## Reuse Global Block Outputs in the Generated Code

Reduce ROM and RAM consumption and data copies and increase execution speed of generated code. Configure the code generator to reuse global variables by selecting the model configuration parameter **Reuse global block outputs**.

### Example

In the Command Window, type `rtwdemo_reuse_global`.

### Generate Code Without Optimization

- 1 On the Configuration Parameters dialog box, verify that **Signal storage reuse** is selected.
- 2 Clear **Reuse global block outputs** and click **Apply**.
- 3 On the **Code Generation > Report** pane, select **Generate static code metrics**.
- 4 In your system's temporary folder, create a folder for the build and inspection process.

Press **Ctrl+B** to generate code.

```
Starting build procedure for: rtwdemo_reuse_global
Successful completion of build procedure for: rtwdemo_reuse_global
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_reuse_global	Code generated and compiled.	Code generation information file does not exist

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 23.73s
```

View the generated code without the optimization. Here is a portion of `rtwdemo_reuse_global.c`.

```
/* Model step function */
```

```

void rtwdemo_reuse_global_step(void)
{
 /* Sum: '<Root>/Sum' incorporates:
 * Delay: '<Root>/Delay'
 * Inport: '<Root>/In1'
 */
 rtDW.Delay_DSTATE += rtU.In1;

 /* Output: '<Root>/Out1' incorporates:
 * Delay: '<Root>/Delay'
 */
 rtY.Out1 = rtDW.Delay_DSTATE;
}

```

The generated code contains a data copy to the global variable `rtDW.Delay_DSTATE`. Open the Static Code Metrics Report. The total number of reads and writes for global variables is 8. The total size is 32 bytes.

### Enable Optimization and Generate Code

- 1 On the Configuration Parameters dialog box, select **Reuse global block outputs** and click **Apply**.
- 2 Generate code.
- 3 View the generated code with the optimization. Here is a portion of `rtwdemo_reuse_global.c`.

```

Starting build procedure for: rtwdemo_reuse_global
Successful completion of build procedure for: rtwdemo_reuse_global

```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_reuse_global	Code generated and compiled.	Generated code was out of date.

```

1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 17.212s

```

```

/* Model step function */
void rtwdemo_reuse_global_step(void)
{
 /* Sum: '<Root>/Sum' incorporates:
 * Delay: '<Root>/Delay'
 * Inport: '<Root>/In1'
 */
 rtY.Out1 += rtU.In1;
}

```

The code generator eliminates a data copy, reduces two statements to one statement and three global variables to two global variables.

Open the Static Code Metrics Report. For global variables, this optimization reduces the total number of reads and writes for global variables from 8 to 5 and the total size from 32 bytes to 24 bytes.

- “Optimize Global Variable Usage” on page 78-2

## Virtualized Output Ports Optimization

The *virtualized output ports* optimization lets you store the signal entering the root output port as a global variable. Clearing the **MAT-file logging** option and setting the TLC variable `FullRootOutputVector` to 0, both defaults for Embedded Coder, eliminate code and data storage associated with root output ports.

Consider the model in the following block diagram. The signal `exportedSig` has `exportedGlobal` storage class.

In the default case, the output of the Gain block is written to the signal storage location, `exportedSig`. The code generator does not generate code or data for the `Out1` block, which has become a virtual block.

```
/* Gain Block: <Root>/Gain */
exportedSig = rtb_PulseGen * VirtOutPortLogOFF_P.Gain_Gain;
```

In cases where you enable **MAT-file logging** or set `FullRootOutputVector = 1`, the generated code represents root output ports as members of an external outputs vector.

The following code fragment was generated with **MAT-file logging** enabled. The output port is represented as a member of the external outputs vector `VirtOutPortLogON_Y`. The Gain block output value is copied to `exportedSig` and to the external outputs vector.

```
/* Gain Block: <Root>/Gain */
exportedSig = rtb_PulseGen * VirtOutPortLogON_P.Gain_Gain;

/* Outport Block: <Root>/Out1 */
VirtOutPortLogON_Y.Out1 = exportedSig;
```

Data maintenance in the external outputs vector can be significant for smaller models that perform benchmarks.

You can force root output ports to be stored in the external outputs vector (regardless of the setting of **MAT-file logging**) by setting the TLC variable `FullRootOutputVector` to 1. Add the statement

```
%assign FullRootOutputVector = 1
```

to the Embedded Coder system target file. Alternatively, you can enter the assignment from the MATLAB command line using the `set_param` command, the model parameter `TLCOptions`, and the TLC option `-a`. For more information, see “Specify TLC for Code Generation” and “Configure TLC”.

For more information on how to control signal storage in generated code, see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 36-49 and “C Code Generation Configuration for Model Interface Elements” on page 33-2.

- “Optimize Global Variable Usage” on page 78-2

## Specify Buffer Reuse for Signals in a Path

If your model has the optimal parameter settings for removing data copies, you might be able to remove additional data copies by using the `Reusable` storage class on the signals through the Code Mappings editor or `Simulink.Signal` data objects. This optimization decreases data copies and memory consumption and increases code execution speed. After studying the generated code and the Static Code Metrics Report and identifying areas where you think buffer reuse is possible, you specify the `Reusable` storage class on signal lines.

You can specify buffer reuse on signals that include a pair of root inport and outport signals. You can also specify buffer reuse on just a pair of root inport and outport signals. This optimization reduces ROM and RAM consumption because there are less global variables and data copies in the generated code. Code execution speed also increases.

### Example Model

The model `ex_reusable_csc` contains the nonreusable subsystem `DeltaSubsystem` and the MATLAB Function block `Downsample`. `DeltaSubsystem` contains the MATLAB Function blocks `DeltaX` and `DeltaY`.

```
model = 'ex_reusable_csc';
open_system(model);
```

Testing - Copyright 2021 The MathWorks, Inc.

### Specify Reusable Storage Class in Code Mappings Editor

- 1 Open the **Embedded Coder** app.
- 2 To open the Code Mappings editor, click **Code Interface > Individual Element Code Mappings**.
- 3 In the model, select the `RCSC_REAL` signal line. To view this signal or any signal in the Code Mappings editor, on the **Signals/States** tab, click the **Add selected signals to code mappings** button.
- 4 For the row that represents the signal line, set the **Storage Class** column to `Reusable`.
- 5 Similarly, add these signals to the Code Mappings editor and set **Storage Class** to `Reusable`:
  - `RCSC_IMAG`
  - `RCSC_REAL2`
  - `RCSC_IMAG2`

And these signals inside the subsystem:

- `RCSC_REAL`

- RCSC\_IMAG
- RCSC\_REAL2
- RCSC\_IMAG2

Alternatively, use these commands in the MATLAB® Command Window:

```
cmo = coder.mapping.utils.create(model);
cm = coder.mapping.api.get(model);

portHandles = get_param(...
 'ex_reusable_csc/Complex to Real-Imag', 'portHandles');
addSignal(cm, [portHandles.Outputport(1), portHandles.Outputport(2)], ...
 'StorageClass', 'Reusable');

portHandles = get_param(...
 'ex_reusable_csc/Downsample', 'portHandles');
addSignal(cm, [portHandles.Outputport(1), portHandles.Outputport(2)], ...
 'StorageClass', 'Reusable');

portHandles = get_param(...
 'ex_reusable_csc/DeltaSubsystem/DeltaX', 'portHandles');
addSignal(cm, [portHandles.Outputport(1), portHandles.Outputport(2)], ...
 'StorageClass', 'Reusable');

portHandles = get_param(...
 'ex_reusable_csc/DeltaSubsystem/DeltaY', 'portHandles');
addSignal(cm, [portHandles.Outputport(1), portHandles.Outputport(2)], ...
 'StorageClass', 'Reusable');
```

Build the model.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
slbuild(model);

Starting build procedure for: ex_reusable_csc
Successful completion of build procedure for: ex_reusable_csc
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
ex_reusable_csc	Code generated and compiled.	Code generation information file does not exist.

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 39.107s

For buffer reuse, the `ex_reusable_csc.c` file contains these global variables:

```
cfile = fullfile(cgDir, ...
 'ex_reusable_csc_ert_rtw', 'ex_reusable_csc.c');
rtwdemodbtype(cfile, ...
 '/* Definition for custom storage class: Reusable */', ...
 '/* External inputs (root inport signals with default storage) */', 1, 0);

/* Definition for custom storage class: Reusable */
```

```

static real_T RCSC_IMAG[1048576]; /* '<Root>/Complex to Real-Imag' */
static real_T RCSC_IMAG2[262144]; /* '<Root>/Downsample' */
static real_T RCSC_REAL[1048576]; /* '<Root>/Complex to Real-Imag' */
static real_T RCSC_REAL2[262144]; /* '<Root>/Downsample' */

```

The `ex_reusable_csc.c` file contains this code:

```

cfile = fullfile(cgDir,...
 'ex_reusable_csc_ert_rtw','ex_reusable_csc.c');
rtwdemodbtype(cfile,...
 /* Output and update for atomic system: '<Root>/DeltaSubsystem' */,...
 /* Output and update for atomic system: '<Root>/Downsample' */ ,1,0);
rtwdemodbtype(cfile,...
 /* Model step function */ , /* Model initialize function */ ,1,0);

/* Output and update for atomic system: '<Root>/DeltaSubsystem' */
static void DeltaSubsystem(void)
{
 /* ComplexToRealImag: '<Root>/Complex to Real-Imag' incorporates:
 * MATLAB Function: '<S1>/DeltaX'
 * SignalConversion generated from: '<S1>/DeltaX'
 * */
 DeltaX(&RCSC_REAL2[0], &RCSC_IMAG2[0], &RCSC_REAL[0], &RCSC_IMAG[0]);

 /* SignalConversion generated from: '<Root>/Downsample' incorporates:
 * ComplexToRealImag: '<Root>/Complex to Real-Imag'
 * MATLAB Function: '<S1>/DeltaY'
 * SignalConversion generated from: '<S1>/DeltaY'
 * */
 DeltaY(&RCSC_REAL[0], &RCSC_IMAG[0], &RCSC_REAL2[0], &RCSC_IMAG2[0]);
}

/* Model step function */
void ex_reusable_csc_step(void)
{
 int32_T i;

 /* ComplexToRealImag: '<Root>/Complex to Real-Imag' incorporates:
 * Inport: '<Root>/ComplexData'
 */
 for (i = 0; i < 1048576; i++) {
 RCSC_REAL[i] = rtU.ComplexData[i].re;
 RCSC_IMAG[i] = rtU.ComplexData[i].im;
 }

 /* End of ComplexToRealImag: '<Root>/Complex to Real-Imag' */

 /* MATLAB Function: '<Root>/Downsample' */
 Downsample(&RCSC_REAL[0], &RCSC_IMAG[0], &RCSC_REAL2[0], &RCSC_IMAG2[0]);

 /* Outputs for Atomic SubSystem: '<Root>/DeltaSubsystem' */
 DeltaSubsystem();

 /* End of Outputs for SubSystem: '<Root>/DeltaSubsystem' */

 /* Outport: '<Root>/Out1' incorporates:
 * RealImagToComplex: '<Root>/Real-Imag to Complex'

```

```

 * SignalConversion generated from: '<S1>/DeltaY'
 * */
 for (i = 0; i < 261121; i++) {
 rtY.Out1[i].re = RCSC_REAL2[i];
 rtY.Out1[i].im = RCSC_IMAG2[i];
 }

 /* End of Output: '<Root>/Out1' */
}

```

The variables `RCSC_REAL` and `RCSC_IMAG` hold the outputs of the Complex to Real-Image block and `DeltaX`. These variables hold the inputs to the `DeltaY` block. The variables `RCSC_REAL2` and `RCSC_IMAG2` hold the outputs of `Downsample` and `DeltaY`. These variables hold the inputs to the `DeltaX` block. By interleaving buffers in this way, you eliminate redundant data copies in the generated code.

To remove the signals from the Code Mappings editor, on the **Signals/States** tab, select the signals and click the **Remove selected signals to code mappings** button.

Alternatively, use these commands in the MATLAB Command Window:

```

portHandles = get_param(...
 'ex_reusable_csc/Complex to Real-Imag', 'portHandles');
removeSignal(cm, [portHandles.Outputport(1), portHandles.Outputport(2)]);

portHandles = get_param(...
 'ex_reusable_csc/Downsample', 'portHandles');
removeSignal(cm, [portHandles.Outputport(1), portHandles.Outputport(2)]);

portHandles = get_param(...
 'ex_reusable_csc/DeltaSubsystem/DeltaX', 'portHandles');
removeSignal(cm, [portHandles.Outputport(1), portHandles.Outputport(2)]);

portHandles = get_param(...
 'ex_reusable_csc/DeltaSubsystem/DeltaY', 'portHandles');
removeSignal(cm, [portHandles.Outputport(1), portHandles.Outputport(2)]);

```

When you generate code for the model, the `ex_reusable_csc.h` contains two extra global variables:

```

slbuild(model);
cfile = fullfile(cgDir, ...
 'ex_reusable_csc_ert_rtw', 'ex_reusable_csc.h');
rtwdemodbtype(cfile, ...
 '/* Block signals and states', ...
 '} D_Work;', 1, 0);

Starting build procedure for: ex_reusable_csc
Successful completion of build procedure for: ex_reusable_csc

```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
ex_reusable_csc	Code generated and compiled.	Generated code was out of date.

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 31.536s

```
/* Block signals and states (default storage) for system '<Root>' */
typedef struct {
 real_T z2[262144]; /* '<S1>/DeltaY' */
 real_T z1[262144]; /* '<S1>/DeltaY' */
 real_T z1_m[261632]; /* '<S1>/DeltaX' */
 real_T z2_c[261632]; /* '<S1>/DeltaX' */
 real_T RCSC_REAL[1048576]; /* '<Root>/Complex to Real-Imag' */
 real_T RCSC_IMAG[1048576]; /* '<Root>/Complex to Real-Imag' */
}
```

The `ex_reusable_csc.c` file now contains this code.

```
cfile = fullfile(cgDir,...
 'ex_reusable_csc_ert_rtw','ex_reusable_csc.c');
rtwdemodbtype(cfile,...
 '/* Output and update for atomic system: '<Root>/DeltaSubsystem' */',...
 '/* Output and update for atomic system: '<Root>/Downsample' */',1,0);
rtwdemodbtype(cfile,...
 '/* Model step function */','/* Model initialize function */',1,0);

/* Output and update for atomic system: '<Root>/DeltaSubsystem' */
static void DeltaSubsystem(void)
{
 /* MATLAB Function: '<S1>/DeltaX' */
 DeltaX(rtDWork.z2, rtDWork.z1, rtDWork.z1_m, rtDWork.z2_c);

 /* MATLAB Function: '<S1>/DeltaY' */
 DeltaY(rtDWork.z1_m, rtDWork.z2_c, &rtDWork.z1[0], &rtDWork.z2[0]);
}

/* Model step function */
void ex_reusable_csc_step(void)
{
 int32_T i;

 /* ComplexToRealImag: '<Root>/Complex to Real-Imag' incorporates:
 * Inport: '<Root>/ComplexData'
 */
 for (i = 0; i < 1048576; i++) {
 rtDWork.RCSC_REAL[i] = rtU.ComplexData[i].re;
 rtDWork.RCSC_IMAG[i] = rtU.ComplexData[i].im;
 }

 /* End of ComplexToRealImag: '<Root>/Complex to Real-Imag' */

 /* MATLAB Function: '<Root>/Downsample' */
 Downsample(rtDWork.RCSC_REAL, rtDWork.RCSC_IMAG, rtDWork.z2, rtDWork.z1);

 /* Outputs for Atomic SubSystem: '<Root>/DeltaSubsystem' */
 DeltaSubsystem();

 /* End of Outputs for SubSystem: '<Root>/DeltaSubsystem' */

 /* Outport: '<Root>/Out1' incorporates:
 * RealImagToComplex: '<Root>/Real-Imag to Complex'
 */
}
```

```

*/
for (i = 0; i < 261121; i++) {
 rtY.Out1[i].re = rtDWork.z1[i];
 rtY.Out1[i].im = rtDWork.z2[i];
}

/* End of Outport: '<Root>/Out1' */
}

```

The generated code contains two additional global variables for holding block inputs and outputs.

### Limitations for the Model That Use Reusable Storage Class in Code Mappings Editor

For reused data elements, you can specify the same value for the **Identifier** property. If you do not specify a value for the **Identifier**, the code generator uses the same signal label to name the reusable signal in the generated code. The code generator does not reuse signals if:

- The signals have the same labels but different identifiers.
- The signals have the same identifier but different values for these properties: **DataScope**, **HeaderFile**, **DefinitionFile**, and **Owner**. If there is a mismatch in any of the properties, the code generator stops and produces an error if the model configuration parameter **Detect non-reused custom storage classes** is set to error.

### Specify a Simulink Signal Object for Reuse

1. Open the model `rtwdemo_reusable`.

```

model = 'rtwdemo_reusable_csc';
open_system(model);

```

Copyright 2017-2020 The MathWorks, Inc.

2. The signals in the model resolve to the corresponding `Simulink.Signal` data objects in the Base Workspace. Right-click on the `RCSC_REAL` signal line. From the context menu, select **Properties**. In the Signal Properties dialog box, inspect that the signal name is `RCSC_REAL` and the parameter **Signal name must resolve to Simulink signal object** is selected. This setting indicates that there is a `Simulink.Signal` data object in the Base Workspace with the same name as `RCSC_REAL`.

3. In the model, navigate into the `DeltaSubsystem` subsystem. Select the `RCSC_REAL` signal line in this subsystem. This signal also resolves to the signal object in the Base Workspace.

4. In the Base Workspace, double click the data object `RCSC_REAL`. The `Simulink.Signal` dialog box opens.

5. On the **Code Generation** tab, inspect that the **Storage class** parameter is set to `Reusable`. This setting instructs the code generator to generate code for the signal as a global variable named

RCSC\_REAL. With the Reusable storage class, the generated code can store the output of the Complex to Real-Imag block (at the root-level of the model) and the output of the MATLAB Function block DeltaX (in the subsystem) in the RCSC\_REAL global variable.

6. In the **Apps** gallery, under **Code Generation**, click **Embedded Coder**. The **C Code** tab opens.

7. Click the **Build** button.

The generated code achieves the same results as the preceding workflow where you add signals to the Code Mappings editor and set **Storage Class** to Reusable.

Note: You can specify buffer reuse on signals that the code generator cannot implement. For those cases, use two diagnostics to specify the message type that the model displays. In the Configuration Parameters dialog box, these diagnostics are **Detect non-reused custom storage classes** and **Detect ambiguous custom storage class final values**.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

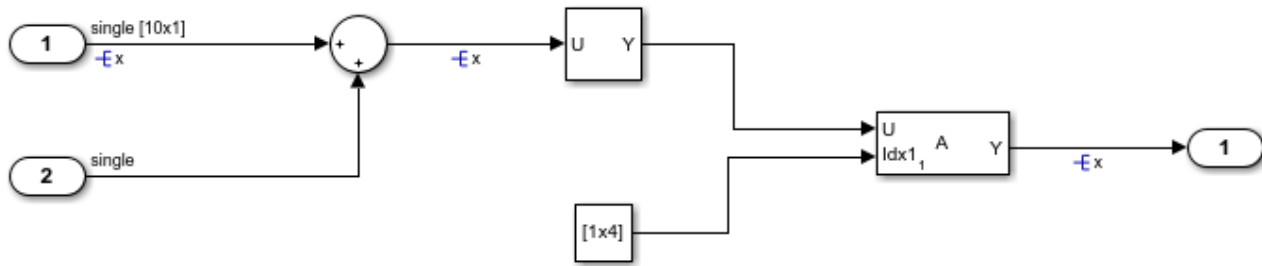

### Buffer Reuse for Unit Delay and Delay Blocks

To reuse the signal of a Unit Delay or Delay block, use the same reusable storage class specification for a pair of input and state arguments or a pair of output and state arguments of a Unit Delay or a Delay block. For Delay blocks, you must set the **Delay length** parameter to 1 and **Initial condition > Source** to Dialog. To access these parameters, in the model, open the Property Inspector and click the block in the model.

### Limitations for Root Inport and Outport Signals

These limitations apply to a model in which you specify buffer reuse for a pair of root inport and outport signals:

- The output ports cannot be conditional.
- If the code generator cannot reuse the same buffer in a top model, the generated code contains additional buffers. If the top model is a referenced model, the code generator reports an error. To resolve the error, remove the Simulink.Signal specification from the signal that connects to the outport port.
- When you run the executable that the code generator produces, and you reuse a pair of root inport and outport signals, when the root input value is zero, the root output value must also be zero. If the output value is nonzero and you reuse the signals, then the results from the simulation can differ from the results that the executable produces.
- There might be a simulation versus code generation mismatch when you assign the same Reusable storage class to pair of root inport and root outport signals. This mismatch occurs when an Assignment block drives the Root Outport block, and the Assignment block does not assign a value to every element of the output signal because the Y port of the Assignment block is not active. This image shows a model in which the mismatch occurs:

During simulation, the unwritten Assignment block output values are zero. During code generation, the unwritten output values are the same as the input.

### Limitations for the Model That Use Simulink Signal Object

These limitations apply to a model in which you specify buffer reuse for signals by using a `Simulink.Signal` data object:

- Signals that you specify for reuse must have the same data types and sampling rates.
- For user-specified buffer reuse, blocks that modify a signal specified for reuse must execute before blocks that use the original signal value. Sometimes the code generator has to change the block operation order so that buffer reuse can occur. For models in which the code generator is unable to reorder block operations, buffer reuse does not occur.
- For models in which the code generator reorders block operations so that `Simulink.Signal` reuse can occur, you can observe the difference in the sorted order. On the **Debug** tab, in the **Diagnostics** section select the **Information Overlays** drop-down arrow. In the **Blocks** section of the dialog, select **Execution Order**. To display the sorted execution order during simulation, on the **Modeling** tab, select **Update Model**. To display the execution order in the generated code, on the **C Code** tab, select **Build Model**.
- You can specify buffer reuse for a chain of reusable subsystems as long as these subsystems do not get reused anywhere in the model.

## Specify Buffer Reuse for MATLAB Function Blocks in a Path

### In this section...

“Example Model” on page 78-25

“Generate Code with Optimization” on page 78-25

You can specify buffer reuse across MATLAB Function blocks by using the same variable name for the input and output arguments. The code generator tries to reuse the output of one MATLAB Function block as the input to the next MATLAB Function block. This optimization conserves RAM and ROM consumption and reduces data copies.

### Example Model

- 1 Use Inport, Outport, and MATLAB Function blocks to create the model `mf_inplace`.

- 2 Open each MATLAB Function block and copy the following code:

```
function y = fcn(y)
%#codegen
```

```
y=y+4;
```

- 3 Open the Configuration Parameters dialog box. On the **Code Generation** tab, change the **System target file** to `ert.tlc`.
- 4 On the **Solver** tab, change the **Type** parameter to Fixed-step.

### Generate Code with Optimization

Generate code for the model. The `mf_inplace.c` file contains this code:

```
void mf_inplace_MATLABFunction(real_T *rty_y)
{
 *rty_y += 4.0;
}

void mf_inplace_step(void)
{
 real_T rtb_y_p5;
 rtb_y_p5 = mf_inplace_U.In1;
 mf_inplace_MATLABFunction(&rtb_y_p5);
 mf_inplace_MATLABFunction(&rtb_y_p5);
 mf_inplace_MATLABFunction(&rtb_y_p5);
 mf_inplace_Y.Out1 = rtb_y_p5;
 mf_inplace_MATLABFunction(&mf_inplace_Y.Out1);
}
```

The code generator reuses the variable `rtb_y_p5` for the input and output arguments of each MATLAB Function block.

---

**Note** On the **Code Generation** tab in the Subsystem Block Parameters dialog box, if the **Function packaging** parameter is set to **Nonreusable function** and the **Function interface** parameter is set to **Allow arguments (Optimized)**, the code generator cannot reuse the input and output arguments.

---

## Remove Data Copies by Reordering Block Operations in the Generated Code

This example shows how to remove data copies by changing the **Optimize block order in the generated code** parameter from off to Improved Execution Speed. Changing this setting indicates to the code generator to reorder block operations where possible to remove data copies. This parameter is in the Configuration Parameters dialog box. This optimization conserves RAM and ROM consumption.

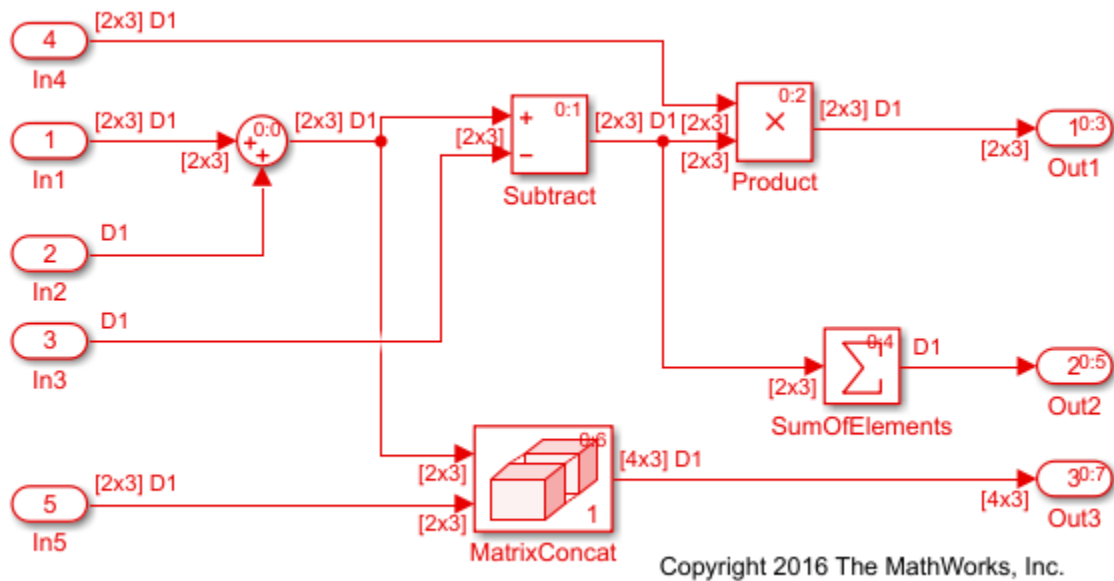

### Example Model

In the model `ex_optimizeblockorder`, the signal that leaves the Sum block enters a Subtract block and a Concatenate block. The signal that leaves the Subtract block enters a Product block and a Sum of Elements block.

### Generate Code without Optimization

The image shows the model `ex_optimizeblockorder` after a model build. The red numbers indicate the default block order in the generated code. The Subtract block executes before the Concatenate block. The Product block executes before the Sum of Elements block.

View the generated code without the optimization. Here is the `ex_optimizeblockorder_step` function.

```

/* Model step function */
void ex_optimizeblockorder_step(void)
{
 real_T rtb_Sum2x3[6];
 int32_T i;
 real_T rtb_Sum2x3_d;
 real_T rtb_Subtract;

 /* Sum: '<Root>/SumOfElements' */
 rtY.Out2 = -0.0;
 for (i = 0; i < 6; i++) {
 /* Sum: '<Root>/Sum2x3' incorporates:
 * Inport: '<Root>/In1'
 * Inport: '<Root>/In2'
 */
 rtb_Sum2x3_d = rtU.In1[i] + rtU.In2;

 /* Sum: '<Root>/Subtract' incorporates:
 * Inport: '<Root>/In3'
 */
 rtb_Subtract = rtb_Sum2x3_d - rtU.In3;

 /* Outport: '<Root>/Out1' incorporates:
 * Inport: '<Root>/In4'
 * Product: '<Root>/Product'
 */
 rtY.Out1[i] = rtU.In4[i] * rtb_Subtract;

 /* Sum: '<Root>/Sum2x3' */
 rtb_Sum2x3[i] = rtb_Sum2x3_d;
 }
}

```

```

/* Sum: '<Root>/SumOfElements' */
rtY.Out2 += rtb_Subtract;
}

/* Concatenate: '<Root>/MatrixConcat ' */
for (i = 0; i < 3; i++) {
/* Outport: '<Root>/Out3' incorporates:
 * Inport: '<Root>/In5'
 */
rtY.Out3[i << 2] = rtb_Sum2x3[i << 1];
rtY.Out3[2 + (i << 2)] = rtU.In5[i << 1];
rtY.Out3[1 + (i << 2)] = rtb_Sum2x3[(i << 1) + 1];
rtY.Out3[3 + (i << 2)] = rtU.In5[(i << 1) + 1];
}

/* End of Concatenate: '<Root>/MatrixConcat ' */
}

```

With the default order, the generated code contains three buffers, `rtb_Sum2x3[6]`, `rtb_Sum2x3_d`, and `rtb_Subtract`. The generated code contains these temporary variables and associated data copies because the Matrix Concatenate block must use the output from the Sum block and the Sum of Elements block must use the output from the Subtract block.

## Generate Code with Optimization

The image shows the `ex_optimizeblockorder` model after setting the **Optimize block operation order in the generated code** parameter to Improved Execution Speed and building the model. The Subtract block executes after the Concatenate block. The Product block executes after the Sum of Elements block.

In the optimized code, the three buffers `rtb_Sum2x3[6]`, `rtb_Sum2x3_d`, and `rtb_Subtract` and their associated data copies are gone. The generated code does not require these temporary variables to hold the outputs of the Sum and Subtract blocks because the Subtract block executes after the Concatenate block and the Product block executes after the Sum of Elements block.

```

/* Model step function */
void ex_optimizeblockorder_step(void)
{
 int32_T i;

 /* Sum: '<Root>/Sum2x3' incorporates:
 * Inport: '<Root>/In1'
 * Inport: '<Root>/In2'
 */
 for (i = 0; i < 6; i++) {
 rtY.Out1[i] = rtU.In1[i] + rtU.In2;
 }

 /* End of Sum: '<Root>/Sum2x3' */

 /* Concatenate: '<Root>/MatrixConcat ' */
 for (i = 0; i < 3; i++) {
 /* Outport: '<Root>/Out3' incorporates:
 * Inport: '<Root>/In5'
 */
 rtY.Out3[i << 2] = rtY.Out1[i << 1];
 rtY.Out3[2 + (i << 2)] = rtU.In5[i << 1];
 rtY.Out3[1 + (i << 2)] = rtY.Out1[(i << 1) + 1];
 rtY.Out3[3 + (i << 2)] = rtU.In5[(i << 1) + 1];
 }

 /* End of Concatenate: '<Root>/MatrixConcat ' */

 /* Sum: '<Root>/SumOfElements' */
 rtY.Out2 = -0.0;
 for (i = 0; i < 6; i++) {
 /* Sum: '<Root>/Subtract' incorporates:
 * Inport: '<Root>/In3'
 */
 rtY.Out1[i] -= rtU.In3;

 /* Sum: '<Root>/SumOfElements' */
 rtY.Out2 += rtY.Out1[i];

 /* Outport: '<Root>/Out1' incorporates:
 * Inport: '<Root>/In4'
 * Product: '<Root>/Product'
 */
 rtY.Out1[i] *= rtU.In4[i];
 }
}

```

To implement buffer reuse, the code generator does not violate user-specified block priorities.

## Data Copy Reduction for Data Store Read and Data Store Write Blocks

This example shows how the code generator removes temporary buffers for Data Store Read and Data Store Write blocks. This optimization improves execution speed and reduces RAM consumption.

### Example Model

The model `rtwdemo_optimizedatastorebuffers` contains the Function caller `UpdateFunc`, which calls the Simulink Function `DefineUpdateFunc`. The Data Store Read block `DSR` reads from `mem`. The Data Store Write block `DSW` writes to `mem`.

```
model='rtwdemo_optimizedatastorebuffers';
open_system(model);
```

Copyright 2016-2020 The MathWorks, Inc.

### Generate Code Without Optimization

In the Configuration Parameters dialog box, deselect the **Reuse buffers for Data Store Read and Data Store Write blocks parameter** or at the MATLAB® command prompt, enter this command:

```
set_param(model,'OptimizeDataStoreBuffers','off');
```

Build the model.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
slbuild(model)
```

```
Starting build procedure for: rtwdemo_optimizedatastorebuffers
Successful completion of build procedure for: rtwdemo_optimizedatastorebuffers
```

## Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_optimizedatastorebuffers	Code generated and compiled.	Code generation information file

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 23.684s

View the generated code without the optimization. This code is in  
`rtwdemo_optimizedatastorebuffers.c`.

```

cfile = fullfile(cgDir,'rtwdemo_optimizedatastorebuffers_ert_rtw',...
 'rtwdemo_optimizedatastorebuffers.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);

/* Model step function */
void step(void)
{
 real_T rtb_DSR_last;
 real_T rtb_SimFuncCall_o1;
 real_T rtb_Sum_p;

 /* DataStoreRead: '<Root>/DSR' */
 rtb_DSR_last = mem.last;

 /* Switch: '<Root>/Switch' incorporates:
 * Constant: '<Root>/Constant'
 * DataStoreRead: '<Root>/DSR'
 * Inport: '<Root>/Clear'
 */
 if (rtU.Clear) {
 rtb_SimFuncCall_o1 = 0.0;
 } else {
 rtb_SimFuncCall_o1 = mem.max;
 }

 /* End of Switch: '<Root>/Switch' */

 /* FunctionCaller: '<Root>/SimFuncCall' incorporates:
 * Inport: '<Root>/DataNew'
 */
 UpdateFunc(rtb_SimFuncCall_o1, rtU.DataNew, &rtb_SimFuncCall_o1, &rtb_Sum_p);

 /* DataStoreWrite: '<Root>/DSW' */
 mem.last = rtb_SimFuncCall_o1;
 mem.max = rtb_Sum_p;

 /* Output: '<Root>/Delta' incorporates:
 * DataStoreRead: '<Root>/DSR'
 * Inport: '<Root>/DataNew'
 * Sum: '<Root>/Sum'
 */
 rtY.Delta = rtU.DataNew - rtb_DSR_last;
}

```

The generated code contains data copies for the Data Store Read and Data Store Write blocks, respectively.

### Generate Code with Optimization

In the Configuration Parameters dialog box, clear the **Reuse buffers for Data Store Read and Data Store Write blocks** parameter or at the MATLAB command prompt, enter this command:

```
set_param(model, 'OptimizeDataStoreBuffers', 'on');
```

Build the model.

```
slbuild(model)
```

```
Starting build procedure for: rtwdemo_optimizedatastorebuffers
Successful completion of build procedure for: rtwdemo_optimizedatastorebuffers
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_optimizedatastorebuffers	Code generated and compiled.	Generated code was out of date.

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 19.531s
```

View the generated code with the optimization. This code is in `rtwdemo_optimizedatastorebuffers.c`.

```
cfile = fullfile(cgDir, 'rtwdemo_optimizedatastorebuffers_ert_rtw', ...
 'rtwdemo_optimizedatastorebuffers.c');
rtwdemodbtype(cfile, /* Model step', /* Model initialize', 1, 0);
```

```
/* Model step function */
void step(void)
{
 real_T rtb_DSR_last;
 real_T tmp;

 /* DataStoreRead: '<Root>/DSR' */
 rtb_DSR_last = mem.last;

 /* Switch: '<Root>/Switch' incorporates:
 * Constant: '<Root>/Constant'
 * DataStoreRead: '<Root>/DSR'
 * Inport: '<Root>/Clear'
 */
 if (rtU.Clear) {
 tmp = 0.0;
 } else {
 tmp = mem.max;
 }

 /* FunctionCaller: '<Root>/SimFuncCall' incorporates:
 * DataStoreWrite: '<Root>/DSW'
```

```

* Inport: '<Root>/DataNew'
* Switch: '<Root>/Switch'
*/
UpdateFunc(tmp, rtU.DataNew, &mem.last, &mem.max);

/* Output: '<Root>/Delta' incorporates:
* DataStoreRead: '<Root>/DSR'
* Inport: '<Root>/DataNew'
* Sum: '<Root>/Sum'
*/
rtY.Delta = rtU.DataNew - rtb_DSR_last;
}

```

The data copy for the Data Store Write block is not in the generated code. The code contains the data copy for the Data Store Read block because the Sum block executes after the Data Store Write block. The generated code contains the variable `rtb_DSR_last` to hold the output of the Sum block. Therefore, the Sum block gets the values that `SimFuncCall` calculates at the start of the time step rather than those values at the next time step. If the priority of the Sum block is lower than `SimFuncCall`, the code generator can remove the data copy for the Data Store Read block. Some other cases in which the code generator might not eliminate data copies are:

- A Simulink Function internally writes to the Data Store Memory block.
- The Data Store Read or Data Store Write blocks select elements of an array from the Data Store Memory block.
- The Data Store Memory block has a custom storage class.
- The Data Store Read and Data Store Write blocks occur on the same block unless that block is a Bus Assignment block or an Assignment block.

Close the model and clean up.

```

bdclose(model)
rtwdemoclean;
cd(currentDir)

```

## Reduce Data Copies for Bus Assignment Blocks in Generated Code

For models containing a Bus Assignment block, if possible, the code generator uses the same variable for the block input and output. Reusing these variables reduces data copies, conserves RAM consumption and increases code execution speed.

### Example Model

For example, in `bus_assignoptim`, a bus signal containing six elements feeds into a Bus Assignment block and a Bus Selector block. The Bus Assignment block assigns new values to the bus element `a1_real_array`. This bus signal feeds into `Out1`.

### Generate Code Without Optimization

Generate code without the optimization by setting the **Perform in-place updates for Assignment and Bus Assignment blocks** parameter to off. Without the optimization the `bus_assignoptim_step` function contains this code:

```
void bus_assignoptim_step(void)
{
 real_T rtb_Assignment[36];
 int32_T i;

 /* Assignment: '<Root>/Assignment' incorporates:
 * Inport: '<Root>/In1'
 * Inport: '<Root>/In2'
 * Product: '<Root>/Product'
 * Selector: '<Root>/Selector'
 * Sum: '<Root>/Sum1'
 */
 for (i = 0; i < 36; i++) {
 rtb_Assignment[i] = bus_assignoptim_U.In1.a1_real_array[i];
 }

 for (i = 0; i < 2; i++) {
 rtb_Assignment[(int32_T)(i + 22)] = (bus_assignoptim_U.In1.a1_real_array
 [(int32_T)(i + 22)] + bus_assignoptim_U.In1.a1_num) *
 bus_assignoptim_U.In2;
 }

 /* End of Assignment: '<Root>/Assignment' */

 /* Output: '<Root>/Out' incorporates:
```

```

 * BusAssignment: '<Root>/Bus Assignment'
 * Inport: '<Root>/In1'
 */
bus_assignoptim_Y.Out = bus_assignoptim_U.In1;

/* BusAssignment: '<Root>/Bus Assignment' incorporates:
 * Output: '<Root>/Out'
 */
for (i = 0; i < 36; i++) {
 bus_assignoptim_Y.Out.a1_real_array[i] = rtb_Assignment[i];
}
}

```

The generated code contains the temporary array `rtb_Assignment` for holding data before this data is assigned to `bus_assignoptim_Y.Out.a1_real_array`.

## Generate Code with Optimization

Generate code with the optimization by setting the **Perform in-place updates for Assignment and Bus Assignment blocks** parameter to on. With the optimization, the `bus_assignoptim_step` function contains this code:

```

/* Model step function */
void bus_assignoptim_step(void)
{
 int32_T i;

 /* Output: '<Root>/Out' incorporates:
 * Inport: '<Root>/In1'
 * SignalConversion: '<Root>/TmpBusAssignmentBufferAtBus AssignmentInport1'
 */
 bus_assignoptim_Y.Out = bus_assignoptim_U.In1;

 /* Assignment: '<Root>/Assignment' incorporates:
 * Inport: '<Root>/In1'
 * Inport: '<Root>/In2'
 * Output: '<Root>/Out'
 * Product: '<Root>/Product'
 * Selector: '<Root>/Selector'
 * Sum: '<Root>/Sum1'
 */
 for (i = 0; i < 36; i++) {
 bus_assignoptim_Y.Out.a1_real_array[i] =
 bus_assignoptim_U.In1.a1_real_array[i];
 }

 for (i = 0; i < 2; i++) {
 bus_assignoptim_Y.Out.a1_real_array[(int32_T)(i + 22)] =
 (bus_assignoptim_U.In1.a1_real_array[(int32_T)(i + 22)] +
 bus_assignoptim_U.In1.a1_num) * bus_assignoptim_U.In2;
 }

 /* End of Assignment: '<Root>/Assignment' */
}

```

The generated code does not contain the temporary array `rtb_Assignment1` for holding data. The generated code directly assigns this data to `bus_assignoptim_Y.Out.a1_real_array`.

## Optimize Generated Code by Using Signal Labels to Guide Buffer Reuse

If your model has the optimal parameter settings for removing data copies, you might be able to remove additional data copies by using signal labels. After studying the generated code and the Static Code Metrics Report and identifying areas where you think buffer reuse is possible, you can add labels to signal lines. If possible, the code generator reorders block operations to implement the reuse specification.

Specifying buffer reuse improves execution speed and may reduce RAM consumption.

### Example Model

The model `rtwdemo_label_guided_reuse` demonstrates how you can use signal labels to request buffer reuse for block input and output signals. For this model, the code generator can use the same variable for the Atomic Subsystem and either the Gain or Saturation block outputs. The generated code uses the same variable for the Saturation and Atomic Subsystem block outputs because those signals contain the same label and the **Use Signal Labels to Guide Buffer Reuse** parameter is selected.

### Generate Code Without Optimization

- 1 Open the model.
 

```
model='rtwdemo_label_guided_reuse';
open_system(model);
```
- 2 In the Configuration Parameters dialog box, clear the **Use Signal Labels to Guide Buffer Reuse** parameter.
- 3 Build the model. The `rtwdemo_label_guided_reuse_step` function contains this code:

```
void rtwdemo_label_guided_reuse_step(void)
{
 real_T rtb_Saturation[4];
 real_T rtb_Bias[4];
 int32_T i;
 AtomicSubsystem(rtU.In1, rtb_Bias);
 for (i = 0; i < 4; i++) {
```

```

 if (rtb_Bias[i] > 10.0) {
 rtb_Saturation[i] = 10.0;
 } else if (rtb_Bias[i] < -10.0) {
 rtb_Saturation[i] = -10.0;
 } else {
 rtb_Saturation[i] = rtb_Bias[i];
 }

 rtb_Bias[i] *= 3.0;
}

AtomicSubsystem1(rtb_Saturation, rtb_Bias, rtY.Out1);
}

```

By default, within the `for` loop, the Gain block executes after the Saturation block. The generated code uses the same variable for the output of the Atomic Subsystem and the Gain blocks. As a result, the generated code contains two local variables `rtb_Saturation` and `rtb_Bias` for holding intermediate results.

## Generate Code with Optimization

In the Configuration Parameters dialog box, select the **Use Signal Labels to Guide Buffer Reuse** parameter and build the model. The `rtwdemo_label_guided_reuse_step` function contains this code:

```

void rtwdemo_label_guided_reuse_step(void)
{
 real_T rtb_Gain1[4];
 int32_T i;
 AtomicSubsystem(rtU.In1, rtY.Out1);
 for (i = 0; i < 4; i++) {
 rtb_Gain1[i] = 3.0 * rtY.Out1[i];
 if (rtY.Out1[i] > 10.0) {
 rtY.Out1[i] = 10.0;
 } else {
 if (rtY.Out1[i] < -10.0) {
 rtY.Out1[i] = -10.0;
 }
 }
 }
}

AtomicSubsystem1(rtY.Out1, rtb_Gain1, rtY.Out1);
}

```

The code generator changed the block execution order so that within the `for` loop, the Saturation block executes after the Gain block. The generated code contains one local variable `rtb_Gain1` for holding intermediate results.

In addition to requesting which buffers to reuse, another possible use case is to request buffer reuse for block input and output signals that are complex.

## Using Label-Based Reuse Versus Reusable Storage Classes

You can also use the same `Reusable` storage class specification on different signal lines to specify which buffers to reuse. As compared to using `Reusable` storage classes, using signal labels to specify reuse has these benefits:

- Signal labels are not observation points in the generated code, so using them does not block other optimizations such as dead code elimination and expression folding.
- The code generator does not force a signal with a label to be a global variable in the generated code. The signal can be a local or global variable.
- Signals with labels can reuse buffers with signals that do not have labels, so reuse among local and global variables is possible.

Using signal labels is a more conservative method of specifying reuse than using `Reusable` storage classes. The code generator does not implement label-based reuse when it can implement reuse by using `Reusable` storage classes in these cases:

- Reuse that can potentially prevent other optimizations from occurring in the generated code.
- Reuse on root inport and outport ports.
- Reuse across model reference or subsystem boundaries.
- Within a subsystem, buffer reuse on an intermediary signal and an input or output port.

## Reduce Memory Usage for Signals

The configuration parameter **Signal storage reuse** reduces the memory requirements of your real-time program by enabling parameters that reuse the memory allocated for signals with an `auto` storage class. These parameters are the following:

- **Enable local block outputs**
- **Reuse local block outputs**
- **Reuse global block outputs**
- **Optimize global data access**

When the **Enable local block outputs** parameter is on, where possible the code generator declares block outputs as local variables instead of global variables. Replacing global variables with local variables improves execution speed and reduces RAM/ROM consumption. Creating more local variables can increase stack usage. Some of the global variables that the code generator can localize include:

- Global signals that cross subsystem boundaries
- Global signals across Simulink and Stateflow domains
- Unused global state variables
- Redundant local Data Store Memory block signals

When the **Reuse local block outputs** parameter is on, wherever possible the code generator reuses local (function) variables for block outputs. When you select **Reuse global block outputs**, the code generator reuses global (function) variables wherever possible.

The **Optimize global data access** parameter has these settings:

- None
- Use global to hold temporary results
- Minimize global data access

When you select `None`, the code generator uses the default optimizations. The setting `Use global to hold temporary results` maximizes the use of global variables. The setting `Minimize global data access` minimizes the use of global variables by using local variables to hold intermediate values.

Clearing **Signal storage reuse** makes all block outputs global and unique, which often significantly increases RAM and ROM usage.

The code generator does not localize global variables for MATLAB system objects or AUTOSAR.

## Remove Zero Initialization Code

The Remove root level I/O zero initialization and Remove internal data zero initialization parameters control whether the generated code contains initialization code for internal data (block states and block outputs) and external data (root inports and outports) whose value is zero. Eliminating zero initialization code accelerates model initialization, reduces ROM consumption, and increases the execution speed of the generated code.

During startup, standards-compliant C and C++ compilers initialize global data to zero eliminating the need to include zero initialization code for this data in the generated code. Standards-compliant compilers do not necessarily initialize dynamically allocated data and local variables to zero. Before leaving the **Remove root level I/O zero initialization** and **Remove internal data zero initialization** parameters selected, confirm the following:

- If your compiler is not standards compliant, confirm that it initializes global data to zero.
- If you set the “Code interface packaging” to Reusable function or C++ class, confirm that data is either statically allocated or that dynamically allocated data is initialized to zero.

If you set the **Code interface packaging** parameter to Reusable function and select the “Use dynamic memory allocation for model initialization” parameter, the **Remove root level I/O zero initialization** and **Remove internal data zero initialization** check boxes are cleared and at the command line, ZeroExternalMemoryAtStartup and ZeroInternalMemoryAtStartup parameters are set to 'on'.

For a model in which the **Code interface packaging** parameter is set to C++ class and the “Use dynamic memory allocation for model block instantiation” parameter is selected, the **Remove internal data zero initialization** check box is cleared and ZeroInternalMemoryAtStartup is set to 'on' and is read-only.

### Remove Zero Initialization Code for Internal Data

This example shows how to eliminate code that initializes internal data to zero.

#### Example Model

Open the model `rtwdemo_internal_init`. The model contains an enabled subsystem whose initial output is zero. The subsystem contains a Unit Delay block whose initial condition is 0.

```
model = 'rtwdemo_internal_init';
open_system(model);
```

Copyright 2014-2020 The MathWorks, Inc.

## Generate Code Without Optimization

Build the model by using Embedded Coder®.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
evalc('slbuild(model)');
```

This code is in the `rtwdemo_internal_init.c` file.

```
cfile = fullfile(cgDir,'rtwdemo_internal_init_ert_rtw','rtwdemo_internal_init.c');
rtwdemodbtype(cfile,'/* Model initialize', '* File trailer', 1, 0);
```

```
/* Model initialize function */
void rtwdemo_internal_init_initialize(void)
{
 /* Registration code */

 /* initialize error status */
 rtmSetErrorStatus(rtM, (NULL));

 /* states (dwork) */
 (void) memset((void *)&rtDWork, 0,
 sizeof(D_Work));

 /* SystemInitialize for Enabled SubSystem: '<Root>/Enabled Subsystem' */
 /* InitializeConditions for UnitDelay: '<S1>/Unit Delay' */
 rtDWork.UnitDelay_DSTATE = 0.0;

 /* End of SystemInitialize for SubSystem: '<Root>/Enabled Subsystem' */
}

/*
```

## Enable Optimization

Open the Configuration Parameters dialog box. On the **Optimization** pane, select **Remove internal data zero initialization**.

Alternatively, you can use the command prompt to enable the optimization. Set the model parameter `ZeroInternalMemoryAtStartup` to 'off'.

```
set_param(model, 'ZeroInternalMemoryAtStartup', 'off');
set_param(model, 'ZeroInternalMemoryAtStartup', 'off');
```

## Generate Code with Optimization

Build the model by using Embedded Coder.

```
evalc('slbuild(model)');
```

This code is in the `rtwdemo_internal_init.c` file. The generated code does not initialize internal data by assignment to zero.

```
rtwdemodbtype(cfile,'/* Model initialize', '* File trailer', 1, 0);
```

```
/* Model initialize function */
```

```

void rtwdemo_internal_init_initialize(void)
{
 /* (no initialization code required) */
}

/*

bdclose(model)
rtwdemoclean;
cd(currentDir)

```

## Remove Initialization Code from Root-Level Inports and Outports Set to Zero

This example shows how to remove initialization code from root-level inports and outports set to zero.

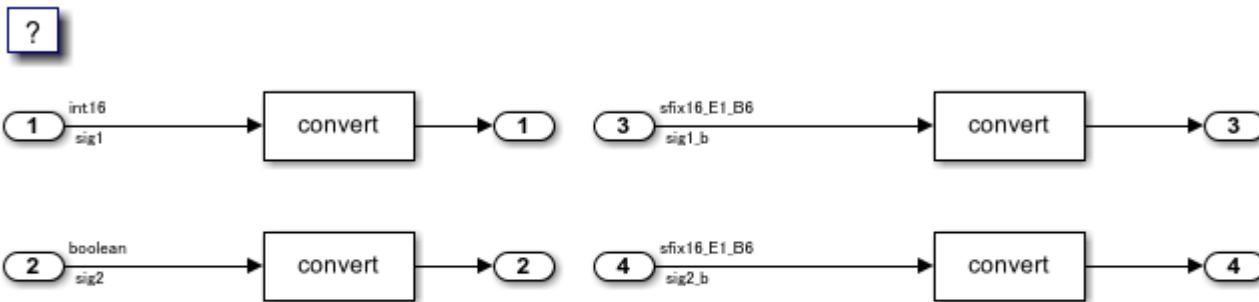

### Example Model

In the model `rtwdemo_rootlevel_zero_initialization`, all of the input and output signals have a numeric value of zero. Because signals `sig1` and `sig2` have data types `int16` and `Boolean`, respectively, and all of the output signals have data type `double`, these signals also have initial values of bitwise zero. The signals have an integer bit pattern of 0, meaning that all bits are off. Signals `sig1_b` and `sig2_b` have a fixed-point data type with bias, so their initial value is not bitwise zero.

```

model = 'rtwdemo_rootlevel_zero_initialization';
open_system(model);

```

Copyright 2014-2020 The MathWorks, Inc

### Generate Code

In your system temporary folder, create a temporary folder for the build and inspection process.

```

currentDir = pwd;
[~,cgDir] = rtwdemodir();

```

Build the model by using Embedded Coder.

```

set_param(model, 'ZeroExternalMemoryAtStartup','on');
evalc('slbuild(model)');

```

These lines of `rtwdemo_rootlevel_zero_initialization.c` code show the initialization of root-level inports and outports without the optimization. The four input signals are individually initialized as global variables. The four output signals are members of a global structure that the `memset` function initializes to bitwise zero.

```
cfile = fullfile(cgDir, 'rtwdemo_rootlevel_zero_initialization_ert_rtw', ...
 'rtwdemo_rootlevel_zero_initialization.c');
rtwdemodbtype(cfile, 'rtwdemo_rootlevel_zero_initialization_initialize', ...
 'trailer for generated code', 1, 0);
```

```
void rtwdemo_rootlevel_zero_initialization_initialize(void)
{
 /* Registration code */

 /* external inputs */
 sig1 = 0;
 sig1_b = -3;
 sig2 = false;
 sig2_b = -3;

 /* external outputs */
 (void)memset(&rtY, 0, sizeof(ExternalOutputs));
}

/*
```

### Enable Optimization

- 1 Open the Configuration Parameters dialog box.
- 2 On the **Optimization** pane, select **Remove root level I/O zero initialization**.

Alternatively, use the command-line API to enable the optimization:

```
set_param(model, 'ZeroExternalMemoryAtStartup', 'off');
```

### Generate Code with Optimization

The optimized code does not contain initialization code for the input signals `sig1`, `sig2`, and the four output signals because their initial values are bitwise zero.

Build the model.

```
evalc('slbuild(model)');
```

Here is the `rtwdemo_rootlevel_zero_initialization.c` optimized code in the initialization function.

```
cfile = fullfile(cgDir, 'rtwdemo_rootlevel_zero_initialization_ert_rtw', ...
 'rtwdemo_rootlevel_zero_initialization.c');
rtwdemodbtype(cfile, 'rtwdemo_rootlevel_zero_initialization_initialize', ...
 'trailer for generated code', 1, 0);
```

```
void rtwdemo_rootlevel_zero_initialization_initialize(void)
{
 /* Registration code */
```

```
/* external inputs */
sig1_b = -3;
sig2_b = -3;
}

/*
```

Close the model and the code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

## Additional Information

- You can use the **Use memset to initialize floats and doubles** parameter to control the representation of zero during initialization. See [Use memset to initialize floats and doubles to 0.0](#).
- The code still initializes data structures whose value is not zero when you select the **Remove internal data zero initialization** and **Remove root level I/O zero initialization** parameters.
- The data of `ImportedExtern` or `ImportedExternPointer` storage classes are not initialized, regardless of the settings of the **Remove internal data zero initialization** and **Remove root level I/O zero initialization** parameters.

## Simplify Multiply Operations in Array Indexing

### In this section...

“Example Model” on page 79-9

“Generate Code” on page 79-9

“Generate Code with Optimization” on page 79-10

The generated code might have multiply operations when indexing an element of an array. You can select the optimization parameter Simplify array indexing to replace multiply operations in the array index with a temporary variable. This optimization can improve execution speed by reducing the number of times the multiply operation executes.

### Example Model

If you have the following model:

The Constant blocks have the following **Constant value**:

- Const1: `reshape(1:30,[1 5 3 2])`
- Const2: `reshape(1:20,[1 5 2 2])`
- Const3: `reshape(1:90,[1 5 9 2])`

The Concatenate block parameter **Mode** is set to `Multidimensional array`. The Constant blocks **Sample time** parameter is set to `-1`.

### Generate Code

Building the model with the **Simplify array indexing** parameter turned off generates the following code:

```
int32_T i;
int32_T i_0;
int32_T i_1;

for (i = 0; i < 2; i++) {
 for (i_1 = 0; i_1 < 3; i_1++) {
 for (i_0 = 0; i_0 < 5; i_0++) {
 ex_arrayindex_Y.Out[(i_0 + 5 * i_1) + 70 * i] =
```

```

 ex_arrayindex_P.Constant1_Value[(5 * i_1 + i_0) + 15 * i];
 }
}
}
for (i = 0; i < 2; i++) {
 for (i_1 = 0; i_1 < 2; i_1++) {
 for (i_0 = 0; i_0 < 5; i_0++) {
 ex_arrayindex_Y.Out[(i_0 + 5 * (i_1 + 3)) + 70 * i] =
 ex_arrayindex_P.Constant2_Value[(5 * i_1 + i_0) + 10 * i];
 }
 }
}
for (i = 0; i < 2; i++) {
 for (i_1 = 0; i_1 < 9; i_1++) {
 for (i_0 = 0; i_0 < 5; i_0++) {
 ex_arrayindex_Y.Out[(i_0 + 5 * (i_1 + 5)) + 70 * i] =
 ex_arrayindex_P.Constant3_Value[(5 * i_1 + i_0) + 45 * i];
 }
 }
}
}

```

## Generate Code with Optimization

Open the Configuration Parameters dialog box and select the **Simplify array indexing** parameter. Build the model again. In the generated code,  $[(i\_0 + tmp\_1) + tmp]$  replaces a multiply operation in the array index,  $[(i\_0 + 5 * i\_1) + 70 * i]$ . The generated code is now:

```

int32_T i;
int32_T i_0;
int32_T i_1;
int32_T tmp;
int32_T tmp_0;
int32_T tmp_1;

tmp = 0;
tmp_0 = 0;
for (i = 0; i < 2; i++) {
 tmp_1 = 0;
 for (i_1 = 0; i_1 < 3; i_1++) {
 for (i_0 = 0; i_0 < 5; i_0++) {
 ex_arrayindex_Y.Out[(i_0 + tmp_1) + tmp] =
 ex_arrayindex_P.Constant1_Value[(i_0 + tmp_1) + tmp_0];
 }

 tmp_1 += 5;
 }

 tmp += 70;
 tmp_0 += 15;
}

tmp = 0;
tmp_0 = 0;
for (i = 0; i < 2; i++) {
 tmp_1 = 0;

```

```

for (i_1 = 0; i_1 < 2; i_1++) {
 for (i_0 = 0; i_0 < 5; i_0++) {
 ex_arrayindex_Y.Out[((i_0 + tmp_1) + tmp) + 15] =
 ex_arrayindex_P.Constant2_Value[(i_0 + tmp_1) + tmp_0];
 }

 tmp_1 += 5;
}

tmp += 70;
tmp_0 += 10;
}

tmp = 0;
tmp_0 = 0;
for (i = 0; i < 2; i++) {
 tmp_1 = 0;
 for (i_1 = 0; i_1 < 9; i_1++) {
 for (i_0 = 0; i_0 < 5; i_0++) {
 ex_arrayindex_Y.Out[((i_0 + tmp_1) + tmp) + 25] =
 ex_arrayindex_P.Constant3_Value[(i_0 + tmp_1) + tmp_0];
 }

 tmp_1 += 5;
 }

 tmp += 70;
 tmp_0 += 45;
}

```

## Replace boolean with Specific Integer Data Type

Depending on the architecture of the processor that your production hardware uses, you can improve the execution speed of the generated code. Select a specific integer data type for the built-in type `boolean`. Using data type replacement, in the generated code you can replace the `boolean` built-in data type with one of these integer types:

- `int8`
- `uint8`
- `intn`

To match the integer word size for the production hardware, replace  $n$  with 8, 16, or 32 .

### Example Model

The model `ex_bool` contains two blocks that output `boolean` values and two blocks that take `boolean` values as inputs. This example shows how to replace the data type `boolean` with the integer data type `int32` in the code generated for a 32-bit hardware target.

### Generate Code That Contains the Default boolean Data Type

View the generated file `rtwtypes.h`. The `typedef` statements contain the generic type definition of `boolean_T`, which is the code generation name for `boolean`.

```
/*=====
 * Generic type definitions: boolean_T, char_T, byte_T, int_T, uint_T,
 *
```

```

* real_T, time_T, ulong_T. *
=====/
typedef double real_T;
typedef double time_T;
typedef unsigned char boolean_T;
typedef int int_T;
typedef unsigned int uint_T;
typedef unsigned long ulong_T;
typedef char char_T;
typedef unsigned char uchar_T;
typedef char_T byte_T;

```

View the generated file `ex_bool.c`. The code declares `boolean` variables by using the type `boolean_T`.

```

/* External inputs (root inport signals with auto storage) */
typedef struct {
 real_T In1; /* '<Root>/In1' */
 real_T In2; /* '<Root>/In2' */
 boolean_T In3; /* '<Root>/In3' */
 boolean_T In4; /* '<Root>/In4' */
 real_T In5; /* '<Root>/In5' */
} ExtU_ex_bool_T;

/* External outputs (root outports fed by signals with auto storage) */
typedef struct {
 boolean_T Out1; /* '<Root>/Out1' */
 boolean_T Out2; /* '<Root>/Out2' */
 real_T Out3; /* '<Root>/Out3' */
} ExtY_ex_bool_T;

```

## Generate Code That Contains the Target boolean Data Type

- 1 Define a `Simulink.AliasType` object with a base type of `int32`. Name the object using the replacement name that you want to appear in the generated code.

```

mybool = Simulink.AliasType;
mybool.BaseType = 'int32';

```

- 2 In the Configuration Parameters dialog box, specify the **Replacement Name** field for the data type `boolean` as `mybool`.

Data type names		
Simulink Name	Code Generation Name	Replacement Name
double	real_T	<input type="text"/>
single	real32_T	<input type="text"/>
int32	int32_T	<input type="text"/>
int16	int16_T	<input type="text"/>
int8	int8_T	<input type="text"/>
uint32	uint32_T	<input type="text"/>
uint16	uint16_T	<input type="text"/>
uint8	uint8_T	<input type="text"/>
boolean	boolean_T	mybool
int	int_T	<input type="text"/>
uint	uint_T	<input type="text"/>
char	char_T	<input type="text"/>

View the generated file `rtwtypes.h`. The code maps the identifier `mybool` to the native integer type of the target hardware by creating `typedef` statements.

```
/* Generic type definitions ... */
...
typedef int boolean_T;
...
/* Define Simulink Coder replacement data types. */
typedef boolean_T mybool; /* User defined replacement datatype for boolean_T */
```

View the generated file `ex_bool.c`. The code declares `boolean` variables that use the type `mybool`.

```
/* External inputs (root inport signals with auto storage) */
typedef struct {
 real_T In1; /* '<Root>/In1' */
 real_T In2; /* '<Root>/In2' */
 mybool In3; /* '<Root>/In3' */
 mybool In4; /* '<Root>/In4' */
 real_T In5; /* '<Root>/In5' */
} ExtU_ex_bool_T;

/* External outputs (root outports fed by signals with auto storage) */
typedef struct {
 mybool Out1; /* '<Root>/Out1' */
 mybool Out2; /* '<Root>/Out2' */
 real_T Out3; /* '<Root>/Out3' */
} ExtY_ex_bool_T;
```

## Remove Code from Tunable Parameter Expressions That Saturate Against Integer Overflow

Optimize generated code by removing code that protects parameter expressions from integer overflow for integers and fixed-point data. If you are sure that you will not tune the terms of tunable parameter expressions to cause them to evaluate to a value that is below or above the representable value of a data type, enable this optimization. This optimization increases execution speed and results in smaller code that reduces ROM consumption.

### Risks

When you select the `EfficientTunableParamExpr` parameter, and you tune the terms of the expression so that it encounters an integer overflow, the result will wrap around in the generated code. This behavior can cause the application to behave unexpectedly at run-time.

**NOTE:** If you enable this optimization, it is possible that simulation results and results from generated code are not in bit-for-bit agreement. This example requires Embedded Coder®.

### Example Model

In the model `matlab:mEfficientParamExpr`, an input signal of type `int8` feeds into a Gain block.

```
model = 'mEfficientParamExpr';
open_system(model);
```

Copyright 2021 The MathWorks, Inc.

### Generate Code

In your system temporary folder, create another temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
set_param(model, 'EfficientTunableParamExpr', 'off');
evalc('slbuild(model)');
```

View the generated code without the optimization. Here is a portion of `mEfficientParamExpr.c`.

```
cfile = fullfile(cgDir,'mEfficientParamExpr_ert_rtw','mEfficientParamExpr.c');
rtwdemodbtype(cfile,'/* Model step function ','/* Model initialize function',1, 1);

/* Model step function */
void mEfficientParamExpr_step(void)
{
```

```

int32_T tmp;

/* Gain: '<Root>/Gain' */
tmp = P + Q;
if (tmp > 127) {
 tmp = 127;
} else if (tmp < -128) {
 tmp = -128;
}

/* Outport: '<Root>/Out1' incorporates:
 * Gain: '<Root>/Gain'
 * Inport: '<Root>/In1'
 */
rtY.Out1 = (int8_T)(tmp * rtU.In1);
}

```

### Enable Optimization

- 1 Open the Configuration Parameters dialog box.
- 2 On the **Optimization** pane, select **Remove code from tunable parameter expressions that saturates out-of-range values**.

Alternatively, use the command-line API to enable the optimization:

```
set_param(model, 'EfficientTunableParamExpr', 'on');
```

### Generate Code with Optimization

The optimized code does not contain code that checks the bounds of the representable value of a data type.

Build the model.

```
evalc('slbuild(model)');
```

The following is a portion of `mEfficientParamExpr.c`. The code that protects against expression overflow is not in the generated code.

```

rtwdemodbtype(cfile, '/* Model step function ', '/* Model initialize function', 1, 1);

/* Model step function */
void mEfficientParamExpr_step(void)
{
 /* Outport: '<Root>/Out1' incorporates:
 * Gain: '<Root>/Gain'
 * Inport: '<Root>/In1'
 */
 rtY.Out1 = (int8_T)((int8_T)(P + Q) * rtU.In1);
}

```

Close the model and code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

## Remove Code That Guards Against Division Exceptions for Integers and Fixed-Point Data

Optimize generated code by removing code that protects against division by zero and overflows in division  $\text{INT\_MIN} / -1$  operations for integers and fixed-point data. If you are sure that these arithmetic exceptions do not occur during program execution, enable this optimization but it may lead to a quotient that cannot be represented.

This optimization:

- Increases execution speed.
- Results in smaller code thereby reducing ROM consumption.

### Risks

When you select the `NoFixptDivByZeroProtection` parameter, the code generator removes code that protects against the following errors:

- When you divide by zero it is undefined and results in a runtime error in the generated code.
- When you divide the minimum representable value of a signed integer by negative one, the ideal result is equal to the maximum representable value plus one ( $\text{INT\_MAX} + 1$ ), which is not representable. This exception may cause the application to unexpectedly halt or crash at run-time.

**NOTE:** If you enable this optimization, it is possible that simulation results and results from generated code are not in bit-for-bit agreement. This example requires an Embedded Coder® license.

### Example Model

In the model `rtwdemo_nzcheck`, two signals of type `int8` feed into a divide block.

```
model = 'rtwdemo_nzcheck';
open_system(model);
```

Copyright 2014-2020 The MathWorks, Inc.

### Generate Code

In your system's temporary folder, create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
set_param(model, 'NoFixptDivByZeroProtection', 'off');
slbuild(model);

Starting build procedure for: rtwdemo_nzcheck
Successful completion of code generation for: rtwdemo_nzcheck
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason

 * Inport: '<Root>/In2'
 */
 Y = U1 / U2;
}
```

Close the model and code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

**Additional Information**

There are several other factors that can affect the appearance of the generated code for division operations. The generated code for blocks containing MATLAB® code with integer or fixed-point division operations differs from the built-in Divide block in Simulink®. To balance the efficiency and semantics of fixed-point and integer divisions in these blocks, use `fi` objects and set the `fimath` properties to fit your needs and requires a Fixed-Point Designer™ license. Rounding and overflow modes also affect the size and efficiency of the generated code.

## Optimize Generated Code by Consolidating Redundant If-Else Statements

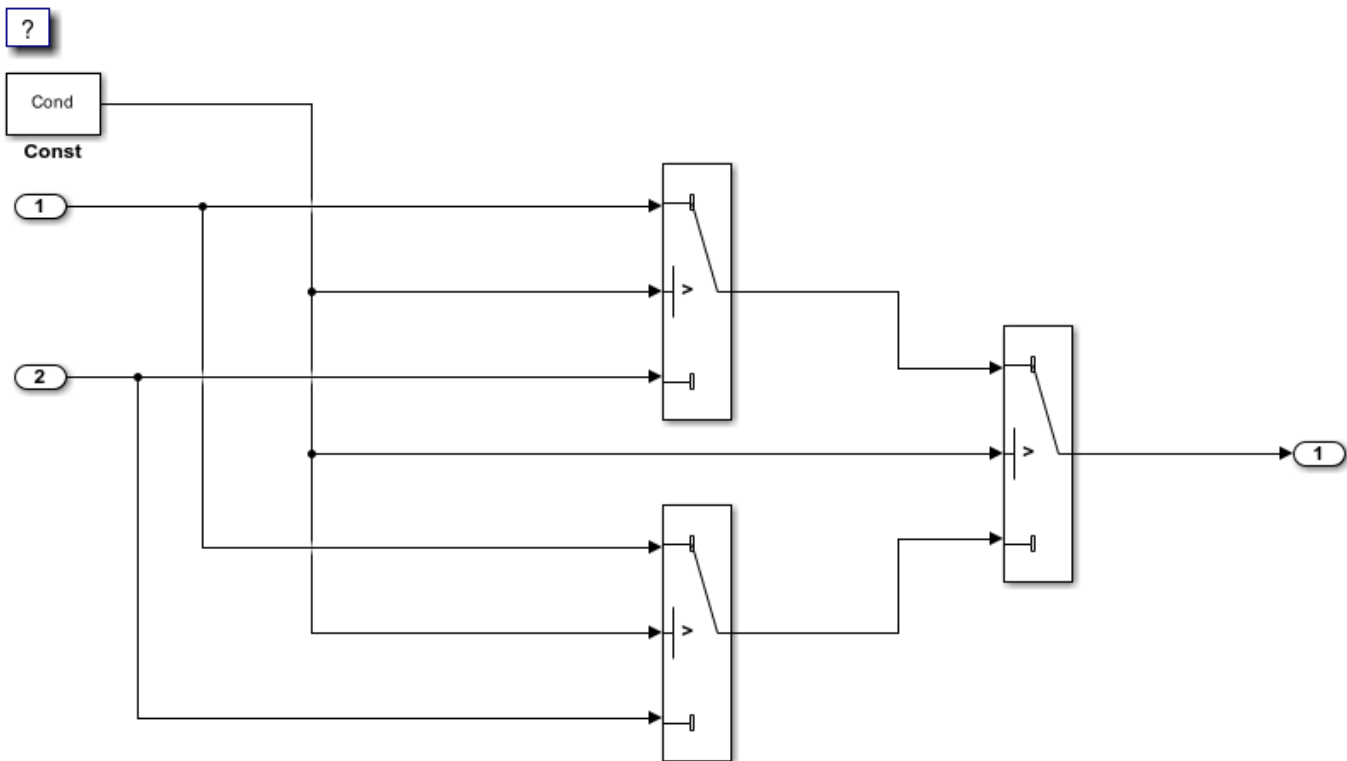

This example shows how to optimize generated code by combining `if-else` statements that share the same condition. This optimization:

- Improves control flow.
- Reduces code size.
- Reduces RAM consumption.
- Increases execution speed.

### Example

The model `rtwdemo_controlflow_opt` contains three Switch blocks. The Constant block provides the control input to the Switch blocks. The variable named `Cond` determines the value of the Constant block.

```
model = 'rtwdemo_controlflow_opt';
open_system(model);
```

Copyright 2014-2020 The MathWorks, Inc.

### Generate Code

Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
slbuild(model)
```

```
Starting build procedure for: rtwdemo_controlflow_opt
Successful completion of build procedure for: rtwdemo_controlflow_opt
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_controlflow_opt	Code generated and compiled.	Code generation information file does not

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 16.719s

These lines of `rtwdemo_controlflow_opt.c` code show that in the generated code, two `if-else` statements and one `else-if` statement represent the three Switch blocks.

```
cfile = fullfile(cgDir,'rtwdemo_controlflow_opt_ert_rtw',...
 'rtwdemo_controlflow_opt.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);
```

```
/* Model step function */
void rtwdemo_controlflow_opt_step(void)
{
 /* Switch: '<Root>/Switch3' incorporates:
 * Constant: '<Root>/Const'
 * Switch: '<Root>/Switch2'
 */
 if (Cond) {
 /* Switch: '<Root>/Switch1' */
 if (Cond) {
 /* Output: '<Root>/Out1' incorporates:
 * Inport: '<Root>/In1'
 */
 rtY.Out1 = rtU.In1;
 } else {
 /* Output: '<Root>/Out1' incorporates:
 * Inport: '<Root>/In2'
 */
 rtY.Out1 = rtU.In2;
 }

 /* End of Switch: '<Root>/Switch1' */
 } else if (Cond) {
 /* Switch: '<Root>/Switch2' incorporates:
 * Inport: '<Root>/In1'
 * Output: '<Root>/Out1'
 */
 rtY.Out1 = rtU.In1;
 } else {
```

```

 /* Outport: '<Root>/Out1' incorporates:
 * Inport: '<Root>/In2'
 */
 rtY.Out1 = rtU.In2;
}

/* End of Switch: '<Root>/Switch3' */
}

```

### Enable Optimization

- 1 Open the Configuration Parameters dialog box.
- 2 On the **Code generation->Code Style** pane, clear **Preserve condition expression in if statement**. This parameter is on by default.

Alternatively, use the command-line API to turn off the parameter:

```
set_param(model, 'PreserveIfCondition', 'off');
```

### Generate Code with Optimization

In the optimized code, the code generator consolidates the two `if-else` statements and one `else-if` statement into one `if-else` statement. The code generator consolidates these statements because they all share the same condition. There is no intervening code that affects the outcomes of these statements.

Build the model.

```
slbuild(model)
```

```
Starting build procedure for: rtwdemo_controlflow_opt
Successful completion of build procedure for: rtwdemo_controlflow_opt
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_controlflow_opt	Code generated and compiled.	Generated code was out of date.

1 of 1 models built (0 models already up to date)

Build duration: 0h 0m 18.23s

Here is the `rtwdemo_controlflow_opt.c` optimized code.

```
rtwdemodbtype(cfile, '/* Model step', '/* Model initialize', 1, 0);
```

```

/* Model step function */
void rtwdemo_controlflow_opt_step(void)
{
 /* Switch: '<Root>/Switch1' incorporates:
 * Constant: '<Root>/Const'
 * Switch: '<Root>/Switch3'
 */
 if (Cond) {
 /* Outport: '<Root>/Out1' incorporates:

```

```
 * Inport: '<Root>/In1'
 */
 rtY.Out1 = rtU.In1;
} else {
 /* Outport: '<Root>/Out1' incorporates:
 * Inport: '<Root>/In2'
 */
 rtY.Out1 = rtU.In2;
}

/* End of Switch: '<Root>/Switch1' */
}
```

Close the model and clean up.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

## Optimize Generated Code for Fixed-Point Data Operations

This example shows how the code generator optimizes fixed-point operations by replacing expensive division operations with highly efficient product operations. This optimization improves execution speed.

### Example Model

In the model `rtwdemo_fixptdiv`, two fixed point signals connect to a Divide block. The **Number of inputs** parameter has the value `/*`.

```
model='rtwdemo_fixptdiv';
load_system(model)
set_param(model,'HideAutomaticNames','off','SimulationCommand','Update')
open_system(model);
```

Copyright 1994-2020 The MathWorks, Inc.

### Generate Code

Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
set_param(model,'GenCodeOnly','on');
slbuild(model);
```

```
Starting build procedure for: rtwdemo_fixptdiv
Successful completion of code generation for: rtwdemo_fixptdiv
```

Build Summary

Top model targets built:

```

Model Action Rebuild Reason
=====
rtwdemo_fixptdiv Code generated. Code generation information file does not exist.

1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 16.018s

```

View the generated code. Here is a portion of `rtwdemo_fixptdiv.c`.

```

cfile = fullfile(cgDir,'rtwdemo_fixptdiv_ert_rtw','rtwdemo_fixptdiv.c');
rtwdemodbtype(cfile,'/* Model step','/* Model initialize', 1, 0);

/* Model step function */
void rtwdemo_fixptdiv_step(void)
{
 /* Outport: '<Root>/Out1' incorporates:
 * Inport: '<Root>/In1'
 * Product: '<Root>/Divide'
 */
 rtY.Out1 = (int16_T)(rtU.In1 >> 3);
}

```

The generated code contains a highly efficient right shift operation instead of an expensive division operation. The generated code also contains the precomputed value for the constant input to the Product block.

Note that the resulting operation also includes the adjustment in signal scaling from  $2^{-3}$  to  $2^{-5}$ .

Close the model and code generation report.

```

bdclose(model)
rtwdemoclean;
cd(currentDir)

```

## Unroll Parallel for-Loop That Has Small Number of Iterations

This example shows how to use the model configuration parameter Loop unrolling threshold to generate optimized code by unrolling parallel for-loops (parfor-loops). For a small number of loop iterations that perform some simple calculation, parallelization is inefficient as it introduces overhead, which includes time taken for thread creation, data synchronization between threads, and thread deletion. By unrolling small parallel for-loops, you can achieve improved execution speed. Unrolling loops that have a large number of iterations can significantly increase code generation time and generate inefficient code.

### Example Model

Open the example model `rtwdemo_unroll_parfor`. The model is configured to generate multithreaded code by selecting the **Generate parallel for loops** parameter.

```
model = 'rtwdemo_unroll_parfor';
open_system(model)
```

The MATLAB Function block contains this code:

```
type('myloop.m')

function y = myloop(u)
 y = ones(1,100);
 parfor (i = 1:5)
 y(i) = i+u;
 end
end
```

The code contains a parfor-loop that has five iterations.

### Generate Code by Using the Default Threshold Value

1. Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

2. Build the model.

```
slbuild(model);

Starting build procedure for: rtwdemo_unroll_parfor
Successful completion of build procedure for: rtwdemo_unroll_parfor
```

## Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_unroll_parfor	Code generated and compiled.	Code generation information file does not exist

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 37.248s

Inspect the generated `rtwdemo_unroll_parfor_step` step function in the `rtwdemo_unroll_parfor.c`.

```
file = fullfile('rtwdemo_unroll_parfor_ert_rtw','rtwdemo_unroll_parfor.c');
rtwdemodbtype(file,'/* Model step function */','/* Model initialize function',1,1);
```

```
/* Model step function */
void rtwdemo_unroll_parfor_step(void)
{
 int32_T i;
 int32_T i_0;

 /* MATLAB Function: '<Root>/MATLAB Function' */
 for (i_0 = 0; i_0 < 100; i_0++) {
 rtwdemo_unroll_parfor_Y.Outport[i_0] = 1.0;
 }

#pragma omp parallel for num_threads(omp_get_max_threads())

 for (i = 0; i < 5; i++) {
 rtwdemo_unroll_parfor_Y.Outport[i] = ((real_T)i + 1.0) + 2.0;
 }

 /* End of MATLAB Function: '<Root>/MATLAB Function' */
}
```

The code generator generates a parallel for-loop for the MATLAB Function block because it has 5 iterations which is equal to the default threshold value.

### Generate Code by Raising the Threshold Value

1. Open the Configuration Parameters dialog box. On the **Optimization** pane, set the **Loop unrolling threshold** to 6. Alternatively, use the command-line API:

```
set_param(model, 'RollThreshold','6')
```

Build the model. Inspect the generated `rtwdemo_unroll_parfor_step` step function in the `rtwdemo_unroll_parfor.c`.

```
slbuild(model);
file = fullfile('rtwdemo_unroll_parfor_ert_rtw','rtwdemo_unroll_parfor.c');
rtwdemodbtype(file,'/* Model step function */','/* Model initialize function',1,1);

Starting build procedure for: rtwdemo_unroll_parfor
Successful completion of build procedure for: rtwdemo_unroll_parfor
```

### Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_unroll_parfor	Code generated and compiled.	Generated code was out of date.

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 25.993s

```
/* Model step function */
void rtwdemo_unroll_parfor_step(void)
{
 int32_T i;

 /* MATLAB Function: '<Root>/MATLAB Function' */
 for (i = 0; i < 100; i++) {
 rtwdemo_unroll_parfor_Y.Outputport[i] = 1.0;
 }

 rtwdemo_unroll_parfor_Y.Outputport[0] = 3.0;
 rtwdemo_unroll_parfor_Y.Outputport[1] = 4.0;
 rtwdemo_unroll_parfor_Y.Outputport[2] = 5.0;
 rtwdemo_unroll_parfor_Y.Outputport[3] = 6.0;
 rtwdemo_unroll_parfor_Y.Outputport[4] = 7.0;

 /* End of MATLAB Function: '<Root>/MATLAB Function' */
}
```

The code generator unrolls the parallel for-loop and produces a copy of the loop body for each iteration because it has fewer iterations compared to the threshold value.

### Clean Up Example Folders and Files

Close the model and remove temporary folders and files.

```
bdclose(model);
cd(currentDir);
rtwdemoclean;
```

## Optimize Generated Code by Developing and Using Code Replacement Libraries - Simulink

Develop and use code replacement libraries to replace function and operators in generated code. Code replacement is a technique to change the code that the code generator produces for functions and operators to meet application code requirements. For example, you can replace generated code to meet requirements such as:

- Optimization for a specific run-time environment, including, but not limited to, specific target hardware
- Integration with existing application code
- Compliance with a standard, such as AUTOSAR
- Modification of code behavior, such as enabling or disabling nonfinite or inline support
- Application- or project-specific code requirements, such as use of BLAS or elimination of `math.h`, system header files, or calls to `memcpy` or `memset`.

You can configure a model such that the code generator uses a code replacement library that MathWorks® provides. If you have an Embedded Coder® license, you can develop your own code replacement library interactively with the Code Replacement Tool or programmatically.

This example uses models to show a variety of ways you can define code replacement mappings programmatically. Each model includes buttons that you can use to

- View the code replacement library table definitions from the Code Replacement Viewer
- Open the library table definition file in the editor
- Open the library registration file in the editor
- View the model configuration
- Generate code

For more information, see “Define Code Replacement Library Optimizations” on page 72-36 and “Register Code Replacement Library” on page 72-51.

### Steps for Developing a Code Replacement Library

- 1 Identify your code replacement requirements with respect to function or operating mappings, build information, and registration information.
- 2 Prepare for code replacement library development (for example, identify or develop models to test your library).
- 3 Define code replacement mappings.
- 4 Specify build information for replacement code.
- 5 Register code replacement mappings.
- 6 Verify code replacements.
- 7 Deploy the library.

For more information, see “Quick Start Code Replacement Library Development - Simulink” on page 72-21.

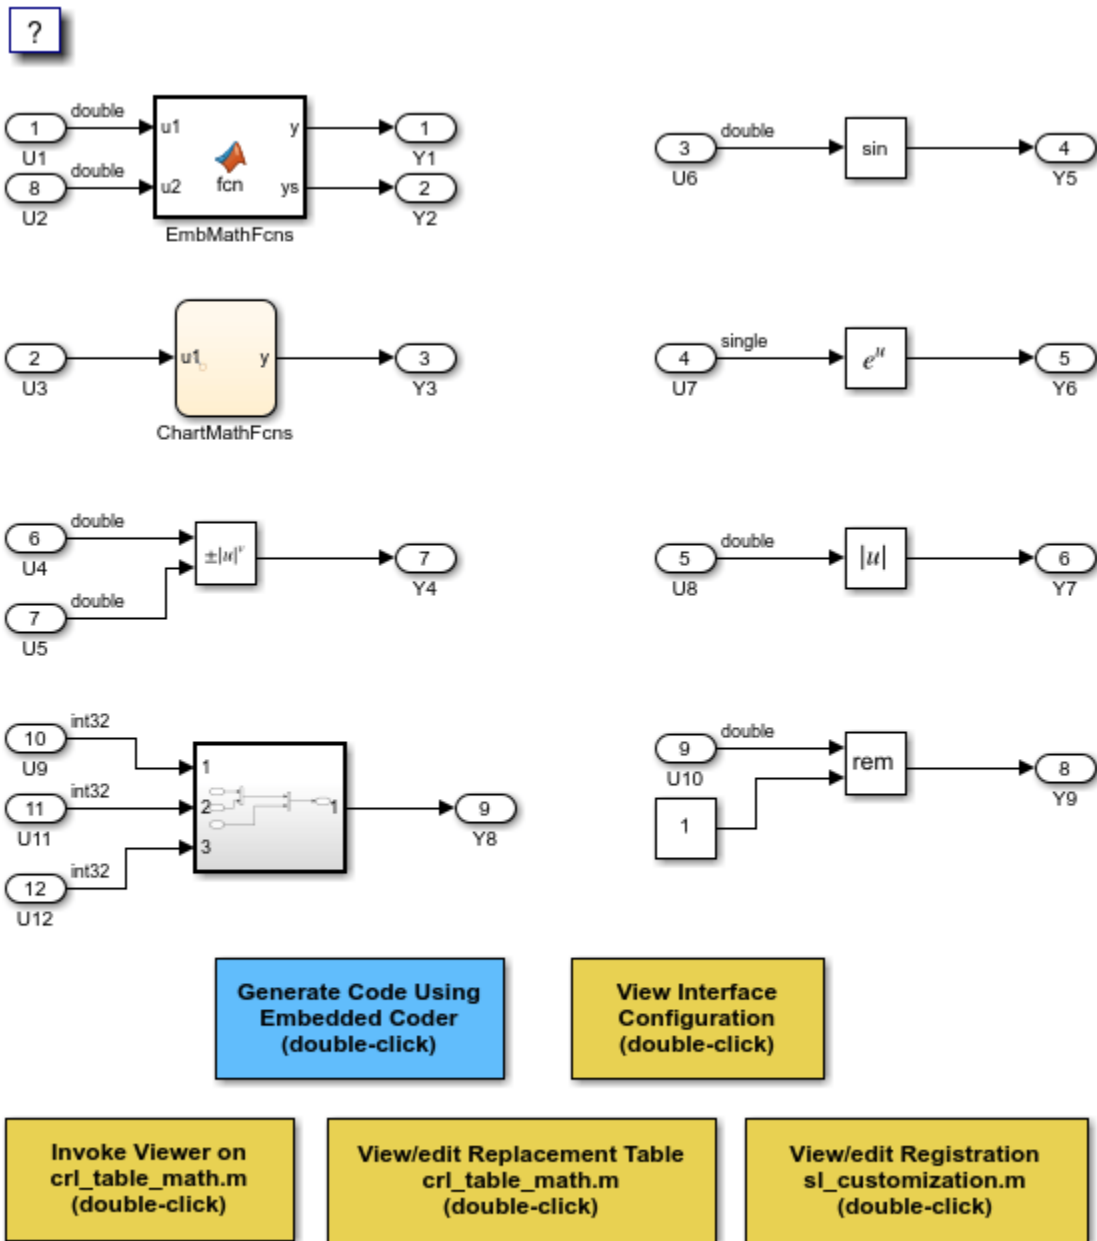

### **Math Function Replacement**

This example defines and registers code replacement mappings for math functions. You can define code replacement mappings for a variety of functions (see “Code You Can Replace From Simulink Models” on page 72-6).

Open the model `rtwdemo_crlmath` and use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

For more information, see “Math Function Code Replacement” on page 72-64.

```
open_system('rtwdemo_crlmath')
```

Copyright 2007-2020 The MathWorks, Inc.

### Addition and Subtraction Operator Replacement

This example shows how to define and register code replacement mappings for addition (+) and subtraction (-) operations. When defining entries for addition and subtraction operations, you can specify which of the following algorithms (EntryInfoAlgorithm) your library functions implement:

- Cast-before-operation (CBO) (RTW\_CAST\_BEFORE\_OP), the default
- Cast-after-operation (CAO) (RTW\_CAST\_AFTER\_OP)

1. Open the model `rtwdemo_crladdsub`. The model shows how to define and register code replacement mappings for scalar addition subtraction (-) operations on two operands with the following pairings of built-in integer data types:

- `int8, uint8`
- `int16, uint16`
- `int32, uint32`

CBO, the default algorithm, is assumed.

```
open_system('rtwdemo_crladdsub')
```

?

**Generate Code Using Embedded Coder (double-click)**

**View Interface Configuration (double-click)**

**Invoke Viewer on `crl_table_addsub.m` (double-click)**

**View/edit Replacement Table `crl_table_addsub.m` (double-click)**

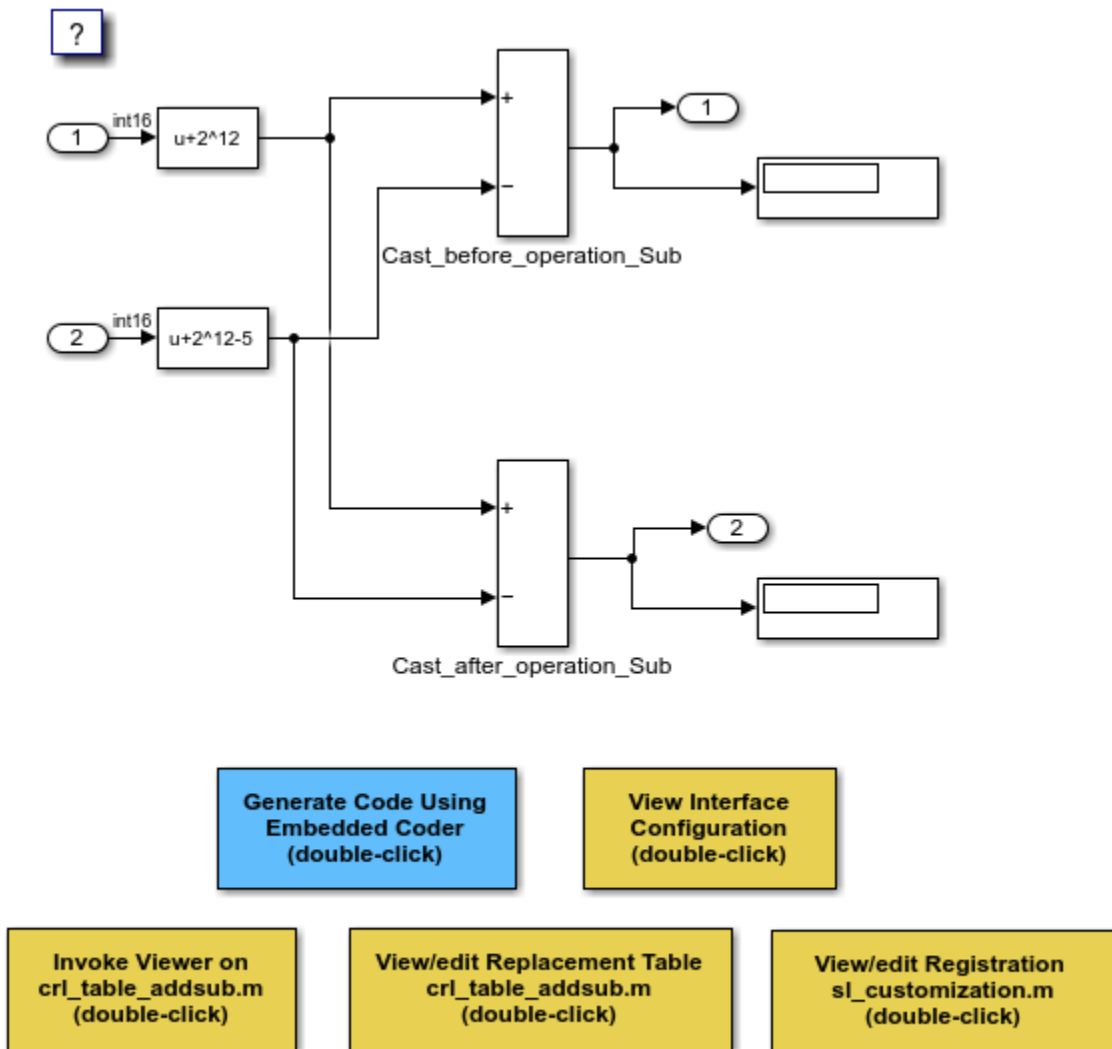

**View/edit Registration `sl_customization.m` (double-click)**

2. Use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

3. Explore the differences between the CBO and CAO algorithms by opening the model `rtwdemo_crl_cbo_cao`. The model shows two SUM blocks, each demonstrating one of the algorithm settings to match a corresponding code replacement entry.

- For the `Cast_before_operation_Sub` block, the code generator calculates the subtraction operation in the accumulator data type (`int8`), which is smaller than the input data type (`int16`). This is equivalent to a CBO because the code generator converts the input to the output data type before calculating the result.
- For the `Cast_after_operation_Sub` block, the code generator calculates the subtraction operation in the accumulator data type (`int32`), which is larger than the input data type (`int16`). This is equivalent to a CAO because the code generator produces the same result by calculating the result without loss of range or precision before converting to the output data type.

```
open_system('rtwdemo_crl_cbo_cao')
```

Copyright 2014-2020 The MathWorks, Inc.

4. Use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

For more information on addition and subtraction operator replacement, see “Replace Addition and Subtraction Operator Code” on page 72-151. For more information on the addition and subtraction algorithm (EntryInfoAlgorithm) options, see `setTfLCOperationEntryParameters`.

### Multiplication and Division Operator Replacement for Built-In Integers

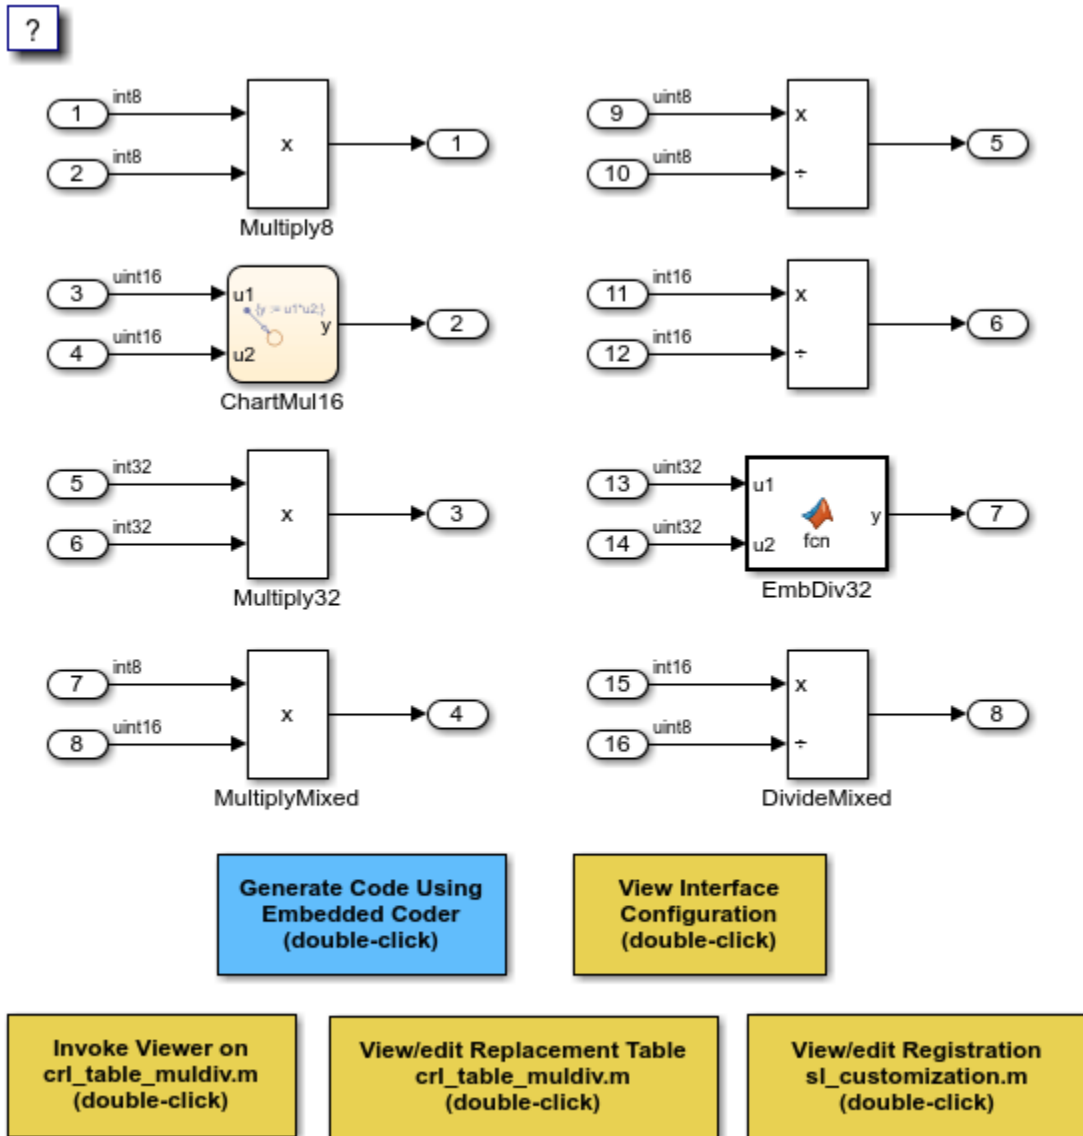

This example defines and registers code replacement mappings for scalar multiplication (\*) and division (/) operations. The operations take two operands with the following pairings of built-in integer data types:

- `int8, uint8`

- int16, uint16
- int32, uint32

Open the model `rtwdemo_crlmuldiv` and use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

`open_system('rtwdemo_crlmuldiv')`

Copyright 2007-2020 The MathWorks, Inc.

### Scalar Operator Replacement

This example defines and registers code replacement mappings for scalar operations: addition, subtraction, multiplication, complex conjugate, cast, arithmetic shift right, and arithmetic shift left.

Supported types include:

- single, double
- int8, uint8
- int16, uint16
- int32, uint32
- csingle, cdouble
- cint8, cuint8
- cint16, cuint16
- cint32, cuint32
- fixed-point integers
- mixed types (different type on each input)

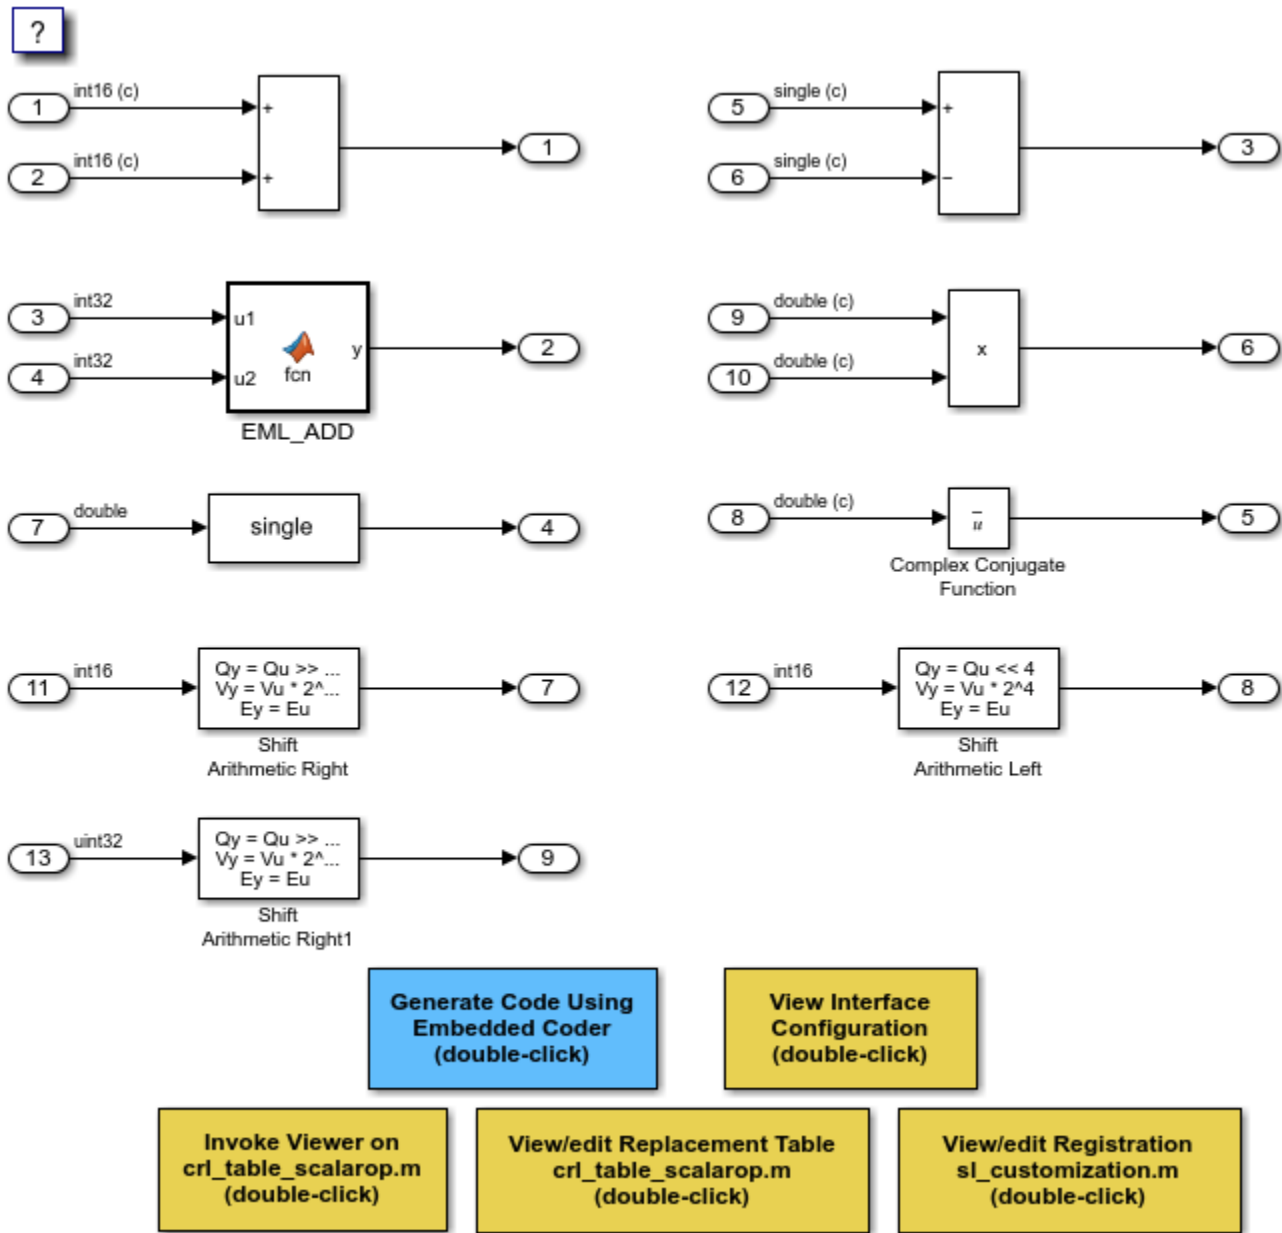

Open the model `rtwdemo_crlscalarops` and use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

For more information on scalar operator replacement, “Scalar Operator Code Replacement” on page 72-143.

CBO, the default algorithm for addition and subtraction operations, is assumed.

```
open_system('rtwdemo_crlscalarops')
```

Copyright 2007-2020 The MathWorks, Inc.

### Matrix Operator Replacement

This example defines and registers code replacement mappings for matrix operations: addition, subtraction, multiplication, transposition, conjugate, and Hermitian.

Supported types include:

- single, double
- int8, uint8

- `int16, uint16`
- `int32, uint32`
- `csingle, cdouble`
- `cint8, cuint8`
- `cint16, cuint16`
- `cint32, cuint32`
- fixed-point integers
- mixed types (different type on each input)

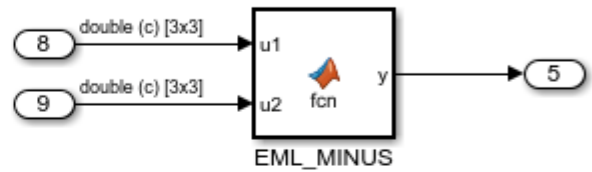

Open the model `rtwdemo_crlmatops`, which shows some of these replacements. Use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

For more information on matrix operator replacement, see “Small Matrix Operation to Processor Code Replacement” on page 72-175.

CBO, the default algorithm for addition and subtraction operations, is assumed.

```
open_system('rtwdemo_crlmatops')
```

### **Matrix Multiplication Replacement for BLAS**

This example defines and registers code replacement mappings for Basic Linear Algebra Subroutines (BLAS) subroutines xGEMM and xGEMV. You can map the following operations to a BLAS subroutine:

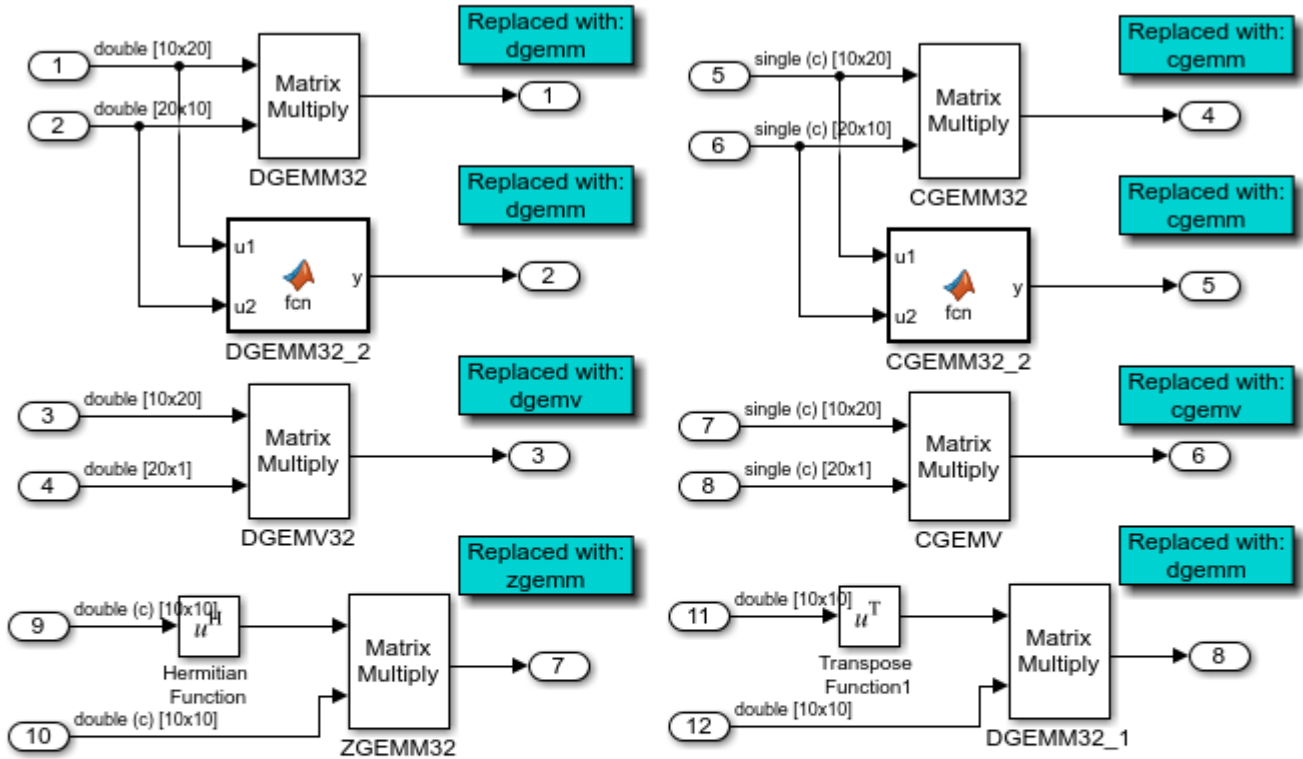

- Matrix multiplication
- Matrix multiplication with transpose on single or both inputs
- Matrix multiplication with Hermitian operation on single or both inputs

Open the model `rtwdemo_cr\blas` and use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

For more information on matrix multiplication replacement for BLAS, see “Matrix Multiplication Operation to MathWorks BLAS Code Replacement” on page 72-158.

```
open_system('rtwdemo_cr\blas')
```

### Fixed-Point Operator Replacement for Basic Operators

This example defines and registers code replacement mappings for scalar addition (+), subtraction (-), multiplication (\*), and division (/) operations. The operations take two operands with fixed-point data types.

You can define code replacements as matching:

- Slope/bias scaling combination on the inputs and output
- Binary-point scaling combination on the inputs and output

- Relative scaling between the inputs and output
- Same slope value and a zero net bias across the inputs and output

Open the model `rtwdemo_crlfixpt` and use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

- By default, for addition and subtraction operator code replacements, the code generator assumes that replacement code implements a cast-before-operation (CBO) algorithm.
- Using fixed-point data types in a model requires a Fixed-Point Designer™ license.

For more information about fixed-point operator code replacement, see “Fixed-Point Operator Code Replacement” on page 72-186.

```
open_system('rtwdemo_crlfixpt')
```

### Match and Replacement Process Customization for Functions

This example defines and registers code replacement mappings for custom entries. You can create your own entry by subclassing from `RTW.TflCFunctionEntryML` or `RTW.TflCOperationEntryML`. Your entry class must implement a `do_match` method that customizes your matching logic or modifies the matched entry. The `do_match` method must have a fixed preset signature.

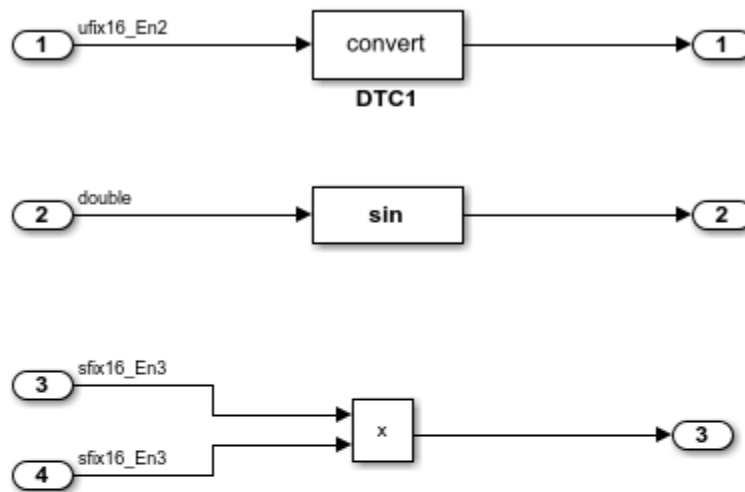

Open the model `rtwdemo_crlcustomentry`. The model shows how to modify the matched entry by injecting constants as additional implementation function arguments. `DTC1`, `Trigonometric Function`, and `Product` show custom entry code replacement for:

- Cast operation that demonstrates how to extract the fraction lengths from types and pass them into the implementation function - `Out1 = custom_cast(In1, 2, 4)`.
- Sine that demonstrates how to pass a constant value to the implementation function - `Out2=custom_sin(In2, 1)`.
- Multiplication operation that demonstrates how to compute the net slope of an operation and pass that into the implementation function - `Out3=custom_multiply_shift_right(In3,In4,3)`.

Use the buttons at the bottom of the model window to explore the files that define and register the code replacement mappings.

For more information on custom entries, see “Customize Match and Replacement Process” on page 72-132.

```
open_system('rtwdemo_crlcustomentry')
```

**Generate Code Using Embedded Coder (double-click)**

## MATLAB Function Replacement

This example defines and registers code replacement mappings for MATLAB® functions specified in the MATLAB Function block. The function can be opted for replacement by specifying `coder.replace` within it. This feature supports replacement of MATLAB functions with the following:

- Single or multiple inputs
- Single or multiple outputs
- Scalar and matrix inputs and outputs

Open the model `rtwdemo_crlcoderreplace`. The model shows some of these requirements. Supported types include:

- `single`, `double`
- `int8`, `uint8`
- `int16`, `uint16`
- `int32`, `uint32`
- `csingle`, `cdouble`
- `cint8`, `cuint8`
- `cint16`, `cuint16`
- `cint32`, `cuint32`
- Fixed-point integers
- Mixed types (different type on each input)

Use the buttons at the bottom of the model window to explore the files that define and register the code replacement mappings.

For more information on MATLAB function replacement, see `coder.replace`.

```
open_system('rtwdemo_crlcoderreplace')
```

Copyright 2012-2020 The MathWorks, Inc.

## Data Alignment for Function Implementations

This example shows how to specify the alignment of matrix operands passed into a replacement function. Some target-specific function implementations require data to be aligned to optimize application performance. To configure data alignment for a function implementation:

- Specify the data alignment requirements in a table entry. You can specify alignment for implementation function arguments individually or collectively.
- Specify the data alignment capabilities and syntax for your compiler. Attach an `AlignmentSpecification` object to the `TargetCharacteristics` object of the registry entry specified in your `rtwTargetInfo.m` file.

Open the model `rtwdemo_crlalign`. The model shows three data alignment code replacement scenarios:

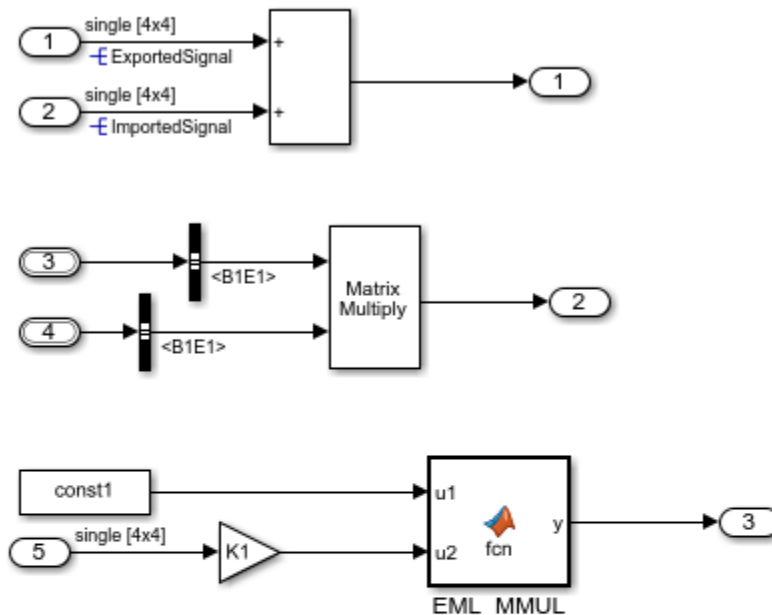

- Add - Alignment of exported and imported signals. You can specify an exact value for the alignment in the Signal Properties dialog box or allow the code generator to determine the best alignment based on usage by leaving the alignment value set to -1.

- **Product** - Alignment of virtual and nonvirtual bus types. You can specify an exact value for the alignment for the **Alignment** property of the Simulink.Bus object or allow the code generator to determine the best alignment based on usage by leaving the **Alignment** property set to -1.
- **EML\_MMUL** - Alignment of local variables, global variables, and block parameters.

Use the buttons at the bottom of the model window to explore the files that define and register the code replacement mappings. Note that the model is configured to use a GCC, Clang, MSVC, or MinGW compiler.

For more information on specifying data alignment for code replacement, see “Data Alignment for Code Replacement” on page 72-105.

```
open_system('rtwdemo_crlalign')
```

### Code Replacement Library Exploration and Verification

This example shows Code Replacement Viewer. You can use the Code Replacement Viewer to:

- Explore which code replacement library to use
- Verify the list of tables in a library and the entries in each table
- Review table entry specifications
- Troubleshoot code replacement misses

The following commands open the Code Replacement Viewer for code replacement table `crl_tablemuldiv`:

```
crl = crl_table_muldiv;
crviewer(crl);
```

For more information on the Code Replacement Viewer, see “Verify Code Replacement Library” on page 72-55.

### Build Information

For each entry in a code replacement table, you can specify build information such as the following, for replacement functions:

- Header file dependencies
- Source file dependencies
- Additional include paths
- Additional source paths
- Additional link flags

Additionally, you can specify `RTW.copyFileToBuildDir` to copy header, source, or object files, which are required to generate replacement code, to the build folder before code generation. You can specify `RTW.copyFileToBuildDir` by setting it as the value of:

- Property `GenCallback` in a call to `setTflCFunctionEntryParameters`, `setTflCOperationEntryParameters`, or `setTflCSemaphoreEntryParameters`.
- Argument `genCallback` in a call to `registerCFunctionEntry`, `registerCOperationEntry`, or `registerCSemaphoreEntry`.

**Note:** Models in this example are configured for code generation only because the implementations for the replacement functions are not provided.

For more information on specifying build information, see Specify build information in “Define Code Replacement Library Optimizations” on page 72-36.

### Reserved Identifiers

Each function implementation name defined by a code replacement table entry is reserved as a unique identifier. You can specify other identifiers with a table on a per-header-file basis. Providing additional reserved identifiers can help prevent duplicate symbols and other identifier related compile and link issues.

For more information on specifying reserved identifiers, see “Reserved Identifiers and Code Replacement” on page 72-131.

## Remove Example Code Replacement Libraries

When you finish using the example models, remove the example code replacement libraries and close the example models with these commands:

```
rmpath(fullfile(matlabroot, 'toolbox', 'rtw', 'rtwdemos', 'crl_demo'));
sl_refresh_customizations;

close_system('rtwdemo_crladdsub', 0)
close_system('rtwdemo_crl_cbo_cao', 0)
close_system('rtwdemo_crlmuldiv', 0)
close_system('rtwdemo_crlfixpt', 0)
close_system('rtwdemo_crlmath', 0)
close_system('rtwdemo_crlmatops', 0)
close_system('rtwdemo_crlblas', 0)
close_system('rtwdemo_crlscalarops', 0)
close_system('rtwdemo_crlcustomentry', 0)
close_system('rtwdemo_crlcoderreplace', 0)
close_system('rtwdemo_crlalign', 0)

drawnow;
if exist('h', 'var') && ishghandle(h)
 close(h);
end

clear h;
clear isDaDemoSupported;
clear crl;

rtwdemoclean;

Warning: Unrecognized function or variable

Warning: Unrecognized function or variable 'customizationXpcCrlRegistration'.
```

## Improve Execution Efficiency by Reordering Block Operations in the Generated Code

To improve execution efficiency, the code generator can change the block execution order. In the Configuration Parameters dialog box, when you set the **Optimize Block Order** parameter to **Improved Execution Speed**, the code generator can change the block operation order to implement these optimizations:

- Eliminate data copies for blocks that perform inplace operations (that is, use the same input and output variable) and contain algorithm code with unnecessary data copies.
- Combine more `for` loops by executing blocks together that have the same size.
- Reuse the same variable for the input, output, and state of a Unit Delay block by executing the Unit Delay block before upstream blocks.

These optimizations improve execution speed and conserve RAM and ROM consumption.

### Example Model

Open the model `rtwdemo_optimizeblockorder`. This model contains three subsystems for demonstrating how reordering block operations improves execution efficiency.

Copyright 2017 The MathWorks, Inc.

### for Loop Fusion

The subsystem LoopFusionScheduling shows how the code generator reorders block operations so that blocks that have the same output size execute together. This reordering enables for loop fusion. Set the **Optimize block order in the generated code** parameter to Off.

In your system's temporary folder, create a folder for the build and inspection process and build the model.

```
Starting build procedure for: rtwdemo_optimizeblockorder
Successful completion of build procedure for: rtwdemo_optimizeblockorder
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
-------	--------	----------------

rtwdemo\_optimizeblockorder Code generated and compiled. Code generation information file does not exist.

1 of 1 models built (0 models already up to date)

Build duration: 0h 0m 29.679s

View the generated code without the optimization. Code for the LoopFusionScheduling subsystem:

```

/* Output and update for atomic system: '<Root>/LoopFusionScheduling' */
static void LoopFusionScheduling(const real_T rtu_In1[6], const real_T rtu_In2[6],
 const real_T rtu_In3[6], const real_T rtu_In4[6], real_T rty_Out1[6], real_T
 rty_Out2[9], real_T rty_Out3[6], real_T rty_Out4[9])
{
 int32_T i;
 int32_T i_0;
 int32_T tmp;
 int32_T tmp_0;

 /* Bias: '<S2>/Bias' incorporates:
 * Gain: '<S2>/Gain'
 */
 for (i = 0; i < 6; i++) {
 rty_Out1[i] = -0.3 * rtu_In1[i] + 0.5;
 }

 /* End of Bias: '<S2>/Bias' */

 /* Product: '<S2>/Product' */
 for (i = 0; i < 3; i++) {
 for (i_0 = 0; i_0 < 3; i_0++) {
 tmp = 3 * i + i_0;
 rty_Out2[tmp] = 0.0;
 tmp_0 = i << 1;
 rty_Out2[tmp] += rtu_In2[tmp_0] * rtu_In1[i_0];
 rty_Out2[tmp] += rtu_In2[tmp_0 + 1] * rtu_In1[i_0 + 3];
 }
 }

 /* End of Product: '<S2>/Product' */

 /* Bias: '<S2>/Bias1' incorporates:
 * Gain: '<S2>/Gain1'
 */
 for (i = 0; i < 6; i++) {
 rty_Out3[i] = -0.3 * rtu_In3[i] + 0.5;
 }

 /* End of Bias: '<S2>/Bias1' */

 /* Product: '<S2>/Product1' */
 for (i = 0; i < 3; i++) {
 for (i_0 = 0; i_0 < 3; i_0++) {
 tmp = 3 * i + i_0;
 rty_Out4[tmp] = 0.0;
 tmp_0 = i << 1;
 rty_Out4[tmp] += rtu_In4[tmp_0] * rtu_In3[i_0];
 rty_Out4[tmp] += rtu_In4[tmp_0 + 1] * rtu_In3[i_0 + 3];
 }
 }
}

```

```

 }
}

/* End of Product: '<S2>/Product1' */
}

```

With the default execution order, the blocks execute from left to right and from top to bottom. As a result, there are separate **for** loops for the two combinations of Gain and Bias blocks and the Product blocks.

Generate code with the optimization. Set the **Optimize block order in the generated code** parameter to **Improved Execution Speed** and build the model.

```

Starting build procedure for: rtwdemo_optimizeblockorder
Successful completion of build procedure for: rtwdemo_optimizeblockorder

```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_optimizeblockorder	Code generated and compiled.	Generated code was out of date.

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 24.297s

View the generated code with the optimization.

```

/* Output and update for atomic system: '<Root>/LoopFusionScheduling' */
static void LoopFusionScheduling(const real_T rtu_In1[6], const real_T rtu_In2[6],
 const real_T rtu_In3[6], const real_T rtu_In4[6], real_T rty_Out1[6], real_T
 rty_Out2[9], real_T rty_Out3[6], real_T rty_Out4[9])
{
 int32_T i;
 int32_T i_0;
 int32_T tmp;
 int32_T tmp_0;
 for (i = 0; i < 3; i++) {
 for (i_0 = 0; i_0 < 3; i_0++) {
 /* Product: '<S2>/Product' incorporates:
 * Product: '<S2>/Product1'
 */
 tmp = 3 * i + i_0;
 rty_Out2[tmp] = 0.0;

 /* Product: '<S2>/Product1' */
 rty_Out4[tmp] = 0.0;

 /* Product: '<S2>/Product' incorporates:
 * Product: '<S2>/Product1'
 */
 tmp_0 = i << 1;
 rty_Out2[tmp] += rtu_In2[tmp_0] * rtu_In1[i_0];

 /* Product: '<S2>/Product1' */
 rty_Out4[tmp] += rtu_In4[tmp_0] * rtu_In3[i_0];
 }
 }
}

```

```

 /* Product: '<S2>/Product' */
 rty_Out2[tmp] += rtu_In2[tmp_0 + 1] * rtu_In1[i_0 + 3];

 /* Product: '<S2>/Product1' incorporates:
 * Product: '<S2>/Product'
 */
 rty_Out4[tmp] += rtu_In4[tmp_0 + 1] * rtu_In3[i_0 + 3];
 }
}

for (i = 0; i < 6; i++) {
 /* Bias: '<S2>/Bias' incorporates:
 * Gain: '<S2>/Gain'
 */
 rty_Out1[i] = -0.3 * rtu_In1[i] + 0.5;

 /* Bias: '<S2>/Bias1' incorporates:
 * Gain: '<S2>/Gain1'
 */
 rty_Out3[i] = -0.3 * rtu_In3[i] + 0.5;
}
}

```

In the optimized code, blocks with the same output size execute together. The two sets of Gain and Bias blocks have an output dimension size of 6, so they execute together. The Product blocks have an output dimension size of 9, so they execute together. The fusion of for loops enables the code generator to set the value of the expression  $3 * i + i\_0$  equal to the temporary variable `tmp_0`. This optimization also improves execution efficiency.

### Buffer Reuse for the Input, Output, and State of Unit Delay Blocks

The subsystem `RegionScheduling` shows how the code generator reorders block operations to enable buffer reuse for the input, output, and state of Unit Delay blocks. When computation is part of separate regions that connect only through Delay blocks, the code generator can change the block execution order so that the downstream regions execute before the upstream regions. This execution order enables maximum reuse of Delay block states and input and output variables. Set the **Optimize block order in the generated code** parameter to `Off` and build the model.

```

Starting build procedure for: rtwdemo_optimizeblockorder
Successful completion of build procedure for: rtwdemo_optimizeblockorder

```

Build Summary

Top model targets built:

```

/* Output and update for atomic system: '<Root>/RegionScheduling' */

```

```

static void RegionScheduling(const real_T rtu_In1[6], const real_T rtu_In2[6],
 real_T rty_Out1[6], rtDW_RegionScheduling *localDW)
{
 real_T rtb_Sum_h;
 int32_T i;
 for (i = 0; i < 6; i++) {
 /* Sum: '<S3>/Sum' incorporates:
 * UnitDelay: '<S3>/Delay'
 * UnitDelay: '<S3>/UnitDelay'
 */
 rtb_Sum_h = localDW->Delay_DSTATE[i] + localDW->UnitDelay_DSTATE[i];

 /* UnitDelay: '<S3>/UnitDelay2' */
 rty_Out1[i] = localDW->UnitDelay2_DSTATE[i];

 /* Update for UnitDelay: '<S3>/Delay' incorporates:
 * Bias: '<S3>/Bias'
 */
 localDW->Delay_DSTATE[i] = rtu_In1[i] + 3.0;

 /* Update for UnitDelay: '<S3>/UnitDelay' incorporates:
 * Gain: '<S3>/Gain'
 */
 localDW->UnitDelay_DSTATE[i] = 2.0 * rtu_In2[i];

 /* Update for UnitDelay: '<S3>/UnitDelay2' */
 localDW->UnitDelay2_DSTATE[i] = rtb_Sum_h;
 }
}

```

With the default execution order, the generated code contains the extra, temporary variable `rtb_Sum` and a data copy.

Generate code with the optimization. Set the **Optimize block order in the generated code** parameter to **Improved Execution Speed** and build the model.

```

Starting build procedure for: rtwdemo_optimizeblockorder
Successful completion of build procedure for: rtwdemo_optimizeblockorder

```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason

1 of 1 models built (0 models already up to date)  
 Build duration: 0h 0m 24.193s

View the generated code with the optimization.

```

/* Output and update for atomic system: '<Root>/RegionScheduling' */
static void RegionScheduling(const real_T rtu_In1[6], const real_T rtu_In2[6],
 real_T rty_Out1[6], rtDW_RegionScheduling *localDW)
{
 int32_T i;

```

```

for (i = 0; i < 6; i++) {
 /* UnitDelay: '<S3>/UnitDelay2' */
 rty_Out1[i] = localDW->UnitDelay2_DSTATE[i];

 /* Sum: '<S3>/Sum' incorporates:
 * UnitDelay: '<S3>/Delay'
 * UnitDelay: '<S3>/UnitDelay'
 * UnitDelay: '<S3>/UnitDelay2'
 */
 localDW->UnitDelay2_DSTATE[i] = localDW->Delay_DSTATE[i] +
 localDW->UnitDelay_DSTATE[i];

 /* Bias: '<S3>/Bias' incorporates:
 * UnitDelay: '<S3>/Delay'
 */
 localDW->Delay_DSTATE[i] = rty_In1[i] + 3.0;

 /* Gain: '<S3>/Gain' incorporates:
 * UnitDelay: '<S3>/UnitDelay'
 */
 localDW->UnitDelay_DSTATE[i] = 2.0 * rty_In2[i];
}
}

```

In the optimized code, the blocks in Regions 3, 2, and 1 execute in that order. With that execution order, the generated code does not contain the temporary variable `rtb_Sum` and the corresponding data copy.

### Eliminate Data Copies for Blocks That Perform Inplace Operations

The subsystem `InplaceScheduling` shows how the code generator reorders block operations to eliminate data copies for blocks that perform inplace operations. In the Configuration Parameters dialog box, set the **Optimize block order in the generated code** parameter to `Off` and build the model.

```

Starting build procedure for: rtwdemo_optimizeblockorder
Successful completion of build procedure for: rtwdemo_optimizeblockorder

```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_optimizeblockorder	Code generated and compiled.	Generated code was out of date.

1 of 1 models built (0 models already up to date)

Build duration: 0h 0m 21.62s

View the generated code without the optimization. Code for the `InplaceScheduling` subsystem:

```

/* Output and update for atomic system: '<Root>/InplaceScheduling' */
static void InplaceScheduling(void)
{
 real_T rtb_Max[6];
 real_T acc;
 int32_T idx1;

```

```

int32_T idx2;
int32_T k;
for (idx1 = 0; idx1 < 6; idx1++) {
 /* Sum: '<S1>/Sum2x3' incorporates:
 * Inport: '<Root>/In7'
 * UnitDelay: '<S1>/Unit Delay'
 */
 rtDWork.UnitDelay_DSTATE[idx1] += rtU.In7[idx1];

 /* MinMax: '<S1>/Max' */
 acc = rtDWork.UnitDelay_DSTATE[idx1];
 if (acc <= 2.0) {
 rtb_Max[idx1] = 2.0;
 } else {
 rtb_Max[idx1] = acc;
 }

 /* End of MinMax: '<S1>/Max' */
}

/* S-Function (sdsp2norm2): '<S1>/Normalization' incorporates:
 * Outport: '<Root>/Out7'
 */
idx1 = 0;
idx2 = 0;
acc = 0.0;
for (k = 0; k < 6; k++) {
 acc += rtb_Max[idx1] * rtb_Max[idx1];
 idx1++;
}

acc = 1.0 / (sqrt(acc) + 1.0E-10);
for (k = 0; k < 6; k++) {
 rtY.Out7[idx2] = rtb_Max[idx2] * acc;
 idx2++;

 /* Outport: '<Root>/Out6' incorporates:
 * Bias: '<S1>/Bias'
 * Inport: '<Root>/In8'
 * Outport: '<Root>/Out7'
 * Product: '<S1>/Product'
 */
 rtY.Out6[k] = (rtU.In8 + 1.0) * rtDWork.UnitDelay_DSTATE[k];

 /* Switch: '<S1>/Switch' incorporates:
 * Inport: '<Root>/In9'
 */
 if (rtU.In9[k] > 0.0) {
 /* Update for UnitDelay: '<S1>/Unit Delay' incorporates:
 * Sum: '<S1>/Sum2x3'
 */
 rtDWork.UnitDelay_DSTATE[k] = 0.0;
 } else {
 /* Update for UnitDelay: '<S1>/Unit Delay' incorporates:
 * Sum: '<S1>/Sum2x3'
 */
 rtDWork.UnitDelay_DSTATE[k] = rtb_Max[k];
 }
}

```

```

 /* End of Switch: '<S1>/Switch' */
 }

 /* End of S-Function (sdsp2norm2): '<S1>/Normalization' */
}

```

With the default execution order, the Max block executes before the Product block. To hold the Sum block output, the generated code contains two variables, UnitDelay\_DSTATE and rtb\_Max.

Generate code with the optimization. Set the **Optimize block order in the generated code** parameter to **Improved Execution Speed** and build the model.

```

Starting build procedure for: rtwdemo_optimizeblockorder
Successful completion of build procedure for: rtwdemo_optimizeblockorder

```

Build Summary

/* Output and update for atomic system: '<Root>/InplaceScheduling' */
static void InplaceScheduling(void)
{
 real_T acc;
 int32_T idx1;
 int32_T idx2;
 int32_T k;
 for (idx1 = 0; idx1 < 6; idx1++) {
 /* Sum: '<S1>/Sum2x3' incorporates:
 * Inport: '<Root>/In7'
 * MinMax: '<S1>/Max'
 * UnitDelay: '<S1>/Unit Delay'
 */
 rtDWork.UnitDelay_DSTATE[idx1] += rtU.In7[idx1];

 /* Outport: '<Root>/Out6' incorporates:
 * Bias: '<S1>/Bias'
 * Inport: '<Root>/In8'
 * Product: '<S1>/Product'
 */
 rtY.Out6[idx1] = (rtU.In8 + 1.0) * rtDWork.UnitDelay_DSTATE[idx1];

 /* MinMax: '<S1>/Max' */
 acc = rtDWork.UnitDelay_DSTATE[idx1];
 if (acc <= 2.0) {
 rtDWork.UnitDelay_DSTATE[idx1] = 2.0;
 } else {
 rtDWork.UnitDelay_DSTATE[idx1] = acc;
 }
 }
}

```

```

 }

 /* End of MinMax: '<S1>/Max' */
}

/* S-Function (sdsp2norm2): '<S1>/Normalization' incorporates:
 * Output: '<Root>/Out7'
 */
idx1 = 0;
idx2 = 0;
acc = 0.0;
for (k = 0; k < 6; k++) {
 acc += rtDWork.UnitDelay_DSTATE[idx1] * rtDWork.UnitDelay_DSTATE[idx1];
 idx1++;
}

acc = 1.0 / (sqrt(acc) + 1.0E-10);
for (k = 0; k < 6; k++) {
 rtY.Out7[idx2] = rtDWork.UnitDelay_DSTATE[idx2] * acc;
 idx2++;
}

/* End of S-Function (sdsp2norm2): '<S1>/Normalization' */

/* Update for UnitDelay: '<S1>/Unit Delay' */
for (idx1 = 0; idx1 < 6; idx1++) {
 /* Switch: '<S1>/Switch' incorporates:
 * Inport: '<Root>/In9'
 * MinMax: '<S1>/Max'
 */
 if (rtU.In9[idx1] > 0.0) {
 rtDWork.UnitDelay_DSTATE[idx1] = 0.0;
 }

 /* End of Switch: '<S1>/Switch' */
}

/* End of Update for UnitDelay: '<S1>/Unit Delay' */
}

```

The optimized code does not contain the variable `rtb_Max` or the data copy. The generated code contains one variable, `UnitDelay_DSTATE`, for holding the Sum block output. The Product block reads from `UnitDelay_DSTATE` and the Max block reads from and writes to `UnitDelay_DSTATE`.

To implement buffer reuse, the code generator does not violate user-specified block priorities.

## Optimize SIMD Code by Performing Fused Multiply Add Operations

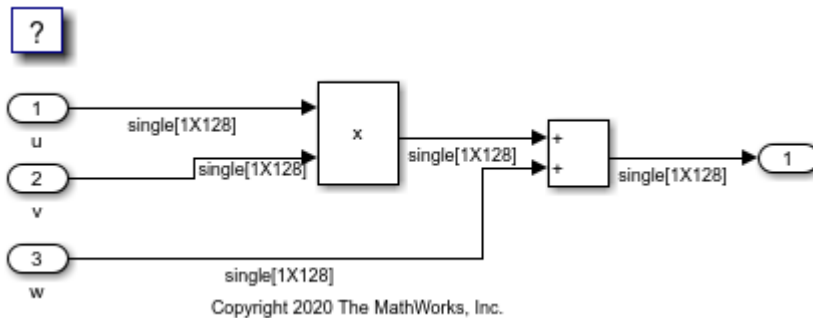

This example shows how to generate optimized single instruction, multiple data (SIMD) code that performs fused multiply-add operations. A fused multiply-add operation is performed in one step with a single rounding rather than performing a multiplication operation followed by an addition, with multiple roundings.

For processors that support fused multiply-add (FMA) instructions, when you set the **Leverage target hardware instruction set** to FMA, the code generator generates code with FMA intrinsics to perform fused multiply-add operations. Using this optimization improves the execution speed of the generated SIMD code. Because of the single rounding behavior of fused multiply-add operations, this optimization might introduce a mismatch between simulation and code generation results.

### Example Model

Open the example model `rtwdemo_simd_with_fma`. The model contains a multiplication operation followed by an addition.

```
model = 'rtwdemo_simd_with_fma';
open_system(model)
```

### Generate SIMD Code Without FMA Optimization

1. Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

2. On the **Optimization** pane, set the **Leverage target hardware instruction set extensions** to SSE2. Alternatively, you can use the command-line API:

```
set_param(model, 'InstructionSetExtensions', 'SSE2');
```

3. Build the model.

```
slbuild(model);
```

```
Starting build procedure for: rtwdemo_simd_with_fma
Successful completion of build procedure for: rtwdemo_simd_with_fma
```

## Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_simd_with_fma	Code generated and compiled.	Code generation information file does not exist

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 26.11s

4. Inspect the generated `rtwdemo_simd_with_fma_step` step function in the `rtwdemo_simd_with_fma.c`.

```
file = fullfile('rtwdemo_simd_with_fma_ert_rtw','rtwdemo_simd_with_fma.c');
rtwdemodbtype(file,'/* Model step function */','/* Model initialize function',1,1);
```

```
/* Model step function */
void rtwdemo_simd_with_fma_step(void)
{
 int32_T i;
 for (i = 0; i <= 124; i += 4) {
 /* Outport: '<Root>/Out1' incorporates:
 * Inport: '<Root>/u'
 * Inport: '<Root>/v'
 * Inport: '<Root>/w'
 */
 _mm_storeu_ps(&rtwdemo_simd_with_fma_Y.Out1[i], _mm_add_ps(_mm_mul_ps
 (_mm_loadu_ps(&rtwdemo_simd_with_fma_U.single1X128[i]), _mm_loadu_ps
 (&rtwdemo_simd_with_fma_U.single1X128_f[i])), _mm_loadu_ps
 (&rtwdemo_simd_with_fma_U.single1X128_k[i])));
 }
}
```

The generated code contains a vectorized loop that performs the multiplication and addition operations sequentially, with two roundings.

### Generate SIMD Code with FMA Optimization

1. To enable FMA optimization, on the **Optimization** pane, set the **Leverage target hardware instruction set extensions** to FMA Alternatively, you can use the command-line API:

```
set_param(model, 'InstructionSetExtensions', 'FMA');
```

2. Build the model again.

```
[status, message, messageid] = rmdir('slprj', 's')
currentDir = pwd;
[~,cgDir] = rtwmoddir();
slbuild(model);
```

```
status =
 logical
```

```

1

message =

 0x0 empty char array

messageid =

 0x0 empty char array

Starting build procedure for: rtwdemo_simd_with_fma
Successful completion of build procedure for: rtwdemo_simd_with_fma

Build Summary

Top model targets built:

Build duration: 0h 0m 27.197s

```

3. Inspect the generated `rtwdemo_simd_with_fma_step` step function in the `rtwdemo_simd_with_fma.c`.

```

file = fullfile('rtwdemo_simd_with_fma_ert_rtw','rtwdemo_simd_with_fma.c');
rtwdemodbtype(file,'/* Model step function */','/* Model initialize function',1,1);

/* Model step function */
void rtwdemo_simd_with_fma_step(void)
{
 int32_T i;
 for (i = 0; i <= 120; i += 8) {
 /* Output: '<Root>/Out1' incorporates:
 * Inport: '<Root>/u'
 * Inport: '<Root>/v'
 * Inport: '<Root>/w'
 */
 _mm256_storeu_ps(&rtwdemo_simd_with_fma_Y.Out1[i], _mm256_fmadd_ps
 (_mm256_loadu_ps(&rtwdemo_simd_with_fma_U.single1X128[i]),
 _mm256_loadu_ps(&rtwdemo_simd_with_fma_U.single1X128_f[i]),
 _mm256_loadu_ps(&rtwdemo_simd_with_fma_U.single1X128_k[i])));
 }
}

```

The vectorized loop contains the intrinsic function `mm256_fmadd_ps` that performs multiplication-addition in one step, with a single rounding. This optimization improves the execution speed of the generated code. It is possible that the execution of the generated code does not produce the same result as the simulation.

The presence of FMA optimization is reported in the code generation report as follows.

**Code Information**

System Target File	ert.tlc
Hardware Device Type	Intel->x86-64 (Windows64)
Simulink Coder Version	9.6 (R2021b) 14-May-2021
Timestamp of Generated Source Code	Mon Jun 28 16:20:46 2021
Location of Generated Source Code	C:\Users\sferdous\Documents\Examples\ecoder-ex02442880\rtwdemo_simd_with_fma_ert_rtw
Type of Build	Model
Objectives Specified	Unspecified

**Additional Information**

Code Generation Advisor	Not run
FMA Instruction Set Extensions	FMA optimization is triggered

It is reported that the code generator used FMA instruction set extensions and the FMA optimization is triggered for the `rtwdemo_simd_with_fma` model code. If you are working with a model hierarchy and FMA optimization is triggered only for referenced models, the code generator does not report the presence of FMA optimization in the code generation report created for the top model.

**Clean Up Example Folders and Files**

Close the model and remove temporary folders and files.

```
bdclose(model);
cd(currentDir);
rtwdemoclean;
```

## Generate Parallel for-Loops Using the Open Multiprocessing (OpenMP) Application Interface

When you generate code from MATLAB Function, MATLAB System, and For Each subsystem blocks, by default the code generator produces code that implements for-loops in a single thread. If you have Parallel Computing Toolbox, you can specify that these for-loops run in parallel by selecting the **Generate parallel for-loops** parameter and by including the parfor statement in your MATLAB Function block and MATLAB System block code. Running iterations in parallel can significantly improve the execution speed of the generated code.

The code generator implements the for-loops in parallel by using the Open Multiprocessing (OpenMP) application interface to support shared-memory, multicore code generation. By default, the code generator uses as many threads as it finds available. For MATLAB Function and MATLAB System blocks using parfor, if you specify the number of threads to use, the code generator uses at most that number of threads, even if additional threads are available. The code generator cannot generate parallel for-loops for For Each Subsystem blocks that contain S-functions.

### Generate OpenMP Code from MATLAB Function or MATLAB System Blocks

In this example, you generate OpenMP code from a MATLAB Function block that contains the parfor statement as part of its code. Use the parfor to speed up execution when you have many iterations of a simple calculation or a loop iteration takes a long time to execute. For more on how parfor-loops improve execution speed and when to use them, see “Algorithm Acceleration Using Parallel for-Loops (parfor)”.

- 1 Create a model that contains a MATLAB Function or MATLAB System block. This example uses a MATLAB Function block.
- 2 Add this code to the MATLAB Function block.

```
function y = openmpex(u) %#codegen
% Copyright 2019 The MathWorks, Inc.

A = ones(20,50);
t = 0;

parfor (i = 1:10,4)
 A(i,1) = A(i,1) + 1;
end

y = A(1,4) + u + t;
```

Note the parfor input value of 4 specifies the maximum number of threads to use.

- 3 Connect the blocks.

- 4 Open the Configuration Parameters dialog box. On the **Code Generation** pane, and set the **System Target File** parameter to `ert.tlc`.
- 5 On the **Solver** pane, set the **Type** parameter to `Fixed-step`.
- 6 On the **Optimization** pane, set the **Priority** parameter to `Maximize execution speed`. Now, the **Generate parallel for-loops** parameter is automatically selected. This parameter enables the compiler to compute loops in parallel.
- 7 Build the model and generate code.

In the generated code, the pragma instructs the compiler to execute the looping in OpenMP parallel for-loops through multithreading:

```
#pragma omp parallel for num_threads(4 >
 omp_get_max_threads() ? omp_get_max_threads() : 4)
```

The number 4 indicates the number of processing threads.

Because the loop body can execute in parallel on multiple threads, it must conform to certain restrictions. If Embedded Coder detects loops that do not conform to `parfor` specifications, it produces an error. For more information, see “`parfor` Restrictions”.

## Optimize Generated Code Using Minimum and Maximum Values

To optimize the generated code for your model, you can choose an option to use input range information, also known as design minimum and maximum, that you specify on signals and parameters. These minimum and maximum values usually represent environmental limits, such as temperature, or mechanical and electrical limits, such as output ranges of sensors.

In the Configuration Parameters dialog box, on the **Optimization** pane, when you select the **Optimize using specified minimum and maximum values** check box, the software uses the minimum and maximum values to derive range information for downstream signals in the model. It then uses this derived range information to determine if it is possible to streamline the generated code by:

- Reducing expressions to constants
- Removing dead branches of conditional statements
- Eliminating unnecessary mathematical operations

This optimization results in:

- Reduced ROM and RAM consumption
- Improved execution speed

### Configure Your Model

To make optimization more likely:

- Provide as much design minimum and maximum information as possible. Specify minimum and maximum values for signals and parameters in the model for:
  - Inport and Outport blocks
  - Block outputs
  - Block inputs, for example, for the MATLAB Function and Stateflow Chart blocks
  - `Simulink.Signal` objects
- Before generating code, test the minimum and maximum values for signals and parameters. Otherwise, optimization might result in numerical mismatch with simulation. You can simulate your model with simulation range checking enabled. If errors or warnings occur, fix these issues before generating code.

#### Enable Simulation Range Checking

- 1 In the Configuration Parameters dialog box, select **Diagnostics > Data Validity**.
  - 2 On the **Data Validity** pane, under **Signals**, set **Simulation range checking** to warning or error.
- Provide design minimum and maximum information upstream of blocks as close to the inputs of the blocks as possible. If you specify minimum and maximum values for a block output, these values are most likely to affect the outputs of the blocks immediately downstream.

## Optimize Generated Code Using Specified Minimum and Maximum Values

This example shows how the minimum and maximum values specified on signals and parameters in a model are used to optimize the generated code.

### Overview

The specified minimum and maximum values usually represent environmental limits, such as temperature, or mechanical and electrical limits, such as output ranges of sensors.

This optimization uses these values to streamline the generated code. For example, it reduces expressions to constants or removes dead branches of conditional statements.

**NOTE:** Make sure the minimum and maximum values that you specify are valid limits. Otherwise, this optimization might result in numerical mismatch with simulation.

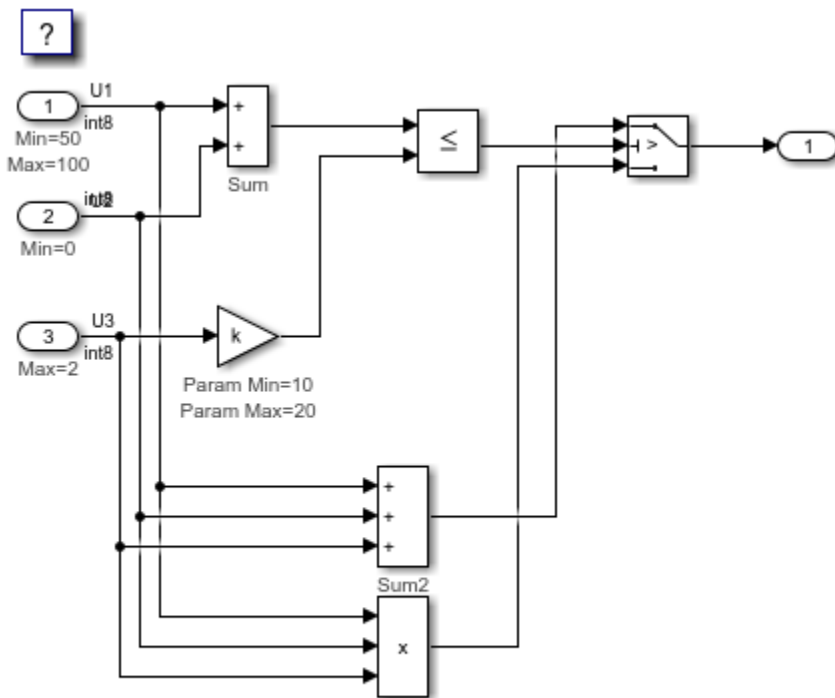

The benefits of optimizing the generated code are:

- Reducing the ROM and RAM consumption.
- Improving the execution speed.

### Review Minimum and Maximum Information

Consider the model `rtwdemo_minmax`. In this model, there are minimum and maximum values specified on Inports and on the gain parameter of the Gain block.

```
model = 'rtwdemo_minmax';
open_system(model);
```

Copyright 2010-2020 The MathWorks, Inc.

### Generate Code Without This Optimization

First, generate code for this model without considering the min and max values.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
rtwconfiguredemo(model, 'ERT')
slbuild(model)
```

```
Starting build procedure for: rtwdemo_minmax
Successful completion of build procedure for: rtwdemo_minmax
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_minmax	Code generated and compiled.	Code generation information file does not exist.

1 of 1 models built (0 models already up to date)

Build duration: 0h 0m 22.29s

A portion of `rtwdemo_minmax.c` is listed below.

```
cfile = fullfile(cgDir, 'rtwdemo_minmax_ert_rtw', 'rtwdemo_minmax.c');
rtwdemodbtype(cfile, /* Model step', /* Model initialize', 1, 0);
```

```
/* Model step function */
```

```

void rtwdemo_minmax_step(void)
{
 int32_T tmp;

 /* Sum: '<Root>/Sum' incorporates:
 * Inport: '<Root>/U1'
 * Inport: '<Root>/U2'
 * Sum: '<Root>/Sum2'
 * Switch: '<Root>/Switch'
 */
 tmp = U1 + U2;

 /* Switch: '<Root>/Switch' incorporates:
 * Gain: '<Root>/Gain'
 * Inport: '<Root>/U3'
 * RelationalOperator: '<Root>/Relational Operator'
 * Sum: '<Root>/Sum'
 */
 if (tmp <= k * U3) {
 /* Output: '<Root>/Out1' incorporates:
 * Sum: '<Root>/Sum2'
 */
 rtY.Out1 = tmp + U3;
 } else {
 /* Output: '<Root>/Out1' incorporates:
 * Inport: '<Root>/U1'
 * Inport: '<Root>/U2'
 * Product: '<Root>/Product'
 */
 rtY.Out1 = U1 * U2 * U3;
 }
}

```

### Enable This Optimization

- 1 Open the Configuration Parameters dialog box.
- 2 On the **Optimization** pane, select **Optimize using the specified minimum and maximum values**.

Alternatively, you can enable this optimization by setting the command-line parameter.

```
set_param(model, 'UseSpecifiedMinMax', 'on');
```

### Generate Code with This Optimization

In the model, with the specified minimum and maximum values for U1 and U2, the sum of U1 and U2 has a minimum value of 50. Considering the range of U3 and the specified minimum and maximum values for the Gain block parameter, the maximum value of the Gain block's output is 40.

The output of the Relational Operator block remains false, and the output of the Switch block remains the product of the three inputs.

Configure and build the model using Embedded Coder®.

```

rtwconfiguredemo(model, 'ERT')
slbuild(model)

Starting build procedure for: rtwdemo_minmax
Successful completion of build procedure for: rtwdemo_minmax

```

## Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_minmax	Code generated and compiled.	Generated code was out of date.

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 19.73s

View the optimized code from `rtwdemo_minmax.c`.

```
cfile = fullfile(cgDir, 'rtwdemo_minmax_ert_rtw', 'rtwdemo_minmax.c');
rtwdemodbtype(cfile, '/* Model step', '/* Model initialize', 1, 0);
```

```
/* Model step function */
void rtwdemo_minmax_step(void)
{
 /* Output: '<Root>/Out1' incorporates:

 * Product: '<Root>/Product'
 * Switch: '<Root>/Switch'
 */
 rtY.Out1 = U1 * U2 * U3;
}
```

Close the model and cleanup.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

## Limitations

- This optimization does not take into account minimum and maximum values for:
  - Merge block inputs. To work around this issue, use a `Simulink.Signal` object on the Merge block output and specify the range on this object.
  - Bus elements.
  - Conditionally-executed subsystem (such as a triggered subsystem) block outputs that are directly connected to an Output block.

Output blocks in conditionally-executed subsystems can have an initial value specified for use only when the system is not triggered. In this case, the optimization cannot use the range of the block output because the range might not cover the initial value of the block.

- If you use Polyspace software to verify code generated using this optimization, it might mark code that was previously green as orange. For example, if your model contains a division where the range of the denominator does not include zero, the generated code does not include protection against division by zero. Polyspace might mark this code orange because it does not have information about the minimum and maximum values for the inputs to the division.

Polyspace Code Prover automatically captures some minimum and maximum values specified in the MATLAB workspace, for example, for `Simulink.Signal` and `Simulink.Parameter` objects. In this example, to provide range information to the Polyspace software, use a `Simulink.Signal` object on the input of the division and specify a range that does not include zero.

Polyspace Code Prover stores these values in a Data Range Specification (DRS) file. However, they do not capture all minimum and maximum values in your Simulink model. To provide additional minimum and maximum information to Polyspace, you can manually define a DRS file.

- If you are using double-precision data types and the **non-finite numbers** configuration parameter is selected, this optimization does not occur.
- If your model contains multiple instances of a reusable subsystem and each instance uses input signals with different minimum and maximum values, this optimization might result in different generated code for each subsystem so code reuse does not occur. Without this optimization, code is generated once for the subsystem and shares this code among the multiple instances of the subsystem.
- The Model Advisor check Check safety-related optimization settings generates a warning if this option is selected. For many safety-critical applications, removing dead code automatically is unacceptable because doing so might make code untraceable.

## Reduce Global Variables in Nonreusable Subsystem Functions

Global variables can increase memory requirements and reduce execution speed. To reduce global RAM for a nonreusable subsystem, you can generate a function interface that passes data through arguments instead of global variables. The Subsystem block parameter **Function interface** provides this option. To compare the outputs for the **Function interface** options, first generate a function for a subsystem with a `void-void` interface, and then generate a function with arguments.

### Generate void-void Function

By default, when you configure a Subsystem block as a nonreusable function, it generates a `void-void` interface.

- 1 Open the example model `rtwdemo_roll`.
- 2 Right-click the subsystem `RollAngleReference`. From the list select `Block Parameter (Subsystem)`.
- 3 In the `Block Parameters` dialog box, confirm that the **Treat as atomic unit** check box is selected.
- 4 Click the **Code Generation** tab and set the **Code interface packaging** parameter to `Nonreusable function`.
- 5 The **Function interface** parameter is already set to `void_void`.
- 6 Click **Apply** and **OK**.
- 7 Repeat steps 2-6, for the other subsystems `HeadingMode` and `BasicRollMode`.
- 8 Generate code and the static code metrics report for `rtwdemo_roll`. This model is configured to generate a code generation report and to open the report automatically. For more information, see “Generate Static Code Metrics Report for Simulink Model” on page 54-29.

In the code generation report, in `rtwdemo_roll.c`, the generated code for subsystem `RollAngleReference` contains a `void-void` function definition:

```
static void RollAngleReference(void)
{
 ...
}
```

In the static code metrics report, navigate to **Global Variables**. With the `void_void` option, the number of bytes for global variables is 47.

## 2. Global Variables [\[hide\]](#)

Global variables defined in the generated code.

Global Variable	Size (bytes)	Reads / Writes	Reads / Writes in a Function
[+] <a href="#">rtU</a>	26	14	6
[+] <a href="#">rtDW</a>	17	34	24
[+] <a href="#">rtY</a>	4	1	1
<b>Total</b>	<b>47</b>	<b>49</b>	

Next, generate the same function with the `Allow arguments (Optimized)` option to compare the results.

## Generate Function with Arguments

To reduce global RAM, improve ROM usage and execution speed, generate a function that allows arguments:

- 1 Open the Subsystem Block Parameter dialog box for RollAngleReference.
- 2 Click the **Code Generation** tab. Set the **Function interface** parameter to `Allow arguments (Optimized)`.
- 3 Click **Apply** and **OK**.
- 4 Repeat steps 2 and 3, for the other subsystems HeadingMode and BasicRollMode.
- 5 Generate code and the static code metrics report for `rtwdemo_roll`.

In the code generation report, in `rtwdemo_roll.c`, the generated code for subsystem RollAngleReference now has arguments:

```
static real32_T RollAngleReference(real32_T rtu_Phi,...
 boolean_T rtu_AP_Eng,...
 real32_T rtu_Turn_Knob)
{
 ...
}
```

In the static code metrics report, navigate to **Global Variables**. With the `Allow arguments` option set, the total number of bytes for global variables is now 39 bytes.

## 2. Global Variables [\[hide\]](#)

Global variables defined in the generated code.

Global Variable	Size (bytes)	Reads / Writes	Reads / Writes in a Function
[+] <a href="#">rtU</a>	26	11	11
[+] <a href="#">rtDW</a>	9	17	14
[+] <a href="#">rtY</a>	4	2	2
<b>Total</b>	<b>39</b>	<b>30</b>	

In some cases, when generating optimized code, the code generator might not generate a function that has arguments. To generate a predictable function interface that has arguments, set **Function interface** to `Allow arguments (Match graphical interface)`.

## Optimize Generated Code by Packing Boolean Data into Bitfields

This example shows how to optimize the generated code by packing Boolean data into bitfields. When you select the model configuration parameter **Pack Boolean data into bitfields**, Embedded Coder® packs the Boolean signals into 1-bit bitfields, reducing RAM consumption. By default, the optimization is enabled. This optimization reduces the RAM consumption. Be aware that this optimization can potentially increase code size and execution speed.

### Example Model

Consider the model `rtwdemo_pack_boolean`.

```
model = 'rtwdemo_pack_boolean';
open_system(model);
```

Copyright 2014-2020 The MathWorks, Inc.

### Disable Optimization

- 1 Open the Configuration Parameters dialog box.
- 2 On the **Optimization** pane, clear **Pack Boolean data into bitfields**.

Alternatively, you can use the command-line API to disable the optimization:

```
set_param(model, 'BooleansAsBitfields', 'off');
```

Create a temporary folder (in your system temporary folder) for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

### Generate Code Without Optimization

Build the model using Embedded Coder.

```
slbuild(model)
```

```
Starting build procedure for: rtwdemo_pack_boolean
Successful completion of build procedure for: rtwdemo_pack_boolean
```

```
Build Summary
```

```
Top model targets built:
```

Model	Action	Rebuild Reason
rtwdemo_pack_boolean	Code generated and compiled.	Code generation information file does not exist.

```
1 of 1 models built (0 models already up to date)
```

```
Build duration: 0h 0m 21.263s
```

View the generated code without the optimization. These lines of code are in `rtwdemo_pack_boolean.h`.

```
hfile = fullfile(cgDir, 'rtwdemo_pack_boolean_ert_rtw', 'rtwdemo_pack_boolean.h');
rtwdemodbtype(hfile, /* Block signals and states', /* External inputs',1,0);
```

```
/* Block signals and states (default storage) for system '<Root>' */
typedef struct {
 boolean_T LogicalOp1; /* '<Root>/Logical Op1' */
 boolean_T LogicalOp2; /* '<Root>/Logical Op2' */
 boolean_T LogicalOp5; /* '<Root>/Logical Op5' */
 boolean_T LogicalOp3; /* '<Root>/Logical Op3' */
 boolean_T LogicalOp4; /* '<Root>/Logical Op4' */
 boolean_T RelationalOperator; /* '<Root>/Relational Operator' */
 boolean_T UnitDelay_DSTATE; /* '<Root>/Unit Delay' */
} DW;
```

### Enable Optimization

- 1 Open the Configuration Parameters dialog box.
- 2 On the **Optimization** pane, select **Pack Boolean data into bitfields**.

Alternatively, you can use the command-line API to enable the optimization:

```
set_param(model, 'BooleansAsBitfields', 'on');
```

### Generate Code with Optimization

Build the model using Embedded Coder.

```
slbuild(model)
```

```
Starting build procedure for: rtwdemo_pack_boolean
Successful completion of build procedure for: rtwdemo_pack_boolean
```

```
Build Summary
```

```
Top model targets built:
```

Model	Action	Rebuild Reason
-------	--------	----------------

```
rtwdemo_pack_boolean Code generated and compiled. Generated code was out of date.
```

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 22.013s
```

View the generated code with the optimization. These lines of code are in `rtwdemo_pack_boolean.h`.

```
hfile = fullfile(cgDir, 'rtwdemo_pack_boolean_ert_rtw', 'rtwdemo_pack_boolean.h');
rtwdemodbtype(hfile, '/* Block signals and states', '/* External inputs', 1, 0);
```

```
/* Block signals and states (default storage) for system '<Root>' */
typedef struct {
 struct {
 uint_T LogicalOp1:1; /* '<Root>/Logical Op1' */
 uint_T LogicalOp2:1; /* '<Root>/Logical Op2' */
 uint_T LogicalOp5:1; /* '<Root>/Logical Op5' */
 uint_T LogicalOp3:1; /* '<Root>/Logical Op3' */
 uint_T LogicalOp4:1; /* '<Root>/Logical Op4' */
 uint_T RelationalOperator:1; /* '<Root>/Relational Operator' */
 uint_T UnitDelay_DSTATE:1; /* '<Root>/Unit Delay' */
 } bitsForTID0;
} DW;
```

Selecting **Pack Boolean data into bitfields** enables model configuration parameter **Bitfield declarator type specifier**. To optimize your code further, select `uchar_t`. However, the optimization benefit of the **Bitfield declarator type specifier** setting depends on your choice of target.

Close the model and code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

## Optimize Generated Code by Passing Reusable Subsystem Outputs as Individual Arguments

This example shows how passing reusable subsystem outputs as individual arguments instead of as a pointer to a structure stored in global memory optimizes the generated code. This optimization conserves RAM consumption and increases code execution speed by reducing global memory usage and eliminating data copies from local variables back to global block I/O structures.

### Example Model

Consider the model `rtwdemo_reusable_sys_outputs`. In this model, the reusable subsystem outputs feed the root outputs of the model.

```
model = 'rtwdemo_reusable_sys_outputs';
open_system(model);
```

Copyright 2014-2020 The MathWorks, Inc.

### Generate Code Without This Optimization

Generate code for this model while passing subsystem outputs as a structure reference. Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
slbuild(model)
```

```
Starting build procedure for: rtwdemo_reusable_sys_outputs
Successful completion of build procedure for: rtwdemo_reusable_sys_outputs
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_reusable_sys_outputs	Code generated and compiled.	Code generation information file does

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 23.61s

The code snippet shows portions of `rtwdemo_reusable_sys_outputs.c`. Notice the global block I/O structure and in the model step function a data copy from this structure.

```

cfile = fullfile(cgDir,'rtwdemo_reusable_sys_outputs_ert_rtw',...
'rtwdemo_reusable_sys_outputs.c');
rtwdemodbtype(cfile,'/* Output and update for atomic system',...
'/* Model initialize', 1, 0);

/* Output and update for atomic system: '<Root>/ReusableSubsystem' */
static void ReusableSubsystem(real_T rtu_In1, real_T rtu_In2, real_T rtu_In3,
 DW_ReusableSubsystem *localDW)
{
 /* Gain: '<S1>/Gain' */
 localDW->Gain = 5.0 * rtu_In1;

 /* Gain: '<S1>/Gain1' */
 localDW->Gain1 = 6.0 * rtu_In2;

 /* Gain: '<S1>/Gain2' */
 localDW->Gain2 = 7.0 * rtu_In3;
}

/* Model step function */
void rtwdemo_reusable_sys_outputs_step(void)
{
 /* Outputs for Atomic SubSystem: '<Root>/ReusableSubsystem' */

 /* Inport: '<Root>/In1' incorporates:
 * Inport: '<Root>/In2'
 * Inport: '<Root>/In3'
 */
 ReusableSubsystem(rtU.In1, rtU.In2, rtU.In3, &rtDW.ReusableSubsystem_d);

 /* End of Outputs for SubSystem: '<Root>/ReusableSubsystem' */

 /* Output: '<Root>/Out1' */
 rtY.Out1 = rtDW.ReusableSubsystem_d.Gain;

 /* Output: '<Root>/Out2' */
 rtY.Out2 = rtDW.ReusableSubsystem_d.Gain1;

 /* Output: '<Root>/Out3' */
 rtY.Out3 = rtDW.ReusableSubsystem_d.Gain2;
}

```

### Enable This Optimization

- 1 Open the Configuration Parameters dialog box.
- 2 On the **Optimization** pane, set **Pass reusable subsystem outputs as** to Individual arguments.

Alternatively, you can use the command-line API to enable the optimization:

```
set_param(model, 'PassReuseOutputArgsAs', 'Individual arguments');
```

### Generate Code with This Optimization

With this optimization, the ReusableSubsystem function has three output arguments, which are direct references to the external outputs. The `rtDW` global structure no longer exists, and the data copies from this structure to the `rtY` (external outputs) structure are not in the generated code.

Build the model.

```
slbuild(model)
```

```
Starting build procedure for: rtdemo_reusable_sys_outputs
Successful completion of build procedure for: rtdemo_reusable_sys_outputs
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtdemo_reusable_sys_outputs	Code generated and compiled.	Generated code was out of date.

1 of 1 models built (0 models already up to date)

Build duration: 0h 0m 19.339s

The code snippet below is a portion of `rtdemo_reusable_sys_outputs.c`. Observe the optimized code.

```
rtwdemodbtype(cfile, /* Output and update for atomic system',...
/* Model initialize', 1, 0);

/* Output and update for atomic system: '<Root>/ReusableSubsystem' */
static void ReusableSubsystem(real_T rtu_In1, real_T rtu_In2, real_T rtu_In3,
 real_T *rty_Out1, real_T *rty_Out2, real_T *rty_Out3)
{
 /* Gain: '<S1>/Gain' */
 *rty_Out1 = 5.0 * rtu_In1;

 /* Gain: '<S1>/Gain1' */
 *rty_Out2 = 6.0 * rtu_In2;

 /* Gain: '<S1>/Gain2' */
 *rty_Out3 = 7.0 * rtu_In3;
}

/* Model step function */
void rtdemo_reusable_sys_outputs_step(void)
{
 /* Outputs for Atomic SubSystem: '<Root>/ReusableSubsystem' */

 /* Inport: '<Root>/In1' incorporates:
 * Inport: '<Root>/In2'
 * Inport: '<Root>/In3'
 * Outport: '<Root>/Out1'
```

```
* Output: '<Root>/Out2'
* Output: '<Root>/Out3'
*/
ReusableSubsystem(rtU.In1, rtU.In2, rtU.In3, &rtY.Out1, &rtY.Out2, &rtY.Out3);

/* End of Outputs for SubSystem: '<Root>/ReusableSubsystem' */
}
```

Close the model and cleanup.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

## Convert Data Copies to Pointer Assignments

The code generator optimizes generated code for vector signal assignments by trying to replace for loop controlled element assignments and memcpy function calls with pointer assignments. Pointer assignments avoid expensive data copies. Therefore, they use less stack space and offer faster execution speed than for loop controlled element assignments and memcpy function calls. If you assign large data sets to vector signals, this optimization can result in significant improvements to code efficiency.

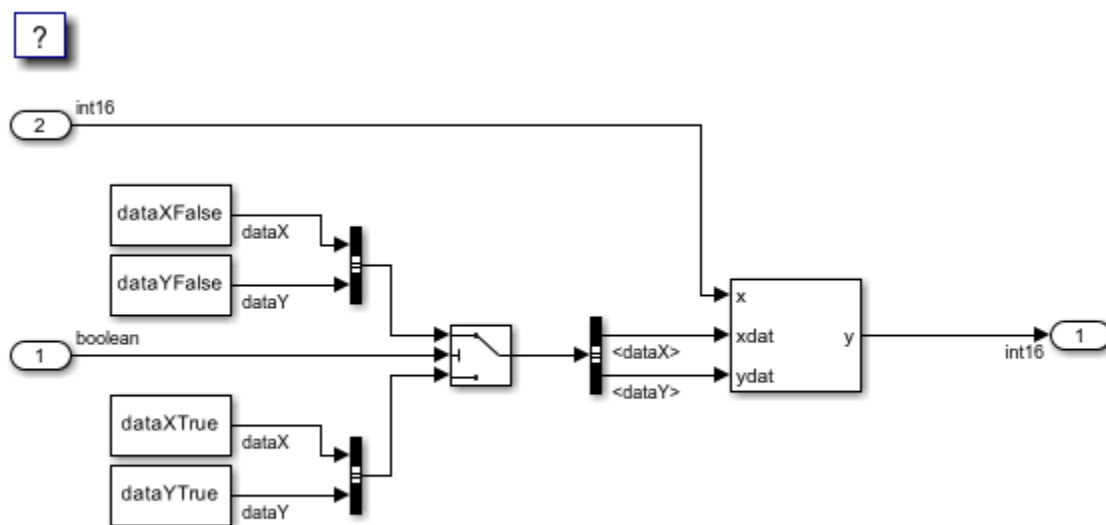

### Configure Model to Optimize Generated Code for Vector Signal Assignments

To apply this optimization:

- 1 Verify that your target supports the memcpy function.
- 2 Determine whether your model uses vector signal assignments (such as `Y=expression`) to move large amounts of data. For example, your model could use a Selector block to select input elements from a vector, matrix, or multidimension signal.
- 3 On the **Optimization** pane, the **Use memcpy for vector assignment parameter**, which is on by default, enables the associated **Memcpy threshold (bytes)** parameter.
- 4 Examine the setting of **Memcpy threshold (bytes)**. By default, it specifies 64 bytes as the minimum array size for which memcpy function calls or pointer assignments can replace for loops in the generated code. Based on the array sizes in your application's vector signal assignments, and target environment considerations on the threshold selection, accept the default value or specify another array size.

### Example Model

Consider the following model named `rtwdemo_pointer_conversion`. This model uses a Switch block to assign data to a vector signal. This signal then feeds into a Bus Selector block.

Copyright 2016-2020, The MathWorks, Inc.

## Generate Code Without Optimization

- 1 In the Configuration Parameters dialog box, clear the **Use memcopy for vector assignment** parameter.
- 2 Create a temporary folder for the build and inspection process.
- 3 Press **Ctrl+B** to generate code.

```
Starting build procedure for: rtwdemo_pointer_conversion
Successful completion of build procedure for: rtwdemo_pointer_conversion
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_pointer_conversion	Code generated and compiled.	Code generation information file does not exist

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 21.717s

View the generated code without the optimization. Here is a portion of `rtwdemo_pointer_conversion.c`.

```
/* Model step function */
void rtwdemo_pointer_conversion_step(void)
{
 int32_T i;
 int16_T rtb_dataX[100];
 int16_T rtb_dataY[100];

 /* Switch generated from: '<Root>/Switch' incorporates:
 * Constant: '<Root>/Constant'
 * Constant: '<Root>/Constant1'
 * Constant: '<Root>/Constant2'
 * Constant: '<Root>/Constant3'
 * Inport: '<Root>/In1'
 */
 for (i = 0; i < 100; i++) {
 if (rtU.In1) {
 rtb_dataX[i] = rtCP_Constant_Value[i];
 rtb_dataY[i] = rtCP_Constant1_Value[i];
 } else {
 rtb_dataX[i] = rtCP_Constant2_Value[i];
 rtb_dataY[i] = rtCP_Constant3_Value[i];
 }
 }
}

/* End of Switch generated from: '<Root>/Switch' */

/* S-Function (sfix_look1_dyn): '<Root>/Lookup Table Dynamic' incorporates:
 * Inport: '<Root>/In2'
 * Output: '<Root>/Out1'
 */
/* Dynamic Look-Up Table Block: '<Root>/Lookup Table Dynamic'
 * Input0 Data Type: Integer S16
```

```

* Input1 Data Type: Integer S16
* Input2 Data Type: Integer S16
* Output0 Data Type: Integer S16
* Lookup Method: Linear_Endpoint
*
*/
Lookup_S16_S16(&(rtY.Out1), &rtb_dataY[0], rtU.In2, &rtb_dataX[0], 99U);
}

```

Without the optimization, the generated code contains for loop controlled element assignments.

### Enable Optimization and Generate Code

- 1 In the Configuration Parameter dialog box, select the **Use memcpy for vector assignment** parameter.
- 2 Generate code.

```

Starting build procedure for: rtwdemo_pointer_conversion
Successful completion of build procedure for: rtwdemo_pointer_conversion

```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_pointer_conversion	Code generated and compiled.	Generated code was out of date.

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 19.741s

View the generated code without the optimization. Here is a portion of `rtwdemo_pointer_conversion.c`.

```

/* Model step function */
void rtwdemo_pointer_conversion_step(void)
{
 const int16_T *rtb_dataX_0;
 const int16_T *rtb_dataY_0;

 /* Inport: '<Root>/In1' */
 if (rtU.In1) {
 /* Switch generated from: '<Root>/Switch' incorporates:
 * Constant: '<Root>/Constant'
 */
 rtb_dataX_0 = &rtCP_Constant_Value[0];

 /* Switch generated from: '<Root>/Switch' incorporates:
 * Constant: '<Root>/Constant1'
 */
 rtb_dataY_0 = &rtCP_Constant1_Value[0];
 } else {
 /* Switch generated from: '<Root>/Switch' incorporates:
 * Constant: '<Root>/Constant2'
 */
 rtb_dataX_0 = &rtCP_Constant2_Value[0];
 }
}

```

```

/* Switch generated from: '<Root>/Switch' incorporates:
 * Constant: '<Root>/Constant3'
 */
rtb_dataY_0 = &rtCP_Constant3_Value[0];
}

/* End of Inport: '<Root>/In1' */

/* S-Function (sfix_look1_dyn): '<Root>/Lookup Table Dynamic' incorporates:
 * Inport: '<Root>/In2'
 * Output: '<Root>/Out1'
 */
/* Dynamic Look-Up Table Block: '<Root>/Lookup Table Dynamic'
 * Input0 Data Type: Integer S16
 * Input1 Data Type: Integer S16
 * Input2 Data Type: Integer S16
 * Output0 Data Type: Integer S16
 * Lookup Method: Linear_Endpoint
 *
 */
Lookup_S16_S16(&(rtY.Out1), &rtb_dataY_0[0], rtU.In2, &rtb_dataX_0[0], 99U);
}

```

Because the setting of the **Memcpy threshold (bytes)** parameter is below the array sizes in the generated code, the optimized code contains pointer assignments for the vector signal assignments.

## Reuse Buffers of Different Sizes and Dimensions

You can reuse buffers for matrices that have different sizes and shapes. In the Configuration Parameters dialog box, you enable this optimization by selecting **Reuse buffers of different sizes and dimensions**. This optimization conserves RAM and ROM usage and improves code execution speed.

### Example Model

The model `rtwdemo_differentsizereuse` contains signals of different sizes and dimensions.

```
model='rtwdemo_differentsizereuse';
open_system(model);
```

Copyright 2017-2020 The MathWorks, Inc.

### Generate Code Without Optimization

In the Configuration Parameters dialog box, set **Reuse buffers of different sizes and dimension** parameter to `off` or in the MATLAB® Command Window, enter:

```
set_param('rtwdemo_differentsizereuse','DifferentSizesBufferReuse','off');
```

Create a folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Turn off comments and build the model.

```
set_param('rtwdemo_differentsizereuse','GenerateComments','off');
slbuild('rtwdemo_differentsizereuse');
```

```
Starting build procedure for: rtwdemo_differentsizereuse
Successful completion of build procedure for: rtwdemo_differentsizereuse
```

Build Summary

Top model targets built:

 int32_T i;
 for (i = 0; i < 3969; i++) {
 rty_z[i] = fabs(rtu_u[i] - rtu_u[i + 63]);
 }
}

static void NoninplaceableSS3(void)
{
 DeltaY(rtDWork.z_j, rtDWork.z_h);
 DeltaY(rtDWork.z_hh, rtDWork.z);
}

void rtwdemo_differentsizereuse_step(void)
{
 int32_T i;
 for (i = 0; i < 16384; i++) {
 rtDWork.ComplextoRealImag_o1[i] = rtU.ComplexData[i].re;
 rtDWork.ComplextoRealImag_o2[i] = rtU.ComplexData[i].im;
 }

 NoninplaceableSS1();
 NoninplaceableSS2();
 NoninplaceableSS3();
 for (i = 0; i < 3969; i++) {
 rtY.Out1[i].re = rtDWork.z_h[i];
 rtY.Out1[i].im = rtDWork.z[i];
 }
}
```

```

 }
}

```

The `D_work` structure contains eight global variables for holding the inputs and outputs of `Downsample`, `DeltaX`, and `DeltaY`. These variables have different sizes.

### Generate Code with Optimization

- 1 In the Configuration Parameters dialog box, verify that **Signal storage reuse** is selected.
- 2 Set the **Reuse buffers of different sizes and dimensions** parameter to on or in the MATLAB Command Window, enter:

```
set_param('rtwdemo_differentsizereuse','DifferentSizesBufferReuse','on');
```

Build the model.

```
set_param('rtwdemo_differentsizereuse','GenerateComments','off');
slbuild(model);
```

```
Starting build procedure for: rtwdemo_differentsizereuse
Successful completion of build procedure for: rtwdemo_differentsizereuse
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_differentsizereuse	Code generated and compiled.	Generated code was out of date.

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 24.351s

View the generated code without the optimization. The `D_Work` structure is:

```
rtwdemodbtype(hfile,'typedef struct {' D_Work',1,1);
```

```
typedef struct {
 real_T z[4096];
 real_T z_h[16384];
 real_T z_o[16384];
} D_Work;
```

The portion of `rtwdemo_differentsizereuse.c` is:

```
cfile = fullfile(cgDir,'rtwdemo_differentsizereuse_ert_rtw',...
 'rtwdemo_differentsizereuse.c');
rtwdemodbtype(cfile,'#include "rtwdemo_differentsizereuse.h"',...
 'void rtwdemo_differentsizereuse_initialize(void)',1,0);
```

```
#include "rtwdemo_differentsizereuse.h"
#include "rtwtypes.h"
#include <math.h>
```

```
D_Work rtDWork;

 Downsample(rtDWork.z_o, &rtDWork.z_h[0]);
}

static void DeltaX(const real_T rtu_u[4096], real_T rty_z[4032])
{
 int32_T tmp;
 int32_T x;
 int32_T y;
 for (x = 0; x < 63; x++) {
 for (y = 0; y < 64; y++) {
 tmp = (y << 6) + x;
 rty_z[x + 63 * y] = fabs(rtu_u[tmp] - rtu_u[tmp + 1]);
 }
 }
}

static void NoninplaceableSS2(void)
{
 DeltaX(rtDWork.z, &rtDWork.z_o[0]);
 DeltaX(&rtDWork.z_h[0], &rtDWork.z[0]);
}

static void DeltaY(const real_T rtu_u[4032], real_T rty_z[3969])
{
 int32_T tmp;
 int32_T x;
 int32_T y;

```

```

 for (x = 0; x < 63; x++) {
 for (y = 0; y < 63; y++) {
 tmp = 63 * y + x;
 rty_z[tmp] = fabs(rtu_u[tmp] - rtu_u[(y + 1) * 63 + x]);
 }
 }
}

static void NoninplaceableSS3(void)
{
 DeltaY(&rtDWork.z_o[0], &rtDWork.z_h[0]);
 DeltaY(&rtDWork.z[0], &rtDWork.z_o[0]);
}

void rtwdemo_differentsizereuse_step(void)
{
 int32_T i;
 for (i = 0; i < 16384; i++) {
 rtDWork.z_h[i] = rtU.ComplexData[i].re;
 rtDWork.z_o[i] = rtU.ComplexData[i].im;
 }

 NoninplaceableSS1();
 NoninplaceableSS2();
 NoninplaceableSS3();
 for (i = 0; i < 3969; i++) {
 rtY.Out1[i].re = rtDWork.z_h[i];
 rtY.Out1[i].im = rtDWork.z_o[i];
 }
}

```

The `D_work` structure now contains three global variables instead of eight global variables for holding the inputs and outputs of `Downsample`, `DeltaX`, and `DeltaY`. The generated code uses these variables to hold the differently-sized inputs and outputs.

Close the model and code generation report.

```

bdclose(model)
rtwdemoclean;
cd(currentDir)

```

### Limitations

- If you use a `Reusable` custom storage class to specify reuse on signals that have different sizes and shapes, you must select the **Reuse buffers of different sizes and dimensions** parameter. Otherwise, the model does not build.
- The code generator does not replace a buffer with a lower priority buffer that has a smaller size.
- The code generator does not reuse buffers that have different sizes and symbolic dimensions.

## Remove Reset and Disable Functions from the Generated Code

### In this section...

“Example Model” on page 80-28

“Generate Code” on page 80-29

“Enable Optimization” on page 80-29

This example shows how the code generator removes unreachable (dead code) instances of the reset and disable functions from the generated code for ERT-based systems that include model referencing hierarchies. Optimizing the generated code to remove unreachable code is a requirement for safety-critical systems. This optimization also improves execution speed and reduces ROM consumption.

If a model contains blocks with states, the generated code contains reset and disable functions. If the model is not part of a conditionally executed system, such as an enabled subsystem, the code generator can remove the disable function because the generated code does not call it. If the model is not part of a conditionally executed system that can reset states when a control input enables it, the code generator can remove the reset function because the generated code does not call it.

### Example Model

A referenced model, `rtwdemo_optionalDisableResetFunc_bot`, is in `rtwdemo_optionalDisableResetFunc_top`. The referenced model contains two blocks with states, a Delay block and a Discrete-Time Integrator block.

Copyright 2016 The MathWorks, Inc

Copyright 2016 The MathWorks, Inc

## Generate Code

- 1 Open the models. In the Command Window, type `rtwdemo_optionalDisableResetFunc_bot` and `rtwdemo_optionalDisableResetFunc_top`.
- 2 In your system temporary folder, create a temporary folder for the build and inspection process.
- 3 Build the model.
- 4 Open the `rtwdemo_optionalDisableResetFunc_top.c` and `rtwdemo_optionalDisableResetFunc_bot.c` files.

The `rtwdemo_optionalDisableResetFunc_bot.c` file contains these reset and disable functions.

```

/* System reset for referenced model: 'rtwdemo_optionalDisableResetFunc_bot' */
void rtwdemo_optionalDisableResetFunc_bot_Reset
(DW_rtwdemo_optionalDisableResetFunc_bot_f_T *localDW)
{
 /* InitializeConditions for Delay: '<Root>/Delay' */
 localDW->Delay_DSTATE = 0.0;

 /* InitializeConditions for DiscreteIntegrator: '<Root>/Discrete-Time Integrator' */
 localDW->DiscreteTimeIntegrator_DSTATE = 3.0;
}

/* Disable for referenced model: 'rtwdemo_optionalDisableResetFunc_bot' */
void rtwdemo_optionalDisableResetFunc_bot_Disable(real_T *rty_Out1,
DW_rtwdemo_optionalDisableResetFunc_bot_f_T *localDW)
{
 /* Disable for DiscreteIntegrator: '<Root>/Discrete-Time Integrator' */
 localDW->DiscreteTimeIntegrator_DSTATE = *rty_Out1;
}

```

The `rtwdemo_optionalDisableResetFunc_top_step` function does not call the `rtwdemo_optionalDisableResetFunc_bot_Disable` function because the model is not part of a conditionally executed system. The `rtwdemo_optionalDisableResetFunc_top_step` function does not call the `rtwdemo_optionalDisableResetFunc_bot_Reset` function because the model is not part of a conditionally executed system that can reset states when a control input enables it.

## Enable Optimization

- 1 Open the Model Configuration Parameters dialog box for `rtwdemo_optionalDisableResetFunc_bot`.
- 2 Select **Remove Disable Function** and **Remove Reset Function**.

Open the `rtwdemo_optionalDisableResetFunc_bot.c` file. The code does not contain the `rtwdemo_optionalDisableResetFunc_bot_Reset` function or the `rtwdemo_optionalDisableResetFunc_bot_Disable` function.

## Control Operator Type in Generated Code

This example shows how to optimize the generated code by controlling the operator type in the code. You can generate code with Bitwise or Logical operators or a combination of both for inputs with Boolean data type. Selecting bitwise operators in the code might improve ROM efficiency when the code contains bitwise operators.

When you select a value for the **Operator to represent Bitwise and Logical Operator blocks** parameter, the generated code maintains the operators as modelled or converts all operators into either bitwise or logical operators independent of the modeling blocks.

**NOTE:** This example requires Embedded Coder®.

### Example Model

In the model `matlab:logicalandbitwise`, a Logical AND block connects to a Bitwise AND block.

```
model = 'logicalandbitwise';
open_system(model);
```

Copyright 2021 The MathWorks, Inc.

### Generate Code as Modeled

Use your system temporary folder for building and inspection process.

```
currentDir = pwd;
```

- 1 Open the Configuration Parameters dialog box.
- 2 On the **Optimization** pane, set the **Operator to represent Bitwise and Logical Operator blocks** parameter to **Same as modeled**.

Alternatively, use the command-line API to set the parameter value:

```
set_param(model, 'BitwiseOrLogicalOp', 'Same as modeled');
evalc('slbuild(model)');
```

View the generated code with operators in the code that matches the modeled blocks. Here is a portion of `logicalandbitwise.c`.

```
cfile = fullfile(currentDir, 'logicalandbitwise_ert_rtw', 'logicalandbitwise.c');
rtwdemodbtype(cfile, '/* Model step function ', '/* Model initialize function', 1, 1);

/* Model step function */
void logicalandbitwise_step(void)
```

```

{
 /* Outport: '<Root>/Out1' incorporates:
 * Inport: '<Root>/Input'
 * Inport: '<Root>/Input1'
 * Inport: '<Root>/Input2'
 * Logic: '<Root>/Logical AND'
 * S-Function (sfix_bitop): '<Root>/Bitwise AND'
 */
 logicalandbitwise_Y.Out1 = (logicalandbitwise_U.Input1 &&
 logicalandbitwise_U.Input2) & logicalandbitwise_U.Input;
}

```

The generated code contains both a logical && operator and a bitwise & operator representing the Logical AND block and Bitwise AND block in the code.

### Generate Code with Logical Operators

- 1 Open the Configuration Parameters dialog box.
- 2 On the **Optimization** pane, set the **Operator to represent Bitwise and Logical Operator blocks** parameter to Logical operator.

Alternatively, use the command-line API to set the parameter value:

```

set_param(model, 'BitwiseOrLogicalOp', 'Logical operator');
evalc('slbuild(model)');

```

View the generated code with only logical operators. Here is a portion of `logicalandbitwise.c`.

```

cfile = fullfile(currentDir, 'logicalandbitwise_ert_rtw', 'logicalandbitwise.c');
rtwdemodbtype(cfile, '/* Model step function ', '/* Model initialize function', 1, 1);

/* Model step function */
void logicalandbitwise_step(void)
{
 /* Outport: '<Root>/Out1' incorporates:
 * Inport: '<Root>/Input'
 * Inport: '<Root>/Input1'
 * Inport: '<Root>/Input2'
 * Logic: '<Root>/Logical AND'
 * S-Function (sfix_bitop): '<Root>/Bitwise AND'
 */
 logicalandbitwise_Y.Out1 = (logicalandbitwise_U.Input &&
 (logicalandbitwise_U.Input1 && logicalandbitwise_U.Input2));
}

```

The generated code contains only the logical && operator. The Bitwise AND block in the model is converted into the logical && operator in the code.

### Generate Code with Bitwise Operators

- 1 Open the Configuration Parameters dialog box.
- 2 On the **Optimization** pane, set the **Operator to represent Bitwise and Logical Operator blocks** parameter to Bitwise operator.

Alternatively, use the command-line API to set the parameter value:

```
set_param(model, 'BitwiseOrLogicalOp', 'Bitwise operator');
evalc('slbuild(model)');
```

View the generated code with only bitwise operators. Here is a portion of `logicalandbitwise.c`.

```
cfile = fullfile(currentDir, 'logicalandbitwise_ert_rtw', 'logicalandbitwise.c');
rtwdemodbttype(cfile, '/* Model step function ', '/* Model initialize function', 1, 1);
```

```
/* Model step function */
void logicalandbitwise_step(void)
{
 /* Outport: '<Root>/Out1' incorporates:
 * Inport: '<Root>/Input'
 * Inport: '<Root>/Input1'
 * Inport: '<Root>/Input2'
 * Logic: '<Root>/Logical AND'
 * S-Function (sfix_bitop): '<Root>/Bitwise AND'
 */
 logicalandbitwise_Y.Out1 = (boolean_T)(logicalandbitwise_U.Input1 &
 logicalandbitwise_U.Input2) & logicalandbitwise_U.Input;
}
```

The generated code contains only the bitwise & operator. The Logical AND block in the model is converted into the bitwise & operator in the code.

Close the model and code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

## Reduce Memory Usage for Models Containing Referenced Models

This example shows how you can generate RAM efficient code for models containing referenced models that have no function prototype control specifications. When you select the configuration parameter **Reuse output buffers of Model blocks**, the code generator analyzes the referenced model contents and interacts with other optimizations to determine if buffer reuse is possible. If buffer reuse is possible, the code generator tries to reuse existing signal memory or generates reusable temporary buffers to hold referenced model outputs.

Reusing buffers can significantly reduce RAM consumption. However, this optimization can produce extra data copies in the generated code.

### Open Example Model

Open the example model `RefBufferReuse` containing two instances of the referenced model `RefModel`, which does not have a function prototype control specification.

```
model = 'RefBufferReuse';
open_system(model)
Rmodel= 'RefModel';
load_system(Rmodel);
```

### Generate Code Without This Buffer Reuse Optimization

Open the configuration parameters for the model. Clear the **Reuse output buffers of Model blocks** parameter check box. Alternatively, use the command line.

```
set_param(model, 'ReuseModelBlockBuffer', 'off');
```

Open the configuration parameters for the referenced model. Select the **Reuse output buffers of Model blocks** parameter check box and save the changes. Alternatively, use the command line.

```
set_param(Rmodel, 'ReuseModelBlockBuffer', 'off');
save_system(Rmodel);
```

Build the model.

```
slbuild(model);

Starting serial model reference code generation build.
Starting build procedure for: RefModel
Successful completion of build procedure for: RefModel
```

```
Starting build procedure for: RefBufferReuse
Successful completion of build procedure for: RefBufferReuse
```

Build Summary

Code generation targets built:

Model	Action	Rebuild Reason
RefModel	Code generated and compiled.	RefModel.c does not exist.

Top model targets built:

Model	Action	Rebuild Reason
RefBufferReuse	Code generated and compiled.	Code generation information file does not exist.

2 of 2 models built (0 models already up to date)

Build duration: 0h 0m 41.777s

Inspect the generated code.

```
file = fullfile('RefBufferReuse_ert_rtw','RefBufferReuse.c');
rtwdemodbtype(file,'/* Model step function */','/* Model initialize function',1,1);
```

```
/* Model step function */
void RefBufferReuse_step(void)
{
 /* local block i/o variables */
 real_T rtb_RefModel1[100];
 real_T rtb_Add[100];
 int32_T i;

 /* ModelReference: '<Root>/RefModel1' incorporates:
 * Inport: '<Root>/In1'
 */
 RefModel(&rtU.In1[0], &rtb_RefModel1[0]);

 /* Sum: '<Root>/Add' */
 for (i = 0; i < 100; i++) {
 rtb_Add[i] = rtb_RefModel1[i] + rtb_RefModel1[i];
 }

 /* End of Sum: '<Root>/Add' */

 /* ModelReference: '<Root>/RefModel2' incorporates:
 * Output: '<Root>/Out1'
 */
 RefModel(&rtb_Add[0], &rtY.Out1[0]);
}
```

The generated code generates the unique `rtb_Model1` buffer to hold the output of `RefModel1`.

### Generate Code With This Buffer Reuse Optimization

Open the configuration parameters for the model. Select the **Reuse output buffers of Model blocks** parameter check box. Alternatively, use the command line.

```
set_param(model, 'ReuseModelBlockBuffer', 'on');
```

Open the configuration parameters for the referenced model. Select the **Reuse output buffers of Model blocks** parameter check box and save the changes. Alternatively, use the command line.

```
set_param(Rmodel, 'ReuseModelBlockBuffer', 'on');
save_system(Rmodel);
```

Build the model.

```
slbuild(model);
```

```
Starting serial model reference code generation build.
Starting build procedure for: RefModel
Successful completion of build procedure for: RefModel
Starting build procedure for: RefBufferReuse
Successful completion of build procedure for: RefBufferReuse
```

Build Summary

Code generation targets built:

Model	Action	Rebuild Reason
RefModel	Code generated and compiled.	Model or library RefModel changed.

Top model targets built:

Model	Action	Rebuild Reason
RefBufferReuse	Code generated and compiled.	Referenced models were updated.

2 of 2 models built (0 models already up to date)  
Build duration: 0h 0m 41.175s

Inspect the generated code.

```
file = fullfile('RefBufferReuse_ert_rtw','RefBufferReuse.c');
rtwdemodbtype(file,'/* Model step function */','/* Model initialize function',1,1);
```

```
/* Model step function */
void RefBufferReuse_step(void)
{
 /* local block i/o variables */
 real_T rtb_Add[100];
 int32_T i;

 /* ModelReference: '<Root>/RefModel1' incorporates:
 * Inport: '<Root>/In1'
 */
 RefModel(&rtU.In1[0], &rtb_Add[0]);
 for (i = 0; i < 100; i++) {
 /* Sum: '<Root>/Add' */
 rtb_Add[i] += rtb_Add[i];
 }

 /* ModelReference: '<Root>/RefModel2' incorporates:
 * Outport: '<Root>/Out1'
 */
}
```

```
 */
 RefModel(&rtb_Add[0], &rtY.Out1[0]);
}
```

The generated code reuses the `rtb_Add` buffer to hold the output of `RefModel1`.

### **Clean Up Example Folders and Files**

Close the model and remove generated files.

```
bdclose(model);
rtwdemoclean;
```

## Create Execution-Time Profile for Generated Code

You can configure a software-in-the-loop (SIL), processor-in-the-loop (PIL) on page 88-2, or XCP-based external mode on page 60-8 simulation to produce execution-time metrics for tasks and functions in your generated code. The software calculates execution times from data that is obtained through code instrumentation added to the target application or the generated code under test. You can use the execution-time metrics to determine whether the generated code meets the requirements for real-time deployment on your target hardware.

For example, you can perform the following analysis:

- 1 Identify tasks that require the most time. Tasks are main entry points into the generated code. For example, the step function for a sample rate or the `model_initialize` function.
- 2 In these tasks, investigate code sections that require the most time.
- 3 Identify variations in execution time over time steps.

If you are trying to reduce execution times, the analysis results help you to focus on the most critical code sections. To observe performance changes for an updated model, rerun the SIL, PIL, or external mode simulation and compare the new metrics against previous metrics.

When the SIL, PIL, or external mode simulation is complete, you can:

- View execution-time metrics through a display window or report.
- Use the Simulation Data Inspector to view and compare the variation of execution times over a simulation.
- Analyze the measurements within the MATLAB environment.

## Configure Code Execution Profiling

This table lists system target files that are supported for code execution profiling.

Simulation Mode	System Target File
SIL or PIL	GRT, ERT, or ERT-based
XCP-based external	ERT or ERT-based

To configure code execution profiling for a SIL, PIL, or XCP-based external mode simulation:

- 1 In your top model, open the Configuration Parameters dialog box.
- 2 Select the **Measure task execution time** check box.
- 3 For function execution times, from the **Measure function execution times** drop-down list, select one of these options:
  - **Coarse (referenced models and subsystems only)** -- if you want to analyse generated function code for the main model components.
  - **Detailed (all function call sites)** -- if you want to analyse generated function code for all blocks in the model.
- 4 In the **Workspace variable** field, specify a name. When you run the simulation, the software generates a variable with this name in the MATLAB base workspace. The variable contains the execution-time measurements, and is an object of type `coder.profile.ExecutionTime`.

If the **Data Import/Export > Single simulation output** check box is selected, the software creates the variable in the Simulink.SimulationOutput object that you specify.

- 5 From the “Save options” drop-down list, select one of these options:
  - **Summary data only** — Stream execution times to the Simulation Data Inspector during the simulation. Store minimal information at the end of the simulation. Use this option if you want to generate only a report and reduce memory usage, for example, in a long simulation.
  - **All data** — Stream execution times to the Simulation Data Inspector during the simulation. Store execution-time profiles in the base workspace and generate a report. After the simulation, you can use methods from the `coder.profile.ExecutionTime` and `coder.profile.ExecutionTimeSection` classes to retrieve execution-time measurements for every call to each profiled section of code that occurs during the simulation.

If you select this option, the metrics display window and generated report display the Simulation Data Inspector icon . When you click the icon, the software imports simulation results into the Simulation Data Inspector. You can then plot execution times and manage and compare plots from various simulations.

- **Metrics only** -- Reduces bandwidth usage for the communication channel between Simulink and the target application. During the simulation, the software does not stream execution times to the Simulation Data Inspector. On the target hardware, the software stores maximum execution times, average execution times, and number of calls. At the end of the simulation, Simulink uploads the data from the target hardware to your development computer.
- 6 Click **OK**.

For a PIL simulation:

- You must configure a hardware-specific timer. When you set up target connectivity, create a timer object. This action is not required for a SIL simulation. For more information, see “Set Up PIL Connectivity by Using target Package” on page 88-48 or “Create PIL Target Connectivity Configuration for Simulink” on page 88-38.
- You can remove instrumentation overheads from execution times. For more information, see “Remove Instrumentation Overheads from Execution Time Measurements” on page 81-23.

## Control Profiling Granularity

You can control the granularity of execution-time profiling, that is, prevent the addition of code instrumentation to specific function-call sites. Through the control of profiling granularity, you can:

- Focus on the performance of model components that require improvement. For example, after an initial run, disable profiling for blocks that require little processing time. This action reduces the number of items displayed by the profiling report.
- Reduce the code instrumentation overhead. For example, for simple functions, the code instrumentation overhead can be greater than the execution time of the function code.

To generate execution-time metrics for tasks only, on the **Code Generation > Verification** pane of the Configuration Parameters dialog box, select the **Measure task execution time** check box and set **Measure function execution times** to **Off**.

To generate function execution data for referenced models and atomic subsystems in the top model, on the **Code Generation > Verification** pane, select the **Measure task execution time** check box

and set **Measure function execution times** to Coarse (referenced models and subsystems only).

The generation of function execution data requires the insertion of measurement probes into the generated code. The software inserts measurement probes for an atomic subsystem only if you set the **Function packaging** field (on the **Code Generation** tab of the Function Block Parameters dialog box) to either **Nonreusable function** or **Reusable function**. If the field is set to **Auto**, then the insertion of probes depends on the packaging choice that results from the **Auto** setting. If the field is set to **Inline**, the software does not insert probes.

**Note** In the generated code, the software wraps each function call with measurement probes except when:

- The call site cannot be wrapped because of expression folding (see “Minimize Computations and Storage for Intermediate Results at Block Outputs”).
- The call site is located in the shared utility code (see “Sharing Utility Code”).

To generate function execution times for model reference hierarchies:

- 1 In the top model, open the Configuration Parameters dialog box, and select the **Code Generation > Verification** pane.
- 2 Select the **Measure task execution time** check box
- 3 For each Model block that you want to profile, specify **Measure function execution times** only at the reference level for which you require function execution times.

For example, consider a top model that has Model block A, which in turn contains Model block B.

If you want to generate execution times for functions from model B, select **Measure task execution time** for the top model and specify **Measure function execution times** for model B.

These parameters of the top model override the corresponding parameters of referenced models:

- **Measure task execution time.** If you disable this parameter for the top model, you also disable function profiling for referenced models.
- **Workspace variable**
- **Save options**

To control code execution profiling for a block in a model, for example, a subsystem block, use the `CodeProfilingOverride` block parameter:

- 1 In the Simulink Editor, select the block.
- 2 In the Command Window, run:

```
set_param(gcb, 'CodeProfilingOverride', blockParameterValue)
```

Use one of these values for *blockParameterValue*:

- 'off' -- Disables profiling for the block.
- 'on' -- Enables profiling for the block if profiling is enabled for the parent model.
- 'inherit' (default) -- Applies profiling settings of parent block.

Changing the block profiling configuration does not cause the regeneration of production code.

If your top model has a PIL block, the execution profiling settings that apply to the PIL block are the settings from the original model that you used to create the PIL block. See “Simulation with Subsystem Blocks” on page 88-17. You cannot use `CodeProfilingOverride` to control profiling for a PIL block.

## View and Compare Code Execution Times

You can run a software-in-the-loop (SIL), processor-in-the-loop (PIL), or XCP-based external mode simulation that produces execution-time metrics for your generated code.

During the simulation, you can use the Simulation Data Inspector to observe streamed execution times. In an XCP-based external mode simulation, you can also visualize task scheduling and related target hardware activity.

At the end of the simulation, you can:

- View execution-time metrics for a profiled model component.
- Open a report of execution-time metrics for profiled components. Through report icons, you can view, for example, the profiled code section and the execution-time distribution for each profiled code section.
- Use the Simulation Data Inspector to plot and compare execution times from various simulations.

### Run Simulation That Generates Execution-Time Metrics

In this section, to generate execution-time metrics, you run a SIL simulation. For an example that runs an XCP-based external mode simulation, see “Visualize Task Scheduling in XCP External Mode Simulation” on page 81-31.

Open the `SILTopModel` model, which has two subsystems `CounterTypeA` and `CounterTypeB`. At the command line, enter:

```
openExample('ecoder/SILPILVerificationExample', ...
 supportingFile='SILTopModel.slx')
```

To run a SIL simulation that generates execution-time metrics, on the **SIL/PIL** tab:

- 1 In the **Mode** section, select **SIL/PIL Simulation Only**.
- 2 In the **Prepare** section, specify these settings:
  - a **System Under Test** — Top model
  - b **SIL/PIL Mode** — Software-in-the-Loop (SIL)
- 3 To measure code execution times for the subsystems, in the **Prepare** section:
  - a Click **Settings**.
  - b Under **Time Profiling**:
    - Click the **Task Profiling** button on. This action selects the **Measure task execution time** configuration parameter, which provides execution-time metrics for the task generated from the top model `SILTopModel`.
    - Click the **Save Options** button until it displays **ALL DATA**. This action sets the **Save options** configuration parameter to **All data**.
    - Click the **Functions** button until it displays **COARSE**. This action sets the **Measure function execution times** configuration parameter to **Coarse (referenced models and subsystems only)**, which provides execution-time metrics for the functions generated from the subsystems `CounterTypeA` and `CounterTypeB`.

- c Under **Coverage**, click the **Coverage Collection** button off, which disables code coverage analysis. You collect code coverage data separately from profiling data.
  - d Click the **Settings** button to open the Configuration Parameters dialog box. On the **Data Import/Export** pane, clear **Single simulation output** and then click **OK**.
- 4 To view streamed execution times during the simulation, open the Simulation Data Inspector. In the **Results** section, click .
  - 5 In the **Run** section, click **Run SIL/PIL**.

In the MATLAB base workspace, the simulation generates a variable with the default name, `executionProfile`, which stores the execution profiling data. You can specify an alternative name through the **Workspace variable** configuration parameter.

**Note** If the **Data Import/Export > Single simulation output** check box is selected, the simulation creates the variable in your specified Simulink.SimulationOutput object.

During the simulation, use the Simulation Data Inspector to observe, for example, the variation of execution times for the `step` function.

When the simulation is complete, the profiled model components are colored blue and the Code view displays the generated code. To view execution-time metrics for a profiled component, click the component. For example, subsystem `CounterTypeB`.

The screenshot shows the Profiling window for the task 'rtwdemo\_sil\_topmodel'. The main display shows a table of execution metrics for the 'CounterTypeB' block. The table has columns for Maximum Execution Time in ns, Average Execution Time in ns, Maximum Self Time in ns, Average Self Time in ns, and Calls. The data is as follows:

Block: CounterTypeB	Maximum Execution Time in ns	Average Execution Time in ns	Maximum Self Time in ns	Average Self Time in ns	Calls
initialize:CounterTypeB	11	11	11	11	1
step [0.1 0]:CounterTypeB	649	33	649	33	101

Below the table is a link to 'View full code execution profiling report'. The background shows a Simulink block diagram with a 'CounterTypeB' block and its associated code view. An orange arrow points from the 'initialize' row in the table to the corresponding code section in the Code view.

For top-model SIL or PIL simulations, the Simulink Editor background is also colored blue. When you click the background, the display window shows execution-time metrics for top-model tasks.

You can trace from a model component to the profiled code section in the Code view. In the Profiling display window, on a code section row, click the icon . For example, if you click the model background and then click the icon for the SILTopModel\_initialize task, you see the measurement probes around the call site in the SIL application. To see the profiling metrics for the component, place your cursor on the call site.

The screenshot shows the Code view with a tooltip displaying profiling metrics for the 'initialize' function. The code is as follows:

```

62 {
63 return XIL_INTERFACE_SUCCESS;
64 }
65
66 XIL_ uint32_T xilFcnId)
67 {
68 XI XIL_INTERFACE_SUCCESS;
69
70 /* In-the-Loop */
71 /*
72 if
73
74 initialize();
75 taskTimeEnd_rt_0c8405b404040924(1U);
76 } else {
77 errorCode = XIL_INTERFACE_UNKNOWN_FCNOID;
78 }

```

The tooltip shows the following profiling data:

Code profiling	
Maximum Execution Time	602
Average Execution Time	602
Maximum Self Time	348
Average Self Time	348
Number of Calls	1

Unit of time : seconds

If you click the icon for a function, the call site is highlighted. The Code view displays the average execution time and number of function calls to the left of the code line. In this example, the maximum and average times are the same because the initialization function was called only one time.

```

136 /* Outputs for Enabled SubSystem: '<Root>/CounterTypeA' */
312 101 137 CounterTypeA();
138
139 /* End of Outputs for SubSystem: '<Root>/CounterTypeA' */

```

The Profiling display window also has links to:

- The complete profiling report, which provides execution-time metrics for all profiled code sections.
- The Simulation Data Inspector, which allows you to plot and compare execution-time measurements for the profiled code section.
- The execution-time distribution for the profiled code section.
- Pie charts that show the relative execution times of caller and called functions

If you close the model or display window, you can reopen the colored model and display window with this line command:

```
annotate(executionProfile)
```

## Code Execution Profiling Report Sections

At the end of the simulation, you can open the report through the Profiling display window or by using this line command:

```
report(executionProfile)
```

The report contains these sections:

### 1 Summary

This section gives information about the creation of the report.

#### 1. Summary

Total time	19232
Unit of time	ns
Command	report(executionProfile, 'Units', 'seconds', 'ScaleFactor', '1e-09', 'NumericFormat', '%0.0f');
Timer frequency (ticks per second)	3.6e+09
Profiling data created	30-Nov-2021 19:04:25

### 2 Feasibility Checks

If the number of timer ticks per second is known, the simulation performs feasibility checks and displays results in this section. The checks are shown in this table.

Check	Comments
Overall average CPU utilization lower than threshold	The default threshold value is 70%. To change the threshold value, for example, to 85%, use this command: <code>executionProfile.CPUUtilization=0.85;</code>  For information about CPU utilization, see section 5.
Overall maximum CPU utilization lower than threshold	
All average execution times are shorter than their task period	Use the results of these checks to verify that task overrun does not occur.
All maximum execution times are shorter than their task period	

**Note** An external mode simulation does not produce this section.

In the **Results** column, the report displays Passed or Failed.

## 2. Feasibility Checks [\[hide\]](#)

Check Description	Results
Overall average CPU utilization lower than threshold (70%)	Passed
Overall maximum CPU utilization lower than threshold (70%)	Passed
All average execution times are shorter than their task period	Passed
All maximum execution times are shorter than their task period	Passed

## 3 Profiled Sections of Code

This section contains information about profiled code sections. In the **Section** column, expand and collapse profiled sections by clicking [+] and [-] respectively. This graphic shows fully expanded sections.

### 3. Profiled Sections of Code

Section	Maximum Execution Time in ns	Average Execution Time in ns	Maximum Self Time in ns	Average Self Time in ns	Calls	
[-] <a href="#">initialize</a>	72	72	42	42	1	
<a href="#">CounterTypeA</a>	19	19	19	19	1	
<a href="#">CounterTypeB</a>	11	11	11	11	1	
[-] <a href="#">step [0.1 0]</a>	973	190	309	103	101	
<a href="#">CounterTypeA</a>	353	53	353	53	101	
<a href="#">CounterTypeB</a>	649	33	649	33	101	

In this example, the report contains time measurements for:

- The model initialization function `initialize`.
- A task represented by the step function `step [0.1 0]`.
- Functions generated from the subsystems `CounterTypeA` and `CounterTypeB`.

From the report, you can trace the model component that produces a set of metrics. For example, in the **Section** column, if you click the `CounterTypeA` hyperlink, the Simulink Editor identifies the subsystem.

By default, the report displays time in nanoseconds ( $10^{-9}$  seconds). You can specify the time unit and numeric display format. For example, to display time in microseconds ( $10^{-6}$  seconds), use the following command:

```
report(executionProfile, ...
 'Units', 'Seconds', ...
 'ScaleFactor', '1e-06', ...
 'NumericFormat', '%0.3f')
```

The report displays time in seconds only if the timer is calibrated, that is, the number of timer ticks per second is known. On a Windows machine, the software determines this value for a SIL simulation. On a Linux machine, calibrate the timer manually. For example, if your processor speed is 1 GHz, specify the number of timer ticks per second:

```
executionProfile.TimerTicksPerSecond = 1e9;
```

To view execution-time metrics for a task or function in the Command Window, on the corresponding row, click .

```
>> executionProfile.Sections(5)
ExecutionTimeCodeSection with properties:

 Name: 'CounterTypeA'
 Number: 5
 ExecutionTimeInTicks: [122 102 100 86 88 88 88 86 88 88 156 122 ...]
 SelfTimeInTicks: [122 102 100 86 88 88 88 86 88 88 156 122 ...]
 TurnaroundTimeInTicks: [122 102 100 86 88 88 88 86 88 88 156 122 ...]
 TotalExecutionTimeInTicks: 19436
 TotalSelfTimeInTicks: 19436
 TotalTurnaroundTimeInTicks: 19436
 MaximumExecutionTimeInTicks: 1270
 MaximumExecutionTimeCallNum: 27
 MaximumSelfTimeInTicks: 1270
 MaximumSelfTimeCallNum: 27
```

```

MaximumTurnaroundTimeInTicks: 1270
MaximumTurnaroundTimeCallNum: 27
 NumCalls: 101
ExecutionTimeInSeconds: [3.3889e-08 2.8333e-08 2.7778e-08 2.3889e-08 ...]
 Time: [101x1 double]

```

To display measured execution times in the Simulation Data Inspector, click the icon . Then, select the step [0.1 0] and CounterTypeB check boxes.

You can see how execution times for the step and child functions vary over simulation time.

The execution time for the step function step [0 0.1] is the sum of its self-time and execution times for the child functions CounterTypeA and CounterTypeB. You can use the Simulation Data Inspector to manage and compare plots from various simulations.

To display the execution-time distribution, click the icon .

In this example, to create the histogram, the software uses these commands:

```

section=executionProfile.Sections(5);
data=section.ExecutionTimeInSeconds;
histogram(data, 30, 'Normalization', 'probability');

```

The software creates the histogram only if the number of calls is greater than one.

If the generated code for your model contains nested functions, the simulation generates pie charts that show the relative execution times of caller and called functions. To display the pie charts, click the icon  for the caller function. For example, step [0.1 0].

The pie charts, which display average and maximum execution time distributions, can help you to identify functions that are bottlenecks in code execution.

This table describes the information that **Profiled Sections of Code** provides.

Column	Description
Section	Name of task, top model, subsystem, or Model block. Click the link to go to the model.  With a task, the sample period and sample offset are listed next to the task name. For example, <i>SILTopModel_step [0.1 0]</i> indicates that the sample period is 0.1 seconds and the sample offset is 0.
Maximum Turnaround Time (Simulink Real-Time and support packages in real-time mode)	Longest time between start and end of code section. Includes preemption time.
Average Turnaround Time (Simulink Real-Time and support packages in real-time mode)	Average time between start and end of code section. Includes preemption time.
Maximum Execution Time	Longest time between start and end of code section.
Average Execution Time	Average time between start and end of code section.
Maximum Self Time	Maximum execution time, excluding time in child sections.
Average Self Time	Average execution time, excluding time in child sections.

Column	Description
	Number of calls to the code section.
	Icon that you click to see the profiled code section in the Code view of the SIL/PIL app. The code section can be a task or a function.  The specified workspace variable, for example, <code>executionProfile</code> , must be present in the base workspace.
	Icon that you click to display the profiled code section in the Command Window. Equivalent to executing the command <code>executionProfile.Sections(i)</code> .  The specified workspace variable, for example, <code>executionProfile</code> , must be present in the base workspace.
	Icon that you click to display measured execution times with Simulation Data Inspector.  The specified workspace variable, for example, <code>executionProfile</code> , must be present in the base workspace.
	Icon that you click to display the execution-time distribution for the profiled code section.  The specified workspace variable, for example, <code>executionProfile</code> , must be present in the base workspace.
	Icon that you click to display pie charts that show the relative execution times of caller and called functions in the generated code.

#### 4 Execution Times in Percentages

This section provides function execution times as percentages of caller function and total execution times, which can help you to identify performance bottlenecks in generated code.

#### 4. Execution Times in Percentages [\[hide\]](#)

Section	Self Time / Caller Function	Self Time / Task	Self Time / Simulation	Function / Simulation
[ - ] <a href="#">initialize</a>	58.14%	58.14%	0.21665%	0.37264%
<a href="#">CounterTypeA</a>	27.132%	27.132%	0.1011%	0.1011%
<a href="#">CounterTypeB</a>	14.729%	14.729%	0.054885%	0.054885%
[ - ] <a href="#">step [0.1.0]</a>	54.501%	54.501%	54.298%	99.627%
<a href="#">CounterTypeA</a>	28.177%	28.177%	28.072%	28.072%
<a href="#">CounterTypeB</a>	17.321%	17.321%	17.257%	17.257%

This table describes the information that each column provides.

Column	Comparison Performed
<b>Self Time / Caller Function</b>	Function self time compared with the total execution time of the caller function.

Column	Comparison Performed
<b>Self Time / Task</b>	Function self time compared with the total execution time of the task.
<b>Self Time / Simulation</b>	Function self time compared with the total execution time of the simulation.
<b>Function / Simulation</b>	Function execution time, which includes self time and time spent in child functions, compared with the total execution time of the simulation.

---

**Note** An external mode simulation does not produce this section.

---

## 5 CPU Utilization

To help you to decide whether you can run the generated code on your target hardware, this section of the code execution profiling report provides CPU workload information:

- Average and maximum CPU time required by each task during a sample period.
- Total CPU usage in a sample period.

The software computes the percentage of CPU time assigned to a task by dividing task execution time by sample time.

### 5. CPU Utilization [\[hide\]](#)

Task	Average CPU Utilization	Maximum CPU Utilization
<a href="#">step [0.1 0]</a>	0.0001897%	0.0009728%
Overall CPU Utilization	0.0001897%	0.0009728%

The software generates **CPU Utilization** only if the number of timer ticks per second is known.

## 6 Definitions

This section provides descriptions of some metrics.

### 6. Definitions

**CPU Utilization:** Percentage of CPU time assigned to a task. Computed by dividing task execution time by sample time.

**CPU Utilization Threshold:** Maximum CPU utilization that allows task scheduling without deadline misses or overruns. To override the default (70%), use the CPUUtilization parameter.

**Execution Time:** Time between start and end of code section.

**Self Time:** Execution time, excluding time in child sections.

## View Code Execution Profiles for Multiple Model Blocks

You can configure a top-model simulation that runs multiple Model blocks in SIL or PIL mode with code execution profiling enabled. When you run the simulation, it generates separate code execution profiling reports for the referenced models.

- 1 Open the top model that contains Model blocks. For example, at the command line, enter:  

```
openExample('ecoder/SILPILVerificationExample', ...
 supportingFile='SILModelBlock.slx')
```
- 2 On the **SIL/PIL** tab, in the **Mode** section, specify **SIL/PIL Simulation Only**.
- 3 In the **Prepare** section, specify these settings:
  - **System Under Test** -- Model blocks in SIL/PIL mode
  - **Top Model Mode** -- Normal
- 4 Model block Counter A is already configured to run in SIL mode. For Model block Counter B, set the block parameter **Simulation mode** to Software-in-the-loop (SIL).
- 5 Both Model blocks reference the model SILCounter. To generate execution times for the Model blocks:
  - a Select CounterA or CounterB.
  - b On the **Model Block** tab, in the **Actions** section, click **Open as Top Model**.
  - c On the **SIL/PIL** tab, in the **Settings** gallery, click **Functions** to COARSE, which sets the **Measure function execution times** configuration parameter for SILCounter to Coarse (referenced models and subsystems only).
- 6 To run a top-model simulation:
  - a Select the SILModelBlock window.
  - b On the **SIL/PIL** tab, in the **Run** section, click **Run SIL/PIL**.

Since the **Single simulation output** check box is selected, the simulation creates the variable `executionProfile` in `out`, a `Simulink.SimulationOutput` object.
- 7 When the simulation is complete, to show the number of Model blocks that are profiled, in the Command Window, enter:  

```
NumOfReports=out.executionProfile.getModuleNumber()

NumOfReports =
 2
```
- 8 To open the report for CounterA, the first Model block, run:  

```
report(out.executionProfile.getModule(1))
```

## 1. Summary

Total time	4955
Unit of time	ns
Command	report('Units', 'seconds', 'ScaleFactor', '1e-09', 'NumericFormat', '%0.0f');
Timer frequency (ticks per second)	3.6e+09
Profiling data created	03-Dec-2021 12:24:45

The simulation ran multiple model blocks in SIL or PIL mode with code execution profiling enabled. To view execution-time metrics for a model block, click the corresponding report link:

<a href="#">rtwdemo_sil_modelblock/CounterA</a>	This report
<a href="#">rtwdemo_sil_modelblock/CounterB</a>	<a href="#">Open report</a>

## 2. Profiled Sections of Code

- 9 In the **Summary** section, the report provides a link to the second Model block report. To open the report for CounterB, click Open report or run:

```
report(out.executionProfile.getModule(2))
```

For more information about generating function execution times for model reference hierarchies, see “Control Profiling Granularity” on page 81-3.

## Compare Code Execution-Time Performance Against Baseline

You can create a code execution profiling report that compares the performance of the generated code against the performance of a reference version. For example, suppose you want to use the current execution-time metrics in `executionProfile` as the baseline for `SILTopModel`.

- 1 In the Workspace browser, rename `executionProfile` to `executionProfileBaseline`.
- 2 Run another SIL simulation.
- 3 To create a report that compares the latest performance against the baseline, in the Command Window, run:

```
report(executionProfile, 'baseline', executionProfileBaseline)
```

In the report, the **Comparison with Baseline Performance** and **CPU Utilization** sections provide comparisons of execution-time metrics. The differences in execution-time metrics are color-coded:

- Red — An increase in execution times or CPU usage.
- Green — A decrease in execution times or CPU usage.
- Black — No change.

5. Comparison with Baseline Performance [hide]

Section	Maximum Execution Time	Average Execution Time	Maximum Self Time	Average Self Time
[ - ] initialize	-22.75%	-22.75%	-20.86%	-20.86%
CounterTypeA	-26.47%	-26.47%	-26.47%	-26.47%
CounterTypeB	-23.53%	-23.53%	-23.53%	-23.53%
[ - ] step [0.1.0]	+53.35%	+11.26%	+52.67%	+7.55%
CounterTypeA	+125.25%	+20.19%	+125.25%	+20.19%
CounterTypeB	-69.86%	+9.09%	-69.86%	+9.09%

6. CPU Utilization [hide]

Task	Average CPU Utilization Baseline in brackets	Maximum CPU Utilization Baseline in brackets
step [0.1.0]	0.0001181% (0.0001062%)	0.0003689% (0.0002406%)
Overall CPU Utilization	0.0001181% (0.0001062%)	0.0003689% (0.0002406%)

## Visualize Task Scheduling

You can use the Simulation Data Inspector to visualize task scheduling and related target hardware activity.

Simulation Mode	What You Can Observe	How
SIL or PIL	Task scheduling and the order of function calls	<p>When the SIL or PIL simulation is complete, perform one of these actions:</p> <ul style="list-style-type: none"> <li>Run the <code>schedule</code> function. For details, see “Visualize Task Scheduling in SIL Simulation”</li> <li>From the <b>SIL/PIL</b> tab, in the <b>Results</b> gallery, click <b>Generate Schedule</b>. For more information, see “Analyze Results and Export Test Cases” on page 88-73.</li> </ul>
XCP-based external	Task activity, task diagnostics (run-time only), CPU activity, and CPU utilization	<p>During the XCP external mode simulation, use the Simulation Data Inspector to view displays for task scheduling and related activity.</p> <p>After the simulation, use the <code>schedule</code> function to regenerate displays (except for task diagnostics).</p> <p>For more information, see “Visualize Task Scheduling in XCP External Mode Simulation” on page 81-31.</p>

- “Tips and Limitations” on page 81-41

## Analyze Code Execution Data

After a software-in-the-loop (SIL), processor-in-the-loop (PIL), or XCP-based external mode simulation, you can analyze execution-time data using methods from the `coder.profile.ExecutionTime` and `coder.profile.ExecutionTimeSection` classes.

- 1 Open the model `SILTopModel`.

```
openExample('ecoder/SILPILVerificationExample', ...
 supportingFile='SILTopModel.slx')
```

- 2 In the **Mode** section, select **SIL/PIL Simulation Only**.

- 3 In the **Settings** gallery, specify options to enable profiling:

- Under **SIL/PIL Settings**, click **Portable Word Sizes** on.
- Under **Time Profiling**, click **Task Profiling** on, click **Save Options** to ALL DATA, and click **Functions** off.
- Under **Coverage**, click **Coverage Collection** off.

- 4 In the **Run** section, click **Run SIL/PIL**.

The software generates out, a `Simulink.SimulationOutput` object that contains `executionProfile`, a `coder.profile.ExecutionTime` object.

To get the total number of code sections that have profiling data, use the `Sections` method:

```
no_of_Sections = out.executionProfile.Sections
```

```
no_of_Sections =
```

```
1x2 ExecutionTimeTaskSection array with properties:
```

```
Name
Number
ExecutionTimeInTicks
SelfTimeInTicks
TurnaroundTimeInTicks
TotalExecutionTimeInTicks
TotalSelfTimeInTicks
TotalTurnaroundTimeInTicks
MaximumExecutionTimeInTicks
MaximumExecutionTimeCallNum
MaximumSelfTimeInTicks
MaximumSelfTimeCallNum
MaximumTurnaroundTimeInTicks
MaximumTurnaroundTimeCallNum
NumCalls
ExecutionTimeInSeconds
Time
```

To get the `coder.profile.ExecutionTimeSection` object for a profiled code section, use the method `Sections`.

```
FirstSectionProfile = out.executionProfile.Sections(1)
```

```
SecondSectionProfile = out.executionProfile.Sections(2)
```

```
FirstSectionProfile =
```

```
ExecutionTimeTaskSection with properties:
```

```
 Name: 'initialize'
 Number: 1
ExecutionTimeInTicks: 154
```

```

 SelfTimeInTicks: 154
 TurnaroundTimeInTicks: 154
 TotalExecutionTimeInTicks: 154
 TotalSelfTimeInTicks: 154
 TotalTurnaroundTimeInTicks: 154
 MaximumExecutionTimeInTicks: 154
 MaximumExecutionTimeCallNum: 1
 MaximumSelfTimeInTicks: 154
 MaximumSelfTimeCallNum: 1
 MaximumTurnaroundTimeInTicks: 154
 MaximumTurnaroundTimeCallNum: 1
 NumCalls: 1
 ExecutionTimeInSeconds: 4.2778e-08
 Time: 0

```

SecondSectionProfile =

ExecutionTimeTaskSection with properties:

```

 Name: 'step [0.1 0]
 Number: 2
 ExecutionTimeInTicks: [262 216 176 174 174 174 178 172 ...]
 SelfTimeInTicks: [262 216 176 174 174 174 178 172 ...]
 TurnaroundTimeInTicks: [262 216 176 174 174 174 178 172 ...]
 TotalExecutionTimeInTicks: 22366
 TotalSelfTimeInTicks: 22366
 TotalTurnaroundTimeInTicks: 22366
 MaximumExecutionTimeInTicks: 748
 MaximumExecutionTimeCallNum: 68
 MaximumSelfTimeInTicks: 748
 MaximumSelfTimeCallNum: 68
 MaximumTurnaroundTimeInTicks: 748
 MaximumTurnaroundTimeCallNum: 68
 NumCalls: 101
 ExecutionTimeInSeconds: [7.2778e-08 6.0000e-08 4.8889e-08 4.8333e-08 ...]
 Time: [101x1 double]

```

Use `coder.profile.ExecutionTimeSection` methods to extract profiling information for a particular code section. For example, use `Name` to obtain the name of a profiled task.

```
name_of_section = SecondSectionProfile.Name
```

```
name_of_section =
 'step [0.1 0]'
```

If the timer is uncalibrated and you know the timer rate, for example 2.2 GHz, you can use the `coder.profile.ExecutionTime` method `TimerTicksPerSecond` to calibrate the timer.

```
out.executionProfile.TimerTicksPerSecond = 2.2e9;
SecondSectionProfile = out.executionProfile.Sections(2);
```

## Code Execution Profiling From the Command Line

This example shows how you can use line commands to produce execution-time metrics for generated code.

- 1 Open `SILTopModel`, which has two subsystems and is configured to run a software-in-the-loop (SIL) simulation.

```
openExample('ecoder/SILPILVerificationExample', ...
 supportingFile='SILTopModel.slx')
```

- 2 Configure code execution time profiling:

- a Produce execution-time metrics for the task generated from the top model.

```
set_param(gcs, 'CodeExecutionProfiling', 'on');
```

- b Produce execution-time metrics for functions generated from the subsystems in the model.

```
set_param(gcs, 'CodeProfilingInstrumentation', 'coarse');
```

- c Save all code profiling data to an object in the base workspace.

```
set_param(gcs, ...
 'CodeProfilingSaveOptions', 'AllData');
```

- 3 Disable Simulink Coverage and third-party code coverage analysis.

```
set_param(gcs, ...
 'CovEnable', 'off');
covSettings = get_param(gcs, 'CodeCoverageSettings');
covSettings.CoverageTool = 'None';
set_param(gcs, 'CodeCoverageSettings', covSettings);
```

- 4 Run the simulation.

```
simOut = sim(gcs);
```

The simulation generates the variable `executionProfile` (default) in the object `simOut`.

- 5 When the simulation is complete, open the code execution report.

```
report(simOut.executionProfile)
```

- 6 To visualize how the tasks are scheduled and the generated code is executed, run:

```
schedule(simOut.executionProfile)
```

## Remove Instrumentation Overheads from Execution Time Measurements

To improve execution-time profiling of generated code that runs on deterministic hardware, you can run processor-in-the-loop (PIL) simulations that automatically filter the overheads associated with code instrumentation. You can use the target hardware to estimate the average overhead value or you can specify the value manually.

---

**Note** By default, the software filters the execution times of AUTOSAR Runtime Environment (RTE) code and functions that run within Simulink, for example, Function Caller blocks.

---

### Approach for Estimating and Removing Instrumentation Overhead

When you set up target connectivity for PIL simulations, you can specify objects or functions for estimating and removing instrumentation overheads from execution-time measurements.

You can:

- Set up a benchmark program that Simulink runs a specified number of times at the start of a PIL simulation. The benchmark program estimates the overheads for the timer API and for timer freezing and unfreezing, task, and function instrumentation code. Simulink obtains average values for the instrumentation overheads.
- Manually specify instrumentation overhead values.

During the PIL simulation, Simulink subtracts the instrumentation overhead values from the execution-time measurements. The Simulation Data Inspector and the code execution profiling report display the corrected measurement values.

This figure shows how the uncorrected and corrected timer values correspond to invocations of code sections.

The corrected timer value excludes execution time associated with instrumentation code, RTE code, and function code that runs within Simulink.

To estimate and remove instrumentation overheads from execution-time measurements:

- If PIL connectivity is set up by using the `target` package, use overhead classes from the package.
- If PIL connectivity is set up by using the `rtw.connectivity.Config` class, use functions from the class.

## Remove Instrumentation Overheads by Using target Package

To provide the software with instrumentation overhead values, use one of these methods:

- Set up the benchmark program that estimates overhead values.
- Using overhead classes, manually specify overhead values.

### Set Up Benchmark Program

When you set up target connectivity on page 88-48, implement these steps:

- 1 Retrieve the `target.Processor` and `target.Timer` objects.

```
processor = target.get('Processor', myProcessorObjectId);
timer = target.get('Timer', myTimerObjectId);
```

- 2 Create a `target.ProfilingTaskOverhead` object.

```
taskOverhead = target.create('ProfilingTaskOverhead', ...
 'Name', 'Timer Task Overhead');
taskOverhead.Counter = timer;
taskOverhead.MinimumBenchmarkIterations = 150;
```

- 3 Associate the overhead values with the processor.

```
processor.Overheads = taskOverhead;
```

### Specify Overhead Values

When you set up target connectivity on page 88-48, create overhead class objects and use the `Value` property to specify your value for the corresponding instrumentation overhead.

- 1 Retrieve the `target.Processor` and `target.Timer` objects.

```
processor = target.get('Processor', myProcessorObjectId);
timer = target.get('Timer', myTimerObjectId);
```

- 2 Create a `target.ProfilingTaskOverhead` object.

```
taskOverhead = target.create('ProfilingTaskOverhead', ...
 'Name', 'Timer Task Overhead');
taskOverhead.Value = 10;
taskOverhead.Counter = timer;
```

- 3 Create a `target.ProfilingFunctionOverhead` object.

```
functionOverhead = target.create('ProfilingFunctionOverhead', ...
 'Name', 'Timer Function Overhead');
functionOverhead.Value = 20;
functionOverhead.Counter = timer;
```

- 4 Create a `target.ProfilingFreezingOverhead` object.

```
freezingOverhead = target.create('ProfilingFreezingOverhead', ...
 'Name', 'Timer Freezing Overhead');
```

```
freezingOverhead.Value = 30;
freezingOverhead.Counter = timer;
```

- 5 Associate the overhead values with the processor.

```
processor.Overheads = ...
[taskOverhead, functionOverhead, freezingOverhead];
```

## Remove Instrumentation Overheads by Using Functions from `rtw.connectivity.Config`

The `rtw.connectivity.Config` class provides these functions for the removal of instrumentation overheads.

Function	Description
<code>activateOverheadFiltering</code>	<code>obj.activateOverheadFiltering (value)</code> ; activates filtering of instrumentation overheads if <code>value</code> is <code>true</code> . Deactivates overhead filtering if <code>value</code> is <code>false</code> .
<code>isOverheadFilteringActive</code>	<code>obj.isOverheadFilteringActive</code> returns <code>true</code> if instrumentation overhead filtering is activated. Otherwise, returns <code>false</code> .
<code>runOverheadBenchmark</code>	<code>obj.runOverheadBenchmark (value)</code> ; runs a benchmark program if <code>value</code> is <code>true</code> . Does not run the benchmark program if <code>value</code> is <code>false</code> .
<code>isOverheadBenchmarkExecuted</code>	<code>obj.isOverheadBenchmarkExecuted</code> ; returns <code>true</code> if execution of benchmark program is complete. Otherwise, returns <code>false</code> .
<code>setOverheadBenchmarkSteps</code>	<code>obj.setOverheadBenchmarkSteps (steps)</code> ; specifies number of steps for benchmark program.
<code>getOverheadBenchmarkSteps</code>	<code>steps = obj.getOverheadBenchmarkSteps</code> returns the number of specified steps for the benchmark program.
<code>setOverheads</code>	<code>obj.setOverheads (taskInstrumentationOverhead, functionInstrumentationOverhead, freezingInstrumentation)</code> ; specifies the overhead values for task, function, and freezing instrumentation respectively.
<code>getOverheads</code>	<code>[taskInstrumentationOverhead, functionInstrumentationOverhead, freezingInstrumentation] = obj.getOverheads</code> ; returns overhead values for task, function, and freezing instrumentation respectively.

When you set up target connectivity on page 88-38 for PIL simulations, configure the removal of the instrumentation overheads through an `rtw.connectivity.Config` subclass. For example, this code shows how you can run the benchmark program.

```

classdef overheadConnectivityConfig < rtw.connectivity.Config
 methods
 function this = customConnectivityConfig(componentArgs)

 % Create builder
 targetApplicationFramework = ...
 mypil.TargetApplicationFramework(componentArgs);
 builder = rtw.connectivity.MakefileBuilder(componentArgs, ...
 targetApplicationFramework, '');

 % Create launcher
 launcher = mypil.Launcher(componentArgs, builder);

 % Set up communication
 hostCommunicator = rtw.connectivity.RtIOStreamHostCommunicator(...
 componentArgs, ...
 launcher, ...
 rtiostreamLibTCPIP);

 % Call super class constructor to register components
 this@rtw.connectivity.Config(componentArgs,...
 builder,...
 launcher,...
 hostCommunicator);

 % Register hardware-specific timer, which enables
 % code execution profiling. This example uses a
 % timer for the host platform.
 timer = coder.profile.crlHostTimer();
 this.setTimer(timer);

 % Specify removal of profiling instrumentation overheads
 this.activateOverheadFiltering(true);
 this.runOverheadBenchmark(true);
 this.setOverheadBenchmarkSteps(50);

 end
 end
end

```

Instead of running the benchmark program, you can use `setOverheads` to provide your values for instrumentation overheads.

```

...

% Remove instrumentation overhead using manually specified values
this.activateOverheadFiltering(true);
this.setOverheads (taskInstrumentationOverhead, ...
 functionInstrumentationOverhead, freezingInstrumentation);

...

```

## Retrieve Benchmark Results

When a PIL simulation is complete, you can retrieve benchmark results from the variable that you specify in the **Code Generation > Verification > Workspace variable** field (CodeExecutionProfileVariable), for example, myExecutionProfile.

```
benchmarkResults = myExecutionProfile.getOverheadBenchmarkData();
```

*benchmarkResults* is a structure that contains code instrumentation overhead values.

```
>> benchmarkResults
ans =
 struct with fields:
 TimestampOverhead: [1x1 struct]
 TaskOverhead: [1x1 struct]
 FunctionOverhead: [1x1 struct]
 FreezingOverhead: [1x1 struct]

>> benchmarkResults.TaskOverhead
ans =
 struct with fields:
 Data: [1x100 uint64]
 NumSamples: 100
 Average: 45.2800
```

## Reduce Bandwidth Usage During Code Execution Profiling

This topic shows how you can reduce communication channel bandwidth usage when running software-in-the-loop (SIL), processor-in-the-loop (PIL), or XCP-based external mode simulations with code execution profiling enabled.

### Capture Main Profiling Metrics on Target Hardware

For code execution profiling, to reduce the communication channel bandwidth usage during a software-in-the-loop (SIL) simulation, processor-in-the-loop simulation (PIL), or XCP-based external mode simulation, you can capture and store only these profiling metrics on the target hardware:

- Maximum execution time of code section
- Average execution time of code section
- Number of calls to code section

Enable the capture of the main profiling metrics by setting the configuration parameter **Save options** to **Metrics only**. At the end of the simulation, Simulink uploads the metrics from the target hardware to your development computer.

To run a SIL simulation that generates only the main execution-time metrics:

- 1 Open the model `SILTopModel`, which has two subsystems `CounterTypeA` and `CounterTypeB`.

```
openExample('ecoder/SILPILVerificationExample', ...
 supportingFile='SILTopModel.slx')
```

- 2 On the SIL/PIL tab, in the **Mode** section, select **SIL/PIL Simulation Only**.

- 3 In the **Prepare** section, specify these settings:

- a **System Under Test** — Top model

- b **SIL/PIL Mode** — Software-in-the-Loop (SIL)

- 4 To measure code execution times for the subsystems:

- a Click .

- b In the Configuration Parameters dialog box, select **Measure task execution time**, which provides execution-time metrics for the task generated from the top model `SILTopModel`.

- c Set **Measure function execution times** to **Coarse (referenced models and subsystems only)**, which provides execution-time metrics for the functions generated from the subsystems `CounterTypeA` and `CounterTypeB`.

- d Specify a **Workspace variable**, for example, `executionProfile`. If the **Data Import/Export > Single simulation output** check box is selected, the software creates the variable in the `Simulink.SimulationOutput` object that you specify.

- e From the **Save options** drop-down list, select **Metrics only**.

- f Click **OK**.

- 5 In the **Prepare** section, click **Settings**. Under **Coverage**, click the **Coverage Collection** button off.

- 6 In the **Run** section, click **Run SIL/PIL**.

To open the code execution profiling report, in the Profiling window, click the displayed link. In section 2, the report displays the profiled code sections as a flattened list.

## 2. Profiled Sections of Code

Section	Maximum Execution Time in ns	Average Execution Time in ns	Calls	
<a href="#">rtwdemo_sil_topmodel_initialize</a>	299	299	1	 
<a href="#">rtwdemo_sil_topmodel_step [0,1,0]</a>	450	275	101	 
<a href="#">CounterTypeA (CounterTypeA)</a>	106	78	101	 
<a href="#">CounterTypeB (CounterTypeB)</a>	72	37	101	 
<a href="#">CounterTypeA (CounterTypeA_Init)</a>	57	57	1	 
<a href="#">CounterTypeB (CounterTypeB_Init)</a>	33	33	1	 

The software cannot extract the hierarchy of calls to code sections because this information is not stored on the target hardware.

Overhead filtering on page 81-23 is not supported when **Save options** is set to **Metrics** only.

## Display Absolute Time

During an XCP-based external mode simulation, the Simulation Data Inspector displays, by default, streamed signal values and execution-time metrics with respect to simulation time: after the execution of a task, the target application uploads data samples from the profiling buffer and associates all data samples from the profiling buffer with the same simulation time.

There are potential issues with streaming simulation time:

- During data uploading, memory usage can be suboptimal if the target application uploads the whole profiling buffer even when the profiling buffer contains only a few data samples. The maximum size of the profiling buffer is 255 bytes.
- Data uploading can slow down the execution of the target application.

If the communication channel for the external mode simulation has a low bandwidth or the target application runs tasks with high sampling rates, the generation of profiling data can exceed data uploading, which leads to data loss.

To improve bandwidth usage during data uploading, specify the display of absolute time:

```
set_param(modelName, 'CodeProfilingXCPUUseAbsoluteTime', 'on')
```

When the external mode simulation runs, the target application uploads data samples only when the profiling buffer is full. The Simulation Data Inspector displays streamed values with respect to absolute time instead of simulation time.

# Visualize Task Scheduling in XCP External Mode Simulation

If you run an XCP-based external mode simulation with code execution profiling enabled, you can use the Simulation Data Inspector to visualize how the target hardware executes generated code.

This example shows how to configure and run the simulation and display task activity and diagnostics and CPU activity and utilization.

## Model Configuration

### 1 Create and configure a model in a folder.

In the Command Window, enter these commands:

```
% Create work folder
if mkdir('workFolder')
 rmdir 'workFolder' s
 mkdir('workFolder')
end
cd workFolder
open_system(new_system('myModel'));

% Add, configure, and connect blocks
add_block('simulink/Sources/Sine Wave','myModel/Signal',...
 'Bias','5',...
 'Amplitude','2',...
 'SampleTime','0.01');
set_param('myModel/Signal','position',[140,80,180,120]);

add_block('simulink/Math Operations/Gain','myModel/Signal Gain',...
 'Gain','2');
set_param('myModel/Signal Gain','position',[340,80,380,120]);
add_line('myModel','Signal/1','Signal Gain/1');

% Label signal
signal=get_param('myModel/Signal','PortHandles');
set_param(signal.Outport(1),'Name','test_signal');

% And so on
add_block('simulink/Math Operations/Product','myModel/Product');
set_param('myModel/Product','position',[540,160,580,200]);
add_line('myModel','Signal Gain/1','Product/1');

add_block('simulink/Sources/Sine Wave','myModel/Carrier',...
 'Bias','5',...
 'Amplitude','10',...
 'Frequency','3',...
 'SampleTime','0.02');

set_param('myModel/Carrier','position',[140,240,180,280]);

add_block('simulink/Math Operations/Gain','myModel/Carrier Gain');
set_param('myModel/Carrier Gain','position',[340,240,380,280]);
add_line('myModel','Carrier/1','Carrier Gain/1');

signal=get_param('myModel/Carrier','PortHandles');
set_param(signal.Outport(1),'Name','test_carrier');

add_block('simulink/Signal Attributes/Rate Transition',...
 'myModel/Rate Transition');
set_param('myModel/Rate Transition','position',[440,200,480,240]);
add_line('myModel','Carrier Gain/1','Rate Transition/1');
add_line('myModel','Rate Transition/1','Product/2');

add_block('simulink/Sources/Constant','myModel/Constant',...
 'Value','0');
set_param('myModel/Constant','position',[340,320,380,360]);
```

```
add_block('simulink/Logic and Bit Operations/Relational Operator',...
 'myModel/Relational Operator','Operator','>=');
set_param('myModel/Relational Operator','position',[540,300,580,340]);
add_line('myModel','Carrier Gain/1','Relational Operator/1');
add_line('myModel','Constant/1','Relational Operator/2');

signal=get_param('myModel/Carrier Gain','PortHandles');
set_param(signal.Outport(1),'Name','pos_carrier');

add_block('simulink/Sinks/Scope','myModel/ScopeA');
set_param('myModel/ScopeA','position',[740,160,780,200]);
add_line('myModel','Product/1','ScopeA/1');

signal=get_param('myModel/Product','PortHandles');
set_param(signal.Outport(1),'Name','test_output');

add_block('simulink/Sinks/Scope','myModel/ScopeB');
set_param('myModel/ScopeB','position',[740,300,780,340]);
add_line('myModel','Relational Operator/1','ScopeB/1');

signal=get_param('myModel/Relational Operator','PortHandles');
set_param(signal.Outport(1),'Name','cmp_output');

% Specify the ERT system target file
set_param('myModel','SystemTargetFile','ert.tlc');

% Configure an XCP-based external mode simulation
set_param('myModel','SimulationMode','external');

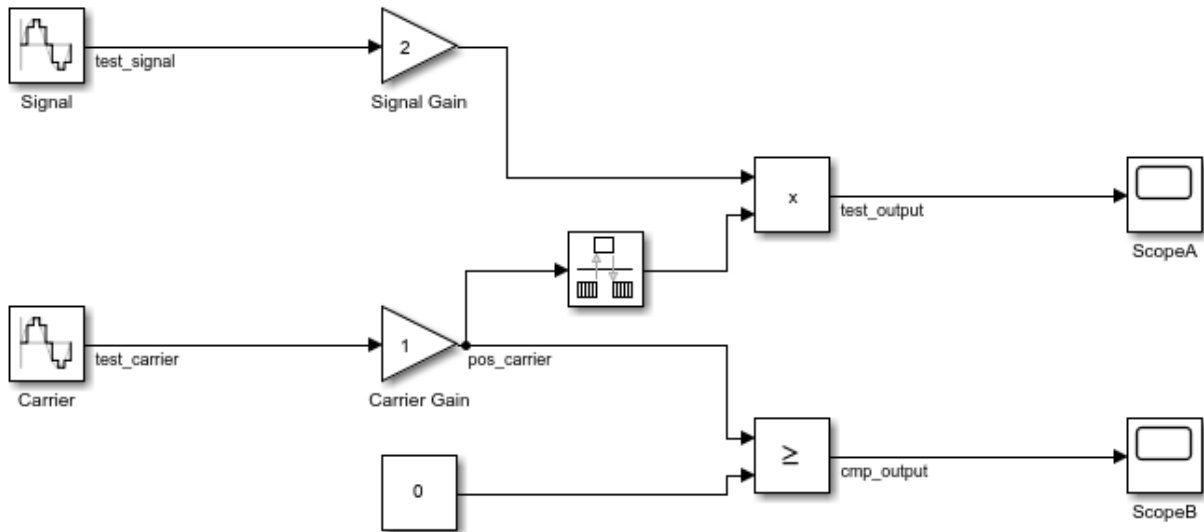

set_param('myModel','SolverType','Fixed-step');
set_param('myModel','ExtMode','on');

cs = getActiveConfigSet('myModel');
index = Simulink.ExtMode.Transports.getExtModeTransportIndex(cs, 'XCP on TCP/IP');
set_param('myModel','ExtModeTransport',index);

set_param('myModel','GenerateSampleERTMain','on');
set_param('myModel','TargetOS','BareBoardExample');

set_param('myModel','ReturnWorkspaceOutputs','off');

% Save the model
save_system('myModel');
```

- 2 Treat each discrete rate as a separate task.

```
set_param(gcs, 'EnableMultiTasking', 'on');
```

- 3 Enable code execution profiling.

```
set_param(gcs, 'CodeExecutionProfiling', 'on');
set_param(gcs, 'CodeProfilingInstrumentation', 'Detailed');
set_param(gcs, 'CodeProfilingSaveOptions', 'AllData');
```

- 4 Open the Simulation Data Inspector.

```
Simulink.sdi.view;
```

- 5 Start the simulation.

```
set_param(gcs, 'SimulationCommand', 'start');
```

## Run-Time Visualization

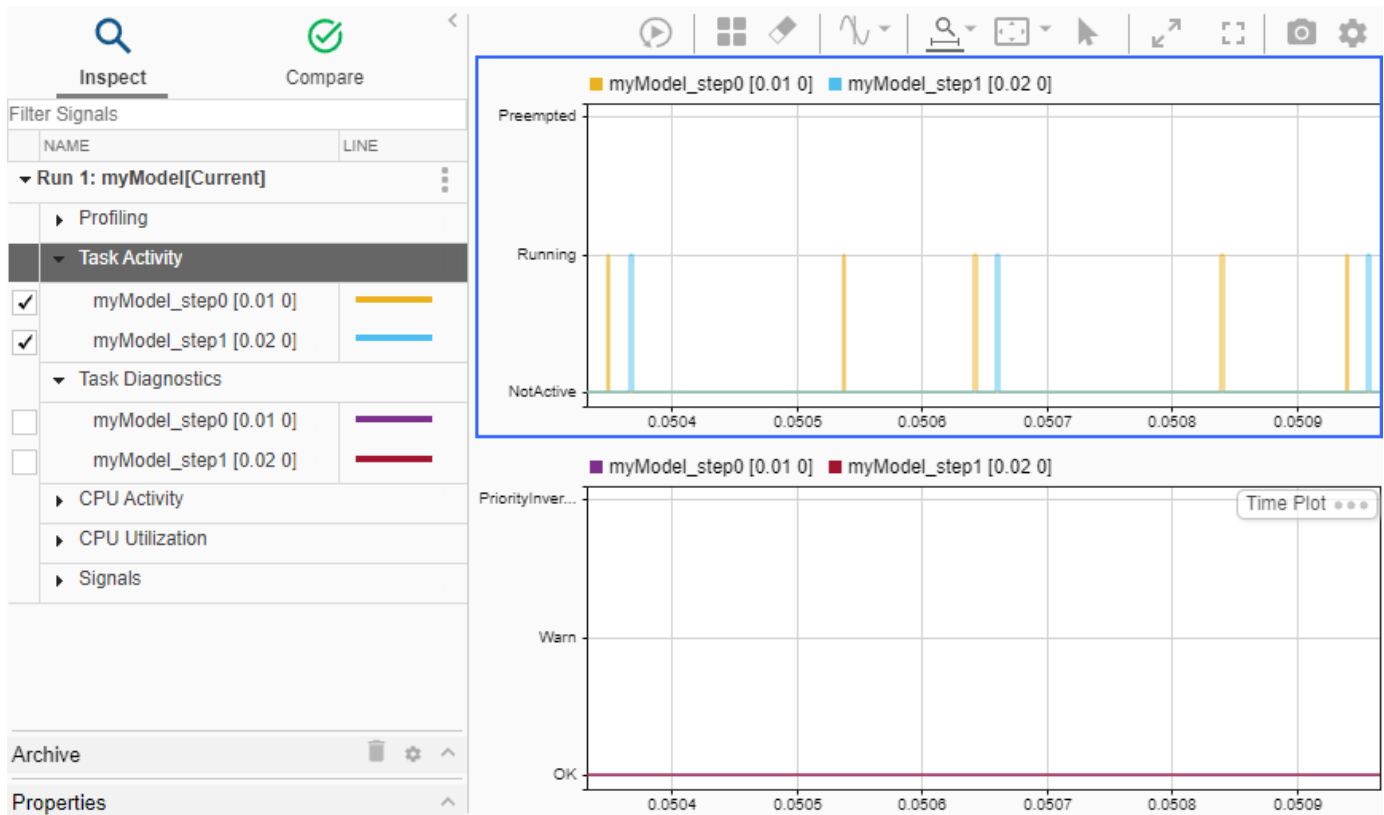

In the Simulation Data Inspector, the **Inspect** pane provides display groups. This table describes the profiling information that is available.

Display Group	Information Available
<b>Profiling</b>	For each task, the variation of execution time over simulation time.
<b>Task Activity</b>	For each task, the variation of its state over time. A task can be in one of these states: <ul style="list-style-type: none"> <li>• <b>NotActive</b> — Task has not started.</li> <li>• <b>Running</b> — Task is running on a processor core.</li> <li>• <b>Preempted</b> — Execution of task is preempted by another task that has a higher priority.</li> </ul>

Display Group	Information Available
<b>Task Diagnostics</b>	<p>For each task, the variation of task diagnostic values over simulation time. A task diagnostic can have one of these values:</p> <ul style="list-style-type: none"> <li>• <b>OK</b> — No scheduling issue detected.</li> <li>• <b>Warn</b> — Warning that the task is preempted by a task with lower priority.</li> <li>• <b>PriorityInversion</b> — Priority inversion detected</li> </ul> <p>The software uses a rate-monotonic analysis to determine task priorities.</p> <p>Task diagnostics are available only for target applications that are generated to run on:</p> <ul style="list-style-type: none"> <li>• Your development computer</li> <li>• Target devices that are Linux-based.</li> </ul>
<b>CPU Activity</b>	<p>For each CPU core, the names of tasks that run on the CPU core over simulation time. At any instant, if no task is running on the CPU core, the value <code>idle</code> is displayed.</p>
<b>CPU Utilization</b>	<p>For each CPU core that tasks run on, normalized utilization over simulation time. Utilization values range between 0.0 and 1.0. For example, a value of 0.5 indicates that the CPU core is idle for 50% of the time.</p>

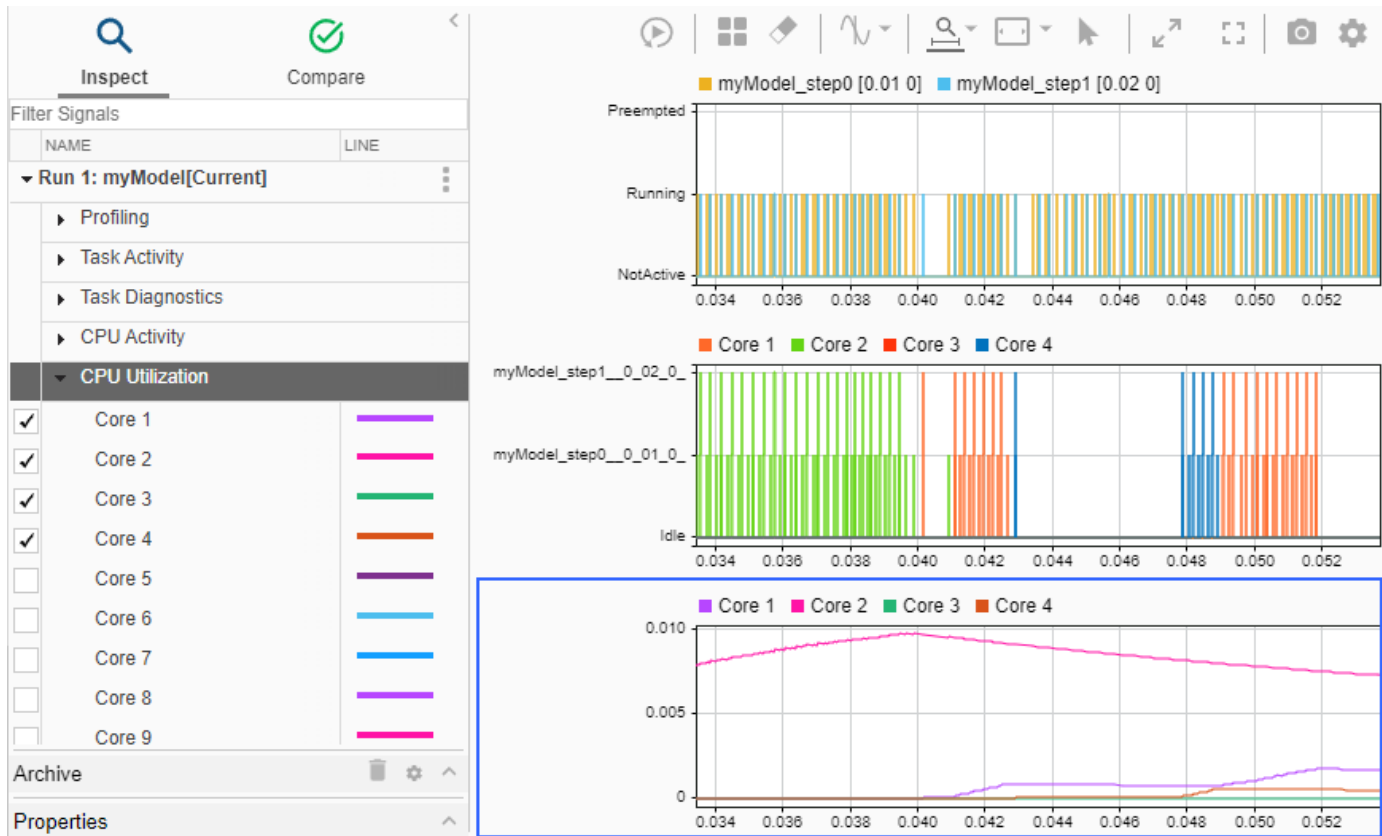

To monitor task preemption and priority inversion:

- 1 Select a subplot. Then, on the **Inspect** pane, from the **Task Activity** display group, select the **myModel\_step0 [0.01 0]** and **myModel\_step1 [0.02 0]** check boxes.
- 2 Select the next subplot. Then, on the **Inspect** pane, from the **Task Diagnostics** display group, select the **myModel\_step0 [0.01 0]** and **myModel\_step1 [0.02 0]** check boxes.
- 3 Using the **Zoom in Time (Ctrl+Shift+T)** control, view a specific time section.

To monitor CPU core activity and utilization:

- 1 Select a subplot. On the **Inspect** pane, from the **CPU Activity** display group, select, for example, the **Core 1**, **Core 2**, **Core 3**, and **Core 4** check boxes.
- 2 Select the next subplot. On the **Inspect** pane, from the **CPU Utilization** display group, select, for example, the **Core 1**, **Core 2**, **Core 3**, and **Core 4** check boxes.
- 3 Using the **Zoom in Time (Ctrl+Shift+T)** control, view a specific time section.

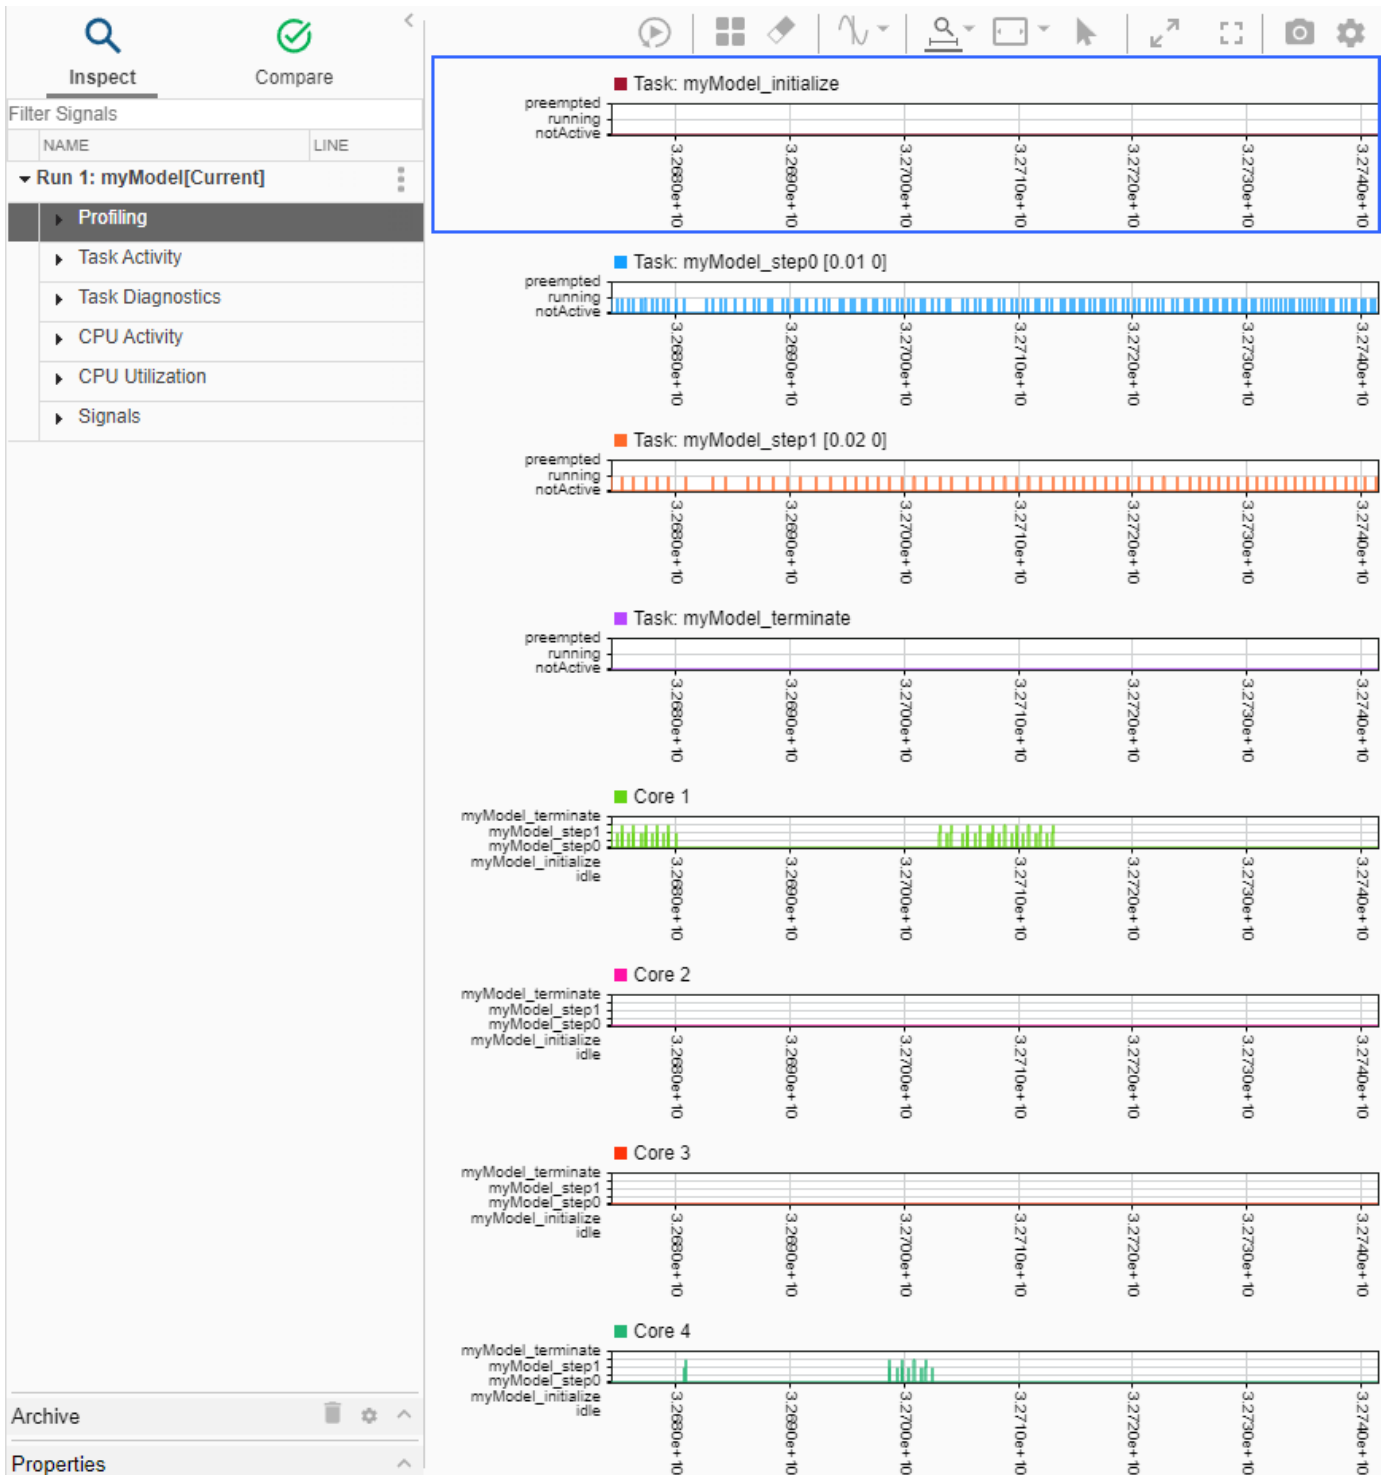

## Offline Visualization

After the completion of the simulation, you can use the `schedule` function to regenerate displays (except for task diagnostics). For this example, run:

```
schedule(executionProfile)
```

The function adds the task activity, CPU core activity, and CPU core utilization displays to the **Profiling** group. By default, the function produces eight subplots.

To visualize specific task scheduling and related CPU activity for specific tasks, you can use `Simulink.sdi` functions. For example, to observe task activity for `myModel_step0` and `myModel_step1` and CPU core activity and utilization for Core 4:

- 1 Clear the displays and specify three subplots.

```
Simulink.sdi.clearAllSubPlots;
Simulink.sdi.setSubPlotLayout(3,1);
```

- 2** In the Simulation Data Inspector, perform these actions:
  - Click subplot 1, and then select the **Task: myModel\_step0 [0.01 0]** and **Task: myModel\_step1 [0.02 0]** check boxes.
  - Click subplot 2, and then select the **Core 4** check box.
  - Click subplot 3, and then select the **Usage Core 4** check box.
- 3** Using the **Zoom in Time (Ctrl+Shift+T)** control, view activity for a specific time section.

## Tips and Limitations

### Triggered Model Block

Consider the case where a triggered Model block is configured to run in the SIL or PIL simulation mode. The software generates one execution-time measurement each time the referenced model is triggered to run. If there are multiple triggers in a single time step, the software generates multiple measurements for the triggered Model block. Conversely, if there is no trigger in a given time step, the software generates no time measurements.

### Outliers in Execution-Time Profiles

When you run a SIL simulation with execution time profiling enabled, you might see spikes in execution-time measurements.

The spikes are due to process preemption that occurs with a multitasking host operating system. If the operating system preempts the SIL process and runs another process, the measured execution time includes the time during which the SIL process is suspended. With a PIL simulation, you do not see spikes because code execution on the target is not preempted.

Counter wrapping produces execution-time measurements that are smaller than expected. For SIL, the counter wraps when an execution-time period is greater than  $2^{64}$  ticks ( $2^{32}$  ticks if the MEX compiler is LCC). For PIL, the wrapping point depends on the timer you specify and can be  $2^8$ ,  $2^{16}$ ,  $2^{32}$ , or  $2^{64}$  ticks.

Consider a PIL example where the timer frequency is 20 MHz. For a 32-bit timer, wrapping occurs when the execution-time period is greater than  $1/(20\text{e}6) * (2^{32} - 1)$ , that is, 214.7 s. However, for a 16-bit timer, the point at which wrapping occurs is 0.0033 s.

For a real-time, multi-core application, the software accommodates synchronization discrepancies when recording timer values for different cores, which effectively reduces the timer measurement range.

## Hardware-Specific Timer

If your target configuration does not already specify a timer, create a timer object that provides details of the hardware-specific timer and associated source files:

- For SIL simulation, the timer word length is 64 bits.
- For PIL simulation, specify an unsigned 8-, 16-, 32-, or 64-bit timer. For more information, see “Specify Hardware Timer for Simulink” on page 88-45.

## Effect of Instrumentation Code on Instruction Cycle

Instrumentation code increases the volume of code to run and can result in the CPU requiring more cycles to fetch code blocks from memory. This is one of the effects of instrumentation code on the fetch stage and depends on how the code is aligned in memory. If the instrumented code does not fit in the same number of blocks as code that is not instrumented, the prefetch unit must transfer more blocks.

## Task Context Switching Due to Preemption

Profiling instrumentation is intrusive and affects the quantity that it is meant to measure. Therefore, the design goal is to maximize code understanding with a minimum of instrumentation. For example, with a real-time system, there can be task context switches due to preemption. These context switches are not explicitly instrumented. To record the start and end of each task, the software must infer context switches from instrumentation. As a result, the software reports behavior that is an estimate. The estimate is subject to error because of incomplete instrumentation within the kernel.

In some cases, when the software cannot accurately determine behavior, the software generates a warning:

```
Warning: Analysis unsuccessful for one or more profiling data points. ...
```

For example, the software might generate this warning when not all mutex take system calls (associated with rate transitions) are instrumented. In the case of Simulink Real-Time, this situation might arise if you generate code for a model reference hierarchy without enabling function profiling for all referenced models (`set_param(model, 'CodeProfilingInstrumentation', 'on')`). If a mutex take system call is not instrumented, a task context switch might occur that is not visible to the execution profiling analysis.

In other cases, although the software cannot accurately determine behavior, the software does *not* generate a warning.

## Subsystem Code Reuse

You cannot generate execution-time profiles for function call sites within subsystem code that is reused across a model or multiple models. For information about subsystem code reuse, see “Generate Reusable Code from Library Subsystems Shared Across Models”.

## **Cannot Load Execution-Time Measurements from Previous Release**

You cannot load execution-time measurements saved with a previous release. For example, using R2014a, you save workspace variables to a MAT-file. One of the workspace variables contains execution-time measurements. In R2015b, if you try to load the MAT-file, you see this error:

```
Format of execution profiling data is invalid. This error can occur if
you load data from a previous release. Loading data from a previous
release is not supported.
```

## Stack Usage Profiling for Code Generated from Simulink Models

To determine the size of stack memory that is required to run generated code, you can run a software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulation that generates a stack usage profile. The SIL or PIL simulation instruments the generated code and uses the instrumentation to calculate stack usage. When the simulation is complete, you can view a code stack profiling report that shows minimum, average, and maximum memory demand. Using the Simulation Data Inspector, you can observe streamed stack usage information during and after the simulation. The profiles that you generate enable you to observe the effect of compiler optimization and data input on stack usage.

You can generate stack usage profiles by using the top-model or Model block SIL/PIL workflows. Subsystem SIL/PIL workflows do not support stack usage profiling.

### Benefits of Dynamic Stack Usage Profiling

Static stack usage analysis has some limitations. For example, it does not consider:

- Memory optimization performed by a compiler. For example, variables that are optimized away or stored in registers.
- Additional memory that the compiler uses in a function call. Compilers store the address to which the execution returns after the function call.
- Memory alignment that the compiler applies.

The dynamic stack usage profiling provided by a SIL or PIL simulation does not have the listed limitations because the simulation calculates actual memory usage.

### Configure Stack Usage Profiling

To run a SIL or PIL simulation that generates stack usage metrics:

- 1 In the Simulink Editor, open your model.
- 2 On the **Apps** tab, click **SIL/PIL Manager**.
- 3 In the **Mode** section, select **SIL/PIL Simulation Only**.
- 4 In the **Prepare** section, specify **System Under Test** and, if required, **SIL/PIL Mode**. A PIL simulation requires a driver implementation that obtains stack usage data from the target hardware. For more information, see [Implement Driver to Obtain PIL Stack Usage Data](#).
- 5 To enable stack usage profiling, in the **Prepare** section:
  - a Click **Settings**.
  - b Under **Profiling**, click the **Task Profiling** button off, which disables the generation of execution-time metrics.
  - c Under **Coverage**, click the **Coverage Collection** button off, which disables code coverage analysis.
  - d Under **Stack Profiling**, click the **Stack Profiling** button on. This action selects the **Measure task stack usage** configuration parameter, which provides stack usage measurements for each generated task. The top model setting for the parameter overrides the corresponding setting in referenced models.

- e Click the **Settings** button to open the Configuration Parameters dialog box. On the **Data Import/Export** pane, clear the **Single simulation output** check box.
- 6 To view streamed stack usage during the simulation, open the Simulation Data Inspector. In the **Results** section, click .
- 7 In the **Run** section, click **Run SIL/PIL**.

In the MATLAB base workspace, the simulation generates a variable with the default name, `stackProfile`, which stores the stack usage data. You can specify an alternative name through the **Stack workspace variable** configuration parameter.

## Observe Stack Usage of Generated Code

Suppose you run a SIL simulation of this model:

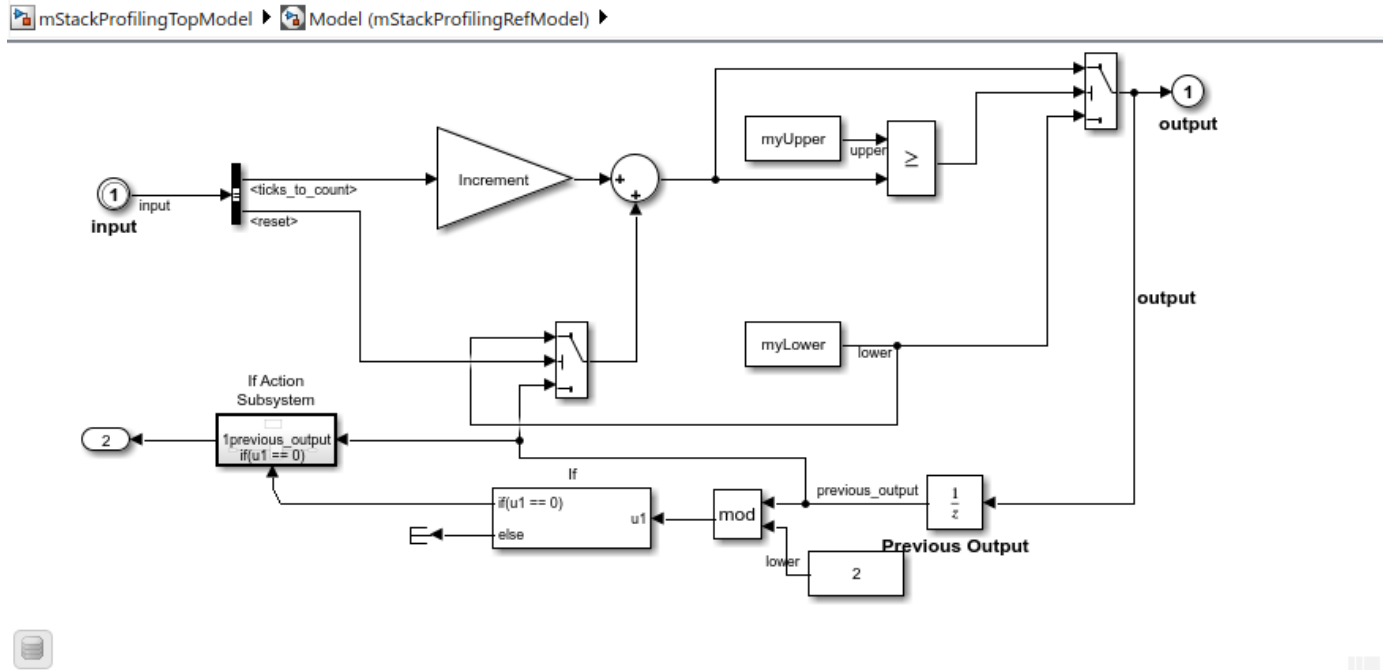

### mStackProfilingTopModel

The top model, `mStackProfilingTopModel`, is a modification of the shipped model `SILModelBlock`.

 `mStackProfilingTopModel` ▶

The referenced model, `mStackProfilingRefModel`, is a modification of the shipped model `SILCounter`.

The If Action Subsystem block contains this subsystem.

When the SIL simulation is complete, the code stack profiling report opens.

## Code Stack Profiling Report for mStackProfilingTopModel/Model

The code stack profiling report provides metrics based on data collected from a SIL or PIL execution. Stack usage is calculated from data recorded by instrumentation probes added to the SIL or PIL test harness and inside the code generated for each component. See [Code Execution Profiling](#) for more information.

### 1. Summary

Largest atomic integer type	Long
Word size (bits)	32
Pointer size (bits)	64
Stack driver	Target specific
Profiling data created	18-Oct-2021 17:07:16

### 2. Profiled Tasks

Task	Minimum Stack Usage in bytes	Average Stack Usage in bytes	Maximum Stack Usage in bytes	Calls	
<a href="#">mStackProfilingRefModel_initialize</a>	48	48	48	1	
<a href="#">mStackProfilingRefModel_step</a>	64	89	112	101	 

**Note** If you close the report, you can reopen the report. In the **Results** gallery, under **Stack Profiling Results**, click **Generate Report**.

In section 1, the report:

- Provides information that indicates how the target compiler views memory and aligns variables.
- States whether a target-specific or generic driver obtained stack usage data from the target hardware.
- Provides a timestamp for the report.

For each task, section 2 of the report provides this information:

- Minimum, average, and maximum stack usage in bytes.
- Number of times that the generated code is called.

The report provides more information through clickable icons. The specified workspace variable, for example, `stackProfile`, must be present in the base workspace.

If you click , you can view the stack usage distribution for the simulation.

If you click , you can view the variation of stack usage over the simulation.

Stack memory usage for `mStackProfilingRefModel_step` fluctuates between 112 and 64 bytes. The fluctuation occurs because the nested function generated from the If Action Subsystem block is called by `mStackProfilingRefModel_step` only when the signal `previous_output` has an even value.

```

...
if ((int32_T)(uint8_T)((int32_T)rtb_previous_output % 2) == 0) {
 /* Outputs for IfAction SubSystem: '<Root>/If Action Subsystem' incorporates:
 * ActionPort: '<S1>/Action Port'
 */

 /* Outputs for Atomic SubSystem: '<S1>/Subsystem' */
 Subsystem(rtb_previous_output, &rtY.Out1);

 /* End of Outputs for SubSystem: '<S1>/Subsystem' */
 /* End of Outputs for SubSystem: '<Root>/If Action Subsystem' */
}
...

```

If you specify a value for **Maximum stack size (bytes)** (`MaxStackSize`), the report provides Section 3. This section displays the maximum stack use for each task with reference to the maximum stack size permitted, which the bar chart displays as a horizontal red line. If the `MaxStackSize` value is much greater than the stack usage of the tasks, the bar chart does not display the red line. To help your visual analysis of stack usage requirements, you can use the `MaxStackUsageAllowed` property of the workspace variable to respecify the maximum stack size value. For example:

```

stackProfile.MaxStackUsageAllowed = 64;
report(stackProfile);

```

## Implement Driver to Obtain Stack Usage Data During PIL Simulation

A PIL simulation requires a driver implementation that obtains stack usage data from the target hardware. The driver must return the value of the stack register.

---

**Note** If you do not specify a driver for your target hardware, the PIL simulation tries to use a default generic driver.

---

When you set up PIL target connectivity, specify the driver through an `rtw.connectivity.Config` subclass. This code provides an example.

```
classdef overheadConnectivityConfig < rtw.connectivity.Config
 methods
 function this = customConnectivityConfig(componentArgs)

 % Create builder
 targetApplicationFramework = ...
 mypil.TargetApplicationFramework(componentArgs);
 builder = rtw.connectivity.MakefileBuilder(componentArgs, ...
 targetApplicationFramework, '');

 % Create launcher
 launcher = mypil.Launcher(componentArgs, builder);

 % Set up communication
 hostCommunicator = rtw.connectivity.RtIOStreamHostCommunicator(...
 componentArgs, ...
 launcher, ...
 rtiostreamLibTCPIP);

 % Call super class constructor to register components
 this@rtw.connectivity.Config(componentArgs,...
 builder,...
 launcher,...
 hostCommunicator);

 % Specify driver implementation that obtains stack usage
 % data from the target hardware
 stackUsageDriver = coder.profile.StackDriver();

 stackUsageDriver.PtrDataType = 'uint64';
 stackUsageDriver.HeaderFile = 'myHeaderFile.h';
 stackUsageDriver.SourceFile = 'mySourceFile.c';
 stackUsageDriver.IncludePaths = {'path/To/myFolder1', ...
 'path/To/myFolder2', ...
 'path/To/myFolder3'};

 stackUsageDriver.DriverFunction = 'myDriverFunction';
 this.setStackDriver(stackUsageDriver);
 end
 end
end
```

For more information about setting up PIL target connectivity, see:

- “Create PIL Target Connectivity Configuration for Simulink” on page 88-38

## Execution Time Profiling for SIL and PIL

During a software-in-the-loop (SIL) or processor-in-the-loop (PIL) execution, you can produce a profile of execution times for code generated from entry-point functions. The software calculates execution times from data that is obtained through instrumentation probes added to the SIL or PIL application.

Use the execution time profile to check whether your code runs within the required time on your target hardware:

- If code execution overruns, look for ways to reduce execution time.
- If your code easily meets time requirements, consider enhancing functionality to exploit the unused processing power.

At the end of the SIL or PIL execution, you can:

- View a report of code execution times.
- Use the Simulation Data Inspector to view and compare plots of function execution times.
- Access and analyze execution time profiling data.

### See Also

#### Related Examples

- “Generate Execution Time Profile” on page 82-3
- “View Execution Times” on page 82-4
- “Analyze Execution Time Data” on page 82-9

## Generate Execution Time Profile

Before running a software-in-the-loop (SIL) or processor-in-the-loop (PIL) execution, enable execution time profiling:

- 1 To open the MATLAB Coder app, on the MATLAB Toolstrip **Apps** tab, under **Code Generation**, click the app icon.
- 2  To open your project, click  and then click **Open existing project**. Select the project.
- 3 On the **Generate Code** page, click **Verify Code**.
- 4 Select the **Enable entry point execution profiling for SIL/PIL** check box.
- 5 If you also want to generate execution time profiles for functions that are called within entry-point functions, select the **Enable function execution profiling** check box.

---

**Note** Function profiling does not support the OpenMP library. Before you generate code, on the **Generate Code** page, click the arrow next to **Generate**. Then, click **More Settings**. Under **Advanced**, set **Enable OpenMP library if possible** to No.

---

On a Mac operating system, SIL and PIL execution does not support execution-time profiling for functions that are called within entry-point functions.

---

Or, from the Command Window, specify properties of your `coder.EmbeddedCodeConfig` object. For example:

```
% Enable entry point execution profiling
config.CodeExecutionProfiling = true;

% Enable function execution profiling
config.CodeProfilingInstrumentation = true;

% Disable OpenMP
config.EnableOpenMP = false;
```

### More About

- “Execution Time Profiling for SIL and PIL” on page 82-2

## View Execution Times

### In this section...

“Code Execution Profiling Report” on page 82-4

“Visualize Task Scheduling” on page 82-8

You can run a software-in-the-loop (SIL) or processor-in-the-loop (PIL) execution that produces execution-time metrics for tasks and functions in your generated code. During execution, you can use the Simulation Data Inspector to observe streamed execution times. When execution is complete, you can:

- View execution-time metrics for a profiled entry-point function.
- Open a report of execution-time metrics for all profiled functions. Through report icons, you can view, for example, the profiled code section and the execution-time distribution for each profiled function.
- Use the Simulation Data Inspector to plot and compare execution times from various execution runs.

### Code Execution Profiling Report

When you run a SIL or PIL execution with execution time profiling enabled, the software generates a message in the **Test Output** tab. For example:

```
Current plot held
Starting SIL execution for 'euclidean'
 To terminate execution: clear euclidean_sil
 Execution profiling data is available for viewing. Go to Simulation Data Inspector.
 Execution profiling report available after termination.
```

To observe streamed execution times while the execution runs, click the **Simulation Data Inspector** link.

To open the code execution profiling report:

- 1 Click the `clear euclidean_sil` link.

The software terminates the execution process and displays a new link.

```
Stopping SIL execution for 'euclidean'
 Execution profiling report: report(getCoderExecutionProfile('euclidean'))
```

- 2 Click the new link.

The report contains these sections:

- 1 **Summary**

This section gives information about the creation of the report.

## 1. Summary

Total time	105583
Unit of time	ns
Command	report('Units', 'seconds', 'ScaleFactor', '1e-09', 'NumericFormat', '%0.0f');
Timer frequency (ticks per second)	3.6e+09
Profiling data created	01-Dec-2021 19:33:56

## 2 Profiled Sections of Code

This section contains information about profiled code sections. In the **Section** column, expand and collapse profiled sections by clicking [+] and [-] respectively. This graphic shows fully expanded sections.

### 2. Profiled Sections of Code

Section	Maximum Execution Time in ns	Average Execution Time in ns	Maximum Self Time in ns	Average Self Time in ns	Calls	
<a href="#">euclidean_initialize</a>	155	155	155	155	1	 
[-] <a href="#">euclidean</a>	52841	52631	27382	27242	2	   
<a href="#">fabs</a>	126	124	126	124	2	  
<a href="#">fabs</a>	27	26	27	26	2	  
<a href="#">fabs</a>	27	26	27	26	2	  
<a href="#">sqrt</a>	428	322	428	322	2	  
<a href="#">fabs</a>	183	30	183	30	430	  
<a href="#">fabs</a>	42	27	42	27	430	  
<a href="#">fabs</a>	32	27	32	27	430	  
<a href="#">sqrt</a>	67	32	67	32	430	  
<a href="#">euclidean_terminate</a>	166	166	166	166	1	 

The report contains time measurements for:

- The *entry\_point\_fn\_initialize* function, for example, `euclidean_initialize`.
- The entry-point function, for example, `euclidean`.
- The *entry\_point\_fn\_terminate* function, for example, `euclidean_terminate`.

By default, the report displays time in nanoseconds ( $10^{-9}$  seconds). You can specify the time unit and numeric display format. For example, to display time in microseconds ( $10^{-6}$  seconds), use the report command:

```
% Create workspace variable
executionProfile=getCoderExecutionProfile('kalman01');

report(executionProfile, ...
 'Units', 'Seconds', ...
```

```
'ScaleFactor', '1e-06', ...
'NumericFormat', '%0.3f')
```

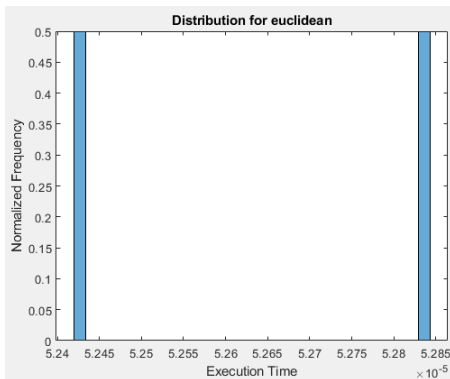

The report displays time in seconds only if the timer is calibrated, that is, the number of timer ticks per second is known. On a Windows machine, the software determines this value for a SIL simulation. On a Linux machine, you must manually calibrate the timer. For example, if your processor speed is 1 GHz, specify the number of timer ticks per second:

```
executionProfile.TimerTicksPerSecond = 1e9;
```

To view execution-time metrics for a code section in the Command Window, on the corresponding row, click the icon .

To display measured execution times, click the Simulation Data Inspector icon . You can use the Simulation Data Inspector to manage and compare plots from various executions.

To display the execution-time distribution, click the icon .

In this example, to create the histogram, the software uses these commands:

```
executionProfile=getCoderExecutionProfile('kalman01')
section=executionProfile.Sections(2);
data=section.ExecutionTimeInSeconds;
histogram(data, 30,'Normalization','probability');
```

The software creates the histogram only if the number of calls to the function is greater than one.

If the generated code contains nested functions, the execution generates pie charts that show the relative execution times of caller and called functions. To display the pie charts, click the icon  for the caller function.

The following table lists the information provided in the code section profiles.

Column	Description
Section	Name of function from which code is generated.
Maximum Execution Time	Longest time between start and end of code section.
Average Execution Time	Average time between start and end of code section.

Column	Description
Maximum Self Time	Maximum execution time, excluding time in child sections.
Average Self Time	Average execution time, excluding time in child sections.
Calls	Number of calls to the code section.
	Icon that you click to display the profiled code section.
	Icon that you click to display measured execution times with Simulation Data Inspector.
	Icon that you click to display the execution-time distribution for the profiled code section.
	Icon that you click to display pie charts that show the relative execution times of caller and called functions in the generated code.

### 3 Execution Times in Percentages

This section provides function execution times as percentages of caller function and total execution times, which can help you to identify performance bottlenecks in generated code.

#### 3. Execution Times in Percentages [\[hide\]](#)

Section	Self Time / Caller Function	Self Time / Task	Self Time / Simulation	Function / Simulation
<a href="#">euclidean_initialize</a>	100%	100%	0.1468%	0.1468%
[ - ] <a href="#">euclidean</a>	51.761%	51.761%	51.604%	99.696%
<a href="#">fabs</a>	0.23539%	0.23539%	0.23468%	0.23468%
<a href="#">fabs</a>	0.049612%	0.049612%	0.049461%	0.049461%
<a href="#">fabs</a>	0.049084%	0.049084%	0.048935%	0.048935%
<a href="#">sqrt</a>	0.61117%	0.61117%	0.60932%	0.60932%
<a href="#">fabs</a>	12.094%	12.094%	12.057%	12.057%
<a href="#">fabs</a>	11.086%	11.086%	11.052%	11.052%
<a href="#">fabs</a>	11.109%	11.109%	11.075%	11.075%
<a href="#">sqrt</a>	13.006%	13.006%	12.966%	12.966%
<a href="#">euclidean_terminate</a>	100%	100%	0.1568%	0.1568%

This table describes the information that each column provides.

Column	Comparison Performed
<b>Self Time / Caller Function</b>	Function self time compared with the total execution time of the caller function.
<b>Self Time / Task</b>	Function self time compared with the total execution time of the task.
<b>Self Time / Simulation</b>	Function self time compared with the total execution time.
<b>Function / Simulation</b>	Function execution time, which includes self time and time spent in child functions, compared with the total execution time.

#### **4 Definitions**

This section provides descriptions of some metrics.

##### **4. Definitions**

**Execution Time:** Time between start and end of code section.

**Self Time:** Execution time, excluding time in child sections.

### **Visualize Task Scheduling**

You can use the Simulation Data Inspector to visualize task scheduling and the order of function calls. At the end of the execution, run the `schedule` function. For more information, see “Visualize Task Scheduling”.

### **See Also**

#### **Related Examples**

- “Generate Execution Time Profile” on page 82-3
- “Analyze Execution Time Data” on page 82-9
- Simulation Data Inspector

## Analyze Execution Time Data

After a software-in-the-loop (SIL) or processor-in-the-loop (PIL) execution, you can analyze execution-time data using methods from the `coder.profile.ExecutionTime` and `coder.profile.ExecutionTimeSection` classes.

In the following example, you run a SIL execution and apply supplied methods to execution-time data.

### Extract Execution Time Data for Kalman Estimator Code

#### 1 Run SIL execution to generate execution time data

Copy MATLAB code to your working folder.

```
src_dir = ...
 fullfile(docroot, 'toolbox', 'coder', 'examples', 'kalman');

copyfile(fullfile(src_dir, 'kalman01.m'), '.')
copyfile(fullfile(src_dir, 'test01_ui.m'), '.')
copyfile(fullfile(src_dir, 'plot_trajectory.m'), '.')
copyfile(fullfile(src_dir, 'position.mat'), '.')
```

For a description of the Kalman estimator, see “Generate C Code at the Command Line”.

Create a `coder.EmbeddedCodeConfig` object.

```
config = coder.config('lib');
config.GenerateReport = true; % HTML report
```

Configure the object for SIL and enable execution time profiling.

```
config.VerificationMode = 'SIL';
config.CodeExecutionProfiling = true;
```

If you want to generate execution time profiles for functions that are called within entry-point functions, you must also disable the OpenMP library.

```
config.CodeProfilingInstrumentation = true;
config.EnableOpenMP = false;
```

On a Mac operating system, SIL and PIL execution does not support execution-time profiling for functions that are called within entry-point functions.

Generate library code for the `kalman01` MATLAB function and the SIL interface.

```
codegen('-config', config, '-args', {zeros(2,1)}, 'kalman01');
```

Run the MATLAB test file `test01_ui` with `kalman01_sil`. `kalman01_sil` is the SIL interface for `kalman01`.

```
coder.runTest('test01_ui', ['kalman01_sil.' mexext]);
```

You see the following message.

```
Starting SIL execution for 'kalman01'
To terminate execution: clear kalman01_sil
Execution profiling data is available for viewing. Go to Simulation Data Inspector.
```

Execution profiling report available after termination.  
Current plot released

Terminate the SIL execution process. Click the link `clear kalman01_sil`.

```
Stopping SIL execution for 'kalman01'
Execution profiling report: report(getCoderExecutionProfile('kalman01'))
```

## 2 Create workspace variable that holds execution time data

Use the `getCoderExecutionProfile` function to create a workspace variable that holds execution time profiling data.

```
executionProfile=getCoderExecutionProfile('kalman01');
```

## 3 Extract code sections

Use the `Sections` method.

```
allSections = executionProfile.Sections
```

The software displays the number of code sections and a list of properties.

```
allSections =
 1x3 ExecutionTimeTaskSection array with properties:
 Name
 Number
 ExecutionTimeInTicks
 SelfTimeInTicks
 TurnaroundTimeInTicks
 TotalExecutionTimeInTicks
 TotalSelfTimeInTicks
 TotalTurnaroundTimeInTicks
 MaximumExecutionTimeInTicks
 MaximumExecutionTimeCallNum
 MaximumSelfTimeInTicks
 MaximumSelfTimeCallNum
 MaximumTurnaroundTimeInTicks
 MaximumTurnaroundTimeCallNum
 NumCalls
 ExecutionTimeInSeconds
 Time
```

## 4 Extract execution time data from specific code section

Specify the code section that you want to examine.

```
secondSectionProfile = executionProfile.Sections(2)
```

The software displays profile data for the code section.

```
secondSectionProfile =
 ExecutionTimeTaskSection with properties:
 Name: 'kalman01'
 Number: 2
 ExecutionTimeInTicks: [1x300 uint64]
 SelfTimeInTicks: [1x300 uint64]
 TurnaroundTimeInTicks: [1x300 uint64]
 TotalExecutionTimeInTicks: 6641016
 TotalSelfTimeInTicks: 6641016
 TotalTurnaroundTimeInTicks: 6641016
 MaximumExecutionTimeInTicks: 48864
 MaximumExecutionTimeCallNum: 158
 MaximumSelfTimeInTicks: 48864
 MaximumSelfTimeCallNum: 158
```

```

MaximumTurnaroundTimeInTicks: 48864
MaximumTurnaroundTimeCallNum: 158
 NumCalls: 300
ExecutionTimeInSeconds: [1x300 double]
 Time: [300x1 double]

```

You can extract specific properties, for example, the name of a profiled function.

```
nameOfSection = secondSectionProfile.Name
```

The software displays the name.

```
nameOfSection =
'kalman01'
```

The following table lists the information that you can extract from each code section.

Property	Description
Name	Name of entry-point function
Number	Code section number
ExecutionTimeInTicks	Vector of execution times, measured in timer ticks. Each element contains the difference between the timer reading at the start and at the end of the code section. The data type is the same data type as the data type of the timer used on the target, which allows you to infer the maximum range of the timer measurements.
SelfTimeInTicks	Vector of timer tick numbers. Each element contains the number of ticks recorded for the code section, excluding the time spent in calls to child functions.
TurnaroundTimeInTicks	Vector of timer tick numbers. Each element contains the number of ticks recorded between the start and the finish of the code section. Unless the code is preempted, this number is the same number as the execution time.
TotalExecutionTimeInTicks	Total number of timer ticks recorded for the code section over the entire execution.
TotalSelfTimeInTicks	Total number of timer ticks recorded for the profiled code section over the entire execution. However, this number excludes the time spent in calls to child functions.
TotalTurnaroundTimeInTicks	Total number of timer ticks recorded between the start and the finish of the profiled code section over the entire execution. Unless the code is preempted, this number is the same as the total execution time.
MaximumExecutionTimeInTicks	Maximum number of timer ticks recorded for a single invocation of the code section over the execution.
MaximumExecutionTimeCallNum	Number of call in which MaximumExecutionTimeInTicks occurs.
MaximumSelfTimeInTicks	Maximum number of timer ticks recorded for a single code section invocation, but excluding the time spent in calls to child functions.
MaximumSelfTimeCallNum	Number of call in which MaximumSelfTimeInTicks occurs.

Property	Description
MaximumTurnaroundTimeInTicks	Maximum number of timer ticks recorded between the start and the finish of a single invocation of the profiled code section over the execution. Unless the code is preempted, this time is the same as the maximum execution time.
MaximumTurnaroundTimeCallNum	Number of call in which MaximumTurnaroundTimeInTicks occurs.
NumCalls	Total number of calls to the code section over the entire execution.
ExecutionTimeInSeconds	Vector of execution times, measured in seconds. Each element contains the difference between the timer reading at the start and at the end of the code section. Produced only if TimerTicksPerSecond is set.
Time	Vector of execution time measurements for the code section.

- Simulation Data Inspector

## Stack Usage Profiling for Code Generated From MATLAB Code

To determine the size of stack memory that is required to run generated code, you can run a software-in-the-loop (SIL) or processor-in-the-loop (PIL) execution that generates a stack usage profile. The SIL or PIL execution instruments the generated code and uses the instrumentation to calculate stack usage. When the execution is complete, you can view a code stack profiling report that shows minimum, average, and maximum memory demand. Using the Simulation Data Inspector, you can observe streamed stack usage information during and after the execution. The profiles that you generate enable you to observe the effect of compiler optimization and data input on stack usage.

### Benefits of Dynamic Stack Usage Profiling

Static stack usage analysis has some limitations. For example, it does not consider:

- Memory optimization performed by a compiler. For example, variables that are optimized away or stored in registers.
- Additional memory that the compiler uses in a function call. Compilers store the address to which the execution returns after the function call.
- Memory alignment that the compiler applies.

The dynamic stack usage profiling provided by a SIL or PIL execution does not have the listed limitations because the execution calculates actual memory usage.

### Generate Stack Usage Profile

Before running a software-in-the-loop on page 90-4 or processor-in-the-loop (PIL) on page 90-23 execution, enable stack usage profiling:

- 1 To open the MATLAB Coder app, on the MATLAB Toolstrip **Apps** , under **Code Generation**, click the app icon.
- 2 To open your project, click  and then click **Open existing project**. Select the project.
- 3 On the **Generate Code** page, click the arrow next to **Generate**.
- 4 In the Generate dialog box:
  - a Click **More Settings**.
  - b Click **Debugging**.
  - c Under **SIL/PIL**, select the **Enable entry point stack profiling** check box.
  - d Click **Close**.
  - e Click **Generate**.

---

**Note** Stack usage profiling does not support the OpenMP library. Before you generate code, on the **Generate Code** page, click the arrow next to **Generate**. Then, click **More Settings**. Under **Advanced**, set **Enable OpenMP library if possible** to **No**.

---

Or, from the Command Window, specify properties of your coder.EmbeddedCodeConfig object. For example:

```
% Enable entry point stack usage profiling
config.CodeStackProfiling = true;

% Disable OpenMP
config.EnableOpenMP = false;
```

## View Stack Usage Profile From SIL Execution

For a MATLAB function, perform a software-in-the-loop execution that generates stack usage measurements and then use the data to determine stack memory requirements.

In your local working folder, create the function `foo.m`, which evaluates an integer factorial by using a recursive function.

```
function out = foo(in)
 coder.inline('never');
 out = factorial_(in);
end

function out = factorial_(in)
 coder.inline('never');
 if in == 1
 out = 1;
 else
 out = in * factorial_(in-1);
 end
end
```

Configure stack usage profiling for the SIL execution.

```
config = coder.config('lib');
config.GenerateReport = true;
config.VerificationMode = 'SIL';
config.CodeStackProfiling = true;
config.EnableOpenMP = false;
```

In the folder, create `test_example.m`, a MATLAB script that calls the compiled function multiple times.

```
for idx = 1: size(X,1)
 Y(idx,1) = foo(X(idx,1));
end
```

Create a test vector of integers.

```
X=[1 2 5 8]';
```

Generate library code for the `foo` MATLAB function and the SIL interface and start the SIL execution.

```
codegen -report -config config foo -args {1} -test test_example
```

Code generation successful: [View report](#)

Running test file: 'test\_example' with MEX function 'foo\_sil.mexw64'.

### Starting SIL execution for 'foo'

To terminate execution: `clear foo_sil`

Stack profiling data is available for viewing. Open Simulation Data Inspector.

Stack profiling report available after termination.

To observe streamed stack usage measurements while the execution runs, click the [Simulation Data Inspector](#) link.

To open the code stack profiling report, terminate the SIL execution process by clicking the link `clear foo_sil`.

```
Application stopped
Stopping SIL execution for 'foo'
 Stack profiling report: report(getCoderStackProfile('foo'))
```

Then, click the link `report(getCoderStackProfile('foo'))`.

You can create a workspace variable that holds the execution time data.

```
stackUsageProfile= getCoderStackProfile('foo');
```

If you close the report, you can reopen the report by running:

```
report(stackUsageProfile)
```

## Code Stack Profiling Report for foo

The code stack profiling report provides metrics based on data collected from a SIL or PIL execution. Stack usage is calculated from data recorded by instrumentation probes added to the SIL or PIL test harness and inside the code generated for each component. See [Code Stack Profiling](#) for more information.

### 1. Summary

Largest atomic integer type	Char
Word size (bits)	64
Pointer size (bits)	64
Maximum stack (bytes)	200000
Stack driver	Target specific
Profiling data created	28-Oct-2021 12:15:19

### 2. Profiled Tasks

Task	Minimum Stack Usage in bytes	Average Stack Usage in bytes	Maximum Stack Usage in bytes	Calls	
<a href="#">foo_initialize</a>	48	48	48	1	
<a href="#">foo</a>	112	304	560	4	
<a href="#">foo_terminate</a>	48	48	48	1	

Section 1:

- Provides information that indicates how the target compiler views memory and aligns variables.
- States whether a target-specific or generic driver obtained stack usage data from the target hardware.
- Provides a timestamp for the report.

Section 2 provides, for each task, this information:

- Minimum, average, and maximum stack usage in bytes.
- Number of times the generated code is called.

The report provides more information through clickable icons. The workspace variable, for example, `stackUsageProfile`, must be present in the base workspace.

If you click , you can view the stack usage distribution for the execution.

If you click , you can view the variation of stack usage over the execution.

The integer value of the input argument for `foo` increases with successive calls to the function. As the integer value increases, the number of recursive calls to the function `factorial_()` also increases, which results in the observed increases of stack memory usage.

Section 3 displays the maximum stack use for each task with reference to the maximum stack size permitted. In the SIL or PIL execution, the MATLAB Coder configuration setting `StackUsageMax` parameter specifies the maximum stack size, which the bar chart displays as a horizontal red line. If the `StackUsageMax` value is much greater than the stack usage of the tasks, the bar chart does not display a red line. To help your visual analysis of stack usage requirements, you can use the `MaxStackUsageAllowed` property of the workspace variable to respecify the maximum stack size value. For example:

```
stackUsageProfile= getCoderStackProfile('foo');
stackUsageProfile.MaxStackUsageAllowed = 550;
report(stackUsageProfile);
```

## Implement Driver to Obtain Stack Usage Data During PIL Execution

A PIL execution requires a driver implementation that obtains stack usage data from the target hardware. The driver must return the value of the stack register.

---

**Note** If you do not specify a driver for your target hardware, the PIL execution tries to use a default generic driver.

---

When you set up PIL target connectivity, specify the driver through an `rtw.connectivity.Config` subclass. This code provides an example.

```
classdef overheadConnectivityConfig < rtw.connectivity.Config
 methods
```

```
function this = customConnectivityConfig(componentArgs)

 % Create builder
 targetApplicationFramework = ...
 mypil.TargetApplicationFramework(componentArgs);
 builder = rtw.connectivity.MakefileBuilder(componentArgs, ...
 targetApplicationFramework, '');

 % Create launcher
 launcher = mypil.Launcher(componentArgs, builder);

 % Set up communication
 hostCommunicator = rtw.connectivity.RtIOStreamHostCommunicator(...
 componentArgs, ...
 launcher, ...
 rtiostreamLibTCPIP);

 % Call super class constructor to register components
 this@rtw.connectivity.Config(componentArgs,...
 builder,...
 launcher,...
 hostCommunicator);

 % Specify driver implementation that obtains stack usage
 % data from the target hardware
 stackUsageDriver = coder.profile.StackDriver();

 stackUsageDriver.PtrDataType = 'uint64';
 stackUsageDriver.HeaderFile = 'myHeaderFile.h';
 stackUsageDriver.SourceFile = 'mySourceFile.c';
 stackUsageDriver.IncludePaths = {'path/To/myFolder1', ...
 'path/To/myFolder2', ...
 'path/To/myFolder3'};
 stackUsageDriver.DriverFunction = 'myDriverFunction';
 this.setStackDriver(stackUsageDriver);
end
end
end
```

## Removal of Unused Class Properties in Generated C/C++ Code

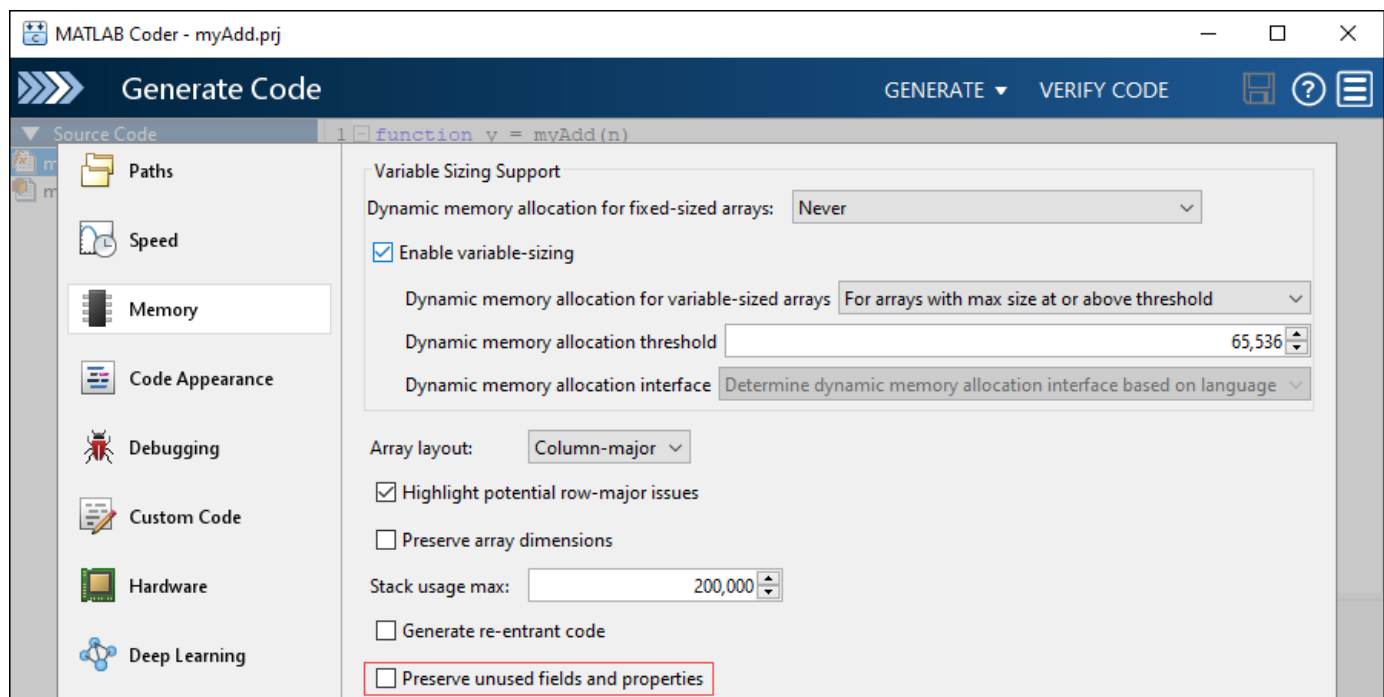

C/C++ code generated by Embedded Coder contains unused class properties or structure fields. Removing unused properties or fields helps improve the memory footprint and run time of the code. By default, the code generator removes properties or fields that are unused in the generated C/C++ code.

This feature applies to standalone code generation. You can preserve the unused properties or fields in generated C/C++ code by using the MATLAB Coder app or at the command line.

### Preserve Unused Class Properties or Structure Fields by using MATLAB Coder App

To preserve unused properties or fields:

- 1 Open the MATLAB Coder app.
- 2 On the **Generate Code** page, click **More Settings**.
- 3 On the **Memory** tab, select the **Preserve unused fields and properties** check box.

### Preserve Unused Class Properties or Structure Fields at the Command Line

To preserve the unused properties or fields, set the configuration parameter `PreserveUnusedStructFields` to `true` and use the configuration object `cfg` in the `codegen` command.

```
cfg = coder.config('lib');
cfg.PreserveUnusedStructFields = true;
```

## Examples

The following examples demonstrate the usage of the `PreserveUnusedStructFields` configuration option to generate C/C++ code.

### Generate C++ Code for MATLAB Classes

This table compares the generated C++ code for `myClass`, with unused properties removed and with unused properties preserved.

MATLAB Code	Unused Class Properties Removed (default)	Unused Class Properties Preserved
<pre>% Entry-point function function y = myAdd(n)     %#codegen     o = myClass(n);     y = o.a + o.b; end  classdef myClass     properties         a         b         c     end      methods         function obj = myClass(x)             coder.inline('never')             obj.a = x;             obj.b = x + 1;             obj.c = x + 2;         end     end end</pre>	<p><b>Code generation command</b></p> <pre>cfg = coder.config('lib'); cfg.TargetLang = "C++"; codegen myAdd -args {5} -config cfg</pre> <p><b>Generated C++ Code</b></p> <pre>class myClass { public:     void init(double x);     double a;     double b; };  void myClass::init(double x) {     a = x;     b = x + 1.0; }</pre>	<p><b>Code generation command</b></p> <pre>cfg = coder.config('lib'); cfg.PreserveUnusedStructFields = true; cfg.TargetLang = "C++"; codegen myAdd -args {5} -config cfg -re</pre> <p><b>Generated C++ Code</b></p> <pre>class myClass { public:     void init(double x);     double a;     double b;     double c; };  void myClass::init(double x) {     a = x;     b = x + 1.0;     c = x + 2.0; }</pre>

### Generate C Code for MATLAB Structures

This table compares the generated C code for `myStruct`, with unused fields removed and with unused fields preserved.

MATLAB Code	Unused Structure Fields Removed (default)	Unused Structure Fields Preserved
<pre> % Entry-point function function out = myStruct(n)     %# codegen     s.a = [n n n];     s.b = n+2;     s.c = n;     out = myAdd([s s]); end  function out = myAdd(s)     coder.inline('never');     out = s(1).b + s(2).b; end </pre>	<p><b>Code generation command</b></p> <pre> cfg = coder.config('lib'); codegen myStruct -args {0} -config cfg </pre> <p><b>Generated C Code</b></p> <pre> typedef struct {     double b; } struct_T;  /*  * Arguments      : double n  * Return Type   : double  */ double myStruct(double n) {     struct_T b_s[2];     struct_T s;     s.b = n + 2.0;     b_s[0] = s;     b_s[1] = s;     return myAdd(b_s); } </pre>	<p><b>Code generation command</b></p> <pre> cfg = coder.config('lib'); cfg.PreserveUnusedStructFields = true; codegen myStruct -args {0} -config cfg </pre> <p><b>Generated C Code</b></p> <pre> typedef struct {     double a[3];     double b;     double c; } struct_T;  /*  * Arguments      : double n  * Return Type   : double  */ double myStruct(double n) {     struct_T b_s[2];     struct_T s;     s.a[0] = n;     s.a[1] = n;     s.a[2] = n;     s.b = n + 2.0;     s.c = n;     b_s[0] = s;     b_s[1] = s;     return myAdd(b_s); } </pre>

## Usage Notes

- When `PreserveUnusedStructFields` is set to `false`, the code generator preserves properties or fields of the entry-point function input and output arguments and values passed to `coder.ceval`.
- When `PreserveUnusedStructFields` is set to `true`, the code generator removes properties or fields whose data types are unknown.

## Code Generation for Deep Learning Simulink Model That Performs Lane and Vehicle Detection

This example shows how to generate C++ code from a Simulink® model that performs lane and vehicle detection by using convolutional neural networks (CNNs). The example takes the frames of a traffic video as an input, outputs two lane boundaries that correspond to the left and right lanes of the ego vehicle, and detects vehicles in the frame. This example uses a pretrained lane detection network and a pretrained vehicle detection network from the *Object Detection Using YOLO v2 Deep Learning* example of the Computer Vision Toolbox™. For more information, see “Object Detection Using YOLO v2 Deep Learning” (Computer Vision Toolbox).

This example illustrates the following concepts:

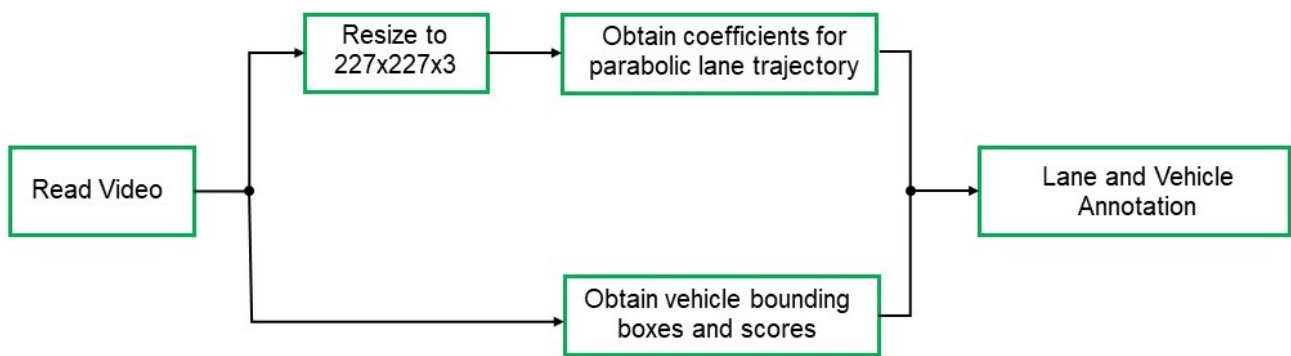

- Model the lane detection application in Simulink. First you process the traffic video by resizing to 227-by-227-by-3 and multiplying by a constant factor of 255. Subsequently, you process the traffic video by using the pretrained network loaded in the Predict block from Deep Learning Toolbox™. Finally, if the left and right lane boundaries are detected, the parabolic coefficients to model the trajectories of the lane boundaries are obtained.
- Model the vehicle detection application in Simulink by processing the traffic video using a pretrained YOLO v2 detector. This network detects vehicles in the video and outputs the coordinates of the bounding boxes for these vehicles and their confidence score.
- Configure the model for code generation.

### Prerequisites

- Intel Math Kernel Library for Deep Neural Networks (MKL-DNN).
- Refer to MKLDNN CPU Support for the list of processors that support MKL-DNN library.
- Deep Learning Toolbox™ for using the DAGNetwork object.
- Computer Vision Toolbox™ for video I/O operations.

### Algorithmic Workflow

The block diagram for the algorithmic workflow of the Simulink model follows.

## Get Pretrained Lane and Vehicle Detection Networks

This example uses the `trainedLaneNet` and `yolov2ResNet50VehicleExample` MAT files containing the pretrained networks. The files are approximately 143 MB and 98 MB in size, respectively. Download the files.

```
lanenetFile = matlab.internal.examples.downloadSupportFile('gpcoder/cnn_models/lane_detection',
vehiclenetFile = matlab.internal.examples.downloadSupportFile('vision/data','yolov2ResNet50VehicleExample');
```

## Download Test Traffic Video

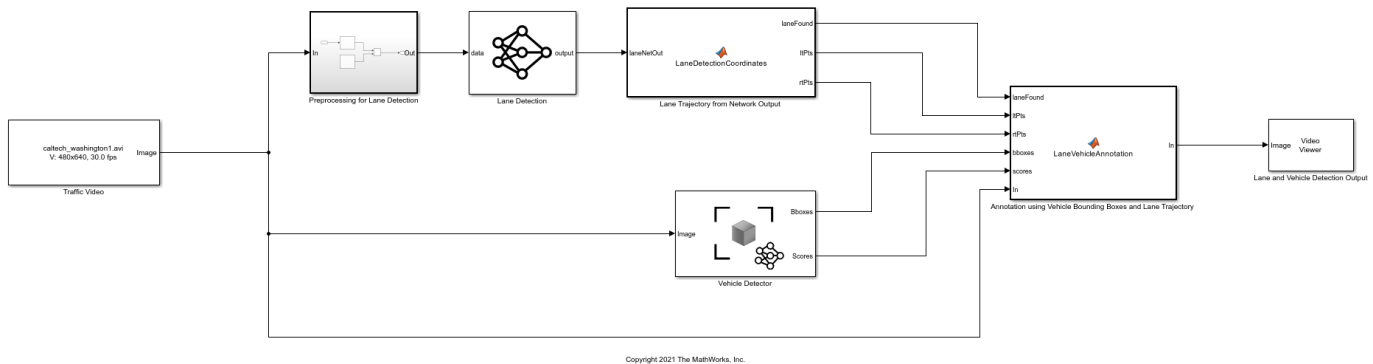

To test the model, the example uses the Caltech lanes data set. The file is approximately 16 MB in size. Download this file.

```
mediaFile = matlab.internal.examples.downloadSupportFile('gpcoder/media','caltech_washington1.avi');
```

## Lane and Vehicle Detection Simulink Model

The following diagram shows the Simulink model for performing lane and vehicle detection on the traffic video. When the model runs, the Video Viewer block displays the traffic video with lane and vehicle annotations.

```
model='laneAndVehicleDetection';
open_system(model);
```

Set the file paths of the downloaded network model in the Predict and Detector blocks of the Simulink model.

```
set_param('laneAndVehicleDetection/Lane Detection','NetworkFilePath',lanenetFile)
set_param('laneAndVehicleDetection/Vehicle Detector','DetectorFilePath',vehiclenetFile)
```

Set the location of the test video that you load to the Simulink model.

```
set_param('laneAndVehicleDetection/Traffic Video','inputFileName',mediaFile)
```

## Lane Detection

The Predict block loads the pretrained lane detection network from the `trainedLaneNet.mat` file. This network takes an image as an input and outputs two lane boundaries that correspond to the left and right lanes of the ego vehicle. Each lane boundary is represented by the parabolic equation:

$$y = ax^2 + bx + c$$

Here,  $y$  is the lateral offset and  $x$  is the longitudinal distance from the vehicle. The network outputs the three parameters  $a$ ,  $b$ , and  $c$  per lane. The LaneDetectionCoordinates MATLAB Function block defines a function `lane_detection_coordinates` that takes the output from the predict block and outputs three parameters: `laneFound`, `ltPts`, and `rtPts`. The block uses thresholding to determine if both left and right lane boundaries are both found. If are found, `laneFound` is set to be true and the trajectories of the boundaries are calculated and stored in `ltPts` and `rtPts`.

```
type lane_detection_coordinates
```

```
function [laneFound,ltPts,rtPts] = lane_detection_coordinates(laneNetOut)

% Copyright 2020 The MathWorks, Inc.

persistent laneCoeffMeans;
if isempty(laneCoeffMeans)
 laneCoeffMeans = [-0.0002 0.0002 1.4740 -0.0002 0.0045 -1.3787];
end

persistent laneCoeffStds;
if isempty(laneCoeffStds)
 laneCoeffStds = [0.0030 0.0766 0.6313 0.0026 0.0736 0.9846];
end

params = laneNetOut .* laneCoeffStds + laneCoeffMeans;

isRightLaneFound = abs(params(6)) > 0.5; %c should be more than 0.5 for it to be a right lane
isLeftLaneFound = abs(params(3)) > 0.5;

persistent vehicleXPoints;
if isempty(vehicleXPoints)
 vehicleXPoints = 3:30; %meters, ahead of the sensor
end

ltPts = coder.nullcopy(zeros(28,2,'single'));
rtPts = coder.nullcopy(zeros(28,2,'single'));

if isRightLaneFound && isLeftLaneFound
 rtBoundary = params(4:6);
 rt_y = computeBoundaryModel(rtBoundary, vehicleXPoints);
 ltBoundary = params(1:3);
 lt_y = computeBoundaryModel(ltBoundary, vehicleXPoints);

 % Visualize lane boundaries of the ego vehicle
 tform = get_tformToImage;
 % map vehicle to image coordinates
 ltPts = tform.transformPointsInverse([vehicleXPoints', lt_y]);
 rtPts = tform.transformPointsInverse([vehicleXPoints', rt_y]);
 laneFound = true;
else
 laneFound = false;
end
end
```

## Vehicle Detection

A YOLO v2 object detection network is composed of two subnetworks: a feature extraction network followed by a detection network. This pretrained network uses a ResNet -50 for feature extraction. The detection sub-network is a small CNN compared to the feature extraction network and is composed of a few convolutional layers and layers specific to YOLO v2. The Simulink model performs vehicle detection using the Object Detector block. This block takes an image as input and outputs the bounding box coordinates along with the confidence scores for vehicles in the image.

## Annotation of Vehicle Bounding Boxes and Lane Trajectory in Traffic Video

The LaneVehicleAnnotation MATLAB Function block defines a function `lane_vehicle_annotation`, which annotates the vehicle bounding boxes with the confidence scores. Also, if `laneFound` is true, then the left and right lane boundaries stored in `ltPts` and `rtPts` are annotated in the traffic video.

```
type lane_vehicle_annotation

function In = lane_vehicle_annotation(laneFound, ltPts, rtPts, bboxes, scores, In)

% Copyright 2020 The MathWorks, Inc.

if ~isempty(bboxes)
 In = insertObjectAnnotation(In, 'rectangle', bboxes, scores);
end

pts = coder.nullcopy(zeros(28, 4, 'single'));
if laneFound
 prevpt = [ltPts(1,1) ltPts(1,2)];
 for k = 2:1:28
 pts(k,1:4) = [prevpt ltPts(k,1) ltPts(k,2)];
 prevpt = [ltPts(k,1) ltPts(k,2)];
 end
 In = insertShape(In, 'Line', pts, 'LineWidth', 2);
 prevpt = [rtPts(1,1) rtPts(1,2)];
 for k = 2:1:28
 pts(k,1:4) = [prevpt rtPts(k,1) rtPts(k,2)];
 prevpt = [rtPts(k,1) rtPts(k,2)];
 end
 In = insertShape(In, 'Line', pts, 'LineWidth', 2);
 In = insertMarker(In, ltPts);
 In = insertMarker(In, rtPts);
end

end
```

## Get Pretrained Lane and Vehicle Detection Networks

This function downloads the `yolov2ResNet50VehicleExample.mat` file.

```
getVehicleDetectionAndLaneDetectionNetworks()
```

## Run Simulation

Open Configuration Parameters dialog box. On the **Simulation Target** pane, in the **Deep Learning** group, select the Target library as MKL - DNN.

```
set_param(model, 'SimDLTargetLibrary', 'MKL-DNN');
```

On the **Interface** pane, in the **Deep Learning** group, select the **Target library** as MKL - DNN.

```
set_param(model, 'DLTargetLibrary', 'MKL-DNN');
```

To verify the lane and vehicle detection algorithms and display the lane trajectories, vehicle bounding boxes, and scores for the traffic video loaded in the Simulink model, run the simulation.

```
set_param('laneAndVehicleDetection', 'SimulationMode', 'Normal');
sim('laneAndVehicleDetection');
```

## Generate and Build Simulink Model

In the **Code Generation** pane, select the **Language** as **C++**.

```
set_param(model, 'TargetLang', 'C++');
```

Generate and build the Simulink model using the `slbuild` command. The code generator places the files in the `laneAndVehicleDetection_grt_rtw` build subfolder under your current working folder.

```
currentDir = pwd;
status = evalc("slbuild('laneAndVehicleDetection')");
```

## Generated C++ Code

The subfolder named `laneAndVehicleDetection_grt_rtw` contains the generated C++ code corresponding to the different blocks in the Simulink model and the specific operations being performed in those blocks. For example, the file `trainedLaneNet0_0.h` contains the C++ class, which contains attributes and member functions representing the pretrained lane detection network.

```
hfile = fullfile(currentDir, 'laneAndVehicleDetection_grt_rtw',...
 'trainedLaneNet0_0.h');
rtwdemodbtype(hfile, '#ifndef RTW_HEADER_trainedLaneNet0_0_h',...
 '#endif')
```

```
#ifndef RTW_HEADER_trainedLaneNet0_0_h_
#define RTW_HEADER_trainedLaneNet0_0_h_
#include "MWOndnnTargetNetworkImpl.hpp"
#include "rtwtypes.h"
#include "MWTensorBase.hpp"
#include "MWTensor.hpp"

#include "MW0nednnCommonHeaders.hpp"

class yolov2ResNet50VehicleExample0_0
{
public:
 boolean_T isInitialized;
 boolean_T matlabCodegenIsDeleted;
 yolov2ResNet50VehicleExample0_0();
 void setSize();
 void resetState();
 void setup();
 void predict();
 void activations(int32_T layerIdx);
 void cleanup();
 real32_T *getLayerOutput(int32_T layerIndex, int32_T portIndex);
 int32_T getLayerOutputSize(int32_T layerIndex, int32_T portIndex);
 real32_T *getInputDataPointer(int32_T index);
 real32_T *getInputDataPointer();
 real32_T *getOutputDataPointer(int32_T index);
 real32_T *getOutputDataPointer();
 int32_T getBatchSize();
 ~yolov2ResNet50VehicleExample0_0();
private:
 int32_T numLayers;
 MWTensorBase *inputTensors;
 MWTensorBase *outputTensors;
 MWCNNLayer *layers[57];
 MW0nednnTarget::MWTargetNetworkImpl *targetImpl;
 void allocate();
 void postsetup();
 void deallocate();
};

```

**Note:** If the **System target file** parameter is set to `grt.tlc`, you must select the **Generate code only** model configuration parameter. If you set the **System target file** to `ert.tlc`, you can clear the **Generate code only** parameter, but to create an executable file, you must generate an example main program.

### Cleanup

Close the Simulink model.

```

save_system('laneAndVehicleDetection');
close_system('laneAndVehicleDetection');

```

## Generate Generic C/C++ for Sequence-to-Sequence Deep Learning Simulink Models

This example shows how to generate a generic C/C++ executable that does not depend on any third-party deep learning libraries from a deep learning Simulink® model. The example predicts the remaining useful life (RUL) of a turbofan engine, measured in cycles at each step of an input time series that represents data from various sensors in an engine.

For a video demonstration of this example, see [Generate Generic C/C++ Code for Deep Learning Networks in Simulink](#).

This example is based on the *Generate Generic C/C++ Code for Sequence-to-Sequence Regression That Uses Deep Learning* example from MATLAB® Coder™. For more information, see “Generate Generic C/C++ Code for Sequence-to-Sequence Regression That Uses Deep Learning”.

### Prerequisites

For PIL verification, you will need:

- STMicroelectronics STM32F407G-Discovery, STM32F746G-Discovery, or STM32F769I-Discovery board
- USB type A to Mini-B cable
- USB TTL-232 cable - TTL-232R 3.3V (serial communication for STM32F4-Discovery board)
- Embedded Coder® Support Package for STMicroelectronics Discovery Boards. To install this support package, use the **Add-Ons** menu in the **Environment** section of the MATLAB **Home** tab.

### Pretrained RUL Network

This example uses a pretrained LSTM network to predict the remaining useful life of an engine, measured in cycles. The LSTM network consists of an LSTM layer with 200 hidden units, followed by a fully connected layer of size 50 and a dropout layer with dropout probability 0.5. The network was trained using the *Turbofan Engine Degradation Simulation Data Set* as described in [1]. The training data contains simulated time series data for 100 engines. Each sequence varies in length and corresponds to a full run to failure (RTF) instance. The test data contains 100 partial sequences and corresponding values of the remaining useful life at the end of each sequence. For more information on training the network, see the example “Sequence-to-Sequence Regression Using Deep Learning” (Deep Learning Toolbox).

```
net = coder.loadDeepLearningNetwork('rulNetwork.mat')
```

```
net =
 SeriesNetwork with properties:
 Layers: [6×1 nnet.cnn.layer.Layer]
 InputNames: {'sequenceinput'}
 OutputNames: {'regressionoutput'}
```

For information on the networks, layers, and classes supported for code generation, see “Networks and Layers Supported for Code Generation”.

## Prepare Test Data

Load the `TurboFanRULValidate` MAT-file that contains the *Turbofan Engine Degradation Validation Data Set*. This MAT-file stores the variable `XValidate` that contains 100 sample observations representing sensor readings that you use to test the Simulink model.

```
load('TurboFanRULValidate.mat')
```

To make the input validation data compatible with Simulink code generation, the sequence lengths for each of the independent 100 observations are zero-padded to create uniformly-sized, 17-by-303 input arrays.

```
sequenceLengths = cellfun(@length,XValidate,'UniformOutput',true);
maxSequenceLen = max(sequenceLengths);
padFcn = @(x) [x,zeros(size(x,1),maxSequenceLen-size(x,2))];
XValidatePad = cellfun(padFcn,XValidate,'UniformOutput',false);
```

The padded values are then converted to a 17-by-303-100 numeric array. To import this data into the Simulink model, specify a structure variable containing the data values and an empty time vector. During simulation, the input for the first time step is read from the first 17-by-303 element of the array. The value for the second time step is read from the second element, and so on, for a total of 100 steps.

```
simin.time = [];
simin.signals.values = cell2mat(reshape(XValidatePad,1,1,[]));
simin.signals.dimensions = size(XValidatePad{1});
```

## Simulink Model for Prediction

The Simulink model for predicts the remaining useful life of a turbofan engine is shown. The model uses the `Predict` block from the `Deep Neural Networks` library that imports the trained network from a `rulNetwork` MAT-file. Additionally, the `Mini-batch size` parameter of the block is set to 1.

```
model = 'rulPredict';
open_system(model)
```

?

## Generate Generic C++ Code for Sequence-to-Sequence Regression Deep Learning Models

Copyright 2021 The MathWorks, Inc.

### Run the Simulation

To validate the Simulink model, run the simulation.

```
set_param(model, 'SimulationMode', 'Normal');
sim(model);
```

The output YPred of the Simulink model contains the predicted remaining useful life values from the network. This output is first trimmed to remove the results from the zero-padded values and then converted to a cell array.

```
YPred_cell = squeeze(mat2cell(YPred,1,maxSequenceLen,ones(1,100)));
```

```
for t = 1:length(sequenceLengths)
 YPred_cell{t}(:,sequenceLengths(t) + 1:end) = [];
end
```

Plot the predicted remaining useful life (RUL) values for four randomly-selected observations and compare them to the validation data.

```
observationIdx = randperm(100,4);
rulExamplePlots(observationIdx,YValidate,YPred_cell);
```

### Configure Model for Code Generation

To generate C/C++ code that does not depend on any third-party deep learning libraries and build an executable, select the generic real-time (ERT) target from Embedded Coder™.

```
cs = getActiveConfigSet(model);
switchTarget(cs, 'ert.tlc', []);
```

Configure code generation specific parameters. Setting MAT-file logging enables the generated code to redirect simulation data to a MAT-file.

```
set_param(cs, 'TargetLang', 'C');
set_param(cs, 'Toolchain', 'Automatically locate an installed toolchain');
set_param(cs, 'ObjectivePriorities', 'Execution efficiency');
set_param(cs, 'DLTargetLibrary', 'None');
set_param(cs, 'GenerateReport', 'on');
set_param(cs, 'CodeInterfacePackaging', 'Nonreusable function');
set_param(cs, 'MatFileLogging', 'on');
```

### Generate and Build the Simulink Model

Generate and build the Simulink model by using the `slbuild` command. The code generator places the files in a *build folder*, a subfolder named `rulPredict_ert_rtw` under your current working folder.

```
evalc("slbuild('rulPredict')");
```

### Run the Generated Executable

Run the generated executable. After successful execution, the `rulPredict` executable creates a `rulPredict` MAT-file in the current working folder.

```
if ispc
 status = system('rulPredict.exe');
else
 status = system('./rulPredict');
end
```

```
** created rulPredict.mat **
```

```
load('rulPredict.mat')
```

The output `rt_YPred` contains the predicted remaining useful life values from the network. This output is first trimmed to remove the results from the zero-padded values and then converted to a cell array.

```
rt_YPred_cell = squeeze(mat2cell(rt_YPred,1,maxSequenceLen,ones(1,100)));
```

```
for t = 1:length(sequenceLengths)
 rt_YPred_cell{t}(:,sequenceLengths(t) + 1:end) = [];
end
```

Plot the predicted remaining useful life (RUL) values for four randomly-selected observations and compare them to the validation data.

```
rulExamplePlots(observationIdx,YValidate,rt_YPred_cell);
```

### Code Verification with Processor-in-the-Loop (PIL) Simulation

To ensure that the behavior of the deployment code matches the design, you can configure the Simulink model to run a PIL simulation on embedded boards. In a PIL simulation, the generated code runs on embedded boards such as the STMicroelectronics® Discovery. The results of the PIL simulation are transferred to Simulink to verify numerical equivalence of the simulation and the code generation results.

This example shows PIL verification on the STMicroelectronics Discovery board by using the *Embedded Coder® Support Package for STMicroelectronics Discovery Boards*. This example is pre-configured to run on the STM32F746G-Discovery board. You can configure this model to use other supported embedded boards by selecting them as the "Hardware board" on the Hardware Implementation pane of the Model Configuration Parameters.

### Prepare Test Data

For PIL simulation, this example sorts the observations by sequence length and picks the first 10. These observations are zero-padded to create uniformly-sized, 17-by-54 input arrays. The padded values are then converted to a 17-by-54-10 numeric array. To import this data into the Simulink model, specify a structure variable containing the data values and an empty time vector. During simulation, the input for the first time step is read from the first 17-by-54 element of the array. The value for the second time step is read from the second element, and so on, for a total of 10 steps.

```
[~,idx] = sort(cellfun(@length,XValidate));
XValidatePIL = XValidate(idx(1:10));
YValidatePIL = YValidate(idx(1:10));
```

```

sequenceLengths = cellfun(@length,XValidatePIL,'UniformOutput',true);
maxSequenceLen = max(sequenceLengths);
padFcn = @(x) [x,zeros(size(x,1),maxSequenceLen-size(x,2))];
XValidatePILPad = cellfun(padFcn,XValidatePIL,'UniformOutput',false);
simin.time = [];
simin.signals.values = cell2mat(reshape(XValidatePILPad,1,1,[]));
simin.signals.dimensions = size(XValidatePILPad{1});

```

### Top Model PIL

The `rulPredict_pil` is a modified version of the `rulPredict` model for PIL verification. To load the test vectors, the `rulPredict_pil` model replaces the From Workspace block with an Inport block. The Inport block is configured to accept a 17-by-54 array of double data type.

```

pilModel = 'rulPredict_pil';
open_system(pilModel);

```

### Top Model PIL

Copyright 2021 The MathWorks, Inc.

Configure the `rulPredict_pil` model for the **STM32F467G-Discovery** target.

```

cs = getActiveConfigSet(pilModel);
set_param(cs,'HardwareBoard','STM32F746G-Discovery');
set_param(cs,'Toolchain','GNU Tools for ARM Embedded Processors');

```

The STM32F4-Discovery board supports two different communication interfaces for PIL: ST-LINK and serial. The ST-LINK communication interface does not require any additional cables or hardware besides a USB type A to Mini-B cable used to connect the STM32F4-Discovery board to the host computer. The serial communication interface requires a USB TTL-232 cable. Running a PIL simulation using the serial communication interface is much faster than the running a PIL simulation using ST-LINK. This example is configured to use the serial interface.

Additionally, you must set the COM port parameter in Configuration Parameters > Hardware Implementation > Target Hardware Resources > PIL to match the port number of the serial interface on your Windows computer.

### Run PIL Simulation

To compare the PIL results with simulation, run the `rulPredict_pil` model in normal mode and then in PIL mode.

```
set_param(cs, 'LoadExternalInput', 'on');
set_param(cs, 'ExternalInput', 'simin');
set_param(pilModel, 'SimulationMode', 'Normal');

sim(pilModel);
YPred_ref = YPred_pil;

set_param(pilModel, 'SimulationMode', 'Processor-in-the-Loop (PIL)');
sim(pilModel);
```

### Plot Results

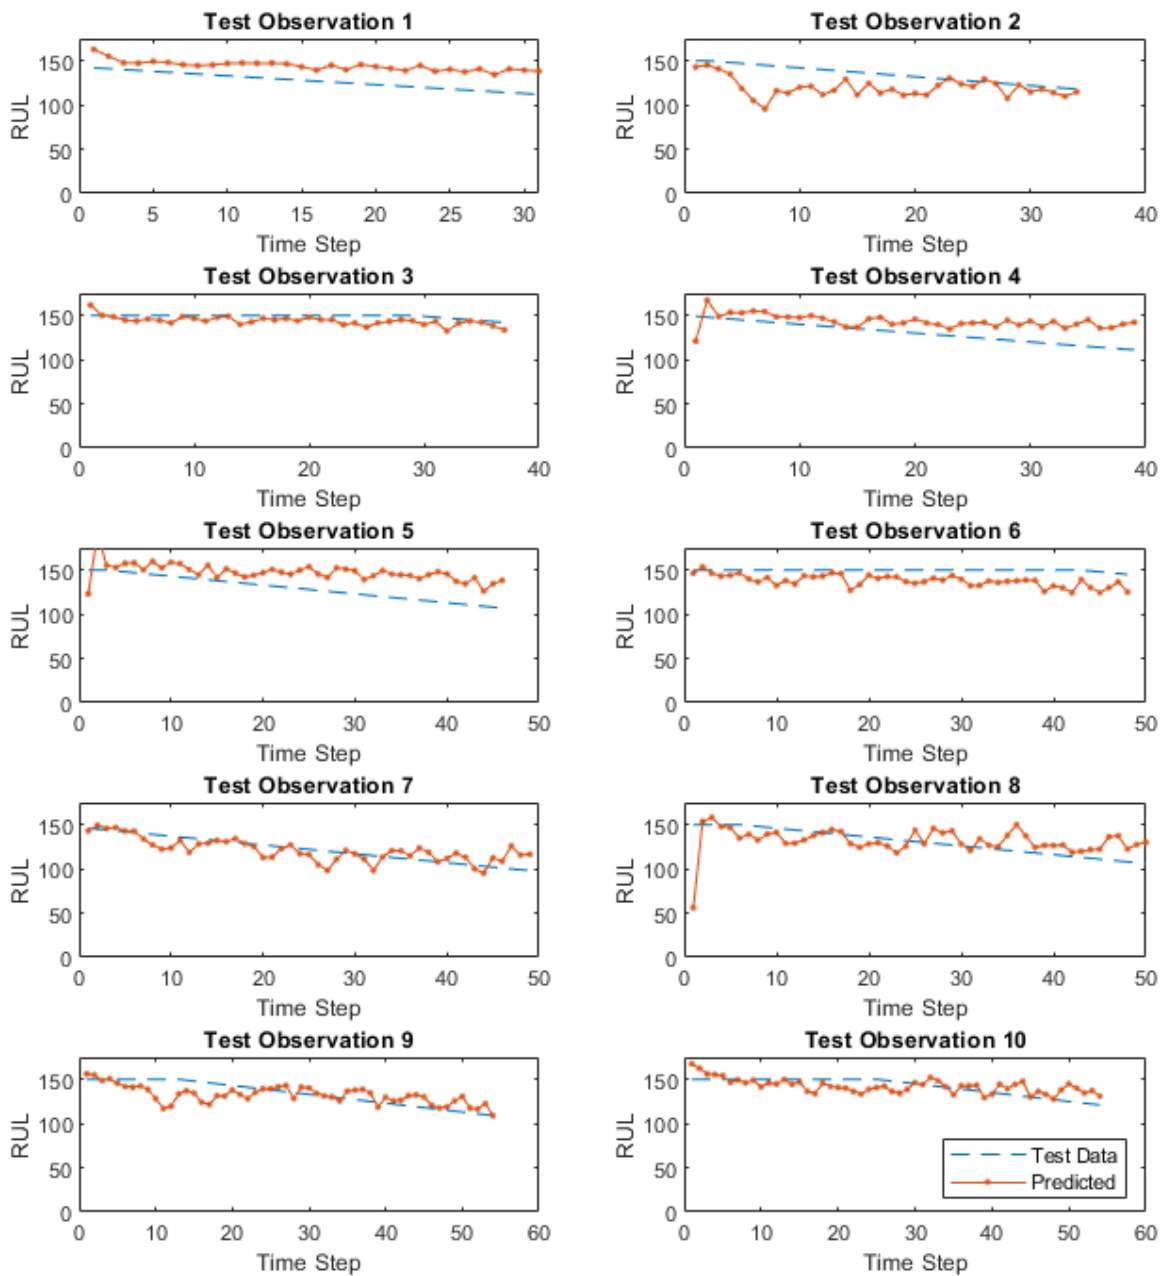

The output `YPred_pil` and `YPred_ref` contain the predicted remaining useful life values from the network. This output is first trimmed to remove the results from the zero-padded values and then converted to a cell array.

Plot the predicted remaining useful life (RUL) values for PIL and compare them to the validation data.

```
YPred_ref_cell = squeeze(mat2cell(YPred_ref, 1, maxSequenceLen, ones(1, 10)));
YPred_pil_cell = squeeze(mat2cell(YPred_pil, 1, maxSequenceLen, ones(1, 10)));

for t = 1:length(sequenceLengths)
 YPred_ref_cell{t}(:, sequenceLengths(t) + 1:end) = [];
 YPred_pil_cell{t}(:, sequenceLengths(t) + 1:end) = [];
end

rulExamplePlots([1:10], YValidatePIL, YPred_pil_cell);
```

Compute the error from the PIL simulation and plot the results.

```
YPred_error = YPred_ref-YPred_pil;
```

```
figure('Name', 'PIL Error')
```

```

for i = 1:10
 subplot(5,2,i)

 plot(YPred_error(:,:,i),'.-')
 maxerror = string(max(YPred_error(:,:,i)));
 ylim([-1e-4 1e-4])
 title("Test Observation " + i)
 xlabel("Time Step")
 ylabel("Difference")
end
legend(["Difference in Simulation Modes"],'Location','southeast')

```

### Supporting Functions

```

function rulExamplePlots(observationIdx,YTest,YPred)
N = numel(observationIdx);

```

```
figure
for i = 1:N
 subplot(N/2,2,i)

 plot(YTest{observationIdx(i)},'--')
 hold on
 plot(YPred{observationIdx(i)},'-.')
 hold off

 ylim([0 175])
 title("Test Observation " + observationIdx(i))
 xlabel("Time Step")
 ylabel("RUL")
end
legend(["Test Data" "Predicted"],'Location','southeast')

end
```

## Generate Code for Deep Learning Networks Using MATLAB Function Block

You can generate optimized code for Simulink models containing a variety of trained deep learning networks. You can implement the deep learning functionality in Simulink by using MATLAB Function blocks or by using blocks from the **Deep Neural Networks** library. When implementing deep learning functionality with MATLAB Function blocks, use the `coder.loadDeepLearningNetwork` function to load a trained deep learning network and use the object functions of the network object to obtain the desired responses. You can configure the code generator to take advantage of the Intel Math Kernel library for Deep Neural Networks (MKL-DNN). You can also generate generic C or C++ code that does not depend on third-party libraries. The generated code implements the deep convolutional neural network (CNN) by using the architecture, the layers, and parameters that you specify in a network object.

### Classify Images by Using GoogLeNet

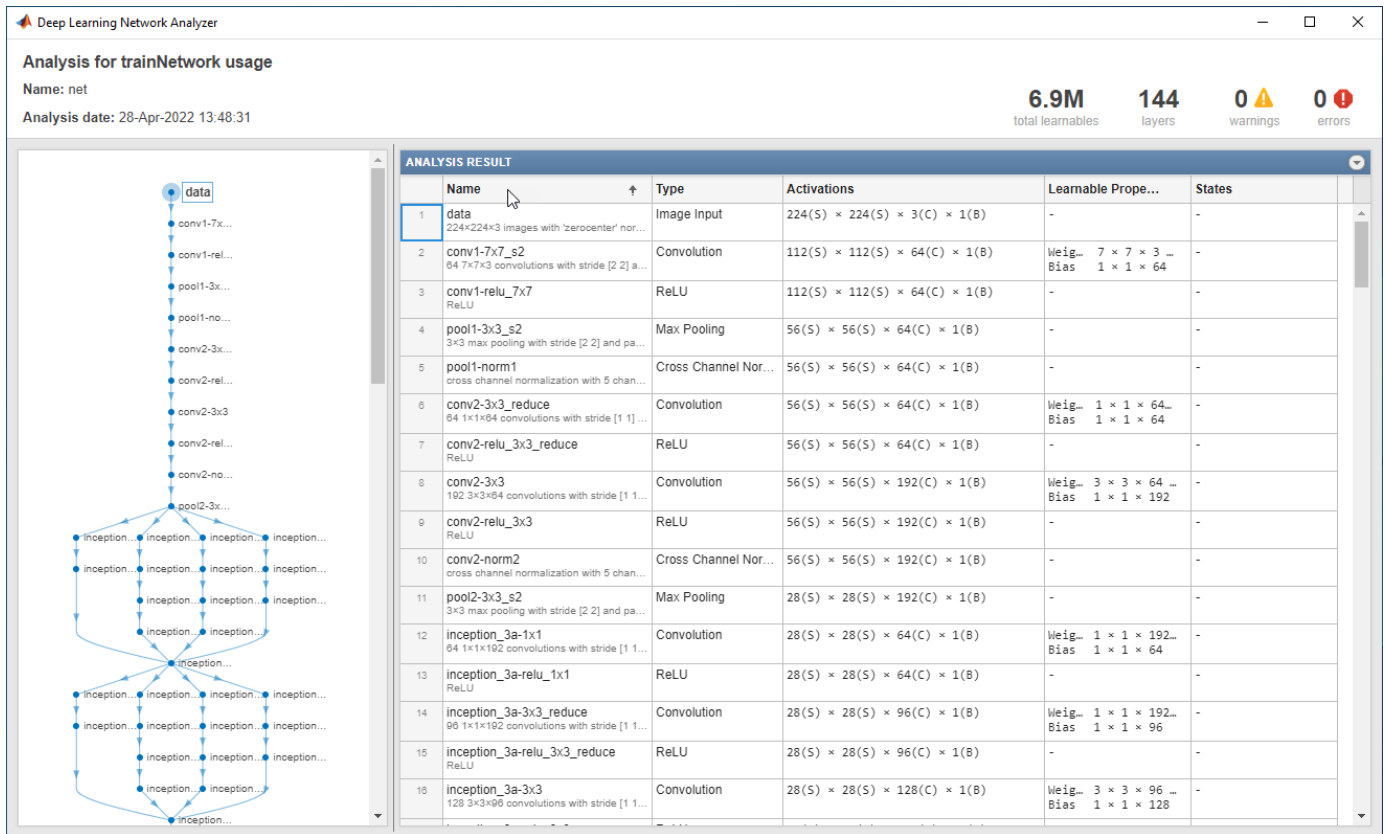

GoogLeNet is a convolutional neural network that is 22 layers deep. The network has been trained on over a million images and can classify an image into 1000 object categories (such as a keyboard, coffee mug, pencil, and animals). The network takes an image as input, and then outputs a label for the object in the image together with the probabilities for each of the object categories. This example shows you how to perform simulation and generate C++ code for the pretrained GoogLeNet deep convolutional neural network and classify an image.

- 1 Load the pretrained GoogLeNet network. You can choose to load a different pretrained network for image classification. This function requires the Deep Learning Toolbox Model for GoogLeNet Network support package. If this support package is not installed, then the function provides a download link.

```
net = googlenet;
```

- 2 The object `net` contains the `DAGNetwork` object. Use the function to display an interactive visualization of the network architecture, to detect errors and issues in the network, and to display detailed information about the network layers. The layer information includes the sizes of layer activations and learnable parameters, the total number of learnable parameters, and the sizes of state parameters of recurrent layers.

```
analyzeNetwork(net);
```

- 3 The image that you want to classify must have the same size as the input size of the network. For GoogLeNet, the size of the `imageInputLayer` is 224-by-224-by-3. The `Classes` property of the output `classificationLayer` contains the names of the classes learned by the network. View 10 random class names out of the total of 1000.

```
classNames = net.Layers(end).Classes;
numClasses = numel(classNames);
disp(classNames(randperm(numClasses,10)))
```

```
speedboat
window screen
isopod
wooden spoon
lipstick
drake
hyena
dumbbell
strawberry
custard apple
```

## Create GoogLeNet Model

- 1 Create a Simulink model and insert a MATLAB Function block from the **User-Defined Functions** library.
- 2 Add an Image From File block from the **Computer Vision Toolbox** library and set the File name parameter to `peppers.png`.

- 3 Add a Resize block from the **Computer Vision Toolbox** library to the model. Set the **Specify** parameter of the Resize block to Number of output rows and columns and enter [224 224] as the value for **Number of output rows and columns**. This block resizes the input image to that of the input layer of the network.

- 4 Double-click the MATLAB Function block. A default function signature appears in the MATLAB Function Block Editor.
- 5 Define a function called `googlenet_predict`, which implements the prediction entry-point function. The function header declares `in` as an argument to the `googlenet_predict` function, with `scores` and `indxTop` as the return value.

```
function [scores,indxTop] = googlenet_predict(in) %#codegen
persistent mynet;
if isempty(mynet)
 mynet = coder.loadDeepLearningNetwork('googlenet');
end
% pass in input
predict_scores = predict(mynet,in);
[scores,indx] = sort(predict_scores, 'descend');
indxTop = indx(1:5);
```

A persistent object `mynet` loads the `DAGNetwork` object. At the first call to the entry-point function, the persistent object is constructed and set up. On subsequent calls to the function, the same object is reused to call `predict` on inputs, avoiding reconstructing and reloading the network object.

You can use the `activations` method to network activations for a specific layer. For example, the following line of code returns the network activations for the layer specified in `layerIdx`.

```
out = activations(mynet,in,layerIdx,'OutputAs','Channels');
```

You can use the `classify` method to predict class labels for the image data in `in` using the trained network `mynet`.

```
[out,scores] = classify(mynet,in);
```

For LSTM networks, you can use the `predictAndUpdateState` and `resetState` methods.

- 6 Open the block parameters of the MATLAB Function block. On the **Code Generation** tab, select **Reusable** function for **Function packaging**.
- 7 Connect these blocks as shown in the diagram. Save the model as `googlenetModel`.

## Simulate Model

- 1 Open the Configuration Parameters dialog box. Select the **Solver** pane. Set the **Type** parameter to Fixed-step. This setting maintains a constant (fixed) step size, which is required for code generation.
- 2 Select the **Simulation Target** pane. Set the **Language** to C++.
- 3 On the **Simulation Target** pane, set the **Target Library** parameter in the **Deep learning** group to MKL-DNN.
- 4 Click **OK** to save and close the Configuration Parameters dialog box.
- 5 To build and simulate the model, use this command:

```
out = sim('googlenetModel');
```

- 6 Display the top five predicted labels and their associated probabilities as a histogram. Because the network classifies images into so many object categories, and many categories are similar, it is common to consider the top-five accuracy when evaluating networks. The network classifies the image as a bell pepper with a high probability.

```
im = imread('peppers.png');
classNamesTop = classNames(out.yout{2}.Values.Data(:,:,1))
```

```
h = figure;
h.Position(3) = 2*h.Position(3);
ax1 = subplot(1,2,1);
ax2 = subplot(1,2,2);
```

```
image(ax1,im);
barh(ax2,out.yout{1}.Values.Data(1,5:-1:1,1))
xlabel(ax2,'Probability')
yticklabels(ax2,classNamesTop(5:-1:1))
ax2.YAxisLocation = 'right';
sgtitle('Top 5 predictions using GoogLeNet')
```

## Generate Code

- 1 Open the **Simulink Coder** or **Embedded Coder** app. The **C Code** tab opens.
- 2 In the Configuration Parameters dialog box, if you have a Simulink Coder license, set the **System target file** to `grt.tlc`. If you have Embedded Coder, set the **System target file** parameter to `ert.tlc`.
- 3 Set the **Language** to C++.
- 4 Select **Generate code only**.
- 5 On the **Code Generation > Interface** pane, set the **Target Library** in the **Deep learning** group to MKL-DNN.
- 6 Clear the **MAT-file logging** parameter.
- 7 Click **OK** to save and close the Configuration Parameters dialog box.
- 8 On the **C++ Code** app, click **Generate Code**.

disp(classNames(randperm(numClasses, 10)))
```

```
speedboat
window screen
isopod
wooden spoon
lipstick
drake
hyena
dumbbell
strawberry
custard apple
```

## Create GoogLeNet Model

- 1 Create a Simulink model.
- 2 Add an Image From File block from the **Computer Vision Toolbox** library and verify that the File name parameter is set to `peppers.png`.
- 3 Insert an Image Classifier block from the **Deep Learning Toolbox > Deep Neural Networks** library. Set these block configuration parameters:

- Set the **Network** parameter to Network from MATLAB function.
- Set the **MATLAB function** parameter to googlenet.
- Select the **Resize input** parameter.
- Select the **Predictions** parameter.
- Clear the **Classifications** parameter.

- 4 Add two Output blocks and connect them to the Image Classifier block. Connect the Image Classifier block to the Image From File block.

- 5 Save the model as googlenetModel.slx.

## Simulate Model

- 1 Open the Configuration Parameters dialog box. Select the **Solver** pane. Set the **Type** parameter to **Fixed-step**. This setting maintains a constant (fixed) step size, which is required for code generation.
- 2 Select the **Simulation Target** pane. Set the **Language** to C++.
- 3 On the **Simulation Target** pane, verify that the **Target Library** parameter in the **Deep learning** group is set to MKL-DNN.
- 4 Click **OK** to save and close the Configuration Parameters dialog box.
- 5 To build and simulate the model, use this command:

```
out = sim('googlenetModel');
```

- 6 Display the top five predicted labels and their associated probabilities as a histogram. Because the network classifies images into so many object categories, and many categories are similar, it is common to consider the top-five accuracy when evaluating networks. The network classifies the image as a bell pepper with a high probability.

```
im = imread('peppers.png');
predict_scores = out.yout{1}.Values.Data(:, :, 1);
[scores, indx] = sort(predict_scores, 'descend');
topScores = scores(1:5);
classNamesTop = classNames(indx(1:5))
```

```
h = figure;
h.Position(3) = 2*h.Position(3);
ax1 = subplot(1,2,1);
ax2 = subplot(1,2,2);
```

```
image(ax1, im);
barh(ax2, topScores(1,5:-1:1,1))
xlabel(ax2, 'Probability')
yticklabels(ax2, classNamesTop(5:-1:1))
ax2.YAxisLocation = 'right';
sgtitle('Top 5 predictions using GoogLeNet')
```

## Generate Code

- 1 Open the **Simulink Coder** or **Embedded Coder** app. The **C Code** tab opens.
- 2 In the Configuration Parameters dialog box, if you have a Simulink Coder license, set the **System target file** to `grt.tlc`. If you have Embedded Coder, set the **System target file** parameter to `ert.tlc`.
- 3 Set the **Language** to C++.
- 4 Select **Generate code only**.
- 5 On the **Code Generation > Interface** pane, set the **Target Library** in the **Deep learning** group to MKL-DNN.
- 6 On the **Interface** pane, clear the **MAT-file logging** parameter.
- 7 If the **System target file** parameter is set to `ert.tlc`, on the **Interface** pane, select the **variable-size signals** parameter.
- 8 Click **OK** to save and close the Configuration Parameters dialog box.
- 9 On the **C++ Code** app, click **Build**.

## Workflow for Deep Learning C/C++ Code Generation for Simulink Models

With Simulink Coder, you can generate code from deep learning neural networks you design and implement using the Deep Learning Toolbox. To use Simulink Coder to generate code for deep learning networks, you must also install the MATLAB Coder Interface for Deep Learning Libraries. Deep learning uses neural networks to learn useful representations of features directly from data. You can obtain a pretrained neural network or train one yourself using the Deep Learning Toolbox. For more information, see “Train Deep Learning Network to Classify New Images” (Deep Learning Toolbox) and “Pretrained Deep Neural Networks” (Deep Learning Toolbox).

Implement the trained neural network in Simulink by using blocks from the Deep Neural Networks library or by using a MATLAB Function block. When implementing the trained neural network with a MATLAB Function block, use the `coder.loadDeepLearningNetwork` to load a trained deep learning network and use the object functions of the network object to obtain the desired responses. The network must be supported for code generation. See “Networks and Layers Supported for Code Generation”.

You can generate C++ code that targets an embedded platform that uses an Intel processor or an ARM processor. The generated code calls the Intel Math Kernel Library for Deep Neural Networks (MKL-DNN) or the ARM Compute Library to apply high performance. The hardware and software requirements depend on the target platform. To apply these libraries, in the Model Configuration Parameters dialog box, set these parameter settings.

Pane	Parameter	Setting
Simulation Target	Language	C++
Simulation Target	Target library	MKL - DNN
Code Generation	Language	C++
Interface	Target library	<ul style="list-style-type: none"> <li>• MKL - DNN</li> <li>• ARM Compute</li> </ul>

For an example that uses the MKL-DNN library, see “Code Generation for Deep Learning Simulink Model That Performs Lane and Vehicle Detection” on page 83-2.

You can also generate generic C or C++ code that does not depend on third-party libraries. To generate generic C or C++ code, set these parameter settings.

Pane	Parameter	Setting
Simulation Target	Language	C or C++
Code Generation	Language	C or C++
Interface	Target library	None

For an example, see “Generate Generic C/C++ for Sequence-to-Sequence Deep Learning Simulink Models” on page 83-10.

Deep learning models typically work on large sets of labeled data. Performing inference on these models is computationally intensive, consuming a significant amount of memory. You can use pruning in combination with network quantization to reduce the inference time and memory footprint of the deep learning network, making it easier to deploy to low-power microcontrollers and FPGAs. For more information, see:

- “Quantization of Deep Neural Networks” (Deep Learning Toolbox)
- “Generate int8 Code for Deep Learning Networks”
- “Prune Image Classification Network Using Taylor Scores” (Deep Learning Toolbox)

To perform quantization, you must install the Deep Learning Toolbox Model Quantization Library support package.

# Verification

# Simulation and Code Comparison in Simulink Coder

---

## Simulation and Code Comparison

### In this section...

“Configure Signal Data for Logging” on page 84-2

“Log Simulation Data” on page 84-3

“Run Executable and Load Data” on page 84-4

“Visualize and Compare Results” on page 84-5

“Compare States for Simulation and Code Generation” on page 84-7

This example shows how to verify the answers computed by code generated from the `slexAircraftExample` model. It shows how to capture and compare two sets of output data. Simulating the model produces one set of output data. Executing the generated code produces a second set of output data.

**Note** To obtain a valid comparison between model output and the generated code, use the same **Solver selection** and **Step size** for the simulation run and the build process.

### Configure Signal Data for Logging

Configure the model for logging and recording signal data.

- 1 Make sure that `slexAircraftExample` is closed. Clear the base workspace to eliminate the results of previous simulation runs. In the Command Window, type:

```
clear
```

The clear operation clears variables created during previous simulations and all workspace variables, some of which are standard variables that the `slexAircraftExample` model requires.

- 2 To open the model, in the Command Window, enter:

```
openExample('slexAircraftExample')
```

- 3 In the model window, choose **File > Save As**, navigate to the working folder, and save a copy of the `slexAircraftExample` model as `myAircraftExample`.
- 4 Set up your model to log signal data for signals: `Stick`, `alpha`, `rad`, and `q`, `rad/sec`. For each signal:
  - a Right-click the signal. From the context menu, select **Properties**.
  - b In the Signal Properties dialog box, select **Log signal data**.
  - c In the **Logging name** section, from the drop-down list, select **Custom**.
  - d In the text field, enter the logging name for the corresponding signal.

Signal Name	Logging Name
Stick	Stick_input
alpha, rad	Alpha

Signal Name	Logging Name
q, rad/sec	Pitch_rate

- e Click **Apply** and **OK**.

For more information, see “Export Signal Data Using Signal Logging”.

- 5 In the Configuration Parameters dialog box:
  - a Set **Type** to Fixed-step.
  - b Set **Format** to Structure with time.
  - c Clear the **States** check box.
  - d Select the **Signal logging** check box.
  - e Select the **Record logged workspace data in Simulation Data Inspector** check box.
- 6 Save the model.

Proceed to “Log Simulation Data” on page 84-3.

## Log Simulation Data

Run the simulation, log the signal data, and view the data in the Simulation Data Inspector.

- 1 Run the model. When the simulation is done, on the Simulink Editor toolbar, the **Simulation Data Inspector** button is highlighted to indicate that new simulation output is available in the Simulation Data Inspector.

- 2 Click the **Simulation Data Inspector** button to open the Simulation Data Inspector.
- 3 Group the signals:
  - a On the **Visualize** tab, click **Group Signals**.
  - b In the Group Signals dialog box, select Data Hierarchy from the **Then By** list.

- c Click **OK**.

- 4 Click the **Logout** expander to view the logged signals.
- 5 Click the **Format** tab.
- 6 Click the **Subplots** button and select 3x1 to show three subplots.
- 7 For each signal:
  - a Click the top subplot. A blue border indicates the plot selection.
  - b Select the check box next to the Alpha signal name. The signal data appears in the subplot.
  - c Plot the Pitch\_rate signal in the middle subplot.
  - d Plot the Stick\_input signal in the bottom subplot.

Proceed to “Run Executable and Load Data” on page 84-4.

## Run Executable and Load Data

You must rebuild and run the `myAircraftExample` executable to obtain a valid data file because you have modified the model.

- 1 In the Configuration Parameters dialog box, set the **MAT-file variable name modifier** parameter to `rt_`. `rt_` is prefixed to each variable that you selected for logging in the first part of this example.
- 2 Click **Apply** and **OK**.
- 3 Save the model.
- 4 To generate code, on the **C Code** tab, click **Build** button.
- 5 When the build is finished, run the standalone program from the Command Window.

```
!myAircraftExample
```

The executing program writes the following messages to the Command Window.

```
** starting the model **
** created myAircraftExample.mat **
```

- 6 Load the data file `myAircraftExample.mat`.

```
load myAircraftExample
```

---

**Tip** For UNIX platforms, run the executable program in the Command Window with the syntax `!./executable_name`. If preferred, run the executable program from an OS shell with the syntax `./executable_name`. For more information, see “Run External Commands, Scripts, and Programs”.

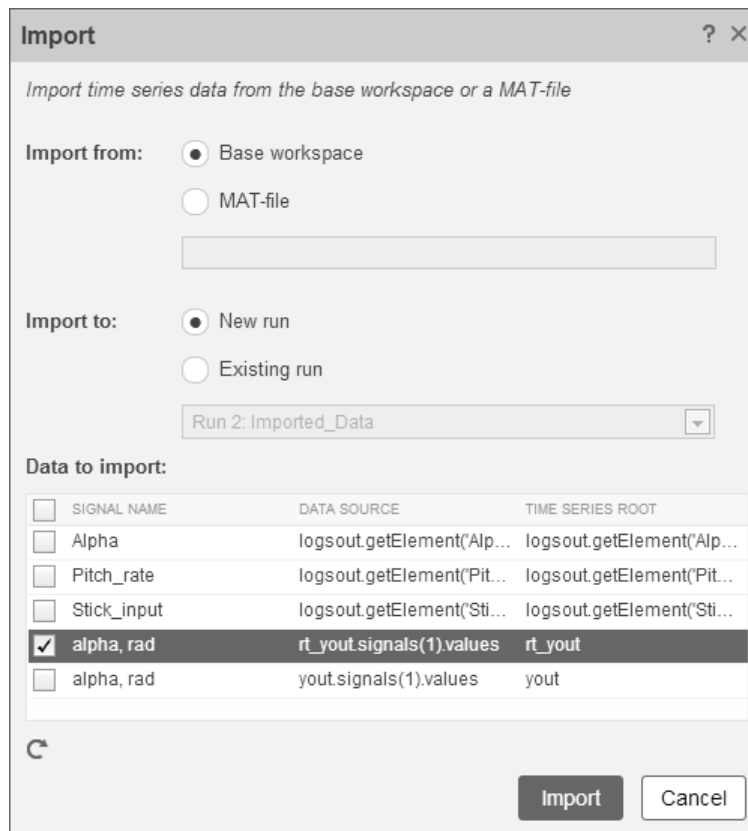

---

Proceed to “Visualize and Compare Results” on page 84-5.

## Visualize and Compare Results

When you follow the example sequence that began in “Configure Signal Data for Logging” on page 84-2, you obtain data from a Simulink run of the model and from a run of the program generated from the model.

- 1 To view the execution output for `alpha , rad`, import the data into the Simulation Data Inspector.
  - a On the Simulation Data Inspector **Visualize** tab, click the **Import** button to open the Import dialog.
  - b Specify **Import from** as **Base workspace**.
  - c Specify **Import to** as **New run**.
  - d To the left of **Signal Name**, click the check mark to clear the check boxes.
  - e Select the check box for the `alpha , rad` data where the **Time Series Root** is `rt_yout`.
  - f Click **Import**.

The selected data is now under **Run 2: Imported\_Data**.

- 2 View a plot of the executed data.
  - a Click the `rt_yout` expander.
  - b Click the top subplot and select the check box next to the `alpha, rad` signal name. The signal data appears in the top subplot.

The `alpha, rad` signal from Run 1 and Run 2 overlap in the subplot because the signals are equivalent.

It is possible to see a very small difference between simulation and code generation results. A slight difference can be caused by many factors, including:

- Different compiler optimizations
- Statement ordering
- Run-time libraries

For example, a function call such as `sin(2.0)` can return a slightly different value depending on which C library you use. Such variations can also cause differences between your results and these results.

## Compare States for Simulation and Code Generation

The order in which Simulink logs states during simulation is different than the order in which Simulink Coder logs states during code generation. If you want to compare states between simulation and code generation, sort the states by block name.

For example, by default, Simulink exports state data to the MATLAB variable, `xout`. Simulink Coder exports state data to the variable `rt_xout`. To sort the state data for these variables, enter the following commands in the MATLAB Command Window:

```
[~,idx1]=sort({xout.signals.blockName});
xout_sorted=[xout.signals(idx1).values];
[~,idx2]=sort({rt_xout.signals.blockName});
rt_xout_sorted=[rt_xout.signals(idx2).values];
```

You can confirm that the logging order is the same between code generation and simulation by entering the following command in the MATLAB Command Window:

```
isequal(xout_sorted, rt_xout_sorted)
```

## Verify Generated Code by Using Code Tracing

Code tracing (traceability) uses hyperlinks to navigate between a line of generated code and its corresponding elements in a model. To find the lines of code and their corresponding elements, you can also right-click an element or elements in a model. This two-way navigation is *bidirectional* traceability.

Using code tracing, you can:

- Verify that generated code is as you expect. You can identify which model elements correspond to a line of code. You can track code from different elements that you have or have not reviewed.
- Verify that generated code meets the design requirements. You can link requirements to the model element and use code tracing to verify that the generated code for a model element meets the assigned requirements.

When you generate code from a Simulink model, traceability information is embedded in the generated code, unless explicitly unspecified. The traceability information includes links for tracing between the generated source code and the model. You can view the generated code by either the:

- “Code View” on page 85-3: View the generated code in the Code view of the Code perspective.
- “Code Generation Report” on page 85-4: View the generated code as an HTML report in the MATLAB web browser.

The generated code includes resources that support code tracing:

- Code element hyperlinks (indicated by underlining when you place your cursor over the code) to trace variables or types in the generated code to their declarations or definitions in the header files.
- Tags in code comments that identify elements in a model from which lines of code are generated.
- Line number hyperlinks that link to the model component from which the line of code was generated.

### Traceable Elements

Bidirectional traceability is supported for Simulink blocks and these Stateflow elements:

- States
- Transitions
- State transition tables
- MATLAB functions. Traceability is not supported for external code that you call from a MATLAB function.
- Truth table blocks
- Graphical functions
- Simulink functions

Traceability in one direction is supported for these Stateflow elements:

- Events (code-to-model)

Code-to-model traceability works for explicit events, but not implicit events. Clicking a hyperlink for an explicit event in the generated code highlights that item in the **Contents** pane of the Model Explorer.

- Junctions (model-to-code)

Model-to-code traceability works for junctions with at least one outgoing transition. Right-clicking such a junction in the Stateflow Editor highlights the line of code that corresponds to the first outgoing transition for that junction.

For more information, see “Trace Stateflow Elements in Generated Code” on page 85-12.

MATLAB Function blocks that you insert directly into a Simulink model are also traceable. For more information, see “Use Traceability in MATLAB Function Blocks” on page 85-35.

## Traceability in Generated Code

- “Code View” on page 85-3
- “Code Generation Report” on page 85-4

### Code View

- 1 Open the model `rtwdemo_comments`.
- 2 Open the Embedded Coder app. Build the model. On the **C Code** tab, click **Build**.

The HTML code generation report opens by default. To use the report, see “Code Generation Report” on page 85-4.

- 3 View the generated code in the Code view in the Code perspective.
- 4 Switch between the generated source files by using the drop-down list at the top of the Code view.
- 5 The source code contains traceability information such as hyperlinked comments, line numbers, variables, and operators. Place your cursor over or click a comment or line number hyperlink. The Simulink Editor highlights the corresponding block or blocks in the model.

The screenshot displays the Embedded Coder environment. On the left, a Simulink model named 'rtwdemo\_comments' is shown. A 'Matrix Multiply' block is selected and highlighted in blue. A blue callout box indicates 'Generate Code Using Embedded Coder (double-click)'. The 'Code' window on the right shows the generated C code for the selected block. Line 64 is highlighted, showing the declaration of the 'indexed\_data' variable with a hyperlink to the block in the model. The 'Code Mappings - C' window at the bottom shows a table of model element categories and their storage classes.

Model Element Category	Storage Class
Inports	Default
Outputs	Default
Model parameters	Default
Model parameter arguments	Default
External parameter objects	Default

- 6 To highlight the generated code for a block in the model, select the block. The generated code for the block is highlighted in the Code view.
- 7 To open the generated code for a referenced model, open the referenced model and view the generated code in the Code view.

### Code Generation Report

- 1 Open the model `rtwdemo_comments`.
- 2 Open the Embedded Coder app. On the **C Code** tab, click **Settings** to open the Configuration Parameters dialog box. Select **Create code generation report** if it is not already selected. By default, **Open report automatically**, **Code-to-model**, and **Model-to-code** are selected.
- 3 If your model contains referenced models and you want to enable traceability for the referenced model's code generation report, repeat the previous step for each referenced model.
- 4 Build the model. On the **C Code** tab, click **Build**. The build process opens the code generation report in a MATLAB web browser.
- 5 In the left navigation pane, select a source code file. The source code and line numbers in the right pane contain hyperlinks to blocks in the model.
- 6 Click a comment or line number hyperlink. The Simulink Editor displays and highlights the corresponding block or blocks in the model.

- 7 To highlight the generated code for a block in the model, right-click the block and select **C/C++ Code > Navigate to C/C++ Code**. The generated code for the block is then highlighted in the HTML code generation report. To highlight the generated code for multiple blocks that you select, hold the **SHIFT** key, select multiple blocks, and then right-click any one block to select **C/C++ Code > Navigate to C/C++ Code**. The generated code for the blocks is then highlighted in the HTML code generation report.
- 8 If you have a referenced model in your model, in the left navigation pane, under **Reference Models**, click the link to a referenced model. The code generation report for the referenced model is now displayed in the MATLAB web browser.
- 9 In the left navigation pane, you can click the **Back** button to go back to the previous code generation report.

## Traceability Tags

A traceability tag appears in a comment above the corresponding line of generated code. The format of the tag is `<system>/block_name`.

- *system* is one of the following:
  - The text Root
  - A unique system number assigned by the Simulink engine
- *block\_name* is the name of the source block.

The code generator documents the tags for a model in the comments section of the generated header file `model.h`. For example, this comment appears in the header file for a model, `foo`, that has a subsystem `Outer` and a nested subsystem `Inner`:

```

/* Here is the system hierarchy for this model.
 *
 * <Root> : foo
 * <S1> : foo/Outer
 * <S2> : foo/Outer/Inner
 */

```

This code shows a tag comment above the generated line of code. A Gain block at the root level of a source model generates this code:

```

/* Gain: '<Root>/UnDeadGain1' */
rtb_UnDeadGain1_h = dead_gain_U.In1 * dead_gain_P.UnDeadGain1_Gain;

```

This code shows a tag comment above the generated line of code. A Gain block within a subsystem one level below the root level of the source model generates this code:

```

/* Gain: '<S1>/Gain' */
dead_gain_B.temp0 *= (dead_gain_P.s1_Gain_Gain);

```

## Operator Traceability

The generated code provides traceability between operators in the generated code and Simulink blocks, Stateflow elements, or MATLAB Function blocks.

To verify the generated code by using operator traceability, in the generated code, click an operator hyperlink to highlight the source block in the model.

These operators are supported.

Operator Type	Operators
Arithmetic	+ , - , * , / , % + = , - = , * = , / = , % = ++ , -- (prefix and postfix)
Logical	! , && ,
Relational	= = , ! = , < , > , < = , > =
Bit	~ ,   , ^ , & , >> , << & = , ^ = ,   = , << = , >> =
Conditional	? :

These operators are not supported.

Operator Type	Operator Examples
Assignment operator	=
Member of and pointer operators	Array subscript: a [ b ] Address of and pointer dereference: &a , *a Member of: a . b , a ->b
Other operators	Parenthesis in function call: foo ( a , b ) Comma: a , b

Operator Type	Operator Examples
	Scope resolution: <code>a : b</code>
	Cast: <code>type(a)</code>
	<code>new, new[]</code>
	<code>delete, delete[]</code>

## Traceability Limitations

These limitations apply to reports generated by Embedded Coder software:

- Under the following conditions, model-to-code traceability is disabled for a block if the block name contains:
  - A single quote (`'`).
  - An asterisk (`*`) that causes a name-mangling ambiguity relative to other names in the model. This name-mangling ambiguity occurs if in a block name or at the end of a block name, an asterisk precedes or follows a slash (`/`).
  - The character `ÿ` (`char(255)`).
- If a block name contains a newline character (`\n`), the generated code comment for the block path hyperlink replaces the newline character with a space for readability.
- You cannot trace blocks representing these types of subsystems to generated code:
  - Virtual subsystems
  - Masked subsystems
  - Nonvirtual subsystems for which code has been removed due to optimization

If you cannot trace a subsystem at subsystem level, you can trace individual blocks within the subsystem.

- If you open a model on a platform that is different from the platform used to generate code, you cannot use model-to-code and code-to-model traceability.
- Inline traceability is not available for files that are generated in `shared_utils` folder.

- “Use Traceability in MATLAB Function Blocks” on page 85-35

## Trace Simulink Model Elements in Generated Code

To verify the generated code, Embedded Coder provides bidirectional traceability between the Simulink model and the generated code. You can use either method for traceability:

- Code-to-model: The generated code displays these hyperlinks in comment lines in the generated code:
  - Block/subsystems names
  - Line numbers
  - Operators

To highlight the corresponding block or subsystem in the Simulink Editor, click the hyperlinks.

- Model-to-code: You can select single or multiple blocks of a model in the Simulink Editor and navigate to the corresponding generated code.

---

**Note** The Code view in code perspective provides bidirectional traceability by default.

---

### Code-to-Model Traceability

To use hyperlinks for tracing code-to-model elements:

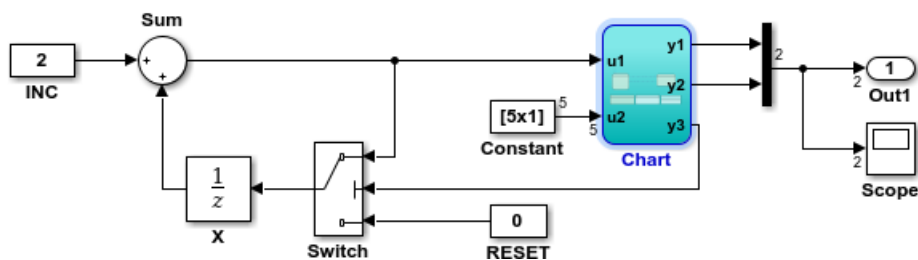

- 1 Open the model and configure it as an ERT target.
- 2 Build or generate code for the model. The Code view opens by default to display the generated code next to the model.
- 3 In the generated code, place your cursor over the block names in comments to highlight source blocks. For example, generate an HTML report for the model `rtwdemo_hyperlinks`. In the generated code for the model step function in `rtwdemo_hyperlinks.c`, place your cursor over the `UnitDelay: '<Root>/X'` block. In the model window, the corresponding `UnitDelay` block is highlighted.

The screenshot shows the Simulink environment with the model window on the left and the code window on the right. The model window displays a block diagram with an 'INC' block, a '1/z' block, a 'Switch' block, a 'RESET' block, a 'Chart' block, and an 'Out1' block. The code window shows the generated C code for the 'Chart' block, with line 153 highlighted. The code includes comments for the chart's structure and state transitions.

To use line numbers for tracing code-to-model elements:

- 1 In the previous model, `rtwdemo_hyperlinks`, click the hyperlink at line number 153. The line numbers can differ from the numbers that appear in your generated code.
- 2 In the model window, the Chart subsystem is highlighted and contains the functionality on line 153.

### Traceability to Hidden Blocks

The code generator sometimes inserts hidden blocks during the code generation process for various reasons, for example, to maintain data integrity. Comments for the hidden blocks are included in the generated code. These comments, and the code generated from the hidden block, trace back to the original block in the model that triggered the insertion of the hidden block. Comments to hidden blocks follow this template:

```
/* <Hidden_Block_Type> generated from: <Hyperlinked_Original_Block_Name> */
```

For example,

```
/* SignalConversion generated from: '<Root>/Subsystem' */
Varianttground_B.VM_Conditional_Signal_Subsystem_0 = 0.0;
```

The hidden block SignalConversion is not present in the model. You can trace to the '<Root>/Subsystem' block in the model that triggered the insertion of the hidden block by clicking on the hyperlink on '<Root>/Subsystem'. For more information on this example, see “Code Generation for Variant Blocks with One Variant Choice” on page 27-17.

## Model-to-Code Traceability

To trace model elements to their corresponding generated code:

- 1 Complete steps 1 and 2 as in “Code-to-Model Traceability” on page 85-8
- 2 Build or generate code for the model. The generated code is displayed in the Code view window next to the model.
- 3 In the model window, click on a model element. To select multiple blocks, hold the **SHIFT** key and select additional blocks.
- 4 In the generated code in Code view window, you see the first instance of highlighted code that is generated for the model element. At the top of the Code view, numbers that appear to the right of generated file names indicate the total number of highlighted lines in each file. This figure shows the result of tracing the Unit Delay block in model `rtwdemo_hyperlinks`.

The screenshot displays the MATLAB Embedded Coder environment. On the left, the model window shows a Simulink diagram for `rtwdemo_hyperlinks`. A blue box highlights a Unit Delay block (labeled 'X'). Below the model, two buttons are visible: "Generate Code Using Embedded Coder (double-click)" and "View Report Configuration (double-click)".

On the right, the Code view window shows the generated C code for `rtwdemo_hyperlinks.c`. The code is highlighted to show the traceability of the Unit Delay block. The highlighted code includes:

```
148 * Constant: '<Root>/INC'
149 * Sum: '<Root>/Sum'
150 * UnitDelay: '<Root>/X'
151 */
152 /* Gateway: Chart */
153 if (rtDWork.temporalCounter_i1 < 3U) {
154 rtDWork.temporalCounter_i1++;
155 }
156
157 if (rtDWork.temporalCounter_i2 < 3U) {
158 rtDWork.temporalCounter_i2++;
159 }
160
161 /* During: Chart */
162 if (rtDWork.bitsForTID0.is_active_c1_rtwdemo_hyperlinks == 0U) {
163 /* Entry: Chart */
164 rtDWork.bitsForTID0.is_active_c1_rtwdemo_hyperlinks = 1U;
165
166 /* Entry Internal: Chart */
167 /* Transition: '<S1>:4' */
168 rtDWork.bitsForTID0.is_c1_rtwdemo_hyperlinks = IN_S1;
169
170 /* Entry 'S1': '<S1>:1' */
171 rtDWork.loc = 2.0;
172
173 /* Entry Internal 'S1': '<S1>:1' */
174 /* Entry 'S1a': '<S1>:2' */
175 rtDWork.loc++;
176 } else if (rtDWork.bitsForTID0.is_c1_rtwdemo_hyperlinks == IN_S1) {
177 /* During 'S1': '<S1>:1' */
178 if (rtB.y1 > 50.0) {
179 /* Transition: '<S1>:14' */
180 /* Exit Internal 'S1': '<S1>:1' */
181 /* Exit 'S1': '<S1>:1' */
182 rtB.y3 = gfcn(rtDWork.X + 2.0, rtCP_Constant_Value);
183 rtDWork.bitsForTID0.is_c1_rtwdemo_hyperlinks = IN_S2;
184 }
185 }
```

At the top of the Code view window, the file name `rtwdemo_hyperlinks.c` is followed by the number `1/8`, indicating that 1 line of code is highlighted in this file.

At the top of the code window, use the navigation bar to move forward and backward through multiple instances of highlighted lines. Use the navigation sidebar to go directly to a line of code.

If you close and reopen a model, the Code view does not open until you open the **Embedded Coder** app. The Code view might not be available because Embedded Coder cannot find a build folder for your model in the current working folder. Reset the current working folder to the parent folder of the existing build folder.

If you are using the code generation report and want to reload existing traceability information, see “Reload Existing Traceability Information” on page 85-28.

## See Also

### Related Examples

- “Verify Generated Code by Using Code Tracing” on page 85-2
- “Trace Stateflow Elements in Generated Code” on page 85-12

## Trace Stateflow Elements in Generated Code

To verify the generated code for your Stateflow elements, you can trace Stateflow elements in your model to the generated code by using these types of navigation:

- **Code-to-model:** Trace generated code back to the model by clicking hyperlinks in the comments or the hyperlinked line numbers, which highlights the corresponding model element in the Simulink Editor.
- **Model-to-code:** Trace the model elements in the Simulink Editor to corresponding lines in generated code by right-clicking the model element and navigating to the generated code. This traceability is not supported for some Stateflow elements in Code view.

These examples illustrate how to trace different Stateflow elements.

### Inline Traceability for Stateflow Elements

Inline traceability refers to the line-level traceability available in the generated code. You can click the hyper-linked line numbers to trace single or multiple Stateflow elements at the same time.

- 1 Open the model.  

```
openExample('old_sf_car')
```
- 2 Configure the model as an ERT target.
- 3 On the **Code Generation > Report** pane, select these model configuration parameters:
  - **Create code generation report**
  - **Open report automatically**
  - **Code-to-model**
  - **Model-to-code**
- 4 Select **Code Generation > Comments > Stateflow object comments** configuration parameter. This parameter enables the traceability comments for Stateflow elements.
- 5 Go to the **Code Generation > Interface** pane. In the **Software environment** section, select **continuous time**. Click **Apply**. Before generating code, you must perform this step because this model contains a block with a continuous sample time.
- 6 On the **C Code** tab, click **Build**.

After the code generation process is complete, the code generation report appears.

- 7 In the report, on the left navigation pane, click the `old_sf_car.c` hyperlink.
- 8 To view the inline traceability hyperlinks, scroll through the code. These line numbers can differ from the numbers that appear in your code generation report.

```

185 /* Function for Chart: '<Root>/shift_logic' */
186 static void old_sf_car_gear_state(const int32_T *sfEvent)
187 {
188 switch (old_sf_car_DW.is_gear_state) {
189 case old_sf_car_IN_first:
190 old_sf_car_B.gear = 1.0;
191 if (*sfEvent == old_sf_car_event_UP) {
192 old_sf_car_DW.is_gear_state = old_sf_car_IN_second;
193 old_sf_car_B.gear = 2.0;
194 }
195 break;

```

- 9 Click the hyperlink on line number 190. The corresponding element is highlighted.

## Bidirectional Traceability for States and Transitions

- 1 Open the model.  

```
openExample('old_sf_car')
```
- 2 Complete steps 2 through 5 in “Inline Traceability for Stateflow Elements” on page 85-12.
- 3 Press **Ctrl+B** to generate source code and header files for the `old_sf_car` model that contains the `shift_logic` chart. After the code generation process is complete, the code generation report appears.

- 4 In the report, click the `old_sf_car.c` hyperlink.

### View Results

- 1 To see the traceability comments, scroll through the code. These line numbers can differ from the numbers that appear in your code generation report.

```

188 /* Function for Chart: '<Root>/shift_logic' */
189 static void old_sf_car_gear_state(const int32_T *sfEvent)
190 {
191 /* During 'gear_state': '<S5>:2' */
192 switch (old_sf_car_DW.is_gear_state) {
193 case old_sf_car_IN_first:
194 old_sf_car_B.gear = 1.0;
195
196 /* During 'first': '<S5>:6' */
197 if (*sfEvent == old_sf_car_event_UP) {
198 /* Transition: '<S5>:12' */
199 old_sf_car_DW.is_gear_state = old_sf_car_IN_second;
200
201 /* Entry 'second': '<S5>:4' */
202 old_sf_car_B.gear = 2.0;

```

- 2 Click the `<S5>:2` hyperlink in this traceability comment:

```
/* During 'gear_state': '<S5>:2' */
```

The corresponding state appears highlighted in the chart.

- 3 Click the `<S5>:12` hyperlink in this traceability comment:

```
/* Transition: '<S5>:12' */
```

The corresponding transition appears highlighted in the chart. To remove highlighting from an element in the chart, press the **Esc** key.

- 4 You can also trace elements in the model to lines of generated code. In the chart, right-click the element `gear_state` and select **C/C++ Code > Navigate to C/C++ Code**.

The code for that state appears highlighted in `old_sf_car.c`.

```

188 /* Function for Chart: '<Root>/shift_logic' */
189 static void old_sf_car_gear_state(const int32_T *sfEvent)
190 {
191 /* During 'gear_state': '<S5>:2' */
192 switch (old_sf_car_DW.is_gear_state) {
193 case old_sf_car_IN_first:
194 old_sf_car_B.gear = 1.0;

```

- 5 In the chart, right-click the transition with the condition `[speed > up_th]` and select **C/C++ Code > Navigate to C/C++ Code**.

The code for that transition appears highlighted in `old_sf_car.c`.

```

492 case old_sf_car_IN_steady_state:
493 /* During 'steady_state': '<S5>:9' */
494 if (old_sf_car_B.mph > interp_up) {
495 /* Transition: '<S5>:18' */
496 old_sf_car_DW.is_selection_state = old_sf_car_IN_upshifting;
497 old_sf_car_DW.temporalCounter_i1 = 0U;
498 } else {
499 if (old_sf_car_B.mph < interp_down) {
500 /* Transition: '<S5>:19' */

```

---

**Note** For a list of the Stateflow elements in your model that are traceable, click the **Traceability Report** hyperlink in the code generation report.

---

## Bidirectional Traceability for State Transition Tables

This example shows how to navigate bidirectionally between elements in a state transition table and the generated C/C++ and HDL code for traceability.

- 1 Open the model. This model is already configured for traceability.  

```
openExample('sf_cdplayer_STT')
```
- 2 Press **Ctrl+B** to generate source code and header files for the sf\_cdplayer\_STT model. After the code generation process is complete, the code generation report appears.
- 3 Click the sf\_cdplayer\_STT.c hyperlink in the report.
- 4 To see the traceability comments, scroll through the code. The line numbers shown can differ from the numbers that appear in your code generation report.

```

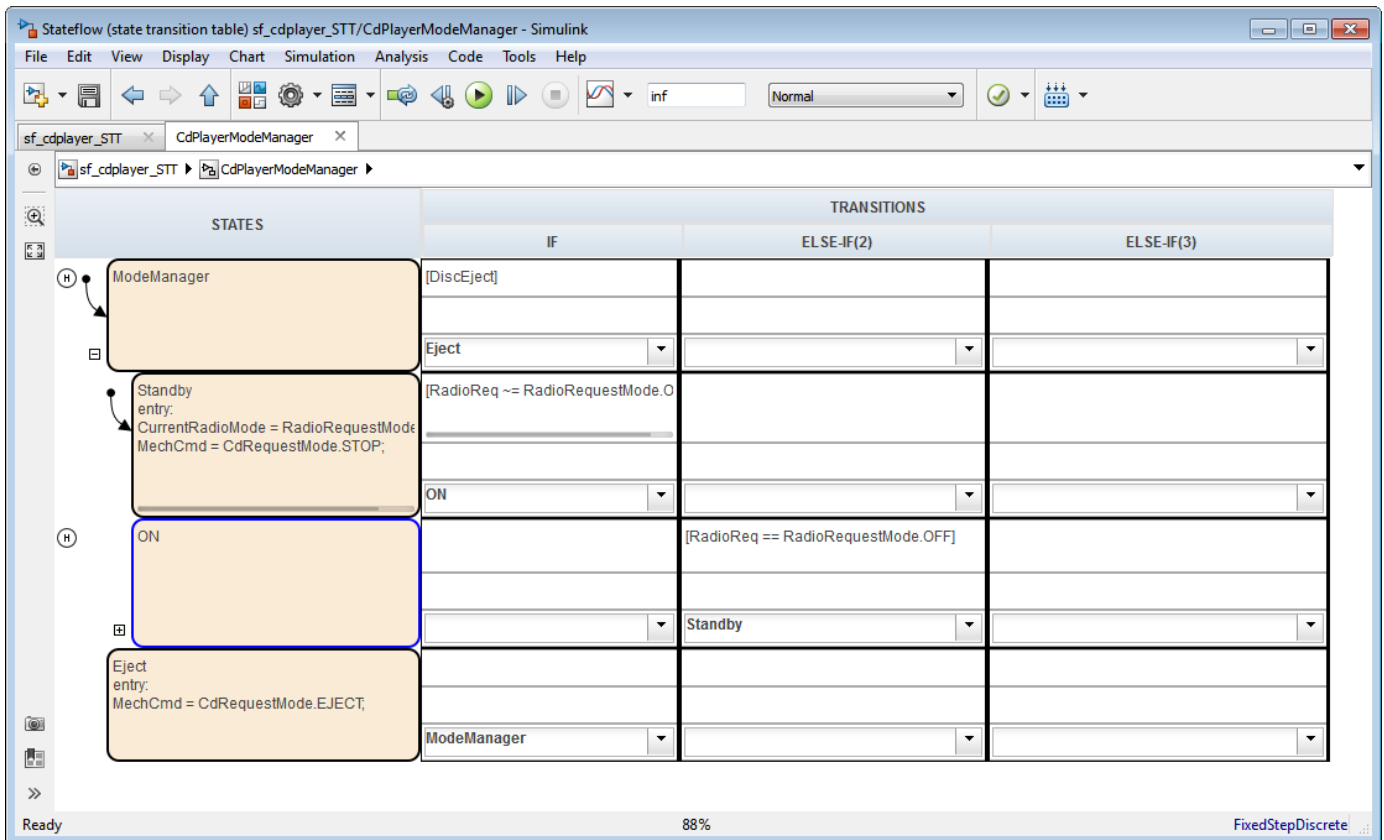

60 /* Function for State Transition Table: '<Root>/CdPlayerModeManager' */
61 static void sf_cdplayer_S_enter_internal_ON(void)
62 {
63 /* Entry Internal 'ON': '<S2>:58' */
64 switch (sf_cdplayer_STT_DWork.bitsForTID1.was_ON) {
65 case sf_cdplayer_STT_IN_AMMode:
66 sf_cdplayer_STT_DWork.bitsForTID1.is_ON = sf_cdplayer_STT_IN_AMMode;
67 sf_cdplayer_STT_DWork.bitsForTID1.was_ON = sf_cdplayer_STT_IN_AMMode;
68
69 /* Entry 'AMMode': '<S2>:61' */
70 sf_cdplayer_STT_B.CurrentRadioMode = AM;
71 sf_cdplayer_STT_B.MechCmd = STOP;
72 break;
73

```

- 5 Click the <S2>:58 hyperlink in this traceability comment:

```
/* Entry Internal 'ON': '<S2>:58' */
```

The corresponding state 'ON' appears highlighted in the state transition table.

- 6 You can trace a state or transition from the state transition table to the generated code. Right-click the state Standby and select **C/C++ Code > Navigate to C/C++ Code**.

The entry code for the state Standby is highlighted in the generated code.

```

206 /* During 'ON': '<S2>:58' */
207 if (sf_cdplayer_STT_P.RR_Value == OFF) {
208 /* Transition: '<S2>:71' */
209 sf_cdplayer_ST_exit_internal_ON();
210 sf_cdplayer_STT_DWork.bitsForTID1.is_ModeManager =
211 sf_cdplayer_STT_IN_Standby;
212 sf_cdplayer_STT_DWork.bitsForTID1.was_ModeManager =
213 sf_cdplayer_STT_IN_Standby;
214
215 /* Entry 'Standby': '<S2>:57' */
216 sf_cdplayer_STT_B.MechCmd = STOP;
217 } else if (*RadioReq_prev != sf_cdplayer_STT_DWork.RadioReq_start) {
218 /* Transition: '<S2>:75' */
219 if (sf_cdplayer_STT_P.RR_Value == CD) {

```

## Bidirectional Traceability for Truth Table Blocks

- 1 Open the model.  

```
openExample('sf_climate_control')
```
- 2 Complete steps 2 through 5 in “Inline Traceability for Stateflow Elements” on page 85-12.
- 3 To build the model, press **Ctrl+B**.
- 4 In the code generation report, click the `sf_climate_control.c` hyperlink.
- 5 To see the traceability comments, scroll through the code. These line numbers can differ from the numbers that appear in your code.

```

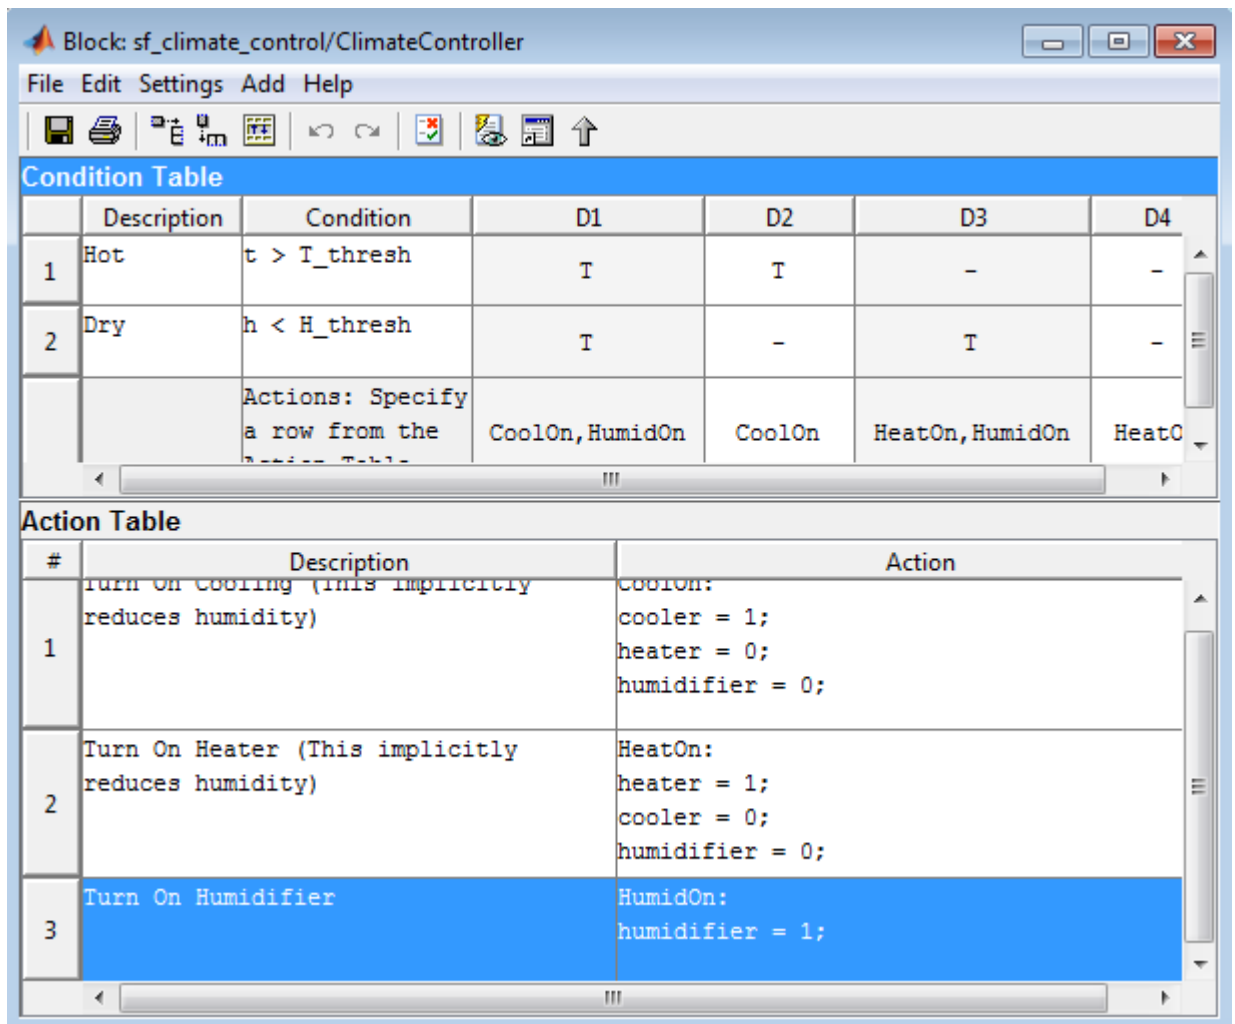

68 /* Turn On Humidifier */
69 /* Action '3': '<S1>:1:47' */
70 rtb_humidifier = 1;
71 } else if (aVarTruthTableCondition_1) {
72 /* Decision 'D2': '<S1>:1:18' */
73 /* Turn On Cooling (This implicitly reduces humidity) */
74 /* Action '1': '<S1>:1:31' */
75 rtb_cooler = 1;

```

- 6 Click the `<S1>:1:47` hyperlink in this traceability comment:

```
/* Action '3': '<S1>:1:47' */
```

In the Truth Table Editor, row 3 of the Action Table appears highlighted.

- 7 You can also trace a condition, decision, or action in the table to a line of generated code. For example, right-click a cell in the column D2 and select **C/C++ Code > Navigate to C/C++ Code**.

The code for that decision appears highlighted in sf\_climate\_control.c.

```

68 /* Turn On Humidifier */
69 /* Action '3': '<S1>:1:47' */
70 rtb_humidifier = 1;
71 } else if (aVarTruthTableCondition_1) {
72 /* Decision 'D2': '<S1>:1:18' */
73 /* Turn On Cooling (This implicitly reduces humidity) */
74 /* Action '1': '<S1>:1:31' */
75 rtb_cooler = 1;

```

**Tip** To select **C/C++ Code > Navigate to C/C++ Code** for a condition, decision, or action, right-click a cell in the row or column that corresponds to that truth table element.

## Bidirectional Traceability for Graphical Functions

- 1 Open the model.

```
openExample("stateflow/ClutchWithEnabledSubsystemsExample")
```

- 2 Complete steps 2 through 5 in “Inline Traceability for Stateflow Elements” on page 85-12.
- 3 In the Configuration Parameters dialog box, go to the **Solver** pane. In the **Solver selection** section, select Fixed-step in the **Type** field. Click **Apply**. Before generating code, you must perform this step because the model does not work with variable-step solvers.
- 4 To build the model, press **Ctrl+B**.
- 5 In the code generation report, click the `sf_clutch_enabled_subsystems.c` hyperlink.
- 6 To see the traceability comments, scroll through the code. These line numbers can differ from the numbers that appear in your code generation report.

```
376 /* During 'Slipping': '<S1>:1' */
377 /* Graphical Function 'detectLockup': '<S1>:10' */
378 /* Transition: '<S1>:28' */
379 /* Graphical Function 'getSlipTorque': '<S1>:3' */
380 /* Transition: '<S1>:12' */
```

- 7 Click the `<S1>:3` hyperlink in this traceability comment:

```
/* Graphical Function 'getSlipTorque': '<S1>:3' */
```

In the chart, the graphical function `getSlipTorque` appears highlighted.

- 8 You can trace a graphical function in the chart to a line of generated code. For example, right-click the graphical function `detectSlip` and select **C/C++ Code > Navigate to C/C++ Code**.

The code for that graphical function appears highlighted in `sf_clutch_enabled_subsystems.c`.

```
309 /* During 'Locked': '<S1>:2' */
310 /* Graphical Function 'detectSlip': '<S1>:6' */
311 /* Transition: '<S1>:15' */
312 /* Graphical Function 'getLockedTorque': '<S1>:5' */
313 /* Transition: '<S1>:14' */
314 if (fabs((5.0 * sf_clutch_enabled_subsystems_B.Tin - (5.0 * 2.0 - 1.0 *
315 1.0) *
316 sf_clutch_enabled_subsystems_X.EngineVehicleIntegrator_CSTATE) /
317 (5.0 + 1.0)) > RatioofstatictoKinetic) {
318 /* Transition: '<S1>:17' */
```

## Code-to-Model Traceability for Events

- 1 Open the model.

```
openExample('sf_security')
```

- 2 Complete steps 2 through 5 in “Inline Traceability for Stateflow Elements” on page 85-12.

- 3 To build the model, press **Ctrl+B**.
- 4 In the code generation report, click the `sf_security.c` hyperlink.
- 5 To see this traceability comment, scroll through the code. These numbers can differ from the numbers that appear in your code generation report.

```

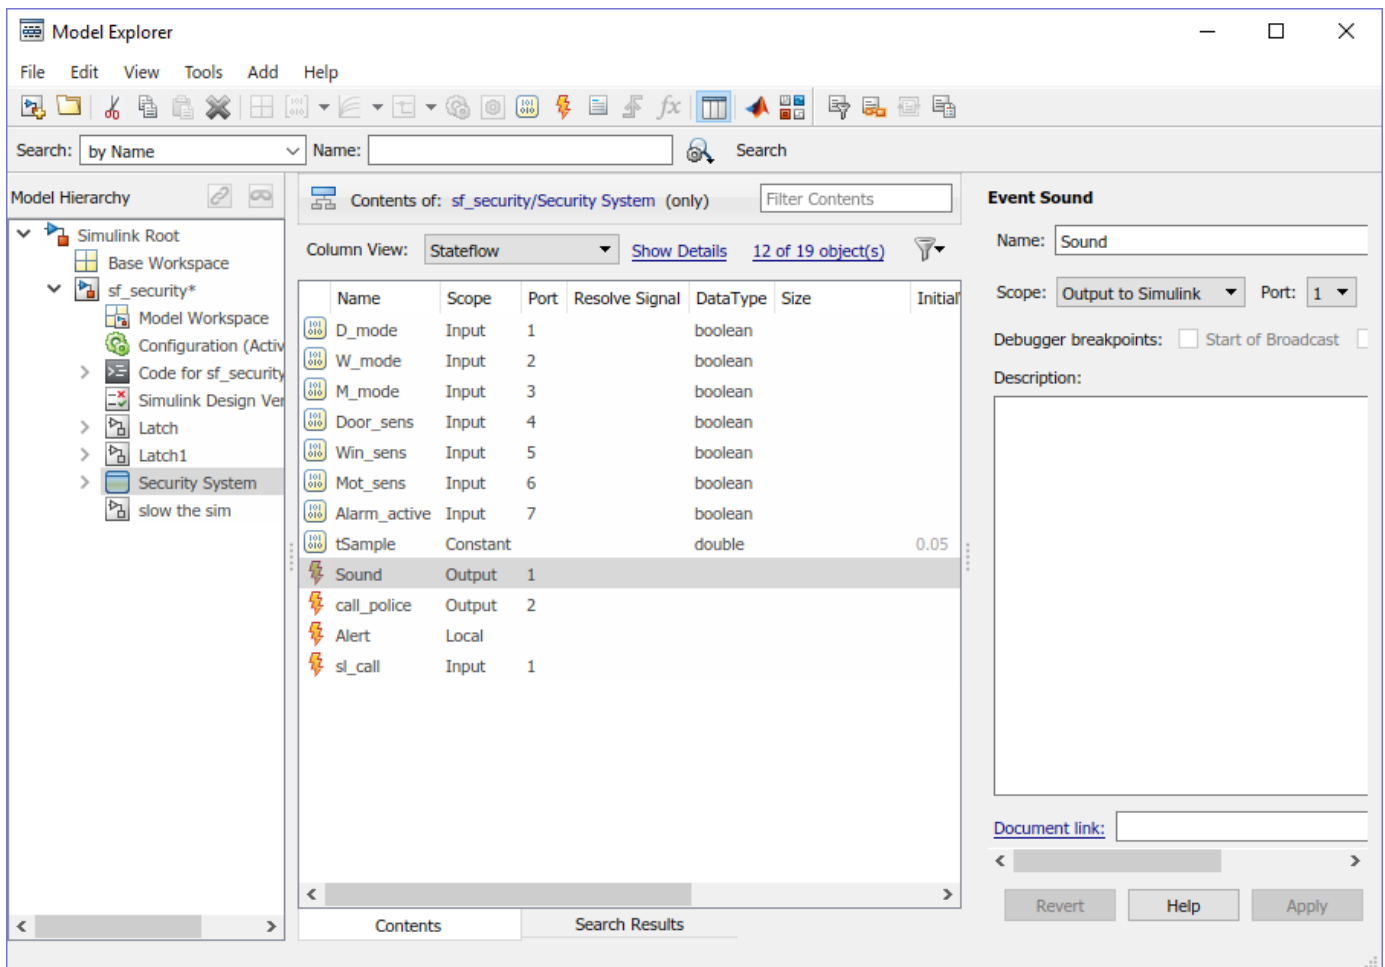

236 /* Entry 'Pending': '<S3>:5' */
237 /* Event: '<S3>:56' */
238 sf_security_DW.SoundEventCounter++;
239 }
240 break;

```

- 6 Click the `<S3>:56` hyperlink in this traceability comment:

```
/* Event: '<S3>:56' */
```

In the **Contents** pane of the Model Explorer, the event `Sound` appears highlighted.

## Model-to-Code Traceability for Junctions

- 1 Open the model.

```
openExample('ex_if_else_SF')
```

- 2 Complete steps 2 through 5 in “Inline Traceability for Stateflow Elements” on page 85-12.
- 3 To build the model, press **Ctrl+B**.
- 4 In the code generation report, open the Stateflow chart named Chart.
- 5 Right-click the top-left junction and select **C/C++ Code > Navigate to C/C++ Code**.

The code for the first outgoing transition of that junction appears highlighted in `ex_if_else_SF.c`.

```
39 if (U.u1 > U.u2) {
40 /* Output: '<Root>/y1' */
41 /* Transition: '<S1>:13' */
42 /* Transition: '<S1>:12' */
43 y.y1 = U.u1;
```

## Format of Traceability Comments for Stateflow Elements

The format of a traceability comment depends on the Stateflow element type.

### State

#### Syntax

```
/* <ActionType> '<StateName>': '<elementHyperlink>' */
```

#### Example

```
/* During 'gear_state': '<S5>:2' */
```

This comment refers to the during action of the state `gear_state`, which has the hyperlink `<S5>:2`.

### Transition

#### Syntax

```
/* Transition: '<elementHyperlink>' */
```

#### Example

```
/* Transition: '<S5>:12' */
```

This comment refers to a transition, which has the hyperlink `<S5>:12`.

### MATLAB Function

#### Syntax

```
/* MATLAB Function '<Name>': '<elementHyperlink>' */
```

Within the inlined code for a MATLAB function, comments that link to individual lines of the function have this syntax:

```
/* '<elementHyperlink>' */
```

#### Examples

```
/* MATLAB Function 'test_function': '<S50>:99' */
```

```
/* '<S50>:99:20' */
```

The first comment refers to the MATLAB function named `test_function`, which has the hyperlink `<S50>:99`.

The second comment refers to line 20 of the MATLAB function in your chart.

### Truth Table Block

#### Syntax

```
/* Truth Table Function '<Name>': '<elementHyperlink>' */
```

Within the inlined code for a Truth Table block, comments for conditions, decisions, and actions have this syntax:

```
/* Condition '#<Num>': '<elementHyperlink>' */
/* Decision 'D<Num>': '<elementHyperlink>' */
/* Action '<Num>': '<elementHyperlink>' */
```

`<Num>` is the row or column number that appears in the Truth Table Editor.

#### Examples

```
/* Truth Table Function 'truth_table_default': '<S10>:100' */
/* Condition '#1': '<S10>:100:8' */
/* Decision 'D1': '<S10>:100:16' */
/* Action '1': '<S10>:100:31' */
```

The first comment refers to a Truth Table block named `truth_table_default`, which has the hyperlink `<S10>:100`.

The other three comments refer to elements of that Truth Table block. Each condition, decision, and action in the Truth Table block has a unique hyperlink.

### Truth Table Function

For syntax and examples, see “Truth Table Block” on page 85-22.

### Graphical Function

#### Syntax

```
/* Graphical Function '<Name>': '<elementHyperlink>' */
```

#### Example

```
/* Graphical Function 'hello': '<S1>:123' */
```

This comment refers to a graphical function named `hello`, which has the hyperlink `<S1>:123`.

### Simulink Function

#### Syntax

```
/* Simulink Function '<Name>': '<elementHyperlink>' */
```

#### Example

```
/* Simulink Function 'simfcn': '<S4>:10' */
```

This comment refers to a Simulink function named `simfcn`, which has the hyperlink `<S4>:10`.

**Event****Syntax**

```
/* Event: '<elementHyperlink>' */
```

**Example**

```
/* Event: '<S3>:33' */
```

This comment refers to an event, which has the hyperlink `<S3>:33`.

- “Trace Data, Events, and Messages” (Stateflow)

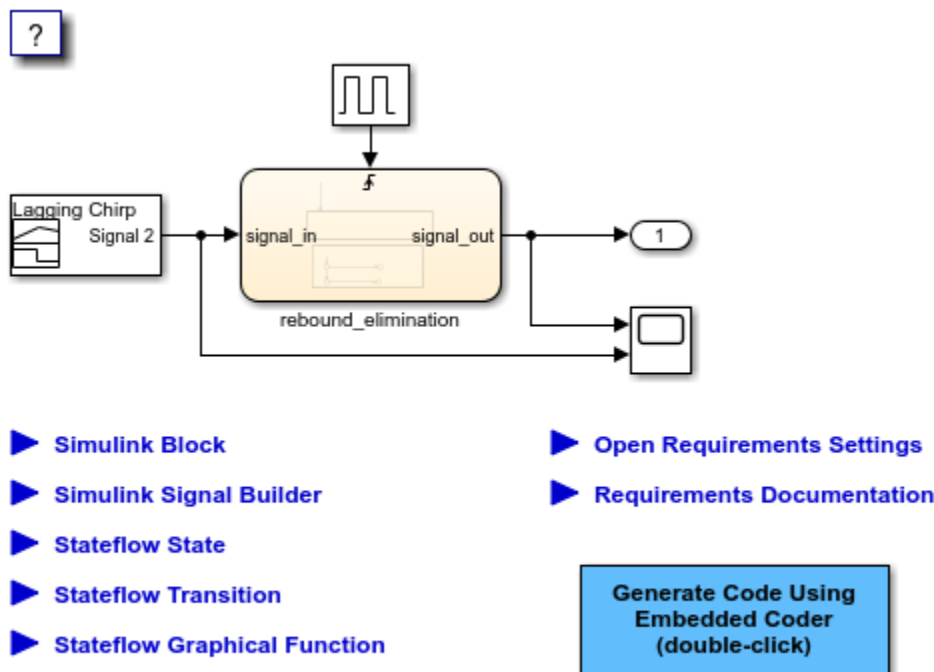

## Link Generated Code to Requirements

Link generated code to model element requirements. Using configuration parameters, you can specify whether to include requirement descriptions as comments in the generated code.

### Open Model

Open the `rtwdemo_requirements` model. The model contains Simulink® and Stateflow® elements with associated requirements.

```
model='rtwdemo_requirements';
open_system(model);
```

Copyright 1994-2020 The MathWorks, Inc.

### View Requirements

You can view requirements linked to the model by using the Requirements Editor. In the Simulink Editor, open the **Requirements Manager** app. On the **Requirements** tab, click **Requirements Editor**. You can view requirements specific to model objects by using the object context menu. Right-click an element and select **Requirements > Open Outgoing Links dialog**. To view the requirements, use these commands:

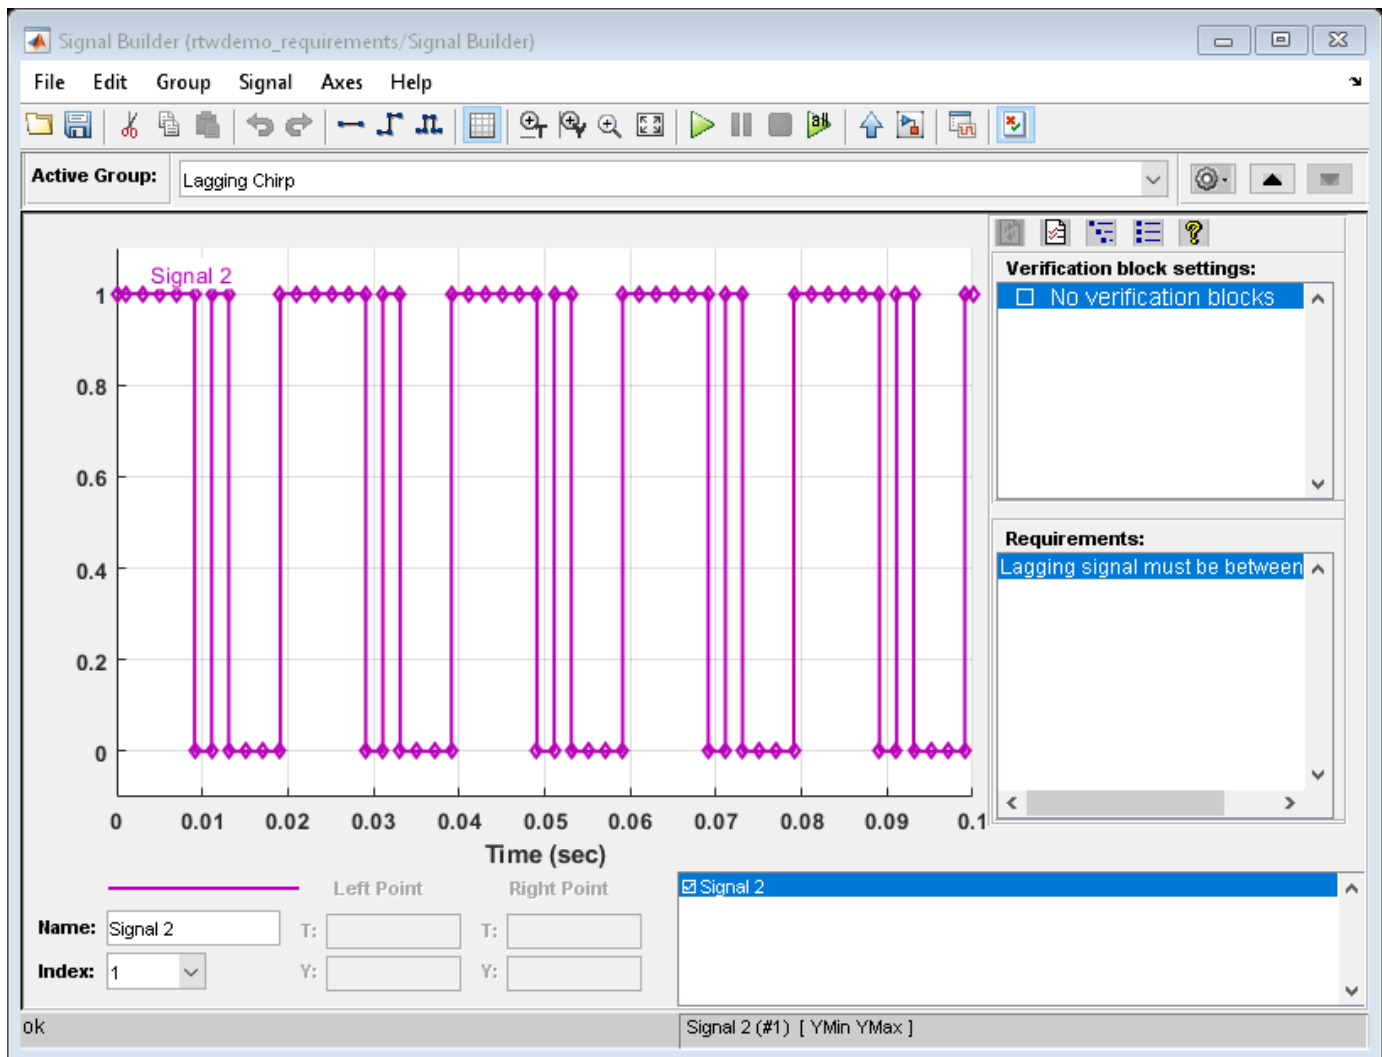

1. To view the requirements for the `DiscretePulseGenerator` block, right-click the `DiscretePulseGenerator` block and select **Requirements > Open Outgoing Links dialog** to open Outgoing Links Editor. Using Outgoing Links Editor, you can create, edit, and delete requirements traceability links.

```
clockblock='rtwdemo_requirements/clock';
clockblockh=get_param(clockblock,'handle');
rmi('edit',clockblockh);
```

2. To view the requirements, open the **Signal Builder** block by double-clicking it.

```
sigbblock='rtwdemo_requirements/Signal Builder';
open_system(sigbblock)
```

3. To view the requirements for the Stateflow® state, open the Outgoing Links Editor.

```
state=find(sfroot,'-isa','Stateflow.State','-and','Tag','req_state');
rmi('edit',state.id);
```

4. To view the requirements for the Stateflow transition, open the Outgoing Links Editor.

```
trans=find(sfroot,'-isa','Stateflow.Transition','-and','Tag','req_trans');
rmi('edit',trans.id);
```

5. To view the requirements for the Stateflow function, open the Outgoing Links Editor.

```
func=find(sfroot, '-isa', 'Stateflow.Function', '-and', 'Tag', 'req_function');
rmi('edit', func.id);
```

Close the open windows.

```
close_system(sigblock);
```

### Set Configuration Parameters

Open the Configuration Parameters dialog box **Code Generation > Comments** pane. View the configuration parameter settings.

```
model = bdroot;
configSet = getActiveConfigSet(model);
openDialog(configSet);
```

### Generate Code

Generate code for the model.

```
slbuild('rtwdemo_requirements')
```

```
Starting build procedure for: rtwdemo_requirements
Successful completion of build procedure for: rtwdemo_requirements
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_requirements	Code generated and compiled.	Code generation information file does not exist.

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 31.446s

In the generated code, view the comments containing the requirements. To view all the requirements, click the hyperlinked requirement comment.

```
rtwdemodbtype('rtwdemo_requirements_ert_rtw/rtwdemo_requirements.c', ...
 /* Function for Chart: ', 'return result;', 1, 0);

/* Function for Chart: '<Root>/rebound_elimination' */
static real_T rebound_fcn(real_T prev_in, real_T prev_out, real_T curr_in)
{
 real_T result;

 /* Graphical Function 'rebound_fcn': '<S2>:2':
 * 1. Result Computation
 */
 /* Transition: '<S2>:4' */
 if (prev_in == curr_in) {
 /* Transition: '<S2>:5' */
 result = curr_in;
 } else {
 /* Transition: '<S2>:6' */
 /* Transition: '<S2>:7' */
```

```
 result = prev_out;
}
```

### **Close Model**

```
rtwdemoclean;
close_system('rtwdemo_requirements',0);
```

## Reload Existing Traceability Information

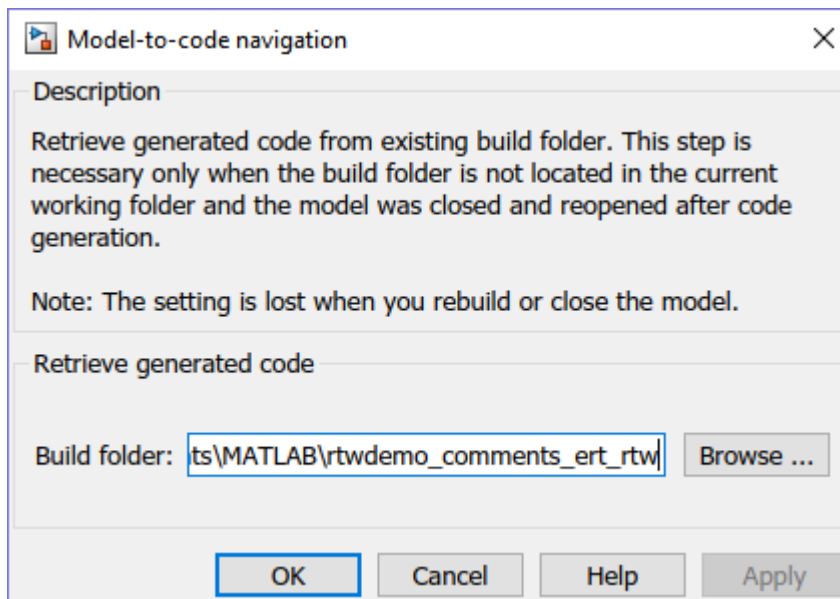

When you build a model, the traceability information is stored in the build folder. The format of the build folder for an ERT-based target is `model_ert_rtw`.

**Model-to-code** parameter should be selected in the original build to be able to reload the traceability information in a new Simulink session. To reload existing traceability information for a model:

- 1 Reset the current working folder to the parent folder of the existing build folder.
- 2 In the Configuration Parameters dialog box, next to **Model-to-code**, click **Configure**.
- 3 In the Model-to-code navigation dialog box, in the **Build folder** field, type or browse to the build folder that contains the existing traceability information.

If you close and reopen a model, the **Navigate to Code** context menu option might not be available because Embedded Coder cannot find a build folder for your model in the current working folder. In that case, perform these steps:

- 1 To open the Model-to-code navigation dialog box, click **Configure**.
- 2 In the Model-to-code navigation dialog box, click **Browse**.
- 3 Browse to the build folder for your model and select the folder. The build folder path is displayed in the **Build folder** field.

- 4 If you selected **Model-to-code** for the build, clicking **Apply** or **OK** loads traceability information from the earlier build into your Simulink session.
- 5 To open the context menu and trace a model element to corresponding code, right-click a model element and select **C/C++ Code > Navigate to C/C++ Code**.

### **Related Examples**

- “Generate Code Generation Report” on page 54-5

## Customize Traceability Reports

Even a relatively small model can generate hundreds of lines of C/C++ code. To help you navigate more easily between the generated code and your source model, Embedded Coder provides the traceability report section. When you enable traceability, Embedded Coder displays the generated code in Code view or code generation report. You can generate reports in the Configuration Parameters dialog box or at the command line.

In the Configuration Parameters dialog box, the **Code Generation > Report** pane lists parameters that you can select and clear to customize the content of your traceability reports.

Select or clear any combination of these parameters. These parameters are on by default.

- **Eliminated / virtual blocks** (account for blocks that are untraceable)
- **Traceable Simulink blocks**
- **Traceable Stateflow elements**
- **Traceable MATLAB functions**

If you select all parameters, you get a complete mapping between model elements and the generated code.

This figure shows the top section of the traceability report, which is generated when you select all traceability content parameters for model `rtwdemo_hyperlinks`. The **Generate Traceability Matrix** button appears only if you have DO Qualification Kit or IEC Certification Kit and are using a Windows host.

# Traceability Report for rtwdemo\_hyperlinks

Generate Traceability Matrix

## Generate a Traceability Matrix

The traceability matrix provides traceability among model elements, generated code, and model requirements in a Microsoft Excel® file format.

If you have DO Qualification Kit software or IEC Certification Kit software and are using a Windows host, you can generate a traceability matrix into Microsoft Excel format directly from the traceability report.

Go to the **Traceability Report** section of the HTML code generation report and click **Generate Traceability Matrix**.

Generate Traceability Matrix

To select an existing matrix file to update or specify a matrix file to create, use the options in the Generate Traceability Matrix dialog box. Optionally, you can select and create an order to the columns that appear in the generated matrix. After specifying the location where you want the matrix file, click the **Generate** button.

For more information, see "Generating a Traceability Matrix" in either the DO Qualification Kit documentation (DO Qualification Kit).

### Related Examples

- "Reports for Code Generation" on page 54-2

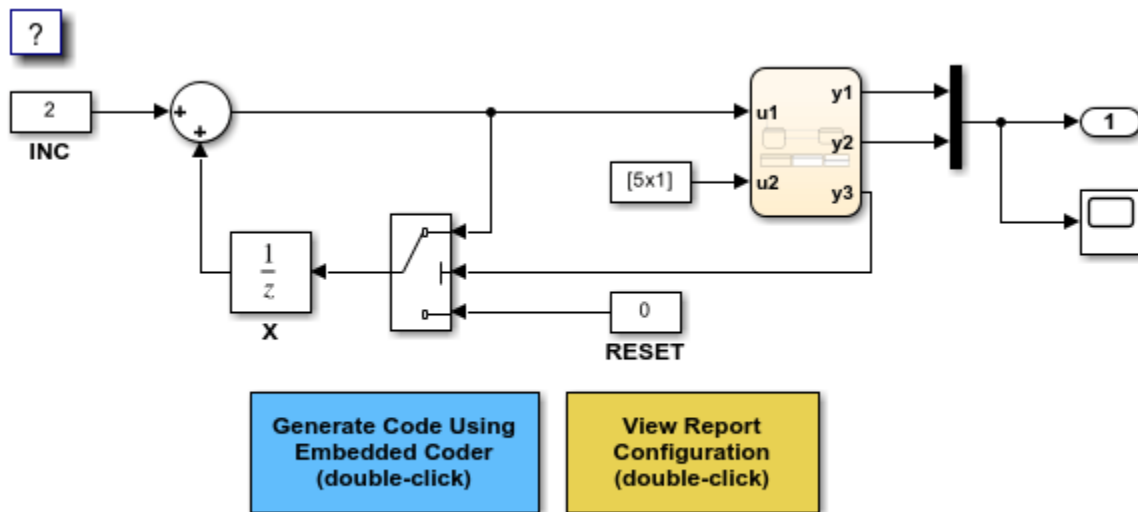

## Trace Generated Code to Blocks

Navigate and trace between generated code and its source model for verification.

### Open Example Model

Open the example model `rtwdemo_hyperlinks`.

```
model='rtwdemo_hyperlinks';
open_system(model)
```

### Code to Model Navigation

Navigate from the generated code to the model.

- 1 In the Configuration Parameters dialog box, open the **Code Generation > Report** pane.
- 2 Verify that the following parameters are selected: **Create code generation report**, **Open report automatically** and **Code-to-model**.
- 3 In the model editor window, press **Ctrl+B** to generate code. After the code generation process is complete, the code generation report appears.
- 4 In the generated report, click the `rtwdemo_hyperlinks.c` link to see the code with embedded hyperlinks.
- 5 Click links in the code to trace generated code segments to the highlighted elements in the model. For example, if you click the hyperlink `<Root>/Sum`, the Sum block in the model is highlighted.

### Model to Code Navigation

Navigate from the model to the generated code.

- 1 In the Configuration Parameters dialog box, open the **Code Generation > Report** pane.

- 2 Verify that the following parameters are selected: **Create code generation report, Open report automatically** and **Model-to-code**.
- 3 In the model editor window, press **Ctrl+B** to generate code. After the code generation process is complete, the code generation report appears.
- 4 In the model window, right-click any block and select **C/C++ Code > Navigate To C/C++ Code**. The software highlights the generated code for this block in the code generation report.
- 5 Inspect the highlighted lines in the code generation report. The total number of highlighted lines is displayed next to each source file name in the left pane of the report. Use the **Previous** and **Next** buttons to navigate through the highlighted lines.

Note: **Model-to-code** navigation also works for Stateflow® objects and **MATLAB** functions.

Note: The report displays a diagnostic message if there is no code to highlight for the selected block (for example, if you select a virtual block).

### Traceability Report

Generate and inspect the **Traceability Report**.

- 1 In the Configuration Parameters dialog box, open the **Code Generation > Report** pane.
- 2 Verify that the following parameters are selected: **Create code generation report, Open report automatically**
- 3 Search for the traceability report parameters using keyword `GenerateTraceReport`. Verify all the listed parameters are selected.
- 4 In the model editor window, press **Ctrl+B** to generate code. After the code generation process is complete, the code generation report appears.
- 5 To see a report of the untraceable (not in the generated code) and traceable blocks in your model, on the left pane of the generated report click **Traceability Report**.
- 6 In the **Traceability Report**, inspect the **Eliminated / Virtual Blocks** and **Traceable Blocks** lists. For example, the **Scope** block is an untraceable block. It is listed under **Eliminated / Virtual Blocks** because the code generator does not generate code for this block.

## Use Traceability in MATLAB Function Blocks

### Extent of Traceability in MATLAB Function Blocks

Like other Simulink blocks, MATLAB Function blocks support bidirectional traceability, but extend navigation to lines of source code. That is, you can navigate between a line of generated code and its corresponding line of source code. In other Simulink blocks, you can navigate between a line of generated code and its corresponding object.

In addition, you can select to include the source code as comments in the generated code. When you select **MATLAB source code as comments** parameter, the MATLAB source code appears immediately after the associated traceability tag. For more information, see “Include MATLAB Code as Comments in Generated Code” on page 48-23.

For information about how traceability works in Simulink blocks, see “Verify Generated Code by Using Code Tracing” on page 85-2.

### Traceability Requirements

To enable traceability comments in your code, you must have a license for Embedded Coder software. These comments appear only in code that you generate for an Embedded Real-Time (ERT) target.

---

**Note** Traceability is not supported for MATLAB files that you call from a MATLAB Function block.

---

### Using Traceability in a MATLAB Function Block

This example shows how to trace between source code and generated code in a MATLAB Function block in the `rtwdemo_dynamicio` model. Follow these steps:

- 1 Open model `rtwdemo_dynamicio`.
- 2 Open the **Embedded Coder** app.
- 3 Change the system target file to `ert.tlc` when prompted. Traceability comments appear hyperlinked in generated code only for embedded real-time (`ert.tlc`) targets.
- 4 In the Configuration Parameters dialog box, on the **Code Generation > Report** pane, select these parameters, if not already selected:
  - **Create code generation report**
  - **Code-to-model**
  - **Model-to-code**
- 5 In the **Code Generation > Comments** pane, select the **MATLAB source code as comments** and **Stateflow object comments** parameters. These parameters control different parts of the traceability comment.
- 6 In the model window, press **Ctrl+B**.

This action generates source code and header files for the `rtwdemo_dynamicio` model that contains the `emlHorizontalSum` and `emlVerticalSum` blocks. After the code generation process is complete, the Code view appears automatically to the right of the model and displays the `rtwdemo_dynamicio.c` file.

- 7 Scroll down through the code to see the traceability comments, which appear as links inside `/*...*/` brackets, as in this example.

```

91 /* Output: '<Root>/Out1' incorporates:
92 * Chart: '<Root>/sfVerticalSum'
93 * MATLAB Function: '<Root>/emlHorizontalSum'
94 */
95 /* MATLAB Function 'emlHorizontalSum': '<S1>:1' */
96 /* '<S1>:1:2' y = sum(u,2); */
97 rtwdemo_dynamicio_Y.Out1 = (tmp[0] * rtwdemo_dynamicio_P.K + tmp[1] *
98 rtwdemo_dynamicio_P.K) + tmp[2] * rtwdemo_dynamicio_P.K;

```

- 8 Click the `<S1>:1:2` hyperlink in this traceability comment:

```
/* '<S1>:1:2' y = sum(u,2); */
```

Line 2 of the function in the source code appears highlighted in the MATLAB Function Block Editor.

- 9 You can trace a line in a MATLAB function to lines of generated code. For example, right-click on line 2 of your function and select **Code Generation** > **Navigate to Code** from the context menu.

The code location for line 2 appears highlighted in `rtwdemo_dynamicio.c`.

- 10 You can trace a line of generated code to a line of source code in a MATLAB function using the line number hyperlinks in the generated code.

# Component Verification in Embedded Coder

---

## Component Verification in Target Environment

After you generate production code for a component design, you need to integrate, compile, link, and deploy the code as a complete application on the embedded system. One approach is to manually integrate the code into an existing software framework that consists of an operating system, device drivers, and support utilities. The algorithm can include externally written legacy or custom code.

An easier approach to verifying a component in a target environment is to use processor-in-the-loop (PIL) simulation. For information about PIL simulations, see “SIL and PIL Simulations” on page 88-2.

### Goals of Component Verification

Assuming that you have generated production source code and integrated required externally written code, such as drivers and a scheduler, you can verify that the integrated software operates as expected by testing it in the target environment. During testing, you can achieve either of the following goals, depending on whether you export code that is strictly ANSI C/C++ or mixes ANSI C/C++ with code optimized for a target environment.

Goal	Type of Code Export
Maximize code portability and configurability	ANSI C/C++
Simplify integration and maximize use of processor resources and code efficiency	Mixed code

Regardless of your goal, you must integrate required external drivers and scheduling software. To achieve real-time execution, you must integrate the real-time scheduling software.

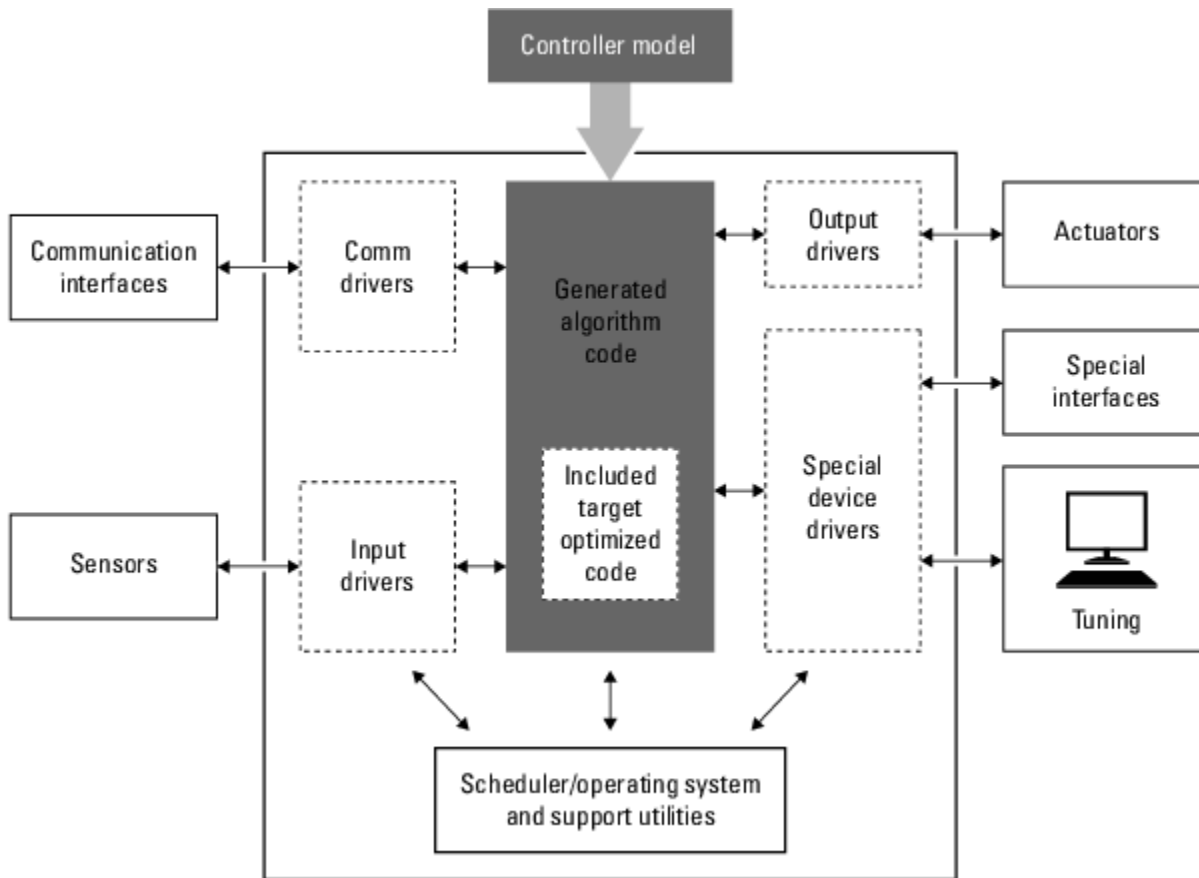

To maximize code portability and configurability, limit the application code to ANSI/ISO C or C++ code only, as the following figure shows.

To simplify code integration and maximize code efficiency for a target environment, use Embedded Coder features for:

- Controlling code interfaces
- Exporting subsystems
- Including target-specific code, including compiler optimizations

The following figure shows a mix of ANSI C/C++ code with code that is optimized for a target environment.

## Run Component Tests

The workflow for running software component tests in the target environment is:

- 1 Integrate external code, for example, for device drivers and a scheduler, with the generated C or C++ code for your component model. For more information, see “S-Functions and Code Generation”. For more specific references that depend on your verification goals, see the following table.

For	See
ANSI C/C++ code integration	“Integrate C Functions Using Legacy Code Tool”. Also, open <code>rtwdemos</code> and navigate to the <b>Custom Code</b> folder.

For	See
Mixed code integration	<ul style="list-style-type: none"> <li>• “Generate Component Source Code for Export to External Code Base” on page 58-40 and example <code>rtwdemo_exporting_functions</code></li> <li>• “Configure Generated C Function Interface for Model Entry-Point Functions” on page 33-114, “Interactively Configure C++ Interface” on page 44-2, and example <code>rtwdemo_fcnprotoctrl</code></li> <li>• “What Is Code Replacement?” on page 57-2, “What Is Code Replacement Customization?” on page 72-3, and example <code>rtwdemo_crl_script</code></li> </ul>

- 2 Simulate the integrated component model.
- 3 Generate code for the integrated component model.
- 4 Connect to data interfaces for the generated C code data structures. See “Exchange Data Between Generated and External Code Using C API” and “Export ASAP2 File for Data Measurement and Calibration”. Also see examples `rtwdemo_capi` and `rtwdemo_asap2`.
- 5 Customize and control the build process, if required. See “Customize Post-Code-Generation Build Processing”, and example `rtwdemo_buildinfo`.
- 6 Create a zip file that contains generated code files, static files, and dependent data to build the generated code in an environment other than your host computer. See “Relocate or Share Generated Code”, and example `rtwdemo_buildinfo`.

# **Component Verification With a Real-Time Target Environment in Embedded Coder**

---

## Real-Time Software Component Verification

One approach to verifying a software component is to build the component into a complete software system that can execute in real time in the target environment. A complete software system includes:

- Algorithm for the software component
- Scheduling algorithms
- Calls to drivers for board-specific devices

This single build approach is more time consuming to set up, but makes it easier to get the complete application running in the target environment.

The following figure shows code generated for an algorithm being built into a complete system executable for the target environment.

The workflow for testing component software as part of a complete real-time target environment is:

- 1 Develop a component model and generate source code for production.

For information on building in scheduling and real-time system support, see:

- "Time-Based Scheduling and Code Generation" and "Modeling for Multitasking Execution". For an example, open `rtwdemos` and navigate to the **Multirate Support** folder.

- “Asynchronous Events” and example `rtwdemo_async`
  - “Deploy Applications to Target Hardware” on page 71-2
  - “Workflows for AUTOSAR” (AUTOSAR Blockset) and example “Develop a Model That Complies with the AUTOSAR Standard” on page 23-14.
- 2 Optimize generated code for a specific run-time environment, using specialized function libraries. For more information, see “What Is Code Replacement?” on page 57-2, “What Is Code Replacement Customization?” on page 72-3, and “Optimize Generated Code by Developing and Using Code Replacement Libraries - Simulink” on page 79-31.
  - 3 Customize post code generation build processing to accommodate third-party tools and processes, as required. See “Customize Post-Code-Generation Build Processing” and example `rtwdemo_buildinfo`.
  - 4 Integrate external code, for example, for device drivers and a scheduler, with the generated C or C++ code for your component model. For more information, see “S-Functions and Code Generation”. For more specific references depending on your verification goals, see the following table.

For...	See...
ANSI C/C++ code integration	“Integrate C Functions Using Legacy Code Tool”. Also, open <code>rtwdemos</code> and navigate to the <b>Custom Code</b> folder.

 “Scheduling Considerations” on page 88-6  
 “Imported Data and Additional Generated Code” on page 88-6

### What Are SIL and PIL Simulations?

With Embedded Coder, you can run software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulations of your model. These simulations generate source code for either the top model or part of the model. A SIL simulation compiles and runs the generated code on your development computer. A PIL simulation cross-compiles source code on your development computer, and then downloads and runs the object code on a target processor or an equivalent instruction set simulator.

With SIL and PIL simulations, you can:

- Test whether your model and generated code are numerically equivalent.
- Observe code coverage.
- Perform code execution profiling.

### Why Use SIL and PIL

Through SIL and PIL, you can early on test and fix defects. For example, you can model and test a system component in normal mode. Then, you can reuse your test suites in a SIL or PIL simulation that runs compiled generated code. To check numerical equivalence, you compare normal and SIL or PIL simulation results. You do not have to leave the Simulink environment to test generated code on a separate infrastructure.

This table describes situations where you can use SIL and PIL.

Situation	Use
Test numerical equivalence between model and generated code by reusing test vectors developed for normal mode simulation to verify numerical output of generated (or legacy) code. See “SIL/PIL Manager Verification Workflow” on page 88-70 and “Test Two Simulations for Equivalence” (Simulink Test)	SIL and PIL
Collect metrics for generated code: <ul style="list-style-type: none"> <li>• Code coverage. See “Code Coverage”.</li> <li>• Execution profiling. See “Create Execution-Time Profile for Generated Code” on page 81-2</li> </ul>	SIL and PIL

Situation	Use
<p>(Requires an IEC Certification Kit license.)</p> <p>Perform verification and validation activities on the generated C/C++ code in accordance to the requirements of the overall software safety lifecycle as defined by the ISO 26262-6, IEC 61508-3, IEC 62304, EN 50128, and EN 50657 functional safety standards. For detailed information about the SIL and PIL verification activities in the IEC Certification Kit Model-Based Design workflow, see the <i>Reference Workflow for Embedded C/C++ Applications</i> (certkitiec_ecoder_workflow.docx/pdf) artifact in the Artifacts Explorer.</p>	SIL and PIL
<p>(Requires a DO Qualification Kit license.)</p> <p>Test the output of the integration process to satisfy relevant objectives in the DO-178C and DO-333 safety standards. For additional information, see Testing of Outputs of Integration Process (DO Qualification Kit). This information is available also in the <i>Model-Based Design Workflow for DO-178C</i> (qualkitdo_do178_workflow.pdf) artifact in the Artifacts Explorer.</p>	SIL and PIL
Without target hardware, get a convenient alternative to PIL.	SIL
<p>With target hardware, for example, an evaluation board or instruction set simulator:</p> <ul style="list-style-type: none"> <li>• Verify behavior of target-specific code, for example, code replacement optimizations, and legacy code. See “What Is Code Replacement?” on page 57-2 and “What Is Code Replacement Customization?” on page 72-3.</li> <li>• Optimize the execution speed and memory footprint of your code. In this table, see the information about collecting execution profiling and stack profiling metrics.</li> <li>• Investigate effects of compiler settings and optimizations, for example, deviation from ANSI C overflow behavior.</li> </ul> <p>Normal simulation techniques do not account for restrictions and requirements that the hardware imposes, such as limited memory resources or behavior of target-specific optimized code.</p> <p>For information about running PIL simulations on specific targets, see “Sample Custom Targets” in the Simulink Coder documentation.</p>	PIL

**Note** The SIL and PIL simulation modes are not designed for the reduction of model simulation times. If you want to speed up the simulation of your model, use the rapid accelerator mode. For more information, see “What Is Acceleration?”.

## How SIL and PIL Simulations Work

In a SIL or PIL simulation, code is generated for either the top model or part of the model. With SIL, this code is compiled for and executed on your development computer. With PIL, the code is cross-compiled for the target hardware and runs on the target processor.

Through a communication channel, Simulink sends stimulus signals to the code on your computer or target processor for each sample interval of the simulation.

- For a top model, Simulink uses stimulus signals from the base or model workspace.
- If you have designated only part of the model to simulate in SIL or PIL mode, then a part of the model remains in Simulink and code is not generated for this part of the model. Typically, you configure this part of the model to provide test vectors for the software executing on the hardware. This part of the model can represent other parts of the algorithm or the environment in which the algorithm operates.

When your computer or target processor receives signals from Simulink, the processor executes the SIL or PIL algorithm for one sample step. The SIL or PIL algorithm returns output signals calculated during this step to Simulink through a communication channel. One sample cycle of the simulation is complete, and Simulink proceeds to the next sample interval. The process keeps repeating itself and the simulation progresses. SIL and PIL simulations do not run in real time. In each sample period, Simulink and the object code exchange I/O data.

## Comparison of SIL and PIL Simulations

Type of SIL or PIL Simulation	What Happens in SIL Simulation	What Happens in PIL Simulation
Specify through: <ul style="list-style-type: none"> <li>• Top-model simulation mode</li> <li>• Model block <b>Simulation mode</b> parameter</li> </ul>	<ul style="list-style-type: none"> <li>• Test behavior of generated source code on development computer. Simulation does not test code compiled for target hardware because code is compiled for the development computer (different compiler and different processor architecture than the target).</li> <li>• Generated production code compiled and executed on development computer as separate process, independent of MATLAB process.</li> <li>• Execution is host/host and nonreal time.</li> </ul>	<ul style="list-style-type: none"> <li>• Test object code that you intend to deploy in production on either real target hardware or an instruction set simulator.</li> <li>• On development computer, generated production code cross-compiled for target. Object code downloaded and executed on target processor or instruction set simulator.</li> <li>• Execution is host/target and nonreal time.</li> </ul>
Use SIL or PIL block created from subsystem.	<ul style="list-style-type: none"> <li>• Simulation runs compiled object code through S-function. S-function communicates with object code executing as standalone application on development computer. SIL block execution is independent of the MATLAB process.</li> <li>• Execution is host/host and nonreal time.</li> </ul>	<ul style="list-style-type: none"> <li>• Simulation runs cross-compiled object code through S-function on development computer. S-function communicates with object code executing as standalone application on target processor or instruction set simulator.</li> <li>• Execution is host/target and nonreal time.</li> </ul>

## Code Interfaces for SIL and PIL

You generate standalone code when you perform, for example, a top-model or right-click subsystem build for a single deployable component. You can compile and link standalone code into a standalone executable or integrate it with other code. For more information on the standalone code interface, see “Configure Generated C Function Interface for Model Entry-Point Functions”.

When you generate code for a referenced model hierarchy, the software generates standalone executable code for the top model and a library module called a *model reference target* for each referenced model. When the code executes, the standalone executable invokes the applicable model reference targets to compute the referenced model outputs. For more information, see “Build Model Reference Targets”.

To integrate generated code with legacy code, use standalone code because the standalone code interface is documented.

---

**Note** SIL and PIL simulations do not provide direct support for custom code interfaces. You can incorporate these interfaces into Simulink as an S-function, for example, using the Legacy Code Tool, S-Function Builder, or handwritten code. Then, you can verify the custom code by using SIL and PIL simulations.

---

This table provides the interfaces that SIL and PIL simulations generate.

SIL/PIL Simulation	Code Interface
Top-model	SIL/PIL simulation generates the standalone code interface. If the code exists, simulation calls the standalone code for the model . If the code does not exist, simulation generates the standalone code.
Model block	<p>If you set the <b>Code interface</b> block parameter to <b>Top model</b>, SIL/PIL simulation generates the standalone code interface. Simulation calls the standalone code for the model if it exists. Otherwise, simulation generates standalone code by using the <code>slbuild('model')</code> command.</p> <p>If you set the <b>Code interface</b> block parameter to <b>Model reference</b>, SIL/PIL simulation generates the model reference code interface. Simulation calls the model reference target for the Model block if it exists. Otherwise, simulation generates the model reference target by using the <code>slbuild('model', 'ModelReferenceCoderTarget')</code> command.</p>
SIL or PIL block	The block uses the standalone code interface.

## Scheduling Considerations

Item	Information
Algebraic loops	<p>There are algebraic loops that occur in SIL and PIL simulations but not in normal mode simulations:</p> <ul style="list-style-type: none"> <li>• <b>Single output/update function</b> in code generation optimization can introduce algebraic loops because the option introduces direct feedthrough via a combined output and update function.</li> </ul> <p><b>Single output/update function</b> is not compatible with <b>Minimize algebraic loop occurrences</b> (in the Subsystem Parameters dialog box and <b>Configuration Parameters &gt; Model Referencing</b> pane). <b>Minimize algebraic loop occurrences</b> allows code generation to remove algebraic loops by partitioning generated code between output and update functions to avoid direct feedthrough.</p> <ul style="list-style-type: none"> <li>• If you generate code for a virtual subsystem, code generation treats the subsystem as atomic and generates the code accordingly. The resulting code can change the execution behavior of your model, for example, by applying algebraic loops, and introduce inconsistencies to the simulation behavior.</li> </ul> <p>To enable consistent simulation and execution behavior for your model, declare virtual subsystems as atomic subsystems.</p> <p>For more information, see:</p> <ul style="list-style-type: none"> <li>• “Algebraic Loop Concepts”</li> <li>• “Algebraic Loops”</li> <li>• “Simulink Modeling Components”</li> </ul>
Exported functions in feedback loops	<p>If your model has function-call subsystems and you export a subsystem that has context-dependent inputs (for example, feedback signals), the results of a SIL/PIL simulation with the generated code and the results of the normal mode simulation of your model can differ. One approach to make SIL/PIL and normal mode simulations yield identical results is to use Function-Call Feedback Latch blocks in your model. You can make context-dependent inputs become context-independent.</p> <p>If you set the <b>Context-dependent inputs</b> configuration parameter to <code>warning</code>, Embedded Coder generates a warning that identifies context-dependent inputs of exported function-call subsystems.</p> <p>For more information, see:</p> <ul style="list-style-type: none"> <li>• “Simulink Modeling Components”</li> <li>• Function-Call Feedback Latch</li> <li>• “Context-dependent inputs”</li> </ul>

## Imported Data and Additional Generated Code

A SIL or PIL simulation does not modify the code generated from the model. If you use imported data, the SIL or PIL simulation generates additional code that is required to support compiling and linking

of the SIL or PIL target application. The additional generated code corresponds to interfaces that you specify in the model.

This section describes:

- For imported data, when the SIL or PIL simulation defines storage and when you must define storage.
- Interfaces for which a SIL or PIL simulation generates additional code

### Imported Data in SIL or PIL Simulations

In SIL and PIL simulations, you can use signals, parameters, and data stores that specify storage classes with imported data definitions. The simulations define storage for imported data associated with:

- Signals at the root level of the component (on the I/O boundary).
- Parameters in the base workspace or a data dictionary. For parameters in the model workspace:
  - Top-model SIL/PIL and SIL/PIL block simulations define storage.
  - Model block SIL/PIL simulations do not define storage. You must define storage and specify initial values that match MATLAB values.
- Global data stores.

SIL and PIL simulations do not define storage for other imported data. For example, the simulations do not define storage for imported data associated with:

- Internal signals (not on the I/O boundary). Note that, if the data for internal signals is in structures that are imported through the use of pointers, the simulations define storage.
- Local data stores.

In these cases, define the storage through custom code included by the component under test or through the PIL `rtw.pil.RtIOStreamApplicationFramework` API.

See also “Tunable Parameters and SIL/PIL” on page 88-77.

### Interfaces That Produce Additional Generated Code

This table describes scenarios where a SIL or PIL simulation generates additional code for interfaces.

Scenario	Details
GetSet custom storage class	SIL and PIL simulations support the GetSet custom storage class. The SIL/PIL test harness provides C definitions of the Get and Set functions that are used during simulations. For more information, see “Access Data Through Functions with Storage Class GetSet” on page 40-25.

Scenario	Details
Custom storage class of type <code>Other</code>	<p>To enable SIL and PIL support for the custom storage class where <b>Type</b> is set to <code>Other</code>, create a custom attributes class for the custom storage class and associate the custom attributes class with a Boolean property, <code>SupportSILPIL</code>, set to <code>true</code>.</p> <pre> classdef CSCOtherAttributes &lt; Simulink.CustomStorageClassAttributes     properties(PropertyType = 'logical scalar')         SupportSILPIL = true;     end end </pre> <p>For more information about custom attributes, see “Further Customize Generated Code by Writing TLC Code” on page 40-22 and “Finely Control Data Representation by Writing TLC Code for a Storage Class” on page 40-23.</p> <p>To build the SIL or PIL application interface, the code generator calls the <code>DataAccess</code> and <code>ClassAccess</code> functions in the associated custom TLC file to get required information. The code generator stores the extracted information in build artifacts in the build folder.</p> <p>For a custom storage class that is not grouped:</p> <ul style="list-style-type: none"> <li>• The code generator calls <code>DataAccess</code> with the request argument taking values of <code>define</code>, <code>declare</code>, <code>layout</code>, <code>contents</code>, <code>address</code>, or <code>set</code>.</li> <li>• The code generator uses the string returned by <code>DataAccess(record, "define", "", "")</code> to define the variable in the SIL or PIL application if one of these is true: <ul style="list-style-type: none"> <li>• The signal or parameter has an <code>Imported</code> data scope.</li> <li>• The model uses a model reference code interface.</li> <li>• The model uses a top model code interface, <code>EnableDataOwnership</code> is on, and the <code>Owner</code> attribute for the custom storage class is not empty and not equal to the name of the current model</li> </ul> </li> <li>• The code generator uses the string returned by <code>DataAccess(record, "declare", "", "")</code> to declare the variable in the SIL or PIL application if the following are true: <ul style="list-style-type: none"> <li>• The model uses a top model code interface.</li> <li>• The signal or parameter uses an <code>Exported</code> storage class.</li> <li>• <code>EnableDataOwnership</code> is off, or <code>EnableDataOwnership</code> is on and the <code>Owner</code> attribute for the custom storage class is empty or equal to the model name.</li> <li>• Code packaging is configured so that the variable is not declared in <code>model.h</code> or a header file that is included by <code>model.h</code></li> </ul> </li> </ul> <p>For a custom storage class that is grouped:</p> <ul style="list-style-type: none"> <li>• The code generator calls <code>DataAccess</code> with the request argument taking values of <code>layout</code>, <code>address</code>, or <code>set</code>.</li> </ul>

Scenario	Details
	<ul style="list-style-type: none"> <li>• The code generator calls <code>ClassAccess</code> with the <code>request</code> argument taking the value of <code>groupTypeDeclDefn</code>.</li> <li>• You must provide the grouped type (<code>struct</code>) definition and the <code>extern</code> declaration of the grouped variable if one of these is true: <ul style="list-style-type: none"> <li>• The signal or parameter has an <code>Imported</code> data scope.</li> <li>• The model uses a model reference code interface.</li> <li>• The model uses a top model code interface, <code>EnableDataOwnership</code> is on, and the <code>Owner</code> attribute for the custom storage class is not empty and not equal to the name of the current model</li> </ul> </li> </ul> <p>Provide the definition and declaration in a header file associated with the custom storage class by using the <code>HeaderFile</code> attribute or custom code that you include through the <code>model.h</code> file. To define the variable in the SIL or PIL application, the code generator uses the string returned by <code>ClassAccess(record, "groupTypeDeclDefn")</code>.</p> <ul style="list-style-type: none"> <li>• Static initialization can assume an order of <code>struct</code> elements that is different from the order that is generated if the data scope is <code>Exported</code>. When the code generator queries <code>ClassAccess(record, "groupTypeDeclDefn")</code>, it temporarily overrides the data initialization attribute of the custom storage class with the value <code>None</code>.</li> </ul> <p>To determine whether the SIL or PIL application can access the variable in the code by address, the code generator uses the elements returned by <code>DataAccess(record, "layout", "", "")</code>. To create the functionality in the application that transfers input or output port, tunable parameter, or global data store memory values between the development computer and target hardware, the code generator uses the output from:</p> <ul style="list-style-type: none"> <li>• <code>DataAccess(record, "address", idx, reim)</code> if the first returned element is <code>scalar</code>, <code>vector</code>, <code>row-mat</code>, or <code>col-mat</code>.</li> <li>• <code>DataAccess(record, "contents", idx, reim)</code> (or <code>DataAccess(record, "set", idx, reim)</code>) if the first returned element is <code>other</code>.</li> </ul> <p>The code generator assumes that for <code>row-mat</code> and <code>col-mat</code>, matrices are stored in row-major format respectively. The assumption is independent of the array layout for the rest of the model. The code generator assumes that if the array layout of the storage implemented by the custom storage class differs from the rest of the model, the TLC file associated with the custom storage file performs the required transformations.</p> <p>You can construct the custom TLC file associated with a custom storage class of type <code>Other</code> to perform other functions (in addition to returning the requested code fragments). For example, write directly to a custom file or call MATLAB functions that change the state of the base workspace. If you do not always want to execute these functions when <code>DataAccess</code> or <code>ClassAccess</code> are called, use the <code>LibIsAccessingCustomDataForSILPIL(record)</code> TLC function to distinguish between target code generation and requests for code fragments for the construction of the SIL or PIL application. For example:</p>

Scenario	Details
	<pre data-bbox="516 298 1349 491"> ... %case "contents"   %if !LibIsAccessingCustomDataForSILPIL(record)     %matlab functionWithSideEffects()   %endif %return LibDefaultCustomStorageContents(record, idx, reim) ... </pre> <p data-bbox="516 520 1279 550">See also Other custom storage class limitations on page 88-81.</p>
AUTOSAR Runtime Environment	<p data-bbox="516 567 1466 751">You can use top-model and Model block SIL/PIL and SIL/PIL block simulations to perform model-based testing of an AUTOSAR software component. The software links generated code for the AUTOSAR software component with a basic component-specific AUTOSAR Runtime Environment (RTE) to create a test application. This application tests AUTOSAR API calls made by the AUTOSAR software component.</p> <p data-bbox="516 781 1425 873">For a top-level AUTOSAR software component that contains referenced models, you can run top-model or Model block (<b>Code interface</b> set to Top model) SIL or PIL simulations. In the simulations, the software:</p> <ul data-bbox="516 898 1466 1003" style="list-style-type: none"> <li>• Before compilation of referenced models, generates AUTOSAR RTE header files.</li> <li>• Provides the RTE include path for referenced model compilation.</li> </ul> <p data-bbox="516 1033 1466 1180">You can also run Model block (<b>Code interface</b> set to Model reference) SIL or PIL simulations for a referenced model within the top-level AUTOSAR SWC. In this case, before you run a simulation, you must build the parent component to generate the RTE header files. If you do not build the parent component, the SIL or PIL simulation fails.</p>

## Choose a SIL or PIL Approach

### In this section...

“Test Top-Model Code” on page 88-12

“Test Referenced Model Code” on page 88-12

“Test Subsystem Code” on page 88-12

“Summary” on page 88-13

Consider a top model that consists of components A, B, C, and D:

- A and B are existing components for which code has previously been generated and tested.
- C, a referenced model, and D, a subsystem, are new components.

With software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulations, you can use the following approaches to numerical equivalence testing:

- Test code from all components together. See “Test Top-Model Code” on page 88-12.
- Test new components separately (before testing code from all components). See “Test Referenced Model Code” on page 88-12 and “Test Subsystem Code” on page 88-12.

For some forms of testing, you require a test harness model. The test harness model:

- Generates test vectors or stimulus inputs that feed the block under test.
- Makes it possible for you to observe or capture output from the block.

The following example shows a simple test harness model.

The block under test is a Model block. The Sine Wave block generates the input for the Model block. Through the Scope block, you can observe the output from the Model block. For information about creating and using test harnesses, see “Create Test Harnesses and Select Properties” (Simulink Test) and “Code Generation Verification Workflow with Simulink Test” (Simulink Test).

## Test Top-Model Code

To test code generated from the top-model components together (A, B, C, and D), you can use top-model SIL/PIL or Model block SIL/PIL.

- Top-model SIL/PIL:
  - 1 Create test vectors or stimulus inputs in the MATLAB workspace.
  - 2 Run the top model in normal, SIL, and PIL simulation modes. The software loads the test vectors or stimulus inputs from the MATLAB workspace.
  - 3 For each simulation mode, observe or capture outputs.
  - 4 Verify numerical equivalence by comparing normal outputs against SIL and PIL outputs.
- Model block SIL/PIL:
  - 1 Create a Model block that contains the top-model components.
  - 2 Insert the Model block in a simulation model, for example, your test harness model.
  - 3 Run simulations, switching the Model block between normal, SIL, and PIL modes. For the SIL and PIL simulation modes, set the **Code interface** Model block parameter to `Top model`.
  - 4 Verify numerical equivalence by comparing normal outputs against SIL and PIL outputs.

For more information, see “Simulation with Top Model” on page 88-15 and “SIL/PIL Manager Verification Workflow” on page 88-70.

## Test Referenced Model Code

To test code generated from the component C as part of a model reference hierarchy, use the Model block SIL/PIL approach:

- Insert the Model block C in a simulation model, for example, your test harness model.
- Run simulations, switching the Model block between normal, SIL, and PIL modes. For the SIL and PIL simulation modes, set the **Code interface** Model block parameter to `Model reference`.
- Verify numerical equivalence by comparing normal outputs against SIL and PIL outputs.

For more information, see “Simulation with Model Blocks” on page 88-16 and “SIL/PIL Manager Verification Workflow” on page 88-70.

## Test Subsystem Code

To test code that is generated from the subsystem D, use one of these workflows.

Workflow	Description
Simulink Test harness with SIL/PIL Manager	<p>Perform unit tests on subsystem code that is part of the code generated from the parent model.</p> <ol style="list-style-type: none"> <li><b>1</b> Generate code for the model that contains the subsystem by running <code>slbuild(model)</code> or <code>slbuild(model, 'RTWModelReferenceTargetOnly')</code>.</li> <li><b>2</b> In the model, right-click the subsystem and then create a test harness for the subsystem.</li> <li><b>3</b> Open the SIL/PIL Manager. If required, enable code coverage analysis. Then run back-to-back model and SIL or PIL simulations.</li> <li><b>4</b> If required, export an equivalence test case.</li> </ol> <p>For more information, see “Unit Test Subsystem Code with SIL/PIL Manager” on page 88-31.</p> <p>If the subsystem is not supported by this workflow, use the SIL or PIL block workflow. ## Configure and Run SIL Simulation

In this section...
“Simulation with Top Model” on page 88-15
“Simulation with Model Blocks” on page 88-16
“Simulation with Subsystem Blocks” on page 88-17
“SIL or PIL Block Simulation” on page 88-18
“Configure Hardware Implementation Settings” on page 88-18
“Log Signals of a Component” on page 88-20
“Prevent Code Changes in Multiple Simulations” on page 88-21
“Speed Up Testing” on page 88-22
“Simulation with Function Calls” on page 88-23

There are three ways of running SIL and PIL simulations. You can use:

- The top model.
- Model blocks.
- SIL and PIL blocks that you create from subsystems.

### Simulation with Top Model

To configure and run a top-model SIL or PIL simulation:

- 1 In the Simulink Editor, open your model.
- 2 On the **Apps** tab, click **SIL/PIL Manager**.
- 3 In the **Mode** section, select **SIL/PIL Simulation Only**.
- 4 In the **Prepare** section, set **System Under Test** to Top model.
- 5 In the **SIL/PIL Mode** field, select either Software-in-the-Loop (SIL) or Processor-in-the-Loop (PIL). The option supports only ERT, GRT, or AUTOSAR system target files. See “Model Configuration Parameters: Code Generation” and “Configure AUTOSAR Code Generation” (AUTOSAR Blockset) for configuration information.
- 6 To monitor component signals and state data and compare values from the model and SIL or PIL simulations:
  - a For each signal that you want to log:
    - i In the Simulink Editor, select the signal.
    - ii On the **SIL/PIL** tab, click **Monitor Signals**. From the gallery, select these options:
      - **Log Selected Signals**
      - **Make Selected Signals Testpoints**
      - **Signal Logging**
  - b To log state data, from the **Monitor Signals** gallery, select **State Logging**.
  - c If the **Language** configuration parameter is C++, in the **Code Mappings** editor, set the **Data Visibility** for the signals, states, and internal data model element categories to public.

- 7 If you are configuring a SIL simulation, specify the portable word sizes option. You can then switch seamlessly between the SIL and PIL modes. In the Configuration Parameters dialog box, select the **Enable portable word sizes** check box.
- 8 If required, configure:
  - Code coverage.
  - Code execution profiling on page 81-2.
  - Creation of code generation report and static code metrics on page 88-68.
- 9 In the **Run** section, in the **Stop Time** field, specify simulation time.
- 10 Click **Run SIL/PIL**.
- 11 At the end of the simulation, in the **Results** section, click **Data Inspector** to view simulation results.

---

**Note** On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL simulation. To allow the simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

---

You cannot:

- Close the model while the simulation is running. To interrupt the simulation, in the Command Window, press **Ctrl+C**.
- Alter the model during the simulation. You can move blocks and lines as long as it does not alter the behavior of the model.

You can run a top-model SIL or PIL simulation with the command `sim(model)`. The software supports the `sim` command option `SrcWorkspace` for the value `'base'`.

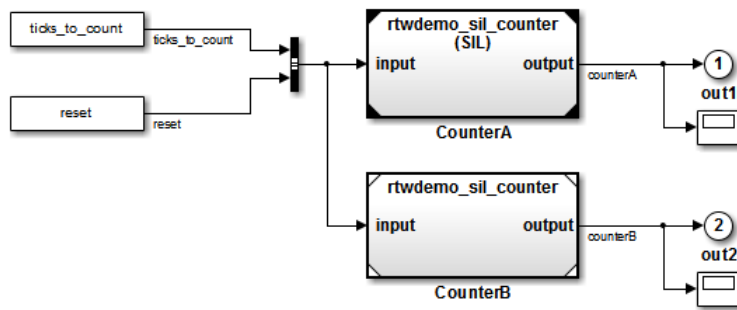

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

## Simulation with Model Blocks

To configure a Model block for a SIL or PIL simulation:

- 1 Open your model, for example, `SILModelBlock`:

```
openExample('ecoder/SILPILVerificationExample', ...
 supportingFile='SILModelBlock.slx')
```
- 2 Right-click your Model block, for example, `Counter A`. In the context menu, select **Block Parameters (ModelReference)**, which opens the Function Block Parameters dialog box.
- 3 From the **Simulation Mode** drop-down list, select the required mode, for example, `Software-in-the-loop (SIL)`.
- 4 From the **Code interface** drop-down list, specify the code that you want to test, for example, `Model` reference.
- 5 Click **OK**. The software displays the simulation mode as a block label.

If you select `Top model`, the software displays the block label (`SIL: Top`).

- 6 If you are configuring a SIL simulation, specify the portable word sizes option. You can then switch seamlessly between the SIL and PIL modes. In the Configuration Parameters dialog box, select the **Enable portable word sizes** check box.
- 7 On the **Apps** tab, click **SIL/PIL Manager**.
- 8 In the **Mode** section, select **SIL/PIL Simulation Only**.
- 9 In the **Prepare** section, set **System Under Test** to `Model` blocks in SIL/PIL mode.
- 10 In the **Top Model Mode** field, select either `Normal` or `Accelerator`.
- 11 If required, configure:
  - “Code Coverage”.
  - Code execution profiling on page 81-2 for your `Model` block, by configuring execution profiling for the top model.
  - Creation of code generation report and static code metrics on page 88-68.
- 12 In the **Run** section:
  - In the **Stop Time** field, specify simulation time.
  - If you want to avoid rebuilding code after the initial build, click **Fast Restart**. See “Prevent Code Changes in Multiple Simulations” on page 88-28.
  - Click **Run SIL/PIL**.
- 13 At the end of the simulation, in the **Results** section, click `Data Inspector` to view simulation results.

---

**Note** On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL simulation. To allow the simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

---

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

## Simulation with Subsystem Blocks

You can use one of these workflows:

- Simulink Test harness with the SIL/PIL Manager—If you have a model that contains subsystems, you can use Simulink Test and the SIL/PIL Manager to perform unit tests on code generated from

the subsystems. This workflow tests the generated subsystem code as part of the code generated from the parent model. For workflow details, see “Unit Test Subsystem Code with SIL/PIL Manager” on page 88-31.

If this workflow does not support a subsystem, use the SIL or PIL block workflow as an alternative.

- **SIL or PIL block**—Create a SIL or PIL block from the subsystem, and then run the block in an environment or test harness model that supplies test vectors or stimulus input. This workflow generates and tests new standalone code from the subsystem. For more information, see “SIL or PIL Block Simulation” on page 88-27.

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

## SIL or PIL Block Simulation

To create a SIL or PIL block from a subsystem and use this block to test the code generated from the subsystem:

- 1 From the **Configuration Parameters > Code Generation > Verification > Advanced Parameters > Create block** drop-down list, select either SIL or PIL.
- 2 If required, configure code execution profiling.
- 3 Click **OK**.
- 4 In your model window, right-click the subsystem that you want to simulate.
- 5 Select **C/C++ Code > Build This Subsystem**, which starts the subsystem build process that creates a SIL or PIL block for the generated subsystem code.
- 6 Add the generated block to an environment or test harness model that supplies test vectors or stimulus input.
- 7 Run simulations with the environment or test harness model.

---

**Note** On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL simulation. To allow the simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

---

You cannot create a SIL or PIL block if you do one of the following:

- Disable the CreateSILPILBlock property.
- Select a code coverage tool.

**Create block** appears dimmed.

## Configure Hardware Implementation Settings

For a SIL simulation, you must configure hardware implementation settings, which enables generated code compilation for your development computer. These settings can differ from the hardware implementation settings that you use when building the model for your production hardware. Use one of these approaches.

Approach	Details
Portable word sizes	<p>Switch between SIL and PIL modes without regenerating code. You use the same generated source code files for the SIL simulation on your development computer and for production deployment on the target platform.</p> <p>To configure a model to use portable word sizes, set:</p> <ul style="list-style-type: none"> <li>• <code>ProdEqTarget</code> to 'on'.</li> <li>• <code>PortableWordSizes</code> to 'on'.</li> </ul> <p>When you generate code for a model with portable word sizes specified, the code generator conditionalizes data type definitions in <code>rtwtypes.h</code>:</p> <pre data-bbox="440 646 1479 905"> #ifdef PORTABLE_WORDSIZES                /* PORTABLE_WORDSIZES defined */ ... #else                                      /* PORTABLE_WORDSIZES not defined */ ... #endif                                     /* PORTABLE_WORDSIZES */ </pre> <p>The template makefile that you use to build code for your target must not contain the <code>PORTABLE_WORDSIZES</code> definition.</p> <p>For the template makefile and toolchain approaches to building code, the software specifies <code>-DPORTABLE_WORDSIZES</code> for the compiler only for host-based builds.</p> <p>For information about the template makefile and toolchain approaches to building code, see “Configure Toolchain (ToolchainInfo) or Template Makefile Build Process” on page 59-18.</p> <p>Consider the case where your target uses code that your development computer cannot compile. When you switch from the PIL mode to the SIL mode and try to simulate the model, you see compilation errors. You can try to work around this problem by adding the source code files to the <code>SkipForSil</code> group in the build information object <code>RTW.BuildInfo</code>. The SIL build on the host platform does not compile source files present in the <code>SkipForSil</code> group. For information about how you add source code files to a group in the build information object, see:</p> <ul style="list-style-type: none"> <li>• <code>addSourceFiles</code> in the Simulink Coder documentation</li> <li>• “Customize Post-Code-Generation Build Processing” in the Simulink Coder documentation</li> </ul>

Approach	Details
	<p>Numerical results can differ between generated code executing in a SIL simulation and generated code executing on the production hardware under one of these conditions:</p> <ul style="list-style-type: none"> <li>• Your model contains blocks implemented in TLC, for which C integral promotion in expressions can behave differently between the MATLAB host and the production hardware target. Normal and PIL simulation results match, but SIL simulation results can differ.</li> <li>• Your production hardware implements rounding to Floor for signed integer division, and divisions in your model use rounding mode Ceiling, Floor, Simplest, or Zero. Normal and PIL simulation results match, but SIL simulation results can differ.</li> <li>• The byte ordering for your production hardware is Big Endian. Normal and PIL simulation results match, but SIL simulation results can differ. For example, when generated code depends on byte order <i>and</i> generated production code is implemented with the aim that its behavior matches normal simulation behavior.</li> <li>• You use custom code with the Stateflow product. In this case, type conversion statements are not inserted into the custom code, which target overflow behavior on the host can require. Normal and PIL simulation results match, but SIL simulation results can differ.</li> </ul>
Test hardware	<p>Use this approach only when you want to work around a limitation of portable word sizes.</p> <p>Set:</p> <ul style="list-style-type: none"> <li>• PortableWordSizes to 'off'.</li> <li>• ProdEqTarget to 'off'.</li> <li>• TargetHWDeviceType to 'Custom Processor-&gt;MATLAB Host Processor'.</li> </ul>
Production hardware	<p>Use this approach only when the production hardware settings match your development computer architecture.</p> <p>Set:</p> <ul style="list-style-type: none"> <li>• PortableWordSizes to 'off'.</li> <li>• ProdEqTarget to 'on'.</li> <li>• ProdHWDeviceType to match your development computer architecture.</li> </ul>

For information about test and production targets, see “Configure Run-Time Environment Options” in the Simulink Coder documentation.

## Log Signals of a Component

SIL and PIL component outputs are available for observation and comparison with other simulation mode outputs. If you want to examine an internal signal, you can enable internal signal logging for top-model or Model block SIL or PIL. With signal logging, you can:

- Collect signal logging outputs during SIL/PIL simulations, for example, `logout`.
- Log the internal signals and the root-level outputs of a SIL/PIL component.

- Manage the SIL/PIL signal logging settings with the Simulink Signal Logging Selector.
- Use the Simulation Data Inspector to:
  - Observe streamed signals during normal, SIL, and PIL simulations.
  - Compare logged signals from normal, SIL, and PIL simulations.

To enable signal logging to the MATLAB workspace and signal streaming to the Simulation Data Inspector during SIL or PIL simulations:

- 1 For each signal that you want to monitor:
  - a In the Simulink Editor, select the signal.
  - b On the **SIL/PIL** tab, click **Monitor Signals**. From the gallery, select these options:
    - **Log Selected Signals**
    - **Make Selected Signals Testpoints**
    - **Signal Logging**
- 2 If the **Language** configuration parameter is C++, in the **Code Mappings** editor, set the **Data Visibility** for the signals, states, and internal data model element categories to `public`.

You can use other methods to examine internal signals of the SIL or PIL component:

- Manually route the signal to the top level.
- Use global data stores to access internal signals:
  - 1 Inside the component, connect a Data Store Write block to the required signal.
  - 2 Outside the component, use a Data Store Read block to access the signal value.
- Use MAT-file logging. Note that:
  - MAT-file logging does not support signal logging. If signal logging is enabled, `logout` is generated but not stored in the MAT-file.
  - For PIL, the target environment must support MAT-file logging.

For more information, see:

- “Configure Signals as Test Points”
- “Export Signal Data Using Signal Logging”
- “Local and Global Data Stores”
- “Global Data Store Example”
- “Log Program Execution Results”

## Prevent Code Changes in Multiple Simulations

Use Model block SIL/PIL or the SIL/PIL block with fast restart when you want to run multiple SIL or PIL simulations with:

- Varying test vectors (parameter sets and input data).
- Unchanged generated code, that is, none of the simulations regenerate or rebuild code after the initial build. For example, you want to avoid the incremental code generation that an initial value change can trigger.

For Model block SIL/PIL, you can also use one of these methods:

- In your test harness model, in the Configuration Parameters dialog box, set **Rebuild** to **Never**. If the Model block **Code interface** parameter is **Model reference**, the software does not rebuild the referenced model code. (If the **Code interface** parameter is **Top model**, the software ignores the **Rebuild** setting.)
- Create a protected model and generate source or binary code. Then, insert the protected model in your test harness model. With this method, you can verify top-model code (with the standalone code interface) or model reference code.

For the alternative methods of running Model block SIL/PIL, the following table summarizes code generation behavior after the initial build.

SIL and PIL Approach		Code Generation Behavior After Initial Build
Model block	<b>Rebuild</b> configuration parameter of test harness model set to <b>Never</b> .	<ol style="list-style-type: none"> <li><b>1</b> Component (algorithm) code from initial build is not regenerated.</li> <li><b>2</b> Component code makefile is not called.</li> <li><b>3</b> SIL/PIL application files from initial build are not regenerated.</li> <li><b>4</b> SIL/PIL application makefile is called.</li> </ol>
Model block (protected model)	Source code from protected model.	You observe the same behavior except for feature 2. In this case, the component code makefile is run. The component code is recompiled and linked to produce new object code.
	Binary code from protected model.	You observe features 1-4.

For more information, see:

- “Model Configuration Parameters: Model Referencing”
- “Protect Models to Conceal Contents”

## Speed Up Testing

If your model has SIL/PIL blocks or Model blocks in SIL/PIL mode, you can speed up SIL/PIL testing by:

- Running the top-model simulation in accelerator mode. This mode accelerates the simulation of model components that are not in SIL or PIL mode.
- Turning on fast restart. After the first simulation, you can tune parameters and rerun simulations without model recompilation. The SIL/PIL Manager provides a **Fast Restart** button.

---

**Note** The SIL and PIL simulation modes are not designed for the reduction of model simulation times. If you want to speed up the simulation of your model, use the rapid accelerator mode. For more information, see “What Is Acceleration?”.

---

## Simulation with Function Calls

Use the Simulink Function block and Simulink Function block when you want to:

- Generate code that makes a function-call to external code, for example, driver or legacy code.
- Provide a subsystem that behaves like the external code in normal, SIL, or PIL simulations.

The example in “Configure Calls to AUTOSAR NVRAM Manager Service” (AUTOSAR Blockset) shows how you can configure client calls to Basic Software (BSW) NVRAM Manager (NvM) service interfaces from your AUTOSAR software component. In a simulation, Simulink implements the BSW NvM calls through Simulink Function and preconfigured Function Caller blocks. For the final system, you link function-call stubs with external BSW function code that runs in the AUTOSAR Runtime Environment (RTE).

For more information, see “Simulink Function Blocks and Code Generation”.

## Configure and Run PIL Simulation

### In this section...

“Simulation with Top Model” on page 88-24  
 “Simulation with Model Blocks” on page 88-25  
 “Simulation with Subsystem Blocks” on page 88-26  
 “SIL or PIL Block Simulation” on page 88-27  
 “Log Signals of a Component” on page 88-27  
 “Prevent Code Changes in Multiple Simulations” on page 88-28  
 “Speed Up Testing” on page 88-29  
 “Simulation with Function Calls” on page 88-30

There are three ways of running SIL and PIL simulations. You can use:

- The top model.
- Model blocks.
- SIL and PIL blocks that you create from subsystems.

### Simulation with Top Model

To configure and run a top-model SIL or PIL simulation:

- 1 In the Simulink Editor, open your model.
- 2 On the **Apps** tab, click **SIL/PIL Manager**.
- 3 In the **Mode** section, select **SIL/PIL Simulation Only**.
- 4 In the **Prepare** section, set **System Under Test** to Top model.
- 5 In the **SIL/PIL Mode** field, select either **Software-in-the-Loop (SIL)** or **Processor-in-the-Loop (PIL)**. The option supports only ERT, GRT, or AUTOSAR system target files. See “Model Configuration Parameters: Code Generation” and “Configure AUTOSAR Code Generation” (AUTOSAR Blockset) for configuration information.
- 6 To monitor component signals and state data and compare values from the model and SIL or PIL simulations:
  - a For each signal that you want to log:
    - i In the Simulink Editor, select the signal.
    - ii On the **SIL/PIL** tab, click **Monitor Signals**. From the gallery, select these options:
      - **Log Selected Signals**
      - **Make Selected Signals Testpoints**
      - **Signal Logging**
  - b To log state data, from the **Monitor Signals** gallery, select **State Logging**.
  - c If the **Language** configuration parameter is C++, in the **Code Mappings** editor, set the **Data Visibility** for the signals, states, and internal data model element categories to **public**.

- 7 If you are configuring a SIL simulation, specify the portable word sizes option. You can then switch seamlessly between the SIL and PIL modes. In the Configuration Parameters dialog box, select the **Enable portable word sizes** check box.
- 8 If required, configure:
  - Code coverage.
  - Code execution profiling on page 81-2.
  - Creation of code generation report and static code metrics on page 88-68.
- 9 In the **Run** section, in the **Stop Time** field, specify simulation time.
- 10 Click **Run SIL/PIL**.
- 11 At the end of the simulation, in the **Results** section, click **Data Inspector** to view simulation results.

---

**Note** On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL simulation. To allow the simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

---

You cannot:

- Close the model while the simulation is running. To interrupt the simulation, in the Command Window, press **Ctrl+C**.
- Alter the model during the simulation. You can move blocks and lines as long as it does not alter the behavior of the model.

You can run a top-model SIL or PIL simulation with the command `sim(model)`. The software supports the `sim` command option `SrcWorkspace` for the value `'base'`.

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

## Simulation with Model Blocks

To configure a Model block for a SIL or PIL simulation:

- 1 Open your model, for example, `SILModelBlock`:
 

```
openExample('ecoder/SILPILVerificationExample', ...
 supportingFile='SILModelBlock.slx')
```
- 2 Right-click your Model block, for example, `Counter A`. In the context menu, select **Block Parameters (ModelReference)**, which opens the Function Block Parameters dialog box.
- 3 From the **Simulation Mode** drop-down list, select the required mode, for example, `Software-in-the-loop (SIL)`.
- 4 From the **Code interface** drop-down list, specify the code that you want to test, for example, `Model` reference.
- 5 Click **OK**. The software displays the simulation mode as a block label.

If you select `Top model`, the software displays the block label (`SIL: Top`).

- 6 If you are configuring a SIL simulation, specify the portable word sizes option. You can then switch seamlessly between the SIL and PIL modes. In the Configuration Parameters dialog box, select the **Enable portable word sizes** check box.
- 7 On the **Apps** tab, click **SIL/PIL Manager**.
- 8 In the **Mode** section, select **SIL/PIL Simulation Only**.
- 9 In the **Prepare** section, set **System Under Test** to `Model` blocks in SIL/PIL mode.
- 10 In the **Top Model Mode** field, select either `Normal` or `Accelerator`.
- 11 If required, configure:
  - “Code Coverage”.
  - Code execution profiling on page 81-2 for your `Model` block, by configuring execution profiling for the top model.
  - Creation of code generation report and static code metrics on page 88-68.
- 12 In the **Run** section:
  - In the **Stop Time** field, specify simulation time.
  - If you want to avoid rebuilding code after the initial build, click **Fast Restart**. See “Prevent Code Changes in Multiple Simulations” on page 88-28.
  - Click **Run SIL/PIL**.
- 13 At the end of the simulation, in the **Results** section, click `Data Inspector` to view simulation results.

---

**Note** On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL simulation. To allow the simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

---

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

## Simulation with Subsystem Blocks

You can use one of these workflows:

- Simulink Test harness with the SIL/PIL Manager—If you have a model that contains subsystems, you can use Simulink Test and the SIL/PIL Manager to perform unit tests on code generated from

the subsystems. This workflow tests the generated subsystem code as part of the code generated from the parent model. For workflow details, see “Unit Test Subsystem Code with SIL/PIL Manager” on page 88-31.

If this workflow does not support a subsystem, use the SIL or PIL block workflow as an alternative.

- **SIL or PIL block**—Create a SIL or PIL block from the subsystem, and then run the block in an environment or test harness model that supplies test vectors or stimulus input. This workflow generates and tests new standalone code from the subsystem. For more information, see “SIL or PIL Block Simulation” on page 88-27.

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

## SIL or PIL Block Simulation

To create a SIL or PIL block from a subsystem and use this block to test the code generated from the subsystem:

- 1 From the **Configuration Parameters > Code Generation > Verification > Advanced Parameters > Create block** drop-down list, select either SIL or PIL.
- 2 If required, configure code execution profiling.
- 3 Click **OK**.
- 4 In your model window, right-click the subsystem that you want to simulate.
- 5 Select **C/C++ Code > Build This Subsystem**, which starts the subsystem build process that creates a SIL or PIL block for the generated subsystem code.
- 6 Add the generated block to an environment or test harness model that supplies test vectors or stimulus input.
- 7 Run simulations with the environment or test harness model.

---

**Note** On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL simulation. To allow the simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

---

You cannot create a SIL or PIL block if you do one of the following:

- Disable the CreateSILPILBlock property.
- Select a code coverage tool.

**Create block** appears dimmed.

## Log Signals of a Component

SIL and PIL component outputs are available for observation and comparison with other simulation mode outputs. If you want to examine an internal signal, you can enable internal signal logging for top-model or Model block SIL or PIL. With signal logging, you can:

- Collect signal logging outputs during SIL/PIL simulations, for example, `logout`.

- Log the internal signals and the root-level outputs of a SIL/PIL component.
- Manage the SIL/PIL signal logging settings with the Simulink Signal Logging Selector.
- Use the Simulation Data Inspector to:
  - Observe streamed signals during normal, SIL, and PIL simulations.
  - Compare logged signals from normal, SIL, and PIL simulations.

To enable signal logging to the MATLAB workspace and signal streaming to the Simulation Data Inspector during SIL or PIL simulations:

- 1 For each signal that you want to monitor:
  - a In the Simulink Editor, select the signal.
  - b On the **SIL/PIL** tab, click **Monitor Signals**. From the gallery, select these options:
    - **Log Selected Signals**
    - **Make Selected Signals Testpoints**
    - **Signal Logging**
- 2 If the **Language** configuration parameter is C++, in the **Code Mappings** editor, set the **Data Visibility** for the signals, states, and internal data model element categories to `public`.

You can use other methods to examine internal signals of the SIL or PIL component:

- Manually route the signal to the top level.
- Use global data stores to access internal signals:
  - 1 Inside the component, connect a Data Store Write block to the required signal.
  - 2 Outside the component, use a Data Store Read block to access the signal value.
- Use MAT-file logging. Note that:
  - MAT-file logging does not support signal logging. If signal logging is enabled, `logout` is generated but not stored in the MAT-file.
  - For PIL, the target environment must support MAT-file logging.

For more information, see:

- “Configure Signals as Test Points”
- “Export Signal Data Using Signal Logging”
- “Local and Global Data Stores”
- “Global Data Store Example”
- “Log Program Execution Results”

## Prevent Code Changes in Multiple Simulations

Use Model block SIL/PIL or the SIL/PIL block with fast restart when you want to run multiple SIL or PIL simulations with:

- Varying test vectors (parameter sets and input data).

- Unchanged generated code, that is, none of the simulations regenerate or rebuild code after the initial build. For example, you want to avoid the incremental code generation that an initial value change can trigger.

For Model block SIL/PIL, you can also use one of these methods:

- In your test harness model, in the Configuration Parameters dialog box, set **Rebuild** to **Never**. If the Model block **Code interface** parameter is `Model` reference, the software does not rebuild the referenced model code. (If the **Code interface** parameter is `Top model`, the software ignores the **Rebuild** setting.)
- Create a protected model and generate source or binary code. Then, insert the protected model in your test harness model. With this method, you can verify top-model code (with the standalone code interface) or model reference code.

For the alternative methods of running Model block SIL/PIL, the following table summarizes code generation behavior after the initial build.

SIL and PIL Approach		Code Generation Behavior After Initial Build
Model block	<b>Rebuild</b> configuration parameter of test harness model set to <b>Never</b> .	<ol style="list-style-type: none"> <li><b>1</b> Component (algorithm) code from initial build is not regenerated.</li> <li><b>2</b> Component code makefile is not called.</li> <li><b>3</b> SIL/PIL application files from initial build are not regenerated.</li> <li><b>4</b> SIL/PIL application makefile is called.</li> </ol>
Model block (protected model)	Source code from protected model.	You observe the same behavior except for feature 2. In this case, the component code makefile is run. The component code is recompiled and linked to produce new object code.
	Binary code from protected model.	You observe features 1-4.

For more information, see:

- “Model Configuration Parameters: Model Referencing”
- “Protect Models to Conceal Contents”

## Speed Up Testing

If your model has SIL/PIL blocks or Model blocks in SIL/PIL mode, you can speed up SIL/PIL testing by:

- Running the top-model simulation in accelerator mode. This mode accelerates the simulation of model components that are not in SIL or PIL mode.

- Turning on fast restart. After the first simulation, you can tune parameters and rerun simulations without model recompilation. The SIL/PIL Manager provides a **Fast Restart** button.

---

**Note** The SIL and PIL simulation modes are not designed for the reduction of model simulation times. If you want to speed up the simulation of your model, use the rapid accelerator mode. For more information, see “What Is Acceleration?”.

---

## Simulation with Function Calls

Use the Simulink Function block and Simulink Function block when you want to:

- Generate code that makes a function-call to external code, for example, driver or legacy code.
- Provide a subsystem that behaves like the external code in normal, SIL, or PIL simulations.

The example in “Configure Calls to AUTOSAR NVRAM Manager Service” (AUTOSAR Blockset) shows how you can configure client calls to Basic Software (BSW) NVRAM Manager (NvM) service interfaces from your AUTOSAR software component. In a simulation, Simulink implements the BSW NvM calls through Simulink Function and preconfigured Function Caller blocks. For the final system, you link function-call stubs with external BSW function code that runs in the AUTOSAR Runtime Environment (RTE).

For more information, see “Simulink Function Blocks and Code Generation”.

## Unit Test Subsystem Code with SIL/PIL Manager

If you have a model that contains subsystems, you can use Simulink Test and the **SIL/PIL Manager** to perform unit tests on code generated from the subsystems. This workflow tests the generated subsystem code as part of the code generated from the parent model.

To perform unit tests on code generated from an atomic subsystem:

- 1 Open the model that contains the atomic subsystem. For example, in the Command Window, enter:

```
openExample('ecoder/SILPILVerificationExample', ...
 supportingFile='SILBlock.slx')
```

- 2 In a new folder, save the model as `plant_model`.

- 3 Modify configuration parameter settings that are not supported for this workflow. In the Command Window, enter:

```
set_param('plant_model', ...
 'CreateSILPILBlock', 'None', ...
 'PreserveStaticInFcnDecls', 'Off');

% For this example, use these values for block parameters.
set_param('plant_model/Controller', ...
 'RTWSystemCode', 'Nonreusable function', ...
 'RTWFileNameOpts', 'Auto');
```

For more information about limitations, see “Atomic Subsystem Workflow Limitations” on page 88-86.

- 4 Generate code for the model that contains the atomic subsystem. In the Command Window, enter:

```
slbuild('plant_model')
```

- 5 Create a test harness for the subsystem. Right-click the Controller subsystem and select **Test Harness > Create for 'Controller'**.

- 6 Set the harness properties:

- **Name** -- controller\_subsystem\_harness
- **Sources and Sinks:** Inport and Outport
- Select **Open harness after creation**.

Click **OK**.

Simulink Test creates a test harness for the Controller subsystem.

7 Specify format for saving data. In the Command Window, enter:

```
set_param('controller_subsystem_harness', ...
 'SaveFormat', 'Dataset')
```

8 In the Test Harness window, open the SIL/PIL Manager. On the **Apps** tab, click **SIL/PIL Manager**.

9 If required, configure code coverage.

10 Run back-to-back model and SIL simulations:

**a** In the **Mode** section, select **Automated Verification**.

**b** In the **Run Automated Verification** section, click **Run Verification**.

11 From the **Results** gallery, you can:

- Use the Simulation Data Inspector to analyze results. For example, compare the `controller_model_output` signals from the model and SIL simulations.
- Export an equivalence test case.

For more information, see “Analyze Results and Export Test Cases” on page 88-73.

For more information about limitations, see “Subsystem Block SIL/PIL Limitations” on page 88-86.

## Simulation Mode Override Behavior in Model Reference Hierarchy

When the top model contains a Model block, the simulation mode of the top model can override the simulation mode of the Model block. The model referenced by the Model block can be a parent model that contains Model blocks at lower levels of the model hierarchy. When you simulate the model hierarchy, the simulation mode of a parent model can override the simulation mode of Model blocks that the parent model contains.

You can specify the simulation mode of a top model to be normal, accelerator, rapid accelerator, SIL, or PIL. With a Model block, you can specify all modes *except* rapid accelerator. This table shows how the software determines the effective simulation mode of a Model block in a model hierarchy.

Simulation Mode Used by Parent Model	Simulation Mode of Model Block			
	Normal	Accelerator	SIL	PIL
<b>Normal</b>	Compatible	Compatible	Compatible	Compatible
<b>Accelerator</b>	Overridden	Compatible	Compatible if top model mode is accelerator. Error if parent block mode is accelerator.	Compatible if top model mode is accelerator. Error if parent block mode is accelerator.
<b>Rapid accelerator</b> (top model only)	Overridden	Compatible	Error	Error
<b>SIL</b>	Overridden	Overridden	Compatible	Error
<b>PIL</b>	Overridden	Overridden	Error	Compatible

The different types of behavior are:

- **Compatible** — The software simulates the Model block in the mode specified for it.
- **Error** — The simulation produces an error. For example, if a top model specifies rapid accelerator mode but contains a Model block in SIL or PIL mode, then running a simulation produces an error: the rapid accelerator mode cannot override the SIL and PIL mode of Model blocks. This behavior avoids the risk of false positives, that is, the simulation of a model in rapid accelerator mode does not lead to the conclusion that generated source or object code of Model blocks is tested or verified.
- **Overridden** — The simulation mode of the top model or parent model overrides the simulation mode of the Model block. For example, if a top model or parent model that you configured for a SIL simulation contains a Model block with normal or accelerator simulation mode, then the software simulates the referenced model in SIL mode. The override behavior:
  - Allows a Model block in the model hierarchy to have SIL or PIL mode.
  - Makes lower-level referenced models execute in SIL or PIL mode if you simulate the top model or parent model in SIL or PIL mode. You do not have to switch the simulation mode of every referenced model in the hierarchy.

Multiple Model blocks, starting at the top of a model hierarchy, can execute in SIL or PIL mode. However, if code coverage or code execution profiling is enabled, only one Model block can execute at a time in SIL or PIL mode.

---

**Note** You can view your model hierarchy in the Dependency Analyzer. In the Model Instances view, the software displays Model blocks differently to indicate their simulation modes, for example, normal, accelerator, SIL, and PIL. In this view, the software does not indicate the simulation mode of the top model.

---

## Debug Generated Code During SIL Simulation

If a software-in-the-loop (SIL) simulation fails or you notice differences between the outputs of your original functions and the generated code, you can rerun the SIL simulation with a debugger enabled. By inserting breakpoints, you can observe the behavior of code sections, which can help you to understand the cause of the issue.

For a SIL simulation failure, you can also view information from the standard output and standard error streams in the Diagnostic Viewer. For example:

- Output from `printf` statements in your code.
- Error messages sent to `stderr`.
- Some low-level system messages.

During a SIL simulation, the SIL application redirects the `stdout` and `stderr` streams. When the application terminates, the Diagnostic Viewer displays the information from the redirected streams. The SIL application also provides a basic signal handler, which captures the POSIX® signals `SIGFPE`, `SIGILL`, `SIGABRT`, and `SIGSEV`. For this signal handler, the SIL application includes the file `signal.h`.

This table gives information about debugger support.

Operating System	Supported Debuggers
Windows	Microsoft Visual Studio IDE.
	Visual Studio Code with MinGW GDB. Requires installation of MATLAB Coder Interface for Visual Studio Code Debugging support package, which you can download from MATLAB Central™ File Exchange.
macOS	LLDB.
	Visual Studio Code with LLDB. Requires installation of MATLAB Coder Interface for Visual Studio Code Debugging support package, which you can download from MATLAB Central File Exchange.
Linux	GNU Data Display Debugger (DDD).
	Visual Studio Code with GDB. Requires installation of MATLAB Coder Interface for Visual Studio Code Debugging support package, which you can download from MATLAB Central File Exchange.

---

**Note** You can perform SIL debugging only if the Simulink product family supports your Microsoft Visual C++, Xcode, or GNU GCC compiler. For more information, see supported compilers.

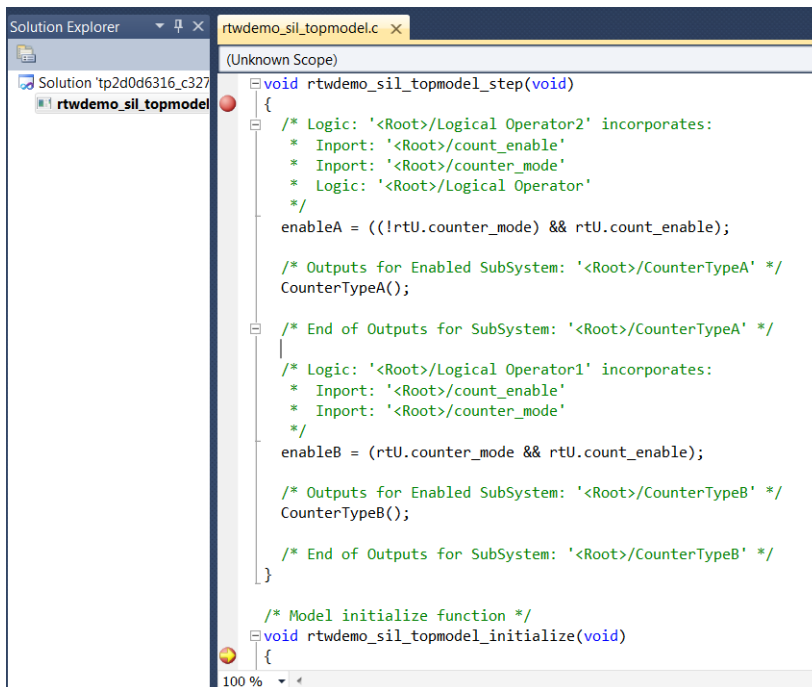

---

To enable your debugger for a SIL simulation, perform one of these actions:

- On the **SIL/PIL** tab, click **Settings > SIL Debugging**.
- In the Configuration Parameters dialog box, select the **Enable source-level debugging for SIL** check box.

If your top model has Model blocks, the **Enable source-level debugging for SIL** parameter for the top model overrides the corresponding parameter for referenced models.

When you run the SIL simulation, your *model.c* or *model.cpp* file opens, for example, in the Microsoft Visual Studio IDE with debugger breakpoints at the start of the *model\_initialize* and *model\_step* functions.

```

Solution Explorer
Solution 'tp2d0d6316_c327'
 rtwdemo_sil_topmodel

rtwdemo_sil_topmodel.c
(Unknown Scope)
void rtwdemo_sil_topmodel_step(void)
{
 /* Logic: '<Root>/Logical Operator2' incorporates:
 * Inport: '<Root>/count_enable'
 * Inport: '<Root>/counter_mode'
 * Logic: '<Root>/Logical Operator'
 */
 enableA = ((!rtU.counter_mode) && rtU.count_enable);

 /* Outputs for Enabled SubSystem: '<Root>/CounterTypeA' */
 CounterTypeA();

 /* End of Outputs for SubSystem: '<Root>/CounterTypeA' */
 /* Logic: '<Root>/Logical Operator1' incorporates:
 * Inport: '<Root>/count_enable'
 * Inport: '<Root>/counter_mode'
 */
 enableB = (rtU.counter_mode && rtU.count_enable);

 /* Outputs for Enabled SubSystem: '<Root>/CounterTypeB' */
 CounterTypeB();

 /* End of Outputs for SubSystem: '<Root>/CounterTypeB' */
}

/* Model initialize function */
void rtwdemo_sil_topmodel_initialize(void)
{
}
100 %

```

You can now use the debugger features to observe code behavior. For example, you can step through code and examine variables.

To end the debugging session:

- 1 Remove all breakpoints.
- 2 Click the Continue button (**F5**).

The SIL simulation runs to completion and the Microsoft Visual Studio IDE closes.

**Note** In the Microsoft Visual Studio IDE, if you select **Debug > Stop Debugging**, the SIL simulation times out with the following error message:

The timeout of 1 seconds for receiving data from the rtiostream interface has been exceeded. There are multiple possible causes for this failure.

...  
...

## Create PIL Target Connectivity Configuration for Simulink

### In this section...

“Target Connectivity Configurations for PIL” on page 88-38  
“Create a Target Connectivity API Implementation” on page 88-38  
“Register a Connectivity API Implementation” on page 88-40  
“Verify Target Connectivity Configuration” on page 88-40  
“Target Connectivity API Examples” on page 88-40

### Target Connectivity Configurations for PIL

Use target connectivity configurations and the target connectivity API to customize processor-in-the-loop (PIL) simulation for your target environments.

Through a target connectivity configuration, you specify:

- A configuration name for a target connectivity API implementation.
- Settings that define the set of compatible Simulink models. For example, the set of models that have a particular system target file, template makefile, and hardware implementation.

A PIL simulation requires a target connectivity API implementation that integrates third-party tools for:

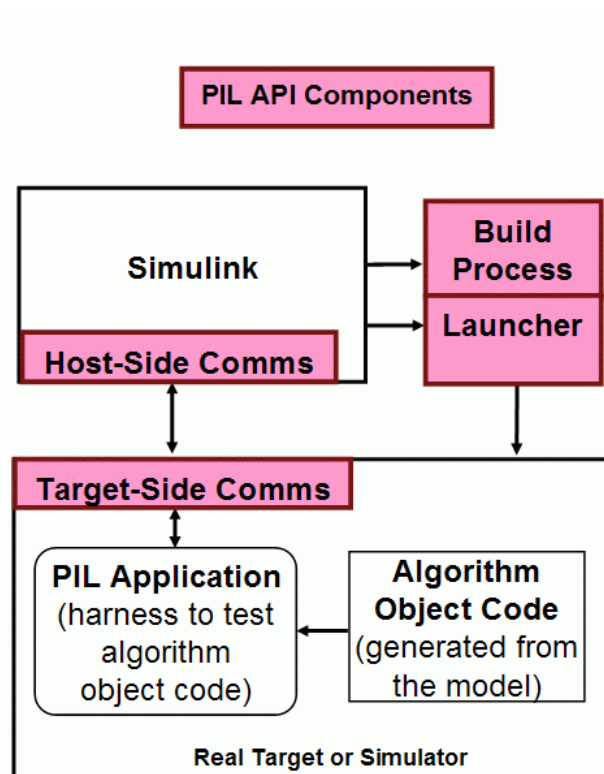

- Cross-compiling generated code, creating the PIL application that runs on the target hardware.
- Downloading, starting, and stopping the application on the target.
- Communicating between Simulink and the target.

You can have many different target connectivity configurations for PIL simulation. Register a connectivity configuration with Simulink by creating an `sl_customization.m` file and placing it on the MATLAB search path.

When you run a PIL simulation, the software determines which of the available connectivity configurations to use. The software looks for a connectivity configuration that is compatible with the model under test. If the software finds multiple or no compatible connectivity configurations, the software generates an error message with information about resolving the problem.

### Create a Target Connectivity API Implementation

This diagram shows the components of the PIL target connectivity API.

You must provide implementations of the three API components:

- Build API — Specify the Simulink Coder toolchain or template makefile approach for building generated code.
- Launcher API — Control how Simulink starts and stops the PIL executable.
- Communications API — Customize connectivity between Simulink and the PIL target. Embedded Coder provides host-side support for TCP/IP and serial communications, which you can adapt for other protocols.

These steps outline how you create a target connectivity API implementation. The example code shown in the steps is taken from `ConnectivityConfig.m` in “Configure Processor-In-The-Loop (PIL) for a Custom Target” on page 88-107.

**1** Create a subclass of `rtw.connectivity.Config`.

```
ConnectivityConfig < rtw.connectivity.Config
```

**2** In the subclass:

- Instantiate `rtw.connectivity.MakefileBuilder`, which configures the build process.

```
builder = rtw.connectivity.MakefileBuilder(componentArgs, ...
 targetApplicationFramework, ...
 exeExtension);
```

- Create a subclass of `rtw.connectivity.Launcher`, which downloads and executes the application using a third-party tool.

```
launcher = mypil.Launcher(componentArgs, builder);
```

**3** Configure your `rtiostream` API implementation of the host-target communications on page 88-42 channel.

- For the target side, you must provide the driver code for communications, for example, TCP/IP or serial communications. To integrate this code into the build process, create a subclass of `rtw.pil.RtIOStreamApplicationFramework`.
- For the host side, you can use a supplied library for TCP/IP or serial communications. Instantiate `rtw.connectivity.RtIOStreamHostCommunicator`, which loads and initializes the library that you specify.

```
hostCommunicator = rtw.connectivity.RtIOStreamHostCommunicator(componentArgs, ...
 launcher, ...
 rtiostreamLib);
```

- 4 If you require execution-time profiling for generated code, create a timer object that provides details of the hardware-specific timer and associated source files. For more information, see “Specify Hardware Timer for Simulink” on page 88-45.
- 5 If you require stack usage profiling for generated code, specify a driver implementation that obtains stack usage data from the target hardware. The driver must return the value of the stack register. If you do not specify a driver, the PIL simulation tries to use a default generic driver. For more information, see “Implement Driver to Obtain Stack Usage Data During PIL Simulation” on page 81-50.

---

**Note** Each time you modify a connectivity implementation, close and reopen the models to refresh them.

---

## Register a Connectivity API Implementation

To register a target connectivity API implementation as a target connectivity configuration in Simulink:

- 1 Create or update an `sl_customization.m` file. In this file:
  - Create a target connectivity configuration object that specifies, for example, the configuration name for a target connectivity API implementation and compatible models.
  - Invoke `registerTargetInfo`.
- 2 Add the folder containing `sl_customization.m` to the search path and refresh your customizations.

```
addpath(sl_customization_path);
sl_refresh_customizations;
```

For more information, see `rtw.connectivity.ConfigRegistry`.

## Verify Target Connectivity Configuration

To verify your target connectivity configuration early on and independently of your model development and code generation, use the supplied `piltest` function. With the function, you can run a suite of tests. In the tests, the function runs various normal, SIL, and PIL simulations. The function compares results and produces errors if it detects differences between simulation modes.

## Target Connectivity API Examples

For step-by-step examples, see:

- “Configure Processor-In-The-Loop (PIL) for a Custom Target” on page 88-107

This example shows you how to create a custom PIL implementation using the target connectivity APIs. You can examine the code that configures the build process to support PIL, a downloading and execution tool, and a communication channel between host and target. To activate a full host-based PIL configuration, follow the steps in the example.

- “Create a Target Communication Channel for Processor-in-the-Loop (PIL) Simulation” on page 88-102

This example shows you how to implement a communication channel for use with the Embedded Coder product and your embedded target. This communication channel enables exchange of data between different processes. PIL simulation requires exchange of data between the Simulink software running on your development computer and deployed code executing on target hardware.

The `rtiostream` interface provides a generic communication channel that you can implement in the form of target connectivity drivers for a range of connection types. The example shows how to configure your own target-side driver for TCP/IP, to operate with the default host-side TCP/IP driver. The default TCP/IP communications allow high-bandwidth communication between host and target, which you can use for transferring data such as video.

---

**Note** If you customize the `rtiostream` TCP/IP implementation for your PIL simulations, you must turn off Nagle's algorithm for the server side of the connection. If Nagle's algorithm is not turned off, your PIL simulations can run at a significantly slower speed. The `matlabroot/toolbox/coder/rtiostream/src/rtiostreamtcpip/rtiostream_tcpip.c` file shows how you can turn off Nagle's algorithm:

```
/* Disable Nagle's Algorithm*/
option = 1;
sockStatus = setsockopt(lFd, IPPROTO_TCP, TCP_NODELAY, (char*)&option, sizeof(option));
```

---

The code for your custom TCP/IP implementation can require modification.

---

The example also shows how to implement custom target connectivity drivers, for example, using serial, CAN, or USB for both host and target sides of the communication channel.

## Host-Target Communication for Simulink PIL Simulation

### In this section...

“Communications rtiostream API” on page 88-42  
 “Synchronize Host and Target” on page 88-43  
 “Test an rtiostream Driver” on page 88-43  
 “Troubleshooting Host-Target Communication” on page 88-43  
 “Word Addressable Target Hardware” on page 88-44

This section provides information about using the `rtiostream` API for communication between your development computer and target hardware during a processor-in-the-loop (PIL) simulation.

### Communications rtiostream API

The `rtiostream` API supports communications for the target connectivity API. Use the `rtiostream` API to implement a communication channel that enables data exchange between different processes.

PIL simulation requires a host-target communications channel. This communications channel comprises driver code that runs on the host and target. The `rtiostream` API defines the signature of target-side and host-side functions that this driver code must implement.

The API is independent of the physical layer that sends the data. Possible physical layers include RS232, Ethernet, or Controller Area Network (CAN).

A full `rtiostream` implementation requires both host-side and target-side drivers. Code generation software includes host-side drivers for the default TCP/IP implementation and a version for serial communications. To use:

- The TCP/IP `rtiostream` communications channel, you must provide, or obtain from a third party, target-specific TCP/IP device drivers.
- The serial communications channel, you must provide, or obtain from a third party, target-specific serial device drivers.

For other communication channels and platforms, the code generation software does not provide default implementations. You must provide both the host-side and the target-side drivers.

The `rtiostream` API comprises the following functions:

- `rtIOStreamOpen`
- `rtIOStreamSend`
- `rtIOStreamRecv`
- `rtIOStreamClose`

For information about:

- Using `rtiostream` functions in a connectivity implementation, see “Create a Target Connectivity API Implementation” on page 88-38.
- Testing the `rtiostream` shared library methods from MATLAB code, see `rtiostream_wrapper`.
- Debugging and verifying the behavior of custom `rtiostream` interface implementations, see “Test an rtiostream Driver” on page 88-43 and `rtiostreamtest`.

## Synchronize Host and Target

If you use the `rtiostream` API to implement the communications channel, the host and target must be synchronized, which prevents Simulink from transmitting and receiving data before the target application is fully initialized.

To synchronize the host and target for TCP/IP `rtiostream` implementations, use the `setInitCommsTimeout` method from `rtw.connectivity.RtIOStreamHostCommunicator`. This approach works well for connection-oriented TCP/IP `rtiostream` implementations because Simulink automatically waits until the target server is running.

With other `rtiostream` implementations, for example, serial, the Simulink side of the `rtiostream` connection opens without waiting for the target to be fully initialized. In this case, you must make your `Launcher` implementation wait until the target application is fully initialized. Use one of the following approaches to synchronize your host and target:

- Add a pause at the end of the `Launcher` implementation that makes the `Launcher` wait until target initialization is complete.
- In the `Launcher` implementation, use third-party downloader or debugger APIs that wait until target initialization is complete.
- Implement a handshaking mechanism in the `Launcher` / `rtiostream` implementation that confirms completion of target initialization.

## Test an rtiostream Driver

Use a test suite to debug and verify the behavior of custom `rtiostream` interface implementations.

The test suite can help you to:

- Reduce the time required for integrating custom hardware that does not have built-in `rtiostream` support.
- Reduce the time required for testing custom `rtiostream` drivers.
- Analyze the performance of custom `rtiostream` drivers.

The test suite consists of two parts. One part is an application that runs on the target hardware. The other part runs in MATLAB. For details, see `rtiostreamtest`.

## Troubleshooting Host-Target Communication

To display communication I/O information in the Diagnostic Viewer during the PIL simulation, in the Command Window, enter:

```
set_param(model, 'SILPILVerboseOutput', 'on');
```

By default, the configuration parameter `SILPILVerboseOutput` is set to `off`.

If you run a SIL simulation with `SILPILVerboseOutput` set to on, the simulation displays I/O information for communication that occurs between Simulink and the target application that runs as a separate process on your development computer.

## Word Addressable Target Hardware

In the Configuration Parameters dialog box, when you specify settings for **Device vendor** and **Device type**, you provide PIL simulations with memory addressing information about the target hardware.

For example, consider the case when **Device vendor** is set to Texas Instruments and **Device type** is set to C5000.

The settings specify that the target hardware uses 16-bit word addresses and big-endian word order. The `rtiostream` implementation operates with 16-bit words.

On the target hardware, if an `rtIOStream` function specifies a size of 1, then the target hardware must send or receive one 16-bit word (2 bytes). `sizeof(char)` and `sizeof(short)` return 1, which corresponds to one 16-bit word. The `rtIOStream` function expects the byte order within the word to be little-endian, that is, less significant bytes are transmitted before more significant bytes.

`rtiostreamtest` identifies the target hardware and handles data in terms of 16-bit words, for example, a byte value is transferred as a 16-bit word value.

## Specify Hardware Timer for Simulink

For processor-in-the-loop (PIL) code execution profiling, you must create a timer object that provides details of the hardware-specific timer and associated source files. You can use the **Code Replacement Tool** or the code replacement library API to specify this hardware-specific timer.

To specify the timer with the Code Replacement Tool:

- 1** Open the Code Replacement Tool. In the Command Window, enter `crtool`.
- 2** Create a new code replacement table. Select **File > New table**.
- 3** Create a new function entry. Under **Tables List**, right-click the new table. Then, from the context-menu, select **New entry > Function**.
- 4** In the middle view, select the new unnamed function.
- 5** On the **Mapping Information** pane:
  - a** From the **Function** drop-down list, select `code_profile_read_timer`.
  - b** Specify the count direction for your timer. For example, from the **Count direction** drop-down list, select **Up**.
  - c** In the **Ticks per second** field, specify the number of ticks per second for your timer, for example, `1e+09`.

The default value is 0. In this case, the software reports time measurements in terms of ticks, not seconds.

- d** In the **Conceptual function** section, from the **Data type** list, select `uint8`, `uint16`, `uint32`, or `uint64`.
- e** In the **Function prototype** section, in the **Name** field, specify a replacement function name, for example, `MyTimer`.
- f** Click **Apply**.

- g** To validate the function entry, click **Validate entry**.
- 6** On the **Build Information** pane, specify the required build information. See Specify build information in “Define Code Replacement Library Optimizations” on page 72-36.
- 7** Save the table (**Ctrl+S**). When you save the table for the first time, use the Save As dialog box to specify the file name and location.

You must save the table in a location that is on the MATLAB search path. For example, you can save this file in the folder for your subclass of `rtw.connectivity.Config`.

The software stores your timer information as a code replacement library table.

- 8** Assuming you save the table as `MyCr1Table.m`, in your subclass of `rtw.connectivity.Config`, add the following line:

```
setTimer(this, MyCr1Table)
```

## Set Up PIL Connectivity by Using target Package

Before you can run processor-in-the-loop (PIL) simulations, you must set up connectivity between Simulink and your target hardware. The connectivity enables the PIL simulation to:

- Build the target application.
- Download, start, and stop the application on the target hardware.
- Support communication between Simulink and the target hardware.

Use one of these workflows.

Workflow	When to use
target package with rtiostream API	<p>Use this workflow if your target application has large I/O requirements that need high-bandwidth communication.</p> <p>For more information, see “Use rtiostream API for PIL Target Connectivity” on page 88-48.</p>
target package with debugger	<p>Use this workflow if:</p> <ul style="list-style-type: none"> <li>• You want a single debugger integration to provide PIL connectivity for target hardware systems that are supported by the debugger. This workflow requires little or no target-specific code.</li> <li>• The I/O requirements of the target application are small. For example, unit tests on a component. If you use this workflow for a target application that has large I/O requirements, the execution of the application is slower.</li> </ul> <p>For more information, see “Use Debugger for PIL Target Connectivity” on page 88-51.</p>

### Use rtiostream API for PIL Target Connectivity

To provide PIL connectivity between Simulink and the target hardware, you can use the `target` Package with the `rtiostream` API on page 88-42. In this example, your development computer is the target hardware.

#### 1 Create the board description

Create a `target.Board` object that provides MATLAB with a description of your target hardware.

```
hostTarget = target.create('Board', ...
 'Name', 'Example Intel Board');
```

To support code generation and data I/O in PIL simulations, associate the object with processor, connection, and communication descriptions.

## 2 Associate the board with a processor

To support code generation, associate the board with a `target.Processor` object that contains a language implementation. For this example, create a `target.Processor` object and reuse an existing `target.LanguageImplementation` object. For information about setting up a custom `target.LanguageImplementation` object, see “Register New Hardware Devices” on page 10-11.

```
processor = target.create('Processor', 'Name', 'ExampleProcessor');
processor.LanguageImplementations = target.get('LanguageImplementation', ...
 'Intel-x86-64 (Windows64)');
```

Associate the `target.Board` object with the new `target.Processor` object by using the `Processors` property

```
hostTarget.Processors = processor;
```

## 3 Specify execution information for the target hardware

Create an object that contains details about executing the target application. The object describes the tool that is required to run the target application on the target hardware. To capture system commands for starting and stopping the target application, you can use the `HostProcessExecutionTool` or `SystemCommandExecutionTool` class.

```
applicationExecution = target.create('HostProcessExecutionTool');
applicationExecution.Name = 'Windows Application';
```

Create a `Command` object for downloading and running the target application. Assign the string variable `'$(EXE)'` to the `String` property as a place holder for the target application name, which is not known until execution.

```
runCommand = target.create('Command');
runCommand.String = '$(EXE)';
applicationExecution.StartCommand = runCommand;
hostTarget.Tools.ExecutionTools = applicationExecution;
```

## 4 Create the communication interface for the target hardware

Create a `CommunicationInterface` object that provides the target hardware with details of the communication channel and the `rtiostream` API on page 88-42 implementation.

Use:

- The shipped TCP/IP `rtiostream` implementation source file.
- A `BuildDependencies` object to specify, for the `rtiostream` API, the source files that are compiled with the target application.
- A `MainFunction` object to pass arguments to the target application

```
comms = target.create('CommunicationInterface');
comms.Name = 'Windows TCP Interface';
comms.Channel = 'TCPChannel';
comms.APIImplementations = target.create('APIImplementation', ...
 'Name', 'x86 RTIOStream Implementation');
comms.APIImplementations.API = target.create('API', 'Name', 'RTIO Stream');
comms.APIImplementations.BuildDependencies = target.create('BuildDependencies');
comms.APIImplementations.BuildDependencies.SourceFiles = ...
 {fullfile('${MATLAB_ROOT}', ...
 'toolbox', ...
 'coder', ...
 'rtiostream', ...
 'src', ...
 'rtiostreamtcpip', ...
 'rtiostream_tcpip.c')};
```

```
comms.APIImplementations.MainFunction = target.create('MainFunction', ...
 'Name', 'TCP RtIOStream Main');
comms.APIImplementations.MainFunction.Arguments = {'-blocking', '1', '-port', '0'};
hostTarget.CommunicationInterfaces = comms;
```

## 5 Specify PIL protocol information

This step is optional. A PIL simulation uses a communication protocol for the transfer of data between Simulink and the target hardware. The `target.PILProtocol` class describes the parameters of the protocol. For this example, you can improve target run-time performance by increasing the I/O buffer size that the protocol uses.

Create a `target.PILProtocol` object and specify I/O buffer size.

```
pilProtocol = target.create('PILProtocol');
pilProtocol.Name = 'Windows PIL Protocol';
pilProtocol.SendBufferSize = 50000;
pilProtocol.ReceiveBufferSize = 50000;
hostTarget.CommunicationProtocolStacks = pilProtocol;
```

If you do not perform this step, default `target.PILProtocol` values are used.

## 6 Add profiling timer

You can configure a PIL simulation to produce execution-time profiles for the generated code. To support code execution profiling, you must create a timer object that describes the retrieval of current time from generated code running on the target hardware. The timer object description must include a description of the function that retrieves time and its implementation.

This example uses a C function, `timestamp_x86`, which returns the current time as a `uint64` data type.

```
timerSignature = target.create('Function');
timerSignature.Name = 'timestamp_x86';
timerSignature.ReturnType = 'uint64';
```

Capture the function in an API object.

```
timerApi = target.create('API');
timerApi.Functions = timerSignature;
timerApi.Language = target.Language.C;
timerApi.Name = 'Windows Timer API';
```

Capture the dependencies of the function, that is, the source and header files that are required to run the function.

```
timerDependencies = target.create('BuildDependencies');
timerDependencies.IncludeFiles = {'host_timer_x86.h'};
timerDependencies.IncludePaths = {'$(MATLAB_ROOT)/toolbox/coder/profile/src'};
timerDependencies.SourceFiles = {'host_timer_x86.c'};
```

Create an object that combines the API and dependencies.

```
timerImplementation = target.create('APIImplementation');
timerImplementation.API = timerApi;
timerImplementation.BuildDependencies = timerDependencies;
timerImplementation.Name = 'Windows Timer Implementation';
```

Create the timer object and associate it with the timer information.

```
timer = target.create('Timer');
timer.APIImplementation = timerImplementation;
timer.Name = 'Windows Timer';
```

Assign the timer to the processor object.

```
processor.Timers = timer;
```

## 7 Specify connection between development computer and target hardware

The previous steps created target hardware support for communications and running the target application. Now, set up a connection between your development computer and the target hardware by creating a `TargetConnection` object. Specify:

- The communication channel, which is the same channel specified in the target hardware communication interface -- see step 4.
- The connection properties.
- The target, which is the board description specified in previous steps.

```
connection = target.create('TargetConnection');
connection.Name = 'Host Process Connection';
connection.Target = hostTarget;
connection.CommunicationChannel = target.create('TCPChannel');
connection.CommunicationChannel.Name = 'External Process TCPCommunicationChannel';
connection.CommunicationChannel.IPAddress = 'localhost';
connection.CommunicationChannel.Port = '0';
```

## 8 Make board and connection objects persist across MATLAB sessions

To register the connectivity in MATLAB, add the target hardware and connection information to an internal database by using the `target.add` function. By default, the information is only available for the current MATLAB session. To make the registration persist across MATLAB sessions, specify the name-value pair `'UserInstall', true`.

```
target.add([hostTarget connection], 'UserInstall', true);
```

## 9 Specify board for model

You can now specify your development computer as the target hardware for PIL simulations. Before you run a PIL simulation, in the Configuration Parameters dialog box, set **Hardware board** to Example Intel Board.

# Use Debugger for PIL Target Connectivity

To provide PIL connectivity between Simulink and the target hardware, you can use the `target` Package with a debugger, for example, the GNU Debugger.

## 1 Implement the target.DebugIOTool debugger abstraction interface

Implement the interface in a class called `myImplementationClass`. For an example pseudocode implementation, see “`DebugIOTool` Template” on page 88-52.

```
classdef myImplementationClass < target.DebugIOTool
 properties (Access=private)
 ...
 end

 methods
 ...
 end

 methods (Access=private)
 ...
 end
end
```

## 2 Create the board description

Create `target.Board` object that provides MATLAB with a description of your target hardware.

```
hostTarget = target.create('Board', ...
 'Name', 'GDB Debug PIL IO');
```

### 3 Associate the board with a processor

To support code generation, associate the board with a `target.Processor` object that contains a language implementation. For this example, create a `target.Processor` object and reuse an existing `target.LanguageImplementation` object. For information about setting up a custom `target.LanguageImplementation` object, see “Register New Hardware Devices” on page 10-11.

```
hostTarget.Processors = target.get('Processor', ...
 'Intel-x86-64 (Linux 64)');
```

### 4 Describe the debugger execution service implementation

Create a `target.ExecutionService` object that references the debugger abstraction interface.

```
matlabExecution = target.create('ExecutionService', ...
 'Name', 'GDB Launch');
matlabExecution.APIImplementation = ...
 target.create('APIImplementation', ...
 'Name', 'myServiceImplementation');
matlabExecution.APIImplementation.BuildDependencies = ...
 target.create('MATLABDependencies');
matlabExecution.APIImplementation.BuildDependencies.Classes = ...
 {'myImplementationClass'};
matlabExecution.APIImplementation.API = ...
 target.get('API', ...
 'DebugIOTool');
```

### 5 Associate debugger execution service with the board

Associate the `target.ExecutionService` object with the `target.Board` object.

```
hostTarget.Tools.DebugTools = matlabExecution;
```

### 6 Make board object persist across MATLAB sessions

Add the board object to an internal database and make the object persist across MATLAB sessions.

```
target.add(hostTarget, 'UserInstall', true);
```

### 7 Specify board for model

Before you run a PIL simulation, in the Configuration Parameters dialog box, set **Hardware board** to GDB Debug PIL IO.

## DebugIOTool Template

This section provides a pseudocode example of `target.DebugIOTool` debugger abstraction. Use a `target.DebugIOTool` object to:

- Control the lifetime of an application running in the debugger.
- Automate common debugger actions. For example, applying breakpoints and continuing execution from a paused state.
- Read and write to memory that the application uses.

For interactions with the debugger, you can use MATLAB external language interfaces to APIs, which the debugger vendor supplies.

**Section Descriptions for target.DebugIOTool Debugger Abstraction Example**

target.DebugIOTool Object	Comments

 % debugger.
 %
 % The path to the application to load is stored in the
 % Application property of this class which can be accessed
 % using this.Application in this method.
 %
 % Additional command line arguments to pass to the
 % application are stored in
 % this.ApplicationCommandLineArguments.
 %
 % Breakpoints to set are stored in this.Breakpoints

 this.callExternalDebugger('start application');

 errFlag = false;
end

% Stop the application execution in the debugger. Optional.
function errFlag = stopApplication(this)

 % Add logic here to stop the application execution in the
 % debugger.

 % If your 'startApplication' method opened the debugger,
 % perform the opposite action here, i.e. close the
 % debugger.
 %
 % If your 'startApplication' method loaded the application,
 % perform the opposite action here, i.e. unload the
 % application from the debugger.

 this.callExternalDebugger('stop application');

 errFlag = false;
end

% Unloads the application from the debugger. Optional.
function errFlag = unloadApplication(this)

 % If you implemented the 'loadApplication' method,
 % then add logic here to unload the application from
 % the debugger.

 % If your 'loadApplication' method opened the debugger,
 % perform the opposite action here, i.e. close the
 % debugger.

 this.callExternalDebugger('unload application');

 errFlag = false;
end

% Closes the debugger. Optional.
function errFlag = close(this)

 % Add logic here to close the debugger. If you implemented the
 % 'open' method you should implement this method.

 this.callExternalDebugger('close');

 errFlag = false;
end

% Asks if the debugger is currently stopped at the specified
% breakpoint. Returns true if at the specified breakpoint, false
% otherwise. Required.

```

```

function [atBreakpoint, errFlag] = ...
 stoppedAtBreakpoint(this, breakpoint)

 % Add logic to determine if the debugger has broken execution
 % at the breakpoint passed into the function.
 %
 % The 'breakpoint' input variable is of type target.Breakpoint
 % which provides the description of the breakpoint. It contains
 % properties Function, File and Line which describes the
 % location of the breakpoint.
 %
 % Set the atBreakpoint return value to true if the debugger is
 % stopped at the breakpoint, or false if not.

 result = this.callExternalDebugger('determine breakpoint hit', ...
 breakpoint.File, ...
 breakpoint.Line, ...
 breakpoint.Function);

 atBreakpoint = ~isempty(result);

errFlag = false;
end

% Continues execution if application execution is paused in the
% debugger. Required.
function errFlag = continueExecution(this)

 this.callExternalDebugger('continue execution');
 errFlag = false;
end

% Write the specified memory stream to the target platform memory
% specified by the given variable name.
function errFlag = write(this, variableName, memoryStream)

 % Add logic to write the memoryStream data to the variableName
 % variable in the target. This function should assume that the
 % appropriate breakpoint has been hit to perform such an
 % action.
 %
 % memoryStream is a vector of uint64 values to be written to
 % the target platform. The uint64 values act as a container for
 % the smallest addressable integer on the target platform. In
 % most cases this will be a container for the size of char on
 % the target platform, which will commonly be 8-bit.
 %
 % The specified variable will represent a pointer to the
 % smallest addressable integer type.

 % As an example write operations on a target platform where
 % char represents the smallest addressable integer should be
 % equivalent to the following memcpy call in C code:
 %
 % (void*)memcpy(<variableName>,
 % (unsigned char[<sizeofMemoryStream>])
 % {<memoryStream(1)>,<memoryStream(2)>, ...},
 % <sizeofMemoryStream>);
 %
 % A lot of debuggers allow for immediate execution of code when
 % execution is broken, if so, attempt to use the above command
 % to write data to the variable like the below example:

 sizeofMemoryVariable = uint64(numel(memoryStream));
 arrayFormat = repmat('%d,', [1 sizeofMemoryVariable]);
 arrayFormat(end) = [];

 this.callExternalDebugger(sprintf(['execute (void*)memcpy(%s,' ...
 '(unsigned char [%d]){%s}, %d)'], ...
 variableName, ...
 sizeofMemoryVariable, ...
 sprintf(arrayFormat, memoryStream), ...
 sizeofMemoryVariable));

```

```

 errFlag = false;
 end

 % read the memory stream from the target platform memory specified
 % by the given variable name.
 function [memoryStream, errFlag] = read(this, ...
 variableName, ...
 sizeToRead)

 % Add logic to read from the variableName variable on the
 % target. This function should assume that the appropriate
 % breakpoint has been hit to perform such an action.
 %
 % The memoryStream return value should be a vector of uint64
 % values. The uint64 values act as a container for the smallest
 % addressable integer on the target platform. In most cases
 % this will be a container for the size of char on the target
 % platform, which will commonly be 8-bit.
 %
 % The specified variable will represent a pointer to the
 % smallest addressable integer type.

 % Read operations should be equivalent to inspecting the result
 % of the following C code:
 % (unsigned char [<sizeToRead>])*<variableName>
 %
 % A lot of debuggers allow for immediate execution of code when
 % execution is broken, if so, attempt to use the above command
 % to inspect the value of the buffer and return it to MATLAB.

 memoryStream = this.callExternalDebugger(...
 sprintf("read (unsigned char [%d])*%s", ...
 sizeToRead, variableName));

 % The memory stream must be returned as a vector of uint64
 % values
 memoryStream = uint64(memoryStream);

 errFlag = false;
 end
end

methods (Access=private)

 function output = callExternalDebugger(~, varargin)

 output = [];
 fprintf("\nInstructed the debugger to '%s'\n", varargin{1});

 if nargin > 2
 disp('Using arguments:');
 disp(varargin(2:end));
 end
 end
end
end
end

```

## Custom Toolchain Directives Required for Code Coverage and Execution Profiling

If you use a custom toolchain for building a processor-in-the-loop (PIL) target application that supports Simulink Coverage analysis or Embedded Coder code execution profiling, in the toolchain definition file, you must provide these compiler directives:

- `CompileFlag` — Specify the flag that C or C++ compiler uses to compile source files without linking. For example, if the compiler in the toolchain is GNU C or C++, set the directive to `-c`.
- `PreprocessFile` — Specify the flag that C or C++ compiler uses to preprocess the source files without running other compiler stages. For example, if the compiler in the toolchain is GNU C or C++, set the directive to `-E`.

This section from a toolchain definition file example shows how you can use the `setDirective` method to provide the directives.

```
tc = coder.make.ToolchainInfo('BuildArtifact','nmake makefile');
tc.Name = 'My Toolchain Name';

## PIL Simulation Sequence

A processor-in-the-loop (PIL) simulation cross-compiles production source code, and then downloads and runs object code on your target hardware. The connectivity configuration that you create controls the way code is compiled and executed on the target. This table describes the sequence of stages in a PIL simulation.

Stage		Description
1	Start	<p>For top-model PIL, on the Simulink Editor toolbar, you select the <b>Processor-in-the-Loop (PIL)</b> mode, and then click the Run button.</p> <p>For Model block PIL, you set the <b>Simulation mode</b> parameter of the Model block to <b>Processor-in-the-loop (PIL)</b>, and then run a simulation of the harness model that contains the Model block.</p> <p>For the PIL block, you run a simulation of the harness model that contains the PIL block.</p>
2	Validate target connectivity	The software verifies that a target connectivity configuration is registered for PIL. Otherwise, the software produces an error.
3	Generate production source code and build object code for target	<p>The generated source code is identical to the code that is produced when you run the <code>slbuild</code> command.</p> <ul style="list-style-type: none"> <li>• For top-model PIL or Model block PIL with block parameter <b>Code interface</b> set to <code>Top model</code>, the generated code is identical to the code produced when you run <code>slbuild('model')</code>.</li> <li>• For Model block PIL with block parameter <b>Code interface</b> set to <code>Model reference</code>, the generated code is identical to the code produced when you run <code>slbuild('model', 'ModelReferenceCoderTarget')</code>.</li> </ul> <p>The software builds object code for the target by using the template makefile or toolchain that you specify.</p>
4	Create instances of PIL API components	The software instantiates your <code>rtw.connectivity.Config</code> class, which creates instances of <code>rtw.connectivity.MakefileBuilder</code> , <code>rtw.connectivity.Launcher</code> , <code>rtw.pil.RtIOStreamApplicationFramework</code> , and <code>rtw.connectivity.RtIOStreamHostCommunicator</code> .
5	Generate PIL files	The generated PIL files are in the <code>pil</code> folder. At the end of the simulation, use the code generation report to view the files.

Stage		Description
6	Build target application	<p>The software:</p> <ul style="list-style-type: none"> <li>• Uses your instance of <code>rtw.connectivity.MakefileBuilder</code> to build the target application.</li> <li>• Compiles the PIL interface file, <code>xil_interface.c</code>, and other PIL files into the target executable file. On a Windows system, for example, this file is called <code>modelName.exe</code>. The object code, including the executable file, is in the <code>pil</code> folder.</li> <li>• If configured, produces the code generation report.</li> </ul>
7	Start target application	The software uses <code>rtw.connectivity.Launcher</code> to start the application on the target.
8	Simulink engine interacts with PIL S-function	<p>The Simulink engine interacts with the PIL S-function in the same way that it interacts with a C S-function.</p> <p>From the host-side, the PIL S-function communicates with the target executable code through <code>rtIOStream</code> commands. On the target side, <code>xil_interface</code> executes generated code.</p>
9	Stop target application	The software uses <code>rtw.connectivity.Launcher</code> to stop the application on the target.
10	End PIL simulation	<p>For top-model PIL, at the end of the simulation, the software destroys the <code>rtw.connectivity.Config</code> instance.</p> <p>For Model block PIL and PIL block, the block creates and owns the <code>rtw.connectivity.Config</code> instance, which is not destroyed at the end of the simulation. You can rerun the simulation, which now does not require the creation of another <code>rtw.connectivity.Config</code> instance. If you want to destroy the instance, close the parent model.</p>

## Verification of Code Generation Assumptions

At the start of a software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulation, the software verifies some configuration parameter settings with reference to the target hardware.

For example, in the Configuration Parameters dialog box, the **Hardware Implementations** settings specify target behavior, which result in the implementation of implicit assumptions in the generated code. Incorrect settings can lead to:

- Suboptimal code
- Code execution failure, incorrect code output, and nondeterministic code behavior

The software checks:

- The correctness of settings. For example, the integer bit length in the **Number of bits: int** field.
- Whether the settings are optimized. For example, the rounding of signed integer division in the **Signed integer division rounds to** field.

The simulation generates a Coder Assumptions page on page 58-13 for the code generation report, which provides a list of:

- Code generation assumptions that are checked
- Expected results for the assumption checks

This table shows when checks occur and outcomes when code generation assumptions are incorrect.

Stage	What is Checked	Outcome
Preprocessor	<p><b>Number of bits</b> per:</p> <ul style="list-style-type: none"> <li>• <b>char</b> (ProdBitPerChar)</li> <li>• <b>short</b> (ProdBitPerShort)</li> <li>• <b>int</b> (ProdBitPerInt)</li> <li>• <b>long</b> (ProdBitPerLong)</li> </ul> <p>If <b>Support long long</b> (ProdLongLongMode) is selected, number of bits per long long</p> <p>For each data type, the preprocessor check is not performed if the number of bits exceeds these settings for the target C preprocessor:</p> <ul style="list-style-type: none"> <li>• For signed integer math, TargetPreprocMaxBitsSint.</li> <li>• For unsigned integer math, TargetPreprocMaxBitsUint.</li> </ul>	Error if data type sizes for model and target hardware do not match.

Stage	What is Checked	Outcome
Run-time	<b>Number of bits</b> per: <ul style="list-style-type: none"> <li>• <b>char</b> (ProdBitPerChar)</li> <li>• <b>short</b> (ProdBitPerShort)</li> <li>• <b>int</b> (ProdBitPerInt)</li> <li>• <b>long</b> (ProdBitPerLong)</li> </ul>	Error if data type sizes for model and target hardware do not match.
	If <b>Support long long</b> (ProdLongLongMode) is selected, number of bits per long long	Error if: <ul style="list-style-type: none"> <li>• Target hardware does not support long long.</li> <li>• Data type sizes for model and target hardware do not match.</li> </ul>
	Size of: <ul style="list-style-type: none"> <li>• float</li> <li>• double</li> </ul> <p>You cannot configure these data type sizes through the <b>Hardware Implementation</b> pane. The check is performed only if <b>Support: floating-point numbers</b> is selected.</p>	Warning if data type sizes for model and target hardware do not match. <p>For double, warning is generated if size of target hardware data type is not 32 or 64 bits.</p>
	<b>Number of bits</b> per: <ul style="list-style-type: none"> <li>• <b>pointer</b> (ProdBitPerPointer)</li> <li>• <b>size_t</b> (ProdBitPerSizeT)</li> <li>• <b>ptrdiff_t</b> (ProdBitPerPtrDiffT)</li> </ul>	Error if data type sizes for model and target hardware do not match.
	<b>Signed integer division rounds to</b> (ProdIntDivRoundTo) setting	Warning if model parameter setting is Undefined. <p>Error if target hardware behavior is undefined and model parameter setting is not Undefined.</p> <p>Error if target hardware behavior is defined but settings for model and target hardware do not match.</p>
	<b>Byte ordering</b> (ProdEndianness) setting	Warning if setting is Unspecified. Otherwise, error if settings for model and target hardware do not match.

Stage	What is Checked	Outcome
	<b>Shift right on a signed integer as arithmetic shift</b> (ProdShiftRightIntArith) setting	Error if settings for model and target hardware do not match.
	<b>Remove root level I/O zero initialization</b> (ZeroExternalMemoryAtStartup) setting	Warning if ZeroExternalMemoryAtStartup is 'off' and initial values of global variables in the target application are not zero.
	<b>Remove internal data zero initialization</b> (ZeroInternalMemoryAtStartup) setting	Warning if ZeroInternalMemoryAtStartup is 'off' and initial values of global variables in the target application are not zero.
	<b>Use dynamic memory allocation for model initialization</b> (GenerateAllocFcn) setting	Warning if GenerateAllocFcn is 'on' and initial values of dynamically allocated memory in the target application are not zero.
	<b>Simulation behavior for denormal numbers</b> (DenormalBehavior) setting	Error if behavior for model and target hardware does not match.

## View SIL and PIL Files in Code Generation Report

With top-model and Model block SIL and PIL simulations, you can produce a code generation report and static code metrics that cover SIL and PIL files. The information helps you to:

- Understand and review the SIL and PIL testing process.
- See how your registered custom target connectivity files fit into the target application that runs during a SIL or PIL simulation.

This capability is not supported for simulations that you run with the PIL block.

To configure the creation of a code generation report and static code metrics, in the Configuration Parameters dialog box, select the **Create code generation report**, **Open report automatically**, and **Generate static code metrics** check boxes. Then click **OK**.

At the end of the simulation, in the Code Generation Report window:

- To review code metrics, in the **Contents** view, click **Static Code Metrics Report**.
- To review SIL and PIL files, in the **Generated Code** view, expand the **SIL/PIL files** node. For example:
  - To review the S-function that runs on the host, click `modelName_sbs.c` or `modelName_pbs.c`.
  - To view the SIL or PIL interface that runs on the target, click `xil_interface.c`.

## SIL/PIL Manager Verification Workflow

The **SIL/PIL Manager** is an app that provides a simplified workflow for verifying generated model code.

### Open the App

To open the SIL/PIL Manager in the Simulink Editor, on the **Apps** tab, click **SIL/PIL Manager**. Or, on the **C Code** tab in the Embedded Coder app, select **Verify Code > SIL/PIL Manager**.

### Select the Mode

In the **Mode** section, specify the simulations that you want the app to run. You can select:

- **Automated Verification** -- The app runs two simulations back-to-back. The first simulation is a model simulation in normal, accelerator, or rapid accelerator mode. The second simulation is a software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulation. After the second simulation is complete, the app uses the Simulation Data Inspector to compare the results of the simulations.

For the first simulation, if the model contains a Model block with the **Simulation mode** block parameter set to **Software-in-the-loop (SIL)** or **Processor-in-the-loop (PIL)**, at the start of the simulation, the app changes the block parameter to **Normal**. At the end of the simulation, the app reverts the block parameter to the previous value.

- **Simulation Only** -- The app runs a model simulation in normal, accelerator, or rapid accelerator mode.

If the model contains a Model block with the **Simulation mode** block parameter set to **Software-in-the-loop (SIL)** or **Processor-in-the-loop (PIL)**, at the start of the simulation, the app changes the block parameter to **Normal**. At the end of the simulation, the app reverts the block parameter to the previous value.

- **SIL/PIL Simulation Only** -- The app runs a SIL or PIL simulation.

### Prepare the Model

In the **Prepare** section:

- Specify the numeric testing approach.
- Specify the main configuration parameters.
- Enable or disable code execution profiling and code coverage analysis.

This table shows how the field settings in the **Prepare** section control simulations that the app runs.

<b>Workflow</b>	<b>Field Settings</b>	<b>Model Simulation</b>	<b>SIL or PIL Simulation</b>
Top model	<p><b>System Under Test</b> — Top model</p> <p><b>Simulation Mode</b> — Normal, Accelerator, or Rapid Accelerator</p> <p><b>SIL/PIL Mode</b> — Software-in-the-Loop (SIL) or Processor-in-the-Loop (PIL)</p>	<p>Top model simulation mode specified by <b>Simulation Mode</b> setting.</p> <p>Model blocks in SIL or PIL mode are set to normal mode.</p>	<p>Top model simulation mode specified by <b>SIL/PIL Mode</b> setting.</p> <p>Model blocks use specified simulation modes.</p>
Model block	<p><b>System Under Test</b> — Model blocks in SIL/PIL mode</p> <p><b>Top Model Mode</b> — Normal or Accelerator</p>	<p>Top model simulation mode specified by <b>Top Model Mode</b> setting.</p> <p>Model blocks in SIL or PIL mode are set to normal mode.</p>	<p>Top model simulation mode specified by <b>Top Model Mode</b> setting.</p> <p>Model blocks use specified simulation modes.</p>
<p>Test harness</p> <p>The app supports test harnesses that you create from models and Model blocks. For information about creating test harnesses, see “Create Test Harnesses and Select Properties” (Simulink Test).</p>	<p><b>System Under Test</b> — Harness owner. Not editable.</p> <p><b>Simulation Mode</b> — Normal, Accelerator, or Rapid Accelerator</p> <p><b>SIL/PIL Mode</b> — Software-in-the-Loop (SIL) or Processor-in-the-Loop (PIL)</p>	<p>Harness model in normal mode.</p> <p>Model block mode for harness owner specified by <b>Simulation Mode</b> setting.</p> <p>Internal Model blocks of harness owner in SIL or PIL mode set to normal mode.</p>	<p>Harness model in normal mode.</p> <p>Model block for harness owner specified by SIL/PIL Mode setting.</p> <p>Internal Model blocks of harness owner use specified simulation modes.</p>

If you click **Settings**, the app provides these controls:

- Under **SIL/PIL Settings**:
  - **Settings** — Display **Verification** parameters in the Configuration Parameters dialog box.
  - **Portable Word Sizes** — Select or clear **Enable portable word sizes**. For information about how you can generate code that supports compilation on your development computer, see “Configure Hardware Implementation Settings” on page 88-18.
  - **SIL Debugging** — Select or clear **Enable source-level debugging for SIL**.
- Under **Coverage**:
  - **Coverage Settings** — Display **Coverage** parameters in the Configuration Parameters dialog box.

- **Coverage Collection** — Enable or disable code coverage. If code coverage with Simulink Coverage is enabled, clicking the button toggles CovEnable between 'on' and 'off'. For more information, see “Code Coverage”.
- Under **Time Profiling**:
  - **Task Profiling** — Select or clear **Measure task execution time**.
  - **Save Options** — If **Task Profiling** is selected, clicking the button sets the **Save options** configuration parameter to **Summary data only**, **All data**, and **Metrics only** cyclically. If **Task Profiling** is not selected, the button is dimmed.
  - **Functions** — Clicking the button sets the **Measure function execution times** configuration parameter to **Off**, **Coarse (referenced models and subsystems only)**, and **Detailed (all function call sites)** cyclically.

For more information, see “Configure Code Execution Profiling” on page 81-2 and “Control Profiling Granularity” on page 81-3.

- Under **Stack Profiling**, **Stack Profiling**— Select or clear **Measure task stack usage**. For more information, see “Stack Usage Profiling for Code Generated from Simulink Models” on page 81-44.

If you click **Monitor Signals**, the app provides these controls:

- Under **Monitor Signals**:
  - **Log Selected Signals** — Enable signal logging for model simulation.
  - **Make Selected Signals Testpoints** — Required for signal observation in SIL or PIL simulations.
- Under **Logging Options**:
  - **Signal Logging** — Set the **SignalLogging** configuration parameter to 'on' or 'off', which enables or disables signal logging to the MATLAB workspace and signal streaming to the Simulation Data Inspector.
  - **State Logging** — Set the **SaveState** configuration parameter to 'on' or 'off', which enables or disables state data logging to the MATLAB workspace and state data streaming to the Simulation Data Inspector.
  - **Signal Table** — Display the **Signals** tab in the Model Data Editor.
  - **Configure Logging** — Display the **Data Import/Export** parameters in the Configuration Parameters dialog box.
  - **Normal Mode Visibility** — Open the Model Block Normal Mode Visibility dialog box.

To monitor component signals and state data and compare values from the model and SIL or PIL simulations:

- 1 For each signal that you want to log:
  - a In the Simulink Editor, select the signal.
  - b On the **SIL/PIL** tab, click **Monitor Signals**. From the gallery, select these options:
    - **Log Selected Signals**
    - **Make Selected Signals Testpoints**
    - **Signal Logging**

- 2 To log state data, from the **Monitor Signals** gallery, select **State Logging**.
- 3 If the **Language** configuration parameter is C++, in the **Code Mappings** editor, set the **Data Visibility** for the signals, states, and internal data model element categories to `public`.

For more information, see “Log Signals of a Component” on page 88-27.

## Run Automated Verification, Model Simulation, or SIL/PIL Simulation

With one click, you can run back-to-back model and SIL or PIL simulations. You can also run individual simulations.

If you select the **Automated Verification** mode, the **SIL/PIL** tab displays the **Run Automated Verification** section. To run back-to-back simulations:

- 1 In the **Stop Time** field, specify the simulation time. For the **Automated Verification** mode, you cannot specify `inf`.
- 2 Click **Run Verification**.

If you select the **Simulation Only** or **SIL/PIL Simulation Only** mode, the **SIL/PIL** tab displays the **Run** section. In this case, the toolstrip provides additional controls:

- **Fast Restart** — Click to turn on fast restart. For the **Simulation Only** mode, the compiled model does not contain components in SIL or PIL mode.
- **Step Back and Step Forward** — You can configure stepping through a simulation by using the Simulation Stepping Options dialog box. To open the dialog box, click **Step Back**, and then select **Configure simulation stepping**.

Simulation stepping is not available if the mode is **SIL/PIL Simulation Only** and **System Under Test** is `Top model`.

To run an individual simulation:

- 1 In the **Stop Time** field, specify the simulation time.
- 2 Click **Run Simulation** or **Run SIL/PIL**.

## Analyze Results and Export Test Cases

In the app **Results** section, you can analyze results. If you click **Compare Runs** or **Data Inspector**, the app provides these controls in the Results gallery.

Section	Control	Description
<b>Numerical Equivalence Results</b>	<b>Compare Runs</b>	<p>Compare results from the last model and SIL/PIL simulations by using the Simulation Data Inspector. Use the comparison to decide whether the results are numerically consistent.</p> <p>If the mode is <b>Automated Verification</b>, at the end of back-to-back simulations, the Simulation Data Inspector compares logged signals from the model and SIL or PIL simulations.</p>

Section	Control	Description
	<b>Data Inspector</b>	Open the Simulation Data Inspector.
<b>Code</b>	<b>Code View</b>	By default, at the end of SIL or PIL simulations, the SIL/PIL Manager displays the Code view, which enables you to: <ul style="list-style-type: none"> <li>Analyze generated code.</li> <li>See code metrics.</li> <li>Trace between model elements and generated code.</li> </ul> If the view is closed and you want to reopen it, click <b>Code View</b> .
<b>Execution Profiling Results</b>	<b>Highlight Profiling</b>	Highlight blocks profiled in the last SIL or PIL simulation.
	<b>Generate Report</b>	Open code execution profiling report for the last SIL or PIL simulation. For more information, see “View and Compare Code Execution Times” on page 81-6.
	<b>Generate Schedule</b>	In the Simulation Data Inspector, show task scheduling for the last SIL or PIL simulation. For more information, see “Visualize Task Scheduling in SIL Simulation”.
<b>Stack Profiling Results</b>	<b>Generate Report</b>	Open stack usage profiling report for the last SIL or PIL simulation. For more information, see “Observe Stack Usage of Generated Code” on page 81-45.
<b>Coverage Analysis Results</b>  (Controls available only if you have a Simulink Coverage license)	<b>Coverage Highlighting</b>	Highlight blocks that are analyzed for coverage and provide summary results.
	<b>Coverage Details</b>	Display the code coverage report in the Simulink Editor.
	<b>Results Explorer</b>	Open Results Explorer. For more information, see “Access, Manage, and Aggregate Coverage Results” (Simulink Coverage).
	<b>Generate Report</b>	Generate the code coverage report in a web browser.

Section	Control	Description
<b>Simulink Test</b>	<b>Export to Test Manager</b>	<p>If you have Simulink Test, using the current app settings, you can create and export an equivalence test case. The test case enables you to run to back-to-back simulations and check whether model components and the generated code are numerically equivalent.</p> <ol style="list-style-type: none"> <li><b>1</b> Click <b>Export to Test Manager</b>.</li> <li><b>2</b> In the Export SIL/PIL Test Cases dialog box: <ol style="list-style-type: none"> <li><b>a</b> Click <b>Use a new test file</b> or <b>Reuse an existing file</b>.</li> <li><b>b</b> In the <b>Test file</b> field, specify the name of the test file. By default, the dialog box specifies: <p style="margin-left: 40px;"><i>currentWorkingFolderPath\modelName_Testfile.mldatx</i></p> <p>If the test file exists and you click <b>Use a new test file</b>, the app overwrites the existing file. If you click <b>Reuse an existing file</b>, the app adds the test case to the existing file.</p> </li> </ol> </li> <li><b>3</b> Click <b>OK</b>. The app creates an equivalence test case in the specified test file.</li> </ol> <p>For information about using exported test cases, see “Import Test Cases for Equivalence Testing” (Simulink Test).</p>

## Security for PIL Simulations

Ensure that access to your development computer and the target hardware is secure.

Provide a secure communication channel between your development computer and the target application by applying the security measures listed in this table.

<b>Communication Protocol</b>	<b>Security Measure</b>
TCP/IP	Run your development computer and target application within a trusted private network or virtual private network (VPN).
Serial	Use a point-to-point link between your development computer and target application, for example, a serial cable.

## SIL and PIL Limitations

### In this section...

"About SIL and PIL Limitations" on page 88-77

"General SIL and PIL Limitations" on page 88-77

"Top-Model SIL/PIL Limitations" on page 88-84

"Model Block SIL/PIL Limitations" on page 88-85

"Subsystem Block SIL/PIL Limitations" on page 88-86

### About SIL and PIL Limitations

With Embedded Coder, you can run software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulations by using:

- The top-model.
- Model blocks.
- Blocks from subsystems.

The following sections describe modeling and code generation features that are either unsupported or partially supported by SIL and PIL simulations.

### General SIL and PIL Limitations

#### Tunable Parameters and SIL/PIL

For Model block SIL/PIL and SIL/PIL block simulations, you can tune tunable *workspace* parameters but not tunable *dialog box* parameters. For information about tuning parameters, see "Tune and Experiment with Block Parameter Values".

For a top model with tunable parameters, you can run a SIL/PIL simulation but you cannot tune the parameters during the simulation.

The software cannot define, initialize, or tune the following types of tunable workspace parameters.

Parameter description	Software response		
	Top-Model SIL/PIL	Model Block SIL/PIL	SIL/PIL Block
Parameters with storage class that applies "static" scope or "const" keyword. For example, Custom, Const, or ConstVolatile	Warning	Warning	Warning
Parameters with multiword, fixed-point data types	Warning	Error	Warning
Parameters with data types that have different sizes on host and target	Warning	Error	Warning

For C++ class code, SIL/PIL you can tune tunable workspace parameters when **Parameter visibility** is public. If **Parameter visibility** is private or protected, tuning is supported only if **Parameter access** is Method or Inlined method.

For top-model SIL/PIL and the SIL/PIL block, consider the case where all of the following conditions apply:

- **Code Generation > Interface > Code interface packaging** is Reusable function.
- **Code Generation > Interface > Use dynamic memory allocation for model initialization** is not selected.
- **Optimization > Default parameter behavior** is Tunable.
- In the Code Mapping Editor for the model, the default storage class for the **Global parameters** or **Local parameters** category is set to Default, and the model contains corresponding parameters that use the storage classes Auto or Model default.

If the SIL/PIL component cannot dynamically initialize tunable parameters in the rtP model parameter structure, you see an error message like the following:

```
Parameter Dialog:InitialOutput in 'SILTopModel/CounterTypeA/count'
is part of the imported "rtP" structure in the generated code but cannot be
initialized by SIL or PIL. To avoid this error, make sure the parameter
corresponds to a tunable workspace variable. Alternatively, set
"Configuration Parameters > Code Generation > Interface > Code interface packaging"
to 'Nonreusable function', or search for 'Use dynamic memory allocation
for model initialization' in the Configuration Parameters dialog box
and select the checkbox.
```

If you select **Code Generation > Interface > Use dynamic memory allocation for model initialization**, this limitation does not apply.

For Model block SIL/PIL, if you specify **Code interface** to be Top model, you can tune parameters while a simulation runs. If you tune parameters between successive runs of the simulation, the software generates new code for the later run. The new code uses your latest settings as initial parameter values.

For top model or Model block SIL/PIL, if you change the value of a MATLAB variable or parameter object (such as Simulink.Parameter) that you store in a workspace, Simulink Coder regenerates the C code.

Model block SIL/PIL does not support test harness data definition, dynamic initialization, or tuning of model workspace parameters.

### Global and Local Data Stores

SIL/PIL supports global data stores. For components that are not export-function models, SIL/PIL block simulations that access global data stores must be single rate. Otherwise, the software produces an error.

SIL/PIL does not support local data stores.

Model block SIL/PIL does not support local Data Store Memory blocks that have these parameter settings:

- **Share across model instances** - Selected.
- **Storage class** - Auto or Model default.

You cannot create SIL/PIL blocks from models that use local Data Store Memory blocks with the **Share across model instances** parameter selected.

### **SIL/PIL Does Not Check Simulink Coder Error Status**

SIL/PIL does not check the Simulink Coder error status of the generated code under test. This error status flags exceptional conditions during execution of the generated code.

Blocks in the model can also set the Simulink Coder error status, for example, custom blocks that you create. SIL/PIL does not check this error status and report errors.

### **Missing Code Interface Description File Errors**

SIL/PIL requires a code interface description file, which is created during code generation for the component under test. If the code interface description file is missing, the SIL/PIL simulation cannot proceed. You see an error reporting that the file does not exist. If you select the unsupported option **Classic call interface**, this error can occur. Therefore, do not select the option.

### **To Workspace Block**

If you enable MAT-file logging, top-model SIL/PIL and SIL/PIL blocks support To Workspace blocks.

Model block SIL/PIL does not support To Workspace blocks.

### **Cannot Connect SIL/PIL Outputs to Merge Block**

If you connect Model block SIL/PIL or SIL/PIL block outputs to a Merge block, you see an error because S-function memory is not reusable.

### **Unsupported Blocks**

SIL/PIL does not support the following blocks:

- Scope blocks, and all types of run-time display. For example, display of port values and signal values.
- Stop blocks. SIL/PIL ignores the Stop Simulation block and continues simulating.

### **Multiword Fixed-Point I/O**

You cannot run SIL and PIL simulations of models that have multiword, fixed-point signals across component boundaries.

### **Fixed-Point Data Types Wider Than 32 Bits**

SIL/PIL supports fixed-point data types that are wider than 32 bits. For example:

- 64-bit long and long long
- 64-bit execution profiling timer data type
- int64 and uint64 in MATLAB Coder SIL execution.

The following constraints apply:

- For 64-bit data type support, the data type must be representable as `long` or `long long` on the MATLAB host *and* the target. Otherwise, the software uses the multiword, fixed-point approach, which SIL/PIL does not support.
- The software does not support the 40-bit `long` data type of the TI's C6000™ target.

Through the **Configuration > Hardware Implementation** pane, you can enable support for the 64-bit `long long` data type. For data types with widths between 33 and 40 bits (inclusive), the software implements the data types using the 40-bit `long` data type, which SIL/PIL does not support.

### Data Type Replacement

For SIL/PIL, the data type replacement name for `boolean` must resolve to `boolean`, `uint8`, or `int8`.

### Simulink.ImageType Data Type

SIL/PIL does not support Simulink Function and Data Store Memory blocks that require the transfer of `Simulink.ImageType` data between Simulink and the target application. At the interface:

- For Simulink Function blocks, the data type of function arguments must not be `Simulink.ImageType`.
- Data Store Memory blocks must not use `Simulink.ImageType` data.

If the Simulink Function and Data Store Memory blocks are not at the interface but inside the target application, the limitation does not apply.

### Continuous Sample Times

Top-model SIL/PIL and SIL/PIL block do not support continuous sample times at the SIL or PIL component boundary. However, they support continuous sample times within the component.

Model block SIL/PIL does not support continuous sample times.

### Variable-Size Signals

Model block SIL/PIL simulations support variable-size signals only if **Diagnostics > Model Referencing > Propagate sizes of variable-size signals** is `During execution`.

Top-model SIL/PIL and SIL/PIL block simulations treat variable-size signals at the I/O boundary of the SIL/PIL component as fixed-size signals, which can lead to errors during propagation of signal sizes. To avoid such errors, use only fixed-size signals at the I/O boundary of the SIL/PIL component.

There can be cases where no error occurs during propagation of signal sizes. In these cases, the software treats variable-size input signals as zero-size signals.

### Internal Signal Logging

SIL/PIL blocks do not support signal logging. For a workaround, see “Log Signals of a Component” on page 88-20.

The following internal signal logging limitations apply to top-model and Model block SIL/PIL simulations.

Limitation	Applies To	
	Top-Model SIL/PIL	Model Block SIL/PIL
Signals feeding merge blocks are not supported for logging in normal simulation but are logged in SIL/PIL mode. The logged values during SIL/PIL are the same as the logged values for the output of the merge block.	Yes	No
Top-model normal simulation logs data at a periodic rate but top-model SIL/PIL simulation logs data at a constant rate under these circumstances: <ul style="list-style-type: none"> <li>• <b>Default parameter behavior</b> is Tunable.</li> <li>• A constant sample time signal from a Model block is logged in the top model.</li> <li>• The logged signal is not directly connected to a root-level output port.</li> </ul> To avoid this behavior and log at the constant rate in all simulation modes, set <b>Default parameter behavior</b> to Inlined.	Yes	No
Features not supported: <ul style="list-style-type: none"> <li>• Signal logging in models referenced by the SIL/PIL component.</li> <li>• Signal logging in Simulink Function block.</li> <li>• Virtual signals.</li> <li>• Virtual buses.</li> <li>• Frame-based signals, which are logged as sample-based signals.</li> <li>• Continuous, asynchronous, and triggered sample times. At the top-level of export-function models, you can log signals with triggered sample times.</li> <li>• Logging of Stateflow states and local data.</li> </ul>	Yes	Yes
Variable-size, function-call, and Action signals are not supported. A normal simulation produces an error. A SIL/PIL simulation produces a warning.	Yes	No
State port signals are not supported. A normal simulation produces an error. A SIL/PIL simulation does not produce a warning.	Yes	No

### Custom Storage Class of Type Other

SIL/PIL simulations support the custom storage class where **Type** is set to **Other** on page 88-7. These limitations apply:

- If the code fragments returned by the TLC file associated with the custom storage class are incomplete, the SIL/PIL application might fail to compile, or produce incorrect results.
- Custom storage classes with **Imported** scope and **Pointer** access are supported, but you must provide code to initialize the pointer. For example, you can modify the response to `DataAccess(record, "define", "", "")` to provide a definition of the storage implementation, and initialize the pointer to the address of the implementation variable.

- To determine whether a variable is `const` and therefore not tunable, the build process for the SIL/PIL application uses the memory section definition in the custom storage class. If the custom storage class defines a variable as `const` and is not associated with a `const` memory section, the target application might fail to compile, or produce an error during the simulation. In this case, associate the custom storage class with a memory section for which `Is const` is specified, for example, `MemConst`. Alternatively, if `SupportSILPIL` is an instance-specific parameter in the custom attributes class, for the associated signal or parameter, set `CoderInfo.CustomAttributes.SupportSILPIL` to `false`.

### Unsupported Implementation Errors

If you use a data store, signal, or parameter implementation that SIL/PIL does not support, you can see errors like the following:

The following *data interfaces* have implementations that are not supported by SIL or PIL.

*data interfaces* can be global data stores, `inports`, `outports`, or parameters.

The model output port has been optimized through virtual output port optimization. See “Virtualized Output Ports Optimization” on page 78-15. The error occurs because the properties (for example, data type, dimensions) of the signal or signals entering the virtual root output port have been modified by routing the signals in one of the following ways:

- Through a Mux block.
- Through a block that changes the signal data type. To check the consistency of data types in the model, display **Port Data Types**.
- Through a block that changes the signal dimensions. To check the consistency of data types in the model, display **Signal Dimensions**.

### Hardware Implementation

PIL does not support multiword data types where the word order differs from the target byte order. The PIL simulation fails, displaying undefined behavior.

PIL requires that you configure the correct **Hardware Implementation** settings for the target environment, including byte ordering for targets. If you do not specify the correct byte ordering, the PIL simulation fails, displaying undefined behavior.

### Bus Elements Mapped to Imported Bit-Field Definitions

If you map Simulink bus elements to bit fields through an imported header file, a SIL or PIL simulation produces a build error. For example, if your model has an `Inport` block connected to a bus that is a `Simulink.Bus` object with these properties:

- **Name** — `myBus`
- **Bus elements** — An array of `Simulink.BusElement` objects with these properties.

Name	Data Type	Complexity	Dimensions
<code>bitField0</code>	<code>boolean</code>	<code>real</code>	<code>1</code>
<code>bitField1</code>	<code>boolean</code>	<code>real</code>	<code>1</code>
<code>bitField2</code>	<code>boolean</code>	<code>real</code>	<code>1</code>

Name	Data Type	Complexity	Dimensions
bitField3	boolean	real	1
bitField4	boolean	real	1
bitField5	boolean	real	1

- **Data scope** — Imported
- **Header file** — `busSpecification.h`. This file contains `myBus`, which defines C bit-field data types for the bus elements.

```
typedef struct myBus
{
 unsigned int bitField0 : 1;
 unsigned int bitField1 : 1;
 unsigned int bitField2 : 1;
 unsigned int bitField3 : 1;
 unsigned int bitField4 : 1;
 unsigned int bitField5 : 1;
} myBus;
```

### Size Mismatch Between Simulink and Target Hardware Data Types

When a Simulink data type and the corresponding target hardware data type differ in size, a SIL or PIL simulation produces an error. This size mismatch can occur if you map a Simulink data type to the target hardware data type through definitions in an imported header file. For example, if you create a data type alias, `T_BOOL`, which is a `Simulink.AliasType` object with these properties:

- **Base type** — `boolean`.
- **Mode** — `Built in`, `boolean`.
- **Data scope** — Imported.
- **Header file** — `myDefinitions.h`. This file defines `T_BOOL` as an enumerated data type:

```
typedef enum _BOOL_TYPE
{
 FALSE = 0,
 TRUE = 1
} BOOL_TYPE;

typedef BOOL_TYPE T_BOOL;
```

In this case, the compiler for the target hardware determines the size of `T_BOOL`, which can differ from the size of the Simulink data type, `boolean`.

### SIL Simulations with Target-Specific Custom Code

Target-specific custom code that is not portable for execution on your development computer can produce compilation or run-time failures during a SIL simulation.

For example, SIL does not support the use of custom code that explicitly casts pointers to integer-type variables that are smaller than the length of a pointer variable on your development computer. Consider using one of these alternatives:

- Run a PIL simulation.

- If you have custom code that casts pointers to a 32-bit integer type, for your development computer, set up a PIL target connectivity configuration that uses a toolchain that is configured to build a 32-bit binary application.

### Sample Time Differences in Simulation Data Inspector Comparisons

If you use the Simulation Data Inspector to compare logged model outputs from normal and SIL or PIL simulations, the sample times of the outputs might differ. You can still use the Simulation Data Inspector to verify that the outputs match numerically.

## Top-Model SIL/PIL Limitations

### Top-Model Root-Level Logging

Top-model SIL/PIL supports signal logging for signals connected to root-level inports and outports. The C API is not required. Root-level logging has the following limitations:

- The characteristics of the logged data such as data type, sample time, and dimensions must match the characteristics of the root-level inports and outports (rather than the characteristics of the connected signal).

In some cases, there can be differences in data type and dimensions between the signal being logged and the root inport or outport that the signal is connected to. Consider the following examples.

- If a signal being logged has matrix dimensions [1x5] but the outport connected to the signal has vector dimensions (5), then the data logged during a SIL or PIL simulation has vector dimensions (5).
- If a signal being logged has scalar dimensions but the outport connected to the signal has matrix dimensions [1x1], then the data logged during a SIL or PIL simulation has matrix dimensions [1x1].
- Signals connected to duplicated inports are not logged during SIL/PIL simulation. No warning is issued.

During normal simulation, signals connected directly to duplicated inports are logged.

- The Signal Logging Selector / `DataLoggingOverride` override mechanism is not supported.
- Normal and SIL/PIL simulations log bus signals with names that are different when all of the following conditions apply:
  - The `SaveOutput` or `SignalLogging` configuration parameter is on.
  - The names of the elements in the bus signal are different from the corresponding names in the bus object. For example, when the `InheritFromInputs` parameter for a Bus Creator block is set to 'on'.
- The software inserts the suffix `_wrapper` for *output logging* if the save format is `Structure` or `Structure with time` and you run the `sim` command without specifying the single-output format. The software adds `_wrapper` to the block name for signals in `yout`. If the save format is `Array`, the software does not add the suffix. For example:

```
>> yout.signals
ans =
 values: [11x1 double]
```

```

dimensions: 1
 label: 'SignalLogging'
 blockName: 'sillogging_wrapper/OutputLogging'

```

To avoid this behavior, run command-line simulations with the `sim` command specifying the single-output format. See “Run Simulations Programmatically”.

### Callback Support

SIL/PIL does not support the callbacks (model or block) `StartFcn` and `StopFcn`.

---

**Note** Top-model SIL/PIL supports the callback `InitFcn`.

---

### Incremental Build

When you start a top-model SIL/PIL simulation, the software regenerates code if it detects changes to your model. The software detects changes by using a checksum for the model. The software does not detect changes that you make to:

- The `HeaderFile` property of a `Simulink.AliasType` object
- Legacy S-functions

If you make these changes, build (**Ctrl-B**) your model again before starting the next PIL simulation.

## Model Block SIL/PIL Limitations

### Top-Model Code Testing

The following limitations apply:

- Because model arguments do not apply to a top model, when the **Code interface** block parameter is set to `Top model`, the software does not support the **Model arguments** block parameter.
- Conditional execution does not apply to a top model. If a Model block is set up to execute conditionally and the **Code interface** block parameter is set to `'Top model'`, the software produces an error when you run a SIL or PIL simulation.
- For sample time independent models, you must set **Configuration Parameters > Solver > Periodic sample time constraint** to Ensure sample time independent.

### Conditionally Executed Subsystem

You see an error if:

- You place your Model block, in either SIL or PIL simulation mode, in a conditionally executed subsystem and the referenced model is multirate (that is, has multiple sample times). Single-rate, referenced models (with only a single sample time) are not affected.
- Your Model block, in either SIL or PIL simulation mode, has blocks that depend on absolute time **and** is conditionally executed.

### Outputs with Constant Sample Time

If the block parameter **Code interface** is `Top model`, Model block SIL/PIL supports outputs with constant sample time.

### Noninlined S-Functions

Model-block SIL/PIL simulations do not support noninlined S-functions.

### Referenced Models That Use Same Target Connectivity Configuration

Consider a top model with two or more Model blocks that reference models that use the same target connectivity configuration. If the Model blocks are in PIL mode simultaneously, you cannot run a simulation of the top model. An error occurs.

### SIL and PIL Instances of a Referenced Model

Consider a top model that contains two instances of a Model block that reference the same model. If one instance is in SIL mode and the other instance is in PIL mode, you cannot run a simulation of the top model. An error occurs.

## Subsystem Block SIL/PIL Limitations

### Atomic Subsystem Workflow Limitations

The workflow described in “Unit Test Subsystem Code with SIL/PIL Manager” on page 88-31 does not support:

- These subsystem types:
  - Virtual
  - Function-call
  - Stateflow
  - For Each
  - Action
  - Initialize Function
  - Reset Function
  - Terminate Function
  - Simulink Function
- The 'Compact' option for ERTFilePackagingFormat if PreserveStaticInFcnDecl is set to 'on'.
- Subsystems that generate in-lined code. The subsystem block parameter RTWSystemCode must be 'Nonreusable function' or 'Reusable function'.
- Subsystems that contain:
  - Referenced models.
  - Simulink Function blocks.
  - Data Store Memory, Data Store Read, and Data Store Write blocks.
- The LDRA tool suite and the BullseyeCoverage tool for code coverage analysis.
- Virtual buses at the subsystem interface.

The results from model and SIL or PIL simulations might differ numerically if:

- The subsystem uses non-finite numbers, for example, NaN and Inf.
- The subsystem and the parent model have multiple sample rates and rate transitions.
- A lookup table block in the subsystem is connected to a Prelookup block across the subsystem boundary.

### **Variant Condition Propagation with Variant Source and Variant Sink Blocks**

SIL/PIL block simulations do not support the propagation of variant conditions across component boundaries.

### **PIL Block Mux**

The PIL block supports mux signals, except mixed data-type mux signals that expand into individual signals during a right-click subsystem build.

### **Code Coverage**

SIL block simulations do not support the generation of code coverage results. PIL block support for code coverage depends on your target connectivity configuration and third-party product support.

### **Subsystem with Inherited Sample Time Blocks**

When you create a SIL/PIL block from a subsystem that has blocks with inherited sample times, the generated code and SIL/PIL wrapper acquire the sample time of the original parent model. If you use the SIL/PIL block in a context that does not allow explicit sample times, for example, within a triggered subsystem, you see an error.

Try one of these workarounds:

- Before you create the SIL/PIL block, in the parent model, set **Configuration Parameters > Solver > Periodic sample time constraint** to Ensure sample time independent.
- Using the subsystem, create a Model block that is independent of sample time. With this block, run Model block SIL/PIL simulations.

- “Choose a SIL or PIL Approach” on page 88-11

## Test Generated Code with SIL and PIL Simulations

Test numerical equivalence between model components and production code that you generate from the components by using software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulations.

With a SIL simulation, you test source code on your development computer. With a PIL simulation, you test the compiled object code that you intend to deploy in production by running the object code on real target hardware or an instruction set simulator. To determine whether model components and generated code are numerically equivalent, compare SIL and PIL results against normal mode results.

There are three ways of running SIL and PIL simulations. You can use the top model, Model blocks, or SIL and PIL blocks that you create from a subsystem. See “Choose a SIL or PIL Approach” on page 88-11.

### Target Connectivity Configuration for PIL

Before you can run PIL simulations, you must configure target connectivity. The target connectivity configuration enables the PIL simulation to:

- Build the target application.
- Download, start, and stop the application on the target.
- Support communication between Simulink and the target.

To produce a target connectivity configuration, you can use the supplied target connectivity API. For details, see “Create PIL Target Connectivity Configuration for Simulink” on page 88-38.

For supported hardware, you can use target support packages. For details, see “Embedded Coder Supported Hardware”.

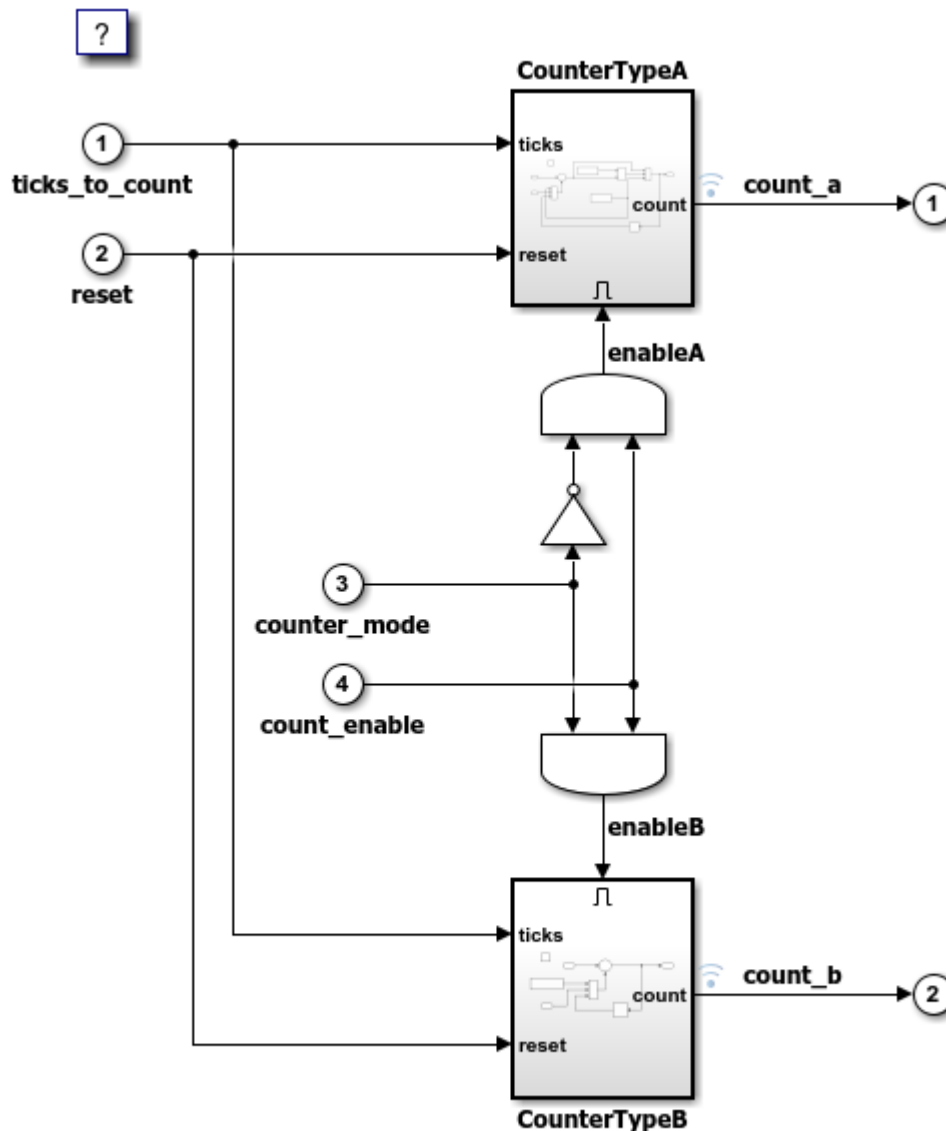

### SIL or PIL Simulation with a Top Model

Test generated model code by running a top-model SIL or PIL simulation. With this approach:

- You test code generated from the top model, which uses the standalone code interface.
- You configure the model to load test vectors or stimulus inputs from the MATLAB workspace.
- You can easily switch the top model between the normal, SIL, and PIL simulation modes.

Open a simple counter top model.

```
model='SILTopModel';
close_system(model,0)
open_system(model)
```

Copyright 1994-2021 The MathWorks, Inc.

To focus on numerical equivalence testing, turn off:

- Model coverage
- Code coverage
- Execution time profiling

```
set_param(gcs, 'RecordCoverage', 'off');
coverageSettings = get_param(model, 'CodeCoverageSettings');
coverageSettings.CoverageTool='None';
set_param(model, 'CodeCoverageSettings', coverageSettings);
set_param(model, 'CodeExecutionProfiling', 'off');
```

Configure the input stimulus data.

```
[ticks_to_count, reset, counter_mode, count_enable] = ...
 SILTopModelData(T);
```

Configure logging options in the model.

```
set_param(model, 'LoadExternalInput', 'on');
set_param(model, 'ExternalInput', 'ticks_to_count, reset, counter_mode, count_enable');
set_param(model, 'SignalLogging', 'on');
set_param(model, 'SignalLoggingName', 'logsOut');
set_param(model, 'SaveOutput', 'on')
```

Run a normal mode simulation.

```
set_param(model, 'SimulationMode', 'normal')
sim_output = sim(model, 10);
yout_normal = [sim_output.yout.signals(1).values sim_output.yout.signals(2).values];
```

Run a top-model SIL simulation.

```
set_param(model, 'SimulationMode', 'Software-in-the-Loop (SIL)')
sim_output = sim(model, 10);
yout_sil = [sim_output.yout.signals(1).values sim_output.yout.signals(2).values];
```

```
Starting build procedure for: SILTopModel
Successful completion of build procedure for: SILTopModel
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
SILTopModel	Code generated and compiled.	Code generation information file does not exist.

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 22.224s
Preparing to start SIL simulation ...
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Updating code generation report with SIL files ...
Starting SIL simulation for component: SILTopModel
Application stopped
Stopping SIL simulation for component: SILTopModel
```

Unless up-to-date code for this model exists, new code is generated and compiled. The generated code runs as a separate process on your computer.

Plot and compare the results of the normal and SIL simulations. Observe that the results match.

```
fig1 = figure;
subplot(3,1,1), plot(yout_normal), title('Counter Output for Normal Simulation')
subplot(3,1,2), plot(yout_sil), title('Counter Output for SIL Simulation')
subplot(3,1,3), plot(yout_normal-yout_sil), ...
 title('Difference Between Normal and SIL');
```

Clean up.

```
close_system(model,0);
if ishandle(fig1), close(fig1), end
clear fig1
simResults = {'yout_sil','yout_normal','model','T',...
 'ticks_to_count','reset'};
save([model '_results'],simResults{:});
clear(simResults{:},'simResults')
```

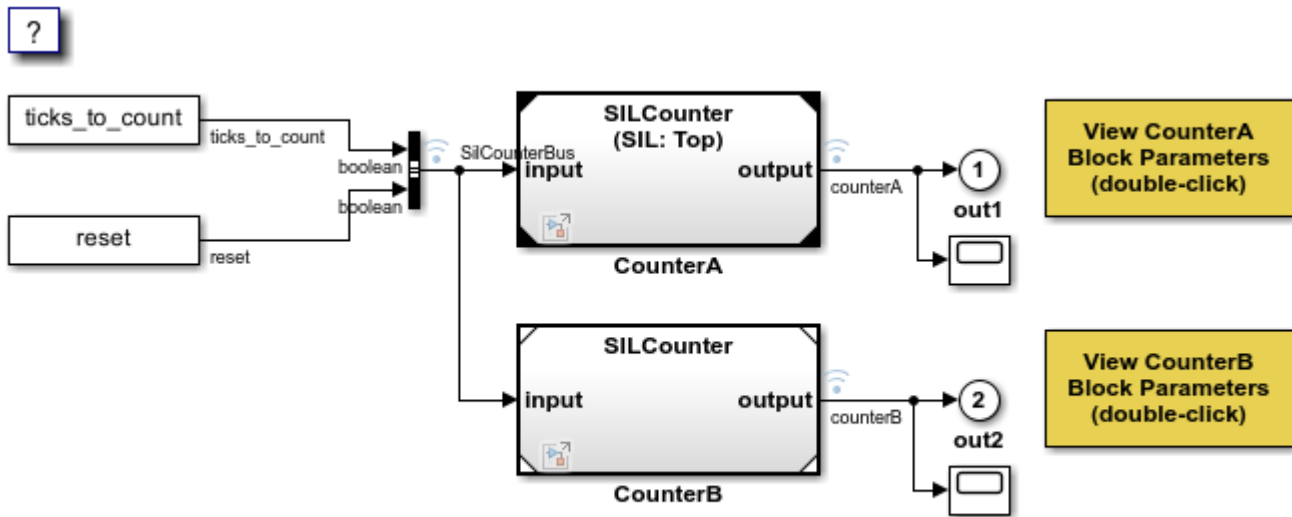

### SIL or PIL Simulation with a Model Block

Test generated model code by using a test harness model that runs a Model block in SIL mode. With this approach:

- You can test code that is generated from a top model or a referenced model. The code from the top model uses the standalone code interface. The code from the referenced model uses the model reference code interface. For more information, see “Code Interfaces for SIL and PIL” on page 88-4.
- You use a test harness model or a system model to provide test vector or stimulus inputs.
- You can easily switch a Model block between the normal, SIL, and PIL simulation modes.

Open an example model that has two Model blocks which reference the same model. In a simulation, you run one Model block in SIL mode and the other Model block in normal mode.

```
model='SILModelBlock';
open_system(model);
```

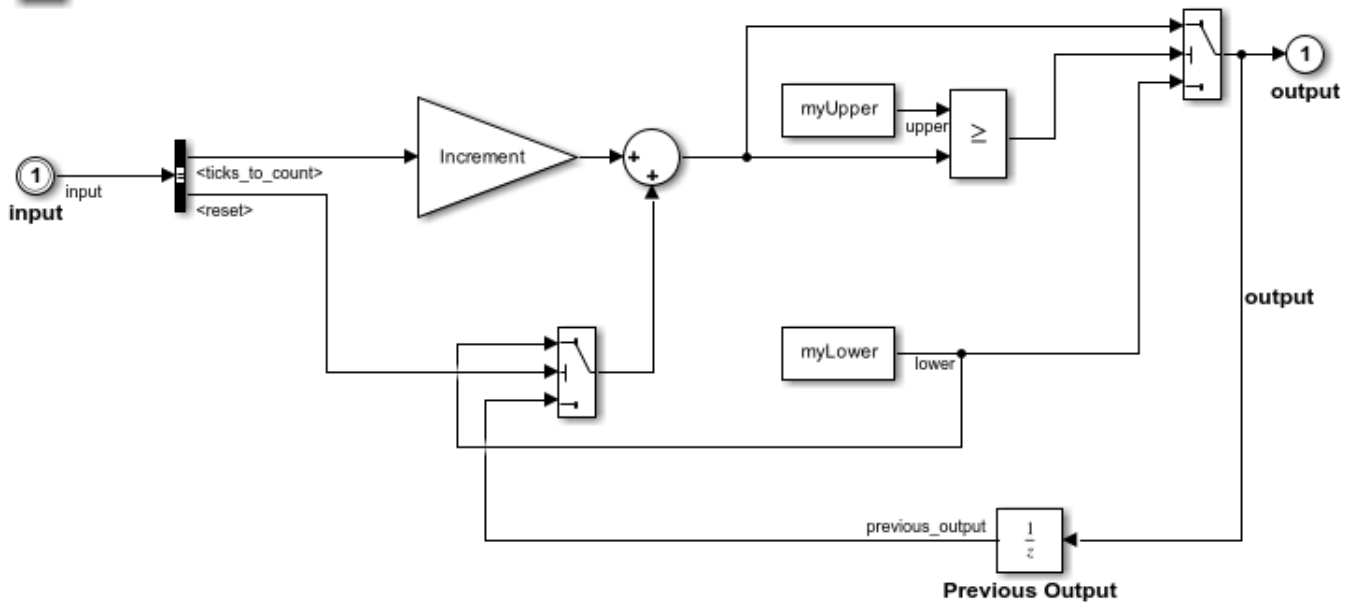

Copyright 2008-2020 The MathWorks, Inc.

Turn off:

- Code coverage
- Execution time profiling

```
coverageSettings = get_param(model, 'CodeCoverageSettings');
coverageSettings.CoverageTool='None';
set_param(model, 'CodeCoverageSettings',coverageSettings);
open_system('SILModelBlock')
set_param('SILModelBlock', 'CodeExecutionProfiling','off');
open_system('SILCounter')
set_param('SILCounter', 'CodeExecutionProfiling','off');
currentFolder=pwd;
save_system('SILCounter', fullfile(currentFolder,'SILCounter.slx'))
```

Copyright 1994-2020 The MathWorks, Inc.

Configure state logging for the models.

```
set_param('SILCounter', 'SaveFormat', 'Dataset');
save_system('SILCounter', fullfile(currentFolder, 'SILCounter.slx'))
set_param(model, 'SaveFormat', 'Dataset');
set_param(model, 'SaveState', 'on');
set_param(model, 'StateSaveName', 'xout');
```

### Test Top-Model Code

For the Model block in SIL mode, specify generation of top-model code, which uses the standalone code interface.

```
set_param([model '/CounterA'], 'CodeInterface', 'Top model');
```

Run a simulation of the test harness model.

```
out = sim(model, 20);
```

```
Starting build procedure for: SILCounter
Successful completion of build procedure for: SILCounter
```

Build Summary

 plot(xout_normal), title('State Logging for Model Block SIL (Top-Model) Simulation')
subplot(3,1,3), plot(xout_normal-xout_sil), ...
 title('Difference Between Normal and SIL');

```

### Test Model Reference Code

For the Model block in SIL mode, specify generation of referenced model code, which uses the model reference code interface.

```
set_param([model '/CounterA'], 'CodeInterface', 'Model reference');
```

Run a simulation of the test harness model.

```
out2 = sim(model,20);
```

```

Starting serial model reference code generation build.
Starting build procedure for: SILCounter
Successful completion of build procedure for: SILCounter

```

Build Summary

save([model '_results'],simResults{:});
clear(simResults{:},'simResults')
```

### SIL or PIL Block Simulation

Test generated subsystem code by using a SIL or PIL block in a simulation. With this approach:

- You test code generated from subsystems, which uses the standalone code interface.

- You provide a test harness or a system model to supply test vector or stimulus inputs.
- You replace your original subsystem with the generated SIL or PIL block.

Open a simple model, which consists of a control algorithm and a plant model in a closed loop. The control algorithm regulates the output from the plant.

```
model='SILBlock';
close_system(model,0)
open_system(model)
```

Copyright 2004-2020 The MathWorks, Inc.

Run a normal mode simulation

```
out = sim(model,10);
yout_normal = out.yout;
clear out
```

Configure the build process to create the SIL block for testing.

```
set_param(model, 'CreateSILPILBlock', 'SIL');
```

To test the behavior on production hardware, specify a PIL block.

To create the SIL block, generate code for the control algorithm subsystem. You see the SIL block at the end of the build process. Its input and output ports match those of the control algorithm subsystem.

```
close_system('untitled',0);
slbuild([model '/Controller'])

Starting build procedure for: Controller
Successful completion of build procedure for: Controller
Creating SIL block ...
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
Controller	Code generated and compiled.	Code generation information file does not exist.

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 46.817s

Alternatively, you can right-click the subsystem and select C/C++ Code > Build This Subsystem. In the dialog box that opens, click Build.

To perform a SIL simulation of the controller and plant model in a closed loop, replace the original control algorithm with the new SIL block. To avoid losing your original subsystem, do not save your model in this state.

```
controllerBlock = [model '/Controller'];
blockPosition = get_param(controllerBlock, 'Position');
delete_block(controllerBlock);
add_block('untitled/Controller', [controllerBlock '(SIL)', ...
 'Position', blockPosition);
close_system('untitled', 0);
clear controllerBlock blockPosition
```

Run the SIL simulation.

```
out = sim(model, 10);

Preparing to start SIL block simulation: <a href="matlab: targets_hyperlink_manager('run',2)
Starting SIL simulation for component: SILBlock
Application stopped
Stopping SIL simulation for component: SILBlock
```

The control algorithm uses single-precision, floating-point arithmetic. You can expect the order of magnitude for differences between SIL and normal simulations to be close to the machine precision for single-precision data.

Define an error tolerance for SIL simulation results that is based on the machine precision for the single-precision, normal simulation results.

```
machine_precision = eps(single(yout_normal));
tolerance = 4 * machine_precision;
```

Compare normal and SIL simulation results. In the third plot, the differences between the simulations lie well within the defined error tolerance.

```
yout_sil = out.yout;
tout = out.tout;
fig1 = figure;
subplot(3,1,1), plot(yout_normal), title('Controller Output for Normal Simulation')
subplot(3,1,2), plot(yout_sil), title('Controller Output for SIL Simulation')
```

```
subplot(3,1,3), plot(tout,abs(yout_normal-yout_sil),'g-'), tout,tolerance,'r-'), ...
 title('Normal and SIL Difference and Error Tolerance');
```

Clean up.

```
close_system(model,0);
if ishandle(fig1), close(fig1), end
clear fig1
simResults={'out','yout_sil','yout_normal','tout','machine_precision'};
save([model '_results'],simResults{:});
clear(simResults{:},'simResults')
```

### Hardware Implementation Settings

When you run a SIL simulation, you must configure your hardware implementation settings (characteristics such as native word sizes) to allow compilation for your development computer. These settings can differ from the hardware implementation settings that you use when building the model for your production hardware. To avoid the need to change hardware implementation settings

between SIL and PIL simulations, enable portable word sizes. For more information, see “Configure Hardware Implementation Settings” on page 88-18.

## Create a Target Communication Channel for Processor-in-the-Loop (PIL) Simulation

Implement a communication channel for processor-in-the-loop (PIL) simulation.

The communication channel enables exchange of data between different processes. The communication channel supports capabilities that require the exchange of data between the Simulink® software environment that runs on your development computer (host) and deployed code that runs on target hardware. For example, a PIL simulation.

You learn about the `rtiostream` interface and how it provides a generic communication channel that you can implement in the form of target connectivity drivers for different connection types. This example describes how to use the default TCP/IP implementation.

Two entities, Station A and Station B, use the `rtiostream` interface to set up a communication channel and exchange data. For this example, Station A and Station B are configured within the same process on your desktop computer.

The target connectivity drivers support an on-target PIL simulation. In the simulation, Station A and Station B represent the target and host computers that exchange data via the communication channel. On the host side, the target connectivity driver is implemented as a shared library that is loaded and called from within the MATLAB® product. On the target side, the driver is source code or a library that is linked to the application that runs on the target.

Additionally, you can:

- Configure your own target-side driver for TCP/IP to operate with the default host-side TCP/IP driver.
- Configure the supplied host-side driver for serial communications.
- Implement custom target connectivity drivers, for example, by using CAN or USB for host and target sides of the communication channel.

See also “Test Generated Code with SIL and PIL Simulations” on page 88-88 and “Configure Processor-In-The-Loop (PIL) for a Custom Target” on page 88-107.

### View Source Code for the Default TCP/IP Implementation

The file `rtiostream_tcpip.c` implements client-side and server-side TCP/IP communication. A startup parameter configures the driver to operate in either client or server mode. You can use this source file as a starting point for a custom implementation. Each side of the communication channel requires only one or the other of the server or client implementations. If the client and server drivers run on different architectures, consider placing the driver code for each architecture in a separate source file.

The header file `rtiostream.h` contains prototypes for the functions `rtIOStreamOpen/Send/Recv/Close`. Include it (using `#include`) for custom implementations.

Extract the location of TCP/IP driver source code.

```
rtiostream_src_dir=fullfile(matlabroot,'toolbox','coder','rtiostream','src');
tcpip_dir=fullfile(rtiostream_src_dir,'rtiostreamtcpip');
```

View `rtiostream_tcpip.c`.

```
edit(fullfile(tcpip_dir, 'rtiostream_tcpip.c'));
```

View `rtiostream.h`.

```
edit(fullfile(rtiostream_src_dir, 'rtiostream.h'));
```

### Location of Shared Library Files

To access the target connectivity drivers from the MATLAB product, you must compile them to a shared library. The shared library must be located on your system path. A shared library for the default TCP/IP drivers is located in `matlabroot/bin/$ARCH` (`$ARCH` is your system architecture, for example, `win64`).

The shared library filename extension and location depends on your operating system.

```
[~, ~, sharedLibExt] = coder.BuildConfig.getStdLibInfo;
```

Identify the shared library for Station A and Station B.

```
libTcpip = ['libmwrrtiostreamtcpip' sharedLibExt];
disp(libTcpip)
```

```
libmwrrtiostreamtcpip.dll
```

### Test the Target Connectivity Drivers

If you are implementing a custom target connectivity driver, it is helpful to test it from within the MATLAB product. The following example shows how to load the default TCP/IP target connectivity drivers and use them for data exchange between Station A and Station B.

To access the drivers, you can use the MEX-file `rtiostream_wrapper`. With this MEX-file, you can load the shared library and access the `rtiostream` functions to open and close an `rtiostream` channel, and send and receive data.

Station A and Station B run on the host computer. Station A is configured as a TCP/IP server and Station B as a TCP/IP client. For host to target communication, you typically configure the host as a TCP/IP client and the target as a TCP/IP server.

Choose a port number for TCP.

```
if usejava('jvm')
 % Find a free port
 tempSocket = java.net.ServerSocket(0);
 port = num2str(tempSocket.getLocalPort);
 tempSocket.close;
else
 % Use a hard-coded port
 port = '14646';
end
```

Open the Station A `rtiostream` as a TCP/IP server.

```
stationA = rtiostream_wrapper(libTcpip, 'open', ...
 '-client', '0', ...
 '-blocking', '0', ...
 '-port', port);
```

If the communication channel opens, the return value is a handle to the connection. A return value of -1 indicates an error.

Check the return value.

```
assert(stationA!=-1)
```

Open the Station B rtiostream as a TCP/IP client.

```
stationB = rtiostream_wrapper(libTcpi, 'open', ...
 '-client', '1', ...
 '-blocking', '0', ...
 '-port', port, ...
 '-hostname', 'localhost');
```

If the communication channel opens, the return value is a handle to the connection. A return value of -1 indicates an error.

Check the return value.

```
assert(stationB!=-1)
```

### Send Data from Station B to Station A

The target connectivity drivers send a stream of data in 8-bit bytes. For processors that are not byte-addressable, the data is sent in the smallest addressable word size.

Send message data from Station B to Station A.

```
msgOut = uint8('Station A, this is Station B. Are you there? OVER');
```

```
[retVal, sizeSent] = rtiostream_wrapper(libTcpi, ...
 'send', ...
 stationB, ...
 msgOut, ...
 length(msgOut));
```

A return value of zero indicates success.

```
assert(retVal==0);
```

Make sure that bytes in the message were sent.

```
assert(sizeSent==length(msgOut));
```

Allow time for data transmission to be completed.

```
pause(0.2)
```

Receive data in Station A.

```
[retVal, msgRecvd, sizeRecvd] = rtiostream_wrapper(libTcpi, ...
 'recv', ...
 stationA, ...
 100);
```

A return value of zero indicates success.

```
assert(retVal==0);
```

Make sure that bytes in the message were received.

```
assert(sizeRecvd==sizeSent);
```

Display the received data.

```
disp(char(msgRecvd))
```

```
Station A, this is Station B. Are you there? OVER
```

### Send a Response from Station A to Station B

Send response data from Station A to Station B.

```
msgOut = uint8('Station B, this is Station A. Yes, I'm here! OVER. ');
[~, sizeSent] = rtiostream_wrapper(libTcpi, ... %#ok
 'send', ...
 stationA, ...
 msgOut, ...
 length(msgOut));
```

Allow time for data transmission to be completed.

```
pause(0.2)
```

Receive data in Station B.

```
[~, msgRecvd, sizeRecvd] = rtiostream_wrapper(libTcpi, ... %#ok
 'recv', ...
 stationB, ...
 100);
```

Display the received data.

```
disp(char(msgRecvd))
```

```
Station B, this is Station A. Yes, I'm here! OVER.
```

### Close Connection and Unload Shared Libraries

Close rtiostream on Station B.

```
retVal = rtiostream_wrapper(libTcpi, 'close', stationB);
```

A return value of zero indicates success.

```
assert(retVal==0);
```

Close rtiostream on Station A.

```
retVal = rtiostream_wrapper(libTcpi, 'close', stationA);
```

A return value of zero indicates success.

```
assert(retVal==0)
```

Unload the shared library.

```
rtiostream_wrapper(libTcpi, 'unloadlibrary');
```

## Host-Side Driver for Serial Communications

You can use the supplied host-side driver for serial communications as an alternative to the drivers for TCP/IP. To configure the serial driver, see `rtiostream_wrapper` in the Embedded Coder® reference documentation.

## Configure Your Own Target-Side Driver

If your target has an Ethernet connection and you have a TCP/IP stack available, follow these steps:

- 1 Write a wrapper for your TCP/IP stack that makes it available via the `rtiostream` interface defined in `rtiostream.h`.
- 2 Write a test application for your target that sends and receives some data.
- 3 Use the `rtiostream_wrapper` MEX-file and host-side TCP/IP driver to test your driver software that is running on the target.
- 4 When you have a working target-side driver, include the driver source files in the build for your automatically generated code.

You can configure your target-side driver to operate only as a TCP/IP server because the default host-side driver for PIL is configured as a TCP/IP client.

If you need to use a communications channel that is not already supported on the host-side, write drivers for host and target. In this case, you can still use the `rtiostream_wrapper` MEX-file for testing your `rtiostream` drivers.

## Configure Your Own Host-Side Driver

You can implement the target connectivity drivers by using different communication channels. For example, you can implement host-target communications via a special serial connection, which requires that you provide drivers for the host and target.

On the host side, you can test the drivers by using the `rtiostream_wrapper` MEX-file. If your driver includes diagnostic output from `printf` statements and `rtiostream_wrapper` loads the shared library, you must replace the `printf` statements with `mexPrintf` statements.

When you have a working host-side device driver, you must make it available within the Simulink software environment. For PIL simulation, register the shared host-side shared library via `sl_customization`.

## Configure Processor-In-The-Loop (PIL) for a Custom Target

Create a target connectivity configuration by using target connectivity APIs. With a target connectivity configuration, you can run processor-in-the-loop (PIL) simulations on custom embedded hardware.

You learn how to:

- Adapt the build process to support PIL simulations.
- Configure a tool for downloading and starting execution of a PIL executable on your target hardware.
- Configure a communication channel between host and target to support PIL simulation on the target hardware.

Start with a model configured for software-in-the-loop (SIL) simulation. This example guides you through the process of creating a target connectivity configuration so that you can simulate the model in PIL mode. The example runs entirely on your development computer. You can use the same steps to create a connectivity configuration for your own embedded target hardware.

See also “Test Generated Code with SIL and PIL Simulations” on page 88-88 and “Create a Target Communication Channel for Processor-in-the-Loop (PIL) Simulation” on page 88-102.

### Preliminaries

Later in this example, you will add a folder to the search path. Create the folder path.

```
sl_customization_path = pwd;
```

If this folder is already on the search path, remove it.

```
if contains(path,sl_customization_path)
 rmpath(sl_customization_path)
end
```

Reset customizations.

```
sl_refresh_customizations
```

### Test Generated Code with SIL Simulation

Simulate a model configured for SIL. Verify the generated code compiled for your development computer by comparing the SIL simulation behavior with the normal simulation behavior.

Make sure that the example model is newly opened.

```
close_system('SILModelBlock',0);
close_system('SILCounter',0)
open_system('SILModelBlock')
```

The CounterA Model block displays the text (SIL), which indicates that its referenced model is configured for SIL simulation.

Run a simulation of the system.

```
set_param('SILModelBlock','StopTime','10');
sim('SILModelBlock');

Starting build procedure for: SILCounter
Successful completion of build procedure for: SILCounter
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
SILCounter	Code generated and compiled.	Code generation information file does not exist.

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 17.772s
Preparing to start SIL simulation ...
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Updating code generation report with SIL files ...
Starting SIL simulation for component: SILCounter
Application stopped
Stopping SIL simulation for component: SILCounter
```

### Target Connectivity Configuration

Start work on a target connectivity configuration for PIL.

Make a local copy of the target connectivity configuration classes.

```
src_dir = ...
 fullfile(matlabroot,'toolbox','coder','simulinkcoder','+coder','+mypil');
if exist(fullfile('.','+mypil'),'dir')
 rmdir('+mypil','s')
end
mkdir +mypil
copyfile(fullfile(src_dir,'Launcher.m'), '+mypil');
copyfile(fullfile(src_dir,'TargetApplicationFramework.m'), '+mypil');
copyfile(fullfile(src_dir,'ConnectivityConfig.m'), '+mypil');
```

Make the copied files writable.

```
fileattrib(fullfile('+mypil','*'),'w');
```

Update the package name to reflect the new location of the files.

```
coder.mypil.Utils.UpdateClassName(...
 './+mypil/ConnectivityConfig.m',...
 'coder.mypil',...
 'mypil');
```

Verify that you now have a folder +mypil in the current folder, which has the files Launcher.m, TargetApplicationFramework.m, and ConnectivityConfig.m.

```
dir './+mypil'

. Launcher.m
.. TargetApplicationFramework.m
ConnectivityConfig.m
```

## Review Code to Launch the PIL Executable

The class that configures a tool for launching the PIL executable is `mypil.Launcher`. Open this class in the editor.

```
edit(which('mypil.Launcher'))
```

Review the content of this file. The method `setArgString` supplies additional command-line parameters to the executable. These parameters can include a TCP/IP port number. For an embedded processor implementation, you can choose to hard-code these settings.

## Configure the Overall Target Connectivity Configuration

View the class `mypil.ConnectivityConfig`.

```
edit(which('mypil.ConnectivityConfig'))
```

Review the content of this file. You should be able to identify:

- The creation of an instance of `rtw.connectivity.RtIOStreamHostCommunicator` that configures the host side of the TCP/IP communications channel.
- A call to the `setArgString` method of `Launcher` that configures the target side of the TCP/IP communications channel.
- A call to `setTimer` that configures a timer for execution time measurement

To define your own target-specific timer for execution time profiling, you must use the Code Replacement Library to specify a replacement for the function `code_profile_read_timer`. Use a command-line API or the `crtool` user interface.

## Review the Target-Side Communications Drivers

View the file `rtiostream_tcpip.c`.

```
rtiostreamtcpip_dir=fullfile(matlabroot,'toolbox','coder','rtiostream','src',...
 'rtiostreamtcpip');
edit(fullfile(rtiostreamtcpip_dir,'rtiostream_tcpip.c'))
```

Scroll down to the end of this file. See that this file contains a TCP/IP implementation of the functions `rtIOStreamOpen`, `rtIOStreamSend`, and `rtIOStreamRecv`. These functions are required for the target hardware to communicate with your development computer. You must provide an implementation for each of these functions that is specific to your target hardware and communication channel.

## Add Target-Side Communications Drivers to the Connectivity Configuration

The class that configures additional files to include in the build is `mypil.TargetApplicationFramework`. Open this class in the editor.

```
edit(which('mypil.TargetApplicationFramework'))
```

## Use `sl_customization` to Register the Target Connectivity Configuration

To use the new target connectivity configuration, you must provide an `sl_customization` file. The `sl_customization` file registers your new target connectivity configuration and specifies the required conditions for its use. The conditions specified in this file can include the name of your system target file and your hardware implementation settings.

You can view the `sl_customization` file. For this example, you do not have to make changes to the file.

```
edit(fullfile(sl_customization_path, 'sl_customization.m'))
```

Add the `sl_customization` folder to the search path and refresh the customizations.

```
addpath(sl_customization_path);
sl_refresh_customizations;
```

### Test Generated Code with PIL Simulation

Run the PIL simulation.

```
close_system('SILModelBlock',0)
open_system('SILModelBlock')
set_param('SILModelBlock/CounterA','SimulationMode','processor-in-the-loop (pil)');
set_param('SILModelBlock','StopTime','10');
sim('SILModelBlock');
```

```
Starting build procedure for: SILCounter
Generated code for 'SILCounter' is up to date because no structural, parameter or code replac
Successful completion of build procedure for: SILCounter
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
SILCounter	Code compiled.	Compilation artifacts were out of date.

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 4.9121s
Connectivity configuration for component "SILCounter": My PIL Example
EXECUTING METHOD SETARGSTRING
SETARGSTRING called from line 65 of ConnectivityConfig.m
Preparing to start PIL simulation ...
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Updating code generation report with PIL files ...
Starting application: 'SILCounter_ert_rtw\pil\SILCounter.exe'
Starting PIL simulation
Started new process, pid = 52708
Stopping PIL simulation
Terminated process, pid = 52708
```

Review the preceding messages. Confirm that the simulation ran without errors. You have now implemented a target connectivity configuration for PIL. You can use the same APIs to implement a connectivity configuration for your own combination of embedded processor, download tool, and communications channel.

### Cleanup

Remove the search path for this example.

```
rmpath(sl_customization_path)
```

Reset customizations.

```
sl_refresh_customizations
```

Close the models.

```
close_system('SILModelBlock',0)
close_system('SILCounter',0)
```

## Field-Oriented Control of Permanent Magnet Synchronous Machine

This example shows the basic workflow and key APIs for generating C code from a motor control algorithm, and for verifying its compiled behavior and execution time. You will use processor-in-the-loop (PIL) simulation to gain confidence that the C code will perform as expected when you integrate it with embedded software that interfaces with the motor hardware. Although this workflow uses a motor control application for a specific processor, you can apply this workflow to virtually any application or processor.

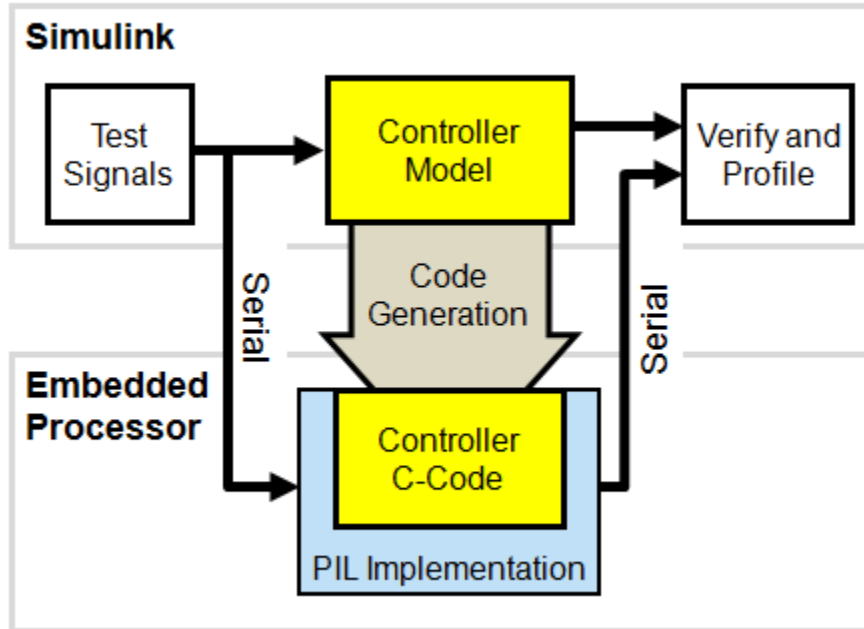

We use a Field-Oriented Control algorithm for a Permanent Magnet Synchronous Machine to show this workflow. This control technique is common in motor drive systems for hybrid electric vehicles, manufacturing machinery, and industrial automation.

### Overview

In this example, generate and verify C code from a control algorithm model, which you can integrate with additional embedded software required to interface to motor hardware.

You will use a simulation environment to model and verify the behavior of a closed-loop motor control system. Once the control system behavior is within specification, you will generate C code from the controller model. After inspecting the code, you will assess its functional behavior and execution time using processor-in-the-loop (PIL) testing.

To facilitate PIL testing, you will select test signals to exercise the controller model and establish reference outputs. You will review an example PIL implementation for a Texas Instruments™ F28335 processor that communicates with Simulink® on the host computer over a serial connection. You can use this example as a starting point to create a PIL implementation for your own processor. You will run the controller model in PIL mode to measure execution time and verify execution behavior of the code running on the embedded processor against the simulation reference outputs.

In the final implementation on the embedded processor, you would integrate the generated controller C code with additional embedded software, such as peripherals and interrupts, required to interface with the motor hardware.

### Notes

- Simscape™ Electrical™ is required for system simulation in the section "Verify Behavior through System Simulation." It is not required for other tasks.
- The Texas Instruments F28335 PIL implementation is a reference approach that you can apply to virtually any processor. However, if you wish to use this implementation directly, you will need additional support files, compilers, and tools from Texas Instruments. You can find more information about those in "Create PIL Implementation and Register with Simulink" section of this example. This reference PIL implementation does not require the Texas Instrument's C2000™ Embedded Target feature of Embedded Coder®, but C2000 users are encouraged to install Texas Instruments C2000 Support Package using Add-On Explorer.

### Verify Behavior Through System Simulation

In this section, you will verify the controller in a closed loop system simulation.

The system model test bench consists of test inputs, the embedded processor, the power electronics and motor hardware, and visualizations. You can use the system model to exercise the controller and explore its expected behavior. You can use the following commands to execute the model and plot logged signals.

```

open_system('rtwdemo_pmsmfoc_system')
out_system = sim('rtwdemo_pmsmfoc_system')
rtwdemo_pmsmfoc_plotsignals(out_system.logout)

out_system =

 Simulink.SimulationOutput:
 logout: [1x1 Simulink.SimulationData.Dataset]

 SimulationMetadata: [1x1 Simulink.SimulationMetadata]
 ErrorMessage: [0x0 char]

```

?

## Field-Oriented Control of Permanent Magnet Synchronous Machine System Test Bench

Model Description: Field-Oriented Control of Permanent Magnet Synchronous Machine

Demonstrates a Field-Oriented Control algorithm with Space Vector Modulation for a Permanent Magnet Synchronous Machine (PMSM). The test bench can be used to evaluate the system performance. Examples include turning the motor on, searching for a valid rotor position, transitioning to closed loop operation, and changing speed and torque during closed loop control. The Embedded Processor subsystem contains the controller algorithm (which supports C code generation) as well as simulation models of peripherals.

Copyright 2010-2020 The MathWorks, Inc.

The plots show that the motor is stationary until the `motor_on` signal is true. The motor then spins in an open loop until a known position is detected, which is indicated by the encoder index pulse. The controller then transitions to closed loop operation and the motor reaches a steady state speed.

### Explore Model Architecture

In this section, you will explore the model architecture including how data is specified, how the controller is partitioned from the test bench, and how controller is scheduled. This architecture facilitates system simulation, algorithmic code generation, and PIL testing.

A data definition file creates the MATLAB® data required for simulation and code generation. This data file is automatically run within the `PreLoadFcn` callback of the system test bench model.

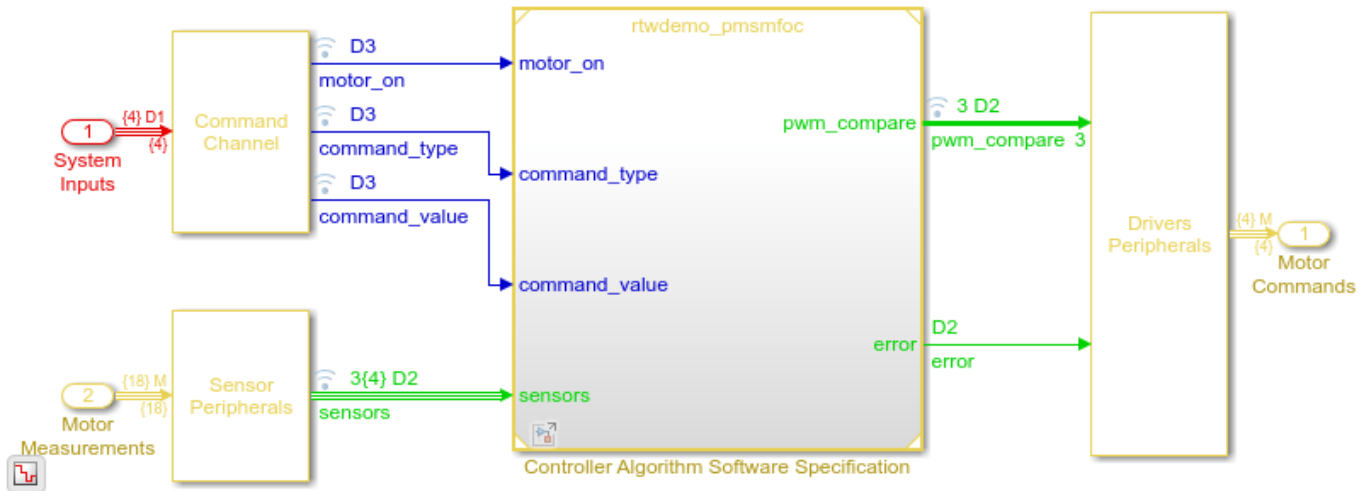

```
edit('rtwdemo_pmsmfoc_data.m')
```

Within the system test bench model, the embedded processor is modeled as a combination of the peripherals and the controller software.

```
open_system('rtwdemo_pmsmfoc_system/Embedded Processor')
```

## Embedded Processor

Models hardware on the embedded processor, including the controller algorithm software specification and peripherals.

The controller software is specified in a separate model. Within this model, the Mode\_Scheduler subsystem uses Stateflow® to schedule different modes of operation of the Motor\_Control algorithm.

```
open_system('rtwdemo_pmsmfoc')
```

## Controller Algorithm for Permanent Magnet Synchronous Machine

### Model Description: Controller Algorithm for Permanent Magnet Synchronous Machine

Specifies controller software component for Permanent Magnet Synchronous Machine (PMSM) using Field-Oriented Control. The sensors bus/structure contains values returned by the Analog to Digital Converter (ADC) and quadrature encoder peripherals. The controller outputs compare values used by the Pulse Width Modulators (PWMs) to generate the phase voltages.

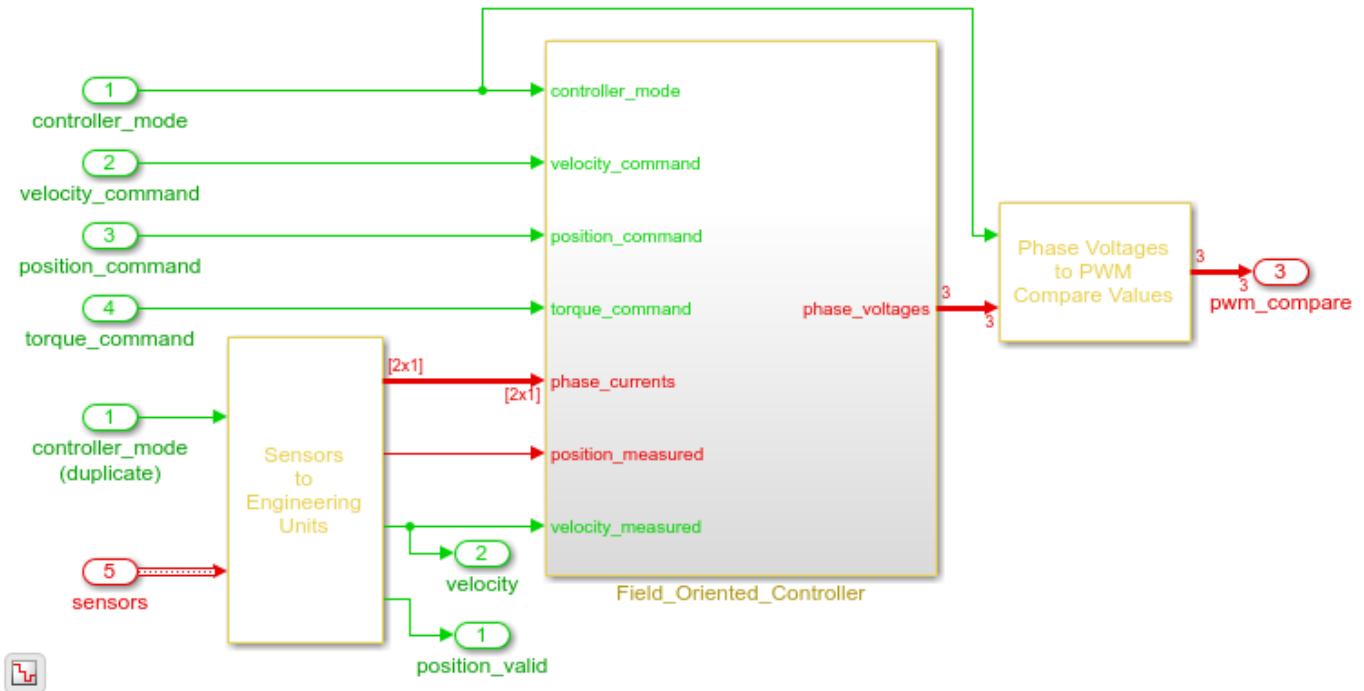

Copyright 2010-2020 The MathWorks, Inc.

Within the Motor\_Control subsystem, sensor signals are converted to engineering units and passed to the core controller algorithm. The controller algorithm calculates voltages. The voltages are then converted to a driver signal.

```
open_system('rtwdemo_pmsmfoc/Motor_Control')
```

## Motor Control

This layer converts driver units to engineering units, executes the control law, and calculates compare values used by the PWM driver. The sensors bus/structure contains values returned by the Analog to Digital Converter (ADC) and quadrature encoder peripherals. The controller outputs compare values used by the Pulse Width Modulators (PWMs) to generate the phase voltages.

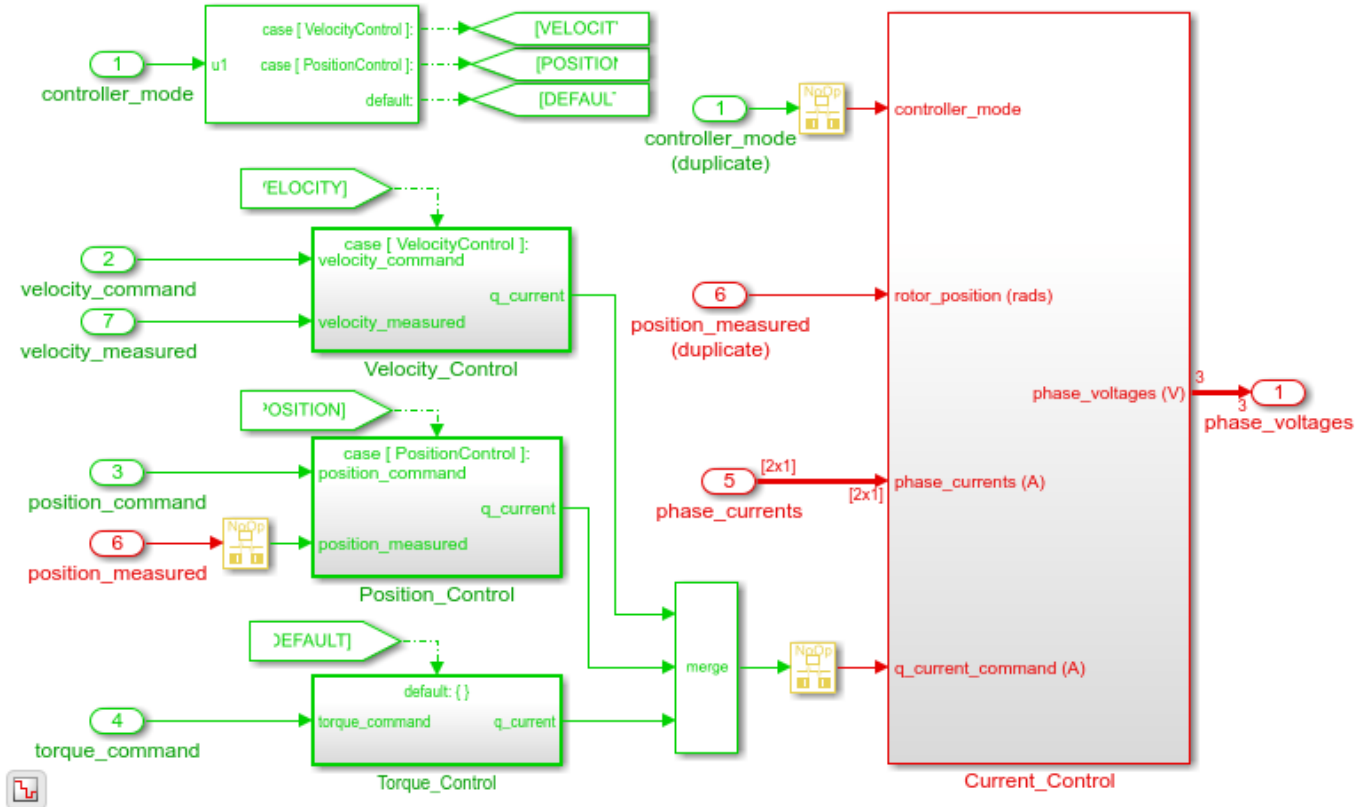

The primary control law is a field-oriented controller. The controller has a low rate outer loop that controls the speed, and a higher rate inner loop that controls the current.

```
open_system('rtwdemo_pmsmfoc/Motor_Control/Field_Oriented_Controller')
```

## Field Oriented Controller

The current controller always executes. Startup, velocity, and torque controllers are optionally enabled.

The Velocity Controller outer loop is executed as a multiple of the Current Control loop time. You can view the MATLAB variables, which specify these sample times:

```
fprintf('High rate sample time = %f seconds\n', ctrlConst.TsHi)
fprintf('Low rate sample time = %f seconds\n', ctrlConst.TsLo)
```

```
High rate sample time = 0.000040 seconds
Low rate sample time = 0.005000 seconds
```

Notice that the highest rate in the controller algorithm is 25 kHz.

```
fprintf('High rate frequency = %5.0f Hz\n', 1/ctrlConst.TsHi)
```

```
High rate frequency = 25000 Hz
```

### Generate Controller C Code for Integration into Embedded Application

In this section, you will generate and visually inspect the C code function for the controller.

To ease integration, the controller model is configured in single-tasking mode so that the generated code can be invoked using one function call. This function handles the lower and higher rates. The generated controller function must be executed at the high rate sample time.

The function prototype is specified in the model configuration parameters and the input and output ports are passed as arguments. You can view the function specification for the controller algorithm.

```
mdlFcn = RTW.getFunctionSpecification('rtwdemo_pmsmfoc');
disp(mdlFcn.getPreview('init'))
disp(mdlFcn.getPreview('step'))

Controller_Init ()
error = Controller (motor_on, command_type, current_request, * sensors, * pwm_compare)
```

Through use of a global structure in the generated code, you can access the field-oriented controller proportional and integral gains. This global structure is specified in the data definition file.

```
disp(ctrlParams.Value)
disp(ctrlParams.CoderInfo)

 Current_P: 10
 Current_I: 10000
 Velocity_P: 0.0050

```

You generate C code from the model as follows.

```
slbuild('rtwdemo_pmsmfoc')

Starting build procedure for: rtwdemo_pmsmfoc
Successful completion of build procedure for: rtwdemo_pmsmfoc

Build Summary

Top model targets built:

Model Action Rebuild Reason
=====
rtwdemo_pmsmfoc Code generated and compiled Code generation information file does not exist.

1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 51.795s
```

Use the generated report to inspect the generated C code file and verify that the correct step and initialization functions were generated. Also verify that the parameter structure was created as a global variable.

## Establish Reference Behavior for Controller Model

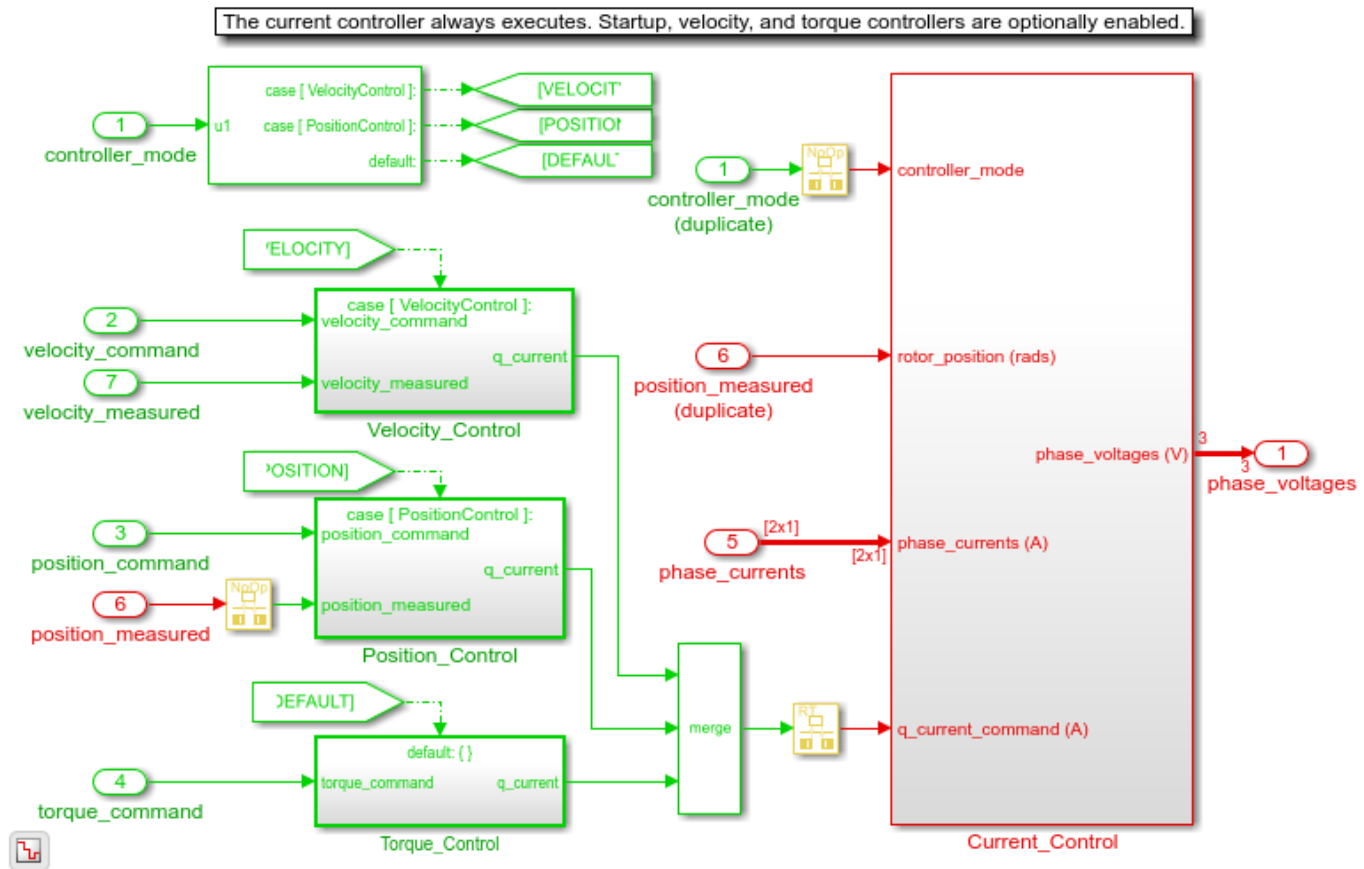

In this section, you will establish test inputs and a reference output to help verify behavior and profile execution time during PIL testing. You will make a local copy of the controller model then load a set of test input signals that exercise the different modes within the controller. You will then configure the controller model to attach these logged signals to input ports, execute the controller model, and log the output port signal to the workspace.

Configuration parameters of the controller model used to establish the reference behavior and test environment will change as described below. Blocks and parameters used to specify the controller model's design and generate production code will not change. However, to avoid modifying any part of the installed controller model, save the model and change its name to `rtwdemo_pmsmfoc_local.slx`.

```
save_system('rtwdemo_pmsmfoc','rtwdemo_pmsmfoc_local.slx')
close_system('rtwdemo_pmsmfoc_system',0);
close_system('rtwdemo_pmsmfoc',0);
```

omCallMethod failed on slmsgviewer.renameTab

## Field Oriented Controller

To profile execution times, select a set of test inputs that will execute the paths of interest within the controller. One way to acquire these test inputs and reference output is to log them from the system simulation model.

```

in.motor_on = out_system.logout.getElement('motor_on').Values;
in.command_type = out_system.logout.getElement('command_type').Values;
in.command_value = out_system.logout.getElement('command_value').Values;
in.sensors = out_system.logout.getElement('sensors').Values;
display(in)

```

```
in =
```

```
struct with fields:
```

```

 motor_on: [1x1 timeseries]
 command_type: [1x1 timeseries]
 command_value: [1x1 timeseries]
 sensors: [1x1 struct]

```

These signals can now be attached to the input ports and imported into the controller model such that it can execute directly and independently from the system model. An advantage of this approach is that the controller model can be tested and verified as a standalone component, facilitating reuse and integration with other system models or closed-loop test benches. To elaborate, or prepare, the controller model for testing, change its Configuration Parameters to attach input signals and log signals in the MATLAB workspace. These changes can be made graphically in the model's Configuration Parameters dialog, or programmatically as shown below.

```

set_param('rtwdemo_pmsmfoc_local',...
 'LoadExternalInput', 'on',...
 'ExternalInput', 'in.motor_on, in.command_type, in.command_value, in.sensors',...
 'StopTime', '0.06',...
 'ZeroInternalMemoryAtStartup', 'on',...
 'SimulationMode', 'normal')
save_system('rtwdemo_pmsmfoc_local.slx')

```

You can now execute the controller model and plot the signal associated with the PWM Compare output port.

```

out = sim('rtwdemo_pmsmfoc_local')
controller_mode = out.logout.getElement('controller_mode').Values;
pwm_compare_ref = out.logout.getElement('pwm_compare').Values;
rtwdemo_pmsmfoc_plotpwmcompare(controller_mode, pwm_compare_ref)

```

```
out =
```

```

Simulink.SimulationOutput:
 logout: [1x1 Simulink.SimulationData.Dataset]

SimulationMetadata: [1x1 Simulink.SimulationMetadata]
 ErrorMessage: [0x0 char]

```

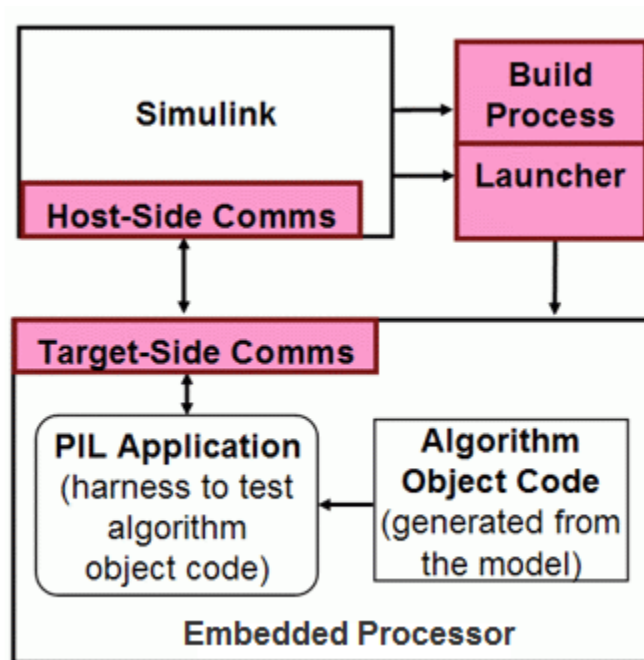

The logged output will be used as the reference behavior for PIL testing.

Notice that the plot is annotated with information about the mode of the controller at each time step. This mode information will be useful when interpreting execution profiling information.

### Create PIL Implementation

In this section, you will study and use an example PIL implementation. You will begin by reviewing prerequisite help documentation from Embedded Coder. You will then copy the example PIL implementation into your local directory and register it with Simulink. You will review the approach used to develop the PIL implementation and can explore the associated files to gain additional insight. If you are using a Spectrum Digital Inc. eZdsp F28335 board with Code Composer v4 and a serial connection, you will be able to configure this PIL implementation to directly work with the controller model. If you are using a different processor, you can use this PIL implementation as a starting point to create your own implementation.

The fundamentals of creating a custom PIL implementation are described in “Create PIL Target Connectivity Configuration for Simulink” on page 88-38 . You should familiarize yourself with the basic concept of using the rtiostream API to facilitate communication between Simulink (host-side) and the embedded processor (target-side) during PIL testing. Note that Embedded Coder provides host-side drivers for the default TCP/IP implementation (for all platforms supported by Simulink) as well as a Windows® only version for serial communication. Building the generated code is accomplished using a makefile as described in “Customize Template Makefiles” . To create a PIL implementation you will need to perform several tasks in the embedded environment including writing a target-side communications driver, writing a makefile to build the generated code, and automating download and execution of the built executable.

Using the above approach, a PIL implementation was created for a Spectrum Digital Inc. eZdsp F28335 board. Below is a summary of the target connectivity API components used in this implementation.

- **Host-Side Communication** - The host-side connectivity driver is configured to use serial communication.
- **Target-Side Communication** - The target-side communication is achieved using a handwritten serial implementation of the `rtiostream` functions as well as timer access functions.
- **Build Process** - A makefile based approach is used to build the executable application.
- **Launcher** - Downloading and running the executable is accomplished using the Debug Server Scripting (DSS) utility of Code Composer Studio™ v4 (CCSv4).

The PIL implementation was iteratively developed in three stages. Below is a description of these stages and the tasks performed in these stages. You may find it helpful to follow a similar approach when developing your own PIL implementation

### Stage 1: Create serial communication application with CCSv4

- Install CCSv4 and verify that it can connect with the F28335 eZdsp board.
- Write an embedded application that sends and receives serial data.
- Test the serial communication between the host computer and the embedded application.
- Identify the commands and options for the compiler, linker, and archiver to build the application using a makefile.
- Download and run the application from a Windows Command Prompt using the DSS utility.

### Stage 2: Implement and test embedded serial `rtiostream` and launch automation with MATLAB

- Extend the serial application to implement the `rtiostream` API functions for echoing data. Write the `rtIOStreamOpen` to perform general board initialization, including configuring the serial port.

- Verify sending and receiving serial data with the embedded processor from MATLAB using the `rtiostream_wrapper` function.
- Download and run the application from MATLAB using the system command to call the DSS utility.

### Stage 3: Implement and test connectivity configuration with Simulink

- Create a connectivity configuration class to configure the host-side serial communication, specify which target-side code files from the `rtiostream` application should be included in the build process, specify how to access a timer that will be used to collect profiling data, and integrate calling the DSS utility to launch the embedded application.
- Create a tool specification makefile (`target_tools.mk`) which specifies the commands and options for the compiler, linker, and archiver. This makefile is included by the template makefile (`target_tools.mk`).
- Create a template makefile (`ec_target.tmf`) that includes `target_tools.mk`.
- Identify parameters which may be installation dependent and store them as MATLAB preferences.
- Create a Simulink customization file which specifies when the PIL implementation is valid.

The files associated with this PIL implementation are included with Embedded Coder, but are not on the MATLAB path. To explore these files, you can copy them into a local directory. You can register this PIL implementation by adding this directory to the MATLAB path and refreshing the Simulink customizations.

```
%copyfile(fullfile(matlabroot,'toolbox','rtw','rtwdemos','examplePilF28335'),'examplePilF28335',
addpath(genpath(fullfile(matlabroot,'toolbox','rtw','rtwdemos','examplePilF28335'))))
sl_refresh_customizations
```

MATLAB preferences are used to specify path information and the host serial COM port number. If you are using this PIL implementation directly, you must specify these preferences as appropriate for your configuration.

Note that the `TI_F28xxx_SysSWDir` preference points to a directory provided by Texas Instruments in their **C2000 Experimenter Kit Application Software** (`sprc675.zip`). These files are not included with Embedded Coder.

```
setpref('examplePilF28335','examplePilF28335Dir', fullfile(matlabroot,'toolbox','rtw','rtwdemos',
setpref('examplePilF28335','CCSRootDir', 'C:\Program Files\Texas Instruments\ccsv4');
setpref('examplePilF28335','TI_F28xxx_SysSWDir', 'C:\Program Files\Texas Instruments\TI_F28xxx_9
setpref('examplePilF28335','targetConfigFile', fullfile(matlabroot,'toolbox','rtw','rtwdemos',
setpref('examplePilF28335','baudRate', 115200);
setpref('examplePilF28335','cpuClockRateMHz', 150);
setpref('examplePilF28335','boardConfigPLL', 10);
setpref('examplePilF28335','COMPort', 'COM4');
```

The PIL implementation is now ready to be used.

### Prepare Controller Model for PIL Testing

In this section you will configure the controller model to use the PIL implementation. You will review the customization file used to register the PIL implementation, set the configuration parameters of the model to use the PIL implementation, and enable logging controller outputs and execution profiling data.

When you begin a simulation in PIL mode, Simulink will check if any of the registered PIL implementations are valid. A customization file specifies which configuration parameters correspond

to a valid PIL implementation. You can explore the customization file for this implementation by invoking the following command.

```
edit(fullfile(matlabroot, 'toolbox', 'rtw', 'rtwdemos', 'examplePilF28335', 'sl_customization.m'));
```

Notice that this file specifies setting for the hardware device and the template makefile which are required to use this PIL implementation. You can modify the configuration parameters in the controller model to match these settings. These changes can be made graphically in the model's Configuration Parameters dialog, or programmatically as shown below.

```
set_param('rtwdemo_pmsmfoc_local', ...
 'ProdHWDeviceType', 'Texas Instruments->C2000', ...
 'TemplateMakefile', 'ec_target.tmf', ...
 'GenCodeOnly', 'off', ...
 'SimulationMode', 'processor-in-the-loop (pil)')
```

You can specify collecting execution profiling information during PIL testing by logging the simulation output values as the variable `pilOut` and logging the execution profiling information as the variable `executionProfile`. These changes can be made graphically in the model's Configuration Parameters dialog, or programmatically as shown below.

```
set_param('rtwdemo_pmsmfoc_local', ...
 'CodeExecutionProfiling', 'on', ...
 'CodeExecutionProfileVariable', 'executionProfile', ...
 'CodeProfilingSaveOptions', 'AllData');
save_system('rtwdemo_pmsmfoc_local.slx')
```

The controller model is now ready to be run in PIL mode.

### Test Behavior and Execution Time of Generated Code

In this section you will run the controller model in PIL mode and explore the behavioral and execution profiling results. You will verify that the behavior of the compiled controller code matches the reference simulation behavior, and then verify that the execution of the code meets timing requirements.

You can run the model and plot the PIL simulation results. When you start the model for the first time, Embedded Coder will generate code for the algorithm, link the algorithm code with the serial communication interface code, build the embedded application, download the application to the board, and begin the on-target simulation. Note that during subsequent PIL simulations, code is only regenerated if the model changes. Due to the overhead associated with the serial communication interface, the PIL simulation may run slower than the model in normal mode.

The MATLAB commands below are intentionally commented out as they require connection to hardware and use of embedded development tools described previously. If you have the hardware connected and embedded development tools installed, uncomment and execute these lines to run the model, plot the results, and verify the behavior is numerically equivalent to the simulation running in normal mode. Otherwise, continue reviewing this section to learn about PIL execution analysis options.

```
% UNCOMMENT THE BELOW LINES TO RUN THE SIMULATION AND PLOT THE RESULTS
% if exist('slprj','dir'), rmdir('slprj','s'); end
% out = sim('rtwdemo_pmsmfoc_local')
% pwm_compare_pil = out.logout.getElement('pwm_compare').Values;
% rtwdemo_pmsmfoc_plotpwmcompare_pil(controller_mode, pwm_compare_pil, executionProfile)
```

The upper plot is the output of the controller, PWM Compare. Note that the outputs in PIL mode look the same as the outputs of the simulation in normal mode shown in the section "Establish Reference Behavior for Controller Model". You can subtract the outputs of normal mode simulation from the PIL mode simulation output to verify that they are numerically equivalent:

```
% UNCOMMENT THE BELOW LINE TO VERIFY NUMERICAL EQUIVALENCE OF THE OUTPUTS
% pilErrorWithRespectToReference = sum(abs(pwm_compare_pil.Data - pwm_compare_pil.Data))

pilErrorWithRespectToReference =
 0 0 0
```

The lower plot is the amount of time spent executing the controller model at each simulation time step. The "Stand By" state requires the least time. Small periodic spikes in execution time occur because the controller is multi-rate and single tasking. The periodic spikes correspond to the time required to run both the base rate and 5 millisecond rate code in the same task.

Since the controller must be executed at 25 kHz on the embedded processor, the algorithm must complete its execution within 40 microseconds (minus additional headroom requirements by other code, which may also be executing on the final application.) The profiling results indicate that the algorithm will execute within the time allotted for this configuration of the embedded environment.

The generated code is now verified to provide numerically equivalent results and meets the execution timing requirements for this test case.

```
close_system('rtwdemo_pmsmfoc_local',0);
close_system('power_util',0);
```

The MATLAB preferences used in this PIL implementation are persistent between MATLAB sessions. If you want to remove these preferences, run the following commands.

```
rmpref('examplePilF28335');
rmexamplePilF28335hooks();
```

### **Conclusion**

This example showed system level simulation and algorithmic code generation using a Field-Oriented Control algorithm for a Permanent Magnet Synchronous Machine to explore functional behavior of the controller algorithm. It also showed a general approach for target integration, functional testing, and execution profiling for any embedded processor. Once the algorithm was behaviorally correct, code was generated from the controller model, tested on the target processor and profiled. The algorithm code is now verified and can be integrated with embedded software that interfaces with the motor hardware for further testing.

## Check Configuration

Use the `cgv.Config` class to check model settings for a SIL or PIL simulation. You can review your model configuration and determine the settings that you must change. By default, `cgv.Config` changes configuration parameter values to the value that it recommends, but does not save the model. Alternatively, you can:

- Change configuration parameter values to the values that `cgv.Config` recommends, and save the model. Specify this approach using the `SaveModel` property.
- List the values that `cgv.Config` recommends for the configuration parameters, but not change the configuration parameters or the model. Specify this approach using the `ReportOnly` property.

---

### Note

- Execution in the target environment can require additional modifications to configuration parameter values or the model.
  - Do not use referenced configuration sets in models that you are changing using `cgv.Config`. If the model uses a referenced configuration set, update the model with a copy of the configuration set. Use the `getRefConfigSet` method of the `Simulink.ConfigSetRef` class.
  - If you use `cgv.Config` on a model that executes a callback function, the callback function can change configuration parameter values each time the model loads. The callback function can revert changes that `cgv.Config`. For more information, see “Customize Model Behavior with Callbacks”.
- 

To verify that your model is configured for SIL or PIL:

- 1 Construct a `cgv.Config` object that changes the configuration parameter values without saving the model.
- 2 Determine and change the configuration parameter values that the object recommends using the `configModel` method.
- 3 Display a report of the changes that `configModel` makes.
- 4 Review the changes.
- 5 To apply the changes to your model, save the model.

- “Verify Numerical Equivalence with CGV” on page 88-130
- “Verify Numerical Equivalence Between Two Modes of Execution of a Model” on page 88-131

## Verify Numerical Equivalence with CGV

Before verifying numerical equivalence:

- Configure your model for SIL or PIL simulation.
- Use the `cgv.Config` class of the CGV API to verify the model configuration for SIL or PIL simulation.
- Configure your model for code generation. For more information, see “Configure Model for Code Generation Objectives by Using Code Generation Advisor” on page 49-2.
- Save your model. If you modify a model without saving it, CGV can issue an error.

To verify numerical equivalence:

- Set up the tests for the first execution environment. For example, simulation.
- Use `run` to run the tests for the first execution environment.
- Set up the tests for the second execution environment. For example, top-model PIL.
- Use `cgv.CGV.run` to run the tests for the second execution environment.
- Use `getOutputData` to get the output data for each execution environment.
- Use `getSavedSignals` to display the signal names in the output data. (optional)
- Build a list of signal names for input to other `cgv.CGV` methods. (optional)
- Use `createToleranceFile` to create a file correlating tolerance information with output signal names. (optional)
- Use `compare` to compare the output signals of the first and second execution environments for numerical equivalence.

---

**Note** Simulink Test is a separate product that provides additional capabilities for SIL and PIL testing, for example, test sequence construction and test management.

# Verify Numerical Equivalence Between Two Modes of Execution of a Model

## In this section...

“Configure the Model” on page 88-131  
 “Execute the Model” on page 88-131  
 “Compare All Output Signals” on page 88-132  
 “Compare Individual Output Signals” on page 88-133  
 “Plot Output Signals” on page 88-134

The following example describes configuring, executing, and comparing the results of the `rtwdemo_cgv` model in normal and software-in-the-loop (SIL) simulation modes.

## Configure the Model

The first task for verifying numerical equivalence is to check the configuration of your model.

- 1 Open the `rtwdemo_cgv` model.

```
cgvModel = 'rtwdemo_cgv';
load_system(cgvModel);
```

- 2 Save the model to a working directory.

```
save_system(cgvModel, fullfile(pwd, cgvModel));
close_system(cgvModel); % avoid original model shadowing saved model
```

- 3 Use the `cgv.Config` to create a `cgv.Config` object. Specify parameters that check and modify configuration parameter values and save the model for top-model SIL mode of execution.

```
cgvCfg = cgv.Config('rtwdemo_cgv', 'connectivity', 'sil', 'SaveModel', 'on');
```

- 4 Use the `configModel` method to review your model configuration and to change the settings to configure your model for SIL. When 'connectivity' is set to 'sil', the system target file is automatically set to 'ert.tlc'. If you specified the parameter/value pair, ('SaveModel', 'on') when you created the `cgvCfg` object, the `cgv.Config.configModel` method saves the model.

---

**Note** CGV runs on models that are open. If you modify a model without saving it, CGV can issue an error.

---

```
cgvCfg.configModel(); % Evaluate, change, and save your model for SIL
```

- 5 Display a report of the changes that `cgv.Config.configModel` makes to the model.

```
cgvCfg.displayReport(); % In this example, this reports no changes
```

## Execute the Model

Use the CGV API to execute the model in two modes. The two modes in this example are normal mode simulation and SIL mode. In each execution of the model, the CGV object for each mode captures the output data and writes the data to a file.

- 1 If you have not already done so, follow the steps described in “Configure the Model” on page 88-131.
- 2 Create a `cgv.CGV` object that specifies the `rtwdemo_cgv` model in normal mode simulation.

```
cgvSim = cgv.CGV(cgvModel, 'connectivity', 'sim');
```

---

**Note** When the top model is set to normal simulation mode, the CGV API sets referenced models in PIL mode to accelerator mode.

---

- 3 Provide the input file to the `cgvSim` object.
- 4 Before execution of the model, specify the MATLAB files to execute or MAT-files to load. This step is optional.

```
cgvSim.addInputData(1, [cgvModel '_data']);
```

```
cgvSim.addPostLoadFiles({'[cgvModel '_init.m']});
```

- 5 Specify a location where the object writes all output data and metadata files for execution. This step is optional.

```
cgvSim.setOutputDir('cgv_output');
```

- 6 Execute the model.

```
result1 = cgvSim.run();
```

- 7 Get the output data associated with the input data.

```
outputDataSim = cgvSim.getOutputData(1);
```

- 8 For the next mode of execution, SIL, repeat steps 2-7.

```
cgvSil = cgv.CGV(cgvModel, 'Connectivity', 'sil');
cgvSil.addInputData(1, [cgvModel '_data']);
cgvSil.addPostLoadFiles({'[cgvModel '_init.m']});
cgvSil.setOutputDir('cgv_output');
result2 = cgvSil.run();
```

## Compare All Output Signals

After setting up and running the test, compare the outputs by doing the following:

- 1 If you have not already done so, configure and test the model, as described in “Configure the Model” on page 88-131 and “Execute the Model” on page 88-131.

- 2 Test that the execution result of the model:

```
if ~result1 || ~result2
 error('Execution of model failed.');
```

```
end
```

- 3 Use the `getOutputData` method to get the output data from the `cgv.CGV` objects.

```
simData = cgvSim.getOutputData(1);
silData = cgvSil.getOutputData(1);
```

- 4 Display a list of signals by name using the `getSavedSignals` method.

```
cgvSim.getSavedSignals(simData);
```

- 5 Using the list of signals, build a list of signals in a cell array of character vectors. The signal list can contain a number of signals.

```
signalList = {'simData.getElement(4).Values.Data'};
```

- 6 Use the `createToleranceFile` method to create a file, in this example, `'localtol'`, correlating tolerance information with output signal names.

```
toleranceList = {'absolute', 0.5};
cgv.CGV.createToleranceFile('localtol', signalList, toleranceList);
```

- 7 Compare the output data signals. By default, the `compare` method looks at all signals which have a common name between both executions. If a tolerance file is present, `cgv.CGV.compare` uses the associated tolerance for a specific signal during comparison; otherwise the tolerance is zero. In this example, the `'Plot'` parameter is set to `'mismatch'`. Therefore, only mismatched signals produce a plot.

```
[matchNames, ~, mismatchNames, ~] = ...
 cgv.CGV.compare(simData, silData, 'Plot', 'mismatch', ...
 'Tolerancefile', 'localtol');
fprintf('%d Signals match, %d Signals mismatch\n', ...
 length(matchNames), length(mismatchNames));
disp('Mismatched Signal Names:');
disp(mismatchNames);
```

At the MATLAB command line, you see:

```
14 Signals match, 1 Signals mismatch
Mismatched Signal Names:
 'simData.getElement(4).Values.Data'
```

A plot results from the signal mismatch.

The lower plot displays the numeric difference between the results.

## Compare Individual Output Signals

After setting up and running the test, compare the outputs of individual signals by doing the following:

- 1 If you have not already done so, configure and test the model, as described in “Configure the Model” on page 88-131 and “Execute the Model” on page 88-131.
- 2 Use the `getOutputData` method to get the output data from the `cgv.CGV` objects.
- 3 Use the `getSavedSignals` method to display the output data signal names. Build a list of specific signal names in a cell array of character vectors. The signal list can contain a number of signals.

```
simData = cgvSim.getOutputData(1);
silData = cgvSil.getOutputData(1);

cgv.CGV.getSavedSignals(simData);

signalList = {'simData.getElement(3).Values.hil.mid0.lo1.Data', ...
'simData.getElement(3).Values.hil.mid0.lo2.Data', ...
'simData.getElement(2).Values.Data(:,3)'};
```

- 4 Use the specified signals as input to the `compare` method to compare the signals from separate runs.

```
[matchNames, ~, mismatchNames, ~] = ...
 cgv.CGV.compare(simData, silData, 'Plot', 'mismatch', ...
 'signals', signalList);
fprintf('%d Signals match, %d Signals mismatch\n', ...
 length(matchNames), length(mismatchNames));
if ~isempty(mismatchNames)
 disp('Mismatched Signal Names:');
 disp(mismatchNames);
end
```

At the MATLAB command line, the result is:

```
3 Signals match, 0 Signals mismatch
```

## Plot Output Signals

After setting up and running the test, use the `plot` method to plot output signals.

- 1 If you have not already done so, configure and test the model, as described in “Configure the Model” on page 88-131 and “Execute the Model” on page 88-131.
- 2 Use the `getOutputData` method to get the output data from the `cgv.CGV` objects.
- 3 Use the `getSavedSignals` method to display the output data signal names. Build a list of specific signal names in a cell array of character vectors. The signal list can contain a number of signals.

```
cgv.CGV.getSavedSignals(simData);
signalList = {'simData.getElement(2).Values.Data(:,1)'};
```

- 4 Use the specified signal list as input to the `plot` method to compare the signals from separate runs.

```
[signalNames, signalFigures] = cgv.CGV.plot(simData, ...
 'Signals', signalList);
```

# Numerical Consistency between Model and Generated Code

---

## Numerical Consistency of Model and Generated Code Simulation Results

### In this section...

“Numerical Consistency” on page 89-2

“Numerical Consistency in Complex Systems” on page 89-2

“Reasons for Block-Level Numerical Differences” on page 89-4

### Numerical Consistency

In the Model-Based Design workflow, you use MathWorks products to generate code for numerical applications that employ fixed-point and floating-point arithmetic.

- To develop models, you use MATLAB, Simulink, and Stateflow.
- To generate source code, you use Simulink Coder and Embedded Coder.
- To test numerical equivalence between your model and generated code, you compare model and generated code simulation results. For example, normal mode simulation results compared with software-in-the-loop (SIL) simulation results.

The results from the model and generated code simulations are numerically consistent if:

- In fixed-point applications, the results agree in a bit-wise comparison.
- In floating-point applications, the results agree with an error tolerance that you specify.

Use the Simulation Data Inspector to compare results. To determine whether discrepancies exist or are significant, you can specify absolute and relative tolerance values:

- For fixed-point applications, you can specify an absolute tolerance of zero.
- For floating-point applications, you can specify tolerance with respect to a reference value or signal. The choice of reference depends on your application. Consider these examples:
  - An algorithm that solves a linear algebraic equation by iterative, feed-forward error calculations. You can specify tolerance with respect to `eps`.
  - A Proportional-Integral-Derivative (PID) controller for a closed-loop system. For transient behavior, you can specify tolerance with criteria from a standard. For steady-state behavior, you can specify tolerance with reference to the PID controller characteristics.

Programmatically, you can specify absolute and relative tolerance values through the `absTol` and `relTol` properties of the `Simulink.sdi.Signal` object.

### Numerical Consistency in Complex Systems

For complex systems, numerical differences between model and generated code simulations can be a result of block-level differences propagating through the system. If you observe numerical differences at the system level:

- 1 Identify blocks for which block-level numerical differences exceed the error tolerance.
- 2 Investigate each identified block.

Consider the following plant-controller model.

- T produces reference or test signals.
- C is the controller component. The controller output is the plant input. C can be a Model block that comprises multiple Model blocks.
- P is the plant component. The plant output is subtracted from the reference signal to produce the controller input.

To test numerical equivalence between the model controller and the generated code version:

- 1 Run the model in normal mode, and, using the Simulation Data Inspector, record the output of C.
- 2 Specify SIL mode for C. Rerun the simulation, recording the output of C.
- 3 Using the Simulation Data Inspector, compare normal and SIL mode outputs with reference to your specified error tolerance.

If the Simulation Data Inspector comparison indicates a match, the model and generated code results are numerically consistent.

If the normal and SIL mode outputs do not match:

- 1 Within C, enable signal logging for block outputs.
- 2 Run the model in normal mode.
- 3 Rerun the simulation with C in SIL mode.

- 4 Using the Simulation Data Inspector, compare the logged output signals with reference to your specified error tolerance. See “Compare Simulation Data”.
- 5 Identify blocks for which normal and SIL mode output differences exceed the error tolerance.
- 6 Analyze each identified block and look for the cause. For example, the generated code might use a different math library than MATLAB.

---

**Note** If the comparison of a large number of signals is required, you can automate the workflow with Simulink Test. See “SIL Verification for a Subsystem” (Simulink Test).

---

## Reasons for Block-Level Numerical Differences

In fixed-point and floating-point application development, there are factors that can affect numerical agreement between block-level results from model and generated code simulations.

Some factors can affect both fixed-point and floating-point applications. For example, the use of:

- Code generation optimization.
- Custom code.
- Code replacement library entries whose results differ from MATLAB results.
- Code replacement libraries that implement different algorithms.

Other factors affect only floating-point applications. For example:

- Numerical soundness of algorithm.
- Algorithm sensitivity to input.
- Closed loop and open loop behavior.

## Code Verification Through Software-in-the-Loop and Processor-in-the-Loop Execution

MATLAB Coder supports software-in-the-loop (SIL) and processor-in-the-loop (PIL) execution, which enables you to verify production-ready source code and compiled object code. With these execution modes, you can reuse test vectors developed for your MATLAB functions to verify the numerical behavior of library code.

In SIL execution, through a MATLAB SIL interface, the software compiles and runs library code on your development computer. In PIL execution, through a MATLAB PIL interface, the software cross-compile and runs production object code on a target processor or an equivalent instruction set simulator. Before you run a PIL execution, you must set up a PIL connectivity configuration for your target.

The workflow for generating and verifying code is:

- 1 Set up MATLAB Coder.
- 2 Fix errors detected at design time.
- 3 Generate MEX function.
- 4 Test MEX function.
- 5 Generate C/C++ library code.
- 6 Verify generated C/C++ code through SIL or PIL execution — requires Embedded Coder license.

In step 4, you verify code that is generated for execution within MATLAB. However, this code is different from the standalone code generated for libraries. In step 6, with an Embedded Coder license, you use SIL or PIL execution to verify the standalone code.

For more information, use the following table.

## Software-in-the-Loop Execution with the MATLAB Coder App

Use software-in-the-loop (SIL) execution to verify the numerical behavior of the generated C/C++ code with reference to your original MATLAB functions.

- 1 To open the MATLAB Coder app, on the MATLAB Toolstrip **Apps** tab, under **Code Generation**, click the app icon.
- 2 To open your project, click , and then click **Open existing project**. Select the project. For example, `kalman_filter01.prj`.
- 3 On the **Generate Code** page, click the **Generate** arrow .
- 4 In the **Generate** dialog box:
  - a Set **Build type** to `Static Library` or `Dynamic Library`.
  - b In the **Output file name** field, use the default value. For example, `kalman01`.
  - c Specify **Language**.
  - d Clear the **Generate code only** check box.
  - e In the **Hardware Board** field, use the default value (`MATLAB Host Computer`).

You do not have to specify the **Toolchain** setting. By default, the MATLAB Coder app locates an installed toolchain.

- 5 To generate the C or C++ code, click **Generate**.
- 6 Click **Verify Code**.
- 7 In the command field, specify the test file that calls the original MATLAB functions, for example, `test01_ui.m`.
- 8 If required, select the **Enable source-level debugging for SIL** check box.
- 9 To start the SIL execution, click **Run Generated Code**.

The MATLAB Coder app:

- Generates a standalone library, for example, `codegen\lib\kalman01`.
  - Generates SIL interface code, for example, `codegen\lib\kalman01\sil`.
  - Runs the test file, replacing calls to the MATLAB function with calls to the generated code in the library.
  - Displays messages from the SIL execution in the **Test Output** tab.
- 10 Verify that the results from the SIL execution match the results from the original MATLAB functions.
  - 11 To terminate the SIL execution process, click **Stop SIL Verification**. Alternatively, on the **Test Output** tab, click the link that follows `To terminate execution`.

---

**Note** On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL execution. To allow the execution, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

---

## Software-in-the-Loop Execution From Command Line

Use software-in-the-loop (SIL) execution to verify the numerical behavior of the generated C/C++ code with reference to your original MATLAB functions.

To set up and start a SIL execution from the command line:

- 1 Create a `coder.EmbeddedCodeConfig` object.
- 2 Configure the object for SIL.
- 3 Use the `codegen` function to generate library code for your MATLAB function and the SIL interface.
- 4 Use the `coder.runTest` function to run the test file for your original MATLAB function.

To terminate the SIL execution, use the `clear function_sil` or `clear mex` command.

The following example shows how you can set up and run a SIL execution from the command line.

### SIL Execution of Code Generated for a Kalman Estimator

#### 1 Copy MATLAB code for Kalman estimator

From `docroot\toolbox\coder\examples\kalman`, copy the following files to your working folder:

- `kalman01.m` — MATLAB function for the Kalman estimator
- `test01_ui.m` — MATLAB file to test `kalman01.m`
- `plot_trajectory.m` — File that plots actual target trajectory and Kalman estimator output
- `position.mat` — Input data

```
src_dir = ...
 fullfile(docroot, 'toolbox', 'coder', 'examples', 'kalman');

copyfile(fullfile(src_dir, 'kalman01.m'), '.')
copyfile(fullfile(src_dir, 'test01_ui.m'), '.')
copyfile(fullfile(src_dir, 'plot_trajectory.m'), '.')
copyfile(fullfile(src_dir, 'position.mat'), '.')
```

For a description of the Kalman estimator in this example, see “Generate C Code at the Command Line”.

#### 2 Configure SIL execution

- a From your working folder, create a `coder.EmbeddedCodeConfig` object.

```
config = coder.config('lib');
config.GenerateReport = true; % Optional, documents code in HTML report
```

- b Configure the object for SIL.

```
config.VerificationMode = 'SIL';

% Check that production hardware setting is the default
% i.e. 'Generic->MATLAB Host Computer'
disp(config.HardwareImplementation.ProdHWDeviceType);
```

- c If required, enable the Microsoft Visual Studio debugger for SIL execution:

```
config.SILDebugging = true;
```

### 3 Generate code and run SIL execution

Generate library code for the `kalman01` MATLAB function and the SIL interface, and run the MATLAB test file, `test01_ui`. The test file uses `kalman01_sil`, the generated SIL interface for `kalman01`.

```
codegen -config config -args {zeros(2,1)} kalman01 -test test01_ui
```

The software creates the following output folders:

- `codegen\lib\kalman01` — Standalone code for `kalman01`.
- `codegen\lib\kalman01\sil` — SIL interface code for `kalman01`.

Verify that the output of this run matches the output from the original `kalman01.m` function.

---

**Note** On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL execution. To allow the execution, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

---

### 4 Debug code during SIL execution

If you enable the Microsoft Visual Studio debugger, then running the test file opens the Microsoft Visual Studio IDE with debugger breakpoints at the start of the `kalman01_initialize` and `kalman01` functions.

You can use the debugger features to observe code behavior. For example, you can step through code and examine variables.

To end the debugging session:

- a Remove all breakpoints.
- b Click the **Continue** button (F5).

The SIL execution runs to completion.

### 5 Terminate SIL execution

Terminate the SIL execution process.

```
clear kalman01_sil;
```

You can also use the command `clear mex`, which clears MEX functions from memory.

---

**Note** Suppose that the MATLAB current working directory (the folder that `pwd` displays) is a UNC path (for example, `\\server\a\b\c`) on a Windows platform. If you launch a SIL executable from this path, the location where the SIL executable is launched can be unpredictable and different from the MATLAB current working directory (for example, `C:\Windows`).

---

To fix this issue, use a mapped network drive for the UNC path as your MATLAB current working directory.

---

- “Code Verification Through Software-in-the-Loop and Processor-in-the-Loop Execution” on page 90-2

## Debug Generated Code During SIL Execution

If a SIL execution fails or you notice differences between the outputs of your original functions and the generated code, you can rerun the SIL execution with a debugger enabled. By inserting breakpoints, you can observe the behavior of code sections, which might help you to understand the cause of the problem.

For a SIL execution failure, you can also view information from the standard output and standard error streams in the MATLAB Command Window. For example:

- Output from `printf` statements in your code.
- If you enable run-time error detection, messages sent to `stderr`.
- Some low-level system messages.

---

**Note** During a SIL execution, the SIL application redirects the `stdout` and `stderr` streams. When the application terminates, the MATLAB Command Window displays the information from the redirected streams. The SIL application also provides a basic signal handler, which captures the POSIX signals `SIGFPE`, `SIGILL`, `SIGABRT`, and `SIGSEV`. For this signal handler, the SIL application includes the file `signal.h`.

---

This table gives information about debugger support.

Operating System	Supported Debuggers
Windows	Microsoft Visual Studio IDE.
	Visual Studio Code with MinGW GDB. Requires installation of MATLAB Coder Interface for Visual Studio Code Debugging support package, which you can download from MATLAB Central File Exchange.
macOS	LLDB.
	Visual Studio Code with LLDB. Requires installation of MATLAB Coder Interface for Visual Studio Code Debugging support package, which you can download from MATLAB Central File Exchange.
Linux	GNU Data Display Debugger (DDD).
	Visual Studio Code with GDB. Requires installation of MATLAB Coder Interface for Visual Studio Code Debugging support package, which you can download from MATLAB Central File Exchange.

---

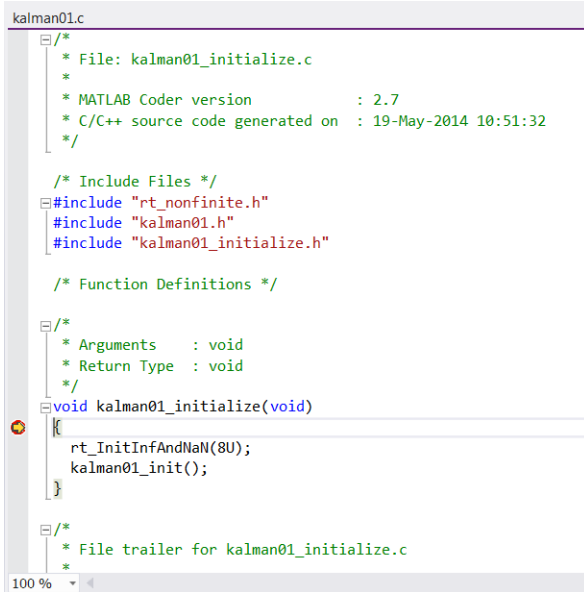

**Note** You can perform SIL debugging only if the MATLAB product family supports your Microsoft Visual C++, Xcode, or GNU GCC compiler. For more information, see supported compilers.

---

To run a SIL execution with debugging enabled:

- 1 On the **Generate Code** page, click **Verify Code**.
- 2 Select the **Enable source-level debugging for SIL** check box.
- 3 Click **Run Generated Code**.

On a Windows computer, your `user_fn.c` or `user_fn.cpp` file opens, for example, in the Microsoft Visual Studio IDE with debugger breakpoints at the start of the `user_fn_initialize` and `user_fn` functions.

```

kalman01.c
/*
 * File: kalman01_initialize.c
 *
 * MATLAB Coder version : 2.7
 * C/C++ source code generated on : 19-May-2014 10:51:32
 */

/* Include Files */
#include "rt_nonfinite.h"
#include "kalman01.h"
#include "kalman01_initialize.h"

/* Function Definitions */

/*
 * Arguments : void
 * Return Type : void
 */
void kalman01_initialize(void)
{
 rt_InitInfAndNaN(8U);
 kalman01_init();
}

/*
 * File trailer for kalman01_initialize.c
 */

```

You can now use the debugger features to observe code behavior. For example, you can step through code and examine variables.

To end the debugging session:

- 1 Remove all breakpoints.
- 2 Click the **Continue** button (**F5**).

The SIL execution runs to completion.

- 3 To terminate the SIL execution process, on the **Test Output** tab, click the link that follows To terminate execution, for example, clear `kalman01_sil`.

The Microsoft Visual Studio IDE closes automatically.

---

**Note** If you select **Debug > Stop Debugging**, the SIL execution times out with the following error message:

Communications error: failed to send data to the target. There might be multiple reasons for this failure.

...  
...

## Create PIL Target Connectivity Configuration for MATLAB

### In this section...

“Target Connectivity Configurations for PIL” on page 90-12  
“Create a Target Connectivity API Implementation” on page 90-12  
“Register Target Connectivity Configuration” on page 90-14  
“Verify Target Connectivity Configuration” on page 90-14

### Target Connectivity Configurations for PIL

Use target connectivity configurations and the target connectivity API to customize processor-in-the-loop (PIL) execution for your target environments.

Through a target connectivity configuration, you specify:

- A target connectivity configuration name for a target connectivity API implementation.
- Settings that define compatible MATLAB code. For example, the code that is generated for a particular hardware implementation.

A PIL execution requires a target connectivity PIL API implementation that integrates third-party tools for:

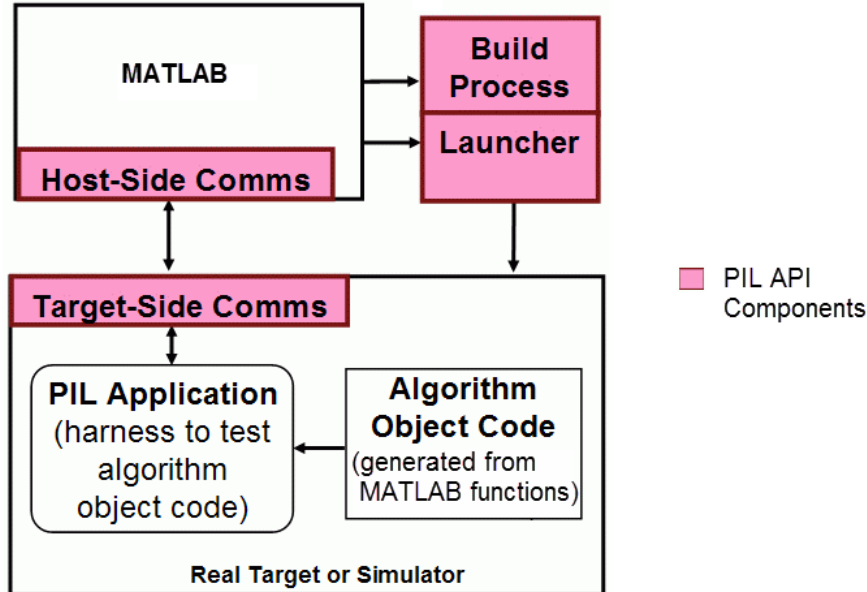

- Building the PIL application that runs on the target hardware
- Downloading, starting, and stopping the application on the target
- Communicating between MATLAB and the target

You can have many different connectivity configurations for PIL execution. Register a connectivity configuration with MATLAB by creating an `rtwTargetInfo.m` file and placing it on the MATLAB search path.

In a PIL execution, the software determines which of the available connectivity configurations to use. The software looks for a connectivity configuration that is compatible with the MATLAB code under test. If the software finds multiple or no compatible connectivity configurations, the software generates an error message with information about resolving the problem.

### Create a Target Connectivity API Implementation

This diagram shows the components of the PIL target connectivity API.

You must provide implementations of the three API components:

- Build API — Specify a toolchain approach for building generated code.
- Launcher API — Control how MATLAB starts and stops the PIL executable.
- Communications API — Customize connectivity between MATLAB and the PIL target. Embedded Coder provides host-side support for TCP/IP and serial communications, which you can adapt for other protocols.

These steps outline how you create a target connectivity API implementation. The example code shown in the steps is taken from the `ConnectivityConfig.m` file used in “Processor-in-the-Loop Execution From Command Line” on page 90-25.

**1** Create a subclass of `rtw.connectivity.Config`.

```
ConnectivityConfig < rtw.connectivity.Config
```

**2** In the subclass:

- Instantiate `rtw.connectivity.MakefileBuilder`, which configures the build process.

```
builder = rtw.connectivity.MakefileBuilder(componentArgs, ...
 targetApplicationFramework, ...
 exeExtension);
```

- Create a subclass of `rtw.connectivity.Launcher`, which downloads and executes the application using a third-party tool.

```
launcher = mypil.Launcher(componentArgs, builder);
```

**3** Configure your `rtiostream` API implementation of the host-target communications on page 90-16 channel.

- For the target side, you must provide the driver code for communications, for example, code for TCP/IP or serial communications. To integrate this code into the build process, create a subclass of `rtw.pil.RtIOStreamApplicationFramework`.

- For the host side, you can use a supplied library for TCP/IP or serial communications. Instantiate `rtw.connectivity.RtIOStreamHostCommunicator`, which loads and initializes the library that you specify.

```
hostCommunicator = rtw.connectivity.RtIOStreamHostCommunicator(...
 componentArgs, ...
 launcher, ...
 rtiostreamLib);
```

- 4 If you require execution-time profiling for generated code, create a timer object that provides details of the hardware-specific timer and associated source files. See “Specify Hardware Timer for MATLAB” on page 90-19.
- 5 If you require stack usage profiling for generated code, specify a driver implementation that obtains stack usage data from the target hardware. The driver must return the value of the stack register. If you do not specify a driver, the PIL simulation tries to use a default generic driver. See “Implement Driver to Obtain Stack Usage Data During PIL Execution” on page 82-17.

## Register Target Connectivity Configuration

To register a target connectivity API implementation as a target connectivity configuration in MATLAB:

- 1 Create or update an `rtwTargetInfo.m` file. In this file:
  - Create a target connectivity configuration object that specifies, for example, the configuration name for a target connectivity API implementation and compatible MATLAB code.
  - Invoke `registerTargetInfo`.
- 2 Add the folder containing `rtwTargetInfo.m` to the search path and refresh the MATLAB Coder library registration information.

For more information, see `rtw.connectivity.ConfigRegistry`.

## Verify Target Connectivity Configuration

To verify your target connectivity configuration early on and independently of your algorithm development and code generation, use the `piltest` function. With the function, you can run a suite of tests. The function:

- Runs the MATLAB function and performs PIL executions.
- Compares results and produces errors if it detects differences.

For an example, see “PIL Execution of Code Generated for a Kalman Estimator” on page 90-25.

## Host-Target Communication for MATLAB PIL Execution

### In this section...

- “Communications rtiostream API” on page 90-16
- “Synchronize Host and Target” on page 90-17
- “Test an rtiostream Driver” on page 90-17
- “Troubleshooting Host-Target Communication” on page 90-17

This section provides information about using the `rtiostream` API for communication between your development computer and target hardware during PIL execution.

### Communications rtiostream API

The `rtiostream` API supports communications for the target connectivity API. Use the `rtiostream` API to implement a communication channel that enables data exchange between different processes.

PIL verification requires a host-target communications channel. This communications channel comprises driver code that runs on the host and target. The `rtiostream` API defines the signature of target-side and host-side functions that must be implemented by this driver code.

The API is independent of the physical layer that sends the data. Possible physical layers include RS232, Ethernet, or Controller Area Network (CAN).

A full `rtiostream` implementation requires both host-side and target-side drivers. Code generation software includes host-side drivers for the default TCP/IP implementation as well as a version for serial communications. To use:

- The TCP/IP `rtiostream` communications channel, you must provide, or obtain from a third party, target-specific TCP/IP device drivers.
- The serial communications channel, you must provide, or obtain from a third party, target-specific serial device drivers.

For other communication channels and platforms, the code generation software does not provide default implementations. You must provide both the host-side and the target-side drivers.

The `rtiostream` API comprises the following functions:

- `rtIOStreamOpen`
- `rtIOStreamSend`
- `rtIOStreamRecv`
- `rtIOStreamClose`

For information about:

- Using `rtiostream` functions in a connectivity implementation, see “Create a Target Connectivity API Implementation” on page 90-12.
- Testing the `rtiostream` shared library methods from MATLAB code, see `rtiostream_wrapper`.
- Debugging and verifying the behavior of custom `rtiostream` interface implementations, see “Test an `rtiostream` Driver” on page 90-17 and `rtiostreamtest`.

## Synchronize Host and Target

If you use the `rtiostream` API to implement the communications channel, the host and target must be synchronized, which prevents MATLAB from transmitting and receiving data before the target application is fully initialized.

To synchronize the host and target for TCP/IP `rtiostream` implementations, use the `setInitCommsTimeout` method from `rtw.connectivity.RtIOStreamHostCommunicator`. This approach works well for connection-oriented TCP/IP `rtiostream` implementations because MATLAB automatically waits until the target server is running.

With other `rtiostream` implementations, for example, serial, the MATLAB side of the `rtiostream` connection opens without waiting for the target to be fully initialized. In this case, you must make your `Launcher` implementation wait until the target application is fully initialized. Use one of the following approaches to synchronize your host and target:

- Add a pause at the end of the `Launcher` implementation that makes the `Launcher` wait until target initialization is complete.
- In the `Launcher` implementation, use third-party downloader or debugger APIs that wait until target initialization is complete.
- Implement a handshaking mechanism in the `Launcher` / `rtiostream` implementation that confirms completion of target initialization.

## Test an rtiostream Driver

Use a test suite to debug and verify the behavior of custom `rtiostream` interface implementations.

The test suite can help you to:

- Reduce the time required for integrating custom hardware that does not have built-in `rtiostream` support.
- Reduce the time required for testing custom `rtiostream` drivers.
- Analyze the performance of custom `rtiostream` drivers.

The test suite consists of two parts. One part is an application that runs on the target hardware. The other part runs in MATLAB. For details, see `rtiostreamtest`.

## Troubleshooting Host-Target Communication

To display communication I/O information during PIL execution, in the MATLAB Coder app, on the **All Settings** tab, set **SIL/PIL Verbosity** to `On`. Or, in a `coder.EmbeddedCodeConfig` object, set the `SILPILVerbosity` property to `true`.

By default, **SIL/PIL Verbosity** is set to `Off`.

For SIL execution with **SIL/PIL Verbosity** set to `On`, the app displays I/O information for communication that occurs between MATLAB and the target application that runs as a separate process on your development computer.

### **See Also**

- “Create PIL Target Connectivity Configuration for MATLAB” on page 90-12

## Specify Hardware Timer for MATLAB

For processor-in-the-loop (PIL) code execution profiling, you must create a timer object that provides details of the hardware-specific timer and associated source files. You can use the **Code Replacement Tool** or the code replacement library API to specify this hardware-specific timer.

To specify the timer with the Code Replacement Tool:

- 1** Open the Code Replacement Tool. In the Command Window, enter `crtool`.
- 2** Create a new code replacement table. Select **File > New table**.
- 3** Create a new function entry. Under **Tables List**, right-click the new table. Then, from the context-menu, select **New entry > Function**.
- 4** In the middle view, select the new unnamed function.
- 5** On the **Mapping Information** pane:
  - a** From the **Function** drop-down list, select `code_profile_read_timer`.
  - b** Specify the count direction for your timer. For example, from the **Count direction** drop-down list, select **Up**.
  - c** In the **Ticks per second** field, specify the number of ticks per second for your timer, for example, `1e+09`.

The default value is 0. In this case, the software reports time measurements in terms of ticks, not seconds.

- d** In the **Conceptual function** section, from the **Data type** list, select `uint8`, `uint16`, `uint32`, or `uint64`.
- e** In the **Function prototype** section, in the **Name** field, specify a replacement function name, for example, `MyTimer`.
- f** Click **Apply**.

- g To validate the function entry, click **Validate entry**.
- 6 On the **Build Information** pane, specify the required build information. See Specify build information in “Define Code Replacement Library Optimizations” on page 72-36.
- 7 Save the table (**Ctrl+S**). When you save the table for the first time, use the Save As dialog box to specify the file name and location.

You must save the table in a location that is on the MATLAB search path. For example, you can save this file in the folder for your subclass of `rtw.connectivity.Config`.

The software stores your timer information as a code replacement library table.

- 8 Assuming you save the table as `MyCrlTable.m`, in your subclass of `rtw.connectivity.Config`, add the following line:

```
setTimer(this, MyCrlTable)
```

## Custom Toolchain Directives Required for Code Execution Profiling

If you use a custom toolchain for building a processor-in-the-loop (PIL) target application that supports code execution profiling, in the toolchain definition file, you must provide these compiler directives:

- `CompileFlag` — Specify the flag that C or C++ compiler uses to compile source files without linking. For example, if the compiler in the toolchain is GNU C or C++, set the directive to `-c`.
- `PreprocessFile` — Specify the flag that C or C++ compiler uses to preprocess the source files without running other compiler stages. For example, if the compiler in the toolchain is GNU C or C++, set the directive to `-E`.

This section from a toolchain definition file example shows how you can use the `setDirective` method to provide the directives.

```
tc = coder.make.ToolchainInfo('BuildArtifact','nmake makefile');
tc.Name = 'My Toolchain Name';
tc.Platform = 'win64';
tc.SupportedVersion = '14';
...
% -----
% C Compiler
% -----
tool = tc.getBuildTool('C Compiler');
tool.setName('My C Compiler');
...
tool.setDirective('CompileFlag','-c');
tool.setDirective('PreprocessFile','-E');
...
```

## Processor-in-the-Loop Execution with the MATLAB Coder App

Use processor-in-the-loop (PIL) execution to verify the numerical behavior of cross-compiled object code with reference to your original MATLAB functions.

Before you run a PIL execution, you must define a target connectivity configuration. In “Processor-in-the-Loop Execution From Command Line” on page 90-25, steps 1 and 2 of the example “PIL Execution of Code Generated for a Kalman Estimator” on page 90-25 show how you can set up and register a connectivity configuration for PIL execution on your development computer.

- 1 To open the MATLAB Coder app, on the MATLAB Toolstrip **Apps** tab, under **Code Generation**, click the app icon.
- 2 To open your project, click , and then click `Open existing project`. Select the project. For example, `kalman_filter.prj`.
- 3 On the **Generate Code** page, click the **Generate** arrow .
- 4 In the **Generate** dialog box:
  - a Set **Build type** to `Static Library` or `Dynamic Library`.
  - b In the **Output file name** field, use the default value. For example, `kalman01`.
  - c Clear the **Generate code only** check box.
  - d From the **Hardware Board** drop-down list, select `None - Select device below`.
  - e In the **Device** fields, specify vendor and type. These settings must match the target hardware settings in the `rtwTargetInfo.m` file of your target connectivity configuration. For host-based PIL, select settings that match your host computer. For example:
    - For a Windows 64-bit system, set **Device vendor** to `Intel` and **Device type** to `x86-64 (Windows64)`. In addition, set **Enable long long** to `Yes`.
    - For a Linux 64-bit system, set **Device vendor** to `Intel` and **Device type** to `x86-64 (Linux 64)`.
    - For a Mac OS X system, set **Device vendor** to `Intel` and **Device type** to `x86-64 (Mac OS X)`.

You do not have to specify the **Toolchain** setting. By default, the MATLAB Coder app locates an installed toolchain.

- 5 To generate the C or C++ code, click **Generate**.
- 6 Click **Verify Code**.
- 7 In the command field, specify the test file that calls the original MATLAB functions, for example, `test01_ui.m`.
- 8 To start the PIL execution, click **Run Generated Code**.

The MATLAB Coder app:

- Generates a standalone library, for example, `codegen\lib\kalman01`.
- Generates PIL interface code, for example, `codegen\lib\kalman01\pil`.
- Runs the test file, replacing calls to the MATLAB function with calls to the generated code in the library.

- Displays messages from the PIL execution in the **Test Output** tab.
- 9** Verify that the results from the PIL execution match the results from the original MATLAB functions.
  - 10** To terminate the PIL execution process, click **Stop PIL Verification**. Alternatively, on the **Test Output** tab, click the link that follows To terminate execution.

---

**Note** On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL execution. To allow the execution, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

---

## Processor-in-the-Loop Execution From Command Line

Use processor-in-the-loop (PIL) execution to verify code that you intend to deploy in production.

To set up and start a PIL execution from the command line:

- 1 Create, register, and verify your target connectivity configuration.
- 2 Create a `coder.EmbeddedCodeConfig` object.
- 3 Configure the object for PIL.
- 4 Use the `codegen` function to generate library code for your MATLAB function and the PIL interface.
- 5 Use the `coder.runTest` function to run the test file for your original MATLAB function.

To terminate the PIL execution, use the `clear function_pil` or `clear mex` command.

The following example shows how you can use line commands to set up and run a PIL execution on your development computer.

### PIL Execution of Code Generated for a Kalman Estimator

#### 1 Create a target connectivity API implementation

- a In your current working folder, make a local copy of the connectivity classes.

```
src_dir = ...
 fullfile(matlabroot, 'toolbox', 'coder', 'simulinkcoder', '+coder', '+mypil');
if exist(fullfile('.', '+mypil'), 'dir')
 rmdir('+mypil', 's')
end
mkdir +mypil
copyfile(fullfile(src_dir, 'Launcher.m'), '+mypil');
copyfile(fullfile(src_dir, 'TargetApplicationFramework.m'), '+mypil');
copyfile(fullfile(src_dir, 'ConnectivityConfig.m'), '+mypil');
```

- b Make the copied files writable.

```
fileattrib(fullfile('+mypil', '*'), '+w');
```

- c Update the package name to reflect the new location of the files.

```
coder.mypil.Utils.UpdateClassName(...
 './+mypil/ConnectivityConfig.m', ...
 'coder.mypil', ...
 'mypil');
```

- d Check that you now have a folder `+mypil` in the current folder, which includes three files, `Launcher.m`, `TargetApplicationFramework.m`, and `ConnectivityConfig.m`.

```
dir './+mypil'
```

- e Review the code that starts the PIL application. The `mypil.Launcher` class configures a tool for starting the PIL executable. Open this class in the editor.

```
edit(which('mypil.Launcher'))
```

Review the content of this file. For example, consider the `setArgString` method. This method allows additional command line parameters to be supplied to the application. These parameters can include a TCP/IP port number. For an embedded processor implementation, you might have to hard code these settings.

- f The class `mypil.ConnectivityConfig` configures target connectivity.

```
edit(which('mypil.ConnectivityConfig'))
```

Review the content of this file. For example:

- The creation of an instance of `rtw.connectivity.RtIOStreamHostCommunicator` that configures the host side of the TCP/IP communications channel.
- A call to the `setArgString` method of `Launcher` that configures the target side of the TCP/IP communications channel.
- A call to `setTimer` that configures a timer for execution time measurement. To define your own target-specific timer for execution time profiling, you must use the Code Replacement Library to specify a replacement for the function `code_profile_read_timer`.

**g** Review the target-side communication drivers.

```
rtiostreamtcpip_dir=fullfile(matlabroot,'toolbox','coder','rtiostream','src',...
 'rtiostreamtcpip');
edit(fullfile(rtiostreamtcpip_dir,'rtiostream_tcpip.c'))
```

Scroll down to the end of this file. The file contains a TCP/IP implementation of the functions `rtIOStreamOpen`, `rtIOStreamSend`, and `rtIOStreamRecv`. These functions are required for target communication with the host. For each of these functions, you must provide an implementation that is specific to your target hardware and communication channel.

The `mypil.TargetApplicationFramework` class adds target-side communication drivers to the connectivity configuration.

```
edit(which('mypil.TargetApplicationFramework'))
```

The file specifies additional files to include in the build.

## 2 Register a target connectivity configuration

Use an `rtwTargetInfo.m` file to:

- Create a target connectivity configuration object.
- Invoke `registerTargetInfo`, which registers the target connectivity configuration.

The target connectivity configuration object specifies, for example:

- The configuration name and associated API implementation. See `rtw.connectivity.ConfigRegistry`.
- A toolchain for your target hardware. This example assumes that the target hardware is your host computer, and uses the toolchain supplied for host-based PIL verification. For information about toolchains, see “Custom Toolchain Registration”.

**a** Insert the following code into your `rtwTargetInfo.m` file, and save the file in the current working folder or in a folder that is on the MATLAB search path:

```
function rtwTargetInfo(tr)
% Register PIL connectivity config: mypil.ConnectivityConfig

tr.registerTargetInfo(@loc_createConfig);

% local function
function config = loc_createConfig

% Create object for connectivity configuration
config = rtw.connectivity.ConfigRegistry;
% Assign connectivity configuration name
config.ConfigName = 'My PIL Example';
```

```

% Associate the connectivity configuration with the connectivity
% API implementation
config.ConfigClass = 'mypil.ConnectivityConfig';

% Specify toolchains for host-based PIL
config.Toolchain = rtw.connectivity.Utils.getHostToolchainNames;

% Through the HardwareBoard and TargetHWDeviceType properties,
% define compatible code for the target connectivity configuration
config.HardwareBoard = {}; % Any hardware board
config.TargetHWDeviceType = {'Generic->32-bit x86 compatible' ...
 'Generic->Custom' ...
 'Intel->x86-64 (Windows64)', ...
 'Intel->x86-64 (Mac OS X)', ...
 'Intel->x86-64 (Linux 64)'};

```

- b** Refresh the MATLAB Coder library registration information.

```
RTW.TargetRegistry.getInstance('reset');
```

### 3 Verify target connectivity configuration

Use the supplied `piltest` function to verify your target connectivity configuration.

- a** Create a `coder.EmbeddedCodeConfig` object for verifying the target connectivity configuration.

```
configVerify = coder.config('lib');
```

- b** Specify the manufacturer and test hardware type. For example, PIL execution on a 64-bit Windows development computer requires:

```
configVerify.HardwareImplementation.TargetHWDeviceType = ...
 'Intel->x86-64 (Windows64)';
configVerify.HardwareImplementation.ProdLongLongMode = true;
```

- c** Run `piltest`.

```
piltest(configVerify, 'ConfigParam', {'ProdLongLongMode'})
```

### 4 Copy MATLAB code for Kalman estimator

Copy the MATLAB code to your working folder.

```
src_dir = ...
 fullfile(docroot, 'toolbox', 'coder', 'examples', 'kalman');

copyfile(fullfile(src_dir, 'kalman01.m'), '.')
copyfile(fullfile(src_dir, 'test01_ui.m'), '.')
copyfile(fullfile(src_dir, 'plot_trajectory.m'), '.')
copyfile(fullfile(src_dir, 'position.mat'), '.')

```

For a description of the Kalman estimator in this example, see “Generate C Code at the Command Line”.

### 5 Configure the PIL execution

- a** Create a `coder.EmbeddedCodeConfig` object.

```
config = coder.config('lib');
```

- b** Configure the object for PIL.

```
config.VerificationMode = 'PIL';
```

- c** Specify production hardware, which must match one of the test hardware settings in `rtwTargetInfo.m`. For PIL execution on your development computer, specify settings that match the computer. For example, if your computer is a Windows 64-bit system, specify:

```
config.HardwareImplementation.ProdHWDeviceType =...
 'Intel->x86-64 (Windows64)';
config.HardwareImplementation.ProdLongLongMode = true;
```

For a Linux 64-bit system, set `ProdHWDeviceType` to `'Intel->x86-64 (Linux 64)'`.

For a Mac OS X system, set `ProdHWDeviceType` to `'Intel->x86-64 (Mac OS X)'`.

## 6 Generate code and run PIL execution

Generate library code for the `kalman01` MATLAB function and the PIL interface, and run the MATLAB test file, `test01_ui`. The test file uses `kalman01_pil`, the generated PIL interface for `kalman01`.

```
codegen -config config -args {zeros(2,1)} kalman01 -test test01_ui
```

The software creates the following output folders:

- `codegen\lib\kalman01` — Standalone code for `kalman01`.
- `codegen\lib\kalman01\pil` — PIL interface code for `kalman01`.

Verify that the output of this run matches the output from the original `kalman01.m` function.

---

**Note** On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL execution. To allow the execution, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

---

## 7 Terminate PIL execution

Terminate the PIL execution process.

```
clear kalman01_pil;
```

### More About

- “Code Verification Through Software-in-the-Loop and Processor-in-the-Loop Execution” on page 90-2

## Verification of Code Generation Assumptions

The settings on the **More Settings > Hardware** tab specify target behavior, which result in the implementation of implicit assumptions in the generated code. Incorrect settings can lead to:

- Suboptimal code
- Code execution failure, incorrect code output, and nondeterministic code behavior

At the start of a processor-in-the-loop (PIL) execution, the software verifies the **Hardware** tab settings with reference to the target hardware. The software checks:

- The correctness of settings. For example, the integer bit length in the **Sizes > int** field.
- Whether the settings are optimized. For example, the rounding of signed integer division in the **Signed integer division rounds to** field.

If required, the software generates warnings and errors.

## SIL/PIL Execution Support and Limitations

Feature		Supported
Output types	Static library	Yes
	Dynamic library	Yes
	Executable	No
Languages	C	Yes
	C++	Yes
Interface types	Inputs	Yes
	Outputs	Yes
	Constant inputs	Yes
	Global data	<p>Yes. SIL and PIL execution supports four types of storage classes on page 98-2 for MATLAB Coder global variables. The synchronization of global data between MATLAB and the SIL or PIL application depends on the type of storage class that you specify:</p> <ul style="list-style-type: none"> <li>• <code>ExportedGlobal</code> (default) — The synchronization of global data between MATLAB and a SIL or PIL application is identical to the synchronization between MATLAB and a MEX function.</li> <li>• <code>ExportedDefine</code> — There is no synchronization of global data between MATLAB and the SIL or PIL application. The application uses the values of the global variables in MATLAB at the time of code generation.</li> <li>• <code>ImportedExtern</code> and <code>ImportedExternPointer</code> — There is no synchronization of global data between MATLAB and the SIL or PIL application. The application uses initial values of global variables, which you specify in the external code. If the global variables are not initialized in the external code, the SIL or PIL execution results are undefined.</li> </ul>
	Constant global data	Yes
	Reentrant code	Yes
	Multiple entry points	Yes
Data types	Basic types	Yes
	Enumerated types	Yes
	Structures	Yes

Feature		Supported
	Complex data	Yes
	Fixed-point data	Yes
	Multiword fixed-point data	SIL only
	char arrays	Yes
	Empty values	Yes
	Cell arrays	Yes
Size	Scalars	Yes
	Fixed-size arrays	Yes
	Static variable-size arrays	Yes
	Dynamic variable-size size arrays	Yes

## Speed Up SIL/PIL Execution by Disabling Constant Input Checking and Global Data Synchronization

By default, a SIL or PIL execution performs constant input checking and global data synchronization. Constant input checking compares the value that a test file provides for a constant input argument with the value specified at code generation time. If the values do not match, an error occurs. Global data synchronization makes the values of global variables in the SIL or PIL execution environment consistent with the values in the MATLAB workspace. If a global variable is constant and its value in the SIL or PIL execution environment differs from its value in the MATLAB workspace, an error occurs.

It is possible to speed up a SIL or PIL execution by disabling constant input checking or global data synchronization. However, if you disable these features, the SIL or PIL execution results might differ from the results in MATLAB.

### Disable Constant Input Checking or Global Data Synchronization at the Command Line

In a coder .EmbeddedCodeConfig object that you configured for SIL or PIL execution:

- To disable constant input checking, set the `SILPILCheckConstantInputs` property to `false`. For example, for an object `cfg`, use this code:

```
cfg.SILPILCheckConstantInputs = false;
```

- To disable global data synchronization, set the `SILPILSyncGlobalData` property to `false`. For example, for an object `cfg`, use this code:

```
cfg.SILPILSyncGlobalData = false;
```

### Disable Constant Input Checking or Global Data Synchronization in the MATLAB Coder App

In the settings for a project that you set up for SIL or PIL execution, on the **Debugging** tab:

- To disable constant input checking, set **Check constant inputs in SIL/PIL** to **No**.
- To disable global data synchronization, set **Synchronize global data in SIL/PIL** to **No**.

## SIL and PIL Verification for Deployment on Raspberry Pi

This example shows how to verify the generated code by using the software-in-the-loop (SIL) and processor-in-the-loop (PIL) executions. In this example, the PIL execution uses a Raspberry Pi® hardware board.

### Run MATLAB Code

This example uses these supporting files:

- `kalman01.m` contains the MATLAB® function `kalman01` for the Kalman estimator.
- `position.mat` contains the input data about the trajectory of an object.
- `test01_ui.m` is a MATLAB script that loads the input data from `position.mat` into the workspace, calls `kalman01` to estimate the object location by using the Kalman filtering algorithm, and finally calls the `plot_trajectory` function that plots both the actual trajectory of the object and the Kalman estimate.
- `plot_trajectory.m` contains the `plot_trajectory` function described above.

To test the MATLAB code, run the script `test01_ui`.

```
test01_ui
```

```
Current plot held
```

```
Current plot released
```

In the plot that is displayed, you see that the Kalman estimate closely follows the actual trajectory of the object. The test data includes two sudden shifts or discontinuities in position. These discontinuities check that the Kalman filter can quickly readjust its estimate and get back to tracking the object accurately.

For more information, see “C Code Generation for a MATLAB Kalman Filtering Algorithm”.

### Software-in-the-Loop (SIL) Execution

In SIL execution, through a MATLAB SIL interface, the code generator compiles and runs library code on your development computer.

#### Configure SIL Execution

Create a `coder.EmbeddedCodeConfig` object to generate a static C library. Set the `VerificationMode` property to 'SIL'. Optionally, enable the Microsoft® Visual Studio® debugger for SIL execution.

```
config = coder.config('lib');
config.VerificationMode = 'SIL';
% config.SILDebugging = true;
```

Check that the production hardware setting is set to the default value 'Generic->MATLAB Host Computer'.

```
disp(config.HardwareImplementation.ProdHWDeviceType);
```

```
Generic->MATLAB Host Computer
```

#### Generate Static Library and Run SIL Execution

Use the `codegen` command with the configuration object `config` to generate a static C library and the SIL interface for the `kalman01` function. To perform SIL execution, you can simply call the generated SIL interface `kalman01_sil` at the MATLAB command line.

In the `codegen` command, the `-test` option enables you to run the test script `test01_ui` with calls to the `kalman01` function replaced by calls to the generated SIL interface `kalman01_sil`.

```
codegen -config config -args {zeros(2,1)} kalman01 -report -test test01_ui
```

```
Code generation successful: View report
```

```
Running test file: 'test01_ui' with MEX function 'kalman01_sil.mexw64'.
```

```
Current plot held
```

```
Starting SIL execution for 'kalman01'
```

```
 To terminate execution: clear kalman01_sil
```

Current plot released

The code generator creates these output folders:

- `codegen\lib\kalman01` — Static library for `kalman01`.
- `codegen\lib\kalman01\sil` — SIL interface code for `kalman01`.

Observe that the output of this run matches the output from the `kalman01` MATLAB function.

### Debug Code During SIL Execution

If you enable the Microsoft Visual Studio debugger, then running the test file opens the Microsoft Visual Studio IDE with debugger breakpoints at the start of the `kalman01_initialize` and `kalman01` functions.

You can use the debugger features to observe code behavior. For example, you can step through code and examine variables.

To end the debugging session:

- Remove all breakpoints.
- Click the Continue button (**F5**).

The SIL execution runs to completion.

### Terminate SIL Execution

Terminate the SIL execution process.

```
clear kalman01_sil;
Stopping SIL execution for 'kalman01'
```

You can also use the command `clear mex`, which clears MEX functions from memory.

### Usage Notes for Windows® platform

Usage notes for SIL execution on a Windows platform:

- The Windows Firewall can potentially block a SIL execution. To allow the execution, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.
- Suppose that the MATLAB current working directory (the folder that `pwd` displays) is a UNC path (for example, `\\server\a\b\c`) on a Windows platform. If you launch a SIL executable from this path, the location where the SIL executable is launched can be unpredictable and different from the MATLAB current working directory (for example, `C:\Windows`). To fix this issue, use a mapped network drive for the UNC path as your MATLAB current working directory.

### Processor-in-the-Loop (PIL) Execution

In PIL execution, through a MATLAB PIL interface, the code generator cross-compiles and runs production object code on a target processor or an equivalent instruction set simulator. Before you run a PIL execution, you must set up a PIL connectivity configuration for your target. In this example, the PIL execution uses a Raspberry Pi® hardware board.

### Configure PIL Execution

Create a `coder.EmbeddedCodeConfig` object to generate a static C library. Set the `VerificationMode` property to `'PIL'`. Set the `Hardware` property to a hardware board configuration object for Raspberry Pi.

```
config = coder.config('lib');
config.VerificationMode = 'PIL';
config.Hardware = coder.hardware('Raspberry Pi');
```

If you are to your Raspberry Pi hardware board for the first time, you must also specify the `Username`, `DeviceAddress`, and `Password` properties of the `config.Hardware` parameter.

### Generate Static Library and Run PIL Execution

Use the `codegen` command with the configuration object `config` to generate a static C library and the PIL interface for the `kalman01` function. To perform PIL execution, you can simply call the generated PIL interface `kalman01_pil` at the MATLAB command line.

In the `codegen` command, the `-test` option enables you to run the test script `test01_ui` with calls to the `kalman01` function replaced by calls to the generated PIL interface `kalman01_pil`.

```
codegen -config config -args {zeros(2,1)} kalman01 -report -test test01_ui
```

```
Connectivity configuration for function 'kalman01': 'Raspberry Pi'
Location of the generated elf : /home/pi/MATLAB_ws/R2021b/C/Users/aghosh/Documents/Examples/ecod
Code generation successful: View report
```

```

Running test file: 'test01_ui' with MEX function 'kalman01_pil.mexw64'.
Current plot held
Connectivity configuration for function 'kalman01': 'Raspberry Pi'
Starting application: 'codegen\lib\kalman01\pil\kalman01.elf'
 To terminate execution: clear kalman01_pil
Launching application kalman01.elf...

```

Current plot released

The code generator creates these output folders:

- codegen\lib\kalman01 — Static library for kalman01.
- codegen\lib\kalman01\pil — PIL interface code for kalman01.

Observe that the output of this run matches the output from the kalman01 MATLAB function.

The Windows Firewall can potentially block a PIL execution. To allow the execution, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

### Terminate PIL Execution

Terminate the PIL execution process.

```
clear kalman01_pil;
```

```
Host application produced the following standard output (stdout) and standard error (stderr)
```

You can also use the command `clear mex`, which clears MEX functions from memory.

### **More About**

- “Code Verification Through Software-in-the-Loop and Processor-in-the-Loop Execution” on page 90-2

# Software-in-the-loop Execution For MATLAB Function with Multiple Signatures

## In this section...

“Generate Multisignature SIL MEX File for an Entry-Point Function” on page 90-39

“Generate Multisignature SIL MEX File for Multiple Entry-Point Functions” on page 90-40

For MATLAB function with multiple signatures, software-in-the-loop (SIL) enables you to verify the generated C/C++ code by using a SIL MEX file that supports multiple signatures. This feature enables you to generate one SIL MEX file for verification instead of generating separate SIL MEX files for each signature.

## Generate Multisignature SIL MEX File for an Entry-Point Function

### 1 MATLAB code for myAdd function

Copy the MATLAB code of one entry-point function `myAdd`, and save it in your working directory.

The entry-point function, `myAdd`, returns the sum of two values.

```
function y = myAdd(a,b)
%#codegen
y = a+b;
end
```

### 2 Configure SIL execution

Create a `coder.EmbeddedCodeConfig` object and configure the object for SIL.

```
cfg = coder.config('lib');
cfg.VerificationMode = "SIL";
```

### 3 Generate code using codegen command

The `codegen` command generates a SIL MEX file `myAdd_sil` that works with three different data types: `double`, `int8`, and `vector of doubles`. You specify the entry-point function followed by `-args` for each signature of the entry-point function.

```
codegen -config cfg myAdd-args {1,2} -args {int8(2),int8(3)} -args {1:10,1:10} -report
```

### 4 Run generated SIL MEX file myAdd\_sil

At the command prompt, call the generated SIL MEX file `myAdd_sil`. Make sure that the values you pass to `myAdd_sil` match the input properties that you specified in the `codegen` command.

```
myAdd_sil(3,4)
ans =
 7

myAdd_sil(int8(5),int8(6))
ans =
 int8
```

```

11
myAdd_sil(1:10,2:11)
ans =
 3 5 7 9 11 13 15 17 19 21

```

Running the MATLAB function `myAdd` with these input values produces the same output. These test cases verify that `myAdd` and `myAdd_sil` have the same behavior.

## 5 Terminate SIL execution

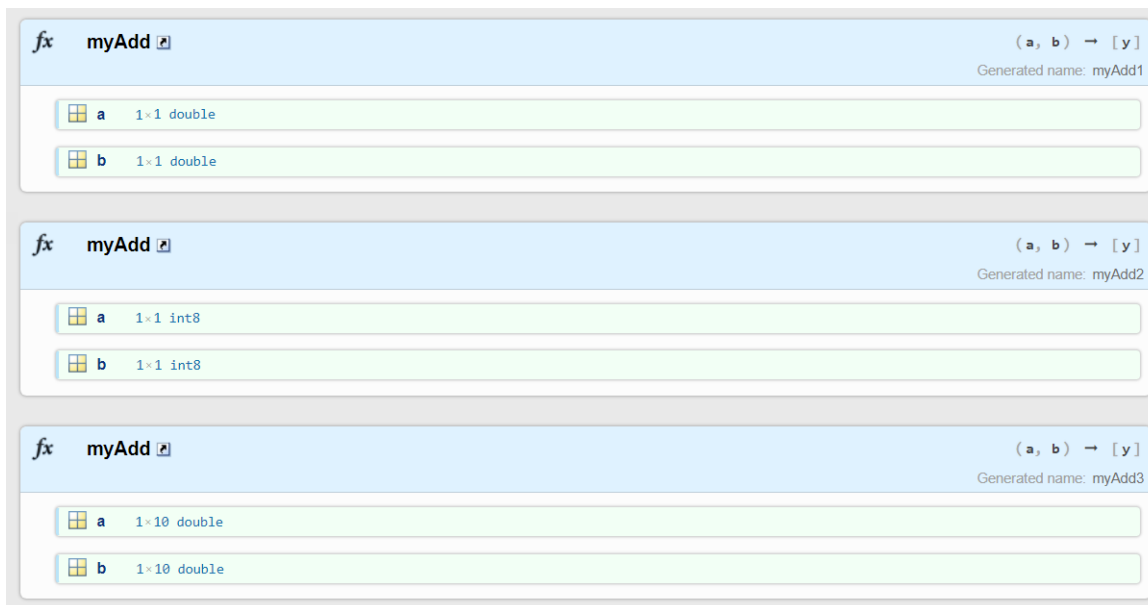

Terminate the SIL execution process.

```
clear myAdd_sil;
```

You can also use the command `clear mex`, which clears MEX files from memory.

## 6 Entry Point Summary Report

In the generated code, different signatures are mapped to versioned entry-point functions `myAdd1`, `myAdd2`, and `myAdd3` as shown in the figure.

## Generate Multisignature SIL MEX File for Multiple Entry-Point Functions

### 1 MATLAB code for myAdd and myMul functions

Copy the MATLAB codes of two entry-point functions, `myAdd` and `myMul` and save it in your working directory.

The first entry-point function, `myAdd`, returns the sum of two values:

```
function y = myAdd(a,b)
%#codegen
```

```
y = a+b;
end
```

The second entry-point function, `myMul`, returns the multiplication of two values:

```
function y = myMul(a,b)
%#codegen
y = a*b;
end
```

## 2 Configure SIL execution

Create a `coder.EmbeddedCodeConfig` object and configure the object for SIL.

```
cfg = coder.config('lib');
cfg.VerificationMode = "SIL";
```

## 3 Generate code using codegen command

The `codegen` command generates a SIL MEX file `myMath_sil` for the signatures that you specified in the `codegen` command. The SIL MEX file `myMath_sil` works for `myAdd` and `myMul` with two different data types: `double`, and `int8`. You specify the entry-point function followed by `-args` for each signature of the entry-point function.

```
codegen -config cfg myAdd.m -args {1,2} -args {int8(1),int8(2)} myMul.m -args {1,2} -args {in
```

## 4 Run generated SIL MEX file myMath\_sil

At the command prompt, call the generated SIL MEX file `myMath_sil`. Make sure that the values you pass to `myMath_sil` match the input properties that you specified in the `codegen` command.

```
myMath_sil("myAdd",3,4)
```

```
ans =
```

```
7
```

```
myMath_sil("myAdd",int8(5),int8(6))
```

```
ans =
```

```
int8
```

```
11
```

```
myMath_sil("myMul",3,4)
```

```
ans =
```

```
12
```

```
myMath_sil("myMul",int8(5),int8(6))
```

```
ans =
```

```
int8
```

```
30
```

Running the MATLAB function `myAdd` and `myMul` with these input values produces the same output. These test cases verify that `myAdd`, `myMul` and the generated SIL MEX file `myMath_sil` have the same behavior.

## 5 Terminate SIL execution

Terminate the SIL execution process.

```
clear myMath_sil;
```

You can also use the command `clear mex`, which clears MEX files from memory.

## 6 Entry Point Summary Report

In the generated code, different signatures are mapped to versioned entry-point functions `myAdd1`, `myAdd2`, `myMul1` and `myMul2` as shown in the figure.

Example main file provides information about how to use entry-points in your application. “Incorporate Generated Code Using an Example Main Function”, helps to generate example main.c file.

**Note** You can implement the multisignature PIL MEX for an entry-point function and multiple entry-point functions in the same way that the multisignature SIL MEX is implemented.

## Limitations

The multisignature SIL MEX and PIL MEX generation does not have graphical user interface (GUI) support.

## Simulink Code Coverage Metrics

### In this section...

“Statement Coverage” on page 91-2  
 “Condition Coverage” on page 91-2  
 “Decision Coverage” on page 91-3  
 “Modified Condition/Decision Coverage (MCDC)” on page 91-4  
 “Cyclomatic Complexity” on page 91-4  
 “Relational Boundary Coverage” on page 91-5

If you have a Simulink Coverage license, you can run a SIL or PIL simulation that produces code coverage metrics for generated model code. The simulation performs several types of code coverage analysis.

### Statement Coverage

Statement coverage measures the number of source code statements that execute when the code runs. Use this type of coverage to determine whether every statement in the program has been invoked at least once.

The percentage of statement coverage is represented by the following equation:

$$\text{Statement coverage} = (\text{Number of executed statements} / \text{Total number of statements}) * 100$$

#### Statement Coverage Example

This code snippet contains five statements. To achieve 100% statement coverage, you need at least one test with positive  $x$  values, one test with negative  $x$  values, and one test with  $x$  values of zero.

```

if (x > 0)
 printf("x is positive");
else if (x < 0)
 printf("x is negative");
else
 printf("x is 0");

```

### Condition Coverage

Condition coverage analyzes statements that include conditions in source code. Conditions are C/C++ Boolean expressions that contain relation operators (<, >, <=, or >=), equation operators (!= or ==), or logical negation operators (!), but that do not contain logical operators (&& or ||). This type of coverage determines whether every condition has been evaluated to all possible outcomes at least once.

The percentage of condition coverage is represented by the following equation:

$$\text{Condition coverage} = (\text{Number of executed condition outcomes} / \text{Total number of condition outcomes}) * 100$$

## Condition Coverage Example

In this expression:

```
y = x<=5 || x!=7;
```

there are two conditions:

```
x<=5
x!=7
```

To achieve 100% condition coverage, your test cases need to demonstrate a true and false outcome for both conditions. For example, a test case where  $x$  is equal to 4 demonstrates a true case for both conditions, and a case where  $x$  is equal to 7 demonstrates a false case for both conditions.

## Decision Coverage

Decision coverage analyzes statements that represent decisions in source code. Decisions are Boolean expressions composed of conditions and one or more of the logical C/C++ operators `&&` or `||`. Conditions within branching constructs (if/else, while, and do-while) are decisions. Decision coverage determines the percentage of the total number of decision outcomes the code exercises during execution. Use this type of coverage to determine whether all decisions, including branches, in your code are tested.

---

**Note** The decision coverage definition for DO-178C compliance differs from the Simulink Coverage definition. For decision coverage compliance with DO-178C, in the Configuration Parameters, set the **Structural Coverage Level** to Condition Decision for Boolean expressions not containing `&&` or `||` operators.

---

The percentage of decision coverage is represented by the following equation:

$$\text{Decision coverage} = (\text{Number of executed decision outcomes} / \text{Total number of decision outcomes}) * 100$$

## Decision Coverage Example

This code snippet contains three decisions:

```
y = x<=5 && x!=7; // decision #1

if(x > 0) // decision #2
 printf("decision #2 is true");
else if(x < 0 && y) // decision #3
 printf("decision #3 is true");
else
 printf("decisions #2 and #3 are false");
```

To achieve 100% decision coverage, your test cases must demonstrate a true and false outcome for each decision.

## Modified Condition/Decision Coverage (MCDC)

Modified condition/decision coverage (MCDC) analyzes whether the conditions within decisions independently affect the decision outcome during execution. To achieve 100% MCDC, your test cases must demonstrate:

- All conditions within decisions have been evaluated to all possible outcomes at least once.
- Every condition within a decision independently affects the outcome of the decision.

The percentage of MCDC is represented by the following equation:

$$\text{MCDC coverage} = (\text{Number of conditions evaluated to all possible outcomes affecting the outcome of the decision} / \text{Total number of conditions within the decisions}) * 100$$

### Modified Condition/Decision Coverage Example

For this decision:

```
X || (Y && Z)
```

the following set of test cases delivers 100% MCDC coverage.

	X	Y	Z
Test case #1	0	0	1
Test case #2	0	1	0
Test case #3	0	1	1
Test case #4	1	0	1

In order to demonstrate that the conditions Y and Z can independently affect the decision outcome, the condition X must be false for those test cases. If the condition X is true, then the decision is already known to be true. Therefore, the conditions Y and Z would not affect the decision outcome.

## Cyclomatic Complexity

Cyclomatic complexity measures the structural complexity of code by using the McCabe complexity measure. To compute the cyclomatic complexity of code, code coverage uses this formula:

$$c = \sum_{1}^{N} (o_n - 1)$$

$N$  is the number of decisions in the code.  $o_n$  is the number of outcomes for the  $n^{\text{th}}$  decision point. Code coverage adds 1 to the complexity number for each C/C++ function.

### Coverage Example

For this code snippet, the cyclomatic complexity is 3:

```
void evalNum(int x)
{
 if (x > 0) // decision #1
 printf("x is positive");
 else if (x < 0) // decision #2
```

```
 printf("x is negative");
else
 printf("x is 0");
}
```

The code contains one function that has two decision points. Each decision point has two outcomes. Using the preceding formula,  $N$  is 2,  $o_1$  is 2, and  $o_2$  is 2. Code coverage uses the formula with these decisions and outcomes and adds 1 for the function. The cyclomatic complexity for this code snippet is:

$$c = (o_1 - 1) + (o_2 - 1) + 1 = (2 - 1) + (2 - 1) + 1 = 3$$

## Relational Boundary Coverage

Relational boundary code coverage examines code that has relational operations. Relational boundary code coverage metrics align with those for model coverage, as described in “Relational Boundary Coverage” (Simulink Coverage). Fixed-point values in your model are integers during code coverage.

## See Also

### Related Examples

- “Code Coverage for Models in Software-in-the-Loop (SIL) Mode and Processor-in-the-Loop (PIL) Mode” on page 91-6

## Code Coverage for Models in Software-in-the-Loop (SIL) Mode and Processor-in-the-Loop (PIL) Mode

If you have Embedded Coder and Simulink Coverage, you can analyze coverage for generated code during a software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulation.

### In this section...

“Enable SIL or PIL Code Coverage for a Model” on page 91-6

“Review the Coverage Results for Models in SIL or PIL Mode” on page 91-6

“Limitations” on page 91-7

### Enable SIL or PIL Code Coverage for a Model

To record SIL or PIL code coverage for a model:

- 1 Ensure you have a supported compiler installed. For a list of supported compilers, see Supported and Compatible Compilers.
- 2 In the Configuration Parameters dialog box, on the left pane, click **Code Generation**. From the list, select **Verification**.
- 3 Under **Code profiling**, set **Measure function execution times** to Off.
- 4 Under **Code coverage for SIL or PIL**, set **Third-party tool** to None (use Simulink Coverage).
- 5 Enable coverage for a model in SIL or PIL mode or a reference model in SIL or PIL mode. For more information about enabling coverage, see “Specify Coverage Options” (Simulink Coverage).
- 6 Run a SIL or PIL simulation.

---

**Note** The **Coverage (Run)** button in the Coverage toolstrip forces a Normal mode simulation for the top-level model and does not yield SIL or PIL code coverage.

---

To run a SIL or PIL simulation:

- a In the Simulink window, click **Apps** and then click **SIL/PIL Manager**.
- b In the **SIL/PIL** tab, click **Automated Verification > SIL/PIL Simulation Only**.
- c Click **Run SIL/PIL**.

### Review the Coverage Results for Models in SIL or PIL Mode

To view the code coverage information in the Code view, from the drop-down list to the right of the search box, select **Show code coverage**. If the option is disabled, then on the **Coverage** tab, click **Coverage Highlighting**. The code displays highlighting and annotations that show code coverage information. You can navigate from the code to the associated model blocks by using the links in the line numbers, code elements, and comments.

At the bottom of the Code view, the coverage section shows a summary of the code coverage report.

## Limitations

Coverage for models in SIL and PIL mode has these limitations:

- The model must meet the requirements listed in “Enable SIL or PIL Code Coverage for a Model” on page 91-6.
- Code coverage results must not include external C/C++ files in read-only folders.
- The **Coverage (Run)** button in the Coverage toolstrip forces a Normal simulation and will not yield SIL or PIL code coverage.

## **See Also**

### **Related Examples**

- “Custom Toolchain Directives Required for Code Coverage and Execution Profiling” on page 88-62
- “Software-in-the-Loop Code Coverage” (Simulink Coverage)
- “SIL/PIL Manager Verification Workflow” on page 88-70

## Configure Code Coverage with Third-Party Tools

During a top-model or Model block SIL or PIL simulation, you can collect code coverage metrics for generated code using a third-party tool. Embedded Coder supports the following tools:

- The LDRA tool suite from LDRA Software Technology. For information about installing and using this tool, go to [www.ldra.com](http://www.ldra.com).

The software supports LDRA code coverage for SIL and PIL.

- BullseyeCoverage from Bullseye Testing Technology. For information about installing and using this tool, go to [www.bullseye.com](http://www.bullseye.com).

The software supports BullseyeCoverage code coverage for SIL and, in certain cases, PIL.

---

**Note** SIL and PIL simulation support for BullseyeCoverage will be removed in a future release.

---

To configure a code coverage tool for a top-model or Model block SIL or PIL simulation, in the Configuration Parameters dialog box, select the **Verification** pane:

- 1 From the **Third-party tool** drop-down list, select a tool, for example, BullseyeCoverage or LDRAcover or LDRA tool suite.
- 2 Click **Configure** to open the Code Coverage Settings dialog box.
- 3 In the **Installation folder** field, specify the location where your coverage tool is installed. If you click **Browse**, the Select Installation Folder dialog box opens, which allows you to navigate to the folder where your coverage tool is installed. The software detects and displays the tool version.

Description

Configure the code coverage tool to instrument the automatically generated code and collect coverage data. Use SIL or PIL simulation mode to collect this information.

For instructions on how to obtain the code coverage tool and other information, click Help.

Code coverage tool

The code coverage tool is LDRAcover or LDRA tool suite from LDRA Ltd. For supported version numbers, refer to the documentation.

Installation folder: C:\LDRA\v\_9\_8\_4\win64 Browse...

Detected tool version: 9.8.4

Select models

Code coverage for this model (rtwdemo\_sil\_topmodel)

Code coverage for referenced models

OK Cancel Help Apply

By default, the following parameters are enabled:

- **Code coverage for this model** — Generate coverage data for the current (top) model.
- **Code coverage for referenced models** — Generate data for models referenced by the current (top) model.

If your top model has Model blocks, these parameters of the top model override the corresponding parameters of referenced models.

**4** Click **OK**.

With the LDRA tool suite:

- The evaluation of cumulative code coverage begins from the point when you last added a new file to the existing set of source files. For example, existing code coverage results are deleted when you:
  - Run a simulation with a new model using the existing code generation folder.
  - Run a simulation that results in additional source code files being instrumented.
- If you switch between SIL and PIL simulations of a model, the software generates separate cumulative code coverage results for the SIL and PIL simulations.

For a model in a reference hierarchy, the software does not support simultaneous function execution time measurement and code coverage.

## View Code Coverage Information at the End of SIL or PIL Simulations

### In this section...

“View LDRA Tool Suite Results” on page 91-11

“View BullseyeCoverage Results” on page 91-11

If you configure third-party code coverage for a SIL or PIL simulation, when the simulation is complete, the code generation report opens automatically and you see hyperlinks in the Command Window.

### View LDRA Tool Suite Results

If you specified the LDRA tool suite, you see three links in the Command Window:

```
...
Starting SIL simulation for component: SILTopModel
Stopping SIL simulation for component: SILTopModel
Starting analysis of coverage data
Use the following links to view code coverage results:
 LDRAcover or LDRA tool suite GUI
 LDRAcover or LDRA tool suite Code Coverage Overview Report
 HTML code generation report with code coverage annotations
Completed code coverage analysis
>>
```

To open the LDRA GUI, click the `LDRAcover or LDRA tool suite GUI` link.

To open the LDRA report with your Web browser, click the `LDRAcover or LDRA tool suite Code Coverage Overview Report` link. For information about using the report, refer to the LDRA documentation.

LDRA analysis results for all code in the current code generation folder belong to a set. In this set, you can find analysis results for models that share the same code generation folder. The `LDRAcover or LDRA tool suite Code Coverage Overview Report` link identifies the location of the LDRA analysis results, which is determined by:

- The LDRA tool suite configuration.
- The name of the LDRA tool suite set associated with the current code generation folder.

To view summary data and code annotations with coverage information in the code generation report, click the `HTML code generation report with code coverage annotations` link. To view the code coverage information in the Code view, from the drop-down list to the right of the search box, select **Show code coverage**.

### View BullseyeCoverage Results

---

**Note** SIL and PIL simulation support for BullseyeCoverage will be removed in a future release.

---

If you specified the BullseyeCoverage tool, you see two links in the Command Window:

```
Starting SIL simulation for component: SILTopModel
Stopping SIL simulation for component: SILTopModel
```

```
Processing code coverage data
Use the following links to view code coverage results:
 BullseyeCoverage browser (coverage for last run)
 HTML code generation report (cumulative coverage)
Completed code coverage analysis
>>
```

To view the coverage report using the BullseyeCoverage Browser, click the [BullseyeCoverage browser \(coverage for last run\)](#) link.

The BullseyeCoverage Browser shows coverage data for instrumented files associated with your latest top-model simulation. The coverage data shown in the browser is not cumulative and pertains only to the most recent simulation. For information about the BullseyeCoverage Browser, go to [www.bullseye.com](http://www.bullseye.com).

To view summary data and code annotations with coverage information in the code generation report, click the [HTML code generation report \(cumulative coverage\)](#) link. To view the code coverage information in the Code view, from the drop-down list to the right of the search box, select **Show code coverage**.

- “Collect Code Coverage Metrics with a Third-Party Tool” on page 91-25
- “Code Coverage Summary and Annotations” on page 91-15

## Configure Code Coverage Programmatically

For a software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulation, you can configure third-party code coverage analysis by using command-line APIs.

### Set Up Third Party Code Coverage From Command Line

For BullseyeCoverage, you can use this workflow:

- 1 Using `get_param`, retrieve the object containing coverage settings for the current model. For example:

```
covSettings = get_param(gcs, 'CodeCoverageSettings')
```

```
covSettings =
```

```
CodeCoverageSettings with properties:
```

```
 TopModelCoverage: 'off'
 ReferencedModelCoverage: 'off'
 CoverageTool: 'None'
```

The property `TopModelCoverage` determines whether the software generates code coverage data for just the top model, while `ReferencedModelCoverage` determines whether the software generates coverage data for models referenced by the top model. If neither property is 'on', the code generator does not produce code coverage data during a SIL or PIL simulation.

When you save your model, the properties `TopModelCoverage`, `ReferencedModelCoverage`, and `CoverageTool` are also saved.

- 2 Check the class of `covSettings`.

```
class(covSettings)
```

```
ans =
```

```
 'coder.coverage.CodeCoverageSettings'
```

- 3 Turn on BullseyeCoverage code coverage analysis for the top model and referenced models.

```
covSettings.TopModelCoverage='on';
covSettings.ReferencedModelCoverage='on';
covSettings.CoverageTool='BullseyeCoverage';
```

To specify the LDRA tool suite as the code coverage tool, set the property `CoverageTool` to 'LDRAcover or LDRA tool suite'.

- 4 Using `set_param`, apply the new coverage settings to the model.

```
set_param(gcs, 'CodeCoverageSettings', covSettings);
```

- 5 Assuming the third-party code coverage tool is installed, specify the installation path.

```
coder.coverage.BullseyeCoverage.setPath('C:\Program Files\BullseyeCoverage')
```

For the LDRA tool suite, use `coder.coverage.LDRA.setPath('C:\...')`.

- 6 Check that the path is saved as a preference.

```
coder.coverage.BullseyeCoverage.getPath
```

For the LDRA tool suite, use `coder.coverage.LDRA.getPath`.

## Code Coverage for Model That Uses Configuration Reference

If your model uses a configuration set that is not attached to the model, for example, a configuration reference, then the **Configure** button is dimmed in the Configuration Parameters dialog box. You cannot open the Code Coverage Settings dialog box and you must use line commands to specify code coverage settings.

To configure third-party code coverage analysis for a model that uses a configuration reference:

- 1 Get the active configuration set from the model.

```
cs = getActiveConfigSet(gcs)
```

- 2 Retrieve the current code coverage settings.

```
covSettings = get_param(cs, 'CodeCoverageSettings')
```

- 3 Specify the code coverage settings that you require. For example:

```
covSettings.TopModelCoverage = 'on';
covSettings.ReferencedModelCoverage='on';
covSettings.CoverageTool='BullseyeCoverage';
```

- 4 Get the configuration set that is specified by the configuration reference.

```
csBase = cs.getRefConfigSet
```

- 5 Apply the required code coverage settings to the referenced configuration set.

```
set_param(csBase, 'CodeCoverageSettings', covSettings);
```

The active configuration set for the model contains the code coverage settings that you require.

## Code Coverage Summary and Annotations

In this section...
“LDRA Tool Suite Coverage” on page 91-15
“BullseyeCoverage Information” on page 91-17

If you specify a code coverage tool for a SIL or PIL simulation, the software provides summary data and code annotations with coverage information in the Code view. Each code annotation is associated with a code feature and indicates the nature of the feature coverage during code execution. The Code view also allows you to navigate easily between blocks in your model and the corresponding sections in the source code.

### LDRA Tool Suite Coverage

The cumulative coverage data in the Code view is derived from instrumented files associated with your latest top-model simulation **and** coverage data collected from simulations with other top models that share referenced models with your current top model.

The software provides LDRA tool suite annotations in the Code view to help you to review code coverage.

---

**Note** Do not use the Code view alone to verify that you have achieved your coverage goals. You must refer to the LDRA report.

---

In the Code view, the color of each bar and annotations shows the amount of coverage of the corresponding line of code or code feature. Green indicates full coverage, yellow indicates partial coverage, and red indicates no coverage.

```

104 */
105 if (enableB) {
106 /* Switch: '<S2>/Switch1' incorporates:
107 * Constant: '<S2>/C1'
108 * Inport: '<Root>/reset'
109 * Inport: '<Root>/ticks_to_count'
110 * Output: '<Root>/count_b'
111 * Sum: '<S2>/Add'
112 */
113 if (rtU.reset) {
114 rtY.count_b = 0U;
115 }
116
117 rtY.count_b = (uint8_T)(uint32_T)((uint32_T)rtU.ticks_to_count + (uint32_T)
118 rtY.count_b);
119
120 /* End of Switch: '<S2>/Switch1' */
121 }

```

Place your cursor over the annotation `^b` to see a tooltip. the tooltip indicates which branch destinations are covered and which are not covered.

```

104 */
105 if (enableB) {
106 /* Switch: Branch destinations covered <line>c<column>: 123c3; branch destinations not covered: 105c16
107 * Constant: '<S2>/C1'
108 * Inport: '<Root>/reset'
109 * Inport: '<Root>/ticks_to_count'
110 * Output: '<Root>/count_b'
111 * Sum: '<S2>/Add'
112 */
113 if (rtU.reset) {
114 rtY.count_b = 0U;
115 }

```

This table describes the LDRA code annotations that you might see in the Code view produced by SIL and PIL simulations.

Code feature	Annotation symbol	What happened during simulation
Function	Fcn	Function <i>name</i> returned through this exit point.
	=>	Function <i>name</i> never returned through this exit point.
Branch/condition	=>	Condition not encountered.
	=>t	Condition evaluated true only.
	=>f	Condition evaluated false only.
	tf	Condition evaluated both true and false.
Branch/decision	=>	Branch never encountered.
	=>b	Branch to at least one destination covered and branch to at least one other destination not covered.
	b	Branch fully exercised.
Modified Condition/Decision Coverage (MC/DC)	=>mc	Condition did not independently affect outcome of decision.
	mc	Condition independently affected outcome of decision.
Statement	•	Statements associated with line covered.
	•	Not all statements associated with line covered.
Code that is reformatted by LDRA tool suite and does not match the original source code. For example, source code with <code>#include</code> statements to include other files, and source code with <code>#define</code> statements for macros.  For detailed coverage information, refer to the LDRA report.	=> $\Sigma$	Zero coverage — probes within source code line or files included by source code line not exercised.
	=> $\Sigma$	Coverage probes within source code line or any included file partially exercised.
	$\Sigma$	Coverage probes within source code line or included files fully exercised.

## BullseyeCoverage Information

The cumulative coverage data in the Code view is derived from instrumented files associated with your latest top-model simulation **and** coverage data collected from simulations with other top models that share referenced models with your current top model.

The software provides BullseyeCoverage annotations in the Code view to help you to review code coverage.

In the Code view, the color of each bar and annotations shows the amount of coverage of the corresponding line of code or code feature. Green indicates full coverage, yellow indicates partial coverage, and red indicates no coverage.

```

=>F 105 if (enableB) {
106 /* Switch: '<S2>/Switch1' incorporates:
107 * Constant: '<S2>/C1'
108 * Inport: '<Root>/reset'
109 * Inport: '<Root>/ticks_to_count'
110 * Outport: '<Root>/count_b'
111 * Sum: '<S2>/Add'
112 */

```

This table describes the BullseyeCoverage code annotations that you might see in a code generation report produced by a SIL simulation.

Code feature	Annotation symbol	What happened during simulation
Decision	=>	Decision not executed.
	TF	Decision evaluated both true and false.
	=>T	Decision evaluated true only.
	=>F	Decision evaluated false only.
Function	=>	Function not called.
	Fcn	Function called.
Switch label	=>	Switch command not used.
	Sw	Switch command used.
Constant	k	Decision or condition was constant, which did not allow any variation in coverage.
Condition	=>	Condition not encountered.
	tf	Condition evaluated both true and false.
	=>t	Condition evaluated true only.
	=>f	Condition evaluated false only.
Try	=>	Try block never completed.
	Try	Try block covered.
Catch	=>	Catch block not covered.
	Cat	Catch block covered.

## Code Coverage Tool Support

Embedded Coder code coverage provides the following support for BullseyeCoverage and the LDRA tool suite.

Operating system	BullseyeCoverage		LDRA Tool Suite	
	Version supported	Compiler supported	Version supported	Compiler supported
Windows	8.15.41	Microsoft Visual C++ (MSVC)	9.8.4	<ul style="list-style-type: none"> <li>• Microsoft Visual C++ (MSVC)</li> <li>• LCC</li> <li>• MinGW</li> </ul>
Linux	8.15.41	gcc	9.8.4	gcc
Mac	Not supported		9.8.4	<ul style="list-style-type: none"> <li>• Clang</li> <li>• gcc</li> </ul>

### See Also

### Related Examples

- “Configure Code Coverage with Third-Party Tools” on page 91-9
- “Select and Configure C or C++ Compiler”

## Tips and Limitations

### Model Build and SIL/PIL Blocks Not Supported

Code coverage does not support:

- The model build process, for example, the `Ctrl+B` command.
- SIL or PIL blocks.

Code coverage settings are ignored by the `Ctrl+B` command and SIL or PIL blocks.

### BullseyeCoverage License Wait

When you build your model, you might have to wait for a BullseyeCoverage license. If you want to see information about the wait, before you build your model, in the Configuration Parameters dialog box, select **Verbose build**.

---

**Note** SIL and PIL simulation support for BullseyeCoverage will be removed in a future release.

---

### Current Working Folder Cannot be UNC Path

If your MATLAB current working folder is a Universal Naming Convention (UNC) path, code coverage fails.

### Characters in matlabroot and File Path

If `matlabroot` or the path to your generated files contains a space or the `.` (period) character, code coverage might fail.

### Header Files with Identical Names

Consider a model that is configured for LDRA code coverage. During the build process, if the software detects two header files with the same name in the folder for generated code, the software generates an error.

### Code Coverage for Source Files in Shared Utility Folders

The software supports code coverage for source files generated in shared utility folders. If you configure code coverage for a model that uses shared utility code generation, when you build the model, you also build all source files in the shared utilities folder with code coverage enabled.

Whenever you build a model, the code coverage settings of the model must be consistent with source files that you previously built in the shared utilities folder. Otherwise, the software reports that code in the shared utilities folder is inconsistent with the current model configuration and must be rebuilt. For example, if you run a SIL simulation for a model with code coverage enabled and then run a SIL simulation for another model with code coverage disabled, the software must rebuild all source files in the shared utilities folder.

## BullseyeCoverage Behavior with Inline Macros

The BullseyeCoverage tool, by default, does not provide code coverage data for inline macros.

For example, if a model generates a file `slprj/ert/_sharedutils/rt_SATURATE.h` that contains the macro

```
#define rt_SATURATE(sig,ll,ul) (((sig) >= (ul)) ? (ul) : (((sig) <= (ll)) ? (ll) : (sig)))
```

and the macro is in `sat_ert_rtw/sat.c`, then the coverage report provides a measurement for `sat.c`, but no coverage data for the conditions within the macro `rt_SATURATE`.

To configure the BullseyeCoverage tool to provide code coverage data for inline macros:

- 1 Open the BullseyeCoverage Browser.
- 2 Select **Tools > Options** to open the Options dialog box.
- 3 On the **Build** tab, select the **Instrument macro expansions** check box.
- 4 Click **OK**.
- 5 Rerun your simulation.

Alternatively, you can add the text `-macro` to the BullseyeCoverage configuration file. For more information, go to [www.bullseye.com/help](http://www.bullseye.com/help).

---

**Note** SIL and PIL simulation support for BullseyeCoverage will be removed in a future release.

---

## SIL and PIL Simulations with Open LDRA GUI

If you enable LDRA code coverage, you must verify that the LDRA tool suite GUI is not open when you run your SIL or PIL simulation. If the set name in the GUI differs from the set name used by the SIL or PIL simulation, the SIL or PIL simulation fails.

## Minor SIL and PIL Differences for LDRA Tool Suite

The target connectivity API supports LDRA code coverage for top-model and Model block PIL.

There are minor differences in the code coverage information collected during SIL and PIL simulations. In particular, with PIL, the software does not explicitly show function exit point coverage. However, you can infer the coverage of function exit points by examining statement coverage.

```
File: rtwdemo_sil_topmodel.c
LDRA Testbed code coverage enabled
Function exit points: 100%
Branch/decision: 57%
Statement: 87%
MC/DC: 0%
Branch/condition: 37%
```

```
1 /*
2 * File: rtwdemo_sil_topmodel.c
3 *
```

SIL

```
File: rtwdemo_sil_topmodel.c
LDRA Testbed code coverage enabled
Statement: 87%
MC/DC: 0%
Branch/condition: 37%
Branch/decision: 57%
```

```
1 /*
2 * File: rtwdemo_sil_topmodel.c
3 *
```

PIL

## PIL Zero Coverage LDRA Annotations

For a PIL simulation with LDRA code coverage specified, recorded coverage for some source files might be zero. In this case, the software provides summary information indicating that:

- There is coverage to measure.
- The coverage is zero.

You do not see information for individual probes on each line. The displayed summary information has an associated annotation tooltip:

0 out of N coverage probes were exercised (detailed breakdown unavailable)

## Custom Header File Changes and Regeneration of LDRA Instrumentation

When you run a SIL simulation with LDRA code coverage enabled, the code generator uses LDRA software to instrument the generated code only if the code generator determines that the generated code has changed since the last generation of instrumentation code. You can change a custom header file without regenerating code. In this case, the code generator does not update the instrumentation code. The SIL simulation produces this error:

The call to the LDRA code coverage tool did not generate the expected report. One possible cause of this error is that the Embedded Coder software did not detect the change in a previously analyzed source file and skipped the static analysis. The source file that changed might be a custom header file. For more information, review the above output from the LDRA tool command. A static analysis will be forced on the next simulation. You must rerun the simulation.

## PIL Support for BullseyeCoverage

Code coverage with BullseyeCoverage is available for top-model and Model block PIL provided your PIL application can write directly to the host file system. Your target for the PIL application must provide fopen and fread access to the host file system.

If code coverage is not available when you run the PIL application on your target hardware, you might be able to collect code coverage measurements by running the PIL application on an instruction set simulator that supports direct file I/O with the host file system.

---

**Note** SIL and PIL simulation support for BullseyeCoverage will be removed in a future release.

---

## Modify Legacy Code

If you modify legacy code and rerun a SIL or PIL simulation, the legacy code is recompiled. However, the code from the model may be up-to-date. In this case, the code generation report is not updated and does not show the modified legacy code. Instead, the code coverage information for the modified legacy code is displayed with reference to the original legacy code. You must regenerate the report. For more information, see “Generate Code Generation Report” on page 54-5.

## Collect Code Coverage Metrics with a Third-Party Tool

If you have a Simulink Coverage license, you can collect code coverage metrics during a software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulation -- see "Collect Coverage for Code" (Simulink Coverage). This example shows how you can collect code coverage metrics with a third-party tool, that is, BullseyeCoverage or LDRA tool suite. You must install the third-party tool -- see "Code Coverage Tool Support" on page 91-20.

You measure model coverage during a normal mode simulation and then use the third-party tool in a SIL simulation to collect coverage metrics for the generated code. By using the hyperlinks in the model coverage and code coverage reports, you can compare model coverage and code coverage results. For more information about SIL simulations, see "Test Generated Code with SIL and PIL Simulations" on page 88-88.

### Initial Setup

Open the model SILTopModel.

```
openExample('ecoder/SILPILVerificationExample', ...
 supportingFile='SILTopModel.slx')
model='SILTopModel';
```

Remove existing build folders.

```
buildFolder=RTW.getBuildDir(model);
if exist(buildFolder.BuildDirectory,'dir')
 rmdir(buildFolder.BuildDirectory,'s');
end
```

Configure generation of model coverage report.

```
set_param(model, 'RecordCoverage', 'on')
clear covCumulativeData
```

Set up the stimulus data by running the function SILTopModelData.

```
T=0.1; % sample time
[ticks_to_count, reset, counter_mode, count_enable, ...
 counter_mode_values_run1, counter_mode_values_run2, ...
 count_enable_values_run1, count_enable_values_run2] = ...
 SILTopModelData(T);
```

### Run a Simulation in Normal Mode

The model is configured to collect model coverage metrics. When a simulation is complete, the model coverage report opens. Use the coverage display window to navigate from blocks in the model to the corresponding sections of the coverage report.

```
counter_mode.signals.values = counter_mode_values_run1;
count_enable.signals.values = count_enable_values_run1;
set_param(model, 'SimulationMode', 'normal');
```

Set up Simulation Data Inspector for interactive viewing and comparison of simulation results.

```
Simulink.sdi.view;
Simulink.sdi.clear;
```

Run the simulation.

```
simout_normal_run1 = sim(model, 'ReturnWorkspaceOutputs', 'on');
```

Capture the results.

```
Simulink.sdi.createRun('Run 1 (normal mode)', 'namevalue',...
 {'simout_normal_run1'}, {simout_normal_run1});
```

## Run a Second Simulation in Normal Mode

For the first simulation, the report shows that the achieved coverage is less than 100%. Run a second simulation with different input signals that increase the level of MC/DC coverage to 100%. Note that the model coverage report is configured to show cumulative coverage across both simulation runs.

```
counter_mode.signals.values = counter_mode_values_run2;
count_enable.signals.values = count_enable_values_run2;
set_param(model, 'SimulationMode', 'normal');
```

```
simout_normal_run2 = sim(model, 'ReturnWorkspaceOutputs', 'on');
```

```
Simulink.sdi.createRun('Run 2 (normal mode)', 'namevalue',...
 {'simout_normal_run2'}, {simout_normal_run2});
```

## Configure the Model to Measure Code Coverage

Before running a SIL simulation, check the availability of third-party tools, and configure the model to collect code coverage metrics. If a third-party tool is not available, the model uses Simulink Coverage.

```
covToolPath = '';
ldraPath = coder.coverage.LDRA.getPath;
bullseyePath = coder.coverage.BullseyeCoverage.getPath;

coverageSettings = get_param(model, 'CodeCoverageSettings');
coverageSettings.TopModelCoverage='on';
if ~isempty(ldraPath)
 coverageSettings.CoverageTool='LDRAcover or LDRA tool suite';
elseif ~isempty(bullseyePath)
 coverageSettings.CoverageTool='BullseyeCoverage';
else
 coverageSettings.CoverageTool='None';
end
set_param(model, 'CodeCoverageSettings', coverageSettings);
```

## Run Simulations in SIL Mode

The normal mode simulations produce coverage metrics for the model. With a SIL simulation, you can apply the same input stimulus signals to the generated code and measure code coverage.

Run the first simulation in SIL mode.

```
counter_mode.signals.values = counter_mode_values_run1;
count_enable.signals.values = count_enable_values_run1;
set_param(model, 'SimulationMode', 'software-in-the-loop');
```

```

set_param(model, 'CodeExecutionProfiling', 'off');
set_param(model, 'CodeProfilingInstrumentation', 'off');
simout_sil_run1 = sim(model, 'ReturnWorkspaceOutputs', 'on');
Simulink.sdi.createRun('Run 1 (SIL mode)', 'namevalue', ...
 {'simout_sil_run1'}, {simout_sil_run1});

```

Run the second simulation in SIL mode.

```

counter_mode.signals.values = counter_mode_values_run2;
count_enable.signals.values = count_enable_values_run2;
set_param(model, 'SimulationMode', 'software-in-the-loop');
set_param(model, 'CodeExecutionProfiling', 'off');
set_param(model, 'CodeProfilingInstrumentation', 'off');
simout_sil_run2 = sim(model, 'ReturnWorkspaceOutputs', 'on');
Simulink.sdi.createRun('Run 2 (SIL mode)', 'namevalue', ...
 {'simout_sil_run2'}, {simout_sil_run2});

```

When a simulation is complete, click the link in the Command Window to open the code coverage report and view the cumulative code coverage results. The link is available only if you have a third-party tool installed.

Use hyperlinks in the code coverage report to go to corresponding locations in the block diagram. Then, by using the coverage display window, you can open corresponding sections of the model coverage report. Compare model coverage and code coverage results.

The Simulation Data Inspector opens automatically, allowing interactive viewing and analysis of the results. Use the Compare and Inspect panes to confirm that the SIL and normal mode logged signals are identical for both runs.

## Concluding Remarks

In this example, you:

- Collected model coverage metrics during a normal mode simulation.
- Collected code coverage metrics during a SIL simulation.
- Navigated between the code coverage and model coverage reports.
- Cross-checked metrics from both reports.

## Customize Generated ASAP2 File

### In this section...

“About ASAP2 File Customization” on page 92-2  
 “ASAP2 File Structure on the MATLAB Path” on page 92-2  
 “Customize the Contents of the ASAP2 File” on page 92-2  
 “ASAP2 Templates” on page 92-3  
 “Customize Computation Method Names” on page 92-5  
 “Suppress Computation Methods for FIX\_AXIS” on page 92-6

**Note** TLC based customization will be deprecated in a future release. To customize the ASAP2 file, see “Customize Generated ASAP2 File” on page 65-2.

### About ASAP2 File Customization

The Embedded Coder product provides a number of Target Language Compiler (TLC) files to enable you to customize the ASAP2 file generated from a Simulink model.

### ASAP2 File Structure on the MATLAB Path

The ASAP2 related files are organized within the folders identified below:

- TLC files for generating ASAP2 file

The *matlabroot*/rtw/c/tlc/mw (open) folder contains TLC files that generate ASAP2 files, *asamlib.tlc*, *asap2lib.tlc*, *asap2main.tlc*, and *asap2grouplib.tlc*. These files are included by the setting of model configuration parameter **System target file**. (See “System Target Files Supporting ASAP2” on page 63-2.)

- ASAP2 target files

The *matlabroot*/toolbox/rtw/targets/asap2/asap2 (open) folder contains the ASAP2 system target file and other control files.

- Customizable TLC files

The *matlabroot*/toolbox/rtw/targets/asap2/asap2/user (open) folder contains files that you can modify to customize the content of your ASAP2 files.

- ASAP2 templates

The *matlabroot*/toolbox/rtw/targets/asap2/asap2/user/templates (open) folder contains templates that define each type of CHARACTERISTIC in the ASAP2 file.

### Customize the Contents of the ASAP2 File

The ASAP2 related TLC files enable you to customize the appearance of the ASAP2 file generated from a Simulink model. Most customization is done by modifying or adding to the files contained in the *matlabroot*/toolbox/rtw/targets/asap2/asap2/user (open) folder. This section refers to this folder as the *asap2/user* folder.

The user-customizable files provided are divided into two groups:

- The *static* files define the parts of the ASAP2 file that are related to the environment in which the generated code is used. They describe information specific to the user or project. The static files are not model dependent.
- The *dynamic* files define the parts of the ASAP2 file that are generated based on the structure of the source model.

The procedure for customizing the ASAP2 file is as follows:

- 1 Make a copy of the `asap2/user` folder before making modifications.
- 2 Remove the old `asap2/user` folder from the MATLAB path, or add the new `asap2/user` folder to the MATLAB path above the old folder. The MATLAB session uses the ASAP2 setup file, `asap2setup.tlc`, in the new folder.

`asap2setup.tlc` specifies the folders and files to include in the TLC path during the ASAP2 file generation process. Modify `asap2setup.tlc` to control the folders and folders included in the TLC path.

- 3 Modify the static parts of the ASAP2 file. These include
  - Project and header symbols, which are specified in `asap2setup.tlc`
  - Static sections of the file, such as file header and tail, `A2ML`, `MOD_COMMON`, and so on. These are specified in `asap2userlib.tlc`.
  - Specify the appearance of the dynamic contents of the ASAP2 file by modifying the existing ASAP2 templates or by defining new ASAP2 templates. Sections of the ASAP2 file affected include

`RECORD_LAYOUT`: modify parts of the ASAP2 template files.

`CHARACTERISTIC`: modify parts of the ASAP2 template files. For more information on modifying the appearance of `CHARACTERISTIC` records, see “ASAP2 Templates” on page 92-3.

- `MEASUREMENT`: These are specified in `asap2userlib.tlc`.
- `COMPU_METHOD`: These are specified in `asap2userlib.tlc`.

## ASAP2 Templates

The appearance of `CHARACTERISTIC` records in the ASAP2 file is controlled using a different template for each type of `CHARACTERISTIC`. The `asap2/user` folder contains template definition files for scalars, 1-D Lookup Table blocks and 2-D Lookup Table blocks. You can modify these template definition files, or you can create additional templates as required.

The procedure for creating a new ASAP2 template is as follows:

- 1 Create a template definition file. See “Create Template Definition Files” on page 92-4.
- 2 Include the template definition file in the TLC path. The path is specified in the ASAP2 setup file, `asap2setup.tlc`.

## Create Template Definition Files

This section describes the components that make up an ASAP2 template definition file. This description is in the form of code examples from `asap2lookup1d.tlc`, the template definition file for the Lookup1D template. This template corresponds to the Lookup1D parameter group.

---

**Note** When creating a new template, use the corresponding parameter group name in place of Lookup1D in the code shown.

---

### Template Registration Function

The input argument is the name of the parameter group associated with this template:

```
%<LibASAP2RegisterTemplate("Lookup1D")>
```

### RECORD\_LAYOUT Name Definition Function

Record layout names (aliases) can be arbitrarily specified for each data type. This function is used by the other components of this file.

```
%function ASAP2UserFcnRecordLayoutAlias_Lookup1D(dtId) void
 %switch dtId
 %case tSS_UINT8
 %return "Lookup1D_UBYTE"
 ...
 %endswitch
%endfunction
```

### Function to Write RECORD\_LAYOUT Definitions

This function writes RECORD\_LAYOUT definitions associated with this template. The function is called by the built-in functions involved in the ASAP2 file generation process. The function name must be defined as shown, with the template name after the underscore:

```
%function ASAP2UserFcnWriteRecordLayout_Lookup1D() Output
 /begin RECORD_LAYOUT
 %<ASAP2UserFcnRecordLayoutAlias_Lookup1D(tSS_UINT8)>
 ...
 /end RECORD_LAYOUT
%endfunction
```

### Function to Write the CHARACTERISTIC

This function writes the CHARACTERISTIC associated with this template. The function is called by the built-in functions involved in the ASAP2 file generation process. The function name must be defined as shown, with the template name after the underscore.

The input argument to this function is a pointer to a parameter group record. The example shown is for a Lookup1D parameter group that has two members. The references to the associated x and y data records are obtained from the parameter group record as shown.

This function calls a number of built-in functions to obtain the required information. For example, `LibASAP2GetSymbol` returns the symbol (name) for the specified data record:

```
%function ASAP2UserFcnWriteCharacteristic_Lookup1D(paramGroup)
Output
```

```

%assign xParam = paramGroup.Member[0].Reference
%assign yParam = paramGroup.Member[1].Reference
%assign dtId = LibASAP2GetDataTypeId(xParam)
 /begin CHARACTERISTIC
 /* Name */ %<LibASAP2GetSymbol(xParam)>
 /* Long identifier */ %<LibASAP2GetLongID(xParam)>"
 ...
 /end CHARACTERISTIC
%endfunction

```

## Customize Computation Method Names

In generated ASAP2 files, computation methods translate the electronic control unit (ECU) internal representation of measurement and calibration quantities into a physical model oriented representation. Simulink Coder software provides the ability to customize the names of computation methods. You can provide names that are more intuitive, enhancing ASAP2 file readability, or names that meet organizational requirements.

To customize computation method names, use the MATLAB function `getCompuMethodName`, which is defined in `matlabroot/toolbox/rtw/targets/asap2/asap2/user/getCompuMethodName.m`.

The `getCompuMethodName` function constructs a computation method name. The function prototype is

```
cmName = getCompuMethodName(dataTypeName, cmUnits)
```

where *dataTypeName* is the name of the data type associated with the computation method, *cmUnits* is the units as specified in the Unit property of a Simulink.Parameter or Simulink.Signal object (for example, rpm or m/s), and *cmName* returns the constructed computation method name.

The default constructed name returned by the function has the format

```
<localPrefix><datatype>_<cmUnits>
```

where

- `<local_Prefix>` is a local prefix, `CM_`, defined in `matlabroot/toolbox/rtw/targets/asap2/asap2/user/getCompuMethodName.m`.
- `<datatype>` and `<cmUnits>` are the arguments you specified to the `getCompuMethodName` function.

Additionally, in the generated ASAP2 file, the constructed name is prefixed with `<ASAP2CompuMethodName_Prefix>`, a model prefix defined in `matlabroot/toolbox/rtw/targets/asap2/asap2/user/asap2setup.tlc`.

For example, if you call the `getCompuMethodName` function with the *dataTypeName* argument 'int16' and the *cmUnits* argument 'm/s', and generate an ASAP2 file for a model named `myModel`, the computation method name would appear in the generated file as follows:

```

/begin COMPU_METHOD
 /* Name of CompuMethod */ myModel_CM_int16_m_s
 /* Units */ "m/s"
 ...
/end COMPU_METHOD

```

## Suppress Computation Methods for FIX\_AXIS

Versions 1.51 and later of the ASAP2 specification state that for certain cases of lookup table axis descriptions (integer data type and no doc units), a computation method is not required and the Conversion Method parameter must be set to the value `NO_COMPU_METHOD`. You can control whether or not computation methods are suppressed when not required using the Target Language Compiler (TLC) option `ASAP2GenNoCompuMethod`. This TLC option is disabled by default. If you enable the option, ASAP2 file generation does not generate computation methods for lookup table axis descriptions when not required, and instead generates the value `NO_COMPU_METHOD`. For example:

```
/begin CHARACTERISTIC
/* Name */
luld_fix_axisTable_data
...
/begin AXIS_DESCR
 ...
 /* Conversion Method */
 NO_COMPU_METHOD
 ...
/end CHARACTERISTIC
```

The `ASAP2GenNoCompuMethod` option is defined in `matlabroot/toolbox/rtw/targets/asap2/asap2/user/asap2setup.tlc`.

## Control Build Process Compiling and Linking

After generating code for a model, the build process determines whether to compile and link an executable program. Various factors guide this determination:

- **Generate code only** option

When you select this option, the code generator produces code for the model, including a makefile.

- **Generate makefile** option

When you clear this option, the code generator does not produce a makefile for the model. You must specify post code generation processing, including compilation and linking, as a user-defined command, as explained in “Customize Post-Code-Generation Build Processing” on page 93-7.

- **Makefile-only target**

The Microsoft Visual C++ Project Makefile versions of the `grt` and Embedded Coder target configurations generate a Visual C++ project makefile (`model.mak`). To build an executable, you must open `model.mak` in the Visual C++ IDE and compile and link the model code.

- **HOST template makefile variable**

The template makefile variable `HOST` identifies the type of system upon which your executable is intended to run. The variable can be set to one of three possible values: `PC`, `UNIX`, or `ANY`.

By default, `HOST` is set to `UNIX` in template makefiles designed for use with The Open Group UNIX platforms (such as `grt_unix.tmf`), and to `PC` in the template makefiles designed for use with development systems for the PC (such as `grt_vcx64.tmf`).

If the Simulink software is running on the same type of system as the system specified by the `HOST` variable, then the executable is built. Otherwise,

- If `HOST = ANY`, an executable is still built. This option is useful when you want to cross-compile a program for a system other than the one that the Simulink software is running on.
- Otherwise, processing stops after generating the model code and the makefile; the following message is displayed on the MATLAB command line.

```
Make will not be invoked - template makefile is for a different host
```

## Control Library Location and Naming During Build

When you generate precompiled, non-precompiled, and model reference libraries, you can control the library location and library name by using configuration parameters. These parameters control values in generated makefiles during model builds:

- For build processes that use the toolchain approach, control the generated library location by using the `TargetPreCompLibLocation` configuration parameter.
- For build processes that use the template makefile approach, control the generated library location by using the `TargetPreCompLibLocation` configuration parameter and control the generated library name by using the `TargetLibSuffix` configuration parameter.

### Library Control Parameters

Use the library control parameters to:

- Specify the location of precompiled libraries, such as blockset libraries or the Simulink Coder block library. Typically, a target has cross-compiled versions of these libraries and places them in a target-specific folder.
- Control the suffix applied to library file names (for example, `_target.a` or `_target.lib`).

Targets can set the parameters inside the system target file (STF) select callback. For example:

```
function mytarget_select_callback_handler(varargin)
 hDig=varargin{1};
 hSrc=varargin{2};
 slConfigUISetVal(hDig, hSrc, 'TargetPreCompLibLocation',...
 'c:\mytarget\precomplibs');
 slConfigUISetVal(hDig, hSrc, 'TargetLibSuffix',...
 '_target.library');
```

The TMF has corresponding expansion tokens:

```
|>EXPAND_LIBRARY_LOCATION<|
|>EXPAND_LIBRARY_SUFFIX<|
```

Alternatively, you can use a call to the `set_param` function. For example:

```
set_param(model,'TargetPreCompLibLocation',...
 'c:\mytarget\precomplibs');
```

---

**Note** If your model contains referenced models, you can use the make option `USE_MDLREF_LIBPATHS` to control whether libraries used by the referenced models are copied to the build folder of the parent model. For more information, see “Location of Model Reference Libraries” on page 93-5.

---

### Identify Library File Type for Toolchain Approach

The toolchain approach for model builds does not use the value of the `TargetLibSuffix` configuration parameter to select the library file name *suffix* and *extension*.

With the toolchain approach, the final binary name is composed of the *modelname*, the *compilername*, and the *extension* provided by the build tool description in the toolchain definition:

```
model_compilername.extension
```

You can identify the static library file name extension from the build tool description in the toolchain definition. To get this information for the default toolchain, use this procedure:

- 1 Get the default toolchain name. For example, enter:

```
tc_name = coder.make.getDefaultToolchain()
```

- 2 Get the default toolchain handle. For example, enter:

```
tc = coder.make.getToolchainInfoFromRegistry(tc_name)
```

- 3 Get the handle to the toolchain object. For example, enter:

```
tool_archiver = tc.getBuildTool('Archiver');
```

- 4 Get the extension. For example, enter:

```
ext_archiver = tool_archiver.getFileExtension('Static Library');
```

---

**Note** If you do not set the `TargetLibSuffix` parameter, template makefile and toolchain approaches produce the same static library file name *extension*.

---

## Specify the Location of Precompiled Libraries

Use the `TargetPreCompLibLocation` configuration parameter to:

- Override the precompiled library location specified in the `rtwmakecfg.m` file (see “Use `rtwmakecfg.m` API to Customize Generated Makefiles” on page 93-17 for details)
- Precompile and distribute target-specific versions of product libraries (for example, the DSP System Toolbox product)

For a precompiled library, such as a blockset library or the Simulink Coder block library, the location specified in `rtwmakecfg.m` is typically a location specific to the blockset or the Simulink Coder product. The code generator expects that the library exists in this location and links against the library during builds.

For some applications, such as custom targets, it is preferable to locate the precompiled libraries in a target-specific or other alternate location rather than in the location specified in `rtwmakecfg.m`. For a custom target, the code generator expects that the target-specific cross-compiler creates the library, and you place the library in the target-specific location. Compile and place libraries supported by the target in the target-specific location, so they can be used during the build process.

You can set up the `TargetPreCompLibLocation` parameter in its select callback. The path that you specify for the parameter must be a fully qualified, absolute path to the library location. Relative paths are not supported. For example:

```
slConfigUISetVal(hDlg, hSrc, 'TargetPreCompLibLocation',...
'c:\mytarget\precomplibs');
```

Alternatively, you set the parameter with a call to the `set_param` function. For example:

```
set_param(model, 'TargetPreCompLibLocation',...
'c:\mytarget\precomplibs');
```

During makefile generation, the build process replaces the tokens with the location from the `rtwmakecfg.m` file. For example, if the library name in the `rtwmakecfg.m` file is `'rtwlib'`, the template makefile build approach expands the token from:

```
LIBS += |>EXPAND_LIBRARY_LOCATION<|\>EXPAND_LIBRARY_NAME<|\
_target.library
```

to:

```
LIBS += c:\mytarget\precomplibs\rtwlib_target.library
```

By default, `TargetPreCompLibLocation` is an empty character vector. The build process uses the location in `rtwmakecfg.m` for the token replacement.

## Location of Model Reference Libraries

The build process assigns a path such as `../slprj/grt/sub/sub_rtwlib.lib` to `MODELREF_LINK_LIBS`. The build process uses the path to gain access to the library file at link time.

## Control the Suffix Applied to Library File Names

With the template makefile approach for model builds, use the `TargetLibSuffix` configuration parameter to control the suffix applied to library names (for example, `_target.lib` or `_target.a`). The specified suffix scheme must include a period (.). You can apply `TargetLibSuffix` to the following libraries:

- Libraries on which a target depends, as specified in the `rtwmakecfg.m` API. You can use `TargetLibSuffix` to change the suffix of both precompiled and non-precompiled libraries configured from the `rtwmakecfg` API. For details, see “Use `rtwmakecfg.m` API to Customize Generated Makefiles” on page 93-17.

In this case, a target can set the parameter in its select callback. For example:

```
slConfigUISetVal(hDlg, hSrc, 'TargetLibSuffix',...
'_target.library');
```

Alternatively, you can use a call to the `set_param` function. For example:

```
set_param(model, 'TargetLibSuffix', '_target.library');
```

During the TMF-to-makefile conversion, the build process replaces the token `|>EXPAND_LIBRARY_SUFFIX<|` with the specified suffix. For example, if the library name specified in the `rtwmakecfg.m` file is `'rtwlib'`, the TMF expands from:

```
LIBS += |>EXPAND_LIBRARY_LOCATION<|\>EXPAND_LIBRARY_NAME<|\
|>EXPAND_LIBRARY_SUFFIX<|
```

to:

```
LIBS += c:\mytarget\precomplibs\rtwlib_target.library
```

By default, `TargetLibSuffix` is set to an empty character vector. In this case, the build process replaces the token `|>EXPAND_LIBRARY_SUFFIX<|` with an empty character vector.

- Model libraries created with model reference. For these cases, associated makefile variables do not require the `|>EXPAND_LIBRARY_SUFFIX<|` token. Instead, the build process includes `TargetLibSuffix` implicitly. For example, for a top model named `topmodel` with referenced models named `refmodel1` and `refmodel2`, the TMF of the top model is expanded from:

```
MODELLIB = |>MODELLIB<|
MODELREF_LINK_LIBS = |>MODELREF_LINK_LIBS<|
```

to:

```
MODELLIB = topmodellib_target.library
MODELREF_LINK_LIBS = \
refmodell_rtwlib_target.library refmodel2_rtwlib_target.library
```

By default, the `TargetLibSuffix` parameter is an empty character vector. In this case, the build process chooses a default suffix for these three tokens using a file extension of `.lib` on Windows hosts and `.a` on UNIX hosts. For model reference libraries, the default suffix also includes `_rtwlib`. For example, on a Windows host, the expanded makefile values are:

```
MODELLIB = topmodellib.lib
MODELREF_LINK_LIBS = refmodell_rtwlib.lib refmodel2_rtwlib.lib
```

## Customize Post-Code-Generation Build Processing

The code generator provides a set of tools, including a build information object, you can use to customize build processing that occurs after code generation. You can use such customizations for target development or the integration of third-party tools into your application development environment.

### Workflow for Setting Up Customizations

The following figure and the steps that follow show the general workflow for setting up post-code-generation customizations.

- 1 Program the post code generation command on page 93-8.
- 2 Define the post code generation command on page 93-9.
- 3 Suppress makefile generation on page 93-11, if applicable.
- 4 Build the model.
- 5 Modify the command and rebuild the model until the build results are acceptable.

### Build Information Object

At the start of a model build, the build process logs the following build option and dependency information to a temporary build information object:

- Compiler options

- Preprocessor identifier definitions
- Linker options
- Source files and paths
- Include files and paths
- Precompiled external libraries

You can retrieve information from and add information to this object by using an extensive set of functions. For a list of available functions and detailed function descriptions, see “Build Process Customization”. “Program a Post Code Generation Command” on page 93-8 explains how to use the functions to control post code generation build processing.

## Program a Post Code Generation Command

For certain applications, you could want to control aspects of the build process after the code generation. For example, you can use this approach if you develop your own target, or you want to apply an analysis tool to the generated code before continuing with the build process. You can apply this level of control to the build process by programming and then defining a post code generation command.

A post code generation command is a MATLAB language file that typically calls functions that get data from or add data to the build information object of the model. You can program the command as a script or function.

If you program the command as a:	Then the:
Script	Script can gain access to the model name and the build information directly
Function	Function can pass the model name and the build information as arguments

If your post code generation command calls user-defined functions, make sure that the functions are on the MATLAB path. If the build process cannot find a function you use in your command, the build process errors out.

You can then call a combination of build information functions, as listed in “Build Process Customization”, to customize the post code generation build processing of the model.

The following example shows a fragment of a post code generation command that gets the file names and paths of the source and include files generated for a model for analysis.

```
function analyzegeneratecode(buildInfo)
% Get the names and paths of source and include files
% generated for the model and then analyze them.

% buildInfo - build information for my model.

% Define cell array to hold data.
MyBuildInfo={};

% Get source file information.
MyBuildInfo.srcfiles=getSourceFiles(buildInfo, true, true);
MyBuildInfo.srcpaths=getSourcePaths(buildInfo, true);

% Get include (header) file information.
MyBuildInfo.incfiles=getIncludeFiles(buildInfo, true, true);
```

```
MyBuildInfo.incpaths=getIncludePaths(buildInfo, true);
% Analyze generated code.
.
.
.
```

## Define a Post Code Generation Command

After you program a post code generation command, inform the build process that the command exists and to add it to the build processing of the model. Define the command with the `PostCodeGenCommand` model configuration parameter. When you define a post code generation command, the build process evaluates the command after generating and writing the generated code to disk and before generating a makefile.

As the following syntax lines show, the arguments that you specify when setting the configuration parameter varies depending on whether you program the command as a script, function, or set of functions.

---

**Note** When defining the command as a function, you can specify an arbitrary number of input arguments. To pass the name and build information of the model to the function, specify identifiers `modelName` and `buildInfo` as arguments.

---

### Script

```
set_param(model, 'PostCodeGenCommand',...
'pcgScriptName');
```

### Function

```
set_param(model, 'PostCodeGenCommand',...
'pcgFunctionName(modelName)');
```

### Multiple Functions

```
pcgFunctions=...
'pcgFunction1Name(modelName);...
pcgFunction2Name(buildInfo)';
set_param(model, 'PostCodeGenCommand',...
pcgFunctions);
```

The following call to `set_param` defines `PostCodGenCommand` to evaluate the function `analyzegencode`.

```
set_param(model, 'PostCodeGenCommand',...
'analyzegencode(buildInfo)');
```

## Customize Build Process with PostCodeGenCommand and Relocate Generated Code to an External Environment

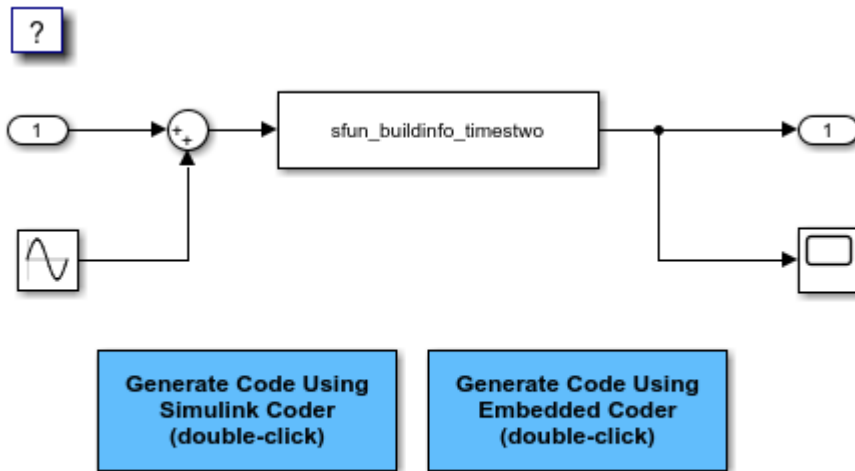

This example shows how to use the build information programming interface and the model configuration parameter **Post code generation command** (`PostCodeGenCommand`) to customize the build process. For this example, **Post code generation command** is set to `rtwdemo_buildinfo_data`. The build process invokes that function after code generation.

The example also shows how to use build configuration function `rtwmakecfg.m`.

### Open Example Model

Open the example model `rtwdemo_buildinfo`.

```
open_system('rtwdemo_buildinfo');
```

Copyright 1994-2020 The MathWorks, Inc.

### Generate Code from Model

Generate code. The code generator produces the file `BuildInfo.html`, which documents the build information object.

### Examine the Build Process Customizations and Output

Examine the build process customizations and the post code generation query of the build information object. In a Web browser, open the file `BuildInfo.html`. The file provides hyperlinks that you can use to examine the code produced for the model. Alternatively, in the MATLAB Command Window:

- To view the function configured to execute during the post code generation stage of the build process, enter:

```
get_param('rtwdemo_buildinfo','PostCodeGenCommand');
```

- To study the programming interface for the build information object, enter:

```
rtwdemo_buildinfo_data(buildInfo);
```

- To study how the example uses the `rtwmakecfg` function, enter:

```
edit rtwmakecfg.m;
```

- To view the build information object data that the build process saves in the `buildInfo.mat` file, open the file `rtwdemo_<target>_rtw\buildInfo.mat`.
- To view the contents of the post code generation function `rtwdemo_buildinfo_data.m`, enter:

```
edit rtwdemo_buildinfo_data.m;
```

At the end of the file, the function calls `packNGo` to package the source and object files that the build information object identifies for relocation.

- “Relocate or Share Generated Code”

## Suppress Makefile Generation

The code generator lets you suppress makefile generation during the build process. For example, you can use this support when you integrate tools into the build process that do not use makefiles.

To instruct the code generator not to produce a makefile, do one of the following:

- Clear the **Generate makefile** option on the **Code Generation** pane of the Configuration Parameters dialog box.
- Set the value of the configuration parameter `GenerateMakefile` to `off`.

When you suppress makefile generation,

- You cannot explicitly specify a make command or template makefile.
- Specify your own instructions for a post code generation processing, including compilation and linking, in a post code generation command as explained in “Program a Post Code Generation Command” on page 93-8 and “Define a Post Code Generation Command” on page 93-9.

`RTW.BuildInfo`

## Configure Generated Code with TLC

You can use the Target Language Compiler (TLC) to fine-tune your generated code. TLC supports extended code generation variables and options in addition to parameters available on the **Code Generation** pane on the Configuration Parameters dialog box. There are two ways to set TLC variables and options, as described in this section.

---

**Note** Do not customize TLC files in the folder *matlabroot/rtw/c/tlc* even though the capability exists to do so. It is possible that such TLC customizations are not applied during the code generation process. Such customizations can lead to unpredictable results.

---

### Assigning Target Language Compiler Variables

The `%assign` statement lets you assign a value to a TLC variable, as in:

```
%assign MaxStackSize = 4096
```

This assignment is also known as creating a *parameter name/parameter value pair*.

For a description of the `%assign` statement, see “Target Language Compiler Directives”. Write your `%assign` statements in the Configure RTW code generation settings section of the system target file.

The following table lists the code generation variables you can set with the `%assign` statement.

## Target Language Compiler Optional Variables

Variable	Description
MaxStackSize= <i>N</i>	<p>When the <b>Enable local block outputs</b> check box is selected, the total allocation size of local variables that are declared by block outputs in the model cannot exceed <b>MaxStackSize</b> (in bytes). <b>MaxStackSize</b> can be a positive integer. If the total size of local block output variables exceeds this maximum, the remaining block output variables are allocated in global, rather than local, memory. The default value for <b>MaxStackSize</b> is <code>rtInf</code>, that is, unlimited stack size.</p> <p><b>Note:</b> Local variables in the generated code from sources other than local block outputs, such as from a Stateflow diagram or MATLAB Function block, and stack usage from sources such as function calls and context switching are not included in the <b>MaxStackSize</b> calculation. For overall executable stack usage metrics, do a target-specific measurement by using run-time (empirical) analysis or static (code path) analysis with object code.</p>
MaxStackVariableSize= <i>N</i>	<p>When the <b>Enable local block outputs</b> check box is selected, this selection limits the size of a local block output variable declared in the code to <i>N</i> bytes, where <math>N &gt; 0</math>. A variable whose size exceeds <b>MaxStackVariableSize</b> is allocated in global, rather than local, memory. The default is 4096.</p>
RemoveFixptWordSizeChecks= <i>value</i>	<p>For a model that uses fixed-point data types, control the generation of preprocessor directives that perform fixed-point word size checks. If <i>value</i> is:</p> <ul style="list-style-type: none"> <li>• 0, generate the preprocessor directives. The generated code contains fixed-point word size checks.</li> <li>• 1, suppress the generation of the preprocessor directives. The generated code does not contain fixed-point word size checks.</li> </ul> <p>You can also suppress the generation of the preprocessor directives by running this command:</p> <pre>set_param(gcs, 'TLCOptions', ...             '-aRemoveFixptWordSizeChecks=1')</pre> <p>If you generate code that does not contain the fixed-point word size checks, you can use processor-in-the-loop (PIL) simulations that check <b>Hardware Implementation</b> settings with reference to the target hardware. For more information, see “Verification of Code Generation Assumptions” on page 88-65.</p>

Variable	Description
WarnNonSaturatedBlocks= <i>value</i>	<p>Flag to control display of overflow warnings for blocks that have saturation capability, but have it turned off (not selected) in their dialog box. Options include:</p> <ul style="list-style-type: none"><li>• 0 — Warning is not displayed.</li><li>• 1 — Displays one warning for the model during code generation</li><li>• 2 — Displays one warning that contains a list of offending blocks</li></ul>

## Set Target Language Compiler Options

You can specify TLC command-line options for code generation using the model parameter `TLCOptions` in a `set_param` function call. For information about these options, see “Specify TLC for Code Generation” and “Configure TLC”.

## Use makecfg to Customize Generated Makefiles for S-Functions

With the toolchain or template makefile approach for building code, you can customize generated makefiles for S-functions. Through the customization, you can specify additional items for the S-function build process:

- Source files and folders
- Include files and folders
- Library names
- Preprocessor macro definitions
- Compiler flags
- Link objects

To customize the generated makefile:

- 1 In the S-function MEX file folder that contains your S-function components, create a `makecfg.m` or `specificSFunction_makecfg.m` file. If you create a `makecfg.m` file, it is active for any S-function in the S-function MEX file folder that the model uses. A `specificSFunction_makecfg.m` file is active only if the model uses the corresponding S-function.
- 2 In the file that you create, use `RTW.BuildInfo` functions to specify additional items for the S-function build process. For example, you can use:
  - `addCompileFlags` to specify compiler options.
  - `addDefines` to specify preprocessor macro definitions.
- 3 Save the created file.

After code generation, in the S-function MEX file folder, the code generator searches for `makecfg.m` and `specificSFunction_makecfg.m` files. If the files are present, the code generator uses these files to customize the generated makefile, `model.mk`.

For example, consider a folder that contains `signalConvert.mexa64` (S-function binary file) and `signalConvert.tlc` (inlined S-function implementation) after the TLC phase of the build process. The S-function requires an additional source code file, `filterV1.c`, which is located in `anotherFolder`. You can create a file, `signalConvert_makecfg.m`, that uses `RTW.BuildInfo` functions to specify `filterV1.c` for the build process.

```
function signalConvert_makecfg(objBuildInfo)

absolutePath = fullfile('${START_DIR}', 'anotherFolder');
addSourceFiles(objBuildInfo, 'filterV1.c', absolutePath);
```

- “Use rtwmakecfg.m API to Customize Generated Makefiles”

## Use rtwmakecfg.m API to Customize Generated Makefiles

---

**Note** To customize generated makefiles for S-functions, MathWorks recommends the use of the `makecfg` approach instead of the `rtwmakecfg` function. For more information, see “Use `makecfg` to Customize Generated Makefiles for S-Functions” on page 93-15.

---

Both the toolchain approach and the template makefile approach for builds let you add the following items to generated makefiles:

- Source folders
- Include folders
- Library names
- Module objects

### About the `rtwmakecfg` Function

Using an `rtwmakecfg` function, you add this information to the makefile during the build operation for S-functions. The `rtwmakecfg` function is useful when specifying added sources and libraries to build a model that contains one or more of your S-function blocks.

To add information pertaining to an S-function to the makefile:

- 1 Create the MATLAB language `rtwmakecfg` function in the `rtwmakecfg.m` file. The code generator associates this file with your S-function based on its folder location. “Create the `rtwmakecfg` Function” on page 93-17 describes the requirements for the `rtwmakecfg` function and the data it returns.
- 2 If you are using the template makefile approach, modify the TMF of your target such that it supports macro expansion for the information that the `rtwmakecfg` function returns. “Modify the Template Makefile for `rtwmakecfg`” on page 93-19 describes the required modifications. If you are using the toolchain approach, the information that the `rtwmakecfg` function returns is used by the generated makefile; no further configuration is required.

After the TLC phase of the build process, when generating a makefile, the code generator searches for an `rtwmakecfg.m` file in the folder that contains the S-function MEX file. If it finds the file, the build process calls the `rtwmakecfg` function.

### Create the `rtwmakecfg` Function

Create the `rtwmakecfg.m` file containing the `rtwmakecfg` function in the same folder as your S-function component (a MEX-file with a platform-dependent extension, such as `.mexext` on Microsoft Windows systems). The function must return a structured array that contains these fields.

Field	Description
<code>makeInfo.includePath</code>	A cell array that specifies additional include folder names, organized as a row vector. The build process expands the folder names into include instructions in the generated makefile.

Field	Description
<code>makeInfo.sourcePath</code>	A cell array that specifies additional source folder names, organized as a row vector. Include the folder names of files entered into the <b>S-function modules</b> field on the S-Function Block Parameters dialog box or into the <code>SFunctionModules</code> parameter of the block if they are not in the same folder as the S-function. The build process expands the folder names into make rules in the generated makefile.
<code>makeInfo.sources</code>	A cell array that specifies additional source file names (C or C++), organized as a row vector. Do not include the name of the S-function or files entered into the <b>S-function modules</b> field on the S-Function Block Parameters dialog box or into the <code>SFunctionModules</code> parameter of the block. The build process expands the file names into make variables that contain the source files. Specify only file names (with extension). Specify path information with the <code>sourcePath</code> field.
<code>makeInfo.linkLibsObjs</code>	A cell array that specifies additional, fully qualified paths to object or library files against which the generated code links. The build process does not compile the specified objects and libraries. However, it includes them when linking the final executable. This inclusion can be useful for incorporating libraries that you do not want the build process to recompile or for which the source files are not available. You can also use this element to integrate source files from languages other than C and C++. This integration is possible if you first create a C compatible object file or library outside of the build process.
<code>makeInfo.precompile</code>	A Boolean flag that indicates whether the libraries specified in the <code>rtwmakecfg.m</code> file exist in a specified location ( <code>precompile==1</code> ) or if you must create the libraries in the build folder during the build process ( <code>precompile==0</code> ).
<code>makeInfo.library</code>	A structure array that specifies additional run-time libraries and module objects, organized as a row vector. The build process expands the information into make rules in the generated makefile. For a list of the library fields, see the next table.

The `makeInfo.library` field consists of the following elements.

Element	Description
<code>makeInfo.library(n).Name</code>	A character array that specifies the name of the library (without an extension).
<code>makeInfo.library(n).Location</code>	A character array that specifies the folder in which the library is located when precompiled. For more information, see the description of <code>makeInfo.precompile</code> in the preceding table. A target can use the <code>TargetPreCompLibLocation</code> parameter to override this value. See “Specify the Location of Precompiled Libraries”.
<code>makeInfo.library(n).Modules</code>	A cell array that specifies the C or C++ source file base names (without an extension) that comprise the library. Do not include the file extension. The makefile appends the object extension.

---

**Note** The `makeInfo.library` field must fully specify each library and how to build it. The modules list in the `makeInfo.library(n).Modules` element cannot be empty. To specify a link-only library, use the `makeInfo.linkLibsObjs` field instead.

---

**Example:**

```
disp(['Running rtwmakecfg from folder: ',pwd]);
makeInfo.includePath = { fullfile(pwd, 'somedir2') };
makeInfo.sourcePath = {fullfile(pwd, 'somedir2'), fullfile(pwd, 'somedir3')};
makeInfo.sources = { 'src1.c', 'src2.cpp'};
makeInfo.linkLibsObjs = { fullfile(pwd, 'somedir3', 'src3.object'),...
 fullfile(pwd, 'somedir4', 'mylib.library')};
makeInfo.precompile = 1;
makeInfo.library(1).Name = 'myprecompiledlib';
makeInfo.library(1).Location = fullfile(pwd, 'somedir2', 'lib');
makeInfo.library(1).Modules = {'srcfile1' 'srcfile2' 'srcfile3' };
```

---

**Note** If a path that you specify in the `rtwmakecfg.m` API contains spaces, the build process does not convert the path to its nonspace equivalent. If the build environments you intend to support do not support spaces in paths, refer to “Build Process Support for File and Folder Names”.

---

## Modify the Template Makefile for rtwmakecfg

To expand the information that an `rtwmakecfg` function generates, modify the following sections in the TMF of your target:

- Include Path
- C Flags and/or Additional Libraries
- Rules

It is possible that these TMF code examples do not apply to your make utility. For additional examples, see the GRT or ERT TMFs located in *matlabroot/toolbox/coder/compile/tmf*.

### Add Folder Names to the Makefile Include Path

The following TMF code example adds folder names to the include path in the generated makefile:

```
ADD_INCLUDES = \
|>START_EXPAND_INCLUDES<| -I|>EXPAND_DIR_NAME<| \
|>END_EXPAND_INCLUDES<|
```

Also, the `ADD_INCLUDES` macro must be added to the `INCLUDES` line.

```
INCLUDES = -I. -I.. $(ADD_INCLUDES) $(USER_INCLUDES)
```

### Add Library Names to the Makefile

The following TMF code example adds library names to the generated makefile.

```
LIBS =
|>START_PRECOMP_LIBRARIES<|
LIBS += |>EXPAND_LIBRARY_NAME<|.a |>END_PRECOMP_LIBRARIES<|
|>START_EXPAND_LIBRARIES<|
LIBS += |>EXPAND_LIBRARY_NAME<|.a |>END_EXPAND_LIBRARIES<|
```

For more information, see “Control Library Location and Naming During Build” on page 93-3.

## Add Rules to the Makefile

The TMF code example adds rules to the generated makefile.

```
|>START_EXPAND_RULES<|
$(BLD)/%.o: |>EXPAND_DIR_NAME<|/%.c $(SRC)/$(MAKEFILE) rtw_proj.tmw
@$(BLANK)
@echo ### "|>EXPAND_DIR_NAME<|\$.c"
$(CC) $(CFLAGS) $(APP_CFLAGS) -o (BLD)(DIRCHAR)$.o \
|>EXPAND_DIR_NAME<|$(DIRCHAR)$.c > (BLD)(DIRCHAR)$.lst
|>END_EXPAND_RULES<|

|>START_EXPAND_LIBRARIES<|MODULES_|>EXPAND_LIBRARY_NAME<| = \
|>START_EXPAND_MODULES<| |>EXPAND_MODULE_NAME<|.o \
|>END_EXPAND_MODULES<|

|>EXPAND_LIBRARY_NAME<|.a : $(MAKEFILE) rtw_proj.tmw
$(MODULES_|>EXPAND_LIBRARY_NAME<|:%.o=$(BLD)/%.o)
@$(BLANK)
@echo ### Creating $@
$(AR) -r $@ $(MODULES_|>EXPAND_LIBRARY_NAME<|:%.o=$(BLD)/%.o)
|>END_EXPAND_LIBRARIES<|

|>START_PRECOMP_LIBRARIES<|MODULES_|>EXPAND_LIBRARY_NAME<| = \
|>START_EXPAND_MODULES<| |>EXPAND_MODULE_NAME<|.o \
|>END_EXPAND_MODULES<|

|>EXPAND_LIBRARY_NAME<|.a : $(MAKEFILE) rtw_proj.tmw
$(MODULES_|>EXPAND_LIBRARY_NAME<|:%.o=$(BLD)/%.o)
@$(BLANK)
@echo ### Creating $@
$(AR) -r $@ $(MODULES_|>EXPAND_LIBRARY_NAME<|:%.o=$(BLD)/%.o)
|>END_PRECOMP_LIBRARIES<|
```

## Register Custom Toolchain and Build Executable

This example shows how to register and use a toolchain to build an executable file. This example uses the Intel® compiler. However, the concepts and programming interface apply for other toolchains. Once you register a toolchain, you can configure a model such that the code generator uses the toolchain to build an executable file for the model.

### Toolchain

A toolchain is a collection of tools required to compile and link code for a specified platform. A toolchain consists of multiple tools, such as a compiler, linker, and archiver. You can configure the tools in a toolchain with multiple options and group tool specifications into types of configurations.

### Create a New Folder and Copy Relevant Files

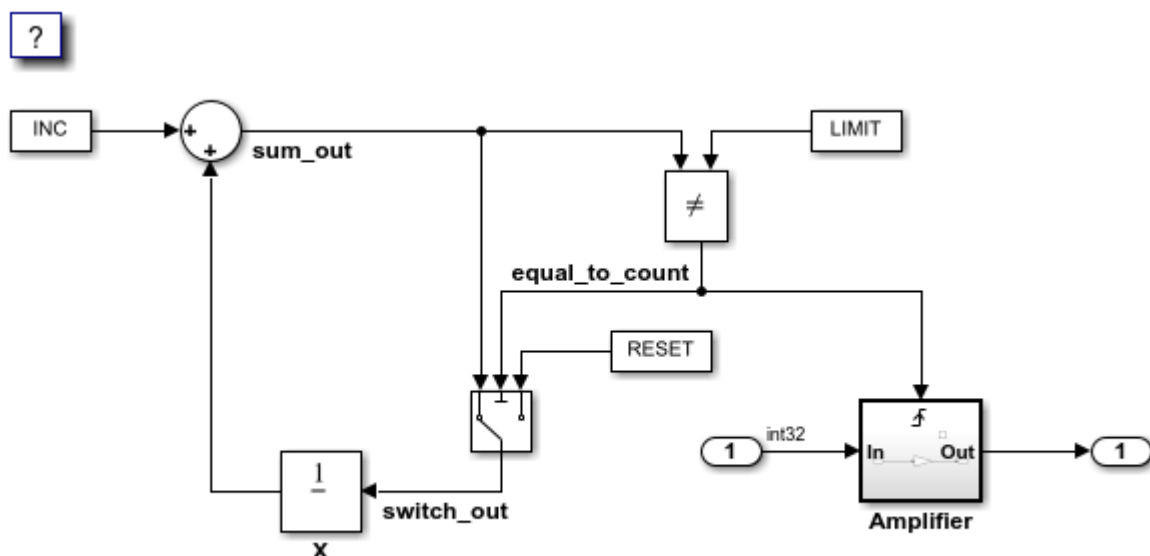

The following code creates a folder in your current working folder (pwd). The new folder contains files for this example. If you do not want to affect the current folder, or cannot generate files in this folder, change your working folder before invoking the command.

```
copyfile(fullfile(matlabroot, 'toolbox', 'rtw', 'rtwdemos', 'toolchain_demo'), 'toolchain_demo', 'f')
cd toolchain_demo
```

### Open a Model

Open the `rtwdemo_counter` model. By default, this model is configured to use the Generic Real-Time Target (GRT) configuration and the toolchain approach for building an executable file. The capability demonstrated in this example is available for models configured to use the toolchain approach.

```
model = 'rtwdemo_counter';
open_system(model)
```

Copyright 1994-2021 The MathWorks, Inc.

### Choose a Toolchain

Open the **Configuration Parameters** dialog box. Select **Code Generation**. The **Toolchain settings** section contains parameters for configuring a toolchain. From the **Toolchain** drop-down list, select the toolchain installed on your development system for building an executable file from the code generated from your model.

By default, the **Faster Runs** build configuration is selected. Click **Show settings** to see the toolchain flags specified for building the generated code. Choose a build configuration based on your current application development goal.

Close the **Configuration Parameters** dialog box.

### Create a ToolchainInfo Object

This example shows how you can register a custom toolchain and add it as a selectable **Toolchain** option.

The first step to registering a custom toolchain is to create a `ToolchainInfo` object that contains information about the toolchain. Methods are available to set toolchain specifications. You can share a `ToolchainInfo` object across installations.

Open the toolchain definition file for an Intel compiler. This file creates a `ToolchainInfo` object that contains information about the Intel toolchain on a 64-bit Windows® platform.

```
edit intel_tc
```

You can display the errors and warnings in the diagnostics messages pane from builds generated by custom compilers. For more information, see “Diagnostic Message Pane”.

Run the toolchain definition file to generate the `ToolchainInfo` object.

```
tc = intel_tc;
```

Save the `ToolchainInfo` object `tc` to a MAT file.

```
save intel_tc tc
```

### Register the Custom Toolchain

After you create the `ToolchainInfo` object for the new toolchain, register it. Register a toolchain in `RTW.TargetRegistry`. To register the toolchain, write an `rtwTargetInfo.m` file. Then, add that file to the MATLAB path so the system loads it automatically.

```
edit rtwTargetInfo
```

Reset the `TargetRegistry` to use the new `rtwTargetInfo.m` file.

```
RTW.TargetRegistry.getInstance('reset');
```

### Choose the Custom Toolchain

Reopen the **Configuration Parameters** dialog box. Click **Toolchain**. You should see the new toolchain in the list. Select the Intel v18 toolchain.

Programmatically, you can accomplish the same task with the following commands:

```
cs = getActiveConfigSet(model);
set_param(cs, 'Toolchain', tc.Name)
```

Verify your selection.

```
toolchain = get_param(cs, 'Toolchain')
```

```
toolchain =
```

```
 'Intel v18 | nmake makefile (64-bit Windows)'
```

### Build the Model Using the Custom Toolchain

You can now build the model with the new custom toolchain.

Note: If you do not have the Intel toolchain installed, you can use the following command to generate the code and makefile only.

```
set_param(cs, 'GenCodeOnly', 'on')
```

Build the model to generate the code and makefile that uses the new toolchain.

```
slbuild(model)
```

```
Starting build procedure for: rtwdemo_counter
Successful completion of code generation for: rtwdemo_counter
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_counter	Code generated	Code generation information file does not exist.

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 16.819s
```

Obtain the build directory information.

```
dirInfo = RTW.getBuildDir(model);
```

Examine the generated makefile.

```
edit(fullfile(dirInfo.BuildDirectory, [model '.mk']))
```

If Intel compilers are installed, then when the build process is complete, you can run the executable file.

```
if ispc
 system([model '.exe'])
else
 system(model)
end
```

### Restore

You can optionally remove the folder you created earlier.

```
cd ..
rmdir('toolchain_demo', 's')
```

Reset the TargetRegistry to remove the toolchain that you registered above.

```
RTW.TargetRegistry.getInstance('reset');
```

Close the model.

```
close_system(model, 0)
```

Clear the variables introduced in the workspace.

```
clear INC K LIMIT RESET model tc cs toolchain
```

## Customize Build Process with `STF_make_rtw_hook` File

The build process lets you supply optional custom code in hook methods that are executed at specified points in the code generation and make process. You can use hook methods to add target-specific actions to the build process.

### `STF_make_rtw_hook` File

You can modify hook methods in a file generically referred to as `STF_make_rtw_hook.m`, where `STF` is the name of a system target file, such as `ert` or `mytarget`. This file implements a function, `STF_make_rtw_hook`, that dispatches to a specific action, depending on the `hookMethod` argument passed in.

The build process calls `STF_make_rtw_hook`, passing in the `hookMethod` argument and other arguments. You implement only those hook methods that your build process requires.

If your model contains reference models, you can implement an `STF_make_rtw_hook.m` for each reference model as required. The build process calls each `STF_make_rtw_hook` for reference models, processing these files recursively (in dependency order).

### Conventions for Using the `STF_make_rtw_hook` File

For the build process to call the `STF_make_rtw_hook`, check that the following conditions are met:

- The `STF_make_rtw_hook.m` file is on the MATLAB path.
- The file name is the name of your system target file (`STF`), appended to the text `_make_rtw_hook.m`. For example, if you generate code with a custom system target file `mytarget.tlc`, name your hook file `mytarget_make_rtw_hook.m`, and name the hook function implemented within the file `mytarget_make_rtw_hook`.
- The hook function implemented in the file uses the function prototype described in “`STF_make_rtw_hook.m` Function Prototype and Arguments” on page 93-25.

### `STF_make_rtw_hook.m` Function Prototype and Arguments

The function prototype for `STF_make_rtw_hook` is:

```
function STF_make_rtw_hook(hookMethod, modelName, rtwRoot, templateMakefile,
 buildOpts, buildArgs, buildInfo)
```

The arguments are defined as:

- `hookMethod`: Character vector specifying the stage of build process from which the `STF_make_rtw_hook` function is called. The following flow chart summarizes the build process, highlighting the hook points. Valid values for `hookMethod` are `'entry'`, `'before_tlc'`, `'after_tlc'`, `'before_make'`, `'after_make'`, `'exit'`, and `'error'`. The `STF_make_rtw_hook` function dispatches to the relevant code with a `switch` statement.

- `modelName`: Character vector specifying the name of the model. Valid at all stages of the build process.
- `rtwRoot`: Reserved.
- `templateMakefile`: Name of template makefile.
- `buildOpts`: A MATLAB structure that contains the Boolean field `codeWasUpToDate`. Valid for the `'before_make'`, `'after_make'`, and `'exit'` stages only.
- `buildArgs`: Character vector containing the argument to `make_rtw`. When you invoke the build process, `buildArgs` is copied from the argument following `"make_rtw"` in the **Configuration Parameters + Code Generation + Make command** field.

For example, the following make arguments from the **Make command** field

```
make_rtw VAR1=0 VAR2=4
```

generate the following:

```
% make -f untitled.mk VAR1=0 VAR2=4
```

The `buildArgs` argument does not apply for toolchain approach builds because these builds do not allow adding make arguments to the `make_rtw` call. On the compiler command line, to provide custom definitions (for example, `VAR1=0 VAR2=4`) that apply for both TMF approach and toolchain approach builds, use the **Configuration Parameters > Code Generation > Custom Code > Defines** field.

- `buildInfo`: The `RTW.BuildInfo` object that contains information for compiling and linking generated code. Available only for the `'after_tlc'`, `'before_make'`, `'after_make'`, and `'exit'` stages. The information in the object at the end of the `'after_tlc'` stage might not be complete. In later stages, the `'before_make'` and `'after_make'` hook methods can also add information to the object. For more information about using the `RTW.BuildInfo` object, see “Code Compilation Customization”.

## Applications for STF\_make\_rtw\_hook.m

This section shows how you can use the `STF_make_rtw_hook.m` hook methods.

In general, use the `'entry'` hook to initialize the build process, for example, to change or validate settings before code is generated. One application for the `'entry'` hook is to rerun the auto-configuration script that initially ran at target selection time to compare model parameters before and after the script executes, for validation purposes.

The other hook points, `'before_tlc'`, `'after_tlc'`, `'before_make'`, `'after_make'`, `'exit'`, and `'error'` are useful for interfacing with external tool chains, source control tools, and other environment tools.

For example, you can use the `STF_make_rtw_hook.m` file at a stage after `'entry'` to obtain the path to the build folder. At the `'exit'` stage, you can then locate generated code files within the build folder and check them into your version control system. You can use `'error'` to clean up static or global data used by the hook function when an error occurs during code generation or the build process.

---

**Note** The build process temporarily changes the MATLAB working folder to the build folder for stages `'before_make'`, `'after_make'`, `'exit'`, and `'error'`. Your `STF_make_rtw_hook.m` file must not make incorrect assumptions about the location of the build folder. At a point after the `'entry'` stage, you can obtain the path to the build folder. In the following MATLAB code example, the build folder path is returned as a character vector to the variable `buildDirPath`.

```
buildDirPath = rtwprivate('get_makertwsettings',gcs,'BuildDirectory');
```

---

**Note** Do not use the `STF_make_rtw_hook.m` file to change the model configuration. For example, do not use a hook method to:

- Switch between model variants.
- Call the `set_param` function.

Changing the model configuration might produce unexpected code generation results.

---

## Control Code Regeneration Using STF\_make\_rtw\_hook.m

When you rebuild a model, by default, the build process performs checks to determine whether changes to the model or relevant settings require regeneration of the top model code. (For details on

the criteria, see “Control Regeneration of Top Model Code” on page 59-41.) If the checks determine that top model code generation is required, the build process fully regenerates and compiles the model code. If the checks indicate that the top model generated code is current with respect to the model, and model settings do not require full regeneration, the build process omits regeneration of the top model code.

Regardless of whether the top model code is regenerated, the build process subsequently calls the build process hooks, including *STF\_make\_rtw\_hook* functions and the post code generation command. The following mechanisms allow you to perform actions related to code regeneration in the *STF\_make\_rtw\_hook* functions:

- To force code regeneration, use the following function call from the 'entry' hook:

```
rtw.targetNeedsCodeGen('set', true);
```

- In hooks from 'before\_tlc' through 'exit', the *buildOpts* structure passed to the hook has a Boolean field *codeWasUpToDate*. The field is set to *true* if model code was up to date and code was not regenerated, or *false* if code was not up to date and code was regenerated. You can customize hook actions based on the value of this field. For example:

```
...
case 'before_tlc'
 if buildOpts.codeWasUpToDate
 %Perform hook actions for up to date model
 else
 %Perform hook actions for full code generation
 end
end
...
```

## Use *STF\_make\_rtw\_hook.m* for Your Build Procedure

To create a custom *STF\_make\_rtw\_hook* hook file for your build procedure, copy and edit the example *ert\_make\_rtw\_hook.m* file, which is located in the folder *matlabroot/toolbox/coder/embeddedcoder* (open), as follows:

- 1 Copy *ert\_make\_rtw\_hook.m* to a folder in the MATLAB path. Rename it in accordance with the naming conventions described in “Conventions for Using the *STF\_make\_rtw\_hook* File” on page 93-25. For example, to use it with the GRT target *grt.tlc*, rename it to *grt\_make\_rtw\_hook.m*.
- 2 Rename the *ert\_make\_rtw\_hook* function within the file to match the file name.
- 3 Implement the hooks that you require by adding code to case statements within the *switch hookMethod* statement.

## Hook Method *after\_tlc*

The *after\_tlc* hook method is available solely for backwards compatibility.

The format of the generated code during the *after\_tlc* stage is not the final format.

### Related Examples

- “Customize Build Process with *sl\_customization.m*” on page 93-29

## Customize Build Process with `sl_customization.m`

The Simulink customization file `sl_customization.m` is a mechanism that allows you to use MATLAB to customize the build process interface. The Simulink software reads the `sl_customization.m` file, if present on the MATLAB path, when it starts and the customizations specified in the file are applied to the Simulink session. For more information on the `sl_customization.m` customization file, see “Register Customizations with Simulink”.

### The `sl_customization.m` File

The `sl_customization.m` file can be used to register installation-specific hook functions to be invoked during the build process. The hook functions that you register through `sl_customization.m` complement System Target File (STF) hooks (described in “Customize Build Process with `STF_make_rtw` hook File” on page 93-25) and post-code generation commands (described in “Customize Post-Code-Generation Build Processing” on page 93-7).

The following figure shows the relationship between installation-level hooks and the other available mechanisms for customizing the build process.

## Register Build Process Hook Functions Using `sl_customization.m`

To register installation-level hook functions that are invoked during the build process, you create a MATLAB function called `sl_customization.m` and include it on the MATLAB path of the Simulink installation that you want to customize. The `sl_customization` function accepts one argument: a handle to a customization manager object. For example,

```
function sl_customization(cm)
```

As a starting point for your customizations, the `sl_customization` function must first get the default (factory) customizations, using the following assignment statement:

```
hObj = cm.RTWBuildCustomizer;
```

You then invoke methods to register your customizations. The customization manager object includes the following method for registering build process hook customizations:

- `addUserHook(hObj, hookType, hook)`

Registers the MATLAB hook script or function specified by `hook` for the build process stage represented by `hookType`. The valid values for `hookType` are `'entry'`, `'before_tlc'`, `'after_tlc'`, `'before_make'`, `'after_make'`, and `'exit'`.

Use this method to register installation-specific hook functions in your instance of the `sl_customization` function.

The Simulink software reads the `sl_customization.m` file when it starts. If you subsequently change the file, you must restart the Simulink session or enter the following command in the Command Window to enable the changes:

```
sl_refresh_customizations
```

## Variables Available for `sl_customization.m` Hook Functions

The following variables are available for `sl_customization.m` hook functions to use:

- `modelName` — The name of the Simulink model (valid for all stages)
- `dependencyObject` — An object containing the dependencies of the generated code (valid only for the `'after_make'` stage)

A hook script can directly access the valid variables. A hook function can pass the valid variables as arguments to the function. For example:

```
hObj.addUserHook('after_make', 'afterMakeFunction(modelName,dependencyObject)');
```

## Example of Build Process Customization with `sl_customization.m`

The `sl_customization.m` file shown in the example, **`sl_customization.m` for Build Process Customizations**, uses the `addUserHook` method to specify installation-specific build process hooks to be invoked at the `'entry'` and `'after_tlc'` stages of the build process. For the hook function source code, see the **`CustomRTWEntryHook.m`** and **`CustomRTWPostProcessHook.m`** examples.

### Example 93.1. `sl_customization.m` for Build Process Customizations

```
function sl_customization(cm)
% Register user customizations

% Get default (factory) customizations
hObj = cm.RTWBuildCustomizer;

% Register build process hooks
hObj.addUserHook('entry', 'CustomRTWEntryHook(modelName)');
hObj.addUserHook('after_tlc', 'CustomRTWPostProcessHook(modelName)');

end
```

### Example 93.2. `CustomRTWEntryHook.m`

```
function [str, status] = CustomRTWEntryHook(modelName)
str = sprintf('Custom entry hook for model ''%s.''',modelName);
disp(str)
status =1;
```

### Example 93.3. `CustomRTWPostProcessHook.m`

```
function [str, status] = CustomRTWPostProcessHook(modelName)
str = sprintf('Custom post process hook for model ''%s.''',modelName);
```

```
disp(str)
status =1;
```

If you include the above three files on the MATLAB path of the Simulink installation that you want to customize, the coded hook function messages appear in the displayed output for builds. For example, if you open the ERT-based model `UserDefinedDataTypes`, open the **Code Generation** pane of the Configuration Parameters dialog box, and press **Ctrl+B** to initiate a build, the following messages are displayed:

```
>> UserDefinedDataTypes

Starting build procedure for model: UserDefinedDataTypes
Custom entry hook for model 'UserDefinedDataTypes.'
Custom post process hook for model 'UserDefinedDataTypes.'
Successful completion of build procedure for model: rtwdemo_udt
>>
```

### Related Examples

- “Use `STF_make_rtw_hook.m` for Your Build Procedure” on page 93-28

## Replace STF\_rtw\_info\_hook Supplied Target Data

Prior to MATLAB Release 14, custom targets supplied target-specific information with a hook file (referred to as *STF\_rtw\_info\_hook.m*). The *STF\_rtw\_info\_hook* specified properties such as word sizes for integer data types (for example, char, short, int, and long), and C implementation-specific properties of the custom target.

The *STF\_rtw\_info\_hook* mechanism has been replaced by the **Hardware Implementation** pane of the Configuration Parameters dialog box. Using this dialog box, you can specify properties that were formerly specified in your *STF\_rtw\_info\_hook* file.

For backward compatibility, existing *STF\_rtw\_info\_hook* files are available. However, you should convert your target and models to use of the **Hardware Implementation** pane. See “Configure Production and Test Hardware”.

## Custom Targets

A custom target is a software package that you create to deploy MATLAB and Simulink designs to target hardware. Using the package, you can perform tasks to optimize, prototype, verify, and deploy an application to your hardware. This table lists tasks that you can perform by using target classes and functions.

Task	See
Register new hardware devices and hardware boards for <b>Hardware Implementation</b> settings.	"Register New Hardware Devices" on page 10-11 <code>target.Board</code> <code>target.Processor</code> <code>target.LanguageImplementation</code>
Build a target application using a CMake-based toolchain.	"Create Custom CMake Toolchain Definition" on page 59-15 "Generated Code Compilation"
Deploy, download, and run an application on target hardware.	<code>target.ExecutionTool</code> <code>target.SystemCommandExecutionTool</code>
Tune parameters and monitor target application signals during an external mode simulation.	"Set Up External Mode Connectivity Between Simulink and Target Hardware" on page 60-34 "External Mode Simulation by Using XCP Communication" on page 60-8 "Customize XCP Server Software" on page 60-44
Test numerical equivalence between your MATLAB code or Simulink model and the generated code by running a processor-in-the-loop (PIL) simulation.	"Set Up PIL Connectivity by Using target Package" on page 88-48 "Configure and Run PIL Simulation" on page 88-24
Perform code execution profiling through a PIL simulation.	"Set Up PIL Connectivity by Using target Package" on page 88-48 "Create Execution-Time Profile for Generated Code" on page 81-2

This table lists additional tasks that you can perform with a custom target defined by target classes and functions.

Task	See
Generate or register a main file to schedule the generated code	<p>“Deploy Applications to Target Hardware” on page 71-2</p> <p>“Model Multicore Concurrent Tasking Application” on page 3-86</p> <p>Generate an example main program</p> <p>Target operating system</p> <p>“Generate Source and Header Files with a Custom File Processing (CFP) Template” on page 55-62</p> <p>“Support C Function Prototype Control” on page 94-67</p> <p>“Support C++ Class Interface Control” on page 94-69</p>
Register build hooks.	<p>“Customize Build Process with sl_customization.m” on page 93-29</p> <p>“Customize Post-Code-Generation Build Processing” on page 93-7</p>
Optimize generated code by using a processor-specific code-replacement library.	“Code Replacement”
Integrate real-time operating systems and device drivers.	“Device Drivers” on page 94-72
Define a custom system target file with hooks and custom settings to add target-specific actions to the build process.	<p>“Target Platform Device Customization”</p> <p>“Customize System Target Files” on page 94-19</p> <p>“Customize Build Process with STF_make_rtw_hook File” on page 93-25</p>

You can also create custom software for ARM processors, which is based on MathWorks reference targets. For example, see:

- “Embedded Coder Support Package for ARM Cortex-A Processors”
- “Embedded Coder Support Package for ARM Cortex-M Processors”

## See Also

## Sample Custom Targets

There are technical solutions on the MathWorks Web site that you can use as a starting point to create your own target solution. The solutions provide guides to the following tasks for creating custom targets:

- Methods of embedding code onto a custom processor
- Creating a system target file
- Customizing the makefile and main file
- Adding compiler, chip, and board specific information
- Integrating legacy code and device drivers
- Creating blocks and libraries
- Implementing processor-in-the-loop (PIL) testing.

Consider these options:

- Download the embedded targets development guide zip file from this web page:

Is there an example guide on developing an embedded target...?

The zip file provides example files and a guide to developing a custom embedded target. The guide is divided into two parts, one on creating a generic custom target and another on creating a target for the Freescale™ S12X processor using the Cosmic Compiler.

Read the example guide along with this document to understand the tasks for developing embedded targets.

- For more detailed example files for specific processors, see:
  - Is there an example Freescale S12X target... using the Cosmic Compiler?
  - Is there an example Freescale S12X target... using the CodeWarrior Compiler?

These example kits contain example models, code generation files, and instruction guides on generating and testing code for the processor. The Cosmic example illustrates the use of the target connectivity API for processor-in-the-loop (PIL) testing. The CodeWarrior example does not have PIL but shows CAN Calibration Protocol (CCP) and Simulink external mode.

The intent of the example kits is to provide working examples that you can use as a base to create your own target solution. The intent is not to provide a full featured and maintained Embedded Target product like those provided by MathWorks or third-party products, as listed on the Embedded Coder Hardware Support Web page.

- You can watch a video that shows an overview of the example kit [www.mathworks.com/videos/programming-the-freescale-s12x-target-68811.html](http://www.mathworks.com/videos/programming-the-freescale-s12x-target-68811.html).
- For an example target for the ARM9 (STR9) processor, see [Is there an example ARM9 \(STR9\) target... using the GNU ARM Compiler and Hitex STR9-comStick?](#).

If you have questions on specific targets, email [mytarget@mathworks.com](mailto:mytarget@mathworks.com).

The example kits and this document describe Embedded Coder features such as customized ert system target files and processor-in-the-loop testing, but you can study the examples as a starting point for use with Simulink Coder targets.

## Target Development Folders, Files, and Builds

Target development mechanics work with a number of folder and file types. The following topics provide the information to develop custom targets, configure folder usage, and use custom targets in the build process.

### Folder and File Naming Conventions

You can use a single folder for your custom target files, or if desired you can use subfolders, for example containing files associated with specific development environments or tools.

For a custom target implementation, the recommended folder and file naming conventions are

- Use *only* lowercase in folder names, filenames, and extensions.
- Do not embed spaces in folder names. Spaces in folder names cause errors with many third-party development environments.
- Include desired folders in the MATLAB path
- Do *not* place your custom target folder anywhere in the MATLAB folder tree (that is, in or under the *matlabroot* folder). If you place your folder under *matlabroot* you risk losing your work if you install a new MATLAB version (or reinstall the current version).

The following sections explain how to organize your target folders and files and add them to your MATLAB path. They also provide high-level descriptions of the files.

In this document, *mytarget* is a placeholder name that represents folders and files that use the target's name. The names *dev\_tool1*, *dev\_tool2*, and so on represent subfolders containing files associated with development environments or tools. This document describes an example structure where the folder *mytarget* contains subfolders for *mytarget*, *blocks*, *dev\_tool1*, *dev\_tool2*. The top level folder *mytarget* is the *target root folder*.

### Components of a Custom Target

- “Overview” on page 94-6
- “Code Components” on page 94-7
- “Control Files” on page 94-8

#### Overview

The components of a custom target are files located in a hierarchy of folders. The top-level folder in this structure is called the *target root folder*. The target root folder and its contents are named, organized, and located on the MATLAB path according to conventions described in “Folder and File Naming Conventions” on page 94-6.

The components of a custom target include

- Code components: C source code that supervises and supports execution of generated model code.
- Control files:
  - A system target file to control the code generation process.

- File(s) to control the building of an executable from the generated code. In a traditional make-based environment, a template makefile (TMF) generates a makefile for this purpose. Another approach is to generate project files in support of a modern integrated development environment (IDE) such as the Freescale Semiconductor CodeWarrior IDE.
- Hook files: Optional TLC and MATLAB program files that can be invoked at well-defined stages of the build process. Hook files let you customize the build process and communicate information between various phases of the process.
- Other target files: Files that let you integrate your target into the MATLAB environment. For example, you can provide an `info.xml` file to make your target block libraries and examples available from a MATLAB session.

The next sections introduce key concepts and terminology you need to know to develop each component. References to more detailed information sources are provided.

## Code Components

An executable program containing code generated from a Simulink model consists of a number of code modules and data structures. These fall into two categories: application components and execution support files.

### Application Components

Application components are those which are specific to a particular model; they implement the functions represented by the blocks in the model. Application components are not specific to the target. Application components include

- Modules generated from the model
- User-written blocks (S-functions)
- Parameters of the model that are visible, and can be interfaced to, external code

### Execution Support Files

A number of code modules and data structures, referred to collectively as the *execution support files*, are responsible for managing and supporting the execution of the generated program. The execution support files modules are not automatically generated. Depending on the requirements of your target, you must implement certain parts of the execution support files. Execution Support Files summarizes the execution support files.

### Execution Support Files

You Provide...	The Code Generator Provides...
Customized main program	Generic main program
Timer interrupt handler to run model	Execution engine and integration solver (called by timer interrupt handler)
Other interrupt handlers	Example interrupt handlers (Asynchronous Interrupt blocks)
Device drivers	Example device drivers
Data logging, parameter tuning, signal monitoring, and external mode support	Data logging, parameter tuning, signal monitoring, and external mode APIs

### User-Written Execution Support Files

The code generator provides most of the execution support files. Depending on the requirements of your target, you must implement some or all of the following elements:

- A timer *interrupt service routine* (ISR). The timer runs at the program's base sample rate. The timer ISR is responsible for operations that must be completed within a single clock period, such as computing the current output sample. The timer ISR usually calls the `rt_OneStep` function.

If you are targeting a real-time operating system (RTOS), your generated code usually executes under control of the timing and task management mechanisms provided by the RTOS. In this case, you may not have to implement a timer ISR.

- The *main program*. Your main program initializes the blocks in the model, installs the timer ISR, and executes a background task or loop. The timer periodically interrupts the main loop. If the main program is designed to run for a finite amount of time, it is also responsible for cleanup operations — such as memory deallocation and masking the timer interrupt — before terminating the program.

If you are targeting a real-time operating system (RTOS), your main program most likely spawns tasks (corresponding to the sample rates used in the model) whose execution is timed and controlled by the RTOS.

Your main program typically is based on a generated or static main program. For details on the structure of the execution support files, code execution, and guidelines for customizing main programs, see “Deploy Applications to Target Hardware” on page 71-2.

- *Device drivers*. Drivers communicate with I/O devices on your target hardware. In production code, device drivers are normally implemented as inlined S-functions.
- *Other interrupt handlers*. If your models need to support asynchronous events, such as hardware generated interrupts and asynchronous read and write operations, you must supply interrupt handlers. The Interrupt Templates library provides examples.
- *Data logging, parameter tuning, signal monitoring, and external mode support*. It is atypical to implement rapid prototyping features such as external mode support in an embedded target. However, it is possible to support these features by using standard code generator APIs. See “Calibration and Measurement” for details.

### Control Files

The code generation and build process is directed by a number of TLC and MATLAB files collectively called *control files*. This section introduces and summarizes the main control files.

#### Top-Level Control File (`make_rtw`)

The build process is initiated when you press **Ctrl+B**. At this point, the build process parses the **Make command** field of the **Code Generation** pane of the Configuration Parameters dialog box, expecting to find the name of a MATLAB command that controls the build process (as well as optional arguments to that command). The default command is `make_rtw`, and the default top-level control file for the build process is `make_rtw.m`.

---

**Note** `make_rtw` is an internal MATLAB command used by the build process. Normally, target developers do not need detailed knowledge of how `make_rtw` works. (The details for target developers are described in “Target Development and the Build Process” on page 94-14.) You should not invoke `make_rtw` directly from MATLAB code, and you should not customize `make_rtw.m`.

---

The `make_rtw.m` file contains the logic required to execute your target-specific control files, including a number of hook points for execution of your custom code. `make_rtw` does the following:

- Passes optional arguments in to the build process
- Performs required preprocessing before code generation
- Executes the system target file to perform code generation (and optional HTML report generation)
- Processes the TMF to generate a makefile
- Invokes a make utility to execute the makefile and build an executable
- Performs required post-processing (such as generating calibration data files or downloading the generated executable to the target)

### System Target File

The Target Language Compiler (TLC) generates target-specific C or C++ code from a partial description of your Simulink block diagram (`model.rtw`). The Target Language Compiler reads `model.rtw` and executes a program consisting of several target files (`.tlc` files.) The system target file, at the top level of this program, controls the code generation process. The output of this process is a number of source files, which are fed to your development system's make utility.

You need to create a customized system target file to set code generation parameters for your target. You should copy, rename, and modify the standard ERT system target file (`matlabroot/rtw/c/ert/ert.tlc`).

The detailed structure of the system target file is described in “Customize System Target Files” on page 94-19.

---

**Note** The system target file selects whether the target supports the toolchain approach or template makefile approach for code generation. See “Customize System Target Files” on page 94-19.

---

### Template Makefile (TMF)

A TMF provides information about your model and your development system. The build process uses this information to create a makefile (`.mk` file) that builds an executable program.

Some targets implement more than one TMF, in order to support multiple development environments (for example, two or more cross-compilers) or multiple modes of code generation (for example, generating a binary executable versus generating a project file for your compiler).

The Embedded Coder software provides a large number of TMFs suitable for different types of development computer systems. These TMFs are located in `matlabroot/toolbox/coder/compile/tmf`. The standard TMFs are described in “Template Makefiles and Make Options”.

The detailed structure of the TMF is described in “Customize Template Makefiles” on page 94-44.

---

**Note** The system target file selects whether the target supports the toolchain approach or template makefile approach for code generation. See “Customize System Target Files” on page 94-19.

---

### Hook Files

The build process allows you to supply optional *hook files* that are executed at specified points in the code generation and make process. You can use hook files to add target-specific actions to the build process.

The hook files must follow well-defined naming and location requirements. “Folder and File Naming Conventions” on page 94-6 describes these requirements.

## Key Folders Under Target Root (mytarget)

- “Target Root Folder (mytarget)” on page 94-10
- “Target Folder (mytarget/mytarget)” on page 94-10
- “Target Block Folder (mytarget/blocks)” on page 94-10
- “Development Tools Folder (mytarget/dev\_tool1, mytarget/dev\_tool2)” on page 94-11
- “Target Source Code Folder (mytarget/src)” on page 94-11

### Target Root Folder (mytarget)

This folder contains the key subfolders for the target (see “Folder and File Naming Conventions” on page 94-6). You can also locate miscellaneous files (such as a `readme` file) in the target root folder. The following sections describe required and optional subfolders and their contents.

### Target Folder (mytarget/mytarget)

This folder contains files that are central to the target, such as the system target file (STF) and template makefile (TMF). “Key Files in Target Folder (mytarget/mytarget)” on page 94-12 summarizes the files that should be stored in `mytarget/mytarget`, and provides pointers to detailed information about these files.

---

**Note** `mytarget/mytarget` should be on the MATLAB path.

---

### Target Block Folder (mytarget/blocks)

If your target includes device drivers or other blocks, locate the block implementation files in this folder. `mytarget/blocks` contains

- Compiled block MEX-files
- Source code for the blocks
- TLC inlining files for the blocks
- Library models for the blocks (if you provide your blocks in one or more libraries)

---

**Note** `mytarget/blocks` should be on the MATLAB path.

---

You can also store example models and supporting files in `mytarget/blocks`. Alternatively, you can create a `mytarget/mytargetdemos` folder, which should also be on the MATLAB path.

To display your blocks in the standard Simulink Library Browser and/or integrate your example models into the MATLAB session environment, you can create the files described below and store them in `mytarget/blocks`.

### **mytarget/blocks/slblocks.m**

This file allows a group of blocks to be integrated into the Simulink Library and Simulink Library Browser.

#### **Example 94.1. Example slblocks.m File**

```
function blkStruct = slblocks
% Information for "Blocksets and Toolboxes" subsystem
blkStruct.Name = sprintf('Embedded Target\n for MYTARGET');
blkStruct.OpenFcn = 'mytargetlib';
blkStruct.MaskDisplay = 'disp(''MYTARGET'')';

% Information for Simulink Library Browser
Browser(1).Library = 'mytargetlib';
Browser(1).Name = 'Embedded Target for MYTARGET';
Browser(1).IsFlat = 1;% Is this library "flat" (i.e. no subsystems)?

blkStruct.Browser = Browser;
```

### **mytarget/blocks/demos.xml**

This file provides information about the components, organization, and location of example models. MATLAB software uses this information to place the example in the MATLAB session environment.

#### **Example 94.2. Example demos.xml File**

```
<?xml version="1.0" encoding="utf-8"?>
<demos>
 <name>Embedded Target for MYTARGET</name>
 <type>simulink</type>
 <icon>$toolbox/matlab/icons/boardicon.gif</icon>
 <description source = "file">mytarget_overview.html</description>

 <demosession>
 <label>Multirate model</label>
 <demoitem>
 <label>MYTARGET demo</label>
 <file>mytarget_overview.html</file>
 <callback>mytarget_model</callback>
 </demoitem>
 </demosession>
</demos>
```

### **Development Tools Folder (mytarget/dev\_tool1, mytarget/dev\_tool2)**

These folders contain files associated with specific development environments or tools (`dev_tool1`, `dev_tool2`, etc.). Normally, your target supports at least one such development environment and invokes its compiler, linker, and other utilities during the build process. `mytarget/dev_tool1` includes linker command files, startup code, hook functions, and other files required to support this process.

For each development environment, you should provide a separate folder.

### **Target Source Code Folder (mytarget/src)**

This folder is optional. If the complexity of your target requires it, you can use `mytarget/src` to store common source code and configuration code (such as boot and startup code).

## Key Files in Target Folder (mytarget/mytarget)

- “Introduction” on page 94-12
- “mytarget.tlc” on page 94-12
- “mytarget.tmf” on page 94-12
- “mytarget\_genfiles.tlc” on page 94-12
- “mytarget\_main.c” on page 94-13
- “STF\_make\_rtw\_hook.m” on page 94-13
- “STF\_rtw\_info\_hook.m (obsolete)” on page 94-13
- “info.xml” on page 94-13
- “mytarget\_overview.html” on page 94-13

### Introduction

The target folder `mytarget/mytarget` contains key files in your target implementation. These include the system target file, template makefile, main program module, and optional M and TLC hook files that let you add target-specific actions to the build process. The following sections describe the key target folder files.

### mytarget.tlc

`mytarget.tlc` is the system target file. Functions of the system target file include

- Making the target visible in the System Target File Browser
- Definition of code generation options for the target (inherited and target-specific)
- Providing an entry point for the top-level control of the TLC code generation process

You should base your system target file on `ert.tlc`, the system target file provided by Embedded Coder software.

“Customize System Target Files” on page 94-19 gives detailed information on the structure of the system target file, and also gives instructions on how to customize a system target file to

- Display your target in the System Target File Browser
- Add your own target options to the Configuration Parameters dialog box
- Tailor the code generation and build process to the requirements of your target

### mytarget.tmf

`mytarget.tmf` is the template makefile for building an executable for your target.

For basic information on the structure and operation of template makefiles, see “Customize Template Makefiles” on page 94-44.

### mytarget\_genfiles.tlc

This file is optional. `mytarget_genfiles.tlc` is useful as a central file from which to invoke target-specific TLC files that generate additional files as part of your target build process. For example, your target may create sub-makefiles or project files for a development environment, or command scripts for a debugger to do automatic downloads. See “Using `mytarget_genfiles.tlc`” on page 94-31 for details.

## mytarget\_main.c

A main program module is required for your target. To provide a main module, you can either

- Modify the `rt_main.c` or `rt_cppclass_main.cpp` module provided by the software
- Generate `mytarget_main.c` or `.cpp` during the build process

For a description of the operation of main programs, see “Deploy Applications to Target Hardware” on page 71-2. The section also contains guidelines for generating and modifying a main program module.

## STF\_make\_rtw\_hook.m

`STF_make_rtw_hook.m` is an optional hook file that you can use to invoke target-specific functions or executables at specified points in the build process. `STF_make_rtw_hook.m` implements a function that dispatches to a specific action depending on the `method` argument that is passed into it.

“Customize Build Process with `STF_make_rtw_hook` File” describes the operation of the `STF_make_rtw_hook.m` hook file in detail.

## STF\_rtw\_info\_hook.m (obsolete)

Prior to Release 14, custom targets supplied target-specific information with a hook file (referred to as `STF_rtw_info_hook.m`). The `STF_rtw_info_hook` specified properties such as word sizes for integer data types (for example, `char`, `short`, `int`, and `long`), and C implementation-specific properties of the custom target.

The `STF_rtw_info_hook` mechanism has been replaced by the **Hardware Implementation** pane of the Configuration Parameters dialog box. Using this dialog box, you can specify the properties that were formerly specified in your `STF_rtw_info_hook` file.

For backward compatibility, existing `STF_rtw_info_hook` files are still available. However, you should convert your target and models to use the **Hardware Implementation** pane. See “Configure Run-Time Environment Options”.

## info.xml

This file provides information to MATLAB software that specifies where to display the target toolbox in the MATLAB session environment. For more information, see “Display Custom Documentation”.

## mytarget\_overview.html

By convention, this file serves as home page for the target examples.

The `<description>` field in `demos.xml` should point to `mytarget_overview.html` (see “mytarget/blocks/demos.xml” on page 94-11).

### Example mytarget\_overview.html File

```

<html>
<head><title>Embedded Target for MYTARGET</title></head><body>
<p style="color:#990000; font-weight:bold; font-size:x-large">Embedded Target
for MYTARGET Example Model</p>

<p>This example provides a simple model that allows you to generate an executable
for a supported target board. You can then download and run the executable and
set breakpoints to study and monitor the execution behavior.</p>

```

```
</body>
</html>
```

## Additional Files for Externally Developed Targets

- “Introduction” on page 94-14
- “mytarget/mytarget/mytarget\_setup.m” on page 94-14
- “mytarget/mytarget/doc” on page 94-14

### Introduction

If you are developing an embedded target that is not installed into the MATLAB tree, you should provide a target setup script and target documentation within `mytarget/mytarget`, for the convenience of your users. The following sections describe the required materials and where to place them.

#### `mytarget/mytarget/mytarget_setup.m`

This file script adds paths for your target to the MATLAB path. Your documentation should instruct users to run the script when installing the target.

You should include a call to the MATLAB function `savepath` in your `mytarget_setup.m` script. This function saves the added paths, so users need to run `mytarget_setup.m` only once.

The following code is an example `mytarget_setup.m` file.

```
function mytarget_setup()
curpath = pwd;
tgtpath = curpath(1:end-length('\mytarget'));
addpath(fullfile(tgtpath, 'mytarget'));
addpath(fullfile(tgtpath, 'dev_tool1'));
addpath(fullfile(tgtpath, 'blocks'));
addpath(fullfile(tgtpath, 'mytargetdemos'));
savepath;
disp('MYTARGET Target Path Setup Complete.');
```

#### `mytarget/mytarget/doc`

You should put the documentation related to your target in the folder `mytarget/mytarget/doc`.

## Target Development and the Build Process

- “About the Build Process” on page 94-14
- “Build Process Phases and Information Passing” on page 94-15
- “Additional Information Passing Techniques” on page 94-16

### About the Build Process

To develop an embedded target, you need a thorough understanding of the build process. Your embedded target uses the build process and may require you to modify or customize the process. A general overview of code generation and the build process is given in “Code Generation” and “Build Process”.

This section supplements that overview with a description of the build process as customized by the Embedded Coder software. The emphasis is on points in the process where customization hooks are available and on passing information between different phases of the process.

This section concludes with “Additional Information Passing Techniques” on page 94-16, describing assorted tips and tricks for passing information during the build process.

### Build Process Phases and Information Passing

It is important to understand where (and when) the build process obtains required information. Sources of information include

- The *model.rtw* file, which provides information about the generating model. The information in *model.rtw* is available to target TLC files.
- The code generation panes of the Configuration Parameters dialog box. Options (both general and target-specific) are provided through check boxes, menus, and edit fields. You can associate options with TLC variables in the *rtwoptions* data structure. Use the **Configuration Parameters > Code Generation > Custom Code > Code information > Defines** field to define makefile tokens .
- The selected toolchain (for toolchain approach builds) or selected template makefile .tmf (for template makefile approach builds); these generate the model-specific makefile.
- Environment variables on the host computer. Environment variables provide additional information about installed development tools.
- Other target-specific files such as target-related TLC files, linker command files, or project files.

It is also important to understand the several phases of the build process and how to pass information between the phases. The build process comprises several high-level phases:

- Execution of the top-level file (*slbuild.m*) to sequence through the build process for a target
- Conversion of the model into the TLC input file (*model.rtw*)
- Generation of the target code by the TLC compiler
- Compilation of the generated code with *make* or other utilities
- Transmission of the final generated executable to the target hardware with a debugger or download utility

It is helpful to think of each phase of the process as a different “environment” that maintains its own data. These environments include

- MATLAB code execution environment (MATLAB)
- Simulink
- Target Language Compiler execution environment
- makefile
- Development environments such as and IDE or debugger

In each environment, you might get information from the various sources mentioned above. For example, during the TLC phase, execute MATLAB file might execute to obtain information from the MATLAB environment. Also, a given phase may generate information for a subsequent phase.

See “Key Files in Target Folder (mytarget/mytarget)” on page 94-12 for details on the available MATLAB file and TLC hooks for information passing, with code examples.

### Additional Information Passing Techniques

This section describes a number of useful techniques for passing information among different phases of the build process.

#### tlcvariable Field in rtoptions Structure

Parameters on the code generation panes of the Configuration Parameters dialog box can be associated with a TLC variable, and specified in the `tlcvariable` field of the option's entry in the `rtoptions` structure. The variable value is passed on the command line when TLC is invoked. This provides a way to make code generation parameters and their values available in the TLC phase.

See "System Target File Structure" on page 94-19 for further information.

#### makevariable Field in rtoptions Structure

You can associate code generation parameters with a template makefile token, that you specify in the `makevariable` field of the option's entry in the `rtoptions` structure. If a token of the same name as the `makevariable` name exists in the TMF, the token is updated with the option value when the final makefile is created. If the token does not exist in the TMF, the `makevariable` is passed in on the command line when `make` is invoked. Thus, in either case, the `makevariable` is available to the makefile.

See "System Target File Structure" on page 94-19 for further information.

#### Accessing Host Environment Variables

You can access host shell environment variables at the MATLAB command line by entering the `getenv` command. For example:

```
getenv ('MSDEVDIR')
```

```
ans =
```

```
D:\Applications\Microsoft Visual Studio\Common\MSDev98
```

To access the same information from TLC, use the `FEVAL` directive to invoke `getenv`.

```
%assign eVar = FEVAL("getenv", "<varname>")
```

#### Supplying Development Environment Information to Your Template Makefile

An embedded target must tie the build process to target-specific development tools installed on a host computer. For the `make` process to run these tools, the TMF must be able to determine the name of the tools, the path to the compiler, linker, and other utilities, and possibly the host operating system environment variable settings.

Require the end user to modify the target TMF. The user enters path information (such as the location of a compiler executable), and possibly host operating system environment variables, as `make` variables. This allows the TMF to be tailored to specific needs.

#### Using MATLAB Application Data

Application data provides a way for applications to save and retrieve data stored with the GUI. This technique enables you to create what is essentially a user-defined property for an object, and use this property to store data for use in the build process. For more information, see `setappdata` and `getappdata`.

The following code examples illustrates the use of application data to pass information to TLC.

This file, `tlc2appdata.m`, stores the data passed in as application data under the name passed in (`appDataName`).

```
function k = tlc2appdata(appDataName,data)
 disp([mfilename,': ',appDataName,' ', data]);
 setappdata(0,appDataName,data);
 k = 0; % TLC expects a return value for FEVAL.
```

The following sample TLC file uses the FEVAL directive to invoke `tlc2appdata.m` to store arbitrary application data, under the name `z80`.

```
%% test.tlc
%%
%assign myApp = "z80"
%assign myData = "314159"
%assign dummy = FEVAL("tlc2appdata",myApp,myData)
```

To test this technique:

- 1 Create the `tlc2appdata.m` file as shown. Check that `tlc2appdata.m` is stored in a folder on the MATLAB path.
- 2 Create the TLC file as shown. Save it as `test.tlc`.
- 3 Enter the following command at the MATLAB prompt to execute the TLC file:

```
tlc test.tlc
```

- 4 Get the application data at the MATLAB prompt:

```
k = getappdata(0,'z80')
```

The function returns the value 314159.

- 5 Enter the following command.

```
who
```

Note that application data is not stored in the MATLAB workspace. Also observe that the `z80` data is not visible. Using application data in this way has the advantage that it does not clutter the MATLAB workspace. Also, it helps prevent you from accidentally deleting your data, since it is not stored directly in your workspace.

A real-world use of application data might be to collect information from the `model.rtw` file and store it for use later in the build process.

### Adding Block-Specific Information to the Makefile

The `rtwmakecfg` mechanism provides a method for inlined S-functions such as driver blocks to add information to the makefile. This mechanism is described in “Use `rtwmakecfg.m` API to Customize Generated Makefiles”.

## **See Also**

### **More About**

- “Custom Targets”

## Customize System Target Files

This section provides information on the structure of the system target file, guidelines for customizing a system target file, and a basic tutorial that helps you to produce a skeletal system target file.

### Control Code Generation With the System Target File

The system target file controls the code generation stage of the build process. The system target file also lets you control the presentation of your target to the end user. The system target file provides

- Definitions of variables that are fundamental to the build process, such as the value for the CodeFormat TLC variable
- The main entry point to the top-level TLC program that generates code
- Target information for display in the System Target File Browser
- A mechanism for defining target-specific code generation options (and other parameters related to the build process) and for displaying them in the Configuration Parameters dialog box
- A mechanism for inheriting options from another target (such as the Embedded Real-Time (ERT) target)

Note that, although the system target file is a Target Language Compiler (TLC) file, it contains embedded MATLAB code. Before creating or modifying a system target file, you should acquire a working knowledge of TLC and of the MATLAB language. “Target Language Compiler” and “Scripts vs. Functions” describe the features and syntax of both the TLC and MATLAB languages.

While reading this section, you may want to refer to the system target files provided with the code generator. Most of these files are stored in the target-specific folders under *matlabroot*/rtw/c (open). Additional system target files are stored under *matlabroot*/toolbox/rtw/targets (open).

### System Target File Naming and Location Conventions

A system target file must be located in a folder on the MATLAB path for the target to be displayed in the System Target File Browser and invoked in the build process. Follow the location and naming conventions for system target files and related target files given in “Folder and File Naming Conventions” on page 94-6.

### System Target File Structure

- “Overview” on page 94-20
- “Header Comments” on page 94-21
- “TLC Configuration Variables” on page 94-22
- “TLC Program Entry Point and Related %includes” on page 94-22
- “RTW\_OPTIONS Section” on page 94-23
- “rtwgensettings Structure” on page 94-23
- “Additional Code Generation Options” on page 94-25
- “Model Reference Considerations” on page 94-25

## Overview

This section is a guide to the structure and contents of a system target file. The following listing shows the general structure of a system target file. Note that this is not a complete code listing of a system target file. The listing consists of excerpts from each of the sections that make up a system target file.

```

%%-----
%% Header Comments Section
%%-----
%% SYSTLC: Example Real-Time Target
%% TMF: my_target.tmf MAKE: make_rtw
%% Initial comments contain directives for STF Browser.
%% Documentation, date, copyright, and other info may follow.
 ...

%%-----
%% rtwgensettings Structure
%%-----
%% Define suffix text for naming build folder here.
rtwgensettings.BuildDirSuffix = '_mytarget_rtw'
%% Callback compatibility declaration
rtwgensettings.Version = '1';

%% (OPTIONAL) target inheritance declaration
rtwgensettings.DerivedFrom = 'ert.tlc';
%% (OPTIONAL) other rtwGenSettings fields...
 ...
END_RTW_OPTIONS
%/
%%-----
%% targetComponentClass - MATHWORKS INTERNAL USE ONLY
%% REMOVE NEXT SECTION FROM USER_DEFINED CUSTOM TARGETS
%%-----

```

```

/%
BEGIN_CONFIGSET_TARGET_COMPONENT
targetComponentClass = 'Simulink.ERTTargetCC';
END_CONFIGSET_TARGET_COMPONENT
%/

```

If you are creating a custom target based on an existing system target file, you must remove the `targetComponentClass` section (bounded by the directives `BEGIN_CONFIGSET_TARGET_COMPONENT` and `END_CONFIGSET_TARGET_COMPONENT`). This section is reserved for the use of targets developed internally by MathWorks.

## Header Comments

These lines at the head of the file are formatted as TLC comments. They provide required information to the System Target File Browser and to the build process. Note that you must place the browser comments at the head of the file, before other comments or TLC statements.

The presence of the comments enables the code generator to detect system target files. When the System Target File Browser is opened, the code generator scans the MATLAB path for TLC files that have formatted header comments. The comments contain the following directives:

- **SYSTLC**: The descriptor that appears in the browser.
- **TMF**: Name of the template makefile (TMF) to use during build process. When the target is selected, this filename is displayed in the Template makefile field of the **Code Generation** pane of the Configuration Parameters dialog box.
- **MAKE**: make command to use during build process. When the target is selected, this command is displayed in the **Make command** field of the **Code Generation** pane of the Configuration Parameters dialog box.

The following header comments are from `matlabroot/rtw/c/ert/ert.tlc`.

```

%% SYSTLC: Embedded Coder TMF: ert_default_tmf MAKE: make_rtw
%% SYSTLC: Create Visual C/C++ Solution File for Embedded Coder\
%% TMF: RTW.MSVCCBuild MAKE: make_rtw
.
.
.

```

Each comment can only contain a maximum of two lines.

If you do not specify the TMF field in the system target file, the file is still valid. To change the value for the `TemplateMakefile` parameter, you can instead use the callback function specified by `rtwgensettings.SelectCallback`.

You can also use the callback function specified by `rtwgensettings.SelectCallback` to change the value for external mode parameters, `ExtMode`, `ExtModeTransport`, `ExtModeMexFile`, or `ExtModeIntrrfLevel`.

You can specify more than one group of directives in the header comments. Each such group is displayed as a different target configuration in the System Target File Browser. In the above example, the first two lines of code specify the default configuration of the ERT target. The next two lines specify a configuration that creates and builds a Microsoft Visual C++ Solution (.sln) file. The figure below shows how these configurations appear in the System Target File Browser.

System Target File:	Description:
asap2.tlc	ASAM-ASAP2 Data Definition Target
autosar.tlc	AUTOSAR
ert.tlc	Embedded Coder
ert.tlc	Create Visual C/C++ Solution File for Embedd
ert_shrllib.tlc	Embedded Coder (host-based shared library ta
grt.tlc	Generic Real-Time Target
grt.tlc	Create Visual C/C++ Solution File for Simuli
idelink_ert.tlc	IDE Link ERT
idelink_grt.tlc	IDE Link GRT
my_ert_target.tlc	My ERT-based Target
my_ert_target.tlc	Create Visual C/C++ Solution File for Embedd
realtime.tlc	Run on Target Hardware
rsim.tlc	Rapid Simulation Target

See “Create a Custom Target Configuration” on page 94-33 for an example of customized header comments.

### TLC Configuration Variables

This section of the system target file assigns global TLC variables that relate to the overall code generation process.

For an embedded target, in most cases you should simply use the global TLC variable settings used by the ERT target (`ert.tlc`). It is especially important that your system target file use the 'Embedded-C' value for the `CodeFormat` TLC variable and uses the corresponding `rtwgensettings.DerivedFrom = 'ert.tlc'` in the `RTW_OPTIONS` section of the TLC file. Verify that values are assigned to the following variables:

- **CodeFormat:** The `CodeFormat` TLC variable selects generated code features. The 'Embedded-C' value for this variable is used by the ERT target. Your ERT-based target should specify 'Embedded-C' as the value for `CodeFormat`. This selection is designed for production code, minimal memory usage, static memory allocation, and a simplified interface to generated code.

For information on other values for the `CodeFormat` TLC variable, see “Compare System Target File Support Across Products”.

- **Language:** The only valid value is `C`, which enables support for C or C++ code generation as specified by the configuration parameter `TargetLang`.
- **TargetType:** The code generator defines the preprocessor symbols `RT` and `NRT` to distinguish simulation code from real-time code. These symbols are used in conditional compilation. The `TargetType` variable determines whether `RT` or `NRT` is defined.

Most targets are intended to generate real-time code. They assign `TargetType` as follows.

```
%assign TargetType = "RT"
```

Some targets, such as the model reference simulation target, accelerated simulation target, `RSim` target, and S-function target, generate code for use in nonreal time only. Such targets assign `TargetType` as follows.

```
%assign TargetType = "NRT"
```

### TLC Program Entry Point and Related `%includes`

The code generation process normally begins with `codegenentry.tlc`. The system target file invokes `codegenentry.tlc` as follows.

```
%include "codegenentry.tlc"
```

---

**Note** `codegenentry.tlc` and the lower-level TLC files assume that `CodeFormat`, `TargetType`, and `Language` have been assigned. Set these variables before including `codegenentry.tlc`.

---

If you need to implement target-specific code generation features, you should include the TLC file `mytarget_genfiles.tlc` in your system target file. This file provides a mechanism for executing custom TLC code before and after invoking `codegenentry.tlc`. For information on this mechanism, see

- “Using `mytarget_genfiles.tlc`” on page 94-31 for an example of custom TLC code for execution after the main code generation entry point.
- “Target Development and the Build Process” on page 94-14 for general information on the build process, and for information on other build process customization hooks.

Another way to customize the code generation process is to call lower-level functions (normally invoked by `codegenentry.tlc`) directly, and include your own TLC functions at each stage of the process. This approach should be taken with caution. See “TLC Files” for more information.

The lower-level functions called by `codegenentry.tlc` are

- `genmap.tlc`: maps block names to corresponding language-specific block target files.
- `commonsetup.tlc`: sets up global variables.
- `commonentry.tlc`: starts the process of generating code.

### RTW\_OPTIONS Section

The `RTW_OPTIONS` section is bounded by the directives:

```
/%
 BEGIN_RTW_OPTIONS
 .
 .
 .
 END_RTW_OPTIONS
%/
```

The first part of the `RTW_OPTIONS` section defines an array of `rtwoptions` structures. This structure is discussed in “Using `rtwoptions` to Display Custom Target Options” on page 94-25.

The second part of the `RTW_OPTIONS` section defines `rtwgensettings`, a structure defining the build folder name and other settings for the code generation process. See “`rtwgensettings` Structure” on page 94-23 for information about `rtwgensettings`.

### `rtwgensettings` Structure

The final part of the system target file defines the `rtwgensettings` structure. This structure stores information that is written to the `model.rtw` file and used by the build process. The `rtwgensettings` fields of most interest to target developers are

- `rtwgensettings.Version`: Use this property to enable `rtwoptions` callbacks and to use the Callback API in `rtwgensettings.SelectCallback`.

---

**Note** To use callbacks, you *must* set:

```
rtwgensettings.Version = '1';
```

---

Add the statement above to the **Configure RTW code generation settings** section of the system target file.

- `rtwgensettings.DerivedFrom`: This structure field defines the system target file from which options are to be inherited. See “Inheriting Target Options” on page 94-30.
- `rtwgensettings.SelectCallback`: This structure field specifies a `SelectCallback` function. You must set `rtwgensettings.Version = '1'`; or your callback will be ignored. `SelectCallback` is associated with the target rather than with any of its individual options. The `SelectCallback` function is triggered when you:
  - Load the model.
  - Update any configuration settings in the Configuration Parameters dialog box.
  - Build the model.

The `SelectCallback` function is useful for setting up (or disabling) configuration parameters specific to the target.

The following code installs a `SelectCallback` function:

```
rtwgensettings.SelectCallback = 'my_select_callback_handler(hDlg,hSrc)';
```

The arguments to the `SelectCallback` function (`hDlg`, `hSrc`) are handles to private data used by the callback API functions.

---

**Note** If you have developed a custom target and you want it to be compatible with model referencing, you must implement a `SelectCallback` function to declare model reference compatibility. See “Support Model Referencing” on page 94-61.

---

- `rtwgensettings.ActivateCallback`: this property specifies an `ActivateCallback` function. The `ActivateCallback` function is triggered when the active configuration set of the model changes. This could happen during model loading, and also when the user changes the active configuration set.

The following code installs an `ActivateCallback` function:

```
rtwgensettings.ActivateCallback = 'my_activate_callback_handler(hDlg,hSrc)';
```

The arguments to the `ActivateCallback` function (`hDlg`, `hSrc`) are handles to private data used by the callback API functions.

- `rtwgensettings.PostApplyCallback`: this property specifies a `PostApplyCallback` function. The `PostApplyCallback` function is triggered when the user clicks the **Apply** or **OK** button after editing options in the Configuration Parameters dialog box. The `PostApplyCallback` function is called after the changes have been applied to the configuration set.

The following code installs an `PostApplyCallback` function:

```
rtwgensettings.PostApplyCallback = 'my_postapply_callback_handler(hDlg,hSrc)';
```

The arguments to the `PostApplyCallback` function (`hDlg`, `hSrc`) are handles to private data used by the callback API functions.

- `rtwgensettings.BuildDirSuffix`: To identify the build folder created by the build process, most system target files define a folder name suffix. To form the name of the build folder, the build process appends the suffix defined in the `rtwgensettings.BuildDirSuffix` field to the model name. You can modify the suffix by specifying a new string value for `rtwgensettings.BuildDirSuffix`. For example:

```
rtwgensettings.BuildDirSuffix = '_mytarget_rtw'
```

The build process creates a build folder named `model_mytarget_rtw`. For more information, see “Build Process Folders” on page 52-31.

Do *not* use a function to specify the new string value. For example:

```
rtwgensettings.BuildDirSuffix = my_get_build_suffix(bdroot);
```

### Additional Code Generation Options

“Configure Generated Code with TLC” describes additional TLC code generation variables. End users of a target can assign these variables by entering a MATLAB command of the form

```
set_param(modelName, 'TLCOptions', '-aVariable=val');
```

(For more information, see “Specify TLC for Code Generation”.)

However, the preferred approach is to assign these variables in the system target file using statements of the form:

```
%assign Variable = val
```

For readability, we recommend that you add such assignments in the section of the system target file after the comment **Configure RTW code generation settings**.

### Model Reference Considerations

See “Support Model Referencing” on page 94-61 for important information on system target file and other modifications you may need to make to support the code generator model referencing features.

## Define and Display Custom Target Options

- “Using `rtwoptions` to Display Custom Target Options” on page 94-25
- “Example System Target File With Customized `rtwoptions`” on page 94-29
- “Inheriting Target Options” on page 94-30

### Using `rtwoptions` to Display Custom Target Options

You control the options to display in the **Code Generation** pane in the Configuration Parameters dialog box by customizing the `rtwoptions` structure in your system target file.

The fields of the `rtwoptions` structure define variables and associated user interface elements to be displayed in the Configuration Parameters dialog box. Using the `rtwoptions` structure array, you can define target-specific options displayed in the dialog box and organize options into categories. You can also write callback functions to specify how these options are processed.

When the **Code Generation** pane opens, the `rtwoptions` structure array is scanned and the listed options are displayed. Each option is represented by an assigned user interface element (check box, edit field, menu, or push button), which displays the current option value.

The user interface elements can be in an enabled or disabled (appears dimmed) state. If an option is enabled, the user can change the option value. If an option is disabled, the option uses the default value and the user cannot change the option value.

You can also use the `rtwoptions` structure array to define special NonUI elements that cause callback functions to be executed, but that are not displayed in the **Code Generation** pane. See “NonUI Elements” on page 94-29.

The elements of the `rtwoptions` structure array are organized into groups. Each group of items begins with a header element of type `Category`. The default field of a `Category` header must contain a count of the remaining elements in the category.

The `Category` header is followed by options to be displayed on the **Code Generation** pane. The header in each category is followed by one or more option definition elements.

Each category of target options corresponds to options listed under **Code Generation** in the Configuration Parameters dialog box.

The table `rtwoptions` Structure Fields Summary summarizes the fields of the `rtwoptions` structure.

### Example `rtwoptions` Structure

The following `rtwoptions` structure is excerpted from an example system target file, `matlabroot/toolbox/rtw/rtwdemos/rtwoptions_demo/usertarget.tlc`. The code defines an `rtwoptions` structure array. The default field of the first (header) element is set to 4, indicating the number of elements that follow the header.

```
rtwoptions(1).prompt = 'userPreferred target options (I)';
rtwoptions(1).type = 'Category';
rtwoptions(1).enable = 'on';
rtwoptions(1).default = 4; % number of items under this category
 % excluding this one.
rtwoptions(1).popupstrings = ''; % At the first item, user has to
rtwoptions(1).tlcvariable = ''; % initialize all supported fields
rtwoptions(1).tooltip = '';
rtwoptions(1).callback = '';
rtwoptions(1).makevariable = '';

rtwoptions(2).prompt = 'Execution Mode';
rtwoptions(2).type = 'Popup';
rtwoptions(2).default = 'Real-Time';
rtwoptions(2).popupstrings = 'Real-Time|UserDefined';
rtwoptions(2).tlcvariable = 'tlcvariable1';
rtwoptions(2).tooltip = ['See this text as tooltip'];

rtwoptions(3).prompt = 'Log Execution Time';
rtwoptions(3).type = 'Checkbox';
rtwoptions(3).default = 'on';
rtwoptions(3).tlcvariable = 'RL32LogTETModifier';
rtwoptions(3).tooltip = ['']; % no tooltip

rtwoptions(4).prompt = 'Real-Time Interrupt Source';
rtwoptions(4).type = 'Popup';
rtwoptions(4).default = 'Timer';
rtwoptions(4).popupstrings = 'Timer|5|6|7|8|9|10|11|12|13|14|15';
rtwoptions(4).tlcvariable = 'tlcvariable3';
rtwoptions(4).callback = 'usertargetcallback(hDlG, hSrc, ''tlcvariable3'')';
rtwoptions(4).tooltip = [''];
rtwoptions(4).tooltip = ['See TLC file for how to use reserved '...'];
```

```

 ' keyword 'hdlg'', and 'hSrc''.');
...
rtwoptions(5).prompt = 'Signal Logging Buffer Size in Doubles';
rtwoptions(5).type = 'Edit';
rtwoptions(5).default = '100000';
rtwoptions(5).tlcvariable = 'tlcvariable2';
rtwoptions(5).tooltip = [''];

```

The first element adds a **userPreferred target options (I)** pane under **Code Generation** in the Configuration Parameters dialog box. The pane displays the options defined in `rtwoptions(2)`, `rtwoptions(3)`, `rtwoptions(4)`, and `rtwoptions(5)`.

If you want to define a large number of options, you can define multiple **Category** groups within a single system target file.

Note the `rtwoptions` structure and callbacks are written in MATLAB code, although they are embedded in a TLC file. To verify the syntax of your `rtwoptions` structure definitions and code, you can execute the commands at the MATLAB prompt by copying and pasting them to the MATLAB Command Window.

To learn more about `usertarget.tlc` and the example callback files provided with it, see “Example System Target File With Customized `rtwoptions`” on page 94-29. For more examples of target-specific `rtwoptions` definitions, see the `target.tlc` files under `matlabroot/rtw/c` (open).

rtwoptions Structure Fields Summary lists the fields of the rtwoptions structure.

### rtwoptions Structure Fields Summary

Field Name	Description
callback	For examples of callback usage, see “Example System Target File With Customized rtwoptions” on page 94-29.
closecallback (obsolete)	Do not use closecallback. Use rtwgensettings.PostApplyCallback instead (see “rtwgensettings Structure” on page 94-23).  closecallback is ignored.  For examples of callback usage, see “Example System Target File With Customized rtwoptions” on page 94-29.
default	Default value of the option (empty if the type is Pushbutton).
enable	Must be 'on' or 'off'. If 'on', the option is displayed as an enabled item; otherwise, as a disabled item.
makevariable	Template makefile token (if any) associated with the option. The makevariable is expanded during processing of the template makefile. See “Template Makefile Tokens” on page 94-44.
modelReferenceParameter- Check	Specifies whether the option must have the same value in a referenced model and its parent model. If this field is unspecified or has the value 'on' the option values must be same. If the field is specified and has the value 'off' the option values can differ. See “Controlling Configuration Option Value Agreement” on page 94-63.
NonUI	Element that is not displayed, but is used to invoke a close or open callback. See “NonUI Elements” on page 94-29.
opencallback (obsolete)	Do not use opencallback. Use rtwgensettings.SelectCallback instead (see “rtwgensettings Structure” on page 94-23).  For examples of callback usage, see “Example System Target File With Customized rtwoptions” on page 94-29.
popupstrings	If type is Popup, popupstrings defines the items in the menu. Items are delimited by the " " (vertical bar) character. The following example defines the items of the <b>MAT-file variable name modifier</b> menu used by the GRT target.  'rt_ _rt none'
prompt	Label for the option.
tlcvariable	Name of TLC variable associated with the option.
tooltip	Help text displayed when mouse is over the item.
type	Type of element: Checkbox, Edit, NonUI, Popup, Pushbutton, or Category.

## NonUI Elements

Elements of the `rtwoptions` array that have type `NonUI` exist solely to invoke callbacks. A `NonUI` element is not displayed in the Configuration Parameters dialog box. You can use a `NonUI` element if you want to execute a callback that is not associated with a user interface element, when the dialog box opens or closes. See the next section, “Example System Target File With Customized `rtwoptions`” on page 94-29 for an example.

---

**Note** The default value of an element of type `NonUI` or `Edit` determines the set of values allowed for that element.

- If the default value is '0' or '1':
    - For type `NonUI`, the element stores a Boolean value.
    - For type `Edit`, the element stores a value of type `int32`.
  - If the default value contains an integer other than '0' or '1', the element stores a value of type `int32`.
  - If the default value does not contain an integer, the element is evaluated as a character vector.
- 

## Example System Target File With Customized `rtwoptions`

A working system target file, with MATLAB file callback functions, has been provided as an example of how to use the `rtwoptions` structure to display and process custom options on the **Code Generation** pane. The examples are compatible with the callback API.

The example target files are in the folder (open):

```
matlabroot/toolbox/rtw/rtwdemos/rtwoptions_demo
```

The example target files include:

- `usertarget.tlc`: The example system target file. This file illustrates how to define custom menus, check boxes, and edit fields. The file also illustrates the use of callbacks.
- `usertargetcallback.m`: A MATLAB file callback invoked by a menu.

Refer to the example files while reading this section. The example system target file, `usertarget.tlc`, illustrates the use of `rtwoptions` to display the following custom target options:

- The **Execution Mode** menu.
- The **Log Execution Time** check box.
- The **Real-Time Interrupt Source** menu. The menu executes a callback defined in an external file, `usertargetcallback.m`. The TLC variable associated with the menu is passed in to the callback, which displays the menu's current value.
- The edit field **Signal Logging Buffer Size in Doubles**.

Try studying the example code while interacting with the example target options in the Configuration Parameters dialog box. To interact with the example target file,

- 1 Make `matlabroot/toolbox/rtw/rtwdemos/rtwoptions_demo` (open) your working folder.
- 2 Open a model of your choice.

- 3 Open the Configuration Parameters dialog box and select the **Code Generation** pane.
- 4 Click **Browse**. The System Target File Browser opens. Select `usertarget.tlc`. Then click **OK**.
- 5 Observe that the **Code Generation** pane contains a custom sub-tab: **userPreferred target options (I)**.
- 6 As you interact with the options in this category and open and close the Configuration Parameters dialog box, observe the messages displayed in the MATLAB Command Window. These messages are printed from code in the system target file, or from callbacks invoked from the system target file.

### Inheriting Target Options

`ert.tlc` provides a basic set of Embedded Coder code generation options. If your target is based on `ert.tlc`, your system target file should normally inherit the options defined in ERT.

Use the `rtwgensettings.DerivedFrom` field in the `rtwgensettings` structure to define the system target file from which options are to be inherited. You should convert your custom target to use this mechanism as follows.

Set the `rtwgensettings.DerivedFrom` field value as in the following example:

```
rtwgensettings.DerivedFrom = 'stf.tlc';
```

where `stf` is the name of the system target file from which options are to be inherited. For example:

```
rtwgensettings.DerivedFrom = 'ert.tlc';
```

When the Configuration Parameters dialog box executes this line of code, it includes the options from `stf.tlc` automatically. If `stf.tlc` is a MathWorks internal system target file that has been converted to a new layout, the dialog box displays the inherited options using the new layout.

### Handling Unsupported Options

If your target does not support all of the options inherited from `ert.tlc`, you should detect unsupported option settings and display a warning or error message. In some cases, if a user has selected an option your target does not support, you may need to abort the build process. For example, if your target does not support the **Generate an example main program** option, the build process should not be allowed to proceed if that option is selected.

Even though your target may not support all inherited ERT options, it is required that the ERT options are retained in the **Code Generation** pane of the Configuration Parameters dialog box. Do not simply remove unsupported options from the `rtwoptions` structure in the system target file. Options must be in the dialog box to be scanned by the code generator when it performs optimizations.

For example, you may want to prevent users from turning off the **Single output/update function** option. It may seem reasonable to remove this option from the dialog box and simply assign the TLC variable `CombineOutputUpdateFcns` to `on`. However, if the option is not included in the dialog box, the code generator assumes that output and update functions are *not* to be combined. Less efficient code is generated as a result.

### Tips and Techniques for Customizing Your System Target File

- “Introduction” on page 94-31

- “Required and Recommended %includes” on page 94-31
- “Handling Aliases for Target Option Values” on page 94-32
- “Supporting Multiple Development Environments” on page 94-33
- “Updating Your Custom System Target File” on page 94-33

## Introduction

The following sections include information on techniques for customizing your system target file, including:

- How to invoke custom TLC code from your system target file
- Approaches to supporting multiple development environments
- Considerations for when you update your system target file

## Required and Recommended %includes

If you need to implement target-specific code generation features, we recommend that your system target file include the TLC file `mytarget_genfiles.tlc`.

Once your system target file has set up the required TLC environment, you must include `codegenentry.tlc` to start the standard code generation process.

`mytarget_genfiles.tlc` provides a mechanism for executing custom TLC code after the main code generation entry point. See “Using `mytarget_genfiles.tlc`” on page 94-31.

## Using `mytarget_genfiles.tlc`

`mytarget_genfiles.tlc` (optional) is useful as a central file from which to invoke target-specific TLC files that generate additional files as part of your target build process. For example, your target may create sub-makefiles or project files for a development environment, or command scripts for a debugger to do automatic downloads.

The build process can then invoke these generated files either directly from the make process or after the executable is created. This is done with the `STF_make_rtw_hook.m` mechanism, as described in “Customize Build Process with `STF_make_rtw_hook` File”.

The following TLC code shows an example `mytarget_genfiles.tlc` file.

```
%selectfile NULL_FILE

%assign ModelName = CompiledModel.Name

%% Create Debugger script
%assign model_script_file = "%<ModelName>.cfg"
%assign script_file = "debugger_script_template.tlc"

%if RTWVerbose
 %selectfile STDOUT
 ### Creating %<model_script_file>
 %selectfile NULL_FILE
%endif

%include "%<script_file>"
%openfile bld_file = "%<model_script_file>"
```

```
%<CreateDebuggerScript()>
%closefile bld_file
```

### Handling Aliases for Target Option Values

This section describes utility functions that can be used to detect and resolve alias values or legacy values when testing user-specified values for the target device type (`ProdHWDeviceType`) and the code replacement library (`CodeReplacementLibrary`).

#### RTW.isHWDeviceTypeEq

To test if two target device type values represent the same hardware device, invoke the following function:

```
result = RTW.isHWDeviceTypeEq(type1, type2)
```

where *type1* and *type2* are character vectors containing target device type values or aliases.

The `RTW.isHWDeviceTypeEq` function returns true if *type1* and *type2* are character vectors representing the same hardware device. For example, the following call returns true:

```
RTW.isHWDeviceTypeEq('Specified', 'Generic->Custom')
```

For a description of the target device type option `ProdHWDeviceType`, see the command-line information for the **Hardware Implementation** pane parameters “Device vendor” and “Device type”.

#### RTW.resolveHWDeviceType

To return the device type value for a hardware device, given a value that might be an alias or legacy value, invoke the following function:

```
result = RTW.resolveHWDeviceType(type)
```

where *type* is a character vector containing a target device type value or alias.

The `RTW.resolveHWDeviceType` function returns the device type value of the device. For example, the following calls both return 'Generic->Custom':

```
RTW.resolveHWDeviceType('Specified')
RTW.resolveHWDeviceType('Generic->Custom')
```

For a description of the target device type option `ProdHWDeviceType`, see the command-line information for the **Hardware Implementation** pane parameters “Device vendor” and “Device type”.

#### RTW.isTfLEq

To test if two code replacement library (CRL) names represent the same CRL, invoke the following function:

```
result = RTW.isTfLEq(name1, name2)
```

where *name1* and *name2* are character vectors containing CRL values or aliases.

The `RTW.isTfLEq` function returns true if *name1* and *name2* are character vectors representing the same code replacement library. For example, the following call returns true:

```
RTW.isTfLEq('GNU', 'GNU C99 extensions')
```

For a description of the `CodeReplacementLibrary` parameter, see “Code replacement library”.

### **RTW.resolveTflName**

To return the CRL value for a code replacement library, given a value that might be an alias or legacy value, invoke the following function:

```
result = RTW.resolveTflName(name)
```

where *name* is a character vector containing a CRL value or alias.

The `RTW.resolveTflName` function returns the value of the referenced code replacement library. For example, the following calls both return 'GNU C99 extensions':

```
RTW.resolveTflName('GNU')
RTW.resolveTflName('GNU C99 extensions')
```

For a description of the `CodeReplacementLibrary` parameter, see “Code replacement library”.

## **Supporting Multiple Development Environments**

Your target may require support for multiple development environments (for example, two or more cross-compilers) or multiple modes of code generation (for example, generating a binary executable versus generating a project file for your compiler).

One approach to this requirement is to implement multiple system target files. Each system target file invokes a template makefile for the development environment. This amounts to providing two separate targets.

## **Updating Your Custom System Target File**

Updating your custom system target file can impact the option values of a model that you load that uses the updated system target file. If you disable an option, the updated system target file uses the default value for that option. If a model has a different value for that option, when you load the model with the updated system target file, the value from the model is discarded and the system target file uses the default value instead.

## **Create a Custom Target Configuration**

- “Introduction” on page 94-33
- “my\_ert\_target Overview” on page 94-34
- “Creating Target Folders” on page 94-35
- “Create ERT-Based, Toolchain Compliant System Target File” on page 94-36
- “Create ERT-Based Template MakeFile” on page 94-40
- “Create Test Model and S-Function” on page 94-41
- “Verify Target Operation” on page 94-42

### **Introduction**

This tutorial can supplement the example target guides described in “Sample Custom Targets” on page 94-4. For an introduction and example files, try the example targets first.

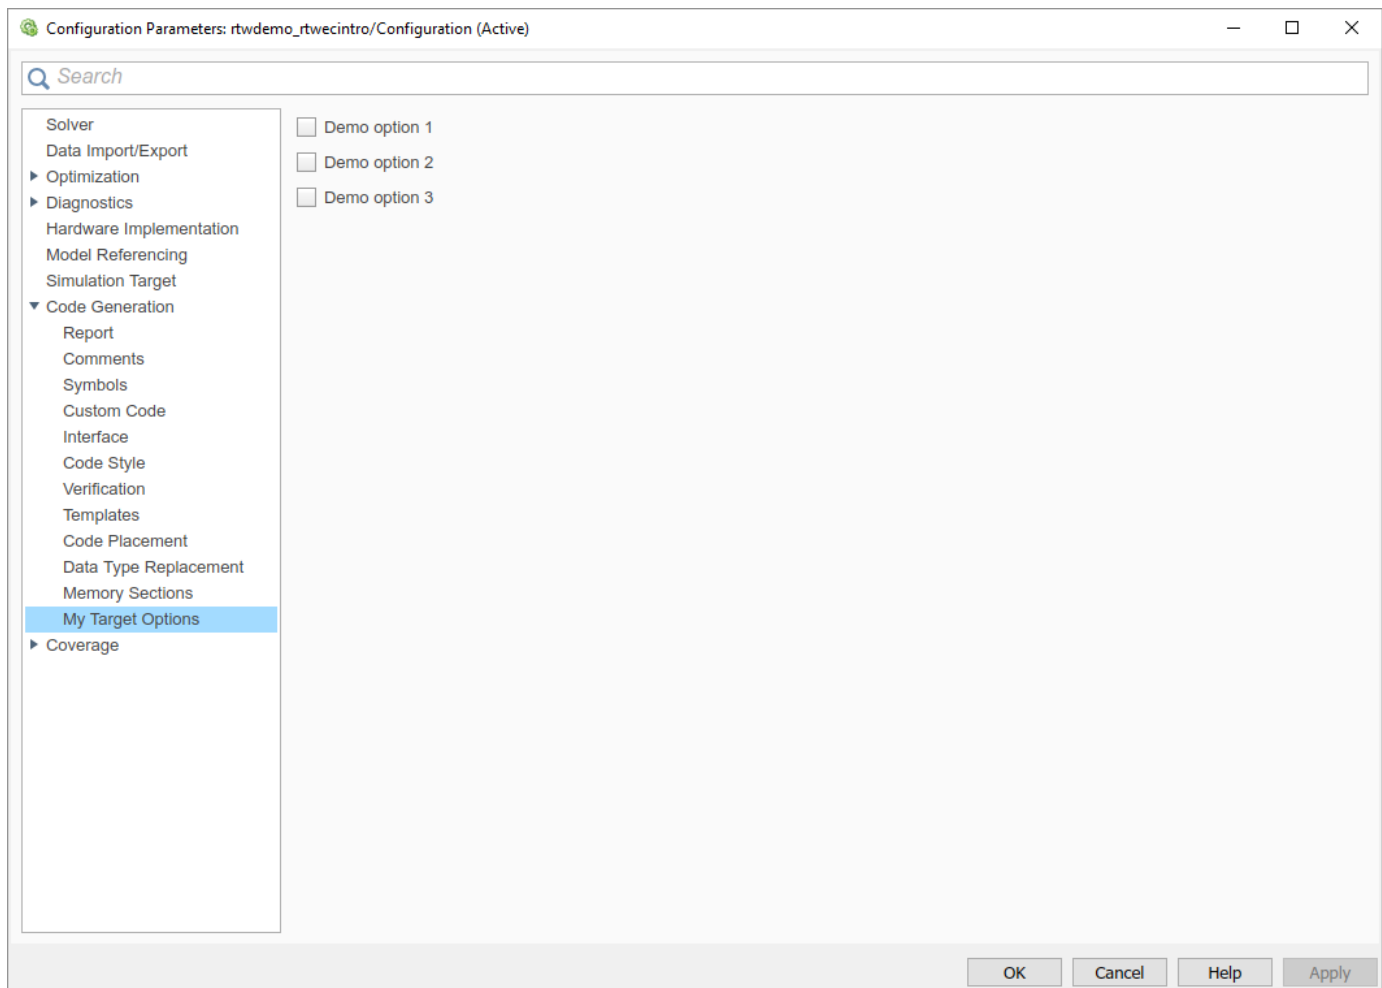

This tutorial guided you through the process of creating an ERT-based target, `my_ert_target`. This exercise illustrates several tasks, which are typical for creating a custom target:

- Setting up target folders and modifying the MATLAB path.
- Making modifications to a standard system target file and TMF such that the custom target is visible in the System Target File Browser, inherits ERT options, displays target-specific options, and generates code with the default host-based compiler.
- Testing the build process with the custom target, using a simple model that incorporates an inlined S-function.

During this exercise, you implement an operational, but skeletal, ERT-based target. This target can be useful as a starting point in a complete implementation of a custom embedded target.

### my\_ert\_target Overview

In the following sections, you create a skeletal target, `my_ert_target`. The target inherits and supports the standard options of the ERT target and displays additional target-specific options in the Configuration Parameters dialog box (see “Target-Specific Options for `my_ert_target`” on page 94-34).

### Target-Specific Options for my\_ert\_target

`my_ert_target` supports a toolchain-based build, generating code and executables that run on the host system. `my_ert_target` uses the `lcc` compiler on a Microsoft Windows platform. The chosen

compiler is readily available and is distributed with the code generator. On a Microsoft Windows platform, if you use a different compiler, you can set up `lcc` temporarily as your default compiler through the following MATLAB command:

```
mex -setup
```

The software displays links for supported compilers that are installed on your computer. Click the `lcc` link.

---

**Note** On Linux systems, make sure that you have an installed C compiler. If so, you can use Linux folder syntax to complete this exercise.

`my_ert_target` can also support template makefile-based builds. For more information about using this target with the template makefile approach, see “Create ERT-Based Template MakeFile” on page 94-40.

---

You can test `my_ert_target` with a model that is compatible with the ERT target (see “Configure a System Target File” on page 50-2). Generated programs operate identically to ERT generated programs.

To simplify the testing of your target, test with `targetmodel`, a very simple fixed-step model (see “Create Test Model and S-Function” on page 94-41). The S-Function block in `targetmodel` uses the source code from the `timestwo` example, and generates fully inlined code. See “S-Function Examples” and “Inline S-Functions with TLC” for further discussion of the `timestwo` example S-function.

### Creating Target Folders

Create folders to store the target files and add them to the MATLAB path, following the recommended conventions (see “Folder and File Naming Conventions” on page 94-6). You also create a folder to store the test model, S-function, and generated code.

This example assumes that your target and model folders are located within the folder `c:/work`. Do not place your target and model folders within the MATLAB folder tree (that is, in or under the `matlabroot` folder).

To create the folders and make them accessible:

- 1 Create a target root folder, `my_ert_target`. From the MATLAB Command Window on a Windows platform, enter:

```
cd c:/work
mkdir my_ert_target
```

- 2 Within the target root folder, create a subfolder to store your target files.

```
mkdir my_ert_target/my_ert_target
```

- 3 Add these folders to your MATLAB path.

```
addpath c:/work/my_ert_target
addpath c:/work/my_ert_target/my_ert_target
```

- 4 Create a folder, `my_targetmodel`, to store the test model, S-function, and generated code.

```
mkdir my_targetmodel
```

## Create ERT-Based, Toolchain Compliant System Target File

Create a system target file for your target by copying and modifying the standard system target file for the ERT target. Then, validate the system target file by viewing the new target in the System Target File Browser and in the Configuration Parameters dialog box.

### Editing the System Target File

To edit the system target file, use these steps:

- 1 Change your working folder to the folder you created in “Creating Target Folders” on page 94-35.

```
cd c:/work/my_ert_target/my_ert_target
```

- 2 Place a copy of `matlabroot/rtw/c/ert/ert.tlc` in `c:/work/my_ert_target/my_ert_target` and rename it to `my_ert_target.tlc`. The file `ert.tlc` is the system target file for the ERT target.

- 3 Open `my_ert_target.tlc` in a text editor of your choice.

- 4 Customize the system target file, replacing the header comment lines with directives that make your system target file visible in the System Target File Browser and define the associated TMF, make command, and external mode interface file (if any). For more information about these directives, see “Header Comments” on page 94-21 .

Replace the header comments in `my_ert_target.tlc` with the following header comments.

```
%% SYSTLC: My ERT-based Target TMF: my_ert_target_lcc.tmf MAKE: make_rtw
```

- 5 The file `my_ert_target.tlc` inherits the standard ERT options, using the mechanism described in “Inheriting Target Options” on page 94-30. Therefore, the existing `rtwoptions` structure definition is superfluous. Edit the `RTW_OPTIONS` section such that it includes only the following code.

```
/%
BEGIN_RTW_OPTIONS

%-----%
% Configure RTW code generation settings %
%-----%

rtwgenSettings.BuildDirSuffix = '_ert_rtw';

END_RTW_OPTIONS
%/
```

- 6 Delete the code after the end of the `RTW_OPTIONS` section, which is delimited by the directives `BEGIN_CONFIGSET_TARGET_COMPONENT` and `END_CONFIGSET_TARGET_COMPONENT`. This code is for use only by internal MathWorks developers.
- 7 Modify the build folder suffix in the `rtwgenSettings` structure in accordance with the conventions described in “`rtwgenSettings` Structure” on page 94-23.

To set the suffix to a character vector for the `_my_ert_target` custom target, change the line

```
rtwgenSettings.BuildDirSuffix = '_ert_rtw'
```

to

```
rtwgenSettings.BuildDirSuffix = '_my_ert_target_rtw'
```

- 8 Modify the `rtwgenSettings` structure to inherit options from the ERT target and declare Release 14 or later compatibility as described in “`rtwgenSettings` Structure” on page 94-23. Add the following code to the `rtwgenSettings` definition:

```
rtwgenSettings.DerivedFrom = 'ert.tlc';
rtwgenSettings.Version = '1';
```

- 9 Add an `rtwoptions` structure that defines a target-specific options category with three check boxes just after the `BEGIN_RTW_OPTIONS` directive. The following code shows the complete `RTW_OPTIONS` section, including the previous `rtwgenSettings` changes.

```
/%
BEGIN_RTW_OPTIONS

 rtwoptions(1).prompt = 'My Target Options';
 rtwoptions(1).type = 'Category';
 rtwoptions(1).enable = 'on';
 rtwoptions(1).default = 3; % number of items under this category

 %-----%
 % Configure RTW code generation settings %
 %-----%

 rtwgenSettings.BuildDirSuffix = '_my_ert_target_rtw';
 rtwgenSettings.DerivedFrom = 'ert.tlc';
 rtwgenSettings.Version = '1';
 rtwgenSettings.SelectCallback = 'enableToolchainCompliant(hSrc, hDlg)';
 %SelectCallback provides toolchain approach support, but requires custom function
 %Omit this SelectCallback if using the template makefile approach

END_RTW_OPTIONS
%/
```

- 10 Save your changes to `my_ert_target.tlc` and close the file.

### Create ToolchainCompliant Function

To enable builds using the toolchain approach, you create a function that corresponds to the `SelectCallback` near the end of the custom system target file. This function sets properties for toolchain compliance.

```
function enableToolchainCompliant(hSrc, hDlg)
 % The following parameters enable toolchain compliance.
 slConfigUISetVal(hDlg, hSrc, 'UseToolchainInfoCompliant', 'on');
```

```

slConfigUISetVal(hDlg, hSrc, 'GenerateMakefile','on');

% The following parameters are not required for toolchain compliance.
% But, it is recommended practice to set these default values and
% disable the parameters (as shown).
slConfigUISetVal(hDlg, hSrc, 'RTWCompilerOptimization','off');
slConfigUISetVal(hDlg, hSrc, 'MakeCommand','make_rtw');
slConfigUISetEnabled(hDlg, hSrc, 'RTWCompilerOptimization',false);
slConfigUISetEnabled(hDlg, hSrc, 'MakeCommand',false);
hSrc.refreshDialog;
end

```

**Note** If you are using the template makefile approach, omit calling the function enabling toolchain compliance from your system target file. Instead, use the information in “Create ERT-Based Template MakeFile” on page 94-40.

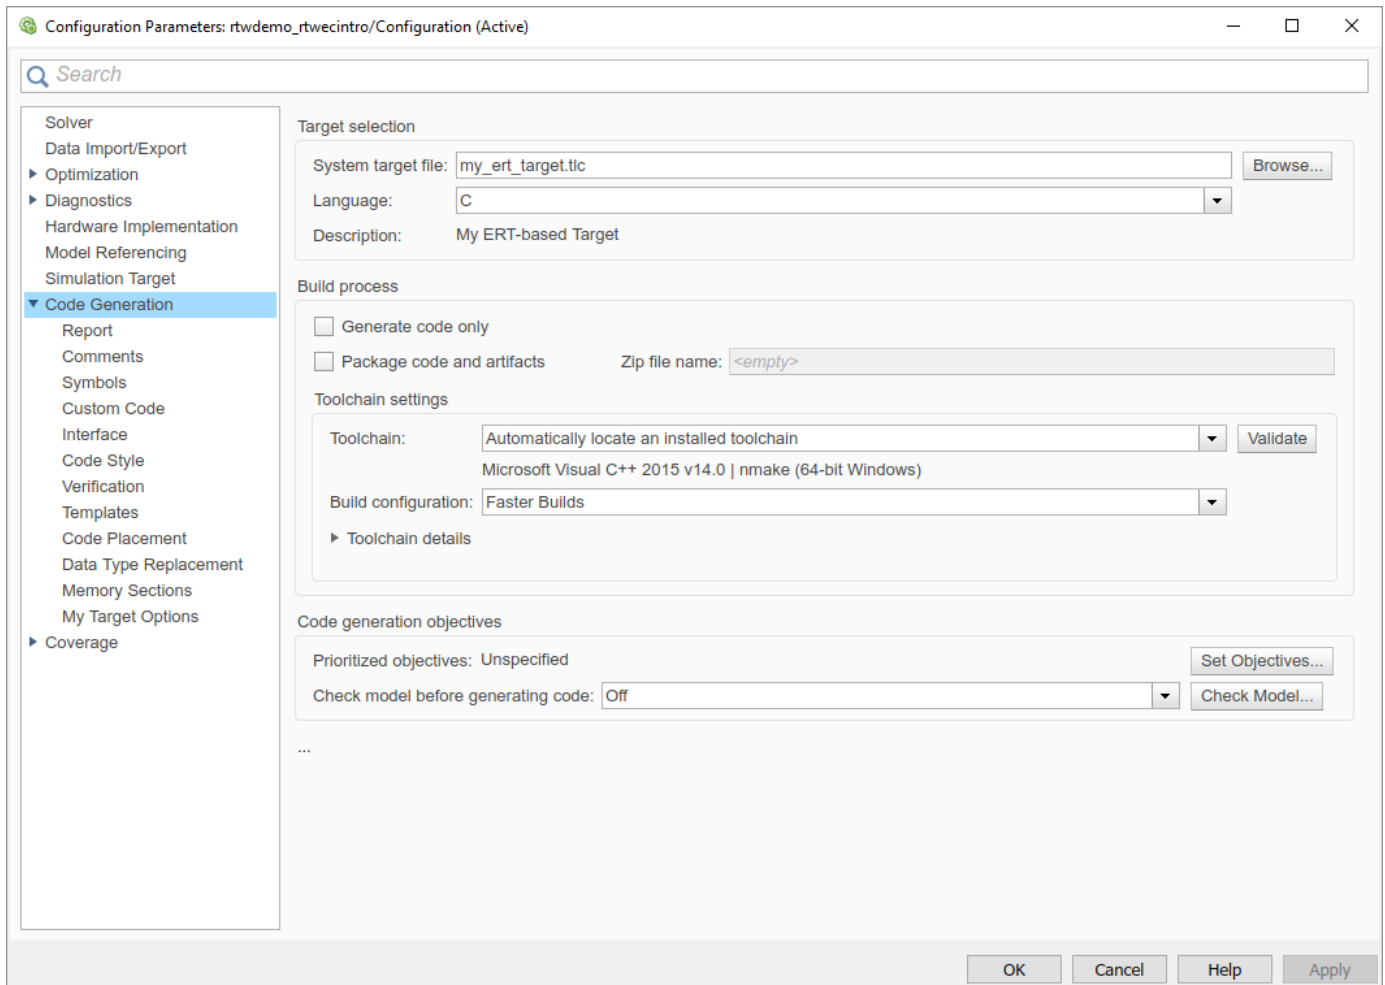

### Viewing the System Target File

At this point, you can verify that the target inherits and displays ERT options as follows:

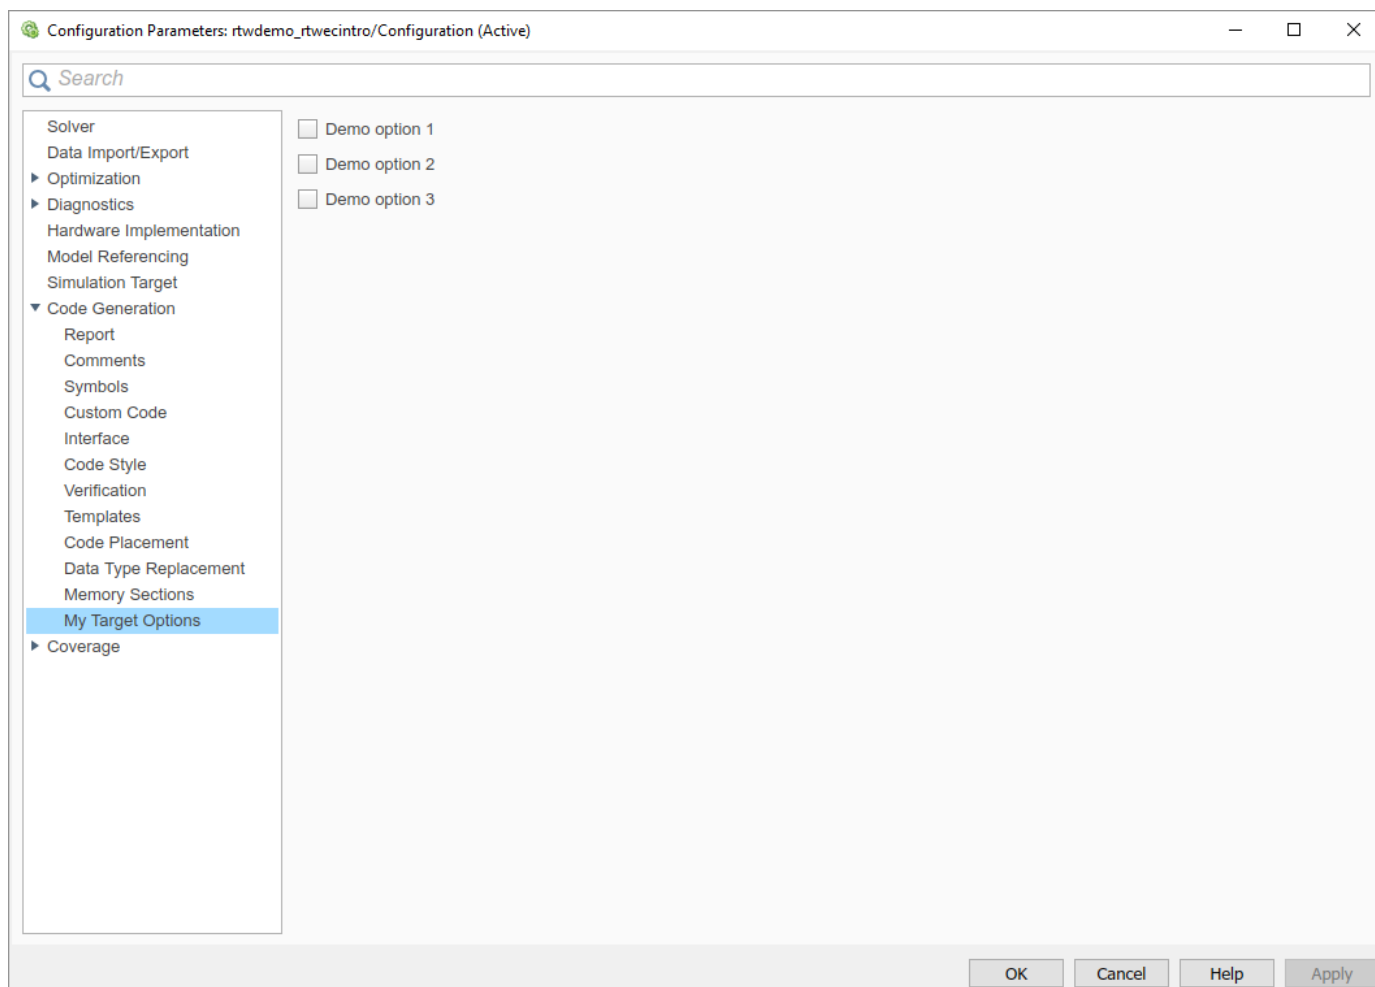

- 1 Create a new model.
- 2 Open the Model Explorer or the Configuration Parameters dialog box.
- 3 Select the **Code Generation** pane.
- 4 Click **Browse** to open the System Target File browser.
- 5 In the file browser, scroll through the list of targets to find the new target, `my_ert_target.tlc`. (This step assumes that your MATLAB path contains `c:/work/my_ert_target/my_ert_target`, as previously set in “Creating Target Folders” on page 94-35.)
- 6 Select My ERT-based Target and click **OK**.

- 7 The **Code Generation** pane now shows that the model is configured for the `my_ert_target.tlc` target. The **System target file**, **Language**, **Toolchain**, and **Build configuration** fields should appear:

- 8 Select the **My Target Options** pane. The target displays the three check box options defined in the `rtwoptions` structure.

- 9 Select the **Code Generation** pane and reopen the System Target File Browser.
- 10 Select the Embedded Coder target (`ert.tlc`). The target displays the standard ERT options.
- 11 Close the model. You do not need to save it.

The system target file for the skeletal target is complete. If you are using the toolchain approach, you are ready to invoke the build process for your target.

If you prefer to use the template makefile approach, the reference to a TMF, `my_ert_target_lcc.tmf`, in the system target file header comments prevents you from invoking the build process for your target until the TMF file is in place. First, you must create a `my_ert_target_lcc.tmf` file.

### Create ERT-Based Template MakeFile

If you are using the toolchain makefile approach with a toolchain compliant custom target, omit the steps that apply to the template makefile approach. (Skip this section.)

If you are using the template makefile approach, follow the steps that apply to a template makefile and omit calling the function that enables toolchain-compliance from your system target file, which is described in “Create ERT-Based, Toolchain Compliant System Target File” on page 94-36.

Create a template makefile for your target by copying and modifying a supplied ERT template makefile. Select the template makefile that fits your target best. This example uses `ert_lcc64.tmf`, but you can also use `ert_vcx64.tmf` or `ert_unix.tmf`.

- 1 Make sure that your working folder is still set to the target file folder you created previously in “Creating Target Folders” on page 94-35.

```
c:/work/my_ert_target/my_ert_target
```

- 2 Place a copy of `matlabroot/toolbox/coder/compile/tmf/ert_lcc64.tmf` in `c:/work/my_ert_target/my_ert_target` and rename it `my_ert_target_lcc.tmf`. The file `ert_lcc64.tmf` is the ERT compiler-specific template makefile for the LCC compiler.

- 3 Open `my_ert_target_lcc.tmf` in a text editor.

- 4 Change the `SYS_TARGET_FILE` parameter so that the file reference for your `.tlc` file is generated in the make file. Change the line

```
SYS_TARGET_FILE = any
```

to

```
SYS_TARGET_FILE = my_ert_target.tlc
```

- 5 Save changes to `my_ert_target_lcc.tmf` and close the file.

Your target can now generate code and build a host-based executable. In the next sections, you create a test model and test the build process using `my_ert_target`.

### Create Test Model and S-Function

In this section, you build a simple test model for later use in code generation:

- 1 Set your working folder to `c:/work/my_targetmodel`.

```
cd c:/work/my_targetmodel
```

For the remainder of this tutorial, `my_targetmodel` is assumed to be the working folder. Your target writes the output files of the code generation process into a build folder within the working folder. When inlined code is generated for the `timestwo` S-function, the build process looks for the TLC implementation of the S-function in the working folder.

- 2 Copy the following C and TLC files for the `timestwo` S-function to your working folder:

- `matlabroot/toolbox/simulink/simdemos/simfeatures/src/timestwo.c`
- `matlabroot/toolbox/simulink/simdemos/simfeatures/tlc_c/timestwo.tlc`

- 3 Build the `timestwo` MEX-file in `c:/work/my_targetmodel`.

```
mex timestwo.c
```

- 4 Create the following model, using an S-Function block from the Simulink User-Defined Functions library. Save the model in your working folder as `targetmodel`.

- 5 Double-click the S-Function block to open the Block Parameters dialog box. Enter the S-function name `timestwo`. Click **OK**. The block is now bound to the `timestwo` MEX-file.

- 6 Open Model Explorer or the Configuration Parameters dialog box and select the **Solver** pane.
- 7 Set the solver **Type** to `fixed-step` and click **Apply**.
- 8 Save the model.
- 9 Open the scope and run a simulation. Verify that the `timestwo` S-function multiplies its input by 2.0.

Keep the `targetmodel` model open for use in the next section, in which you generate code using the test model.

### Verify Target Operation

In this section you configure `targetmodel` for the `my_ert_target` custom target, and use the target to generate code and build an executable:

- 1 In the Configuration Parameters dialog box, select the **Code Generation** pane.
- 2 Click **Browse** to open the System Target File Browser.
- 3 In the Browser, select `My ERT-based Target` and click **OK**.
- 4 The Configuration Parameters dialog box now displays the **Code Generation** pane for `my_ert_target`.
- 5 Select the **Code Generation > Report** pane and select the **Create code generation report** option.
- 6 Click **Apply** and save the model. The model is configured for `my_ert_target`.
- 7 Build the model. If the build succeeds, the MATLAB Command Window displays the message below.

```
Created executable: ../targetmodel.exe
Successful completion of build procedure for model:
targetmodel
```

Your working folder contains the `targetmodel.exe` file and the build folder, `targetmodel_my_ert_target_rtw`, which contains generated code and other files. The working folder also contains an `s\prj` folder, used internally by the build process.

The code generator also creates a code generation report.

- 8 To view the generated code, on the **C Code** tab, click **View Code**. In the **Contents** pane of the code generation report, click the `targetmodel.c` link.
- 9 In `targetmodel.c`, locate the model step function, `targetmodel_step`. Observe the following code.

```
/* S-Function Block: <Root>/S-Function */
/* Multiply input by two */
targetmodel_B.SFunction = targetmodel_B.SineWave * 2.0;
```

The presence of this code confirms that the `my_ert_target` custom target has generated an inlined output computation for the S-Function block in the model.

## Customize Template Makefiles

To configure or customize a template makefile (TMF), you should be familiar with how the `make` command works and how it processes a makefile (.mk file). You should also understand makefile build rules. For information on these topics, refer to the documentation provided with the `make` utility that you use.

### Template Makefiles and Tokens

A template makefile contains tokens. The build process expands the tokens and creates makefiles:

- `model.mk` -- Compiles and links code generated from model components.
- `rtwshared.mk` -- Compiles generated shared utility code.

The makefiles (`model_or_sharedutils.mk`) use commands that are specific to your development computer.

### Template Makefile Tokens

The `make_rtw` command (or a different command provided with some targets) directs the process of generating `model_or_sharedutils.mk`. The `make_rtw` command processes the TMF specified on the **Code Generation** pane of the Configuration Parameters dialog box. `make_rtw` copies the TMF, line by line, expanding each token encountered. Template Makefile Tokens Expanded by `make_rtw` lists the tokens and their expansions.

These tokens are used in several ways by the expanded makefile:

- To control the conditional behavior in the makefile. The conditionals are used to control the source file lists, library names, target to be built, and other build-related information.
- To provide the macro definitions for compiling the files, for example, `-DINTEGER_CODE=1`.

### Template Makefile Tokens Expanded by make\_rtw

Token	Expansion
<b>General purpose</b>	
>ADDITIONAL_LDFLAGS<	Linker flags automatically added by blocks.
>ALT_MATLAB_BIN<	Alternate full pathname for the MATLAB executable; value is different than value for MATLAB_BIN token when the full pathname contains spaces.
>ALT_MATLAB_ROOT<	Alternate full pathname for the MATLAB installation; value is different than value for MATLAB_ROOT token when the full pathname contains spaces.
>BUILDARGS<	Options passed to make_rtw. This token is provided so that the contents of your <i>model_or_sharedutils.mk</i> file change when you change the build arguments, thus forcing an update of modules when your build options change.
>COMBINE_OUTPUT_UPDATE_FCNS<	True (1) when you select model configuration parameter <b>Single output/update function</b> , otherwise False (0). Used for the macro definition -DONESTEPFCN=1.
>COMPILE_FLAGS_OTHER<	<p>Compiler flags in a group other than 'OPTS', 'OPT_OPTS', and 'OPTIMIZATION_FLAGS'. The build process produces a warning if  &gt;COMPILE_FLAGS_OTHER&lt;  is absent and these conditions apply:</p> <ul style="list-style-type: none"> <li>• The build information contains a compiler flag that is not in 'OPTS', 'OPT_OPTS', or 'OPTIMIZATION_FLAGS'.</li> <li>• The compiler flag is not in the template makefile.</li> </ul>
>COMPUTER<	Computer type. See the MATLAB computer command.

Token	Expansion
>DEFINES_OTHER<	<p>Preprocessor macro definitions in a group other than 'OPTS', 'OPT_OPTS', 'OPTIMIZATION_FLAGS', and 'Custom'.</p> <p>A preprocessor macro definition in 'OPTS', 'OPT_OPTS', 'OPTIMIZATION_FLAGS', or 'Custom' that has a corresponding variable/token pair in the template makefile is not expanded in <code>DEFINES_OTHER</code>. This behavior helps to avoid the provision of duplicate preprocessor macro definitions.</p> <p>For example, some template makefiles contain these statements:</p> <pre> ... NUMST =  &gt;NUMST&lt;  ... CPP_REQ_DEFINES1 = ... -DNUMST=\$(NUMST) ... </pre> <p>If the template makefile contains the variable/token pair <code>NUMST =  &gt;NUMST&lt; </code> and <code>NUMST</code> is a preprocessor macro definition in <code>buildInfo</code>, then the build process does not expand it in <code>DEFINES_OTHER</code>.</p> <p>The build process produces a warning if <code> &gt;DEFINES_OTHER&lt; </code> is absent and these conditions apply:</p> <ul style="list-style-type: none"> <li>The build information contains a preprocessor macro definition that is not in 'OPTS', 'OPT_OPTS', 'OPTIMIZATION_FLAGS', or 'Custom'.</li> <li>The preprocessor macro definition, for example, <code>NUMST</code>, is not in the template makefile.</li> </ul>
>EXPAND_LIBRARY_LOCATION<	<p>Location of precompiled library file. The <code>TargetPreCompLibLocation</code> configuration parameter can override this setting. For examples, see “Control Library Location and Naming During Build”.</p>
>EXPAND_LIBRARY_NAME<	<p>Library name. For examples, see “Control Library Location and Naming During Build” and “Modify the Template Makefile for <code>rtwmakecfg</code>”.</p>
>EXPAND_LIBRARY_SUFFIX<	<p>Library suffix. The <code>TargetLibSuffix</code> configuration parameter can override this setting. For examples, see “Control Library Location and Naming During Build”.</p>
>EXT_MODE<  (Not required for R2018a and later provided template makefile specifies <code>TOOLCHAIN_NAME</code> )	<p>True (1) to enable generation of external mode support code, otherwise False (0).</p>
>EXTMODE_TRANSPORT<  (Not required for R2018a and later provided template makefile specifies <code>TOOLCHAIN_NAME</code> )	<p>Index of transport mechanism (for example, <code>tcpip</code>, <code>serial</code>) for external mode.</p>

Token	Expansion
>EXTMODE_STATIC<  (Not required for R2018a and later provided template makefile specifies TOOLCHAIN_NAME)	True (1) if static memory allocation is selected for external mode. False (0) if dynamic memory allocation is selected.
>EXTMODE_STATIC_SIZE<  (Not required for R2018a and later provided template makefile specifies TOOLCHAIN_NAME)	Size of static memory allocation buffer for external mode.
>GENERATE_ERT_S_FUNCTION<	True (1) when model configuration parameter <b>Create block</b> is set to SIL, otherwise False (0). Used for control of the makefile target of the build.
>INCLUDE_MDL_TERMINATE_FCN<	True (1) when model configuration parameter <b>Terminate function required</b> is selected, otherwise False (0). Used for the macro definition <code>-DTERMFCN==1</code> .
>INTEGER_CODE<	True (1) when model configuration parameter <b>Support floating-point numbers</b> is cleared, otherwise False (0). INTEGER_CODE is a required macro definition when compiling the source code and is used when selecting precompiled libraries to link against.
>MAKEFILE_NAME<	<i>model_or_sharedutils.mk</i> — The name of the makefile that was created from the TMF.
>MAT_FILE<	True (1) when model configuration parameter <b>MAT-file logging</b> is selected, otherwise False (0). MAT_FILE is a required macro definition when compiling the source code and also is used to include logging code in the build process.
>MATLAB_BIN<	Location of the MATLAB executable program.
>MATLAB_ROOT<	Path to where MATLAB is installed.
>MEM_ALLOC<	RT_MALLOC or RT_STATIC. Indicates how memory is to be allocated.
>MEXEXT<	MEX-file extension. See the MATLAB mexext command.
>MODEL_MODULES<	Additional generated source modules. For example, you can split a large model into two files, <i>model.c</i> and <i>model1.c</i> . In this case, this token expands to <i>model1.c</i> .
>MODEL_MODULES_OBJ<	Object filenames (.obj) corresponding to additional generated source modules.
>MODEL_NAME<	Name of the Simulink block diagram currently being built.
>MULTITASKING<	True (1) if solver mode is multitasking, otherwise False (0).
>NCSTATES<	Number of continuous states.
>NUMST<	Number of sample times in the model.
>RELEASE_VERSION<	The MATLAB release version.
>S_FUNCTIONS_LIB<	List of S-function libraries available for linking.
>SOLVER<	Solver source filename, for example, <i>ode3.c</i> .
>SOLVER_OBJ<	Solver object (.obj) filename, for example, <i>ode3.obj</i> .
>START_DIR<	Code generation folder at the start of the build.

Token	Expansion
>TARGET_LANG_EXT<	c when model configuration parameter <b>Language</b> is set to C, cpp when <b>Language</b> is set to C++. Used in the makefile to control the extension on generated source files.
>TID01EQ<	True (1) if sampling rates of the continuous task and the first discrete task are equal, otherwise False (0).
<b>S-function and build information support</b>	
<b>Note</b> For examples of the tokens in this section, see “Modify the Template Makefile for rtwmakecfg”.	
>START_EXPAND_INCLUDES<   >EXPAND_DIR_NAME<   >END_EXPAND_INCLUDES<	List of folder names to add to the include path. Additionally, the ADD_INCLUDES macro must be added to the INCLUDES line.
>START_EXPAND_LIBRARIES<   >EXPAND_LIBRARY_NAME<   >END_EXPAND_LIBRARIES<	List of library names.
>START_EXPAND_MODULES<   >EXPAND_MODULE_NAME<   >END_EXPAND_MODULES<	Library module names within  >START_EXPAND_LIBRARIES<  and  >START_PRECOMP_LIBRARIES<  library lists.
>START_EXPAND_RULES<   >EXPAND_DIR_NAME<   >END_EXPAND_RULES<	Makefile rules.
>START_PRECOMP_LIBRARIES<   >EXPAND_LIBRARY_NAME<   >END_PRECOMP_LIBRARIES<	List of precompiled library names.
<b>Model reference support</b>	
<b>Note</b> For examples of the tokens in this section, see “Providing Model Referencing Support in the TMF” on page 94-62.	
>MODELLIB<	Name of the library file generated for the current model.
>MODELREFS<	List of models referenced by the top model.
>MODELREF_LINK_LIBS<	List of referenced model libraries against which the top model links.
>MODELREF_LINK_RSPFILE_NAME<	Name of a response file against which the top model links. This token is valid only for build environments that support linker response files. For an example of its use, see <i>matlabroot/toolbox/coder/compile/tmf/grt_vcx64.tmf</i> .
>MODELREF_TARGET_TYPE<	Type of target being built. Possible values are <ul style="list-style-type: none"> <li>• NONE: Standalone model or top model referencing other models</li> <li>• RTW: Model reference target build</li> <li>• SIM: Model reference simulation target build</li> </ul>

Token	Expansion
>RELATIVE_PATH_TO_ANCHOR<	Relative path, from the location of the generated makefile, to the MATLAB working folder.

These tokens are expanded by substitution of parameter values known to the build process. For example, if the source model contains blocks with two different sample times, the TMF statement

```
NUMST = |>NUMST<|
```

expands to:

```
NUMST = 2
```

In addition to the above, `make_rtw` expands tokens from other sources:

- Target-specific tokens defined in the target options of the Configuration Parameters dialog box
- Structures in the `rtwoptions` section of the system target file. Structures in the `rtwoptions` structure array that contain the field `makevariable` are expanded.

The following example is extracted from `matlabroot/rtw/c/grt/grt.tlc`. The section starting with `BEGIN_RTW_OPTIONS` contains MATLAB code that sets up `rtwoptions`. The following directive causes the `|>EXT_MODE<|` token to be expanded to 1 (on) or 0 (off), depending on how you set the external mode options.

```
rtwoptions(2).makevariable = 'EXT_MODE'
```

## Invoke the make Utility

- “make Command” on page 94-49
- “make Utility Versions” on page 94-50

### make Command

After creating `model_or_sharedutils.mk` from your TMF, the build process invokes a `make` command. To invoke `make`, the build process issues this command.

```
makecommand -f model_or_sharedutils.mk
```

`makecommand` is defined by the `MAKECMD` macro in your system target file TMF (see “Structure of the Template Makefile” on page 94-50). You can specify additional options to `make` by using the model configuration parameter **Make command**. (See the sections “Specify a Make Command” and “Template Makefiles and Make Options”.)

For example, specifying `OPT_OPTS=-02` in the **Make command** field causes `make_rtw` to generate the following `make` command.

```
makecommand -f model_or_sharedutils.mk OPT_OPTS=-02
```

A comment at the top of the TMF specifies the available `make` command options. If these options do not provide you with enough flexibility, you can configure your own TMF.

## make Utility Versions

The make utility lets you control nearly every aspect of building your real-time program. There are several different versions of make available. The code generator provides the Free Software Foundation GNU make for both UNIX<sup>7</sup> and PC platforms in platform-specific subfolders under

*matlabroot/bin*

It is possible to use other versions of make with the code generator, although GNU Make is recommended. To be compatible with the code generator, verify that your version of make supports the following command format.

```
makecommand -f model_or_sharedutils.mk
```

## Structure of the Template Makefile

A TMF has multiple sections, including the following:

- **Abstract** — Describes what the makefile targets. Here is a representative abstract from the ERT TMFs in *matlabroot/toolbox/coder/compile/tmf*:

```
Abstract:
Template makefile for building a Windows-based stand-alone embedded
real-time version of Simulink model using generated C code and the
Microsoft Visual C/C++ compiler for x64.
#
Note that this template is automatically customized by the build
procedure to create "<model>.mk"
#
The following defines can be used to modify the behavior of the
build:
OPT_OPTS - Optimization option. See DEFAULT_OPT_OPTS in
vctools.mak for default.
OPTS - User specific options.
CPP_OPTS - C++ compiler options.
USER_SRCS - Additional user sources, such as files needed by
S-functions.
USER_INCLUDES - Additional include paths
(i.e. USER_INCLUDES="-Iwhere-ever -Iwhere-ever2")
#
To enable debugging:
set DEBUG_BUILD = 1, which will trigger OPTS=-Zi (may vary with
compiler version, see compiler doc)
#
This template makefile is designed to be used with a system target
file that contains 'rtwgensettings.BuildDirSuffix' see ert.tlc
```

- **Macros read by make\_rtw section** — Defines macros that tell make\_rtw how to process the TMF. Here is a representative Macros read by make\_rtw section from the GRT TMFs in *matlabroot/toolbox/coder/compile/tmf*:

```
#----- Macros read by make_rtw -----
#
The following macros are read by the build procedure:
#
MAKECMD - This is the command used to invoke the make utility
HOST - What platform this template makefile is targeted for
(i.e. PC or UNIX)
BUILD - Invoke make from the build procedure (yes/no)?
SYS_TARGET_FILE - Name of system target file.
#
MAKECMD = nmake
HOST = PC
```

<sup>7</sup> UNIX is a registered trademark of The Open Group in the United States and other countries.

```

BUILD = yes
SYS_TARGET_FILE = any
BUILD_SUCCESS = ^#^#^# Created

Opt in to simplified format by specifying compatible Toolchain
TOOLCHAIN_NAME = [\
 "Microsoft Visual C++ 2019 v16.0 | nmake (64-bit Windows)", \
 "Microsoft Visual C++ 2017 v15.0 | nmake (64-bit Windows)", \
 "Microsoft Visual C++ 2015 v14.0 | nmake (64-bit Windows)"]

```

The macros in this section might include:

- **MAKECMD** — Specifies the command used to invoke the make utility. For example, if **MAKECMD** = **mymake**, then the make command invoked is

```
mymake -f model_or_sharedutils.mk
```

- **HOST** — Specifies the platform targeted by this TMF. This can be **PC**, **UNIX**, *computer\_name* (see the **MATLAB** **computer** command), or **ANY**.
- **BUILD** — Instructs **make\_rtw** whether or not it should invoke **make** from the build procedure. Specify **yes** or **no**.
- **SYS\_TARGET\_FILE** — Specifies the name of the system target file or the value **any**. This is used for consistency checking by **make\_rtw** to verify the system target file specified in the **Target selection** panel of the **Code Generation** pane of the Configuration Parameters dialog box. If you specify **any**, you can use the TMF with any system target file.
- **BUILD\_SUCCESS** — When the makefile creates a static library, it produces the **BUILD\_SUCCESS** string as defined, for example, by this rule in **ert\_vcx64.tmf**:

```

$(PRODUCT) : $(OBJS) $(LIBS) $(MODELREF_LINK_LIBS)
 @cmd /C "echo ### Linking ..."
 $(LD) $(LDFLAGS) $(LIBS) \
 @$ (CMD_FILE) @$ (MODELREF_LINK_RSPFILE) -dll -def:$(MODEL).def -out:$@
 @cmd /C "echo $(BUILD_SUCCESS) dynamically linked library $(PRODUCT)"

```

When the build process finds the **BUILD\_SUCCESS** string, it polls for the existence of the updated static library file. The build process does not link the library file to the executable file until the build process can confirm the presence of the library file, with an updated timestamp, on the file system.

If the build process does not find **BUILD\_SUCCESS** in the compilation log, then the build process assumes that the updated library archive is available on the file system. If required, the build process links the library to the executable file.

- **Tokens expanded by make\_rtw section** — Defines the tokens that **make\_rtw** expands. Here is a brief excerpt from a representative **Tokens expanded by make\_rtw section** from the ERT TMFs in *matlabroot/toolbox/coder/compile/tmf/*:

```

#----- Tokens expanded by make_rtw -----
#
The following tokens, when wrapped with ">" and "<" are expanded by the
build procedure.
#
MODEL_NAME - Name of the Simulink block diagram
MODEL_MODULES - Any additional generated source modules
MAKEFILE_NAME - Name of makefile created from template makefile <model>.mk
MATLAB_ROOT - Path to where MATLAB is installed.
...

MODEL = |>MODEL_NAME<|
MODULES = |>MODEL_MODULES<|
PRODUCT = |>PRODUCT<|
MAKEFILE = |>MAKEFILE_NAME<|

```

```
MATLAB_ROOT = |>MATLAB_ROOT<|
...
```

For more information about TMF tokens, see `Template Makefile Tokens Expanded by make_rtw`.

- Subsequent sections vary based on compiler, host, and target. Some common sections include `Model` and `reference models`, `External mode`, `Tool Specifications` or `Tool Definitions`, `Include Path`, `C Flags`, `Additional Libraries`, and `Source Files`.
- `Rules` section — Contains the make rules used in building an executable from the generated source code. The build rules are typically specific to your version of make. The `Rules` section might be followed by related sections such as `Dependencies`.

## Customize and Create Template Makefiles

- “Introduction” on page 94-52
- “Setting Up a Template Makefile” on page 94-52
- “Using Macros and Pattern Matching Expressions in a Template Makefile” on page 94-52
- “Customizing Generated Makefiles with `rtwmakecfg`” on page 94-54
- “Supporting Continuous Time in Custom Targets” on page 94-54
- “Model Reference Considerations” on page 94-55
- “Timeout Error When Building Shared Utility Code with Custom Template Makefile” on page 94-55

### Introduction

This section describes the mechanics of setting up a custom template makefile (TMF) and incorporating it into the build process. It also discusses techniques for modifying a TMF and MATLAB file mechanisms associated with the TMF.

Before creating a custom TMF, you should read “Folder and File Naming Conventions” on page 94-6 to understand the folder structure and MATLAB path requirements for custom targets.

### Setting Up a Template Makefile

To customize or create a new TMF, copy an existing GRT or ERT TMF from `matlabroot/toolbox/coder/compile/tmf`.

Place the copy in the same folder as the associated system target file. Usually, this is the `mytarget/mytarget` folder within the target folder structure. Then, rename your TMF (for example, `mytarget.tmf`) and modify it.

To allow the build process to locate and select your TMF, you must provide information in the system target file file header (see “System Target File Structure” on page 94-19). For a target that implements a single TMF, the standard way to specify the TMF to be used in the build process is to use the TMF directive of the system target file file header.

```
TMF: mytarget.tmf
```

### Using Macros and Pattern Matching Expressions in a Template Makefile

This section shows, through an example, how to use macros and file-pattern-matching expressions in a TMF to generate commands in `model_or_sharedutils.mk`.

The `make` utility processes `model_or_sharedutils.mk` and generates a set of commands based upon dependency rules defined in `model_or_sharedutils.mk`. After `make` generates the set of commands for building or rebuilding `test`, `make` executes them.

For example, to build a program called `test`, `make` must link the object files. However, if the object files don't exist or are out of date, `make` must compile the source code. Thus there is a dependency between source and object files.

Each version of `make` differs slightly in its features and how rules are defined. For example, consider a program called `test` that gets created from two sources, `file1.c` and `file2.c`. Using most versions of `make`, the dependency rules would be

```
test: file1.o file2.o
 cc -o test file1.o file2.o

file1.o: file1.c
 cc -c file1.c

file2.o: file2.c
 cc -c file2.c
```

In this example, a UNIX<sup>8</sup> environment is assumed. In a PC environment the file extensions and compile and link commands are different.

In processing the first rule

```
test: file1.o file2.o
```

`make` sees that to build `test`, it needs to build `file1.o` and `file2.o`. To build `file1.o`, `make` processes the rule

```
file1.o: file1.c
```

If `file1.o` doesn't exist, or if `file1.o` is older than `file1.c`, `make` compiles `file1.c`.

The format of TMFs follows the above example. Our TMFs use additional features of `make` such as macros and file-pattern-matching expressions. In most versions of `make`, a macro is defined with

```
MACRO_NAME = value
```

References to macros are made with `$(MACRO_NAME)`. When `make` sees this form of expression, it substitutes `value` for `$(MACRO_NAME)`.

You can use pattern matching expressions to make the dependency rules more general. For example, using GNU<sup>9</sup> `Make`, you could replace the two “`file1.o: file1.c`” and “`file2.o: file2.c`” rules with the single rule

```
%.o : %.c
 cc -c $<
```

Note that `$<` in the previous example is a special macro that equates to the dependency file (that is, `file1.c` or `file2.c`). Thus, using macros and the “%” pattern matching character, the previous example can be reduced to

8 UNIX is a registered trademark of The Open Group in the United States and other countries.

9 GNU is a registered trademark of the Free Software Foundation.

```

SRCS = file1.c file2.c
OBJS = $(SRCS:.c=.o)

test: $(OBJS)
 cc -o $@ $(OBJS)

%.o : %.c
 cc -c $<

```

Note that the `$@` macro above is another special macro that equates to the name of the current dependency target, in this case `test`.

This example generates the list of objects (`OBJS`) from the list of sources (`SRCS`) by using the text substitution feature for macro expansion. It replaces the source file extension (for example, `.c`) with the object file extension (`.o`). This example also generalized the build rule for the program, `test`, to use the special "`$@`" macro.

### Customizing Generated Makefiles with `rtwmakecfg`

TMFs provide tokens that let you add the following items to generated makefiles:

- Source folders
- Include folders
- Run-time library names
- Run-time module objects

S-functions can add this information to the makefile by using an `rtwmakecfg.m` file function. This function is particularly useful when building a model that contains one or more of your S-Function blocks, such as device driver blocks.

To add information pertaining to an S-function to the makefile,

- 1 Create the function `rtwmakecfg` in file `rtwmakecfg.m`. The code generator associates this file with your S-function based on its folder location.
- 2 Modify your target's TMF such that it supports macro expansion for the information returned by `rtwmakecfg` functions.

After the TLC phase of the build process, when generating a makefile from the TMF, the build process searches for an `rtwmakecfg.m` file in the folder that contains the S-function component. If it finds the file, the build process calls the `rtwmakecfg` function. For more information, see "Use `rtwmakecfg.m` API to Customize Generated Makefiles".

### Supporting Continuous Time in Custom Targets

If you want your custom ERT-based target to support continuous time, you must update your template makefile (TMF) and the static main program module (for example, `mytarget_main.c`) for your target.

#### Template Makefile Modifications

Add the `NCSTATES` token expansion after the `NUMST` token expansion, as follows:

```

NUMST = |>NUMST<|
NCSTATES = |>NCSTATES<|

```

In addition, add NCSTATES to the CPP\_REQ\_DEFINES macro, as in the following example:

```
CPP_REQ_DEFINES = -DMODEL=$(MODEL) -DNUMST=$(NUMST) -DNCSTATES=$(NCSTATES) \
-DMAT_FILE=$(MAT_FILE)
-DINTEGER_CODE=$(INTEGER_CODE) \
-DONESTEPFCN=$(ONESTEPFCN) -DTERMFCN=$(TERMFCN) \
-DHAVESTDIO
-DMULTI_INSTANCE_CODE=$(MULTI_INSTANCE_CODE) \
```

### Modifications to Main Program Module

The main program module defines a static main function that manages task scheduling for the supported tasking modes of single- and multiple-rate models. NUMST (the number of sample times in the model) determines whether the main function calls multirate or single-rate code. However, when a model uses continuous time, do not rely on NUMST directly.

When the model has continuous time and the flag TID01EQ is true, both continuous time and the fastest discrete time are treated as one rate in generated code. The code associated with the fastest discrete rate is guarded by a major time step check. When the model has only two rates, and TID01EQ is true, the generated code has a single-rate call interface.

To support models that have continuous time, update the static main module to take TID01EQ into account, as follows:

- 1 Before NUMST is referenced in the file, add the following code:

```
#if defined(TID01EQ) && TID01EQ == 1 && NCSTATES == 0
#define DISC_NUMST (NUMST - 1)
#else
#define DISC_NUMST NUMST
#endif
```

- 2 Replace instances of NUMST in the file by DISC\_NUMST.

### Model Reference Considerations

See “Support Model Referencing” on page 94-61 for important information on TMF modifications you may need to make to support the code generator model referencing features.

---

**Note** If you are using a TMF without the variable MODELREFS, the file might have been used with a previous release of Simulink software. If you want your TMF to support model referencing, add MODELREFS to the make file.

---

### Timeout Error When Building Shared Utility Code with Custom Template Makefile

If the build process uses a custom template makefile to create a makefile for the shared utility code, the build process produces a timeout error when all of these conditions apply:

- The configuration parameter GenCodeOnly is 'off'.
- The BUILD\_SUCCESS message is output during the make call to rtwshared.mk.
- The make call to rtwshared.mk does not update the final product (typically rtwshared.lib).

To avoid the error, update the custom template makefile so that the make call generates the BUILD\_SUCCESS message only when the final product is generated (as identified by the make variable PRODUCT). Alternatively, if the build process does not use the generated makefile, disable makefile generation by setting the configuration parameter GenerateMakefile to 'off'.

- [“Sample Custom Targets”](#)
- [“Customize System Target Files”](#)
- [“Custom Target Optional Features”](#)
- [“Support Toolchain Approach with Custom Target”](#)

## Custom Target Optional Features

This section describes how to configure a custom embedded target to support these optional features.

To ...	Use Target Configuration Parameters ...	For more information, see ...
Indicate a custom target is toolchain-compliant	UseToolchainInfoCompliant GenerateMakefile	“Support Toolchain Approach with Custom Target”
Build a model that includes referenced models and uses a custom target	ModelReferenceCompliant ParMdlRefBuildCompliant (parallel build support)	“Support Model Referencing”
Control the compiler optimization level building generated code for a custom target	CompOptLevelCompliant	“Support Compiler Optimization Level Control”
Control C function prototypes of initialize and step functions that are generated for a model that uses a custom target	ModelStepFunctionPrototypeControlCompliant (ERT only)	“Support C Function Prototype Control”
Control C++ class interfaces that are generated for a model that uses a custom target	CPPClassGenCompliant (ERT only)	“Support C++ Class Interface Control”
Enable concurrent execution of multiple tasks on a multicore platform for a model that uses a custom target	ConcurrentExecutionCompliant	“Support Concurrent Execution of Multiple Tasks”

The required configuration changes are modifications to your system target file, and in some cases also modifications to your template makefile (TMF) or your custom static main program.

The API for system target file callbacks provides a function `SelectCallback` for use in system target files. `SelectCallback` is associated with the target rather than with its individual options. If you implement a `SelectCallback` function for a target, it is triggered whenever the user selects the target in the System Target File Browser.

The API provides the functions `slConfigUIGetVal`, `slConfigUISetEnabled`, and `slConfigUISetVal` for controlling custom target configuration options from a user-written `SelectCallback` function. (For function descriptions and examples, see the function reference pages.)

The general requirements for supporting one of the optional features include:

- To support model referencing or compiler optimization level control, the target must be derived from the GRT or the ERT target. To support C function prototype control or C++ class interface control, the target must be derived from the ERT target.
- The system target file must declare feature compliance by including one of the target configuration parameters listed above in a `SelectCallback` function call.

- Additional changes such as TMF modifications or static main program modifications may be required, depending on the feature. See the detailed steps in the subsections for individual features.

For an example that shows how to configure custom target optional features, see “Customize System Target Files”.

## Support Toolchain Approach with Custom Target

This section describes how to configure a custom system target file to support builds with the toolchain approach.

In the Configuration Parameters dialog box, on the Code Generation pane of, you can set the build controls for the toolchain approach or the template makefile approach. The model configuration parameters that contribute to determining which build controls appear include these parameters.

Model Parameter	Value	Notes
UseToolchainInfoCompliant	on	For toolchain approach, set this parameter to 'on'. For TMF approach, set this parameter to 'off'.
GenerateMakefile	on	For toolchain approach, set this parameter to 'on'.

When the dialog box detects that the selected target has these properties, the dialog box recognizes the target as toolchain-compliant and displays the build controls for the toolchain approach.

Because the custom target file cannot set these properties directly, use a `SelectCallback` function in the custom target file to set the properties. The `SelectCallback` function call in the `RTW_OPTION` section of the TLC file can take the form:

```
rtwgensettings.SelectCallback = 'enableToolchainCompliant(hSrc, hDlg)';
```

A corresponding callback function can contain:

```
function enableToolchainCompliant(hSrc, hDlg)
% The following parameters enable toolchain compliance.
slConfigUISetVal(hDlg, hSrc, 'UseToolchainInfoCompliant', 'on');
slConfigUISetVal(hDlg, hSrc, 'GenerateMakefile', 'on');

% The following parameters are not required for toolchain compliance.
% But, it is recommended practice to set these default values and
% disable the parameters (as shown).
slConfigUISetVal(hDlg, hSrc, 'RTWCompilerOptimization', 'off');
slConfigUISetVal(hDlg, hSrc, 'MakeCommand', 'make_rtw');
slConfigUISetEnabled(hDlg, hSrc, 'RTWCompilerOptimization', false);
slConfigUISetEnabled(hDlg, hSrc, 'MakeCommand', false);
hSrc.refreshDialog;
end
```

When you select your custom target, the configuration parameters dialog box displays the toolchain approach build controls. For an example, see “Create a Custom Target Configuration” on page 94-33.

For an example that shows how to configure custom target optional features, see “Customize System Target Files”.

## Support Model Referencing

If you want to use a custom system target file for building a model that has referenced models, you must configure the custom system target file to support model referencing.

### Requirements for Model Referencing with a Custom System Target File

To build a model that references other models:

- Use a custom system target file that is derived from a GRT or ERT system target file.
- The custom system target file must declare model reference compliance -- see “Declaring Model Referencing Compliance” on page 94-61.
- The template makefile must define some entities that support model referencing -- see “Providing Model Referencing Support in the TMF” on page 94-62.

### Declaring Model Referencing Compliance

To declare model reference compliance for your target, you must implement a callback function that sets the `ModelReferenceCompliant` flag, and then install the callback function in the `SelectCallback` field of the `rtwgensettings` structure in your system target file. The callback function is triggered whenever the user selects the target in the System Target File Browser. For example, the following system target file code installs a `SelectCallback` function named `custom_select_callback_handler`:

```
rtwgensettings.SelectCallback = 'custom_select_callback_handler(hDlg,hSrc)';
```

The arguments to the `SelectCallback` function (`hDlg`, `hSrc`) are handles to private data used by the callback API functions. These handles are restricted to use in system target file callback functions. They should be passed in without alteration.

Your callback function should set the `ModelReferenceCompliant` flag as follows:

```
slConfigUISetVal(hDlg,hSrc,'ModelReferenceCompliant','on');
slConfigUISetEnabled(hDlg,hSrc,'ModelReferenceCompliant',false);
hSrc.refreshDialog;
```

If you might use the target to build models containing large model reference hierarchies, consider configuring the target to support parallel builds, as discussed in “Reduce Build Time for Referenced Models by Using Parallel Builds”.

To configure a target for parallel builds, your callback function must also set the `ParMdlRefBuildCompliant` flag as follows:

```
slConfigUISetVal(hDlg,hSrc,'ParMdlRefBuildCompliant','on');
slConfigUISetEnabled(hDlg,hSrc,'ParMdlRefBuildCompliant',false);
hSrc.refreshDialog;
```

For more information about the system target file callback API, see the `slConfigUIGetVal`, `slConfigUISetEnabled`, and `slConfigUISetVal` function reference pages.

## Providing Model Referencing Support in the TMF

To configure the template makefile (TMF) for model referencing:

- 1 Add the following make variables and tokens to be expanded when the makefile is generated:

```
MODELREFS = |>MODELREFS<|
MODELLIB = |>MODELLIB<|
MODELREF_LINK_LIBS = |>MODELREF_LINK_LIBS<|
MODELREF_LINK_RSPFILE = |>MODELREF_LINK_RSPFILE_NAME<|
RELATIVE_PATH_TO_ANCHOR = |>RELATIVE_PATH_TO_ANCHOR<|
MODELREF_TARGET_TYPE = |>MODELREF_TARGET_TYPE<|
```

The following code excerpt shows how makefile tokens are expanded for a referenced model.

```
MODELREFS =
MODELLIB = engine3200cc_rtwlib.a
MODELREF_LINK_LIBS =
MODELREF_LINK_RSPFILE =
RELATIVE_PATH_TO_ANCHOR = ../../..
MODELREF_TARGET_TYPE = RTW
```

The following code excerpt shows how makefile tokens are expanded for the top model that references the referenced model.

```
MODELREFS = engine3200cc transmission
MODELLIB =
MODELREF_LINK_LIBS = engine3200cc_rtwlib.a transmission_rtwlib.a
MODELREF_LINK_RSPFILE =
RELATIVE_PATH_TO_ANCHOR = ..
MODELREF_TARGET_TYPE = NONE
```

Token	Expands to
MODELREFS for the top model	List of referenced model names.
MODELLIB	Name of the library generated for the model.
MODELREF_LINK_LIBS token for the top model	List of referenced model libraries that the top model links against.
MODELREF_LINK_RSPFILE token for the top model	Name of a response file that the top model links against. This token is valid only for build environments that support linker response files. For an example of its use, see <i>matlabroot/toolbox/coder/compile/tmf/grt_vcx64.tmf</i> .
RELATIVE_PATH_TO_ANCHOR	Relative path, from the location of the generated makefile, to the MATLAB working folder.
MODELREF_TARGET_TYPE	Signifies the type of target being built. Possible values are <ul style="list-style-type: none"> <li>• <b>NONE</b>: Standalone model or top model referencing other models</li> <li>• <b>RTW</b>: Model reference target build</li> <li>• <b>SIM</b>: Model reference simulation target build</li> </ul>

- 2 Add the RELATIVE\_PATH\_TO\_ANCHOR include path to the overall INCLUDES variable.

```
INCLUDES = -I. -I$(RELATIVE_PATH_TO_ANCHOR) $(ADD_INCLUDES) \
$(USER_INCLUDES) $(SHARED_INCLUDES)
```

- 3 Change the SRCS variable in your TMF so that it initially lists only common modules. Additional modules are then appended conditionally, as described in the next step. For example, change

```
SRCS = $(MODEL).c $(MODULES) ert_main.c $(ADD_SRCS) $(EXT_SRC)
```

to

```
SRCS = $(MODULES)
```

- 4 Create variables to define the final target of the makefile. You can remove variables that may have existed for defining the final target. For example, remove

```
PROGRAM = ../$(MODEL)
```

and replace it with

```
ifeq ($(MODELREF_TARGET_TYPE), NONE)
Top model for RTW
PRODUCT = $(RELATIVE_PATH_TO_ANCHOR)/$(MODEL)
BIN_SETTING = $(LD) $(LDFLAGS) -o $(PRODUCT) $(SYSLIBS)
BUILD_PRODUCT_TYPE = "executable"
ERT based targets
SRCS += $(MODEL).c ert_main.c $(EXT_SRC)
GRT based targets
SRCS += $(MODEL).c grt_main.c rt_sim.c $(EXT_SRC) $(SOLVER)
else
sub-model for RTW
PRODUCT = $(MODELLIB)
BUILD_PRODUCT_TYPE = "library"
endif
```

---

**Note** If the template makefile is associated with a toolchain, remove `$(MODEL).c` or `$(MODEL).$(TARGET_LANG_EXT)` from the SRCS list.

---

- 5 Create rules for the final target of the makefile (replace existing final target rules). For example:

```
ifeq ($(MODELREF_TARGET_TYPE), NONE)
Top model for RTW
$(PRODUCT) : $(OBJS) $(LIBS) $(MODELREF_LINK_LIBS)
 $(BIN_SETTING) $(LINK_OBJS) $(MODELREF_LINK_LIBS)
 $(LIBS)
 @echo "### Created $(BUILD_PRODUCT_TYPE): $@"
else
sub-model for RTW
$(PRODUCT) : $(OBJS) $(LIBS)
 @rm -f $(MODELLIB)
 $(ar) ruvs $(MODELLIB) $(LINK_OBJS)
 @echo "### Created $(MODELLIB)"
 @echo "### Created $(BUILD_PRODUCT_TYPE): $@"
endif
```

- 6 Create a rule to allow referenced models to compile files that reside in the MATLAB working folder (`pwd`).

```
%.o : $(RELATIVE_PATH_TO_ANCHOR)/%.c
 $(CC) -c $(CFLAGS) $<
```

---

**Note** If you are using a TMF without the variable `MODELREFS`, the file might have been used with a previous release of Simulink software. If you want your TMF to support model referencing, add either variable `MODELREFS` to the make file.

---

## Controlling Configuration Option Value Agreement

By default, the value of a configuration option defined in the system target file for a TLC-based custom target must be the same in a referenced model and its parent model. To relax this

requirement, include the `modelReferenceParameterCheck` field in the `rtwoptions` structure element that defines the configuration option, and set the value of the field to 'off'. For example:

```
rtwoptions(2).prompt = 'My Custom Parameter';
rtwoptions(2).type = 'Checkbox';
rtwoptions(2).default = 'on';
rtwoptions(2).modelReferenceParameterCheck = 'on';
rtwoptions(2).tlcvariable = 'mytlcvariable';
...
```

The configuration option **My Custom Parameter** can differ in a referenced model and its parent model. See “Customize System Target Files” on page 94-19 for information about TLC-based system target files, and `rtwoptions` Structure Fields Summary for a list of `rtwoptions` fields.

## Preventing Resource Conflicts (Optional)

Hook files are optional TLC and MATLAB program files that are invoked at well-defined stages of the build process. Hook files let you customize the build process and communicate information between various phases of the process.

If you are adapting your custom target for code generation compatibility with model reference features, consider adding checks to your hook files for handling referenced models differently than top models to prevent resource conflicts.

For example, consider adding the following check to your `STF_make_rtw_hook.m` file:

```
% Check if this is a referenced model
mdlRefTargetType = get_param(codeGenModelName, 'ModelReferenceTargetType');
isNotModelRefTarget = strcmp(mdlRefTargetType, 'NONE'); % NONE, SIM, or RTW
if isNotModelRefTarget
 % code that is specific to the top model
else
 % code that is specific to the referenced model
end
```

You may need to do a similar check in your TLC code.

```
%if !IsModelReferenceTarget()
 %% code that is specific to the top model
%else
 %% code that is specific to the referenced model
%endif
```

## Support Compiler Optimization Level Control

This section describes how to configure a custom embedded target to support compiler optimization level control. Without the described modifications, you cannot use model configuration parameter **Compiler optimization level** to control the compiler optimization level for building generated code. For more information about compiler optimization level control, see [Compiler optimization level](#).

### About Compiler Optimization Level Control and Custom Targets

The requirements for supporting compiler optimization level control are as follows:

- The target must be derived from the GRT target or the ERT target.
- The system target file must declare compiler optimization level control compliance, as described in [“Declaring Compiler Optimization Level Control Compliance”](#) on page 94-65.
- The target makefile must honor the setting for model configuration parameter **Compiler optimization level**, as described in [“Providing Compiler Optimization Level Control Support in the Target Makefile”](#) on page 94-66.

For an example that shows how to configure custom target optional features, see [“Customize System Target Files”](#).

### Declaring Compiler Optimization Level Control Compliance

To declare compiler optimization level control compliance for your target, you must implement a callback function that sets the `CompOptLevelCompliant` flag, and then install the callback function in the `SelectCallback` field of the `rtwgensettings` structure in your system target file. The callback function is triggered whenever the user selects the target in the System Target File Browser. For example, the following system target file code installs a `SelectCallback` function named `custom_select_callback_handler`:

```
rtwgensettings.SelectCallback = 'custom_select_callback_handler(hDlg,hSrc)';
```

The arguments to the `SelectCallback` function (`hDlg`, `hSrc`) are handles to private data used by the callback API functions. These handles are restricted to use in system target file callback functions. They should be passed in without alteration.

Your callback function should set the `CompOptLevelCompliant` flag as follows:

```
slConfigUISetVal(hDlg,hSrc,'CompOptLevelCompliant','on');
slConfigUISetEnabled(hDlg,hSrc,'CompOptLevelCompliant',false);
hSrc.refreshDialog;
```

For more information about the system target file callback API, see the `slConfigUIGetVal`, `slConfigUISetEnabled`, and `slConfigUISetVal` function reference pages.

When the `CompOptLevelCompliant` target configuration parameter is set to on, the **Compiler optimization level** parameter is displayed in the **Code Generation** pane of the Configuration Parameters dialog box for your model.

## Providing Compiler Optimization Level Control Support in the Target Makefile

As part of supporting compiler optimization level control for your target, you must modify the target makefile to honor the setting for model configuration parameter **Compiler optimization level**. Use a GRT or ERT target provided by MathWorks as a model for making the modifications.

## Support C Function Prototype Control

This section describes how to configure a custom embedded target to support function prototype control. Without the described modifications, you will not be able to use available interfaces for customizing entry-point function interfaces.

Function prototype control is not supported for component models configured with a service interface. For more information, see “Model Code Interfaces” on page 3-2 and “Configure Code Interfaces for Code Generation” on page 3-4.

For more information, see “Configure Generated C Function Interface for Model Entry-Point Functions” on page 33-114.

### About C Function Prototype Control and Custom Targets

The requirements for supporting C function prototype control are as follows:

- The system target file must be derived from the ERT system target file.
- The system target file must declare C function prototype control compliance, as described in “Declaring C Function Prototype Control Compliance” on page 94-67.
- If your system target file uses a custom static main program, and if a nondefault function prototype control configuration is associated with a model, the static main program must call the function prototype controlled initialize and step functions, as described in “Providing C Function Prototype Control Support in the Custom Static Main Program” on page 94-68.

For an example that shows how to configure custom target optional features, see “Customize System Target Files”.

### Declaring C Function Prototype Control Compliance

To declare C function prototype control compliance for your target, you must implement a callback function that sets the `ModelStepFunctionPrototypeControlCompliant` flag, and then install the callback function in the `SelectCallback` field of the `rtwgensettings` structure in your system target file. The callback function is triggered whenever the user selects the target in the System Target File Browser. For example, the following system target file code installs a `SelectCallback` function named `custom_select_callback_handler`:

```
rtwgensettings.SelectCallback = 'custom_select_callback_handler(hDlg,hSrc)';
```

The arguments to the `SelectCallback` function (`hDlg`, `hSrc`) are handles to private data used by the callback API functions. These handles are restricted to use in system target file callback functions. They should be passed in without alteration.

Your callback function should set the `ModelStepFunctionPrototypeControlCompliant` flag as follows:

```
slConfigUISetVal(hDlg,hSrc,'ModelStepFunctionPrototypeControlCompliant','on');
slConfigUISetEnabled(hDlg,hSrc,'ModelStepFunctionPrototypeControlCompliant',false);
hSrc.refreshDialog;
```

For more information about the system target file callback API, see the `slConfigUIGetVal`, `slConfigUISetEnabled`, and `slConfigUISetVal` function reference pages.

When the `ModelStepFunctionPrototypeControlCompliant` target configuration parameter is set to `on`, you can use the `Configure C Step Function Interface` dialog box to control the function prototype of the base-rate step function generated for a rate-based model.

## Providing C Function Prototype Control Support in the Custom Static Main Program

If your target uses a custom static main program, and if a nondefault function prototype control configuration is associated with a model, you must update the static main program to call the function prototype controlled initialize and step functions. You can do this in either of the following ways:

- 1 Manually adapt your static main program to declare model data and call the function prototype controlled initialize and step functions.
- 2 Generate your main program by selecting model configuration parameter **Generate an example main program**. The generated main program declares model data and calls the function prototype controlled initialize and step function.

## Support C++ Class Interface Control

This section describes how to configure a custom embedded target to support C++ class interface control. Without the described modifications, you will not be able to use C++ class code interface packaging to generate and configure C++ class interfaces to model code. For more information about C++ class interface control, see “Interactively Configure C++ Interface” on page 44-2.

### About C++ Class Interface Control and Custom Targets

The requirements for supporting C++ class interface control are as follows:

- The target must be derived from the ERT system target file.
- The system target file must declare C++ class interface control compliance, as described in “Declaring C++ Class Interface Control Compliance” on page 94-69.

For an example that shows how to configure custom target optional features, see “Customize System Target Files”.

### Declaring C++ Class Interface Control Compliance

To declare C++ class interface control compliance for your target, you must implement a callback function that sets the `CPPClassGenCompliant` flag, and then install the callback function in the `SelectCallback` field of the `rtwgensettings` structure in your system target file. The callback function is triggered whenever the user selects the target in the System Target File Browser. For example, the following system target file code installs a `SelectCallback` function named `custom_select_callback_handler`:

```
rtwgensettings.SelectCallback = 'custom_select_callback_handler(hDlg,hSrc)';
```

The arguments to the `SelectCallback` function (`hDlg`, `hSrc`) are handles to private data used by the callback API functions. These handles are restricted to use in system target file callback functions. They should be passed in without alteration.

Your callback function should set the `CPPClassGenCompliant` flag as follows:

```
slConfigUISetVal(hDlg,hSrc,'CPPClassGenCompliant','on');
slConfigUISetEnabled(hDlg,hSrc,'CPPClassGenCompliant',false);
hSrc.refreshDialog;
```

For more information about the system target file callback API, see the `slConfigUIGetVal`, `slConfigUISetEnabled`, and `slConfigUISetVal` function reference pages.

When the `CPPClassGenCompliant` target configuration parameter is set to `on`, you can use the C++ class code interface packaging to generate and configure C++ class interfaces to model code.

### Providing C++ Class Interface Control Support in the Custom Static Main Program

Selecting C++ class code interface packaging for your model enables model configuration parameter **Generate an example main program**. When you select this parameter, the code generator produces an example main program, `ert_main.cpp`. The generated example main program declares model data and calls the C++ class interface configured model step method, and illustrates how the generated code can be deployed.

To customize the build process and disable generation and inclusion of an example main program, see the `setTargetProvidesMain` function. Disabling example main generation permits including a custom main program.

## Support Concurrent Execution of Multiple Tasks

If a custom embedded target must support concurrent execution of multiple tasks on a multicore platform, the target must declare support for concurrent execution by setting the target configuration option `ConcurrentExecutionCompliant`. Otherwise, you will not be able to configure a multicore target model for concurrent execution.

If `ConcurrentExecutionCompliant` is not already configured for your custom target, you can set the option in the following ways:

- Include the following code directly in your system target file (*mytarget.tlc*):

```
rtwgensettings.SelectCallback = 'slConfigUISetVal(hDlg,hSrc,...
 ''ConcurrentExecutionCompliant'',''on'');';
rtwgensettings.ActivateCallback = 'slConfigUISetVal(hDlg,hSrc,...
 ''ConcurrentExecutionCompliant'',''on'');';
```

- Implement a callback function that sets the `ConcurrentExecutionCompliant` option, and then install the callback function in the `SelectCallback` field of the `rtwgensettings` structure in your system target file. The callback function is triggered whenever the user selects the target in the System Target File Browser. For example, the following system target file code installs a `SelectCallback` function named `custom_select_callback_handler`:

```
rtwgensettings.SelectCallback = 'custom_select_callback_handler(hDlg,hSrc)';
```

The arguments to the `SelectCallback` function (`hDlg`, `hSrc`) are handles to private data used by the callback API functions. These handles are restricted to use in system target file callback functions. They should be passed in without alteration.

Your callback function should set the `ConcurrentExecutionCompliant` option as follows:

```
slConfigUISetVal(hDlg,hSrc,'ConcurrentExecutionCompliant','on');
slConfigUISetEnabled(hDlg,hSrc,'ConcurrentExecutionCompliant',false);
hSrc.refreshDialog;
```

For more information about the system target file callback API, see the `slConfigUIGetVal`, `slConfigUISetEnabled`, and `slConfigUISetVal` function reference pages.

When the `ConcurrentExecutionCompliant` target configuration option is set to 'on', you can select the custom target and configure your multicore target model for concurrent execution.

For an example that shows how to configure custom target optional features, see “Customize System Target Files”.

## Device Drivers

Device drivers that communicate with target hardware are essential to many real-time development projects.

You can integrate existing C (or C++) device driver functions into Simulink models by using the Legacy Code Tool. When you use the code generator to generate code from a model, the Legacy Code Tool can insert a call to your C function into the generated code. For details, see “Import Calls to External Code into Generated Code with Legacy Code Tool” and “Integrate C Functions into Simulink Models with Legacy Code Tool”.

# Build Configurations for Embedded Targets in Embedded Coder

---

## Model Setup

### In this section...

“Block Selection” on page 95-2

“Configure Target Hardware Resources” on page 95-2

### Block Selection

You can create models for targeting the same way you create other Simulink models—by combining standard blocks and C-MEX S-functions.

You can use blocks from the following sources:

- The Embedded Coder Support Packages.
- The Embedded Targets library (`embeddedtargetslib`) in the Embedded Coder product.
- Blocks from the System Toolboxes products
- Custom blocks

Avoid using blocks that do not generate code, including the following blocks.

Block Name/Category	Library	Description
Scope	Simulink, DSP System Toolbox software	Provides oscilloscope view of your output. Do not use the <b>Save data to workspace</b> option on the <b>Data history</b> pane in the Scope Parameters dialog.
To Workspace	Simulink	Return data to your MATLAB workspace.
From Workspace	Simulink	Send data to your model from your MATLAB workspace.
Spectrum Scope	DSP System Toolbox	Compute and display the short-time FFT of a signal. It has internal buffering that can slow your process without adding value.
To File	Simulink	Send data to a file on your host machine.
From File	Simulink	Get data from a file on your host machine.
Triggered to Workspace	DSP System Toolbox	Send data to your MATLAB workspace.
Signal To Workspace	DSP System Toolbox	Send a signal to your MATLAB workspace.
Signal From Workspace	DSP System Toolbox	Get a signal from your MATLAB workspace.
Triggered Signal From Workspace	DSP System Toolbox	Get a signal from your MATLAB workspace.
To Wave device	DSP System Toolbox	Send data to a <code>.wav</code> device.
From Wave device	DSP System Toolbox	Get data from a <code>.wav</code> device.

### Configure Target Hardware Resources

To configure your Simulink model for your target hardware and toolchain:

- 1** In the Configuration Parameters dialog box, select **Hardware Implementation**, and then specify your **Hardware board**.

Specifying a **Hardware board** automatically sets many **Code Generation** parameters to values appropriate for the hardware.

- 2** On the **Target Hardware Resources** tab, review the other parameters.
- 3** (Optional) In the Configuration Parameters dialog box, select **Code Generation**, and then review and modify other code generation features for your model.
- 4** Click **Apply**, and save the changes to your model.

## Replace Code for Embedded Targets

<b>In this section...</b>
---------------------------

“Using a Processor-Specific Code Replacement Library to Optimize Code” on page 96-2
-------------------------------------------------------------------------------------

“Process of Determining Optimization Effects Using Real-Time Profiling Capability” on page 96-2
-------------------------------------------------------------------------------------------------

### Using a Processor-Specific Code Replacement Library to Optimize Code

You can optimize the code the code generator produces for a specific processor by configuring the code generator to use a code replacement library (CRL) during code generation. If you have an Embedded Coder license, you can develop and apply custom code replacement libraries.

For more information about replacing code, using code replacement libraries that MathWorks provides, see “What Is Code Replacement?” on page 57-2 and “Replace Code Generated from Simulink Models” on page 57-8. For information about developing code replacement libraries, see “What Is Code Replacement Customization?” on page 72-3 and “Develop a Code Replacement Library” on page 72-20.

### Process of Determining Optimization Effects Using Real-Time Profiling Capability

You can use the real-time profiling capability to examine the results of applying the processor-specific library functions and operators to your generated code. After you select a processor-specific code replacement library, use the real-time execution profiling capability to examine the change in program execution time.

Use the following process to evaluate the effects of applying a processor-specific code replacement library when you generate code:

- 1 Enable real-time profiling in your model. Refer to “Code Execution Profiling”.
- 2 Generate code for your project without specifying a code replacement library (the default **Code replacement library** setting is None).
- 3 Profile the code, and save the report.
- 4 Rebuild your project using a processor-specific code replacement library.
- 5 Profile the code, and save the second report.
- 6 Compare the profile report from running your application with the processor-specific library selected to the profile results in the first report with no code replacement library selected.

For an example of verifying the code optimization, search help for “Optimizing Embedded Code via Code Replacement Library” and select the example that matches your IDE.

## Specify Comment Style for C/C++ Code

### In this section...

“Specify Comment Style Using the MATLAB Coder App” on page 97-2

“Specify Comment Style Using the Command-Line Interface” on page 97-2

If you have an Embedded Coder, you can specify the comment style for C/C++ code generated from MATLAB code. Specify single-line style to generate single-line comments preceded by `//`. Specify multiline style to generate single-line or multiline comments delimited by `/*` and `*/`. Single-line style is the default for C++ code generation. Multiline style is the default for C code generation. For C code generation, select single-line comment style only if your compiler supports it.

### Specify Comment Style Using the MATLAB Coder App

- 1 On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow .
- 2 Set **Build type** to one of the following:
  - Source Code
  - Static Library (.lib)
  - Dynamic Library (.dll)
  - Executable (.exe)
- 3 Click **More Settings**.
- 4 On the **Code Appearance** tab, select the **Include comments** check box if it is not already selected. By default, the **Include comments** check box is selected.
- 5 Set **Comment Style** to one of the following options.

Value	Description
Auto(Use standard comment style of the target language)	For C, generate multiline comments. For C++, generate single-line comments. (default)
Single-line (Use C++-style comments)	Generate single-line comments preceded by <code>//</code> .
Multi-line (Use C-style comments)	Generate single-line or multiline comments delimited by <code>/*</code> and <code>*/</code> .

### Specify Comment Style Using the Command-Line Interface

- 1 Create a code configuration object for C/C++ code generation. For example, create a configuration object for C/C++ static library generation:

```
cfg = coder.config('lib', 'ecoder', true);
```

- 2 Set the `CommentStyle` property to one of the following values:

Value	Description
'Auto'	For C, generate multiline comments. For C++, generate single-line comments. (default)
'Single-line'	Generate single-line comments preceded by <code>//</code> .

Value	Description
'Multi-line'	Generate single-line or multiline comments delimited by /* and */.

For example, this code sets the comment style to single-line style:

```
cfg.CommentStyle='Single-line';
```

- “Configure Build Settings”

## Specify Indent Style for C/C++ Code

### In this section...

“Specify Indent Style Using the MATLAB Coder App” on page 97-4

“Specify Indent Style Using the Command-Line Interface” on page 97-5

If you have an Embedded Coder license, you can control the indent style and indent size in C/C++ code generated from MATLAB code. Indent style controls the placement of braces. Indent size controls the number of characters per indentation level.

You can specify the K&R indent style or the Allman indent style. Both styles:

- Place the function opening and closing braces on their own lines at the same indentation level as the function header.
- Indent code within the function according to the indent size.
- For blocks within a function, place closing braces on a new line at the same indentation level as the control statement.
- Indent code within a block according to the indent size.

The K&R style and the Allman style differ in their placement of the opening brace for a control statement. If you want the opening brace on the same line as its control statement, select the K&R style. Here is code that has the K&R indent style:

```
void addone(const double x[6], double z[6])
{
 int i;
 for (i = 0; i < 6; i++) {
 z[i] = x[i] + 1.0;
 }
}
```

If you want the opening brace on its own line, select the Allman style. Here is code that has the Allman indent style:

```
void addone(const double x[6], double z[6])
{
 int i;
 for (i = 0; i < 6; i++)
 {
 z[i] = x[i] + 1.0;
 }
}
```

### Specify Indent Style Using the MATLAB Coder App

- 1 On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow .
- 2 Set **Build type** to one of the following:
  - Source Code
  - Static Library (.lib)
  - Dynamic Library (.dll)

- Executable (.exe)
- 3 Click **More Settings**.
  - 4 On the **All Settings** tab, under **Advanced**, set **Indent style** to K&R or Allman.
  - 5 On the **All Settings** tab, under **Advanced**, set **Indent size** to an integer from 2 to 8.

## Specify Indent Style Using the Command-Line Interface

- 1 Create a code configuration object for 'lib', 'dll', or 'exe'. For example:

```
cfg = coder.config('lib','ecoder',true); % or dll or exe
```

- 2 Set the `IndentStyle` property to 'K&R' or 'Allman'. For example:

```
cfg.IndentStyle = 'Allman';
```

- 3 Set the `IndentSize` property to an integer from 2 to 8. For example:

```
cfg.IndentSize = 4;
```

- “Configure Build Settings”

## Generate Custom File and Function Banners for C/C++ Code

When you generate C and C++ code from MATLAB code, you can use a code generation template (CGT) file to specify custom:

- File banners
- Function Banners
- File trailers
- Comments before code sections

This example shows how you can create your own CGT file and customize it to generate your own file and function banners.

- 1 Create a local copy of the default CGT file for MATLAB Coder and rename it. The default CGT file is `matlabcoder_default_template.cgt` in the `matlabroot/toolbox/coder/matlabcoder/templates/` folder.
- 2 Store the copy in a folder that is outside of the MATLAB folder structure, but on the MATLAB path. If necessary, add the folder to the MATLAB path. If you intend to use the CGT file with a custom target, locate the CGT file in a folder under your target root folder. If the file is not on the MATLAB path, specify a full path to the file when adding the file to your configuration.
- 3 View the default template and generated output. For example, here is the default File Banner section:

```

%%
%% Custom File Banner section (optional)
%% Customize File banners by using either custom tokens or the following
%% predefined tokens:
%% %<FileName>, %<MATLABCoderVersion>, %<EmbeddedCoderVersion>
%% %<SourceGeneratedOn>, %<HardwareSelection>, %<OutputType>
%%
%% You can also use "custom tokens" in all of the sections below. See the
%% documentation center for more details.
%%
<FileBanner style="classic">
File: %<FileName>

MATLAB Coder version : %<MATLABCoderVersion>
C/C++ source code generated on : %<SourceGeneratedOn>
</FileBanner>

```

When you generate code using this default, the file banner looks similar to this file banner:

```

/*
 * File: coderand.c
 *
 * MATLAB Coder version : 2.7
 * C/C++ source code generated on : 06-Apr-2014 14:34:15
 */

```

- 4 Edit your local copy of the CGT file. You can change the default values and add your own custom tokens. For example, here is the File Banner section with the style changed to `box` and a custom token `myCustomToken`:

```

%%
%% Custom File Banner section (optional)
%% Customize File banners by using either custom tokens or the following
%% predefined tokens:
%% %<FileName>, %<MATLABCoderVersion>, %<EmbeddedCoderVersion>
%% %<SourceGeneratedOn>, %<HardwareSelection>, %<OutputType>
%%

```

```

%% You can also use "custom tokens" in all of the sections below. See the
%% documentation center for more details.
%%
<FileBanner style="box">
File: %<FileName>

My custom token : %<myCustomToken>

MATLAB Coder version : %<MATLABCoderVersion>
C/C++ source code generated on : %<SourceGeneratedOn>
</FileBanner>

```

For more information, see “Code Generation Template Files for MATLAB Code” on page 97-9.

- 5 Create a configuration object for generation of a C static library for an embedded target.

```

% Create configuration object for an embedded target
cfgObj = coder.config('lib', 'ecoder', true);

```

- 6 Create a MATLABCodeTemplate object from your CGT file and add it to the configuration object.

```

% Specify the custom CGT file
CGTFile = 'myCGTFile.cgt';
% Use custom template
cfgObj.CodeTemplate = coder.MATLABCodeTemplate(CGTFile);

```

- 7 Assign values for custom tokens that you added to the template. For example, assign the value 'myValue' to the myCustomToken token that you added in a previous step.

```

cfgObj.CodeTemplate.setTokenValue('myCustomToken', 'myValue');

```

- 8 Make sure that generation of comments is enabled. Otherwise, the code generator does not produce file or function banners.

```

cfgObj.GenerateComments=true;

```

- 9 Generate code using the configuration object that you created.

```

codegen -config cfgObj coderand

```

- 10 View the changes to the generated file banner. For example, here is the file banner for coderand.c using the customized CGT file:

```

/*****
/* File: coderand.c */
/* */
/* My custom token : myValue */
/* */
/* MATLAB Coder version : 2.7 */
/* C/C++ source code generated on : 06-Apr-2014 14:42:55 */
*****/

```

Changes to a CGT file do not affect the generated code unless you create a MATLABCodeTemplate object from the modified CGT file, and then add it to the configuration object. If you modify the CGT File, myCGTFile.cgt, used in the previous example, you must repeat these steps:

- 1 Create a MATLABCodeTemplate object from myCGTFile.cgt and add it to the configuration object.

```

CGTFile = 'myCGTFile.cgt';
cfgObj.CodeTemplate = coder.MATLABCodeTemplate(CGTFile);

```

- 2 Assign the value 'myValue' to the myCustomToken token.

```

cfgObj.CodeTemplate.setTokenValue('myCustomToken', 'myValue');

```

**3** Generate code.

```
codegen -config cfgObj coderand
```

### **See Also**

### **More About**

- “Code Generation Template Files for MATLAB Code” on page 97-9

## Code Generation Template Files for MATLAB Code

### In this section...

“Default CGT File” on page 97-9

“CGT File Structure” on page 97-9

“Components of the CGT File Sections” on page 97-10

A code generation template (CGT) file defines the sections in generated code that you can customize using comments and tokens. Using a code generation template (CGT) file for the generation of C and C++ code from MATLAB code, you can specify custom file banners and function banners for generated code. File banners are comment sections in the header and trailer sections of a generated file. Function banners are comment sections for each function in the generated code. You can also customize comments before code sections. Use these banners to:

- Add a company copyright statement.
- Specify a special version symbol for your configuration management system.
- Remove timestamps.
- Add other custom information to your generated files.

For information on creating, customizing, and using a CGT file, see “Generate Custom File and Function Banners for C/C++ Code” on page 97-6.

### Default CGT File

You can base your custom template on the default CGT file, `matlabcoder_default_template.cgt`, in the `matlabroot/toolbox/coder/matlabcoder/templates/` folder.

---

**Note** If you choose not to customize banners for your generated code, the default template is used for code generation.

---

### CGT File Structure

A CGT file consists of 13 optional sections.

#### File Banner Section

Contains comments and tokens for use in generating a custom file banner.

#### Function Banner Section

Contains comments and tokens for use in generating a custom function banner.

#### Shared Utility Function Banner

Contains comments and tokens for use in generating custom banners for shared utility functions.

#### File Trailer Section

Contains comments for use in generating a custom trailer banner.

**Include Files Banner**

Contains comments for use in generating a custom banner for the include files section.

**Type Definitions**

Contains comments for use in generating a custom banner for the type definitions section.

**Named Constants**

Contains comments for use in generating a custom banner for the named constants section.

**Variable Declarations**

Contains comments for use in generating a custom banner for the variable declarations section.

**Variable Definitions**

Contains comments for use in generating a custom banner for the variable definitions section.

**Function Declarations**

Contains comments for use in generating a custom banner for the function declarations section.

**Function Definitions**

Contains comments for use in generating a custom banner for the function definitions section.

**Custom Source Code**

Contains comments for use in generating a custom banner for the custom source code section.

**Custom Header Code**

Contains comments for use in generating a custom banner for the custom header code section.

**Components of the CGT File Sections**

Each CGT file section is defined by open and close tags.

CGT File Section	Open Tag	Close Tag
“File Banner” on page 97-13	<FileBanner>	</FileBanner>
“Function Banner Section” on page 97-9	<FunctionBanner>	</FunctionBanner>
“Shared Utility Function Banner” on page 97-9	<SharedUtilityBanner>	</SharedUtilityBanner>
“File Trailer Section” on page 97-9	<FileTrailer>	</FileTrailer>
“Include Files Banner” on page 97-10	<IncludeFilesBanner>	</IncludeFilesBanner>

CGT File Section	Open Tag	Close Tag
"Type Definitions" on page 97-10	<TypeDefinitionsBanner>	</TypeDefinitionsBanner>
"Named Constants" on page 97-10	<NamedConstantsBanner>	</NamedConstantsBanner>
"Variable Declarations" on page 97-10	<VariableDeclarationsBanner>	</VariableDeclarationsBanner>
"Variable Definitions" on page 97-10	<VariableDefinitionsBanner>	</VariableDefinitionsBanner>
"Function Declarations" on page 97-10	<FunctionDeclarationsBanner>	</FunctionDeclarationsBanner>
"Function Definitions" on page 97-10	<FunctionDefinitionsBanner>	</FunctionDefinitionsBanner>
"Custom Source Code" on page 97-10	<CustomSourceCodeBanner>	</CustomSourceCodeBanner>
"Custom Header Code" on page 97-10	<CustomHeaderCodeBanner>	</CustomHeaderCodeBanner>

You can customize your banners by including tokens and comments between the open and close tags for each section. Tokens are replaced with values in the generated code. The following rules apply to tokens in your CGT file:

- You can have only one token per line.
- Token values must not contain a '\t' for formatting.

---

**Note** In the contents of your banner, C comment indicators, `'/*' or '*/'`, can introduce an error in the generated code.

---

An open tag includes tag attributes. Enclose the value of the attribute in double quotes. The attributes available for an open tag are:

- `width`: specifies the width of the file or function banner comments in the generated code. The default value is 80.
- `style`: specifies the boundary for the file or function banner comments in the generated code.

The open tag syntax is:

```
<OpenTag style = "style_value" width = "num_width">
```

There are five options for the banner style. The `CommentStyle` and `TargetLang` configuration object properties determine the use of C or C++ comment style. The built-in style options for the `style` attribute are:

- `classic`

Using C style comments

```
/* single line comments */
```

```

/*
 * multiple line comments
 * second line
 */

```

Using C++ style comments

```

// single line comments

//
// multiple line comments
// second line
//

```

- box

Using C style comments

```

/*****
/* banner contents */
*****/

```

Using C++ style comments

```

////////////////////////////////////
// banner contents //
////////////////////////////////////

```

- open\_box

Using C style comments

```

/*****
 * banner contents
 *****/

```

Using C++ style comments

```

////////////////////////////////////
// banner contents //
////////////////////////////////////

```

- doxygen

Using C style comments

```

/** single line comments */

/**

```

//!single line comments

//!
//! multiple line comments
//!second line
//!

```

## File Banner

This section contains comments and tokens for use in generating a custom file banner that precedes the generated C and C++ code. If you omit the file banner section from the CGT file, the code generator does not generate a file banner in the generated code. The file banner section provided in the default CGT file is:

```

%%
%% Custom File Banner section (optional)
%% Customize File banners by using either custom tokens or the following
%% predefined tokens:
%% %<FileName>, %<MATLABCoderVersion>, %<EmbeddedCoderVersion>
%% %<SourceGeneratedOn>, %<HardwareSelection>, %<OutputType>
%%
%% You can also use "custom tokens" in all of the sections below. See the
%% documentation center for more details.
%%
<FileBanner style="classic">
File: %<FileName>

MATLAB Coder version : %<MATLABCoderVersion>
C/C++ source code generated on : %<SourceGeneratedOn>
</FileBanner>

```

## Summary of Tokens for File Banner Generation

FileName	Name of the generated file (for example, "kalman.c")
SourceGeneratedOn	Timestamp of generated file
MATLABCoderVersion	Version of MATLAB Coder
EmbeddedCoderVersion	Version of Embedded Coder
HardwareSelection	Selected target
OutputType	Type of output (for example, lib, exe, or dll)

## Function Banner

This section contains comments and tokens for use in generating a custom function banner that precedes a generated C or C++ function. If you omit the function banner section from the CGT file, the code generator does not generate function banners. The function banner section provided in the default CGT file is:

```

%%
%% Custom Function Banner section (optional)
%% Customize function banners by using the following predefined tokens:
%% %<FunctionName>, %<FunctionDescription>, %<FunctionPrototype>
%% %<Arguments>, %<ReturnType>
%%
<FunctionBanner style="classic">
%<FunctionPrototype>
%<FunctionDescription>
Arguments : %<Arguments>
Return Type : %<ReturnType>
</FunctionBanner>

```

**Summary of Tokens for Function Banner Generation**

FunctionName	Name of function
FunctionDescription	Short abstract about the function  If the configuration parameter MATLABFcnDesc is true, the function description appears in the function banner. Otherwise, the code generator treats the function description as user comments.
FunctionPrototype	MATLAB function prototype  The function prototype appears in the function banner only if the MATLABSourceComments configuration parameter is true.
Arguments	List of function arguments
ReturnType	Return type of function

**Shared Utility Banner**

This section contains comments and tokens for use in generating a custom shared utility function banner that precedes a generated C or C++ shared utility function. If you omit the shared utility function banner section from the CGT file, the code generator does not generate shared utility function banners. The shared utility function banner section provided in the default CGT file is:

```

%%
%% Custom Shared Utility Function Banner section (optional)
%% Customize shared utility function banners by using the following
%% predefined tokens:
%% %<FunctionName>, %<FunctionDescription>
%% %<Arguments>, %<ReturnType>
%%
<SharedUtilityBanner style="classic">
Arguments : %<Arguments>
Return Type : %<ReturnType>
</SharedUtilityBanner>

```

**Summary of Tokens for Shared Utility Function Banner Generation**

FunctionName	Name of function
FunctionDescription	Short abstract about the function
Arguments	List of function arguments
ReturnType	Return type of function

## File Trailer

The file trailer section contains comments for generating a custom file trailer that follows the generated C or C++ code. If you omit the file trailer section from the CGT file, the code generator does not generate a file trailer. The file trailer section provided in the default CGT file is:

```
%%
%% Custom file trailer section (optional)
%% You can use any of the predefined tokens used for File Banner
%%
<FileTrailer style="classic">
File trailer for %<FileName>

[EOF]
</FileTrailer>
```

Tokens for the file banner are available for the file trailer. See Summary of Tokens for File Banner Generation.

## Include Files Banner

The include files banner section contains comments for generating a custom banner that precedes the include files section in the generated code. If you omit the include files banner section from the CGT file, the code generator does not generate a banner for this section. The include files banner section provided in the default CGT file is:

```
<IncludeFilesBanner style="classic">
Include Files
</IncludeFilesBanner>
```

## Type Definitions Banner

The type definitions banner section contains comments for generating a custom banner that precedes the type definitions section in the generated code. If you omit the type definitions banner section from the CGT file, the code generator does not generate a banner for this section. The type definitions banner section provided in the default CGT file is:

```
<TypeDefinitionsBanner style="classic">
Type Definitions
</TypeDefinitionsBanner>
```

## Named Constants Banner

The named constants banner section contains comments for generating a custom banner that precedes the named constants section in the generated code. If you omit the named constants banner section from the CGT file, the code generator does not generate a banner for this section. The named constants banner section provided in the default CGT file is:

```
<NamedConstantsBanner style="classic">
Named Constants
</NamedConstantsBanner>
```

## Variable Declarations

The variable declarations banner section contains comments for generating a custom banner that precedes the variable declarations section in the generated code. If you omit the variable declarations banner section from the CGT file, the code generator does not generate a banner for this section. The variable declarations banner section provided in the default CGT file is:

```
<VariableDeclarationsBanner style="classic">
Variable Declarations
</VariableDeclarationsBanner>
```

### Variable Definitions

The variable definitions banner section contains comments for generating a custom banner that precedes the variable definitions section in the generated code. If you omit the variable definitions banner section from the CGT file, the code generator does not generate a banner for this section. The variable definitions banner section provided in the default CGT file is:

```
<VariableDefinitionsBanner style="classic">
Variable Definitions
</VariableDefinitionsBanner>
```

### Function Declarations

The function declarations banner section contains comments for generating a custom banner that precedes the function declarations section in the generated code. If you omit the function declarations banner section from the CGT file, the code generator does not generate a banner for this section. The function declarations banner section provided in the default CGT file is:

```
<functionDeclarationsBanner style="classic">
Function Declarations
</FunctionDeclarationsBanner>
```

### Function Definitions

The function definitions banner section contains comments for generating a custom banner that precedes the function definitions section in the generated code. If you omit the function definitions banner section from the CGT file, the code generator does not generate a banner for this section. The function definitions banner section provided in the default CGT file is:

```

## **More About**

- “Generate Custom File and Function Banners for C/C++ Code” on page 97-6

## Customize Generated Identifiers

### In this section...

“Customize Identifiers by Using the MATLAB Coder App” on page 97-18

“Customize Generated Identifiers by Using the Command-Line Interface” on page 97-19

If you have Embedded Coder, you can customize the identifiers in C/C++ code generated from MATLAB code. For each kind of identifier that you want to customize, set the appropriate identifier format parameter to a macro that specifies the format of the generated identifiers. The macro can include:

- Valid C or C++ language identifiers (a-z, A-Z, \_, 0-9).
- The tokens listed in the following table. \$M is required.

Token	Description
\$M	Code generator inserts name mangling text to avoid naming collisions.  Required.
\$N	Code generator inserts the name of the object (global variable, global type, local function, local temporary variable, or constant macro) for which the identifier is generated. Improves readability of generated code.  Required.
\$R	Code generator inserts the root project name into identifier, replacing unsupported characters with the underscore ( _ ) character.

### Customize Identifiers by Using the MATLAB Coder App

- 1 On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow .
- 2 Set **Build type** to one of the following:
  - Source Code
  - Static Library
  - Dynamic Library
  - Executable
- 3 Click **More Settings**.
- 4 On the **Code Appearance** tab, under **Identifier Format**, for each kind of identifier that you want to customize, enter the macro.

Parameter	Default Macro
<b>Global variables</b>	\$M\$N
<b>Global types</b>	\$M\$N
<b>Field name of global types</b>	\$M\$N
<b>Local functions</b>	\$M\$N
<b>Local temporary variables</b>	\$M\$N

Parameter	Default Macro
Constant macros	\$M\$N
EMX Array Types	emxArray_ \$M\$N
EMX Array Utility Functions	emx\$M\$N

For example, suppose that **Global variables** has the value `glob_ $M$N`. For a global variable named `g`, when name mangling is not required, the generated identifier is `glob_g`. If name mangling is required, the generated identifier includes the name mangling text.

## Customize Generated Identifiers by Using the Command-Line Interface

- 1 Create a code configuration object for a library or executable program. For example:

```
cfg = coder.config('lib','ecoder',true);
```
- 2 For each kind of identifier that you want to customize, specify the macro as a character vector.

Parameter	Description	Default Macro
CustomSymbolStrGlobalVar	Global variables	' \$M\$N '
CustomSymbolStrType	Global types	' \$M\$N '
CustomSymbolStrField	Field name of global types	' \$M\$N '
CustomSymbolStrFcn	Local functions	' \$M\$N '
CustomSymbolStrTmpVar	Local temporary variables	' \$M\$N '
CustomSymbolStrMacro	Constant macros	' \$M\$N '
CustomSymbolStrEMXArray	EMX Array Types	'emxArray_ \$M\$N '
CustomSymbolStrEMXArrayFcn	EMX Array Utility Functions	'emx\$M\$N '

For example:

```
cfg.CustomSymbolStrGlobalVar = 'glob_ MN';
```

For a global variable named `g`, when name mangling is not required, the generated identifier is `glob_g`. If name mangling is required, the generated identifier includes the name mangling text.

## Customize C/C++ File Names Generated from MATLAB Code

### In this section...

“Customize File Names by Using the MATLAB Coder App” on page 97-20

“Customize Generated File Names by Using the Command-Line Interface” on page 97-20

If you have Embedded Coder, you can customize the file names of the C/C++ code generated from MATLAB code. By changing the file names, you can avoid name clashes when integrating different C/C++ code projects together. Customize the file names by setting the file name format parameter `CustomFileNameStr` to a macro. The macro can include:

- Valid file name characters.
- The tokens listed in the following table. `$M` and `$N` are required.

Token	Description
<code>\$M</code>	Code generator inserts name mangling text to avoid naming collisions. Required.
<code>\$N</code>	Code generator inserts the non-customized file name. Required.
<code>\$R</code>	Code generator inserts the root project name into the file name, replacing unsupported characters with the underscore ( <code>_</code> ) character.

By default, the macro is set to `$N$M`.

### Customize File Names by Using the MATLAB Coder App

- 1 On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow .
- 2 Set **Build type** to one of the following:
  - Source Code
  - Static Library
  - Dynamic Library
  - Executable
- 3 Click **More Settings**.
- 4 Enter the macro on the **Code Appearance** tab, next to **Generated source and header files**:

For example, suppose you set the macro to the value `ec_ $N$M`. For an entry-point function called `foo`, when name mangling is not required, the generated file name for `foo` becomes `ec_ foo`. If name mangling is required, the generated file name includes the name mangling text.

### Customize Generated File Names by Using the Command-Line Interface

- 1 Create a code generation configuration object for a library or executable program. For example:
 

```
cfg = coder.config('lib', 'ecoder', true);
```

- 2 Specify the file name macro as a character vector in the `CustomFileNameStr` object property. For example:

```
cfg.CustomFileNameStr = 'ec_$$M$M';
```

For an entry-point function called `foo`, when name mangling is not required, the generated file name for `foo` becomes `ec_foo`. If name mangling is required, the generated file name includes the name mangling text.

## Control Signed Left Shifts in Generated Code

### In this section...

“Control Signed Left Shifts Using the MATLAB Coder App” on page 97-22

“Control Signed Left Shifts Using the Command-Line Interface” on page 97-22

If you have an Embedded Coder license, you can control whether MATLAB Coder replaces multiplications by powers of two with signed left bitwise shifts. Some coding standards, such as MISRA, do not allow bitwise operations on signed integers.

By default, MATLAB Coder replaces multiplication by powers of two with signed left shifts. Here is an example of generated C code that uses a signed left shift for multiplication by eight.

```
i <<= 3;
```

To increase the likelihood of generating MISRA C:2012 compliant code, disable the replacement of multiplication by powers of two with signed left shifts. Here is an example of generated C code that does not use a signed left shift for multiplication by eight:

```
i = i * 8;
```

### Control Signed Left Shifts Using the MATLAB Coder App

- 1 On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow .
- 2 Set **Build type** to one of the following:
  - Source Code
  - Static Library (.lib)
  - Dynamic Library (.dll)
  - Executable (.exe)
- 3 Click **More Settings**.
- 4 On the **Code Appearance** tab, select or clear the **Use signed shift left for fixed-point operations and multiplication by powers of 2** check box.

### Control Signed Left Shifts Using the Command-Line Interface

- 1 Create a code configuration object for 'lib', 'dll', or 'exe'. For example:

```
cfg = coder.config('lib','ecoder',true); % or dll or exe
```

- 2 Set the `EnableSignedLeftShifts` property to true or false. For example:

```
cfg.EnableSignedLeftShifts = false;
```

## Control Data Type Casts in Generated Code

### In this section...

“Specify Casting Mode Using the MATLAB Coder App” on page 97-24

“Specify Casting Mode Using the Command-Line Interface” on page 97-24

If you have an Embedded Coder license, you can control data type casts in C/C++ code generated from MATLAB code. You can specify one of the following casting modes.

Casting Mode	Description
Nominal	<p>Nominal casting mode is the default casting mode. Generated C/C++ code uses the default C compiler data type casting. When you do not have special data type information requirements, choose this option. Here is an example of code generated using nominal casting mode:</p> <pre data-bbox="865 835 1166 1115"> short addone(short x) {     int i;     i = x + 1;     if (i &gt; 32767) {         i = 32767;     }      return (short)i; } </pre>
Standards Compliant	<p>Generated C/C++ code has data type casts that conform to MISRA standards. The MISRA data type casting eliminates common MISRA standard violations, including address arithmetic and assignment. It reduces 10.1, 10.2, 10.3, and 10.4 violations. Here is an example of code generated using standards-compliant casting mode:</p> <pre data-bbox="865 1381 1198 1661"> short addone(short x) {     int i;     i = (int)x + (int)1;     if (i &gt; (int)32767) {         i = (int)32767;     }      return (short)i; } </pre>

Casting Mode	Description
Explicit	<p>Generated C/C++ code has explicit data type casts. Explicit data type casts provide information about the amount of memory that the variable uses and the level of precision for calculations using the variable. Here is an example of code generated using explicit casting mode:</p> <pre data-bbox="865 512 1162 795"> short addone(short x) {     int i;     i = (int)x + 1;     if (i &gt; 32767) {         i = 32767;     }      return (short)i; } </pre>

## Specify Casting Mode Using the MATLAB Coder App

- 1 On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow .
- 2 Set **Build type** to one of the following:
  - Source Code
  - Static Library (.lib)
  - Dynamic Library (.dll)
  - Executable (.exe)
- 3 Click **More Settings**.
- 4 On the **All Settings** tab, under **Advanced**, set **Casting mode** to one of the following values:
  - Nominal
  - Standards Compliant
  - Explicit

## Specify Casting Mode Using the Command-Line Interface

- 1 Create a code configuration object for 'lib', 'dll', or 'exe'. For example:

```
cfg = coder.config('lib','ecoder',true); % or dll or exe
```

- 2 Set the `CastingMode` property to one of the following values:

- 'Nominal'
- 'Standards'
- 'Explicit'

For example:

```
cfg.CastingMode = 'Standards';
```

## Simplify Multiply Operations for Array Indexing in Loops

If you use Embedded Coder to generate C/C++ code from MATLAB code, you can enable an optimization that simplifies array indexing in loops in the generated code. When possible, for array indices in loops, this optimization replaces multiply operations with add operations. Multiply operations can be expensive. This optimization, referred to as strength reduction, is useful when the C/C++ compiler on the target platform does not optimize the array indexing.

Here is code generated without the optimization:

```
for (i = 0; i < 10; i++) {
 z[5 * (1 + i) - 1] = x[5 * (1 + i)];
}
```

Here is code generated with the optimization:

```
for (b_i = 0; b_i < 10; b_i++) {
 z[i + 4] = x[i + 5];
 i += 5;
}
```

By default, the strength reduction optimization is disabled. To enable it:

- At the command line, set the configuration object parameter `EnableStrengthReduction` to `true`.
- In the MATLAB Coder app, project build settings, on the **All Settings** tab, set **Simplify array indexing** to Yes.

Even when the optimization replaces the multiply operations in the generated code, it is possible that the C/C++ compiler can generate multiply instructions.

## Generate SIMD Code for MATLAB Functions

You can generate single instruction, multiple data (SIMD) code from certain MATLAB functions by using Intel SSE and, if you have Embedded Coder, Intel AVX technology. SIMD is a computing paradigm in which a single instruction processes multiple data. Many modern processors have SIMD instructions that, for example, perform several additions or multiplications at once. For computationally intensive operations among supported functions, SIMD intrinsics can significantly improve the performance of the generated code on Intel platforms.

### MATLAB Functions That Support SIMD Code

When certain conditions are met, you can generate SIMD code by using Intel SSE or Intel AVX technology. The following table lists MATLAB functions that support SIMD code generation. The table also details the conditions under which the support is available.

MATLAB Function	Conditions
plus	<ul style="list-style-type: none"> <li>For AVX, SSE, and FMA, the input signal has a data type of <code>single</code> or <code>double</code>.</li> <li>For AVX2, SSE4.1, and SSE2, the input signal has a data type of <code>single</code>, <code>double</code>, <code>int8</code>, <code>int16</code>, <code>int32</code> or <code>int64</code>.</li> <li>For AVX512F, the input signal has a data type of <code>single</code> or <code>double</code>.</li> <li>For integer data types, the value of <b>Saturate on integer overflow</b> is set to <code>No</code>.</li> </ul>
minus	<ul style="list-style-type: none"> <li>For AVX, SSE, and FMA, the input signal has a data type of <code>single</code> or <code>double</code>.</li> <li>For AVX2, SSE4.1, and SSE2, the input signal has a data type of <code>single</code>, <code>double</code>, <code>int8</code>, <code>int16</code>, <code>int32</code> or <code>int64</code>.</li> <li>For AVX512F, the input signal has a data type of <code>single</code> or <code>double</code>.</li> <li>For integer data types, the value of <b>Saturate on integer overflow</b> is set to <code>No</code>.</li> </ul>
times	<ul style="list-style-type: none"> <li>For AVX, SSE, and FMA, the input signal has a data type of <code>single</code> or <code>double</code>.</li> <li>For AVX2, SSE4.1, and SSE2, the input signal has a data type of <code>single</code>, <code>double</code>, <code>int16</code>, or <code>int32</code>.</li> <li>For AVX512F, the input signal has a data type of <code>single</code> or <code>double</code>.</li> <li>For integer data types, the value of <b>Saturate on integer overflow</b> is set to <code>No</code>.</li> </ul>
rdivide	The input signal has a data type of <code>single</code> or <code>double</code> .

MATLAB Function	Conditions
sqrt	The input signal has a data type of single or double.
ceil	<ul style="list-style-type: none"> <li>• For AVX2, AVX, SSE4.1, SSE2, and SSE, the input signal has a data type of single or double.</li> <li>• AVX512F is not supported.</li> </ul>
floor	<ul style="list-style-type: none"> <li>• For AVX2, AVX, SSE4.1, SSE2, and SSE, the input signal has a data type of single or double.</li> <li>• AVX512F is not supported.</li> </ul>
max	<ul style="list-style-type: none"> <li>• The input signal has a data type of single or double.</li> <li>• The value of the <b>Support nonfinite numbers</b> parameter is set to off.</li> </ul>
min	<ul style="list-style-type: none"> <li>• The input signal has a data type of single or double.</li> <li>• The value of the <b>Support nonfinite numbers</b> parameter is set to off.</li> </ul>
sum	<ul style="list-style-type: none"> <li>• For AVX, SSE, and FMA, the input signal has a data type of single or double.</li> <li>• For AVX2, SSE4.1, and SSE2, the input signal has a data type of single, double, int8, int16, int32 or int64.</li> <li>• For AVX512F, the input signal has a data type of single or double.</li> <li>• The <b>Optimize reductions</b> configuration parameter is set to on.</li> <li>• For integer data types, the value of <b>Saturate on integer overflow</b> is set to No.</li> </ul>
prod	<ul style="list-style-type: none"> <li>• For AVX, SSE, and FMA, the input signal has a data type of single or double.</li> <li>• For AVX2, SSE4.1, and SSE2, the input signal has a data type of single, double, int16, or int32.</li> <li>• For AVX512F, the input signal has a data type of single or double.</li> <li>• The <b>Optimize reductions</b> configuration parameter is set to on.</li> <li>• For integer data types, the value of <b>Saturate on integer overflow</b> is set to No.</li> </ul>

MATLAB Function	Conditions
bitand	<ul style="list-style-type: none"> <li>For SSE2, the input signal has a data type of int8, int16, int32, or int64.</li> <li>For AVX2, and AVX512F, the input signal has a data type of int8, int16, int32, or int64.</li> </ul>
bitor	<ul style="list-style-type: none"> <li>For SSE2, the input signal has a data type of int8, int16, int32, or int64.</li> <li>For AVX2, and AVX512F, the input signal has a data type of int8, int16, int32, or int64.</li> </ul>
bitxor	<ul style="list-style-type: none"> <li>For SSE2, the input signal has a data type of int8, int16, int32, or int64.</li> <li>For AVX2, and AVX512F, the input signal has a data type of int8, int16, int32, or int64.</li> </ul>
bitshift	<ul style="list-style-type: none"> <li>The input signal has a data type of int32.</li> </ul>

If you have a DSP System Toolbox, you can generate SIMD code from certain MATLAB System objects. For more information, see “System objects in DSP System Toolbox that Support SIMD Code Generation” (DSP System Toolbox).

If you have the Embedded Coder Support Package for ARM Cortex-A Processors, you can generate SIMD code optimized for ARM Cortex A processors by setting the **Code replacement library** parameter to GCC ARM Cortex-A. You will also need to set the **Device vendor** parameter to ARM Compatible and the **Device type** parameter to ARM Cortex-A.

## Generate SIMD Code Versus Plain C Code

Consider the MATLAB function `dynamic`. This function consists of addition and multiplication operations between the variable-size arrays A and B. These arrays have a data type of `single` and an upper bound of  $100 \times 100$ .

```
function C = dynamic(A, B)
 assert(all(size(A) <= [100 100]));
 assert(all(size(B) <= [100 100]));
 assert(isa(A, 'single'));
 assert(isa(B, 'single'));

 C = zeros(size(A), 'like', A);
 for i = 1:numel(A)
 C(i) = (A(i) .* B(i)) + (A(i) .* B(i));
 end
end
```

To generate plain C code at the command line:

- 1 For C library code generation, create a code generation configuration object.

```
cfg = coder.config('lib');
```

- 2 To generate a static library in the default location, `codegen\lib\dynamic`, use the `codegen` function.

```
codegen('-config', cfg, 'dynamic');
```

- 3 In the list of generated files, click `dynamic.c`. In the plain (non-SIMD) C code, each loop iteration produces one result.

```
void dynamic(const float A_data[], const int A_size[2], const float B_data[],
 const int B_size[2], float C_data[], int C_size[2])
{
 float C_data_tmp;
 int i;
 int loop_ub;
 (void)B_size;
 C_size[0] = (signed char)A_size[0];
 C_size[1] = (signed char)A_size[1];
 loop_ub = (signed char)A_size[0] * (signed char)A_size[1];
 if (0 <= loop_ub - 1) {
 memset(&C_data[0], 0, loop_ub * sizeof(float));
 }
 loop_ub = A_size[0] * A_size[1];
 for (i = 0; i < loop_ub; i++) {
 C_data_tmp = A_data[i] * B_data[i];
 C_data[i] = C_data_tmp + C_data_tmp;
 }
}
```

To generate SIMD C code at the command line:

- 1 For C library code generation, use the `coder.config` function to create a code generation configuration object.

```
cfg = coder.config('lib');
```

- 2 Set the `coder.HardwareImplementation` object `TargetHWDeviceType` property to `'Intel->x86-64 (Linux 64)'` or `'Intel->x86-64 (Windows64)'`.

```
cfg.HardwareImplementation.TargetHWDeviceType = 'Intel->x86-64 (Windows64)';
```

- 3 Set the `coder.HardwareImplementation` object `ProdHWDeviceType` property to `'Intel->x86-64 (Linux 64)'` or `'Intel->x86-64 (Windows64)'`

```
cfg.HardwareImplementation.ProdHWDeviceType = 'Intel->x86-64 (Windows64)';
```

If you are using the MATLAB Coder app to generate code:

- Set the **Hardware Board** parameter to `None-Select` device below.
  - Set the **Device vendor** parameter to `Intel`, `AMD`, or `Generic`.
  - Set the **Device type** to `x86-64 (Linux 64)`, `x86-64 (Windows64)`, or `MATLAB Host Computer`.
- 4 Set the `InstructionSetExtensions` property to an instruction set extension that your processor supports. This example uses SSE2 for Windows.

```
cfg.InstructionSetExtensions = 'SSE2';
```

The library that you choose depends on which instruction set extension your processor supports. If you use Embedded Coder, you can also select from the instruction sets SSE, SSE4.1, AVX, AVX2, FMA, and AVX512F.

For more information, see <https://www.intel.com/content/www/us/en/support/articles/000005779/processors.html>.

If you are using the MATLAB Coder app to generate code, on the **Speed** tab, set the **Leverage target hardware instruction set extensions** parameter to an instruction set that your processor supports.

- Optionally, select the `OptimizeReductions` parameter to generate SIMD code for reduction operations such as sum and product functions.

```
cfg.OptimizeReductions = 'on';
```

If you are using the MATLAB Coder app to generate code, on the **Speed** tab, select the **Optimize reductions** parameter.

- Use the `codegen` function to generate a static library in the default location, `codegen\lib\dynamic`.

```
codegen('-config', cfg, 'dynamic');
```

- In the list of generated files, click `dynamic.c`.

```
void dynamic(const float A_data[], const int A_size[2], const float B_data[],
 const int B_size[2], float C_data[], int C_size[2])
{
 __m128 r;
 float C_data_tmp;
 int i;
 int loop_ub;
 int scalarLB;
 int vectorUB;
 (void)B_size;
 C_size[0] = (signed char)A_size[0];
 C_size[1] = (signed char)A_size[1];
 loop_ub = (signed char)A_size[0] * (signed char)A_size[1];
 if (0 <= loop_ub - 1) {
 memset(&C_data[0], 0, loop_ub * sizeof(float));
 }
 loop_ub = A_size[0] * A_size[1];
 scalarLB = (loop_ub / 4) << 2;
 vectorUB = scalarLB - 4;
 for (i = 0; i <= vectorUB; i += 4) {
 r = _mm_mul_ps(_mm_loadu_ps(&A_data[i]), _mm_loadu_ps(&B_data[i]));
 _mm_storeu_ps(&C_data[i], _mm_add_ps(r, r));
 }
 for (i = scalarLB; i < loop_ub; i++) {
 C_data_tmp = A_data[i] * B_data[i];
 C_data[i] = C_data_tmp + C_data_tmp;
 }
}
```

The SIMD instructions are the intrinsic functions that start with the identifier `_mm`. These functions process multiple data in a single iteration of the loop because the loop increments by four for single data types. For double data types, the loop increments by two. For MATLAB code that processes more data and is more computationally intensive, than the code in this example, the presence of SIMD instructions can significantly speed up the code execution time.

The second `for` loop is in the generated code because the `for` loop that contains SIMD code must be divisible by four for single data types. The second loop processes the remainder of the data.

For a list of a Intel intrinsic functions for supported MATLAB functions, see <https://www.intel.com/content/www/us/en/docs/intrinsics-guide/index.html>.

## Limitations

The generated code does not contain SIMD code when the MATLAB code meets these conditions:

- Scalar operations outside a loop. For example, if `a`, `b`, and `c` are scalars, the generated code does not contain SIMD code for an operation such as `c=a+b`.

- Indirectly indexed arrays or matrices. For example, if A, B, C, and D are vectors, the generated code does not contain SIMD code for an operation such as  $D(A) = C(A) + B(A)$ .
- Parallel for-Loops (`parfor`). The `parfor` loop does not contain SIMD code, but loops within the body of the `parfor` loop might contain SIMD code.
- Polyspace does not support analysis of generated code that includes SIMD instructions. Disable SIMD code generation by setting the **Leverage target hardware instruction set extensions** parameter to `None`.
- Reduction operations that operate on floating-point values when support for nonfinite numbers is enabled. To generate SIMD code for reduction operations that operate on floating-point values, in the MATLAB Coder app, set **Support nonfinite numbers** to `No`. Or, in a code generation configuration object, set the `SupportNonFinite` property to `false`.

## Generate C/C++ Code with Improved MISRA Compliance

The Motor Industry Software Reliability Association (MISRA)<sup>10</sup> has established “Guidelines for the Use of the C Language in Critical Systems” (MISRA C). When you generate code from MATLAB code, if you have Embedded Coder, you can configure certain code generation parameters to increase the likelihood of generating C and C++ code that comply with the MISRA C:2012 and MISRA C++:2008 guidelines.

The following describes the separate command line and app workflows.

### Configure Code Generation Configuration Object Properties

- 1 Create an Embedded Coder code generation configuration object.

```
cfg = coder.config('lib', 'ecoder', true);
```

- 2 Set the properties listed in the table to the values for improved MISRA compliance.

Property	Value for Improved MISRA Compliance
CastingMode	'Standards'
CppNamespace	Any valid namespace name for C++
DataTypeReplacement	'CoderTypedefs'
DynamicMemoryAllocation	'Off'
EnableRuntimeRecursion	false
EnableSignedLeftShifts	false
EnableSignedRightShifts	false
GenerateDefaultInSwitch	true
ParenthesesLevel	'Maximum'
RuntimeChecks	false
TargetLangStandard	'C99 (ISO)' for C, 'C++03 (ISO)' for C++

To set these properties in one step, use `coder.setupMISRAConfig`.

```
coder.setupMISRAConfig(cfg);
```

Alternatively, set properties individually. For example:

```
cfg.CastingMode = 'Standards';
```

If the `CppNamespace` property is unset, and the `TargetLang` property is 'C++', then `coder.setupMISRAConfig` sets the `CppNamespace` property to a default character vector, 'Codegen'. Modify this value to a namespace name that is particular to your project.

- 3 Pass the configuration object to `codegen` by using the `-config` option.

```
codegen myFunction -config cfg ...
```

<sup>10</sup> MISRA and MISRA C are registered trademarks of HORIBA MIRA Ltd., held on behalf of the MISRA Consortium.

## Configure MATLAB Coder App Settings

- 1 On the **Generate Code** page, set **Build type** to Source Code, Static Library, Dynamic Library, or Executable.
- 2 Click **More Settings**.
- 3 Click **MISRA Compliance**.

The app displays the settings that might impact MISRA compliance.

Use the following settings to improve MISRA compliance of generated code.

Setting	Current Value	Recommended Value
Dynamic memory allocation	For arrays with max size at or above thres...	Never
Enable run-time recursion	Yes	No
Use signed shift left for fixed-point ...	Yes	No
Allow right shifts on signed integers	Yes	No
Casting mode	Nominal	Standards Compliant
Data Type Replacement	Use built-in C data types in the generated ...	Use MathWorks typedefs in the generated
Parentheses	Nominal (Optimize for readability)	Maximum (Specify precedence with parer
Always generate a default case for s...	No	Yes

Set to Recommended Values

- 4 To set all of these settings to the recommended values, click **Set to Recommended Values**.

To modify an individual setting, click **All Settings**, and then search for the setting.

## Additional Settings for MISRA C++ Compliance

By default, the C++ code that you generate uses a custom type definition for `bool` to maximize compatibility with certain precompiled libraries. This custom type definition can cause violations for MISRA C++:2008 Rule 5-0-13 and Rule 5-3-1.

To use the built-in `bool` type in generated C++ code, and avoid these violations, change the **Hardware Board** setting in the configuration object from MATLAB Host Computer. To see how to change this setting in the App, see “Access Hardware Implementation Properties with a Dialog Box”. For example, for code generation and build on a 64-bit Windows platform, change the **Hardware Board** to `None - Select device below`, and then set **Device vendor** to `Intel` and **Device type** to `x86-64 (Windows64)`.

## Customize Data Type Replacement

While generating C/C++ code from MATLAB code, the **Data Type Replacement** option enables you to use built-in C data types or MathWorks typedefs in the generated code. Code generation supports these data types for custom renaming: double, single, uint8, uint16, uint32, uint64, int8, int16, int32, int64, char, and logical.

The **Data Type Replacement** option is available in the **Generate Code** window (**More Settings**), on the **Code Appearance** tab. You can select one of these options:

- Use built-in C data types in the generated code
- Use MathWorks typedefs in the generated code

**Note** The code generator does not replace variable-size character arrays with `char*` type strings in the generated code.

If you have Embedded Coder installed, you can specify custom names for MATLAB built-in data types in the generated C/C++ code. For example, you can customize double as `Custom_Double`.

## Specify Custom Data Type Names by Using the MATLAB Coder App

To specify custom names for the MATLAB data types:

- 1 Open the MATLAB Coder app.
- 2 Navigate to the **Generate Code** step.
- 3 Click **More Settings**.
- 4 In the **Code Appearance** tab, select **Enable custom data type replacement** under **Custom Data Type Replacement**.
- 5 The table lists the name of the supported data types. Specify your custom names for these data types and press **Enter**. The specified custom names replace the built-in data type names in the generated code. If you do not specify a custom name, the code generator uses a default name.

## Specify Custom Data Type Names by Using the Command-Line Interface

Use the `EnableCustomReplacementTypes` and `ReplacementTypes` properties in an Embedded Coder configuration object when you generate code by using `codegen`.

- 1 Write a MATLAB function from which you can generate code. This example uses the function `myAdd` that returns the sum of its inputs.

```
function c = myAdd(a,b)
c = a + b;
end
```

- 2 Create a code configuration object for generation of a static library.

```
cfg = coder.config('lib','ecoder',true);
```

- 3 Set the `EnableCustomReplacementTypes` property to `true`.

```
cfg.EnableCustomReplacementTypes = true;
```

- 4 Specify custom name for the data types. Here, the built-in data type name `uint8` is customized to `Custom_Uint8`.

```
cfg.ReplacementTypes.uint8 = "Custom_Uint8";
```

- 5 Generate code by using `codegen` and `-config` option.

```
codegen myAdd.m -args {1,uint8(1)} -config cfg -report
```

## More About

- “Import Custom Data Type Definitions from External Header Files” on page 97-38

## Import Custom Data Type Definitions from External Header Files

By default, MATLAB Coder uses the predefined data types in the generated code. You can use customized data type names by importing custom type definitions from external header files. You can then use your own type definitions in the generated C/C++ code. If you have existing legacy code, you can integrate that code, in the generated C/C++ code. You can import a header file by using either the MATLAB Coder app or the command-line interface.

### Import Custom Types by Using the MATLAB Coder App

To import custom types from external header files:

- 1 Open the MATLAB Coder app and proceed to the **Generate Code** page.
- 2 Click **More Settings**.
- 3 In the **Code Appearance** tab, select **Enable custom data type replacement**.
- 4 Specify your custom names for the data types in **Enable custom data type replacement** table and press **Enter**.
- 5 Select the **Import custom types from external header files** check box.

- 6 In the **Header files** text field, enter a semicolon-separated list of external header file names and press **Enter**. For example, `myHeader1.h;myHeader2.h;myHeader3.h`.

## Import Custom Types by Using the Command-Line Interface

Use the `ReplacementTypes.IsExtern` and `ReplacementTypes.HeaderFiles` properties in a `coder.EmbeddedCodeConfig` object when you generate code by using `codegen`.

- 1 Create a code configuration object for generation of a static library.

```
cfg = coder.config('lib','ecoder',true);
```

- 2 Specify custom names for the data types. For example, `double` is named as `Custom_Double` and `int8` is named as `Custom_Int8` in the code.

```
cfg.EnableCustomReplacementTypes = true;
cfg.ReplacementTypes.double = "Custom_Double";
cfg.ReplacementTypes.int8 = "Custom_Int8";
```

- 3 Specify configuration properties for importing the external header files.

```
% Include single header file
```

```
cfg.ReplacementTypes.IsExtern = true;
cfg.ReplacementTypes.HeaderFiles = "myHeader.h";
cfg.CustomInclude = 'C:\myFiles'; % Include path of the header file
```

```
% Include multiple header files
```

```
cfg.ReplacementTypes.IsExtern = true;
cfg.ReplacementTypes.HeaderFiles = "myHeader1.h;myHeader2.h;myHeader3.h";
cfg.CustomInclude = 'C:\Program Files\MATLAB\myFiles'; % Include path of the header files
```

For more information on `CustomInclude`, see “Configure Build by Using the Configuration Object”.

- 4 Generate code by using `codegen` and the `-config` option.

```
codegen myAdd.m -args {1,int8(1)} -config cfg -report
```

## MATLAB Code Patterns That Require a Nonempty Initialize Function in Generated Code

### Issue

When generating standalone code from MATLAB code, you choose not to generate the initialize function:

- In a `coder.EmbeddedCodeConfig` object, `IncludeInitializeFcn` is set to `false`.
- Alternatively, in the MATLAB Coder app, on the **All Settings** tab, **Initialize Function Required** is set to **No**.

Also, you ensure that the custom code to appear in the generated initialize function is empty:

- In a `coder.EmbeddedCodeConfig` object, `CustomInitializer` is set to `''`.
- Alternatively, in the MATLAB Coder app, on the **Custom Code** tab, **Custom C Code for Generated Files** for initialize function is empty.

You still get this error message:

```
The initialize function is not empty, but the IncludeInitializeFcn configuration setting requests the initialize function be omitted.
```

### Solution

In certain situations, the code generator determines that the initialize function must be nonempty and produces code for the initialize function. This code generation can occur even if the custom code for the initialize function that you specify is empty. Not including this generated code in the initialize function causes the generated entry-point functions to operate on an invalid state. In such situations, if you choose to not generate the initialize function, the code generator produces an error message.

To fix this issue, include the initialize function in your generated code by doing one of the following:

- In a `coder.EmbeddedCodeConfig` object, set `IncludeInitializeFcn` to `true` (this value is the default value).
- In the MATLAB Coder app, on the **All Settings** tab, set **Initialize Function Required** to **Yes** (this setting is the default setting).

Examples of MATLAB code patterns that require a nonempty initialize function in the generated code are:

- Your MATLAB code contains an operation that can generate nonfinite values (`Inf` or `NaN`). For example, define a MATLAB function `foo` that calls `factorial`. The `factorial` function grows quickly and returns `Inf` for inputs greater than a certain threshold. For an input of type `double`, the threshold is 170. Executing `factorial(171)` in MATLAB returns `Inf`.

```
function y = foo(a)
y = factorial(a);
end
```

Generate a static library for `foo`. In the `coder.EmbeddedCodeConfig` object `cfg`, set the parameter `CustomInitializer` to an empty character array. Set the parameter `IncludeInitializeFcn` to `true`. These values are the default values for the parameters.

```
cfg = coder.config('lib');

cfg.CustomInitializer = ''; %These are the default values
cfg.IncludeInitializeFcn = true;

codegen -config cfg foo -args {1}
```

The code generator automatically produces a nonempty initialize function `foo_initialize` that calls supporting code for nonfinite data. This function calls `rt_InitInfAndNaN`, which is defined in another generated file `rt_nonfinite.c`.

```
/* Include Files */
#include "foo_initialize.h"
#include "foo.h"
#include "foo_data.h"
#include "rt_nonfinite.h"

/* Function Definitions */

/*
 * Arguments : void
 * Return Type : void
 */
void foo_initialize(void)
{
 rt_InitInfAndNaN();
 isInitialized_foo = true;
}

/*
 * File trailer for foo_initialize.c
 *
 * [EOF]
 */
```

- Your MATLAB code uses global or persistent variables. For example, define this MATLAB function:

```
function y = bar
global g
y = g;
end
```

Generate a static library for `bar`. Specify the initial value of `g` as 1. In the `coder.EmbeddedCodeConfig` object `cfg`, set the parameter `CustomInitializer` to an empty character array. Set the parameter `IncludeInitializeFcn` to `true`. These values are the default values for the parameters.

```
cfg = coder.config('lib');

cfg.CustomInitializer = ''; %These are the default values
cfg.IncludeInitializeFcn = true;

codegen -config cfg -globals {'g',1} bar
```

The code generator automatically produces a nonempty initialize function `bar_initialize` that initializes `g`.

```
/* Include Files */
#include "bar_initialize.h"
#include "bar.h"
#include "bar_data.h"

/* Function Definitions */

/*
 * Arguments : void
 * Return Type : void
 */
void bar_initialize(void)
{
 g = 1.0;
 isInitialized_bar = true;
}

/*
 * File trailer for bar_initialize.c
 *
 * [EOF]
 */
```

# Storage Classes for Code Generation from MATLAB Code

---

- “Storage Classes for Code Generation from MATLAB Code” on page 98-2
- “Control Declarations and Definitions of Global Variables in Code Generated from MATLAB Code” on page 98-4

## Storage Classes for Code Generation from MATLAB Code

If you have an Embedded Coder license, you can use storage classes to control the declaration and definition of a global variable in the generated C/C++ code.

In the context of code generation, a storage class is a specification that determines the declaration and definition of a variable in the generated code. For code generation, the term storage class is not the same as the C language term storage class specifier.

Storage classes help you to integrate generated code with external code. You can make a generated variable visible to external code. You can also make variables declared in the external code visible to the generated code. For code generation from MATLAB code, you can use storage classes with global variables only. The storage class determines:

- The file placement of a global variable declaration and definition.
- Whether the global variable is imported from external code or exported for use by external code.

To assign a storage class to a global variable, in your MATLAB code, use the `coder.storageClass` function. Only when you use an Embedded Coder project or configuration object for generation of C/C++ libraries or executables does the code generator recognize `coder.storageClass` calls.

The syntax for `coder.storageClass` is:

```
coder.storageClass(global_name, storage_class)
```

`global_name` is the name of a global variable, specified as a character vector. `global_name` must be a compile-time constant.

`storage_class` can be one of the following values.

Storage Class	Description
'ExportedGlobal'	<ul style="list-style-type: none"> <li>• Defines the variable in the Variable Definitions section of the C file <code>entry_point_name.c</code>.</li> <li>• Declares the variable as an extern in the Variable Declarations section of the header file <code>entry_point_name.h</code></li> <li>• Initializes the variable in the function <code>entry_point_name_initialize.h</code>.</li> </ul>
'ExportedDefine'	Declares the variable with a <code>#define</code> directive in the Exported data define section of the header file <code>entry_point_name.h</code> .
'ImportedExtern'	Declares the variable as an extern in the Variable Declarations section of the header file <code>entry_point_name_data.h</code> . The external code must supply the variable definition.
'ImportedExternPointer'	Declares the variable as an extern pointer in the Variable Declarations section of the header file <code>entry_point_name_data.h</code> . The external code must define a valid pointer variable.

Storage classes have these requirements and limitations:

- Assign the storage class to a global variable in a function that declares the global variable. You do not have to assign the storage class in more than one function.
- After you assign a storage class to a global variable, you cannot assign a different storage class to that global variable.
- You cannot assign a storage class to a constant global variable.
- A global variable with an `ExportedDefine` storage class must be a scalar but not a complex or multi-word scalar. The global variable must only be read and not written to in the code.

If you do not assign a storage class to a global variable, except for the declaration location, the variable behaves like it has an `'ExportedGlobal'` storage class. For an `'ExportedGlobal'` storage class, the global variable is declared in the file `entry_point_name.h`. When the global variable does not have a storage class, the variable is declared in the file `entry_point_name_data.h`.

## Related Examples

- “Control Declarations and Definitions of Global Variables in Code Generated from MATLAB Code” on page 98-4
- “Generate Code for Global Data”

## Control Declarations and Definitions of Global Variables in Code Generated from MATLAB Code

This example uses storage classes to control the declarations and definitions of global variables in C/C++ code generated from MATLAB code. Using storage classes helps you to interface generated code with external code.

This example requires an Embedded Coder license.

Write a function `addglobals` that adds four global variables. Declare the global variables in the function.

```
function y = addglobals %#codegen
% Define the global variables.
global u;
global v;
global x;
global z;

% Assign the storage classes.
coder.storageClass('u','ExportedGlobal');
coder.storageClass('v','ImportedExtern');
coder.storageClass('x','ImportedExternPointer');
coder.storageClass('z','ExportedDefine');
y = u + v + x + z;
end
```

Create a file `c:\myfiles\myfile.c` that defines and initializes the imported global variables `u` and `v`.

```
#include <stdio.h>

/* Variable definitions for imported variables */
double v = 1.0;
double *x = &v;
```

Create a code configuration object. Configure the code generation parameters to include `myfile.c`. For output type `'lib'`, or if you generate source code only, you can generate code without providing this file. Otherwise, you must provide this file.

```
cfg = coder.config('dll','ecoder', true);
cfg.CustomSource = 'myfile.c';
cfg.CustomInclude = 'c:\myfiles';
```

Generate the code. This example uses the `-globals` argument to specify the types and initial values of the global variables `u`, `v`, `x`, and `z`. Alternatively, you can define global variables in the MATLAB global workspace. For the imported global variables `v` and `x`, the code generator uses the initial values only to determine the type.

```
codegen -config cfg -globals {'u', 1, 'v', 2, 'x', 3, 'z', 4} addglobals -report
```

From the initial values 1, 2, 3, and 4 `codegen` determines that `u`, `v`, `x` and `z` have type `double`. `codegen` defines and declares the exported global variables `u` and `z`. It generates code that initializes `u` to 1.0 and `z` to 4.0. `codegen` declares the imported global variables `v` and `x`. It does not define these variables or generate code that initializes them. `myfile.c` provides the code that defines and initializes `v` and `x`.

To view the code generated for the global variables, open the report. Click the **View report** link.

View the definition for the exported global `z` in the Exported data define section in `addglobals.h`.

```
/* Definition for custom storage class: ExportedDefine */
#define z 4.0
```

View the definition and declaration for the exported global `u`.

- `u` is defined in the Variable Definitions section in `addglobals.c`.

```
/* Variable Definitions */
/* Definition for custom storage class: ExportedGlobal */
double u;
```

- `u` is declared as `extern` in the Variable Declarations section in `addglobals.h`.

```
/* Variable Declarations */
/* Declaration for custom storage class: ExportedGlobal */
extern double u;
```

- `u` is initialized in `addglobals_initialize.c`.

```
/* Include Files */
#include "addglobals_initialize.h"
#include "addglobals.h"
#include "addglobals_data.h"

/* Function Definitions */

/*
 * Arguments : void
 * Return Type : void
 */
void addglobals_initialize(void)
{
 u = 1.0;
 isInitialized_addglobals = true;
}
```

View the definition and declaration for the imported external global `v` and the imported external global pointer `x`.

`v` and `x` are declared as `extern` in the Variable Declarations section in `addglobals_data.h`.

```
/* Variable Declarations */
/* Declaration for custom storage class: ImportedExtern */
extern double v;
```

```
/* Declaration for custom storage class: ImportedExternPointer */
extern double *x;
```

## Highlight Potential Data Type Issues in a Report

### In this section...

“Enable Highlight Option Using the MATLAB Coder App” on page 99-2

“Enable Highlight Option Using the Command Line Interface” on page 99-2

If you have Embedded Coder, you have the option to highlight potential data types issues in the code generation report for standalone code generated from MATLAB code. If you enable this option, on the **Code Insights** tab, the report identifies single-precision and double-precision operations in the generated C/C++ code. If you have Fixed-Point Designer, the report also identifies expensive fixed-point operations.

To view potential data type issues in a code generation report:

- 1 Click the **Code Insights** tab.
- 2 Expand the **Potential data type issues** section.
- 3 Expand the data type issues section that you want to see.

For example, this report identifies MATLAB code that results in double-precision operations in the generated code.

The option to highlight potential data type issues is disabled by default.

### Enable Highlight Option Using the MATLAB Coder App

- 1 On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow .
- 2 Set **Build type** to one of the following:
  - Source Code
  - Static Library (.lib)
  - Dynamic Library (.dll)
  - Executable (.exe)
- 3 Click **More Settings**.
- 4 On the **Debugging** tab, select the **Always create a report** and **Highlight potential data type issues** check boxes.

### Enable Highlight Option Using the Command Line Interface

- 1 Create an embedded code configuration object for 'lib', 'dll', or 'exe':
 

```
cfg = coder.config('lib','ecoder',true); % or dll or exe
```

- 2 Set the `GenerateReport` and `HighlightPotentialDataTypeIssues` configuration object properties to `true`:

```
cfg.GenerateReport = true;
cfg.HighlightPotentialDataTypeIssues = true;
```

## See Also

## Find Potential Data Type Issues in Generated Code

### In this section...

- “Data Type Issues Overview” on page 99-4
- “Enable Highlighting of Potential Data Type Issues” on page 99-4
- “Find and Address Cumbersome Operations” on page 99-5
- “Find and Address Expensive Rounding” on page 99-5
- “Find and Address Expensive Comparison Operations” on page 99-6
- “Find and Address Multiword Operations” on page 99-7

### Data Type Issues Overview

When you generate C code from MATLAB code, you can highlight potential data type issues in the C code generation report. The report highlights MATLAB code that requires single-precision, double-precision, or expensive fixed-point operations. The expensive fixed-point operations checks require a Fixed-Point Designer.

- The double-precision check highlights expressions that result in a double-precision operation. When trying to achieve a strict-single or fixed-point design, manual inspection of code can be time-consuming and error prone.

For a strict-single precision design, specify a language standard that supports single-precision implementations. To change the library for a project, during the Generate Code step, in the project settings dialog box, on the **Custom Code** tab, set the **Language standard** to C99 (ISO).

- The single-precision check highlights expressions that result in a single operation.
- The expensive fixed-point operations check identifies optimization opportunities for fixed-point code. It highlights expressions in the MATLAB code that require cumbersome multiplication or division, expensive rounding, expensive comparison, or multiword operations. For more information on optimizing generated fixed-point code, see “Tips for Making Generated Code More Efficient” (Fixed-Point Designer).

### Enable Highlighting of Potential Data Type Issues

#### Enable the highlight option using the MATLAB Coder app

- 1** On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow .
- 2** Set **Build type** to one of the following:
  - Source Code
  - Static Library (.lib)
  - Dynamic Library (.dll)
  - Executable (.exe)
- 3** Click **More Settings**.
- 4** On the **Debugging** tab, select the **Always create a report** and **Highlight potential data type issues** check boxes.

## Enable the highlight option using the command-line interface

- 1 Create an embedded code configuration object for 'lib', 'dll', or 'exe':

```
cfg = coder.config('lib','ecoder',true); % or dll or exe
```

- 2 Set the GenerateReport and HighlightPotentialDataTypeIssues configuration object properties to true:

```
cfg.GenerateReport = true;
cfg.HighlightPotentialDataTypeIssues = true;
```

## Find and Address Cumbersome Operations

Cumbersome operations usually occur due to an insufficient range of output. Avoid inputs to a multiply or divide operation that have word lengths larger than the base integer type of your processor. Software can process operations with larger word lengths, but this approach requires more code and runs slower.

This example requires Embedded Coder and Fixed-Point Designer. The target word length for the processor in this example is 64.

- 1 Create the function myMul.

```
function out = myMul(in1, in2)
 out = fi(in1*in2, 1, 64, 0);
end
```

- 2 Generate code for myMul.

```
cfg = coder.config('lib');
cfg.GenerateReport = true;
cfg.HighlightPotentialDataTypeIssues = true;
fm = fimath('ProductMode', 'SpecifyPrecision', 'ProductWordLength', 64);
codegen -config cfg myMul -args {fi(1, 1, 64, 4, fm), fi(1, 1, 64, 4, fm)}
```

- 3 Click **View report**.

- 4 In the code generation report, click the **Code Insights** tab.

- 5 Expand the **Potential data type issues** section. Then, expand the **Expensive fixed-point operations** section.

The report flags the expression `in1 * in2`. To resolve the issue, modify the data types of `in1` and `in2` so that the word length of the product does not exceed the target word length of 64.

## Find and Address Expensive Rounding

Traditional handwritten code, especially for control applications, almost always uses "no effort" rounding. For example, for unsigned integers and two's complement signed integers, shifting right and dropping the bits is equivalent to rounding to floor. To get results comparable to, or better than, what you expect from traditional handwritten code, use the floor rounding method.

This example requires Embedded Coder and Fixed-Point Designer.

- 1 Create the function `myRounding`.

```
function [quot] = myRounding(in1, in2)
 quot = in1 / in2;
end
```

- 2 Generate code for `myRounding`.

```
cfg = coder.config('lib');
cfg.GenerateReport = true;
cfg.HighlightPotentialDataTypeIssues = true;
codegen -config cfg myRounding -args {fi(1, 1, 16, 2), fi(1, 1, 16, 4)}
```

- 3 Click **View report**.

- 4 In the code generation report, click the **Code Insights** tab.

- 5 Expand the **Potential data type issues** section. Then, expand the **Expensive fixed-point operations** section.

SUMMARY	ALL MESSAGES (0)	BUILD LOGS	CODE INSIGHTS (1)	VARIABLES
<div style="border: 1px solid #ccc; padding: 5px;"> <div style="background-color: #f0f0f0; padding: 2px;"> <span>⊞</span> <span>📄</span> Potential data type issues (1) <i>MATLAB code that requires single-precision, double-precision, or expensive fixed-point operations.</i> </div> <div style="padding: 2px;"> <span>⊞</span> <span>📄</span> Expensive fixed-point operations           <ul style="list-style-type: none"> <li><span>↳</span> <code>myRounding</code> 2: <code>quot = in1 / in2;</code></li> </ul> </div> </div>				

The division operation `in1/in2` uses the default rounding method, nearest. Changing the rounding method to `Floor` provides a more efficient implementation.

## Find and Address Expensive Comparison Operations

Comparison operations generate extra code when a casting operation is required to do the comparison. For example, before comparing an unsigned integer to a signed integer, one of the inputs must be cast to the signedness of the other. Consider optimizing the data types of the input arguments so that a cast is not required in the generated code.

This example requires Embedded Coder and Fixed-Point Designer.

- 1 Create the function `myRelop`.

```
function out = myRelop(in1, in2)
 out = in1 > in2;
end
```

- 2 Generate code for `myRelop`.

```
cfg = coder.config('lib');
cfg.GenerateReport = true;
cfg.HighlightPotentialDataTypeIssues = true;
codegen -config cfg myRelop -args {fi(1, 1, 14, 3, 1), fi(1, 0, 14, 3, 1)}
```

- 3 Click **View report**.

- 4 In the code generation report, click the **Code Insights** tab.

- 5 Expand the **Potential data type issues** section. Then, expand the **Expensive fixed-point operations** section.

SUMMARY	ALL MESSAGES (0)	BUILD LOGS	CODE INSIGHTS (1)	VARIABLES
<div style="border: 1px solid #ccc; padding: 5px;"> <div style="background-color: #f0f0f0; padding: 2px;"> <span>⊞</span> <span>📄</span> Potential data type issues (1) <i>MATLAB code that requires single-precision, double-precision, or expensive fixed-point operations.</i> </div> <div style="padding: 2px;"> <span>⊞</span> <span>📄</span> Expensive fixed-point operations           <ul style="list-style-type: none"> <li><span>↳</span> <code>myRelop</code> 2: <code>out = in1 &gt; in2;</code></li> </ul> </div> </div>				

The first input argument, `in1`, is signed, while `in2` is unsigned. Extra code is generated because a cast must occur before the two inputs can be compared.

Change the signedness and scaling of one of the inputs to generate more efficient code.

## Find and Address Multiword Operations

Multiword operations can be inefficient on hardware. When an operation has an input or output data type larger than the largest word size of your processor, the generated code contains multiword operations. You can avoid multiword operations in the generated code by specifying local `fimath` properties for variables. You can also manually specify input and output word lengths of operations that generate multiword code.

This example requires Embedded Coder and Fixed-Point Designer. In this example, the target word length is 64.

- 1 Create the function `myMul`.

```
function out = myMul(in1, in2)
 out = in1 * in2;
end
```

- 2 Generate code for `myMul`.

```
cfg = coder.config('lib');
cfg.GenerateReport = true;
cfg.HighlightPotentialDataTypesIssues = true;
codegen -config cfg myMul -args {fi(1, 1, 33, 4), fi(1, 1, 32, 4)}
```

- 3 Click **View report**.

In the code generation report, click the **Code Insights** tab.

- 5 Expand the **Potential data type issues** section. Then, expand the **Expensive fixed-point operations** section.

- 6 The report flags the `in1 * in2` operation in line 2 of `myMul`. In the code pane, pause over `in1`, `in2`, and the expression `in1 * in2`. You see that:
  - The word length of `in1` is 33 bits and the word length of `in2` is 32 bits.
  - The word length of the expression `in1 * in2` is 65 bits.

The software detects a multiword operation because the word length 65 is larger than the target word length of 64.

- 7 To resolve this issue, modify the data types of `in1` and `in2` so that the word length of the product does not exceed the target word length. Alternatively, specify the `ProductMode` property of the local `fimath` object.

## PIL Execution with ARM Cortex-A at the Command Line

This example shows how to set up a PIL execution to verify generated code at the command line.

You can use processor-in-the-loop (PIL) executions to verify generated code that you deploy to target hardware by using a MATLAB Coder procedure. You can profile algorithm performance and speed for your generated code. To verify generated code with the MATLAB Coder app, you must have an Embedded Coder license.

This PIL execution is available with these hardware support packages. To use the PIL execution, install one of these support packages.

- Embedded Coder Support Package for BeagleBone® Black Hardware
- Embedded Coder Support Package for ARM Cortex-A Processors

In the Command Window, select the hardware for PIL execution.

```
hw = coder.hardware('ARM Cortex-A9 (QEMU)')
```

```
hw =
```

```
Hardware with properties:
```

```
 Name: 'ARM Cortex-A9 (QEMU)'
 CPUClockRate: 1000
```

When using the BeagleBone hardware, more hardware properties are supported (Username, Password, and DeviceAddress). Set these properties based on your specific hardware or application.

```
hw = coder.hardware('BeagleBone Black')
```

```
hw =
```

```
Hardware with properties:
```

```
 Name: 'BeagleBone Black'
 CPUClockRate: 1000
 Password: 'root'
 Username: 'admin'
 DeviceAddress: '192.168.1.10'
```

Add the hardware to the MATLAB Coder configuration object.

```
cfg = coder.config('lib','ecoder',true);
cfg.VerificationMode = 'PIL';
cfg.Hardware = hw;
```

Generate PIL code for a function, `averaging_filter`.

```
codegen -config cfg averaging_filter -args {zeros(1,16)}
```

For more information on the `averaging_filter` function, see “Generate Code for an Averaging Filter”.

For another example of PIL verification, see the “Processor-in-the-Loop Verification of MATLAB Functions” (Embedded Coder Support Package for ARM Cortex-A Processors) page in the

documentation of the Embedded Coder Support Package for ARM Cortex-A Processors. To install the Embedded Coder Support Package for ARM Cortex-A Processors, see “Embedded Coder Supported Hardware”.

## PIL Execution with ARM Cortex-A by Using the MATLAB Coder App

You can use processor-in-the-loop (PIL) executions to verify generated code that you deploy to target hardware by using a MATLAB Coder procedure. You can profile algorithm performance and speed for your generated code. To verify generated code with the MATLAB Coder app, you must have an Embedded Coder license.

This PIL execution is available with these hardware support packages. To use the PIL execution, install one of these support packages.

- Embedded Coder Support Package for BeagleBone Black Hardware
- Embedded Coder Support Package for ARM Cortex-A Processors

You can set up PIL execution with the MATLAB Coder app.

To configure the build type and hardware board:

- 1** On the **Generate Code** page, in the **Generate** dialog box:
  - Set the **Build type** to `Static Library`.
  - Clear the **Generate code only** check box.
  - Set the **Hardware Board** to `BeagleBone Black` or `ARM Cortex-A9 (QEMU)`.
- 2** If necessary, modify the settings for your board. To modify the settings, click **More Settings**, and then click **Hardware**.
- 3** To generate the library, click **Generate**.
- 4** Set up your PIL execution. Click **Verify Code** to open the **Verify Code** dialog box.

Because the hardware board is not MATLAB Host Computer, the **Verify Code** dialog box is configured for PIL execution.

In the **Verify Code** dialog box:

- Enter the name of the test file to use for PIL execution.
  - Select **Generated code**.
- 5** To start the PIL execution, click **Run Generated Code**.
  - 6** To stop the PIL execution, click **Stop**.

For another example of PIL verification, see the "Processor-in-the-Loop Verification of MATLAB Functions" page in the documentation of the Embedded Coder Support Package for ARM Cortex-A Processors. Install the support package to view the documentation.

## Interactively Trace Between MATLAB Code and Generated C/C++ Code

This example shows how to trace between MATLAB source code and the generated C/C++ code. Tracing between source code and generated code helps you to:

- Understand how the code generator implemented your algorithm.
- Debug issues in the generated code.
- Evaluate the quality of the generated code.

If you have Embedded Coder and enable production of a code generation report with traceability, you can view MATLAB source code and generated C/C++ code next to each other. As you move your pointer over code, you can follow highlighted traces to the corresponding generated code or source MATLAB code.

### Create the MATLAB Source Code

To illustrate interactive traceability, this example produces a report for generation of a C static library for a MATLAB function `lpsolve` that solves the linear program:

- maximize  $y = c*x$
- subject to  $A*x \leq b$
- where  $x \geq 0$  and  $b \geq 0$

#### `lpsolve`

```
%Attempts to solve the linear program:
%
% maximize y = c*x
% subject to: A*x <= b,
% where x >= 0 and b >= 0
%
% using the dictionary form of the simplex algorithm.
%
% c must be a double, real row vector.
% b must be a double, real column vector.
% A must be a double, real, non-empty matrix with
% size(A) = [length(b),length(c)].
%
% Compare to
% x = linprog(-c(:),A,b,[],[],zeros(length(c),1))
% y = c*x
%
% Copyright 2011-2018 The MathWorks, Inc.

function [x,y] = lpsolve(c,A,b)
%#codegen
narginchk(3,3);
m = int32(size(A,1));
n = int32(size(A,2));
if ~validInputs(c,A,b)
 % Something is wrong with the inputs. Return NaNs.
 x = nan(n,1);
```

```

 y = nan;
 return
 end
 cn = c;
 nIdx = 1:n; % indices of non-basic variables
 bIdx = n + (1:m); % indices of basic variables
 % Perform iterations.
 j = findPivotColumn(cn,nIdx);
 unbounded = false;
 while j > 0 && ~unbounded
 [i,r] = findPivotRow(j,A,b);
 if i == 0 || isinf(r)
 unbounded = true;
 else
 b(i) = r;
 % Take account of the variables entering and leaving the basis.
 entering = nIdx(j);
 leaving = bIdx(i);
 bIdx(i) = entering;
 nIdx(j) = leaving;
 [cn,A,b] = pivot(cn,A,b,i,j);
 j = findPivotColumn(cn,nIdx);
 end
 end
 % Construct the solution.
 if unbounded
 x = nan(n,1);
 y = inf;
 else
 x = zeros(n,1);
 y = 0;
 for k = 1:m
 j = bIdx(k);
 if j <= n
 x(j) = b(k);
 y = y + c(j)*x(j);
 end
 end
 end
end

%-----

function p = validInputs(c,A,b)
coder.inline('never');
% All inputs must be double.
p = isa(c,'double') && isa(A,'double') && isa(b,'double');
% All inputs must be real.
p = p && isreal(c) && isreal(A) && isreal(b);
% A must be a non-empty matrix.
p = p && ismatrix(A) && ~isempty(A);
% c must be a row-vector with length = size(A,2).
p = p && isrow(c) && size(c,2) == size(A,2);
% b must be a column-vector with length = size(A,1).
p = p && iscolumn(b) && size(b,1) == size(A,1);
% The elements of b must be non-negative.
p = p && all(b(:) >= 0);

%-----

```

```

function [c,A,b] = pivot(c,A,b,i,j)
% Pivot on element i,j.
coder.inline('never');
m = int32(size(A,1));
aij = A(i,j);
A(i,j) = 1;
A(i,:) = A(i,+)/aij;
for k = 1:m
 if k ~= i
 akj = A(k,j);
 A(k,j) = 0;
 A(k,:) = A(k,:) - akj*A(i,:);
 b(k) = b(k) - akj*b(i);
 end
end
cj = c(j);
c(j) = 0;
c = c - cj*A(i,:);

%-----

function j = findPivotColumn(c,idx)
% Find a suitable variable to enter the basis using the smallest
% subscript rule to prevent cycling.
coder.inline('never');
j = int32(0);
nc = int32(numel(c));
lastidx = int32(0);
for k = 1:nc
 if c(k) > 0 && (lastidx < 1 || idx(k) < lastidx)
 j = k;
 lastidx = idx(k);
 end
end

%-----

function [i,r] = findPivotRow(j,A,b)
% Find the pivot row in column j of A and also return r = b(i)/A(i,j).
coder.inline('never');
r = inf;
i = int32(0);
nb = int32(numel(b));
for k = 1:nb
 if A(k,j) > 0
 rtmp = b(k)/A(k,j);
 if rtmp < r
 r = rtmp;
 i = k;
 end
 end
end

%-----

```

The example also uses a test function `lpsolve_test` that calls `lpsolve` with representative input values.

## lpsolve\_test

```
% Test function for lpsolve
%
% Copyright 2011-2018 The MathWorks, Inc.
```

```
function lpsolve_test()
c = [2 3 1 1];
A = [2 3 1 -1;1 0 2 1;0 2 1 1];
b = [27;9;18];
[x,y] = lpsolve(c,A,b);
x % display x
y % display y
```

Copy `lpsolve.m` and `lpsolve_test.m` to a writable folder.

```
copyfile(fullfile(docroot, 'toolbox', 'ecoder', 'examples', 'lpsolve.m'))
copyfile(fullfile(docroot, 'toolbox', 'ecoder', 'examples', 'lpsolve_test.m'))
```

## Prepare for Code Generation

Before you generate C/C++ code, it is a best practice to screen your MATLAB code for code generation readiness.

```
coder.screener('lpsolve')
```

The code generation readiness report indicates that `lpsolve` is suitable for code generation.

It is also a best practice to check for run-time issues by generating and testing a MEX function.

- To specify the types of the inputs arguments, pass representative input values to the `codegen -args` option. Alternatively, because you have a test function, you can use `coder.getArgTypes` to determine the types.
- To generate and test a MEX function, use the `-test` option.

```
c = [2 3 1 1];
A = [2 3 1 -1;1 0 2 1;0 2 1 1];
b = [27;9;18];
codegen lpsolve -args {c A b} -test lpsolve_test
```

Running test file: 'lpsolve\_test' with MEX function 'lpsolve\_mex'.

```
x =
```

```
5
7
0
4
```

```
y =
```

```
35
```

codegen successfully generates and runs the MEX function.

## Produce a Code Generation Report with Traceability

To generate a report that has interactive traceability:

- Create a `coder.EmbeddedCodeConfig` object. The `EnableTraceability` property controls traceability. By default, the `EnableTraceability` property is `true`.
- Specify the types of the input arguments by passing representative input values to the `-args` option.
- Enable production of a code generation report by using the `-report` option.

```
cfg = coder.config('lib', 'ecoder', true);
codegen -config cfg lpsolve -args {c A b} -report
```

## Access Trace Mode in the Report

To open the code generation report, click **View report**.

In the code pane, you see `lpsolve.m`.

To enable tracing, on the **Report** tab, click **Trace Code**.

You see the MATLAB source code and the generated C code next to each other.

```

Code
lpsolve.m - [40-51] | 1 trace found
lpsolve.c

21 function [x,y] = lpsolve(c,A,b)
22 %codegen
23 narginchk(3,3);
24 m = int32(size(A,1));
25 n = int32(size(A,2));
26 if ~validInputs(c,A,b)
27 % Something is wrong with the inputs. Return NaNs.
28 x = nan(n,1);
29 y = nan;
30 return
31 end
32 cn = c;

29 */
30 static int findPivotColumn(const double c[4], const int idx[4], const double b[3])
31 {
32 int j;
33 int lastidx;
34 int k;
35
36 /* -----
37 j = 0;
38 lastidx = 0;
39 for (k = 0; k < 4; k++) {
40 if ((c[k] > 0.0) && ((lastidx < 1) || (idx[k] < lastidx)))
41 j = k + 1;
42 lastidx = idx[k];
43 }
44 }

```

## Trace Code

You can trace from the MATLAB code to the C code or from the C code to the MATLAB code. Traceable code is marked with blue on the side that you are tracing from and with orange on the side that you are tracing to. As you move your pointer over traceable code, the code is highlighted in purple and you see the traces to the corresponding code on the other side. When you select highlighted code by clicking it, the code becomes yellow and you can see the traces even when you move your pointer away from the selection. The code remains selected until you press **Esc** or select different code. To change the side that you are tracing from, select code on the other side.

Explore tracing in the example report.

- 1 In the MATLAB code, point to the `while`-loop that starts at line 38 and scroll down until the entire `while`-loop is in view.

```

37 unbounded = false;
38 while j > 0 && ~unbounded
39 [i,r] = findPivotRow(j,A,b);
40 if i == 0 || isinf(r)
41 unbounded = true;
42 else
43 b(i) = r;
44 % Take account of the variables entering and leaving
45 entering = nIdx(j);
46 leaving = bIdx(i);
47 bIdx(i) = entering;
48 nIdx(j) = leaving;
49 [cn,A,b] = pivot(cn,A,b,i,j);
50 j = findPivotColumn(cn,nIdx);
51 end
52 end
53 % Construct the solution.
54 if unbounded
55 x = nan(n,1);
56 y = inf;
57 else
58 x = zeros(n,1);
59 y = 0;
60 for k = 1:m
61 j = bIdx(k);
62 if j <= n
13
14 /* Function Declarations */
15 static int findPivotColumn(const double c[4], const int idx[
16 static void findPivotRow(int j, const double A[12], const do
17 double *r);
18 static void pivot(double c[4], double A[12], double b[3], in
19 static boolean_T validInputs(const double b[3]);
20
21 /* Function Definitions */
22
23 /*
24 * Find a suitable variable to enter the basis using the sma
25 * subscript rule to prevent cycling.
26 * Arguments : const double c[4]
27 const int idx[4]
28
29 222 unbounded = false;
29 223 while ((j > 0) && (!unbounded)) {
30 224 findPivotRow(j, A, b, &i, &r);
31 225 if ((i == 0) || rtIsInf(r)) {
32 226 unbounded = true;
33 227 } else {
34 228 b[i - 1] = r;
35 229
36 230 /* Take account of the variables entering
37 231 lastidx = 0;

```

You see this symbol that tells you that the highlighted MATLAB code has one trace that is not in view.

You see the corresponding C code in a separate window in the C code pane.

- 2 In the C code pane, scroll down until you see the C code that corresponds to the while loop.

```

36 j = findPivotColumn(cn,nIdx);
37 unbounded = false;
38 while j > 0 && ~unbounded
39 [i,r] = findPivotRow(j,A,b);
40 if i == 0 || isinf(r)
41 unbounded = true;
42 else
43 b(i) = r;
44 % Take account of the variables entering and leaving
45 entering = nIdx(j);
46 leaving = bIdx(i);
47 bIdx(i) = entering;
48 nIdx(j) = leaving;
49 [cn,A,b] = pivot(cn,A,b,i,j);
50 j = findPivotColumn(cn,nIdx);
51 end
52 end
53 % Construct the solution.
54 if unbounded
55 x = nan(n,1);
220
221 j = findPivotColumn(c, iv0);
222 unbounded = false;
223 while ((j > 0) && (!unbounded)) {
224 findPivotRow(j, A, b, &i, &r);
225 if ((i == 0) || rtIsInf(r)) {
226 unbounded = true;
227 } else {
228 b[i - 1] = r;
229
230 /* Take account of the variables entering and lea
231 leaving = bIdx[i - 1];
232 bIdx[i - 1] = nIdx[j - 1];
233 nIdx[j - 1] = leaving;
234 pivot(cn, A, b, i, j);
235 j = findPivotColumn(cn, nIdx);
236 }
237
238

```

- 3 In the MATLAB code, move your pointer over different syntax elements in the while loop. Highlight variables, expressions, and code blocks.

When you move your pointer over expressions that are part of larger expressions, different shades of purple help you to find the relevant expression in the corresponding C code. For example, at line 43, pause over `i`.

```

43 b(i) = r;
44 % Take account of the variables entering and leaving
45 entering = nIdx(j);
46 leaving = bIdx(i);
47 bIdx(i) = entering;
224 findPivotRow(j,
225 if ((i == 0) ||
226 unbounded = tr
227 } else {
228 b[i - 1] = r;

```

- 4 In the MATLAB code, move your pointer back to the while-loop that starts at line 38. When the entire loop is highlighted in purple, select it by clicking. When you move your pointer outside of the trace, the yellow highlighting identifies the selected trace.

```

38 while j > 0 && ~unbounded
39 [i,r] = findPivotRow(j,A,b);
40 if i == 0 || isinf(r)
41 unbounded = true;
42 else
43 b(i) = r;
44 % Take account of the variables entering and leaving
45 entering = nIdx(j);
46 leaving = bIdx(i);
47 bIdx(i) = entering;
48 nIdx(j) = leaving;
49 [cn,A,b] = pivot(cn,A,b,i,j);
50 j = findPivotColumn(cn,nIdx);
51 end
52 end
53 % Construct the solution.
54 if unbounded
55 x = nan(n,1);
56 y = inf;
57 else
58 x = zeros(n,1);

```

```

217 for (j = 0; j < 4; j++) {
218 iv0[j] = 1 + j;
219 }
220
221 j = findPivotColumn(c, iv0);
222 unbounded = false;
223 while ((j > 0) && (!unbounded)) {
224 findPivotRow(j, A, b, &i, &r);
225 if ((i == 0) || rtIsInf(r)) {
226 unbounded = true;
227 } else {
228 b[i - 1] = r;
229
230 /* Take account of the variables
231 leaving = bIdx[i - 1];
232 bIdx[i - 1] = nIdx[j - 1];
233 nIdx[j - 1] = leaving;
234 pivot(cn, A, b, i, j);
235 j = findPivotColumn(cn, nIdx);
236 }
237 }

```

To clear the selection, press **Esc** or select different code.

## View Multiple Traces

When code traces to more than one place in the corresponding source or generated code:

- If you pause over the code that you are tracing, at the top of the code pane, you see the number of traces.
- If some traces are not in view, you see a symbol that tells you how many traces are out of view.

- In the code pane, if you select the code that you want to trace, at the top of the code pane, you can select the trace that you want to see.

In the report for `lpsolve`, view multiple traces.

- 1 Pause over line 36.

At the top of the code pane, you see that line 36 has two traces.

- 2 Select line 36.

At the top of the code pane, you see the location of the first trace.

- 3 To list all traces, click the arrow to the right of the traces.

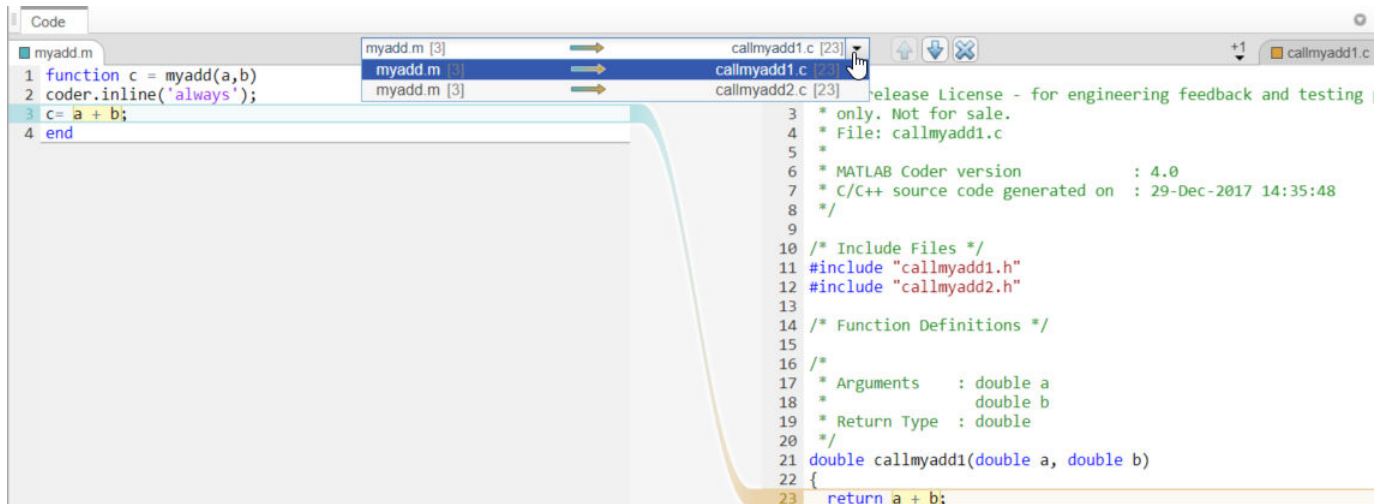

## View Traces to Different Files

In the code generation report for `lpsolve`, all traces from the MATLAB code go to one C file `lpsolve.c`. If MATLAB code traces to multiple C files, above the C code, you see a symbol such as

that provides the number of additional files in which you can find a trace. If you click the symbol, you can select the file that you want to see. If you select the MATLAB code, then you can select the trace that you want to see.

Likewise, above the MATLAB source code, a symbol such as  indicates that the highlighted C code traces to multiple MATLAB files.

## Switch the Locations of the Source and Generated Code

- 1 To view `lpsolve.c` on the left side of the code pane, in the list of generated files, click `lpsolve.c`.
- 2 To view the MATLAB code on the left side of the code pane, click a MATLAB function, for example, `lpsolve`.

## Enable Code Tooltips and Links

When you are not in trace mode:

- In the MATLAB code, if you point to a variable or expression, a tooltip provides information such as the type.
- In the C code, links go to other parts of the code such as type or function definitions.

When you are in trace mode, to enable MATLAB code tooltips and C code links, hold down **Ctrl**. MATLAB code tooltips are available only for a selected MATLAB function.

In the report for `lpsolve`, view type information for a variable.

- 1 In the **MATLAB Source** pane, select `pivot`.
- 2 In the code pane, hold down **Ctrl** and pause over the input argument `i`.

---

**Note** On a Macintosh platform, use the **Command** key instead of **Ctrl**.

---

## Disable Traceability

To produce a code generation report that does not include traceability:

- In a `coder.EmbeddedCodeConfig` object, set the `EnableTraceability` property to `false`.
- In the MATLAB Coder app, set **Enable code traceability** to **No**.

## Polyspace Verification of C/C++ Code Generated by MATLAB Coder

To check for run-time errors in C/C++ code generated from MATLAB code, you can use Polyspace Code Prover. To check for defects, you can use Polyspace Bug Finder. If you have Polyspace and Embedded Coder, Polyspace is integrated into the MATLAB Coder workflow.

- In the MATLAB Coder app, you can run Polyspace analysis without additional setup.
- At the command line, after code generation with `codegen`, you can run Polyspace analysis on the generated code by providing the code generation output folder to `pslinkrun`.

### Run Polyspace Analysis in the MATLAB Coder App

- 1 Generate standalone C/C++ code (a static library, dynamically linked library, or executable program).
- 2 On the **Generate Code** page, click **Polyspace**.
- 3 Select the options. See “Configure Advanced Polyspace Options in MATLAB Coder App” (Polyspace Code Prover).
- 4 Click **Run**.

The app logs the analysis output on the **Polyspace Log** tab and opens the Polyspace user interface.

### Run Polyspace Analysis on Code Generated by `codegen`

- 1 Create a `pslinkoptions` object for verification of code generated by MATLAB Coder.
- 2 As needed, change object properties:
  - In the `ResultDir` property, specify the name of the folder for the Polyspace results.
  - In the `VerificationMode` property, specify the Polyspace verification product.
- 3 Run the verification by using `pslinkrun`. Provide the `pslinkoptions` object and the folder that contains the generated code.
- 4 To view verification results, open the Polyspace user interface.

For example, suppose that you generated a static library for the MATLAB function `myFunction` and that the code generation output folder is `codegen/lib/myFunction`. To run Polyspace Code Prover on the generated code, use this code:

```
opts = pslinkoptions('codegen');
opts.ResultDir = 'polyspace';
opts.VerificationMode = 'CodeProver';
pslinkrun('-codegenfolder', 'codegen/lib/myFunction', opts);
polyspaceCodeProver('polyspace/myFunction.psprj');
```

You can also set the `VerificationMode` property to `'BugFinder'` and view verification results by using `polyspaceBugFinder`.

### Review Analysis Results

In the **Results List** pane of the Polyspace user interface, review the run-time checks. See whether you can trace the issues back to the original MATLAB code. See “Interactively Trace Between MATLAB Code and Generated C/C++ Code” on page 99-12.

For example, an operation in the C code might overflow because Polyspace assumes an unbounded range for a function input. Consider specifying a constraint on the input and reanalyzing the code with Polyspace. See “Run Polyspace on C/C++ Code Generated from MATLAB Code” (Polyspace Code Prover).
