect on numeric results when all these conditions are met:

- **Product output** data type is Inherit: Inherit via internal rule.
- **Accumulator** data type is Inherit: Inherit via internal rule.

With these data type settings, the block operates in full-precision mode.

Saturate on integer overflow — Saturate on integer overflow

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on **saturate** and **wrap**, see **overflow mode for fixed-point operations**.

Limitations

The **Saturate on integer overflow** parameter has no effect on numeric results when all these conditions are met:

- **Product output** data type is Inherit: Inherit via internal rule.
- **Accumulator** data type is Inherit: Inherit via internal rule.

With these data type settings, the block operates in full-precision mode.

Sine table – Data type of sine table values

Inherit: Same word length as input (default) | `fixdt(1,16)`

Choose how you specify the word length of the values of the sine table. The fraction length of the sine table values always equals the word length minus one. You can set this parameter to:

- A rule that inherits a data type, for example, Inherit: Same word length as input
- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Sine table** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) for more information.

Limitations

The sine table values do not obey the **Rounding mode** and **Saturate on integer overflow** parameters; instead, they are always saturated and rounded to Nearest.

Product output – Product output data type

Inherit: Inherit via internal rule (default) | Inherit: Same as input | `fixdt(1,16,0)`

Specify the product output data type. See “Fixed Point” on page 2-714 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) for more information.

Accumulator – Accumulator data type

Inherit: Inherit via internal rule (default) | Inherit: Same as input | Inherit: Same as product output | `fixdt(1,16,0)`

Specify the accumulator data type. See “Fixed Point” on page 2-714 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule. For more information on this rule, see “Inherit via Internal Rule”.

- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) for more information.

Output — Output data type

Inherit: `Inherit via internal rule (default)` | `Inherit: Same as input` | `fixdt(1,16,0)`

Specify the output data type. See “Fixed Point” on page 2-714 for illustrations depicting the use of the output data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`.

When you select `Inherit: Inherit via internal rule`, the block calculates the output word length and fraction length automatically. The equations that the block uses to calculate the ideal output word length and fraction length depend on the setting of the **Divide output by FFT length** check box.

- When you select the **Divide output by FFT length** check box, the ideal output word and fraction lengths are the same as the input word and fraction lengths.
- When you clear the **Divide output by FFT length** check box, the block computes the ideal output word and fraction lengths according to the following equations:

$$WL_{idealoutput} = WL_{input} + \text{floor}(\log_2(FFTlength - 1)) + 1$$

$$FL_{idealoutput} = FL_{input}$$

Using these ideal results, the internal rule then selects word lengths and fraction lengths that are appropriate for your hardware. For more information, see “Inherit via Internal Rule”.

- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Data Types of Signals” (Simulink) for more information.

Output Minimum — Minimum value block should output

`[]` (default) | scalar

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Output Maximum — Maximum value block should output

`[]` (default) | scalar

Specify the maximum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	yes ^a
Zero-Crossing Detection	no

^a Variable-size signals are only supported when the Inherit FFT length from input dimensions checkbox is selected.

Algorithms

FFTW Implementation

The FFTW implementation provides an optimized FFT calculation including support for power-of-two and non-power-of-two transform lengths in both simulation and code generation. Generated code using the FFTW implementation will be restricted to MATLAB host computers. The data type must be floating-point. Refer to Simulink Coder for more details on generating code.

Radix-2 Implementation

The Radix-2 implementation supports bit-reversed processing, fixed or floating-point data, and allows the block to provide portable C-code generation using the Simulink Coder. The dimension M of the M -by- N input matrix must be a power of two. To work with other input sizes, use the Pad block to pad or truncate these dimensions to powers of two, or if possible choose the FFTW implementation.

With Radix-2 selected, the block implements one or more of the following algorithms:

- Butterfly operation
- Double-signal algorithm
- Half-length algorithm
- Radix-2 decimation-in-time (DIT) algorithm
- Radix-2 decimation-in-frequency (DIF) algorithm

Radix-2 Algorithms for Real or Complex Input Complexity

Parameter Settings	Algorithms Used for IFFT Computation
<input type="checkbox"/> Input is in bit-reversed order <input type="checkbox"/> Input is conjugate symmetric	Bit-reversal operation and radix-2 DIT
<input checked="" type="checkbox"/> Input is in bit-reversed order <input type="checkbox"/> Input is conjugate symmetric	Radix-2 DIT
<input type="checkbox"/> Input is in bit-reversed order <input checked="" type="checkbox"/> Input is conjugate symmetric	Bit-reversal operation and radix-2 DIT in conjunction with the half-length and double-signal algorithms
<input checked="" type="checkbox"/> Input is in bit-reversed order <input checked="" type="checkbox"/> Input is conjugate symmetric	Radix-2 DIT in conjunction with the half-length and double-signal algorithms

Radix-2 Optimization for the Table of Trigonometric Values

In certain situations, the block's Radix-2 algorithm computes all the possible trigonometric values of the twiddle factor

$$e^{j\frac{2\pi k}{K}}$$

where K is the greater value of either M or N and $k = 0, \dots, K - 1$. The block stores these values in a table and retrieves them during simulation. The number of table entries for fixed-point and floating-point is summarized in the following table:

Number of Table Entries for N-Point FFT	
floating-point	$3N/4$
fixed-point	N

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- When the following conditions apply, the executable generated from this block relies on prebuilt dynamic library files (.dll files) included with MATLAB:
 - **FFT implementation** is set to FFTW.
 - **Inherit FFT length from input dimensions** is cleared, and **FFT length** is set to a value that is not a power of two.

Use the packNGo function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

- When the FFT length is a power of two, you can generate standalone C and C++ code from this block.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

The following diagrams show the data types used within the IFFT block for fixed-point signals. You can set the sine table, accumulator, product output, and output data types displayed in the diagrams in the IFFT block dialog box, as discussed in “Parameters” on page 2-707.

The IFFT block first casts input to the output data type and then stores it in the output buffer. Each butterfly stage then processes signals in the accumulator data type, with the final output of the butterfly being cast back into the output data type. The block multiplies in a twiddle factor before each butterfly stage in a decimation-in-time IFFT, and after each butterfly stage in a decimation-in-frequency IFFT.

Decimation-in-time IFFT**Decimation-in-frequency IFFT****Butterfly stage data types****Twiddle multiplication data types**

The output of the multiplier is in the accumulator data type because both of the inputs to the multiplier are complex. For details on the complex multiplication performed, see “Multiplication Data Types”.

Note When the block input is fixed point, all internal data types are signed fixed point.

IIR Halfband Interpolator

Interpolate signal using polyphase IIR halfband filter

Library

Filtering/Filter Designs

dspfdesign

Description

The IIR Halfband Interpolator block performs efficient polyphase interpolation of the input signal by a factor of two. To design the halfband filter, you can specify the block to use an elliptic design or a quasi-linear phase design. The block uses these design methods to compute the filter coefficients. To filter the inputs, the block uses a polyphase structure. The allpass filters in the polyphase structure are in a minimum multiplier form.

Elliptic design introduces nonlinear phase and creates the filter using fewer coefficients than quasi linear design. Quasi-linear phase design overcomes phase nonlinearity at the cost of additional coefficients.

Alternatively, instead of designing the halfband filter using a design method, you can specify the filter coefficients directly. When you choose this option, the allpass filters in the two branches of the polyphase implementation can be in a minimum multiplier form or in a wave digital form.

You can also use the block to implement the synthesis portion of a two-band filter bank to synthesize a signal from lowpass and highpass subbands.

The input signal can be a real- or complex-valued column vector or matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel.

Parameters

Filter specification

Parameters used to design the IIR halfband filter. Because the filter design has only two degrees of freedom, you can specify only two of the three parameters:

- Transition width and stopband attenuation (default) — Design the filter using **Transition width (Hz)** and **Stopband attenuation (dB)**. This design is the minimum order design.
- Filter order and transition width — Design the filter using **Filter order** and **Transition width (Hz)**.
- Filter order and stopband attenuation — Design the filter using **Filter order** and **Stopband attenuation (dB)**.

- **Coefficients**— Specify the filter coefficients directly using the enabled parameters.

Transition width (Hz)

Transition width of the IIR halfband filter, specified as a real positive scalar in Hz. The transition width must be less than half the input sample rate. This parameter applies when **Filter specification** is set to **Filter order and transition width** or **Transition width and stopband attenuation**. The default is $4.1e3$.

Filter order

Filter order, specified as a finite positive integer. If you set **Design method** to **Elliptic**, then **Filter order** must be an odd integer greater than one. If you set **Design method** to **Quasi-linear phase**, then **Filter order** must be a multiple of four. This parameter applies when **Filter specification** is set to **Filter order and transition width** or **Filter order and stopband attenuation**. The default is 9.

Stopband attenuation (dB)

Minimum attenuation needed in the stopband of the IIR halfband filter, specified as a real positive scalar in dB. This parameter applies when **Filter specification** is set to **Filter order and stopband attenuation** or **Transition width and stopband attenuation**. The default is 80.

Design method

Design method for the IIR halfband filter.

- **Elliptic (default)** — The filter has nonlinear phase and uses few coefficients.
- **Quasi-linear phase** — The first branch of the polyphase filter structure is a pure delay, which results in an approximately linear phase response.

This parameter applies when you set **Filter specification** to any option except **Coefficients**.

Internal allpass structure

Internal allpass filter implementation structure, specified as **Minimum multiplier** or **Wave Digital Filter**. This parameter applies when you set **Filter specification** to **Coefficients**. Each structure uses a different coefficients set, independently stored in the corresponding coefficients property. The default is **Minimum multiplier**.

Make the first branch a pure delay

When you select this check box, the first branch of the polyphase filter structure becomes a pure delay, and the **Branch 1 allpass polynomial coefficients** and **Branch 1 Wave Digital coefficients** parameters do not apply. This parameter applies when you set **Filter specification** to **Coefficients**.

By default, this check box is selected.

Delay length in samples for branch 1

Length of the first branch delay, specified as a finite positive scalar. This parameter applies when you set **Filter specification** to **Coefficients** and select **Make the first branch a pure delay**. The default is 1.

Specify coefficients from input port

When you select this check box, the branch 1 allpass polynomial coefficients and branch 2 allpass polynomial coefficients are input through the input ports **coeffs1** and **coeffs2**. When you clear this check box, the coefficients are specified on the block dialog through the **Branch 1 allpass polynomial coefficients** and **Branch 2 allpass polynomial coefficients** parameters.

This parameter applies when you set **Filter specification** to Coefficients and **Internal allpass structure** to Minimum multiplier.

Branch 1 allpass polynomial coefficients

Allpass polynomial filter coefficients of the first branch, specified as an N -by-1 or N -by-2 matrix of N first-order or second-order allpass sections. This parameter applies only when you set **Filter specification** to Coefficients and **Internal allpass structure** to Minimum multiplier. The default is [0.1284563; 0.7906755].

This parameter applies when you set **Filter specification** to Coefficients, set **Internal allpass structure** to Minimum multiplier, and clear the **Specify coefficients from input port** parameter.

This parameter is tunable. That is, you can change its value during simulation.

Branch 2 allpass polynomial coefficients

Allpass polynomial filter coefficients of the second branch, specified as an N -by-1 or N -by-2 matrix of N first-order or second-order allpass sections. This parameter applies only when you set **Filter specification** to Coefficients and **Internal allpass structure** to Minimum multiplier. The default is 0.4295667.

This parameter applies when you set **Filter specification** to Coefficients, set **Internal allpass structure** to Minimum multiplier, and clear the **Specify coefficients from input port** parameter.

This parameter is tunable. That is, you can change its value during simulation.

Branch 1 Wave Digital coefficients

Allpass filter coefficients of the first branch in Wave Digital Filter form, specified as an N -by-1 or N -by-2 matrix of N first-order or second-order allpass sections. This parameter applies only when you set **Filter specification** to Coefficients and **Internal allpass structure** to Wave Digital Filter. The default is [0.1284563; 0.7906755].

This parameter applies when you set **Filter specification** to Coefficients and **Internal allpass structure** to Wave Digital Filter.

Branch 2 Wave Digital coefficients

Allpass filter coefficients of the second branch in Wave Digital Filter form, specified as an N -by-1 or N -by-2 matrix of N first-order or second-order allpass sections. This parameter applies only when you set **Filter specification** to Coefficients and **Internal allpass structure** to Wave Digital Filter. The default is 0.4295667.

This parameter applies when you set **Filter specification** to Coefficients and **Internal allpass structure** to Wave Digital Filter.

Last section of branch 2 is first order

When you select this check box, the last section of the second branch is treated as a first order section. This parameter applies only when you set **Filter specification** to Coefficients. When the coefficients of the second branch are in an N -by-2 matrix, the block ignores the second element of the last row of the matrix. The last section of the second branch then becomes a first-order section.

When this check box is cleared, the last section of the second branch is treated as a second-order section. When the coefficients of the second branch are in an N -by-1 matrix, the block ignores this parameter.

By default, this check box is cleared.

Input highpass subband

When you select this check box, the block acts as a synthesis filter bank. The block accepts two inputs to synthesize: lowpass and highpass subbands. When you clear this check box, the block acts as an IIR half band interpolator and accepts a single vector or matrix as input. By default, this check box is cleared.

Inherit sample rate from input

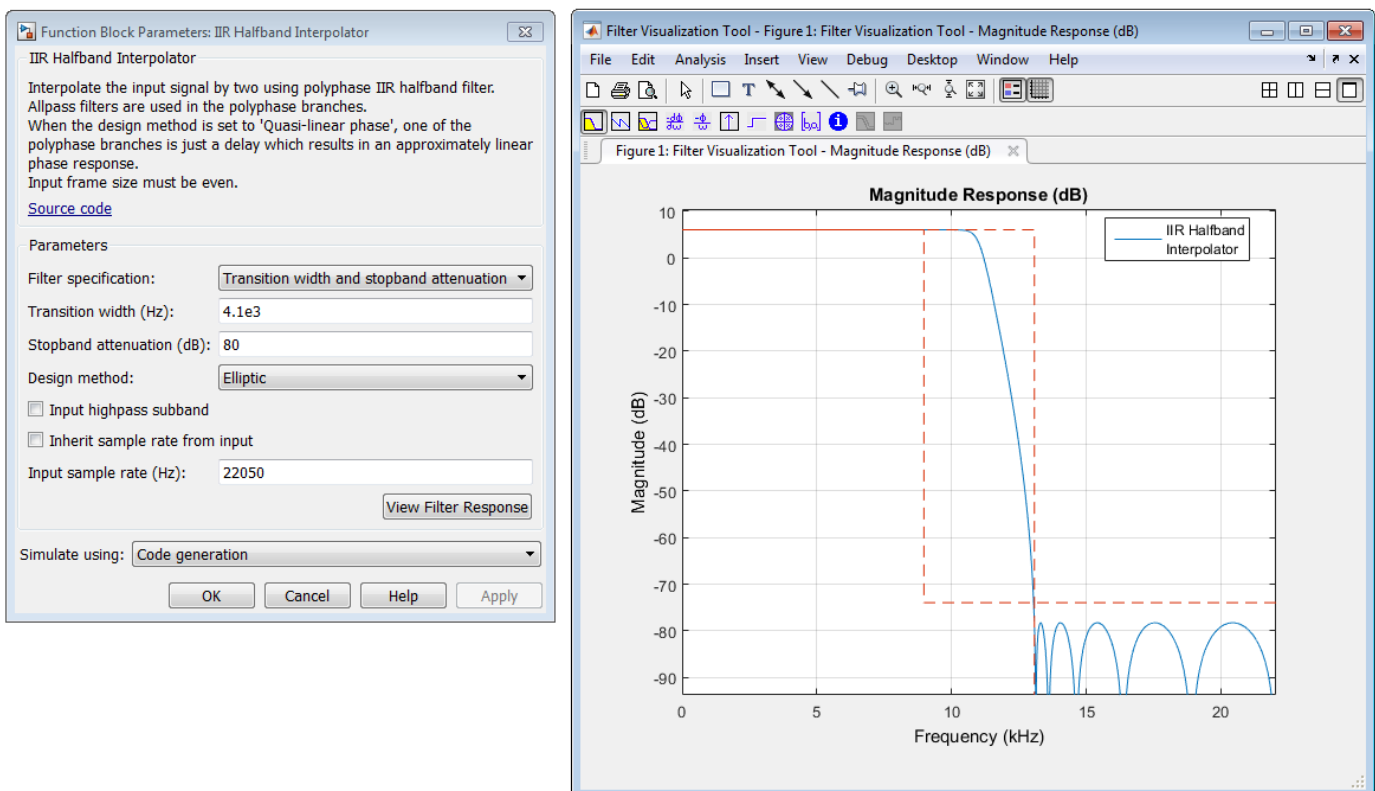

When you select this check box, the block inherits its sample rate from the input signal. The block calculates the sample rate based on the sample time of the input port. When you clear this check box, you specify the sample rate in **Input sample rate (Hz)**.

Input sample rate (Hz)

Input sample rate, specified as a scalar in Hz. The default is 44100. You can specify an input sample rate when the **Inherit sample rate from input** check box is cleared.

View Filter Response

Opens the Filter Visualization Tool FVTool and displays the magnitude/phase response of the IIR Halfband Interpolator. The response is based on the block dialog box parameters. Changes made to these parameters update FVTool.

To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

Simulate using

Type of simulation to run. You can set this parameter to:

- Code generation (default)

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.

- Interpreted execution

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point

IIR Halfband Decimator

Decimate signal using polyphase IIR halfband filter

Library

Filtering/Filter Designs

dspfdesign

Description

The IIR Halfband Decimator block performs polyphase decimation of the input signal by a factor of two. To design the halfband filter, you can specify the block to use an elliptic design or a quasi-linear phase design. The block uses these design methods to compute the filter coefficients. To filter the inputs, the block uses a polyphase structure. The allpass filters in the polyphase structure are in a minimum multiplier form.

Elliptic design introduces nonlinear phase and creates the filter using fewer coefficients than quasi linear design. Quasi-linear phase design overcomes phase nonlinearity at the cost of additional coefficients.

Alternatively, instead of designing the halfband filter using a design method, you can specify the filter coefficients directly. When you choose this option, the allpass filters in the two branches of the polyphase implementation can be in a minimum multiplier form or in a wave digital form.

You can also use the block to implement the analysis portion of a two-band filter bank to filter a signal into lowpass and highpass subbands.

The input signal can be a real- or complex-valued column vector or matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel. The number of rows in the input signal must be a multiple of 2.

Parameters

Filter specification

Parameters used to design the IIR halfband filter. Because the filter design has only two degrees of freedom, you can specify only two of the three parameters:

- Transition width and stopband attenuation (default) — Design the filter using **Transition width (Hz)** and **Stopband attenuation (dB)**. This design is the minimum order design.
- Filter order and transition width — Design the filter using **Filter order** and **Transition width (Hz)**.
- Filter order and stopband attenuation — Design the filter using **Filter order** and **Stopband attenuation (dB)**.

- **Coefficients**— Specify the filter coefficients directly using the enabled parameters.

Transition width (Hz)

Transition width of the IIR halfband filter, specified as a real positive scalar in Hz. The transition width must be less than half the input sample rate. This parameter applies when **Filter specification** is set to **Filter order and transition width** or **Transition width and stopband attenuation**. The default is $4.1e3$.

Filter order

Filter order, specified as a finite positive integer. If you set **Design method** to **Elliptic**, then **Filter order** must be an odd integer greater than one. If you set **Design method** to **Quasi-linear phase**, then **Filter order** must be a multiple of four. This parameter applies when **Filter specification** is set to **Filter order and transition width** or **Filter order and stopband attenuation**. The default is 9.

Stopband attenuation (dB)

Minimum attenuation needed in the stopband of the IIR halfband filter, specified as a real positive scalar in dB. This parameter applies when **Filter specification** is set to **Filter order and stopband attenuation** or **Transition width and stopband attenuation**. The default is 80.

Design method

Design method for the IIR halfband filter.

- **Elliptic (default)** — The filter has nonlinear phase and uses few coefficients.
- **Quasi-linear phase** — The first branch of the polyphase filter structure is a pure delay, which results in an approximately linear phase response.

This parameter applies when you set **Filter specification** to any option except **Coefficients**.

Internal allpass structure

Internal allpass filter implementation structure, specified as **Minimum multiplier** or **Wave Digital Filter**. This parameter applies when you set **Filter specification** to **Coefficients**. Each structure uses a different coefficients set, independently stored in the corresponding coefficients property. The default is **Minimum multiplier**.

Make the first branch a pure delay

When you select this check box, the first branch of the polyphase filter structure becomes a pure delay, and the **Branch 1 allpass polynomial coefficients** and **Branch 1 Wave Digital coefficients** parameters do not apply. This parameter applies when you set **Filter specification** to **Coefficients**.

By default, this check box is selected.

Delay length in samples for branch 1

Length of the first branch delay, specified as a finite positive scalar. This parameter applies when you set **Filter specification** to **Coefficients** and select **Make the first branch a pure delay**. The default is 1.

Specify coefficients from input port

When you select this check box, the branch 1 allpass polynomial coefficients and branch 2 allpass polynomial coefficients are input through the input ports **coeffs1** and **coeffs2**. When you clear this check box, the coefficients are specified on the block dialog through the **Branch 1 allpass polynomial coefficients** and **Branch 2 allpass polynomial coefficients** parameters.

This parameter applies when you set **Filter specification** to Coefficients and **Internal allpass structure** to Minimum multiplier.

Branch 1 allpass polynomial coefficients

Allpass polynomial filter coefficients of the first branch, specified as an N -by-1 or N -by-2 matrix of N first-order or second-order allpass sections. This parameter applies only when you set **Filter specification** to Coefficients and **Internal allpass structure** to Minimum multiplier. The default is [0.1284563; 0.7906755].

This parameter applies when you set **Filter specification** to Coefficients, set **Internal allpass structure** to Minimum multiplier, and clear the **Specify coefficients from input port** parameter.

This parameter is tunable. That is, you can change its value during simulation.

Branch 2 allpass polynomial coefficients

Allpass polynomial filter coefficients of the second branch, specified as an N -by-1 or N -by-2 matrix of N first-order or second-order allpass sections. This parameter applies only when you set **Filter specification** to Coefficients and **Internal allpass structure** to Minimum multiplier. The default is 0.4295667.

This parameter applies when you set **Filter specification** to Coefficients, set **Internal allpass structure** to Minimum multiplier, and clear the **Specify coefficients from input port** parameter.

This parameter is tunable. That is, you can change its value during simulation.

Branch 1 Wave Digital coefficients

Allpass filter coefficients of the first branch in Wave Digital Filter form, specified as an N -by-1 or N -by-2 matrix of N first-order or second-order allpass sections. This parameter applies only when you set **Filter specification** to Coefficients and **Internal allpass structure** to Wave Digital Filter. The default is [0.1284563; 0.7906755].

This parameter applies when you set **Filter specification** to Coefficients and **Internal allpass structure** to Wave Digital Filter.

Branch 2 Wave Digital coefficients

Allpass filter coefficients of the second branch in Wave Digital Filter form, specified as an N -by-1 or N -by-2 matrix of N first-order or second-order allpass sections. This parameter applies only when you set **Filter specification** to Coefficients and **Internal allpass structure** to Wave Digital Filter. The default is 0.4295667.

This parameter applies when you set **Filter specification** to Coefficients and **Internal allpass structure** to Wave Digital Filter.

Last section of branch 2 is first order

When you select this check box, the last section of the second branch is treated as a first order section. This parameter applies only when you set **Filter specification** to Coefficients. When the coefficients of the second branch are in an N -by-2 matrix, the block ignores the second element of the last row of the matrix. The last section of the second branch then becomes a first-order section.

When this check box is cleared, the last section of the second branch is treated as a second-order section. When the coefficients of the second branch are in an N -by-1 matrix, the block ignores this parameter.

By default, this check box is cleared.

Output highpass subband

When you select this check box, the block acts as an analysis filter bank, producing two power-complementary outputs. When you clear this check box, the block acts as an IIR halfband decimator and accepts a single vector or matrix as input. By default, this check box is cleared.

Inherit sample rate from input

When you select this check box, the block inherits its sample rate from the input signal. The block calculates the sample rate based on the sample time of the input port. When you clear this check box, you specify the sample rate in **Input sample rate (Hz)**.

This parameter applies when you set **Filter specification** to any option except Coefficients.

Input sample rate (Hz)

Input sample rate, specified as a scalar in Hz. The default is 44100. You can specify an input sample rate when the **Inherit sample rate from input** check box is cleared.

View Filter Response

Opens the Filter Visualization Tool FVTool and displays the magnitude/phase response of the IIR Halfband Decimator. The response is based on the block dialog box parameters. Changes made to these parameters update FVTool.

To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

Simulate using

Type of simulation to run. You can set this parameter to:

- Code generation (default)

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.

- Interpreted execution

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

Supported Data Types

Inherit Complexity

Change complexity of input to match reference signal

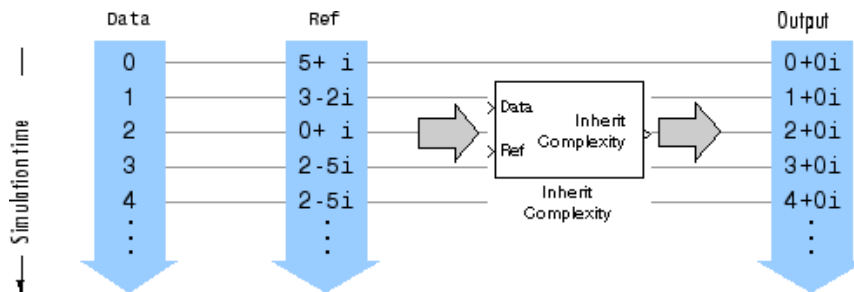

Library

Signal Management / Signal Attributes

dpsigattribs

Description

The Inherit Complexity block alters the input data at the Data port to match the complexity of the reference input at the Ref port. When the Data input is real, and the Ref input is complex, the block appends a zero-valued imaginary component, $0i$, to each element of the Data input.

When the Data input is complex, and the Ref input is real, the block outputs the real component of the Data input.

When both the Data input and Ref input are real, or when both the Data input and Ref input are complex, the block propagates the Data input with no change.

Supported Data Types

Port	Supported Data Types
Data	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Integer Delay (Obsolete)

Delay input by integer number of sample periods

Library

dspobslib

Description

Note The Integer Delay block will be removed from the product in a future release. We strongly recommend replacing this block with the Delay block.

The Integer Delay block delays a discrete-time input by the number of sample intervals specified in the **Delay** parameter. Noninteger delay values are rounded to the nearest integer, and negative delays are clipped at 0.

Sample-Based Operation

When the input is a sample-based M -by- N matrix, the block treats each of the $M \times N$ matrix elements as an independent channel. The **Delay** parameter, v , can be an M -by- N matrix of positive integers that specifies the number of sample intervals to delay each channel of the input, or a scalar integer by which to equally delay all channels.

For example, when the input is M -by-1 and v is the matrix $[v(1) \ v(2) \ \dots \ v(M)]'$, the first channel is delayed by $v(1)$ sample intervals, the second channel is delayed by $v(2)$ sample intervals, and so on. Note that when a channel is delayed for Δ sample-time units, the output sample at time t is the input sample at time $t - \Delta$. When $t - \Delta$ is negative, then the output is the corresponding value specified by the **Initial conditions** parameter.

A 1-D vector of length M is treated as an M -by-1 matrix, and the output is 1-D.

The **Initial conditions** parameter specifies the output of the block during the initial delay in each channel. The initial delay for a particular channel is the time elapsed from the start of the simulation until the first input in that channel is propagated to the output. Both fixed and time-varying initial conditions can be specified in a variety of ways to suit the dimensions of the input.

Fixed Initial Conditions

A fixed initial condition in sample-based mode can be specified as one of the following:

- Scalar value to be repeated at each sample time of the initial delay (for every channel). For a 2-by-2 input with the parameter settings below,

Delay (samples):	[1 2; 3 4]
Initial conditions:	-1

the block generates the following sequence of matrices at the start of the simulation,

$$\begin{bmatrix} -1 & -1 \\ -1 & -1 \end{bmatrix}, \begin{bmatrix} u_{11}^1 & -1 \\ -1 & -1 \end{bmatrix}, \begin{bmatrix} u_{11}^2 & u_{12}^1 \\ -1 & -1 \end{bmatrix}, \begin{bmatrix} u_{11}^3 & u_{12}^2 \\ u_{21}^1 & -1 \end{bmatrix}, \begin{bmatrix} u_{11}^4 & u_{12}^3 \\ u_{21}^2 & u_{22}^1 \end{bmatrix}, \dots$$

where u_{ij}^k is the ij th element of the k th matrix in the input sequence.

- Array of size M -by- N -by- d . In this case, you can set different fixed initial conditions for each element of a sample-based input. This setting is explained further in the Array bullet in “Time-Varying Initial Conditions” on page 2-731.

Initial conditions cannot be specified by full matrices.

Time-Varying Initial Conditions

A time-varying initial condition in sample-based mode can be specified in one of the following ways:

- Vector of length d , where d is the maximum value specified for any channel in the **Delay** parameter. The vector can be a L -by- d , 1-by- d , or 1-by-1-by- d . The d elements of the vector are output in sequence, one at each sample time of the initial delay.

For a scalar input and the parameters shown below,

Delay (samples):	5
Initial conditions:	[-1 -1 0 1]

the block outputs the sequence -1, -1, -1, 0, 1, ... at the start of the simulation.

- Array of dimension M -by- N -by- d , where d is the value specified for the **Delay** parameter (the maximum value when the **Delay** is a vector) and M and N are the number of rows and columns, respectively, in the input matrix. The d pages of the array are output in sequence, one at each sample time of the initial delay. For a 2-by-3 input, and the parameters below,

Delay (samples):	3
Initial conditions:	cat(3, [1 2 3; 4 5 6], [2 4 6; 1 3 5], [3 6 9; 0 4 8])

the block outputs the matrix sequence

$$\begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \end{bmatrix}, \begin{bmatrix} 2 & 4 & 6 \\ 1 & 3 & 5 \end{bmatrix}, \begin{bmatrix} 3 & 6 & 9 \\ 0 & 4 & 8 \end{bmatrix}$$

at the start of the simulation. Note that setting **Initial conditions** to an array with the same matrix for each entry implements constant initial conditions; a different constant initial condition for each input matrix element (channel).

Initial conditions cannot be specified by full matrices.

Frame-Based Operation

When the input is a frame-based M -by- N matrix, the block treats each of the N columns as an independent channel, and delays each channel as specified by the **Delay** parameter.

For frame-based inputs, the **Delay** parameter can be a scalar integer by which to equally delay all channels. It can also be a 1-by- N row vector, each element of which serves as the delay for the corresponding channel of the N -channel input. Likewise, it can also be an M -by-1 column vector, each element of which serves as the delay for one of the corresponding M samples for each channel. The **Delay** parameter can be an M -by- N matrix of positive integers as well; in this case, each element of each channel is delayed by the corresponding element in the delay matrix. For instance, if the fifth element of the third column of the delay matrix was 3, then the fifth element of the third channel of the input matrix is always delayed by three sample-time units.

When a channel is delayed for Δ sample-time units, the output sample at time t is the input sample at time $t - \Delta$. When $t - \Delta$ is negative, then the output is the corresponding value specified in the **Initial conditions** parameter.

The **Initial conditions** parameter specifies the output during the initial delay. Both fixed and time-varying initial conditions can be specified. The initial delay for a particular channel is the time elapsed from the start of the simulation until the first input in that channel is propagated to the output.

Fixed Initial Conditions

The settings shown below specify fixed initial conditions. The value entered in the **Initial conditions** parameter is repeated at the output for each sample time of the initial delay. A fixed initial condition in frame-based mode can be one of the following:

- Scalar value to be repeated for all channels of the output at each sample time of the initial delay. For a general M -by- N input with the parameter settings below,

The image shows a screenshot of a software interface with two input fields. The first field is labeled "Delay (samples):" and contains the number "5". The second field is labeled "Initial conditions:" and contains the number "0".

the first five samples in each of the N channels are zero. Notice that when the frame size is larger than the delay, all of these zeros are all included in the first output from the block.

- Array of size 1-by- N -by- D . In this case, you can also specify different fixed initial conditions for each channel. See “Time-Varying Initial Conditions” on page 2-732 for details.

Initial conditions cannot be specified by full matrices.

Time-Varying Initial Conditions

The following settings specify time-varying initial conditions. For time-varying initial conditions, the values specified in the **Initial conditions** parameter are output in sequence during the initial delay. A time-varying initial condition in frame-based mode can be specified in the following ways:

- Vector of length D , where each of the N channels have the same initial conditions sequence specified in the vector. D is defined as follows:

- When an element of the delay entry is less than the frame size,

$$D = d + 1$$

where d is the maximum delay.

- When the all elements of the delay entry are greater than the input frame size,

$$D = d + \text{input frame size} - 1$$

Only the first d entries of the initial condition vector are used; the rest of the values are ignored, but you must include them nonetheless. For a two-channel ramp input $[1:100; 1:100]'$ with a frame size of 4 and the parameter settings below,

the block outputs the following sequence of frames at the start of the simulation.

$$\begin{bmatrix} -4 & -1 \\ -5 & -2 \\ 1 & -3 \\ 2 & -4 \end{bmatrix}, \begin{bmatrix} 3 & -5 \\ 4 & 1 \\ 5 & 2 \\ 6 & 3 \end{bmatrix}, \begin{bmatrix} 7 & 4 \\ 8 & 5 \\ 9 & 6 \\ 10 & 7 \end{bmatrix}, \dots$$

Note that since one of the delays, 2, is less than the frame size of the input, 4, the length of the **Initial conditions** vector is the sum of the maximum delay and 1 (5+1), which is 6. The first five entries of the initial conditions vector are used by the channel with the maximum delay, and the rest of the entries are ignored. Since the first channel is delayed for less than the maximum delay (2 sample time units), it only makes use of two of the initial condition entries.

- Array of size 1-by- N -by- D , where D is defined in “Time-Varying Initial Conditions” on page 2-732. In this case, the k th entry of each 1-by- N entry in the array corresponds to an initial condition for the k th channel of the input matrix. Thus, a 1-by- N -by- D initial conditions input allows you to specify different initial conditions for each channel. For instance, for a two-channel ramp input $[1:100; 1:100]'$ with a frame size of 4 and the parameter settings below,

the block outputs the following sequence of frames at the start of the simulation.

$$\begin{bmatrix} -1 & -2 \\ -3 & -4 \\ -5 & -6 \\ -7 & -8 \end{bmatrix}, \begin{bmatrix} -9 & -10 \\ 1 & 1 \\ 2 & 2 \\ 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 \\ 5 & 5 \\ 6 & 6 \\ 7 & 7 \end{bmatrix}, \dots$$

Note that the channels have distinct time varying initial conditions; the initial conditions for channel 1 correspond to the first entry of each length-2 row vector in the initial conditions array, and the initial conditions for channel 2 correspond to the second entry of each row vector in the

initial conditions array. Only the first five entries in the initial conditions array are used; the rest are ignored.

The 1-by- N -by- D array entry can also specify different fixed initial conditions for every channel; in this case, every 1-by- N entry in the array would be identical, so that the initial conditions for each column are fixed over time.

Initial conditions cannot be specified by full matrices.

Resetting the Delay

The block resets the delay whenever it detects a reset event at the optional Rst port. The reset sample time must be a positive integer multiple of the input sample time.

You specify the reset event in the **Reset port** parameter:

- **None** disables the Rst port.
- **Rising edge** — Triggers a reset operation when the Rst input does one of the following:
 - Rises from a negative value to a positive value or zero
 - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)

- **Falling edge** — Triggers a reset operation when the Rst input does one of the following:
 - Falls from a positive value to a negative value or zero
 - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)

- **Either edge** — Triggers a reset operation when the Rst input is a **Rising edge** or **Falling edge** (as described above).
- **Non-zero sample** — Triggers a reset operation at each sample time that the Rst input is not zero.

Note When running simulations in the Simulink **MultiTasking** mode, sample-based reset signals have a one-sample latency, and frame-based reset signals have one frame of latency. Thus, there is a one-sample or one-frame delay between the time the block detects a reset event, and when it applies the reset. For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Parameters

Delay

The number of sample periods to delay the input signal.

Initial conditions

The value of the block's output during the initial delay.

Reset port

Determines the reset event that causes the block to reset the delay. For more information, see “Resetting the Delay” on page 2-734.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed only)
- Boolean — The block accepts Boolean inputs to the Rst port, which is enabled by the **Reset port** parameter.
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

Interpolation

Interpolate values of real input samples

Library: DSP System Toolbox / Signal Operations

Description

The Interpolation block interpolates discrete, real inputs by using linear or FIR interpolation. The block accepts a vector, a matrix, or an N -D array. The block outputs a scalar, a vector, a matrix, or an N -D array of the interpolated values.

You must specify the interpolation points, the times at which to interpolate values in a one-based interpolation array I_{pts} . An entry of 1 in I_{pts} refers to the first sample of the input data, an entry of 2.5 refers to the sample halfway between the second and third input sample, and so on. Depending on the dimensions of the input data, I_{pts} can be a scalar, a length- P row, or a column vector, a P -by- N matrix, or an N -D array where P is the size of the first dimension of the N -D array. In most cases, P can be any positive integer. For more information about valid interpolation arrays, refer to the tables in “Pts” on page 2-0 and “Interpolation points” on page 2-0.

In most cases, the block applies I_{pts} across the first dimension of an N -D input array or to each input vector. You can set the block to apply the same interpolation array for all input data, static interpolation points entered on the block mask, or to use a different interpolation array for each N -D array, matrix, or vector input, time-varying interpolation points received through the Pts input port.

Ports

Input

In — Input signal

scalar | vector | matrix | N -D array

Input signal, specified as a scalar, vector, matrix, or N -D array.

This port is unnamed until `Source of interpolation points` is set to `Input port`.

Data Types: `single` | `double`

Pts — Interpolation points

scalar | vector | matrix | N -D array

Interpolation points, specified as a scalar, vector, matrix, or N -D array.

For more details on the block's behavior when the `Source of interpolation points` parameter is set to `Input port`, see “How the Block Applies Interpolation Arrays to Inputs” on page 2-740.

Dependencies

This port is unavailable until `Source of interpolation points` is set to `Input port`.

Data Types: `single` | `double`

Output

Out — Output signal

`scalar` | `vector` | `matrix` | *N-D array*

Output signal, specified as a vector, matrix, or *N-D array*.

This port is unnamed until `Source of interpolation points` is set to `Input port`.

Data Types: `single` | `double`

Parameters

Source of interpolation points — Interpolation point input method

`Specify via dialog (default)` | `Input port`

Choose how you want to specify the interpolation points:

- `Specify via dialog` -- The `Interpolation points` parameter becomes available. Use this option for static interpolation points.
- `Input port` -- The `Pts` port appears on the block. The block uses the input to this port as the interpolation points. Use this option for time-varying interpolation points.

For more information, see “Specifying Static Interpolation Points” on page 2-739 and “Specifying Time-Varying Interpolation Points” on page 2-739.

Interpolation points — Interpolation points

`[1.1 4.8 2.67 1.6 3.2]'` (default) | `scalar` | `vector` | `matrix` | *N-D array*

The array of points in time at which to interpolate the input signal (I_{pts}). An entry of 1 in I_{pts} refers to the first sample of the input, an entry of 2.5 refers to the sample halfway between the second and third input sample, and so on. See “How the Block Applies Interpolation Arrays to Inputs” on page 2-740.

Tunable: Yes

Dependencies

This parameter becomes available only when the `Source of interpolation points` is set to `Specify via dialog`. For more information, see “Specifying Static Interpolation Points” on page 2-739.

Interpolation mode — Interpolation mode

`Linear (default)` | `FIR`

Sets the block to interpolate by either `Linear` or `FIR` interpolation. For more information, see “Linear Interpolation Mode” on page 2-742 and “FIR Interpolation Mode” on page 2-743.

Interpolation filter half-length — Half length of FIR interpolation filter

3 (default) | positive integer

Specify the half-length of the FIR interpolation filter (P). To perform the interpolation in FIR mode, the block uses the nearest $2 \times P$ low-rate samples. In most cases, P low-rate samples must appear below and above each interpolation point. If you interpolate at a low-rate sample point, the block includes that low-rate sample in the required $2 \times P$ samples and requires only $2 \times P - 1$ neighboring low-rate samples. If an interpolation point does not have the required number of neighboring low-rate samples, the block interpolates that point using linear interpolation.

Dependencies

This parameter becomes available only when the `Interpolation` mode is set to FIR. For more information, see “FIR Interpolation Mode” on page 2-743.

Interpolation points per input sample — Interpolation points per sample

3 (default)

Number of points per input sample, upsampling factor (L), at which the block computes a unique FIR interpolation filter. To perform the FIR interpolation, the block uses a polyphase structure that has L filter arms of length $2 \times P$.

For example, if $L=4$, the block constructs a polyphase filter with four arms. The block then interpolates at points corresponding to $1 + i/L$, $2 + i/L$, $3 + i/L$..., where the integers 1, 2, and 3 represent the low-rate samples, and $i=0, 1, 2, 3$. To interpolate at a point that does not directly correspond to an arm of the polyphase filter requires an extra computation. The block first rounds that point down to the nearest value that does correspond to an arm of the polyphase filter. To interpolate at the point 2.2, the block rounds 2.2 down to 2, and computes the FIR interpolation by using the first arm of the polyphase filter structure. Similarly, to interpolate the point 2.65, the block rounds the value down to 2.5 and uses the third arm of the polyphase filter structure.

Dependencies

This parameter becomes available only when the `Interpolation` mode is set to FIR. For more information, see “FIR Interpolation Mode” on page 2-743.

Normalized input bandwidth — Normalized input bandwidth

0.5 (default) | scalar in (0 1]

The bandwidth of the input divided by $F_s/2$ (half the input sample frequency), specified as a scalar in the range (0 1].

Dependencies

This parameter becomes available only when the `Interpolation` mode is set to FIR. For more information, see “FIR Interpolation Mode” on page 2-743.

Out of range interpolation points — Error handling for out-of-range points

Clip (default) | Clip and warn | Error

Valid values in the interpolation array I_{pts} range from 1 to the number of samples in each channel of the input. For instance, given a length-5 input vector D , all entries of I_{pts} must range from 1 to 5. I_{pts} cannot contain entries such as 7 or -9 because there is no 7th or -9th entry in D .

The **Out of range interpolation points** parameter sets how the block handles interpolation points that fall outside the valid range. The parameter has these settings:

- **Clip** — The block replaces any out-of-range values in I_{pts} with the closest value in the valid range (from 1 to the number of input samples), and then proceeds with computations by using the clipped version of I_{pts} .
- **Clip and warn** — In addition to **Clip**, the block issues a warning at the MATLAB command line every time clipping occurs.
- **Error** — When the block encounters an out-of-range value in I_{pts} , the simulation stops, and the block issues an error at the MATLAB command line.

As an example of clipping, suppose the block is set to clip out-of-range interpolation points and gets these input vector and interpolation points:

- $D = [11 \ 22 \ 33 \ 44]'$
- $I_{pts} = [10 \ 2.6 \ -3]'$

Because D has four samples, valid interpolation points range from 1 to 4. The block clips the interpolation point 10 to 4 and the point -3 to 1, resulting in the clipped interpolation vector $I_{ptsClipped} = [4 \ 2.6 \ 1]'$.

Block Characteristics

Data Types	double single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

More About

Specifying Static Interpolation Points

To supply the block with a static interpolation array, that is an interpolation array applied to every vector or N -D array of input data), perform the following steps:

- 1 Set the **Source of interpolation points** parameter to **Specify via dialog**.
- 2 Enter the interpolation array in the **Interpolation points** parameter. To learn about interpolation arrays, see “How the Block Applies Interpolation Arrays to Inputs” on page 2-740.

Specifying Time-Varying Interpolation Points

To supply the block with time-varying interpolation arrays, where the block uses a different interpolation array for each vector or N -D array input, perform the following steps:

- 1 Set the **Source of interpolation points** parameter to **Input port**. The **Pts** port appears on the block.

- 2 Generate a signal of interpolation arrays and supply it to the **Pts** port. The block uses the input to this port as the interpolation points. To learn about interpolation arrays, see “How the Block Applies Interpolation Arrays to Inputs” on page 2-740.

How the Block Applies Interpolation Arrays to Inputs

The interpolation array I_{Pts} represents the points in time at which to interpolate values of the input signal. An entry of 1 in I_{Pts} refers to the first sample of the input, an entry of 2.5 refers to the sample halfway between the second and third input sample, and so on. In most cases, when I_{Pts} is a vector, it can be of any length.

Valid values in the interpolation array, I_{Pts} , range from 1 to the number of samples in each channel of the input. To learn how the block handles out-of-range interpolation values, see **Out of range interpolation points**.

Depending on the dimension of the input and the dimension of I_{Pts} , the block usually applies I_{Pts} to the input in one of the following ways:

- Applies the I_{Pts} array across the first dimension of an N -D array, resulting in an N -D array output.
- Applies the vector I_{Pts} to each input vector (as if the input vector were a single channel), resulting in a vector output with the same orientation as the input (row or column).

These tables summarize how the block applies the interpolation array I_{Pts} to all the possible types of inputs and shows the resulting output dimensions.

The first table describes the block's behavior when the **Source of interpolation points is Specify via dialog**.

Specify Interpolation Points Through Dialog Box

Input Dimensions	Valid Dimensions of Interpolation Array / I_{Pts}	How Block Applies I_{Pts} to Input	Output Dimensions (Frame-Based)
M -by- N -by- K matrix	P -by-1 column	Applies I_{Pts} to the first dimension of the input	P -by- N -by- K array
	P -by- N -by- K matrix	Applies each column of I_{Pts} (each element of I_{Pts}) to the corresponding column of the input matrix	P -by- N -by- K array
M -by- N matrix	1-by- N row	Applies each column of I_{Pts} (each element of I_{Pts}) to the corresponding column of the input matrix	1-by- N row
	P -by-1 column	Applies I_{Pts} to each input column	P -by- N matrix
	P -by- N matrix	Applies the columns of I_{Pts} to the corresponding columns of the input matrix	

Input Dimensions	Valid Dimensions of Interpolation Array / Pts	How Block Applies / Pts to Input	Output Dimensions (Frame-Based)
M -by-1 column	P -by-1 column	Applies I_{Pts} to the input column	P -by-1 column
1-by- N row (not recommended)	1-by- N row	Not Applicable. Block copies input vector	1-by- N row, a copy of the input vector
	P -by-1 column		P -by- N matrix where each row is a copy of the input vector
	P -by- N matrix		

The next table describes the block's behavior when the **Source of interpolation points** is Input port.

Specify Interpolation Points Through Input Port

Input Dimensions	Valid Dimensions of Interpolation Array / Pts	How Block Applies / Pts to Input	Output Dimensions (Frame-Based)
M -by- N -by- K matrix	Unoriented vector or column vector of length P	Applies I_{Pts} to the first dimension of the input	P -by- N -by- K array
	P -by- N -by- K matrix	Applies each column of I_{Pts} (each element of I_{Pts}) to the corresponding column of the input matrix	P -by- N -by- K array
M -by- N matrix	1-by- N row	Applies each column of I_{Pts} (each element of I_{Pts}) to the corresponding column of the input matrix	1-by- N row
	P -by-1 column	Applies I_{Pts} to each input column	P -by- N matrix
	P -by- N matrix	Applies the columns of I_{Pts} to the corresponding columns of the input matrix	
M -by-1 column	P -by-1 column	Applies I_{Pts} to the input column	P -by-1 column
1-by- N row (not recommended)	1-by- N row	Not Applicable. Block copies input vector	1-by- N row, a copy of the input vector
	P -by-1 column		P -by- N matrix where each row is a copy of the input vector
	P -by- N matrix		

Algorithms

Linear Interpolation Mode

When Interpolation mode is set to Linear, the block interpolates data values by assuming that the data varies linearly between samples taken at adjacent sample times.

For instance, if the input signal $D = [1 \ 2 \ 1.5 \ 3 \ 0.25]'$, the plot on the left shows the samples in D and the plot on the right shows the linearly interpolated values between the samples in D .

The following figure illustrates the case of a block in linear interpolation mode that is set to clip out-of-range interpolation points. The vector D supplies the input data and the vector I_{pts} supplies the interpolation points:

- $D = [1 \ 2 \ 1.5 \ 3 \ 0.25]'$
- $I_{pts} = [-4 \ 2.7 \ 4.3 \ 10]'$

The block clips the invalid interpolation points and outputs the linearly interpolated values in a vector, $[1 \ 1.65 \ 2.175 \ 0.25]'$.

Interpolated Values of D at Clipped Interpolation Points

**FIR Interpolation Mode**

When Interpolation mode is set to FIR, the block interpolates data values by using an FIR interpolation filter, specified by various block parameters. For more information, see “FIR Interpolation Mode” on page 2-1364 in the Variable Fractional Delay block reference.

Inverse Short-Time FFT

Recover time-domain signals by performing inverse short-time, fast Fourier transform (FFT)

Library

Transforms

dspxfm3

Description

The Inverse Short-Time FFT block reconstructs the time-domain signal from the frequency-domain output of the Short-Time FFT block using a two-step process. First, the block performs the overlap add algorithm shown below.

$$x[n] = \frac{L}{W(0)} \sum_{p=-\infty}^{\infty} \left[\frac{1}{N} \sum_{k=0}^{N-1} X[pL, k] e^{j2\pi kn/N} \right]$$

Then, the block rebuffers the signal in order to reconstruct the time-domain signal. Depending on the analysis window used by the Short-Time FFT block, the Inverse Short-Time FFT block might or might not achieve perfect reconstruction of the time domain signal.

Connect your complex-valued, single-channel or multichannel input signal to the X(n,k) port. The block accepts unoriented vector, column vector and matrix input. The block outputs the real or complex-valued, single-channel or multichannel inverse short-time FFT at port x(n).

Connect your complex-valued, single-channel analysis window to the w(n) port. When you select the **Assert if analysis window does not support perfect signal reconstruction** check box, the block displays an error when the input signal cannot be perfectly reconstructed. The block uses the values you enter for the **Analysis window length (W)** and **Reconstruction error tolerance**, or maximum amount of allowable error in the reconstruction process, to determine if the signal can be perfectly reconstructed.

Examples

The `dspstsa` example illustrates how to use the Short-Time FFT and Inverse Short-Time FFT blocks to remove the background noise from a speech signal. To open the `dspstsa` model, type `dspstsa` in the MATLAB command prompt.

Parameters

Analysis window length

Enter the length of the analysis window. This parameter is visible when you select the **Assert if analysis window does not support perfect signal reconstruction** check box.

Overlap between consecutive STFFT frames (in samples)

Enter the number of samples of overlap for each frame of the Short-Time FFT block's input signal. This value should be the same as the **Overlap between consecutive windows (in samples)** parameter in the Short-Time FFT block parameters dialog.

Samples per output frame

Enter the desired frame size of the output signal.

Input is conjugate symmetric

Select this check box when the input to the block is both floating point and conjugate symmetric, and you want real-valued outputs. When you select this check box when the input is not conjugate symmetric, the output of the block is invalid. This parameter cannot be used for fixed-point signals.

Assert if analysis window does not support perfect signal reconstruction

Select this check box to display an error when the analysis window used by the Short-Time FFT block does not support perfect signal reconstruction.

Reconstruction error tolerance

Enter the amount of acceptable error in the reconstruction of the original signal. This parameter is visible when you select the **Assert if analysis window does not support perfect signal reconstruction** check box.

Supported Data Types

Port	Supported Data Types
X(n,k)	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point
w(n)	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point
x(n)	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point

Inverse Sinc Filter

Design inverse sinc filter

Library

Filtering / Filter Designs

dspfdesign

Description

This block brings the filter design capabilities of the `filterBuilder` function to the Simulink environment.

This block supports SIMD code generation. For details, see “Code Generation” on page 2-752.

Dialog Box

See “Inverse Sinc Filter Design — Main Pane” on page 5-626 for more information about the parameters of this block. The **Data Types** and **Code Generation** panes are not available for blocks in the DSP System Toolbox Filter Designs library.

View filter response

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

In this group, you specify your filter format, such as the impulse response and the filter order.

Order mode

Select either **Minimum** (the default) or **Specify** from the drop-down list. Selecting **Specify** enables the **Order** option (see the following sections) so you can enter the filter order.

Response type

Select **Lowpass** or **Highpass** to design an inverse sinc lowpass or highpass filter.

Filter type

Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, the block specifies a single-rate filter.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

Order

Enter the filter order. This option is enabled only if you set the **Order mode** to `Specify`.

Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default value is 2.

Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default value is 2.

Frequency Specifications

The parameters in this group allow you to specify your filter response curve.

Regions between specification values such as **Passband frequency** and **Stopband frequency** represent transition regions where the filter response is not constrained.

Frequency constraints

When **Order mode** is `Specify`, select the filter features that the block uses to define the frequency response characteristics. The list contains the following options, when available for the filter specifications.

- **Passband and stopband frequencies** — Define the filter by specifying the frequencies for the edges for the stop- and passbands.
- **Passband frequency** — For IIR filters, define the filter by specifying frequencies for the edges of the passband.
- **Stopband frequency** — For IIR filters, define the filter by specifying frequencies for the edges of the stopbands.
- **Cutoff (6dB) frequency** — For FIR filters, define the filter response by specifying the locations of the 6 dB point. The 6 dB point is the frequency for the point six decibels below the passband value.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0 to 1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input sample rate** parameter.

Input sample rate

F_s , specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the

specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Passband frequency

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Stopband frequency

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Cutoff (6dB) frequency

When **Frequency constraints** is Cutoff (6dB) frequency, specify the frequency of the 6 dB point. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Magnitude Specifications

Parameters in this group specify the filter response in the passbands and stopbands.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. From the drop-down list, select one of the following options:

- Linear — Specify the magnitude in linear units.
- dB — Specify the magnitude in decibels (default)
- Squared — Specify the magnitude in squared units.

Passband ripple

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

Stopband attenuation

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure of your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default FIR method is **Equiripple**.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 20 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Phase constraint

Specify the phase constraint of the filter as **Linear**, **Maximum**, or **Minimum**.

Minimum order

When you select this parameter, the design method determines and design the minimum order filter to meet your specifications. Some filters do not provide this parameter. Select **Any**, **Even**, or **Odd** from the drop-down list to direct the design to be any minimum order, or minimum even order, or minimum odd order.

Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options;

- **Flat** — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- **Linear** — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- **1/f** — Specifies that the stopband attenuation changes exponentially as the frequency increases, where f is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

Stopband Decay

When you set **Stopband shape**, **Stopband decay** specifies the amount of decay applied to the stopband. the following conditions apply to **Stopband decay** based on the value of **Stopband Shape**:

- When you set **Stopband shape** to **Flat**, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to **Linear**, enter the slope of the stopband in units of dB/rad/s. The block applies that slope to the stopband.
- When you set **Stopband shape** to **1/f**, enter a value for the exponent n in the relation $(1/f)^n$ to define the stopband decay. The block applies the $(1/f)^n$ relation to the stopband to result in an exponentially decreasing stopband attenuation.

Sinc frequency factor

A frequency dilation factor. The **Sinc frequency factor**, C , parameterizes the passband magnitude response for a lowpass design through $H(\omega) = \text{sinc}(C\omega)^{-P}$ and through $H(\omega) = \text{sinc}(C(1-\omega))^{-P}$ for a highpass design.

Sinc power

Negative power of passband magnitude response. The **Sinc power**, P , parameterizes the passband magnitude response for a lowpass design through $H(\omega) = \text{sinc}(C\omega)^{-P}$ and through $H(\omega) = \text{sinc}(C(1-\omega))^{-P}$ for a highpass design.

Filter Implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of n unit delays with a single delay by n .
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Input processing

Specify how the block should process the input. The available options may vary depending on the settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- **Enforce single-rate processing** — When you select this option, the block maintains the sample rate of the input.
- **Allow multirate processing** — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to **Elements as channels (sample based)**.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The Inverse Sinc Filter block supports SIMD code generation using Intel AVX2 technology under these conditions:

- **Filter type** is set to Single-rate, Decimator, or Interpolator.
- For **Filter type** that is set to Single-rate, **Structure** is set to Direct-form FIR or Direct-form FIR transposed.
- For **Filter type** that is set to Decimator, **Structure** is set to Direct-form FIR polyphase decimator and **Rate options** is set to Enforce single-rate processing.
- For **Filter type** that is set to Interpolator, **Rate options** is set to Enforce single-rate processing.
- **Input processing** is set to Columns as channels (frame based).
- Input signal has a data type of single or double.

The SIMD technology significantly improves the performance of the generated code.

Kalman Adaptive Filter (Obsolete)

Compute filter estimates for inputs using Kalman adaptive filter algorithm

Library

dspobslib

Description

Note The Kalman Adaptive Filter block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the Kalman Filter block.

The Kalman Adaptive Filter block computes the optimal linear minimum mean-square estimate (MMSE) of the FIR filter coefficients using a one-step predictor algorithm. This Kalman filter algorithm is based on the following physical realization of a dynamic system.

The Kalman filter assumes that there are no deterministic changes to the filter taps over time (that is, the transition matrix is identity), and that the only observable output from the system is the filter output with additive noise. The corresponding Kalman filter is expressed in matrix form as

$$g(n) = \frac{K(n-1)u(n)}{u^H(n)K(n-1)u(n) + Q_M}$$

$$y(n) = u^H(n)\hat{w}(n)$$

$$e(n) = d(n) - y(n)$$

$$\hat{w}(n+1) = \hat{w}(n) + e(n)g(n)$$

$$K(n) = K(n-1) - g(n)u^H(n)K(n-1) + Q_p$$

The variables are as follows

Variable	Description
n	The current algorithm iteration
$u(n)$	The buffered input samples at step n
$K(n)$	The correlation matrix of the state estimation error
$g(n)$	The vector of Kalman gains at step n
$\widehat{w}(n)$	The vector of filter-tap estimates at step n
$y(n)$	The filtered output at step n
$e(n)$	The estimation error at step n
$d(n)$	The desired response at step n
Q_M	The correlation matrix of the measurement noise
Q_P	The correlation matrix of the process noise

The correlation matrices, Q_M and Q_P , are specified in the parameter dialog by scalar variance terms to be placed along the matrix diagonals, thus ensuring that these matrices are symmetric. The filter algorithm based on this constraint is also known as the random-walk Kalman filter.

The implementation of the algorithm in the block is optimized by exploiting the symmetry of the input covariance matrix $K(n)$. This decreases the total number of computations by a factor of two.

The block icon has port labels corresponding to the inputs and outputs of the Kalman algorithm. Note that inputs to the In and Err ports must be sample-based scalars with the same complexity. The signal at the Out port is a scalar, while the signal at the Taps port is a sample-based vector.

Block Ports	Corresponding Variables
In	u , the scalar input, which is internally buffered into the vector $u(n)$
Out	$y(n)$, the filtered scalar output
Err	$e(n)$, the scalar estimation error
Taps	$\widehat{w}(n)$, the vector of filter-tap estimates

An optional Adapt input port is added when you select the **Adapt port** check box in the dialog. When this port is enabled, the block continuously adapts the filter coefficients while the Adapt input is nonzero. A zero-valued input to the Adapt port causes the block to stop adapting, and to hold the filter coefficients at their current values until the next nonzero Adapt input.

The **FIR filter length** parameter specifies the length of the filter that the Kalman algorithm estimates. The **Measurement noise variance** and the **Process noise variance** parameters specify the correlation matrices of the measurement and process noise, respectively. The **Measurement noise variance** must be a scalar, while the **Process noise variance** can be a vector of values to be placed along the diagonal, or a scalar to be repeated for the diagonal elements.

The **Initial value of filter taps** specifies the initial value $\widehat{w}(0)$ as a vector, or as a scalar to be repeated for all vector elements. The **Initial error correlation matrix** specifies the initial value $K(0)$, and can be a diagonal matrix, a vector of values to be placed along the diagonal, or a scalar to be repeated for the diagonal elements.

Parameters

FIR filter length

The length of the FIR filter.

Measurement noise variance

The value to appear along the diagonal of the measurement noise correlation matrix. Tunable (Simulink).

Process noise variance

The value to appear along the diagonal of the process noise correlation matrix. Tunable (Simulink).

Initial value of filter taps

The initial FIR filter coefficients.

Initial error correlation matrix

The initial value of the error correlation matrix.

Adapt port

Enables the Adapt port.

Kalman Filter

Predict or estimate states of dynamic systems

Library

Filtering/Adaptive Filters

dspadpt3

Description

Use the Kalman Filter block to predict or estimate the state of a dynamic system from a series of incomplete and/or noisy measurements. Suppose you have a noisy linear system that is defined by the following equations:

$$\begin{aligned}x_k &= Ax_{k-1} + w_{k-1} \\z_k &= Hx_k + v_k\end{aligned}$$

This block can use the previously estimated state, \hat{x}_{k-1} , to predict the current state at time k , x_k^- , as shown by the following equation:

$$\begin{aligned}x_k^- &= A\hat{x}_{k-1} \\P_k^- &= A\hat{P}_{k-1}A^T + Q\end{aligned}$$

The block can also use the current measurement, z_k , and the predicted state, x_k^- , to estimate the current state value at time k , \hat{x}_k , so that it is a more accurate approximation:

$$\begin{aligned}K_k &= P_k^- H^T (HP_k^- H^T + R)^{-1} \\ \hat{x}_k &= x_k^- + K_k(z_k - Hx_k^-) \\ \hat{P}_k &= (I - K_k H)P_k^-\end{aligned}$$

The variables in the previous equations are defined in the following table.

Variable	Definition	Default Value or Initial Condition
x	State	N/A
\hat{x}	Estimated state	zeros([6, 1])
x^-	Predicted state	N/A

Variable	Definition	Default Value or Initial Condition
A	State transition matrix	$\begin{bmatrix} 1 & 0 & 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}$
w	Process noise	N/A
z	Measurement	N/A
H	Measurement matrix	$\begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}$
v	Measurement noise	N/A
\hat{P}	Estimated error covariance	$10 \cdot \text{eye}(6)$
P	Predicted error covariance	N/A
Q	Process noise covariance	$0.05 \cdot \text{eye}(6)$
K	Kalman gain	N/A
R	Measurement noise covariance	$\text{eye}(4)$
I	Identity matrix	N/A

In the previous equations, z is a vector of measurement values. Most of the time, the block processes Z , an M-by-N matrix, where M is the number of measurement values and N is the number of filters.

Use the **Number of filters** parameter to specify the number of filters to use to predict or estimate the current value.

Use the **Enable filters** parameter to specify which filters are enabled or disabled at each time step. If you select **Always**, the filters are always enabled. If you choose **Specify via input port <Enable>**, the Enable port appears on the block. The input to this port must be a row vector of 1s and 0s whose length is equal to the number of filters. For example, if there are 3 filters and the input to the Enable port is [1 0 1], only the first and third filter are enabled at this time step. If you select the **Reset the estimated state and estimated error covariance when filters are disabled** check box, the estimated and predicted states as well as the estimated error covariance that correspond to the disabled filters are reset to their initial values.

Note All filters have the same state transition matrix, measurement matrix, initial conditions, and noise covariance, but their state, measurement, enable, and MSE signals are unique. Within the state, measurement, enable, and MSE signals, each column corresponds to a filter.

Use the **Measurement matrix source** parameter to specify how to enter the measurement matrix values. If you select **Specify via dialog**, the **Measurement matrix** parameter appears in the dialog box. If you select **Input port <H>**, the H port appears on the block. Use this port to specify your measurement matrix.

Parameters

Number of filters

Specify the number of filters to use to predict or estimate the current value.

Enable filters

Specify which filters are enabled or disabled at each time step. If you select *Always*, the filters are always enabled. If you choose *Specify via input port <Enable>*, the *Enable* port appears on the block.

Reset the estimated state and estimated error covariance when filters are disabled

If you select this check box, the estimated and predicted states as well as the estimated error covariance that correspond to the disabled filters are reset to their initial values. This parameter is visible if, for the **Enable filters** parameter, you select *Specify via input port <Enable>*.

Initial condition for estimated state

Enter the initial condition for the estimated state.

Initial condition for estimated error covariance

Enter the initial condition for the estimated error covariance.

State transition matrix

Enter the state transition matrix.

Process noise covariance

Enter the process noise covariance.

Measurement matrix source

Specify how to enter the measurement matrix values. If you select *Specify via dialog*, the **Measurement matrix** parameter appears in the dialog box. If you select *Input port <H>*, the *H* port appears on the block.

Measurement matrix

Enter the measurement matrix values. This parameter is visible if you select *Specify via dialog* for the **Measurement matrix source** parameter.

Measurement noise covariance

Enter the measurement noise covariance.

Output estimated measurement <Z_est>

Select this check box if you want the block to output the estimated measurement.

Output estimated state <X_est>

Select this check box if you want the block to output the estimated state.

Output MSE of estimated state <MSE_est>

Select this check box if you want the block to output the mean-squared error of the estimated state.

Output predicted measurement <Z_prd>

Select this check box if you want the block to output the predicted measurement.

Output predicted state <X_prd>

Select this check box if you want the block to output the predicted state.

Output MSE of predicted state <MSE_prb>

Select this check box if you want the block to output the mean-squared error of the predicted state.

LDL Factorization

Factor square Hermitian positive definite matrices into lower, upper, and diagonal components

Library: DSP System Toolbox / Math Functions / Matrices and Linear Algebra / Matrix Factorizations

Description

The LDL Factorization block uniquely factors the square Hermitian positive definite input matrix S as

$$S = LDL^*$$

where L is a lower triangular square matrix with unity diagonal elements, D is a diagonal matrix, and L^* is the Hermitian (complex conjugate) transpose of L . Only the diagonal and lower triangle of the input matrix are used. Any imaginary component of the diagonal entries is disregarded.

LDL factorization requires half the computation of Gaussian elimination (LU decomposition), and is always stable. It is more efficient than Cholesky factorization because it avoids computing the square roots of the diagonal elements.

Ports

Input

Port_1 — Input signal

matrix

Input signal, specified as a square matrix.

The algorithm requires that the input be square and Hermitian positive definite. When the input is not positive definite, the block reacts as specified by the **Non-positive definite input** parameter.

If the input is fixed point, it must be signed fixed point with a power-of-two slope and zero bias.

Data Types: single | double | int8 | int16 | int32 | fixed point

Output

Port_1 — Output signal

matrix

The output is a composite matrix with lower triangle elements l_{ij} from L , diagonal elements d_{ij} from D and upper triangle elements u_{ij} from L^* , where L is a lower triangular square matrix that has unity diagonal elements, D is a diagonal matrix, and L^* is the Hermitian (complex conjugate) transpose of L .

The output format is shown below for a 5-by-5 matrix.

d_{11}	u_{12}	u_{13}	u_{14}	u_{15}
l_{21}	d_{22}	u_{23}	u_{24}	u_{25}
l_{31}	l_{32}	d_{33}	u_{34}	u_{35}
l_{41}	l_{42}	l_{43}	d_{44}	u_{45}
l_{51}	l_{52}	l_{53}	l_{54}	d_{55}

$$u_{ij} = l_{ji}^*$$

Data Types: single | double | int8 | int16 | int32 | fixed point

Parameters

Main Tab

Non-positive definite input — Non-positive definite input action

Warning (default) | Ignore | Error

Specify the action when nonpositive definite matrix inputs occur:

- Ignore — Proceed with the computation and do not issue an alert. The output is not a valid factorization. A partial factorization is present in the upper-left corner of the output.
- Warning — Display a warning message in the MATLAB Command Window and continue the simulation. The output is not a valid factorization. A partial factorization is present in the upper-left corner of the output.
- Error — Display an error dialog box and terminate the simulation.

Data Types Tab

Rounding mode — Method of rounding operation

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

Saturate on integer overflow — Method of overflow action

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see `overflow mode for fixed-point operations`.

Intermediate product — Intermediate product data type

Inherit: Same as input (default) | `fixdt(1,16,0)`

Specify the intermediate product data type. As shown in *Fixed-Point Conversion* section in “Extended Capabilities” on page 2-0 , the output of the multiplier is cast to the intermediate product data type before the next element of the input is multiplied into it. You can set the data type to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Alternatively, you can set the **Intermediate product** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

Product output — Product output data type

Inherit: Inherit via internal rule (default) | Inherit: Same as input | `fixdt([],16,0)`

Product output specifies the data type of the output of a product operation in the LDL Factorization block.

- `Inherit: Inherit via internal rule` — The block inherits the product output data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- `Inherit: Same as input` — The block specifies the product output data type to be the same as the input data type.
- `fixdt([],16,0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type that has a word length of 16 bits and a fraction length of 0.

For more information, see “Multiplication Data Types” and *Fixed-Point Conversion* in “Extended Capabilities” on page 2-0 .

Alternatively, you can set the **Product output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink).

Accumulator — Accumulator data type

Inherit: Inherit via internal rule (default) | Inherit: Same as input | Inherit: Same as product output | `fixdt([],16,0)`

Accumulator specifies the data type of the output of an accumulation operation in the LDL Factorization block.

- **Inherit: Inherit via internal rule** — The block inherits the accumulator data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- **Inherit: Same as input** — The block specifies the accumulator data type to be the same as the input data type.
- **Inherit: Same as product output** — The block specifies the accumulator data type to be the same as the product output data type.
- `fixdt([], 16, 0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type that has a word length of 16 bits and a fraction length of 0.

For illustrations on how to use the accumulator data type in this block, see Fixed-Point Conversion in “Extended Capabilities” on page 2-0 .

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink).

Output — Output data type

`Inherit: Same as input (default) | fixdt([], 16, 0)`

Output specifies the data type of the output of the LDL Factorization block. For more information on the output data type, see the 'Fixed-Point Conversion' section in “Extended Capabilities” on page 2-0 .

- **Inherit: Same as input** — The block specifies the output data type to be the same as the input data type.
- `fixdt([], 16, 0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type that has a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink).

Output Minimum — Minimum value that block can output

`[] (default) | scalar`

Specify the minimum value that the block can output. Simulink software uses this minimum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

Output Maximum — Maximum value that block can output

`[] (default) | scalar`

Specify the maximum value that the block can output. Simulink software uses this maximum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Topics

“Matrix Factorizations”

LDL Inverse

Compute inverse of Hermitian positive definite matrix using LDL factorization

Library

Math Functions / Matrices and Linear Algebra / Matrix Inverses

dspinverses

Description

The LDL Inverse block computes the inverse of the Hermitian positive definite input matrix S by performing an LDL factorization.

$$S^{-1} = (LDL^*)^{-1}$$

L is a lower triangular square matrix with unity diagonal elements, D is a diagonal matrix, and L^* is the Hermitian (complex conjugate) transpose of L . Only the diagonal and lower triangle of the input matrix are used, and any imaginary component of the diagonal entries is disregarded.

LDL factorization requires half the computation of Gaussian elimination (LU decomposition), and is always stable. It is more efficient than Cholesky factorization because it avoids computing the square roots of the diagonal elements.

The algorithm requires that the input be Hermitian positive definite. When the input is not positive definite, the block reacts with the behavior specified by the **Non-positive definite input** parameter. The following options are available:

- **Ignore** — Proceed with the computation and do not issue an alert. The output is not a valid inverse.
- **Warning** — Display a warning message in the MATLAB command window, and continue the simulation. The output is not a valid inverse.
- **Error** — Display an error dialog and terminate the simulation.

Note The **Non-positive definite input** parameter is a diagnostic parameter. Like all diagnostic parameters on the Configuration Parameters dialog, it is set to **Ignore** in the code generated for this block by Simulink Coder code generation software.

Parameters

Non-positive definite input

Response to nonpositive definite matrix inputs.

LDL Solver

Solve $SX=B$ for X when S is square Hermitian positive definite matrix

Library

Math Functions / Matrices and Linear Algebra / Linear System Solvers

dpsolvers

Description

The LDL Solver block solves the linear system $SX=B$ by applying LDL factorization to the matrix at the S port, which must be square (M -by- M) and Hermitian positive definite. Only the diagonal and lower triangle of the matrix are used, and any imaginary component of the diagonal entries is disregarded. The input to the B port is the right side M -by- N matrix, B . The M -by- N output matrix X is the unique solution of the equations.

A length- M unoriented vector input for right side B is treated as an M -by-1 matrix.

When the input is not positive definite, the block reacts with the behavior specified by the **Non-positive definite input** parameter. The following options are available:

- **Ignore** — Proceed with the computation and do not issue an alert. The output is not a valid solution.
- **Warning** — Proceed with the computation and display a warning message in the MATLAB Command Window. The output is not a valid solution.
- **Error** — Display an error dialog and terminate the simulation.

Note The **Non-positive definite input** parameter is a diagnostic parameter. Like all diagnostic parameters on the Configuration Parameters dialog, it is set to **Ignore** in the code generated for this block by Simulink Coder code generation software.

Algorithm

The LDL algorithm uniquely factors the Hermitian positive definite input matrix S as

$$S = LDL^*$$

where L is a lower triangular square matrix with unity diagonal elements, D is a diagonal matrix, and L^* is the Hermitian (complex conjugate) transpose of L .

The equation

$$LDL^*X = B$$

is solved for X by the following steps:

- 1 Substitute

$$Y = DL^*X$$

- 2 Substitute

$$Z = L^*X$$

- 3 Solve one diagonal and two triangular systems.

$$LY = B$$

$$DZ = Y$$

$$L^*X = Z$$

Parameters

Non-positive definite input

Response to nonpositive definite matrix inputs.

Supported Data Types

- Double-precision floating point
- Single-precision floating point

Least Squares Polynomial Fit

Compute polynomial coefficients that best fit input data in least-squares sense

Library

Math Functions / Polynomial Functions

dsppolyfun

Description

The Least Squares Polynomial Fit block computes the coefficients of the n th order polynomial that best fits the input data in the least-squares sense, where you specify n in the **Polynomial order** parameter. A distinct set of $n+1$ coefficients is computed for each column of the M -by- N input, u .

For a given input column, the block computes the set of coefficients, c_1, c_2, \dots, c_{n+1} , that minimizes the quantity

$$\sum_{i=1}^M (u_i - \hat{u}_i)^2$$

where u_i is the i th element in the input column, and

$$\hat{u}_i = f(x_i) = c_1 x_i^n + c_2 x_i^{n-1} + \dots + c_{n+1}$$

The values of the independent variable, x_1, x_2, \dots, x_M , are specified as a length- M vector by the **Control points** parameter. The same M control points are used for all N polynomial fits, and can be equally or unequally spaced. The equivalent MATLAB code is shown below.

```
c = polyfit(x,u,n) % Equivalent MATLAB code
```

For convenience, the block treats length- M unoriented vector input as an M -by-1 matrix.

Each column of the $(n+1)$ -by- N output matrix, c , represents a set of $n+1$ coefficients describing the best-fit polynomial for the corresponding column of the input. The coefficients in each column are arranged in order of descending exponents, c_1, c_2, \dots, c_{n+1} .

Examples

In the `ex_leastsqarepolyfit_ref` model below, the Polynomial Evaluation block uses the second-order polynomial

$$y = -2u^2 + 3$$

to generate four values of dependent variable y from four values of independent variable u , received at the top port. The polynomial coefficients are supplied in the vector $[-2 \ 0 \ 3]$ at the bottom port. Note that the coefficient of the first-order term is zero.

The **Control points** parameter of the Least Squares Polynomial Fit block is configured with the same four values of independent variable u that are used as input to the Polynomial Evaluation block, $[1 \ 2 \ 3 \ 4]$. The Least Squares Polynomial Fit block uses these values together with the input values of dependent variable y to reconstruct the original polynomial coefficients.

Parameters

Control points

The values of the independent variable to which the data in each input column correspond. For an M -by- N input, this parameter must be a length- M vector. Tunable (Simulink).

Polynomial order

The order, n , of the polynomial to be used in constructing the best fit. The number of coefficients is $n+1$.

Supported Data Types

- Double-precision floating point
- Single-precision floating point

Levinson-Durbin

Solve linear system of equations using Levinson-Durbin recursion

Library

Math Functions / Matrices and Linear Algebra / Linear System Solvers

dpsolvers

Description

The Levinson-Durbin block solves the n th-order system of linear equations

$$Ra = b$$

in the cases where:

- R is a Hermitian, positive-definite, Toeplitz matrix.
- b is identical to the first column of R shifted by one element and with the opposite sign.

$$\begin{bmatrix} r(1) & r^*(2) & \dots & r^*(n) \\ r(2) & r(1) & \dots & r^*(n-1) \\ \vdots & \vdots & \ddots & \vdots \\ r(n) & r(n-1) & \dots & r(1) \end{bmatrix} \begin{bmatrix} a(2) \\ a(3) \\ \vdots \\ a(n+1) \end{bmatrix} = \begin{bmatrix} -r(2) \\ -r(3) \\ \vdots \\ -r(n+1) \end{bmatrix}$$

The input to the block, $r = [r(1) \ r(2) \ \dots \ r(n+1)]$, can be a vector or a matrix. If the input is a matrix, the block treats each column as an independent channel and solves it separately. Each channel of the input contains lags 0 through n of an autocorrelation sequence, which appear in the matrix R .

The block can output the polynomial coefficients, A , the reflection coefficients, K , and the prediction error power, P , in various combinations. The **Output(s)** parameter allows you to enable the A and K outputs by selecting one of the following settings:

- **A** — For each channel, port A outputs $A = [1 \ a(2) \ a(3) \ \dots \ a(n+1)]$, the solution to the Levinson-Durbin equation. A has the same dimension as the input. You can also view the elements of each output channel as the coefficients of an n th-order autoregressive (AR) process.
- **K** — For each channel, port K outputs $K = [k(1) \ k(2) \ \dots \ k(n)]$, which contains n reflection coefficients and has the same dimension as the input, less one element. A scalar input channel

causes an error when you select K. You can use reflection coefficients to realize a lattice representation of the AR process described later in this page.

- **A and K** — The block outputs both representations at their respective ports. A scalar input channel causes an error when you select **A and K**.

Select the **Output prediction error power (P)** check box to output the prediction error power for each channel, P . For each channel, P represents the power of the output of an FIR filter with taps A and input autocorrelation described by r , where A represents a prediction error filter and r is the input to the block. In this case, A is a whitening filter. P has one element per input channel.

When you select the **If the value of lag 0 is zero, A=[1 zeros], K=[zeros], P=0** check box (default), an input channel whose $r(1)$ element is zero generates a zero-valued output. When you clear this check box, an input with $r(1) = 0$ generates NaNs in the output. In general, an input with $r(1) = 0$ is invalid because it does not construct a positive-definite matrix R . Often, however, blocks receive zero-valued inputs at the start of a simulation. The check box allows you to avoid propagating NaNs during this period.

Applications

One application of the Levinson-Durbin formulation implemented by this block is in the Yule-Walker AR problem, which concerns modeling an unknown system as an autoregressive process. You would model such a process as the output of an all-pole IIR filter with white Gaussian noise input. In the Yule-Walker problem, the use of the signal's autocorrelation sequence to obtain an optimal estimate leads to an $Ra = b$ equation of the type shown above, which is most efficiently solved by Levinson-Durbin recursion. In this case, the input to the block represents the autocorrelation sequence, with $r(1)$ being the zero-lag value. The output at the block's A port then contains the coefficients of the autoregressive process that optimally models the system. The coefficients are ordered in descending powers of z , and the AR process is minimum phase. The prediction error, G , defines the gain for the unknown system, where $G = \sqrt{P}$:

$$H(z) = \frac{G}{A(z)} = \frac{G}{1 + a(2)z^{-1} + \dots + a(n+1)z^{-n}}$$

The output at the block's K port contains the corresponding reflection coefficients, $[k(1) \ k(2) \ \dots \ k(n)]$, for the lattice realization of this IIR filter. The Yule-Walker AR Estimator block implements this autocorrelation-based method for AR model estimation, while the Yule-Walker Method block extends the method to spectral estimation.

Another common application of the Levinson-Durbin algorithm is in linear predictive coding, which is concerned with finding the coefficients of a moving average (MA) process (or FIR filter) that predicts the next value of a signal from the current signal sample and a finite number of past samples. In this case, the input to the block represents the signal's autocorrelation sequence, with $r(1)$ being the zero-lag value, and the output at the block's A port contains the coefficients of the predictive MA process (in descending powers of z).

$$H(z) = A(z) = 1 + a(2)z^{-1} + \dots + a(n+1)z^{-n}$$

These coefficients solve the following optimization problem:

$$\min_{\{a_i\}} E \left[\left| x_n - \sum_{i=1}^N a_i x_{n-i} \right|^2 \right]$$

Again, the output at the block's K port contains the corresponding reflection coefficients, $[k(1) k(2) \dots k(n)]$, for the lattice realization of this FIR filter. The Autocorrelation LPC block in the Linear Prediction library implements this autocorrelation-based prediction method.

Fixed-Point Data Types

The diagrams in this section show the data types used within the Levinson-Durbin block for fixed-point signals.

After initialization the block performs n updates. At the $(j+1)$ update,

$$\text{value in accumulator} = r(j+1) + \sum a_j(i) \times r(j-i+1)$$

The following diagram displays the fixed-point data types used in this calculation:

The block then updates the reflection coefficients K according to

$$K_{j+1} = \text{value in accumulator} / P_j$$

The block then updates the prediction error power P according to

$$P_{j+1} = P_j - P_j \times K_{j+1} \times \text{conj}(K_{j+1})$$

The next diagram displays the fixed-point data types used in this calculation:

The polynomial coefficients A are then updated according to

$$a_{j+1}(i) = a_j(i) + K_{j+1} \times \text{conj}(a_j(j-1+i))$$

This diagram displays the fixed-point data types used in this calculation:

Algorithm

The algorithm requires $O(n^2)$ operations for each input channel. This implementation is therefore much more efficient for large n than standard Gaussian elimination, which requires $O(n^3)$ operations per channel.

Parameters

Main Tab

Output(s)

Specify the solution representation of $Ra = b$ to output: model coefficients (A), reflection coefficients (K), or both (A and K). When the input is a scalar or row vector, you must set this parameter to A.

Output prediction error power (P)

Select to output the prediction error at port P.

If the value of lag 0 is zero, A=[1 zeros], K=[zeros], P=0

When you select this check box and the first element of the input, $r(1)$, is zero, the block outputs the following vectors, as appropriate:

- $A = [1 \text{ zeros}(1, n)]$
- $K = [\text{zeros}(1, n)]$
- $P = 0$

When you clear this check box, the block outputs a vector of NaNs for each channel whose $r(1)$ element is zero.

Data Types Tab

Note Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

Rounding mode

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

Saturate on integer overflow

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see overflow mode for fixed-point operations.

Product output

Specify the product output data type. See “Fixed-Point Data Types” on page 2-777 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Accumulator

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-777 for illustrations depicting the use of the accumulator data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- A rule that inherits a data type, for example, `Inherit: Same as product output`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Polynomial coefficients (A)

Specify the polynomial coefficients (A) data type. See “Fixed-Point Data Types” on page 2-777 for illustrations depicting the use of the A data type in this block. You can set it to an expression that evaluates to a valid data type, for example, `fixdt(1,16,15)`.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **A** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Reflection coefficients (K)

Specify the polynomial coefficients (A) data type. See “Fixed-Point Data Types” on page 2-777 for illustrations depicting the use of the K data type in this block. You can set it to an expression that evaluates to a valid data type, for example, `fixdt(1,16,15)`.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **K** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Prediction error power (P)

Specify the prediction error power (P) data type. See “Fixed-Point Data Types” on page 2-777 for illustrations depicting the use of the P data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **P** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Minimum

Specify the minimum values that the polynomial coefficients, reflection coefficients, or prediction error power should have. The default value is `[]` (unspecified). Simulink uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters” (Simulink))
- Automatic scaling of fixed-point data types

Maximum

Specify the maximum values that the polynomial coefficients, reflection coefficients, or prediction error power should have. The default value is `[]` (unspecified). Simulink uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

LMS Adaptive Filter (Obsolete)

Compute filter estimates for input using LMS adaptive filter algorithm

Library

dspobslib

Description

Note The LMS Adaptive Filter block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the LMS Filter block.

The LMS Adaptive Filter block implements an adaptive FIR filter using the stochastic gradient algorithm known as the normalized least mean-square (LMS) algorithm.

$$\begin{aligned}
 y(n) &= \widehat{\mathbf{w}}^H(n-1)u(n) \\
 e(n) &= d(n) - y(n) \\
 \widehat{\mathbf{w}}(n) &= \widehat{\mathbf{w}}(n-1) + \frac{u(n)}{a + u^H(n)u(n)}\mu e^*(n)
 \end{aligned}$$

The variables are as follows.

Variable	Description
n	The current algorithm iteration
$u(n)$	The buffered input samples at step n
$\widehat{\mathbf{w}}(n)$	The vector of filter-tap estimates at step n
$y(n)$	The filtered output at step n
$e(n)$	The estimation error at step n
$d(n)$	The desired response at step n
μ	The adaptation step size

To overcome potential numerical instability in the tap-weight update, a small positive constant ($a = 1e-10$) has been added in the denominator.

To turn off normalization, clear the **Use normalization** check box in the parameter dialog. The block then computes the filter-tap estimate as

$$\widehat{\mathbf{w}}(n) = \widehat{\mathbf{w}}(n-1) + u(n)\mu e^*(n)$$

The block icon has port labels corresponding to the inputs and outputs of the LMS algorithm. Note that inputs to the In and Err ports must be sample-based scalars. The signal at the Out port is a scalar, while the signal at the Taps port is a sample-based vector.

Block Ports	Corresponding Variables
In	u , the scalar input, which is internally buffered into the vector $u(n)$
Out	$y(n)$, the filtered scalar output
Err	$e(n)$, the scalar estimation error
Taps	$\hat{w}(n)$, the vector of filter-tap estimates

An optional **Adapt** input port is added when you select the **Adapt input** check box in the dialog. When this port is enabled, the block continuously adapts the filter coefficients while the **Adapt** input is nonzero. A zero-valued input to the **Adapt** port causes the block to stop adapting, and to hold the filter coefficients at their current values until the next nonzero **Adapt** input.

The **FIR filter length** parameter specifies the length of the filter that the LMS algorithm estimates. The **Step size** parameter corresponds to μ in the equations. Typically, for convergence in the mean square, μ must be greater than 0 and less than 2. The **Initial value of filter taps** specifies the initial value $\hat{w}(0)$ as a vector, or as a scalar to be repeated for all vector elements. The **Leakage factor** specifies the value of the leakage factor, $1 - \mu\alpha$, in the leaky LMS algorithm below. This parameter must be between 0 and 1.

$$\hat{w}(n+1) = (1 - \mu\alpha)\hat{w}(n) + \frac{u(n)}{u^H(n)u(n)}\mu e^*(n)$$

Examples

See the `lmsadtde` demo.

Parameters

FIR filter length

The length of the FIR filter.

Step-size

The step-size, usually in the range (0, 2). Tunable (Simulink).

Initial value of filter taps

The initial FIR filter coefficients.

Leakage factor

The leakage factor, in the range [0, 1]. Tunable (Simulink).

Use normalization

Select this check box to compute the filter-tap estimate using the normalized equations.

Adapt input

Enables the **Adapt** port when selected.

LMS Filter

Compute output, error, and weights using LMS adaptive algorithm

Library: DSP System Toolbox / Filtering / Adaptive Filters
 DSP System Toolbox HDL Support / Filtering

Description

The LMS Filter block can implement an adaptive FIR filter by using five different algorithms. The block estimates the filter weights or coefficients needed to minimize the error, $e(n)$, between the output signal $y(n)$ and the desired signal, $d(n)$. The output is the filtered input signal, which is the estimate of the desired signal. The Error port outputs the result of subtracting the output signal from the desired signal.

Under specific conditions, this block also supports SIMD code generation. For details, see “Code Generation” on page 2-793.

Ports

Input

Input — Input signal

scalar | vector

Connect the signal that you want to filter, specified as a scalar or column vector.

When the input is fixed-point, it must be signed.

When you set the **Algorithm** parameter to Sign–Error LMS, Sign–Data LMS, or Sign–Sign LMS, the data input through the **Input** port must be real.

Data Types: single | double | fixed point

Desired — Desired signal

vector | matrix

Connect the desired signal, specified as a vector or matrix. The desired signal must have the same data type, complexity, and dimensions as the Input signal.

When **Input** is fixed-point, the desired signal must be a signed fixed-point.

When you set the **Algorithm** parameter to Sign–Error LMS, Sign–Data LMS, or Sign–Sign LMS, the data input through the **Desired** port must be real.

Data Types: single | double | fixed point

Step-size — Step-size

scalar

Enter the step size μ . For convergence of the normalized LMS equations, $0 < \mu < 2$. Input type must match the type of the Input port.

When **Input** is fixed-point, the step-size must be a signed fixed-point.

Dependencies

This port appears only when you set the **Specify step size** via parameter to **Input port**.

Data Types: `single` | `double` | `fixed point`

Adapt — Update filter weights

scalar | vector

When the input to this port is greater than zero, the block continuously updates the filter weights. When the input to this port is less than or equal to zero, the filter weights remain at their current values.

Dependencies

This port appears only when you set the **Adapt port** parameter to **on**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `Boolean`

Reset — Reset filter weights

scalar | vector

Signal to reset the value of the filter weights to their initial values, specified as a vector. The block resets the filter weights whenever a reset event is detected at the Reset port. The reset signal rate must be the same rate as the data signal input.

For reset event types, see the **Reset** parameter.

Dependencies

This port appears only when you set the **Reset port** parameter to **Rising edge**, **Falling edge**, **Either edge**, or **Non-zero sample**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `Boolean`

Output

Output — Output signal

scalar | vector

Outputs the filtered input signal, which is the estimate of the desired signal. It is the same size and complexity as the input signal.

The output signal has the same data type as the desired signal.

Data Types: `single` | `double` | `fixed point`

Error — Error between Output and Desired signals

scalar | vector

Outputs the result of subtracting the output signal from the desired signal.

The error signal has the same data type as the desired signal.

Data Types: `single` | `double` | `fixed point`

Wts — Updated filter weights

`scalar` | `vector`

For each iteration, the block outputs the current updated filter weights from this port.

The weights data type must match the type of the Input port for floating-point signals. Obeys the `Weights` parameter for fixed-point signals.

Dependencies

This port appears only when you set the `Output filter weights` parameter to `On`.

Data Types: `single` | `double` | `fixed point`

Parameters

Main Tab

Algorithm — Select algorithm

`LMS (default)` | `Normalized LMS` | `Sign-Error LMS` | `Sign-Data LMS` | `Sign-Sign LMS`

Choose the algorithm used to calculate the filter weights.

Filter length — Filter length

`32 (default)` | `scalar`

Enter the length of the FIR filter weights vector.

Specify step size via — Specify step size via

`Dialog (default)` | `Input port`

- `Dialog` -- Specify step size by using the **Step size (μ)** parameter.
- `Input port` -- Specify step size by using the `Step-size` port.

Step size (μ) — Step size

`0.1 (default)` | `positive scalar`

Enter the step size μ . For convergence of the normalized LMS equations, $0 < \mu < 2$.

Tunable: Yes

Dependencies

This parameter appears only when you set the `Specify step size via` parameter to `Dialog`.

Leakage factor (0 to 1) — Leakage factor

`1.0 (default)` | `scalar`

Enter the leakage factor, $0 < 1 - \mu\alpha \leq 1$.

Tunable: Yes

Initial value of filter weights — Initial value of filter weights

0 (default) | vector | scalar

Enter the initial filter weights $w(0)$ as a vector or a scalar. When you enter a scalar, the block uses the scalar value to create a vector of filter weights. This vector length is equal to the filter length and all of its values are equal to the scalar value.

Adapt port — Enable Adapt port

on (default) | off

Select this check box to enable the Adapt input port.

Reset port — Reset port

None (default) | Rising edge | Falling edge | Either edge | Non-zero sample

When you want to reset the value of filter weights to their initial values, use the **Reset port** parameter. The reset signal must be the same rate as the data signal input.

Select None to disable the Reset port. To enable the **Reset port**, select one of the following from the list:

- **Rising edge** — Triggers a reset operation when the **Reset** input does one of the following:
 - Rises from a negative value to a positive value or zero
 - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)

- **Falling edge** — Triggers a reset operation when the **Reset** input does one of the following:
 - Falls from a positive value to a negative value or zero
 - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)

- **Either edge** — Triggers a reset operation when the **Reset** input is a Rising edge or Falling edge
- **Non-zero sample** — Triggers a reset operation at each sample time that the Reset input is not zero

Output filter weights — Output filter weights

on (default) | off

Select the **Output filter weights** parameter to export the filter weights from the *Wts* port. For each iteration, the block outputs the current updated filter weights from this port.

Data Type Tab

Rounding mode — Method of rounding operation

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

Saturate on integer overflow — Method of overflow action

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

Parameters — Parameters

Same word length as first input (default) | Specify word length | Binary point scaling

Choose how you specify the word length and the fraction length of the leakage factor and step size:

- **Same word length as first input** -- The word length of the leakage factor and step size match that of the first input to the block. In this mode, the fraction length of the leakage factor and step size is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- **Specify word length** -- You can enter the word length of the leakage factor and step size, in bits. In this mode, the fraction length of the leakage factor and step size is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- **Binary point scaling** -- You can enter the word length and the fraction length of the leakage factor and step size, in bits. The leakage factor and the step size must have the same word length, but the fraction lengths can differ.

For the **Specify step size via** parameter, if you choose **Input port**, the word length of the leakage factor is the same as the word length of the step size input at the **Step-size** port. The fraction length of the leakage factor is automatically set to the best precision possible based on the word length of the leakage factor.

Dependencies

This parameter is visible only if you set the **Specify step size via** parameter to **Dialog**

Weights — Word and fraction length of filter weights

Same as first input (default) | Binary point scaling

Choose how you specify the word length and fraction length of the filter weights of the block:

- **Same as first input** -- The word length and fraction length of the filter weights match those of the first input to the block.
- **Binary point scaling** -- You can enter the word length and the fraction length of the filter weights, in bits.

Product and quotient — Word and fraction length of product and quotient

Same as first input (default) | Binary point scaling

Choose how you specify the word length and fraction length of $\mathbf{u}'\mathbf{u}$, $\mathbf{W}'\mathbf{u}$, $\mu \cdot e$, $Q \cdot \mathbf{u}$, and the quotient, Q . Here, \mathbf{u} is the input vector, \mathbf{W} is the vector of filter weights, μ is the step size, e is the error, and Q is the quotient, which is defined as $Q = \frac{\mu \cdot e}{\mathbf{u}'\mathbf{u}}$

- **Same as first input** -- The word length and fraction length of these quantities match those of the first input to the block.
- **Binary point scaling** -- You can enter the word length and the fraction length of these quantities, in bits. The word length of the quantities must be the same, but the fraction lengths can differ.

Accumulator — Word and fraction lengths of accumulators

Same as first input (default) | Binary point scaling

Use this parameter to specify how you want to designate the word and fraction lengths of the accumulators for the $\mathbf{u}'\mathbf{u}$ and $\mathbf{W}'\mathbf{u}$ operations.

Note Do not use this parameter to designate the word and fraction lengths of the accumulator for the $Q \cdot \mathbf{u}$ operation. The accumulator data type for this quantity is automatically set to be the same as the product data type. The minimum, maximum, and overflow information for this accumulator is logged as part of the product information. Autoscaling treats this product and accumulator as one data type.

- Same as first input -- These characteristics match those of the input to the block.
- Binary point scaling -- You can enter the word length and the fraction length of the accumulators, in bits. The word length of both the accumulators must be the same, but the fraction lengths can differ.

For illustrations depicting the use of the accumulator data type in this block, see “Fixed Point” on page 2-794 and “Multiplication Data Types”.

Lock data type settings against changes by the fixed-point tools – Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

More About

LMS Filter Algorithms

When you select LMS for the Algorithm parameter, the block calculates the filter weights by using the least mean-square (LMS) algorithm. This algorithm is defined by these equations.

$$\begin{aligned}
 y(n) &= \mathbf{w}^T(n-1)\mathbf{u}(n) \\
 e(n) &= d(n) - y(n) \\
 \mathbf{w}(n) &= \alpha\mathbf{w}(n-1) + f(\mathbf{u}(n), e(n), \mu)
 \end{aligned}$$

The various LMS adaptive filter algorithms available in this block are defined as:

- LMS --

$$f(\mathbf{u}(n), e(n), \mu) = \mu e(n) \mathbf{u}^*(n)$$

- Normalized LMS --

$$f(\mathbf{u}(n), e(n), \mu) = \mu e(n) \frac{\mathbf{u}^*(n)}{\varepsilon + \mathbf{u}^H(n) \mathbf{u}(n)}$$

In Normalized LMS, to overcome potential numerical instability in the update of the weights, a small positive constant, ε , has been added in the denominator. For double-precision floating-point input, ε is the output of the `eps` function. For single-precision floating-point input, ε is the output of `eps("single")`. For fixed-point input, ε is 0.

- Sign-Error LMS --

$$f(\mathbf{u}(n), e(n), \mu) = \mu \text{sign}(e(n)) \mathbf{u}^*(n)$$

- Sign-Data LMS --

$$f(\mathbf{u}(n), e(n), \mu) = \mu e(n) \text{sign}(\mathbf{u}(n))$$

where $\mathbf{u}(n)$ is real.

- Sign-Sign LMS --

$$f(\mathbf{u}(n), e(n), \mu) = \mu \text{sign}(e(n)) \text{sign}(\mathbf{u}(n))$$

where $\mathbf{u}(n)$ is real.

Variable	Description
n	The current time index
$\mathbf{u}(n)$	The vector of buffered input samples at step n
$\mathbf{u}^*(n)$	The complex conjugate of the vector of buffered input samples at step n
$\mathbf{w}(n)$	The vector of filter weight estimates at step n
$y(n)$	The filtered output at step n
$e(n)$	The estimation error at step n
$d(n)$	The desired response at step n
μ	The adaptation step size
α	The leakage factor ($0 < \alpha \leq 1$)
ε	A constant that corrects any potential numerical instability that occurs during the update of weights.

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.

The LMS Filter block supports SIMD code generation using Intel AVX2 technology under these conditions:

- **Algorithm** is set to LMS or Normalized LMS.
- Input signal is real-valued.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

By default, the LMS Filter implementation uses a linear sum for the FIR section of the filter.

The LMS Filter implements a tree summation (which has a shorter critical path) under the following conditions:

- The LMS Filter is used with real data.
- The word length of the Accumulator **W'u** data type is at least `ceil(log2(filter length))` bits wider than the word length of the Product **W'u** data type.
- The Accumulator **W'u** data type has the same fraction length as the Product **W'u** data type.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see "ConstrainedOutputPipeline" (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "InputPipeline" (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "OutputPipeline" (HDL Coder).

Complex Data Support

This block supports code generation for complex signals.

Restrictions

- HDL Coder does not support the Normalized LMS algorithm of the LMS Filter.
- The Reset port supports only Boolean and unsigned inputs.
- The Adapt port supports only Boolean inputs.
- **Filter length** must be greater than or equal to 2.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

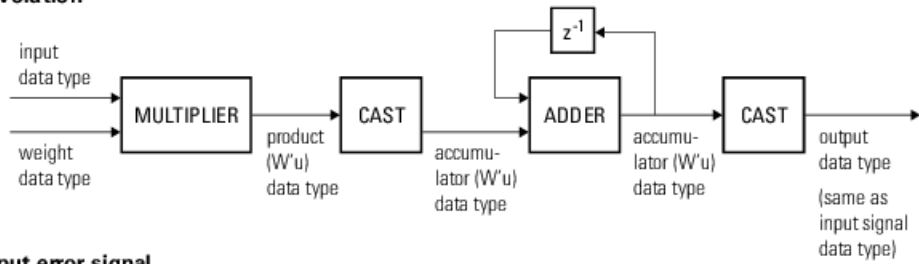

If the input is fixed point, it must be a signed integer or signed fixed point with a power-of-two slope and zero bias.

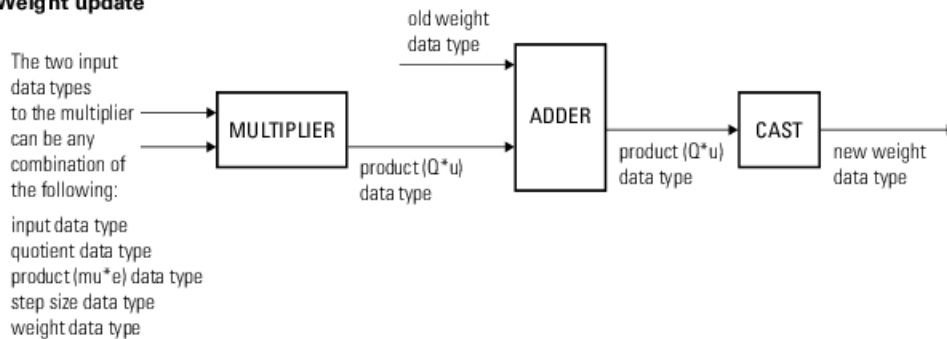

Fixed-Point Data Types

The following diagrams show the data types used within the LMS Filter block for fixed-point signals. The table summarizes the definitions of variables used in the diagrams.

Variable	Definition
u	Input vector
W	Vector of filter weights
μ	Step size
e	Error
Q	Quotient, $Q = \frac{\mu \cdot e}{\mathbf{u}'\mathbf{u}}$
Product $\mathbf{u}'\mathbf{u}$	Product data type in Energy calculation diagram
Accumulator $\mathbf{u}'\mathbf{u}$	Accumulator data type in Energy calculation diagram
Product $\mathbf{W}'\mathbf{u}$	Product data type in Convolution diagram
Accumulator $\mathbf{W}'\mathbf{u}$	Accumulator data type in Convolution diagram
Product $\mu \cdot e$	Product data type in Product of step size and error diagram
Product $Q \cdot \mathbf{u}$	Product and accumulator data type in Weight update diagram. ¹

¹The accumulator data type for this quantity is automatically set to be the same as the product data type. The minimum, maximum, and overflow information for this accumulator is logged as part of the product information. Autoscaling treats this product and accumulator as one data type.

Energy calculation (for normalized LMS algorithm only)**Convolution****Output error signal**

Product of step size and error (for LMS and Sign-Data LMS algorithms only)**Quotient (for normalized LMS only)****Weight update**

You can set the data type of the parameters, weights, products, quotient, and accumulators in the block mask. Fixed-point inputs, outputs, and mask parameters of this block must have these characteristics:

- The input signal and the desired signal must have the same word length, but their fraction lengths can differ.
- The step size and leakage factor must have the same word length, but their fraction lengths can differ.
- The output signal and the error signal have the same word length and the same fraction length as the desired signal.
- The quotient and the product output of the $\mathbf{u}'\mathbf{u}$, $\mathbf{W}'\mathbf{u}$, $\mu \cdot e$, and $Q \cdot \mathbf{u}$ operations must have the same word length, but their fraction lengths can differ.
- The accumulator data type of the $\mathbf{u}'\mathbf{u}$ and $\mathbf{W}'\mathbf{u}$ operations must have the same word length, but their fraction lengths can differ.

The output of the multiplier is in the product output data type if at least one of the inputs to the multiplier is real. If both of the inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details, see “Multiplication Data Types”.

LMS Update

Estimate weights of LMS adaptive filter

Library: DSP System Toolbox / Filtering / Adaptive Filters

Description

The LMS Update block estimates the weights of an LMS adaptive filter. Specify data and error as inputs and the block computes the filter weights based on the algorithm specified in the **Algorithm** parameter. For more details on the algorithms, see “Algorithms” on page 2-803.

You can configure the block to operate as a tapped-delay line FIR filter or as an adaptive linear combiner using the **Adaptive filter mode** parameter. The block can also adapt multiple filters independently when you specify the **Number of adaptive filters** parameter to a value greater than 1.

You can use this block to compute the adaptive filter weights in applications such as system identification, inverse modeling, and filtered-x LMS algorithms, which are used in acoustic noise cancellation. For more details, see “References” on page 2-804.

Input/Output Ports

Input

Input — Data input

scalar | column vector

Data input to the adaptive filter, specified as one of these:

- Scalar -- When you set the **Adaptive filter mode** parameter to Tapped delay-line FIR filter, the input to the block should be a scalar.

The block algorithm buffers the input samples to generate the vector $\mathbf{u}(n) = [u(n), u(n-1), \dots, u(n-L+1)]$, where L is the length of the adaptive filter and n is the time index. The block algorithm then passes the vector through the filter.

- Column vector of length L -- When you set the **Adaptive filter mode** parameter to Adaptive linear combiner, the block does not buffer the input samples, and the input to the block should be in the form of a column vector. The block multiplies the vector with the filter weights to generate the filter output. In this case, there is no relationship between the input samples.

When you set the **Number of adaptive filters** parameter to a value greater than 1, the block assumes that all filters run on the same input.

When you set the **Algorithm** parameter to Sign-Error LMS, Sign-Data LMS, or Sign-Sign LMS, the data input through the **Input** port must be real.

Data Types: `single` | `double`

Error — Error

scalar | column vector

Specify the error between the output signal and the desired signal as a:

- Scalar when the number of adaptive filters $N = 1$.
- Column vector of length N when $N > 1$.

When you set the **Algorithm** parameter to `Sign–Error LMS`, `Sign–Data LMS`, or `Sign–Sign LMS`, the error input through the **Error** port must be real.

Data Types: `single` | `double`

Mu — Filter adaptation step size

0.1 (default) | scalar in the range [0,1]

Specify the filter adaptation step size as a scalar in the range [0,1].

Dependency

To enable this port, set **Step size source** to `Input` port.

Data Types: `single` | `double`

Adapt — Update filter weights

real scalar | vector

The input to this port can be one of these:

- Scalar -- If the number of adaptive filters (N) is greater than 1, then the block updates the filter weights for all filters if the value at the port is nonzero and does not update if the value at the port is 0.
- Vector of length N -- If the number of adaptive filters (N) is greater than 1, then the block determines whether to update each filter during run time depending on the value of the corresponding element in the **Adapt** vector input. When the **Adapt** port input element is not 0, the block updates the filter weights. When the input is 0, the filter weights do not change.

For an example, see “Adapt Multiple Filters Using LMS Update block”.

Dependency

To enable this port, select the **Enable adapt input** parameter on the block dialog.

Data Types: `single` | `double` | `Boolean` | `int16` | `int32` | `int64` | `int8` | `uint16` | `uint32` | `uint64` | `uint8`

Reset — Reset filter weights

real scalar

When the input to this port is not 0, the block resets the filter weights to their initial values. When the input to this port is 0, the filter weights do not change.

Dependency

To enable this port, select the **Enable reset input** parameter on the block dialog.

Data Types: `single` | `double` | `Boolean` | `int16` | `int32` | `int64` | `int8` | `uint16` | `uint32` | `uint64` | `uint8`

Output

Wts — Filter weights

row vector | matrix

The block outputs the filter weights as a 1-by- L row vector or a N -by- L matrix, where N is the number of adaptive filters, and L is the length of each filter.

Data Types: `single` | `double`

Parameters

Algorithm — LMS adaptive algorithm

LMS (default) | Normalized LMS | Sign-Error LMS | Sign-Data LMS | Sign-Sign LMS

The block uses one of the listed algorithms to compute the filter weights. For more details on the algorithms, see “Algorithms” on page 2-803.

Filter length — Length of the filter

32 (default) | positive integer

Specify the length of each adaptive filter L as a positive integer.

When there are N adaptive filters, the weights vector the block generates through the **Wts** output port is an N -by- L matrix.

Number of adaptive filters — Number of adaptive filters

1 (default) | positive integer

Specify the number of adaptive filters N the block supports as a positive integer.

When you specify this value to be an integer greater than 1, each filter can be chosen to adapt independently during run time by providing the **Adapt** input as a logical vector of length N . All filters are assumed to run on the same input and have a common step size, leakage factor, and reset input.

The weights the block generates through the **Wts** output port is an N -by- L matrix, where L is the length of each filter.

For an example that shows how to adapt multiple filters, see “Adapt Multiple Filters Using LMS Update block”.

Step size source — Method to specify the step size

Property (default) | Input port

- Property — Specify the filter adaptation size using the **Step size (mu)** parameter.
- Input port — Pass filter adaptation size using the **Mu** input port.

Step size (μ) – Size of the adaptation step

0.1 (default) | nonnegative scalar

Step size (μ) indicates the amount by which the filter weights are updated in each iteration. Choose an optimal step size so that the filter is stable and the convergence speed is optimal.

This parameter is tunable. You can change its value even during the simulation.

Tunable: Yes

Dependency

To enable this parameter, set **Step size source** to Property.

Leakage factor (0 to 1) – Leakage factor

1.0 (default) | real scalar in the range [0,1]

Leakage factor (0 to 1) prevents unbounded growth of the filter coefficients by reducing the drift of the coefficients from their optimum values. A leakage factor of 1.0 indicates no leakage. If you encounter coefficient drift, that is, large fluctuation about the optimum solution, decrease the leakage factor until the coefficient fluctuation becomes small.

This parameter is tunable. You can change its value even during the simulation.

Tunable: Yes

Initial value of filter weights – Initial value of filter weights

0 (default) | real scalar | vector | matrix

Specify the initial value of filter weights as one of the following:

- Scalar
- Vector of size 1-by- L -- N is set to 1
- Matrix of size N -by- L -- $N > 1$ and $L > 1$

where N is the number of adaptive filters specified in **Number of adaptive filters** and L is the length of each filter specified in **Filter length**.

This parameter specifies the initial value of the filter weights $\mathbf{w}(n-1)$. The block uses this value to compute the weights $\mathbf{w}(n)$, when $n = 1$. For more information, see “Algorithms” on page 2-803.

Adaptive filter mode – Adaptive filter mode

Tapped delay-line FIR filter (default) | Adaptive linear combiner

Specify the adaptive filter mode as one of the following:

- **Tapped delay-line FIR filter** -- The block assumes the variable portion of the adaptive filter to be a tapped delay-line FIR filter. In this mode, the input samples are related using this equation:

$$\mathbf{u}(n) = [u(n), u(n-1), \dots, u(n-L+1)]$$

where n is the current time index and L is the length of the adaptive filter specified in the **Filter length** parameter.

The block accepts scalar input samples in this mode. The block algorithm buffers the samples to form the $\mathbf{u}(n)$ vector.

- **Adaptive linear combiner** -- The block does not buffer the input samples, and the input you provide to the block must be a column vector equal in length to the **Filter length** parameter. In this case, there is no relationship between the input samples.

For more details, see “Algorithms” on page 2-803.

Enable adapt input – Update the filter weights

off (default) | on

When you select this check box, the **Adapt** input port appears on the block. When the input to this port is greater than 0, the block updates the filter weights. When the input to this port is less than or equal to 0, the filter weights do not change.

Enable reset input – Reset the filter weights

off (default) | on

When you select this check box, the **Reset** input port appears on the block. When the input to this port is greater than 0, the block resets the filter weights to their initial values. When the input to this port is less than or equal to 0, the filter weights do not change.

Simulate using – Type of simulation to run

Code generation (default) | Interpreted execution

Specify the type of simulation to run as one of the following:

- **Code generation** -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than **Interpreted execution**.
- **Interpreted execution** -- Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than **Code generation**.

Block Characteristics

Data Types	double single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Algorithms

In a closed loop adaptive filter, the weights or coefficients of the filter are adjusted until the error is minimized. The error is the difference between the filter output and the desired signal. In this block, the error signal is specified through the **Error** input port.

The block computes filter weight estimates using $\mathbf{w}(n) = \alpha \mathbf{w}(n-1) + f(\mathbf{u}(n), e(n), \mu)$.

The function $f(\mathbf{u}(n), e(n), \mu)$ is defined according to the LMS algorithm you specify through the **Algorithm** parameter:

- **LMS** — $f(\mathbf{u}(n), e(n), \mu) = \mu e(n) \mathbf{u}^*(n)$
- **Normalized LMS** — $f(\mathbf{u}(n), e(n), \mu) = \mu e(n) \frac{\mathbf{u}^*(n)}{\varepsilon + \mathbf{u}^H(n) \mathbf{u}(n)}$

In the Normalized LMS algorithm, ε is a small positive constant that overcomes the potential numerical instability in the update of weights.

For double-precision floating-point input, ε is the output of the `eps` function. For single-precision floating-point input, ε is the output of `eps("single")`. For fixed-point input, ε is 0.

- **Sign-Error LMS** — $f(\mathbf{u}(n), e(n), \mu) = \mu \text{sign}(e(n)) \mathbf{u}^*(n)$
- **Sign-Data LMS** — $f(\mathbf{u}(n), e(n), \mu) = \mu e(n) \text{sign}(\mathbf{u}(n))$, where $\mathbf{u}(n)$ is real
- **Sign-Sign LMS** — $f(\mathbf{u}(n), e(n), \mu) = \mu \text{sign}(e(n)) \text{sign}(\mathbf{u}(n))$, where $\mathbf{u}(n)$ is real

In the equations:

- n — The current time index.
- $\mathbf{u}(n)$ — The vector of input samples at step n .

When you set the **Adaptive filter mode** parameter to `Tapped delay-line FIR filter`, the input to the block is a scalar value and the block buffers the input samples to generate the $\mathbf{u}(n)$ vector.

When you set the **Adaptive filter mode** parameter to `Adaptive linear combiner`, the block does not buffer the samples. The input to the block should be in the form of a column vector. In this case, there is no relationship between the input samples.

- $\mathbf{u}^*(n)$ — The complex conjugate of the vector of input samples at step n .
- $\mathbf{w}(n)$ — The vector of filter weight estimates at step n .
- $e(n)$ — The estimation error at step n .
- μ — The adaptation step size.
- α — The leakage factor ($0 \leq \alpha \leq 1$).

Multifilter Support

You can update the weights of multiple adaptive filters using the same LMS Update block. To enable this, specify the **Number of adaptive filters** parameter to be a value greater than 1. You can then adapt each filter independently during run time by providing the input at the **Adapt** port as a logical vector of length N . The block algorithm assumes that all filters run on the same input, adapt using the same algorithm, and have the same filter length, step size, leakage factor, and reset input.

Lowpass Filter

Design FIR or IIR lowpass filter

Library: DSP System Toolbox / Filtering / Filter Designs

Description

The Lowpass Filter block independently filters each channel of the input signal over time using the filter design specified by the block parameters. You can control whether the block implements an IIR or FIR lowpass filter using the **Filter type** parameter.

This block supports ARM Cortex code generation. Under specific conditions, this block also supports SIMD code generation. For details, see “Code Generation” on page 2-809.

Ports

Input

Port_1 — Input signal to filter

column vector | matrix

Input signal, specified as a real- or complex-valued column vector or matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel. The number of rows in the input signal denotes the channel length.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 — Filtered signal

vector | matrix

Filtered signal, specified as a vector or matrix. The output has the same size, data type, and complexity characteristics as the input.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Main

Filter type — FIR or IIR filter

FIR (default) | IIR

Specify whether the block implements an FIR lowpass filter or an IIR lowpass filter.

Design minimum order filter – Design filter with minimum order

on (default) | off

When you select this check box, the block designs a filter with the minimum order and the specified passband, stopband frequency, passband ripple, and stopband attenuation.

When you clear this check box, you can specify the **Filter order** as a positive integer.

Filter order – Order of lowpass filter

50 (default) | positive integer

Filter order of lowpass filter, specified as a positive scalar integer.

Dependencies

To enable this parameter, clear the **Design minimum order filter** check box.

Passband edge frequency (Hz) – Passband edge frequency

8e3 (default) | real positive scalar

Passband edge frequency of the lowpass filter, specified as a real positive scalar in Hz. The passband edge frequency must be less than half the value of the **Input sample rate (Hz)**.

Stopband edge frequency (Hz) – Stopband edge frequency

12e3 (default) | real positive scalar

Stopband edge frequency of the lowpass filter, specified as a real positive scalar in Hz. The stopband edge frequency must be less than half the value of the **Input sample rate (Hz)**.

Dependencies

To enable this parameter, select the **Design minimum order filter** check box.

Maximum passband ripple (dB) – Maximum passband ripple

0.1 (default) | real positive scalar

Maximum ripple of the filter response in the passband, specified as a real positive scalar in dB.

Minimum stopband attenuation (dB) – Minimum stopband attenuation

80 (default) | real positive scalar

Minimum attenuation in the stopband, specified as a real positive scalar in dB.

Inherit sample rate from input – Inherit sample rate from input

off (default) | on

When you select this check box, the block inherits its sample rate from the input signal. When you clear this check box, you specify the sample rate using the **Input sample rate (Hz)** parameter.

Input sample rate (Hz) — Input sample rate

44100 (default) | scalar

Input sample rate, specified as a scalar in Hz.

Dependencies

To enable this parameter, clear the **Inherit sample rate from input** check box.

Simulate using — Type of simulation to run

Interpreted execution (default) | Code generation

Type of simulation to run:

- Interpreted execution (default)

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

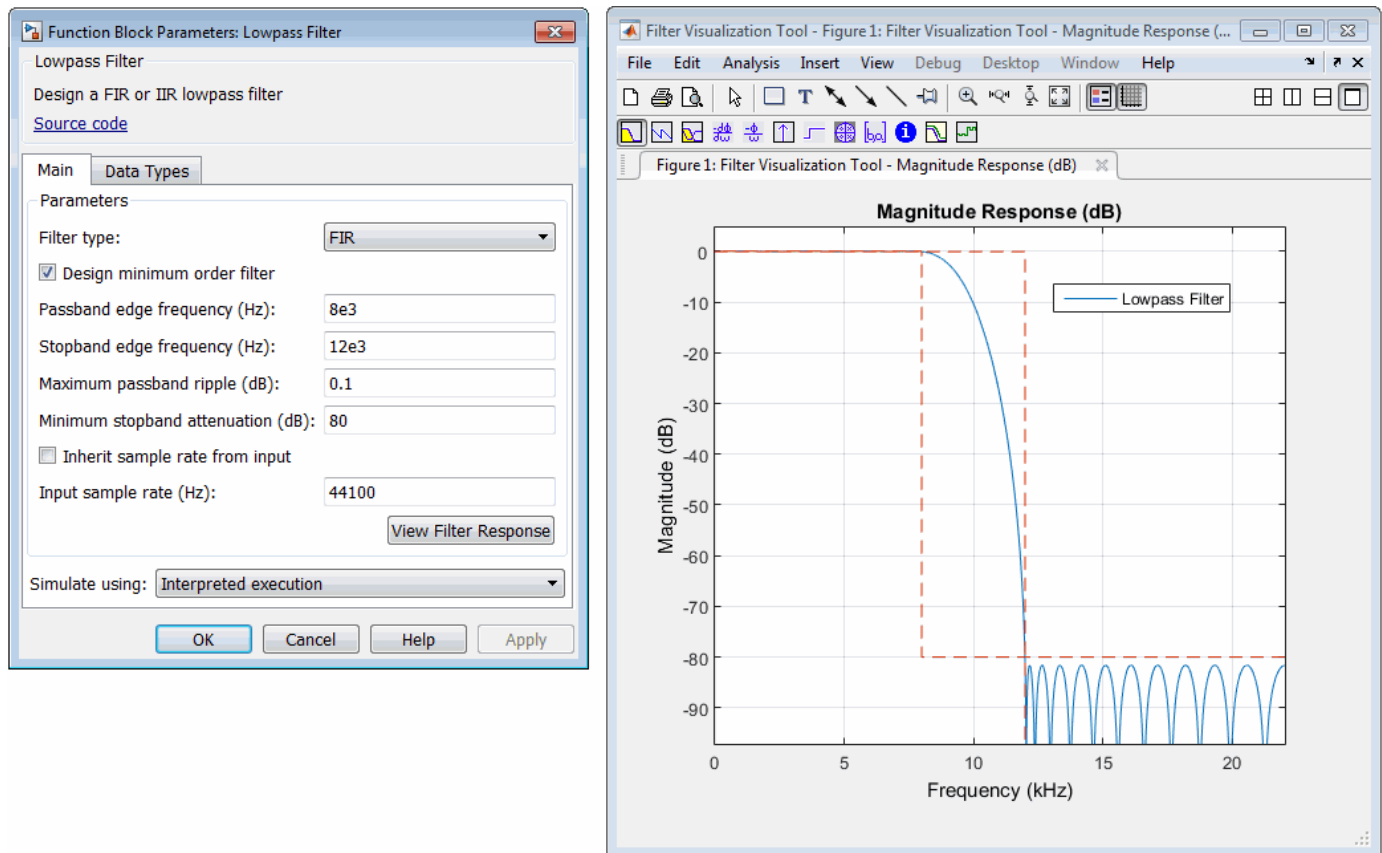

- Code generation

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.

View Filter Response — Open Filter Visualization Tool

button

Opens the Filter Visualization Tool (fvtool) and displays the magnitude/phase response of the Lowpass Filter. The response is based on the block dialog box parameters. Changes made to these parameters update FVTool.

To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

Data Types

Rounding mode — Rounding method

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Rounding method for the output fixed-point operations.

Coefficients — Coefficient data type

fixdt(1,16) (default) | fixdt(1,16,0) | <data type expression>

Fixed-point data type of the coefficients, specified as one of the following:

- `fixdt(1,16)` — Signed fixed-point data type of word length 16, with binary point scaling. The block determines the fraction length automatically from the coefficient values in such a way that the coefficients occupy maximum representable range without overflowing.
- `fixdt(1,16,0)` — Signed fixed-point data type of word length 16 and fraction length 0. You can change the fraction length to any other integer value.
- `<data type expression>` — Specify the data type using an expression that evaluates to a data type object, for example, numeric type (`fixdt([],16,15)`). Specify the sign mode of this data type as `[]` or `true`.

- Refresh Data Type — Refresh to the default data type.

Click the **Show data type assistant** button  to display the data type assistant, which helps you set the data type. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

Algorithms

This block brings the capabilities of the `dsp.LowpassFilter` System object to the Simulink environment.

For information on the algorithms used by this block, see the Algorithms on page 4-801 section of the `dsp.LowpassFilter` System object.

Version History

Introduced in R2015b

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The Lowpass Filter block supports ARM Cortex code generation. To learn more about ARM Cortex code generation, see “Code Generation for ARM Cortex-M and ARM Cortex-A Processors”.

The Lowpass Filter block also supports SIMD code generation using Intel AVX2 technology under these conditions:

- **Filter type** is set to FIR.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

dspfdesign

Description

This block brings the filter design capabilities of the `filterBuilder` function to the Simulink environment.

Parameters

View filter response

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

In this group, you specify your filter format, such as the impulse response and the filter order.

Impulse response

Select either FIR or IIR from the drop-down list. FIR is the default. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

Note The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Order mode

Select **Minimum** (the default) or **Specify**. Selecting **Specify** enables the **Order** option so you can enter the filter order. When you set the **Impulse response** to **IIR**, you can specify different numerator and denominator orders. To specify a different denominator order, you must select the **Denominator order** check box.

Order

Enter the filter order. This option is enabled only if you set the **Order mode** to **Specify**.

Denominator order

Select this check box to specify a different denominator order. This option is enabled only if you set the **Impulse response** to **IIR** and the **Order mode** to **Specify**.

Filter type

Select **Single-rate**, **Decimator**, **Interpolator**, or **Sample-rate converter**. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, the block specifies a single-rate filter.

- Selecting **Decimator** or **Interpolator** activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting **Sample-rate converter** activates both factors.

Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to **Decimator** or **Sample-rate converter**. The default value is 2.

Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to **Interpolator** or **Sample-rate converter**. The default value is 2.

Frequency Specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to the one shown in the following figure.

In the figure, regions between specification values such as F_{pass} and F_{stop} represent transition regions where the filter response is not constrained.

Frequency constraints

When **Order mode** is *Specify*, select the filter features that the block uses to define the frequency response characteristics. The list contains the following options, when available for the filter specifications.

- **Passband and Stopband frequencies** — Define the filter by specifying the frequencies for the edges for the stop- and passbands.
- **Passband frequency** — Define the filter by specifying the edge of the passband.
- **Stopband frequency** — Define the filter by specifying the edge of the stopband.
- **Halfband power (3dB) frequency** — Define the filter response by specifying the location of the 3 dB point. The 3 dB point is the frequency for the point three decibels below the passband value.
- **Cutoff (6dB) frequency** — For FIR filters, define the filter response by specifying the location of the 6 dB point. The 6 dB point is the frequency for the point six decibels below the passband value.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0–1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input sample rate** parameter.

Input sample rate

Input sample rate, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Passband frequency

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Stopband frequency

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Half power (3dB) frequency

When **Frequency constraints** is **Half power (3dB) frequency**, specify the frequency of the 3 dB point. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Cutoff (6dB) frequency

When **Frequency constraints** is **Cutoff (6dB) frequency**, specify the frequency of the 6 dB point. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Magnitude Specifications

Parameters in this group specify the filter response in the passbands and stopbands.

Magnitude constraints

This option is only available when you specify the order of your filter design. Depending on the setting of the **Frequency constraints** parameter, some combination of the following options will

be available for the **Magnitude constraints** parameter: Unconstrained, and Passband ripple and stopband attenuation.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. From the drop-down list, select one of the following options:

- Linear — Specify the magnitude in linear units.
- dB — Specify the magnitude in decibels (default)

Passband ripple

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

Stopband attenuation

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure of your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Elliptic, and the default FIR method is Equiripple.

Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Phase constraint

Specify the phase constraint of the filter as Linear, Maximum, or Minimum.

Minimum order

When you select this parameter, the design method determines and design the minimum order filter to meet your specifications. Some filters do not provide this parameter. Select

Any, Even, or Odd from the drop-down list to direct the design to be any minimum order, or minimum even order, or minimum odd order.

Match Exactly

Specifies that the resulting filter design matches either the passband or stopband or both bands when you select passband or stopband or both from the drop-down list.

Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- **Flat** — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- **Linear** — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- **1/f** — Specifies that the stopband attenuation changes exponentially as the frequency increases, where f is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to **Flat**, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to **Linear**, enter the slope of the stopband in units of dB/rad/s. The block applies that slope to the stopband.
- When you set **Stopband shape** to **1/f**, enter a value for the exponent n in the relation $(1/f)^n$ to define the stopband decay. The block applies the $(1/f)^n$ relation to the stopband to result in an exponentially decreasing stopband attenuation.

Filter Implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of n unit delays with a single delay by n .
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Optimize for unit scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters (Impulse response: IIR).

Input processing

Specify how the block should process the input. The available options may vary depending on the settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

Note The **Inherited** (this choice will be removed – see release notes) option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- **Enforce single-rate processing** — When you select this option, the block maintains the sample rate of the input.
- **Allow multirate processing** — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to **Elements as channels (sample based)**.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point

Version History

Introduced in R2006b

LPC to LSF/LSP Conversion

Convert linear prediction coefficients to line spectral pairs or line spectral frequencies

Library

Estimation / Linear Prediction

`dsp_lp`

Description

The LPC to LSF/LSP Conversion block takes a vector or matrix of linear prediction coefficients (LPCs) and converts it to a vector or matrix of line spectral pairs (LSPs) or line spectral frequencies (LSFs). When converting LPCs to LSFs, the block outputs match those of the `poly2lsf` function.

The block input must be either a matrix, a column vector, or an unoriented vector. Each channel of the input must have at least two samples.

The input LPCs for each channel, $1, a_1, a_2, \dots, a_m$, must be the denominator of the transfer function of a stable all-pole filter with the form given in the first equation of “Requirements for Valid Outputs” on page 2-817. A length- $M+1$ input channel yields a length- M output channel.

See other sections of this reference page to learn about how to ensure that you get valid outputs, how to detect invalid outputs, how the block computes the LSF/LSP values, and more.

Requirements for Valid Outputs

To get valid outputs, your inputs and the **Root finding coarse grid points** parameter value must meet these requirements:

- The input LPCs for each channel, $1, a_1, a_2, \dots, a_m$, must come from the denominator of the following transfer function, $H(z)$, of a stable all-pole filter (all roots of $H(z)$ must be inside the unit circle). Note that the first term in $H(z)$'s denominator must be 1. When the input LPCs do not come from a transfer function of the following form, the block outputs are invalid.

$$H(z) = \frac{1}{1 + a_1z^{-1} + a_2z^{-2} + \dots + a_mz^{-m}}$$

- The **Root finding coarse grid points** parameter value must be large enough so that the block can find all the LSP or LSF values. (The output LSFs and LSPs are roots of polynomials related to the input LPC polynomial; the block looks for these roots to produce the output. For details, see “LSF and LSP Computation Method: Chebyshev Polynomial Method for Root Finding” on page 2-821.) When you do not set **Root finding coarse grid points** to a high enough value relative to the number of LPCs, the block might not find all the LSPs or LSFs and yield invalid outputs as described in “Root Finding Method Limitations: Failure to Find Roots” on page 2-823.

To learn about recognizing invalid inputs and outputs and parameters for dealing with them, see “Handling and Recognizing Invalid Inputs and Outputs” on page 2-819.

Setting Outputs to LSFs or LSPs

Set the **Output** parameter to one of the following settings to determine whether the block outputs LSFs or LSPs:

- **LSF in radians (0 pi)** — Block outputs the LSF values between 0 and π radians in increasing order. The block does not output the guaranteed LSF values, 0 and π .
- **LSF normalized in range (0 0.5)** — Block outputs normalized LSF values in increasing order, computed by dividing the LSF values between 0 and π radians by 2π . The block does not output the guaranteed normalized LSF values, 0 and 0.5.
- **LSP in range (-1 1)** — Block outputs LSP values in decreasing order, equal to the cosine of the LSF values between 0 and π radians. The block does not output the guaranteed LSP values, -1 and 1.

Adjusting Output Computation Time and Accuracy with Root Finding Parameters

The values n and k determine the block's output computation time and accuracy, where

- n is the value of the **Root finding coarse grid points** parameter (choose this value with care; see the note below).
- k is the value of the **Root finding bisection refinement** parameter.
- Decreasing the values of n and k decreases the output computation time, but also decreases output accuracy:
 - The upper bound of block's computation time is proportional to $k \cdot (n - 1)$.
 - Each LSP output is within $1/(n \cdot 2^k)$ of the actual LSP value.
 - Each LSF output is within ΔLSF of the actual LSF value, LSF_{act} , where

$$\Delta LSF = \left| \arccos(LSF_{act}) - \arccos\left(LSF_{act} + 1/(n \cdot 2^k)\right) \right|$$

Note When the value of the **Root finding coarse grid points** parameter is too small relative to the number of LPCs, the block might output invalid data as described in “Requirements for Valid Outputs” on page 2-817. Also see “Handling and Recognizing Invalid Inputs and Outputs” on page 2-819.

Notable Input and Output Properties

- To get valid outputs, your input LPCs and the value of the **Root finding coarse grid points** parameter must meet the requirements described in “Requirements for Valid Outputs” on page 2-817.
- Length- $L+1$ input channel yields length- L output channel
- **Output** parameter determines the output type (see “Setting Outputs to LSFs or LSPs” on page 2-818):
 - LSFs — frequencies, w_k , where $0 < w_k < \pi$ and $w_k < w_{k+1}$
 - Normalized LSFs — $w_k / 2\pi$

- LSPs — $\cos(w_k)$

Handling and Recognizing Invalid Inputs and Outputs

The block outputs invalid data when your input LPCs and the value of the **Root finding coarse grid points** parameter do not meet the requirements described in “Requirements for Valid Outputs” on page 2-817. The following topics describe what invalid outputs look like, and how to set the block parameters provided for handling invalid inputs and outputs:

- “What Invalid Outputs Look Like” on page 2-819
- “Parameters for Handling Invalid Inputs and Outputs” on page 2-819

What Invalid Outputs Look Like

The channels of an invalid output have the same dimensions, sizes, and frame statuses as the channels of a valid output. However, invalid output channels do not contain all the LSP or LSF values. Instead, they contain none or some of the LSP and LSF values and the rest of the output is filled with place holder values (-1, 0.5, or π) depending on the **Output** parameter setting).

In short, all invalid outputs in a channel end in one of the place holder values (-1, 0.5, or π) as illustrated in the following table. To learn how to use the block's parameters for handling invalid inputs and outputs, see the next section.

Output Parameter Setting	Place Holder	Sample Invalid Outputs
LSF in radians (θ π)	π	$[w_1 \ w_2 \ w_3 \ \pi \ \pi \ \pi \ \pi \ \pi]$
LSF normalized in range (θ 0.5)	0.5	$\begin{bmatrix} w_1 \\ w_2 \\ 0.5 \end{bmatrix}$
LSP in range (-1 1)	-1	$\begin{bmatrix} \cos(w_{13}) \\ \cos(w_{23}) \\ -1 \\ -1 \\ -1 \end{bmatrix}$

Parameters for Handling Invalid Inputs and Outputs

You must set how the block handles invalid inputs and outputs by setting these parameters:

- **Show output validity status (1=valid, 0=invalid)** — Set this parameter to activate a second output port that outputs a vector with one Boolean element per channel; 1 when the output of the corresponding channel is valid, and 0 when the output is invalid. The LSF and LSP outputs are invalid when the block fails to find all the LSF or LSP values or when the input LPCs are unstable (for details, see “Requirements for Valid Outputs” on page 2-817). See the previous section to learn how to recognize invalid outputs.
- **If current output is invalid, overwrite with previous output** — Select this check box to cause the block to overwrite invalid outputs with the previous output. When you set this parameter you also need to consider these parameters:
 - **When first output is invalid, overwrite with user-defined values** — When the first input is unstable, you can overwrite the invalid first output with either

- The default values, by clearing this check box
- Values you specify, by selecting this check box

The default initial overwrite values are the LSF or LSP representations of an all-pass filter. The vector that is used to overwrite invalid output is stored as an internal state.

- **User-defined LSP/LSF values for overwriting invalid first output** — Specify a vector of values for overwriting an invalid first output if you selected the **When first output is invalid, overwrite with user-defined values** parameter. For multichannel inputs, provide a matrix with the same number of channels as the input, or one vector that will be applied to every channel. The vector or matrix of LSP/LSF values you specify should have the same dimension, size, and frame status as the other outputs.
- **If first input value is not 1** — The block output in any channel is invalid when the first coefficient in an LPC vector is not 1; this parameter determines what the block does when given such inputs:
 - **Ignore** — Proceed with computations as if the first coefficient is 1.
 - **Normalize** — Divide the input LPCs by the value of the first coefficient before computing the output.
 - **Normalize and warn** — In addition to **Normalize**, display a warning message at the MATLAB command line.
 - **Error** — Stop the simulation and display an error message at the MATLAB command line.

Parameters

Output

Specifies whether to convert the input linear prediction polynomial coefficients (LPCs) to LSP in range $(-1, 1)$, LSF in radians $(0, \pi)$, or LSF normalized in range $(0, 0.5)$. See “Setting Outputs to LSFs or LSPs” on page 2-818 for descriptions of the three settings.

Root finding coarse grid points

The value n , where the block divides the interval $(-1, 1)$ into n subintervals of equal length, and looks for roots (LSP values) in each subinterval. You must pick n large enough or the block output might be invalid as described in “Requirements for Valid Outputs” on page 2-817. To learn how the block uses this parameter to compute the output, see “LSF and LSP Computation Method: Chebyshev Polynomial Method for Root Finding” on page 2-821. Also see “Adjusting Output Computation Time and Accuracy with Root Finding Parameters” on page 2-818. Tunable (Simulink).

Root finding bisection refinement

The value k , where each LSP output is within $1/(n \cdot 2^k)$ of the actual LSP value, where n is the value of the **Root finding coarse grid points** parameter. To learn how the block uses this parameter to compute the output, see “LSF and LSP Computation Method: Chebyshev Polynomial Method for Root Finding” on page 2-821. Also see “Adjusting Output Computation Time and Accuracy with Root Finding Parameters” on page 2-818. Tunable (Simulink).

Show output validity status

Set this parameter to activate a second output port that outputs a vector with one Boolean element per channel; 1 when the output of the corresponding channel is valid, and 0 when the output is invalid. The LSF and LSP outputs are invalid when the block fails to find all the LSF or LSP values or when the input LPCs are unstable (for details, see “Requirements for Valid Outputs” on page 2-817).

If current output is invalid, overwrite with previous output

Selecting this check box causes the block to overwrite invalid outputs with the previous output. Setting this parameter activates other parameters for taking care of initial overwrite values (when the very first output of the block is invalid). For more information, see “Parameters for Handling Invalid Inputs and Outputs” on page 2-819.

When first output is invalid, overwrite with user-defined values

When the first input is unstable, you can overwrite the invalid first output with either

- The default values, by clearing this check box
- Values you specify, by selecting this check box

The default initial overwrite values are the LSF or LSP representations of an all-pass filter. The vector that is used to overwrite invalid output is stored as an internal state. For more information, see “Parameters for Handling Invalid Inputs and Outputs” on page 2-819.

User-defined LSP/LSF values for overwriting invalid first output

Specify a vector of values for overwriting an invalid first output if you selected the **When first output is invalid, overwrite with user-defined values** parameter. For multichannel inputs, provide a matrix with the same number of channels as the input, or one vector that will be applied to every channel. The vector or matrix of LSP/LSF values you specify should have the same dimension, size, and frame status as the other outputs.

If first input value is not 1

Determines what the block does when the first coefficient of an input is not 1. The block can either proceed with computations as when the first coefficient is 1 (**Ignore**); divide the input LPCs by the value of the first coefficient before computing the output (**Normalize**); in addition to **Normalize**, display a warning message at the MATLAB command line (**Normalize and warn**); stop the simulation and display an error message at the MATLAB command line (**Error**). For more information, see “Parameters for Handling Invalid Inputs and Outputs” on page 2-819.

Theory

LSF and LSP Computation Method: Chebyshev Polynomial Method for Root Finding

Note To learn the principles on which the block's LSP and LSF computation method is based, see the reference listed in “References” on page 2-824.

To compute LSP outputs for each channel, the block relies on the fact that LSP values are the roots of two particular polynomials related to the input LPC polynomial; the block finds these roots using the Chebyshev polynomial root finding method, described next. To compute LSF outputs, the block computes the arc cosine of the LSPs, outputting values ranging from 0 to π radians.

Root Finding Method

LSPs, which are the roots of two particular polynomials, always lie in the range (-1, 1). (The guaranteed roots at 1 and -1 are factored out.) The block finds the LSPs by looking for a sign change of the two polynomials' values between points in the range (-1, 1). The block searches a maximum of $k(n - 1)$ points, where

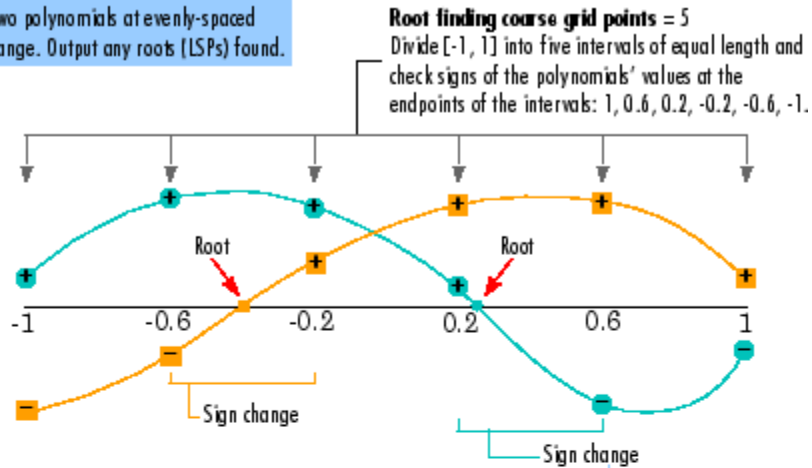

- n is the value of the **Root finding coarse grid points** parameter.

- k is the value of the **Root finding bisection refinement** parameter.

The block's method for choosing which points to check consists of the following two steps:

- 1 Coarse Root Finding** — The block divides the interval $[-1, 1]$ into n intervals, each of length $2/n$, and checks the signs of both polynomials' values at the endpoints of the intervals. The block starts checking signs at 1, and continues checking signs at $1 - 4/n$, $1 - 6/n$, and so on at steps of length $2/n$, outputting any point if it is a root. The block stops searching in these situations:
 - a** The block finds a sign change of a polynomial's values between two adjacent points. An interval containing a sign change is guaranteed to contain a root, so the block further searches the interval as described in Step 2, Root Finding Refinement.
 - b** The block finds and outputs all M roots (given a length- $M+1$ LPC input).
 - c** The block fails to find all M roots and yields invalid outputs as described in “Handling and Recognizing Invalid Inputs and Outputs” on page 2-819.
- 2 Root Finding Refinement** — When the block finds a sign change in an interval, $[a, b]$, it searches for the root guaranteed to lie in the interval by following these steps:
 - a Check if Midpoint Is a Root** — The block checks the sign of the midpoint of the interval $[a, b]$. The block outputs the midpoint if it is a root, and continues Step 1, Coarse Root Finding, at the next point, $a - 2/n$. Otherwise, the block selects the half-interval with endpoints of opposite sign (either $[a, (a + b)/2]$ or $[(a + b)/2, b]$) and executes Step 2b, Stop or Continue Root Finding Refinement.
 - b Stop or Continue Root Finding Refinement** — When the block has repeated Step 2a k times (k is the value of the **Root finding bisection refinement** parameter), the block linearly interpolates the root by using the half-interval's endpoints, outputs the result as an LSP value, and returns to Step 1, Coarse Root Finding. Otherwise, the block repeats Step 2a using the half-interval.

Coarse Root Finding: LSPs are roots of two particular polynomials related to the input LPCs. Check signs of the two polynomials at evenly-spaced points to find all intervals containing a sign change. Output any roots (LSPs) found.

Root Finding Refinement: Whenever Coarse Root Finding identifies an interval containing a sign change, repeatedly bisect the interval to better approximate the root (LSP value).

Bisection 1: Check the sign of the polynomial at the midpoint of the interval and select the half-interval with endpoints of opposite sign: $[0.2, 0.4]$

Bisection 2: Similar to Bisection 1

Bisection 3: The last bisection. Since the midpoint of this interval is not the root, linearly interpolate the root and output the result as an LSP value.

Root finding bisection refinement = 3
Bisect all sign change intervals found in the Coarse Root Finding up to three times to find the root. When the root is not found in the last bisection, linearly interpolate the root.

Coarse Root Finding and Root Finding Refinement

Root Finding Method Limitations: Failure to Find Roots

The block root finding method described above can fail, causing the block to produce invalid outputs (for details on invalid outputs, see “Handling and Recognizing Invalid Inputs and Outputs” on page 2-819).

In particular, the block can fail to find some roots if the value of the **Root finding coarse grid points** parameter, n , is too small. If the polynomials oscillate quickly and have roots that are very close together, the root finding might be too coarse to identify roots that are very close to each other, as illustrated in “Fixing a Failed Root Finding” on page 2-824.

For higher-order input LPC polynomials, you should increase the **Root finding coarse grid points** value to ensure the block finds all the roots and produces valid outputs.

Root Finding Fails: The root search divides the interval $[-1, 1]$ into four intervals, but all three roots are in a single interval. The block can only find one root per interval, so two of the roots are never found.

Fix Root Finding so it Succeeds: Increasing the value of the **Root finding course grid points** parameter to 15 ensures that each root is in its own interval, so all roots are found.

Fixing a Failed Root Finding

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Boolean — Supported only by the optional output port that appears when you set the parameter, **Show output validity status (1=valid, 0=invalid)**

LSF/LSP to LPC Conversion

Convert line spectral frequencies or line spectral pairs to linear prediction coefficients

Library

Estimation / Linear Prediction

dsplp

Description

The LSF/LSP to LPC Conversion block takes a vector or matrix of line spectral pairs (LSPs) or line spectral frequencies (LSFs) and converts it to a vector or matrix of linear prediction polynomial coefficients (LPCs). When converting LSFs to LPCs, the block outputs match those of the `lsf2poly` function.

The block input can be an N -by- M matrix or an unoriented vector. Each column of the matrix is treated as a channel. When the input is an unoriented vector, the input is treated as one channel. Each input channel must be in the same format, which you specify in the **Input** parameter:

- LSF in range (0π) — Vector of LSF values between 0 and π radians in increasing order. Do not include the guaranteed LSF values, 0 and π .
- LSF normalized in range $(0 0.5)$ — Vector of normalized LSF values in increasing order, (compute by dividing the LSF values between 0 and π radians by 2π). Do not include the guaranteed normalized LSF values, 0 and 0.5.
- LSP in range $(-1 1)$ — Vector of LSP values in decreasing order, equal to the cosine of the LSF values between 0 and π radians. Do not include the guaranteed LSP values, -1 and 1.

Parameters

Input

Specifies whether to convert LSP in range $(-1 1)$, LSF in range (0π) , or LSF normalized in range $(0 0.5)$ to linear prediction coefficients (LPCs).

Supported Data Types

- Double-precision floating point
- Single-precision floating point

LPC to/from Cepstral Coefficients

Convert linear prediction coefficients to cepstral coefficients or cepstral coefficients to linear prediction coefficients

Library

Estimation / Linear Prediction

dsplp

Description

The LPC to/from Cepstral Coefficients block either converts linear prediction coefficients (LPCs) to cepstral coefficients (CCs) or cepstral coefficients to linear prediction coefficients. Set the **Type of conversion** parameter to `LPCs to cepstral coefficients` or `Cepstral coefficients to LPCs` to select the domain into which you want to convert your coefficients. The LPC port corresponds to LPCs, and the CC port corresponds to the CCs. For more information, see “Algorithm” on page 2-829.

The block input can be an N -by- M matrix or an unoriented vector. Each column of the matrix is treated as a channel. When the input is an unoriented vector, the input is treated as one channel.

Consider a signal $x(n)$ as the input to an FIR analysis filter represented by LPCs. The output of this analysis filter, $e(n)$, is known as the prediction error signal. The power of this error signal is denoted by P , the prediction error power.

When you select `LPCs to cepstral coefficients` from the **Type of conversion** list, you can specify the prediction error power in two ways. From the **Specify P** list, choose `via input port` to input the prediction error power using input port P . The input to the port must be a vector with length equal to the number of input channels. Select `assume P equals 1` to set the prediction error power equal to 1 for all channels.

When you select `LPCs to cepstral coefficients` from the **Type of conversion** list, the **Output size same as input size** check box appears. When you select this check box, the length of the input vector of LPCs is equal to the output vector of CCs. When you do not select this check box, enter a positive scalar for the **Length of output cepstral coefficients** parameter.

When you select `LPCs to cepstral coefficients` from the **Type of conversion** list, you can use the **If first input value is not 1** parameter to specify the behavior of the block when the first coefficient of the LPC vector is not 1. The following options are available:

- `Replace it with 1` — Changes the first value of the coefficient vector to 1. The other coefficient values are unchanged.

- **Normalize** — Divides the entire vector of coefficients by the first coefficient so that the first coefficient of the LPC vector is 1.
- **Normalize and Warn** — Divides the entire vector of coefficients by the first coefficient so that the first coefficient of the LPC vector is 1. The block displays a warning message telling you that your vector of coefficients has been normalized.
- **Error** — Displays an error telling you that the first coefficient of the LPC vector is not 1.

When you select `Cepstral coefficients to LPCs` from the **Type of conversion** list, the **Output P** check box appears on the block. Select this check box when you want to output the prediction error power from output port P.

Algorithm

The cepstral coefficients are the coefficients of the Fourier transform representation of the logarithm magnitude spectrum. Consider a sequence, $x(n)$, having a Fourier transform $X(\omega)$. The cepstrum, $c_x(n)$, is defined by the inverse Fourier transform of $C_x(\omega)$, where $C_x(\omega) = \log_e X(\omega)$. See the Real Cepstrum block reference page for information on computing cepstrum coefficients from time-domain signals.

LPC to CC

When in this mode, this block uses a recursion technique to convert LPCs to CCs. The LPC vector is defined by $[a_0 \ a_1 \ a_2 \ \dots \ a_p]$ and the CC vector is defined by $[c_0 \ c_1 \ c_2 \ \dots \ c_p \ \dots \ c_{n-1}]$. The recursion is defined by the following equations:

$$c_0 = \log_e P$$

$$c_m = -a_m + \frac{1}{m} \sum_{k=1}^{m-1} [-(m-k) \cdot a_k \cdot c_{(m-k)}], 1 \leq m \leq p$$

$$c_m = \sum_{k=1}^p \left[\frac{-(m-k)}{m} \cdot a_k \cdot c_{(m-k)} \right], p < m < n$$

CC to LPC

When in this mode, this block uses a recursion technique to convert CCs to LPCs. The CC vector is defined by $[c_0 \ c_1 \ c_2 \ \dots \ c_p \ \dots \ c_n]$ and the LPC vector is defined by $[a_0 \ a_1 \ a_2 \ \dots \ a_p]$. The recursion is defined by the following equations

$$a_m = -c_m - \frac{1}{m} \sum_{k=1}^{m-1} [(m-k) \cdot c_{(m-k)} \cdot a_k]$$

$$P = \exp(C_0)$$

where $m = 1, 2, \dots, p$.

Parameters

Type of conversion

Choose `LPCs to cepstral coefficients` or `Cepstral coefficients to LPCs` to specify the domain into which you want to convert your coefficients.

Specify P

Choose `via input port` to input the values of prediction error power using input port P. Select `assume P equals 1` to set the prediction error power equal to 1.

Output size same as input size

When you select this check box, the length of the input vector of LPCs is equal to the output vector of CCs.

Length of output cepstral coefficients

Enter a positive scalar that is the length of each output channel of CCs.

If first input value is not 1

Select what you would like the block to do when the first coefficient of the LPC vector is not 1. You can choose `Replace it with 1`, `Normalize`, `Normalize and Warn`, and `Error`.

Output P

Select this check box to output the prediction error power for each channel from output port P.

LPC to/from RC

Convert linear prediction coefficients to reflection coefficients or reflection coefficients to linear prediction coefficients

Library

Estimation / Linear Prediction

dsp\lp

Description

The LPC to/from RC block either converts linear prediction coefficients (LPCs) to reflection coefficients (RCs) or reflection coefficients to linear prediction coefficients. Set the **Type of conversion** parameter to **LPC to RC** or **RC to LPC** to select the domain into which you want to convert your coefficients. The A port corresponds to LPC coefficients, and the K port corresponds to the RC coefficients. For more information, see “Algorithm” on page 2-832.

The block input can be an N -by- M matrix or an unoriented vector. Each column of the matrix is treated as a channel. When the input is an unoriented vector, the input is treated as one channel.

Consider a signal $x(n)$ as the input to an FIR analysis filter represented by LPC coefficients. The output of the analysis filter, $e(n)$, is known as the prediction error signal. The power of this error signal is denoted by P . When the zero lag autocorrelation coefficient of $x(n)$ is one, the autocorrelation sequence and prediction error power are said to be normalized.

Select the **Output normalized prediction error power** check box to enable port P. The normalized prediction error power output at P is a vector with one element per input channel. Each element varies between zero and one.

Select the **Output LPC filter stability** check box to output the stability of the filter represented by the LPCs or RCs. The synthesis filter represented by the LPCs is stable when the absolute value of each of the roots of the LPC polynomial is less than one. The lattice filter represented by the RCs is stable when the absolute value of each reflection coefficient is less than 1. When the filter is stable, the block outputs a Boolean value of 1 for each input channel at the S port. When the filter is unstable, the block outputs a Boolean value of 0 for each input channel at the S port.

If **first input value is not 1** parameter specifies the behavior of the block when the first coefficient of the LPC coefficient vector in any channel is not 1. The following options are available:

- **Replace it with 1** — Changes the first value of the coefficient channel to 1. The other coefficient values are unchanged.
- **Normalize** — Divides the entire channel of coefficients by the first coefficient so that the first coefficient of the LPC coefficient vector is 1.

- **Normalize and Warn** — Divides the entire channel of coefficients by the first coefficient so that the first coefficient of the LPC coefficient vector is 1. The block displays a warning message telling you that your vector of coefficients has been normalized.
- **Error** — Displays an error telling you that the first coefficient of the LPC coefficient channel is not 1.

Algorithm

LPC to RC

When in this mode, this block uses backward Levinson recursion to convert linear prediction coefficients (LPCs) to reflection coefficients (RCs). For a given Nth order LPC vector $LPC_N = [1 \ a_{N1} \ a_{N2} \ \dots \ a_{NN}]$, the block calculates the Nth reflection coefficient value using the formula $\gamma_N = -a_{NN}$. The block then finds the lower order LPC vectors, $LPC_{N-1}, LPC_{N-2}, \dots, LPC_1$, using the following recursion.

for $p = N, N - 1, \dots, 2$,

$$\gamma_p = a_{pp}$$

$$F = 1 - \gamma_p^2$$

$$a_{p-1,m} = \frac{a_{p,m}}{F} - \frac{\gamma_p a_{p,p-m}}{F}, \quad 1 \leq m < p$$

end

Finally, $\gamma_1 = -a_{11}$. The reflection coefficient vector is $[\gamma_1, \gamma_2, \dots, \gamma_N]$.

RC to LPC

When in this mode, this block uses Levinson recursion to convert reflection coefficients (RCs) to linear prediction coefficients (LPCs). In this case, the input to the block is $RC = [\gamma_1 \ \gamma_2 \ \dots \ \gamma_N]$. The zeroth order LPC vector term is 1. Starting with this term, the block uses recursion to calculate the higher order LPC vectors, $LPC_2, LPC_3, \dots, LPC_N$, until it has calculated the entire LPC matrix.

$$LPC_{matrix} = \begin{bmatrix} LPC_0 \\ LPC_1 \\ LPC_2 \\ \dots \\ LPC_N \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 & \dots & 0 \\ 1 & a_{11} & 0 & 0 & \dots & 0 \\ 1 & a_{21} & a_{22} & 0 & \dots & 0 \\ 1 & a_{31} & a_{32} & a_{33} & \dots & 0 \\ \dots & \dots & \dots & \dots & \dots & \dots \\ 1 & a_{N1} & a_{N2} & a_{N3} & \dots & a_{NN} \end{bmatrix}$$

This LPC matrix consists of LPC vectors of order 0 through N found by using the Levinson recursion. The following are the formulas for the recursion steps, for $p = 0, 1, \dots, N - 1$.

$$a_{p+1,m} = a_{p,m} + \gamma_{p+1} a_{p,p+1-m}, \quad 1 \leq m \leq p$$

$$a_{p+1,p+1} = \gamma_{p+1}$$

Parameters

Type of conversion

Select **LPC to RC** or **RC to LPC** to select the domain into which you want to convert your coefficients.

Output normalized prediction error power

Select this check box to output the normalized prediction error power at port P.

Output LPC filter stability

Select this check box to output the stability of the filter. When the filter represented by the LPCs or RCs is stable, the block outputs a Boolean value of 1 for each input channel at the S port. When the filter represented by the LPCs or RCs is unstable, the block outputs a Boolean value of 0 for each input channel at the S port.

If first input value is not 1

Select what you would like the block to do when the first coefficient of the LPC coefficient vector is not 1. You can choose **Replace it with 1**, **Normalize**, **Normalize and Warn**, and **Error**.

LPC/RC to Autocorrelation

Convert linear prediction coefficients or reflection coefficients to autocorrelation coefficients

Library

Estimation / Linear Prediction

dsp\lp

Description

The LPC/RC to Autocorrelation block either converts linear prediction coefficients (LPCs) to autocorrelation coefficients (ACs) or reflection coefficients (RCs) to autocorrelation coefficients (ACs). Set the **Type of conversion** parameter to `LPC to autocorrelation` or `RC to autocorrelation` to select the domain from which you want to convert your coefficients. The A port corresponds to LPC coefficients, and the K port corresponds to the RC coefficients.

The block input can be an N -by- M matrix or an unoriented vector. Each column of the matrix is treated as a channel. When the input is an unoriented vector, the input is treated as one channel.

Use the **Specify P** parameter to set the value of the prediction error power. You can set this parameter to 1 by selecting `Assume P=1`. When you select `Via input port`, a P port appears on the block. You can use this port to input the value of the actual, non-unity prediction error power for each channel. The length of this vector must equal the number of channels in the input.

The **If first input value is not 1** parameter specifies the behavior of the block when the first coefficient of the LPC coefficient vector is not 1. The following options are available:

- **Replace it with 1** — The block changes the first value of the coefficient vector to 1. The rest of the coefficient values are unchanged.
- **Normalize** — The block divides the entire vector of coefficients by the first coefficient so that the first coefficient of the LPC coefficient vector is 1.
- **Normalize and Warn** — The block divides the entire vector of coefficients by the first coefficient so that the first coefficient of the LPC coefficient vector is 1. The block displays a warning message telling you that your vector of coefficients has been normalized.
- **Error** — The block displays an error telling you that the first coefficient of the LPC coefficient vector is not 1.

Parameters

Type of conversion

From the list select `LPC to autocorrelation` or `RC to autocorrelation` to specify the domain from which you want to convert your coefficients.

Specify P

From the list select Assume $P=1$ or Via input port to specify the value of prediction error power.

If first input value is not 1

Select what you would like the block to do when the first coefficient of the LPC coefficient vector is not 1. You can choose Replace it with 1, Normalize, Normalize and Warn, and Error.

LU Factorization

Factor square matrix into lower and upper triangular components

Library: DSP System Toolbox / Math Functions / Matrices and Linear Algebra / Matrix Factorizations

Description

The LU Factorization block factors a row-permuted version of the square input matrix A as $A_p = L*U$, where L is a unit-lower triangular matrix, U is an upper triangular matrix, and A_p contains the rows of A permuted as indicated by the permutation index vector P . The block uses the pivot matrix A_p instead of the exact input matrix A because it improves the numerical accuracy of the factorization.

Ports

Input

A — Input matrix

M-by-*M* square matrix

Specify the input matrix as an *M*-by-*M* square matrix through this port. If the input matrix is fixed point, it must be signed integer or signed fixed point with power-of-two slope and zero bias.

Data Types: single | double | int8 | int16 | int32 | fixed point

Output

LU — Lower and upper triangular factors

M-by-*M* square matrix

Composite matrix containing both the lower triangle elements of L and the upper triangle elements of U . The composite matrix improves the efficiency of the block. The matrix output is in a different format than the output of the `lu` function, which returns L and U as separate matrices. To convert the output from the **LU** port of the block to separate L and U matrices, use the following code:

```
L = tril(LU,-1)+eye(size(LU)); U = triu(LU);
```

If you compare the results produced by these equations to the actual output of the `lu` function, you might see slightly different values. These differences are due to a rounding error, and are expected. For more information on the LU factorizations, see the `lu` function page.

This composite matrix has the same size, data type, and complexity as the input matrix A .

Data Types: single | double | int8 | int16 | int32 | fixed point

P — Permutation vector

vector

Permutation vector, returned as a vector of length M . The block permutes the input square matrix A using the permutation vector P and factors the permuted matrix into unit-lower triangular L and upper triangular matrix U .

Consider the following input matrix.

$$A = \begin{bmatrix} 1 & -2 & 3 \\ 4 & 0 & 6 \\ 2 & -1 & 3 \end{bmatrix}$$

With a permutation index vector P that is equal to $P = \begin{bmatrix} 2 \\ 1 \\ 3 \end{bmatrix}$, the permuted matrix A_p becomes:

$$A_p = \begin{bmatrix} 4 & 0 & 6 \\ 1 & -2 & 3 \\ 2 & -1 & 3 \end{bmatrix}$$

The block factors this matrix into upper and lower triangular matrices. For a more detailed version of this example, see “Factorize Matrix Using LU Factorization Block”.

Data Types: `single` | `double` | `uint32`

S — Singularity of input matrix

logical scalar

You can determine the singularity of the input matrix A by enabling the optional output port **S**. When A is singular, the block outputs a 1 at port **S**. When A is nonsingular, the block outputs a 0.

Data Types: `Boolean`

Parameters

Main Tab

Show singularity status — Show singularity status

`off` (default) | `on`

Select to output the singularity of the input at port **S**, which outputs Boolean data type values of 1 or 0. An output of 1 indicates that the current input is singular, and an output of 0 indicates the current input is nonsingular.

Data Types Tab

Rounding mode — Method of rounding operation

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling

- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

Saturate on integer overflow — Method of overflow action

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

Product output — Product output data type

Inherit: Inherit via internal rule (default) | Inherit: Same as input |
fixdt(1,16,0)

Product output specifies the data type of the output of a product operation in the LU Factorization block. For more information on the product output data type, see “Fixed Point” on page 2-840 and “Multiplication Data Types”.

- **Inherit: Inherit via internal rule** — The block inherits the product output data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- **Inherit: Same as input** — The block specifies the product output data type to be the same as the input data type.
- **fixdt(1,16,0)** — The block specifies a signed, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Product output** data type by using the **Data Type Assistant**. To use

the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

Accumulator — Accumulator data type

Inherit: Inherit via internal rule (default) | Inherit: Same as input | Inherit:
Same as product output | fixdt(1,16,0)

Accumulator specifies the data type of the output of an accumulation operation in the LU Factorization block. For more information on how to use the accumulator data type in this block, see the “Fixed Point” on page 2-840 section.

- **Inherit: Inherit via internal rule** — The block inherits the accumulator data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- **Inherit: Same as input** — The block specifies the accumulator data type to be the same as the input data type.

- **Inherit:** Same as product output — The block specifies the accumulator data type to be the same as the product output data type.
- `fixdt(1,16,0)` — The block specifies a signed, binary-point scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

Output — Output data type

Inherit: Same as input (default) | `fixdt(1,16,0)`

Output specifies the data type of the output of the LU Factorization block. For more information on the output data type, see the “Fixed Point” on page 2-840 section.

- **Inherit:** Same as input — The block specifies the output data type to be the same as the input data type.
- `fixdt(1,16,0)` — The block specifies a signed, binary-point scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

Output Minimum — Minimum value the block can output

`[]` (default) | scalar

Specify the minimum value the block can output. Simulink software uses this minimum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

Output Maximum — Maximum value block can output

`[]` (default) | scalar

Specify the maximum value the block can output. Simulink software uses this maximum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

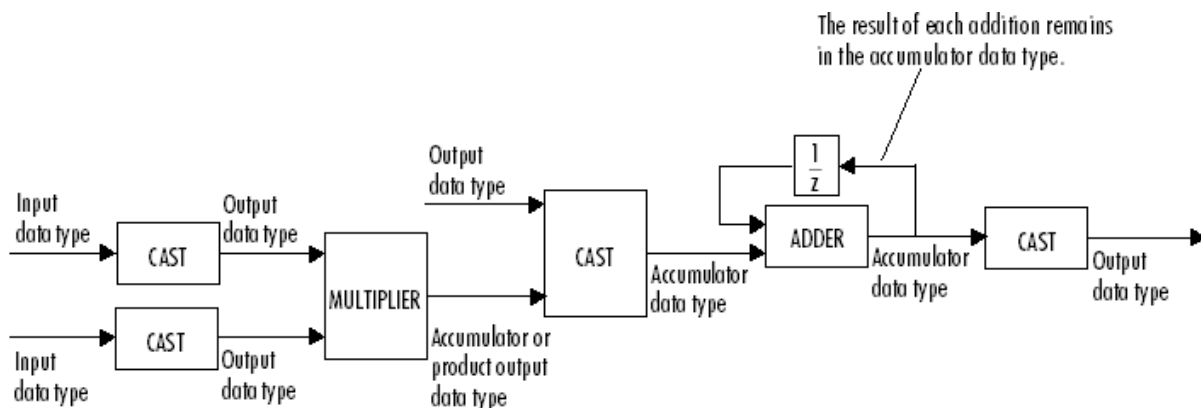

Generated code relies on the memcpy or memset function (string.h) under certain conditions.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

If the input is fixed point, it must be a signed integer or signed fixed point with a power-of-two slope and zero bias.

The following diagram shows the data types used within the LU Factorization block for fixed-point signals.

You can set the product output, accumulator, and output data types in the block dialog as discussed below.

The output of the multiplier is in the product output data type when the input is real. When the input is complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”.

LU Inverse

Compute inverse of square matrix using LU factorization

Library: DSP System Toolbox / Math Functions / Matrices and Linear Algebra / Matrix Inverses

Description

The LU Inverse block computes the inverse of the square input matrix A by factoring and inverting its row-pivoted variant A_p .

$$A_p^{-1} = (LU)^{-1}$$

L is a lower triangular square matrix with unity diagonal elements, and U is an upper triangular square matrix. The block outputs the inverse matrix A^{-1} .

LU Solver

Solve $AX = B$ when A is a square matrix

Library: DSP System Toolbox / Math Functions / Matrices and Linear Algebra / Linear System Solvers

Description

The LU Solver block solves the linear system $AX = B$ by applying LU factorization, where:

- A is an M -by- M square matrix input through the **A** port.
- B is an M -by- N matrix input through the **B** port.
- X is the M -by- N output matrix and is the unique solution to the equations.

Ports

Input

A — Input A matrix

M -by- M matrix

Specify the input M -by- M square matrix A through this port. Inputs A and B must have the same number of rows.

Data Types: `single` | `double`

B — B matrix

M -by- N matrix | M -by-1 vector

Specify the B matrix in the $AX = B$ equation as an M -by- N matrix or an M -by-1 vector.

When you specify an M -by-1 vector, the block treats the length- M unoriented vector input at port **B** as an M -by-1 matrix. Inputs A and B must have the same number of rows.

Data Types: `single` | `double`

Output

X — Solution to system of equations

M -by- N matrix | M -by-1 matrix

The block returns the output as an M -by- N matrix or a M -by-1 matrix. The size of X matrix is same as the size of the B matrix.

Data Types: `single` | `double`

Block Characteristics

Data Types	double single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Algorithms

The LU algorithm factors a row-permuted variant (A_p) of the square input matrix A as

$$A_p = LU$$

where L is a lower triangular square matrix with unity diagonal elements, and U is an upper triangular square matrix.

The matrix factors are substituted for A_p in

$$A_p X = B_p$$

where B_p is the row-permuted variant of B , and the resulting equation

$$LUX = B_p$$

is solved for X by substituting $Y = UX$, and solving two triangular systems.

$$LY = B_p$$

$$UX = Y$$

Magnitude FFT

Compute nonparametric estimate of spectrum using periodogram method

Library

- Estimation / Power Spectrum Estimation

`dspspect3`

- Transforms

`dspxfrm3`

Description

The Magnitude FFT block computes a nonparametric estimate of the spectrum using the periodogram method.

When the **Output** parameter is set to **Magnitude squared**, the block output for an M -by- N input u is equivalent to

$$y = \text{abs}(\text{fft}(u, nfft)).^2 \quad \% M \leq nfft$$

When the **Output** parameter is set to **Magnitude**, the block output for an input u is equivalent to

$$y = \text{abs}(\text{fft}(u, nfft)) \quad \% M \leq nfft$$

When $M > N_{fft}$, the block wraps the input to N_{fft} before computing the FFT using one of the above equations:

$$y(:, k) = \text{datawrap}(u(:, k), nfft) \quad \% 1 \leq k \leq N$$

When $M > N_{fft}$, the block can also truncate the input:

$$y(:, k) = \text{abs}(\text{fft}(u, nfft)) \quad \% 1 \leq k \leq N$$

The block treats an M -by- N matrix input as M sequential time samples from N independent channels. The block computes a separate estimate for each of the N independent channels and generates an N_{fft} -by- N matrix output. Each column of the output matrix contains the estimate of the corresponding input column's power spectral density at N_{fft} equally spaced frequency points in the range $[0, F_s)$, where F_s represents the signal's sample frequency. The block always outputs sample-based data.

The Magnitude FFT block supports real and complex floating-point inputs. The block also supports real fixed-point inputs in both **Magnitude** and **Magnitude squared** modes, and complex fixed-point inputs in the **Magnitude squared** mode.

Fixed-Point Data Types

The following diagram shows the data types used within the Magnitude FFT subsystem block for fixed-point signals.

The settings for the fixed-point parameters of the FFT block in the diagram above are as follows:

- Sine table — Same word length as input
- Integer rounding mode — Floor
- Saturate on integer overflow — unchecked
- Product output — Inherit via internal rule
- Accumulator — Inherit via internal rule
- Output — Inherit via internal rule

The settings for the fixed-point parameters of the Magnitude Squared block in the diagram above are as follows:

- Integer rounding mode — Floor
- Saturate on integer overflow — checked
- Output — Inherit via internal rule

Parameters

Output

Specify whether the block computes the magnitude FFT or magnitude-squared FFT of the input.

FFT implementation

Set this parameter to `FFTW` to support an arbitrary length input signal. The block restricts generated code with FFTW implementation to MATLAB host computers.

Set this parameter to `Radix-2` for bit-reversed processing, fixed or floating-point data, or for portable C-code generation using the Simulink Coder. The first dimension M , of the input matrix must be a power of two. To work with other input sizes, use the Pad block to pad or truncate these dimensions to powers of two, or if possible choose the FFTW algorithm.

Set this parameter to `Auto` to let the block choose the FFT implementation. For non-power-of-two transform lengths, the block restricts generated code to MATLAB host computers.

Inherit FFT length from input dimensions

Select to use the input frame size as the number of data points, on which to perform the FFT.

When you select this check box, this number must be a power of two. When you do not select this check box, the **FFT length** parameter specifies the number of data points.

FFT length

Enter the number of data points on which to perform the FFT, N_{fft} . When N_{fft} is larger than the input frame size, each frame is zero-padded as needed. When N_{fft} is smaller than the input frame

size, each frame is wrapped as needed. This parameter is enabled when you clear the **Inherit FFT length from input dimensions** check box.

When you set the **FFT implementation** parameter to Radix-2, this value must be a power of two.

Wrap input data when FFT length is shorter than input length

Choose to wrap or truncate the input, depending on the **FFT length**. If this parameter is checked, modulo-length data wrapping occurs before the FFT operation, given **FFT length** is shorter than the input length. If this property is unchecked, truncation of the input data to the FFT length occurs before the FFT operation. The default is checked.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • 8-, 16-, and 32-bit signed integers
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers

Version History

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.
- When the following conditions apply, the executable generated from this block relies on prebuilt dynamic library files (`.dll` files) included with MATLAB:
 - **FFT implementation** is set to FFTW.
 - **Inherit FFT length from input dimensions** is cleared, and **FFT length** is set to a value that is not a power of two.

Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

- When the FFT length is a power of two, you can generate standalone C and C++ code from this block.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Matrix 1-Norm

Compute 1-norm of matrix

Library: DSP System Toolbox / Math Functions / Matrices and Linear Algebra / Matrix Operations

Description

The Matrix 1-Norm block computes the 1-norm or maximum column-sum of an M -by- N input matrix A .

$$y = \|A\|_1 = \max_{1 \leq j \leq N} \sum_{i=1}^M |a_{ij}|$$

Equivalent MATLAB code is given by:

```
y = max(sum(abs(A)))
```

Ports

Input

Port_1 — Input signal

vector | matrix

Input signal, specified as a vector or matrix.

The block treats length- M unoriented vector input as an M -by-1 matrix.

The Matrix 1-Norm block supports real and complex floating-point inputs and real fixed-point inputs.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point
Complex Number Support: Yes

Output

Port_1 — Output signal

scalar

Matrix 1-norm or maximum column-sum of the input, returned as a scalar. The output y is always a scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Parameters

Main

There are no parameters on the **Main Tab**.

Data Types

Rounding mode — Method of rounding operation

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see Rounding Modes.

Note The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numerical results when all these conditions are met:

- **Accumulator** data type is `Inherit`: `Inherit via internal rule`.
- **Output** data type is `Inherit`: `Same as accumulator`.

With these data-type settings, the block operates in a full-precision mode.

Saturate on integer overflow — Overflow handling method

`off` (default) | `on`

Select this parameter to saturate the result of the fixed-point operation. Clear this parameter to wrap the result of the fixed-point operation. For details on *saturate* and *wrap*, see Overflow Handling for fixed-point operations.

Note The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numeric results when all these conditions are met:

- **Product output** data type is `Inherit: Inherit via internal rule`.
- **Accumulator** data type is `Inherit: Inherit via internal rule`.

With these data-type settings, the block operates in a full-precision mode.

Accumulator — Accumulator data type

`Inherit: Inherit via internal rule (default) | Inherit: Same as input | fixdt([],16,0)`

Accumulator specifies the data type of the output of an accumulation operation in the Matrix 1-Norm block.

- `Inherit: Inherit via internal rule` — The block inherits the accumulator data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- `Inherit: Same as input` — The block specifies the accumulator data type to be the same as the input data type.
- `fixdt([],16,0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink).

For illustrations on how to use the accumulator data type in this block, see Fixed-Point Conversion in “Extended Capabilities” on page 2-0 .

Output — Output data type

`Inherit: Same as accumulator (default) | Inherit: Same as input | fixdt([],16,0)`

Output specifies the data type of the output of the Matrix 1-Norm block.

- `Inherit: Same as input` — The block specifies the output data type to be the same as the input data type.
- `Inherit: Same as accumulator` — The block specifies the output data type to be the same as the accumulator data type.
- `fixdt([],16,0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink).

For more information on the output data type, see Fixed-Point Conversion in “Extended Capabilities” on page 2-0 .

Output Minimum — Minimum value that block can output

[] (default) | scalar

Specify the minimum value the block can output. Simulink uses this minimum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

Output Maximum — Maximum value that block can output

[] (default) | scalar

Specify the maximum value the block can output. Simulink uses this maximum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

Note Floating-point inheritance takes precedence over the data type settings defined on this tab. When inputs are floating point, the block ignores these settings and all internal data types are floating point.

Blocks

Array-Vector Multiply | Product | Matrix Product | Dot Product

Matrix Product

Multiply matrix elements along rows, columns, or entire input

Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

dspmtx3

Description

The Matrix Product block multiplies the elements of an M -by- N input matrix u along its rows, its columns, or over all its elements.

When the **Multiply over** parameter is set to **Rows**, the block multiplies across the elements of each row and outputs the resulting M -by-1 matrix. The block treats length- N unoriented vector input as a 1-by- N matrix.

$$\begin{bmatrix} u_{11} & u_{12} & u_{13} \\ u_{21} & u_{22} & u_{23} \\ u_{31} & u_{32} & u_{33} \end{bmatrix} = \begin{bmatrix} y_1 \\ y_2 \\ y_3 \end{bmatrix} = \begin{bmatrix} \left(\prod_{j=1}^3 u_{1j} \right) \\ \left(\prod_{j=1}^3 u_{2j} \right) \\ \left(\prod_{j=1}^3 u_{3j} \right) \end{bmatrix}$$

When the **Multiply over** parameter is set to **Columns**, the block multiplies down the elements of each column and outputs the resulting 1-by- N matrix. The block treats length- M unoriented vector input as an M -by-1 matrix.

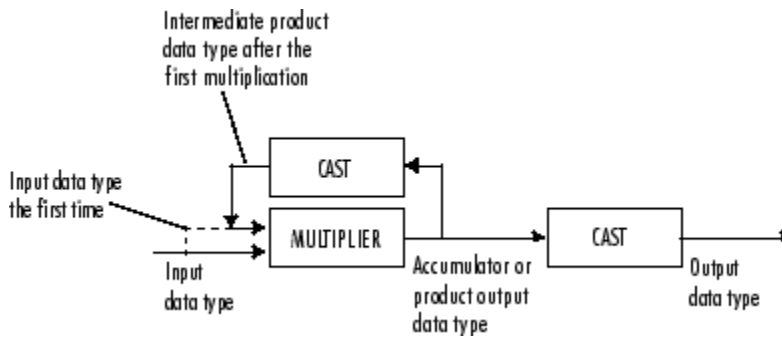

$$\begin{bmatrix} u_{11} & u_{12} & u_{13} \\ u_{21} & u_{22} & u_{23} \\ u_{31} & u_{32} & u_{33} \end{bmatrix} \Downarrow \begin{bmatrix} y_1 & y_2 & y_3 \end{bmatrix} = \left[\left(\prod_{i=1}^3 u_{i1} \right) \left(\prod_{i=1}^3 u_{i2} \right) \left(\prod_{i=1}^3 u_{i3} \right) \right]$$

When the **Multiply over** parameter is set to **Entire** input, the block multiplies all the elements of the input together and outputs the resulting scalar.

$$\begin{bmatrix} u_{11} & u_{12} & u_{13} \\ u_{21} & u_{22} & u_{23} \\ u_{31} & u_{32} & u_{33} \end{bmatrix} \Rightarrow y = \left(\prod_{i=1}^3 \prod_{j=1}^3 u_{ij} \right)$$

Fixed-Point Data Types

The following diagram shows the data types used within the Matrix Product block for fixed-point signals.

The output of the multiplier is in the product output data type when at least one of the inputs to the multiplier is real. When both of the inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”. You can set the accumulator, product output, intermediate product, and output data types in the block dialog as discussed in “Parameters” on page 2-858 below.

Parameters

Main Tab

Multiply over

Indicate whether to multiply together the elements of each row, each column, or the entire input.

Data Types Tab

Note Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

Rounding mode

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

Saturate on integer overflow

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see `overflow mode for fixed-point operations`.

Intermediate product

Specify the intermediate product data type. As shown in “Fixed-Point Data Types” on page 2-858, the output of the multiplier is cast to the intermediate product data type before the next element of the input is multiplied into it. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt([], 16, 0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Product output

Specify the product output data type. See “Fixed-Point Data Types” on page 2-858 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- A rule that inherits a data type, for example, `Inherit: Same as input`.
- An expression that evaluates to a valid data type, for example, `fixdt([], 16, 0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Accumulator

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-858 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- A rule that inherits a data type, for example, `Inherit: Same as input`.
- A rule that inherits a data type, for example, `Inherit: Same as product output`.
- An expression that evaluates to a valid data type, for example, `fixdt([], 16, 0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Output

Specify the output data type. See “Fixed-Point Data Types” on page 2-858 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as product output`
- A rule that inherits a data type, for example, `Inherit: Same as input`.
- An expression that evaluates to a valid data type, for example, `fixdt([], 16, 0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Data Types of Signals” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Minimum

Specify the minimum value that the block should output. The default value is [] (unspecified). Simulink uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Maximum

Specify the maximum value that the block should output. The default value is [] (unspecified). Simulink uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Array-Vector Multiply | Matrix Sum

Matrix Sum (Obsolete)

Sum matrix elements along rows, columns, or entire input

Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

`dspobslib`

Description

The Matrix Sum block sums the elements of an M -by- N input matrix u along its rows, its columns, or over all its elements.

When the **Sum over** parameter is set to **Rows**, the block sums across the elements of each row and outputs the resulting M -by-1 matrix. A length- N 1-D vector input is treated as a 1-by- N matrix.

$$\begin{bmatrix} u_{11} & u_{12} & u_{13} \\ u_{21} & u_{22} & u_{23} \\ u_{31} & u_{32} & u_{33} \end{bmatrix} = \begin{bmatrix} y_1 \\ y_2 \\ y_3 \end{bmatrix} = \begin{bmatrix} \left(\sum_{j=1}^3 u_{1j} \right) \\ \left(\sum_{j=1}^3 u_{2j} \right) \\ \left(\sum_{j=1}^3 u_{3j} \right) \end{bmatrix}$$

When the **Sum over** parameter is set to **Columns**, the block sums down the elements of each column and outputs the resulting 1-by- N matrix. A length- M 1-D vector input is treated as a M -by-1 matrix.

$$\begin{bmatrix} u_{11} & u_{12} & u_{13} \\ u_{21} & u_{22} & u_{23} \\ u_{31} & u_{32} & u_{33} \end{bmatrix} \Downarrow \begin{bmatrix} y_1 & y_2 & y_3 \end{bmatrix} = \left[\left(\sum_{i=1}^3 u_{i1} \right) \left(\sum_{i=1}^3 u_{i2} \right) \left(\sum_{i=1}^3 u_{i3} \right) \right]$$

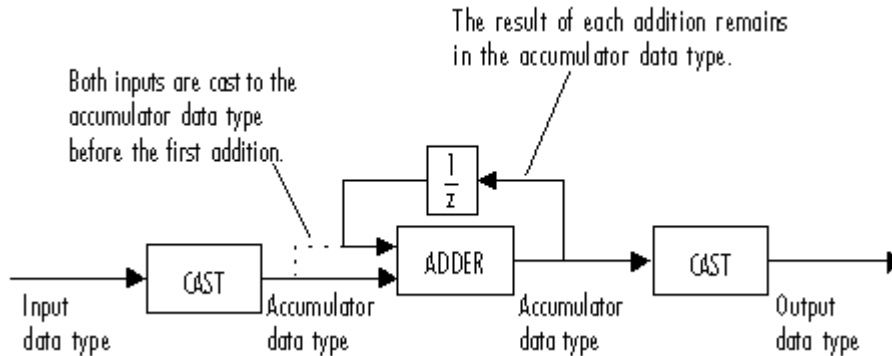

When the **Sum over** parameter is set to **Entire** input, the block sums all the elements of the input together and outputs the resulting scalar.

$$\begin{bmatrix} u_{11} & u_{12} & u_{13} \\ u_{21} & u_{22} & u_{23} \\ u_{31} & u_{32} & u_{33} \end{bmatrix} = y = \left(\sum_{i=1}^3 \sum_{j=1}^3 u_{ij} \right)$$

The output of the Matrix Sum block has the same frame status as the input. This block accepts real and complex fixed-point and floating-point inputs except for complex unsigned fixed-point inputs.

Fixed-Point Data Types

The following diagram shows the data types used within the Matrix Sum block for fixed-point signals.

You can set the accumulator and output data types in the block dialog as discussed in “Dialog Box” on page 2-863 below.

Dialog Box

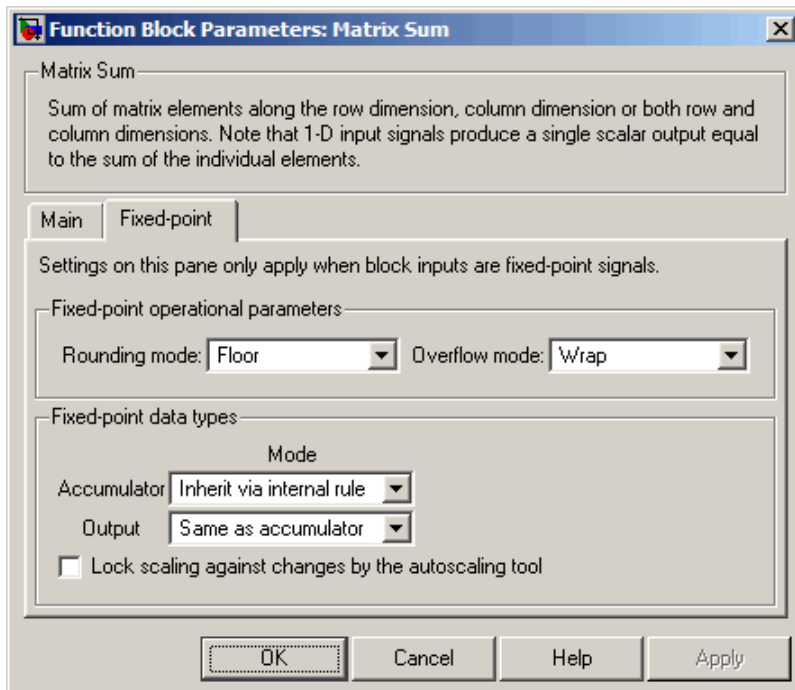

The **Main** pane of the Matrix Sum block dialog appears as follows.

Sum over

Indicate whether to sum the elements of each row, each column, or of the entire input.

The **Fixed-point** pane of the Matrix Sum block dialog appears as follows.

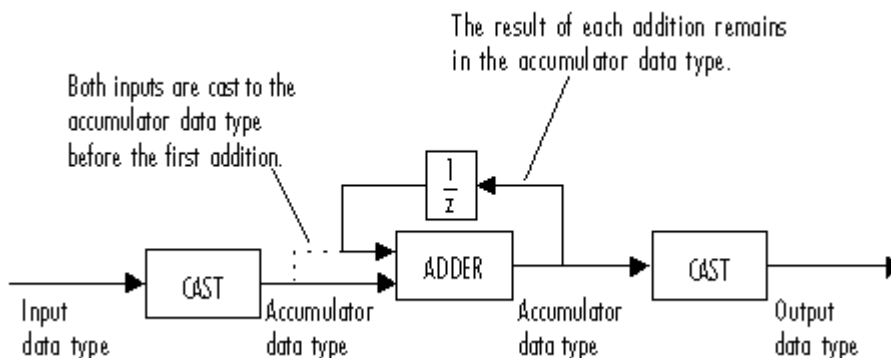

Rounding mode

Select the rounding mode for fixed-point operations.

Overflow mode

Select the overflow mode for fixed-point operations.

Accumulator

As depicted above, the elements of the block input are cast to the accumulator data type before they are added together. The output of the adder remains in the accumulator data type as each element of the input is added to it. Use this parameter to specify how you would like to designate this accumulator word and fraction lengths:

- When you select *Inherit via internal rule*, the accumulator word length and fraction length are calculated automatically. For information about how the accumulator word and fraction lengths are calculated when an internal rule is used, see “*Inherit via Internal Rule*”.
- When you select *Same as input*, these characteristics match those of the input to the block.

- When you select **Binary point scaling**, you can enter the word length and the fraction length of the accumulator, in bits.
- When you select **Slope and bias scaling**, you can enter the word length, in bits, and the slope of the accumulator. This block requires power-of-two slope and a bias of zero.

Output

Choose how you specify the output word length and fraction length:

- When you select **Same as accumulator**, these characteristics match those of the accumulator.
- When you select **Same as input**, these characteristics match those of the input to the block.
- When you select **Binary point scaling**, you can enter the word length and the fraction length of the output, in bits.
- When you select **Slope and bias scaling**, you can enter the word length, in bits, and the slope of the output. This block requires power-of-two slope and a bias of zero.

Lock scaling against changes by the autoscaling tool

Select this parameter to prevent any fixed-point scaling you specify in this block mask from being overridden by the autoscaling feature of the Fixed-Point Tool. See the `fxptdlg` reference page for more information.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Matrix Viewer

(To be removed) Display matrices as color images

Note The Matrix Viewer block will be removed in a future release. Use a different scope instead, see “Scopes and Data Logging”.

Library

Sinks

dspnks4

Description

The Matrix Viewer block displays an M -by- N matrix input by mapping the matrix element values to a specified range of colors. The display is updated as each new input is received. This block treats an unoriented length M vector input as an M -by-1 matrix.

You can use the Matrix Viewer block in models running in Normal or Accelerator simulation modes. The software does not support this block in models running in Rapid Accelerator or External mode. For more information about these modes, see “How Acceleration Modes Work” (Simulink) in the *Simulink User's Guide*.

Image Properties

Select the **Image Properties** tab to show the image property parameters, which control the colormap and display.

You specify the mapping of matrix element values to colors in the **Colormap matrix**, **Minimum input value**, and **Maximum input value** parameters. For a colormap with L colors, the colormap matrix has dimension L -by-3, with one row for each color and one column for each element of the RGB triple that defines the color. Examples of RGB triples are

```
[ 1  0  0 ] (red)
[ 0  0  1 ] (blue)
[0.8 0.8 0.8] (light gray)
```

MATLAB provides a number of functions for generating predefined colormaps, such as `hot`, `cool`, `bone`, and `autumn`. Each of these functions accepts the colormap size as an argument, and can be used in the **Colormap matrix** parameter. For example, when you specify `gray(128)` for the **Colormap matrix** parameter, the matrix is displayed in 128 shades of gray. The color in the first row of the colormap matrix represents the value specified by the **Minimum input value** parameter, and the color in the last row represents the value specified by the **Maximum input value** parameter.

Values between the minimum and maximum are quantized and mapped to the intermediate rows of the colormap matrix.

The documentation for the MATLAB `colormap` function provides complete information about specifying colormap matrices, and includes a complete list of the available colormap functions.

Axis Properties

Select the **Axis Properties** tab to show the axis property parameters, which control labeling and positioning.

The **Axis origin** parameter determines where the first element of the input matrix, $U(1,1)$, is displayed. When you specify **Upper left corner**, the matrix is displayed in matrix orientation, with $U(1,1)$ in the upper-left corner.

$$\begin{bmatrix} U_{11} & U_{12} & U_{13} & U_{14} \\ U_{21} & U_{22} & U_{23} & U_{24} \\ U_{31} & U_{32} & U_{33} & U_{34} \\ U_{41} & U_{42} & U_{43} & U_{44} \end{bmatrix}$$

When you specify **Lower left corner**, the matrix is flipped vertically to image orientation, with $U(1,1)$ in the lower-left corner.

$$\begin{bmatrix} U_{41} & U_{42} & U_{43} & U_{44} \\ U_{31} & U_{32} & U_{33} & U_{34} \\ U_{21} & U_{22} & U_{23} & U_{24} \\ U_{11} & U_{12} & U_{13} & U_{14} \end{bmatrix}$$

Axis zoom, when selected, causes the image display to completely fill the figure window. Axis titles are not displayed. This option can also be selected from the pop-up menu that is displayed when you right-click in the figure window. When **Axis zoom** is cleared, the axis labels and titles are displayed in a gray border surrounding the image axes.

To customize the axis tick range, set **Axis tick mode** to **User-defined** and specify a two-element row vector, [Minvalue Maxvalue], in **X-tick range** and **Y-tick range**. The matrix data does not change even when the axes ticks change. For example, consider displaying a matrix on axes with ticks ranging from 0 to 10. When you set **X-tick range** and **Y-tick range** to [0 1], the range of ticks changes from [0 10] to [0 1].

Figure Window

The image title in the figure title bar is the same as the block title. The axis tick marks reflect the size of the input matrix; the x-axis is numbered from 1 to N (number of columns), and the y-axis is numbered from 1 to M (number of rows).

Right-click the image in the figure window to access the following menu items:

- **Refresh** erases all data on the scope display except for the most recent image.
- **Autoscale** recomputes the minimum and maximum input values to fit the range of values observed in a series of 10 consecutive inputs. The numerical limits selected by the autoscale feature are shown in the **Minimum input value** and **Maximum input value** parameters, where you can make further adjustments to them manually.

- **Axis zoom**, when selected, causes the image to completely fill the figure window. Axis titles are not displayed. When **Axis zoom** is cleared, the axis labels and titles are displayed in a gray border surrounding the scope axes. This option can also be set in the Axis Properties pane of the parameter dialog box.
- **Colorbar**, when selected, displays a bar with the specified colormap to the right of the image axes.
- **Save Position** automatically updates the **Figure position** parameter in the **Axis Properties** pane to reflect the figure window's current position and size on the screen. To make the scope window open at a particular location on the screen when the simulation runs, drag the window to the desired location, resize it, and select **Save Position**. The parameter dialog box must be closed when you select **Save Position** for the **Figure position** parameter to be updated.

Dialog Box

The **Image Properties** pane of the Matrix Viewer block appears as follows.

Colormap matrix

A 3-column matrix defining the colormap as a set of RGB triples, or a call to a colormap-generating function such as `hot` or `spring`.

- See the `colormap` function for a list of colormap-generating functions.
- A color name or a short name: 'red' (or 'r'), 'green' (or 'g'), 'blue' (or 'b'), 'cyan' (or 'c'), 'magenta' (or 'm'), 'yellow' (or 'y'), 'black' (or 'k'), 'white' (or 'w').

- An RGB triplet specified as a 1-by-3 vector whose elements are the intensities of the red, green, and blue components of a color. The intensities must be in the range [0, 1]. For example, [0.7 0.8 1] specifies light blue.

Tunable (Simulink).

Minimum input value

The input value to be mapped to the color defined in the first row of the colormap matrix. Right-click in the figure window and select `Autoscale` from pop-up menu to set this parameter to the minimum value observed in a series of 10 consecutive matrix inputs. Tunable (Simulink).

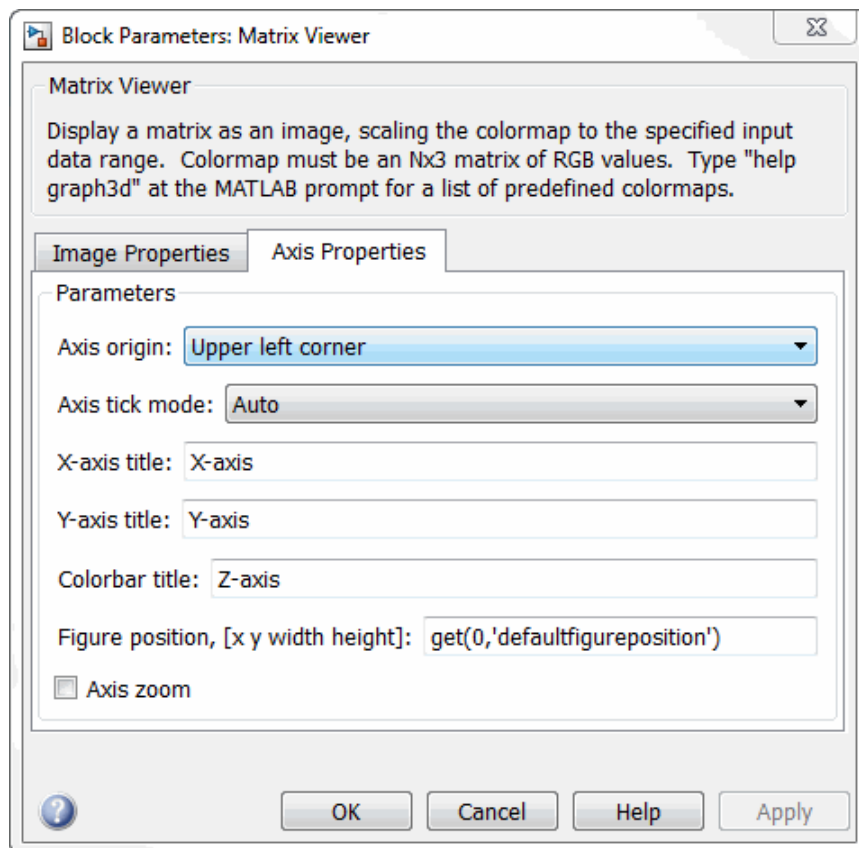

Maximum input value

The input value to be mapped to the color defined in the last row of the colormap matrix. Right-click in the figure window and select `Autoscale` from the pop-up menu to set this parameter to the maximum value observed in a series of 10 consecutive matrix inputs. Tunable (Simulink).

Display colorbar

Select to display a bar with the selected colormap to the right of the image axes. Tunable (Simulink).

The **Axis Properties** pane of the Matrix Viewer block appears as follows.

Axis origin

The position within the axes where the first element of the input matrix, $U(1,1)$, is plotted; bottom left or top left. Tunable (Simulink).

Axis tick mode

The mode used to specify the axis tick range. When you select **Auto**, the x-axis tick range and y-axis tick range are chosen based on the input signal. When you select **User-defined**, the axis tick range is set based on the values you specify in **X-tick range** and **Y-tick range**. The default is **Auto**.

X-tick range

x-axis tick range, specified as a two-element row vector of real scalars, $[X_{\min} \ X_{\max}]$. This parameter applies only when you set **Axis tick mode** to **User-defined**. When you change **X-tick range** during simulation, the axis range on the Matrix Viewer block updates in real time. The default is $[0 \ 1]$.

Y-tick range

y-axis tick range, specified as a two-element row vector of real scalars, $[Y_{\min} \ Y_{\max}]$. This parameter applies only when you set **Axis tick mode** to **User-defined**. When you change **Y-tick range** during simulation, the axis range on the Matrix Viewer block updates in real time. The default is $[0 \ 1]$.

X-axis title

The text to be displayed below the x-axis. Tunable (Simulink).

Y-axis title

The text to be displayed to the left of the y-axis. Tunable (Simulink).

Colorbar title

The text to be displayed to the right of the color bar, when **Display colorbar** is currently selected. Tunable (Simulink).

Figure position, [x y width height]

A 4-element vector of the form $[x \ y \ width \ height]$ specifying the position of the figure window, where $(0, 0)$ is the lower-left corner of the display. Tunable (Simulink).

Axis zoom

Resizes the image to fill the figure window. Tunable (Simulink).

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Version History

Maximum

Maximum values of input or sequence of inputs

Library: DSP System Toolbox / Statistics
 DSP System Toolbox HDL Support / Statistics

Description

The Maximum block identifies the value and position of the largest element in each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the maximum value of the entire input. The Maximum block can also track the maximum values in a sequence of inputs over a period of time. The **Mode** parameter specifies the block's mode of operation and can be set to one of the following:

- **Value** — The block outputs the maximum values in the specified dimension.
- **Index** — The block outputs the index array of the maximum values in the specified dimension.
- **Value and Index** — The block outputs the maximum values and the corresponding index array in the specified dimension.
- **Running** — The block tracks the maximum values in a sequence of inputs over a period of time.

You can specify the dimension using the **Find the maximum value over** parameter.

Note The **Running** mode in the Maximum block will be removed in a future release. To compute the running maximum in Simulink, use the Moving Maximum block instead.

Ports

Input

In — Data input

vector | matrix | *N*-D array

The block accepts real-valued or complex-valued multichannel and multidimensional inputs. The input can be floating-point, fixed-point, or Boolean. Real fixed-point inputs can be either signed or unsigned. Complex fixed-point inputs must be signed.

This port is unnamed until you set the **Mode** parameter to **Running** and the **Reset port** parameter to any option other than **None**.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Rst — Reset port

scalar

Specify the reset event that causes the block to reset the running maximum. The sample time of the **Rst** input must be a positive integer multiple of the input sample time.

Dependencies

To enable this port, set the **Mode** parameter to **Running** and the **Reset port** parameter to any option other than **None**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `Boolean`

Output

Val — Maximum values along the specified dimension

scalar | vector | matrix | N -D array

The data type of the maximum value matches the data type of the input.

When the **Mode** parameter is set to either **Value** and **Index** or **Value**, the following applies:

- The size of the dimension for which the block computes the maximum value is 1. The sizes of all other dimensions match those of the input array. For example, when the input is an M -by- N -by- P array, with the dimension set to 1, the block outputs a 1-by- N -by- P array. When the dimension is set to 3, the block outputs a two-dimensional M -by- N matrix.
- When the input is an M -by- N matrix, with the dimension set to 1, the block outputs a 1-by- N matrix.

If you specify the block to compute the maximum value over the entire input, the block outputs a scalar.

When the **Mode** parameter is set **Running**, the block tracks the maximum value of each channel in a time sequence of M -by- N inputs. In this mode, you must also specify the **Input processing** parameter as one of the following:

- **Elements as channels (sample based)** — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size M -by- N -by- P , the block outputs an M -by- N -by- P array. Each y_{ijk} element of the output contains the maximum value observed in element u_{ijk} for all inputs since the last reset.

When a reset event occurs, the running maximum y_{ijk} in the current frame is reset to the element u_{ijk} .

- **Columns as channels (frame based)** — The block treats each column of the input as a separate channel. This option does not support an N -dimensional input signal, where $N > 2$. For a two-dimensional input signal of size M -by- N , the block outputs an M -by- N matrix. Each element y_{ij} of the output contains the maximum value observed in the j th column of all inputs since the last reset, up to and including element u_{ij} of the current input.

When a reset event occurs, the running maximum for each channel becomes the maximum value of all the samples in the current input frame, up to and including the current input sample.

The block resets the running maximum whenever a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer multiple of the input sample time.

Dependencies

To enable this port, set the **Mode** parameter to either **Value** and **Index** or **Value**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Idx — Index of the maximum values along the specified dimension

`scalar` | `vector` | `matrix` | *N*-D array

When the input is `double`, the index values are also `double`. Otherwise, the index values are `uint32`.

Dependencies

To enable this port, set the **Mode** parameter to either `Value` and `Index` or `Index`.

Data Types: `double` | `uint32`

Parameters

Main Tab

Mode — Mode in which the block operates

`Value` and `Index` (default) | `Value` | `Index` | `Running`

When the **Mode** parameter is set to:

- **Value** — The block computes the maximum value in each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the maximum value of the entire input at each sample time, and outputs the array, *y*. Each element in the output is the maximum value in the corresponding column, row, vector, or entire input. The output *y* depends on the setting of the **Find the maximum value over** parameter. Consider a three dimensional input signal of size *M*-by-*N*-by-*P*. Set **Find the maximum value over** to:
 - **Each row** — The output *y* at each sample time consists of an *M*-by-1-by-*P* array, where each element contains the maximum value of each vector over the second dimension of the input. For an *M*-by-*N* matrix input, the output at each sample time is an *M*-by-1 column vector.
 - **Each column** — The output *y* at each sample time consists of a 1-by-*N*-by-*P* array, where each element contains the maximum value of each vector over the first dimension of the input. For an *M*-by-*N* matrix input, the output at each sample time is a 1-by-*N* row vector.

In this mode, the block treats length-*M* unoriented vector inputs as *M*-by-1 column vectors.

- **Entire input** — The output *y* at each sample time is a scalar that contains the maximum value in the *M*-by-*N*-by-*P* input matrix.
- **Specified dimension** — The output *y* at each sample time depends on **Dimension**. If **Dimension** is set to 1, the output is the same as when you select **Each column**. If **Dimension** is set to 2, the output is the same as when you select **Each row**. If **Dimension** is set to 3, the output at each sample time is an *M*-by-*N* matrix containing the maximum value of each vector over the third dimension of the input.

Complex Inputs

For complex inputs, the block selects the value in each row or column of the input, along vectors of a specified dimension of the input, or of the entire input that has the maximum magnitude squared as shown in the following figure. For complex value $u = a + bi$, the magnitude squared is $a^2 + b^2$.

- **Index** — The block computes the maximum value in each row or column of the input, along vectors of a specified dimension of the input, or of the entire input, and outputs the index array I . Each element in I is an integer indexing the maximum value in the corresponding column, row, vector, or entire input. The output I depends on the setting of the **Find the maximum value over** parameter. Consider a three-dimensional input signal of size M -by- N -by- P :
 - **Each row** — The output I at each sample time consists of an M -by-1-by- P array, where each element contains the index of the maximum value of each vector over the second dimension of the input. For an input that is an M -by- N matrix, the output at each sample time is an M -by-1 column vector.
 - **Each column** — The output I at each sample time consists of a 1-by- N -by- P array, where each element contains the index of the maximum value of each vector over the first dimension of the input. For an input that is an M -by- N matrix, the output at each sample time is a 1-by- N row vector.

In this mode, the block treats length- M unoriented vector inputs as M -by-1 column vectors.

- **Entire input** — The output I at each sample time is a 1-by-3 vector that contains the location of the maximum value in the M -by- N -by- P input matrix. For an input that is an M -by- N matrix, the output is a 1-by-2 vector.
- **Specified dimension** — The output I at each sample time depends on **Dimension**. If **Dimension** is set to 1, the output is the same as when you select **Each column**. If **Dimension** is set to 2, the output is the same as when you select **Each row**. If **Dimension** is set to 3, the output at each sample time is an M -by- N matrix containing the indices of the maximum values of each vector over the third dimension of the input.

When a maximum value occurs more than once, the computed index corresponds to the first occurrence. For example, when the input is the column vector $[3 \ 2 \ 1 \ 2 \ 3]'$, the computed one-based index of the maximum value is 1, rather than 5 when **Each column** is selected.

- **Value and Index** — The block outputs the maximum value in each row or column of the input, along vectors of a specified dimension of the input, or of the entire input, and the corresponding index array I .
- **Running** — The block tracks the maximum value of each channel in a time sequence of M -by- N inputs. In this mode, you must also specify the **Input processing** parameter as one of the following:
 - **Elements as channels (sample based)** — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size M -by- N -by- P , the block outputs an M -by- N -by- P array. Each y_{ijk} element of the output contains the maximum value observed in element u_{ijk} for all inputs since the last reset.

When a reset event occurs, the running maximum y_{ijk} in the current frame is reset to the element u_{ijk} .
 - **Columns as channels (frame based)** — The block treats each column of the input as a separate channel. This option does not support an N -dimensional input signal, where $N > 2$.

For a two-dimensional input signal of size M -by- N , the block outputs an M -by- N matrix. Each element y_{ij} of the output contains the maximum value observed in the j th column of all inputs since the last reset, up to and including element u_{ij} of the current input.

When a reset event occurs, the running maximum for each channel becomes the maximum value of all the samples in the current input frame, up to and including the current input sample.

The block resets the running maximum whenever a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer multiple of the input sample time.

Running Mode for Variable-Size Inputs

When the input is a variable-size signal, and you set the **Mode** to Running, then:

- If you set the **Input processing** parameter to Elements as channels (sample based), the state is reset.
- If you set the **Input processing** parameter to Columns as channels (frame based), then:
 - When the input size difference is in the number of channels (columns), the state is reset.
 - When the input size difference is in the length of channels (rows), there is no reset and the running operation is carried out as usual.

Index base — Base of the maximum value index

One (default) | Zero

Specify whether the index of the maximum value is reported using one-based or zero-based numbering.

Dependencies

To enable this parameter, set **Mode** to either Index or Value and Index.

Find the maximum value over — Dimension over which the block computes the maximum value

Each column (default) | Each row | Entire input | Specified dimension

- Each column — The block outputs the maximum value over each column.
- Each row — The block outputs the maximum value over each row.
- Entire input — The block outputs the maximum value over the entire input.
- Specified dimension — The block outputs the maximum value over the dimension, specified in the **Dimension** parameter.

Dependencies

To enable this parameter, set **Mode** to Value and Index, Value, or Index.

Dimension — Custom dimension

1 (default) | scalar

Specify the dimension (one-based value) of the input signal over which the block computes the maximum. The value of this parameter must be greater than 0 and less than the number of dimensions in the input signal.

Dependencies

To enable this parameter, set **Find the maximum value over** to Specified dimension.

Input processing — Method to process the input in running mode

Columns as channels (frame based) (default) | Elements as channels (sample based)

- **Columns as channels (frame based)** — The block treats each column of the input as a separate channel. This option does not support an N-dimensional input signal, where $N > 2$. For a two-dimensional input signal of size M -by- N , the block outputs an M -by- N matrix. Each element y_{ij} of the output contains the maximum value observed in the j th column of all inputs since the last reset, up to and including element u_{ij} of the current input.

When a reset event occurs, the running maximum for each channel becomes the maximum value of all the samples in the current input frame, up to and including the current input sample.

- **Elements as channels (sample based)** — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size M -by- N -by- P , the block outputs an M -by- N -by- P array. Each y_{ijk} element of the output contains the maximum value observed in element u_{ijk} for all inputs since the last reset.

When a reset event occurs, the running maximum y_{ijk} in the current frame is reset to the element u_{ijk} .

Dependencies

To enable this parameter, set **Mode** to Running.

Reset port — Reset event

None (default) | Rising edge | Falling edge | Either edge | Non-zero sample

The block resets the running maximum whenever a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer, which is a multiple of the input sample time.

- **None** — Disables the **Rst** port.
- **Rising edge** — Triggers a reset operation when the **Rst** input does one of the following:
 - Rises from a negative value to a positive value or zero.
 - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.

- **Falling edge** — Triggers a reset operation when the **Rst** input does one of the following:
 - Falls from a positive value to a negative value or zero.
 - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.

- **Either edge** — Triggers a reset operation when the **Rst** input is a Rising edge or Falling edge.
- **Non-zero sample** — Triggers a reset operation at each sample time that the **Rst** input is not zero.

Note When running simulations in the Simulink `MultiTasking` mode, reset signals have a one-sample latency. Therefore, when the block detects a reset event, there is a one-sample delay at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Dependencies

To enable this parameter, set **Mode** to `Running`.

Data Types Tab

Note To use these parameters, the data input must be complex and fixed-point.

Rounding mode — Method of rounding operation

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

Saturate on integer overflow — Method of overflow action

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

Product output — Product output data type

Inherit: Same as input (default) | fixdt([],16,0)

Product output specifies the data type of the output of a product operation in the Maximum block. For more information on the product output data type, see “Multiplication Data Types”.

- **Inherit: Same as input** — The block specifies the product output data type to be the same as the input data type.
- **fixdt([],16,0)** — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Product output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

Accumulator — Accumulator data type

Inherit: Same as product output (default) | Inherit: Same as input | fixdt([],16,0)

Accumulator specifies the data type of the output of an accumulation operation in the Maximum block.

- **Inherit: Same as product output** — The block specifies the accumulator data type to be the same as the product output data type.
- **Inherit: Same as input** — The block specifies the accumulator data type to be the same as the input data type.

- `fixdt([], 16, 0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

Algorithms

Maximum

When you set **Mode** to one of **Value**, **Index**, or **Value and Index**, and specify a dimension, the block produces results identical to the MATLAB `max` function, when it is called as `[y, I] = max(u, [], D)`.

- `u` is the data input.
- `D` is the dimension.
- `y` is the maximum value.
- `I` is the index of the maximum value.

The maximum value along the entire input is identical to calling the `max` function as `[y, I] = max(u(:))`.

Running Maximum

When you set **Mode** to **Running**, and **Input processing** to **Columns as channels (frame based)**, the block treats each column of the input as a separate channel. In this example, the block processes a two-channel signal with a frame size of three under these settings.

The block outputs the maximum value over each channel since the last reset. At $t = 2$, the reset event occurs. The maximum value in the second column changes to 6, even though 6 is less than 9, which was the maximum value since the previous reset event.

When you set **Mode** to Running, and **Input processing** to Elements as channels (sample based), the block treats each element of the input as a separate channel. In this example, the block processes a two-channel signal with a frame size of three under these settings.

Each y_{ij} element of the output contains the maximum value observed in element u_{ij} for all inputs since the last reset. The reset event occurs at $t = 2$. When a reset event occurs, the running maximum, y_{ij} , in the current frame is reset to element u_{ij} .

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has multi-cycle implementations that introduce additional latency in the generated code. To see the added latency, view the generated model or validation model. See “Generated Model and Validation Model” (HDL Coder).

Architecture	Additional cycles of latency	Description
default Tree	0	Generates a tree structure of comparators.
Cascade	1, when block has a single vector input port.	This implementation is optimized for latency * area, with medium speed. See “Cascade Architecture Best Practices” (HDL Coder).

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
InstantiateStages	Generate a VHDL® entity or Verilog® module for each cascade stage. The default is off. See also “InstantiateStages” (HDL Coder).
SerialPartition	Specify partitions for Cascade-serial implementations as a vector of the lengths of each partition. The default setting uses the minimum number of stages. See also “SerialPartition” (HDL Coder).

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

The parameters on the **Data Types Tab** of the block are used only for complex fixed-point inputs. The sum of the squares of the real and imaginary parts of such an input are formed before a comparison is made, as described under the 'Mode' parameter in “Main Tab” on page 2-874. The results of the squares of the real and imaginary parts are placed into the product output data type. The result of the sum of the squares is placed into the accumulator data type. These parameters are ignored for other types of inputs.

Blocks

Minimum | Moving Maximum | Moving Minimum | Mean

Mean

Find mean value of input or sequence of inputs

Library: DSP System Toolbox / Statistics

Description

The Mean block computes the mean of each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the mean of the entire input. You can specify the dimension using the **Find the mean value over** parameter. The Mean block can also track the mean value in a sequence of inputs over a period of time. To track the mean value in a sequence of inputs, select the **Running mean** parameter.

Note The **Running** mode in the Mean block will be removed in a future release. To compute the running mean in Simulink, use the Moving Average block instead.

Ports

Input

I — Data input

vector | matrix | N -D array

The block accepts real-valued or complex-valued multichannel and multidimensional inputs. The input data type must be double precision, single precision, integer, or fixed point with power-of-two slope and zero bias.

This port is unnamed until you select the **Running mean** parameter and set the **Reset port** parameter to any option other than **None**.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Rst — Reset port

scalar

Specify the reset event that causes the block to reset the running mean. The sample time of the **Rst** input must be a positive integer multiple of the input sample time.

Dependencies

To enable this port, select the **Running mean** parameter and set the **Reset port** parameter to any option other than **None**.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean

Output

Port_1 — Mean value along the specified dimension

scalar | vector | matrix | N -D array

The data type of the output matches the data type of the input.

When you do not select the **Running mean** parameter, the block computes the mean value in each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the mean of the entire input at each individual sample time. Each element in the output array y is the mean value of the corresponding column, row, or entire input. The output array y depends on the setting of the **Find the mean value over** parameter. Consider a three-dimensional input signal of size M -by- N -by- P . When you set **Find the mean value over** to:

- **Entire input** — The output at each sample time is a scalar that contains the mean value of the M -by- N -by- P input matrix.
- **Each row** — The output at each sample time consists of an M -by-1-by- P array, where each element contains the mean value of each vector over the second dimension of the input. For an M -by- N matrix input, the output at each sample time is an M -by-1 column vector.
- **Each column** — The output at each sample time consists of a 1-by- N -by- P array, where each element contains the mean value of each vector over the first dimension of the input. For an M -by- N matrix input, the output at each sample time is a 1-by- N row vector.

In this mode, the block treats length- M unoriented vector inputs as M -by-1 column vectors.

- **Specified dimension** — The output at each sample time depends on the value of the **Dimension** parameter. If you set the **Dimension** to 1, the output is the same as when you select **Each column**. If you set the **Dimension** to 2, the output is the same as when you select **Each row**. If you set the **Dimension** to 3, the output at each sample time is an M -by- N matrix containing the mean value of each vector over the third dimension of the input.

When you select **Running mean**, the block tracks the mean value of each channel in a time sequence of inputs. In this mode, you must also specify a value for the **Input processing** parameter.

- **Elements as channels (sample based)** — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size M -by- N -by- P , the block outputs an M -by- N -by- P array. Each element y_{ijk} of the output contains the mean value of the element u_{ijk} for all inputs since the last reset.

When a reset event occurs, the running mean y_{ijk} in the current frame is reset to the element u_{ijk} .

- **Columns as channels (frame based)** — The block treats each column of the input as a separate channel. This option does not support an N -dimensional input signal, where $N > 2$. For a two-dimensional input signal of size M -by- N , the block outputs an M -by- N matrix. Each element y_{ij} of the output contains the mean of the values in the j th column of all inputs since the last reset, up to and including the element u_{ij} of the current input.

When a reset event occurs, the running mean for each channel becomes the mean value of all the samples in the current input frame, up to and including the current input sample.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Main Tab

Running mean — Option to select running mean

off (default) | on

When you select the **Running mean** parameter, the block tracks the mean value of each channel in a time sequence of inputs.

Find the mean value over — Dimension over which the block computes the mean value

Each column (default) | Entire input | Each row | Specified dimension

- **Each column** — The block outputs the mean value over each column.
- **Each row** — The block outputs the mean value over each row.
- **Entire input** — The block outputs the mean value over the entire input.
- **Specified dimension** — The block outputs the mean value over the dimension, specified in the **Dimension** parameter.

Dependencies

To enable this parameter, clear the **Running mean** parameter.

Dimension — Custom dimension

1 (default) | scalar

Specify the dimension (one-based value) of the input signal over which the mean is computed. The value of this parameter must be greater than 0 and less than the number of dimensions in the input signal.

Dependencies

To enable this parameter, set **Find the mean value over** to **Specified dimension**.

Input processing — Method to process the input in running mode

Columns as channels (frame based) (default) | Elements as channels (sample based)

- **Columns as channels (frame based)** — The block treats each column of the input as a separate channel. This option does not support an N -dimensional input signal, where $N > 2$. For a two-dimensional input signal of size M -by- N , the block outputs an M -by- N matrix. Each element y_{ij} of the output contains the mean of the values in the j th column of all inputs since the last reset, up to and including the element u_{ij} of the current input.

When a reset event occurs, the running mean for each channel becomes the mean value of all the samples in the current input frame, up to and including the current input sample.

- **Elements as channels (sample based)** — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size M -by- N -by- P , the block outputs an M -by- N -by- P array. Each element y_{ijk} of the output contains the mean value of the element u_{ijk} for all inputs since the last reset.

When a reset event occurs, the running mean y_{ijk} in the current frame is reset to the element u_{ijk} .

Variable-Size Inputs

When your inputs are of variable size, and you select the **Running mean** parameter, then:

- If you set the **Input processing** parameter to **Elements as channels (sample based)**, the state is reset.
- If you set the **Input processing** parameter to **Columns as channels (frame based)**, then:
 - When the input size difference is in the number of channels (number of columns), the state is reset.
 - When the input size difference is in the length of channels (number of rows), there is no reset and the running operation is carried out as usual.

Dependencies

To enable this parameter, select the **Running mean** parameter.

Reset port — Reset event

None (default) | Rising edge | Falling edge | Either edge | Non-zero sample

The block resets the running mean whenever a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer multiple of the input sample time.

When a reset event occurs while the **Input processing** parameter is set to **Elements as channels (sample based)**, the running mean for each channel is initialized to the value in the corresponding channel of the current input. Similarly, when the **Input processing** parameter is set to **Columns as channels (frame based)**, the running mean for each channel becomes the mean value of all the samples in the current input frame, up to and including the current input sample.

Use this parameter to specify the reset event.

- **None** — Disables the **Rst** port.
- **Rising edge** — Triggers a reset operation when the **Rst** input does one of the following:
 - Rises from a negative value to either a positive value or zero.
 - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.

- **Falling edge** — Triggers a reset operation when the **Rst** input does one of the following:
 - Falls from a positive value to a negative value or zero.
 - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.

- **Either edge** — Triggers a reset operation when the **Rst** input is a Rising edge or Falling edge.
- **Non-zero sample** — Triggers a reset operation at each sample time, when the **Rst** input is not zero.

Note When running simulations in the Simulink multitasking mode, reset signals have a one-sample latency. Therefore, when the block detects a reset event, there is a one-sample delay at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Dependencies

To enable this parameter, select the **Running mean** parameter.

Data Types Tab

Note To use these parameters, the data input must be fixed-point. For all other inputs, the parameters on the **Data Types** tab are ignored.

Rounding mode — Method of rounding operation

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest

- Round
- Simplest
- Zero

For more details, see rounding mode.

Saturate on integer overflow — Method of overflow action

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

Accumulator — Accumulator data type

Inherit: Same as input (default) | fixdt([],16,0)

Accumulator specifies the data type of the output of an accumulation operation in the Mean block. See “Fixed Point” on page 2-893 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- **Inherit: Same as input** — The block specifies the accumulator data type to be the same as the input data type.
- **fixdt([],16,0)** — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

Output — Output data type

Inherit: Same as accumulator (default) | fixdt([],16,0)

Output specifies the data type of the output of the Mean block. See “Fixed Point” on page 2-893 for illustrations depicting the use of the output data type in this block. You can set it to:

- **Inherit: Same as accumulator** — The block specifies the output data type to be the same as the accumulator data type.
- **fixdt([],16,0)** — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

Output Minimum — Minimum value the block can output

[] (default) | scalar

Specify the minimum value that the block can output. The default value is [] (unspecified). Simulink uses this value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

Output Maximum — Maximum value the block can output

[] (default) | scalar

Specify the maximum value that the block can output. The default value is [] (unspecified). Simulink uses this value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block.

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

Algorithms

Mean

When you clear the **Running mean** parameter and specify a dimension, the block produces results identical to the MATLAB mean function, when it is called as $y = \text{mean}(u, D)$.

- u is the data input.
- D is the dimension.
- y is the mean value.

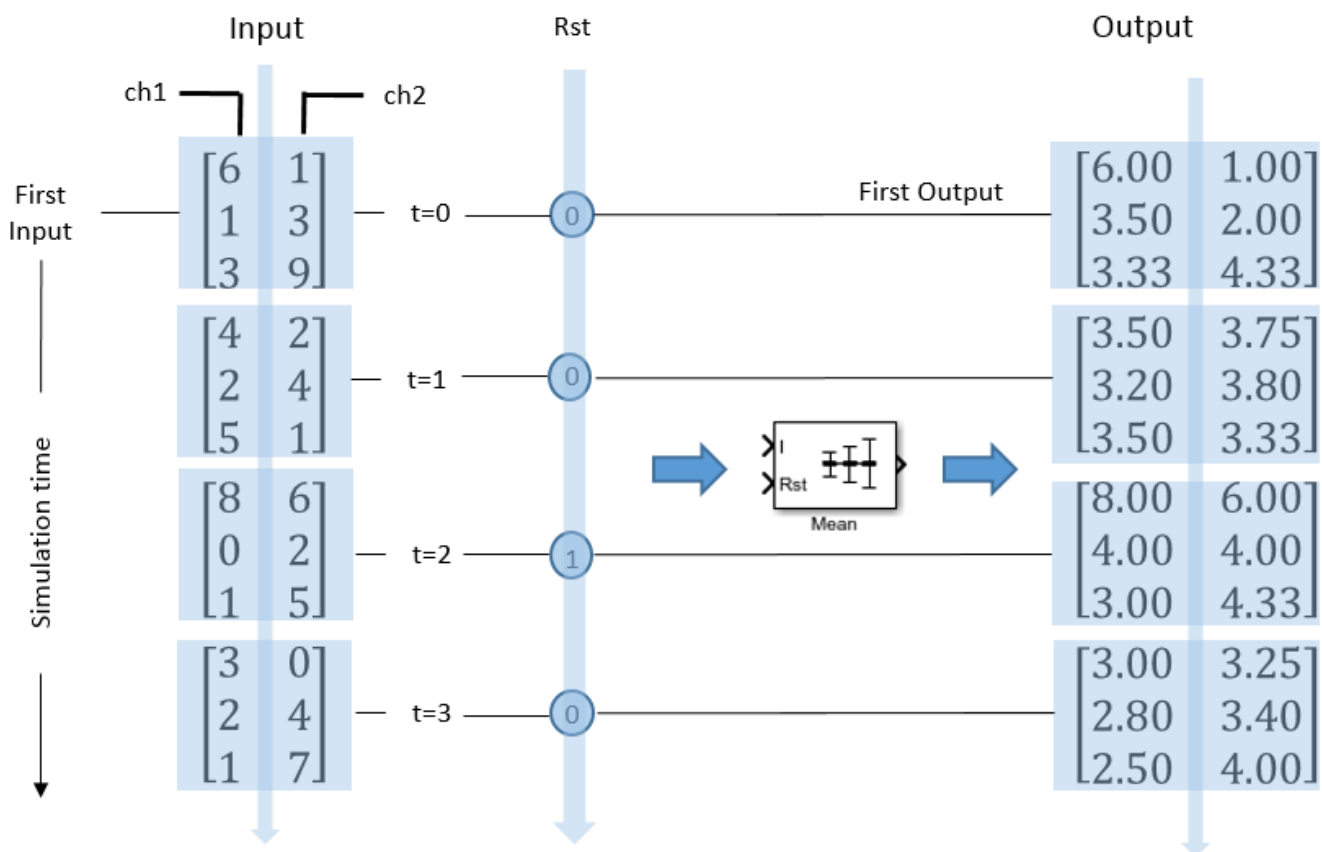

The mean value along the entire input is identical to calling the mean function as $y = \text{mean}(u(:))$.

The mean of a complex input is computed independently for the real and imaginary components.

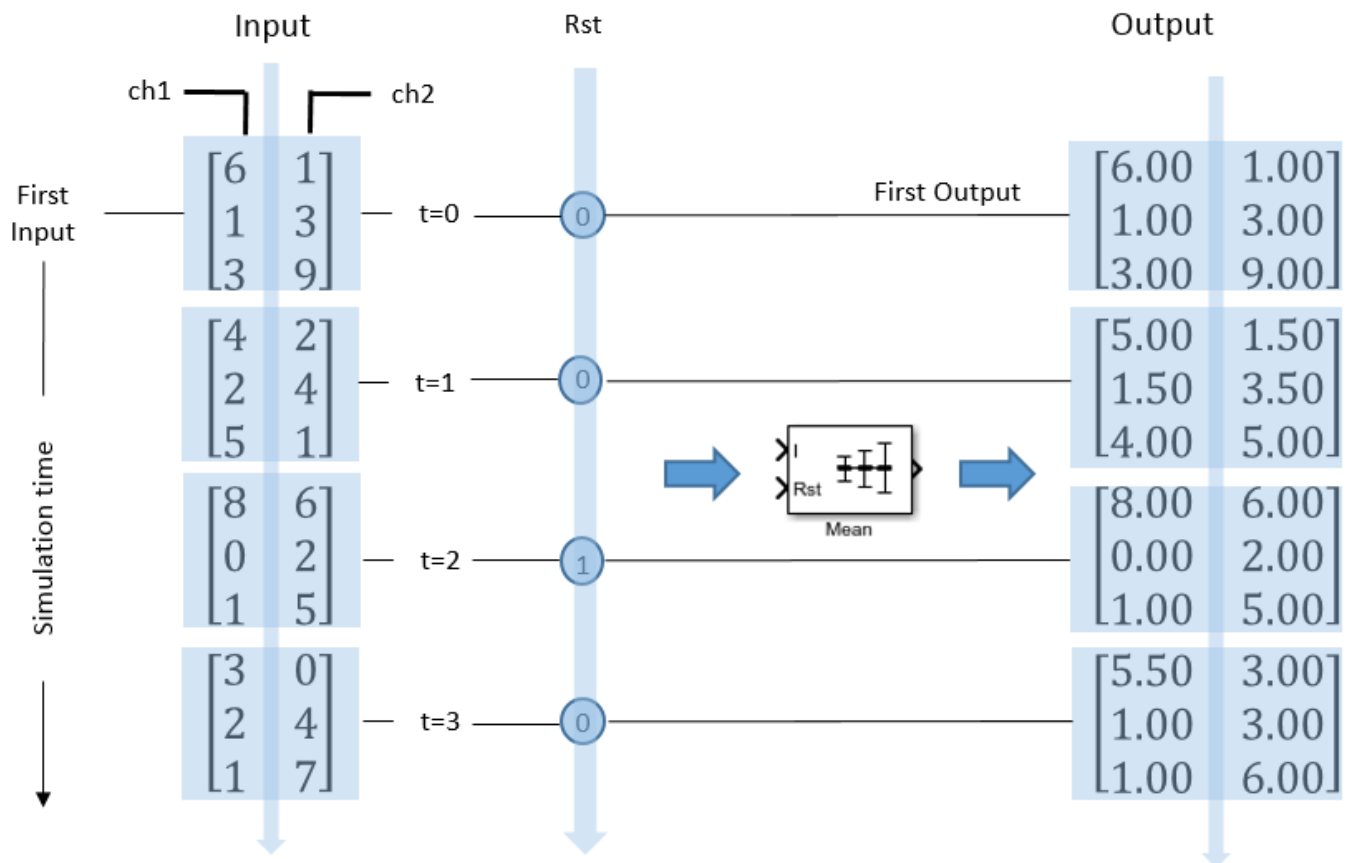

Running Mean

When you select the **Running mean** parameter, and set the **Input processing** parameter to Columns as channels (frame based), the block treats each column of the input as a separate channel. In this example, the block processes a two-channel signal with a frame size of three under these settings.

The block outputs the mean value over each channel since the last reset. At $t = 2$, the reset event occurs. The window of data in the second column now contains only 6.

When you select the **Running mean** parameter, and set the **Input processing** parameter to Elements as channels (sample based), the block treats each element of the input as a separate channel. In this example, the block processes a two-channel signal with a frame size of three under these settings.

Each y_{ij} element of the output contains the mean value observed in element u_{ij} for all inputs since the last reset. The reset event occurs at $t = 2$. When a reset event occurs, the running mean, y_{ij} , in the current frame is reset to element u_{ij} .

Functions

mean

Objects

`dsp.MovingAverage` | `dsp.MedianFilter`

Blocks

Moving Average | Maximum | Median | Median Filter | Minimum

Median

Median value of input

Library: DSP System Toolbox / Statistics

Description

The Median block computes the median of each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the median of the entire input. You can specify the dimension using the **Find the median value over** parameter. While computing the median, the block first sorts the input values. If the number of values is odd, the median is the middle value. If the number of values is even, the median is the average of the two middle values. To sort the data, you can specify the **Sort algorithm** parameter as either `Quick sort` or `Insertion sort`. The block sorts complex inputs according to their magnitude.

Ports

Input

Port_1 — Data input

vector | matrix | N -D array

The block accepts real-valued or complex-valued multichannel and multidimensional inputs. The input data type must be double precision, single precision, integer, or fixed point, with power-of-two slope and zero bias.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Output

Port_1 — Median value along specified dimension

vector | matrix | N -D array

The block computes the median value in each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the median of the entire input. Each element in the output array y is the median value of the corresponding column, row, or entire input. The output array y depends on the setting of the **Find the median value over** parameter.

Consider a three-dimensional input signal of size M -by- N -by- P . When you set **Find the median value over** to:

- **Entire input** — The output at each sample time is a scalar that contains the median value of the M -by- N -by- P input matrix.
- **Each row** — The output at each sample time consists of an M -by-1-by- P array, where each element contains the median value of each vector over the second dimension of the input. For an M -by- N matrix input, the output is an M -by-1 column vector.

- **Each column** — The output at each sample time consists of a 1-by- N -by- P array, where each element contains the median value of each vector over the first dimension of the input. For an M -by- N matrix input, the output at each sample time is a 1-by- N row vector.

In this mode, the block treats length- M unoriented vector inputs as M -by-1 column vectors.

- **Specified dimension** — The output at each sample time depends on the value of the **Dimension** parameter. If you set the **Dimension** to 1, the output is the same as when you select **Each column**. If you set the **Dimension** to 2, the output is the same as when you select **Each row**. If you set the **Dimension** to 3, the output at each sample time is an M -by- N matrix containing the median value of each vector over the third dimension of the input.

The data type of the output matches the data type of the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Parameters

Main Tab

Sort algorithm — Sort method

`Quick sort` (default) | `Insertion sort`

Specify the sorting algorithm as either `Quick sort` or `Insertion sort`.

Find the median value over — Dimension over which the median is computed

`Each column` (default) | `Entire input` | `Each row` | `Specified dimension`

- **Each column** — The block outputs the median value over each column.
- **Each row** — The block outputs the median value over each row.
- **Entire input** — The block outputs the median value over the entire input.
- **Specified dimension** — The block outputs the median value over the dimension specified in the **Dimension** parameter.

Dimension — Custom dimension

1 (default) | scalar

Specify the dimension (one-based value) of the input signal over which the block computes the median. The value of this parameter must be greater than 0 and less than or equal to the number of dimensions in the input signal.

Dependencies

To enable this parameter, set **Find the median value over** to `Specified dimension`.

Data Types Tab

Note To use these parameters, the data input must be fixed point. For all other inputs, the parameters on the **Data Types** tab are ignored.

Rounding mode — Method of rounding operation

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more details, see rounding mode.

Saturate on integer overflow — Method of overflow action

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

Product output — Product output data type

Inherit: Same as input (default) | fixdt([],16,0)

Specify the data type of the output of a product operation in the Median block. For more information, see “Fixed Point” on page 2-900 and “Multiplication Data Types”.

You can set this parameter to:

- **Inherit: Same as input** — The product output data type is the same as the input data type.
- **fixdt([],16,0)** — The product output data type is an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Product output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

Accumulator — Accumulator data type

Inherit: Same as product output (default) | Inherit: Same as input | fixdt([],16,0)

Specify the data type of the output of an accumulation operation in the Median block. For more details, see “Fixed Point” on page 2-900.

You can set this parameter to:

- **Inherit: Same as product output** — The accumulator data type is the same as the product output data type.
- **Inherit: Same as input** — The accumulator data type is the same as the input data type.
- **fixdt([],16,0)** — The accumulator data type is an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

Output — Output data type

Inherit: Same as accumulator (default) | Inherit: Same as input | Inherit: Same as product output | fixdt([],16,0)

Output specifies the data type of the output of the Median block. For more details, see “Fixed Point” on page 2-900.

You can set this parameter to:

- **Inherit: Same as accumulator** — The output data type is the same as the accumulator data type.
- **Inherit: Same as input** — The output data type is the same as the input data type.
- **Inherit: Same as product output** — The output data type is the same as the product output data type.
- **fixdt([],16,0)** — The output data type is an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

Output Minimum — Minimum output value

[] (default) | scalar

Specify the minimum value that the block can output. The default value is [] (unspecified). Simulink uses this value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

Output Maximum — Maximum output value

[] (default) | scalar

Specify the maximum value that the block can output. The default value is [] (unspecified). Simulink uses this value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block.

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

Algorithms

Median

The median of a set of data is calculated using the following steps:

- 1 The values are sorted using the specified sorting algorithm.
- 2 If the number of values is odd, the median is the middle value.
- 3 If the number of values is even, the median is the average of the two middle values.

The block produces results identical to the MATLAB `median` function when called as $y = \text{median}(u, D)$, where

- u is the data input.
- D is the dimension.
- y is the median value.

When the block calculates the median value along the entire input, the result is identical to calling the `median` function as $y = \text{median}(u(:))$.

When the input is complex, the block sorts the data according to the magnitude of each value. The magnitude in this case is defined as the sum of the squares of the real and imaginary components of the complex input.

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

For fixed-point inputs, you can specify the **Accumulator**, **Product output**, and **Output** data types in the block dialog box. Not all of these fixed-point parameters are applicable to all types of fixed-point inputs. The table shows when each kind of data type and scaling is used.

M is the length of the sorted data along the specified dimension. X indicates that the particular data type is applicable.

	Output data type	Accumulator data type	Product output data type
Even M	X	X	Not Applicable
Odd M	X	Not Applicable	Not Applicable
Odd M and complex	X	X	X
Even M and complex	X	X	X

When M is even, the **Accumulator** and **Output** data types and scalings are used for fixed-point signals. While calculating the average of the two central rows of the input matrix, the result of the sum is stored in the **Accumulator** data type and scaling. The total result of the average, which is the median of the data, is stored in the **Output** data type and scaling.

When the fixed-point inputs are complex, both the **Accumulator** and the **Product output** data types are used in addition to the **Output** data type. Before sorting the data, the block computes the sum of the squares of the real and imaginary components of the complex input. The results of the squares are stored in the **Product output** data type and scaling. The result of the sum of the squares is stored in the **Accumulator** data type and scaling.

For fixed-point inputs that are both complex and have even M , the **Accumulator** data type also stores the sum of the two central rows of the input matrix. The average of the two central rows, which is the median of the data, is stored in the **Output** data type.

Blocks

Median Filter | Hampel Filter | Variance | Standard Deviation | Sort | Minimum

Median Filter

Median filter

Library: DSP System Toolbox / Filtering / Filter Designs
 DSP System Toolbox / Statistics

Description

The Median Filter block computes the moving median of the input signal along each channel independently over time. The block uses the sliding window method to compute the moving median. In this method, a window of specified length moves over each channel sample by sample, and the block computes the median of the data in the window. This block performs median filtering on the input data over time. For more details, see “Algorithms” on page 2-902.

Input/Output Ports

Input

Port_1 — Data input

column vector | row vector | matrix

Data over which the block computes moving median. The block accepts real-valued or complex-valued multichannel inputs, that is, m -by- n size inputs, where $m \geq 1$, and $n \geq 1$. The block also accepts variable-size inputs. During simulation, you can change the size of each input channel. However, the number of channels cannot change.

Data Types: single | double

Output

Port_1 — Moving median output

column vector | row vector | matrix

The size of the moving median output matches the size of the input. The block uses the sliding window method to compute the moving median. For more details, see “Algorithms” on page 2-902.

Data Types: single | double

Parameters

Window length — Length of the sliding window

5 (default) | positive scalar integer

Window length specifies the length of the sliding window in samples.

Simulate using — Type of simulation to run

Code generation (default) | Interpreted execution

Specify the type of simulation to run as one of the following:

- **Code generation** -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than **Interpreted execution**.
- **Interpreted execution** -- Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than **Code generation**.

Block Characteristics

Data Types	double single
Multidimensional Signals	No
Variable-Size Signals	Yes

Algorithms

Sliding Window Method

In the sliding window method, the output for each input sample is the median of the current sample and the $Len - 1$ previous samples. Len is the length of the window in samples. To compute the first $Len - 1$ outputs, when the window does not have enough data yet, the algorithm fills the window with zeros. As an example, to compute the median value when the second input sample comes in, the algorithm fills the window with $Len - 2$ zeros. The data vector, x , is then the two data samples followed by $Len - 2$ zeros. This object performs median filtering on the input data over time.

Consider an example of computing the moving median of a streaming input data using the sliding window method. The algorithm uses a window length of 4. With each input sample that comes in, the window of length 4 moves along the data.

MIDI Controls

Output values from controls on MIDI control surface

Note In a future release, the MIDI Controls block will require Audio Toolbox.

Library

Sources

dspsrcs4

Description

The MIDI Controls block outputs values from controls on a MIDI control surface in real time.

Use the **MIDI device** parameter to specify the name of the MIDI control surface device from which to receive control values. You can choose:

- Default
- Specify other

If you choose **Default**, the block looks for a MATLAB preference with a group named `midi` and preference named `DefaultDevice`. You can set this preference using the MATLAB `setpref` function. For example, if the desired device is named `BCF2000`, you can type the following command at the MATLAB command line:

```
>> setpref('midi', 'DefaultDevice', 'BCF2000');
```

If the block does not find this preference, it then attempts to choose a device using an algorithm that is unspecified and platform dependent.

If you choose **Specify other**, then a **MIDI device name** edit box appears for you to enter a MATLAB expression for the device name. Enter any MATLAB expression that can evaluate to a string. Literal names must be enclosed in quotes, (for example, `'BCF2000'`).

You can determine the name of your MIDI device using `midiid`, discussed in “Identifying MIDI Device Names and Control Numbers” on page 2-906.

Use the **MIDI controls** parameter to specify the controls on the MIDI device to which the block should respond. This parameter also determines the size of the block output port. You can choose:

- Respond to any control

- Respond to specified controls

If you choose **Respond to any control**, then the block output will be a scalar. This scalar outputs the value from any and all controls that are manipulated on the MIDI device. Use this option in simple cases when you need only a single control value and the control to which it responds is unimportant.

If you choose **Respond to specified controls**, then a **MIDI control numbers** edit box opens. In this box, enter a MATLAB expression for the device control numbers. Enter any MATLAB expression that can evaluate to a row vector of real double-precision values. The block outputs a 1-D vector with one element corresponding to the output of each specified control.

Use the **Initial values** parameter to specify the value of the block output when simulation starts. The MIDI protocol transmits control values only when a control changes. This protocol provides no means for the block to query the current value of a control. Thus, the block must have some initial value to output until it receives a control change from the device.

Use the **Send initial values to device at start** check box to synchronize the device controls with the block outputs when simulation starts. Some MIDI control surfaces are bidirectional, meaning that they not only send control values but can also receive them. For example, some devices have motorized controls that move to the appropriate position when they receive a control value. If you have such a bidirectional device, select this check box. The block attempts to send the initial values to the device when the simulation starts. No diagnostic message appears if the attempt fails.

The generated code for this block relies on prebuilt .dll files. You can run this code outside the MATLAB environment, or redeploy. However you must account for these extra .dll files when doing so. The packNGo function creates a single .zip file containing all of the pieces required to run or rebuild this code. See packNGo for more information.

Output Port

The MIDI Controls block output is a vector whose width is determined by the **MIDI controls** and **MIDI control numbers** parameters previously described. The output data type can be either real double-precision floating point, or uint8 integer if the output mode is 'Raw MIDI'. The output values range from 0.0 to 1.0, inclusively, and in the raw mode, they range from 0 to 127, inclusively. The output port back inherits its sample time.

Identifying MIDI Device Names and Control Numbers

To specify a particular control on a particular MIDI device, you must know the name assigned to the device by the operating system. In addition, a number is always associated with the control. You can interactively discover this information using the MATLAB function, `midiid`. To use `midiid`, note that you will need to have the Audio Toolbox installed. Follow these steps to identify device names and control numbers:

- 1 Verify that MIDI control surface device is correctly connected to the host computer running MATLAB.

Note For the most consistent behavior, MathWorks recommends that you connect your MIDI control surface device to your computer before starting MATLAB. In some circumstances MATLAB may not be able to find your device if you connect it after starting your MATLAB session. Also, it may not find your device if you disconnect it and reconnect it during your MATLAB session.

- 2 Type the following command at the MATLAB command line.

```
>> [ctlnum devname] = midiid
```

You are prompted to move the control in which you are interested.

```
>> [ctlnum devname] = midiid
Move the control you wish to identify; type ^C to abort.
Waiting for control message ...
```

- 3 Move the control. `midiid` detects the movement and returns the device name and control number.

```
>> [ctlnum devname] = midiid
Move the control you wish to identify; type ^C to abort.
Waiting for control message ... done
ctlnum =
    1081
devname =
    BCF2000
>>
```

- 4 Use the device name in the block dialog, or set it as the default device using `setpref`. Then, enter the control number in the block dialog. Concatenate the number with other control numbers as needed.

Examples

How to Output Values from Controls

Use this example to familiarize yourself with how to set controls in the MIDI Controls block as it interacts with the MIDI control surface.

Open the `ex_simplemidi` model, and follow these steps:

Connect a MIDI device to the computer.

Use `midiid` to determine the name of the device, and set it on the MIDI Controls block.

Verify that any control changes the display value.

Use `midiid` to determine the number of a particular control, and set that on the MIDI Controls block.

Verify that a particular control changes the display value and that other controls do not.

Use `midiid` to determine the number of a few more controls, and set those on the MIDI Controls block.

Verify that the display block shows the correct number of values. Also verify that the controls you specified change the appropriate display values and that the other controls do not change the values.

Set each control to have a unique initial value.

Verify that the correct initial values appear on the display when the model starts.

If your MIDI device is bidirectional, on the MIDI Controls block, select the **Send initial values to device at start** check box.

Verify that the controls are set to the correct initial values when the model starts.

Parameters

MIDI device

Specify whether to use a default MIDI device, or specify a particular device by name.

MIDI device name

Specify the name of a particular MIDI control surface device from which to receive control values.

MIDI controls

Specify whether to respond to any control on the MIDI device or respond to particular specified controls.

MIDI control numbers

Specify particular controls to which the block should respond.

Initial values

Specify initial values to output when simulation starts.

Send initial values to device at start

Select this check box to attempt to synchronize a bidirectional MIDI device with block initial values when simulation starts.

Output mode

Specify the mode in which the control values are generated. When you set **Output mode** to **Normalized (0-1)**, the block generates control values in the range [0 1]. In this mode, control values are represented as a fraction of a full-scale. Hence, you can easily scale this range to your particular application. When you set **Output mode** to **RAW MIDI (0-127)**, the block generates byte-oriented MIDI control values in the range [0 127]. By default, this parameter is set to **Normalized (0-1)**.

Supported Data Types

Port	Supported Data Types
Output	<ul style="list-style-type: none"> Double-precision floating point, uint8 integer

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Host computer only. Excludes Simulink Desktop Real-Time code generation.

Minimum

Minimum values of input or sequence of inputs

Library: DSP System Toolbox / Statistics
 DSP System Toolbox HDL Support / Statistics

Description

The Minimum block identifies the value and position of the smallest element in each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the minimum value of the entire input. The Minimum block can also track the minimum values in a sequence of inputs over a period of time. The **Mode** parameter specifies the block's mode of operation and can be set to one of the following:

- **Value** — The block outputs the minimum values in the specified dimension.
- **Index** — The block outputs the index array of the minimum values in the specified dimension.
- **Value and Index** — The block outputs the minimum values and the corresponding index array in the specified dimension.
- **Running** — The block tracks the minimum values in a sequence of inputs over a period of time.

You can specify the dimension using the **Find the minimum value over** parameter.

Note The **Running** mode in the Minimum block will be removed in a future release. To compute the running minimum in Simulink, use the Moving Minimum block instead.

Ports

Input

In — Data input

vector | matrix | *N*-D array

The block accepts real-valued or complex-valued multichannel and multidimensional inputs. The input can be floating-point, fixed-point, or Boolean. Real fixed-point inputs can be either signed or unsigned. Complex fixed-point inputs must be signed.

This port is unnamed until you set the **Mode** parameter to **Running** and the **Reset port** parameter to any option other than **None**.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Rst — Reset port

scalar

Specify the reset event that causes the block to reset the running minimum. The sample time of the **Rst** input must be a positive integer multiple of the input sample time.

Dependencies

To enable this port, set the **Mode** parameter to **Running** and the **Reset port** parameter to any option other than **None**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

Output

Val — Minimum values along the specified dimension

scalar | vector | matrix | N -D array

The data type of the minimum value matches the data type of the input.

When the **Mode** parameter is set to either **Value** and **Index** or **Value**, the following applies:

- The size of the dimension for which the block computes the minimum value is 1. The sizes of all other dimensions match those of the input array. For example, when the input is an M -by- N -by- P array, with the dimension set to 1, the block outputs a 1-by- N -by- P array. When the dimension is set to 3, the block outputs a two-dimensional M -by- N matrix.
- When the input is an M -by- N matrix, with the dimension set to 1, the block outputs a 1-by- N matrix.

If you specify the block to compute the minimum value over the entire input, the block outputs a scalar.

When the **Mode** parameter is set **Running**, the block tracks the minimum value of each channel in a time sequence of M -by- N inputs. In this mode, you must also specify the **Input processing** parameter as one of the following:

- **Elements as channels (sample based)** — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size M -by- N -by- P , the block outputs an M -by- N -by- P array. Each y_{ijk} element of the output contains the minimum value observed in element u_{ijk} for all inputs since the last reset.

When a reset event occurs, the running minimum y_{ijk} in the current frame is reset to the element u_{ijk} .

- **Columns as channels (frame based)** — The block treats each column of the input as a separate channel. This option does not support an N -dimensional input signal, where $N > 2$. For a two-dimensional input signal of size M -by- N , the block outputs an M -by- N matrix. Each element y_{ij} of the output contains the minimum value observed in the j th column of all inputs since the last reset, up to and including element u_{ij} of the current input.

When a reset event occurs, the running minimum for each channel becomes the minimum value of all the samples in the current input frame, up to and including the current input sample.

The block resets the running minimum whenever a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer multiple of the input sample time.

Dependencies

To enable this port, set the **Mode** parameter to either **Value** and **Index** or **Value**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Idx — Index of the minimum values along the specified dimension

scalar | vector | matrix | *N*-D array

When the input is `double`, the index values are also `double`. Otherwise, the index values are `uint32`.

Dependencies

To enable this port, set the **Mode** parameter to either `Value` and `Index` or `Index`.

Data Types: `double` | `uint32`

Parameters

Main Tab

Mode — Mode in which the block operates

`Value` and `Index` (default) | `Value` | `Index` | `Running`

When the **Mode** parameter is set to:

- **Value**— The block computes the minimum value in each row or column of the input, along vectors of a specified dimension of the input, or of the entire input at each sample time, and outputs the array *y*. Each element in *y* is the minimum value in the corresponding column, row, vector, or entire input. The output *y* depends on the setting of the **Find the minimum value over** parameter. Consider a three dimensional input signal of size *M*-by-*N*-by-*P*. Set **Find the minimum value over** to:
 - **Each row** — The output *y* at each sample time consists of an *M*-by-1-by-*P* array, where each element contains the minimum value of each vector over the second dimension of the input. For an input that is an *M*-by-*N* matrix, the output at each sample time is an *M*-by-1 column vector.
 - **Each column** — The output *y* at each sample time consists of a 1-by-*N*-by-*P* array, where each element contains the minimum value of each vector over the first dimension of the input. For an input that is an *M*-by-*N* matrix, the output at each sample time is a 1-by-*N* row vector.

In this mode, the block treats length-*M* unoriented vector inputs as *M*-by-1 column vectors.
- **Entire input** — The output *y* at each sample time is a scalar that contains the minimum value in the *M*-by-*N*-by-*P* input matrix.
- **Specified dimension** — The output *y* at each sample time depends on **Dimension**. If **Dimension** is set to 1, the output is the same as when you select **Each column**. If **Dimension** is set to 2, the output is the same as when you select **Each row**. If **Dimension** is set to 3, the output at each sample time is an *M*-by-*N* matrix containing the minimum value of each vector over the third dimension of the input.

Complex Inputs

For complex inputs, the block selects the value in each row or column of the input, along vectors of a specified dimension of the input, or of the entire input that has the minimum magnitude squared in the following figure. For complex value $u = a + bi$, the magnitude squared is $a^2 + b^2$.

- **Index** — The block computes the minimum value in each row or column of the input, along vectors of a specified dimension of the input, or of the entire input, and outputs the index array I . Each element in I is an integer indexing the minimum value in the corresponding column, row, vector, or entire input. The output I depends on the setting of the **Find the minimum value over** parameter. Consider a three dimensional input signal of size M -by- N -by- P :
 - **Each row** — The output I at each sample time consists of an M -by-1-by- P array, where each element contains the index of the minimum value of each vector over the second dimension of the input. For an input that is an M -by- N matrix, the output at each sample time is an M -by-1 column vector.
 - **Each column** — The output I at each sample time consists of a 1-by- N -by- P array, where each element contains the index of the minimum value of each vector over the first dimension of the input. For an input that is an M -by- N matrix, the output at each sample time is a 1-by- N row vector.

In this mode, the block treats length- M unoriented vector inputs as M -by-1 column vectors.

- **Entire input** — The output I at each sample time is a 1-by-3 vector that contains the location of the minimum value in the M -by- N -by- P input matrix. For an input that is an M -by- N matrix, the output is a 1-by-2 vector.
- **Specified dimension** — The output I at each sample time depends on **Dimension**. If **Dimension** is set to 1, the output is the same as when you select **Each column**. If **Dimension** is set to 2, the output is the same as when you select **Each row**. If **Dimension** is set to 3, the output at each sample time is an M -by- N matrix containing the indices of the minimum values of each vector over the third dimension of the input.

When a minimum value occurs more than once, the computed index corresponds to the first occurrence. For example, when the input is the column vector $[3 \ 2 \ 1 \ 2 \ 3]'$, the computed one-based index of the minimum value is 1, rather than 5 when **Each column** is selected.

- **Value and Index** — The block outputs the minimum value in each row or column of the input, along vectors of a specified dimension of the input, or of the entire input, and the corresponding index array I .
- **Running** — The block tracks the minimum value of each channel in a time sequence of M -by- N inputs. The block resets the running minimum whenever a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer multiple of the input sample time. In this mode, you must also specify the **Input processing** parameter as one of the following:
 - **Elements as channels (sample based)** — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size M -by- N -by- P , the block outputs an M -by- N -by- P array. Each y_{ijk} element of the output contains the minimum value observed in element u_{ijk} for all inputs since the last reset.

When a reset event occurs, the running minimum y_{ijk} in the current frame is reset to the element u_{ijk} .

- **Columns as channels (frame based)** — The block treats each column of the input as a separate channel. This option does not support an N -dimensional input signal, where $N > 2$. For a two-dimensional input signal of size M -by- N , the block outputs an M -by- N matrix. Each element y_{ij} of the output contains the minimum value observed in the j th column of all inputs since the last reset, up to and including element u_{ij} of the current input.

When a reset event occurs, the running minimum for each channel becomes the minimum value of all the samples in the current input frame, up to and including the current input sample.

The block resets the running minimum whenever a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer multiple of the input sample time.

Running Mode for Variable-Size Inputs

When the input is a variable-size signal, and you set the **Mode** to **Running**, then:

- If you set the **Input processing** parameter to **Elements as channels (sample based)**, the state is reset.
- If you set the **Input processing** parameter to **Columns as channels (frame based)**, then:
 - When the input size difference is in the number of channels (columns), the state is reset.
 - When the input size difference is in the length of channels (rows), there is no reset and the running operation is carried out as usual.

Index base — Base of the minimum value index

One (default) | Zero

Specify whether the index of the minimum value is reported using one-based or zero-based numbering.

Dependencies

To enable this parameter, set **Mode** to either **Index** or **Value** and **Index**.

Find the minimum value over — Dimension over which the block computes the minimum value

Each column (default) | Each row | Entire input | Specified dimension

- **Each column** — The block outputs the minimum value over each column.
- **Each row** — The block outputs the minimum value over each row.
- **Entire input** — The block outputs the minimum value over the entire input.
- **Specified dimension** — The block outputs the minimum value over the dimension specified in the **Dimension** parameter.

Dependencies

To enable this parameter, set **Mode** to **Value** and **Index**, **Value**, or **Index**.

Dimension — Custom dimension

1 (default) | scalar

Specify the dimension (one-based value) of the input signal over which the block computes the minimum. The value of this parameter must be greater than 0 and less than the number of dimensions in the input signal.

Dependencies

To enable this parameter, set **Find the minimum value over** to Specified dimension.

Input processing — Method to process the input in running mode

Columns as channels (frame based) (default) | Elements as channels (sample based)

- **Columns as channels (frame based)** — The block treats each column of the input as a separate channel. This option does not support an N -dimensional input signal, where $N > 2$. For a two-dimensional input signal of size M -by- N , the block outputs an M -by- N matrix. Each element y_{ij} of the output contains the minimum value observed in the j th column of all inputs since the last reset, up to and including element u_{ij} of the current input.

When a reset event occurs, the running minimum for each channel becomes the minimum value of all the samples in the current input frame, up to and including the current input sample.

- **Elements as channels (sample based)** — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size M -by- N -by- P , the block outputs an M -by- N -by- P array. Each y_{ijk} element of the output contains the minimum value observed in element u_{ijk} for all inputs since the last reset.

When a reset event occurs, the running minimum y_{ijk} in the current frame is reset to the element u_{ijk} .

Dependencies

To enable this parameter, set **Mode** to Running.

Reset port — Reset event

None (default) | Rising edge | Falling edge | Either edge | Non-zero sample

The block resets the running minimum whenever a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer which is a multiple of the input sample time.

- **None** — Disables the **Rst** port.
- **Rising edge** — Triggers a reset operation when the **Rst** input does one of the following:
 - Rises from a negative value to a positive value or zero.
 - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.

- **Falling edge** — Triggers a reset operation when the **Rst** input does one of the following:
 - Falls from a positive value to a negative value or zero.
 - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.

- **Either edge** — Triggers a reset operation when the **Rst** input is a Rising edge or Falling edge.
- **Non-zero sample** — Triggers a reset operation at each sample time that the **Rst** input is not zero.

Note When running simulations in the Simulink `MultiTasking` mode, reset signals have a one-sample latency. Therefore, when the block detects a reset event, there is a one-sample delay at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Dependencies

To enable this parameter, set **Mode** to `Running`.

Data Types Tab

Note To use these parameters, the data input must be complex fixed-point.

Rounding mode — Method of rounding operation

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

Saturate on integer overflow — Method of overflow action

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

Product output — Product output data type

Inherit: Same as input (default) | fixdt([],16,0)

Product output specifies the data type of the output of a product operation in the Minimum block. For more information on the product output data type, see “Multiplication Data Types”.

- **Inherit: Same as input** — The block specifies the product output data type to be the same as the input data type.
- **fixdt([],16,0)** — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Product output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

Accumulator — Accumulator data type

Inherit: Same as product output (default) | Inherit: Same as input | fixdt([],16,0)

Accumulator specifies the data type of the output of an accumulation operation in the Minimum block.

- **Inherit: Same as product output** — The block specifies the accumulator data type to be the same as the product output data type.
- **Inherit: Same as input** — The block specifies the accumulator data type to be the same as the input data type.

- `fixdt([], 16, 0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

Algorithms

Minimum

When you set **Mode** to one of Value, Index, or Value and Index, and specify a dimension, the block produces results identical to the MATLAB `min` function, when it is called as `[y, I] = min(u, [], D)`.

- `u` is the data input.
- `D` is the dimension.
- `y` is the minimum value.
- `I` is the index of the minimum value.

The minimum value along the entire input is identical to calling the `min` function as `[y, I] = min(u(:))`.

Running Minimum

When you set **Mode** to Running, and **Input processing** to Columns as channels (frame based), the block treats each column of the input as a separate channel. In this example, the block processes a two-channel signal with a frame size of three under these settings.

The block outputs the minimum value over each channel since the last reset. At $t = 2$, the reset event occurs. The minimum value in the second column changes to 6, and then 2, even though these values are greater than 1, which was the minimum value since the previous reset event.

When you set **Mode** to Running, and **Input processing** to Elements as channels (sample based), the block treats each element of the input as a separate channel. In this example, the block processes a two-channel signal with a frame size of three under these settings.

Each element y_{ij} of the output contains the minimum value observed in element u_{ij} for all inputs since the last reset. The reset event occurs at $t = 2$. When a reset event occurs, the running minimum, y_{ij} , in the current frame is reset to the element u_{ij} .

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has multi-cycle implementations that introduce additional latency in the generated code. To see the added latency, view the generated model or validation model. See “Generated Model and Validation Model” (HDL Coder).

Architecture	Additional cycles of latency	Description
default Tree	0	Generates a tree structure of comparators.
Cascade	1, when block has a single vector input port.	This implementation is optimized for latency * area, with medium speed. See “Cascade Architecture Best Practices” (HDL Coder).

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
InstantiateStages	Generate a VHDL entity or Verilog module for each cascade stage. The default is off. See also “InstantiateStages” (HDL Coder).
SerialPartition	Specify partitions for Cascade-serial implementations as a vector of the lengths of each partition. The default setting uses the minimum number of stages. See also “SerialPartition” (HDL Coder).

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

The parameters on the **Data Types Tab** of the block are used only for complex fixed-point inputs. The sum of the squares of the real and imaginary parts of such an input are formed before a comparison is made, as described under the 'Mode' parameter in “Main Tab” on page 2-912. The results of the squares of the real and imaginary parts are placed into the product output data type. The result of the sum of the squares is placed into the accumulator data type. These parameters are ignored for other types of inputs.

Modified Covariance AR Estimator

Compute estimate of autoregressive (AR) model parameters using modified covariance method

Library

Estimation / Parametric Estimation

dspparest3

Description

The Modified Covariance AR Estimator block uses the modified covariance method to fit an autoregressive (AR) model to the input data. This method minimizes the forward and backward prediction errors in the least squares sense. The input is a frame of consecutive time samples, which is assumed to be the output of an AR system driven by white noise. The block computes the normalized estimate of the AR system parameters, $A(z)$, independently for each successive input.

$$H(z) = \frac{G}{A(z)} = \frac{G}{1 + a(2)z^{-1} + \dots + a(p+1)z^{-p}}$$

You specify the order, p , of the all-pole model in the **Estimation order** parameter. To guarantee a valid output, you must set the **Estimation order** parameter to be less than or equal to two thirds the input vector length.

The output port labeled A outputs the normalized estimate of the AR model coefficients in descending powers of z .

[1 a(2) ... a(p+1)]

The scalar gain, G , is output from the output port labeled G.

See the Burg AR Estimator block reference page for a comparison of the Burg AR Estimator, Covariance AR Estimator, Modified Covariance AR Estimator, and Yule-Walker AR Estimator blocks.

Parameters

Estimation order

Specify the order of the AR model, p .

Modified Covariance Method

Power spectral density estimate using modified covariance method

Library

Estimation / Power Spectrum Estimation

dspspect3

Description

The Modified Covariance Method block estimates the power spectral density (PSD) of the input using the modified covariance method. This method fits an autoregressive (AR) model to the signal. It does so by minimizing the forward and backward prediction errors in the least squares sense. The **Estimation order** parameter value specifies the order of the all-pole model. To guarantee a valid output, the **Estimation order** parameter must be less than or equal to two thirds of the input vector length. The block computes the spectrum from the FFT of the estimated AR model parameters.

The input must be a column vector. This input represents a frame of consecutive time samples from a single-channel signal. The block outputs a column vector containing the estimate of the power spectral density of the signal at N_{fft} equally spaced frequency points. The frequency points are in the range $[0, F_s)$, where F_s is the sampling frequency of the signal.

Selecting **Inherit FFT length from estimation order**, specifies that N_{fft} is one greater than the estimation order. Clearing the **Inherit FFT length from estimation order** parameter allows you to use the **FFT length** parameter to specify N_{fft} as a power of 2. The block zero-pads or wraps the input to N_{fft} before computing the FFT.

When you select the **Inherit sample time from input** check box, the block computes the frequency data from the sample period of the input signal. For the block to produce valid output, the following conditions must hold:

- The input to the block is the original signal, with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** check box. You can then specify a sample time using the **Sample time of original time series** parameter.

See the Burg Method block reference for a comparison of the Burg Method, Covariance Method, Modified Covariance Method, and Yule-Walker Method blocks.

Parameters

Estimation order

Specify the order of the AR model. To guarantee a valid output, the **Estimation order** parameter must be less than or equal to two thirds of the input vector length.

Inherit FFT length from estimation order

When you select this check box, the option specifies that the FFT length is one greater than the estimation order. To specify the number of points on which to perform the FFT, clear this check box. You can then specify a power of two FFT length using the **FFT length** parameter.

FFT length

Enter the number of data points, N_{fft} , on which to perform the FFT. When N_{fft} is larger than the input frame size, the block zero-pads each frame as needed. When N_{fft} is smaller than the input frame size, the block wraps each frame as needed. This parameter becomes visible only when you clear the **Inherit FFT length from estimation order** check box.

Inherit sample time from input

If you select the **Inherit sample time from input** check box, the block computes the frequency data from the sample period of the input signal. For the block to produce valid output, the following conditions must hold:

- The input to the block is the original signal, with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** check box. You can then specify a sample time using the **Sample time of original time series** parameter.

Sample time of original time series

Specify the sample time of the original time-domain signal. This parameter becomes visible only when you clear the **Inherit sample time from input** check box.

Moving Average

Moving average

Library: DSP System Toolbox / Statistics

Description

The Moving Average block computes the moving average of the input signal along each channel independently over time. The block uses the sliding window method or the exponential weighting method to compute the moving average. In the sliding window method, a window of specified length moves over the data sample by sample, and the block computes the average over the data in the window. In the exponential weighting method, the block multiplies the data samples with a set of weighting factors and then sums the weighted data to compute the average. For more details on these methods, see “Algorithms” on page 2-932.

Input/Output Ports

Input

x — Data input

vector | matrix

The block computes the moving average of the data specified at this input port. Specify real- or complex-valued multichannel inputs of the size m -by- n , where $m \geq 1$ and $n \geq 1$.

When the **Allow arbitrary frame length for fixed-size input signals** parameter appears and is not selected, and you input a fixed-size signal, the frame length must be a multiple of the hop size (window length – overlap length). In all other cases, the input frame length can be arbitrary.

The block accepts variable-size inputs (frame length changes during simulation). When you input a variable-size signal, the frame length of the signal can be arbitrary.

This port is unnamed until you set **Method** to Exponential weighting and select the **Specify forgetting factor from input port** parameter.

Data Types: single | double

Lambda — Forgetting factor

positive real scalar in the range (0,1]

The forgetting factor determines how much weight past data is given. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory – all previous samples are given an equal weight.

Dependencies

This port appears when you set **Method** to Exponential weighting and select the **Specify forgetting factor from input port** parameter.

Data Types: `single` | `double`

Output

Port_1 — Moving average output

`vector` | `matrix`

Moving average, returned as a vector or a matrix. The block computes the moving average based on the **Method** parameter settings using either the sliding window method or the exponential weighting method. For more details, see “Algorithms” on page 2-932.

This table provides more details on the dimensions of the output signal.

Input Signal	Input Dimensions	Output Dimensions When Allow arbitrary frame length for fixed-size input signals Appears	Output Dimensions When Allow arbitrary frame length for fixed-size input signals Does Not Appear
Fixed-size signal	m -by- n , where m is a multiple of the hop size (window length – overlap length)	$(m/\text{hop size})$ -by- n	m -by- n
Fixed-size signal	m -by- n , where m is not a multiple of the hop size (window length – overlap length)	$\text{ceil}(m/\text{hop size})$ -by- n when you select Allow arbitrary frame length for fixed-size input signals If you do not select Allow arbitrary frame length for fixed-size input signals , the block errors.	m -by- n
Variable-size signal	m -by- n	$\text{ceil}(m/\text{hop size})$ -by- n	m -by- n

When the output has an upper bound size of $\text{ceil}(m/\text{hop size})$ -by- n , during simulation, the size of the first dimension varies within this bound and the size of the second dimension remains constant. For an example that shows this behavior, see “Compute Moving Average of Noisy Step Signal”.

Data Types: `single` | `double`

Parameters

If a parameter is listed as tunable, then you can change its value during simulation.

Method — Averaging method

`Sliding window (default)` | `Exponential weighting`

- **Sliding window** — A window of length **Window length** moves over the input data along each channel. For every sample the window moves over, the block computes the average over the data in the window.

- **Exponential weighting** — The block multiplies the samples by a set of weighting factors. The magnitude of the weighting factors decreases exponentially as the age of the data increases, but the magnitude never reaches zero. To compute the average, the algorithm sums the weighted data.

Specify window length — Flag to specify window length

on (default) | off

When you select this check box, the length of the sliding window is equal to the value you specify in **Window length**. When you clear this check box, the length of the sliding window is infinite. In this mode, the block computes the average of the current sample and all previous samples in the channel.

Dependencies

To enable this parameter, set **Method** to `Sliding window`.

Window length — Length of sliding window

4 (default) | positive scalar integer

Specifies the length of the sliding window in samples.

Dependencies

To enable this parameter, set **Method** to `Sliding window` and select the **Specify window length** check box.

Overlap length — Overlap length between windows

3 (default) | nonnegative integer

Specify the overlap length between sliding windows as a nonnegative integer. The value of overlap length varies in the range $[0, \mathbf{Window\ length} - 1]$.

Dependencies

To enable this parameter, set **Method** to `Sliding window` and select the **Specify window length** check box.

Allow arbitrary frame length for fixed-size input signals — Allow arbitrary frame length for fixed-size input signals

off (default) | on

Specify whether fixed-size input signals (whose size does not change during simulation) can have an arbitrary frame length, where the frame length does not have to be a multiple of the hop size. Hop size is defined as **Window length** – **Overlap length**. The block uses this parameter setting only for fixed-size input signals and ignores this parameter if the input has a variable-size.

When the input signal is a variable-size signal, the signal can have arbitrary frame length, that is, the frame length does not have to be a multiple of the hop size.

For fixed-size input signals, if you:

- Select the **Allow arbitrary frame length for fixed-size input signals** parameter, the frame length of the signal does not have to be a multiple of the hop size. If the input is not a multiple of

the hop size, then the output is generally a variable-size signal. Therefore, to support arbitrary input size, the block must also support variable-size operations, which you can enable by selecting the **Allow arbitrary frame length for fixed-size input signals** parameter.

- Clear the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length must be a multiple of the hop size.

Dependencies

To enable this parameter, set **Method** to `Sliding window` and select the **Specify window length** check box.

Specify forgetting factor from input port — Flag to specify forgetting factor

off (default) | on

When you select this check box, the forgetting factor is input through the **lambda** port. When you clear this check box, the forgetting factor is specified on the block dialog through the **Forgetting factor** parameter.

Dependencies

To enable this parameter, set **Method** to `Exponential weighting`.

Forgetting factor — Exponential weighting factor

0.9 (default) | positive real scalar in the range (0,1]

The forgetting factor determines how much weight past data is given. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory - all previous samples are given an equal weight.

Tunable: Yes

Dependencies

To enable this parameter, set **Method** to `Exponential weighting` and clear the **Specify forgetting factor from input port** check box.

Simulate using — Type of simulation to run

Code generation (default) | Interpreted execution

Specify the type of simulation to run as one of the following:

- `Code generation` -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.
- `Interpreted execution` -- Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

Block Characteristics

Data Types	double single
-------------------	-----------------

Multidimensional Signals	No
Variable-Size Signals	Yes

Algorithms

Sliding Window Method

In the sliding window method, the output for each input sample is the average of the current sample and $Len - 1$ previous samples. Len is the length of the window in samples. To compute the first output sample, the algorithm waits until it receives the hop size number of input samples. Hop size is defined as window length - overlap length. Remaining samples in the window are considered to be zero. As an example, if the window length is 5 and the overlap length is 2, then the algorithm waits until it receives 3 samples of input to compute the first sample of the output. After generating the first output, it generates the subsequent output samples for every hop size number of input samples.

When you do not specify the window length, the algorithm chooses an infinite window length. In this mode, the output is the moving average of the current sample and all the previous samples in the channel.

For an example, see “Sliding Window Method and Exponential Weighting Method”.

Exponential Weighting Method

In the exponential weighting method, the moving average is computed recursively using these formulas:

$$w_{N,\lambda} = \lambda w_{N-1,\lambda} + 1$$

$$\bar{x}_{N,\lambda} = \left(1 - \frac{1}{w_{N,\lambda}}\right) \bar{x}_{N-1,\lambda} + \left(\frac{1}{w_{N,\lambda}}\right) x_N$$

- $\bar{x}_{N,\lambda}$ — Moving average at the current sample
- x_N — Current data input sample
- $\bar{x}_{N-1,\lambda}$ — Moving average at the previous sample
- λ — Forgetting factor
- $w_{N,\lambda}$ — Weighting factor applied to the current data sample
- $\left(1 - \frac{1}{w_{N,\lambda}}\right) \bar{x}_{N-1,\lambda}$ — Effect of the previous data on the average

For the first sample, where $N = 1$, the algorithm chooses $w_{N,\lambda} = 1$. For the next sample, the weighting factor is updated and used to compute the average, as per the recursive equation. As the age of the data increases, the magnitude of the weighting factor decreases exponentially and never reaches zero. In other words, the recent data has more influence on the current average than the older data.

The value of the forgetting factor determines the rate of change of the weighting factors. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All the previous samples are given an equal weight.

For an example, see “Sliding Window Method and Exponential Weighting Method”.

Version History

Introduced in R2016b

New Overlap length parameter

Starting in R2022b, you can specify the overlap length between sliding windows using the **Overlap length** parameter.

Support for arbitrary input frame length

Moving Average block supports input signals with arbitrary frame lengths when the:

- Input signal is a fixed-size signal (frame length does not change during simulation). If **Allow arbitrary frame length for fixed-size input signals** is enabled, select the parameter.
- Input signal is a variable-size signal (frame length changes during simulation).

When this block supports an arbitrary frame length input signal, the input frame length does not have to be a multiple of the hop size.

Moving Maximum

Moving maximum

Library: DSP System Toolbox / Statistics

Description

The Moving Maximum block determines the moving maximum of the input signal along each channel independently over time. The block uses the sliding window method to determine the moving maximum. In this method, a window of specified length moves over each channel sample by sample, and the block determines the maximum over the data in the window. For more details, see “Algorithms” on page 2-935.

Input/Output Ports

Input

Port_1 — Data input

column vector | row vector | matrix

Data over which the moving maximum is determined using the sliding window method. The block accepts real-valued or complex-valued multichannel inputs, that is, m -by- n size inputs, where $m \geq 1$ and $n \geq 1$. The block also accepts variable-size inputs. During simulation, you can change the size of each input channel. However, the number of channels cannot change.

Data Types: single | double

Output

Port_1 — Moving maximum output

column vector | row vector | matrix

Moving maximum output, determined using the sliding window method. The size of the output matches the size of the input. The window slides column-wise along each channel, and the block determines the maximum of the data in the window. For more details, see “Algorithms” on page 2-935.

Data Types: single | double

Parameters

Specify window length — Flag to specify window length

on (default) | off

When you select this check box, the length of the sliding window is equal to the value you specify through the **Window length** parameter. When you clear this check box, the length of the sliding

window is infinite. In this mode, the block determines the maximum of the current sample and all previous samples in the channel.

Window length — Length of the sliding window

4 (default) | positive scalar integer

Window length specifies the length of the sliding window in samples.

Dependencies

This parameter appears when you select the **Specify window length** check box.

Simulate using — Type of simulation to run

Code generation (default) | Interpreted execution

Specify the type of simulation to run as one of the following:

- **Code generation** -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than **Interpreted execution**.
- **Interpreted execution** -- Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than **Code generation**.

Moving RMS

Moving RMS

Library: DSP System Toolbox / Statistics

Description

The Moving RMS block computes the moving root mean square (RMS) of the input signal along each channel independently over time. The block uses either the sliding window method or the exponential weighting method to compute the moving RMS. In the sliding window method, a window of specified length moves over the data sample by sample, and the block computes the RMS over the data in the window. In the exponential weighting method, the block squares the data samples, multiplies them with a set of weighting factors, and sums the weighed data. The block then computes the RMS by taking the square root of the sum. For more details on these methods, see “Algorithms” on page 2-946.

x — Data input

vector | matrix

The block computes the moving RMS of the data specified at this input port. Specify real- or complex-valued multichannel inputs of the size m -by- n , where $m \geq 1$ and $n \geq 1$.

When the **Allow arbitrary frame length for fixed-size input signals** parameter appears and is not selected, and you input a fixed-size signal, the frame length must be a multiple of the hop size (window length – overlap length). In all other cases, the input frame length can be arbitrary.

The block accepts variable-size inputs (frame length changes during simulation). When you input a variable-size signal, the frame length of the signal can be arbitrary.

This port is unnamed until you set **Method** to `Exponential` weighting and select the **Specify forgetting factor from input port** parameter.

Data Types: `single` | `double`

lambda — Forgetting factor

positive real scalar in the range (0,1]

The forgetting factor determines how much weight past data is given. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory – all previous samples are given an equal weight.

Dependencies

This port appears when you set **Method** to `Exponential` weighting and select the **Specify forgetting factor from input port** parameter.

Data Types: `single` | `double`

Output

Port_1 — Moving RMS output

`vector` | `matrix`

Moving RMS output, returned as a vector or a matrix. The block computes the moving RMS based on the **Method** parameter settings using either the sliding window method or the exponential weighting method. For more details, see “Algorithms” on page 2-946.

This table provides more details on the dimensions of the output signal.

Input Signal	Input Dimensions	Output Dimensions When Allow arbitrary frame length for fixed-size input signals Appears	Output Dimensions When Allow arbitrary frame length for fixed-size input signals Does Not Appear
Fixed-size signal	m -by- n , where m is a multiple of the hop size (window length – overlap length)	$(m/\text{hop size})$ -by- n	m -by- n
Fixed-size signal	m -by- n , where m is not a multiple of the hop size (window length – overlap length)	$\text{ceil}(m/\text{hop size})$ -by- n when you select Allow arbitrary frame length for fixed-size input signals If you do not select Allow arbitrary frame length for fixed-size input signals , the block errors.	m -by- n
Variable-size signal	m -by- n	$\text{ceil}(m/\text{hop size})$ -by- n	m -by- n

When the output has an upper bound size of $\text{ceil}(m/\text{hop size})$ -by- n , during simulation, the size of the first dimension varies within this bound and the size of the second dimension remains constant. For an example that shows this behavior, see “Compute Moving RMS of Noisy Step Signal”.

Data Types: `single` | `double`

Parameters

If a parameter is listed as tunable, then you can change its value during simulation.

Method — Moving RMS method

`Sliding window (default)` | `Exponential weighting`

- **Sliding window** — A window of length **Window length** moves over the input data along each channel. For every sample the window moves over, the block computes the RMS over the data in the window.

- **Exponential weighting** — The block multiplies the squares of the samples by a set of weighting factors. The magnitude of the weighting factors decreases exponentially as the age of the data increases, but the magnitude never reaches zero. To compute the RMS, the algorithm sums the weighted data and takes a square root of the sum.

Specify window length — Flag to specify window length

on (default) | off

When you select this check box, the length of the sliding window is equal to the value you specify in **Window length**. When you clear this check box, the length of the sliding window is infinite. In this mode, the block computes the RMS of the current sample and all the previous samples in the channel.

Dependencies

To enable this parameter, set **Method** to `Sliding window`.

Window length — Length of sliding window

4 (default) | positive scalar integer

Specifies the length of the sliding window in samples.

Dependencies

To enable this parameter, set **Method** to `Sliding window` and select the **Specify window length** check box.

Overlap length — Overlap length between windows

3 (default) | nonnegative integer

Specify the overlap length between sliding windows as a nonnegative integer. The value of overlap length varies in the range $[0, \mathbf{Window\ length} - 1]$.

Dependencies

To enable this parameter, set **Method** to `Sliding window` and select the **Specify window length** check box.

Allow arbitrary frame length for fixed-size input signals — Allow arbitrary frame length for fixed-size input signals

off (default) | on

Specify whether fixed-size input signals (whose size does not change during simulation) can have an arbitrary frame length, where the frame length does not have to be a multiple of the hop size. Hop size is defined as **Window length** – **Overlap length**. The block uses this parameter setting only for fixed-size input signals and ignores this parameter if the input has a variable-size.

When the input signal is a variable-size signal, the signal can have arbitrary frame length, that is, the frame length does not have to be a multiple of the hop size.

For fixed-size input signals, if you:

- Select the **Allow arbitrary frame length for fixed-size input signals** parameter, the frame length of the signal does not have to be a multiple of the hop size. If the input is not a multiple of the hop size, then the output is generally a variable-size signal. Therefore, to support arbitrary input size, the block must also support variable-size operations, which you can enable by selecting the **Allow arbitrary frame length for fixed-size input signals** parameter.
- Clear the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length must be a multiple of the hop size.

Dependencies

To enable this parameter, set **Method** to `Sliding window` and select the **Specify window length** check box.

Specify forgetting factor from input port — Flag to specify forgetting factor

off (default) | on

When you select this check box, the forgetting factor is input through the **lambda** port. When you clear this check box, the forgetting factor is specified on the block dialog through the **Forgetting factor** parameter.

Dependencies

To enable this parameter, set **Method** to `Exponential weighting`.

Forgetting factor — Exponential weighting factor

0.9 (default) | positive real scalar in the range (0,1]

The forgetting factor determines how much weight past data is given. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory - all previous samples are given an equal weight.

Tunable: Yes

Dependencies

To enable this parameter, set **Method** to `Exponential weighting` and clear the **Specify forgetting factor from input port** check box.

Simulate using — Type of simulation to run

Code generation (default) | Interpreted execution

Specify the type of simulation to run as one of the following:

- `Code generation` -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.
- `Interpreted execution` -- Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

Block Characteristics

Data Types	double single
Multidimensional Signals	No
Variable-Size Signals	Yes

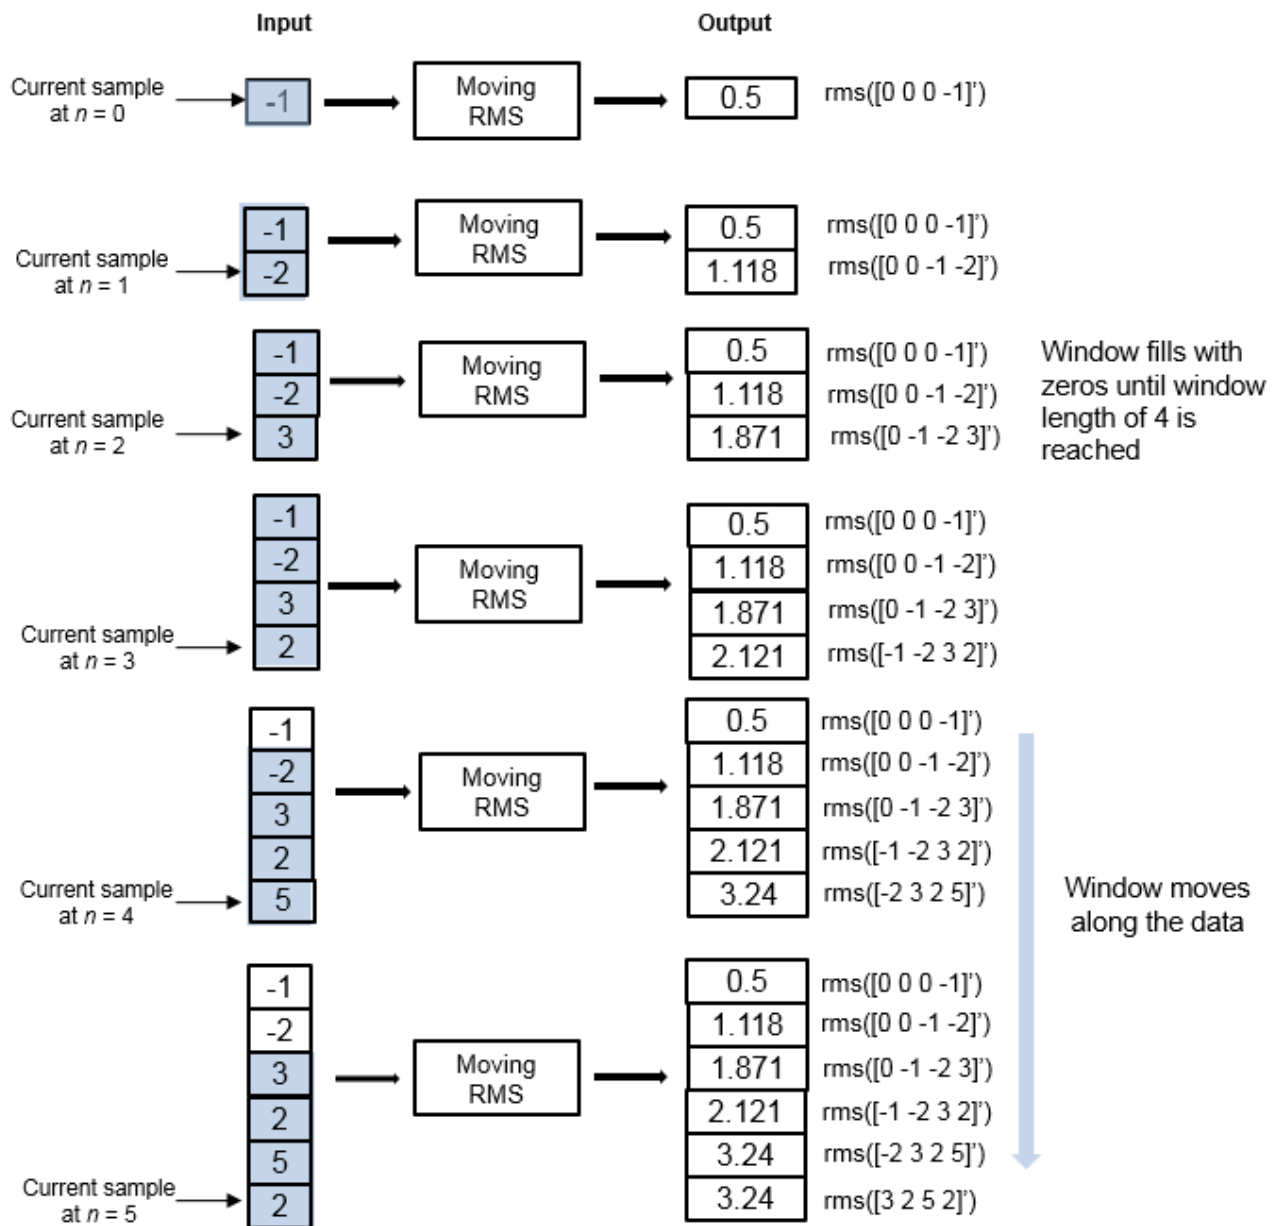

Algorithms

Sliding Window Method

In the sliding window method, the output for each input sample is the RMS of the current sample and $Len - 1$ previous samples. Len is the length of the window in samples. To compute the first output sample, the algorithm waits until it receives the hop size number of input samples. Hop size is defined as window length - overlap length. Remaining samples in the window are considered to be zero. As an example, if the window length is 5 and the overlap length is 2, then the algorithm waits until it receives 3 samples of input to compute the first sample of the output. After generating the first output, it generates the subsequent output samples for every hop size number of input samples.

When you do not specify the window length, the algorithm chooses an infinite window length. In this mode, the output is the moving RMS of the current sample and all the previous samples in the channel.

Consider an example of computing the moving RMS of a streaming input data using the sliding window method. The algorithm uses a window length of 4 and an overlap length of 3. With each input sample that comes in, the window of length 4 moves along the data.

Exponential Weighting Method

In the exponential weighting method, the moving RMS is computed recursively using these formulas:

$$w_{N,\lambda} = \lambda w_{N-1,\lambda} + 1$$

$$x_{rmsN,\lambda} = \sqrt{\left(1 - \frac{1}{w_{N,\lambda}}\right)x_{rmsN-1,\lambda} + \left(\frac{1}{w_{N,\lambda}}\right)x_N^2}$$

- $x_{rmsN,\lambda}$ – Moving RMS at the current sample
- x_N^2 – Square of the current input data sample

- $x_{rms_{N-1,\lambda}}$ — Moving RMS at the previous sample
- λ — Forgetting factor
- $w_{N,\lambda}$ — Weighting factor applied to the current data sample
- $\left(1 - \frac{1}{w_{N,\lambda}}\right)x_{rms_{N-1,\lambda}}$ — Effect of the previous data on the RMS

For the first sample, where $N = 1$, the algorithm chooses $w_{N,\lambda} = 1$. For the next sample, the weighting factor is updated and used to compute the RMS, as per the recursive equation. As the age of the data increases, the magnitude of the weighting factor decreases exponentially and never reaches zero. In other words, the recent data has more influence on the current RMS than the older data.

The value of the forgetting factor determines the rate of change of the weighting factors. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All the previous samples are given an equal weight.

Here is an example of computing the moving RMS using the exponential weighting method. The forgetting factor is 0.9.

Version History

Introduced in R2016b

New Overlap length parameter

Starting in R2022b, you can specify the overlap length between sliding windows using the **Overlap length** parameter.

Support for arbitrary input frame length

Moving RMS block supports input signals with arbitrary frame lengths when the:

- Input signal is a fixed-size signal (frame length does not change during simulation) and you select the **Allow arbitrary frame length for fixed-size input signals** parameter (if enabled).
- Input signal is a variable-size signal (frame length changes during simulation).

When this block supports an arbitrary frame length input signal, the input frame length does not have to be a multiple of the hop size.

Moving Variance

Moving variance

Library: DSP System Toolbox / Statistics

Description

The Moving Variance block computes the moving variance of the input signal along each channel independently over time. The block uses either the sliding window method or the exponential weighting method to compute the moving variance. In the sliding window method, a window of specified length moves over the data sample by sample, and the block computes the variance over the data in the window. In the exponential weighting method, the block subtracts each sample of the data from the average, squares the difference, and multiplies the squared result by a weighting factor. The block then computes the variance by adding all the weighted data. For more details on these methods, see “Algorithms” on page 2-954.

Input/Output Ports

Input

x — Data input

The magnitude of the weighting factors decreases exponentially as the age of the data increases, but the magnitude never reaches zero.

For more details on these methods, see “Algorithms” on page 2-954.

Specify window length — Flag to specify window length

on (default) | off

When you select this check box, the length of the sliding window is equal to the value you specify in **Window length**. When you clear this check box, the length of the sliding window is infinite. In this mode, the block computes the variance of the current sample with respect to all the previous samples in the channel.

Dependencies

To enable this parameter, set **Method** to `Sliding window`.

Window length — Length of sliding window

4 (default) | positive scalar integer

Specifies the length of the sliding window in samples.

Dependencies

To enable this parameter, set **Method** to `Sliding window` and select the **Specify window length** check box.

Overlap length — Overlap length between windows

3 (default) | nonnegative integer

Specify the overlap length between sliding windows as a nonnegative integer. The value of overlap length varies in the range $[0, \mathbf{Window\ length} - 1]$.

Dependencies

To enable this parameter, set **Method** to `Sliding window` and select the **Specify window length** check box.

Allow arbitrary frame length for fixed-size input signals — Allow arbitrary frame length for fixed-size input signals

off (default) | on

Specify whether fixed-size input signals (whose size does not change during simulation) can have an arbitrary frame length, where the frame length does not have to be a multiple of the hop size. Hop size is defined as **Window length** – **Overlap length**. The block uses this parameter setting only for fixed-size input signals and ignores this parameter if the input has a variable-size.

When the input signal is a variable-size signal, the signal can have arbitrary frame length, that is, the frame length does not have to be a multiple of the hop size.

For fixed-size input signals, if you:

- Select the **Allow arbitrary frame length for fixed-size input signals** parameter, the frame length of the signal does not have to be a multiple of the hop size. If the input is not a multiple of the hop size, then the output is generally a variable-size signal. Therefore, to support arbitrary input size, the block must also support variable-size operations, which you can enable by selecting the **Allow arbitrary frame length for fixed-size input signals** parameter.
- Clear the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length must be a multiple of the hop size.

Dependencies

To enable this parameter, set **Method** to `Sliding window` and select the **Specify window length** check box.

Specify forgetting factor from input port — Flag to specify forgetting factor

off (default) | on

When you select this check box, the forgetting factor is input through the **lambda** port. When you clear this check box, the forgetting factor is specified on the block dialog through the **Forgetting factor** parameter.

Dependencies

To enable this parameter, set **Method** to `Exponential weighting`.

Forgetting factor — Exponential weighting factor

0.9 (default) | positive real scalar in the range (0,1]

The forgetting factor determines how much weight past data is given. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory - all previous samples are given an equal weight.

Tunable: Yes

Dependencies

To enable this parameter, set **Method** to `Exponential weighting` and clear the **Specify forgetting factor from input port** check box.

Simulate using — Type of simulation to run

Code generation (default) | Interpreted execution

Specify the type of simulation to run as one of the following:

- `Code generation` -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.
- `Interpreted execution` -- Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

Block Characteristics

Algorithms

Sliding Window Method

In the sliding window method, the output at the current sample is the variance of the current sample with respect to the data in the window. To compute the first output sample, the algorithm waits until it receives the hop size number of input samples. Hop size is defined as window length - overlap length. Remaining samples in the window are considered to be zero. As an example, if the window length is 5 and the overlap length is 2, then the algorithm waits until it receives 3 samples of input to compute the first sample of the output. After generating the first output, it generates the subsequent output samples for every hop size number of input samples.

When you do not specify the window length, the algorithm chooses an infinite window length. In this mode, the output is the moving variance of the current sample with respect to all previous samples in the channel.

Consider an example of computing the moving variance of a streaming input data using the sliding window method. The algorithm uses a window length of 4 and an overlap length of 3. With each input sample that comes in, the window of length 4 moves along the data.

Exponential Weighting Method

In the exponential weighting method, the moving variance is computed recursively using these formulas:

$$s^2_{N,\lambda} = \frac{1}{v_{N,\lambda}} \sum_{k=1}^N \lambda^{N-k} [x_k - \bar{x}_{N,\lambda}]^2$$

$$v_{N,\lambda} = \frac{2\lambda(1 - \lambda^{N-1})}{(1 - \lambda)(1 + \lambda)}$$

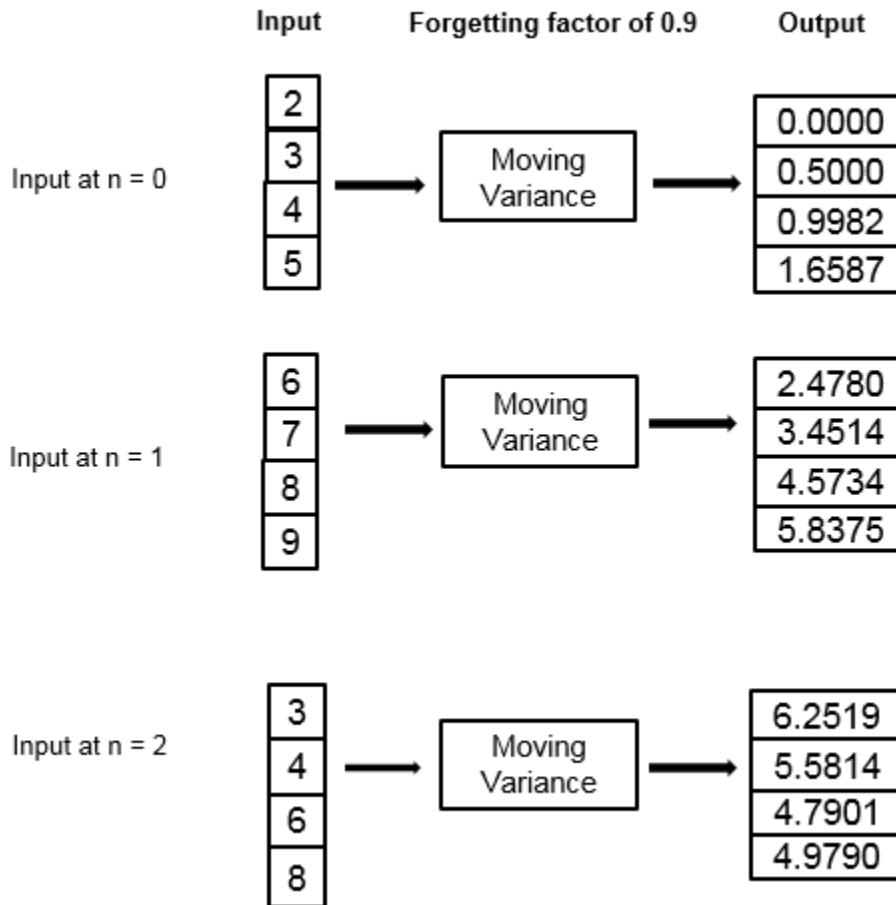

To compute the moving variance, the algorithm implements these equations recursively.

- $s_{N,\lambda}^2$ — Moving variance of the current data sample with respect to the rest of the data in the channel.
- $\bar{x}_{N,\lambda}$ — Moving average at the current sample. For details on computing the moving average, see `dsp.MovingAverage`.
- $[x_k - \bar{x}_{N,\lambda}]^2$ — Difference between each data sample and the average of the data, squared.
- $\sum_{k=1}^N \lambda^{N-k} [x_k - \bar{x}_{N,\lambda}]^2$ — Difference between each data sample and the average of the data, squared and multiplied with the forgetting factor. All the squared terms are added.
- $\frac{1}{v_{N,\lambda}}$ — Weighting factor applied to the sum.
- λ — Forgetting factor you can specify through the `ForgettingFactor` property.

As the age of the data increases, the magnitude of the weighting factor decreases exponentially, and never reaches zero. In other words, the recent data has more influence on the current variance, than the older data.

The value of the forgetting factor determines the rate of change of the weighting factors. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All the past samples are given an equal weight.

Consider an example of computing the moving variance using the exponential weighting method. The forgetting factor is 0.9.

Data Types: `single` | `double`

Parameters

If a parameter is listed as tunable, then you can change its value during simulation.

Method — Moving standard deviation method

`Sliding window (default)` | `Exponential weighting`

- **Sliding window** — A window of length **Window length** moves over the input data along each channel. For every sample the window moves by, the block computes the standard deviation over the data in the window.
- **Exponential weighting** — The block computes the exponentially weighted moving standard deviation and takes the square root. The magnitude of the weighting factors decreases exponentially as the age of the data increases, but the magnitude never reaches zero.

For more details on these methods, see “Algorithms” on page 2-963.

Specify window length — Flag to specify window length

on (default) | off

When you select this check box, the length of the sliding window is equal to the value you specify in **Window length**. When you clear this check box, the length of the sliding window is infinite. In this mode, the block computes the standard deviation of the current sample with respect to all the previous samples in the channel.

Dependencies

To enable this parameter, set **Method** to **Sliding window**.

Window length — Length of sliding window

4 (default) | positive scalar integer

Specifies the length of the sliding window in samples.

Dependencies

To enable this parameter, set **Method** to **Sliding window** and select the **Specify window length** check box.

Overlap length — Overlap length between windows

3 (default) | nonnegative integer

Specify the overlap length between sliding windows as a nonnegative integer. The value of overlap length varies in the range $[0, \mathbf{Window\ length} - 1]$.

Dependencies

To enable this parameter, set **Method** to **Sliding window** and select the **Specify window length** check box.

Allow arbitrary frame length for fixed-size input signals — Allow arbitrary frame length for fixed-size input signals

off (default) | on

Specify whether fixed-size input signals (whose size does not change during simulation) can have an arbitrary frame length, where the frame length does not have to be a multiple of the hop size. Hop size is defined as **Window length** – **Overlap length**. The block uses this parameter setting only for fixed-size input signals and ignores this parameter if the input has a variable-size.

When the input signal is a variable-size signal, the signal can have arbitrary frame length, that is, the frame length does not have to be a multiple of the hop size.

For fixed-size input signals, if you:

- Select the **Allow arbitrary frame length for fixed-size input signals** parameter, the frame length of the signal does not have to be a multiple of the hop size. If the input is not a multiple of the hop size, then the output is generally a variable-size signal. Therefore, to support arbitrary input size, the block must also support variable-size operations, which you can enable by selecting the **Allow arbitrary frame length for fixed-size input signals** parameter.
- Clear the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length must be a multiple of the hop size.

Dependencies

To enable this parameter, set **Method** to `Sliding window` and select the **Specify window length** check box.

Specify forgetting factor from input port — Flag to specify forgetting factor

off (default) | on

When you select this check box, the forgetting factor is input through the **lambda** port. When you clear this check box, the forgetting factor is specified on the block dialog through the **Forgetting factor** parameter.

Dependencies

To enable this parameter, set **Method** to `Exponential weighting`.

Forgetting factor — Exponential weighting factor

0.9 (default) | positive real scalar in the range (0,1]

The forgetting factor determines how much weight past data is given. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory - all previous samples are given an equal weight.

Tunable: Yes

Dependencies

To enable this parameter, set **Method** to `Exponential weighting` and clear the **Specify forgetting factor from input port** check box.

Simulate using — Type of simulation to run

Code generation (default) | Interpreted execution

Specify the type of simulation to run as one of the following:

- `Code generation` -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.

- **Interpreted execution** -- Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

Block Characteristics

Algorithms

Sliding Window Method

In the sliding window method, the output at the current sample is the standard deviation of the current sample with respect to the data in the window. To compute the first output sample, the algorithm waits until it receives the hop size number of input samples. Hop size is defined as window length - overlap length. Remaining samples in the window are considered to be zero. As an example, if the window length is 5 and the overlap length is 2, then the algorithm waits until it receives 3 samples of input to compute the first sample of the output. After generating the first output, it generates the subsequent output samples for every hop size number of input samples.

When you do not specify the window length, the algorithm chooses an infinite window length. In this mode, the output is the moving standard deviation of the current sample with respect to all the previous samples in the channel.

Consider an example of computing the moving standard deviation of a streaming input data using the sliding window method. The algorithm uses a window length of 4 and an overlap length of 3. With each input sample that comes in, the window of length 4 moves along the data.

Exponential Weighting Method

In the exponential weighting method, the moving standard deviation is computed recursively using these formulas:

$$s_{N,\lambda} = \sqrt{\frac{1}{v_{N,\lambda}} \sum_{k=1}^N \lambda^{N-k} [x_k - \bar{x}_{N,\lambda}]^2}$$

$$v_{N,\lambda} = \frac{2\lambda(1 - \lambda^{N-1})}{(1 - \lambda)(1 + \lambda)}$$

- $s_{N,\lambda}$ — Moving standard deviation of the current data sample with respect to the rest of the data.
- $[x_k - \bar{x}_{N,\lambda}]^2$ — Difference between each data sample and the average of the data, squared.
- $\sum_{k=1}^N \lambda^{N-k} [x_k - \bar{x}_{N,\lambda}]^2$ — Difference between each data sample and the average of the data, squared and multiplied with the forgetting factor. All the squared terms are added.
- $\frac{1}{v_{N,\lambda}}$ — Weighting factor applied to the sum.
- λ — Forgetting factor.

As the age of the data increases, the magnitude of the weighting factor decreases exponentially and never reaches zero. In other words, the recent data has more influence on the current standard deviation than the older data.

The value of the forgetting factor determines the rate of change of the weighting factors. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All previous samples are given an equal weight.

Consider an example of computing the moving standard deviation using the exponential weighting method. The forgetting factor is 0.9.

Version History

Introduced in R2016b

New Overlap length parameter

Starting in R2022b, you can specify the overlap length between sliding windows using the **Overlap length** parameter.

Support for arbitrary input frame length

Moving Standard Deviation block supports input signals with arbitrary frame lengths when the:

- Input signal is a fixed-size signal (frame length does not change during simulation) and you select the **Allow arbitrary frame length for fixed-size input signals** parameter (if enabled).
- Input signal is a variable-size signal (frame length changes during simulation).

When this block supports an arbitrary frame length input signal, the input frame length does not have to be a multiple of the hop size.

Multiphase Clock

Generate multiple binary clock signals

Library: DSP System Toolbox / Signal Management / Switches and Counters
DSP System Toolbox / Sources

Description

The Multiphase Clock block generates a 1-by- N vector of clock signals, where you specify the integer N in the **Number of phases** parameter. Each of the N phases has the same frequency, f , specified in hertz by the **Clock frequency** parameter.

The clock signal indexed by the **Starting phase** parameter is the first to become active, at $t=0$. The other signals in the output vector become active in turn, each one lagging the preceding signal's activation by $1/(Nf)$ seconds, the phase interval. The period of the output is therefore $1/(Nf)$ seconds.

The active level can be either high (1) or low (0), as specified by the **Active level (polarity)** parameter. You specify the duration of the active level, D , as an integer between 1 and $N-1$ using the **Number of phase intervals over which the clock is active** parameter. This value specifies the number of phase intervals that each signal remains in the active state after becoming active. The active duty cycle of the signal is D/N .

Ports

Output

Port_1 — Vector of clock signals

vector

1-by- N vector of clock signals, where you specify N using the **Number of phases** parameter. For more information, see “Description” on page 2-967.

Data Types: single | double | Boolean

Parameters

Clock frequency (Hz) — Frequency of all clock signals

1 (default) | positive scalar

The frequency of all output clock signals, specified as a positive scalar.

Number of phases, N — Number of phases in output vector

4 (default) | positive integer

The number of different phases, N , in the output vector, specified as a positive integer scalar.

Starting phase (1 to N) – Vector index for starting phase1 (default) | integer from 1 to N

The vector index of the output signal to first become active, specified as a scalar integer from 1 to N .

Number of phase intervals over which clock is active (1 to N-1) – Duration of active level for each output3 (default) | integer from 1 to $N-1$

The duration of the active level, D , for every output signal specified as a scalar integer from 1 to $N-1$. The value you specify determines the number of phase intervals that each signal remains in the active state after becoming active. The active duty cycle of the signal is D/N .

Active level (polarity) – Active level

High (1) (default) | Low (0)

The active level of the output, specified as High (1) or Low (0).

Output data type – Output data type

Logical (default) | Boolean

The output data type, specified as Logical or Boolean.

Multiport Selector

Distribute arbitrary subsets of input rows or columns to multiple output ports

Library

Signal Management / Indexing

dspindex

Description

The Multiport Selector block extracts multiple subsets of rows or columns from M -by- N input matrix u , and propagates each new submatrix to a distinct output port. The block treats an unoriented length- M vector input as an M -by-1 matrix.

The **Indices to output** parameter is a cell array whose k th cell contains a one-dimensional indexing expression specifying the subset of input rows or columns to be propagated to the k th output port. The total number of cells in the array determines the number of output ports on the block.

When you set the **Select** parameter to **Rows**, the block uses the one-dimensional indices you specify to select matrix rows, and all elements on the chosen rows are included. When you set the **Select** parameter to **Columns**, the block uses the one-dimensional indices you specify to select matrix columns, and all elements on the chosen columns are included. A given input row or column can appear any number of times in any of the outputs, or not at all.

When an index references a nonexistent row or column of the input, the block reacts with the action you specify using the **Invalid index** parameter.

Examples

Example 1

Consider the following **Indices to output** cell array:

```
{4, [1:2 5], [7;8], 10:-1:6}
```

This is a four-cell array, which requires the block to generate four independent outputs (each at a distinct port). The table below shows the dimensions of these outputs when **Select** = **Rows** and the input dimension is M -by- N .

Cell	Expression	Description	Output Size
1	4	Row 4 of input	1-by- N
2	[1:2 5]	Rows 1, 2, and 5 of input	3-by- N
3	[7;8]	Rows 7 and 8 of input	2-by- N

Cell	Expression	Description	Output Size
4	10:-1:6	Rows 10, 9, 8, 7, and 6 of input	5-by- <i>N</i>

Parameters

Select

Specify the dimension of the input to select, Rows or Columns.

Indices to output

A cell array specifying the row- or column-subsets to propagate to each of the output ports. The number of cells in the array determines the number of output ports on the block.

Invalid index

Specify how the block handles an invalid index value. You can select one of the following options:

- `Clip index` — Clip the index to the nearest valid value, and do not issue an alert.

For example, if the block receives a 64-by-4 input and the **Select** parameter is set to Rows, the block clips an index of 72 to 64. For the same input, if the **Select** parameter is set to Columns, the block clips an index of 72 to 4. In both cases, the block clips an index of -2 to 1.

- `Clip and warn` — Clip the index to the nearest valid value and display a warning message at the MATLAB command line.
- `Generate error` — Display an error dialog box and terminate the simulation.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers • Enumerated
Outputs	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers • Enumerated

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the memcopy or memset function (`string.h`) under certain conditions.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has one default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Complex Data Support

This block supports code generation for complex signals.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

N-Sample Enable

Output ones or zeros for specified number of sample times

Library: DSP System Toolbox / Sources
 DSP System Toolbox / Signal Management / Switches and Counters

Description

The N-Sample Enable block outputs the inactive value (0 or 1, whichever is not selected in the **Active level** parameter) during the first N sample times, where N is the **Trigger count** value. Beginning with output sample $N+1$, the block outputs the active value (1 or 0, whichever you select in the **Active level** parameter) until a reset event occurs or the simulation terminates.

The output of the block is always a scalar.

The **Reset input** check box enables the **Rst** input port. At any time during the count, a trigger event at the input port resets the counter to its initial state. You specify the type of trigger event using the **Trigger type** parameter. This block supports triggered subsystems when you select the **Reset input** check box.

Ports

Input

Rst — Reset signal

scalar

Reset input signal, specified as a scalar. At any time during the count, a trigger event at the input port resets the counter to its initial state.

Tip The N-Sample Enable block supports triggered subsystems when you select the **Reset input** check box to enable the **Rst** input port.

Dependencies

To enable this input port, select the **Reset input** check box.

Data Types: Boolean

Output

Port_1 — Output signal

scalar

Scalar output containing the inactive value (0 or 1, whichever is not selected in the **Active level** parameter) during the first N sample times, where N is the **Trigger count** value. Beginning with

output sample $N+1$, the block outputs the active value (1 or 0, whichever you select in the **Active level** parameter) until a reset event occurs or the simulation terminates.

Data Types: Boolean

Parameters

Trigger count, N — Number of samples to output the active value

8 (default) | scalar integer

Specify the number of samples for which the block outputs the active value as a scalar integer, greater than or equal to zero.

Tunable: Yes

Active level — Active level

Low (0) (default) | High (1)

Specify the value to output after the first N sample times as 0 or 1.

Tunable: Yes

Reset input — Enable reset input port

off (default) | on

To enable the reset (**Rst**) input port, select this check box. When you clear this check box, the **Rst** input port is disabled.

Tip When you select the **Reset input** check box, the N-Sample Enable block supports triggered subsystems.

Trigger type — Type of triggering event

Rising edge (default) | Falling edge | Either edge | Non-zero sample

Select type of event that triggers a reset when the **Rst** port is enabled.

You can specify the triggering event as:

- **Rising edge** — Triggers a reset operation when the **Rst** input does one of the following:
 - Rises from a negative value to a positive value or zero
 - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)

- **Falling edge** — Triggers a reset operation when the **Rst** input does one of the following:
 - Falls from a positive value to a negative value or zero
 - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)

- **Either edge** — Triggers a reset operation when the **Rst** input is a Rising edge or Falling edge.
- **Non-zero sample** — Triggers a reset operation at each sample time that the **Rst** input is not zero.

Dependencies

To enable this parameter, select the **Reset input** check box.

Sample time — Output sample period

1 (default) | positive scalar

Specify the sample period, T_s , for the block's counter as a positive finite scalar. The block switches from the active value to the inactive value at $t=T_s(N+1)$.

Output data type — Output data type

Logical (default) | Boolean

Specify the output data type as Logical or Boolean.

Block Characteristics

Data Types	Boolean double
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Blocks

Counter | N-Sample Switch

N-Sample Switch

Switch between two inputs after specified number of sample periods

Library

Signal Management / Switches and Counters

dspswit3

Description

The N-Sample Switch block outputs the signal connected to the top input port during the first N sample times after the simulation begins or the block is reset, where you specify N in the **Switch count** parameter. Beginning with output sample $N+1$, the block outputs the signal connected to the bottom input until the next reset event or the end of the simulation.

You specify the sample period of the output in the **Sample time** parameter (that is, the output sample period is not inherited from the sample period of either input). The block applies a zero-order hold at the input ports, so the value the block reads from a given port between input sample times is the value of the most recent input to that port.

Both inputs must have the same dimension, except in the following two cases:

- When one input is a scalar, the block expands the scalar input to match the size of the other input.
- When one input is an unoriented vector and the other input is a row or column vector with the same number of elements, the block reshapes the unoriented vector to match the dimension of the other input.

The **Reset input** check box enables the Rst input port. At any time during the count, a trigger event at the Rst port resets the counter to zero. The reset sample time must be a positive integer multiple of the input sample time. This block supports triggered subsystems when you select the **Reset input** check box.

You specify the triggering event in the **Trigger type** pop-up menu, and can be one of the following:

- **Rising edge** — Triggers a reset operation when the Rst input does one of the following:
 - Rises from a negative value to a positive value or zero
 - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)

- **Falling edge** — Triggers a reset operation when the Rst input does one of the following:
 - Falls from a positive value to a negative value or zero
 - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)

- **Either edge** — Triggers a reset operation when the Rst input is a Rising edge or Falling edge (as described above).
- **Non-zero sample** — Triggers a reset operation at each sample time that the Rst input is not zero.

Parameters

Switch count

The number of sample periods, N , for which the output is connected to the top input before switching to the bottom input. Tunable (Simulink).

Reset input

Enables the Rst input port when selected. The rate of the reset signal must be a positive integer multiple of the rate of the data signal input.

Trigger type

The type of event at the Rst port that resets the block's counter. This parameter is enabled when you select **Reset input**. Tunable (Simulink).

Sample time

The sample period, T_s , for the block's counter. The block switches inputs at $t=T_s*(N+1)$.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed and unsigned)
- Boolean — The block accepts Boolean inputs to the Rst port, which is enabled when you set the **Reset input** parameter.
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

NCO

Generate real or complex sinusoidal signals

Library: DSP System Toolbox / Signal Operations
DSP System Toolbox / Sources

Description

The NCO block generates a multichannel real or complex sinusoidal signal, with independent frequency and phase in each output channel. The amplitude of the created signal is always 1. The NCO block supports real inputs only. All outputs are real except for the output signal in **Complex exponential** mode. For more information on how the block computes the output, see “Algorithms” on page 2-985.

To produce a multichannel output, specify a vector quantity for the **Phase increment** and **Phase offset** parameters. Both parameters must have the same length, which defines the number of output channels. Each element of each vector is applied to a different output channel.

Ports

Input

inc — Phase increment

scalar | vector

Phase increment signal, specified as a real-valued scalar or vector. The input must have an integer data type, or a fixed-point data type with zero fraction length. The dimensions of the phase increment signal depend on how you choose to specify the **Phase offset** parameter:

- When you specify the **Phase offset** on the block dialog box, the **Phase increment** must be a scalar or a vector with the same length as the **Phase offset** value. The block applies each element of the vector to a different channel, and therefore the vector length defines the number of output channels.
- When you specify the **Phase offset** via the an input port, the **offset** port treats each column of the input as an independent channel. The **Phase increment** length must equal the number of columns in the input to the **offset** port.

Dependencies

To enable this port, set **Phase increment source** to **Input** port.

Data Types: int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

offset — Phase offset

scalar | vector | matrix

Phase offset signal, specified as a real-valued scalar, vector, or a full matrix. The input must have an integer data type, or a fixed-point data type with zero fraction length. The block treats each column of the input to the offset port as an independent channel. The number of channels in the phase offset must match the number of channels in the data input. For each frame of the input, the block can apply different phase offsets to each sample and channel.

Dependencies

To enable this port, set **Phase offset source** to Input port.

Data Types: int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output**sin — Sine output**

scalar | vector | matrix

Sinusoidal output signal specified as a scalar, vector, or matrix. You can specify the data type of the signal using the **Output** data type parameter.

Dependencies

To enable this port, set **Output signal** to Sine or Sine and cosine.

Data Types: single | double | fixed point

cos — Cosine output

scalar | vector | matrix

Cosinusoidal output signal specified as a scalar, vector, or matrix. You can specify the data type of the signal using the **Output Data Type** parameter.

Dependencies

To enable this port, set **Output signal** to Cosine or Sine and cosine.

Data Types: single | double | fixed point

exp — Complex exponential

scalar | vector | matrix

Complex exponential output, specified as a scalar, vector, or matrix. You can specify the data type of the signal using the **Output Data Type** parameter.

Dependencies

To enable this port, set **Output signal** to Complex exponential.

Data Types: single | double | fixed point

Complex Number Support: Yes

Qerr — Phase quantization error

scalar | vector | matrix

Phase quantization error specified as a scalar, vector, or matrix.

Dependencies

To enable this port, select the **Show phase quantization error port** check box.

Data Types: `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Parameters

Main

Phase adder parameters

Phase increment source — Source of phase increment value

`Specify via dialog` | `Input port`

Choose how you specify the phase increment. The phase increment can come from an input port or from the dialog box parameter.

- If you select `Input port`, the **inc** input port appears on the block icon.
- If you select `Specify via dialog`, the **Phase increment** parameter appears.

Dependencies

When the block comes from the Signal Operations library, the default value of the **Phase increment Source** parameter is `Input port`.

When the block comes from the Sources library, the default value of the **Phase increment Source** parameter is `Specify via dialog`.

Phase increment — Phase increment value

`100 (default)` | `scalar` | `vector`

Specify the phase increment as an integer-valued scalar or vector. Only integer data types, including fixed-point data types with zero fraction length, are allowed. The dimensions of the phase increment depend on those of the phase offset:

- When you specify the phase offset on the block dialog box, the phase increment must be a scalar or a vector with the same length as the phase offset. The block applies each element of the vector to a different channel, and therefore the vector length defines the number of output channels.
- When you specify the phase offset via an input port, the offset port treats each column of the input as an independent channel. The phase increment length must equal the number of columns in the input to the offset port.

Dependencies

To enable this parameter, set **Phase increment source** to `Specify via dialog`.

Phase offset source — Source of phase offset

`Specify via dialog (default)` | `Input port`

Choose how you specify the phase offset. The phase offset can come from an input port or from the dialog box.

- If you select **Input port**, the **offset** port appears on the block icon.
- If you select **Specify via dialog**, the **Phase offset** parameter appears.

Phase offset — Phase offset value

0 (default) | scalar | vector

Specify the phase offset as an integer-valued scalar or vector. Only integer data types, including fixed-point data types with zero fraction length, are allowed. When you specify the phase offset using this dialog box parameter, it must be a scalar or vector with the same length as the phase increment. Scalars are expanded to a vector with the same length as the phase increment. Each element of the phase offset vector is applied to a different channel of the input, and therefore the vector length defines the number of output channels.

Dependencies

To enable this parameter, set **Phase offset source** to **Specify via dialog**.

Add internal dither — Add internal dithering

on (default) | off

Select to add internal dithering to the NCO algorithm. Dithering is added using the PN Sequence Generator from the Communications Toolbox™ product.

Number of dither bits — Number of dither bits

4 (default) | positive integer

Specify the number of dither bits as a positive integer.

Dependencies

To enable this port, select the **Add internal dither** check box.

Quantize phase — Enable quantization of accumulated phase

on (default) | off

To enable quantization of the accumulated phase, select this check box.

Number of quantized accumulator bits — Number of quantized accumulator bits

12 (default) | integer scalar

Specify the number of quantized accumulator bits as a scalar integer greater than one, and less than the accumulator word length. This value determines the number of entries in the lookup table.

Dependencies

To enable this port, select the **Quantize phase** check box.

Show phase quantization error port — Output quantization error

off (default) | on

Select to output the phase quantization error. When you select this check box, the **Qerr** port appears on the block icon.

Dependencies

To enable this parameter, select the **Quantize phase** check box.

Output Parameters

Output signal — Output signal

Sine (default) | Cosine | Complex exponential | Sine and cosine

Choose whether the block outputs a Sine, Cosine, Complex exponential, or both Sine and cosine signals. If you select Sine and cosine, the two signals output on different ports.

Sample time — Output sample period

1 (default) | positive scalar

When the block is acting as a source, specify the sample time in seconds as a positive scalar.

Dependencies

To enable this parameter, both **Phase increment source** and **Phase offset source** must be set to Specify via dialog. When either the phase increment or phase offset come in via a block input port, the sample time is inherited and this parameter is not visible.

Samples per frame — Samples per frame

1 (default) | positive integer

Specify the number of samples per frame as a positive integer. When the value is greater than one, the phase increment and phase offset can vary from channel to channel and from frame to frame, but they are constant along each channel in a given frame.

When the phase offset input port exists, it has the same frame status as any output port present. When the phase increment input port exists, it does not support frames.

Dependencies

To enable this parameter set **Phase increment source** and/or **Phase offset source** to Specify via dialog.

Data Types

Rounding mode — Rounding method

Floor (default)

This property is read-only.

When the input is fixed point, the NCO block always uses the rounding mode Floor.

Overflow mode — Overflow method

Wrap (default)

This property is read-only.

When the input is fixed point, the NCO block always uses the overflow mode Wrap.

Accumulator Word Length — Accumulator word length

16 (default) | integer from 2 to 128

Specify a **Word length** for the **Accumulator** as a positive integer from 2 to 128. The **Data Type** is always `Binary point scaling`, and the **Fraction length** is always 0.

Output Data Type — Output data type

double (default) | single | `Binary point scaling`

Specify a **Data Type** for the block **Output**.

- Choose `double` or `single` for a floating-point implementation.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the output, in bits.

Note The lookup table for this block is constructed from double-precision floating-point values. Thus, the maximum amount of precision you can achieve in your output is 53 bits. Setting the word length of the **Output** data type to values greater than 53 bits does not improve the precision of your output.

Output Word Length — Output word length

16 (default) | integer from 2 to 128

Specify a **Word length** for the block **Output** as a positive integer from 2 to 128.

Dependencies

To enable this parameter, set the **Data Type** for the **Output** to `Binary point scaling`.

Output Fraction Length — Output fraction length

14 (default) | integer

Specify a **Fraction length** for the block **Output** as a scalar integer.

Dependencies

To enable this parameter, set the **Data Type** for the **Output** to `Binary point scaling`.

NCO Characterization

The **NCO Characterization** pane provides you with read-only details on the NCO signal currently being implemented by the block:

Number of data points for lookup table — Number of points in lookup table

no default

The lookup table is implemented as a quarter-wave sine table. The number of lookup table data points is defined by

$$2^{\text{number of quantized accumulator bits} - 2} + 1$$

Example: 1025

Quarter wave sine lookup table size – Size of quarter wave sine lookup table

no default

The quarter wave sine lookup table size is defined by

$$\frac{(\text{number of data points for lookup table}) \cdot (\text{output word length})}{8} \text{ bytes}$$

Example: 2050 bytes

Theoretical spurious free dynamic range – Spurious free dynamic range

no default

The spurious free dynamic range (SFDR) is calculated as follows for a lookup table with 2^P entries:

$$\begin{aligned} SFDR &= (6P) \text{ dB} && \text{without dither} \\ SFDR &= (6P + 12) \text{ dB} && \text{with dither} \end{aligned}$$

Example: 84 dBc

Frequency resolution – Frequency resolution

no default

The frequency resolution is the smallest possible incremental change in frequency and is defined by:

$$\Delta f = \frac{1}{T_s \cdot 2^N} \text{ Hz}$$

Example: 15.2588 uHz

Dependencies

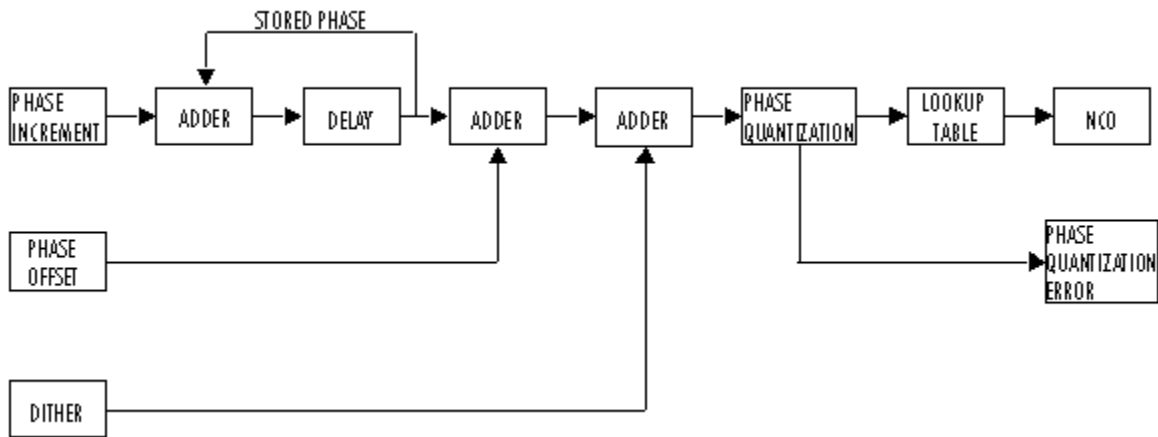

The frequency resolution only appears when you set **Phase increment source** and **Phase offset source** to Specify via dialog.

Block Characteristics

Data Types	fixed point integer
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Algorithms

The block implements the algorithm as shown in the following diagram:

The implementation of a numerically controlled oscillator (NCO) has two distinct parts. First, a phase accumulator accumulates the phase increment and adds in the phase offset. In this stage, an optional internal dither signal can also be added. The NCO output is then calculated by quantizing the results of the phase accumulator section and using them to select values from a lookup table. Since the lookup table contains a finite set of entries, in its normal mode of operation, the NCO block allows the adder's numeric values to overflow and wrap around. The Fixed-Point infrastructure then causes overflow warnings to appear on the command line. This overflow is of no consequence.

Given a desired output frequency F_0 , calculate the value of the **Phase increment** block parameter with

$$phaseincrement = \left(\frac{F_0 \cdot 2^N}{F_s} \right)$$

where N is the accumulator word length and

$$F_s = \frac{1}{T_s} = \frac{1}{sampletime}$$

The frequency resolution of an NCO is defined by

$$\Delta f = \frac{1}{T_s \cdot 2^N} \text{Hz}$$

Given a desired phase offset (in radians), calculate the **Phase offset** block parameter with

$$phaseoffset = \frac{2^N \cdot desiredphaseoffset}{2\pi}$$

The spurious free dynamic range (SFDR) is estimated as follows for a lookup table with 2^P entries, where P is the number of quantized accumulator bits:

$$SFDR = (6P) \text{ dB} \quad \text{without dither}$$

$$SFDR = (6P + 12) \text{ dB} \quad \text{with dither}$$

The NCO block uses a quarter-wave lookup table technique that stores table values from 0 to $\pi/2$. The block calculates other values on demand using the accumulator data type, then casts them into the

output data type. This can lead to quantization effects at the range limits of a given data type. For example, consider a case where you would expect the value of the sine wave to be -1 at π . Because the lookup table value at that point must be calculated, the block might not yield exactly -1 , depending on the precision of the accumulator and output data types.

Version History

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the memcopy or memset function (`string.h`) under certain conditions.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

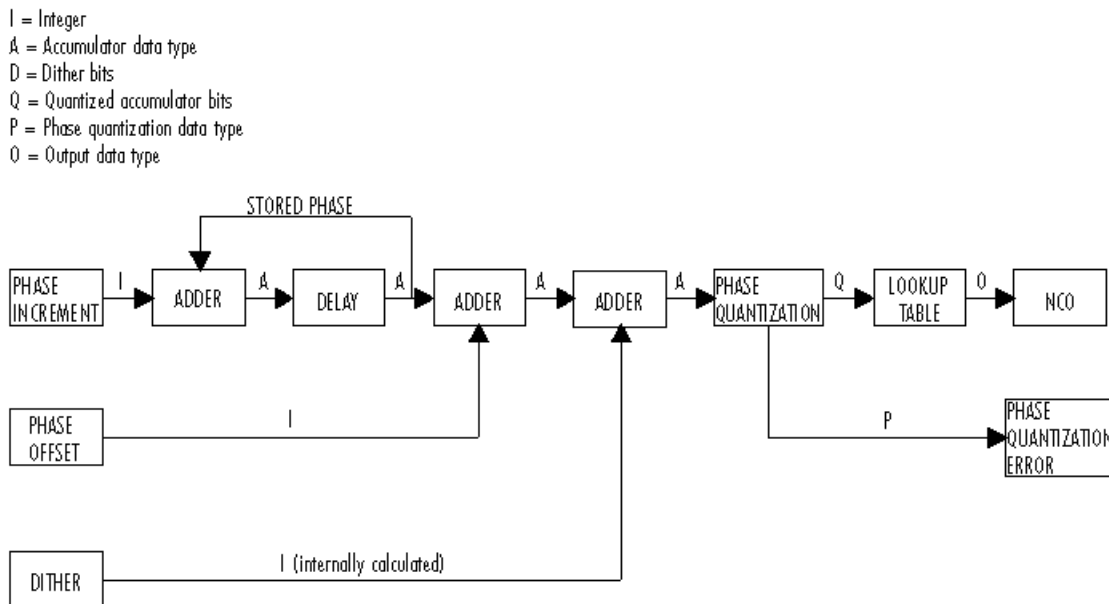

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL support for the NCO block will be removed in a future release. Use the NCO block instead.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

The following diagram shows the data types used within the NCO block.

- You can set the accumulator and output data types in the block dialog box as discussed in “Data Types” on page 2-983.

Note The lookup table for this block is constructed from double-precision floating-point values. Thus, the maximum amount of precision you can achieve in your output is 53 bits. Setting the word length of the **Output** data type to values greater than 53 bits does not improve the precision of your output.

- The phase increment and phase offset inputs must be integers or fixed-point data types with zero fraction length.
- You specify the number of quantized accumulator bits in the **Number of quantized accumulator bits** parameter.
- The phase quantization error word length is equal to the accumulator word length minus the number of quantized accumulator bits, and the fraction length is zero.

Normalization

Perform vector normalization along rows, columns, or specified dimension

Library

Math Functions / Math Operations

dspmathops

Description

The Normalization block independently normalizes each row, column, or vector of the specified dimension of the input. The block accepts both fixed- and floating-point signals in the squared 2-norm mode, but only floating-point signals in the 2-norm mode. The output always has the same dimensions as the input.

This block treats an arbitrarily dimensioned input U as a collection of vectors oriented along the specified dimension. The block normalizes these vectors by either their norm or the square of their norm.

For example, consider a 3-dimensional input $U(i,j,k)$ and assume that you want to normalize along the second dimension. First, define the 2-dimensional intermediate quantity $V(i,k)$ such that each element of V is the norm of one of the vectors in U :

$$V(i, k) = \left(\sum_{j=1}^J U^2(i, j, k) \right)^{1/2}$$

Given V , the output of the block $Y(i, j, k)$ in 2-norm mode is

$$Y(i, j, k) = \frac{U(i, j, k)}{V(i, k) + b}$$

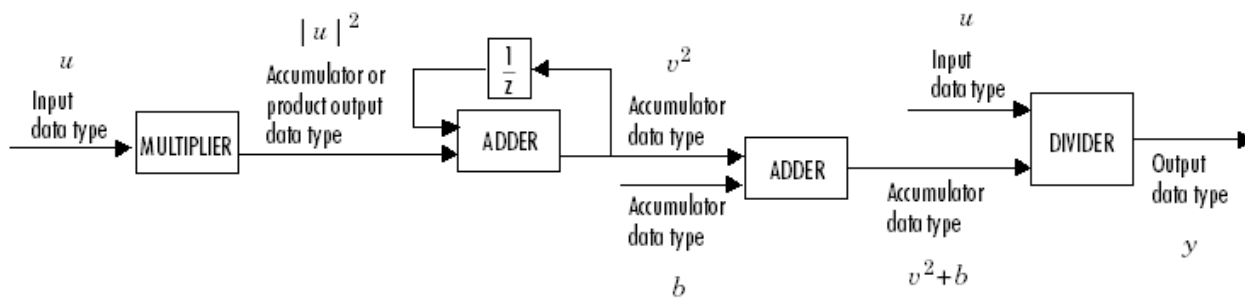

In squared 2-norm mode, the block output is

$$Y(i, j, k) = \frac{U(i, j, k)}{V(i, k)^2 + b}$$

The normalization bias, b , is typically chosen to be a small positive constant (for example, 1e-10) that prevents potential division by zero.

Fixed-Point Data Types

The following diagram shows the data types used within the Normalization block for fixed-point signals (squared 2-norm mode only).

The output of the multiplier is in the product output data type when the input is real. When the input is complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”. You can set the accumulator, product output, and output data types in the block dialog as discussed in “Parameters” on page 2-990.

Examples

See “Zero Algorithmic Delay” in the *DSP System Toolbox User's Guide* for an example.

Parameters

Main Tab

Norm

Specify the type of normalization to perform, 2-norm or Squared 2-norm. 2-norm mode supports floating-point signals only. Squared 2-norm supports both fixed-point and floating-point signals.

Normalization bias

Specify the real value b to be added in the denominator to avoid division by zero. Tunable (Simulink).

Normalize over

Specify whether to normalize along rows, columns, or the dimension specified in the **Dimension** parameter.

Dimension

Specify the one-based value of the dimension over which to normalize. The value of this parameter cannot exceed the number of dimensions in the input signal. This parameter is only visible if Specified dimension is selected for the **Normalize over** parameter.

Data Types Tab

Note The parameters on this pane are only applicable to fixed-point signals when the block is in squared 2-norm mode. See “Fixed-Point Data Types” on page 2-989 for a diagram of how the product output, accumulator, and output data types are used in this case.

Rounding mode

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

Saturate on integer overflow

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

Product output

Specify the product output data type. See “Fixed-Point Data Types” on page 2-989 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt([], 16, 0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Accumulator

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-989 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same as product output`
- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt([], 16, 0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Output

Specify the output data type. See “Fixed-Point Data Types” on page 2-989 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as product output`
- A rule that inherits a data type, for example, `Inherit: Same as input`

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt([], 16, 0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Data Types of Signals” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Output Minimum

Specify the minimum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Output Maximum

Specify the maximum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Notch-Peak Filter

Design second-order tunable notching and peaking IIR filter

Library

Filtering / Filter Designs

dspfdesign

Description

The Notch-Peak Filter block filters each channel of the input signal over time using a specified center frequency and 3 dB bandwidth. This block offers tunable filter design parameters, which enable you to tune the filter characteristics while the simulation is running.

The block designs the filter according to the filter parameters set in the block dialog box. The output port properties such as datatype, complexity, and dimension, are identical to the input port properties.

Each column of the input signal is treated as a separate channel. If the input is a two-dimensional signal, the first dimension represents the channel length (or frame size) and the second dimension represents the number of channels. If the input is a one-dimensional signal, then it is interpreted as a single channel.

This block supports variable-size input, enabling you to change the channel length during simulation. To enable variable-size input, clear the **Inherit sample rate from input** check box. The number of channels must remain constant.

Algorithms

This block brings the capabilities of the `dsp.NotchPeakFilter` System object to the Simulink environment.

The filter uses a coupled allpass structure to optimize joint computation of the peak and notch response. For information on the algorithms used by the Notch-Peak filter block, see the “Algorithms” on page 4-908 section of `dsp.NotchPeakFilter`.

Parameters

Filter specification

Parameters or coefficients used to design the filter, specified as one of the following:

- Bandwidth and center frequency (default) — Design the filter using **3 dB bandwidth (Hz)** and **Notch/Peak center frequency (Hz)**.

- **Coefficients** — Design the filter using **Bandwidth coefficient** and **Center frequency coefficient**.
- **Quality factor and center frequency** — Design the filter using **Quality factor** and **Notch/Peak center frequency (Hz)**.

This parameter is nontunable.

Specify bandwidth from input port

When you select this check box, the 3 dB bandwidth is input through the **BW** port. When you clear this check box, the 3 dB bandwidth is specified on the block dialog through the **3 dB bandwidth (Hz)** parameter.

This parameter applies when you set **Filter specification** to Bandwidth and center frequency.

3 dB bandwidth (Hz)

3 dB bandwidth of the filter, specified as a finite positive numeric scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter specification** to Bandwidth and center frequency, and clear the **Specify bandwidth from input port** parameter. The default is 2205. This parameter is tunable.

Specify center frequency from input port

When you select this check box, the center frequency is input through the **Fc** port. When you clear this check box, the center frequency is specified on the block dialog through the **Notch/Peak center frequency (Hz)** parameter.

This parameter applies when you set **Filter specification** to Bandwidth and center frequency or Quality factor and center frequency.

Notch/Peak center frequency (Hz)

Center frequency of the notch and peak of the filter, specified as a finite positive numeric scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter specification** to Bandwidth and center frequency or Quality factor and center frequency, and clear the **Specify center frequency from input port** parameter. The default is 11025. This parameter is tunable.

Specify bandwidth coefficient from input port

When you select this check box, the bandwidth coefficient is input through the port, **BWCoeff**. When you clear this check box, the bandwidth coefficient is specified on the block dialog through the **Bandwidth coefficient** parameter.

This parameter applies when you set **Filter specification** to Coefficients.

Bandwidth coefficient

Coefficient that determines the 3 dB bandwidth of the filter, specified as a finite numeric scalar in the range [-1 1].

- -1 corresponds to the maximum 3 dB bandwidth (one-fourth the sample rate of the input signal).
- 1 corresponds to the minimum bandwidth (0 Hz, that is, an allpass filter).

This parameter applies when you set **Filter specification** to Coefficients and clear the **Specify bandwidth coefficient from input port** parameter. The default is 0.72654. This parameter is tunable.

Specify center frequency coefficient from input port

When you select this check box, the center frequency coefficient is input through the **FcCoeff** port. When you clear this check box, the center frequency coefficient is specified on the block dialog through the **Center frequency coefficient** parameter.

This parameter applies when you set **Filter specification** to **Coefficients**.

Center frequency coefficient

Coefficient that determines the center frequency of the filter, specified as a finite numeric scalar in the range [-1 1].

- -1 corresponds to the minimum center frequency (0 Hz).
- 1 corresponds to the maximum center frequency (half the sample rate of the input signal).

This parameter applies when you set **Filter specification** to **Coefficients** and clear the **Specify center frequency coefficient from input port** parameter. The default is 0, which corresponds to quarter the sample rate of the input signal. This parameter is tunable.

Specify quality factor from input port

When you select this check box, the quality factor is input through the **Q** port. When you clear this check box, the quality factor is specified on the block dialog through the **Quality factor** parameter.

This parameter applies when you set **Filter specification** to **Quality factor** and center frequency.

Quality factor

Quality factor of the notch and peak filter, specified as a real positive scalar. The quality factor is defined as **Notch/Peak center frequency (Hz) / 3 dB bandwidth (Hz)**. A higher quality factor corresponds to a narrower peak or dip. This parameter applies when you set **Filter specification** to **Quality factor** and center frequency and clear the **Specify quality factor from input port** parameter. The default is 5. This parameter is tunable.

Output

Output of the filter block, specified as one of the following:

- **Notch and Peak** (default) — The block outputs the notch and peak responses of the filter.
- **Notch** — The block outputs the notch response of the filter.
- **Peak** — The block outputs the peak response of the filter.

This parameter is nontunable.

Inherit sample rate from input

When you select this check box, the block sample rate is computed as N/T_s , where N is the frame size of the input signal, and T_s is the sample time of the input signal. When you clear this check box, the block's sample rate is the value specified in **Input sample rate (Hz)**. By default, this check box is selected.

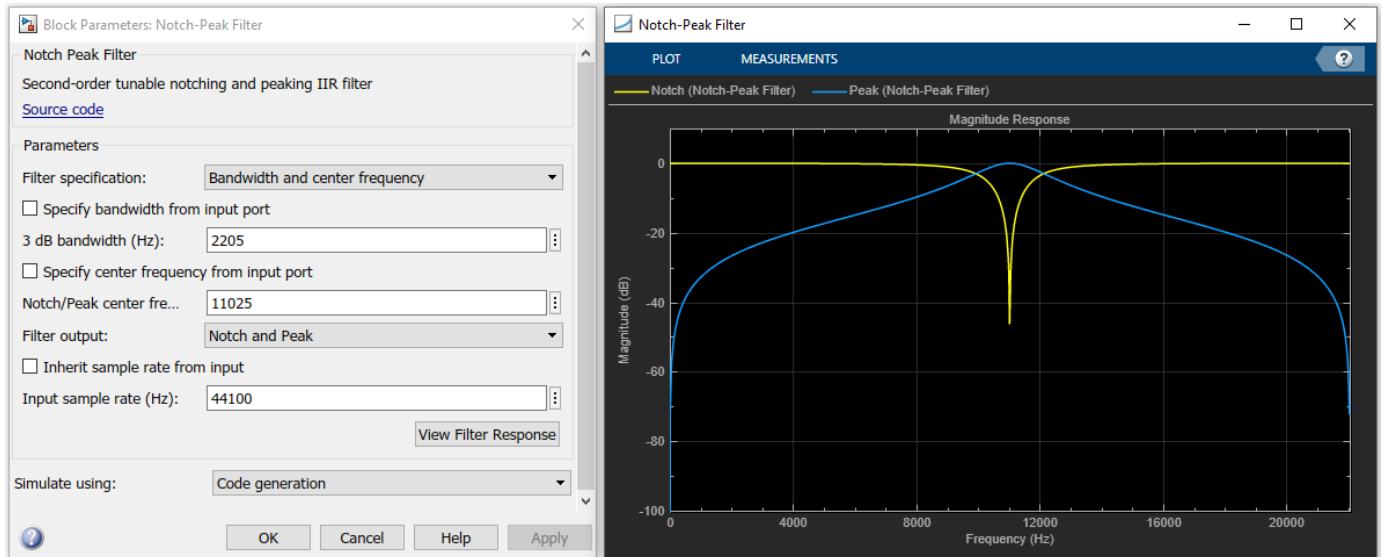

Input sample rate (Hz)

Sample rate of the input signal, specified as a positive scalar value. The default is 44100. This parameter applies when you clear the **Inherit sample rate from input** check box. This parameter is nontunable.

View Filter Response

Opens the Dynamic Filter Visualizer window and displays the magnitude and phase response of the notch-peak filter. The response is based on the parameters you select in the Block Parameters

dialog box. To update the response while the visualizer is running, modify the parameters in the dialog box and click **Apply**.

You can configure the plot settings and the frequency filter response measurements from the interface of the visualizer.

On the **Plot** tab, you can enable the legend, specify to plot both magnitude and phase responses of the filter, modify the plot settings, generate a script to re-create the plot, and even save or share the settings.

On the **Measurements** tab, you can enable data cursors, and display the peak values of the filter response.

For more details on the Dynamic Filter Visualizer interface and its tools, see “Configure Dynamic Filter Visualizer”.

Simulate using

Type of simulation to run. You can set this parameter to:

- Code generation (default)

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.

- Interpreted execution

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point

Filtering / Filter Designs

dspfdesign

Description

This block brings the filter design capabilities of the `filterBuilder` function to the Simulink environment.

This block supports SIMD code generation. For details, see “Code Generation” on page 2-1003.

Dialog Box

See “Nyquist Filter Design — Main Pane” on page 5-634 for more information about the parameters of this block. The **Data Types** and **Code Generation** panes are not available for blocks in the DSP System Toolbox Filter Designs library.

Parameters of this block that do not change filter order or structure are tunable.

View filter response

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

In this group, you specify your filter format, such as the impulse response and the filter order.

Band

Specifies the location of the center of the transition region between the passband and the stopband. The center of the transition region, F_c , is calculated using the value for **Band**:

$$F_c = F_s / (2 \cdot \mathbf{Band}).$$

The default value, 2, corresponds to a halfband filter.

Impulse response

Select either FIR or IIR from the drop-down list. FIR is the default. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly. These options are both available only when **Band** is 2. For values of **Band** greater than 2, only FIR designs are supported.

Note The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Filter order mode

Select either Minimum (the default) or Specify from the drop-down list. Selecting Specify enables the **Order** option (see the following sections) so you can enter the filter order.

Filter type

Select Single-rate, Decimator, Interpolator, or Sample-rate converter. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, the block specifies a single-rate filter.

- Selecting Decimator or Interpolator activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting Sample-rate converter activates both factors.

Order

Enter the filter order. This option is enabled only if Specify was selected for **Filter order mode**.

Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to Decimator or Sample-rate converter. The default value is 2.

Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to Interpolator or Sample-rate converter. The default value is 2.

Frequency Specifications

The parameters in this group allow you to specify your filter response curve.

Frequency constraints

Select the filter features that the block uses to define the frequency response characteristics.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0–1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input sample rate** parameter.

Input sample rate

F_s, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the

specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Transition width

Specify the width of the transition between the end of the passband and the edge of the stopband. Specify the value in normalized frequency units or the absolute units you select in **Frequency units**.

Magnitude Specifications

Parameters in this group specify the filter response in the passbands and stopbands.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. From the drop-down list, select one of the following options:

- Linear — Specify the magnitude in linear units.
- dB — Specify the magnitude in decibels (default)
- Squared — Specify the magnitude in squared units.

Stopband attenuation

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure of your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is Butterworth, and the default FIR method is Kaiser window.

Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 20 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Minimum order

When you select this parameter, the design method determines and design the minimum order filter to meet your specifications. Some filters do not provide this parameter. Select **Any**, **Even**, or **Odd** from the drop-down list to direct the design to be any minimum order, or minimum even order, or minimum odd order.

Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- **Flat** — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- **Linear** — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.

Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to **Flat**, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to **Linear**, enter the slope of the stopband in units of dB/rad/s. The block applies that slope to the stopband.
- When you set **Stopband shape** to $1/f$, enter a value for the exponent n in the relation $(1/f)^n$ to define the stopband decay. The block applies the $(1/f)^n$ relation to the stopband to result in an exponentially decreasing stopband attenuation.

Filter Implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of n unit delays with a single delay by n .
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Input processing

Specify how the block should process the input. The available options may vary depending on he settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- **Enforce single-rate processing** — When you select this option, the block maintains the sample rate of the input.
- **Allow multirate processing** — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to **Elements as channels (sample based)**.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The Nyquist Filter block supports SIMD code generation using Intel AVX2 technology under these conditions:

- **Filter type** is set to **Single-rate**, **Decimator**, or **Interpolator**.
- For **Filter type** that is set to **Single-rate**, **Structure** is set to **Direct-form FIR** or **Direct-form FIR transposed**.
- For **Filter type** that is set to **Decimator**, **Structure** is set to **Direct-form FIR polyphase decimator** and **Rate options** is set to **Enforce single-rate processing**.
- For **Filter type** that is set to **Interpolator**:

- **Interpolation Factor** cannot be equal to 1.
- **Rate options** is set to Enforce single-rate processing.
- **Input processing** is set to Columns as channels (frame based).
- Input signal has a data type of single or double.
- Input port dimensions cannot be equal to [1 1].

The SIMD technology significantly improves the performance of the generated code.

Octave Filter

Design octave filter

Compatibility

Note The Octave Filter block will be removed from DSP System Toolbox in a future release. Existing instances of the block continue to run. For new code, use the Octave Filter block from Audio Toolbox instead.

Library

Filtering / Filter Designs

dspfdesign

Description

This block brings the filter design capabilities of the `filterBuilder` function to the Simulink environment.

Dialog Box

See “Octave Filter Design — Main Pane” on page 5-638 for more information about the parameters of this block. The **Data Types** and **Code Generation** panes are not available for blocks in the DSP System Toolbox Filter Designs library.

Parameters of this block that do not change filter order or structure are tunable.

View filter response

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

Order

Specify filter order. Possible values are: 4, 6, 8, 10.

Bands per octave

Specify the number of bands per octave. Possible values are: 1, 3, 6, 12, 24.

Frequency units

Specify frequency units as Hz or kHz.

Input sample rate

Specify the input sampling frequency in the frequency units specified previously.

Center Frequency

Select from the drop-down list of available center frequency values.

Algorithm

Design Method

Butterworth is the design method used for this type of filter.

Scale SOS filter coefficients to reduce chance of overflow

Select the check box to scale the filter coefficients.

Filter Implementation

Structure

Specify filter structure. Choose from:

- Direct-form I SOS
- Direct-form II SOS
- Direct-form I transposed SOS
- Direct-form II transposed SOS

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of n unit delays with a single delay by n .
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

Input processing

Specify how the block should process the input. The available options may vary depending on the settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- **Enforce single-rate processing** — When you select this option, the block maintains the sample rate of the input.
- **Allow multirate processing** — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to **Elements as channels (sample based)**.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

Offset

Truncate vectors by removing or keeping beginning or ending values

Library: DSP System Toolbox / Signal Operations

Description

The Offset block removes or keeps values from the beginning or end of the input vectors. The number of values to remove or keep is determined by the offset value that you specify through the **O** ports (**O1**, **O2**, ...). The length of the truncated vector is determined by the **Output port length** and **Output length** parameters. The **Number of input data-offset pairs** parameter determines the number of input data-offset pairs.

Ports

Input

In1 — First input data

scalar | vector

Specify the first input data as a scalar or a vector. The inputs to the **In** ports (**In1**, **In2**, ...) must be of the same size and data type.

When the input is fixed-point, it is signed only.

Data Types: single | double | int8 | int16 | int32 | fixed point

O1 — First offset value

integer

Specify the offset value that the block uses to truncate the first input data as an integer. The offset value determines the number of samples the block removes or keeps at the beginning or at the end of the first data.

The inputs to the **O** ports (**O1**, **O2**, ...) must have the same data type. The block rounds any offset value that is a noninteger value to the nearest integer value. If the offset value is out of the $[0 N]$ range, then the **Action for out of range offset value** parameter determines how the block behaves. N is the input vector length.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32

In2 — Second input data

scalar | vector

Specify the second input data as a scalar or a vector. The inputs to the **In** ports (**In1**, **In2**, ...) must be of the same size and data type.

When the input is fixed-point, it is signed only.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

02 — Second offset value

integer

Specify the offset value that the block uses to truncate the second input data as an integer. The offset value determines the number of samples the block removes or keeps at the beginning or at the end of the second data.

The inputs to the **O** ports (**O1**, **O2**, ...) must have the same data type. The block rounds any offset value that is a noninteger value to the nearest integer value. If the offset value is out of the $[0 N]$ range, then the **Action for out of range offset value** parameter determines how the block behaves. N is the input vector length.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Output

Out1 — First truncated data

scalar | vector

The block returns the truncated data as a scalar or a vector. The length of the truncated data depends on the **Output port length** and the **Output length** parameters. If **Output port length** is set to `Same as input`, the truncated data has the same size as the input data. If **Output port length** is set to `User-defined`, then the **Output length** parameter determines the length of the output data.

There is one output port for each pair of **In** and **O** ports.

The truncated output has the same data type as the input data. When the output is fixed-point, it is signed only.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

Out2 — Second truncated data

scalar | vector

The block returns the truncated data as a scalar or a vector. The length of the truncated data depends on the **Output port length** and the **Output length** parameters. If **Output port length** is set to `Same as input`, the truncated data has the same size as the input data. If **Output port length** is set to `User-defined`, then the **Output length** parameter determines the length of the output data.

There is one output port for each pair of **In** and **O** ports.

The truncated output has the same data type as the input data. When the output is fixed-point, it is signed only.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

Parameters

Mode — Specify which values to discard and which values to keep

Remove beginning samples (default) | Remove ending samples | Keep beginning samples
| Keep ending samples

Use this parameter to specify which values the block discards and which values the block keeps from the input vector.

Select from the following:

- **Remove beginning samples** -- Discard the initial values of a vector.
- **Remove ending samples** -- Discard the final values of a vector.
- **Keep beginning samples** -- Retain the initial values of a vector.
- **Keep ending samples** -- Retain the final values of a vector.

Number of input data-offset pairs — Number of input data-offset pairs

2 (default) | positive integer

Use the **Number of input data-offset pairs** parameter to specify the number of inputs to the block. The number of input ports is twice the scalar value you specify in this parameter. For example, if you enter 3, input ports **In1**, **O1**, **In2**, **O2**, **In3**, and **O3** appear on the block.

Output port length — Mode to specify output port length

Same as input (default) | User-defined

Use this parameter to specify the length of the output vectors. If you select **Same as input**, the output vectors have the same length as the input vectors. If you select **User-defined**, you can enter the desired length in the **Output length** parameter.

Output length — Desired length of output vectors

9 (default) | positive integer

Enter a scalar that represents the desired length of the output vectors. If the desired output length that you specify is greater than the number of values that the block extracts from the input vector, the block zero-pads the end of the vector to reach the length that you specify.

Dependencies

This parameter is visible only if you set the **Output port length** parameter to **User-defined**.

Action for out of range offset value — Action for out of range offset value

Clip (default) | Clip and warn | Error

Use this parameter to determine how the block behaves when an offset value is not in the range such that $0 \leq \text{offset value} \leq N$, where N is the input vector length.

- **Clip** -- Offset values less than 0 are set to 0 and offset values greater than N are set to N .
- **Clip and warn** -- Offset values less than 0 are set to 0 and offset values greater than N are set to N . In addition, the block displays a warning message.
- **Error** -- Simulation stops and the block displays an error when the offset values are out of range.

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the memcpy or memset function (string.h) under certain conditions.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

If the input is fixed point, it must be a signed integer or signed fixed point with a power-of-two slope and zero bias.

Overlap-Add FFT Filter (Obsolete)

Implement overlap-add method of frequency-domain filtering

Library

Filtering / Filter Implementations

dsparch4

Description

Note The Overlap-Add FFT Filter block has been replaced with the Frequency-Domain FIR Filter block. Existing instances of the Overlap-Add FFT Filter block continue to run.

The Overlap-Add FFT Filter block uses an FFT to implement the *overlap-add method*, a technique that combines successive frequency-domain filtered sections of an input sequence.

The block accepts vector or matrix inputs, and treats each column of the input as an individual channel. The block unbuffers the input data into row vectors such that the length of the output vector is equal to the number of channels in the input. The data output rate of the block is M times faster than its data input rate, where M is the length of the columns in the input (frame-size).

The block breaks the scalar input sequence u , of length nu , into length- L nonoverlapping data sections,

which it linearly convolves with the filter's FIR coefficients,

$$H(z) = B(z) = b_1 + b_2z^{-1} + \dots + b_{n+1}z^{-n}$$

The numerator coefficients for $H(z)$ are specified as a vector by the **FIR coefficients** parameter. The coefficient vector, $\mathbf{b} = [\mathbf{b}(1) \ \mathbf{b}(2) \ \dots \ \mathbf{b}(n+1)]$, can be generated by one of the filter design functions in the Signal Processing Toolbox product, such as `fir1`. All filter states are internally initialized to zero.

When either the filter coefficients or the inputs to the block are complex, the **Output** parameter should be set to `Complex`. Otherwise, the default **Output** setting, `Real`, instructs the block to take only the real part of the solution.

The block's overlap-add operation is equivalent to

$$y = \text{ifft}(\text{fft}(u(i:i+L-1), \text{nfft}) .* \text{fft}(\mathbf{b}, \text{nfft}))$$

where you specify `nfft` in the **FFT size** parameter as a power-of-two value greater (typically *much* greater) than $n+1$. Values for **FFT size** that are not powers of two are rounded upwards to the nearest power-of-two value to obtain `nfft`.

The block overlaps successive output sections by n points and sums them.

The first L samples of each summation are output in sequence. The block chooses the parameter L based on the filter order and the FFT size.

$$L = \text{nfft} - n$$

Latency

In *single-tasking* operation, the Overlap-Add FFT Filter block has a latency of $\text{nfft} - n + 1$ samples. The first $\text{nfft} - n + 1$ consecutive outputs from the block are zero; the first filtered input value appears at the output as sample $\text{nfft} - n + 2$.

In *multitasking* operation, the Overlap-Add FFT Filter block has a latency of $2 * (\text{nfft} - n) + 1$ samples. The first $2 * (\text{nfft} - n) + 1$ consecutive outputs from the block are zero; the first filtered input value appears at the output as sample $2 * (\text{nfft} - n) + 3$.

Note For more information on latency and the Simulink software tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Parameters

FFT size

The size of the FFT, which should be a power-of-two value greater than the length of the specified FIR filter.

FIR coefficients

The filter numerator coefficients.

Output

The complexity of the output; `Real` or `Complex`. When the input signal or the filter coefficients are complex, this should be set to `Complex`.

Overlap-Save FFT Filter

DSP System Toolbox product

Version History

Introduced before R2006a

Overlap-Save FFT Filter (Obsolete)

Implement overlap-save method of frequency-domain filtering

Library

Filtering / Filter Implementations

dsparch4

Description

Note The Overlap-Save FFT Filter block has been replaced with the Frequency-Domain FIR Filter block. Existing instances of the Overlap-Save FFT Filter block continue to run.

The Overlap-Save FFT Filter block uses an FFT to implement the *overlap-save method*, a technique that combines successive frequency-domain filtered sections of an input sequence.

The block accepts vector or matrix inputs, and treats each column of the input as an individual channel. The block unbuffers the input data into row vectors such that the length of the output vector is equal to the number of channels in the input. The data output rate of the block is M times faster than its data input rate, where M is the length of the columns in the input (frame-size).

Overlapping sections of input u are circularly convolved with the FIR filter coefficients

$$H(z) = B(z) = b_1 + b_2z^{-1} + \dots + b_{n+1}z^{-n}$$

The numerator coefficients for $H(z)$ are specified as a vector by the **FIR coefficients** parameter. The coefficient vector, $\mathbf{b} = [b(1) \ b(2) \ \dots \ b(n+1)]$, can be generated by one of the filter design functions in the Signal Processing Toolbox product, such as `fir1`. All filter states are internally initialized to zero.

When either the filter coefficients or the inputs to the block are complex, the **Output** parameter should be set to **Complex**. Otherwise, the default **Output** setting, **Real**, instructs the block to take only the real part of the solution.

The circular convolution of each section is computed by multiplying the FFTs of the input section and filter coefficients, and computing the inverse FFT of the product.

```
y = ifft(fft(u(i:i+(L-1))),nfft) .* fft(b,nfft)
```

where you specify `nfft` in the **FFT size** parameter as a power of two value greater (typically *much* greater) than $n+1$. Values for **FFT size** that are not powers of two are rounded upwards to the nearest power-of-two value to obtain `nfft`.

The first n points of the circular convolution are invalid and are discarded. The Overlap-Save FFT Filter block outputs the remaining $n_{\text{fft}} - n$ points, which are equivalent to the linear convolution.

Latency

In *single-tasking* operation, the Overlap-Save FFT Filter block has a latency of $n_{\text{fft}} - n + 1$ samples. The first $n_{\text{fft}} - n + 1$ consecutive outputs from the block are zero; the first filtered input value appears at the output as sample $n_{\text{fft}} - n + 2$.

In *multitasking* operation, the Overlap-Save FFT Filter block has a latency of $2 * (n_{\text{fft}} - n + 1)$ samples. The first $2 * (n_{\text{fft}} - n + 1)$ consecutive outputs from the block are zero; the first filtered input value appears at the output as sample $2 * (n_{\text{fft}} - n) + 3$.

Note For more information on latency and the Simulink environment tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Parameters

FFT size

The size of the FFT, which should be a power of two value greater than the length of the specified FIR filter.

FIR coefficients

The filter numerator coefficients.

Output

The complexity of the output; `Real` or `Complex`. When the input signal or the filter coefficients are complex, this should be set to `Complex`.

Overwrite Values

Overwrite submatrix or subdiagonal of input

Library

- Math Functions / Matrices and Linear Algebra / Matrix Operations

`dspmtx3`

- Signal Management / Indexing

`dspindex`

Description

The Overwrite Values block overwrites a contiguous submatrix or subdiagonal of an input matrix. You can provide the overwriting values by typing them in a block parameter, or through an additional input port, which is useful for providing overwriting values that change at each time step.

The block accepts scalars, vectors and matrices. The output always has the same size as the original input signal, not necessarily the same size as the signal containing the overwriting values. The input(s) and output of this block must have the same data type.

Specifying the Overwriting Values

The **Source of overwriting value(s)** parameter determines how you must provide the overwriting values, and has the following settings.

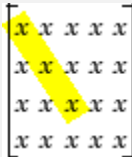

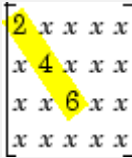

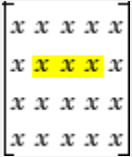

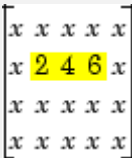

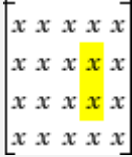

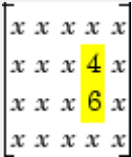

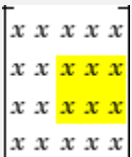

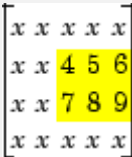

- Specify via dialog** — You must provide the overwriting value(s) in the **Overwrite with** parameter. The block uses the same overwriting values to overwrite the specified portion of the input at each time step. To learn how to specify valid overwriting values, see “Valid Overwriting Values” on page 2-1019.
- Second input port** — You must provide overwriting values through a second block input port, *V*. Use this setting to provide different overwriting values at each time step. The output inherits its size and rate from the input signal, *not* the overwriting values.

The rate at which you provide the overwriting values through input port V must match the rate at which the block receives each input matrix at input port A. In other words, the input signals must have the same Simulink sample time.

Valid Overwriting Values

The overwriting values can be a single constant, vector, or matrix, depending on the portion of the input you are overwriting, regardless of whether you provide the overwriting values through an input port or by providing them in the **Overwrite with** parameter.

Valid Overwriting Values

Portion of Input to Overwrite	Valid Overwriting Values	Example
<p>A single element in the input</p> 	<p>Any constant value, v</p>	<p>$v = 9$</p> 
<p>A length-k portion of the diagonal</p> 	<p>Any length-k column or row vector, v</p>	<p>$k = 3 \quad v = [2 \ 4 \ 6] \quad \text{or} \quad \begin{bmatrix} 2 \\ 4 \\ 6 \end{bmatrix}$</p> 
<p>A length-k portion of a row</p> 	<p>Any length-k row vector, v</p>	<p>$k = 3 \quad v = [2 \ 4 \ 6]$</p> 
<p>A length-k portion of a column</p> 	<p>Any length-k column vector, v</p>	<p>$k = 2 \quad v = \begin{bmatrix} 4 \\ 6 \end{bmatrix}$</p> 
<p>An m-by-n submatrix</p> 	<p>Any m-by-n matrix, v</p>	<p>$m = 2 \quad n = 3 \quad v = \begin{bmatrix} 4 & 5 & 6 \\ 7 & 8 & 9 \end{bmatrix}$</p> 

This block supports Simulink virtual buses.

Parameters

Note Only some of the following parameters are visible in the dialog box at any one time.

Overwrite

Determines whether to overwrite a specified submatrix or a specified portion of the diagonal.

Source of overwriting value(s)

Determines where you must provide the overwriting values: either through an input port, or by providing them in the **Overwrite with** parameter. For more information, see “Specifying the Overwriting Values” on page 2-1018.

Overwrite with

The value(s) with which to overwrite the specified portion of the input matrix. Enabled only when **Source of overwriting value(s)** is set to *Specify via dialog*. To learn how to specify valid overwriting values, see “Valid Overwriting Values” on page 2-1019.

Row span

The range of input rows to be overwritten. Options are *All rows*, *One row*, or *Range of rows*. For descriptions of these options, see “Parameters” on page 2-1021.

Row/Starting row

The input row that is the first row of the submatrix that the block overwrites. For a description of the options for the **Row** and **Starting row** parameters, see *Settings for Row, Column, Starting Row, and Starting Column Parameters*. **Row** is enabled when **Row span** is set to *One row*, and **Starting row** when **Row span** is set to *Range of rows*.

Row index/Starting row index

Index of the input row that is the first row of the submatrix that the block overwrites. See how to use these parameters in *Settings for Row, Column, Starting Row, and Starting Column Parameters*. **Row index** is enabled when **Row** is set to *Index*, and **Starting row index** when **Starting row** is set to *Index*.

Row offset/Starting row offset

The offset of the input row that is the first row of the submatrix that the block overwrites. See how to use these parameters in *Settings for Row, Column, Starting Row, and Starting Column Parameters*. **Row offset** is enabled when **Row** is set to *Offset from middle* or *Offset from last*, and **Starting row offset** is enabled when **Starting row** is set to *Offset from middle* or *Offset from last*.

Ending row

The input row that is the last row of the submatrix that the block overwrites. For a description of this parameter's options, see *Settings for Ending Row and Ending Column Parameters*. This parameter is enabled when **Row span** is set to *Range of rows*, and **Starting row** is set to any option but *Last*.

Ending row index

Index of the input row that is the last row of the submatrix that the block overwrites. See how to use this parameter in *Settings for Ending Row and Ending Column Parameters*. Enabled when **Ending row** is set to *Index*.

Ending row offset

The offset of the input row that is the last row of the submatrix that the block overwrites. See how to use this parameter in Settings for Ending Row and Ending Column Parameters. Enabled when **Ending row** is set to `Offset from middle` or `Offset from last`.

Column span

The range of input columns to be overwritten. Options are `All columns`, `One column`, or `Range of columns`. For descriptions of the analogous row options, see “Parameters” on page 2-1021.

Column/Starting column

The input column that is the first column of the submatrix that the block overwrites. For a description of the options for the **Column** and **Starting column** parameters, see Settings for Row, Column, Starting Row, and Starting Column Parameters. **Column** is enabled when **Column span** is set to `One column`, and **Starting column** when **Column span** is set to `Range of columns`.

Column index/Starting column index

Index of the input column that is the first column of the submatrix that the block overwrites. See how to use these parameters in Settings for Row, Column, Starting Row, and Starting Column Parameters. **Column index** is enabled when **Column** is set to `Index`, and **Starting column index** when **Starting column** is set to `Index`.

Column offset/Starting column offset

The offset of the input column that is the first column of the submatrix that the block overwrites. See how to use these parameters in Settings for Row, Column, Starting Row, and Starting Column Parameters. **Column offset** is enabled when **Column** is set to `Offset from middle` or `Offset from last`, and **Starting column offset** is enabled when **Starting column** is set to `Offset from middle` or `Offset from last`.

Ending column

The input column that is the last column of the submatrix that the block overwrites. For a description of this parameter's options, see Settings for Ending Row and Ending Column Parameters. This parameter is enabled when **Column span** is set to `Range of columns`, and **Starting column** is set to any option but `Last`.

Ending column index

Index of the input column that is the last column of the submatrix that the block overwrites. See how to use this parameter in Settings for Ending Row and Ending Column Parameters. This parameter is enabled when **Ending column** is set to `Index`.

Ending column offset

The offset of the input column that is the last column of the submatrix that the block overwrites. See how to use this parameter in Settings for Ending Row and Ending Column Parameters. This parameter is enabled when **Ending column** is set to `Offset from middle` or `Offset from last`.

Diagonal span

The range of diagonal elements to be overwritten. Options are `All elements`, `One element`, or `Range of elements`. For descriptions of these options, see “Overwriting a Subdiagonal” on page 2-1026.

Element/Starting element

The input diagonal element that is the first element in the subdiagonal that the block overwrites. For a description of the options for the **Element** and **Starting element** parameters, see Element

and Starting Element Parameters. **Element** is enabled when **Element span** is set to One element, and **Starting element** when **Element span** is set to Range of elements.

Element index/Starting element index

Index of the input diagonal element that is the first element of the subdiagonal that the block overwrites. See how to use these parameters in Element and Starting Element Parameters.

Element index is enabled when **Element** is set to Index, and **Starting element index** when **Starting element** is set to Index.

Element offset/Starting element offset

The offset of the input diagonal element that is the first element of the subdiagonal that the block overwrites. See how to use these parameters in Element and Starting Element Parameters.

Element offset is enabled when **Element** is set to Offset from middle or Offset from last, and **Starting element offset** is enabled when **Starting element** is set to Offset from middle or Offset from last.

Ending element

The input diagonal element that is the last element of the subdiagonal that the block overwrites. For a description of this parameter's options, see Ending Element Parameters. This parameter is enabled when **Element span** is set to Range of elements, and **Starting element** is set to any option but Last.

Ending element index

Index of the input diagonal element that is the last element of the subdiagonal that the block overwrites. See how to use this parameter in Ending Element Parameters. This parameter is enabled when **Ending element** is set to Index.

Ending element offset

The offset of the input diagonal element that is the last element of the subdiagonal that the block overwrites. See how to use this parameter in Ending Element Parameters. This parameter is enabled when **Ending element** is set to Offset from middle or Offset from last.

Examples

Overwriting a Submatrix

To overwrite a submatrix, follow these steps:

- 1 Set the **Overwrite** parameter to Submatrix.
- 2 Specify the overwriting values as described in “Specifying the Overwriting Values” on page 2-1018.
- 3 Specify which rows and columns of the input matrix are contained in the submatrix that you want to overwrite by setting the **Row span** parameter to one of the following options and the **Column span** to the analogous column-related options:
 - All rows — The submatrix contains all rows of the input matrix.
 - One row — The submatrix contains only one row of the input matrix, which you must specify in the **Row** parameter, as described in the following table.
 - Range of rows — The submatrix contains one or more rows of the input, which you must specify in the **Starting Row** and **Ending row** parameters, as described in the following tables.
- 4 When you set **Row span** to One row or Range of rows, you need to further specify the row(s) contained in the submatrix by setting the **Row** or **Starting row** and **Ending row** parameters.

Likewise, when you set **Column span** to One column or Range of columns, you must further specify the column(s) contained in the submatrix by setting the **Column** or **Starting column** and **Ending column** parameters. For descriptions of the settings for these parameters, see the following tables.

Settings for Row, Column, Starting Row, and Starting Column Parameters

Settings for Specifying the Submatrix's First Row or Column	First Row of Submatrix (Only row for Row span = One row)	First Column of Submatrix (Only row for Row span = One row)
First	First row of the input	First column of the input
Index	Input row specified in the Row index parameter	Input column specified in the Column index parameter
Offset from last	Input row with the index $M - \text{rowOffset}$ where M is the number of input rows, and rowOffset is the value of the Row offset or Starting row offset parameter	Input column with the index $N - \text{colOffset}$ where N is the number of input columns, and colOffset is the value of the Column offset or Starting column offset parameter
Last	Last row of the input	Last column of the input
Offset from middle	Input row with the index $\text{floor}(M/2 + 1 - \text{rowOffset})$ where M is the number of input rows, and rowOffset is the value of the Row offset or Starting row offset parameter	Input column with the index $\text{floor}(N/2 + 1 - \text{colOffset})$ where N is the number of input columns, and colOffset is the value of the or Column offset or Starting column offset parameter
Middle	Input row with the index $\text{floor}(M/2 + 1)$ where M is the number of input rows	Input columns with the index $\text{floor}(N/2 + 1)$ where N is the number of input columns

Settings for Ending Row and Ending Column Parameters

Settings for Specifying the Submatrix's Last Row or Column	Last Row of Submatrix	Last Column of Submatrix
Index	Input row specified in the Ending row index parameter	Input column specified in the Ending column index parameter
Offset from last	Input row with the index $M - \text{rowOffset}$ where M is the number of input rows, and rowOffset is the value of the Ending row offset parameter	Input column with the index $N - \text{colOffset}$ where N is the number of input columns, and colOffset is the value of the Ending column offset parameter
Last	Last row of the input	Last column of the input
Offset from middle	Input row with the index $\text{floor}(M/2 + 1 - \text{rowOffset})$ where M is the number of input rows, and rowOffset is the value of the Ending row offset parameter	Input column with the index $\text{floor}(N/2 + 1 - \text{colOffset})$ where N is the number of input columns, and colOffset is the value of the Ending column offset parameter
Middle	Input row with the index $\text{floor}(M/2 + 1)$ where M is the number of input rows	Input columns with the index $\text{floor}(N/2 + 1)$ where N is the number of input columns

For example, to overwrite the lower-right 2-by-3 submatrix of a 3-by-5 input matrix with all zeros, enter the following set of parameters:

- **Overwrite** = Submatrix
- **Source of overwriting value(s)** = Specify via dialog
- **Overwrite with** = 0
- **Row span** = Range of rows
- **Starting row** = Index
- **Starting row index** = 2
- **Ending row** = Last
- **Column span** = Range of columns
- **Starting column** = Offset from last
- **Starting column offset** = 2
- **Ending column** = Last

The following figure shows the block with the above settings overwriting a portion of a 3-by-5 input matrix.

There are often several possible parameter combinations that select the *same* submatrix from the input. For example, instead of specifying Last for **Ending column**, you could select the same submatrix by specifying

- **Ending column** = Index
- **Ending column index** = 5

Overwriting a Subdiagonal

To overwrite a subdiagonal, follow these steps:

- 1 Set the **Overwrite** parameter to `Diagonal`.
- 2 Specify the overwriting values as described in “Specifying the Overwriting Values” on page 2-1018.
- 3 Specify the subdiagonal that you want to overwrite by setting the **Diagonal span** parameter to one of the following options:
 - All elements — Overwrite the entire input diagonal.
 - One element — Overwrite one element in the diagonal, which you must specify in the **Element** parameter (described below).
 - Range of elements — Overwrite a portion of the input diagonal, which you must specify in the **Starting element** and **Ending element** parameters, as described in the following table.
- 4 When you set **Diagonal span** to One element or Range of elements, you need to further specify which diagonal element(s) to overwrite by setting the **Element** or **Starting element** and **Ending element** parameters. See the following tables.

Element and Starting Element Parameters

Settings for Element and Starting Element Parameters	First Element in Subdiagonal (Only element when Diagonal span = One element)
First	Diagonal element in first row of the input
Index	k th diagonal element, where k is the value of the Element index or Starting element index parameter
Offset from last	Diagonal element in the row with the index $M - \text{offset}$ where M is the number of input rows, and offset is the value of the Element offset or Starting element offset parameter
Last	Diagonal element in the last row of the input
Offset from middle	Diagonal element in the input row with the index $\text{floor}(M/2 + 1 - \text{offset})$ where M is the number of input rows, and offset is the value of the Element offset or Starting element offset parameter
Middle	Diagonal element in the input row with the index $\text{floor}(M/2 + 1)$ where M is the number of input rows

Ending Element Parameters

Settings for Ending Element Parameter	Last Element in Subdiagonal
Index	k th diagonal element, where k is the value of the Ending element index parameter
Offset from last	Diagonal element in the row with the index $M - \text{offset}$ where M is the number of input rows, and offset is the value of the Ending element offset parameter
Last	Diagonal element in the last row of the input
Offset from middle	Diagonal element in the input row with the index $\text{floor}(M/2 + 1 - \text{offset})$ where M is the number of input rows, and offset is the value of the Ending element offset parameter
Middle	Diagonal element in the input row with the index $\text{floor}(M/2 + 1)$ where M is the number of input rows

Supported Data Types

The input(s) and output of this block must have the same data type.

Port	Supported Data Types
A	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
V	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
B	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Pad

Pad or truncate specified dimension(s)

Library: DSP System Toolbox / Signal Operations

Description

The Pad block extends or crops the dimensions of an input signal by padding or truncating along its columns, rows, columns and rows, or along any other dimension(s) that you specify. The block truncates the input when you specify output dimensions that are shorter than the corresponding input dimensions. If the input and output lengths are the same, the block acts as a pass-through.

You can enter the pad value in the block mask or via an input port. You can enter output sizes in the block mask, or have the block pad the specified dimensions until their length is the next highest power of two. The **Pad signal at** parameter controls whether the block pads or truncates the input signal dimensions at the beginning, end, or both. For odd pad or truncation lengths, the extra pad or truncation value is applied at the end of the signal. When the block is in the **Specified dimensions** mode, you can specify either the output size or the pad size.

You can configure the block to warn or error when an input signal is truncated using the **Action when truncation occurs** parameter.

Ports

Input

Input 1 — Data input

scalar | vector | matrix | N -D array

Specify the input as a scalar, vector, matrix, or an N -D array.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Output 1 — Padded or truncated output

scalar | vector | matrix | N -D array

Output of the Pad block. The size and dimension of the output depends on whether the block has padded or truncated the input along the specified dimension. The data type and complexity of the output matches that of the input.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Parameters

Pad over — Dimension over which to pad or truncate

Columns (default) | Rows | Columns and rows | None | Specified dimensions

Specify the dimensions over which to pad or truncate:

- Columns
- Rows
- Columns and rows
- None
- Specified dimensions

Dimensions to pad — Specify dimension over which to pad or truncate

1 (default) | scalar | vector

Specify the one-based dimension(s) over which to pad or truncate. The value for this parameter can be a scalar or a vector. For example, specify 1 to pad columns. Specify [1 2] to pad columns and rows. Specify [1 3 5] to pad the first, third, and fifth dimensions.

Dependencies

This parameter appears only when you set **Pad over** to Specified dimensions.

Pad value source — Source of pad value

Specify via dialog (default) | Input port

Choose how you specify the pad value. The pad value can come from the dialog or from an input port:

- If you select Specify via dialog, the **Pad value** parameter appears.
- If you select Input port, the PVal port appears on the block icon.

Pad value — Pad value

0 (default) | scalar

Specify the constant scalar value with which to pad the input.

Tunable: Yes

Dependencies

This parameter appears only when you set **Pad value source** to Specify via dialog.

Output column mode — Mode of specifying column length

User-specified | Next power of two

Choose how you specify the column length of the output:

- If you select User-specified, the **Column size** parameter appears.

- If you select `Next power of two`, the block pads the output columns until their length is the next highest power of two. If the column length is already a power of two, the block does not pad the columns.

Dependencies

This parameter appears only when you set **Pad over** to `Columns` or `Columns and rows`.

Column size — Column length of output

1 | scalar

Specify the column length of the output. If the specified column length is longer than the input column length, the block pads the columns. If the specified column length is shorter than the input column length, the block truncates the columns.

Dependencies

This parameter appears only when you set **Output column mode** to `User-specified`.

Output row mode — Mode of specifying row length

`User-specified (default)` | `Next power of two`

Choose how you specify the row length of the output:

- If you select `User-specified`, the **Row size** parameter appears.
- If you select `Next power of two`, the block pads the output rows until their length is the next highest power of two. If the row length is already a power of two, the block does not pad the rows.

Dependencies

This parameter appears only when you set **Pad over** to `Rows` or `Columns and rows`.

Row size — Row length of output

1 | scalar

Specify the row length of the output. If the specified row length is longer than the input row length, the block pads the rows. If the specified row length is shorter than the input row length, the block truncates the rows.

Dependencies

This parameter appears only when you set **Output row mode** to `User-specified`.

Specify — Specify output size or pad size

`Output size (default)` | `Pad size`

Choose whether you want to control the output length of the specified dimensions by specifying the output size or the pad size.

Dependencies

This parameter appears only when you set **Pad over** to `Specified dimensions`.

Output size mode — Mode of specifying output length

User-specified | Next power of two

Choose how you specify the output length of the specified dimensions:

- If you select `User-specified`, the **Output size** parameter appears.
- If you select `Next power of two`, the block pads the specified dimensions until their length is the next highest power of two. If the dimension length is already a power of two, the block does not pad in that dimension.

Dependencies

This parameter appears only when you set **Pad over** to `Specified dimensions` and the **Specify** parameter to `Output size`.

Output size — Output length along specified dimension

1 | scalar | vector

Specify the output length of the specified dimension(s). This parameter must be a scalar or a vector with the same number of elements as the **Dimensions to pad** parameter. Each element in the **Output size** vector gives the output length for the corresponding dimension in the **Dimensions to pad** vector. If the specified length is longer than the input length for a given dimension, the block pads that dimension. If the specified length is shorter than the input length for a given dimension, the block truncates that dimension.

Dependencies

This parameter appears only when you set **Pad over** to `Specified dimensions` and the **Specify** parameter to `Output size`.

Pad size at beginning — Specify number of values to add to beginning of input signal

0 | scalar | vector

Specify how many values to add to the beginning of the input signal along the specified dimension(s). This parameter must be a scalar or a vector with the same number of elements as the **Dimensions to pad** parameter. Each element in the **Pad size at beginning** parameter gives the pad length at the beginning of the corresponding dimension in the **Dimensions to pad** parameter. Values of this parameter must be nonnegative integers.

Dependencies

This parameter appears only when you set **Pad over** to `Specified dimensions` and the **Specify** parameter to `Pad size`.

Pad size at end — Specify number of values to add to end of input signal

0 | scalar | vector

Specify how many values to add to the end of the input signal along the specified dimension(s). This parameter must be a scalar or a vector with the same number of elements as the **Dimensions to pad** parameter. Each element in the **Pad size at end** parameter gives the pad length at the end of the corresponding dimension in the **Dimensions to pad** parameter. Values of this parameter must be nonnegative integers.

Dependencies

This parameter appears only when you set **Pad over** to Specified dimensions and the **Specify** parameter to Pad size.

Pad signal at — Specify where to pad or truncate signal

End (default) | Beginning | Beginning and end

Specify whether to pad or truncate the signal at the Beginning, End, or Beginning and end of the specified dimension(s). When you select Beginning and end, half the pad length is added to the beginning of the signal and the other half is added to the end of the signal. For an odd pad length, the extra value is added to the end of the signal. When you specify to truncate the signal in this mode, an equal number of values are truncated from the beginning and the end of the signal. In the case of an odd truncation length, the extra value is removed from the end of the signal.

Dependencies

This parameter appears only when you set **Pad over** to Columns, Rows, and Columns and rows.

Action when truncation occurs — Action to take when truncation occurs

None | Warning | Error

Specify the action the block takes when it truncates the input.

- None -- The block does not notify when the input is truncated.
- Warning -- The block displays a warning when the input is truncated.
- Error -- The block displays an error message and terminates the simulation when the input is truncated.

Dependencies

This parameter appears only when you set **Pad over** to Columns, Rows, and Columns and rows.

Block Characteristics

Data Types	Boolean double fixed point integer single
Direct Feedthrough	no

View filter response

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications**Order mode**

Select **Minimum** to design a minimum order filter that meets the design specifications, or **Specify** to enter a specific filter order. The order mode also affects the possible frequency constraints, which in turn limit the gain specifications. For example, if you specify a **Minimum** order filter, the available frequency constraints are:

- Center frequency, bandwidth, passband width
- Center frequency, bandwidth, stopband width

If you select **Specify**, the available frequency constraints are:

- Center frequency, bandwidth
- Center frequency, quality factor
- Shelf type, cutoff frequency, quality factor
- Shelf type, cutoff frequency, shelf slope parameter
- Low frequency, high frequency

Order

Specify the filter order. This parameter is enabled only if the **Order mode** is set to **Specify**.

Frequency specifications

Depending on the filter order, the possible frequency constraints change. Once you choose the frequency constraints, the input boxes in this area change to reflect the selection.

Frequency constraints

Select the specification to represent the frequency constraints. The following options are available:

- Center frequency, bandwidth, passband width (available for minimum order only)
- Center frequency, bandwidth, stopband width (available for minimum order only)
- Center frequency, bandwidth (available for a specified order only)
- Center frequency, quality factor (available for a specified order only)
- Shelf type, cutoff frequency, quality factor (available for a specified order only)
- Shelf type, cutoff frequency, shelf slope parameter (available for a specified order only)

- Low frequency, high frequency (available for a specified order only)

Frequency units

Select the frequency units from the available drop down list (Normalized, Hz, kHz, MHz, GHz). If Normalized is selected, then the **Input Fs** box is disabled for input.

Input Fs

Enter the input sampling frequency. This input box is disabled for input if Normalized is selected in the **Frequency units** input box.

Center frequency

Enter the center frequency in the units specified by the value in **Frequency units**.

Bandwidth

The bandwidth determines the frequency points at which the filter magnitude is attenuated by the value specified as the **Bandwidth gain** in the **Gain specifications** section. By default, the **Bandwidth gain** defaults to $\text{db}(\text{sqrt}(.5))$, or -3 dB relative to the center frequency. The **Bandwidth** property only applies when the **Frequency constraints** are: Center frequency, bandwidth, passband width, Center frequency, bandwidth, stopband width, or Center frequency, bandwidth.

Passband width

The passband width determines the frequency points at which the filter magnitude is attenuated by the value specified as the **Passband gain** in the **Gain specifications** section. This option is enabled only if the filter is of minimum order, and the frequency constraint selected is Center frequency, bandwidth, passband width.

Stopband width

The stopband width determines the frequency points at which the filter magnitude is attenuated by the value specified as the **Stopband gain** in the **Gain specifications** section. This option is enabled only if the filter is of minimum order, and the frequency constraint selected is Center frequency, bandwidth, stopband width.

Low frequency

Enter the low frequency cutoff. This option is enabled only if the filter order is user specified and the frequency constraint selected is Low frequency, high frequency. The filter magnitude is attenuated by the amount specified in **Bandwidth gain**.

High frequency

Enter the high frequency cutoff. This option is enabled only if the filter order is user specified and the frequency constraint selected is Low frequency, high frequency. The filter magnitude is attenuated by the amount specified in **Bandwidth gain**.

Gain Specifications

Depending on the filter order and frequency constraints, the possible gain constraints change. Also, once you choose the gain constraints the input boxes in this area change to reflect the selection.

Gain constraints

Select the specification array to represent gain constraints, and remember that not all of these options are available for all configurations. The following is a list of all available options:

- Reference, center frequency, bandwidth, passband
- Reference, center frequency, bandwidth, stopband

- Reference, center frequency, bandwidth, passband, stopband
- Reference, center frequency, bandwidth

Gain units

Specify the gain units either dB or squared. These units are used for all gain specifications in the dialog box.

Reference gain

The reference gain determines the level to which the filter magnitude attenuates in **Gain units**. The reference gain is a *floor* gain for the filter magnitude response. For example, you may use the reference gain together with the **Center frequency gain** to leave certain frequencies unattenuated (reference gain of 0 dB) while boosting other frequencies.

Bandwidth gain

Specifies the gain in **Gain units** at which the bandwidth is defined. This property applies only when the **Frequency constraints** specification contains a bandwidth parameter, or is Low frequency, high frequency.

Center frequency gain

Specify the center frequency in **Gain units**

Passband gain

The passband gain determines the level in **Gain units** at which the passband is defined. The passband is determined either by the **Passband width** value, or the **Low frequency** and **High frequency** values in the **Frequency specifications** section.

Stopband gain

The stopband gain is the level in **Gain units** at which the stopband is defined. This property applies only when the **Order mode** is minimum and the **Frequency constraints** are Center frequency, bandwidth, stopband width.

Boost/cut gain

The boost/cut gain applies only when the designing a shelving filter. Shelving filters include the **Shelf** type parameter in the **Frequency constraints** specification. The gain in the passband of the shelving filter is increased by **Boost/cut gain** dB from a *floor* gain of 0 dB.

Algorithm**Design method**

Select the design method from the drop-down list. Different methods are available depending on the chosen filter constraints.

Scale SOS filter coefficients to reduce chance of overflow

Select the check box to scale the filter coefficients.

Filter Implementation**Structure**

Specify filter structure. Choose from:

- Direct-form I SOS
- Direct-form II SOS
- Direct-form I transposed SOS

- Direct-form II transposed SOS

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of n unit delays with a single delay by n .
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

Input processing

Specify how the block should process the input. The available options may vary depending on the settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

Note The Inherited (this choice will be removed – see release notes) option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- **Enforce single-rate processing** — When you select this option, the block maintains the sample rate of the input.
- **Allow multirate processing** — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to **Elements as channels (sample based)**.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none">• Double-precision floating point• Single-precision floating point
Output	<ul style="list-style-type: none">• Double-precision floating point• Single-precision floating point

Introduced in R2007a

Parametric EQ Filter (Obsolete)

(Removed) Model second-order parametric equalizer filter

Note The Parametric EQ Filter block requires Audio Toolbox. Existing models using the Parametric EQ Filter block continue to run. For new models, use the Parametric EQ block from Audio Toolbox.

Library

dspobslib

Description

The Parametric EQ Filter block filters each channel of the input signal over time using a specified center frequency, bandwidth, and peak (dip) gain. This block offers tunable filter design parameters, which enable you to tune the filter characteristics while the simulation is running.

The block designs the filter according to the filter parameters set in the block dialog box. The output port properties, such as datatype, complexity, and dimension, are identical to the input port properties.

Each column of the input signal is treated as a separate channel. If the input is a two-dimensional signal, the first dimension represents the channel length (or frame size) and the second dimension represents the number of channels. If the input is a one-dimensional signal, then it is interpreted as a single channel.

This block supports variable-size input, enabling you to change the channel length during simulation. To enable variable-size input, clear the **Inherit sample rate from input** check box. The number of channels must remain constant.

Parameters

Filter specification

Parameters or coefficients used to design the filter, specified as one of the following:

- Bandwidth and center frequency (default) — Design the filter using **Filter bandwidth (Hz)**, **Equalizer center frequency (Hz)**, and **Gain (dB)**.
- Coefficients — Design the filter using **Bandwidth coefficient**, **Center frequency coefficient**, and **Gain (Linear Units)**.
- Quality factor and center frequency — Design the filter using **Equalizer center frequency (Hz)**, **Gain (dB)**, and **Quality factor**.

This parameter is nontunable.

Specify bandwidth from input port

When you select this check box, the filter bandwidth is input through the **BW** port. When you clear this check box, the filter bandwidth is specified on the block dialog through the **Filter bandwidth (Hz)** parameter.

This parameter applies when you set **Filter specification** to Bandwidth and center frequency.

Filter bandwidth (Hz)

Bandwidth of the filter, specified as a finite positive numeric scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter specification** to Bandwidth and center frequency and clear the **Specify bandwidth from input port** parameter. The default is 2205. This parameter is tunable.

Specify center frequency from input port

When you select this check box, the equalizer center frequency is input through the **Fc** port. When you clear this check box, the equalizer center frequency is specified on the block dialog through the **Equalizer center frequency (Hz)** parameter.

This parameter applies when you set **Filter specification** to Bandwidth and center frequency or Quality factor and center frequency.

Equalizer center frequency (Hz)

Center frequency of the filter, specified as a finite positive scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter specification** to Bandwidth and center frequency or Quality factor and center frequency, and clear the **Specify center frequency from input port** parameter. The default is 11025. This parameter is tunable.

Specify gain (dB) from input port

When you select this check box, the peak or dip gain of the filter in dB is input through the **PGaindB** port. When you clear this check box, the filter gain is specified on the block dialog through the **Gain (dB)** parameter.

This parameter applies when you set **Filter specification** to Bandwidth and center frequency or Quality factor and center frequency.

Gain (dB)

Peak or dip gain of the filter, specified as a real scalar in dB. A value greater than zero corresponds to a peak. A value less than zero corresponds to a dip. This parameter applies when you set **Filter specification** to Bandwidth and center frequency or Quality factor and center frequency, and clear the **Specify gain (dB) from input port** parameter. The default is 6.0206. This parameter is tunable.

Specify bandwidth coefficient from input port

When you select this check box, the bandwidth coefficient is input through the **BWCoeff** port. When you clear this check box, the bandwidth coefficient is specified on the block dialog through the **Bandwidth coefficient** parameter.

This parameter applies when you set **Filter specification** to Coefficients.

Bandwidth coefficient

Coefficient that determines the filter bandwidth, specified as a finite numeric scalar in the range [-1 1].

- -1 corresponds to the maximum bandwidth (one-fourth the sample rate of the input signal).
- 1 corresponds to the minimum bandwidth (0 Hz, that is, an allpass filter).

This parameter applies when you set **Filter specification** to **Coefficients** and clear the **Specify bandwidth coefficient from input port** parameter. The default is 0.72654. This parameter is tunable.

Specify center frequency coefficient from input port

When you select this check box, the center frequency coefficient is input through the **FcCoeff** port. When you clear this check box, the center frequency coefficient is specified on the block dialog through the **Center frequency coefficient** parameter.

This parameter applies when you set **Filter specification** to **Coefficients**.

Center frequency coefficient

Coefficient that determines the center frequency of the filter, specified as a finite numeric scalar in the range [-1 1].

- -1 corresponds to the minimum center frequency (0 Hz).
- 1 corresponds to the maximum center frequency (half the sample rate of the input signal).

This parameter applies when you set **Filter specification** to **Coefficients** and clear the **Specify center frequency coefficient from input port** parameter. The default is 0, which corresponds to one-fourth the sample rate of the input signal. This parameter is tunable.

Specify gain from input port

When you select this check box, the peak or dip gain of the filter in linear units is input through the **PGain** port. When you clear this check box, the filter gain is specified on the block dialog through the **Gain (Linear Units)** parameter.

This parameter applies when you set **Filter specification** to **Coefficients**.

Gain (Linear Units)

Peak or dip gain of the filter, specified as a real positive scalar in linear units. A value greater than one boosts the input signal. A value less than one attenuates the input signal. This parameter applies when you set **Filter specification** to **Coefficients** and clear the **Specify gain from input port** parameter. The default is 2. This parameter is tunable.

Specify quality factor from input port

When you select this check box, the quality factor is input through the **Q** port. When you clear this check box, the quality factor is specified on the block dialog through the **Quality factor** parameter.

This parameter applies when you set **Filter specification** to **Quality factor** and center frequency.

Quality factor

Quality factor of the filter, specified as a real positive scalar. The quality factor is defined as **Equalizer center frequency (Hz) / Filter bandwidth (Hz)**. A higher quality factor corresponds to a narrower peak or dip. This parameter applies when you set **Filter specification** to **Quality factor** and center frequency and clear the **Specify quality factor from input port** parameter. The default is 5. This parameter is tunable.

Inherit sample rate from input

When you select this check box, the block's sample rate is computed as N/T_s , where N is the frame size of the input signal, and T_s is the sample time of the input signal. When you clear this

check box, the block sample rate is the value specified in **Input sample rate (Hz)**. By default, this check box is selected.

Input sample rate (Hz)

Sample rate of the input signal, specified as a positive scalar value. The default is 44100. This parameter applies when you clear the **Inherit sample rate from input** check box. This parameter is nontunable.

View Filter Response

Opens the Filter Visualization Tool FVTool and displays the magnitude/phase response of the Parametric EQ Filter. The response is based on the block dialog box parameters. Changes made to these parameters update FVTool.

To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

Simulate using

Type of simulation to run. You can set this parameter to:

- Code generation (default)

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.

- Interpreted execution

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none">• Double-precision floating point• Single-precision floating point
Output	<ul style="list-style-type: none">• Double-precision floating point• Single-precision floating point

References

[1] Orfanidis, Sophocles J. *Introduction to Signal Processing*. Upper Saddle River, NJ: Prentice-Hall, 1996.

Algorithms

The parametric equalizer is formed by a linear combination of a peak and a notch filter. See the **Algorithm** section of `dsp.NotchPeakFilter` for details.

$$H(z) = H_{notch}(z) + GH_{peak}(z)$$

Here is a graph of the two cases (boost and cut) of the magnitude squared of the transfer functions:

The transfer function can be written as:

$$H(z) = \frac{\left(\frac{1+G\gamma}{1+\gamma}\right) - 2\left(\frac{\cos\omega_0}{1+\gamma}\right)z^{-1} + \left(\frac{1-G\gamma}{1+\gamma}\right)z^{-2}}{1 - 2\left(\frac{\cos\omega_0}{1+\gamma}\right)z^{-1} + \left(\frac{1-\gamma}{1+\gamma}\right)z^{-2}}$$

where

$$\gamma = \tan\left(\frac{\Delta\omega}{2}\right)$$

and

$$G_B^2 = \frac{1+G^2}{2}$$

G is the parametric equalizer gain, and G_B is the bandwidth gain, that is, the gain level at which the bandwidth $\Delta\omega$ is measured.

The `dsp.NotchPeakFilter` that does most of the work is implemented in a decoupled way so that the center frequency can be tuned independently from the bandwidth. Note that the Q factor is defined as center frequency/bandwidth.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Peak Finder

Determine whether each value of input signal is local minimum or maximum

Library: DSP System Toolbox / Signal Operations

Description

The Peak Finder block counts the number of local extrema in each column of a real-valued input signal. The block outputs the number of local extrema at the **Cnt** port. You can also configure the block to output the extrema indices, the extrema values, and a binary value indicating if the extrema are maxima or minima. To qualify as an extremum, a point has to be larger (or smaller) than both its neighboring points, so the block does not consider end points when counting extrema.

Ports

Input

Port_1 — Data input

column vector of at least three rows | matrix with at least three rows

The Peak Finder blocks accepts real-valued vector or matrix inputs with at least three rows.

Example: `[9 6 10 3 5 5 0 12; 9 6 1 13 4 1 0 12]'`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

Cnt — Number of peak values

scalar | row vector

Number of peak values the block detects in the input signal, returned as a scalar or a row vector of length equal to the number of channels in the data input.

Example: `[4 3]`

Data Types: `uint32`

Idx — Indices of the peak values

column vector | matrix

Indices of the peak values in the input signal, returned as a column vector or matrix. The size of the peak indices output is the same as that of the input. All nonzero elements represent peak indices.

If you set **Index base** to **Zero**, the block outputs zero-based extrema indices. If you set **Index base** to **One**, the block outputs one-based extrema indices.

Example: `[1 2 3 6 0 0 0 0 0; 2 3 6 0 0 0 0 0 0]'`

Dependencies

To enable this output port, select the **Output peak indices** parameter.

Data Types: uint32

Val — Peak values

column vector | matrix

Peak values in the input signal, returned as a column vector or matrix.

Example: [6 10 3 0 0 0 0 0 0 0; 1 13 0 0 0 0 0 0 0 0]'

Dependencies

To enable this output port, select the **Output peak values** parameter.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

Po1 — Peak value polarity

column vector | matrix

Peak value polarity in input signal, returned as a column vector or a matrix of logical 1s and 0s. If the signal value is a maximum, the block outputs 1 at this port. If the signal value is a minimum, the block outputs 0 at this port.

Example: [0 1 0 0 0 0 0 0 0 0; 0 1 0 0 0 0 0 0 0 0]'

Dependencies

To enable this port, select either **Output peak indices** or **Output peak values**, and set the **Peak type(s)** parameter to Maxima and Minima.

Data Types: Boolean

Parameters**Peak type(s) — Type of peaks to identify**

Maxima and Minima (default) | Maxima | Minima

Specify the type of peaks to identify as one of these:

- **Maxima** -- If you select **Ignore peaks within threshold of neighboring values**, the block identifies the current value as a maximum if $(current - previous) > threshold$ and $(current - next) > threshold$. Specify *threshold* in the **Threshold** parameter. If you do not select **Ignore peaks within threshold of neighboring values**, the block identifies a maxima if the current value is larger than both its neighboring points.
- **Minima** -- If you select **Ignore peaks within threshold of neighboring values**, the block identifies the current value as a minimum if $(current - previous) < -threshold$ and $(current - next) < -threshold$. If you do not select **Ignore peaks within threshold of neighboring values**, the block identifies a minima if the current value is smaller than both its neighboring points.
- **Maxima and Minima** -- The block identifies the maxima and the minima points.

Index base — Index base

Zero (default) | One

Specify the base of the extrema indices as either:

- **Zero** -- The first index starts with 0. For example, consider an input vector $[-1.5, 0.5, 0]$. The peak value of this vector is 0.5 and the index of this peak value is 1.
- **One** -- In this setting, the first index starts with 1. The index of the peak value in $[-1.5, 0.5, 0]$ is 2.

Output peak indices — Enable output of peak indices

off (default) | on

Select this check box if you want the block to output the extrema indices at the **Idx** port.

Output peak values — Enable output of peak values

off (default) | on

Select this parameter if you want the block to output the extrema values at the **Val** port.

Maximum number of peaks to find — Maximum number of peak values to identify

10 (default) | integer greater than or equal to 1

Enter the number of extrema to look for in each input signal as an integer greater than or equal to 1. The block stops searching the input signal for extrema once the maximum number of extrema has been found.

Ignore peaks within threshold of neighboring values — Ignore peaks below a threshold

off (default) | on

Select this parameter if you want to eliminate the detection of peaks whose amplitudes are within a specified threshold of neighboring values. This feature allows the block to ignore noise by focusing on values above the specified threshold.

When you clear this parameter, the block identifies the current value as a peak if the current value is larger (or smaller) than both its neighboring points. When you select this parameter, the block identifies the current value as a maximum if $(current - previous) > threshold$ and $(current - next) > threshold$. The block identifies the current value as a minimum if $(current - previous) < -threshold$ and $(current - next) < -threshold$.

Threshold — Threshold below which peaks are ignored

0 (default) | positive real scalar | vector

Specify the threshold below which peaks are ignored as a real scalar greater than or equal to 0 or a vector with all elements greater than or equal to 0. The length of the vector must be equal to the number of channels.

This property identifies the current input value to be a maximum if $(current - previous) > threshold$ and $(current - next) > threshold$. The current value is a minimum if $(current - previous) < -threshold$ and $(current - next) < -threshold$.

Dependencies

To enable this parameter, select the **Ignore peaks within threshold of neighboring values** parameter.

Saturate on integer overflow — Method of overflow action

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operations. When you clear this parameter, the block wraps the result of its fixed-point operations. For details on `saturate` and `wrap`, see `overflow mode for fixed-point operations`.

Dependencies

To enable this parameter, select the **Ignore peaks within threshold of neighboring values** parameter.

Peak-Notch Filter

Design peak or notch filter

Compatibility

Note The Peak-Notch Filter block has been replaced by the Notch-Peak Filter block. Existing instances of the Peak-Notch Filter block will continue to operate. For new models, use the Notch-Peak Filter block.

Library

Filtering / Filter Designs

dspfdesign

Description

This block brings the filter design capabilities of the `filterBuilder` function to the Simulink environment.

Dialog Box

See “Peak/Notch Filter Design — Main Pane” on page 5-642 for more information about the parameters of this block. The **Data Types** and **Code Generation** panes are not available for blocks in the DSP System Toolbox Filter Designs library.

Parameters of this block that do not change filter order or structure are tunable.

Function Block Parameters: Peak-Notch Filter

Peak/Notch Filter

Design a peak or notch filter.

View filter response

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.

- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

In this area you can specify whether you want to design a peaking filter or a notching filter, as well as the order of the filter.

Response

Select **Peak** or **Notch** from the drop-down list. The rest of the parameters that specify are equivalent for either filter type.

Order

Enter the filter order. The order must be even.

Frequency Specifications

This group of parameters allows you to specify frequency constraints and units.

Frequency Constraints

Select the frequency constraints for filter specification. There are two choices as follows:

- Center frequency and quality factor
- Center frequency and bandwidth

Frequency units

The frequency units are normalized by default. If you specify units other than normalized, the block assumes that you wish to specify an input sampling frequency, and enables this input box. The choice of frequency units are: Normalized (0 to 1), Hz, kHz, MHz, GHz.

Input Fs

This input box is enabled if **Frequency units** other than Normalized (0 to 1) are specified. Enter the input sampling frequency.

Center frequency

Enter the center frequency in the units specified previously.

Quality Factor

This input box is enabled only when Center frequency and quality factor is chosen for the **Frequency Constraints**. Enter the quality factor.

Bandwidth

This input box is enabled only when Center frequency and bandwidth is chosen for the **Frequency Constraints**. Enter the bandwidth.

Magnitude Specifications

This group of parameters allows you to specify the magnitude constraints, as well as their values and units.

Magnitude Constraints

Depending on the choice of constraints, the other input boxes are enabled or disabled. Select from four magnitude constraints available:

- Unconstrained
- Passband ripple
- Stopband attenuation
- Passband ripple and stopband attenuation

Magnitude units

Select the magnitude units: either dB or squared.

Apass

This input box is enabled if the magnitude constraints selected are Passband ripple or Passband ripple and stopband attenuation. Enter the passband ripple.

Astop

This input box is enabled if the magnitude constraints selected are Stopband attenuation or Passband ripple and stopband attenuation. Enter the stopband attenuation.

Algorithm

The parameters in this group allow you to specify the design method and structure of your filter.

Design Method

Lists all design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter the methods available to design filters changes as well.

Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Filter Implementation

Structure

Specify filter structure. Choose from:

- Direct-form I SOS
- Direct-form II SOS
- Direct-form I transposed SOS
- Direct-form II transposed SOS

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of n unit delays with a single delay by n .
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

Input processing

Specify how the block should process the input. The available options may vary depending on the settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

Note The Inherited (this choice will be removed – see release notes) option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- **Enforce single-rate processing** — When you select this option, the block maintains the sample rate of the input.
- **Allow multirate processing** — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to **Elements as channels (sample based)**.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

Periodogram

Power spectral density or mean-square spectrum estimate using periodogram method

Library: DSP System Toolbox / Estimation / Power Spectrum Estimation

Description

The Periodogram block estimates the power spectral density (PSD) or mean-square spectrum (MSS) of the input. The block uses the periodogram method and Welch's averaged, modified periodogram method. The block averages the squared magnitude of the FFT function computed over windowed sections of the input. It then normalizes the spectral average by the square of the sum of the window samples. For more information, see "Periodogram" and "Welch's Method".

Ports

Input

Port_1 — Input signal

vector | matrix

Input signal, specified as a vector or a matrix.

The block treats M -by- N matrix input as M sequential time samples from N independent channels.

Data Types: single | double

Output

Port_1 — Output signal

vector | matrix

Output signal, returned as a vector or a matrix.

Each column of the output matrix contains the estimate of the power spectral density of the corresponding input column at N_{fft} equally spaced frequency points. The frequency points are in the range $[0, F_s)$, where F_s is the sampling frequency of the signal.

The block computes a separate estimate for each of the N independent channels and generates an N_{fft} -by- N matrix output.

Data Types: single | double

Parameters

Measurement — Measurement type

Power spectral density (default) | Mean-square spectrum

Specify the type of measurement for the block to perform: Power spectral density or Mean-square spectrum.

Tunable: No

Window — Window type

Hamming (default) | Bartlett | Blackman | Boxcar | Chebyshev | Hann | Hanning | Kaiser | Triang

Select the type of window to apply.

For details, see the Window Function block reference page.

Tunable: Yes

Beta — Beta

5 (default) | scalar

Enter the β parameter for the Kaiser window. Increasing **Beta** widens the mainlobe and decreases the amplitude of the sidelobes in the displayed frequency magnitude response.

For more details, see the Window Function block reference page.

Tunable: Yes

Dependencies

This parameter becomes visible if, for the Window parameter, you chose Kaiser.

Window sampling — Window sampling

Symmetric (default) | Periodic

From the list, choose Symmetric or Periodic.

See the Window Function block reference page for more details.

Tunable: Yes

Dependencies

This parameter becomes visible only if you set the Window parameter to one of Blackman, Hamming, Hann, or Hanning.

FFT implementation — FFT implementation

Auto (default) | Radix-2 | FFTW

Set this parameter to `FFTW` to support an arbitrary length input signal. The block restricts generated code with an FFTW implementation to MATLAB host computers.

Set this parameter to `Radix-2` for bit-reversed processing, fixed or floating-point data, or for portable C-code generation by using Simulink Coder. The first dimension M of the input matrix must be a power of two. To work with other input sizes, use the Pad block to pad or truncate these dimensions to powers of two, or if possible, choose the FFTW implementation.

Set this parameter to `Auto` to enable the block choose the FFT implementation. For non-power-of-two transform lengths, the block restricts generated code to MATLAB host computers.

Tunable: No

Stopband attenuation in dB — Stopband attenuation in dB

50 (default) | scalar

Enter the level, in decibels (dB), of stopband attenuation, R_s , for the Chebyshev window.

Tunable: Yes

Dependencies

This parameter becomes visible if, for the Window parameter, you choose Chebyshev.

Inherit FFT length from input dimensions — Inherit FFT length

off (default) | on

When you select this check box, the block uses the input frame size as the number of data points, N_{fft} , on which to perform the FFT. To specify the number of points on which to perform the FFT, clear the **Inherit FFT length from input dimensions** check box. You can then specify a power of two FFT length by using the “FFT length” on page 2-0 parameter.

Tunable: No

FFT length — Number of data points

256 (default) | scalar

Enter the number of data points on which to perform the FFT, N_{fft} . When N_{fft} is larger than the input frame size, the block zero-pads each frame as needed. When N_{fft} is smaller than the input frame size, the block wraps each frame as needed.

When you set the FFT implementation parameter to `Radix-2`, this value must be a power of two.

Tunable: No

Dependencies

This parameter becomes visible only when you clear the “Inherit FFT length from input dimensions” on page 2-0 check box.

Number of spectral averages — Number of spectral averages

4 (default) | scalar

Specify the number of spectral to average. When you set this value to 1, the block computes the periodogram of the input. When you set this value greater 1, the block implements “Welch's Method” to compute a modified periodogram of the input.

Tunable: No

Inherit sample time from input — Inherit sample time from input

on (default) | off

If you select the **Inherit sample time from input** check box, the block computes the frequency data from the sample period of the input signal. For the block to produce valid output, the following conditions must hold:

- The input to the block is the original signal, with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** check box. You can then specify a sample time by using the `Sample time of original time series` parameter.

Dependencies

This parameter becomes visible only if you set the `Measurement` parameter to `Power spectral density`.

Sample time of original time series — Sample time of original time series

1 (default) | scalar

Specify the sample time of the original time-domain signal.

Tunable: No

Dependencies

This parameter becomes visible only when you clear the `Inherit sample time from input` check box.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.
- When the following conditions apply, the executable generated from this block relies on prebuilt dynamic library files (`.dll` files) included with MATLAB:
 - **FFT implementation** is set to FFTW.
 - **Inherit FFT length from input dimensions** is cleared and **FFT length** is set to a value that is not a power of two.

Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see "How To Run a Generated Executable Outside MATLAB".

- When the FFT length is a power of two, you can generate standalone C and C++ code from this block.

Phase Extractor

Extract the unwrapped phase of a complex input

Library: DSP System Toolbox / Signal Operations

Description

The Phase Extractor block extracts the unwrapped phase of a complex input.

Ports

Input

Input 1 — Input signal

vector | matrix

Specify the input signal as a vector or a matrix. When the input is a matrix, the block treats each column of the signal as an independent channel. The first dimension is the length of the channel. The second dimension is the number of channels. The block treats one dimensional inputs as one channel.

Data Types: single | double

Output

Output 1 — Unwrapped phase

vector | matrix

The block returns the unwrapped phase of the signal.

The block preserves the input size and dimension, and the output port rate equals the input port rate.

Data Types: single | double

Parameters

Unwrap phase only within the frame — Unwrap phase only within the frame

off (default) | on

When you clear this check box, the block ignores boundaries between the input frames. When you select this check box, the block treats each frame of input data independently, and resets the initial phase value for each new input frame.

Simulate using — Type of simulation to run

Code generation (default) | Interpreted execution

Specify the type of simulation to run as one of the following:

- **Code generation** -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than **Interpreted execution**.
- **Interpreted execution** -- Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than **Code generation**.

Block Characteristics

Data Types	double single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

Algorithms

Consider an input frame of length N :

$$\begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_N \end{pmatrix}$$

The `step` method acts on this frame and produces this output:

$$\begin{pmatrix} \Phi_1 \\ \Phi_2 \\ \vdots \\ \Phi_N \end{pmatrix}$$

where:

$$\Phi_i = \Phi_{i-1} + \text{angle}(x_{i-1}^* x_i)$$

Here, i runs from 1 to N . The `angle` function returns the phase angle in radians.

If the input signal consists of multiple frames:

- If you set `TreatFramesIndependently` to `true`, the `step` method treats each frame independently. Therefore, in each frame, the `step` method calculates the phase using the preceding formula where:
 - Φ_0 is 0.

- x_0 is 1.
- If you set `TreatFramesIndependently` to `false`, the `step` method ignores boundaries between frames. Therefore, in each frame, the `step` method calculates the phase using the preceding formula where:
 - Φ_0 is the last unwrapped phase from the previous frame.
 - x_0 is the last sample from the previous frame.

Polynomial Evaluation

Evaluate polynomial expression

Library

Math Functions / Polynomial Functions

dsppolyfun

Description

The Polynomial Evaluation block applies a polynomial function to the real or complex input at the In port.

`y = polyval(u)` % Equivalent MATLAB code

The Polynomial Evaluation block performs these types of operation more efficiently than the equivalent construction using Simulink Sum and Math Function blocks.

When you select the **Use constant coefficients** check box, you specify the polynomial expression in the **Constant coefficients** parameter. When you do not select **Use constant coefficients**, a variable polynomial expression is specified by the input to the **Coeffs** port. In both cases, the polynomial is specified as a vector of real or complex coefficients in order of descending exponents.

The table below shows some examples of the block's operation for various coefficient vectors.

Coefficient Vector	Equivalent Polynomial Expression
[1 2 3 4 5]	$y = u^4 + 2u^3 + 3u^2 + 4u + 5$
[1 0 3 0 5]	$y = u^4 + 3u^2 + 5$
[1 2+i 3 4-3i 5i]	$y = u^4 + (2 + i)u^3 + 3u^2 + (4 - 3i)u + 5i$

Each element of a vector or matrix input to the In port is processed independently, and the output size is the same as the input.

Parameters

Use constant coefficients

Select to enable the **Constant coefficients** parameter and disable the **Coeffs** input port.

Constant coefficients

Specify the vector of polynomial coefficients to apply to the input, in order of descending exponents. This parameter is enabled when you select the **Use constant coefficients** check box.

Supported Data Types

- Double-precision floating point
- Single-precision floating point

Polynomial Stability Test

Use Schur-Cohn algorithm to determine whether all roots of input polynomial are inside unit circle

Library

Math Functions / Polynomial Functions

dsppolyfun

Description

The Polynomial Stability Test block uses the Schur-Cohn algorithm to determine whether all roots of a polynomial are within the unit circle.

```
y = all(abs(roots(u)) < 1) % Equivalent MATLAB code
```

Each column of the M-by-N input matrix u contains M coefficients from a distinct polynomial,

$$f(x) = u_1x^{M-1} + u_2x^{M-2} + \dots + u_M$$

arranged in order of descending exponents, u_1, u_2, \dots, u_M . The polynomial has order M-1 and positive integer exponents.

Inputs to the block represent the polynomial coefficients as shown in the previous equation. The block always treats length-M unoriented vector input as an M-by-1 matrix.

The output is a 1-by-N matrix with each column containing the value 1 or 0. The value 1 indicates that the polynomial in the corresponding column of the input is stable; that is, the magnitudes of all solutions to $f(x) = 0$ are less than 1. The value 0 indicates that the polynomial in the corresponding column of the input might be unstable; that is, the magnitude of at least one solution to $f(x) = 0$ is greater than or equal to 1.

Applications

This block is most commonly used to check the pole locations of the denominator polynomial, $A(z)$, of a transfer function, $H(z)$.

$$H(z) = \frac{B(z)}{A(z)} = \frac{b_1 + b_2z^{-1} + \dots + b_mz^{-(m-1)}}{a_1 + a_2z^{-1} + \dots + a_nz^{-(n-1)}}$$

The poles are the $n-1$ roots of the denominator polynomial, $A(z)$. When any poles are located outside the unit circle, the transfer function $H(z)$ is unstable. As is typical in DSP applications, the transfer function above is specified in descending powers of z^{-1} rather than z .

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Boolean — Block outputs are always Boolean.

Power Meter

Measure power and the CCDF of the power of voltage signal in Simulink

Library: DSP System Toolbox / Statistics

Description

The Power Meter block computes the power measurements of a voltage signal. When you select the **Compute CCDF** parameter, the block also calculates the complementary cumulative distribution function (CCDF) of the power of a voltage signal. The CCDF measurements that the block outputs are relative power and probability (in percentage). The power measurements include average power, peak power, and peak-to-average power ratio.

For more details on how the block computes the power measurements and the CCDF measurements, see “Algorithms” on page 2-1080.

Ports

Input

Port_1 — Input signal

vector | matrix

Specify the input signal in volts as a vector or a matrix. If x is a matrix, the block treats each column as an independent channel and computes the power measurement along each channel.

When the **Allow arbitrary frame length for fixed-size input signals** parameter appears and is not selected, and you input a fixed-size signal, the frame length must be a multiple of the hop size (window length – overlap length). In all other cases, the input frame length can be arbitrary.

The block accepts variable-size inputs (frame length changes during simulation). When you input a variable-size signal, the frame length of the signal can be arbitrary.

Data Types: single | double

Rst — Reset port

scalar

Specify the boolean reset signal as a scalar. If the input on the **Rst** port is `true`, the block clears the internal histograms and statistics before processing the current input. If the input on the **Rst** port is `false`, the block computes the measurements from the start of the simulation or from the last reset.

Dependencies

To enable this port, select the **Compute CCDF** and **Reset port** parameters.

Data Types: Boolean

Output

Avg — Average power

scalar | vector | matrix

Average power of the voltage signal from the start of the simulation or from the last reset, returned as a scalar, vector, or a matrix. The block computes the average power along each channel in the units specified in the **Output power units** parameter. For details on how the block computes the average power, see “Average Power” on page 2-1081.

If you clear the **Compute CCDF** parameter, the block computes the moving average power using the “Sliding Window Method” on page 2-1080.

See this table for details on the output signal dimensions.

Input Signal	Input Dimensions	Output Dimensions When Allow arbitrary frame length for fixed-size input signals Appears	Output Dimensions When Allow arbitrary frame length for fixed-size input signals Does Not Appear
Fixed-size signal	P -by- M , where M is a multiple of the hop size (window length – overlap length)	$(P/\text{hop size})$ -by- M	P -by- M
Fixed-size signal	P -by- M , where M is not a multiple of the hop size (window length – overlap length)	$\text{ceil}(P/\text{hop size})$ -by- M when you select Allow arbitrary frame length for fixed-size input signals If you do not select Allow arbitrary frame length for fixed-size input signals , the block errors.	P -by- M
Variable-size signal	P -by- M	$\text{ceil}(P/\text{hop size})$ -by- M	P -by- M

When the output has an upper bound size of $\text{ceil}(P/\text{hop size})$ -by- M , during simulation, the size of the first dimension varies within this bound, while the size of the second dimension remains constant.

If you select the **Compute CCDF** parameter, the block computes the stationary average power of the entire signal along each channel. In this case, the size of the output is 1-by- M , where M is the number of channels (columns) in the input signal.

Dependencies

To enable this port, set **Measurement** to Average power or All.

Data Types: single | double

Peak — Peak power

scalar | vector | matrix

Peak power of the voltage signal from the start of the simulation or from the last reset, returned as a scalar, vector, or a matrix. The block computes the peak power along each channel in the units specified in the **Output power units** parameter. For details on how the block computes the peak power, see “Peak Power” on page 2-1081.

If you clear the **Compute CCDF** parameter, the block computes the moving peak power using the “Sliding Window Method” on page 2-1080.

See this table for details on the output signal dimensions.

Input Signal	Input Dimensions	Output Dimensions When Allow arbitrary frame length for fixed-size input signals Appears	Output Dimensions When Allow arbitrary frame length for fixed-size input signals Does Not Appear
Fixed-size signal	P -by- M , where M is a multiple of the hop size (window length – overlap length)	$(P/\text{hop size})$ -by- M	P -by- M
Fixed-size signal	P -by- M , where M is not a multiple of the hop size (window length – overlap length)	$\text{ceil}(P/\text{hop size})$ -by- M when you select Allow arbitrary frame length for fixed-size input signals If you do not select Allow arbitrary frame length for fixed-size input signals , the block errors.	P -by- M
Variable-size signal	P -by- M	$\text{ceil}(P/\text{hop size})$ -by- M	P -by- M

When the output has an upper bound size of $\text{ceil}(P/\text{hop size})$ -by- M , during simulation, the size of the first dimension varies within this bound, while the size of the second dimension remains constant.

If you select the **Compute CCDF** parameter, the block computes the stationary peak power of the entire signal along each channel. In this case, the size of the output is 1-by- M , where M is the number of channels (columns) in the input signal.

Dependencies

To enable this port, set **Measurement** to Peak power or All.

Data Types: single | double

PAPR — Peak-to-average power ratio

scalar | vector | matrix

Ratio of the peak power to the average power (PAPR) of the voltage signal, returned as a scalar, vector, or a matrix. The block computes the peak-to-average power ratio along each channel. For details on how the block computes this measurement, see “Peak-to-Average Power Ratio” on page 2-1082.

If you clear the **Compute CCDF** parameter, the block computes the moving peak-to-average power ratio using the “Sliding Window Method” on page 2-1080.

See this table for details on the output signal dimensions.

Input Signal	Input Dimensions	Output Dimensions When Allow arbitrary frame length for fixed-size input signals Appears	Output Dimensions When Allow arbitrary frame length for fixed-size input signals Does Not Appear
Fixed-size signal	P -by- M , where M is a multiple of the hop size (window length – overlap length)	$(P/\text{hop size})$ -by- M	P -by- M
Fixed-size signal	P -by- M , where M is not a multiple of the hop size (window length – overlap length)	$\text{ceil}(P/\text{hop size})$ -by- M when you select Allow arbitrary frame length for fixed-size input signals If you do not select Allow arbitrary frame length for fixed-size input signals , the block errors.	P -by- M
Variable-size signal	P -by- M	$\text{ceil}(P/\text{hop size})$ -by- M	P -by- M

When the output has an upper bound size of $\text{ceil}(P/\text{hop size})$ -by- M , during simulation, the size of the first dimension varies within this bound, while the size of the second dimension remains constant.

If you select the **Compute CCDF** parameter, the block computes the stationary peak-to-average power ratio of the entire signal along each channel. In this case, the size of the output is 1-by- M , where M is the number of channels (columns) in the input signal.

PAPR should be less than 100 dB to obtain accurate CCDF measurements. If PAPR is above 100 dB, the block shows only the highest 100 dB power levels.

Dependencies

To enable this port, set **Measurement** to Peak-to-average power ratio or All.

Data Types: single | double

RelPwr — Relative power

N -by- M matrix

Relative power (dB above average power), returned as an N -by- M matrix, where:

- M is the number of channels (columns) in the input signal.
- When you set **CCDF output** to Relative power (dB above average power), N equals the length of the column vector that you specify in the **Specify probability (%) for relative power output** parameter.

- When you set **CCDF output** to Relative power and probability (whole CCDF curve), N equals $\text{ceil}(\text{Power range (dB)}/\text{Power resolution (dB)}) + 1$.

Relative power is the power in dB by which the instantaneous signal power is above the average signal power with a probability of **Prob**, expressed as a percentage. For details on how the block computes relative power, see “Relative Power” on page 2-1083.

Dependencies

To enable this port, select the **Compute CCDF** parameter and then set the **CCDF output** parameter to Relative power (dB above average power) or Relative power and probability (whole CCDF curve).

Data Types: single | double

Prob — Probability in percentage

N -by- M matrix

Probability in percentage, returned as an N -by- M matrix, where:

- M is the number of channels (columns) in the input signal.
- When you set **CCDF output** to Probability (%), N equals the length of the column vector that you specify in the **Specify relative power (dB) for probability output** parameter.
- When you set **CCDF output** to Relative power and probability (whole CCDF curve), N equals $\text{ceil}(\text{Power range (dB)}/\text{Power resolution (dB)}) + 1$.

Prob(i)/100 is the probability that the instantaneous signal power of the j^{th} channel is above its average signal power by **RelPwr**(i,j) in dB.

Dependencies

To enable this port, select the **Compute CCDF** parameter and then set the **CCDF output** parameter to Probability (%) or Relative power and probability (whole CCDF curve).

Data Types: single | double

Parameters

Measurement — Desired power measurement

Average power (default) | Peak power | Peak-to-average power ratio | All

Specify the desired power measurement as one of the following:

- Average power (default)
- Peak power
- Peak-to-average power ratio
- All

For details on how the block computes these measurements, see “Algorithms” on page 2-1080.

Reference load (ohms) — Reference load in ohms

1 (default) | positive scalar in ohms

Specify the reference load that the power meter uses to compute power values as a real, positive scalar in ohms.

Tunable: Yes

Data Types: single | double

Output power units — Units of measured power values

dBm (default) | dBW | Watts

Specify the units of the measured power values as one of the following:

- dBm
- dBW
- Watts

Compute CCDF — Enable CCDF computations

off (default) | on

Select the **Compute CCDF** parameter to enable the block to compute the CCDF of the power of voltage signals. CCDF measurements include the relative power and the probability (in percentage). Relative power is the amount of power in dB by which the instantaneous signal power is above the average signal power. Probability in percentage refers to the probability that the instantaneous signal power is above the average signal power by the relative power in dB.

These measurements provide a qualitative way to view the power distribution between the amplitude values of an input signal over time. The CCDF curves (plot of probability in percentage against relative power in dB) are useful indicators of the dynamic range of a signal.

When you select **Compute CCDF**:

- The block uses all the input samples from the start of the simulation or from a reset signal on the **Rst** port to compute the statistics. The power measurements are stationary.
- You can specify variable-size input signals.

When you clear **Compute CCDF**,

- The block does not calculate the CCDF measurements and computes the power measurements using the “Sliding Window Method” on page 2-1080.
- The block accepts input signals of arbitrary frame length only when you select the **Allow arbitrary frame length for fixed-size input signals** parameter.

Window length — Window length

256 (default) | positive integer

Specify the window length over which the block computes the measurement as a positive integer.

Dependencies

To enable this parameter, clear the **Compute CCDF** check box. When you select **Compute CCDF**, **Window length** becomes Inf.

Data Types: `single` | `double`

Overlap length — Overlap length between windows

255 (default) | nonnegative integer

Specify the overlap length between sliding windows as a nonnegative integer. The value of overlap length varies in the range [0, **Window length** – 1].

Dependencies

To enable this parameter, clear the **Compute CCDF** check box. When you select **Compute CCDF**, **Overlap length** becomes 0.

Data Types: `single` | `double`

Allow arbitrary frame length for fixed-size input signals — Allow arbitrary frame length for fixed-size input signals

off (default) | on

Specify whether fixed-size input signals (whose size does not change during simulation) can have an arbitrary frame length, where the frame length does not have to be multiple of the hop size. Hop size is defined as **Window length** – **Overlap length**. The block uses this parameter setting only for fixed-size input signals and ignores this parameter if the input has a variable-size.

When the input signal is a variable-size signal, the signal can have arbitrary frame length, that is, the frame length does not have to be a multiple of the hop size.

For fixed-size input signals, if you:

- Select the **Allow arbitrary frame length for fixed-size input signals** parameter, the frame length of the signal does not have to be a multiple of the hop size. If the input is not a multiple of the hop size, then the output is generally a variable-size signal. Therefore, to support arbitrary input size, the block must also support variable-size operations, which you can enable by selecting the **Allow arbitrary frame length for fixed-size input signals** parameter.
- Clear the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length must be a multiple of the hop size.

Dependencies

To enable this parameter, clear the **Compute CCDF** parameter.

Power range (dB) — Power range in dB

50 (default) | positive scalar

Specify the x-axis range of the CCDF curves as a positive scalar in dB. The CCDF curves end at the maximum relative power, namely, the PAPR of the signal, and start at PAPR – **Power range (dB)**. In the CCDF capability of the Power Meter block, relative power is the power in dB by which the instantaneous signal power is above the average signal power.

Dependencies

To enable this parameter, select the **Compute CCDF** check box.

Data Types: `single` | `double`

Power resolution (dB) — Power Resolution in dB

0.1 (default) | positive scalar

Specify the x-axis resolution of the CCDF curves as a positive scalar in dB.

Dependencies

To enable this parameter, select the **Compute CCDF** check box.

Data Types: single | double

CCDF output — CCDF output

Relative power (dB above average power) (default) | Probability (%) | Relative power and probability (whole CCDF curve)

Specify the block to output:

- **RelPwr** -- Relative power (dB above average power). This is the amount of power in dB by which the instantaneous signal power is above the average power.
- **Prob** -- Probability in percentage. This is the probability that the instantaneous signal power is above the average signal power by the value of the relative power in dB.
- Both the **RelPwr** and the **Prob**.

Dependencies

To enable this parameter, select the **Compute CCDF** check box.

Specify probability (%) for relative power output — Specify probability for relative power output

[10;1;0.1;0.01;0.001;0.0001] (default) | column vector

Specify the probability (in percentage) for the relative power output as a column vector. The length of this vector determines the number of rows in the relative power output at the **RelPwr** port.

Dependencies

To enable this parameter, select the **Compute CCDF** check box and set the **CCDF output** parameter to Relative power (dB above average power).

This also enables the **RelPwr** output port.

Data Types: single | double

Specify relative power (dB) for probability output — Specify relative power for probability output

[0;3;6;9;12] (default) | column vector

Specify the relative power (in dB) for the probability output as a column vector. The length of this vector determines the number of rows in the probability output at the **Prob** port.

Dependencies

To enable this parameter, select the **Compute CCDF** check box and set the **CCDF output** parameter to **Probability (%)**.

This also enables the **Prob** output port.

Data Types: `single` | `double`

Reset port — Enable reset port

`off` (default) | `on`

Select this parameter to enable the input port **Rst** that accepts a boolean signal. If the value at the **Rst** port is `true`, then the block clears the internal histograms and statistics before processing the current input.

Dependencies

To enable this parameter, select the **Compute CCDF** check box.

Simulate using — Type of simulation to run

`Code generation` (default) | `Interpreted execution`

Specify the type of simulation to run as one of the following:

- `Code generation` -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.
- `Interpreted execution` -- Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

Block Characteristics

Data Types	<code>double</code> <code>single</code>
Direct Feedthrough	<code>no</code>
Multidimensional Signals	<code>no</code>
Variable-Size Signals	<code>yes</code>
Zero-Crossing Detection	<code>no</code>

Algorithms**Sliding Window Method**

When you do not configure the power meter to compute the CCDF measurements, the power meter computes the moving power measurements using the sliding window method.

In the sliding window method, the block computes the power measurement over a finite duration of the signal. The window length defines the length of the data over which the algorithm computes the

power value. The window moves as new data comes in. The output for each input sample is the measurement over the current sample and $Len - 1$ previous samples. Len is the length of the sliding window in samples. To compute the first output sample, the algorithm waits until it receives the hop size number of input samples. Hop size is defined as window length - overlap length. Remaining samples in the window are considered to be zero. As an example, if the window length is 5 and the overlap length is 2, then the algorithm waits until it receives 3 samples of input to compute the first sample of the output. After generating the first output, it generates the subsequent output samples for every hop size number of input samples.

For a more detailed example, see “Sliding Window Method”.

If the window is large, the power that the block computes is closer to the stationary power of the data. For data that does not change rapidly, use a long window to get a smoother measurement. For data that changes fast, use a smaller window.

When you configure the power meter to compute the CCDF measurements, the algorithm computes the stationary power of the data. It sets the window length to Inf and the overlap length to 0 , making both the parameters read-only.

Average Power

When you do not configure the power meter to compute the CCDF measurements, the power meter computes the moving average power of the voltage signal across each channel using the Sliding Window Method on page 2-1080. When you do configure the power meter to compute the CCDF measurements, the power meter computes the stationary average power of the voltage signal across each channel.

These equations give the average power in dBm, dBW, and in Watts units.

$$AvgPower_{dBm} = 10\log_{10}(Avg(|x|^2)/R) + 30$$

$$AvgPower_{dBW} = 10\log_{10}(Avg(|x|^2)/R)$$

$$AvgPower_{Watts} = Avg(|x|^2)/R$$

where,

- x is the input voltage signal.
- R is the reference load (in ohms) that the block uses to compute the power value.
- Avg represents the moving average power when the power meter does not compute the CCDF measurements. The `powermeter` object in MATLAB uses the `dsp.MovingAverage` object and the Power Meter block in Simulink uses the Moving Average block.

When the power meter does compute the CCDF measurements, Avg represents the stationary average power across each channel.

Peak Power

When you do not configure the power meter to compute the CCDF measurements, the power meter computes the moving peak power of the voltage signal across each channel using the Sliding Window Method on page 2-1080. When you do configure the power meter to compute the CCDF measurements, the power meter computes the stationary peak power of the voltage signal across each channel.

These equations give the peak power in dBm, dBW, and in Watts units.

$$PeakPower_{dBm} = 10\log_{10}(Max(|x|^2)/R) + 30$$

$$PeakPower_{dBW} = 10\log_{10}(Max(|x|^2)/R)$$

$$PeakPower_{Watts} = Max(|x|^2)/R$$

where,

- x is the input voltage signal.
- R is the reference load (in ohms) that the block uses to compute the power value.
- Max represents the moving peak power when the power meter does not compute the CCDF measurements. The `powermeter` object in MATLAB uses the `dsp.MovingMaximum` object and the Power Meter block in Simulink uses the Moving Maximum block.

When the power meter does compute the CCDF measurements, Max represents the stationary peak power across each channel.

Peak-to-Average Power Ratio

When you do not configure the power meter to compute the CCDF measurements, the power meter computes the moving peak-to-average power ratio of the voltage signal across each channel using the Sliding Window Method on page 2-1080. When you do configure the power meter to compute the CCDF measurements, the power meter computes the stationary peak-to-average power ratio of the voltage signal across each channel.

These equations give the peak-to-average power ratio in dBm, dBW, and in Watts units.

$$pkAvgPwr_{dBm} = 10\log_{10}(Max(|x|^2)/Avg(|x|^2))$$

$$pkAvgPwr_{dBW} = 10\log_{10}(Max(|x|^2)/Avg(|x|^2))$$

$$pkAvgPwr_{Watts} = Max(|x|^2)/Avg(|x|^2)$$

where,

- x is the input voltage signal.
- Avg represents the moving average power when the power meter does not compute the CCDF measurements. The `powermeter` object in MATLAB uses the `dsp.MovingAverage` object and the Power Meter block in Simulink uses the Moving Average block.

When the power meter does compute the CCDF measurements, Avg represents the stationary average power across each channel.

- Max represents the moving peak power when the power meter does not compute the CCDF measurements. The `powermeter` object in MATLAB uses the `dsp.MovingMaximum` object and the Power Meter block in Simulink uses the Moving Maximum block.

When the power meter does compute the CCDF measurements, Max represents the stationary peak power across each channel.

Relative Power

The power meter computes the relative power only when you configure the algorithm to compute the CCDF measurements. The algorithm uses a window of infinite duration to compute the relative power.

Relative power is the amount of power in dB by which the instantaneous signal power is above the average signal power. The block calculates the relative power using these equations:

If output power is in dBm,

$$relPower = 10\log_{10}\left(|x|^2/R\right) + 30 - AvgPower_{dBm}$$

If output power is in dBW,

$$relPower = 10\log_{10}\left(|x|^2/R\right) - AvgPower_{dBW}$$

If output power is in Watts,

$$relPower = \left(|x|^2/R\right) - AvgPower_{Watts}$$

where,

- x is the input voltage signal.
- R is the reference load (in ohms) that the block uses to compute the power value.
- $|x|^2/R$ is the instantaneous signal power in Watts.
- $AvgPower$ is the average power of the voltage signal. For more details on how the algorithm computes this measurement, see "Average Power" on page 2-1081.

Probability

The power meter computes the probability only when you configure the algorithm to compute the CCDF measurements. Probability in percentage refers to the probability that the instantaneous signal power is above the average signal power by the relative power in dB.

Version History

Introduced in R2021a

New Overlap length parameter

Starting in R2022b, when the block is not computing the CCDF measurements, you can specify the overlap length between sliding windows using the **Overlap length** parameter.

Support for arbitrary input frame length

Power Meter block supports input signals with arbitrary frame lengths when the:

- Input signal is a fixed-size signal (frame length does not change during simulation) and you select the **Allow arbitrary frame length for fixed-size input signals** parameter (if enabled).

- Input signal is a variable-size signal (frame length changes during simulation).

When this block supports an arbitrary frame length input signal, the input frame length does not have to be a multiple of the hop size.

Pseudoinverse

Compute Moore-Penrose pseudoinverse of matrix

Library

Math Functions / Matrices and Linear Algebra / Matrix Inverses

dspinverses

Description

The Pseudoinverse block computes the Moore-Penrose pseudoinverse of input matrix A .

`[U,S,V] = svd(A,0)` % Equivalent MATLAB code

The pseudoinverse of A is the matrix A^\dagger such that

$$A^\dagger = VS^\dagger U^*$$

where U and V are orthogonal matrices, and S is a diagonal matrix. The pseudoinverse has the following properties:

- $AA^\dagger = (AA^\dagger)^*$
- $A^\dagger A = (A^\dagger A)^*$
- $AA^\dagger A = A$
- $A^\dagger AA^\dagger = A^\dagger$

Parameters

Show error status port

Select to enable the E output port, which reports a failure to converge. The possible values you can receive on the port are:

- 0 — The pseudoinverse calculation converges.
- 1 — The pseudoinverse calculation does not converge.

If the pseudoinverse calculation fails to converge, the output at port X is an undefined matrix of the correct size.

Simulate using

Type of simulation to run. You can set this parameter to:

- Interpreted execution (default)

Simulate model using the MATLAB interpreter. This option shortens startup time. For this block, the simulation speed in this mode is faster than in Code generation.

- Code generation

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but the simulation speed increases with subsequent simulations.

Pulse Shaping Filter (Obsolete)

(Removed) Design pulse shaping filter

Compatibility

Note The Pulse Shaping Filter block has been removed from DSP System Toolbox block library. Existing instances of the Pulse Shaping Filter block will continue to operate. For new models, use the Raised Cosine Receive Filter and Raised Cosine Transmit Filter blocks from the Communications Toolbox library. These blocks replace the functionality of Pulse Shaping Filter block, when **Filter Type** is set to Decimator and Interpolator, respectively.

Library

Filtering / Filter Designs

dspfdesign

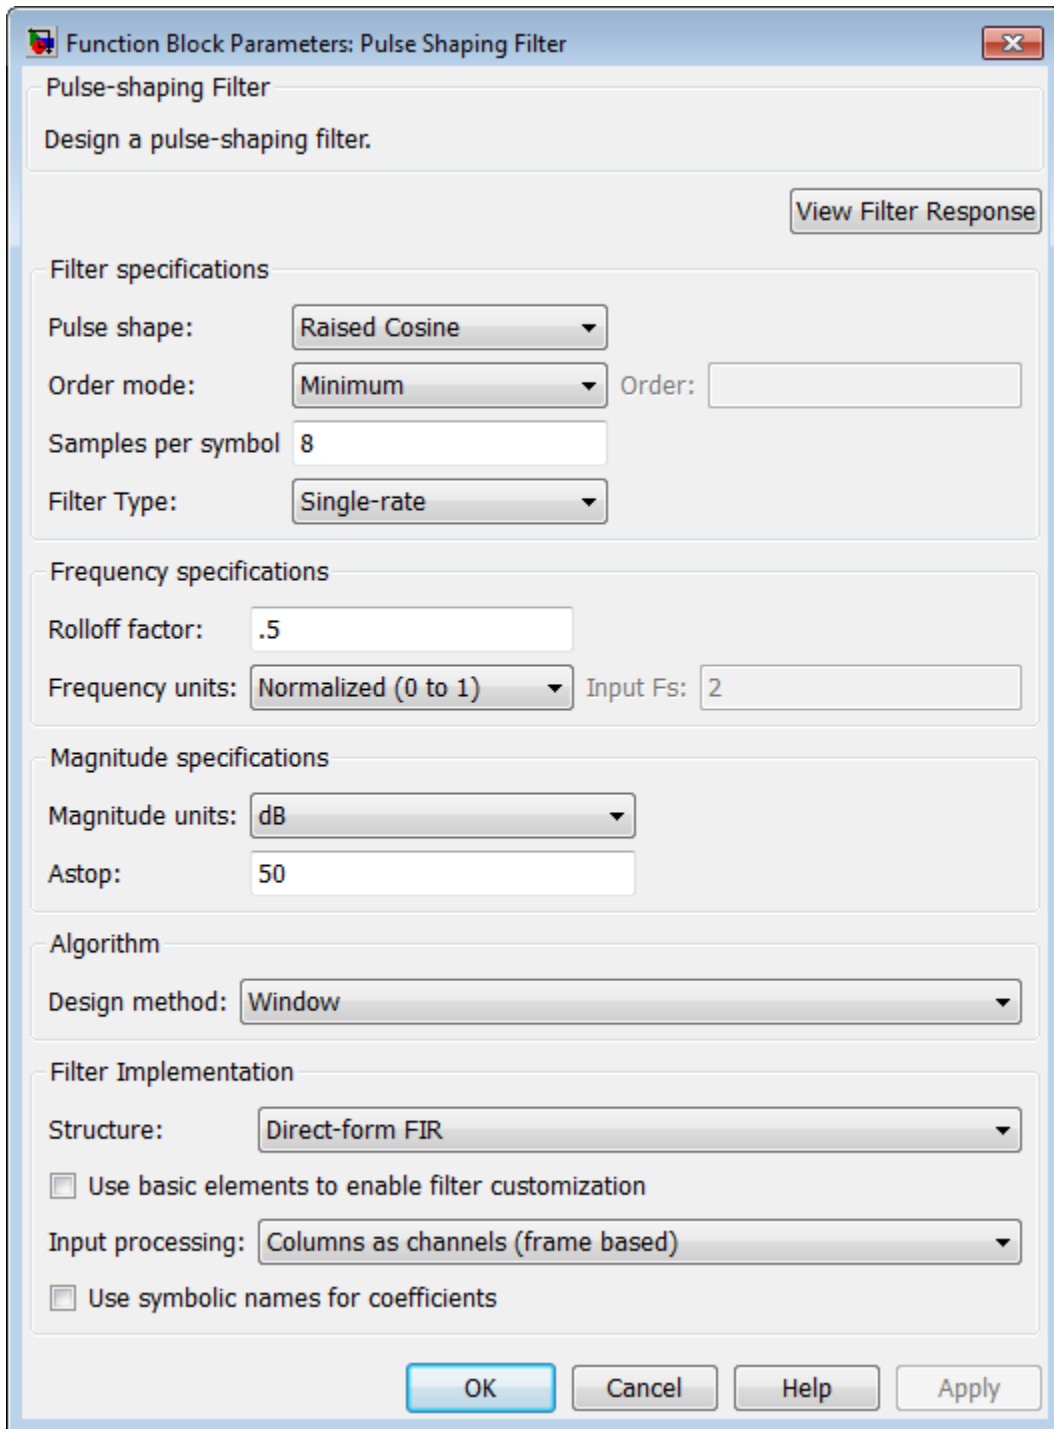

Description

This block brings the filter design capabilities of the `filterBuilder` function to the Simulink environment.

Dialog Box

See “Pulse-shaping Filter Design —Main Pane” on page 5-644 for more information about the parameters of this block. The **Data Types** and **Code** panes are not available for blocks in the DSP System Toolbox Filter Designs library.

Parameters of this block that do not change filter order or structure are tunable.

View filter response

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.

- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

In this group, you specify the shape and length of the filter.

Pulse shape

Select the shape of the impulse response from the following options:

- Raised Cosine
- Square Root Raised Cosine
- Gaussian

Order mode

This specification is only available for raised cosine and square root raised cosine filters. For these filters, select one of the following options:

- **Minimum**— This option will result in the minimum-length filter satisfying the user-specified **Frequency specifications**.
- **Specify order**—This option allows the user to construct a raised cosine or square root cosine filter of a specified order by entering an even number in the **Order** input box. The length of the impulse response will be $\text{Order}+1$.
- **Specify symbols**—This option enables the user to specify the length of the impulse response in an alternative manner. If **Specify symbols** is chosen, the **Order** input box changes to the **Number of symbols** input box.

Samples per symbol

Specify the oversampling factor. Increasing the oversampling factor guards against aliasing and improves the FIR filter approximation to the ideal frequency response. If **Order** is specified in **Number of symbols**, the filter length will be $\text{Number of symbols} * \text{Samples per symbol} + 1$. The product $\text{Number of symbols} * \text{Samples per symbol}$ must be an even number.

If a Gaussian filter is specified, the filter length must be specified in **Number of symbols** and **Samples per symbol**. The product $\text{Number of symbols} * \text{Samples per symbol}$ must be an even number. The filter length will be $\text{Number of symbols} * \text{Samples per symbol} + 1$.

Frequency specifications

In this group, you specify the frequency response of the filter. For raised cosine and square root raised cosine filters, the frequency specifications include:

Rolloff factor

The rolloff factor takes values in the range [0,1]. The smaller the rolloff factor, the steeper the transition in the stopband.

Frequency units

The frequency units are normalized by default. If you specify units other than normalized, the block assumes that you wish to specify an input sampling frequency, and enables this input box. The choice of frequency units are: Normalized (0 to 1), Hz, kHz, MHz, GHz

For a Gaussian pulse shape, the available frequency specifications are:

Bandwidth-time product

This option allows the user to specify the width of the Gaussian filter. Note that this is independent of the length of the filter. The bandwidth-time product (BT) must be a positive real number. Smaller values of the bandwidth-time product result in larger pulse widths in time and steeper stopband transitions in the frequency response.

Frequency units

The frequency units are normalized by default. If you specify units other than normalized, the block assumes that you wish to specify an input sampling frequency, and enables this input box. The choice of frequency units are: Normalized (0 to 1), Hz, kHz, MHz, GHz

Magnitude specifications

If the **Order mode** is specified as minimum, the magnitude units may be selected from:

- dB — Specify the magnitude in decibels (default).
- Linear — Specify the magnitude in linear units.

Algorithm

The only design method available for FIR pulse-shaping filters is the window method.

Filter Implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. FIR filters use direct-form structure.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of n unit delays with a single delay by n .
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

Input processing

Specify how the block should process the input. The available options may vary depending on the settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

Note The **Inherited (this choice will be removed – see release notes)** option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- **Enforce single-rate processing** — When you select this option, the block maintains the sample rate of the input.
- **Allow multirate processing** — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to **Elements as channels (sample based)**.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

Supported Data Types

Port	Supported Data Types

QR Factorization

Factor arbitrary matrix into unitary and upper triangular components

Library

Math Functions / Matrices and Linear Algebra / Matrix Factorizations

dspfactors

Description

The QR Factorization block uses a sequence of Householder transformations to triangularize the input matrix A . The block factors a column permutation of the M -by- N input matrix A as

$$A_e = QR$$

The column-pivoted matrix A_e contains the columns of A permuted as indicated by the contents of length- N permutation vector E .

```
A_e = A(:,E) % Equivalent MATLAB code
```

The block selects a column permutation vector E , which ensures that the diagonal elements of matrix R are arranged in order of decreasing magnitude.

$$|r_{i+1,j+1}| < |r_{i,j}| \quad i = j$$

The size of matrices Q and R depends on the setting of the **Output size** parameter:

- When you select **Economy** for the output size, Q is an M -by- $\min(M,N)$ unitary matrix, and R is a $\min(M,N)$ -by- N upper-triangular matrix.

```
[Q R E] = qr(A,0) % Equivalent MATLAB code
```

- When you select **Full** for the output size, Q is an M -by- M unitary matrix, and R is a M -by- N upper-triangular matrix.

```
[Q R E] = qr(A) % Equivalent MATLAB code
```

The block treats length- M unoriented vector input as an M -by-1 matrix.

QR factorization is an important tool for solving linear systems of equations because of good error propagation properties and the invertibility of unitary matrices:

$$Q^{-1} = Q'$$

where Q' is the complex conjugate transpose of Q .

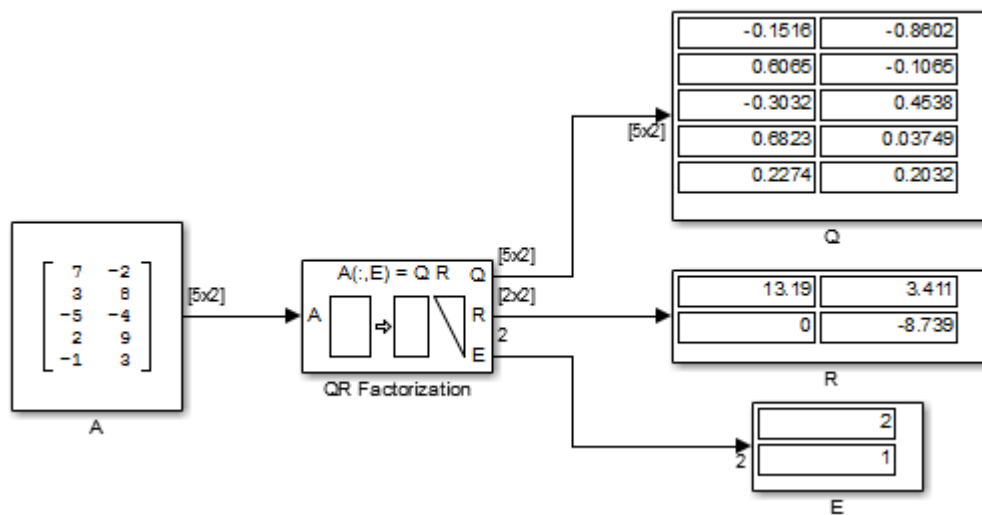

Unlike LU and Cholesky factorizations, the matrix A does not need to be square for QR factorization. However, QR factorization requires twice as many operations as LU Factorization (Gaussian elimination).

Examples

The **Output size** parameter of the QR factorization block has two settings: **Economy** and **Full**. When the M -by- N input matrix A has dimensions such that $M > N$, the dimensions of output matrices Q and R differ depending on the setting of the **Output size** parameter. If, however, the size of the input matrix A is such that $M \leq N$, output matrices Q and R have the same dimensions, regardless of whether the **Output size** is set to **Economy** or **Full**.

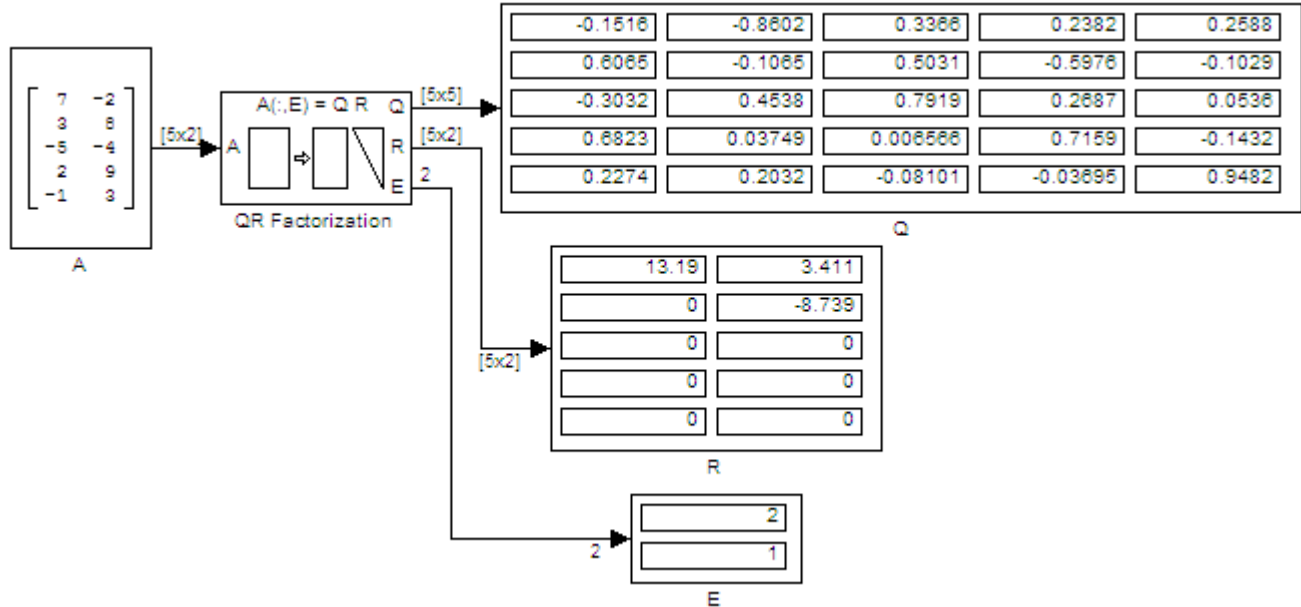

The input to the QR Factorization block in the following model is a 5-by-2 matrix A . When you change the setting of the **Output size** parameter from **Economy** to **Full**, the dimensions of the output given by the QR Factorization block also change.

- 1 Open the model by typing `ex_qrfactorization_ref` at the MATLAB command line.
- 2 Double-click the QR Factorization block, set the **Output size** parameter to **Economy**, and run the model.

The QR Factorization block outputs a 5-by-2 matrix Q and a 2-by-2 matrix R .

- 3 Change the **Output size** parameter of the QR Factorization block to **Full** and rerun the model.

The QR Factorization block outputs a 5-by-5 matrix Q and a 5-by-2 matrix R .

Parameters

Output size

Specify the size of output matrices Q and R :

- **Economy** — When this output size is selected, the block outputs an M -by- $\min(M,N)$ unitary matrix Q and a $\min(M,N)$ -by- N upper-triangular matrix R .
- **Full** — When this output size is selected, the block outputs an M -by- M unitary matrix Q and a M -by- N upper-triangular matrix R .

Simulate using

- **Interpreted execution (default)**

Simulate model using the MATLAB interpreter. This option shortens startup time and has faster simulation speed compared to Code generation.

- **Code generation**

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster subsequent simulations.

QR Solver

Find minimum-norm-residual solution to $AX=B$

Library

Math Functions / Matrices and Linear Algebra / Linear System Solvers

dsp solvers

Description

The QR Solver block solves the linear system $AX=B$, which can be overdetermined, underdetermined, or exactly determined. The system is solved by applying QR factorization to the M-by-N matrix, A, at the A port. The input to the B port is the right side M-by-L matrix, B. The block treats length-M unoriented vector input as an M-by-1 matrix.

The output at the x port is the N-by-L matrix, X. X is chosen to minimize the sum of the squares of the elements of $B-AX$. When B is a vector, this solution minimizes the vector 2-norm of the residual ($B-AX$ is the residual). When B is a matrix, this solution minimizes the matrix Frobenius norm of the residual. In this case, the columns of X are the solutions to the L corresponding systems $AX_k=B_k$, where B_k is the kth column of B, and X_k is the kth column of X.

X is known as the minimum-norm-residual solution to $AX=B$. The minimum-norm-residual solution is unique for overdetermined and exactly determined linear systems, but it is not unique for underdetermined linear systems. Thus when the QR Solver is applied to an underdetermined system, the output X is chosen such that the number of nonzero entries in X is minimized.

Parameters

Simulate using — Type of simulation to run

Interpreted execution (default) | Code generation

- Interpreted execution

Simulate model using the MATLAB interpreter. This option shortens startup time and has faster simulation speed compared to Code generation.

- Code generation

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster subsequent simulations.

Algorithm

QR factorization factors a column-permuted variant (A_e) of the M-by-N input matrix A as

$$A_e = QR$$

where Q is a M-by-min(M,N) unitary matrix, and R is a min(M,N)-by-N upper-triangular matrix.

The factored matrix is substituted for A_e in

$$A_e X = B_e$$

and

$$QRX = B_e$$

is solved for X by noting that $Q^{-1} = Q^*$ and substituting $Y = Q^* B_e$. This requires computing a matrix multiplication for Y and solving a triangular system for X.

$$RX = Y$$

Supported Data Types

- Double-precision floating point
- Single-precision floating point

Queue

Store inputs in FIFO register

Library

Signal Management / Buffers

dspbuff3

Description

The Queue block stores a sequence of input samples in a first in, first out (FIFO) register. The register capacity is set by the **Register size** parameter, and inputs can be scalars, vectors, or matrices.

The block *pushes* the input at the In port onto the end of the queue when a trigger event is received at the Push port. When a trigger event is received at the Pop port, the block *pops* the first element off the queue and holds the Out port at that value. The first input to be pushed onto the queue is always the first to be popped off.

A trigger event at the optional Rst port empties the queue contents. When you select **Clear output port on reset**, then a trigger event at the Rst port empties the queue *and* sets the value at the Out

port to zero. This setting also applies when a disabled subsystem containing the Queue block is reenabled; the Out port value is only reset to zero in this case when you select **Clear output port on reset**.

When you select the **Allow direct feedthrough** check box and two or more of the control input ports are triggered at the same time step, the operations are executed in the following order:

- 1 Rst
- 2 Push
- 3 Pop

When you clear the **Allow direct feedthrough** check box and two or more of the control input ports are triggered at the same time step, the operations are executed in the following order:

- 1 Rst
- 2 Pop
- 3 Push

The rate of the trigger signal must be the same as the rate of the data signal input. You specify the triggering event for the Push, Pop, and Rst ports by the **Trigger type** pop-up menu:

- **Rising edge** — Triggers execution of the block when the trigger input does one of the following:
 - Rises from a negative value to a positive value or zero
 - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero; see the following figure

- **Falling edge** — Triggers execution of the block when the trigger input does one of the following:
 - Falls from a positive value to a negative value or zero
 - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero; see the following figure

- **Either edge** — Triggers execution of the block when the trigger input is a **Rising edge** or **Falling edge** (as described above).
- **Non-zero sample** — Triggers execution of the block at each sample time that the trigger input is not zero.

Note If your model contains any referenced models that use a Queue block with the **Push onto full register** parameter set to **Dynamic reallocation**, you cannot simulate your top-level model in Simulink Accelerator mode.

The **Push onto full register** parameter specifies the block's behavior when a trigger is received at the **Push** port but the register is full. The **Pop empty register** parameter specifies the block's behavior when a trigger is received at the **Pop** port but the register is empty. The following options are available for both cases:

- **Ignore** — Ignore the trigger event, and continue the simulation.
- **Warning** — Ignore the trigger event, but display a warning message in the MATLAB Command Window.
- **Error** — Display an error dialog box and terminate the simulation.

Note The **Push onto full register** and **Pop empty register** parameters are diagnostic parameters. Like all diagnostic parameters on the Configuration Parameters dialog box, they are set to **Ignore** in the code generated for this block by Simulink Coder code generation software.

The **Push onto full register** parameter additionally offers the **Dynamic reallocation** option, which dynamically resizes the register to accept as many additional inputs as memory permits. To find out how many elements are on the queue at a given time, enable the Num output port by selecting the **Show number of register entries port** parameter.

Note When **Dynamic reallocation** is selected, the **System target file** parameter on the **Code Generation** pane of the Model Configuration Parameters dialog box must be set to `grt_malloc.tlc` — Generic Real-Time Target with dynamic memory allocation.

Examples

Example 1

The table below illustrates the Queue block's operation for a **Register size** of 4, **Trigger type** of **Either edge**, and **Clear output port on reset** enabled. Because the block triggers on both rising and falling edges in this example, each transition from 1 to 0 or 0 to 1 in the Push, Pop, and Rst columns below represents a distinct trigger event. A 1 in the Empty column indicates an empty queue, while a 1 in the Full column indicates a full queue.

In	Push	Pop	Rst	Queue	Out	Empty	Full	Num
1	0	0	0	top  bottom	0	1	0	0
2	1	0	0	top  bottom	0	0	0	1
3	0	0	0	top  bottom	0	0	0	2
4	1	0	0	top  bottom	0	0	0	3
5	0	0	0	top  bottom	0	0	1	4
6	0	1	0	top  bottom	2	0	0	3
7	0	0	0	top  bottom	3	0	0	2
8	0	1	0	top  bottom	4	0	0	1
9	0	0	0	top  bottom	5	1	0	0
10	1	0	0	top  bottom	5	0	0	1
11	0	0	0	top  bottom	5	0	0	2
12	1	0	1	top  bottom	0	0	0	1

Note that at the last step shown, the Push and Rst ports are triggered simultaneously. The Rst trigger takes precedence, and the queue is first cleared and then pushed.

Parameters

Register size

The number of entries that the FIFO register can hold.

Trigger type

The type of event that triggers the block's execution. The rate of the trigger signal must be the same as the rate of the data signal input.

Push onto full register

Response to a trigger received at the Push port when the register is full. Inputs to this port must have the same built-in data type as inputs to the Pop and Rst input ports.

When `Dynamic` reallocation is selected, the **System target file** parameter on the **Code Generation** pane of the Model Configuration Parameters dialog box must be set to `grt_malloc.tlc` – Generic Real-Time Target with dynamic memory allocation.

Pop empty register

Response to a trigger received at the Pop port when the register is empty. Inputs to this port must have the same built-in data type as inputs to the Push and Rst input ports.

Show empty register indicator port

Enable the Empty output port, which is high (1) when the queue is empty, and low (0) otherwise.

Show full register indicator port

Enable the Full output port, which is high (1) when the queue is full, and low (0) otherwise. The Full port remains low when you select `Dynamic` reallocation from the **Push onto full register** parameter.

Show number of register entries port

Enable the Num output port, which tracks the number of entries currently on the queue. When inputs to the In port are double-precision values, the outputs from the Num port are double-precision values. Otherwise, the outputs from the Num port are 32-bit unsigned integer values.

Show reset port to clear internal stack buffer

Enable the Rst input port, which empties the queue when the trigger specified by the **Trigger type** is received. Inputs to this port must have the same built-in data type as inputs to the Push and Pop input ports.

Clear output port on reset

Reset the Out port to zero, in addition to clearing the queue, when a trigger is received at the Rst input port.

Allow direct feedthrough

When you select this check box, the input data is available immediately at the output port of the block. You can turn off direct feedthrough and delay the input data by an extra frame by clearing the **Allow direct feedthrough** check box.

Random Source

Generate randomly distributed values

Library: DSP System Toolbox / Sources

Description

The Random Source block generates a frame of M values drawn from a uniform or Gaussian pseudorandom distribution. Specify M in the **Samples per frame** parameter.

Ports

Output

Port_1 — Signal of random values

scalar | vector | matrix

Signal of random values with uniform or Gaussian (normal) distribution.

Data Types: single | double

Parameters

Source type — Uniform or Gaussian

Uniform (default) | Gaussian

The distribution from which to draw the random values, **Uniform** or **Gaussian**.

When you set the **Source type** parameter to **Uniform**, the output samples are drawn from a uniform distribution whose minimum and maximum values are specified by the **Minimum** and **Maximum** parameters, respectively. All values in this range are equally likely to be selected. A length- N vector specified for one or both of these parameters generates an N -channel output (M -by- N matrix) containing a unique random distribution in each channel.

For example, specify

- **Minimum** = [0 0 -3 -3]
- **Maximum** = [10 10 20 20]

to generate a four-channel output whose first and second columns contain random values in the range [0, 10], and whose third and fourth columns contain random values in the range [-3, 20]. When you specify only one of the **Minimum** and **Maximum** parameters as a vector, the block scalar expands the other parameter so it is the same length as the vector.

When you set the **Source type** parameter to **Gaussian**, you must also set the **Method** parameter, which determines the method by which the block computes the output.

Method — Method of computing Gaussian random values

Ziggurat (default) | Sum of uniform values

The method by which the block computes the Gaussian random values:

- **Ziggurat** — Produces Gaussian random values by using the ziggurat method.
- **Sum of uniform values** — Produces Gaussian random values by adding and scaling uniformly distributed random signals based on the central limit theorem. This theorem states that the probability distribution of the sum of a sufficiently high number of random variables approaches the Gaussian distribution. You must set the **Number of uniform values to sum** parameter, which determines the number of uniformly distributed random numbers to sum to produce a single Gaussian random value.

For both settings of the **Method** parameter, the output samples are drawn from the normal distribution defined by the **Mean** and **Variance** parameters. A length- N vector specified for one or both of the **Mean** and **Variance** parameters generates an N -channel output (M -by- N frame matrix) containing a distinct random distribution in each column. When you specify only one of these parameters as a vector, the block scalar expands the other parameter so it is the same length as the vector.

Dependencies

To enable this parameter, set **Source type** to Gaussian. For more information, see “Source type” on page 2-0 .

Number of uniform values to sum — Number of uniform values to sum

12 (default)

The number of uniformly distributed random values to sum to compute a single number in a Gaussian random distribution.

Dependencies

To enable this parameter, set **Source type** to Gaussian and **Method** to Sum of uniform values. For more information, see “Source type” on page 2-0 .

Minimum — Minimum value of uniform distribution

0 (default) | scalar | vector

The minimum value in the uniform distribution specified as a finite scalar or vector.

Tunable: Yes

Dependencies

To enable this parameter, set **Source type** to Uniform.

Limitations

Tunable (Simulink) in Simulation mode only.

Maximum — Maximum value of uniform distribution

1 (default) | scalar | vector

The maximum value in the uniform distribution specified as a finite scalar or vector.

Tunable: Yes

Dependencies

To enable this parameter, set **Source type** to Uniform.

Limitations

Tunable (Simulink) in Simulation mode only.

Mean — Mean value of Gaussian distribution

0 (default) | scalar | vector

The mean of the Gaussian (normal) distribution specified as a finite scalar or vector.

Tunable: Yes

Dependencies

To enable this parameter, set **Source type** to Gaussian.

Limitations

Tunable (Simulink) in Simulation mode only.

Variance — Variance of Gaussian distribution

1 (default) | scalar | vector

The variance of the Gaussian (normal) distribution.

Dependencies

To enable this parameter, set **Source type** to Gaussian.

Limitations

Tunable (Simulink) in Simulation mode only.

Repeatability — Repeatability of block output

Specify seed (default) | Repeatable | Not repeatable

The **Repeatability** parameter determines if the block outputs the same signal each time you run the simulation. You can set the parameter to one of the following options:

- **Repeatable** — Outputs the same signal each time you run the simulation. The first time you run the simulation, the block randomly selects an initial seed. The block reuses these same initial seeds every time you rerun the simulation.
- **Specify seed** — Outputs the same signal each time you run the simulation. Every time you run the simulation, the block uses the initial seeds specified in the **Initial seed** parameter. Also see “Initial seed” on page 2-0 .

- **Not repeatable** — Does not output the same signal each time you run the simulation. Every time you run the simulation, the block randomly selects an initial seed.

Initial seed — Initial seed for random number generator

1 (default) | scalar | vector

The initial seed(s) to use for the random number generator specified as a finite scalar or vector. The generator produces an identical sequence of pseudorandom numbers each time it is executed with a particular initial seed.

To specify the N initial seeds for an N -channel real-valued output, set the **Complexity** parameter to **Real** and provide one of the following in the **Initial seed** parameter:

- Length- N vector of initial seeds — Uses each vector element as an initial seed for the corresponding channel in the N -channel output.
- Single scalar — Uses the scalar to generate N random values as the seeds for the N -channel output.

To specify the initial seeds for an N -channel complex-valued output, set the **Complexity** parameter to **Complex** and provide one of the following in the **Initial seed** parameter:

- Length- N vector of initial seeds — Uses each vector element as an initial seed for generating N channels of *real* random values. The block uses pairs of adjacent values in each of these channels as the real and imaginary components of the final output, as illustrated in the following figure.
- Single scalar — Uses the scalar to generate N random values as the seeds for generating N channels of *real* random values. The block uses pairs of adjacent values in each of these channels as the real and imaginary components of the final output, as illustrated in the following figure.

Use N channels of real random values to create the N -channel complex random output.

Tunable: Yes

Dependencies

To enable this parameter, set **Repeatability** to **Specify seed**.

Limitations

Tunable (Simulink) in Simulation mode only.

Inherit output port attributes — Inherit output port parameters from downstream block

off (default) | on

When you select this check box, the block inherits the sample mode, sample time, output data type, complexity, and signal dimensions of the signal from the downstream block. When you select this check box, the **Sample mode**, **Sample time**, **Samples per frame**, **Output data type**, and **Complexity** parameters are disabled.

Suppose that you want to back propagate a 1-D vector. The output of the Random Source block is a 1-D vector of length M , where length M is inherited from the downstream block. When the **Minimum**, **Maximum**, **Mean**, or **Variance** parameter specifies N channels, the 1-D vector output contains M/N samples from each channel. An error occurs in this case when M is not an integer multiple of N .

Suppose that you want to back propagate a M -by- N signal. When $N > 1$, your signal has N channels. When $N = 1$, your signal has M channels. The value of the **Minimum**, **Maximum**, **Mean**, or **Variance** parameter can be a scalar or a vector of length equal to the number of channels. You can specify these parameters as either row or column vectors, except when the signal is a row vector. In this case, the **Minimum**, **Maximum**, **Mean**, or **Variance** parameter must also be specified as a row vector.

Sample mode — Discrete or continuous

Discrete (default) | Continuous

The sample mode, specified as Continuous or Discrete.

When you set **Sample mode** to Discrete, the **Sample time** parameter value, T_s , specifies the random sequence sample period. In this mode, the block generates the number of samples specified by the **Samples per frame** parameter value, M , and outputs this frame with a period of MT_s .

When you set **Sample mode** to Continuous, the block is configured for continuous-time operation, and the **Sample time** and **Samples per frame** parameters are disabled. Note that many DSP System Toolbox blocks do not accept continuous-time inputs.

Dependencies

To enable this parameter, clear the **Inherit output port attributes** check box.

Sample time — Output sample period

1 (default) | scalar

The sample period, T_s , of the random output sequence when the **Sample mode** is Discrete, specified as a positive, finite, scalar. The output frame period is MT_s .

Dependencies

To enable this parameter, clear the **Inherit output port attributes** check box and set **Sample mode** to Discrete.

Samples per frame — Samples per output frame

1 (default) | positive integer

The number of samples, M , in each output frame, specified as a positive integer. The output frame period is MT_s .

Dependencies

To enable this parameter, clear the **Inherit output port attributes** check box and set **Sample mode** to **Discrete**.

Output data type — Output data type

Double (default) | Single

The data type of the output, specified as single-precision or double-precision.

Dependencies

To enable this parameter, clear the **Inherit output port attributes** check box.

Complexity — Complexity of output

Real (default) | Complex

The complexity of the output, specified as **Real** or **Complex**. These settings control all channels of the output, so real and complex data cannot be combined in the same output. For complex output with a **Uniform** distribution, the real and imaginary components in each channel are both drawn from the same uniform random distribution, defined by the **Minimum** and **Maximum** parameters for that channel.

For complex output with a **Gaussian** distribution, the real and imaginary components in each channel are drawn from normal distributions with different means. In this case, the **Mean** parameter for each channel should specify a complex value; the real component of the **Mean** parameter specifies the mean of the real components in the channel, while the imaginary component specifies the mean of the imaginary components in the channel. When either the real or imaginary component is omitted from the **Mean** parameter, a default value of 0 is used for the mean of that component.

For example, a **Mean** parameter setting of $[5+2i \ 0.5 \ 3i]$ generates a three-channel output with the following means.

Channel 1 mean	$real = 5$	$imaginary = 2$
Channel 2 mean	$real = 0.5$	$imaginary = 0$
Channel 3 mean	$real = 0$	$imaginary = 3$

For complex output, the **Variance** parameter, σ^2 , specifies the *total variance* for each output channel. This is the sum of the variances of the real and imaginary components in that channel.

$$\sigma^2 = \sigma_{\text{Re}}^2 + \sigma_{\text{Im}}^2$$

The specified variance is equally divided between the real and imaginary components, so that

$$\sigma_{\text{Re}}^2 = \frac{\sigma^2}{2}$$

$$\sigma_{\text{Im}}^2 = \frac{\sigma^2}{2}$$

Dependencies

To enable this parameter, clear the **Inherit output port attributes** check box.

Real Cepstrum

Compute real cepstrum of input

Library

Transforms

dspxfm3

Description

The Real Cepstrum block computes the real cepstrum of each column in the real-valued M -by- N input matrix, u . The block treats each column of the input as an independent channel containing M consecutive samples. The block *always* processes unoriented vector inputs as a single channel, and returns the result as a length- M column vector. The block does not accept complex-valued inputs.

The output is a real M_o -by- N matrix, where you specify M_o in the **FFT length** parameter. Each output column contains the length- M_o real cepstrum of the corresponding input column.

```
y = real(ifft(log(abs(fft(u,Mo)))))
```

or, more compactly,

```
y = rceps(u,Mo)
```

When you select the **Inherit FFT length from input port dimensions** check box, the output frame size matches the input frame size ($M_o=M$).

The output port rate is the same as the input port rate.

Parameters

Inherit FFT length from input port dimensions

When you select this check box, the output frame size matches the input frame size.

FFT length

The number of frequency points at which to compute the FFT, which is also the output frame size, M_o . This parameter is visible only when you clear the **Inherit FFT length from input port dimensions** check box.

Supported Data Types

- Double-precision floating point
- Single-precision floating point

Repeat

Resample input at higher rate by repeating values

Library: DSP System Toolbox / Signal Operations
 DSP System Toolbox HDL Support / Signal Operations

Description

The Repeat block upsamples each channel of the M_1 -by- N input to a rate L times higher than the input sample rate. To do so, the block repeats each consecutive input sample L times at the output. You specify the integer L in the **Repetition count** parameter.

You can use the Repeat block in triggered subsystems when you set the **Rate options** parameter to Enforce single-rate processing.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Specify the input signal as a real or a complex-valued scalar, vector, or a matrix.

When you set **Input processing** to Columns as channels (frame based) and **Rate options** to Enforce single-rate processing, the input can be a variable-size signal. That is, the frame size (number of rows) and the number of channels (columns) of the signal can change during simulation.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point

Output

Port_1 — Output signal

scalar | vector | matrix

The Repeat block outputs a signal that has the same data type and complexity as the input signal. The size of the output depends on the **Repetition count** and **Rate options** parameters.

If you set **Repetition count** to L and **Rate options** to:

- Enforce single-rate processing -- The block maintains the input sample rate by increasing the output frame size by a factor of L .
- Allow multirate processing -- The block resamples the signal such that the output sample rate is L times faster than the input sample rate. The output signal has the same frame size as the input signal.

When the input is a variable-size signal, the output is also a variable-size signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Parameters

Repetition count — Repetition count

5 (default) | positive integer

Specify the repetition count L as a positive integer. This value is the number of times that the block repeats the input value at the output. This is the factor by which the block increases the output frame size or sample rate.

Input processing — Method to process input signals

`Columns as channels (frame based)` (default) | `Elements as channels (sample based)`

Specify how the block should process the input by setting this parameter to one of these options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel. In this mode, the block can perform single-rate or multirate processing.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel. In this mode, the block always performs multirate processing.

Rate options — Method by which block upsamples input

`Enforce single-rate processing` (default) | `Allow multirate processing`

Specify the method by which the block upsamples the input by selecting one of these options:

- `Enforce single-rate processing` — When you select this option, the block maintains the input sample rate by increasing the output frame size by a factor of L . To select this option, you must set the **Input processing** parameter to `Columns as channels (frame based)`.
- `Allow multirate processing` — When you select this option, the block resamples the signal such that the output sample rate is L times faster than the input sample rate.

Initial conditions — Initial conditions

0 (default) | scalar | matrix

Specify the value with which the block is initialized for cases of nonzero latency as a scalar or a matrix.

Dependencies

To enable this parameter, set **Rate options** to `Allow multirate processing`.

Block Characteristics

Data Types	<code>Boolean</code> <code>double</code> <code>fixed point</code> <code>integer</code> <code>single</code>

Zero-Crossing Detection	no

More About

Frame-Based Processing

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block upsamples each column of the input over time. In this mode, the block can perform either single-rate or multirate processing. You can use the **Rate options** parameter to specify how the block upsamples the input.

- When you set the **Rate options** parameter to `Enforce single-rate processing`, the input and output of the block have the same sample rate. In this mode, the block outputs a signal with a proportionally larger frame size than the input. The block upsamples each channel independently by repeating each row of the input matrix L times at the output. For upsampling by a factor of L , the output frame size is L times larger than the input frame size ($M_o = M_i * L$), but the input and output frame rates are equal.

For an example that shows how the Repeat block operates in the single-rate processing mode, see “Repeat Signal In Single-Rate Processing Mode”.

- When you set the **Rate options** parameter to `Allow multirate processing`, the block treats an M_i -by- N matrix input as N independent channels. The block generates the output at the faster (upsampled) rate by using a proportionally shorter frame period at the output port than at the input port. For L repetitions of the input, the output frame period is L times shorter than the input frame period ($T_{fo} = T_{fi}/L$). In this mode, the output always has the same frame size as the input.

For an example that shows how the Repeat block operates in the multirate frame-based processing mode, see “Repeat Signal In Multirate Frame-Based Processing Mode”.

Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats an M -by- N matrix input as $M*N$ independent channels, and upsamples each channel over time. The block upsamples each channel over time such that the output sample rate is L times higher than the input sample rate ($T_{so} = T_{si}/L$). In this mode, the output is always the same size as the input.

Nonzero Latency

The Repeat block has tasking latency for a multirate multitasking operation:

- In the multirate sample-based processing mode, the block repeats the initial condition for each channel for the first L output samples. The first element of the input channel appears as output sample $L+1$. The **Initial conditions** parameter can be an M_i -by- N matrix containing one value for each channel, or a scalar value that the block applies to all signal channels.
- In the multirate frame-based processing mode, the block repeats the first row of the initial condition matrix for the first L output samples, the second row of the initial condition matrix for

the next L output samples, and so on. The first row of the first input matrix appears in the output as sample M_1L+1 . The **Initial conditions** parameter can be an M_1 -by- N matrix, or a scalar value that the block repeats across all elements of the M_1 -by- N matrix.

Note For more information on latency and Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Zero Latency

The Repeat block has *zero-tasking latency* for all single-rate operations. The block is in a single-rate mode if you set the **Repetition count** parameter to 1 or if you set the **Input processing** parameter to `Columns as channels (frame based)` and the **Rate options** parameter to `Enforce single-rate processing`.

The Repeat block also has zero-tasking latency for multirate operations if you run your model in Simulink single-tasking mode.

Zero-tasking latency means that the block repeats the first input (received at $t=0$) for the first L output samples, the second input for the next L output samples, and so on.

Version History

Introduced before R2006a

Support for variable-size input signal

Starting in R2022b, when you set **Input processing** to `Columns as channels (frame based)` and **Rate options** to `Enforce single-rate processing`, the input can be a variable-size signal. That is, the frame size (number of rows) and the number of channels (columns) of the signal can change during simulation.

When the input is a variable-size signal, the output is also a variable-size signal.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

Best Practices

The Repeat block uses fewer hardware resources than the Upsample block. If your algorithm does not require zero-padding upsampling, use the Repeat block.

HDL Architecture

This block has one default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see "ConstrainedOutputPipeline" (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "InputPipeline" (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "OutputPipeline" (HDL Coder).

Restrictions

Input processing set to `Columns as channels (frame based)` is not supported.

RLS Adaptive Filter (Obsolete)

Compute filter estimates for input using RLS adaptive filter algorithm

Library

dspobslib

Description

Note The RLS Adaptive Filter block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the RLS Filter block.

The RLS Adaptive Filter block recursively computes the recursive least squares (RLS) estimate of the FIR filter coefficients.

The corresponding RLS filter is expressed in matrix form as

$$k(n) = \frac{\lambda^{-1}P(n-1)u(n)}{1 + \lambda^{-1}u^H(n)P(n-1)u(n)}$$

$$y(n) = \widehat{w}^H(n-1)u(n)$$

$$e(n) = d(n) - y(n)$$

$$\widehat{w}(n) = \widehat{w}(n-1) + k(n)e^*(n)$$

$$P(n) = \lambda^{-1}P(n-1) - \lambda^{-1}k(n)u^H(n)P(n-1)$$

where λ^{-1} denotes the reciprocal of the exponential weighting factor. The variables are as follows

Variable	Description
n	The current algorithm iteration
$u(n)$	The buffered input samples at step n
$P(n)$	The inverse correlation matrix at step n
$k(n)$	The gain vector at step n
$\widehat{w}(n)$	The vector of filter-tap estimates at step n
$y(n)$	The filtered output at step n
$e(n)$	The estimation error at step n
$d(n)$	The desired response at step n
λ	The exponential memory weighting factor

The block icon has port labels corresponding to the inputs and outputs of the RLS algorithm. Note that inputs to the **In** and **Err** ports must be sample-based scalars. The signal at the **Out** port is a scalar, while the signal at the **Taps** port is a sample-based vector.

Block Ports	Corresponding Variables
In	u , the scalar input, which is internally buffered into the vector $u(n)$
Out	$y(n)$, the filtered scalar output
Err	$e(n)$, the scalar estimation error
Taps	$\hat{w}(0)$, the vector of filter-tap estimates

An optional **Adapt** input port is added when you select the **Adapt input** check box in the dialog box. When this port is enabled, the block continuously adapts the filter coefficients while the **Adapt** input is nonzero. A zero-valued input to the **Adapt** port causes the block to stop adapting, and to hold the filter coefficients at their current values until the next nonzero **Adapt** input.

The implementation of the algorithm in the block is optimized by exploiting the symmetry of the inverse correlation matrix $P(n)$. This decreases the total number of computations by a factor of two.

The **FIR filter length** parameter specifies the length of the filter that the RLS algorithm estimates. The **Memory weighting factor** corresponds to λ in the equations, and specifies how quickly the filter “forgets” past sample information. Setting $\lambda=1$ specifies an infinite memory; typically, $0.95 \leq \lambda \leq 1$.

The **Initial value of filter taps** specifies the initial value $\hat{w}(0)$ as a vector, or as a scalar to be repeated for all vector elements. The initial value of $P(n)$ is

$$I \frac{1}{\hat{\sigma}^2}$$

where you specify $\hat{\sigma}^2$ in the **Initial input variance estimate** parameter.

Examples

The `rlsdemo` example illustrates a noise cancellation system built around the RLS Adaptive Filter block.

Parameters

FIR filter length

The length of the FIR filter.

Memory weighting factor

The exponential weighting factor, in the range $[0, 1]$. A value of 1 specifies an infinite memory. Tunable (Simulink).

Initial value of filter taps

The initial FIR filter coefficients.

Initial input variance estimate

The initial value of $1/P(n)$.

Adapt input

Enables the Adapt port.

RLS Filter

Compute filtered output, filter error, and filter weights for given input and desired signal using RLS adaptive filter algorithm

Library

Filtering / Adaptive Filters

dspadpt3

Description

The RLS Filter block recursively computes the least squares estimate (RLS) of the FIR filter weights. The block estimates the filter weights, or coefficients, needed to convert the input signal into the desired signal. Connect the signal you want to filter to the Input port. The input signal can be a scalar or a column vector. Connect the signal you want to model to the Desired port. The desired signal must have the same data type, complexity, and dimensions as the input signal. The Output port outputs the filtered input signal. The Error port outputs the result of subtracting the output signal from the desired signal.

The corresponding RLS filter is expressed in matrix form as

$$\mathbf{k}(n) = \frac{\lambda^{-1} \mathbf{P}(n-1) \mathbf{u}(n)}{1 + \lambda^{-1} \mathbf{u}^H(n) \mathbf{P}(n-1) \mathbf{u}(n)}$$

$$y(n) = \mathbf{w}(n-1) \mathbf{u}(n)$$

$$e(n) = d(n) - y(n)$$

$$\mathbf{w}(n) = \mathbf{w}(n-1) + \mathbf{k}^H(n) e(n)$$

$$\mathbf{P}(n) = \lambda^{-1} \mathbf{P}(n-1) - \lambda^{-1} \mathbf{k}(n) \mathbf{u}^H(n) \mathbf{P}(n-1)$$

where λ^{-1} denotes the reciprocal of the exponential weighting factor. The variables are as follows

Variable	Description
n	The current time index
$\mathbf{u}(n)$	The vector of buffered input samples at step n
$\mathbf{P}(n)$	The inverse covariance matrix at step n
$\mathbf{k}(n)$	The gain vector at step n
$\mathbf{w}(n)$	The vector of filter-tap estimates at step n

Variable	Description
$y(n)$	The filtered output at step n
$e(n)$	The estimation error at step n
$d(n)$	The desired response at step n
λ	The forgetting factor

The implementation of the algorithm in the block is optimized by exploiting the symmetry of the inverse covariance matrix $P(n)$. This decreases the total number of computations by a factor of two.

Use the **Filter length** parameter to specify the length of the filter weights vector.

The **Forgetting factor (0 to 1)** parameter corresponds to λ in the equations. It specifies how quickly the filter “forgets” past sample information. Setting $\lambda=1$ specifies an infinite memory. Typically, $1 - \frac{1}{2L} < \lambda < 1$, where L is the filter length. You can specify a forgetting factor using the input port, Lambda, or enter a value in the **Forgetting factor (0 to 1)** parameter in the Block Parameters: RLS Filter dialog box.

Enter the initial filter weights, $\hat{w}(0)$, as a vector or a scalar for the **Initial value of filter weights** parameter. When you enter a scalar, the block uses the scalar value to create a vector of filter weights. This vector has length equal to the filter length and all of its values are equal to the scalar value.

The initial value of $P(n)$ is

$$\frac{1}{\sigma^2}I$$

where you specify σ^2 in the **Initial input variance estimate** parameter.

When you select the **Adapt port** check box, an Adapt port appears on the block. When the input to this port is nonzero, the block continuously updates the filter weights. When the input to this port is zero, the filter weights remain at their current values.

When you want to reset the value of the filter weights to their initial values, use the **Reset input** parameter. The block resets the filter weights whenever a reset event is detected at the Reset port. The reset signal rate must be the same rate as the data signal input.

From the **Reset input** list, select None to disable the Reset port. To enable the Reset port, select one of the following from the **Reset input** list:

- **Rising edge** — Triggers a reset operation when the Reset input does one of the following:
 - Rises from a negative value to a positive value or zero
 - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero; see the following figure

- **Falling edge** — Triggers a reset operation when the Reset input does one of the following:
 - Falls from a positive value to a negative value or zero
 - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero; see the following figure

- **Either edge** — Triggers a reset operation when the Reset input is a **Rising edge** or **Falling edge**, as described above
- **Non-zero sample** — Triggers a reset operation at each sample time that the Reset input is not zero

Select the **Output filter weights** check box to create a Wts port on the block. For each iteration, the block outputs the current updated filter weights from this port.

Examples

The `rlsdemo` example illustrates a noise cancellation system built around the RLS Filter block.

Parameters

Filter length

Enter the length of the FIR filter weights vector.

Specify forgetting factor via

Select **Dialog** to enter a value for the forgetting factor in the Block parameters: RLS Filter dialog box. Select **Input port** to specify the forgetting factor using the Lambda input port.

Forgetting factor (0 to 1)

Enter the exponential weighting factor in the range $0 \leq \lambda \leq 1$. A value of 1 specifies an infinite memory. Tunable (Simulink).

Initial value of filter weights

Specify the initial values of the FIR filter weights.

Initial input variance estimate

The initial value of $1/P(n)$.

Adapt port

Select this check box to enable the Adapt input port.

Reset input

Select this check box to enable the Reset input port.

Output filter weights

Select this check box to export the filter weights from the Wts port.

RMS

Root mean square value of input or sequence of inputs

Library: DSP System Toolbox / Statistics

Description

The RMS block computes the root mean square (RMS) value of each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the RMS value of the entire input. You can specify the dimension using the **Find the RMS value over** parameter. The RMS block can also track the RMS value in a sequence of inputs over a period of time. To track the RMS value in a sequence of inputs, select the **Running RMS** parameter.

Note The **Running** mode in the RMS block will be removed in a future release. To compute the running RMS in Simulink, use the Moving RMS block instead.

Ports

Input

In — Data input

vector | matrix | N -D array

The block accepts real-valued or complex-valued multichannel and multidimensional inputs.

This port is unnamed until you select the **Running RMS** parameter and set the **Reset port** parameter to any option other than None.

Data Types: single | double

Rst — Reset port

scalar

Specify the reset event that causes the block to reset the running RMS. The sample time of the **Rst** input must be a positive integer multiple of the input sample time.

Dependencies

To enable this port, select the **Running RMS** parameter and set the **Reset port** parameter to any option other than None.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean

Output

Port_1 — RMS value along the specified dimension

scalar | vector | matrix | N -D array

The data type of the output matches the data type of the input.

When you do not select the **Running RMS** parameter, the block computes the RMS value in each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the RMS value of the entire input at each individual sample time. Each element in the output array y is the RMS value of the corresponding column, row, or entire input. The output array y depends on the setting of the **Find the RMS value over** parameter. Consider a three-dimensional input signal of size M -by- N -by- P . When you set **Find the RMS value over** to:

- **Entire input** — The output at each sample time is a scalar that contains the RMS value of the M -by- N -by- P input matrix.
- **Each row** — The output at each sample time consists of an M -by-1-by- P array, where each element contains the RMS value of each vector over the second dimension of the input. For an M -by- N matrix input, the output at each sample time is an M -by-1 column vector.
- **Each column** — The output at each sample time consists of a 1-by- N -by- P array, where each element contains the RMS value of each vector over the first dimension of the input. For an M -by- N matrix input, the output at each sample time is a 1-by- N row vector.

In this mode, the block treats length- M unoriented vector inputs as M -by-1 column vectors.

- **Specified dimension** — The output at each sample time depends on the value of the **Dimension** parameter. If you set the **Dimension** to 1, the output is the same as when you select **Each column**. If you set the **Dimension** to 2, the output is the same as when you select **Each row**. If you set the **Dimension** to 3, the output at each sample time is an M -by- N matrix containing the RMS value of each vector over the third dimension of the input.

When you select **Running RMS**, the block tracks the RMS value of each channel in a time sequence of inputs. In this mode, you must also specify a value for the **Input processing** parameter.

- **Elements as channels (sample based)** — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size M -by- N -by- P , the block outputs an M -by- N -by- P array. Each element y_{ijk} of the output contains the RMS value of the element u_{ijk} for all inputs since the last reset.

When a reset event occurs, the running RMS y_{ijk} in the current frame is reset to the element u_{ijk} .

- **Columns as channels (frame based)** — The block treats each column of the input as a separate channel. This option does not support input signals with more than two dimensions. For a two-dimensional input signal of size M -by- N , the block outputs an M -by- N matrix. Each element y_{ij} of the output contains the RMS value of the elements in the j th column of all inputs since the last reset, up to and including the element u_{ij} of the current input.

When a reset event occurs, the running RMS for each channel becomes the RMS value of all the samples in the current input frame, up to and including the current input sample.

Data Types: `single` | `double`

Parameters

Main Tab

Running RMS — Option to select running RMS

`off` (default) | `on`

When you select the **Running RMS** parameter, the block tracks the RMS value of each channel in a time sequence of inputs.

Find the RMS value over — Dimension over which the block computes the RMS value

Each column (default) | Entire input | Each row | Specified dimension

- **Each column** — The block outputs the RMS value over each column.
- **Each row** — The block outputs the RMS value over each row.
- **Entire input** — The block outputs the RMS value over the entire input.
- **Specified dimension** — The block outputs the RMS value over the dimension specified in the **Dimension** parameter.

Dependencies

To enable this parameter, clear the **Running RMS** parameter.

Dimension — Custom dimension

1 (default) | scalar

Specify the dimension (one-based value) of the input signal over which the RMS value is computed. The value of this parameter must be greater than 0 and less than the number of dimensions in the input signal.

Dependencies

To enable this parameter, set **Find the RMS value over** to Specified dimension.

Input processing — Method to process the input in running mode

Columns as channels (frame based) (default) | Elements as channels (sample based)

- **Columns as channels (frame based)** — The block treats each column of the input as a separate channel. This option does not support input signals with more than two dimensions. For a two-dimensional input signal of size M -by- N , the block outputs an M -by- N matrix. Each element y_{ij} of the output contains the RMS value of the elements in the j th column of all inputs since the last reset, up to and including the element u_{ij} of the current input.

When a reset event occurs, the running RMS for each channel becomes the RMS value of all the samples in the current input frame, up to and including the current input sample.

- **Elements as channels (sample based)** — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size M -by- N -by- P , the block outputs an M -by- N -by- P array. Each element y_{ijk} of the output contains the RMS value of the element u_{ijk} for all inputs since the last reset.

When a reset event occurs, the running RMS y_{ijk} in the current frame is reset to the element u_{ijk} .

Variable-Size Inputs

When your inputs are of variable size, and you select the **Running RMS** parameter, then:

- If you set the **Input processing** parameter to Elements as channels (sample based), the state is reset.

- If you set the **Input processing** parameter to `Columns as channels (frame based)`, then:
 - When the input size difference is in the number of channels (number of columns), the state is reset.
 - When the input size difference is in the length of channels (number of rows), there is no reset and the running operation is carried out as usual.

Dependencies

To enable this parameter, select the **Running RMS** parameter.

Reset port — Reset event

None (default) | Rising edge | Falling edge | Either edge | Non-zero sample

The block resets the running RMS whenever a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer multiple of the input sample time.

When a reset event occurs while the **Input processing** parameter is set to `Elements as channels (sample based)`, the running RMS for each channel is initialized to the value in the corresponding channel of the current input. Similarly, when the **Input processing** parameter is set to `Columns as channels (frame based)`, the running RMS for each channel becomes the RMS value of all the samples in the current input frame, up to and including the current input sample.

Use this parameter to specify the reset event.

- **None** — Disables the **Rst** port.
- **Rising edge** — Triggers a reset operation when the **Rst** input does one of the following:
 - Rises from a negative value to either a positive value or zero.
 - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.

- **Falling edge** — Triggers a reset operation when the **Rst** input does one of the following:
 - Falls from a positive value to a negative value or zero.
 - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.

- **Either edge** — Triggers a reset operation when the **Rst** input is a Rising edge or Falling edge.
- **Non-zero sample** — Triggers a reset operation at each sample time, when the **Rst** input is not zero.

Note When running simulations in the Simulink multitasking mode, reset signals have a one-sample latency. Therefore, when the block detects a reset event, there is a one-sample delay at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Dependencies

To enable this parameter, select the **Running RMS** parameter.

Block Characteristics

Data Types	double single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

More About

Root Mean Square (RMS)

The RMS value of a discrete-time signal is the square root of the arithmetic mean of the squares of the signal sample values.

For an M -by- N input matrix u , the RMS value of the j th column of the input is given by:

$$y_j = \sqrt{\frac{\sum_{i=1}^M |u_{ij}|^2}{M}} \quad 1 \leq j \leq N$$

Algorithms

Root Mean Square (RMS)

When you clear the **Running RMS** parameter in the block and specify a dimension, the block produces results identical to the MATLAB `rms` function, when it is called as `y = rms(u,D)`.

- `u` is the data input.
- `D` is the dimension.
- `y` is the RMS value.

The RMS value along the entire input is identical to calling the `rms` function as `y = rms(u(:))`.

When inputs are complex, the block computes the RMS value of the magnitude of the complex input.

In — Signal port

scalar | vector | matrix

The signal port can accept data in the form of a scalar, vector, or matrix.

Dependencies

This port is named **In<Lo>** when you select the **Latch (buffer) input** parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Trigger — Trigger port

scalar

The trigger input must be a sample-based scalar with sample rate equal to the input frame rate at the signal port. You specify the trigger event using the **Trigger type** parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 — Sample and hold value

scalar | vector | matrix

Sample and hold output, returned as a scalar, vector, or a matrix. The block acquires input at the signal port whenever it receives a trigger event at the trigger port. The block then holds the acquired data until the next triggering event occurs.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Parameters

Trigger type — Type of trigger

Rising edge (default) | Falling edge | Either edge

The type of event that triggers the block to acquire the input signal:

- **Rising edge** -- The trigger input rises from a negative value or zero to a positive value.
- **Falling edge** -- The trigger input falls from a positive value or zero to a negative value.
- **Either edge** -- The trigger input either rises from a negative value or zero to a positive value or falls from a positive value or zero to a negative value.

Initial condition — Block output prior to first trigger event

0 (default) | scalar | vector | matrix

Specify the block's output before the first trigger event using the **Initial condition** parameter. When the acquired input is an M -by- N matrix, the **Initial condition** can be an M -by- N matrix or a scalar repeated across all elements of the matrix. When the input is a length- M unoriented vector, the **Initial condition** can be a length- M row or column vector, or a scalar to be repeated across all elements of the vector.

Latch (buffer) input — Latch buffer input

off (default) | on

If you select the **Latch (buffer) input** check box, the block outputs the value of the input from the previous time step until the next triggering event occurs. To use this block in a loop, select this check box.

Block Characteristics

Data Types	Boolean double fixed point integer single

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL code for the Sample and Hold block is generated as a Triggered Subsystem. Similar restrictions apply to both blocks. See “Using Triggered Subsystems for HDL Code Generation” (HDL Coder).

HDL Block Properties

For HDL block property descriptions, see “HDL Block Properties: General” (HDL Coder).

Best Practices

When using the Sample and Hold block in models targeted for HDL code generation, consider the following:

- For synthesis results to match Simulink results, drive the trigger port with registered logic (with a synchronous clock) on the FPGA.
- It is good practice to put a unit delay on the output signal. Doing so prevents the code generator from inserting extra bypass registers in the HDL code.
- The use of triggered subsystems, such as the Sample and Hold block, can affect synthesis results in the following ways:
 - In some cases, the system clock speed can drop by a small percentage.
 - Generated code uses more resources, scaling with the number of triggered subsystem instances.

Restrictions

The Sample and Hold block must meet the following conditions:

- The DUT (i.e., the top-level subsystem for which code is generated) must not be the Sample and Hold block.
- The trigger signal must be a scalar.
- The data type of the trigger signal must be either `boolean` or `ufix1`.
- The output of the Sample and Hold block must have an initial value of 0.
- The input, output, and trigger signal of the Sample and Hold block must run at the same rate. If one of the input or the trigger signals is an output of a Signal Builder block, see “Using the Signal Builder Block” (HDL Coder) for how to match rates.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Sample-Rate Converter

Multistage sample-rate conversion

Library: DSP System Toolbox / Signal Operations

Description

The Sample-Rate Converter block implements a multistage FIR sample-rate converter. The multistage FIR converter converts the rate of each channel of the input signal from the input sample rate to the output sample rate. Multistage implementations minimize the amount of computation required for the sample-rate conversions by first reducing the sample rate of the input signal. Next, the block determines the optimal number of decimators and interpolators based on the parameters you specify in the block dialog box. The block then accordingly designs filters in the individual stages.

This block supports SIMD code generation. For details, see “Code Generation” on page 2-1141.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Specify the input signal as a real or a complex-valued scalar, vector, or a matrix.

The input frame size must be a multiple of the decimation factor of the rate converter. The decimation factor depends on the parameter setting of the converter. To determine the decimation factor, in the block dialog box, click **View Info**.

The block treats each column of a two-dimensional input signal as a separate channel. If the input is a two-dimensional signal, the first dimension represents the channel length (or frame size), and the second dimension represents the number of channels. If the input is a one-dimensional signal, then the block interprets the signal as having a single channel.

Data Types: single | double

Output

Port_1 — Resampled signal

scalar | vector | matrix

The Sample-Rate Converter block outputs a signal that has the same data type and complexity as the input signal. The size of the output signal depends on the overall interpolation factor and the decimation factor of the Sample-Rate Converter. You can determine this information by clicking the **View Info** button in the block dialog box.

Data Types: single | double

Parameters

Sample rate of input signal (Hz) — Sample rate of input signal in Hz

48e3 (default) | positive scalar

Specify the sample rate of the input signal as a positive scalar in Hz. The input sample rate must be greater than the bandwidth of interest.

Sample rate of output signal (Hz) — Sample rate of output signal in Hz

96e3 (default) | positive scalar

Specify the sample rate of the output signal as a positive scalar in Hz. The output sample rate must be greater than the bandwidth of interest.

Tolerance for output sample rate — Maximum tolerance for output sample rate

0 (default) | positive scalar in the range [0,0.5]

Specify the maximum tolerance for the output sample rate as a positive scalar in the range [0,0.5]. The default is 0.

The actual output sample rate varies but is within the specified range. For example, if you set the **Tolerance for output sample rate** to 0.01, then the actual output sample rate is in the range given by sample rate of output signal $\pm 1\%$. This flexibility allows for a simpler filter design.

Two-sided bandwidth of interest (Hz) — Two-sided bandwidth of interest in Hz

40e3 (default) | positive scalar

Specify the two-sided bandwidth of interest (after the rate of conversion) as a positive scalar in Hz.

Stopband attenuation (dB) — Minimum attenuation for aliased components in dB

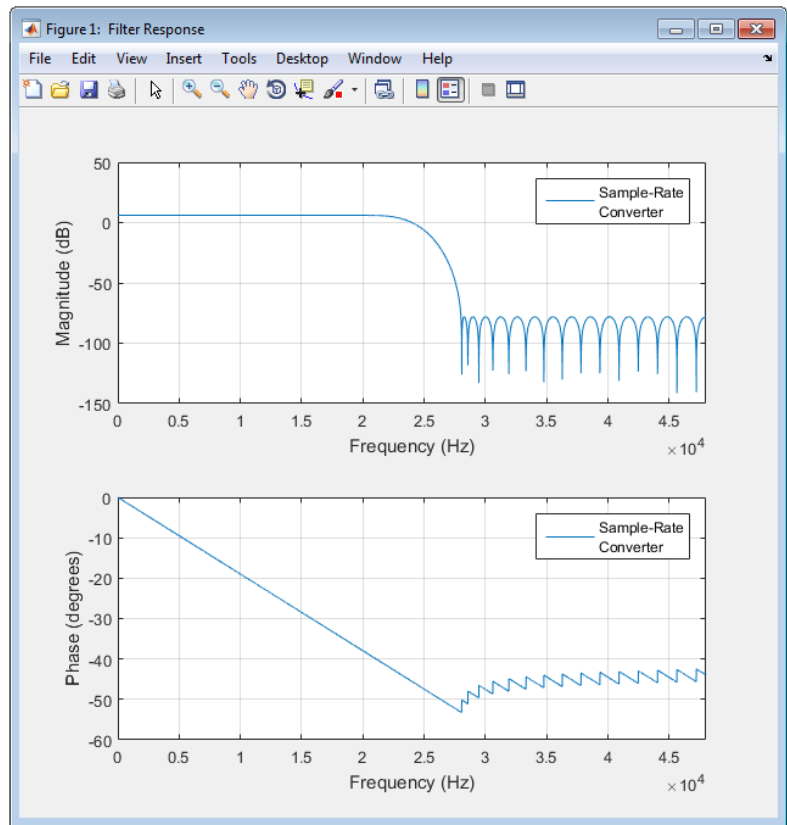

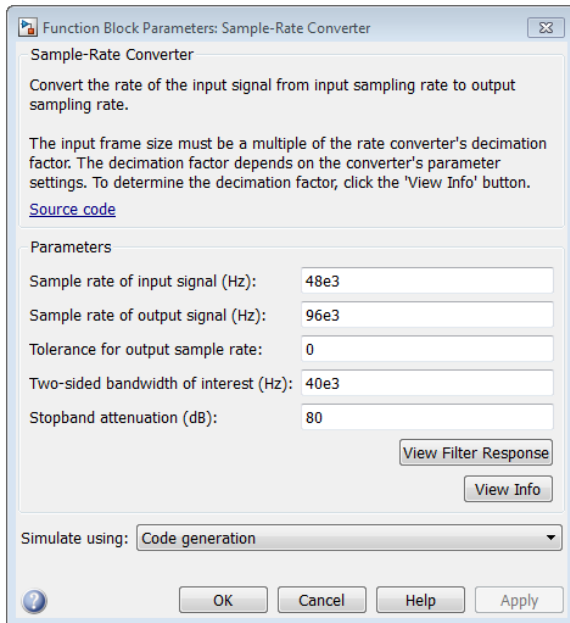

80 (default) | positive scalar

Specify the minimum amount of attenuation for aliased components in the stopband as a positive scalar in dB. This parameter is the minimum amount by which the block attenuates any aliasing involved in the process.

View Filter Response — View Filter Response

button

Opens the Filter Visualization Tool FVTool and displays the magnitude/phase response of the Sample-Rate Converter. The response is based on the block parameters. FVTool updates when you change the parameters.

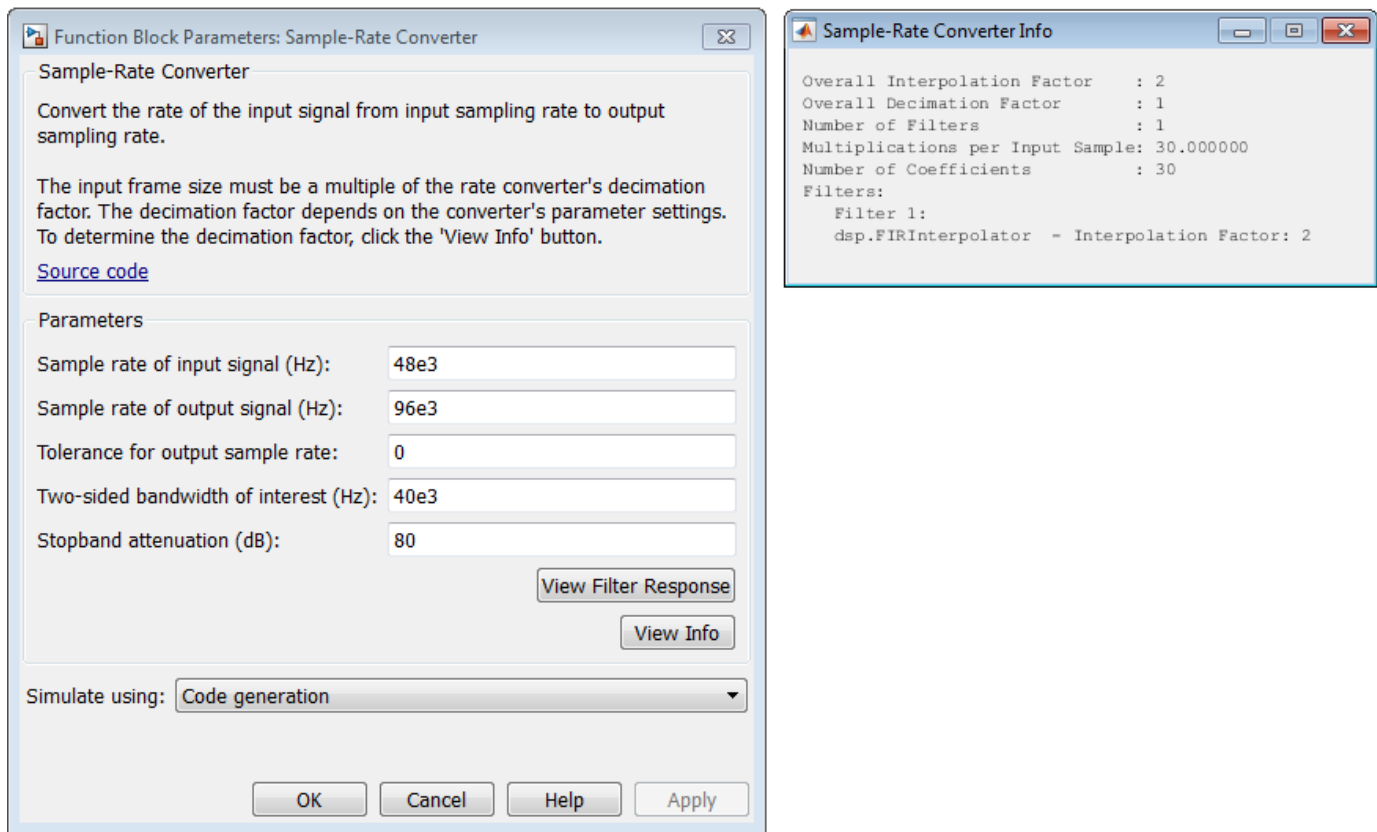

To update the magnitude response while FVTool is running, modify the parameters in the dialog box and click **Apply**.

View Info – Display information about filter button

Click on the **View Info** button to display the filter information of the Sample-Rate Converter block:

- Overall Interpolation Factor
- Overall Decimation Factor
- Number of Filters
- Multiplication per Input Sample
- Number of Coefficients
- Filters

The button brings the functionality of the `info` function into the Simulink environment.

Simulate using – Type of simulation to run

Code generation (default) | Interpreted execution

Type of simulation to run. You can set this parameter to:

- Code generation (default)

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.

- Interpreted execution

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

Block Characteristics

Data Types	double single
Direct Feedthrough	no

Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Algorithms

- The general multistage sample rate converter performs a multistage decimation, a single-stage sample rate conversion, and a multistage interpolation. Actual designs include at most two of these steps.
- The procedure automatically determines the optimal number of decimation or interpolation stages. In special cases, the algorithm can perform a decimation or interpolation in a single stage.
- The algorithm always attempts to start by reducing the sample rate. This decreases the amount of computation required. The decimation step ensures that the intermediate sample rate does not go below the bandwidth of interest and that the block does not filter out any information.
- Each individual stage uses halfband or Nyquist filters to minimize the number of nonzero coefficients.
- The algorithm allows transition-band aliasing because it decreases the implementation cost. It keeps the signal within the bandwidth of interest alias free up to the value specified by the `StopbandAttenuation` property.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The Sample-Rate Converter block supports SIMD code generation using Intel AVX2 technology under these conditions:

- For upsampling, the ratio of output sample rate to input sample rate must be an integer.
- For downsampling, the ratio of input sample rate to output sample rate must be an integer.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

Scalar Quantizer (Obsolete)

Convert input signal into set of quantized output values or index values, or convert set of index values into quantized output signal

Library

dspobslib

Description

Note The Scalar Quantizer block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the Scalar Quantizer Encoder block or the Scalar Quantizer Decoder block.

The Scalar Quantizer block has three modes of operation. In **Encoder** mode, the block maps each input value to a quantization region by comparing the input value to the quantizer boundary points defined in the **Boundary points** parameter. The block outputs the index of the associated region. In **Decoder** mode, the block transforms the input index values into quantized output values, defined in the **Codebook** parameter. In the **Encoder and Decoder** mode, the block performs both the encoding and decoding operations. The block outputs the index values and the quantized output values.

You can select how you want to enter the **Boundary points** and/or **Codebook** values using the **Source of quantizer** parameters. When you select **Specify via dialog**, type the parameters into the block parameters dialog box. Select **Input ports**, and port B and/or C appears on the block. In **Encoder** and **Encoder and decoder** mode, the input to port B is used as the **Boundary points**. In **Decoder** and **Encoder and decoder** mode, the input to port C is used as the **Codebook**.

In **Encoder** and **Encoder and decoder** mode, the **Boundary points** are the values used to break up the input signal into regions. Each region is specified by an index number. When your first boundary point is $-\infty$ and your last boundary point is ∞ , your quantizer is unbounded. When your first and last boundary point is finite, your quantizer is bounded. When only your first or last boundary point is $-\infty$ or ∞ , your quantizer is semi-bounded.

For instance, when your input signal ranges from 0 to 11, you can create a bounded quantizer using the following boundary points:

```
[0 0.5 3.7 5.8 6.0 11]
```

The boundary points can have equal or varied spacing. Any input values between 0 and 0.5 would correspond to index 0. Input values between 0.5 and 3.7 would correspond to index 1, and so on.

Suppose you wanted to create an unbounded quantizer with the following boundary points:

```
[-inf 0 2 5.5 7.1 10 inf]
```

When your input signal has values less than 0, these values would be assigned to index 0. When your input signal has values greater than 10, these values would be assigned to index 6.

When an input value is the same as a boundary point, the **Tie-breaking rule** parameter defines the index to which the value is assigned. When you want the input value to be assigned to the lower index value, select **Choose the lower index**. To assign the input value with the higher index, select **Choose the higher index**.

In **Decoder** and **Encoder** and **decoder** mode, the **Codebook** is a vector of quantized output values that correspond to each index value.

In **Encoder** and **Encoder** and **decoder** mode, the **Searching method** determines how the appropriate quantizer index is found. Select **Linear** and the Scalar Quantizer block compares the input value to the first region defined by the first two boundary points. When the input value does not fall within this region, the block then compares the input value to the next region. This process continues until the input value is determined to be within a region and is associated with the appropriate index value. The computational cost of this process is of the order P , where P is the number of boundary points.

Select **Binary** for the **Searching method** and the block compares the input value to the middle value of the boundary points vector. When the input value is larger than this boundary point, the block discards the boundary points that are lower than this middle value. The block then compares the input value to the middle boundary point of the new range, defined by the remaining boundary points. This process continues until the input value is associated with the appropriate index value. The computational cost of this process is of the order $\log_2 P$, where P is the number of boundary points. In most cases, the **Binary** option is faster than the **Linear** option.

In **Decoder** mode, the input to this block is a vector of index values, where $0 \leq \text{index} < N$ and N is the length of the codebook vector. Use the **Action for out of range input** parameter to determine what happens when an input index value is out of this range. When you want any index values less than 0 to be set to 0 and any index values greater than or equal to N to be set to $N - 1$, select **Clip**. When you want to be warned when any index values less than 0 are set to 0 and any index values greater than or equal to N are set to $N - 1$, select **Clip and warn**. When you want the simulation to stop and display an error when the index values are out of range, select **Error**.

In **Encoder** and **decoder** mode, you can select the **Output the quantization error** check box. The quantization error is the difference between the input value and the quantized output value. Select this check box to output the quantization error for each input value from the **Err** port on this block.

Data Type Support

In **Encoder** mode, the input data values and the boundary points can be the input to the block at ports **U** and **B**. Similarly, in **Encoder** and **decoder** mode, the codebook values can also be the input to the block at port **C**. The data type of the input data values, boundary points, and codebook values can be **double**, **single**, **uint8**, **uint16**, **uint32**, **int8**, **int16**, or **int32**. In **Decoder** mode, the input to the block can be the index values and the codebook values. The data type of the index input to the block at port **Idx** can be **uint8**, **uint16**, **uint32**, **int8**, **int16**, or **int32**. The data type of the codebook values can be **double**, **single**, **uint8**, **uint16**, **uint32**, **int8**, **int16**, or **int32**.

In Encoder mode, the output of the block is the index values. In Encoder and decoder mode, the output can also include the quantized output values and the quantization error. In Encoder and Encoder and decoder mode, use the **Output index data type** parameter to specify the data type of the index output from the block at port `Idx`. The data type of the index output can be `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`. The data type of the quantized output and the quantization error can be `double`, `single`, `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`. In Decoder mode, the output of the block is the quantized output values. Use the **Output data type** parameter to specify the data type of the quantized output values. The data type can be `double`, `single`, `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`.

Note The input data, codebook values, boundary points, quantization error, and the quantized output values must have the same data type whenever they are present in any of the quantizer modes.

Parameters

Quantizer mode

Specify `Encoder`, `Decoder`, or `Encoder and decoder` as a mode of operation.

Source of quantizer parameters

Choose `Specify via dialog` to type the parameters into the block parameters dialog box. Select `Input ports` to specify the parameters using the block's input ports. In `Encoder and Encoder and decoder` mode, input the **Boundary points** using port B. In `Decoder and Encoder and decoder` mode, input the **Codebook** values using port C.

Boundary points

Enter a vector of values that represent the boundary points of the quantizer regions. Tunable (Simulink).

Codebook

Enter a vector of quantized output values that correspond to each index value. Tunable (Simulink).

Searching method

Select `Linear` and the block finds the region in which the input value is located using a linear search. Select `Binary` and the block finds the region in which the input value is located using a binary search.

Tie-breaking rule

Set this parameter to determine the behavior of the block when the input value is the same as the boundary point. When you select `Choose the lower index`, the input value is assigned to lower index value. When you select `Choose the higher index`, the value is assigned to the higher index.

Action for out of range input

Choose the block's behavior when an input index value is out of range, where $0 \leq \text{index} < N$ and N is the length of the codebook vector. Select `Clip`, when you want any index values less than 0 to be set to 0 and any index values greater than or equal to N to be set to $N - 1$. Select `Clip and warn`, when you want to be warned when any index values less than 0 are set to 0 and any index values greater than or equal to N are set to $N - 1$. Select `Error`, when you want the simulation to stop and display an error when the index values are out of range.

Output the quantization error

In Encoder and decoder mode, select this check box to output the quantization error from the Err port on this block.

Output index data type

In Encoder and Encoder and decoder mode, specify the data type of the index output from the block at port Idx. The data type can be uint8, uint16, uint32, int8, int16, or int32.

This parameter becomes visible when you select the **Show additional parameters** check box.

Output data type

In Decoder mode, specify the data type of the quantized output. The data type can be uint8, uint16, uint32, int8, int16, int32, single, or double. This parameter becomes visible when you select Specify via dialog for the **Source of quantizer parameters** and you select the **Show additional parameters** check box.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

For more information on what data types are supported for each quantizer mode, see “Data Type Support” on page 2-1143.

Scalar Quantizer Decoder

Convert each index value into quantized output value

Library

Quantizers

dspquant2

Description

The Scalar Quantizer Decoder block transforms the zero-based input index values into quantized output values. The set of all possible quantized output values is defined by the **Codebook values** parameter.

Use the **Codebook values** parameter to specify a matrix containing all possible quantized output values. You can select how you want to enter the codebook values using the **Source of codebook** parameter. When you select *Specify via dialog*, type the codebook values into the block parameters dialog box. When you select *Input port*, port C appears on the block. The block uses the input to port C as the **Codebook values** parameter.

The input to this block is a vector of integer index values, where $0 \leq \text{index} < N$ and N is the number of distinct codeword vectors in the codebook matrix. Use the **Action for out of range index value** parameter to determine what happens when an input index value is outside this range. When you want any index value less than 0 to be set to 0 and any index value greater than or equal to N to be set to $N - 1$, select *Clip*. When you want to be warned when clipping occurs, select *Clip and warn*. When you want the simulation to stop and the block to display an error when the index values are out of range, select *Error*.

Data Type Support

The data type of the index values input at port I can be `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`. The data type of the codebook values input at port C can be `double`, `single`, or `Fixed-point`.

The output of the block is the quantized output values. If, for the **Source of codebook** parameter, you select *Specify via dialog*, the **Codebook and output data type** parameter appears. You can use this parameter to specify the data type of the codebook and quantized output values. In this case, the data type of the output values can be *Same as input*, `double`, `single`, `Fixed-point`, or *User-defined*. If, for the **Source of codebook** parameter you select *Input port*, the quantized output values have the same data type as the codebook values input at port C.

Dialog Box

The **Main** pane of the Scalar Quantizer Decoder block dialog appears as follows.

Action for out of range index value

Use this parameter to determine the block's behavior when an input index value is out of range, where $0 \leq \text{index} < N$ and N is the length of the codebook vector. Select **Clip**, when you want any index values less than 0 to be set to 0 and any index values greater than or equal to N to be set to $N - 1$. Select **Clip and warn**, when you want to be warned when clipping occurs. Select **Error**, when you want the simulation to stop and the block to display an error when the index values are outside the range.

Source of codebook

Choose **Specify via dialog** to type the codebook values into the block parameters dialog box. Select **Input port** to specify the codebook using input port C.

Codebook values

Enter a vector of quantized output values that correspond to each index value. Tunable (Simulink).

The **Data Types** pane of the Scalar Quantizer Decoder block dialog appears as follows.

Codebook and output data type

Specify the data type of the codebook and quantized output values. You can select one of the following:

- A rule that inherits a data type, for example, `Inherit: Same as input`.
- A built in data type, such as `double`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Data Types of Signals” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

This parameter is available only when you set the **Source of codebook** parameter to `Specify via dialog`. If you set the **Source of codebook** parameter to `Input port`, the output values have the same data type as the input codebook values.

Note The Scalar Quantizer Design block and the associated SQDTool have been removed. For more information, see “Compatibility Considerations”.

Library

Quantizers

dspquant2

Description

Double-click on the Scalar Quantizer Design block to start SQDTool, a GUI that allows you to design and implement a scalar quantizer. Based on your input values, SQDTool iteratively calculates the codebook values that minimize the mean squared error until the stopping criteria for the design process is satisfied. The block uses the resulting quantizer codebook values and boundary points to implement your scalar quantizer encoder and/or decoder.

For the **Training Set** parameter, enter a set of observations, or samples, of the signal you want to quantize. This data can be any variable defined in the MATLAB workspace including a variable created using a MATLAB function, such as the default value `randn(10000,1)`.

You have two choices for the **Source of initial codebook** parameter. Select **Auto-generate** to have the block choose the values of the initial codebook vector. In this case, the minimum training set value becomes the first codeword, and the maximum training set value becomes the last codeword. Then, the remaining initial codewords are equally spaced between these two values to form a codebook vector of length N , where N is the **Number of levels** parameter. When you select **User defined**, enter the initial codebook values in the **Initial codebook** field. Then, set the **Source of initial boundary points** parameter. You can select **Mid-points** to locate the boundary points at the midpoint between the codewords. To calculate the mid-points, the block internally arranges the initial codebook values in ascending order. You can also choose **User defined** and enter your own boundary points in the **Initial boundary points (unbounded)** field. Only one boundary point can be located between two codewords. When you select **User defined** for the **Source of initial boundary points** parameter, the values you enter in the **Initial codebook** and **Initial boundary points (unbounded)** fields must be arranged in ascending order.

Note This block assumes that you are designing an unbounded quantizer. Therefore, the first and last boundary points are always `-inf` and `inf` regardless of any other boundary point values you might enter.

After you have specified the quantization parameters, the block performs an iterative process to design the optimal scalar quantizer. Each step of the design process involves using the Lloyd

algorithm to calculate codebook values and quantizer boundary points. Then, the block calculates the squared quantization error and checks whether the stopping criteria has been satisfied.

The two possible options for the **Stopping criteria** parameter are `Relative threshold` and `Maximum iteration`. When you want the design process to stop when the fractional drop in the squared quantization error is below a certain value, select `Relative threshold`. Then, for **Relative threshold**, type the maximum acceptable fractional drop. When you want the design process to stop after a certain number of iterations, choose `Maximum iteration`. Then, enter the maximum number of iterations you want the block to perform in the **Maximum iteration** field. For **Stopping criteria**, you can also choose `Whichever comes first` and enter a **Relative threshold** and **Maximum iteration** value. The block stops iterating as soon as one of these conditions is satisfied.

With each iteration, the block quantizes the training set values based on the newly calculated codebook values and boundary points. When the training point lies on a boundary point, the algorithm uses the **Tie-breaking rules** parameter to determine which region the value is associated with. When you want the training point to be assigned to the lower indexed region, select `Lower indexed codeword`. To assign the training point with the higher indexed region, select `Higher indexed codeword`.

The **Searching methods** parameter determines how the block compares the training points to the boundary points. Select `Linear search` and SQDTool compares each training point to each quantization region sequentially. This process continues until all the training points are associated with the appropriate regions.

Select `Binary search` for the **Searching methods** parameter and the block compares the training point to the middle value of the boundary points vector. When the training point is larger than this boundary point, the block discards the lower boundary points. The block then compares the training point to the middle boundary point of the new range, defined by the remaining boundary points. This process continues until the training point is associated with the appropriate region.

Click **Design and Plot** to design the quantizer with the parameter values specified on the left side of the GUI. The performance curve and the staircase character of the quantizer are updated and displayed in the figures on the right side of the GUI.

Note You must click **Design and Plot** to apply any changes you make to the parameter values in the SQDTool dialog box.

SQDTool can export parameter values that correspond to the figures displayed in the GUI. Click the **Export Outputs** button, or press **Ctrl+E**, to export the **Final Codebook**, **Final Boundary Points**, and **Error** values to the workspace, a text file, or a MAT-file. The **Error** values represent the mean squared error for each iteration.

In the **Model** section of the GUI, specify the destination of the block that will contain the parameters of your quantizer. For **Destination**, select `Current model` to create a block with your parameters in the model you most recently selected. Type `gcs` in the MATLAB Command Window to display the name of your current model. Select `New model` to create a block in a new model file.

From the **Block type** list, select `Encoder` to design a Scalar Quantizer Encoder block. Select `Decoder` to design a Scalar Quantizer Decoder block. Select `Both` to design a Scalar Quantizer Encoder block and a Scalar Quantizer Decoder block.

In the **Encoder block name** field, enter a name for the Scalar Quantizer Encoder block. In the **Decoder block name** field, enter a name for the Scalar Quantizer Decoder block. When you have a Scalar Quantizer Encoder and/or Decoder block in your destination model with the same name, select the **Overwrite target block(s)** check box to replace the block's parameters with the current parameters. When you do not select this check box, a new Scalar Quantizer Encoder and/or Decoder block is created in your destination model.

Click **Generate Model**. SQDTool uses the parameters that correspond to the current plots to set the parameters of the Scalar Quantizer Encoder and/or Decoder blocks.

Parameters

Training Set

Enter the samples of the signal you would like to quantize. This data set can be a MATLAB function or a variable defined in the MATLAB workspace. The typical length of this data vector is $1e6$.

Source of initial codebook

Select **Auto-generate** to have the block choose the initial codebook values. Select **User defined** to enter your own initial codebook values.

Number of levels

Enter the length of the codebook vector. For a b-bit quantizer, the length should be $N = 2^b$.

Initial codebook

Enter your initial codebook values. From the **Source of initial codebook** list, select **User defined** in order to activate this parameter.

Source of initial boundary points

Select **Mid-points** to locate the boundary points at the midpoint between the codebook values. Choose **User defined** to enter your own boundary points. From the **Source of initial codebook** list, select **User defined** in order to activate this parameter.

Initial boundary points (unbounded)

Enter your initial boundary points. This block assumes that you are designing an unbounded quantizer. Therefore, the first and last boundary point are $-\infty$ and ∞ , regardless of any other boundary point values you might enter. From the **Source of initial boundary points** list, select **User defined** in order to activate this parameter.

Stopping criteria

Choose **Relative threshold** to enter the maximum acceptable fractional drop in the squared quantization error. Choose **Maximum iteration** to specify the number of iterations at which to stop. Choose **Whichever comes first** and the block stops the iteration process as soon as the relative threshold or maximum iteration value is attained.

Relative threshold

Type the value that is the maximum acceptable fractional drop in the squared quantization error.

Maximum iteration

Enter the maximum number of iterations you want the block to perform. From the **Stopping criteria** list, select **Maximum iteration** in order to activate this parameter.

Searching methods

Choose `Linear search` to use a linear search method when comparing the training points to the boundary points. Choose `Binary search` to use a binary search method when comparing the training points to the boundary points.

Tie-breaking rules

When a training point lies on a boundary point, choose `Lower indexed codeword` to assign the training point to the lower indexed quantization region. Choose `Higher indexed codeword` to assign the training point to the higher indexed region.

Design and Plot

Click this button to display the performance curve and the staircase character of the quantizer in the figures on the right side of the GUI. These plots are based on the current parameter settings.

You must click **Design and Plot** to apply any changes you make to the parameter values in the SQDTool GUI.

Export Outputs

Click this button, or press **Ctrl+E**, to export the **Final Codebook**, **Final Boundary Points**, and **Error** values to the workspace, a text file, or a MAT-file.

Destination

Choose `Current model` to create a Scalar Quantizer block in the model you most recently selected. Type `gcs` in the MATLAB Command Window to display the name of your current model. Choose `New model` to create a block in a new model file.

Block type

Select `Encoder` to design a Scalar Quantizer Encoder block. Select `Decoder` to design a Scalar Quantizer Decoder block. Select `Both` to design a Scalar Quantizer Encoder block and a Scalar Quantizer Decoder block.

Encoder block name

Enter a name for the Scalar Quantizer Encoder block.

Decoder block name

Enter a name for the Scalar Quantizer Decoder block.

Overwrite target block(s)

When you do not select this check box and a Scalar Quantizer Encoder and/or Decoder block with the same block name exists in the destination model, a new Scalar Quantizer Encoder and/or Decoder block is created in the destination model. When you select this check box and a Scalar Quantizer Encoder and/or Decoder block with the same block name exists in the destination model, the parameters of these blocks are overwritten by new parameters.

Generate Model

Click this button and SQDTool uses the parameters that correspond to the current plots to set the parameters of the Scalar Quantizer Encoder and/or Decoder blocks.

Scalar Quantizer Encoder

Encode each input value by associating it with index value of quantization region

Library

Quantizers

dspquant2

Description

The Scalar Quantizer Encoder block maps each input value to a quantization region by comparing the input value to the quantizer boundary points defined in the **Boundary points** parameter. The block outputs the zero-based index of the associated region.

You can select how you want to enter the **Boundary points** using the **Source of quantizer parameters**. When you select **Specify via dialog**, type the boundary points into the block parameters dialog box. When you select **Input port**, port B appears on the block. The block uses the input to port B as the **Boundary points** parameter.

Use the **Boundary points** parameter to specify the boundary points for your quantizer. These values are used to break up the set of input numbers into regions. Each region is specified by an index number.

Let N be the number of quantization regions. When the codebook is defined as $[c_1 \ c_2 \ c_3 \ \dots \ c_N]$, and the **Boundary points** parameter is defined as $[p_0 \ p_1 \ p_2 \ p_3 \ \dots \ p_N]$, then $p_0 < c_1 < p_1 < c_2 \ \dots \ p_{(N-1)} < c_N < p_N$ for a regular quantizer. When your quantizer is bounded, from the **Partitioning** list, select **Bounded**. You need to specify $N+1$ boundary points, or $[p_0 \ p_1 \ p_2 \ p_3 \ \dots \ p_N]$. When your quantizer is unbounded, from the **Partitioning** list, select **Unbounded**. You need to specify $N-1$ boundary points, or $[p_1 \ p_2 \ p_3 \ \dots \ p_{(N-1)}]$; the block sets p_0 equal to $-\infty$ and p_N equal to ∞ .

The block uses the **Partitioning** parameter to interpret the boundary points you enter. For instance, to create a bounded quantizer, from the **Partitioning** list, select **Bounded** and enter the following boundary points:

```
[0 0.5 3.7 5.8 6.0 11]
```

The block assigns any input values between 0 and 0.5 to index 0, input values between 0.5 and 3.7 to index 1, and so on. The block assigns any values that are less than 0 to index 0, the lowest index value. The block assigns any values that are greater than 11 to index 4, the highest index value.

To create an unbounded quantizer, from the **Partitioning** list, select Unbounded and enter the following boundary points:

```
[0 0.5 3.7 5.8 6.0 11]
```

The block assigns any input values between 0 and 0.5 to index 1, input values between 0.5 and 3.7 to index 2, and so on. The block assigns any input values less than 0 to index 0 and any values greater than 11 to index 6.

The **Searching method** parameter determines how the appropriate quantizer index is found. When you select **Linear**, the Scalar Quantizer Encoder block compares the input value to the first region defined by the first two boundary points. When the input value does not fall within this region, the block then compares the input value to the next region. This process continues until the input value is determined to be within a region and is associated with the appropriate index value. The computational cost of this process is of the order P , where P is the number of boundary points.

When you select **Binary** for the **Searching method**, the block compares the input value to the middle value of the boundary points vector. When the input value is larger than this boundary point, the block discards the boundary points that are lower than this middle value. The block then compares the input value to the middle boundary point of the new range, defined by the remaining boundary points. This process continues until the input value is associated with the appropriate index value. The computational cost of this process is of the order $\log_2 P$, where P is the number of boundary points. In most cases, the **Binary** option is faster than the **Linear** option.

When an input value is the same as a boundary point, the **Tie-breaking rule** parameter determines the region to which the value is assigned. When you want the input value to be assigned to the lower indexed region, select **Choose the lower index**. To assign the input value with the higher indexed region, select **Choose the higher index**.

Select the **Output codeword** check box to output the codeword values that correspond to each index value at port Q(U).

Select the **Output the quantization error** check box to output the quantization error for each input value from the Err port on this block. The quantization error is the difference between the input value and the quantized output value.

When you select either the **Output codeword** check box or the **Output quantization error** check box, you must also enter your codebook values. If, from the **Source of quantizer parameters** list, you choose **Specify via dialog**, use the **Codebook** parameter to enter a vector of quantized output values that correspond to each region. If, from the **Source of quantizer parameters** list, you choose **Input port**, use input port C to specify your codebook values.

If, for the **Partitioning** parameter, you select **Bounded**, the **Output clipping status** check box and the **Action for out of range input** parameter appear. When you select the **Output clipping status** check box, port S appears on the block. Any time an input value is outside the range defined by the **Boundary points** parameter, the block outputs a 1 at the S port. When the value is inside the range, the blocks outputs a 0.

You can use the **Action for out of range input** parameter to determine the block's behavior when an input value is outside the range defined by the **Boundary points** parameter. Suppose the boundary points for a bounded quantizer are defined as $[p_0 p_1 p_2 p_3 \dots p_N]$ and the possible index values are defined as $[i_0 i_1 i_2 \dots i_{(N-1)}]$, where $i_0=0$ and $i_0 < i_1 < i_2 < \dots < i_{(N-1)}$. When you want any input value less than p_0 to be assigned to index value i_0 and any input values greater than p_N to be assigned to index value $i_{(N-1)}$, select **Clip**. When you want to be warned

when clipping occurs, select `Clip` and `warn`. When you want the simulation to stop and the block to display an error when the index values are out of range, select `Error`.

The Scalar Quantizer Encoder block accepts real floating-point and fixed-point inputs. For more information on the data types accepted by each port, see “Data Type Support” on page 2-1157 or “Supported Data Types” on page 2-1159.

Data Type Support

The input data values, boundary points, and codebook values can be input to the block at ports U, B, and C, respectively. The data type of the inputs can be `double`, `single`, or `Fixed-point`.

The outputs of the block can be the index values, the quantized output values, the quantization error, and the clipping status. Use the **Index output data type** parameter to specify the data type of the index output from the block at port I. You can choose `int8`, `uint8`, `int16`, `uint16`, `int32`, or `uint32`. The data type of the quantized output and the quantization error can be `double`, `single`, or `Fixed-point`. The clipping status values output at port S are Boolean values.

Note The input data, boundary points, codebook values, quantized output values, and the quantization error must have the same data type whenever they are present.

Dialog Box

Main Tab

Source of quantizer parameters

Choose `Specify via dialog` to enter the boundary points and codebook values using the block parameters dialog box. Select `Input port` to specify the parameters using the block's input ports. Input the boundary points and codebook values using ports B and C, respectively.

Partitioning

When your quantizer is bounded, select `Bounded`. When your quantizer is unbounded, select `Unbounded`.

Boundary points

Enter a vector of values that represent the boundary points of the quantizer regions. This parameter is visible when you select `Specify via dialog` from the **Source of quantizer parameters** list. Tunable (Simulink).

Searching method

When you select `Linear`, the block finds the region in which the input value is located using a linear search. When you select `Binary`, the block finds the region in which the input value is located using a binary search.

Tie-breaking rule

Set this parameter to determine the behavior of the block when the input value is the same as the boundary point. When you select `Choose the lower index`, the input value is assigned to lower indexed region. When you select `Choose the higher index`, the value is assigned to the higher indexed region.

Output codeword

Select this check box to output the codeword values that correspond to each index value at port Q(U).

Output quantization error

Select this check box to output the quantization error for each input value at port Err.

Codebook

Enter a vector of quantized output values that correspond to each index value. If, for the **Partitioning** parameter, you select **Bounded** and your boundary points vector has length N , then you must specify a codebook of length $N-1$. If, for the **Partitioning** parameter, you select **Unbounded** and your boundary points vector has length N , then you must specify a codebook of length $N+1$.

This parameter is visible when you select **Specify** via dialog from the **Source of quantizer parameters** list and you select either the **Output codeword** or **Output quantization error** check box. Tunable (Simulink).

Output clipping status

When you select this check box, port S appears on the block. Any time an input value is outside the range defined by the **Boundary points** parameter, the block outputs a 1 at this port. When the value is inside the range, the block outputs a 0. This parameter is visible when you select **Bounded** from the **Partitioning** list.

Action for out of range input

Use this parameter to determine the behavior of the block when an input value is outside the range defined by the **Boundary points** parameter. Suppose the boundary points are defined as $[p_0 p_1 p_2 p_3 \dots p_N]$ and the index values are defined as $[i_0 i_1 i_2 \dots i_{(N-1)}]$. When you want any input value less than p_0 to be assigned to index value i_0 and any input values greater than p_N to be assigned to index value $i_{(N-1)}$, select **Clip**. When you want to be warned when clipping occurs, select **Clip and warn**. When you want the simulation to stop and the block to display an error when the index values are out of range, select **Error**. This parameter is visible when you select **Bounded** from the **Partitioning** list.

Index output data type

Specify the data type of the index output from the block at port I. You can choose **int8**, **uint8**, **int16**, **uint16**, **int32**, **uint32**, or **Inherit** via back propagation.

Data Types Tab**Rounding mode**

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

Saturate on integer overflow

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on **saturate** and **wrap**, see overflow mode for fixed-point operations.

If the input is fixed point, it must be a signed integer or signed fixed point with a power-of-two slope and zero bias.

Short-Time FFT

Nonparametric estimate of spectrum using short-time fast Fourier transform (STFT) method

Library: DSP System Toolbox / Transforms

Description

The Short-Time FFT block computes a nonparametric estimate of the spectrum. The block buffers, applies a window, and zero pads the input signal. The block then takes the FFT of the signal, transforming it into the frequency domain.

Ports

Input

$x[n]$ — Input signal

vector | matrix

Specify the time-domain input signal as a vector or a matrix. If the input is a matrix, the block treats each column as an independent channel. The input can be a variable-size signal. That is, the frame size of the signal can change while the simulation is running. The number of channels must remain the same.

If the input is fixed point, it must be a signed integer or signed fixed point with a power-of-two slope and zero bias.

Data Types: single | double | int8 | int16 | int32 | fixed point

$w[n]$ — Analysis window vector

vector

Connect your single-channel analysis window to the $w[n]$ port. For the **Analysis window length** parameter, enter the length of the analysis window W . The block buffers the input signal such that it has a frame length of W .

If the window vector is fixed point, it must be a signed integer or signed fixed point with a power-of-two slope and zero bias.

Data Types: single | double | int8 | int16 | int32 | fixed point

Output

$X[nL, k]$ — Short-time FFT output

vector | matrix

The block outputs the complex-valued single-channel or multichannel short-time FFT at this port.

Data Types: single | double | int8 | int16 | int32 | fixed point

Parameters

Analysis window length — Length of analysis window

512 (default) | positive integer greater than 1

Specify the frame length of the analysis window as a positive integer greater than 1. The block buffers the input into overlapping window segments using the specified window length and overlap length, and then multiplies each overlapped segment by the window.

Overlap between consecutive windows (in samples) — Overlap length

384 (default) | positive integer

Specify the number of samples by which consecutive windows overlap in each frame of the input signal as a positive integer. The window overlap reduces artifacts at the data boundaries.

FFT length — FFT length

1024 (default) | positive integer

Enter the length up to which the block pads the input signal as a positive integer. After the block buffers and windows the signal, it zero-pads the signal before computing the FFT. This parameter determines the length of the short-time fast Fourier transform output (number of rows). The FFT length must be greater than or equal to the window length.

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

More About

Fixed-Point Data Types

The following diagram shows the data types used within the Short-Time FFT subsystem block for fixed-point signals.

The values of the fixed-point parameters of the Array-Vector Multiply block in this diagram are:

- **Rounding Mode** — Floor
- **Saturate on integer overflow** — Wrap
- **Product output** — Inherit via internal rule
- **Accumulator** — Inherit via internal rule
- **Output** — Same as first input

The values of the fixed-point parameters of the FFT block in this diagram are:

- **Rounding Mode** — Floor
- **Saturate on integer overflow** — Wrap
- **Sine table** — Same word length as input
- **Product output** — Inherit via internal rule
- **Accumulator** — Inherit via internal rule
- **Output** — Inherit via internal rule

See the FFT and Array-Vector Multiply block reference pages for more information.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.
- When the FFT length is not a power of two, the executable generated from this block relies on prebuilt dynamic library files (`.dll` files) included with MATLAB. Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

When the FFT length is a power of two, you can generate standalone C and C++ code from this block.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

If the input is fixed point, it must be a signed integer or signed fixed point with a power-of-two slope and zero bias.

Signal From Workspace

Import signal from MATLAB workspace

Library: DSP System Toolbox / Sources

Description

The Signal From Workspace block imports a signal from the MATLAB workspace into the Simulink model. The **Signal** parameter specifies the name of a MATLAB workspace variable containing the signal to import, or any valid MATLAB expression defining a matrix or 3-D array.

Unlike the Simulink From Workspace block, the Signal From Workspace block holds the output value constant between successive output frames (that is, no linear interpolation takes place). Also, the initial signal values are always produced immediately at $t=0$.

Ports

Output

Port_1 — Signal imported from workspace

scalar | vector | matrix | 3-D array

Signal imported from workspace, as a scalar, vector, matrix, or 3-D array.

When the **Signal** parameter specifies an M -by- N matrix ($M \neq 1$), each of the N columns is treated as a distinct channel. You specify the frame size in the **Samples per frame** parameter, M_o . The output is an M_o -by- N matrix containing M_o consecutive samples from each signal channel. You specify the output sample period in the **Sample time** parameter, T_s , and the output frame period is $M_o T_s$. For convenience, an imported row vector ($M=1$) is treated as a single channel, so the output dimension is M_o -by-1.

When the **Signal** parameter specifies an M -by- N -by- P array, each of the P pages (an M -by- N matrix) is output in sequence with period T_s . The **Samples per frame** parameter must be set to 1.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Signal — Signal to import

1:10 (default) | MATLAB workspace variable | MATLAB expression

The name of the MATLAB workspace variable from which to import the signal, or a valid MATLAB expression specifying the signal.

Sample time — Output sample period

1 (default) | scalar | vector

The sample period, T_s , of the output, specified as a scalar or vector. The output frame period is $M_o T_s$.

Samples per frame — Samples per frame

1 (default) | positive integer

The number of samples, M_o , to buffer into each output frame, specified as a positive integer scalar. This value must be 1 when you specify a 3-D array in the **Signal** parameter.

Form output after final data value by — Values to output after final imported signal value

Setting to zero (default) | Holding final value | Cyclic repetition

Specifies the output after all of the specified signal samples have been generated.

- When you specify **Setting To Zero**, the block generates zero-valued outputs for the duration of the simulation after generating the last frame of the signal.
- When you specify **Holding Final Value**, the block repeats the final sample for the duration of the simulation after generating the last frame of the signal.
- When you specify **Cyclic Repetition**, the block repeats the signal from the beginning after it reaches the last sample in the signal. If the frame size you specify in the **Samples per frame** parameter does not evenly divide the input length, a buffer block is inserted into the Signal From Workspace subsystem, and the model becomes multirate. If you do not want your model to become multirate, make sure that the frame size evenly divides the input signal length.

The block does not extrapolate the imported signal beyond the last sample.

Warn when frame size does not evenly divide input length — Warn when input length is not an integer multiple of frame size

off (default) | on

Select the **Warn when frame size does not evenly divide input length** parameter to be alerted when the input length is not an integer multiple of the frame size. When the input length is not an integer multiple of the frame size, the model becomes multirate. Use the Model Explorer to turn these warnings on or off model-wide:

- In the **Modeling** tab, click **Model Explorer**.
- In the **Search** bar of the Model Explorer, search by **Property Name** for the `ignoreOrWarnInputAndFrameLengths` property. Each block with the **Warn when frame size does not evenly divide input length** check box appears in the list in the **Contents** pane.
- Select each of the blocks for which you want to toggle the warning parameter, and select or clear the check box in the `ignoreOrWarnInputAndFrameLengths` column.

Dependencies

To enable this parameter set **Form output after final data value by** to **Cyclic Repetition**.

Signal To Workspace

Write data to MATLAB workspace

Compatibility

Note The Signal To Workspace block has been replaced by the To Workspace block in Simulink. Replace existing instances of the Signal To Workspace block with To Workspace block. For new models, use the To Workspace block.

Library

Sinks

dspsnks4

Description

The Signal To Workspace block writes data from your simulation into an array or structure in the main MATLAB workspace. You can specify a name for the workspace variable as well as whether the data is saved as an array, structure, or structure with time.

When the **Save format** is set to Array or Structure, the dimensions of the output depend on the input dimensions and the setting of the **Save 2-D signals as** parameter. The following table summarizes the output dimensions under various conditions. In the table, K represents the value of the **Limit data points to last** parameter.

Input Signal Dimensions	Save 2-D Signals as ...	Signal To Workspace Output Dimension
M -by- N matrix	2-D array (concatenate along first dimension)	<p>K-by-N matrix.</p> <p>If you set the Limit data points to last parameter to inf, K represents the total number of samples acquired in each column by the end of simulation. This is equivalent to multiplying the input frame size (M) by the total number of M-by-N inputs acquired by the block.</p>

Input Signal Dimensions	Save 2-D Signals as ...	Signal To Workspace Output Dimension
M -by- N matrix	3-D array (concatenate along third dimension)	M -by- N -by- K array. If you set the Limit data points to last parameter to <code>inf</code> , K represents the total number of M -by- N inputs acquired by the end of the simulation.
Length- N unoriented vector	Any setting	K -by- N matrix
N -dimensional array where $N > 2$	Any setting	Array with $N+1$ dimensions, where the size of the last dimension is equal to K . If you set the Limit data points to last parameter to <code>inf</code> , K represents the total number of M -by- N inputs acquired by the end of simulation

Examples

Example 1: Save 2-D Signals as a 2-D Array

In the `ex_sigtoworkspace_ref2` model, the Signal To Workspace block receives a 2-by-4 matrix input and logs 11 frames (two samples per frame) by the end of the simulation. Because the **Save 2-D signals as** parameter is set to 2-D array (concatenate along first dimension), the block concatenates the input along the first dimension to create a 22-by-4 matrix, A , in the MATLAB workspace.

The following figure illustrates the behavior of the Signal to Workspace block in this example.

In the 2-D output mode, there is no indication of where one frame ends and another begins. To log input frames separately, set the **Save 2-D signals as** parameter to 3-D array (concatenate along third dimension), as shown in Example 2.

Example 2: Save 2-D Signals as a 3-D Array

In the `ex_signaltoworkspace_ref1` model, the input to the Signal To Workspace block is a 2-by-4 matrix. The **Save 2-D signals as** parameter is set to 3-D array (concatenate along third dimension), so by the end of the simulation the Signal To Workspace block logs 11 frames of data as a 2-by-4-by-11 array, *A*, in the MATLAB workspace.

The following figure illustrates the behavior of the Signal to Workspace block in this example.

Parameters

Variable name

Specify the name of the array or structure into which the block logs the simulation data. The block creates this variable in the MATLAB workspace only after the simulation stops running. When you enter the name of an existing workspace variable, the block overwrites that variable with the simulation data.

Limit data points to last

Specify the maximum number of samples or frames the block will save. When the simulation generates more than the specified maximum number of samples or frames, the simulation saves only the most recently generated data. To capture all data, set this parameter to `inf`. See the table in the Description on page 2-1168 section for more information on how this parameter affects the dimensions of the logged data.

Decimation

Specify a positive integer *d* to determine how often the block writes data to the workspace array or structure. The block writes data to the array or structure every *d*th sample. With the default decimation value of 1, the block writes data at every time step.

Save format

Specify the format in which to save simulation output to the workspace. You can select one of the following options:

- **Array** — Select this option to save the data as an N-dimensional array. If the input signal is an unoriented vector, the resulting workspace array is 2-D. Each input vector is saved in a row of the output matrix, vertically concatenated onto the previous vector. If the input signal is 2-dimensional, the dimensions of the resulting workspace array depend on the setting of the **Save 2-D signals as** parameter.

- **Structure** — Select this option to save the data as a structure consisting of three fields: `time`, `signals` and `blockName`. In this mode, the `time` field is empty, and the `blockName` field contains the name of the Signal To Workspace block. The `signals` field contains a structure with three additional fields: `values`, `dimensions`, and `label`. The `values` field contains the array of signal values, the `dimensions` field specifies the dimensions of the values array, and the `label` field contains the label of the input line.
- **Structure with time** — This option is the same as **Structure**, except that the `time` field contains a vector of simulation time steps. This is the only output format that can be read directly by a From Workspace block. When you select this option, the **Save 2-D signals as** parameter is not available. In this mode, the block always saves 2-D input arrays as a 3-D array.

The default setting of this parameter is **Array**.

Save 2-D signals as

Specify whether the block outputs 2-D signals as a 2-D or 3-D array in the MATLAB workspace:

- **2-D array (concatenate along first dimension)** — When you select this option, the block saves an M -by- N input signal as a $(K*M)$ -by- N matrix, where $K*M$ is the total number of samples acquired by the end of the simulation. The block vertically concatenates each M -by- N matrix input with the previous input to produce the 2-D output array. See “Example 1: Save 2-D Signals as a 2-D Array” on page 2-1169 for more information about this mode.
- **3-D array (concatenate along third dimension)** — When you select this option, the block saves an M -by- N input signal as an M -by- N -by- K array, where K is the number of M -by- N inputs logged by the end of the simulation. K has an upper bound equal to the value of the **Limit data points to last** parameter. See “Example 2: Save 2-D Signals as a 3-D Array” on page 2-1170 for more information about this mode.

This parameter is visible only when you set the **Save format** parameter to **Array** or **Structure**. When you set the **Save format** parameter to **Structure with time**, the block outputs the 2-D input signal as a 3-D array.

Note The **Inherit from input** (this choice will be removed - see release notes) option will be removed in a future release. See “Signal To Workspace Block Changes” in the *DSP System Toolbox Release Notes* for more information.

Log fixed-point data as a fi object

Select this check box to log fixed-point data to the MATLAB workspace as a Fixed-Point Designer `fi` object. Otherwise, fixed-point data is logged to the workspace as `double`.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed and unsigned)
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

Sine Wave

Generate continuous or discrete sine wave

Library: DSP System Toolbox / Sources
 DSP System Toolbox HDL Support / Sources

Description

The Sine Wave block generates a multichannel real or complex sinusoidal signal, with independent amplitude, frequency, and phase in each output channel. The block supports floating point and signed fixed-point data types.

The block generates a real sinusoidal signal when you set the **Output complexity** parameter to **Real**. The real sinusoidal output is defined by an expression of the type

$$y = A\sin(2\pi ft + \phi)$$

where you specify A in the **Amplitude** parameter, f in hertz in the **Frequency** parameter, and ϕ in radians in the **Phase offset** parameter.

The block generates a complex exponential signal when you set the **Output complexity** parameter to **Complex**. This complex exponential signal is defined by an expression of the type

$$y = Ae^{j(2\pi ft + \phi)} = A\{\cos(2\pi ft + \phi) + j\sin(2\pi ft + \phi)\}$$

Generating Multichannel Outputs

For both real and complex sinusoids, the **Amplitude**, **Frequency**, and **Phase offset** parameter values (A , f , and ϕ) can be scalars or length- N vectors, where N is the desired number of channels in the output. When you specify at least one of these parameters as a length- N vector, scalar values specified for the other parameters are applied to every channel.

For example, to generate the three-channel output containing the following real sinusoids, set the block parameters as shown:

$$y = \begin{cases} \sin(2000\pi t) & \text{(channel 1)} \\ 2\sin(1000\pi t) & \text{(channel 2)} \\ 3\sin\left(500\pi t + \frac{\pi}{2}\right) & \text{(channel 3)} \end{cases}$$

- **Output complexity** = Real
- **Amplitude** = [1 2 3]
- **Frequency** = [1000 500 250]
- **Phase offset** = [0 0 pi/2]

Ports

Output

Port_1 — Sinusoidal signal

scalar | vector | matrix

Output a sinusoidal signal as a scalar or vector. For more information about output complexity, see “Description” on page 2-1173. For information about multichannel support, see “Generating Multichannel Outputs” on page 2-1173.

Tip To output fixed-point data types, you must set **Sample mode** to Discrete and **Computation method** to Table lookup.

Data Types: single | double | fixed point
Complex Number Support: Yes

Parameters

Main

Amplitude — Amplitude of sine waves

1 (default) | scalar | vector

A length- N vector containing the amplitudes of the sine waves in each of N output channels, or a scalar to be applied to all N channels. The vector length must be the same as that specified for the **Frequency** and **Phase offset** parameters.

Tip This parameter is tunable (Simulink) only when the **Computation method** is Trigonometric fcn or Differential.

Tunable: Yes

Frequency (Hz) — Frequency of each sine wave

100 (default) | scalar | vector

A length- N vector containing frequencies, in hertz, of the sine waves in each of N output channels, or a scalar to be applied to all N channels. The vector length must be the same as that specified for the **Amplitude** and **Phase offset** parameters. You can specify positive, zero, or negative frequencies.

Tip This parameter is tunable (Simulink) when you set either:

- **Sample mode** to Continuous.
 - **Sample mode** to Discrete and **Computation method** to Trigonometric fcn.
-

Tunable: Yes

Phase offset (rad) — Phase offset

0 (default) | scalar | vector

A length- N vector containing the phase offsets, in radians, of the sine waves in each of N output channels, or a scalar to be applied to all N channels. The vector length must be the same as that specified for the **Amplitude** and **Frequency** parameters.
