spreadbyfd

Price European or American spread options using finite difference method

Syntax

```
Price = spreadbyfd(RateSpec,StockSpec1,StockSpec2,Settle,Maturity,OptSpec,
Strike,Corr)
Price = spreadbyfd( ___ ,Name,Value)

[Price,PriceGrid,AssetPrice1,AssetPrice2,Times] = spreadbyfd(RateSpec,
StockSpec1,StockSpec2,Settle,Maturity,OptSpec,Strike,Corr)
[Price,PriceGrid,AssetPrice1,AssetPrice2,Times] = spreadbyfd( ___ ,Name,Value)
```

Description

`Price = spreadbyfd(RateSpec,StockSpec1,StockSpec2,Settle,Maturity,OptSpec, Strike,Corr)` returns the price of European or American call or put spread options using the Alternate Direction Implicit (ADI) finite difference method. The spread is between the asset defined in `StockSpec1` minus the asset defined in `StockSpec2`.

`Price = spreadbyfd( ___ ,Name,Value)` adds optional name-value pair arguments.

`[Price,PriceGrid,AssetPrice1,AssetPrice2,Times] = spreadbyfd(RateSpec, StockSpec1,StockSpec2,Settle,Maturity,OptSpec,Strike,Corr)` returns the `Price`, `PriceGrid`, `AssetPrice1`, `AssetPrice2`, and `Times` for a European or American call or put spread options using the Alternate Direction Implicit (ADI) finite difference method. The spread is between the asset defined in `StockSpec1` minus the asset defined in `StockSpec2`.

`[Price,PriceGrid,AssetPrice1,AssetPrice2,Times] = spreadbyfd( ___ ,Name,Value)` returns the `Price`, `PriceGrid`, `AssetPrice1`, `AssetPrice2`, and `Times` and adds optional name-value pair arguments.

Examples

Compute the Price of a Spread Option Using the Alternate Direction Implicit (ADI) Finite Difference Method

Define the spread option dates.

```
Settle = datetime(2012,1,1);
Maturity = datetime(2012,4,1);
```

Define asset 1. Price and volatility of RBOB gasoline

```
  Price1gallon = 2.85;          % $/gallon
  Price1 = Price1gallon * 42;   % $/barrel
  Vol1 = 0.29;
```

Define asset 2. Price and volatility of WTI crude oil

```
  Price2 = 93.20;         % $/barrel
  Vol2 = 0.36;
```

Define the correlation between the underlying asset prices of asset 1 and asset 2.

```
Corr = 0.42;
```

Define the spread option.

```
OptSpec = 'call';
Strike = 20;
```

Define the `RateSpec`.

```
rates = 0.05;
Compounding = -1;
Basis = 1;
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
'EndDates', Maturity, 'Rates', rates, ...
'Compounding', Compounding, 'Basis', Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9876
            Rates: 0.0500
         EndTimes: 0.2500
       StartTimes: 0
         EndDates: 734960
       StartDates: 734869
    ValuationDate: 734869
            Basis: 1
     EndMonthRule: 1
```

Define the `StockSpec` for the two assets.

```
StockSpec1 = stockspec(Vol1, Price1)
```

```
StockSpec1 = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.2900
         AssetPrice: 119.7000
       DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

```
StockSpec2 = stockspec(Vol2, Price2)
```

```
StockSpec2 = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.3600
         AssetPrice: 93.2000
       DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Compute the spread option price based on the Alternate Direction Implicit (ADI) finite difference method.

```
[Price, PriceGrid, AssetPrice1, AssetPrice2, Times] = ...
 spreadbyfd(RateSpec, StockSpec1, StockSpec2, Settle, ...
 Maturity, OptSpec, Strike, Corr);
```

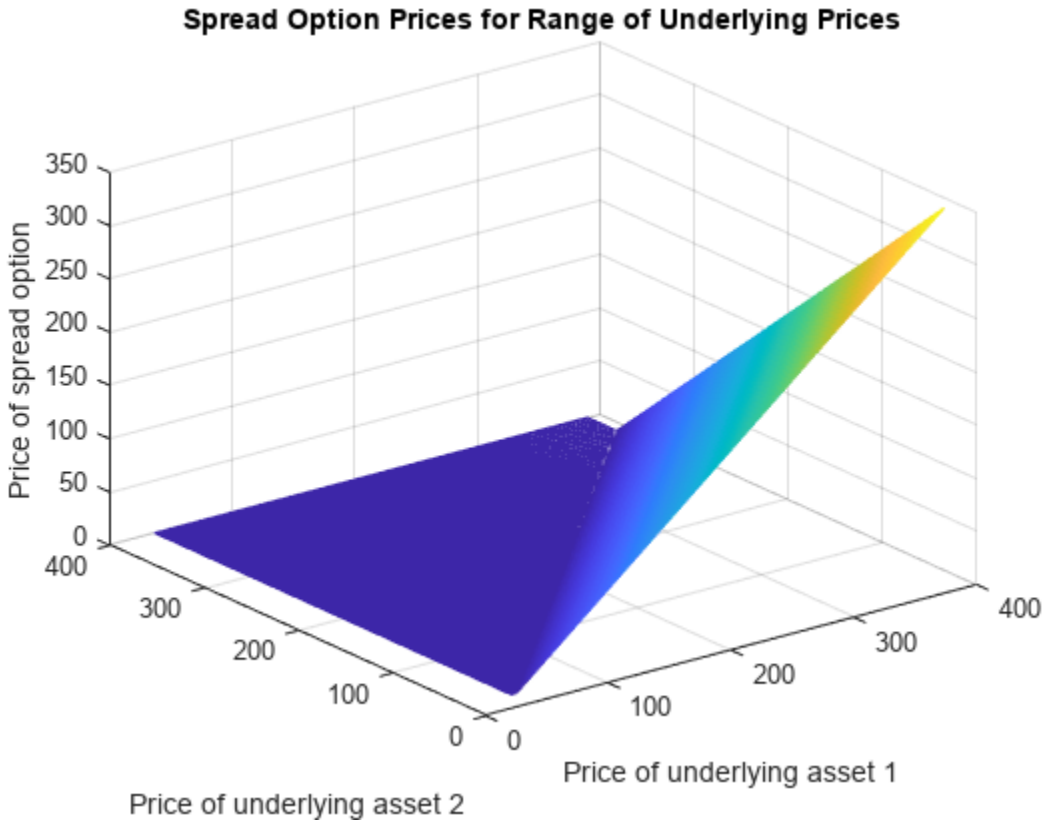
Display the price.

```
Price
```

```
Price = 11.1998
```

Plot the finite difference grid.

```
mesh(AssetPrice1, AssetPrice2, PriceGrid(:, :, 1)');
    title('Spread Option Prices for Range of Underlying Prices');
    xlabel('Price of underlying asset 1');
    ylabel('Price of underlying asset 2');
    zlabel('Price of spread option');
```



Input Arguments

RateSpec — Interest-rate term structure
structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

`StockSpec1` — Stock specification for underlying asset 1
structure

Stock specification for underlying asset 1. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, for physical commodities the price is represented by `StockSpec.Asset`, the volatility is represented by `StockSpec.Sigma`, and the convenience yield is represented by `StockSpec.DividendAmounts`.

Data Types: `struct`

`StockSpec2` — Stock specification for underlying asset 2
structure

Stock specification for underlying asset 2. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, for physical commodities the price is represented by `StockSpec.Asset`, the volatility is represented by `StockSpec.Sigma`, and the convenience yield is represented by `StockSpec.DividendAmounts`.

Data Types: `struct`

`Settle` — Settlement dates for spread option
datetime array | string array | date character vector

Settlement dates for the spread option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `spreadbyfd` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date for spread option
datetime array | string array | date character vector

Maturity date for spread option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `spreadbyfd` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option
character vector with values `'call'` or `'put'` | cell array of character vectors

Definition of option as `'call'` or `'put'`, specified as a `NINST`-by-`1` cell array of character vectors.

Data Types: `char` | `cell`

`Strike` — Option strike price values
integer | vector of integers

Option strike price values, specified as an integer using a `NINST`-by-`1` vector of strike price values.

Data Types: `double`

`Corr` — Correlation between underlying asset prices

integer | vector of integers

Correlation between underlying asset prices, specified as an integer using a `NINST`-by-`1` vector.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceGrid,AssetPrice1,AssetPrice2,Times] = spreadbyfd(RateSpec,StockSpec1,StockSpec2,Settle,Maturity,OptSpec,Strike,Corr,'AssetPriceMin','AssetPriceMax','PriceGridSize','TimeGridSize','AmericanOpt',0)`

`AssetPriceMin` — Minimum price for price grid boundary

if unspecified, `StockSpec` values are calculated based on asset distributions at maturity (default) | array

Minimum price for price grid boundary, specified as the comma-separated pair consisting of `'AssetPriceMin'` and a `1`-by-`2` array. The first entry in the array corresponds to the first asset defined by `StockSpec1` and the second entry corresponds to the second asset defined by `StockSpec2`.

For the finite difference method, the composition of the grid affects the quality of the output and the execution time. It is highly recommended to use the optional arguments `AssetPriceMin`, `AssetPriceMax`, `PriceGridSize`, and `TimeGridSize` to control the composition of the grid to ensure the quality of the output and a reasonable execution time.

Data Types: `single` | `double`

`AssetPriceMax` — Maximum price for price grid boundary

if unspecified, `StockSpec` values are calculated based on asset distributions at maturity (default) | array

Maximum price for price grid boundary, specified as the comma-separated pair consisting of `'AssetPriceMax'` and a `1`-by-`2` array. The first entry in the array corresponds to the first asset defined by `StockSpec1` and the second entry corresponds to the second asset defined by `StockSpec2`.

For the finite difference method, the composition of the grid affects the quality of the output and the execution time. It is highly recommended to use the optional arguments `AssetPriceMin`, `AssetPriceMax`, `PriceGridSize`, and `TimeGridSize` to control the composition of the grid to ensure the quality of the output and a reasonable execution time.

Data Types: `single` | `double`

`PriceGridSize` — Size for finite difference grid

`[300,300]` (default) | array

Size for finite difference grid, specified as the comma-separated pair consisting of `'PriceGridSize'` and a 1-by-2 array. The first entry corresponds to the first asset defined by `StockSpec1` and the second entry corresponds to the second asset defined by `StockSpec2`.

For the finite difference method, the composition of the grid affects the quality of the output and the execution time. It is highly recommended to use the optional arguments`AssetPriceMax`, `PriceGridSize`, and `TimeGridSize` to control the composition of the grid to ensure the quality of the output and a reasonable execution time.

Data Types: `single` | `double`

`TimeGridSize` — Size of the time grid for finite difference grid
`100` (default) | scalar | nonnegative integer

Size of the time grid for finite difference grid, specified as the comma-separated pair consisting of `'TimeGridSize'` and a nonnegative integer.

For the finite difference method, the composition of the grid affects the quality of the output and the execution time. It is highly recommended to use the optional arguments`AssetPriceMax`, `PriceGridSize`, and `TimeGridSize` to control the composition of the grid to ensure the quality of the output and a reasonable execution time.

Data Types: `single` | `double`

`AmericanOpt` — Option type
`0` European (default) | scalar | vector of positive integers`[0,1]`

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and `NINST`-by-`1` positive integer scalar flags with values:

- `0` — European
- `1` — American

Data Types: `single` | `double`

Output Arguments

`Price` — Expected prices of spread option
vector

Expected prices of the spread option, returned as a `NINST`-by-`1` vector.

`PriceGrid` — Grid containing prices calculated by finite difference method
array

Grid containing prices calculated by finite difference method, returned as a 3-D grid with a size of `PriceGridSize(1)` * `PriceGridSize(2)` * `TimeGridSize`. The price for `t` = 0 is contained in `PriceGrid(:, :, 1)`.

`AssetPrice1` — Prices for first asset defined by `StockSpec1`
vector

Prices for first asset defined by `StockSpec1`, corresponding to the first dimension of `PriceGrid`, returned as a vector.

`AssetPrice2` — Prices for second asset defined by `StockSpec2`
vector

Prices for second asset defined by `StockSpec2`, corresponding to the second dimension of `PriceGrid`, returned as a vector.

`Times` — Times corresponding to third dimension of `PriceGrid`
vector

Times corresponding to third dimension of `PriceGrid`, returned as a vector.

More About

Spread Option

A spread option is an option written on the difference of two underlying assets.

For example, a European call on the difference of two assets *X1* and *X2* would have the following pay off at maturity:

$$\max(X1 - X2 - K, 0)$$

where:

K is the strike price.

For more information, see “Spread Option” on page 3-30.

Version History

Introduced in R2013b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `spreadbyfd` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

spreadbyls

Price European or American spread options using Monte Carlo simulations

Syntax

```
Price = spreadbyls(RateSpec,StockSpec1,StockSpec2,Settle,Maturity,OptSpec,
Strike,Corr)
Price = spreadbyls( ___ ,Name,Value)

[Price,Paths,Times,Z] = spreadbyls(RateSpec,StockSpec1,StockSpec2,Settle,
Maturity,OptSpec,Strike,Corr)
[Price,Paths,Times,Z] = spreadbyls( ___ ,Name,Value)
```

Description

`Price = spreadbyls(RateSpec,StockSpec1,StockSpec2,Settle,Maturity,OptSpec, Strike,Corr)` returns the price of a European or American call or put spread option using Monte Carlo simulations.

For American options, the Longstaff-Schwartz least squares method is used to calculate the early exercise premium.

Note Alternatively, you can use the `Spread` object to price spread options. For more information, see "Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments" on page 1-22.

`Price = spreadbyls( ___ ,Name,Value)` returns the price of a European or American call or put spread option using Monte Carlo simulations using optional name-value pair arguments.

`[Price,Paths,Times,Z] = spreadbyls(RateSpec,StockSpec1,StockSpec2,Settle, Maturity,OptSpec,Strike,Corr)` returns the `Price`, `Paths`, `Times`, and `Z` of a European or American call or put spread option using Monte Carlo simulations.

`[Price,Paths,Times,Z] = spreadbyls( ___ ,Name,Value)` returns the `Price`, `Paths`, `Times`, and `Z` of a European or American call or put spread option using Monte Carlo simulations using optional name-value pair arguments.

Examples

Compute the Price of a Spread Option Using Monte Carlo Simulation

Define the spread option dates.

```
Settle = datetime(2012,1,1);
Maturity = datetime(2012,4,1);
```

Define asset 1. Price and volatility of RBOB gasoline

```
Price1gallon = 2.85;          % $/gallon
Price1 = Price1gallon * 42;   % $/barrel
Vol1 = 0.29;
```

Define asset 2. Price and volatility of WTI crude oil

```
Price2 = 93.20;         % $/barrel
Vol2 = 0.36;
```

Define the correlation between the underlying asset prices of asset 1 and asset 2.

```
Corr = 0.42;
```

Define the spread option.

```
OptSpec = 'call';
Strike = 20;
```

Define the `RateSpec`.

```
rates = 0.05;
Compounding = -1;
Basis = 1;
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
'EndDates', Maturity, 'Rates', rates, ...
'Compounding', Compounding, 'Basis', Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9876
            Rates: 0.0500
        EndTimes: 0.2500
       StartTimes: 0
         EndDates: 734960
       StartDates: 734869
    ValuationDate: 734869
            Basis: 1
     EndMonthRule: 1
```

Define the `StockSpec` for the two assets.

```
StockSpec1 = stockspec(Vol1, Price1)
```

```
StockSpec1 = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.2900
         AssetPrice: 119.7000
       DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

```
StockSpec2 = stockspec(Vol2, Price2)
```

```
StockSpec2 = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.3600
```

```
        AssetPrice: 93.2000
      DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Compute the spread option price using Monte Carlo simulation based on the Longstaff-Schwartz model.

```
Price = spreadbyls(RateSpec, StockSpec1, StockSpec2, Settle, ...
Maturity, OptSpec, Strike, Corr)
```

```
Price = 11.0799
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

StockSpec1 — Stock specification for underlying asset 1

structure

Stock specification for underlying asset 1. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, for physical commodities the price is represented by `StockSpec.Asset`, the volatility is represented by `StockSpec.Sigma`, and the convenience yield is represented by `StockSpec.DividendAmounts`.

Data Types: `struct`

StockSpec2 — Stock specification for underlying asset 2

structure

Stock specification for underlying asset 2. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, for physical commodities the price is represented by `StockSpec.Asset`, the volatility is represented by `StockSpec.Sigma`, and the convenience yield is represented by `StockSpec.DividendAmounts`.

Data Types: `struct`

Settle — Settlement date for spread option

datetime scalar | string scalar | date character vector

Settlement date for the spread option specified, as a scalar datetime, string, or date character vector.

To support existing code, `spreadbyls` also accepts serial date numbers as inputs, but they are not recommended.

Maturity — Maturity date for spread option

datetime scalar | string scalar | date character vector

Maturity date for spread option, specified as a scalar datetime, string, or date character vector.

To support existing code, `spreadbyls` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option
character vector with values `'call'` or `'put'`

Definition of option as `'call'` or `'put'`, specified as a character vector.

Data Types: `char`

`Strike` — Option strike price value
nonnegative scalar integer

Option strike price value, specified, as a nonnegative scalar integer.

Data Types: `double`

`Corr` — Correlation between underlying asset prices
scalar integer

Correlation between underlying asset prices, specified as a scalar integer.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Price = spreadbyls(RateSpec,StockSpec1,StockSpec2,Settle,Maturity,OptSpec,Strike,Corr,'AmericanOpt',1)`

`AmericanOpt` — Option type
`0` European (default) | scalar with value `[0,1]`

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and an integer scalar flag with value:

- `0` — European
- `1` — American

Note For American options, the Longstaff-Schwartz least squares method is used to calculate the early exercise premium. For more information on the least squares method, see https://people.math.ethz.ch/%7Ehjfurrer/teaching/LongstaffSchwartzAmericanOptionsLeastSquareMonteCarlo.pdf.

Data Types: `single` | `double`

`NumTrials` — Scalar number of independent sample paths
`1000` (default) | nonnegative scalar integer

Scalar number of independent sample paths (simulation trials), specified as the comma-separated pair consisting of `'NumTrials'` and a nonnegative integer.

Data Types: `single` | `double`

`NumPeriods` — Scalar number of simulation periods per trial
`100` (default) | nonnegative scalar integer

Scalar number of simulation periods per trial, specified as the comma-separated pair consisting of `'NumPeriods'` and a nonnegative integer. `NumPeriods` is considered only when pricing European basket options. For American spread options, `NumPeriod` is equal to the number of exercise days during the life of the option.

Data Types: `single` | `double`

`Z` — Time series array of dependent random variates
vector

Time series array of dependent random variates, specified as the comma-separated pair consisting of `'Z'` and a `NumPeriods`-by-2-by-`NumTrials` 3-D array. The `Z` value generates the Brownian motion vector (that is, Wiener processes) that drives the simulation.

Data Types: `single` | `double`

`Antithetic` — Indicator for antithetic sampling
`false` (default) | scalar logical flag with value of `true` or `false`

Indicator for antithetic sampling, specified as the comma-separated pair consisting of `'Antithetic'` and a value of `true` or `false`.

Data Types: `logical`

Output Arguments

`Price` — Expected price of spread option
scalar

Expected price of the spread option, returned as a 1-by-1 scalar.

`Paths` — Simulated paths of correlated state variables
vector

Simulated paths of correlated state variables, returned as a `NumPeriods + 1`-by-2-by-`NumTrials` 3-D time series array. Each row of `Paths` is the transpose of the state vector $X(t)$ at time t for a given trial.

`Times` — Observation times associated with simulated paths
vector

Observation times associated with simulated paths, returned as a `NumPeriods + 1`-by-1 column vector of observation times associated with the simulated paths. Each element of `Times` is associated with the corresponding row of `Paths`.

Z — Time series array of dependent random variates
vector

Time series array of dependent random variates, returned as a `NumPeriods`-by-2-by-`NumTrials` 3-D array when `Z` is specified as an input argument. If the `Z` input argument is not specified, then the `Z` output argument contains the random variates generated internally.

More About

Spread Option

A spread option is an option written on the difference of two underlying assets.

For example, a European call on the difference of two assets *X1* and *X2* would have the following pay off at maturity:

$$\max(X1 - X2 - K, 0)$$

where:

K is the strike price.

For more information, see “Spread Option” on page 3-30.

Version History

Introduced in R2013b

Serial date numbers not recommended
Not recommended starting in R2022b

Although `spreadbyls` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

spreadsensbykirk

Calculate European spread option prices or sensitivities using Kirk pricing model

Syntax

```
PriceSens = spreadbykirk(RateSpec,StockSpec1,StockSpec2,Settle,Maturity,
OptSpec,Strike,Corr)
PriceSens = spreadsensbykirk( ___ ,Name,Value)
```

Description

`PriceSens = spreadbykirk(RateSpec,StockSpec1,StockSpec2,Settle,Maturity, OptSpec,Strike,Corr)` returns the European spread option prices or sensitivities using the Kirk pricing model.

Note Alternatively, you can use the `Spread` object to calculate price or sensitivities for spread options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`PriceSens = spreadsensbykirk( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Compute the Price and Sensitivities of a Spread Option Using the Kirk Model

Define the spread option dates.

```
Settle = datetime(2012,6,1);
Maturity = datetime(2012,9,1);
```

Define asset 1. Price and volatility of RBOB gasoline

```
Price1gallon = 2.85;          % $/gallon
Price1 = Price1gallon * 42;   % $/barrel
Vol1 = 0.29;
```

Define asset 2. Price and volatility of WTI crude oil

```
Price2 = 93.20;         % $/barrel
Vol2 = 0.36;
```

Define the correlation between the underlying asset prices of asset 1 and asset 2.

```
Corr = 0.42;
```

Define the spread option.

```
OptSpec = 'call';
Strike = 20;
```

Define the `RateSpec`.

```
rates = 0.05;
Compounding = -1;
Basis = 1;
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
'EndDates', Maturity, 'Rates', rates, ...
'Compounding', Compounding, 'Basis', Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9876
            Rates: 0.0500
          EndTimes: 0.2500
        StartTimes: 0
          EndDates: 735113
        StartDates: 735021
    ValuationDate: 735021
            Basis: 1
     EndMonthRule: 1
```

Define the `StockSpec` for the two assets.

```
StockSpec1 = stockspec(Vol1, Price1)
```

```
StockSpec1 = struct with fields:
              FinObj: 'StockSpec'
               Sigma: 0.2900
          AssetPrice: 119.7000
        DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

```
StockSpec2 = stockspec(Vol2, Price2)
```

```
StockSpec2 = struct with fields:
              FinObj: 'StockSpec'
               Sigma: 0.3600
          AssetPrice: 93.2000
        DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Compute the spread option price and sensitivities based on the Kirk model.

```
OutSpec = {'Price', 'Delta', 'Gamma'};
[Price, Delta, Gamma] = spreadsensbykirk(RateSpec, StockSpec1, StockSpec2, Settle, ...
Maturity, OptSpec, Strike, Corr, 'OutSpec', OutSpec)
```

```
Price = 11.1904

Delta = 1×2

    0.6722   -0.6067
```

```
Gamma = 1×2

    0.0191    0.0217
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

StockSpec1 — Stock specification for underlying asset 1

structure

Stock specification for underlying asset 1. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, for physical commodities the price is represented by `StockSpec.Asset`, the volatility is represented by `StockSpec.Sigma`, and the convenience yield is represented by `StockSpec.DividendAmounts`.

Data Types: `struct`

StockSpec2 — Stock specification for underlying asset 2

structure

Stock specification for underlying asset 2. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, for physical commodities the price is represented by `StockSpec.Asset`, the volatility is represented by `StockSpec.Sigma`, and the convenience yield is represented by `StockSpec.DividendAmounts`.

Data Types: `struct`

Settle — Settlement dates for spread option

datetime array | string array | date character vector

Settlement dates for the spread option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `spreadsensbykirk` also accepts serial date numbers as inputs, but they are not recommended.

Maturity — Maturity date for spread option

datetime array | string array | date character vector

Maturity date for spread option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `spreadsensbykirk` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option
character vector with values `'call'` or `'put'` | cell array of character vectors

Definition of option as `'call'` or `'put'`, specified as a `NINST`-by-`1` cell array of character vectors.

Data Types: `char` | `cell`

`Strike` — Option strike price values
integer | vector of integers

Option strike price values, specified as an integer using as `NINST`-by-`1` vector of strike price values.

If `Strike` is equal to zero, this function computes the price and sensitivities of an exchange option.

Data Types: `double`

`Corr` — Correlation between underlying asset prices
integer | vector of integers

Correlation between underlying asset prices, specified as an integer using as `NINST`-by-`1` vector.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `PriceSens = spreadsensbykirk(RateSpec,StockSpec1,StockSpec2,Settle,Maturity,OptSpec,Strike,Corr,OutSpec,{'All'})`

`OutSpec` — Define outputs
`{'Price'}` (default) | character vector with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'` | cell array of character vectors with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`

Define outputs, specified as the comma-separated pair consisting of `'OutSpec'` and a `NOUT`- by-`1` or `1`-by-`NOUT` cell array of character vectors with possible values of `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`.

`OutSpec = {'All'}` specifies that the output should be `Delta`, `Gamma`, `Vega`, `Lambda`, `Rho`, `Theta`, and `Price`, in that order. This is the same as specifying `OutSpec` to include each sensitivity:

Example: `OutSpec = {'delta','gamma','vega','lambda','rho','theta','price'}`

Data Types: `char` | `cell`

Output Arguments

`PriceSens` — Expected price or sensitivities values of spread option
vector

Expected price or sensitivities values (defined by `OutSpec`) of the spread option, returned as a `NINST`-by-1 or `NINST`-by-2 vector.

More About

Spread Option

A spread option is an option written on the difference of two underlying assets.

For example, a European call on the difference of two assets *X1* and *X2* would have the following pay off at maturity:

$$\max(X1 - X2 - K, 0)$$

where:

K is the strike price.

For more information, see “Spread Option” on page 3-30.

Version History

Introduced in R2013b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `spreadsensbykirk` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

spreadsensbybjs

Calculate European spread option prices or sensitivities using Bjerksund-Stensland pricing model

Syntax

```
PriceSens = spreadbybjs(RateSpec,StockSpec1,StockSpec2,Settle,Maturity,
OptSpec,Strike,Corr)
PriceSens = spreadsensbybjs( ___ ,Name,Value)
```

Description

`PriceSens = spreadbybjs(RateSpec,StockSpec1,StockSpec2,Settle,Maturity, OptSpec,Strike,Corr)` returns the European spread option prices or sensitivities using the Bjerksund-Stensland pricing model.

Note Alternatively, you can use the `Spread` object to calculate price or sensitivities for spread options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`PriceSens = spreadsensbybjs( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Compute the Price and Sensitivities of a Spread Option Using the Bjerksund-Stensland Model

Define the spread option dates.

```
Settle = datetime(2012,6,1);
Maturity = datetime(2012,9,1);
```

Define asset 1. Price and volatility of RBOB gasoline

```
   Price1gallon = 2.85;          % $/gallon
   Price1 = Price1gallon * 42;   % $/barrel
   Vol1 = 0.29;
```

Define asset 2. Price and volatility of WTI crude oil

```
  Price2 = 93.20;         % $/barrel
  Vol2 = 0.36;
```

Define the correlation between the underlying asset prices of asset 1 and asset 2.

```
Corr = 0.42;
```

Define the spread option.

```
OptSpec = 'call';
Strike = 20;
```

Define the RateSpec.

```
rates = 0.05;
Compounding = -1;
Basis = 1;
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
'EndDates', Maturity, 'Rates', rates, ...
'Compounding', Compounding, 'Basis', Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9876
            Rates: 0.0500
         EndTimes: 0.2500
       StartTimes: 0
         EndDates: 735113
       StartDates: 735021
    ValuationDate: 735021
            Basis: 1
     EndMonthRule: 1
```

Define the StockSpec for the two assets.

```
StockSpec1 = stockspec(Vol1, Price1)
```

```
StockSpec1 = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.2900
         AssetPrice: 119.7000
       DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

```
StockSpec2 = stockspec(Vol2, Price2)
```

```
StockSpec2 = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.3600
         AssetPrice: 93.2000
       DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Compute the spread option price and sensitivities based on the Kirk model.

```
OutSpec = {'Price', 'Delta', 'Gamma'};
[Price, Delta, Gamma] = spreadsensbybjs(RateSpec, StockSpec1, StockSpec2, Settle, ...
Maturity, OptSpec, Strike, Corr, 'OutSpec', OutSpec)
```

```
Price = 11.2000
```

```
Delta = 1×2
```

```
    0.6737   -0.6082

Gamma = 1×2

    0.0190    0.0216
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

StockSpec1 — Stock specification for underlying asset 1

structure

Stock specification for underlying asset 1. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, for physical commodities the price is represented by `StockSpec.Asset`, the volatility is represented by `StockSpec.Sigma`, and the convenience yield is represented by `StockSpec.DividendAmounts`.

Data Types: `struct`

StockSpec2 — Stock specification for underlying asset 2

structure

Stock specification for underlying asset 2. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, for physical commodities the price is represented by `StockSpec.Asset`, the volatility is represented by `StockSpec.Sigma`, and the convenience yield is represented by `StockSpec.DividendAmounts`.

Data Types: `struct`

Settle — Settlement dates for spread option

datetime array | string array | date character vector

Settlement dates for the spread option, specified a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `spreadsensbybjs` also accepts serial date numbers as inputs, but they are not recommended.

Maturity — Maturity date for spread option

datetime array | string array | date character vector

Maturity date for spread option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `spreadsensbybjs` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option
character vector with values `'call'` or `'put'` | cell array of character vectors

Definition of option as `'call'` or `'put'`, specified as a `NINST`-by-`1` cell array of character vectors.

Data Types: `char` | `cell`

`Strike` — Option strike price values
integer | vector of integers

Option strike price values, specified as an integer using a `NINST`-by-`1` vector of strike price values.

If `Strike` is equal to zero the function computes the price and sensitivities of an exchange option.

Data Types: `double`

`Corr` — Correlation between underlying asset prices
integer | vector of integers

Correlation between underlying asset prices, specified as an integer using a `NINST`-by-`1` vector.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `PriceSens = spreadsensbykirk(RateSpec,StockSpec1,StockSpec2,Settle,Maturity,OptSpec,Strike,Corr,OutSpec,{'All'})`

`OutSpec` — Define outputs
`{'Price'}` (default) | character vector with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'` | cell array of character vectors with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`

Define outputs, specified as the comma-separated pair consisting of `'OutSpec'` and a `NOUT`- by-`1` or `1`-by-`NOUT` cell array of character vectors with possible values of `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`.

`OutSpec = {'All'}` specifies that the output should be `Delta`, `Gamma`, `Vega`, `Lambda`, `Rho`, `Theta`, and `Price`, in that order. This is the same as specifying `OutSpec` to include each sensitivity:

Example: `OutSpec = {'delta','gamma','vega','lambda','rho','theta','price'}`

Data Types: `char` | `cell`

Output Arguments

`PriceSens` — Expected prices or sensitivities values of spread option

vector

Expected prices or sensitivities values (defined by `OutSpec`) of the spread option, returned as a `NINST`-by-`1` or `NINST`-by-`2` vector.

More About

Spread Option

A spread option is an option written on the difference of two underlying assets.

For example, a European call on the difference of two assets *X1* and *X2* would have the following pay off at maturity:

$$\max(X1 - X2 - K, 0)$$

where:

K is the strike price.

For more information, see “Spread Option” on page 3-30.

Version History

Introduced in R2013b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `spreadsensbybjs` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

spreadsensbyls

Calculate price and sensitivities for European or American spread options using Monte Carlo simulations

Syntax

```
PriceSens = spreadsensbyls(RateSpec,StockSpec1,StockSpec2,Settle,Maturity,
OptSpec,Strike,Corr)
PriceSens = spreadsensbyls( ___ ,Name,Value)

[PriceSens,Paths,Times,Z] = spreadsensbyls(RateSpec,StockSpec1,StockSpec2,
Settle,Maturity,OptSpec,Strike,Corr)
[PriceSens,Paths,Times,Z] = spreadsensbyls( ___ ,Name,Value)
```

Description

`PriceSens = spreadsensbyls(RateSpec,StockSpec1,StockSpec2,Settle,Maturity, OptSpec,Strike,Corr)` returns the price of a European or American call or put spread option using Monte Carlo simulations.

For American options, the Longstaff-Schwartz least squares method is used to calculate the early exercise premium.

Note Alternatively, you can use the `Spread` object to calculate price or sensitivities for spread options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`PriceSens = spreadsensbyls( ___ ,Name,Value)` adds optional name-value pair arguments.

`[PriceSens,Paths,Times,Z] = spreadsensbyls(RateSpec,StockSpec1,StockSpec2, Settle,Maturity,OptSpec,Strike,Corr)` returns the `PriceSens`, `Paths`, `Times`, and `Z` of a European or American call or put spread option using Monte Carlo simulations.

`[PriceSens,Paths,Times,Z] = spreadsensbyls( ___ ,Name,Value)` returns the `PriceSens`, `Paths`, `Times`, and `Z` and adds optional name-value pair arguments.

Examples

Compute the Price and Sensitivities of a Spread Option Using Monte Carlo Simulation

Define the spread option dates.

```
Settle = datetime(2012,6,1);
Maturity = datetime(2012,9,1);
```

Define asset 1. Price and volatility of RBOB gasoline

```
  Price1gallon = 2.85;          % $/gallon
  Price1 = Price1gallon * 42;   % $/barrel
  Vol1 = 0.29;
```

Define asset 2. Price and volatility of WTI crude oil

```
  Price2 = 93.20;         % $/barrel
  Vol2 = 0.36;
```

Define the correlation between the underlying asset prices of asset 1 and asset 2.

```
Corr = 0.42;
```

Define the spread option.

```
OptSpec = 'call';
Strike = 20;
```

Define the `RateSpec`.

```
rates = 0.05;
Compounding = -1;
Basis = 1;
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
'EndDates', Maturity, 'Rates', rates, ...
'Compounding', Compounding, 'Basis', Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9876
            Rates: 0.0500
        EndTimes: 0.2500
       StartTimes: 0
         EndDates: 735113
       StartDates: 735021
    ValuationDate: 735021
            Basis: 1
     EndMonthRule: 1
```

Define the `StockSpec` for the two assets.

```
StockSpec1 = stockspec(Vol1, Price1)
```

```
StockSpec1 = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.2900
         AssetPrice: 119.7000
       DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

```
StockSpec2 = stockspec(Vol2, Price2)
```

```
StockSpec2 = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.3600
```

```
        AssetPrice: 93.2000
      DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Compute the spread option price and sensitivities using Monte Carlo simulation based on the Longstaff-Schwartz model.

```
OutSpec = {'Price', 'Delta', 'Gamma'};
[Price, Delta, Gamma] = spreadsensbyls(RateSpec, StockSpec1, StockSpec2, ...
Settle, Maturity, OptSpec, Strike, Corr, 'OutSpec', OutSpec)
```

```
Price = 11.0799

Delta = 1×2

    0.6626   -0.5972

Gamma = 1×2

    0.0209    0.0240
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

StockSpec1 — Stock specification for underlying asset 1

structure

Stock specification for underlying asset 1. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, for physical commodities the price is represented by `StockSpec.Asset`, the volatility is represented by `StockSpec.Sigma`, and the convenience yield is represented by `StockSpec.DividendAmounts`.

Data Types: `struct`

StockSpec2 — Stock specification for underlying asset 2

structure

Stock specification for underlying asset 2. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, for physical commodities the price is represented by `StockSpec.Asset`, the volatility is represented by `StockSpec.Sigma`, and the convenience yield is represented by `StockSpec.DividendAmounts`.

Data Types: `struct`

`Settle` — Settlement date for spread option
datetime scalar | string scalar | date character vector

Settlement date for the spread option, specified as a scalar datetime, string, or date character vector.

To support existing code, `spreadsensbyls` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date for spread option
datetime scalar | string scalar | date character vector

Maturity date for spread option, specified as a scalar datetime, string, or date character vector.

To support existing code, `spreadsensbyls` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option
character vector with values `'call'` or `'put'`

Definition of option as `'call'` or `'put'`, specified as a character vector.

Data Types: `char`

`Strike` — Option strike price value
nonnegative scalar integer

Option strike price value, specified as a scalar integer.

Data Types: `single` | `double`

`Corr` — Correlation between underlying asset prices
scalar integer

Correlation between underlying asset prices, specified as a scalar integer.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `PriceSens = spreadbyls(RateSpec,StockSpec1,StockSpec2,Settle,Maturity,OptSpec,Strike,Corr,'AmericanOpt',1)`

`AmericanOpt` — Option type
`0` European (default) | scalar with values `[0,1]`

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and a scalar integer flag with values:

- `0` — European

- 1 — American

Note For American options, the Longstaff-Schwartz least squares method is used to calculate the early exercise premium. For more information on the least squares method, see https://people.math.ethz.ch/%7Ehjfurrer/teaching/LongstaffSchwartzAmericanOptionsLeastSquareMonteCarlo.pdf.

Data Types: `single` | `double`

`NumTrials` — Number of independent sample paths
`1000` (default) | nonnegative scalar integer

Number of independent sample paths (simulation trials), specified as the comma-separated pair consisting of `'NumTrials'` and a nonnegative scalar integer.

Data Types: `single` | `double`

`NumPeriods` — Number of simulation periods per trial
`100` (default) | nonnegative scalar integer

Number of simulation periods per trial, specified as the comma-separated pair consisting of `'NumPeriods'` and a nonnegative scalar integer. `NumPeriods` is considered only when pricing European basket options. For American spread options, `NumPeriods` is equal to the number of exercise days during the life of the option.

Data Types: `single` | `double`

`Z` — Time series array of dependent random variates
vector

Time series array of dependent random variates, specified as the comma-separated pair consisting of `'Z'` and a `NumPeriods`-by-2-by-`NumTrials` 3-D array. The `Z` value generates the Brownian motion vector (that is, Wiener processes) that drives the simulation.

Data Types: `single` | `double`

`Antithetic` — Indicator for antithetic sampling
`false` (default) | logical flag with value of `true` or `false`

Indicator for antithetic sampling, specified as the comma-separated pair consisting of `'Antithetic'` and a value of `true` or `false`.

Data Types: `logical`

`OutSpec` — Define outputs
`{'Price'}` (default) | character vector with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'` | cell array of character vectors with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`

Define outputs, specified as the comma-separated pair consisting of `'OutSpec'`and a `NOUT`- by-`1` or `1`-by-`NOUT` cell array of character vectors with possible values of `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`.

`OutSpec = {'All'}` specifies that the output should be `Delta`, `Gamma`, `Vega`, `Lambda`, `Rho`, `Theta`, and `Price`, in that order. This is the same as specifying `OutSpec` to include each sensitivity:

Example: `OutSpec = {'delta','gamma','vega','lambda','rho','theta','price'}`

Data Types: `char` | `cell`

Output Arguments

`PriceSens` — Expected price or sensitivities of spread option

scalar

Expected price or sensitivities of the spread option, returned as a 1-by-1 array as defined by `OutSpec`.

`Paths` — Simulated paths of correlated state variables

vector

Simulated paths of correlated state variables, returned as a `NumPeriods + 1`-by-2-by-`NumTrials` 3-D time series array. Each row of `Paths` is the transpose of the state vector $X(t)$ at time t for a given trial.

`Times` — Observation times associated with simulated paths

vector

Observation times associated with simulated paths, returned as a `NumPeriods + 1`-by-1 column vector of observation times associated with the simulated paths. Each element of `Times` is associated with the corresponding row of `Paths`.

`Z` — Time series array of dependent random variates

vector

Time series array of dependent random variates, returned as a `NumPeriods`-by-2-by-`NumTrials` 3-D array when `Z` is specified as an input argument. If the `Z` input argument is not specified, then the `Z` output argument contains the random variates generated internally.

More About

Spread Option

A spread option is an option written on the difference of two underlying assets.

For example, a European call on the difference of two assets *X1* and *X2* would have the following pay off at maturity:

$$\max(X1 - X2 - K, 0)$$

where:

K is the strike price.

For more information, see “Spread Option” on page 3-30.

Version History

Introduced in R2013b

Serial date numbers not recommended
Not recommended starting in R2022b

Although `spreadsensbyls` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

spreadsensbyfd

Calculate price and sensitivities of European or American spread options using finite difference method

Syntax

```
PriceSens = spreadsensbyfd(RateSpec,StockSpec1,StockSpec2,Settle,Maturity,
OptSpec,Strike,Corr)
PriceSens = spreadsensbyfd( ___ ,Name,Value)

[PriceSens,PriceGrid,AssetPrice1,AssetPrice2,Times] = spreadsensbyfd(
RateSpec,StockSpec1,StockSpec2,Settle,Maturity,OptSpec,Strike,Corr)
[PriceSens,PriceGrid,AssetPrice1,AssetPrice2,Times] = spreadsensbyfd( ___ ,
Name,Value)
```

Description

`PriceSens = spreadsensbyfd(RateSpec,StockSpec1,StockSpec2,Settle,Maturity, OptSpec,Strike,Corr)` returns the price and sensitivities of European or American call or put spread options using the Alternate Direction Implicit (ADI) finite difference method. The spread is between the asset defined in `StockSpec1` minus the asset defined in `StockSpec2`.

`PriceSens = spreadsensbyfd( ___ ,Name,Value)` adds optional name-value pair arguments.

`[PriceSens,PriceGrid,AssetPrice1,AssetPrice2,Times] = spreadsensbyfd( RateSpec,StockSpec1,StockSpec2,Settle,Maturity,OptSpec,Strike,Corr)` returns the `PriceSens`, `PriceGrid`, `AssetPrice1`, `AssetPrice2`, and `Times` for European or American call or put spread options using the Alternate Direction Implicit (ADI) finite difference method. The spread is between the asset defined in `StockSpec1` minus the asset defined in `StockSpec2`.

`[PriceSens,PriceGrid,AssetPrice1,AssetPrice2,Times] = spreadsensbyfd( ___ , Name,Value)` returns the `PriceSens`, `PriceGrid`, `AssetPrice1`, `AssetPrice2`, and `Times` and adds optional name-value pair arguments.

Examples

Compute the Price of a Spread Option Using the Alternate Direction Implicit (ADI) Finite Difference Method

Define the spread option dates.

```
Settle = datetime(2012,6,1);
Maturity = datetime(2012,9,1);
```

Define asset 1. Price and volatility of RBOB gasoline

```
  Price1gallon = 2.85;          % $/gallon
  Price1 = Price1gallon * 42;   % $/barrel
  Vol1 = 0.29;
```

Define asset 2. Price and volatility of WTI crude oil

```
Price2 = 93.20;          % $/barrel
Vol2 = 0.36;
```

Define the correlation between the underlying asset prices of asset 1 and asset 2.

```
Corr = 0.42;
```

Define the spread option.

```
OptSpec = 'call';
Strike = 20;
```

Define the `RateSpec`.

```
rates = 0.05;
Compounding = -1;
Basis = 1;
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
'EndDates', Maturity, 'Rates', rates, ...
'Compounding', Compounding, 'Basis', Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9876
            Rates: 0.0500
          EndTimes: 0.2500
        StartTimes: 0
          EndDates: 735113
        StartDates: 735021
    ValuationDate: 735021
            Basis: 1
     EndMonthRule: 1
```

Define the `StockSpec` for the two assets.

```
StockSpec1 = stockspec(Vol1, Price1)
```

```
StockSpec1 = struct with fields:
              FinObj: 'StockSpec'
               Sigma: 0.2900
         AssetPrice: 119.7000
        DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

```
StockSpec2 = stockspec(Vol2, Price2)
```

```
StockSpec2 = struct with fields:
              FinObj: 'StockSpec'
               Sigma: 0.3600
         AssetPrice: 93.2000
        DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Compute the spread option price and sensitivities based on the Alternate Direction Implicit (ADI) finite difference method.

```
OutSpec = {'Price', 'Delta', 'Gamma'};
[Price, Delta, Gamma, PriceGrid, AssetPrice1, AssetPrice2, Times] = ...
spreadsensbyfd(RateSpec, StockSpec1, StockSpec2, Settle, ...
Maturity, OptSpec, Strike, Corr, 'OutSpec', OutSpec);
```

Display the price and sensitivities.

```
Price
```

```
Price = 11.1998
```

```
Delta
```

```
Delta = 1×2

    0.6736   -0.6082
```

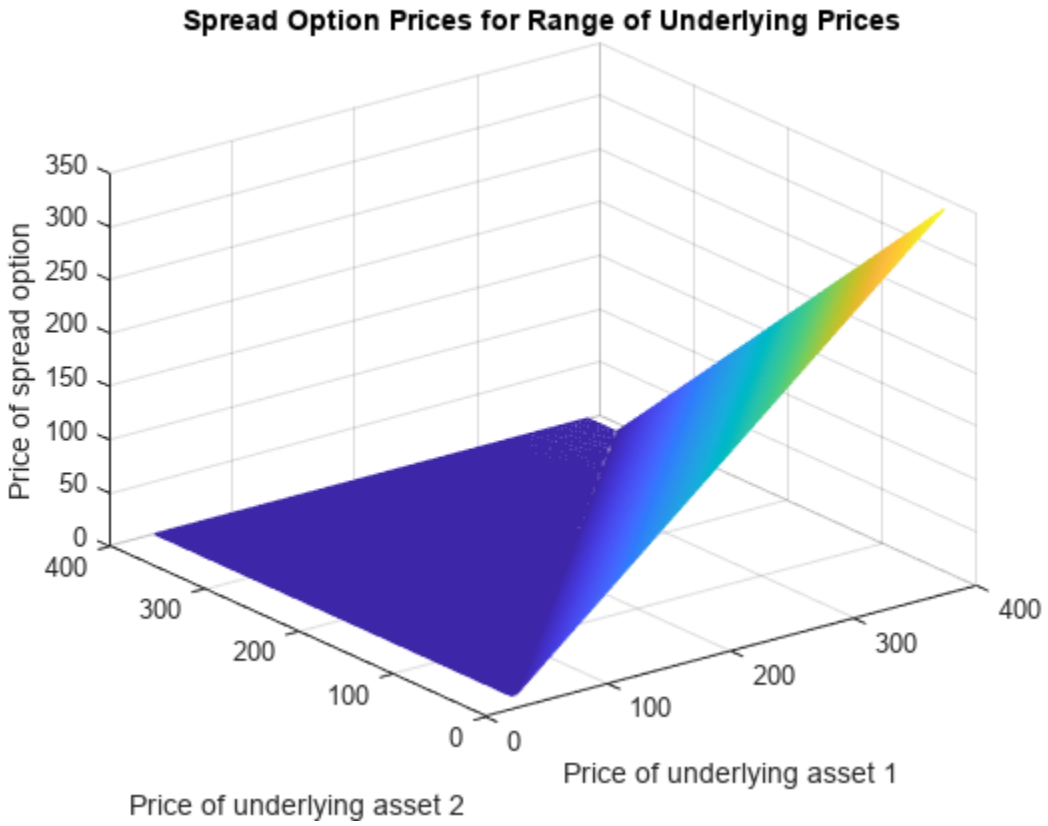
```
Gamma
```

```
Gamma = 1×2

    0.0190    0.0214
```

Plot the finite difference grid.

```
mesh(AssetPrice1, AssetPrice2, PriceGrid(:, :, 1)');
    title('Spread Option Prices for Range of Underlying Prices');
    xlabel('Price of underlying asset 1');
    ylabel('Price of underlying asset 2');
    zlabel('Price of spread option');
```



Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

StockSpec1 — Stock specification for underlying asset 1

structure

Stock specification for underlying asset 1. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, for physical commodities the price is represented by `StockSpec.Asset`, the volatility is represented by `StockSpec.Sigma`, and the convenience yield is represented by `StockSpec.DividendAmounts`.

Data Types: `struct`

StockSpec2 — Stock specification for underlying asset 2

structure

Stock specification for underlying asset 2. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, for physical commodities the price is represented by `StockSpec.Asset`, the volatility is represented by `StockSpec.Sigma`, and the convenience yield is represented by `StockSpec.DividendAmounts`.

Data Types: `struct`

`Settle` — Settlement dates for spread option
datetime array | string array | date character vector

Settlement dates for the spread option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `spreadsensbyfd` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date for spread option
datetime array | string array | date character vector

Maturity date for spread option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `spreadsensbyfd` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option
character vector with values `'call'` or `'put'` | cell array of character vectors

Definition of option as `'call'` or `'put'`, specified as a `NINST`-by-`1` cell array of character vectors.

Data Types: `char` | `cell`

`Strike` — Option strike price values
integer | vector of integers

Option strike price values, specified as an integer using a `NINST`-by-`1` vector of strike price values.

Data Types: `double`

`Corr` — Correlation between underlying asset prices
integer | vector of integers

Correlation between underlying asset prices, specified as an integer using a`NINST`-by-`1` vector.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[PriceSens,PriceGrid,AssetPrice1,AssetPrice2,Times] = spreadsensbyfd(RateSpec,StockSpec1,StockSpec2,Settle,Maturity,OptSpec,Strike, Corr, 'AssetPriceMin','AssetPriceMax','PriceGridSize','TimeGridSize','AmericanOpt', 0,'OutSpec',{'All'})`

OutSpec — Define outputs
{'Price'} (default) | character vector with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All' | cell array of character vectors with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and a NOUT- by-1 or 1-by-NOUT cell array of character vectors with possible values of 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'.

OutSpec = {'All'} specifies that the output should be Delta, Gamma, Vega, Lambda, Rho, Theta, and Price, in that order. This is the same as specifying OutSpec to include each sensitivity:

Example: OutSpec = {'delta','gamma','vega','lambda','rho','theta','price'}

Data Types: char | cell

AssetPriceMin — Minimum price for price grid boundary
if unspecified, StockSpec values are calculated based on asset distributions at maturity (default) | array

Minimum price for price grid boundary, specified as the comma-separated pair consisting of 'AssetPriceMin' and a 1-by-2 array. The first entry in the array corresponds to the first asset defined by StockSpec1 and the second entry corresponds to the second asset defined by StockSpec2.

For the finite difference method, the composition of the grid affects the quality of the output and the execution time. It is highly recommended to use the optional arguments AssetPriceMin, AssetPriceMax, PriceGridSize, and TimeGridSize to control the composition of the grid to ensure the quality of the output and a reasonable execution time.

Data Types: single | double

AssetPriceMax — Maximum price for price grid boundary
if unspecified, StockSpec values are calculated based on asset distributions at maturity (default) | array

Maximum price for price grid boundary, specified as the comma-separated pair consisting of 'AssetPriceMax' and a 1-by-2 array. The first entry in the array corresponds to the first asset defined by StockSpec1 and the second entry corresponds to the second asset defined by StockSpec2.

For the finite difference method, the composition of the grid affects the quality of the output and the execution time. It is highly recommended to use the optional arguments AssetPriceMin, AssetPriceMax, PriceGridSize, and TimeGridSize to control the composition of the grid to ensure the quality of the output and a reasonable execution time.

Data Types: single | double

PriceGridSize — Size for finite difference grid
[300,300] (default) | array

Size for finite difference grid, specified as the comma-separated pair consisting of 'PriceGridSize' and a 1-by-2 array. The first entry corresponds to the first asset defined by StockSpec1 and the second entry corresponds to the second asset defined by StockSpec2.

For the finite difference method, the composition of the grid affects the quality of the output and the execution time. It is highly recommended to use the optional argumentsAssetPriceMax,

PriceGridSize, and TimeGridSize to control the composition of the grid to ensure the quality of the output and a reasonable execution time.

Data Types: single | double

TimeGridSize — Size of time grid for finite difference grid
100 (default) | scalar | nonnegative integer

Size of time grid for finite difference grid, specified as the comma-separated pair consisting of 'TimeGridSize' and a nonnegative integer.

For the finite difference method, the composition of the grid affects the quality of the output and the execution time. It is highly recommended to use the optional argumentsAssetPriceMax, PriceGridSize, and TimeGridSize to control the composition of the grid to ensure the quality of the output and a reasonable execution time.

Data Types: single | double

AmericanOpt — Option type
0 European (default) | scalar | vector of positive integers[0,1]

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and NINST-by-1 positive integer scalar flags with values:

- 0 — European
- 1 — American

Data Types: single | double

Output Arguments

PriceSens — Expected prices or sensitivities of spread option
scalar

Expected price or sensitivities of the spread option, returned as a 1-by-1 array as defined by OutSpec.

PriceGrid — Grid containing prices calculated by finite difference method
array

Grid containing prices calculated by finite difference method, returned as a 3-D grid with a size of PriceGridSize(1) * PriceGridSize(2) * TimeGridSize. The price for t = 0 is contained in PriceGrid(:, :, 1).

AssetPrice1 — Prices for first asset defined by StockSpec1
vector

Prices for first asset defined by StockSpec1, corresponding to the first dimension of PriceGrid, returned as a vector.

AssetPrice2 — Prices for second asset defined by StockSpec2
vector

Prices for second asset defined by StockSpec2, corresponding to the second dimension of PriceGrid, returned as a vector.

`Times` — Times corresponding to third dimension of `PriceGrid`
vector

Times corresponding to third dimension of `PriceGrid`, returned as a vector.

More About

Spread Option

A spread option is an option written on the difference of two underlying assets.

For example, a European call on the difference of two assets *X1* and *X2* would have the following pay off at maturity:

$$\max(X1 - X2 - K, 0)$$

where:

K is the strike price.

For more information, see “Spread Option” on page 3-30.

Version History

Introduced in R2013b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `spreadsensbyfd` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

stockoptspec

Specify European stock option structure

Syntax

```
StockOptSpec = stockoptspec(OptPrice,Strike,Settle,Maturity,OptSpec,
InterpMethod)
StockOptSpec = stockoptspec( ___ ,InterpMethod)
```

Description

`StockOptSpec = stockoptspec(OptPrice,Strike,Settle,Maturity,OptSpec, InterpMethod)` creates a structure encapsulating the properties of a stock option structure.

`StockOptSpec = stockoptspec( ___ ,InterpMethod)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

Examples

Specify a European Stock Option Structure

This example shows how to specify a European stock option structure using the following data quoted from liquid options in the market with varying strikes and maturity.

```
Settle =   datetime(2006,1,1);

Maturity = [datetime(2006,7,1) ; datetime(2006,7,1) ; datetime(2006,7,1) ; datetime(2006,7,1) ; d
    datetime(2007,7,1) ; datetime(2007,7,1) ; datetime(2007,7,1) ; datetime(2008,1,1) ; datetime

Strike = [113;
   101;
   100;
    88;
   128;
   112;
   100;
    78;
   144;
   112;
   100;
    69;
   162;
   112;
   100;
    61];

OptPrice =[                0;
   4.807905472659144;
   1.306321897011867;
   0.048039195057173;
                   0;
```

```
   2.310953054191461;
   1.421950392866235;
   0.020414826276740;
                    0;
   5.091986935627730;
   1.346534812295291;
   0.005101325584140;
                    0;
   8.047628153217246;
   1.219653432150932;
   0.001041436654748];

OptSpec = { 'call';
    'call';
    'put';
    'put';
    'call';
    'call';
    'put';
    'put';
    'call';
    'call';
    'put';
    'put';
    'call';
    'call';
    'put';
    'put'};

StockOptSpec = stockoptspec(OptPrice, Strike, Settle, Maturity, OptSpec)

StockOptSpec = struct with fields:
          FinObj: 'StockOptSpec'
        OptPrice: [16x1 double]
          Strike: [16x1 double]
          Settle: 732678
        Maturity: [16x1 double]
         OptSpec: {16x1 cell}
    InterpMethod: 'price'
```

Input Arguments

`OptPrice` — European option prices

vector

European option prices, specified as an `NINST`-by-`1` vector.

Data Types: `double`

`Strike` — Strike prices

vector

Strike prices, specified as an `NINST`-by-`1` vector.

Data Types: `double`

`Settle` — Settlement date
datetime scalar | string scalar | date character vector

Settlement date, specified as a scalar datetime, string, or date character vector.

To support existing code, `stockoptspec` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity dates
datetime array | string array | date character vector

Maturity dates, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `stockoptspec` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Option type
cell array of character vectors with a value of `'call'` or `'put'`

Option type, specified as an `NINST`-by-`1` cell array of character vectors with a value of `'call'` or `'put'`.

Data Types: `cell`

`InterpMethod` — Interpolation method for option prices
`'price'` (default) | scalar character vector with value of `'price'` or `'vol'`

(Optional) Interpolation method for option prices, specified as a scalar character vector with one of the following values:

- `'price'` indicates that prices are used for interpolation purposes.
- `'vol'` indicates that implied volatilities are used for interpolation purposes. The interpolated values are then used to calculate the implicit interpolated prices.

.

Data Types: `char`

Output Arguments

`StockOptSpec` — Structure encapsulating the properties of a stock options structure
structure

Structure encapsulating the properties of a stock options structure, returned as a structure.

Version History

Introduced in R2007a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `stockoptspec` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

stockspec

Create stock structure

Syntax

```
StockSpec = stockspec(Sigma,AssetPrice)
StockSpec = stockspec( ___ ,DividendType,DividendAmounts,ExDividendDates)
```

Description

`StockSpec = stockspec(Sigma,AssetPrice)` creates a MATLAB structure containing the properties of a stock.

Note `StockSpec` handles other types of underliers when pricing instruments other than equities.

`StockSpec = stockspec( ___ ,DividendType,DividendAmounts,ExDividendDates)` adds optional arguments for `DividendType`, `DividendAmounts`, and `ExDividendDates`.

Examples

Create a StockSpec for Stocks With Cash Dividends

Consider a stock that provides four cash dividends of $0.50 on January 3, 2008, April 1, 2008, July 5, 2008 and October 1, 2008. The stock is trading at $50, and has a volatility of 20% per annum. Using this data, create the structure `StockSpec`:

```
AssetPrice = 50;
Sigma = 0.20;

DividendType = {'cash'};
DividendAmounts = [0.50, 0.50, 0.50, 0.50];
ExDividendDates = [datetime(2008,1,3) , datetime(2008,4,1) , datetime(2008,7,5) , datetime(2008,1
```

```
StockSpec = stockspec(Sigma, AssetPrice, DividendType, DividendAmounts, ExDividendDates)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.2000
         AssetPrice: 50
       DividendType: {'cash'}
    DividendAmounts: [0.5000 0.5000 0.5000 0.5000]
    ExDividendDates: [733410 733499 733594 733682]
```

Examine the `StockSpec` structure.

```
datedisp(StockSpec.ExDividendDates)
```

```
03-Jan-2008   01-Apr-2008   05-Jul-2008   01-Oct-2008
```

```
StockSpec.DividendType
```

```
ans = 1x1 cell array
    {'cash'}
```

The `StockSpec` structure encapsulates the information of the stock and its four cash dividends.

Create a StockSpec for Stocks With Cash and Continuous Dividends

Consider two stocks that are trading at $40 and $35. The first one provides two cash dividends of $0.25 on March 1, 2008 and June 1, 2008. The second stock provides a continuous dividend yield of 3%. The stocks have a volatility of 30% per annum. Using this data, create the structure `StockSpec`:

```
AssetPrice = [40; 35];
Sigma = .30;

DividendType = {'cash'; 'continuous'};
DividendAmount = [0.25, 0.25 ; 0.03 NaN];

DividendDate1 = datetime(2008,3,1);
DividendDate2 = datetime(2008,6,1);

StockSpec = stockspec(Sigma, AssetPrice, DividendType, DividendAmount,...
{ DividendDate1, DividendDate2 ; NaN NaN})
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: [2x1 double]
         AssetPrice: [2x1 double]
       DividendType: {2x1 cell}
    DividendAmounts: [2x2 double]
    ExDividendDates: [2x2 double]
```

Examine the `StockSpec` structure.

```
datedisp(StockSpec.ExDividendDates)
```

```
01-Mar-2008   01-Jun-2008
   NaN           NaN
```

```
StockSpec.DividendType
```

```
ans = 2x1 cell
    {'cash'      }
    {'continuous'}
```

The `StockSpec` structure encapsulates the information of the two stocks and their dividends.

Input Arguments

`Sigma` — Annual price volatility of underlying security

decimal

Annual price volatility of underlying security, specified as a NINST-by-1 decimal.

Data Types: double

AssetPrice — Underlying asset price values at time 0
vector

Underlying asset price values at time 0, specified as a NINST-by-1 vector.

Data Types: double

DividendType — Stock dividend type
cell array of date character vectors

(Optional) Stock dividend type, specified as a NINST-by-1 cell array of character vectors.

Dividend type must be either cash for actual dollar dividends, constant for constant dividend yield, or continuous for continuous dividend yield. This function does not handle stock option dividends.

Note Dividends are assumed to be paid in cash. Noncash dividends (stock) are not allowed. When combining two or more types of dividends, shorter rows should be padded with the value NaN.

Data Types: char | cell

DividendAmounts — Dividend amounts
matrix | vector

(Optional) Dividend amounts, specified as a NINST-by-NDIV matrix of cash dividends or NINST-by-1 vector representing a constant or continuous annualized dividend yield.

Data Types: double

ExDividendDates — Ex-dividend dates
datetime array | string array | date character vector

(Optional) Ex-dividend dates, specified as a NINST-by-NDIV matrix of ex-dividend dates for a cash DividendType or a NINST-by-1 vector of ex-dividend dates for constant DividendType. For dates, use a datetime array, string array, or date character vectors. For a continuous DividendType, this argument should be ignored.

To support existing code, stockspec also accepts serial date numbers as inputs, but they are not recommended.

Output Arguments

StockSpec — Properties of stock structure
structure

Properties of stock structure, returned as a structure encapsulating the properties of a stock.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `stockspec` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

sttprice

Price instruments using standard trinomial tree

Syntax

```
[Price,PriceTree] = sttprice(STTTree,InstSet)
[Price,PriceTree] = sttprice( ___ ,Name,Value)
```

Description

`[Price,PriceTree] = sttprice(STTTree,InstSet)` prices instruments using a standard trinomial (STT) tree.

`[Price,PriceTree] = sttprice( ___ ,Name,Value)` prices instruments using a standard trinomial (STT) tree with an optional name-value pair argument for `Options`.

Examples

Price a sttree Instrument Set

Load the data into the MATLAB® workspace.

```
load deriv.mat
```

`STTTree` and `STTInstSet` are the input arguments required to call the function `sttprice`. Use the command `instdisp` to examine the set of instruments contained in the variable `STTInstSet`.

```
instdisp(STTInstSet)
```

```

```

The instrument set contains eight instruments:

- Two vanilla options (`Call1`, `Put1`)
- One barrier option (`Barrier1`)
- One compound option (`Compound1`)
- Two lookback options (`Lookback1`, `Lookback2`)
- Two Asian options (`Asian1`, `Asian2`)

Use `sttprice` to calculate the price of each instrument in the instrument set.

```
Price = sttprice(STTTree, STTInstSet)
```

```
Price = 8×1

```

Input Arguments

`STTTree` — Stock tree structure for standard trinomial tree

structure

Stock tree structure for a standard trinomial tree, specified by using `stttree`.

Data Types: `struct`

`InstSet` — Variable containing a collection instruments

structure

Variable containing a collection of `NINST` instruments, specified as a structure. Instruments are broken down by type and each type can have different data fields.

Data Types: `struct`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceTree] = sttprice(STTTree,InstSet,'Options',deriv)`

`Options` — Derivatives pricing options

structure

Derivatives pricing options, specified as the comma-separated pair consisting of `'Options'` and a structure that is created with `derivset`.

Data Types: `struct`

Output Arguments

`Price` — Expected prices for each instrument at time `0`
matrix

Expected prices for each instrument at time `0`, returned as a `NINST`-by-`1` vector. The prices are computed by backward dynamic programming on the standard trinomial (STT) stock tree. If an instrument cannot be priced, a `NaN` is returned in that entry.

`PriceTree` — Structure with vector of instrument prices at each node
tree structure

Structure with a vector of instrument prices at each node, returned as a tree structure.

`PriceTree` is a MATLAB structure of trees containing vectors of instrument prices and a vector of observation times for each node.

`PriceTree.PTree` contains the prices.

`PriceTree.tObs` contains the observation times.

`PriceTree.dObs` contains the observation dates.

sttsens

Instrument sensitivities and prices using standard trinomial tree

Syntax

```
[Delta,Gamma,Vega,Price] = sttsens(STTTree,InstSet)
[Delta,Gamma,Vega,Price] = sttsens(___,Name,Value)
```

Description

`[Delta,Gamma,Vega,Price] = sttsens(STTTree,InstSet)` to generate instrument sensitivities and prices using a standard trinomial (STT) tree.

`[Delta,Gamma,Vega,Price] = sttsens(___,Name,Value)` to generate instrument sensitivities and prices using a standard trinomial (STT) tree with an optional name-value pair argument for `Options`.

Examples

Determine the Price and Sensitivities for a `stttree` Instrument Set

Load the data into the MATLAB® workspace.

```
load deriv.mat
```

`STTTree` and `STTInstSet` are the input arguments required to call the function `sttprice`. Use the command `instdisp` to examine the set of instruments contained in the variable `STTInstSet`.

Input Arguments

STTTree — Stock tree structure for standard trinomial tree

structure

Stock tree structure for a standard trinomial tree, specified by using `stttree`.

Data Types: `struct`

`InstSet` — Variable containing a collection instruments
structure

Variable containing a collection of `NINST` instruments, specified as a structure. Instruments are broken down by type and each type can have different data fields.

Data Types: `struct`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Delta,Gamma,Vega,Price] = sttsens(STTTree,InstSet,'Options',deriv)`

`Options` — Derivatives pricing options
structure

Derivatives pricing options, specified as the comma-separated pair consisting of `'Options'` and a structure that is created with `derivset`.

Data Types: `struct`

Output Arguments

`Delta` — Rate of change of instruments prices with respect to changes in the stock price
vector of deltas

Rate of change of instrument prices with respect to changes in the stock price, returned as a `NINST`-by-`1` vector of deltas. For more information on the stock tree, see `stttree`.

`Gamma` — Rate of change of instrument deltas with respect to changes in the stock price
vector of gammas

Rate of change of instrument deltas with respect to changes in the stock price, returned as a `NINST`-by-`1` vector of gammas.

`Vega` — Rate of change of instrument prices with respect to changes in the volatility of the stock price
vector of vegas

Rate of change of instrument prices with respect to changes in the volatility of the stock price, returned as a `NINST`-by-`1` vector of vegas. For more information on the stock tree, see `stttree`.

`Price` — Expected prices for each instrument at time `0`
matrix

Expected prices for each instrument at time `0`, returned as a `NINST`-by-`1` vector. The prices are computed by backward dynamic programming on the standard trinomial (STT) stock tree. If an instrument cannot be priced, a `NaN` is returned in that entry.

stttimespec

Specify time structure for standard trinomial tree

Syntax

```
TimeSpec = stttimespec(ValuationDate,Maturity,NumPeriods)
```

Description

`TimeSpec = stttimespec(ValuationDate,Maturity,NumPeriods)` creates a time spec for a standard trinomial (STT) tree.

Examples

Create a stttimespec to Build a STTTree

Create a `RateSpec`.

```
StartDates = datetime(2014,1,1);
EndDates = datetime(2018,1,1);
Rates = 0.025;
Basis = 1;
Compounding = -1;

RateSpec = intenvset('ValuationDate', StartDates, 'StartDates', StartDates,'EndDates',...
EndDates, 'Rates', Rates,'Compounding', Compounding, 'Basis', Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1

        STree: {1x49 cell}
        Probs: {1x48 cell}
```

Input Arguments

`ValuationDate` — Date marking the pricing date and first observation tree

datetime scalar | string scalar | date character vector

Date marking the pricing date and first observation in the tree, specified as a scalar datetime, string, or date character vector.

To support existing code, `stttimespec` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Date marking the depth of tree

datetime scalar | string scalar | date character vector

Date marking the depth of the tree, specified as a scalar using a scalar datetime, string, or date character vector.

To support existing code, `stttimespec` also accepts serial date numbers as inputs, but they are not recommended.

`NumPeriods` — Determines how many time steps are in tree
nonnegative integer

Determines how many time steps are in tree, specified as a scalar using a nonnegative integer value.

Data Types: `double`

Output Arguments

`TimeSpec` — Time layout for standard trinomial (STT) tree
structure

Time layout for standard trinomial (STT) tree, returned as a structure.

Version History

Introduced in R2015b

Serial date numbers not recommended
Not recommended starting in R2022b

Although `stttimespec` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

     RateSpec: [1x1 struct]
         tObs: [0 0.5000 1 1.5000 2 2.5000 3 3.5000 4]
         dObs: [735600 735782 735965 736147 736330 736513 736695 736878 ... ]
        STree: {1x9 cell}
        Probs: {1x8 cell}
```

Input Arguments

StockSpec — Stock specification for underlying asset

structure

Stock specification for underlying asset, specified using StockSpec obtained from stockspec. For information on the stock specification, see stockspec.

stockspec can handle other types of underlying assets. For example, stocks, stock indices, and commodities. If dividends are not specified in StockSpec, dividends are assumed to be 0.

Data Types: struct

RateSpec — Interest-rate term specification of initial risk-free rate curve

structure

Interest-rate term specification of initial risk-free rate curve, specified by the RateSpec obtained from intenvset. For information on the interest-rate specification, see intenvset.

Data Types: struct

TimeSpec — Tree time layout specification

structure

Tree time layout specification, specified using stttimespec to define the observation dates of the standard trinomial (STT) tree.

Data Types: struct

Output Arguments

STTTree — Tree specifying stock and time information for a standard trinomial (STT) tree

tree structure

Tree specifying stock and time information for a standard trinomial (STT) tree, returned as a tree structure.

Version History

Introduced in R2015b

supersharebybls

Determine price of supershare digital options using Black-Scholes model

Syntax

```
Price = supersharebybls(RateSpec,StockSpec,Settle,Maturity,StrikeLow,
StrikeHigh)
```

Description

`Price = supersharebybls(RateSpec,StockSpec,Settle,Maturity,StrikeLow, StrikeHigh)` computes supershare digital options using the Black-Scholes option pricing model.

Examples

Compute the Price of Supershare Digital Options Using Black-Scholes Model

This example shows how to compute the price of supershare digital options using Black-Scholes model. Consider a supershare based on a portfolio of nondividend paying stocks with a lower strike of 350 and an upper strike of 450. The value of the portfolio on November 1, 2008 is 400. The risk-free rate is 4.5% and the volatility is 18%. Using this data, calculate the price of the supershare option on February 1, 2009.

```
Settle = datetime(2008,11,1);
Maturity = datetime(2009,2,1);
Rates = 0.045;
Basis = 1;
Compounding = -1;

% create the RateSpec
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle,...
'EndDates', Maturity, 'Rates', Rates, 'Compounding', Compounding, 'Basis', Basis);

% define the StockSpec
AssetPrice = 400;
Sigma = .18;
StockSpec = stockspec(Sigma, AssetPrice);

% define the high and low strike points
StrikeLow = 350;
StrikeHigh = 450;

% calculate the price
Pssh = supersharebybls(RateSpec, StockSpec, Settle, Maturity,...
StrikeLow, StrikeHigh)

Pssh = 0.9411
```

Input Arguments

RateSpec — Interest-rate term structure
structure

Interest-rate term structure (annualized and continuously compounded), specified by the RateSpec obtained from intenvset. For information on the interest-rate specification, see intenvset.

Data Types: struct

StockSpec — Stock specification for underlying asset
structure

Stock specification for the underlying asset. For information on the stock specification, see stockspec.

stockspec handles several types of underlying assets. For example, for physical commodities the price is StockSpec.Asset, the volatility is StockSpec.Sigma, and the convenience yield is StockSpec.DividendAmounts.

Data Types: struct

Settle — Settlement or trade date
datetime array | string array | date character vector

Settlement or trade date for the basket option, specified as an NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, supersharebybls also accepts serial date numbers as inputs, but they are not recommended.

Maturity — Maturity date
datetime array | string array | date character vector

Maturity date for the basket option, specified as an NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, supersharebybls also accepts serial date numbers as inputs, but they are not recommended.

StrikeLow — Low strike price values
vector

Low strike price values, specified as an NINST-by-1 vector.

Data Types: double

StrikeHigh — High strike price values
vector

High strike price values, specified as an NINST-by-1 vector.

Data Types: double

Output Arguments

`Price` — Expected prices for supershare option

vector

Expected prices for supershare option, returned as a `NINST`-by-`1` vector.

More About

Supershare Option

A supershare option pays out a proportion of the assets underlying a portfolio if the asset lies between a lower and an upper bound at the expiry of the option.

For more information, see “Digital Option” on page 3-26.

Version History

Introduced in R2009a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `supersharebybls` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

supersharesensbybls

Determine price or sensitivities of supershare digital options using Black-Scholes model

Syntax

```
PriceSens = supersharesensbybls(RateSpec,StockSpec,Settle,Maturity,StrikeLow,
StrikeHigh)
PriceSens = supersharesensbybls( ___ ,Name,Value)
```

Description

`PriceSens = supersharesensbybls(RateSpec,StockSpec,Settle,Maturity,StrikeLow, StrikeHigh)` computes price or sensitivities of supershare digital options using the Black-Scholes option pricing model.

`PriceSens = supersharesensbybls( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Compute Price and Sensitivities of Supershare Digital Options Using Black-Scholes Model

This example shows how to compute price and sensitivities of supershare digital options using a Black-Scholes model. Consider a supershare based on a portfolio of nondividend paying stocks with a lower strike of 350 and an upper strike of 450. The value of the portfolio on November 1, 2008 is 400. The risk-free rate is 4.5% and the volatility is 18%. Using this data, calculate the price and sensitivity of the supershare option on February 1, 2009.

```
Settle = datetime(2008,11,1);
Maturity = datetime(2009,2,1);
Rates = 0.045;
Basis = 1;
Compounding = -1;

% define the RateSpec
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle,...
'EndDates', Maturity, 'Rates', Rates, 'Compounding', Compounding, 'Basis', Basis);

% define the StockSpec
AssetPrice = 400;
Sigma = .18;
StockSpec = stockspec(Sigma, AssetPrice);

% define the high and low strike points
StrikeLow = 350;
StrikeHigh = 450;

% calculate the price
Pssh = supersharebybls(RateSpec, StockSpec, Settle, Maturity,...
StrikeLow, StrikeHigh)
```

```
Pssh = 0.9411

% compute the delta and theta of the supershare option
OutSpec = { 'delta';'theta'};
[Delta, Theta]= supersharesensbybls(RateSpec, StockSpec, Settle,...
Maturity, StrikeLow, StrikeHigh, 'OutSpec', OutSpec)

Delta = -0.0010

Theta = -1.0102
```

Input Arguments

`RateSpec` — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

`StockSpec` — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

`Settle` — Settlement or trade date

datetime array | string array | date character vector

Settlement or trade date for the basket option, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `supersharesensbybls` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date for the basket option, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `supersharesensbybls` also accepts serial date numbers as inputs, but they are not recommended.

`StrikeLow` — Low strike price values

vector

Low strike price values, specified as an `NINST`-by-`1` vector.

Data Types: double

StrikeHigh — High strike price values
vector

High strike price values, specified as an NINST-by-1 vector.

Data Types: double

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: [Gamma,Theta,Price] = supersharesensbybls(RateSpec,StockSpec,Settle,Maturity,StrikeLow,StrikeHigh,'OutSpec',{'gamma';'theta';'price'})

OutSpec — Define outputs
{'Price'} (default) | character vector with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All' | cell array of character vectors with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and a NOUT- by-1 or a 1-by-NOUT cell array of character vectors with possible values of 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'.

OutSpec = {'All'} specifies that the output is Delta, Gamma, Vega, Lambda, Rho, Theta, and Price, in that order. This is the same as specifying OutSpec to include each sensitivity.

Example: OutSpec = {'delta','gamma','vega','lambda','rho','theta','price'}

Data Types: char | cell

Output Arguments

PriceSens — Expected prices or sensitivities for supershare option
vector

Expected prices or sensitivities for supershare option, returned as a NINST-by-1 vector.

More About

Supershare Option

A supershare option pays out a proportion of the assets underlying a portfolio if the asset lies between a lower and an upper bound at the expiry of the option.

For more information, see “Digital Option” on page 3-26.

Version History

Introduced in R2009a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `supersharesensbybls` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

swapbybdt

Price swap instrument from Black-Derman-Toy interest-rate tree

Syntax

```
[Price,PriceTree,CFTree,SwapRate] = swapbybdt(BDTTree,LegRate,Settle,
Maturity)
[Price,PriceTree,CFTree,SwapRate] = swapbybdt( ___ ,Name,Value)
```

Description

`[Price,PriceTree,CFTree,SwapRate] = swapbybdt(BDTTree,LegRate,Settle, Maturity)` prices a swap instrument from a Black-Derman-Toy interest-rate tree. `swapbybdt` computes prices of vanilla swaps, amortizing swaps and forward swaps.

Note Alternatively, you can use the `Swap` object to price swap instruments. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,PriceTree,CFTree,SwapRate] = swapbybdt( ___ ,Name,Value)` adds additional name-value pair arguments.

Examples

Price an Interest-Rate Swap

Price an interest-rate swap with a fixed receiving leg and a floating paying leg. Payments are made once a year, and the notional principal amount is $100. The values for the remaining arguments are:

- Coupon rate for fixed leg: 0.15 (15%)
- Spread for floating leg: 10 basis points
- Swap settlement date: Jan. 01, 2000
- Swap maturity date: Jan. 01, 2003

Based on the information above, set the required arguments and build the `LegRate`, `LegType`, and `LegReset` matrices:

```
Settle = datetime(2000,1,1);
Maturity = datetime(2003,1,1);
Basis = 0;
Principal = 100;
LegRate = [0.15 10]; % [CouponRate Spread]
LegType = [1 0]; % [Fixed Float]
LegReset = [1 1]; % Payments once per year
```

Price the swap using the `BDTTree` included in the MAT-file `deriv.mat`. `BDTTree` contains the time and forward-rate information needed to price the instrument.

```
load deriv.mat;
```

Use `swapbybdt` to compute the price of the swap.

```
Price  = swapbybdt(BDTTree, LegRate, Settle, Maturity,...
LegReset, Basis, Principal, LegType)
```

```
Price = 7.4222
```

Using the previous data, calculate the swap rate, the coupon rate for the fixed leg, such that the swap price at time = 0 is zero.

```
LegRate = [NaN 20];

[Price, PriceTree, CFTree, SwapRate] = swapbybdt(BDTTree,...
LegRate, Settle, Maturity, LegReset, Basis, Principal, LegType)
```

```
Price = -1.4211e-14

PriceTree = struct with fields:
    FinObj: 'BDTPriceTree'
      tObs: [0 1 2 3 4]
     PTree: {1x5 cell}

CFTree = struct with fields:
    FinObj: 'BDTCFTree'
      tObs: [0 1 2 3 4]
    CFTree: {[NaN]  [NaN NaN]  [NaN NaN NaN]  [NaN NaN NaN NaN]  [NaN NaN NaN NaN]}

SwapRate = 0.1205
```

Price an Amortizing Swap

Price an amortizing swap using the `Principal` input argument to define the amortization schedule.

Create the `RateSpec`.

```
Rates = 0.035;
ValuationDate = datetime(2011,1,1);
StartDates = ValuationDate;
EndDates = datetime(2017,1,1);
Compounding = 1;

RateSpec = intenvset('ValuationDate', ValuationDate,'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: 0.8135
            Rates: 0.0350
         EndTimes: 6
       StartTimes: 0
         EndDates: 736696
```

```
       StartDates: 734504
    ValuationDate: 734504
            Basis: 0
     EndMonthRule: 1
```

Create the swap instrument using the following data:

```
Settle = datetime(2011,1,1);
Maturity = datetime(2017,1,1);
Period = 1;
LegRate = [0.04 10];
```

Define the swap amortizing schedule.

```
Principal ={{datetime(2013,1,1) 100;datetime(2014,1,1) 80;datetime(2015,1,1) 60;datetime(2016,1,1
```

Build the BDT tree and assume volatility is 10%.

```
MatDates = [datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1) ; d
BDTTimeSpec = bdttimespec(ValuationDate, MatDates);
Volatility = 0.10;
BDTVolSpec = bdtvolspec(ValuationDate, MatDates, Volatility*ones(1,length(MatDates))');
BDTT = bdttree(BDTVolSpec, RateSpec, BDTTimeSpec);
```

Compute the price of the amortizing swap.

```
Price = swapbybdt(BDTT, LegRate, Settle, Maturity, 'Principal' , Principal)
```

```
Price = 1.4574
```

Price a Forward Swap

Price a forward swap using the `StartDate` input argument to define the future starting date of the swap.

Create the `RateSpec`.

```
Rates = 0.0325;
ValuationDate = datetime(2012,1,1);
StartDates = ValuationDate;
EndDates = datetime(2018,1,1);
Compounding = 1;

RateSpec = intenvset('ValuationDate', ValuationDate,'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: 0.8254
            Rates: 0.0325
         EndTimes: 6
       StartTimes: 0
         EndDates: 737061
       StartDates: 734869
```

```
    ValuationDate: 734869
            Basis: 0
     EndMonthRule: 1
```

Build the tree with a volatility of 10%.

```
MatDates = [datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1) ; datetime(2016,1,1) ; d
BDTTimeSpec = bdttimespec(ValuationDate, MatDates);
Volatility = 0.10;
BDTVolSpec = bdtvolspec(ValuationDate, MatDates, Volatility*ones(1,length(MatDates))');
BDTT = bdttree(BDTVolSpec, RateSpec, BDTTimeSpec);
```

Compute the price of a forward swap that starts in two years (Jan 1, 2014) and matures in three years with a forward swap rate of 3.85%.

```
Settle = datetime(2012,1,1);
Maturity = datetime(2017,1,1);
StartDate = datetime(2014,1,1);
LegRate = [0.0385 10];

Price = swapbybdt(BDTT, LegRate, Settle, Maturity, 'StartDate', StartDate)
```

```
Price = 1.3203
```

Using the previous data, compute the forward swap rate, the coupon rate for the fixed leg, such that the forward swap price at time = 0 is zero.

```
LegRate = [NaN 10];
[Price, ~,~, SwapRate] = swapbybdt(BDTT, LegRate, Settle, Maturity, 'StartDate', StartDate)
```

```
Price = -4.9738e-12

SwapRate = 0.0335
```

Input Arguments

BDTTree — Interest-rate structure

structure

Interest-rate tree structure, created by `bdttree`

Data Types: `struct`

LegRate — Leg rate

matrix

Leg rate, specified as a `NINST`-by-2 matrix, with each row defined as one of the following:

- `[CouponRate Spread]` (fixed-float)
- `[Spread CouponRate]` (float-fixed)
- `[CouponRate CouponRate]` (fixed-fixed)
- `[Spread Spread]` (float-float)

`CouponRate` is the decimal annual rate. `Spread` is the number of basis points over the reference rate. The first column represents the receiving leg, while the second column represents the paying leg.

Data Types: `double`

`Settle` — Settlement date
datetime array | string array | date character vector

Settlement date, specified either as a scalar or `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `swapbybdt` also accepts serial date numbers as inputs, but they are not recommended.

The `Settle` date for every swap is set to the `ValuationDate` of the BDT tree. The swap argument `Settle` is ignored.

`Maturity` — Maturity date
datetime array | string array | date character vector

Maturity date, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors representing the maturity date for each swap.

To support existing code, `swapbybdt` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceTree,CFTree,SwapRate] = swapbybdt(BDTTree,LegRate,Settle,Maturity,LegReset,Basis,Principal,LegType)`

`LegReset` — Reset frequency per year for each swap
`[1 1]` (default) | vector

Reset frequency per year for each swap, specified as the comma-separated pair consisting of `'LegReset'` and a `NINST`-by-`2` vector.

Data Types: `double`

`Basis` — Day-count basis representing the basis for each leg
`0` (actual/actual) (default) | integer from `0` to `13`

Day-count basis representing the basis for each leg, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-`1` array (or `NINST`-by-`2` if `Basis` is different for each leg).

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360

- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amounts or principal value schedules
`100` (default) | vector or cell array

Notional principal amounts or principal value schedules, specified as the comma-separated pair consisting of `'Principal'` and a vector or cell array.

`Principal` accepts a `NINST`-by-`1` vector or `NINST`-by-`1` cell array (or `NINST`-by-`2` if `Principal` is different for each leg) of the notional principal amounts or principal value schedules. For schedules, each element of the cell array is a `NumDates`-by-`2` array where the first column is dates and the second column is its associated notional principal value. The date indicates the last day that the principal value is valid.

Data Types: `cell` | `double`

`LegType` — Leg type
`[1 0]` for each instrument (default) | matrix with values `[1 1]` (fixed-fixed), `[1 0]` (fixed-float), `[0 1]` (float-fixed), or `[0 0]` (float-float)

Leg type, specified as the comma-separated pair consisting of `'LegType'` and a `NINST`-by-`2` matrix with values `[1 1]` (fixed-fixed), `[1 0]` (fixed-float), `[0 1]` (float-fixed), or `[0 0]` (float-float). Each row represents an instrument. Each column indicates if the corresponding leg is fixed (`1`) or floating (`0`). This matrix defines the interpretation of the values entered in `LegRate`. `LegType` allows `[1 1]` (fixed-fixed), `[1 0]` (fixed-float), `[0 1]` (float-fixed), or `[0 0]` (float-float) swaps

Data Types: `double`

`Options` — Derivatives pricing options structure
structure

Derivatives pricing options structure, specified as the comma-separated pair consisting of `'Options'` and a structure obtained from using `derivset`.

Data Types: `struct`

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month having 30 or fewer days
`1` (in effect) (default) | nonnegative integer `[0,1]`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month having 30 or fewer days, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer [`0`, `1`] using a `NINST`-by-`1` (or `NINST`-by-`2` if `EndMonthRule` is different for each leg).

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

`AdjustCashFlowsBasis` — Flag to adjust cash flows based on actual period day count
`false` (default) | value of `0` (false) or `1` (true)

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of `'AdjustCashFlowsBasis'` and a `NINST`-by-`1` (or `NINST`-by-`2` if `AdjustCashFlowsBasis` is different for each leg) of logicals with values of `0` (false) or `1` (true).

Data Types: `logical`

`BusinessDayConvention` — Business day conventions
`actual` (default) | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and a character vector or a `N`-by-`1` (or `NINST`-by-`2` if `BusinessDayConvention` is different for each leg) cell array of character vectors of business day conventions. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (e.g. statutory holidays). Values are:

- `actual` — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- `follow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- `modifiedfollow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `previous` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- `modifiedprevious` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell`

`Holidays` — Holidays used in computing business days
if not specified, the default is to use `holidays.m` (default) | MATLAB dates

Holidays used in computing business days, specified as the comma-separated pair consisting of `'Holidays'` and MATLAB dates using a `NHolidays`-by-`1` vector.

Data Types: `datetime`

`StartDate` — Date swap actually starts
`Settle` date (default) | datetime array | string array | date character vector

Date swap actually starts, specified as the comma-separated pair consisting of `'StartDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `swapbybdt` also accepts serial date numbers as inputs, but they are not recommended.

Use this argument to price forward swaps, that is, swaps that start in a future date

Output Arguments

`Price` — Expected swap prices at time 0

vector

Expected swap prices at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure of instrument prices

structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of swaption instrument prices and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.tObs` contains the observation times.

`CFTree` — Swap cash flows

structure

Swap cash flows, returned as a tree structure with a vector of the swap cash flows at each node. This structure contains only `NaN`s because with binomial recombining trees, cash flows cannot be computed accurately at each node of a tree.

`SwapRate` — Rates applicable to fixed leg

matrix

Rates applicable to the fixed leg, returned as a `NINST`-by-`1` vector of rates applicable to the fixed leg such that the swaps' values are zero at time 0. This rate is used in calculating the swaps' prices when the rate specified for the fixed leg in `LegRate` is `NaN`. The `SwapRate` output is padded with `NaN` for those instruments in which `CouponRate` is not set to `NaN`.

More About

Amortizing Swap

In an amortizing swap, the notional principal decreases periodically because it is tied to an underlying financial instrument with a declining (amortizing) principal balance, such as a mortgage.

Forward Swap

Agreement to enter into an interest-rate swap arrangement on a fixed date in future.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `swapbybdt` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

swapbybk

Price swap instrument from Black-Karasinski interest-rate tree

Syntax

```
[Price,PriceTree,CFTree,SwapRate] = swapbybk(BKTree,LegRate,Settle,Maturity)
[Price,PriceTree,CFTree,SwapRate] = swapbybk( ___ ,Name,Value)
```

Description

`[Price,PriceTree,CFTree,SwapRate] = swapbybk(BKTree,LegRate,Settle,Maturity)` prices a swap instrument from a Black-Karasinski interest-rate tree. `swapbybk` computes prices of vanilla swaps, amortizing swaps and forward swaps.

Note Alternatively, you can use the `Swap` object to price swap instruments. For more information, see "Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments" on page 1-22.

`[Price,PriceTree,CFTree,SwapRate] = swapbybk( ___ ,Name,Value)` adds additional name-value pair arguments.

Examples

Price an Interest-Rate Swap

Price an interest-rate swap with a fixed receiving leg and a floating paying leg. Payments are made once a year, and the notional principal amount is $100. The values for the remaining arguments are:

- Coupon rate for fixed leg: 0.06 (6%)
- Spread for floating leg: 20 basis points
- Swap settlement date: Jan. 01, 2004
- Swap maturity date: Jan. 01, 2006

Based on the information above, set the required arguments and build the `LegRate`, `LegType`, and `LegReset` matrices:

```
Settle = datetime(2004,1,1);
Maturity = datetime(2006,1,1);
Basis = 0;
Principal = 100;
LegRate = [0.06 20]; % [CouponRate Spread]
LegType = [1 0]; % [Fixed Float]
LegReset = [1 1]; % Payments once per year
```

Price the swap using the `BKTree` included in the MAT-file `deriv.mat`. `BKTree` contains the time and forward-rate information needed to price the instrument.

```
load deriv.mat;
```

Use swapbybk to price of the swap.

```
Price = swapbybk(BKTree, LegRate,...
Settle, Maturity, LegReset, Basis, Principal, LegType)
```

```
Price = 5.0425
```

Using the previous data, calculate the swap rate, which is the coupon rate for the fixed leg, such that the swap price at time = 0 is zero.

```
LegRate = [NaN 20];

[Price, PriceTree, SwapRate] = swapbybk(BKTree, LegRate,...
Settle, Maturity, LegReset, Basis, Principal, LegType)
```

```
Price = -2.8422e-14

PriceTree = struct with fields:
     FinObj: 'BKPriceTree'
      PTree: {1x5 cell}
       tObs: [0 1 2 3 4]
    Connect: {[2]  [2 3 4]  [2 2 3 4 4]}
      Probs: {[3x1 double]  [3x3 double]  [3x5 double]}

SwapRate = 0.0336
```

Price an Amortizing Swap

Price an amortizing swap using the Principal input argument to define the amortization schedule.

Create the RateSpec.

```
Rates = 0.035;
ValuationDate = datetime(2011,1,1);
StartDates = ValuationDate;
EndDates = datetime(2017,1,1);
Compounding = 1;

RateSpec = intenvset('ValuationDate', ValuationDate,'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: 0.8135
            Rates: 0.0350
         EndTimes: 6
       StartTimes: 0
         EndDates: 736696
       StartDates: 734504
    ValuationDate: 734504
            Basis: 0
     EndMonthRule: 1
```

Create the swap instrument using the following data:

```
Settle ='1-Jan-2011';
Maturity = '1-Jan-2017';
Period = 1;
LegRate = [0.04 10];
```

Define the swap amortizing schedule.

```
Principal ={{datetime(2013,1,1) 100;datetime(2014,1,1) 80;datetime(2015,1,1) 60;datetime(2016,1,1
```

Build the BK tree and assume volatility is 10%.

```
MatDates = [datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1) ; d
BKTimeSpec = bktimespec(ValuationDate, MatDates);
Volatility = 0.10;
AlphaDates = datetime(2017,1,1);
AlphaCurve = 0.1;
BKVolSpec = bkvolspec(ValuationDate, MatDates, Volatility*ones(1,length(MatDates))',...
AlphaDates, AlphaCurve);
BKT = bktree(BKVolSpec, RateSpec, BKTimeSpec);
```

Compute the price of the amortizing swap.

```
Price = swapbybk(BKT, LegRate, Settle, Maturity, 'Principal' , Principal)
```

```
Price = 1.4574
```

Price a Forward Swap

Price a forward swap using the `StartDate` input argument to define the future starting date of the swap.

Create the `RateSpec`.

```
Rates = 0.0374;
ValuationDate = datetime(2012,1,1);
StartDates = ValuationDate;
EndDates = datetime(2018,1,1);
Compounding = 1;

RateSpec = intenvset('ValuationDate', ValuationDate,'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: 0.8023
            Rates: 0.0374
         EndTimes: 6
       StartTimes: 0
         EndDates: 737061
       StartDates: 734869
    ValuationDate: 734869
            Basis: 0
```

```
    EndMonthRule: 1
```

Build a BK tree.

```
VolDates = [datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1) ; datetime(2016,1,1) ; d
VolCurve = 0.1;
AlphaDates = datetime(2018,1,1);
AlphaCurve = 0.1;

BKVolSpec = bkvolspec(RateSpec.ValuationDate, VolDates, VolCurve,...
AlphaDates, AlphaCurve);
BKTimeSpec = bktimespec(RateSpec.ValuationDate, VolDates, Compounding);
BKT = bktree(BKVolSpec, RateSpec, BKTimeSpec);
```

Compute the price of a forward swap that starts in a year (Jan 1, 2013) and matures in four years with a forward swap rate of 4.25%.

```
Settle = datetime(2012,1,1);
Maturity = datetime(2017,1,1);
StartDate = datetime(2013,1,1);
LegRate = [0.0425 10];

Price = swapbybk(BKT, LegRate, Settle, Maturity, 'StartDate', StartDate)
```

```
Price = 1.4434
```

Using the previous data, compute the forward swap rate, the coupon rate for the fixed leg, such that the forward swap price at time = 0 is zero.

```
LegRate = [NaN 10];
[Price, ~,SwapRate] = swapbybk(BKT, LegRate, Settle, Maturity, 'StartDate', StartDate)
```

```
Price = 1.4211e-14
```

```
SwapRate = 0.0384
```

Input Arguments

BKTree — Interest-rate structure

structure

Interest-rate tree structure, created by `bktree`

Data Types: `struct`

LegRate — Leg rate

matrix

Leg rate, specified as a `NINST`-by-2 matrix, with each row defined as one of the following:

- `[CouponRate Spread]` (fixed-float)
- `[Spread CouponRate]` (float-fixed)
- `[CouponRate CouponRate]` (fixed-fixed)
- `[Spread Spread]` (float-float)

`CouponRate` is the decimal annual rate. `Spread` is the number of basis points over the reference rate. The first column represents the receiving leg, while the second column represents the paying leg.

Data Types: `double`

`Settle` — Settlement date
datetime array | string array | date character vector

Settlement date, specified either as a scalar or `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `swapbybk` also accepts serial date numbers as inputs, but they are not recommended.

The `Settle` date for every swap is set to the `ValuationDate` of the BK tree. The swap argument `Settle` is ignored.

`Maturity` — Maturity date
datetime array | string array | date character vector

Maturity date, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors representing the maturity date for each swap.

To support existing code, `swapbybk` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceTree,CFTree,SwapRate] = swapbybk(BKTree,LegRate,Settle,Maturity,LegReset,Basis,Principal,LegType)`

`LegReset` — Reset frequency per year for each swap
`[1 1]` (default) | vector

Reset frequency per year for each swap, specified as the comma-separated pair consisting of `'LegReset'` and a `NINST`-by-`2` vector.

Data Types: `double`

`Basis` — Day-count basis representing the basis for each leg
`0` (actual/actual) (default) | integer from `0` to `13`

Day-count basis representing the basis for each leg, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-`1` array (or `NINST`-by-`2` if `Basis` is different for each leg).

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360

- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amounts or principal value schedules
`100` (default) | vector or cell array

Notional principal amounts or principal value schedules, specified as the comma-separated pair consisting of `'Principal'` and a vector or cell array.

`Principal` accepts a `NINST`-by-`1` vector or `NINST`-by-`1` cell array (or `NINST`-by-`2` if `Principal` is different for each leg) of the notional principal amounts or principal value schedules. For schedules, each element of the cell array is a `NumDates`-by-`2` array where the first column is dates and the second column is its associated notional principal value. The date indicates the last day that the principal value is valid.

Data Types: `cell` | `double`

`LegType` — Leg type
`[1 0]` for each instrument (default) | matrix with values `[1 1]` (fixed-fixed), `[1 0]` (fixed-float), `[0 1]` (float-fixed), or `[0 0]` (float-float)

Leg type, specified as the comma-separated pair consisting of `'LegType'` and a `NINST`-by-`2` matrix with values `[1 1]` (fixed-fixed), `[1 0]` (fixed-float), `[0 1]` (float-fixed), or `[0 0]` (float-float). Each row represents an instrument. Each column indicates if the corresponding leg is fixed (`1`) or floating (`0`). This matrix defines the interpretation of the values entered in `LegRate`. `LegType` allows `[1 1]` (fixed-fixed), `[1 0]` (fixed-float), `[0 1]` (float-fixed), or `[0 0]` (float-float) swaps

Data Types: `double`

`Options` — Derivatives pricing options structure
structure

Derivatives pricing options structure, specified as the comma-separated pair consisting of `'Options'` and a structure obtained from using `derivset`.

Data Types: `struct`

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month having 30 or fewer days
`1` (in effect) (default) | nonnegative integer `[0,1]`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month having 30 or fewer days, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer [`0`, `1`] using a `NINST`-by-`1` (or `NINST`-by-`2` if `EndMonthRule` is different for each leg).

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

`AdjustCashFlowsBasis` — Flag to adjust cash flows based on actual period day count
`false` (default) | value of `0` (false) or `1` (true)

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of `'AdjustCashFlowsBasis'` and a `NINST`-by-`1` (or `NINST`-by-`2` if `AdjustCashFlowsBasis` is different for each leg) of logicals with values of `0` (false) or `1` (true).

Data Types: `logical`

`BusinessDayConvention` — Business day conventions
`actual` (default) | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and a character vector or a `N`-by-`1` (or `NINST`-by-`2` if `BusinessDayConvention` is different for each leg) cell array of character vectors of business day conventions. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (e.g. statutory holidays). Values are:

- `actual` — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- `follow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- `modifiedfollow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `previous` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- `modifiedprevious` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell`

`Holidays` — Holidays used in computing business days
if not specified, the default is to use `holidays.m` (default) | MATLAB dates

Holidays used in computing business days, specified as the comma-separated pair consisting of `'Holidays'` and MATLAB dates using a `NHolidays`-by-`1` vector.

Data Types: `datetime`

`StartDate` — Date swap actually starts
`Settle` date (default) | datetime array | string array | date character vector

Date swap actually starts, specified as the comma-separated pair consisting of `'StartDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `swapbybk` also accepts serial date numbers as inputs, but they are not recommended.

Use this argument to price forward swaps, that is, swaps that start in a future date

Output Arguments

`Price` — Expected swap prices at time 0

vector

Expected swap prices at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure of instrument prices

structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of swaption instrument prices and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.Connect` contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are `NumNodes` elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- `PriceTree.Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.

`CFTree` — Swap cash flows

structure

Swap cash flows, returned as a tree structure with a vector of the swap cash flows at each node. This structure contains only `NaN`s because with binomial recombining trees, cash flows cannot be computed accurately at each node of a tree.

`SwapRate` — Rates applicable to fixed leg

matrix

Rates applicable to the fixed leg, returned as a `NINST`-by-`1` vector of rates applicable to the fixed leg such that the swaps' values are zero at time 0. This rate is used in calculating the swaps' prices when the rate specified for the fixed leg in `LegRate` is `NaN`. The `SwapRate` output is padded with `NaN` for those instruments in which `CouponRate` is not set to `NaN`.

More About

Amortizing Swap

In an amortizing swap, the notional principal decreases periodically because it is tied to an underlying financial instrument with a declining (amortizing) principal balance, such as a mortgage.

Forward Swap

Agreement to enter into an interest-rate swap arrangement on a fixed date in future.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `swapbybk` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

swapbycir

Price swap instrument from Cox-Ingersoll-Ross interest-rate tree

Syntax

```
[Price,PriceTree,SwapRate] = swapbycir(CIRTree,LegRate,Settle,Maturity)
[Price,PriceTree,SwapRate] = swapbycir( ___ ,Name,Value)
```

Description

`[Price,PriceTree,SwapRate] = swapbycir(CIRTree,LegRate,Settle,Maturity)` prices a swap instrument from a Cox-Ingersoll-Ross (CIR) interest-rate tree. `swapbycir` computes prices of vanilla swaps, amortizing swaps, and forward swaps using a CIR++ model with the Nawalka-Beliaeva (NB) approach.

`[Price,PriceTree,SwapRate] = swapbycir( ___ ,Name,Value)` adds additional name-value pair arguments.

Examples

Price an Interest-Rate Swap Using a CIR Interest-Rate Tree

Define an interest-rate swap with a fixed receiving leg and a floating paying leg. Payments are made once a year and the notional principal amount is $100.

```
Basis = 0;
Principal = 100;
LegRate = [0.06 20]; % [CouponRate Spread]
LegType = [1 0]; % [Fixed Float]
LegReset = [1 1]; % Payments once per year
```

Create a `RateSpec` using the `intenvset` function.

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
Dates = [datetime(2017,1,1) ; datetime(2018,1,1) ; datetime(2019,1,1) ; datetime(2020,1,1) ; date
ValuationDate = datetime(2017,1,1);
EndDates = Dates(2:end)';
Compounding = 1;
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ValuationDate, 'EndDates',End
```

Create a `CIR` tree.

```
NumPeriods = 5;
Alpha = 0.03;
Theta = 0.02;
Sigma = 0.1;
Settle = datetime(2017,1,1);
Maturity = datetime(2022,1,1);
CIRTimeSpec = cirtimespec(ValuationDate, Maturity, NumPeriods);
CIRVolSpec = cirvolspec(Sigma, Alpha, Theta);
```

```
CIRT = cirtree(CIRVolSpec, RateSpec, CIRTimeSpec)

CIRT = struct with fields:
      FinObj: 'CIRFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2 3 4]
        dObs: [736696 737061 737426 737791 738156]
     FwdTree: {1x5 cell}
     Connect: {[3x1 double]  [3x3 double]  [3x5 double]  [3x7 double]}
       Probs: {[3x1 double]  [3x3 double]  [3x5 double]  [3x7 double]}
```

Price the interest-rate swap.

```
[Price,PriceTree] = swapbycir(CIRT,LegRate,Settle,Maturity,'LegReset',LegReset,'Basis',3,'Princi

Price = 2.5522

PriceTree = struct with fields:
     FinObj: 'CIRPriceTree'
       tObs: [0 1 2 3 4 5]
      PTree: {1x6 cell}
    Connect: {[3x1 double]  [3x3 double]  [3x5 double]  [3x7 double]}
```

Input Arguments

`CIRTree` — Interest-rate structure

structure

Interest-rate tree structure, created by `cirtree`

Data Types: `struct`

`LegRate` — Leg rate

matrix

Leg rate, specified as a `NINST`-by-2 matrix, with each row defined as one of the following:

- `[CouponRate Spread]` (fixed-float)
- `[Spread CouponRate]` (float-fixed)
- `[CouponRate CouponRate]` (fixed-fixed)
- `[Spread Spread]` (float-float)

`CouponRate` is the decimal annual rate. `Spread` is the number of basis points over the reference rate. The first column represents the receiving leg, while the second column represents the paying leg.

Data Types: `double`

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date, specified either as a scalar or `NINST`-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, `swapbycir` also accepts serial date numbers as inputs, but they are not recommended.

The `Settle` date for every swap is set to the `ValuationDate` of the CIR tree. The swap argument `Settle` is ignored.

`Maturity` — Maturity date
datetime array | string array | date character vector

Maturity date, specified as a `NINST`-by-1 vector using a datetime array, string array, or date character vectors representing the maturity date for each swap.

To support existing code, `swapbycir` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceTree,SwapRate] = swapbycir(CIRTree,LegRate,Settle,Maturity,LegReset,Basis,Principal,LegType)`

`LegReset` — Reset frequency per year for each swap
`[1 1]` (default) | vector

Reset frequency per year for each swap, specified as the comma-separated pair consisting of `'LegReset'` and a `NINST`-by-2 vector.

Data Types: `double`

`Basis` — Day-count basis representing the basis for each leg
`0` (actual/actual) (default) | integer from `0` to `13`

Day-count basis representing the basis for each leg, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-1 array (or `NINST`-by-2 if `Basis` is different for each leg).

- 0 = actual/actual
- 1 = 30/360 (SIA)

- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amounts or principal value schedules
`100` (default) | vector or cell array

Notional principal amounts or principal value schedules, specified as the comma-separated pair consisting of `'Principal'` and a vector or cell array.

`Principal` accepts a `NINST`-by-`1` vector or `NINST`-by-`1` cell array (or `NINST`-by-`2` if `Principal` is different for each leg) of the notional principal amounts or principal value schedules. For schedules, each element of the cell array is a `NumDates`-by-`2` array where the first column is dates and the second column is its associated notional principal value. The date indicates the last day that the principal value is valid.

Data Types: `cell` | `double`

`LegType` — Leg type
`[1 0]` for each instrument (default) | matrix with values `[1 1]` (fixed-fixed), `[1 0]` (fixed-float), `[0 1]` (float-fixed), or `[0 0]` (float-float)

Leg type, specified as the comma-separated pair consisting of `'LegType'` and a `NINST`-by-`2` matrix with values:

- `[1 1]` (fixed-fixed) swap
- `[1 0]` (fixed-float) swap
- `[0 1]` (float-fixed) swap
- `[0 0]` (float-float) swap

Each row represents an instrument. Each column indicates if the corresponding leg is fixed (`1`) or floating (`0`). This matrix defines the interpretation of the values entered in `LegRate`.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month having 30 or fewer days
`1` (in effect) (default) | nonnegative integer `[0,1]`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month having 30 or fewer days, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer [`0`, `1`] using a `NINST`-by-`1` (or `NINST`-by-`2` if `EndMonthRule` is different for each leg).

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

AdjustCashFlowsBasis — Flag to adjust cash flows based on actual period day count
`false` (default) | value of `0` (false) or `1` (true)

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of `'AdjustCashFlowsBasis'` and a `NINST`-by-`1` (or `NINST`-by-`2` if `AdjustCashFlowsBasis` is different for each leg) of logicals with values of `0` (false) or `1` (true).

Data Types: `logical`

BusinessDayConvention — Business day conventions
`actual` (default) | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and a character vector or a `N`-by-`1` (or `NINST`-by-`2` if `BusinessDayConvention` is different for each leg) cell array of character vectors of business day conventions. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (e.g. statutory holidays). Values are:

- `actual` — Nonbusiness days are effectively ignored. Cash flows that fall on nonbusiness days are assumed to be distributed on the actual date.
- `follow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- `modifiedfollow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `previous` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- `modifiedprevious` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell`

Holidays — Holidays used in computing business days
if not specified, the default is to use `holidays.m` (default) | MATLAB dates

Holidays used in computing business days, specified as the comma-separated pair consisting of `'Holidays'` and MATLAB dates using a `NHolidays`-by-`1` vector.

Data Types: `datetime`

StartDate — Date swap actually starts
`Settle` date (default) | datetime array | string array | date character vector

Date swap actually starts, specified as the comma-separated pair consisting of `'StartDate'` and a `NINST`-by-`1` vector of dates using a datetime array, string array, or date character vectors.

To support existing code, `swapbycir` also accepts serial date numbers as inputs, but they are not recommended.

Use this argument to price forward swaps, that is, swaps that start in a future date

Output Arguments

`Price` — Expected swap prices at time 0

vector

Expected swap prices at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure of instrument prices

structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of swaption instrument prices and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.tObs` contains the observation times.
- `PriceTree.PTree` contains the clean prices.

`SwapRate` — Rates applicable to fixed leg

matrix

Rates applicable to the fixed leg, returned as a `NINST`-by-`1` vector of rates applicable to the fixed leg such that the swaps' values are zero at time 0. This rate is used in calculating the swaps' prices when the rate specified for the fixed leg in `LegRate` is `NaN`. The `SwapRate` output is padded with `NaN` for those instruments in which `CouponRate` is not set to `NaN`.

More About

Amortizing Swap

In an amortizing swap, the notional principal decreases periodically because it is tied to an underlying financial instrument with a declining (amortizing) principal balance, such as a mortgage.

Forward Swap

Agreement to enter into an interest-rate swap arrangement on a fixed date in future.

Version History

Introduced in R2018a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `swapbycir` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

swapbyhjm

Price swap instrument from Heath-Jarrow-Morton interest-rate tree

Syntax

```
[Price,PriceTree,CFTree,SwapRate] = swapbyhjm(HJMTree,LegRate,Settle,
Maturity)
[Price,PriceTree,CFTree,SwapRate] = swapbyhjm( ___ ,Name,Value)
```

Description

`[Price,PriceTree,CFTree,SwapRate] = swapbyhjm(HJMTree,LegRate,Settle, Maturity)` prices a swap instrument from a Heath-Jarrow-Morton interest-rate tree. `swapbyhjm` computes prices of vanilla swaps, amortizing swaps and forward swaps.

`[Price,PriceTree,CFTree,SwapRate] = swapbyhjm( ___ ,Name,Value)` adds additional name-value pair arguments.

Examples

Price an Interest-Rate Swap

This example shows how to price an interest-rate swap with a fixed receiving leg and a floating paying leg. Payments are made once a year, and the notional principal amount is $100. The values for the remaining arguments are:

- Coupon rate for fixed leg: 0.06 (6%)
- Spread for floating leg: 20 basis points
- Swap settlement date: Jan. 01, 2000
- Swap maturity date: Jan. 01, 2003

Based on the information above, set the required arguments and build the `LegRate`, `LegType`, and `LegReset` matrices:

```
Settle = datetime(2000,1,1);
Maturity = datetime(2003,1,1);
Basis = 0;
Principal = 100;
LegRate = [0.06 20]; % [CouponRate Spread]
LegType = [1 0]; % [Fixed Float]
LegReset = [1 1]; % Payments once per year
```

Price the swap using the `HJMTree` included in the MAT-file `deriv.mat`. The `HJMTree` structure contains the time and forward-rate information needed to price the instrument.

```
load deriv.mat;
```

Use `swapbyhjm` to compute the price of the swap.

```
[Price, PriceTree, CFTree] = swapbyhjm(HJMTree, LegRate,...
Settle, Maturity, LegReset, Basis, Principal, LegType)

Price =

   3.6923

PriceTree =

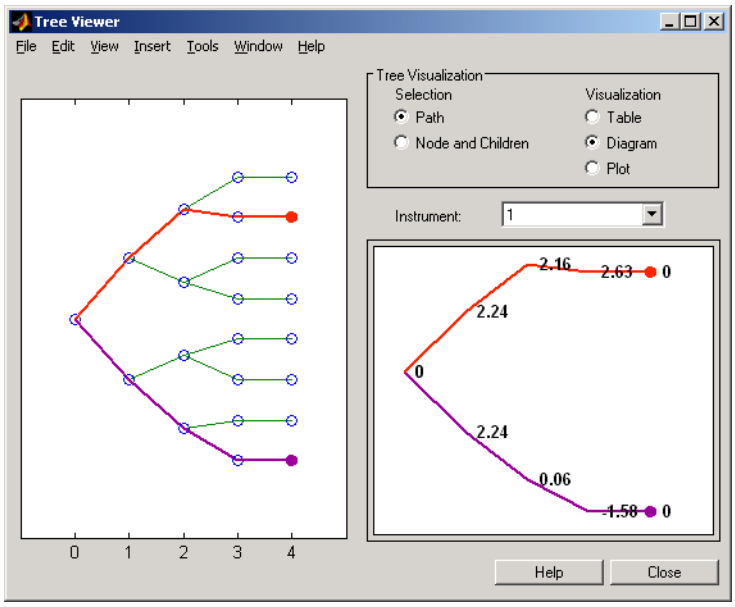
    FinObj: 'HJMPriceTree'
      tObs: [0 1 2 3 4]
     PBush: {1x5 cell}

CFTree =

    FinObj: 'HJMCFTree'
      tObs: [0 1 2 3 4]
    CFBush: {[0] [1x1x2 double] [1x2x2 double] ... [1x8 double]}
```

Use `treeviewer` to examine `CFTree` graphically and see the cash flows from the swap along both the up and the down branches. A positive cash flow indicates an inflow (income - payments > 0), while a negative cash flow indicates an outflow (income - payments < 0).

```
treeviewer(CFTree)
```



In this example, you have sold a swap (receive fixed rate and pay floating rate). At time `t = 3`, if interest rates go down, your cash flow is positive ($2.63), meaning that you receive this amount. But if interest rates go up, your cash flow is negative (-$1.58), meaning that you owe this amount.

`treeviewer` price tree diagrams follow the convention that increasing prices appear on the upper branch of a tree and, so, decreasing prices appear on the lower branch. Conversely, for interest-rate displays, *decreasing* interest rates appear on the upper branch (prices are rising) and *increasing* interest rates on the lower branch (prices are falling).

Using the previous data, calculate the swap rate, which is the coupon rate for the fixed leg, such that the swap price at time = 0 is zero.

```
LegRate = [NaN 20];

[Price, PriceTree, CFTree, SwapRate] = swapbyhjm(HJMTree,...
LegRate, Settle, Maturity, LegReset, Basis, Principal, LegType)
```

```
Price =

   0

PriceTree =

FinObj: 'HJMPriceTree'
  tObs: [0 1 2 3 4]
 PBush:{[0] [1x1x2 double] [1x2x2 double] ... [1x8 double]}

CFTree =

FinObj: 'HJMCFTree'
  tObs: [0 1 2 3 4]
CFBush:{[0] [1x1x2 double] [1x2x2 double] ... [1x8 double]}

SwapRate =

   0.0466
```

Price an Amortizing Swap

Price an amortizing swap using the `Principal` input argument to define the amortization schedule.

Create the `RateSpec`.

```
Rates = 0.035;
ValuationDate = datetime(2011,1,1);
StartDates = ValuationDate;
EndDates = '1-Jan-2017';
Compounding = 1;

RateSpec = intenvset('ValuationDate', ValuationDate,'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: 0.8135
            Rates: 0.0350
          EndTimes: 6
        StartTimes: 0
          EndDates: 736696
        StartDates: 734504
    ValuationDate: 734504
            Basis: 0
     EndMonthRule: 1
```

Create the swap instrument using the following data:

```
Settle = datetime(2011,1,1);
Maturity = datetime(2017,1,1);
```

```
Period = 1;
LegRate = [0.04 10];
```

Define the swap amortizing schedule.

```
Principal ={{datetime(2013,1,1) 100;datetime(2014,1,1) 80;datetime(2015,1,1) 60;datetime(2016,1,1
```

Build the HJM tree using the following data:

```
MatDates = [datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1) ; d
HJMTimeSpec = hjmtimespec(RateSpec.ValuationDate, MatDates);
Volatility = [.10; .08; .06; .04];
CurveTerm = [ 1; 2; 3; 4];
HJMVolSpec = hjmvolspec('Proportional', Volatility, CurveTerm, 1e6);
HJMT = hjmtree(HJMVolSpec,RateSpec,HJMTimeSpec);
```

Compute the price of the amortizing swap.

```
Price = swapbyhjm(HJMT, LegRate, Settle, Maturity, 'Principal', Principal)
```

```
Price = 1.4574
```

Price a Forward Swap

Price a forward swap using the `StartDate` input argument to define the future starting date of the swap.

Create the `RateSpec`.

```
Rates = 0.0374;
ValuationDate = datetime(2012,1,1);
StartDates = ValuationDate;
EndDates = datetime(2018,1,1);
Compounding = 1;

RateSpec = intenvset('ValuationDate', ValuationDate,'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: 0.8023
            Rates: 0.0374
         EndTimes: 6
       StartTimes: 0
         EndDates: 737061
       StartDates: 734869
    ValuationDate: 734869
            Basis: 0
     EndMonthRule: 1
```

Build an HJM tree.

```
MatDates = [datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1) ; datetime(2016,1,1) ; d
HJMTimeSpec = hjmtimespec(RateSpec.ValuationDate, MatDates);
```

```
Volatility = [.10; .08; .06; .04];
CurveTerm = [ 1; 2; 3; 4];
HJMVolSpec = hjmvolspec('Proportional', Volatility, CurveTerm, 1e6);
HJMT = hjmtree(HJMVolSpec,RateSpec,HJMTimeSpec);
```

Compute the price of a forward swap that starts in a year (Jan 1, 2013) and matures in four years with a forward swap rate of 4.25%.

```
Settle = datetime(2012,1,1);
Maturity = datetime(2017,1,1);
StartDate = datetime(2013,1,1);
LegRate = [0.0425 10];

Price = swapbyhjm(HJMT, LegRate, Settle, Maturity, 'StartDate', StartDate)
```

```
Price = 1.4434
```

Using the previous data, compute the forward swap rate, the coupon rate for the fixed leg, such that the forward swap price at time = 0 is zero.

```
LegRate = [NaN 10];
[Price, ~,~, SwapRate] = swapbyhjm(HJMT, LegRate, Settle, Maturity, 'StartDate', StartDate)
```

```
Price = 0

SwapRate = 0.0384
```

Input Arguments

`HJMTree` — Interest-rate structure

structure

Interest-rate tree structure, created by `hjmtree`

Data Types: `struct`

`LegRate` — Leg rate

matrix

Leg rate, specified as a `NINST`-by-2 matrix, with each row defined as one of the following:

- `[CouponRate Spread]` (fixed-float)
- `[Spread CouponRate]` (float-fixed)
- `[CouponRate CouponRate]` (fixed-fixed)
- `[Spread Spread]` (float-float)

`CouponRate` is the decimal annual rate. `Spread` is the number of basis points over the reference rate. The first column represents the receiving leg, while the second column represents the paying leg.

Data Types: `double`

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date, specified either as a scalar or `NINST`-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, `swapbyhjm` also accepts serial date numbers as inputs, but they are not recommended.

The `Settle` date for every swap is set to the `ValuationDate` of the HJM tree. The swap argument `Settle` is ignored.

`Maturity` — Maturity date
datetime array | string array | date character vector

Maturity date, specified as a `NINST`-by-1 vector using a datetime array, string array, or date character vectors representing the maturity date for each swap.

To support existing code, `swapbyhjm` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceTree,CFTree,SwapRate] = swapbyhjm(HJMTree,LegRate,Settle,Maturity,LegReset,Basis,Principal,LegType)`

`LegReset` — Reset frequency per year for each swap
`[1 1]` (default) | vector

Reset frequency per year for each swap, specified as the comma-separated pair consisting of `'LegReset'` and a `NINST`-by-2 vector.

Data Types: `double`

`Basis` — Day-count basis representing the basis for each leg
`0` (actual/actual) (default) | integer from `0` to `13`

Day-count basis representing the basis for each leg, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-1 array (or `NINST`-by-2 if `Basis` is different for each leg).

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)

- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amounts or principal value schedules
`100` (default) | vector or cell array

Notional principal amounts or principal value schedules, specified as the comma-separated pair consisting of `'Principal'` and a vector or cell array.

`Principal` accepts a `NINST`-by-`1` vector or `NINST`-by-`1` cell array (or `NINST`-by-`2` if `Principal` is different for each leg) of the notional principal amounts or principal value schedules. For schedules, each element of the cell array is a `NumDates`-by-`2` array where the first column is dates and the second column is its associated notional principal value. The date indicates the last day that the principal value is valid.

Data Types: `cell` | `double`

`LegType` — Leg type
`[1 0]` for each instrument (default) | matrix with values `[1 1]` (fixed-fixed), `[1 0]` (fixed-float), `[0 1]` (float-fixed), or `[0 0]` (float-float)

Leg type, specified as the comma-separated pair consisting of `'LegType'` and a `NINST`-by-`2` matrix with values `[1 1]` (fixed-fixed), `[1 0]` (fixed-float), `[0 1]` (float-fixed), or `[0 0]` (float-float). Each row represents an instrument. Each column indicates if the corresponding leg is fixed (`1`) or floating (`0`). This matrix defines the interpretation of the values entered in `LegRate`. `LegType` allows `[1 1]` (fixed-fixed), `[1 0]` (fixed-float), `[0 1]` (float-fixed), or `[0 0]` (float-float) swaps

Data Types: `double`

`Options` — Derivatives pricing options structure
structure

Derivatives pricing options structure, specified as the comma-separated pair consisting of `'Options'` and a structure obtained from using `derivset`.

Data Types: `struct`

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month having 30 or fewer days
`1` (in effect) (default) | nonnegative integer `[0,1]`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month having 30 or fewer days, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer [`0`, `1`] using a `NINST`-by-`1` (or `NINST`-by-`2` if `EndMonthRule` is different for each leg).

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.

- 1 = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: logical

AdjustCashFlowsBasis — Flag to adjust cash flows based on actual period day count
false (default) | value of 0 (false) or 1 (true)

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of 'AdjustCashFlowsBasis' and a NINST-by-1 (or NINST-by-2 if AdjustCashFlowsBasis is different for each leg) of logicals with values of 0 (false) or 1 (true).

Data Types: logical

BusinessDayConvention — Business day conventions
actual (default) | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of 'BusinessDayConvention' and a character vector or a N-by-1 (or NINST-by-2 if BusinessDayConvention is different for each leg) cell array of character vectors of business day conventions. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (e.g. statutory holidays). Values are:

- actual — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- follow — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- modifiedfollow — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- previous — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- modifiedprevious — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: char | cell

Holidays — Holidays used in computing business days
if not specified, the default is to use holidays.m (default) | MATLAB dates

Holidays used in computing business days, specified as the comma-separated pair consisting of 'Holidays' and MATLAB dates using a NHolidays-by-1 vector.

Data Types: datetime

StartDate — Date swap actually starts
Settle date (default) | datetime array | string array | date character vector

Date swap actually starts, specified as the comma-separated pair consisting of 'StartDate' and a NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, swapbyhjm also accepts serial date numbers as inputs, but they are not recommended.

Use this argument to price forward swaps, that is, swaps that start in a future date

Output Arguments

`Price` — Expected swap prices at time 0

vector

Expected swap prices at time 0, returned as a `NINST`-by-1 vector.

`PriceTree` — Tree structure of instrument prices

structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of swaption instrument prices and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.tObs` contains the observation times.
- `PriceTree.PBush` contains the clean prices.

`CFTree` — Swap cash flows

structure

Swap cash flows, returned as a tree structure with a vector of the swap cash flows at each node. This structure contains only `NaN`s because with binomial recombining trees, cash flows cannot be computed accurately at each node of a tree.

`SwapRate` — Rates applicable to fixed leg

matrix

Rates applicable to the fixed leg, returned as a `NINST`-by-1 vector of rates applicable to the fixed leg such that the swaps' values are zero at time 0. This rate is used in calculating the swaps' prices when the rate specified for the fixed leg in `LegRate` is `NaN`. The `SwapRate` output is padded with `NaN` for those instruments in which `CouponRate` is not set to `NaN`.

More About

Amortizing Swap

In an amortizing swap, the notional principal decreases periodically because it is tied to an underlying financial instrument with a declining (amortizing) principal balance, such as a mortgage.

Forward Swap

Agreement to enter into an interest-rate swap arrangement on a fixed date in future.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `swapbyhjm` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

swapbyhw

Price swap instrument from Hull-White interest-rate tree

Syntax

```
[Price,PriceTree,CFTree,SwapRate] = swapbyhw(HWTree,LegRate,Settle,Maturity)
[Price,PriceTree,CFTree,SwapRate] = swapbyhw( ___ ,Name,Value)
```

Description

`[Price,PriceTree,CFTree,SwapRate] = swapbyhw(HWTree,LegRate,Settle,Maturity)` prices a swap instrument from a Hull-White interest-rate tree. `swapbyhw` computes prices of vanilla swaps, amortizing swaps and forward swaps.

Note Alternatively, you can use the `Swap` object to price swap instruments. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,PriceTree,CFTree,SwapRate] = swapbyhw( ___ ,Name,Value)` adds additional name-value pair arguments.

Examples

Price an Interest-Rate Swap

Price an interest-rate swap with a fixed receiving leg and a floating paying leg. Payments are made once a year, and the notional principal amount is $100. The values for the remaining arguments are:

- Coupon rate for fixed leg: 0.06 (6%)
- Spread for floating leg: 20 basis points
- Swap settlement date: Jan. 01, 2005
- Swap maturity date: Jan. 01, 2008

Based on the information above, set the required arguments and build the `LegRate`, `LegType`, and `LegReset` matrices:

```
Settle = datetime(2005,1,1);
Maturity = datetime(2008,1,1);
Basis = 0;
Principal = 100;
LegRate = [0.06 20]; % [CouponRate Spread]
LegType = [1 0]; % [Fixed Float]
LegReset = [1 1]; % Payments once per year
```

Price the swap using the `HWTree` included in the MAT-file `deriv.mat`. The `HWTree` structure contains the time and forward-rate information needed to price the instrument.

```
load deriv.mat;
```

Use swapbyhw to compute the price of the swap.

```
[Price, PriceTree, SwapRate] = swapbyhw(HWTree, LegRate, ...
Settle, Maturity, LegReset, Basis, Principal, LegType)
```

```
Warning: Swaps are valued at Tree ValuationDate rather than Settle

Price = 5.9109

PriceTree = struct with fields:
     FinObj: 'HWPriceTree'
      PTree: {[5.9109]  [-1.2692 3.0317 7.5253]  [-5.1049 -2.1588 0.8799 4.0142 7.2471]  [-3.3462
       tObs: [0 1 2 3 4]
    Connect: {[2]  [2 3 4]  [2 2 3 4 4]}
      Probs: {[3×1 double]  [3×3 double]  [3×5 double]}

SwapRate = NaN
```

Using the previous data, calculate the swap rate, which is the coupon rate for the fixed leg, such that the swap price at time = 0 is zero.

```
LegRate = [NaN 20];

[Price, PriceTree, SwapRate] = swapbyhw(HWTree, LegRate, ...
Settle, Maturity, LegReset, Basis, Principal, LegType)
```

```
Warning: Swaps are valued at Tree ValuationDate rather than Settle

Price = 1.4211e-14

PriceTree = struct with fields:
     FinObj: 'HWPriceTree'
      PTree: {[1.4211e-14]  [-5.5941 -1.4265 2.9289]  [-7.9659 -5.0883 -2.1199 0.9423 4.1011]  [
       tObs: [0 1 2 3 4]
    Connect: {[2]  [2 3 4]  [2 2 3 4 4]}
      Probs: {[3×1 double]  [3×3 double]  [3×5 double]}

SwapRate = 0.0438
```

Price an Amortizing Swap

Price an amortizing swap using the Principal input argument to define the amortization schedule.

Create the RateSpec.

```
Rates = 0.035;
ValuationDate = datetime(2011,1,1);
StartDates = ValuationDate;
EndDates = datetime(2017,1,1);
Compounding = 1;

RateSpec = intenvset('ValuationDate', ValuationDate,'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: 0.8135
            Rates: 0.0350
         EndTimes: 6
       StartTimes: 0
         EndDates: 736696
       StartDates: 734504
    ValuationDate: 734504
            Basis: 0
     EndMonthRule: 1
```

Create the swap instrument using the following data:

```
Settle = datetime(2011,1,1);
Maturity = datetime(2017,1,1);
Period = 1;
LegRate = [0.04 10];
```

Define the swap amortizing schedule.

```
Principal ={{datetime(2013,1,1) 100;datetime(2014,1,1) 80;datetime(2015,1,1) 60;datetime(2016,1,1
```

Build the HW tree using the following data:

```
VolDates = [datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1) ; d
VolCurve = 0.1;
AlphaDates = datetime(2017,1,1);
AlphaCurve = 0.1;

HWVolSpec = hwvolspec(RateSpec.ValuationDate, VolDates, VolCurve,...
AlphaDates, AlphaCurve);
HWTimeSpec = hwtimespec(RateSpec.ValuationDate, VolDates, Compounding);
HWT = hwtree(HWVolSpec, RateSpec, HWTimeSpec);
```

Compute the price of the amortizing swap.

```
Price = swapbyhw(HWT, LegRate, Settle, Maturity, 'Principal', Principal)
```

```
Price = 1.4574
```

Price a Forward Swap

Price a forward swap using the `StartDate` input argument to define the future starting date of the swap.

Create the `RateSpec`.

```
Rates = 0.0374;
ValuationDate = datetime(2012,1,1);
StartDates = ValuationDate;
EndDates = datetime(2018,1,1);
Compounding = 1;
```

```
RateSpec = intenvset('ValuationDate', ValuationDate,'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: 0.8023
            Rates: 0.0374
         EndTimes: 6
       StartTimes: 0
         EndDates: 737061
       StartDates: 734869
    ValuationDate: 734869
            Basis: 0
     EndMonthRule: 1
```

Build an HW tree.

```
VolDates = [datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1) ; datetime(2016,1,1) ; d
VolCurve = 0.1;
AlphaDates = datetime(2018,1,1);
AlphaCurve = 0.1;

HWVolSpec = hwvolspec(RateSpec.ValuationDate, VolDates, VolCurve,...
AlphaDates, AlphaCurve);
HWTimeSpec = hwtimespec(RateSpec.ValuationDate, VolDates, Compounding);
HWT = hwtree(HWVolSpec, RateSpec, HWTimeSpec);
```

Compute the price of a forward swap that starts in a year (Jan 1, 2013) and matures in four years with a forward swap rate of 4.25%.

```
Settle = datetime(2012,1,1);
Maturity = datetime(2017,1,1);
StartDate = datetime(2013,1,1);
LegRate = [0.0425 10];

Price = swapbyhw(HWT, LegRate, Settle, Maturity, 'StartDate', StartDate)
```

```
Price = 1.4434
```

Using the previous data, compute the forward swap rate, the coupon rate for the fixed leg, such that the forward swap price at time = 0 is zero.

```
LegRate = [NaN 10];
[Price, ~,SwapRate] = swapbyhw(HWT, LegRate, Settle, Maturity, 'StartDate', StartDate)
```

```
Price = 4.2633e-14
```

```
SwapRate = 0.0384
```

Input Arguments

HWTree — Interest-rate structure

structure

Interest-rate tree structure, created by `hwtree`

Data Types: `struct`

`LegRate` — Leg rate
matrix

Leg rate, specified as a `NINST`-by-2 matrix, with each row defined as one of the following:

- `[CouponRate Spread]` (fixed-float)
- `[Spread CouponRate]` (float-fixed)
- `[CouponRate CouponRate]` (fixed-fixed)
- `[Spread Spread]` (float-float)

`CouponRate` is the decimal annual rate. `Spread` is the number of basis points over the reference rate. The first column represents the receiving leg, while the second column represents the paying leg.

Data Types: `double`

`Settle` — Settlement date
datetime array | string array | date character vector

Settlement date, specified either as a scalar or `NINST`-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, `swapbyhw` also accepts serial date numbers as inputs, but they are not recommended.

The `Settle` date for every swap is set to the `ValuationDate` of the HW tree. The swap argument `Settle` is ignored.

`Maturity` — Maturity date
datetime array | string array | date character vector

Maturity date, specified as a `NINST`-by-1 vector using a datetime array, string array, or date character vectors representing the maturity date for each swap.

To support existing code, `swapbyhw` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceTree,CFTree,SwapRate] = swapbyhw(HWTree,LegRate,Settle,Maturity,LegReset,Basis,Principal,LegType)`

`LegReset` — Reset frequency per year for each swap
`[1 1]` (default) | vector

Reset frequency per year for each swap, specified as the comma-separated pair consisting of `'LegReset'` and a `NINST`-by-2 vector.

Data Types: double

Basis — Day-count basis representing the basis for each leg
0 (actual/actual) (default) | integer from 0 to 13

Day-count basis representing the basis for each leg, specified as the comma-separated pair consisting of 'Basis' and a NINST-by-1 array (or NINST-by-2 if Basis is different for each leg).

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: double

Principal — Notional principal amounts or principal value schedules
100 (default) | vector or cell array

Notional principal amounts or principal value schedules, specified as the comma-separated pair consisting of 'Principal' and a vector or cell array.

Principal accepts a NINST-by-1 vector or NINST-by-1 cell array (or NINST-by-2 if Principal is different for each leg) of the notional principal amounts or principal value schedules. For schedules, each element of the cell array is a NumDates-by-2 array where the first column is dates and the second column is its associated notional principal value. The date indicates the last day that the principal value is valid.

Data Types: cell | double

LegType — Leg type
[1 0] for each instrument (default) | matrix with values [1 1] (fixed-fixed), [1 0] (fixed-float), [0 1] (float-fixed), or [0 0] (float-float)

Leg type, specified as the comma-separated pair consisting of 'LegType' and a NINST-by-2 matrix with values [1 1] (fixed-fixed), [1 0] (fixed-float), [0 1] (float-fixed), or [0 0] (float-float). Each row represents an instrument. Each column indicates if the corresponding leg is fixed (1) or floating (0). This matrix defines the interpretation of the values entered in LegRate. LegType allows [1 1] (fixed-fixed), [1 0] (fixed-float), [0 1] (float-fixed), or [0 0] (float-float) swaps

Data Types: `double`

`Options` — Derivatives pricing options structure
structure

Derivatives pricing options structure, specified as the comma-separated pair consisting of `'Options'` and a structure obtained from using `derivset`.

Data Types: `struct`

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month having 30 or fewer days
`1` (in effect) (default) | nonnegative integer `[0,1]`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month having 30 or fewer days, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer [`0`, `1`] using a `NINST`-by-`1` (or `NINST`-by-`2` if `EndMonthRule` is different for each leg).

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

`AdjustCashFlowsBasis` — Flag to adjust cash flows based on actual period day count
`false` (default) | value of `0` (false) or `1` (true)

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of `'AdjustCashFlowsBasis'` and a `NINST`-by-`1` (or `NINST`-by-`2` if `AdjustCashFlowsBasis` is different for each leg) of logicals with values of `0` (false) or `1` (true).

Data Types: `logical`

`BusinessDayConvention` — Business day conventions
`actual` (default) | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and a character vector or a `N`-by-`1` (or `NINST`-by-`2` if `BusinessDayConvention` is different for each leg) cell array of character vectors of business day conventions. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (e.g. statutory holidays). Values are:

- `actual` — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- `follow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- `modifiedfollow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `previous` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.

- `modifiedprevious` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell`

`Holidays` — Holidays used in computing business days
if not specified, the default is to use `holidays.m` (default) | MATLAB dates

Holidays used in computing business days, specified as the comma-separated pair consisting of `'Holidays'` and MATLAB dates using a `NHolidays`-by-`1` vector.

Data Types: `datetime`

`StartDate` — Date swap actually starts
`Settle` date (default) | datetime array | string array | date character vector

Date swap actually starts, specified as the comma-separated pair consisting of `'StartDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `swapbyhw` also accepts serial date numbers as inputs, but they are not recommended.

Use this argument to price forward swaps, that is, swaps that start in a future date

Output Arguments

`Price` — Expected swap prices at time 0
vector

Expected swap prices at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure of instrument prices
structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of swaption instrument prices and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.Connect` contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are `NumNodes` elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- `PriceTree.Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.

`CFTree` — Swap cash flows
structure

Swap cash flows, returned as a tree structure with a vector of the swap cash flows at each node. This structure contains only `NaN`s because with binomial recombining trees, cash flows cannot be computed accurately at each node of a tree.

SwapRate — Rates applicable to fixed leg

matrix

Rates applicable to the fixed leg, returned as a NINST-by-1 vector of rates applicable to the fixed leg such that the swaps' values are zero at time 0. This rate is used in calculating the swaps' prices when the rate specified for the fixed leg in LegRate is NaN. The SwapRate output is padded with NaN for those instruments in which CouponRate is not set to NaN.

More About

Amortizing Swap

In an amortizing swap, the notional principal decreases periodically because it is tied to an underlying financial instrument with a declining (amortizing) principal balance, such as a mortgage.

Forward Swap

Agreement to enter into an interest-rate swap arrangement on a fixed date in future.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although swapbyhw supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

swapbyzero

Price swap instrument from set of zero curves and price cross-currency swaps

Syntax

```
[Price,SwapRate,AI,RecCF,RecCFDates,PayCF,PayCFDates] = swapbyzero(RateSpec,
LegRate,Settle,Maturity)
[Price,SwapRate,AI,RecCF,RecCFDates,PayCF,PayCFDates] = swapbyzero(RateSpec,
LegRate,Settle,Maturity,Name,Value)
```

Description

`[Price,SwapRate,AI,RecCF,RecCFDates,PayCF,PayCFDates] = swapbyzero(RateSpec, LegRate,Settle,Maturity)` prices a swap instrument. You can use `swapbyzero` to compute prices of vanilla swaps, amortizing swaps, and forward swaps. All inputs are either scalars or `NINST`-by-`1` vectors unless otherwise specified. Any date can be a date character vector. An optional argument can be passed as an empty matrix `[]`.

Note Alternatively, you can use the `Swap` object to price swap instruments. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,SwapRate,AI,RecCF,RecCFDates,PayCF,PayCFDates] = swapbyzero(RateSpec, LegRate,Settle,Maturity,Name,Value)` prices a swap instrument with additional options specified by one or more `Name,Value` pair arguments. You can use `swapbyzero` to compute prices of vanilla swaps, amortizing swaps, forward swaps, and cross-currency swaps. For more information on the name-value pairs for vanilla swaps, amortizing swaps, and forward swaps, see Vanilla Swaps, Amortizing Swaps, Forward Swaps on page 11-0 .

Specifically, you can use name-value pairs for `FXRate`, `ExchangeInitialPrincipal`, and `ExchangeMaturityPrincipal` to compute the price for cross-currency swaps. For more information on the name-value pairs for cross-currency swaps, see Cross-Currency Swaps on page 11-0 .

Examples

Price an Interest-Rate Swap

Price an interest-rate swap with a fixed receiving leg and a floating paying leg. Payments are made once a year, and the notional principal amount is $100. The values for the remaining arguments are:

- Coupon rate for fixed leg: 0.06 (6%)
- Spread for floating leg: 20 basis points
- Swap settlement date: Jan. 01, 2000
- Swap maturity date: Jan. 01, 2003

Based on the information above, set the required arguments and build the LegRate, LegType, and LegReset matrices:

```
Settle = datetime(2000,1,1);
Maturity = datetime(2003,1,1);
Basis = 0;
Principal = 100;
LegRate = [0.06 20]; % [CouponRate Spread]
LegType = [1 0]; % [Fixed Float]
LegReset = [1 1]; % Payments once per year
```

Load the file deriv.mat, which provides ZeroRateSpec, the interest-rate term structure needed to price the bond.

```
load deriv.mat;
```

Use swapbyzero to compute the price of the swap.

```
Price = swapbyzero(ZeroRateSpec, LegRate, Settle, Maturity,...
LegReset, Basis, Principal, LegType)
```

```
Price = 3.6923
```

Using the previous data, calculate the swap rate, which is the coupon rate for the fixed leg, such that the swap price at time = 0 is zero.

```
LegRate = [NaN 20];

[Price, SwapRate] = swapbyzero(ZeroRateSpec, LegRate, Settle,...
Maturity, LegReset, Basis, Principal, LegType)
```

```
Price = 0

SwapRate = 0.0466
```

In swapbyzero , if Settle is not on a reset date (and 'StartDate' is not specified), the effective date is assumed to be the previous reset date before Settle in order to compute the accrued interest and dirty price. In this example, the effective date is ('15-Sep-2009'), which is the previous reset date before the ('08-Jun-2010') Settle date.

Use swapbyzero with name-value pair arguments for LegRate, LegType, LatestFloatingRate, AdjustCashFlowsBasis, and BusinessDayConvention to calculate output for Price, SwapRate, AI, RecCF, RecCFDates, PayCF, and PayCFDates:

```
Settle = datetime(2008,6,1);
RateSpec = intenvset('Rates', [.005 .0075 .01 .014 .02 .025 .03]',...
'StartDates',Settle, 'EndDates',[datetime(2010,12,8) , datetime(2011,6,8) , datetime(2012,6,8) ,
Maturity = datetime(2020,9,15);
LegRate = [.025 50];
LegType = [1 0]; % fixed/floating
LatestFloatingRate = .005;

[Price, SwapRate, AI, RecCF, RecCFDates, PayCF,PayCFDates] = ...
swapbyzero(RateSpec, LegRate, Settle, Maturity,'LegType',LegType,...
'LatestFloatingRate',LatestFloatingRate,'AdjustCashFlowsBasis',true,...
'BusinessDayConvention','modifiedfollow')
```

```
Price = -7.7485
```

```
SwapRate = NaN

AI = 1.4098

RecCF = 1×14

   -1.7623    2.4863    2.5000    2.5000    2.5000    2.5137    2.4932    2.4932    2.5000    2.5

RecCFDates = 1×14

      733560      733666      734031      734396      734761      735129      735493      735857

PayCF = 1×14

   -0.3525    0.4973    1.0006    1.0006    2.0510    2.5944    3.6040    3.8939    4.4152    4.6

PayCFDates = 1×14

      733560      733666      734031      734396      734761      735129      735493      735857
```

Price Swaps By Specifying Multiple Term Structures Using RateSpec

Price three swaps using two interest-rate curves. First, define the data for the interest-rate term structure:

```
StartDates = datetime(2012,5,1);
EndDates = [datetime(2013,5,1) ; datetime(2014,5,1) ; datetime(2015,5,1) ; datetime(2016,5,1)];
Rates = [[0.0356;0.041185;0.04489;0.047741],[0.0366;0.04218;0.04589;0.04974]];
```

Create the `RateSpec` using `intenvset`.

```
RateSpec = intenvset('Rates', Rates, 'StartDates',StartDates,...
'EndDates', EndDates, 'Compounding', 1)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
            Disc: [4x2 double]
           Rates: [4x2 double]
         EndTimes: [4x1 double]
       StartTimes: [4x1 double]
         EndDates: [4x1 double]
       StartDates: 734990
    ValuationDate: 734990
            Basis: 0
     EndMonthRule: 1
```

Look at the `Rates` for the two interest-rate curves.

```
RateSpec.Rates
```

```
ans = 4×2
```

```
    0.0356    0.0366
    0.0412    0.0422
    0.0449    0.0459
    0.0477    0.0497
```

Define the swap instruments.

```
Settle = datetime(2012,5,1);
Maturity = datetime(2015,5,1);
LegRate = [0.06 10];
Principal = [100;50;100];  % Three notional amounts
```

Price three swaps using two curves.

```
Price = swapbyzero(RateSpec, LegRate, Settle, Maturity, 'Principal', Principal)
```

```
Price = 3×2

    3.9688    3.6869
    1.9844    1.8434
    3.9688    3.6869
```

Price Swap By Specifying Multiple Term Structures Using a 1-by-2 RateSpec

Price a swap using two interest-rate curves. First, define data for the two interest-rate term structures:

```
StartDates = datetime(2012,5,1);
EndDates = [datetime(2013,5,1) ; datetime(2014,5,1) ; datetime(2015,5,1) ; datetime(2016,5,1)];
Rates1 = [0.0356;0.041185;0.04489;0.047741];
Rates2 = [0.0366;0.04218;0.04589;0.04974];
```

Create the `RateSpec` using `intenvset`.

```
RateSpecReceiving = intenvset('Rates', Rates1, 'StartDates',StartDates,...
'EndDates', EndDates, 'Compounding', 1);
RateSpecPaying= intenvset('Rates', Rates2, 'StartDates',StartDates,...
'EndDates', EndDates, 'Compounding', 1);
RateSpec=[RateSpecReceiving RateSpecPaying]
```

```
RateSpec=1×2 struct array with fields:
    FinObj
    Compounding
    Disc
    Rates
    EndTimes
    StartTimes
    EndDates
    StartDates
    ValuationDate
    Basis
    EndMonthRule
```

Define the swap instruments.

```
Settle = datetime(2012,5,1);
Maturity = datetime(2015,5,1);
LegRate = [0.06 10];
Principal = [100;50;100];
```

Price three swaps using the two curves.

```
Price = swapbyzero(RateSpec, LegRate, Settle, Maturity, 'Principal', Principal)
```

```
Price = 3×1

    3.9693
    1.9846
    3.9693
```

Compute a Forward Par Swap Rate

To compute a forward par swap rate, set the `StartDate` parameter to a future date and set the fixed coupon rate in the `LegRate` input to `NaN`.

Define the zero curve data and build a zero curve using `IRDataCurve`.

```
ZeroRates = [2.09 2.47 2.71 3.12 3.43 3.85 4.57]'/100;
Settle = datetime(2012,1,1);
EndDates = datemnth(Settle,12*[1 2 3 5 7 10 20]');
Compounding = 1;

ZeroCurve = IRDataCurve('Zero',Settle,EndDates,ZeroRates,'Compounding',Compounding)
```

```
ZeroCurve =
             Type: Zero
           Settle: 734869 (01-Jan-2012)
      Compounding: 1
            Basis: 0 (actual/actual)
     InterpMethod: linear
            Dates: [7x1 double]
             Data: [7x1 double]
```

Create a `RateSpec` structure using the `toRateSpec` method.

```
RateSpec = ZeroCurve.toRateSpec(EndDates)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [7x1 double]
            Rates: [7x1 double]
         EndTimes: [7x1 double]
       StartTimes: [7x1 double]
         EndDates: [7x1 double]
       StartDates: 734869
    ValuationDate: 734869
```

```
           Basis: 0
    EndMonthRule: 1
```

Compute the forward swap rate (the coupon rate for the fixed leg), such that the forward swap price at time = 0 is zero. The forward swap starts in a month (1-Feb-2012) and matures in 10 years (1-Feb-2022).

```
StartDate = datetime(2012,2,1);
Maturity = datetime(2022,2,1);
LegRate = [NaN 0];

[Price, SwapRate] = swapbyzero(RateSpec, LegRate, Settle, Maturity,...
'StartDate', StartDate)
```

```
Price = 0

SwapRate = 0.0378
```

Compute a Forward Swap Rate Using the Optional Input BusinessDayConvention

The swapbyzero function generates the cash flow dates based on the Settle and Maturity dates, while using the Maturity date as the "anchor" date from which to count backwards in regular intervals. By default, swapbyzero does not distinguish non-business days from business days. To make swapbyzero move non-business days to the following business days, you can you can set the optional name-value input argument BusinessDayConvention with a value of follow.

Define the zero curve data and build a zero curve using IRDataCurve.

```
ZeroRates = [2.09 2.47 2.71 3.12 3.43 3.85 4.57]'/100;
Settle = datetime(2012,1,5);
EndDates = datemnth(Settle,12*[1 2 3 5 7 10 20]');
Compounding = 1;
ZeroCurve = IRDataCurve('Zero',Settle,EndDates,ZeroRates,'Compounding',Compounding);
RateSpec = ZeroCurve.toRateSpec(EndDates);
StartDate = datetime(2012,2,5);
Maturity = datetime(2022,2,5);
LegRate = [NaN 0];
```

To demonstrate the optional input BusinessDayConvention, swapbyzero is first used without and then with the optional name-value input argument BusinessDayConvention. Notice that when using BusinessDayConvention, all days are business days.

```
[Price1,SwapRate1,~,~,RecCFDates1,~,PayCFDates1] = swapbyzero(RateSpec,LegRate,Settle,Maturity,.
    'StartDate',StartDate);
datestr(RecCFDates1)
```

```
ans = 11x11 char array
    '05-Jan-2012'
    '05-Feb-2013'
    '05-Feb-2014'
    '05-Feb-2015'
    '05-Feb-2016'
    '05-Feb-2017'
    '05-Feb-2018'
```

```
    '05-Feb-2019'
    '05-Feb-2020'
    '05-Feb-2021'

Price an Amortizing Swap

Price an amortizing swap using the `Principal` input argument to define the amortization schedule.

Create the `RateSpec`.

```
Rates = 0.035;
ValuationDate = datetime(2011,1,1);
StartDates = ValuationDate;
EndDates = datetime(2017,1,1);
Compounding = 1;

RateSpec = intenvset('ValuationDate', ValuationDate,'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding);
```

Create the swap instrument using the following data:

```
Settle = datetime(2011,1,1);
Maturity = datetime(2017,1,1);
LegRate = [0.04 10];
```

Define the swap amortizing schedule.

```
Principal ={{datetime(2013,1,1) 100;datetime(2014,1,1) 80;datetime(2015,1,1) 60;datetime(2016,1,1
```

Compute the price of the amortizing swap.

```
Price = swapbyzero(RateSpec, LegRate, Settle, Maturity, 'Principal' , Principal)
```

```
Price = 1.4574
```

Price a Forward Swap

Price a forward swap using the `StartDate` input argument to define the future starting date of the swap.

Create the `RateSpec`.

```
Rates = 0.0325;
ValuationDate = datetime(2012,1,1);
StartDates = ValuationDate;
EndDates = datetime(2018,1,1);
Compounding = 1;

RateSpec = intenvset('ValuationDate', ValuationDate,'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: 0.8254
            Rates: 0.0325
         EndTimes: 6
```

```
       StartTimes: 0
         EndDates: 737061
       StartDates: 734869
    ValuationDate: 734869
            Basis: 0
     EndMonthRule: 1
```

Compute the price of a forward swap that starts in a year (Jan 1, 2013) and matures in three years with a forward swap rate of 4.27%.

```
Settle = datetime(2012,1,1);
StartDate = datetime(2013,1,1);
Maturity = datetime(2016,1,1);
LegRate = [0.0427 10];

Price = swapbyzero(RateSpec, LegRate, Settle, Maturity, 'StartDate' , StartDate)

Price = 2.5083
```

Using the previous data, compute the forward swap rate, the coupon rate for the fixed leg, such that the forward swap price at time = 0 is zero.

```
LegRate = [NaN 10];
[Price, SwapRate] = swapbyzero(RateSpec, LegRate, Settle, Maturity,...
'StartDate' , StartDate)

Price = 0

SwapRate = 0.0335
```

Specify the Rate at the Instrument's Starting Date When It Cannot Be Obtained from the RateSpec

If `Settle` is not on a reset date of a floating-rate note, `swapbyzero` attempts to obtain the latest floating rate before `Settle` from `RateSpec` or the `LatestFloatingRate` parameter. When the reset date for this rate is out of the range of `RateSpec` (and `LatestFloatingRate` is not specified), `swapbyzero` fails to obtain the rate for that date and generates an error. This example shows how to use the `LatestFloatingRate` input parameter to avoid the error.

Create the error condition when a swap instrument's `StartDate` cannot be determined from the `RateSpec`.

```
Settle = datetime(2000,1,1);
Maturity = datetime(2003,12,1);
Basis = 0;
Principal = 100;
LegRate = [0.06 20]; % [CouponRate Spread]
LegType = [1 0]; % [Fixed Float]
LegReset = [1 1]; % Payments once per year

load deriv.mat;

Price = swapbyzero(ZeroRateSpec,LegRate,Settle,Maturity,...
'LegReset',LegReset,'Basis',Basis,'Principal',Principal, ...
'LegType',LegType)

Error using floatbyzero (line 256)
The rate at the instrument starting date cannot be obtained from RateSpec.
```

```
 Its reset date (01-Dec-1999) is out of the range of dates contained in RateSpec.
 This rate is required to calculate cash flows at the instrument starting date.
 Consider specifying this rate with the 'LatestFloatingRate' input parameter.

Error in swapbyzero (line 289)
[FloatFullPrice, FloatPrice,FloatCF,FloatCFDates] = floatbyzero(FloatRateSpec, Spreads, Settle,...
```

Here, the reset date for the rate at `Settle` was `01-Dec-1999`, which was earlier than the valuation date of `ZeroRateSpec` (`01-Jan-2000`). This error can be avoided by specifying the rate at the swap instrument's starting date using the `LatestFloatingRate` input parameter.

Define `LatestFloatingRate` and calculate the floating-rate price.

```
Price = swapbyzero(ZeroRateSpec,LegRate,Settle,Maturity,...
'LegReset',LegReset,'Basis',Basis,'Principal',Principal, ...
'LegType',LegType,'LatestFloatingRate',0.03)
```

```
Price =

    4.7594
```

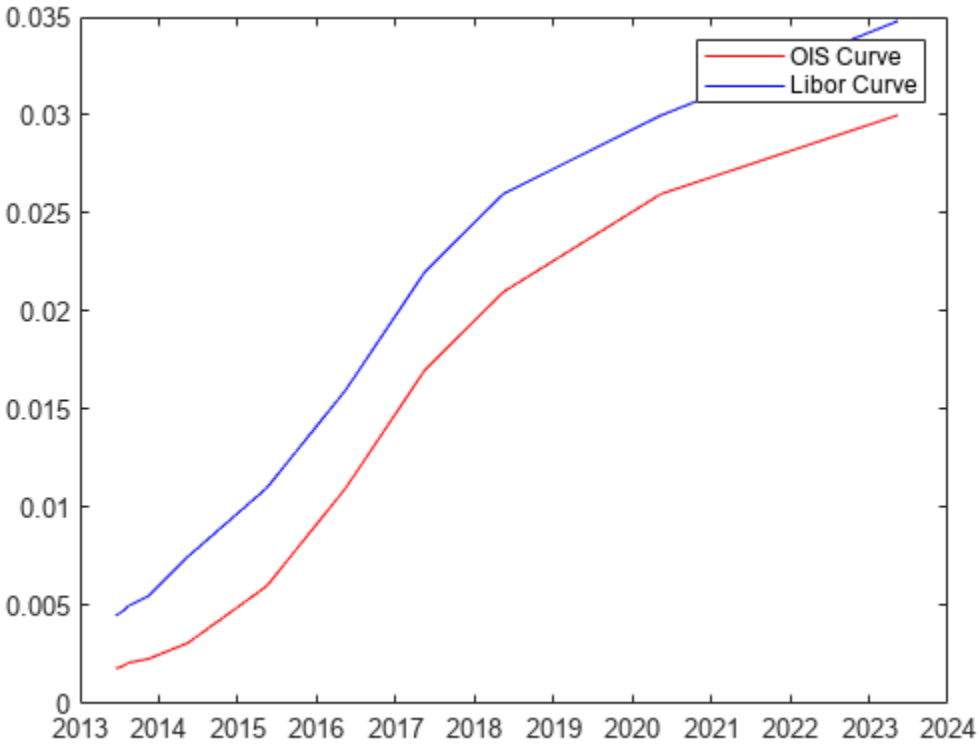
Price a Swap Using a Different Curve to Generate the Cash Flows of the Floating Leg

Define the OIS and Libor rates.

```
Settle = datetime(2013,5,15);
CurveDates = daysadd(Settle,360*[1/12 2/12 3/12 6/12 1 2 3 4 5 7 10],1);
OISRates = [.0018 .0019 .0021 .0023 .0031 .006  .011 .017 .021 .026 .03]';
LiborRates = [.0045 .0047 .005 .0055 .0075 .011 .016 .022 .026 .030 .0348]';
```

Plot the dual curves.

```
figure,plot(CurveDates,OISRates,'r');hold on;plot(CurveDates,LiborRates,'b')
datetick
legend({'OIS Curve', 'Libor Curve'})
```



Create an associated `RateSpec` for the OIS and Libor curves.

```
OISCurve = intenvset('Rates',OISRates,'StartDate',Settle,'EndDates',CurveDates);
LiborCurve = intenvset('Rates',LiborRates,'StartDate',Settle,'EndDates',CurveDates);
```

Define the swap.

```
Maturity = datetime(2018,5,15); % Five year swap
FloatSpread = 0;
FixedRate = .025;
LegRate = [FixedRate FloatSpread];
```

Compute the price of the swap instrument. The `LiborCurve` term structure will be used to generate the cash flows of the floating leg. The `OISCurve` term structure will be used for discounting the cash flows.

```
Price = swapbyzero(OISCurve, LegRate, Settle,...
Maturity,'ProjectionCurve',LiborCurve)
```

```
Price = -0.3697
```

Compare results when the term structure `OISCurve` is used both for discounting and also generating the cash flows of the floating leg.

```
PriceSwap = swapbyzero(OISCurve, LegRate, Settle, Maturity)
```

```
PriceSwap = 2.0517
```

Price a Fixed-Fixed Currency Swap

Price an existing cross currency swap that receives a fixed rate of JPY and pays a fixed rate of USD at an annual frequency.

```
Settle = datetime(2015,8,15);
Maturity = datetime(2018,8,15);
Reset = 1;
LegType = [1 1]; % Fixed-Fixed

r_USD = .09;
r_JPY = .04;

FixedRate_USD = .08;
FixedRate_JPY = .05;

Principal_USD = 10000000;
Principal_JPY = 1200000000;

S = 1/110;

RateSpec_USD = intenvset('StartDate',Settle,'EndDate', Maturity,'Rates',r_USD,'Compounding',-1);
RateSpec_JPY = intenvset('StartDate',Settle,'EndDate', Maturity,'Rates', r_JPY,'Compounding',-1)

Price = swapbyzero([RateSpec_JPY RateSpec_USD], [FixedRate_JPY FixedRate_USD],...
Settle, Maturity,'Principal',[Principal_JPY Principal_USD],'FXRate',[S 1], 'LegType',LegType)
```

```
Price = 1.5430e+06
```

Price a Float-Float Currency Swap

Price a new swap where you pay a EUR float and receive a USD float.

```
Settle = datetime(2015,12,22);
Maturity = datetime(2018,8,15);
LegRate = [0 -50/10000];
LegType = [0 0]; % Float Float
LegReset = [4 4];
FXRate = 1.1;
Notional = [10000000 8000000];

USD_Dates = datemnth(Settle,[1 3 6 12*[1 2 3 5 7 10 20 30]]');
USD_Zero = [0.03 0.06 0.08 0.13 0.36 0.76 1.63 2.29 2.88 3.64 3.89]'/100;
Curve_USD = intenvset('StartDate',Settle,'EndDates',USD_Dates,'Rates',USD_Zero);

EUR_Dates = datemnth(Settle,[3 6 12*[1 2 3 5 7 10 20 30]]');
EUR_Zero = [0.017 0.033 0.088 .27 .512 1.056 1.573 2.183 2.898 2.797]'/100;
Curve_EUR = intenvset('StartDate',Settle,'EndDates',EUR_Dates,'Rates',EUR_Zero);

Price = swapbyzero([Curve_USD Curve_EUR], ...
    LegRate, Settle, Maturity,'LegType',LegType,'LegReset',LegReset,'Principal',Notional,...
    'FXRate',[1 FXRate],'ExchangeInitialPrincipal',false)
```

```
Price = 1.2002e+06
```

Input Arguments

`RateSpec` — Interest-rate structure

structure

Interest-rate structure, specified using `intenvset` to create a `RateSpec`.

`RateSpec` can also be a 1-by-2 input variable of `RateSpecs`, with the second `RateSpec` structure containing one or more discount curves for the paying leg. If only one `RateSpec` structure is specified, then this `RateSpec` is used to discount both legs.

Data Types: `struct`

`LegRate` — Leg rate

matrix

Leg rate, specified as a `NINST`-by-2 matrix, with each row defined as one of the following:

- `[CouponRate Spread]` (fixed-float)
- `[Spread CouponRate]` (float-fixed)
- `[CouponRate CouponRate]` (fixed-fixed)
- `[Spread Spread]` (float-float)

`CouponRate` is the decimal annual rate. `Spread` is the number of basis points over the reference rate. The first column represents the receiving leg, while the second column represents the paying leg.

Data Types: `double`

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date, specified either as a scalar or `NINST`-by-1 vector using a datetime array, string array, or date character vectors with the same value which represents the settlement date for each swap. `Settle` must be earlier than `Maturity`.

To support existing code, `swapbyzero` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as a `NINST`-by-1 vector using a datetime array, string array, or date character vectors representing the maturity date for each swap.

To support existing code, `swapbyzero` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,SwapRate,AI,RecCF,RecCFDates,PayCF,PayCFDates] = swapbyzero(RateSpec,LegRate,Settle, Maturity,'LegType',LegType,'LatestFloatingRate',LatestFloatingRate,'AdjustCashFlowsBasis',true, 'BusinessDayConvention','modifiedfollow')`

Vanilla Swaps, Amortizing Swaps, Forward Swaps

`LegReset` — Reset frequency per year for each swap

`[1 1]` (default) | vector

Reset frequency per year for each swap, specified as the comma-separated pair consisting of `'LegReset'` and a `NINST`-by-2 vector.

Data Types: `double`

`Basis` — Day-count basis of instrument

`0` (actual/actual) (default) | integer from `0` to `13`

Day-count basis representing the basis for each leg, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-1 array (or `NINST`-by-2 if `Basis` is different for each leg).

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amounts or principal value schedules

`100` (default) | vector or cell array

Notional principal amounts or principal value schedules, specified as the comma-separated pair consisting of `'Principal'` and a vector or cell array.

`Principal` accepts a `NINST`-by-1 vector or `NINST`-by-1 cell array (or `NINST`-by-2 if `Principal` is different for each leg) of the notional principal amounts or principal value schedules. For schedules,

each element of the cell array is a `NumDates`-by-2 array where the first column is dates and the second column is its associated notional principal value. The date indicates the last day that the principal value is valid.

Data Types: `cell` | `double`

`LegType` — Leg type
`[1 0]` for each instrument (default) | matrix with values `[1 1]` (fixed-fixed), `[1 0]` (fixed-float), `[0 1]` (float-fixed), or `[0 0]` (float-float)

Leg type, specified as the comma-separated pair consisting of `'LegType'` and a `NINST`-by-2 matrix with values `[1 1]` (fixed-fixed), `[1 0]` (fixed-float), `[0 1]` (float-fixed), or `[0 0]` (float-float). Each row represents an instrument. Each column indicates if the corresponding leg is fixed (`1`) or floating (`0`). This matrix defines the interpretation of the values entered in `LegRate`. `LegType` allows `[1 1]` (fixed-fixed), `[1 0]` (fixed-float), `[0 1]` (float-fixed), or `[0 0]` (float-float) swaps

Data Types: `double`

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month having 30 or fewer days
`1` (in effect) (default) | nonnegative integer `[0,1]`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month having 30 or fewer days, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer [`0`, `1`] using a `NINST`-by-`1` (or `NINST`-by-2 if `EndMonthRule` is different for each leg).

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

`AdjustCashFlowsBasis` — Flag to adjust cash flows based on actual period day count
`false` (default) | value of `0` (false) or `1` (true)

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of `'AdjustCashFlowsBasis'` and a `NINST`-by-`1` (or `NINST`-by-2 if `AdjustCashFlowsBasis` is different for each leg) of logicals with values of `0` (false) or `1` (true).

Data Types: `logical`

`BusinessDayConvention` — Business day conventions
`actual` (default) | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and a character vector or a `N`-by-`1` (or `NINST`-by-2 if `BusinessDayConvention` is different for each leg) cell array of character vectors of business day conventions. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (e.g. statutory holidays). Values are:

- `actual` — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- `follow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.

- `modifiedfollow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `previous` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- `modifiedprevious` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell`

`Holidays` — Holidays used in computing business days
if not specified, the default is to use `holidays.m` (default) | MATLAB dates

Holidays used in computing business days, specified as the comma-separated pair consisting of `'Holidays'` and MATLAB dates using a `NHolidays`-by-`1` vector.

Data Types: `datetime`

`StartDate` — Dates when swaps actually start
If not specified, date is `Settle` (default) | character vector | cell array of character vectors

Dates when the swaps actually start, specified as the comma-separated pair consisting of `'StartDate'` and a `NINST`-by-`1` vector of character vectors or cell array of character vectors.

To support existing code, `swapbyzero` also accepts serial date numbers as inputs, but they are not recommended.

`LatestFloatingRate` — Rate for the next floating payment
If not specified, then `RateSpec` must contain this information (default) | scalar numeric

Rate for the next floating payment, set at the last reset date, specified as the comma-separated pair consisting of `'LatestFloatingRate'` and a scalar numeric value.

`LatestFloatingRate` accepts a Rate for the next floating payment, set at the last reset date. `LatestFloatingRate` is a `NINST`-by-`1` (or `NINST`-by-`2` if `LatestFloatingRate` is different for each leg).

Data Types: `double`

`ProjectionCurve` — Rate curve used in generating cash flows for the floating leg of the swap
if `ProjectionCurve` is not specified, then `RateSpec` is used both for discounting and generating cash flows for the floating leg (default) | `RateSpec` or vector

Rate curve used in generating cash flows for the floating leg of the swap, specified as the comma-separated pair consisting of `'ProjectionCurve'` and a `RateSpec`.

If specifying a fixed-float or a float-fixed swap, the `ProjectionCurve` rate curve is used in generating cash flows for the floating leg of the swap. This structure must be created using `intenvset`.

If specifying a fixed-fixed or a float-float swap, then `ProjectionCurve` is `NINST`-by-`2` vector because each floating leg could have a different projection curve.

Data Types: `struct`

Cross-Currency Swaps

`FXRate` — Foreign exchange (FX) rate applied to cash flows
if not specified, both legs of `swapbyzero` are in same currency (default) | array

Foreign exchange (FX) rate applied to cash flows, specified as the comma-separated pair consisting of `'FXRate'` and a `NINST`-by-2 array of doubles. Since the foreign exchange rate could be applied to either the payer or receiver leg, there are 2 columns in the input array and you must specify which leg has the foreign currency.

Data Types: `double`

`ExchangeInitialPrincipal` — Flag to indicate if initial `Principal` is exchanged
`0` (false) (default) | array

Flag to indicate if initial `Principal` is exchanged, specified as the comma-separated pair consisting of `'ExchangeInitialPrincipal'` and a `NINST`-by-`1` array of logicals.

Data Types: `logical`

`ExchangeMaturityPrincipal` — Flag to indicate if `Principal` exchanged at `Maturity`
`1` (true) (default) | array

Flag to indicate if `Principal` is exchanged at `Maturity`, specified as the comma-separated pair consisting of `'ExchangeMaturityPrincipal'` and a `NINST`-by-`1` array of logicals. While in practice most single currency swaps do not exchange principal at maturity, the default is true to maintain backward compatibility.

Data Types: `logical`

Output Arguments

`Price` — Swap prices
matrix

Swap prices, returned as the number of instruments (`NINST`) by number of curves (`NUMCURVES`) matrix. Each column arises from one of the zero curves. `Price` output is the dirty price. To compute the clean price, subtract the accrued interest (`AI`) from the dirty price.

`SwapRate` — Rates applicable to fixed leg
matrix

Rates applicable to the fixed leg, returned as a `NINST`-by-`NUMCURVES` matrix of rates applicable to the fixed leg such that the swaps' values are zero at time 0. This rate is used in calculating the swaps' prices when the rate specified for the fixed leg in `LegRate` is `NaN`. The `SwapRate` output is padded with `NaN` for those instruments in which `CouponRate` is not set to `NaN`.

`AI` — Accrued interest
matrix

Accrued interest, returned as a `NINST`-by-`NUMCURVES` matrix.

`RecCF` — Cash flows for receiving leg
matrix

Cash flows for the receiving leg, returned as a `NINST`-by-`NUMCURVES` matrix.

Note If there is more than one curve specified in the `RateSpec` input, then the first `NCURVES` row corresponds to the first swap, the second `NCURVES` row correspond to the second swap, and so on.

`RecCFDates` — Payment dates for receiving leg
matrix

Payment dates for the receiving leg, returned as an `NINST`-by-`NUMCURVES` matrix.

`PayCF` — Cash flows for paying leg
matrix

Cash flows for the paying leg, returned as an `NINST`-by-`NUMCURVES` matrix.

`PayCFDates` — Payment dates for paying leg
matrix

Payment dates for the paying leg, returned as an `NINST`-by-`NUMCURVES` matrix.

More About

Amortizing Swap

In an amortizing swap, the notional principal decreases periodically because it is tied to an underlying financial instrument with a declining (amortizing) principal balance, such as a mortgage.

Forward Swap

Agreement to enter into an interest-rate swap arrangement on a fixed date in future.

Cross-currency Swap

Swaps where the payment legs of the swap are denominated in different currencies.

One difference between cross-currency swaps and standard swaps is that an exchange of principal may occur at the beginning and/or end of the swap. The exchange of initial principal will only come into play in pricing a cross-currency swap at inception (in other words, pricing an existing cross-currency swap will occur after this cash flow has happened). Furthermore, these exchanges of principal typically do not affect the value of the swap (since the principal values of the two legs are chosen based on the currency exchange rate) but affect the cash flows for each leg.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `swapbyzero` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

swaptionbybdt

Price swaption from Black-Derman-Toy interest-rate tree

Syntax

```
[Price,PriceTree] = swaptionbybdt(BDTTree,OptSpec,Strike,ExerciseDates,
Spread,Settle,Maturity)
[Price,PriceTree] = swaptionbybdt( ___ ,Name,Value)
```

Description

`[Price,PriceTree] = swaptionbybdt(BDTTree,OptSpec,Strike,ExerciseDates, Spread,Settle,Maturity)` prices swaption using a Black-Derman-Toy tree.

Note Alternatively, you can use the `Swaption` object to price swaption instruments. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,PriceTree] = swaptionbybdt( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Price a 5-Year Call Swaption Using a BDT Interest-Rate Tree

This example shows how to price a 5-year call swaption using a BDT interest-rate tree. Assume that interest rate and volatility are fixed at 6% and 20% annually between the valuation date of the tree until its maturity. Build a tree with the following data.

```
Rates = 0.06 * ones (10,1);
StartDates = [datetime(2007,1,1) ; datetime(2008,1,1) ; datetime(2009,1,1) ; datetime(2010,1,1)

EndDates = [datetime(2008,1,1) ; datetime(2009,1,1) ; datetime(2010,1,1) ; datetime(2011,1,1) ; d

ValuationDate = datetime(2007,1,1);
Compounding = 1;

% define the RateSpec
RateSpec = intenvset('Rates', Rates, 'StartDates', StartDates, 'EndDates', EndDates, ...
'Compounding', Compounding);

% use VolSpec to compute interest-rate volatility
Volatility = 0.20 * ones (10,1);  VolSpec = bdtvolspec(ValuationDate,...
EndDates, Volatility);

% use TimeSpec to specify the structure of the time layout for a BDT tree
TimeSpec = bdttimespec(ValuationDate, EndDates, Compounding);
```

```
% build the BDT tree
BDTTree = bdttree(VolSpec, RateSpec, TimeSpec);

% use the following swaption arguments
ExerciseDates = datetime(2012,1,1);
SwapSettlement = ExerciseDates;
SwapMaturity   = datetime(2015,1,1);
Spread = 0;
SwapReset = 1;
Principal = 100;
OptSpec = 'call';
Strike =.062;
Basis = 1;

% price the swaption
[Price, PriceTree] = swaptionbybdt(BDTTree, OptSpec, Strike, ExerciseDates, ...
Spread, SwapSettlement, SwapMaturity, 'SwapReset', SwapReset, ...
'Basis', Basis, 'Principal', Principal)

Price = 2.0592

PriceTree = struct with fields:
    FinObj: 'BDTPriceTree'
      tObs: [0 1 2 3 4 5 6 7 8 9 10]
     PTree: {1x11 cell}
```

Price a 5-Year Call Swaption with Receiving and Paying Legs Using a BDT Interest-Rate Tree

This example shows how to price a 5-year call swaption with receiving and paying legs using a BDT interest-rate tree. Assume that interest rate and volatility are fixed at 6% and 20% annually between the valuation date of the tree until its maturity. Build a tree with the following data.

```
Rates = 0.06 * ones (10,1);
StartDates = [datetime(2007,1,1) ; datetime(2008,1,1) ; datetime(2009,1,1) ; datetime(2010,1,1)
EndDates = [datetime(2008,1,1) ; datetime(2009,1,1) ; datetime(2010,1,1) ; datetime(2011,1,1) ; d
ValuationDate = datetime(2007,1,1);
Compounding = 1;
```

Define the RateSpec.

```
RateSpec = intenvset('Rates', Rates, 'StartDates', StartDates, 'EndDates', EndDates, ...
'Compounding', Compounding)

RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [10x1 double]
            Rates: [10x1 double]
         EndTimes: [10x1 double]
       StartTimes: [10x1 double]
         EndDates: [10x1 double]
       StartDates: [10x1 double]
    ValuationDate: 733043
            Basis: 0
```

```
     EndMonthRule: 1
```

Use `VolSpec` to compute interest-rate volatility.

```
Volatility = 0.20 * ones (10,1);
VolSpec = bdtvolspec(ValuationDate,EndDates, Volatility);
```

Use `TimeSpec` to specify the structure of the time layout for a BDT tree.

```
TimeSpec = bdttimespec(ValuationDate, EndDates, Compounding);
```

Build the BDT tree.

```
BDTTree = bdttree(VolSpec, RateSpec, TimeSpec)
```

```
BDTTree = struct with fields:
      FinObj: 'BDTFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2 3 4 5 6 7 8 9]
        dObs: [733043 733408 733774 734139 734504 734869 735235 735600 ... ]
        TFwd: {1x10 cell}
      CFlowT: {1x10 cell}
     FwdTree: {1x10 cell}
```

Define the swaption arguments.

```
ExerciseDates = datetime(2012,1,1);
SwapSettlement = ExerciseDates;
SwapMaturity   = datetime(2015,1,1);
Spread = 0;
SwapReset = [1 1]; % 1st column represents receiving leg, 2nd column represents paying leg
Principal = 100;
OptSpec = 'call';
Strike=.062;
Basis= [2 4]; % 1st column represents receiving leg, 2nd column represents paying leg
```

Price the swaption.

```
[Price, PriceTree] = swaptionbybdt(BDTTree, OptSpec, Strike, ExerciseDates, ...
Spread, SwapSettlement, SwapMaturity, 'SwapReset', SwapReset, ...
'Basis', Basis, 'Principal', Principal)
```

```
Price = 2.0592
```

```
PriceTree = struct with fields:
    FinObj: 'BDTPriceTree'
      tObs: [0 1 2 3 4 5 6 7 8 9 10]
     PTree: {1x11 cell}
```

Input Arguments

`BDTTree` — Interest-rate tree structure
structure

Interest-rate tree structure, specified by using `bdttree`.

Data Types: `struct`

`OptSpec` — Definition of option
character vector with values `'call'` or `'put'` | cell array of character vector with values `'call'` or `'put'`

Definition of the option as `'call'` or `'put'`, specified as a `NINST`-by-`1` cell array of character vectors. For more information, see “More About” on page 11-1884.

Data Types: `char` | `cell`

`Strike` — Strike swap rate values
decimal

Strike swap rate values, specified as a `NINST`-by-`1` vector.

Data Types: `double`

`ExerciseDates` — Exercise dates for swaption
datetime array | string array | date character vector

Exercise dates for the swaption, specified as a `NINST`-by-`1` vector or a `NINST`-by-`2` vector using a datetime array, string array, or date character vectors, depending on the option type.

- For a European option, `ExerciseDates` are a `NINST`-by-`1` vector of exercise dates. Each row is the schedule for one option. When using a European option, there is only one `ExerciseDate` on the option expiry date.
- For an American option, `ExerciseDates` are a `NINST`-by-`2` vector of exercise date boundaries. For each instrument, the option can be exercised on any coupon date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is `NINST`-by-`1`, the option can be exercised between the `ValuationDate` of the tree and the single listed `ExerciseDate`.

To support existing code, `swaptionbybdt` also accepts serial date numbers as inputs, but they are not recommended.

`Spread` — Number of basis points over reference rate
numeric

Number of basis points over the reference rate, specified as a `NINST`-by-`1` vector.

Data Types: `double`

`Settle` — Settlement date
datetime array | string array | date character vector

Settlement date (representing the settle date for each swap), specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. The `Settle` date for every swaption is set to the `ValuationDate` of the BDT tree. The swap argument `Settle` is ignored. The underlying swap starts at the maturity of the swaption.

To support existing code, `swaptionbybdt` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date for swap
datetime array | string array | date character vector

Maturity date for each swap, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `swaptionbybdt` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceTree] = swaptionbybdt(BDTTree,OptSpec, ExerciseDates,Spread,Settle,Maturity,'SwapReset',4,'Basis',5,'Principal',10000)`

`AmericanOpt` — Option type
`0` (European) (default) | integer with values `0` or `1`

(Optional) Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and `NINST`-by-`1` positive integer flags with values:

- `0` — European
- `1` — American

Data Types: `double`

`SwapReset` — Reset frequency per year for underlying swap
`1` (default) | numeric

Reset frequency per year for the underlying swap, specified as the comma-separated pair consisting of `'SwapReset'` and a `NINST`-by-`1` vector or `NINST`-by-`2` matrix representing the reset frequency per year for each leg. If `SwapReset` is `NINST`-by-`2`, the first column represents the receiving leg, while the second column represents the paying leg.

Data Types: `double`

`Basis` — Day-count basis of instrument
`0` (actual/actual) (default) | integer from `0` to `13`

Day-count basis representing the basis used when annualizing the input forward rate tree for each instrument, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-`1` vector or `NINST`-by-`2` matrix representing the basis for each leg. If `Basis` is `NINST`-by-`2`, the first column represents the receiving leg, while the second column represents the paying leg.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365

- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amount
`100` (default) | numeric

Notional principal amount, specified as the comma-separated pair consisting of `'Principal'` and a `NINST`-by-`1` vector.

Data Types: `double`

`Options` — Derivatives pricing options structure
structure

Derivatives pricing options structure, specified as the comma-separated pair consisting of `'Options'` and a structure obtained from using `derivset`.

Data Types: `struct`

Output Arguments

`Price` — Expected prices of swaptions at time 0
vector

Expected prices of the swaptions at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure of instrument prices
structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of swaption instrument prices and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.tObs` contains the observation times.

More About

Call Swaption

A call swaption or payer swaption allows the option buyer to enter into an interest-rate swap in which the buyer of the option pays the fixed rate and receives the floating rate.

Put Swaption

A put swaption or receiver swaption allows the option buyer to enter into an interest-rate swap in which the buyer of the option receives the fixed rate and pays the floating rate.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `swaptionbybdt` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

swaptionbybk

Price swaption from Black-Karasinski interest-rate tree

Syntax

```
[Price,PriceTree] = swaptionbybk(BKTree,OptSpec,Strike,ExerciseDates,Spread,
Settle,Maturity)
[Price,PriceTree] = swaptionbybk( ___ ,Name,Value)
```

Description

`[Price,PriceTree] = swaptionbybk(BKTree,OptSpec,Strike,ExerciseDates,Spread, Settle,Maturity)` prices swaption using a Black-Karasinski tree.

Note Alternatively, you can use the `Swaption` object to price swaption instruments. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,PriceTree] = swaptionbybk( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Price a 4-Year Call and Put Swaption Using a BK Interest-Rate Tree

This example shows how to price a 4-year call and put swaption using a BK interest-rate tree, assuming the interest rate is fixed at 7% annually.

```
Rates =0.07 * ones (10,1);
Compounding = 2;
StartDates = [datetime(2007,1,1) ; datetime(2007,7,1) ; datetime(2008,1,1) ; datetime(2008,7,1)
EndDates = [datetime(2007,7,1) ; datetime(2008,1,1) ; datetime(2008,7,1) ; datetime(2009,1,1) ; d
ValuationDate = datetime(2007,1,1);

% define the RateSpec

RateSpec = intenvset('Rates', Rates, 'StartDates', StartDates, 'EndDates', EndDates,...
'Compounding', Compounding);

% use BKVolSpec to compute the interest-rate volatility
Volatility = 0.10*ones(10,1);
AlphaCurve = 0.05*ones(10,1);
AlphaDates = EndDates;
BKVolSpec = bkvolspec(ValuationDate, EndDates, Volatility, AlphaDates, AlphaCurve);

% use BKTimeSpec to specify the structure of the time layout for the BK interest-rate tree
BKTimeSpec = bktimespec(ValuationDate, EndDates, Compounding);
```

```
% build the BK tree
BKTree = bktree(BKVolSpec, RateSpec, BKTimeSpec);

% use the following arguments for a 1-year swap and 4-year swaption
ExerciseDates = datetime(2011,1,1);
SwapSettlement = ExerciseDates;

Price a 4-Year Call and Put Swaption with Receiving and Paying Legs Using a BK Interest-Rate Tree

This example shows how to price a 4-year call and put swaption with receiving and paying legs using a BK interest-rate tree, assuming the interest rate is fixed at 7% annually. Build a tree with the following data.

```
Rates =0.07 * ones (10,1);
Compounding = 2;
StartDates = [datetime(2007,1,1) ; datetime(2007,7,1) ; datetime(2008,1,1) ; datetime(2008,7,1)
EndDates = [datetime(2007,7,1) ; datetime(2008,1,1) ; datetime(2008,7,1) ; datetime(2009,1,1) ; d
ValuationDate = datetime(2007,1,1);
```

Define the `RateSpec`.

```
RateSpec = intenvset('Rates', Rates, 'StartDates', StartDates, 'EndDates', EndDates,...
'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 2
             Disc: [10x1 double]
            Rates: [10x1 double]
         EndTimes: [10x1 double]
       StartTimes: [10x1 double]
         EndDates: [10x1 double]
       StartDates: [10x1 double]
    ValuationDate: 733043
            Basis: 0
     EndMonthRule: 1
```

Use BKVolSpec to compute interest-rate volatility.

```
Volatility = 0.10*ones(10,1);
AlphaCurve = 0.05*ones(10,1);
AlphaDates = EndDates;
BKVolSpec = bkvolspec(ValuationDate, EndDates, Volatility, AlphaDates, AlphaCurve);
```

Use BKTimeSpec to specify the structure of the time layout for a BK tree.

```
BKTimeSpec = bktimespec(ValuationDate, EndDates, Compounding);
```

Build the BK tree.

```
BKTree = bktree(BKVolSpec, RateSpec, BKTimeSpec);
```

Define the arguments for a 1-year swap and 4-year swaption.

```
ExerciseDates = datetime(2011,1,1);
SwapSettlement = ExerciseDates;
SwapMaturity   = datetime(2012,1,1);
Spread = 0;
SwapReset = [2 2]; % 1st column represents swaption receiving leg, 2nd column represents swaptio
Principal = 100;
OptSpec = {'call' ;'put'};
Strike= [ 0.07 ; 0.0725];
Basis= [1 3]; % 1st column represents swaption receiving leg, 2nd column represents swaption pay
```

Price the swaption.

```
PriceSwaption = swaptionbybk(BKTree, OptSpec, Strike, ExerciseDates, ...
Spread, SwapSettlement, SwapMaturity, 'SwapReset', SwapReset, 'Basis', Basis, ...
'Principal', Principal)
```

```
PriceSwaption = 2×1

    0.3634
    0.4798
```

Input Arguments

BKTree — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using bktree.

Data Types: struct

OptSpec — Definition of option

character vector with values 'call' or 'put' | cell array of character vector with values 'call' or 'put'

Definition of the option as 'call' or 'put', specified as a NINST-by-1 cell array of character vectors. For more information, see “More About” on page 11-1890.

Data Types: char | cell

`Strike` — Strike swap rate values
decimal

Strike swap rate values, specified as a `NINST`-by-`1` vector.

Data Types: `double`

`ExerciseDates` — Exercise dates for swaption
datetime array | string array | date character vector

Exercise dates for the swaption, specified as a `NINST`-by-`1` vector or a `NINST`-by-`2` vector using a datetime array, string array, or date character vectors, depending on the option type.

- For a European option, `ExerciseDates` are a `NINST`-by-`1` vector of exercise dates. Each row is the schedule for one option. When using a European option, there is only one `ExerciseDate` on the option expiry date.
- For an American option, `ExerciseDates` are a `NINST`-by-`2` vector of exercise date boundaries. For each instrument, the option can be exercised on any coupon date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is `NINST`-by-`1`, the option can be exercised between the `ValuationDate` of the tree and the single listed `ExerciseDate`.

To support existing code, `swaptionbybk` also accepts serial date numbers as inputs, but they are not recommended.

`Spread` — Number of basis points over reference rate
numeric

Number of basis points over the reference rate, specified as a `NINST`-by-`1` vector.

Data Types: `double`

`Settle` — Settlement date
datetime array | string array | date character vector

Settlement date (representing the settle date for each swap), specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors,. The `Settle` date for every swaption is set to the `ValuationDate` of the BK tree. The swap argument `Settle` is ignored. The underlying swap starts at the maturity of the swaption.

To support existing code, `swaptionbybk` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date for swap
datetime array | string array | date character vector

Maturity date for each swap, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `swaptionbybk` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceTree] = swaptionbykbk(BKTree,OptSpec, ExerciseDates,Spread,Settle,Maturity,'SwapReset',4,'Basis',5,'Principal',10000)`

`AmericanOpt` — Option type

`0` (European) (default) | integer with values `0` or `1`

(Optional) Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and `NINST`-by-`1` positive integer flags with values:

- `0` — European
- `1` — American

Data Types: `double`

`SwapReset` — Reset frequency per year for underlying swap

`1` (default) | numeric

Reset frequency per year for the underlying swap, specified as the comma-separated pair consisting of `'SwapReset'` and a `NINST`-by-`1` vector or `NINST`-by-`2` matrix representing the reset frequency per year for each leg. If `SwapReset` is `NINST`-by-`2`, the first column represents the receiving leg, while the second column represents the paying leg.

Data Types: `double`

`Basis` — Day-count basis of instrument

`0` (actual/actual) (default) | integer from `0` to `13`

Day-count basis representing the basis used when annualizing the input forward rate tree for each instrument, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-`1` vector or `NINST`-by-`2` matrix representing the basis for each leg. If `Basis` is `NINST`-by-`2`, the first column represents the receiving leg, while the second column represents the paying leg.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)

- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amount
`100` (default) | numeric

Notional principal amount, specified as the comma-separated pair consisting of `'Principal'` and a `NINST`-by-`1` vector.

Data Types: `double`

`Options` — Derivatives pricing options structure
structure

Derivatives pricing options structure, specified as the comma-separated pair consisting of `'Options'` and a structure obtained from using `derivset`.

Data Types: `struct`

Output Arguments

`Price` — Expected prices of swaptions at time 0
vector

Expected prices of the swaptions at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure of instrument prices
structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of swaption instrument prices and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.tObs` contains the observation times.

More About

Call Swaption

A call swaption or payer swaption allows the option buyer to enter into an interest-rate swap in which the buyer of the option pays the fixed rate and receives the floating rate.

Put Swaption

A put swaption or receiver swaption allows the option buyer to enter into an interest-rate swap in which the buyer of the option receives the fixed rate and pays the floating rate.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `swaptionbybk` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

swaptionbycir

Price swaption from Cox-Ingersoll-Ross interest-rate tree

Syntax

```
[Price,PriceTree] = swaptionbycir(CIRTree,OptSpec,Strike,ExerciseDates,
Spread,Settle,Maturity)
[Price,PriceTree] = swaptionbycir( ___ ,Name,Value)
```

Description

`[Price,PriceTree] = swaptionbycir(CIRTree,OptSpec,Strike,ExerciseDates, Spread,Settle,Maturity)` prices swaption with a Cox-Ingersoll-Ross (CIR) tree using a CIR++ model with the Nawalka-Beliaeva (NB) approach.

`[Price,PriceTree] = swaptionbycir( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Price a Swaption Using a CIR Interest-Rate Tree

Define a 3-year put swaption.

```
Rates =0.075 * ones (10,1);
Compounding = 2;
StartDates = [datetime(2017,1,1);datetime(2017,7,1);datetime(2018,1,1);datetime(2018,7,1);dateti
EndDates = [datetime(2017,7,1);datetime(2018,1,1);datetime(2018,7,1);datetime(2019,1,1);datetime

ValuationDate = datetime(2017,1,1);
```

Create a `RateSpec` using the `intenvset` function.

```
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ValuationDate, 'EndDates',End
```

Create a `CIR` tree.

```
NumPeriods = length(EndDates);
Alpha = 0.03;
Theta = 0.02;
Sigma = 0.1;
Maturity = datetime(2023,1,1);
CIRTimeSpec = cirtimespec(ValuationDate, Maturity, NumPeriods);
CIRVolSpec = cirvolspec(Sigma, Alpha, Theta);

CIRT = cirtree(CIRVolSpec, RateSpec, CIRTimeSpec)
```

```
CIRT = struct with fields:
      FinObj: 'CIRFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
```

```
    RateSpec: [1x1 struct]
        tObs: [0 0.6000 1.2000 1.8000 2.4000 3 3.6000 4.2000 4.8000 5.4000]
        dObs: [736696 736915 737134 737353 737572 737791 738010 738229 ... ]
     FwdTree: {1x10 cell}
     Connect: {1x9 cell}
       Probs: {1x9 cell}
```

Use the following arguments for a 1-year swap and a 3-year swaption.

```
ExerciseDates = datetime(2020,1,1);
SwapSettlement = ExerciseDates;
SwapMaturity   = datetime(2022,1,1);
Spread = 0;
SwapReset = 2 ;
Principal = 100;
OptSpec = 'put';
Strike= 0.04;
Basis=1;
```

Price the swaption.

```
[Price,PriceTree] = swaptionbycir(CIRT,OptSpec,Strike,ExerciseDates,Spread,SwapSettlement,SwapMa
'Basis',Basis,'Principal',Principal)
```

```
Price = 3.1537
```

```
PriceTree = struct with fields:
     FinObj: 'CIRPriceTree'
      PTree: {1x11 cell}
       tObs: [0 0.6000 1.2000 1.8000 2.4000 3 3.6000 4.2000 4.8000 5.4000 6]
    Connect: {1x9 cell}
      Probs: {1x9 cell}
```

Input Arguments

`CIRTree` — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `cirtree`.

Data Types: `struct`

`OptSpec` — Definition of option

character vector with values `'call'` or `'put'` | cell array of character vector with values `'call'` or `'put'` | string array with values `"call"` or `"put"`

Definition of the option as `'call'` or `'put'`, specified as a `NINST`-by-`1` cell array of character vectors or string arrays. For more information, see “More About” on page 11-1890.

Data Types: `char` | `cell` | `string`

`Strike` — Strike swap rate values

decimal

Strike swap rate values, specified as a `NINST`-by-`1` vector.

Data Types: `double`

`ExerciseDates` — Exercise dates for swaption
datetime array | string array | date character vector

Exercise dates for the swaption, specified as a `NINST`-by-`1` vector or a `NINST`-by-`2` vector using a datetime array, string array, or date character vectors, depending on the option type.

- For a European option, `ExerciseDates` are a `NINST`-by-`1` vector of exercise dates. Each row is the schedule for one option. When using a European option, there is only one `ExerciseDate` on the option expiry date.
- For an American option, `ExerciseDates` are a `NINST`-by-`2` vector of exercise date boundaries. For each instrument, the option can be exercised on any coupon date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is `NINST`-by-`1`, the option can be exercised between the `ValuationDate` of the tree and the single listed `ExerciseDate`.

To support existing code, `swaptionbycir` also accepts serial date numbers as inputs, but they are not recommended.

`Spread` — Number of basis points over reference rate
numeric

Number of basis points over the reference rate, specified as a `NINST`-by-`1` vector.

Data Types: `double`

`Settle` — Settlement date
datetime array | string array | date character vector

Settlement date (representing the settle date for each swap), specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. The `Settle` date for every swaption is set to the `ValuationDate` of the CIR tree. The swap argument `Settle` is ignored. The underlying swap starts at the maturity of the swaption.

To support existing code, `swaptionbycir` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date for swap
datetime array | string array | date character vector

Maturity date for each swap, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `swaptionbycir` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceTree] = swaptionbycir(CIRTree,OptSpec, ExerciseDates,Spread,Settle,Maturity,'SwapReset',4,'Basis',5,'Principal',1000 0)`

`AmericanOpt` — Option type
`0` (European) (default) | integer with values `0` or `1`

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and `NINST`-by-`1` positive integer flags with values:

- `0` — European
- `1` — American

Data Types: `double`

`SwapReset` — Reset frequency per year for underlying swap
`1` (default) | numeric

Reset frequency per year for the underlying swap, specified as the comma-separated pair consisting of `'SwapReset'` and a `NINST`-by-`1` vector or `NINST`-by-`2` matrix representing the reset frequency per year for each leg. If `SwapReset` is `NINST`-by-`2`, the first column represents the receiving leg, and the second column represents the paying leg.

Data Types: `double`

`Basis` — Day-count basis of instrument
`0` (actual/actual) (default) | integer from `0` to `13`

Day-count basis representing the basis used when annualizing the input forward-rate tree for each instrument, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-`1` vector or `NINST`-by-`2` matrix representing the basis for each leg. If `Basis` is `NINST`-by-`2`, the first column represents the receiving leg, while the second column represents the paying leg.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amount
`100` (default) | numeric

Notional principal amount, specified as the comma-separated pair consisting of `'Principal'` and a `NINST`-by-`1` vector.

Data Types: `double`

Output Arguments

`Price` — Expected prices of swaptions at time 0
vector

Expected prices of the swaptions at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure of instrument prices
structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of swaption instrument prices and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.Connect` contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are `NumNodes` elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- `PriceTree.Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.

More About

Call Swaption

A call swaption or payer swaption allows the option buyer to enter into an interest-rate swap in which the buyer of the option pays the fixed rate and receives the floating rate.

Put Swaption

A put swaption or receiver swaption allows the option buyer to enter into an interest-rate swap in which the buyer of the option receives the fixed rate and pays the floating rate.

Version History

Introduced in R2018a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `swaptionbycir` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

swaptionbyblk

Price European swaption instrument using Black model

Syntax

```
Price = swaptionbyblk(RateSpec,OptSpec,Strike,Settle,ExerciseDates,Maturity,
Volatility)
Price = swaptionbyblk( ___ ,Name,Value)
```

Description

`Price = swaptionbyblk(RateSpec,OptSpec,Strike,Settle,ExerciseDates,Maturity, Volatility)` prices swaptions using the Black option pricing model.

Note Alternatively, you can use the `Swaption` object to price swaption instruments. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`Price = swaptionbyblk( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Price a European Swaption Using the Black Model Where the Yield Curve is Flat at 6%

Price a European swaption that gives the holder the right to enter in five years into a three-year paying swap where a fixed-rate of 6.2% is paid and floating is received. Assume that the yield curve is flat at 6% per annum with continuous compounding, the volatility of the swap rate is 20%, the principal is $100, and payments are exchanged semiannually.

Create the `RateSpec`.

```
Rate = 0.06;
Compounding  = -1;
ValuationDate = datetime(2010,1,1);
EndDates =   datetime(2020,1,1);
Basis = 1;

RateSpec = intenvset('ValuationDate', ValuationDate,'StartDates', ValuationDate, ...
'EndDates', EndDates, 'Rates', Rate, 'Compounding', Compounding, 'Basis', Basis);
```

Price the swaption using the Black model.

```
Settle = datetime(2011,1,1);
ExerciseDates = datetime(2016,1,1);
Maturity = datetime(2019,1,1);
Reset = 2;
Principal = 100;
Strike = 0.062;
```

```
Volatility = 0.2;
OptSpec = 'call';

Price= swaptionbyblk(RateSpec, OptSpec, Strike, Settle, ExerciseDates, Maturity, ...
Volatility, 'Reset', Reset, 'Principal', Principal, 'Basis', Basis)
```

```
Price = 2.0710
```

Price a European Swaption with Receiving and Paying Legs Using the Black Model Where the Yield Curve is 6%

This example shows Price a European swaption with receiving and paying legs that gives the holder the right to enter in five years into a three-year paying swap where a fixed-rate of 6.2% is paid and floating is received. Assume that the yield curve is flat at 6% per annum with continuous compounding, the volatility of the swap rate is 20%, the principal is $100, and payments are exchanged semiannually.

```
Rate = 0.06;
Compounding  = -1;
ValuationDate = datetime(2010,1,1);
EndDates =   datetime(2020,1,1);
Basis = 1;
```

Define the RateSpec.

```
RateSpec = intenvset('ValuationDate',ValuationDate,'StartDates',ValuationDate, ...
'EndDates',EndDates,'Rates',Rate,'Compounding',Compounding,'Basis',Basis);
```

Define the swaption arguments.

```
Settle = datetime(2011,1,1);
ExerciseDates = datetime(2016,1,1);
Maturity = datetime(2019,1,1);
Reset = [2 4]; % 1st column represents receiving leg, 2nd column represents paying leg
Principal = 100;
Strike = 0.062;
Volatility = 0.2;
OptSpec = 'call';
Basis = [1 3]; % 1st column represents receiving leg, 2nd column represents paying leg
```

Price the swaption.

```
Price= swaptionbyblk(RateSpec,OptSpec,Strike,Settle,ExerciseDates,Maturity,Volatility, ...
'Reset',Reset,'Principal',Principal,'Basis',Basis)
```

```
Price = 1.6494
```

Price a European Swaption Using the Black Model Where the Yield Curve Is Incrementally Increasing

Price a European swaption that gives the holder the right to enter into a 5-year receiving swap in a year, where a fixed rate of 3% is received and floating is paid. Assume that the 1-year, 2-year, 3-year, 4-year and 5- year zero rates are 3%, 3.4%, 3.7%, 3.9% and 4% with continuous compounding. The swap rate volatility is 21%, the principal is $1000, and payments are exchanged semiannually.

Create the RateSpec.

```
ValuationDate = datetime(2010,1,1);
EndDates = [datetime(2011,1,1) ; datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1) ; d
Rates = [0.03; 0.034 ; 0.037; 0.039; 0.04;];
Compounding = -1;
Basis = 1;

RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ValuationDate, ...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding,'Basis', Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: [5x1 double]
            Rates: [5x1 double]
         EndTimes: [5x1 double]
       StartTimes: [5x1 double]
         EndDates: [5x1 double]
       StartDates: 734139
    ValuationDate: 734139
            Basis: 1
     EndMonthRule: 1
```

Price the swaption using the Black model.

```
Settle = datetime(2011,1,1);
ExerciseDates = datetime(2012,1,1);
Maturity = datetime(2017,1,1);
Strike = 0.03;
Volatility = 0.21;
Principal =1000;
Reset = 2;
OptSpec = 'put';

Price = swaptionbyblk(RateSpec, OptSpec, Strike, Settle,  ExerciseDates, ...
Maturity, Volatility,'Basis', Basis, 'Reset', Reset,'Principal', Principal)
```

```
Price = 0.5771
```

Price a Swaption Using a Different Curve to Generate the Future Forward Rates

Define the OIS and Libor curves.

```
Settle = datetime(2013,3,15);
CurveDates = daysadd(Settle,360*[1/12 2/12 3/12 6/12 1 2 3 4 5 7 10],1);
OISRates = [.0018 .0019 .0021 .0023 .0031 .006  .011 .017 .021 .026 .03]';
LiborRates = [.0045 .0047 .005 .0055 .0075 .0109  .0162 .0216 .0262 .0309 .0348]';
```

Create an associated RateSpec for the OIS and Libor curves.

```
OISCurve = intenvset('Rates',OISRates,'StartDate',Settle,'EndDates',CurveDates,'Compounding',2,'
LiborCurve = intenvset('Rates',LiborRates,'StartDate',Settle,'EndDates',CurveDates,'Compounding'
```

Define the swaption instruments.

```
ExerciseDate = datetime(2018,3,15);
Maturity = [datetime(2020,3,15) ; datetime(2023,3,15)];
OptSpec = 'call';
Strike = 0.04;
BlackVol = 0.2;
```

Price the swaption instruments using the term structure `OISCurve` both for discounting the cash flows and generating the future forward rates.

```
Price = swaptionbyblk(OISCurve, OptSpec, Strike, Settle, ExerciseDate, Maturity, BlackVol,'Reset
```

```
Price = 2×1

    1.0956
    2.6944
```

Price the swaption instruments using the term structure `LiborCurve` to generate the future forward rates. The term structure `OISCurve` is used for discounting the cash flows.

```
PriceLC = swaptionbyblk(OISCurve, OptSpec, Strike, Settle, ExerciseDate, Maturity, BlackVol,'Pro
```

```
PriceLC = 2×1

    1.5346
    3.8142
```

Price a Swaption Using the Shifted Black Model

Create the `RateSpec`.

```
ValuationDate = datetime(2016,1,1);
EndDates = [datetime(2017,1,1) ; datetime(2018,1,1) ; datetime(2019,1,1) ; datetime(2020,1,1) ; d
Rates = [-0.02; 0.024 ; 0.047; 0.090; 0.12;]/100;
Compounding = 1;
Basis = 1;

RateSpec = intenvset('ValuationDate',ValuationDate,'StartDates',ValuationDate, ...
'EndDates',EndDates,'Rates',Rates,'Compounding',Compounding,'Basis',Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [5x1 double]
            Rates: [5x1 double]
         EndTimes: [5x1 double]
       StartTimes: [5x1 double]
         EndDates: [5x1 double]
       StartDates: 736330
    ValuationDate: 736330
            Basis: 1
     EndMonthRule: 1
```

Price the swaption with a negative strike using the Shifted Black model.

```
Settle = datetime(2016,1,1);
ExerciseDates = datetime(2017,1,1);
Maturity = 'Jan-1-2020';
Strike = -0.003; % Set -0.3 percent strike.
ShiftedBlackVolatility = 0.31;
Principal = 1000;
Reset = 1;
OptSpec = 'call';
Shift = 0.008; % Set 0.8 percent shift.

Price = swaptionbyblk(RateSpec,OptSpec,Strike,Settle,ExerciseDates, ...
Maturity,ShiftedBlackVolatility,'Basis',Basis,'Reset',Reset,...
'Principal',Principal,'Shift',Shift)
```

```
Price = 12.8301
```

Price Swaptions Using the Shifted Black Model with a Vector of Shifts

Create the RateSpec.

```
ValuationDate = datetime(2016,1,1);
EndDates = [datetime(2017,1,1) ; datetime(2018,1,1) ; datetime(2019,1,1) ; datetime(2020,1,1) ; d
Rates = [-0.02; 0.024 ; 0.047; 0.090; 0.12;]/100;
Compounding = 1;
Basis = 1;

RateSpec = intenvset('ValuationDate',ValuationDate,'StartDates',ValuationDate, ...
'EndDates',EndDates,'Rates',Rates,'Compounding',Compounding,'Basis',Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [5x1 double]
            Rates: [5x1 double]
         EndTimes: [5x1 double]
       StartTimes: [5x1 double]
         EndDates: [5x1 double]
       StartDates: 736330
    ValuationDate: 736330
            Basis: 1
     EndMonthRule: 1
```

Price the swaptions with using the Shifted Black model.

```
Settle = datetime(2016,1,1);
ExerciseDates = datetime(2017,1,1);
Maturities = [datetime(2018,1,1) ; datetime(2019,1,1) ; datetime(2020,1,1)];
Strikes = [-0.0034;-0.0032;-0.003];
ShiftedBlackVolatilities = [0.33;0.32;0.31]; % A vector of volatilities.
Principal = 1000;
Reset = 1;
OptSpec = 'call';
Shifts = [0.0085;0.0082;0.008]; % A vector of shifts.

Prices = swaptionbyblk(RateSpec,OptSpec,Strikes,Settle,ExerciseDates, ...
```

```
Maturities,ShiftedBlackVolatilities,'Basis',Basis,'Reset',Reset, ...
'Principal',Principal,'Shift',Shifts)

Prices = 3×1

    4.1117
    8.0577
   12.8301
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

If the paying leg is different than the receiving leg, the `RateSpec` can be a `NINST`-by-2 input variable of `RateSpecs`, with the second input being the discount curve for the paying leg. If only one curve is specified, then it is used to discount both legs.

Data Types: `struct`

OptSpec — Definition of option

character vector with values `'call'` or `'put'` | cell array of character vector with values `'call'` or `'put'`

Definition of the option as `'call'` or `'put'`, specified as a `NINST`-by-1 cell array of character vectors.

A `'call'` swaption, or Payer swaption, allows the option buyer to enter into an interest-rate swap in which the buyer of the option pays the fixed rate and receives the floating rate.

A `'put'` swaption, or Receiver swaption, allows the option buyer to enter into an interest-rate swap in which the buyer of the option receives the fixed rate and pays the floating rate.

Data Types: `char` | `cell`

Strike — Strike swap rate values

decimal

Strike swap rate values, specified as a `NINST`-by-1 vector of decimal values.

Data Types: `double`

Settle — Settlement date

datetime array | string array | date character vector

Settlement date (representing the settle date for each swaption), specified as a `NINST`-by-1 vector using a datetime array, string array, or date character vectors. `Settle` must not be later than `ExerciseDates`.

To support existing code, `swaptionbyblk` also accepts serial date numbers as inputs, but they are not recommended.

The Settle date input for swaptionbyblk is the valuation date on which the swaption (an option to enter into a swap) is priced. The swaption buyer pays this price on this date to hold the swaption.

ExerciseDates — Dates on which swaption expires and underlying swap starts
datetime array | string array | date character vector

Dates, specified as a vector using a datetime array, string array, or date character vectors on which the swaption expires and the underlying swap starts. The swaption holder can choose to enter into the swap on this date if the situation is favorable.

To support existing code, swaptionbyblk also accepts serial date numbers as inputs, but they are not recommended.

For a European option, ExerciseDates are a NINST-by-1 vector of exercise dates. Each row is the schedule for one option. When using a European option, there is only one ExerciseDate on the option expiry date.

Maturity — Maturity date for each forward swap
datetime array | string array | date character vector

Maturity date for each forward swap, specified as a NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, swaptionbyblk also accepts serial date numbers as inputs, but they are not recommended.

Volatility — Annual volatilities values
numeric

Annual volatilities values, specified as a NINST-by-1 vector of numeric values.

Data Types: double

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: Price = swaptionbyblk(OISCurve,OptSpec,Strike,Settle,ExerciseDate,Maturity,BlackVol,'Reset',1,'Shift',.5)

Basis — Day-count basis of instrument
0 (actual/actual) (default) | integer from 0 to 13

Day-count basis of the instrument, specified as the comma-separated pair consisting of 'Basis' and a NINST-by-1 vector or NINST-by-2 matrix representing the basis for each leg. If Basis is NINST-by-2, the first column represents the receiving leg, while the second column represents the paying leg. Default is 0 (actual/actual).

- 0 = actual/actual
- 1 = 30/360 (SIA)

- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amount
`100` (default) | numeric

Notional principal amount, specified as the comma-separated pair consisting of `'Principal'` and a `NINST`-by-`1` vector.

Data Types: `double`

`Reset` — Reset frequency per year for underlying forward swap
`1` (default) | numeric

Reset frequency per year for the underlying forward swap, specified as the comma-separated pair consisting of `'Reset'` and a `NINST`-by-`1` vector or `NINST`-by-`2` matrix representing the reset frequency per year for each leg. If `Reset` is `NINST`-by-`2`, the first column represents the receiving leg, while the second column represents the paying leg.

Data Types: `double`

`ProjectionCurve` — Rate curve used in generating future forward rates
if `ProjectionCurve` is not specified, then `RateSpec` is used both for discounting cash flows and projecting future forward rates (default) | structure

The rate curve to be used in generating the future forward rates, specified as the comma-separated pair consisting of `'ProjectionCurve'` and a structure created using `intenvset`. Use this optional input if the forward curve is different from the discount curve.

Data Types: `struct`

`Shift` — Shift in decimals for shifted Black model
`0` (no shift) (default) | positive decimal

Shift in decimals for the shifted Black model, specified as the comma-separated pair consisting of `'Shift'` and a scalar or `NINST`-by-`1` vector of rate shifts in positive decimals. Set this parameter to a positive rate shift in decimals to add a positive shift to the forward swap rate and strike, which effectively sets a negative lower bound for the forward swap rate and strike. For example, a `Shift` of `0.01` is equal to a 1% shift.

Data Types: `double`

Output Arguments

`Price` — Prices for swaptions at time 0

vector

Prices for the swaptions at time 0, returned as a `NINST`-by-`1` vector of prices.

More About

Forward Swap

A forward swap is a swap that starts at a future date.

Shifted Black

The Shifted Black model is essentially the same as the Black's model, except that it models the movements of ($F + Shift$) as the underlying asset, instead of F (which is the forward swap rate in the case of swaptions).

This model allows negative rates, with a fixed negative lower bound defined by the amount of shift; that is, the zero lower bound of Black's model has been shifted.

Algorithms

Black Model

$$dF = \sigma_{Black} F dw$$

$$call = e^{-\gamma T}[FN(d_1) - KN(d_2)]$$

$$put = e^{-\gamma T}[KN(-d_2) - FN(-d_1)]$$

$$d_1 = \frac{\ln\left(\frac{F}{K}\right) + \left(\frac{\sigma_B{}^2}{2}\right)T}{\sigma_B\sqrt{T}}, \quad d_2 = d_1 - \sigma_B\sqrt{T}$$

$$\sigma_B = \sigma_{Black}$$

Where F is the forward value and K is the strike.

Shifted Black Model

$$dF = \sigma_{Shifted\_Black}(F + Shift)dw$$

$$call = e^{-\gamma T}[(F + Shift)N(d_{s1}) - (K + Shift)N(d_{s2})]$$

$$put = e^{-\gamma T}[(K + Shift)N(-d_{s2}) - (F + Shift)N(-d_{s1})]$$

$$d_{s1} = \frac{\ln\left(\frac{F + Shift}{K + Shift}\right) + \left(\frac{\sigma_{sB}{}^2}{2}\right)T}{\sigma_{sB}\sqrt{T}}, \quad d_{s2} = d_{s1} - \sigma_{sB}\sqrt{T}$$

$$\sigma_{sB} = \sigma_{Shifted\_Black}$$

Where *F+Shift* is the forward value and *K+Shift* is the strike for the shifted version.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `swaptionbyblk` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

How to Price Interest Rate Options with Negative Interest Rates (3 min 05 sec)

swaptionbyhjm

Price swaption from Heath-Jarrow-Morton interest-rate tree

Syntax

```
[Price,PriceTree] = swaptionbyhjm(HJMTree,OptSpec,Strike,ExerciseDates,
Spread,Settle,Maturity)
[Price,PriceTree] = swaptionbyhjm( ___ ,Name,Value)
```

Description

`[Price,PriceTree] = swaptionbyhjm(HJMTree,OptSpec,Strike,ExerciseDates, Spread,Settle,Maturity)` prices swaption using a Heath-Jarrow-Morton tree.

`[Price,PriceTree] = swaptionbyhjm( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Price a 1-Year Call Swaption Using an HJM Interest-Rate Tree

This example shows how to price a 1-year call swaption using an HJM interest-rate tree. Assume that interest rate is fixed at 5% annually between the valuation date of the tree until its maturity. Build a tree with the following data.

```
Rates = [ 0.05;0.05;0.05;0.05];
StartDates = datetime(2007,1,1);
EndDates =[datetime(2008,1,1) ; datetime(2009,1,1) ; datetime(2010,1,1) ; datetime(2011,1,1)];
ValuationDate = StartDates;
Compounding = 1;

% define the RateSpec
RateSpec = intenvset('Rates', Rates, 'StartDates', StartDates, 'EndDates',...
EndDates, 'Compounding', Compounding);

% use VolSpec to compute the interest-rate volatility
VolSpec=hjmvolspec('Constant',0.01);

% use TimeSpec to specify the structure of the time layout for the HJM interest-rate tree
TimeSpec = hjmtimespec(ValuationDate, EndDates, Compounding);

% build the HJM tree
HJMTree = hjmtree(VolSpec, RateSpec, TimeSpec);

% use the following swaption arguments
ExerciseDates = datetime(2008,1,1);
SwapSettlement = ExerciseDates;
SwapMaturity   = datetime(2010,1,1);
Spread = [0];
SwapReset = 1;
```

```
Basis  = 1;
Principal = 100;
OptSpec = 'call';
Strike=0.05;

% price the swaption

[Price, PriceTree] = swaptionbyhjm(HJMTree, OptSpec, Strike, ExerciseDates, ...
Spread, SwapSettlement, SwapMaturity,'SwapReset', SwapReset, ...
'Basis', Basis, 'Principal', Principal)

Price = 0.9296

PriceTree = struct with fields:
    FinObj: 'HJMPriceTree'
      tObs: [5x1 double]
     PBush: {[0.9296]  [1x1x2 double]  [1x2x2 double]  [1x4x2 double]  [0 ... ]}
```

Price a 1-Year Call Swaption with Receiving and Paying Legs Using an HJM Interest-Rate Tree

This example shows how to price a 1-year call swaption with receiving and paying legs using an HJM interest-rate tree. Assume that interest rate is fixed at 5% annually between the valuation date of the tree until its maturity. Build a tree with the following data.

```
Rates = [ 0.05;0.05;0.05;0.05];
StartDates = datetime(2007,1,1);
EndDates =[datetime(2008,1,1) ; datetime(2009,1,1) ; datetime(2010,1,1) ; datetime(2011,1,1)];
ValuationDate = StartDates;
Compounding = 1;
```

Define the `RateSpec`.

```
RateSpec = intenvset('Rates',Rates,'StartDates',StartDates,'EndDates',...
EndDates,'Compounding',Compounding);
```

Use `VolSpec` to compute the interest-rate volatility.

```
VolSpec=hjmvolspec('Constant',0.01);
```

Use `TimeSpec` to specify the structure of the time layout for the HJM interest-rate tree.

```
TimeSpec = hjmtimespec(ValuationDate,EndDates,Compounding);
```

Build the HJM tree.

```
HJMTree = hjmtree(VolSpec,RateSpec,TimeSpec);
```

Use the following swaption arguments

```
ExerciseDates = datetime(2008,1,1);
SwapSettlement = ExerciseDates;
SwapMaturity   = datetime(2010,1,1);
Spread = [0];
SwapReset = [1 1];  % 1st column represents receiving leg, 2nd column represents paying leg
```

```
Basis  = [1 3];     % 1st column represents receiving leg, 2nd column represents paying leg
Principal = 100;
OptSpec = 'call';
Strike=0.05;
```

Price the swaption.

```
[Price, PriceTree] = swaptionbyhjm(HJMTree,OptSpec,Strike,ExerciseDates, ...
Spread,SwapSettlement,SwapMaturity,'SwapReset',SwapReset, ...
'Basis',Basis,'Principal',Principal)
```

```
Price = 0.9296
```

```
PriceTree = struct with fields:
    FinObj: 'HJMPriceTree'
      tObs: [5x1 double]
     PBush: {[0.9296]  [1x1x2 double]  [1x2x2 double]  [1x4x2 double]  [0 ... ]}
```

Input Arguments

`HJMTree` — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `hjmtree`.

Data Types: `struct`

`OptSpec` — Definition of option

character vector with values `'call'` or `'put'` | cell array of character vector with values `'call'` or `'put'`

Definition of the option as `'call'` or `'put'`, specified as a `NINST`-by-1 cell array of character vectors. For more information, see “More About” on page 11-1913.

Data Types: `char` | `cell`

`Strike` — Strike swap rate values

decimal

Strike swap rate values, specified as a `NINST`-by-1 vector.

Data Types: `double`

`ExerciseDates` — Exercise dates for swaption

datetime array | string array | date character vector

Exercise dates for the swaption, specified as a `NINST`-by-1 vector or a `NINST`-by-2 vector using a datetime array, string array, or date character vectors, depending on the option type.

- For a European option, `ExerciseDates` are a `NINST`-by-1 vector of exercise dates. Each row is the schedule for one option. When using a European option, there is only one `ExerciseDate` on the option expiry date.
- For an American option, `ExerciseDates` are a `NINST`-by-2 vector of exercise date boundaries. For each instrument, the option can be exercised on any coupon date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is `NINST`-by-1,

the option can be exercised between the `ValuationDate` of the tree and the single listed `ExerciseDate`.

To support existing code, `swaptionbyhjm` also accepts serial date numbers as inputs, but they are not recommended.

`Spread` — Number of basis points over reference rate
numeric

Number of basis points over the reference rate, specified as a `NINST`-by-`1` vector.

Data Types: `double`

`Settle` — Settlement date
datetime array | string array | date character vector

Settlement date (representing the settle date for each swap), specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. The `Settle` date for every swaption is set to the `ValuationDate` of the HJM tree. The swap argument `Settle` is ignored. The underlying swap starts at the maturity of the swaption.

To support existing code, `swaptionbyhjm` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date for swap
datetime array | string array | date character vector

Maturity date for each swap, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `swaptionbyhjm` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceTree] = swaptionbyhjm(HJMTree,OptSpec, ExerciseDates,Spread,Settle,Maturity,'SwapReset',4,'Basis',5,'Principal',10000)`

`AmericanOpt` — Option type
`0` (European) (default) | integer with values `0` or `1`

(Optional) Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and `NINST`-by-`1` positive integer flags with values:

- `0` — European
- `1` — American

Data Types: `double`

SwapReset — Reset frequency per year for underlying swap
1 (default) | numeric

Reset frequency per year for the underlying swap, specified as the comma-separated pair consisting of 'SwapReset' and a NINST-by-1 vector or NINST-by-2 matrix representing the reset frequency per year for each leg. If SwapReset is NINST-by-2, the first column represents the receiving leg, while the second column represents the paying leg.

Data Types: double

Basis — Day-count basis of instrument
0 (actual/actual) (default) | integer from 0 to 13

Day-count basis representing the basis used when annualizing the input forward rate tree for each instrument, specified as the comma-separated pair consisting of 'Basis' and a NINST-by-1 vector or NINST-by-2 matrix representing the basis for each leg. If Basis is NINST-by-2, the first column represents the receiving leg, while the second column represents the paying leg.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: double

Principal — Notional principal amount
100 (default) | numeric

Notional principal amount, specified as the comma-separated pair consisting of 'Principal' and a NINST-by-1 vector.

Data Types: double

Options — Derivatives pricing options structure
structure

Derivatives pricing options structure, specified as the comma-separated pair consisting of 'Options' and a structure obtained from using derivset.

Data Types: struct

Output Arguments

`Price` — Expected prices of swaptions at time 0

vector

Expected prices of the swaptions at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure of instrument prices

structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of swaption instrument prices and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.tObs` contains the observation times.

More About

Call Swaption

A call swaption or payer swaption allows the option buyer to enter into an interest-rate swap in which the buyer of the option pays the fixed rate and receives the floating rate.

Put Swaption

A put swaption or receiver swaption allows the option buyer to enter into an interest-rate swap in which the buyer of the option receives the fixed rate and pays the floating rate.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `swaptionbyhjm` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

swaptionbyhw

Price swaption from Hull-White interest-rate tree

Syntax

```
[Price,PriceTree] = swaptionbyhw(HWTree,OptSpec,Strike,ExerciseDates,Spread,
Settle,Maturity)
[Price,PriceTree] = swaptionbyhw( ___ ,Name,Value)
```

Description

`[Price,PriceTree] = swaptionbyhw(HWTree,OptSpec,Strike,ExerciseDates,Spread, Settle,Maturity)` prices swaption using a Hull-White tree.

Note Alternatively, you can use the `Swaption` object to price swaption instruments. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,PriceTree] = swaptionbyhw( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Price a 3-Year Put Swaption Using an HW Interest-Rate Tree

This example shows how to price a 3-year put swaption using an HW interest-rate tree with the following data.

```
Rates =0.075 * ones (10,1);
Compounding = 2;
StartDates = [datetime(2007,1,1);datetime(2007,7,1);datetime(2008,1,1);datetime(2008,7,1);dateti
EndDates = [datetime(2007,7,1);datetime(2008,1,1);datetime(2008,7,1);datetime(2009,1,1);datetime
ValuationDate = datetime(2007,1,1);

% Define the RatesSpec
RateSpec = intenvset('Rates', Rates, 'StartDates', StartDates, 'EndDates',...
EndDates, 'Compounding', Compounding);

% Use HWVolSpec to compute the interest-rate volatility
Volatility = 0.05*ones(10,1);
AlphaCurve = 0.01*ones(10,1);
AlphaDates = EndDates;
HWVolSpec = hwvolspec(ValuationDate, EndDates, Volatility, AlphaDates, AlphaCurve);

% Use HWTimeSpec to specify the structure of the time layout for an HW interest-rate tree
HWTimeSpec = hwtimespec(ValuationDate, EndDates, Compounding);

% Build the HW tree
```

```
HWTree = hwtree(HWVolSpec, RateSpec, HWTimeSpec);

% Use the following arguments for a 1-year swap and 3-year swaption
ExerciseDates = datetime(2010,1,1);
SwapSettlement = ExerciseDates;
SwapMaturity   = datetime(2012,1,1);
Spread = 0;
SwapReset = 2 ;
Principal = 100;
OptSpec = 'put';
Strike= 0.04;
Basis=1;

% Price the swaption
PriceSwaption = swaptionbyhw(HWTree, OptSpec, Strike, ExerciseDates, ...
Spread, SwapSettlement, SwapMaturity,'SwapReset', SwapReset, ...
'Basis', Basis,'Principal', Principal)

PriceSwaption = 2.9201
```

Price a 3-Year Put Swaption with Receiving and Paying Legs Using an HW Interest-Rate Tree

This example shows how to price a 3-year put swaption with receiving and paying legs using an HW interest-rate tree with the following data.

```
Rates =0.075 * ones (10,1);
Compounding = 2;
StartDates = [datetime(2007,1,1);datetime(2007,7,1);datetime(2008,1,1);datetime(2008,7,1);dateti
EndDates = [datetime(2007,7,1);datetime(2008,1,1);datetime(2008,7,1);datetime(2009,1,1);datetime
ValuationDate = datetime(2007,1,1);
```

Define the `RatesSpec`.

```
RateSpec = intenvset('Rates', Rates, 'StartDates', StartDates, 'EndDates',...
EndDates, 'Compounding', Compounding);
```

Use `HWVolSpec` to compute the interest-rate volatility.

```
Volatility = 0.05*ones(10,1);
AlphaCurve = 0.01*ones(10,1);
AlphaDates = EndDates;
HWVolSpec = hwvolspec(ValuationDate, EndDates, Volatility, AlphaDates, AlphaCurve);
```

Use `HWTimeSpec` to specify the structure of the time layout for an HW interest-rate tree.

```
HWTimeSpec = hwtimespec(ValuationDate, EndDates, Compounding);
```

Build the HW tree.

```
HWTree = hwtree(HWVolSpec, RateSpec, HWTimeSpec);
```

Use the following arguments for a 1-year swap and 3-year swaption

```
ExerciseDates = datetime(2010,1,1);
SwapSettlement = ExerciseDates;
SwapMaturity   = datetime(2012,1,1);
```

```
Spread = 0;
SwapReset = [2 2]; % 1st column represents receiving leg, 2nd column represents paying leg
Principal = 100;
OptSpec = 'put';
Strike= 0.04;
Basis= [1 3];    % 1st column represents receiving leg, 2nd column represents paying leg
```

Price the swaption.

```
PriceSwaption = swaptionbyhw(HWTree, OptSpec, Strike, ExerciseDates, ...
Spread, SwapSettlement, SwapMaturity,'SwapReset', SwapReset, ...
'Basis', Basis,'Principal', Principal)
```

```
PriceSwaption = 2.9201
```

Input Arguments

`HWTree` — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `hwtree`.

Data Types: `struct`

`OptSpec` — Definition of option

character vector with values `'call'` or `'put'` | cell array of character vector with values `'call'` or `'put'`

Definition of the option as `'call'` or `'put'`, specified as a `NINST`-by-1 cell array of character vectors. For more information, see “More About” on page 11-1920.

Data Types: `char` | `cell`

`Strike` — Strike swap rate values

decimal

Strike swap rate values, specified as a `NINST`-by-1 vector.

Data Types: `double`

`ExerciseDates` — Exercise dates for swaption

datetime array | string array | date character vector

Exercise dates for the swaption, specified as a `NINST`-by-1 vector or a `NINST`-by-2 vector using a datetime array, string array, or date character vectors, depending on the option type.

- For a European option, `ExerciseDates` are a `NINST`-by-1 vector of exercise dates. Each row is the schedule for one option. When using a European option, there is only one `ExerciseDate` on the option expiry date.
- For an American option, `ExerciseDates` are a `NINST`-by-2 vector of exercise date boundaries. For each instrument, the option can be exercised on any coupon date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is `NINST`-by-1, the option can be exercised between the `ValuationDate` of the tree and the single listed `ExerciseDate`.

To support existing code, `swaptionbyhw` also accepts serial date numbers as inputs, but they are not recommended.

`Spread` — Number of basis points over reference rate
numeric

Number of basis points over the reference rate, specified as a `NINST`-by-`1` vector.

Data Types: `double`

`Settle` — Settlement date
datetime array | string array | date character vector

Settlement date (representing the settle date for each swap), specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. The `Settle` date for every swaption is set to the `ValuationDate` of the HW tree. The swap argument `Settle` is ignored. The underlying swap starts at the maturity of the swaption.

To support existing code, `swaptionbyhw` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date for swap
datetime array | string array | date character vector

Maturity date for each swap, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `swaptionbyhw` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceTree] = swaptionbyhw(HWTree,OptSpec, ExerciseDates,Spread,Settle,Maturity,'SwapReset',4,'Basis',5,'Principal',10000)`

`AmericanOpt` — Option type
`0` (European) (default) | integer with values `0` or `1`

(Optional) Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and `NINST`-by-`1` positive integer flags with values:

- `0` — European
- `1` — American

Data Types: `double`

`SwapReset` — Reset frequency per year for underlying swap
`1` (default) | numeric

Reset frequency per year for the underlying swap, specified as the comma-separated pair consisting of `'SwapReset'` and a `NINST`-by-`1` vector or `NINST`-by-`2` matrix representing the reset frequency per year for each leg. If `SwapReset` is `NINST`-by-`2`, the first column represents the receiving leg, while the second column represents the paying leg.

Data Types: `double`

`Basis` — Day-count basis of instrument
`0` (actual/actual) (default) | integer from `0` to `13`

Day-count basis representing the basis used when annualizing the input forward rate tree for each instrument, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-`1` vector or `NINST`-by-`2` matrix representing the basis for each leg. If `Basis` is `NINST`-by-`2`, the first column represents the receiving leg, while the second column represents the paying leg.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amount
`100` (default) | numeric

Notional principal amount, specified as the comma-separated pair consisting of `'Principal'` and a `NINST`-by-`1` vector.

Data Types: `double`

`Options` — Derivatives pricing options structure
structure

Derivatives pricing options structure, specified as the comma-separated pair consisting of `'Options'` and a structure obtained from using `derivset`.

Data Types: `struct`

Output Arguments

`Price` — Expected prices of swaptions at time 0

vector

Expected prices of the swaptions at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure of instrument prices

structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of swaption instrument prices and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.tObs` contains the observation times.

More About

Call Swaption

A call swaption or payer swaption allows the option buyer to enter into an interest-rate swap in which the buyer of the option pays the fixed rate and receives the floating rate.

Put Swaption

A put swaption or receiver swaption allows the option buyer to enter into an interest-rate swap in which the buyer of the option receives the fixed rate and pays the floating rate.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `swaptionbyhw` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

swaptionbylg2f

Price European swaption using Linear Gaussian two-factor model

Syntax

```
Price = swaptionbylg2f(ZeroCurve,a,b,sigma,eta,rho,Strike,ExerciseDate,
Maturity)
Price = swaptionbylg2f( ___ ,Name,Value)
```

Description

`Price = swaptionbylg2f(ZeroCurve,a,b,sigma,eta,rho,Strike,ExerciseDate, Maturity)` returns the European swaption price for a two-factor additive Gaussian interest-rate model.

Note Alternatively, you can use the `Swaption` object to price swaption instruments. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`Price = swaptionbylg2f( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Price a European Swaption Using a Linear Gaussian Two-Factor Model

Define the `ZeroCurve`, `a`, `b`, `sigma`, `eta`, and `rho` parameters to compute the price of the swaption.

```
Settle = datetime(2007,12,15);

ZeroTimes = [3/12 6/12 1 5 7 10 20 30]';
ZeroRates = [0.033 0.034 0.035 0.040 0.042 0.044 0.048 0.0475]';
CurveDates = daysadd(Settle,360*ZeroTimes,1);

irdc = IRDataCurve('Zero',Settle,CurveDates,ZeroRates);

a = .07;
b = .5;
sigma = .01;
eta = .006;
rho = -.7;

Reset = 1;
ExerciseDate = daysadd(Settle,360*5,1);
Maturity = daysadd(ExerciseDate,360*[3;4],1);
Strike = .05;

Price = swaptionbylg2f(irdc,a,b,sigma,eta,rho,Strike,ExerciseDate,Maturity,'Reset',Reset)
```

```
Price = 2×1
```

```
    1.1869
    1.5590
```

Input Arguments

`ZeroCurve` — Zero-curve for Linear Gaussian two-factor model

structure

Zero-curve for the Linear Gaussian two-factor model, specified using `IRDataCurve` or `RateSpec`.

Data Types: `struct`

`a` — Mean reversion for first factor for Linear Gaussian two-factor model

scalar

Mean reversion for first factor for the Linear Gaussian two-factor model, specified as a scalar.

Data Types: `single` | `double`

`b` — Mean reversion for second factor for Linear Gaussian two-factor model

scalar

Mean reversion for second factor for the Linear Gaussian two-factor model, specified as a scalar.

Data Types: `single` | `double`

`sigma` — Volatility for first factor for Linear Gaussian two-factor model

scalar

Volatility for first factor for the Linear Gaussian two-factor model, specified as a scalar.

Data Types: `single` | `double`

`eta` — Volatility for second factor for Linear Gaussian two-factor model

scalar

Volatility for second factor for the Linear Gaussian two-factor model, specified as a scalar.

Data Types: `single` | `double`

`rho` — Scalar correlation of the factors

scalar

Scalar correlation of the factors, specified as a scalar.

Data Types: `single` | `double`

`Strike` — Swaption strike price

nonnegative integer | vector of nonnegative integers

Swaption strike price, specified as a nonnegative integer using a `NumSwaptions`-by-`1` vector.

Data Types: `single` | `double`

`ExerciseDate` — Swaption exercise dates

datetime array | string array | date character vector

Swaption exercise dates, specified as a `NumSwaptions`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `swaptionbylg2f` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Underlying swap maturity date
datetime array | string array | date character vector

Underlying swap maturity date, specified using a `NumSwaptions`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `swaptionbylg2f` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Price = swaptionbylg2f(irdc,a,b,sigma,eta,rho,Strike,ExerciseDate,Maturity,'Reset',1,'Notional',100,'OptSpec','call')`

`Reset` — Frequency of swaption payments per year
`2` (default) | positive integer from the set `[1,2,3,4,6,12]` | vector of positive integers from the set `[1,2,3,4,6,12]`

Frequency of swaption payments per year, specified as the comma-separated pair consisting of `'Reset'` and positive integers for the values `1,2,4,6,12` in a `NumSwaptions`-by-`1` vector.

Data Types: `single` | `double`

`Notional` — Notional value of swaption
`100` (default) | nonnegative integer | vector of nonnegative integers

Notional value of swaption, specified as the comma-separated pair consisting of `'Notional'` and a nonnegative integer using a `NumSwaptions`-by-`1` vector of notional amounts.

Data Types: `single` | `double`

`OptSpec` — Option specification for the swaption
`'call'` (default) | character vector with value of `'call'` or `'put'` | cell array of character vectors with values of `'call'` or `'put'`

Option specification for the swaption, specified as the comma-separated pair consisting of `'OptSpec'` and a character vector or a `NumSwaptions`-by-`1` cell array of character vectors with a value of `'call'` or `'put'`.

A `'call'` swaption or Payer swaption allows the option buyer to enter into an interest-rate swap in which the buyer of the option pays the fixed rate and receives the floating rate.

A `'put'` swaption or Receiver swaption allows the option buyer to enter into an interest-rate swap in which the buyer of the option receives the fixed rate and pays the floating rate.

Data Types: `char` | `cell`

Output Arguments

`Price` — Swaption price

scalar | vector

Swaption price, returned as a scalar or an `NumSwaptions`-by-`1` vector.

More About

Call Swaption

A call swaption or payer swaption allows the option buyer to enter into an interest-rate swap in which the buyer of the option pays the fixed rate and receives the floating rate.

Put Swaption

A put swaption or receiver swaption allows the option buyer to enter into an interest-rate swap in which the buyer of the option receives the fixed rate and pays the floating rate.

Algorithms

The following defines the swaption price for a two-factor additive Gaussian interest-rate model, given the `ZeroCurve`, `a`, `b`, `sigma`, `eta`, and `rho` parameters:

$$r(t) = x(t) + y(t) + \phi(t)$$

$$dx(t) = -ax(t)dt + \sigma dW_1(t), \quad x(0) = 0$$

$$dy(t) = -by(t)dt + \eta dW_2(t), \quad y(0) = 0$$

where $dW_1(t)dW_2(t) = \rho dt$ is a two-dimensional Brownian motion with correlation ρ and ϕ is a function chosen to match the initial zero curve.

Version History

Introduced in R2013a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `swaptionbylg2f` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

swaptionbynormal

Price swaptions using Normal or Bachelier option pricing model

Syntax

```
Price = swaptionbynormal(RateSpec,OptSpec,Strike,Settle,ExerciseDates,
Maturity,Volatility)
Price = swaptionbynormal( ___ ,Name,Value)
```

Description

`Price = swaptionbynormal(RateSpec,OptSpec,Strike,Settle,ExerciseDates, Maturity,Volatility)` prices swaptions using the Normal or Bachelier option pricing model.

Note Alternatively, you can use the `Swaption` object to price swaption instruments. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`Price = swaptionbynormal( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Price a Swaption Using the Normal Model

Define the zero curve, and create a `RateSpec`.

```
Settle = datetime(2016,1,20);
ZeroTimes = [.5 1 2 3 4 5 7 10 20 30]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = datemnth(Settle,12*ZeroTimes);
RateSpec = intenvset('StartDate',Settle,'EndDates',ZeroDates,'Rates',ZeroRates)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 2
             Disc: [10x1 double]
            Rates: [10x1 double]
         EndTimes: [10x1 double]
       StartTimes: [10x1 double]
         EndDates: [10x1 double]
       StartDates: 736349
    ValuationDate: 736349
            Basis: 0
     EndMonthRule: 1
```

Define the swaption.

```
ExerciseDate = datetime(2021,1,20);
Maturity = datetime(2026,1,20);
```

```
OptSpec = 'call';
LegReset = [1 1];
```

Compute the par swap rate.

```
[~,ParSwapRate] = swapbyzero(RateSpec,[NaN 0],Settle,Maturity,'LegReset',LegReset)
```

```
ParSwapRate = 0.0216
```

```
Strike = ParSwapRate;
BlackVol = .3;
NormalVol = BlackVol*ParSwapRate;
```

Price with Black volatility.

```
Price = swaptionbyblk(RateSpec,OptSpec,Strike,Settle,ExerciseDate,Maturity,BlackVol)
```

```
Price = 5.9756
```

Price with Normal volatility.

```
Price_Normal = swaptionbynormal(RateSpec,OptSpec,Strike,Settle,ExerciseDate,Maturity,NormalVol)
```

```
Price_Normal = 5.5537
```

Price a Swaption with a Receiving and Paying Leg Using the Normal Model

Create a RateSpec.

```
Rate = 0.06;
Compounding  = -1;
ValuationDate = datetime(2010,1,1);
EndDates = datetime(2020,1,1);
Basis = 1;
RateSpec = intenvset('ValuationDate', ValuationDate,'StartDates', ValuationDate, ...
'EndDates', EndDates, 'Rates', Rate, 'Compounding', Compounding, 'Basis', Basis);
```

Define the swaption.

```
ExerciseDate = datetime(2021,1,20);
Maturity = datetime(2026,1,20);
Settle = datetime(2010,1,1);
OptSpec = 'call';
Strike = .09;
NormalVol = .03;
Reset = [1 4];  % 1st column represents receiving leg, 2nd column represents paying leg
Basis = [1 7];  % 1st column represents receiving leg, 2nd column represents paying leg
```

Price with Normal volatility.

```
Price_Normal = swaptionbynormal(RateSpec,OptSpec,Strike,Settle,ExerciseDate,Maturity,NormalVol,'
```

```
Price_Normal = 5.9084
```

Price a Swaption Using swaptionbynormal and Compare to swaptionbyblk

Define the RateSpec.

```
Settle = datetime(2016,1,20);
ZeroTimes = [.5 1 2 3 4 5 7 10 20 30]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = datemnth(Settle,12*ZeroTimes);
RateSpec = intenvset('StartDate',Settle,'EndDates',ZeroDates,'Rates',ZeroRates)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 2
             Disc: [10x1 double]
            Rates: [10x1 double]
         EndTimes: [10x1 double]
       StartTimes: [10x1 double]
         EndDates: [10x1 double]
       StartDates: 736349
    ValuationDate: 736349
            Basis: 0
     EndMonthRule: 1
```

Define the swaption instrument and price with swaptionbyblk.

```
ExerciseDate = datetime(2021,1,20);
Maturity = datetime(2026,1,20);
OptSpec = 'call';

[~,ParSwapRate] = swapbyzero(RateSpec,[NaN 0],Settle,Maturity,'StartDate',ExerciseDate)
```

```
ParSwapRate = 0.0326
```

```
Strike = ParSwapRate;
BlackVol = .3;
NormalVol = BlackVol*ParSwapRate;

Price = swaptionbyblk(RateSpec,OptSpec,Strike,Settle,ExerciseDate,Maturity,BlackVol)
```

```
Price = 3.6908
```

Price the swaption instrument using swaptionbynormal.

```
Price_Normal = swaptionbynormal(RateSpec,OptSpec,Strike,Settle,ExerciseDate,Maturity,NormalVol)
```

```
Price_Normal = 3.7602
```

Price the swaption instrument using swaptionbynormal for a negative strike.

```
 Price_Normal = swaptionbynormal(RateSpec,OptSpec,-.005,Settle,ExerciseDate,Maturity,NormalVol)
```

```
Price_Normal = 16.3674
```

Input Arguments

RateSpec — Interest-rate term structure
structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

If the discount curve for the paying leg is different than the receiving leg, `RateSpec` can be a `NINST`-by-2 input variable of `RateSpecs`, with the second input being the discount curve for the paying leg. If only one curve is specified, then it is used to discount both legs.

Data Types: `struct`

`OptSpec` — Definition of option
character vector with values `'call'` or `'put'` | cell array of character vector with values `'call'` or `'put'`

Definition of the option as `'call'` or `'put'`, specified as a `NINST`-by-1 cell array of character vectors.

A `'call'` swaption, or Payer swaption, allows the option buyer to enter into an interest-rate swap in which the buyer of the option pays the fixed rate and receives the floating rate.

A `'put'` swaption, or Receiver swaption, allows the option buyer to enter into an interest-rate swap in which the buyer of the option receives the fixed rate and pays the floating rate.

Data Types: `char` | `cell`

`Strike` — Strike swap rate values
decimal

Strike swap rate values, specified as a `NINST`-by-1 vector of decimal values.

Data Types: `double`

`Settle` — Settlement date
datetime array | string array | date character vector

Settlement date (representing the settle date for each swaption), specified as a `NINST`-by-1 vector using a datetime array, string array, or date character vectors. `Settle` must not be later than `ExerciseDates`.

To support existing code, `swaptionbynormal` also accepts serial date numbers as inputs, but they are not recommended.

The `Settle` date input for `swaptionbynormal` is the valuation date on which the swaption (an option to enter into a swap) is priced. The swaption buyer pays this price on this date to hold the swaption.

`ExerciseDates` — Dates on which swaption expires and underlying swap starts
datetime array | string array | date character vector

Dates on which the swaption expires and the underlying swap starts, specified as a `NINST`-by-1 vector using a datetime array, string array, or date character vectors. There is only one `ExerciseDate` on the option expiry date. This is also the `StartDate` of the underlying forward swap.

To support existing code, `swaptionbynormal` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date for each forward swap
datetime array | string array | date character vector

Maturity date for each forward swap, specified as a NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, swaptionbynormal also accepts serial date numbers as inputs, but they are not recommended.

Volatility — Volatilities values
numeric

Volatilities values (for normal volatility), specified as a NINST-by-1 vector of numeric values.

For more information on the Normal model, see “Work with Negative Interest Rates Using Functions” on page 2-18.

Data Types: double

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: Price = swaptionbynormal(OISCurve,OptSpec,Strike,Settle,ExerciseDate,Maturity,NormalVol,'Reset',4)

Reset — Reset frequency per year for underlying forward swap
1 (default) | numeric

Reset frequency per year for the underlying forward swap, specified as the comma-separated pair consisting of 'Reset' and a NINST-by-1 vector or NINST-by-2 matrix representing the reset frequency per year for each leg. If Reset is NINST-by-2, the first column represents the receiving leg, while the second column represents the paying leg.

Data Types: double

Basis — Day-count basis of instrument
0 (actual/actual) (default) | integer from 0 to 13

Day-count basis of the instrument representing the basis used when annualizing the input term structure, specified as the comma-separated pair consisting of 'Basis' and a NINST-by-1 vector or NINST-by-2 matrix representing the basis for each leg. If Basis is NINST-by-2, the first column represents the receiving leg, while the second column represents the paying leg.

Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)

- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amount
`100` (default) | numeric

Notional principal amount, specified as the comma-separated pair consisting of `'Principal'` and a `NINST`-by-`1` vector.

Data Types: `double`

`ProjectionCurve` — Rate curve used in projecting future cash flows
if `ProjectionCurve` is not specified, then `RateSpec` is used both for discounting cash flows and projecting future cash flows (default) | structure

The rate curve to be used in projecting the future cash flows, specified as the comma-separated pair consisting of `'ProjectionCurve'` and a rate curve structure. This structure must be created using `intenvset`. Use this optional input if the forward curve is different from the discount curve.

Data Types: `struct`

Output Arguments

`Price` — Prices for swaptions at time 0
vector

Prices for the swaptions at time 0, returned as a `NINST`-by-`1` vector of prices.

More About

Call Swaption

A Call swaption or Payer swaption allows the option buyer to enter into an interest rate swap in which the buyer of the option pays the fixed rate and receives the floating rate.

Put Swaption

A Put swaption or Receiver swaption allows the option buyer to enter into an interest rate swap in which the buyer of the option receives the fixed rate and pays the floating rate.

Version History

Introduced in R2017a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `swaptionbynormal` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

time2date

Dates from time and frequency

Syntax

```
Maturity = time2date(Settle,Times)
Maturity = time2date( ___ ,Compounding,Basis,EndMonthRule)
```

Description

`Maturity = time2date(Settle,Times)` computes dates corresponding to compounded rate quotes between `Settle` and time factors.

`Maturity = time2date( ___ ,Compounding,Basis,EndMonthRule)` add additional optional arguments.

Examples

Dates From Time and Frequency

This example shows how to compute dates from time and frequency.

```
Settle = datetime(2002,9,1);
Maturity = [datetime(2005,8,31) ; datetime(2006,2,28) ; datetime(2006,6,15) ; datetime(2006,12,31
Compounding = 2;
Basis = 0;
EndMonthRule = 1;
Times = date2time(Settle, Maturity, Compounding, Basis, EndMonthRule)
```

```
Times = 4×1

    5.9945
    6.9945
    7.5738
    8.6576
```

```
Dates_calc = time2date(Settle, Times, Compounding, Basis, EndMonthRule)
```

```
Dates_calc = 4x1 datetime
   31-Aug-2005
   28-Feb-2006
   15-Jun-2006
   31-Dec-2006
```

Input Arguments

`Settle` — Settlement date

datetime scalar | string scalar | date character vector

Settlement date, specified as a scalar datetime, string, or date character vector.

To support existing code, `time2date` also accepts serial date numbers as inputs, but they are not recommended.

`Times` — Time factors corresponding to `Compounding`
vector

Time factors corresponding to `Compounding`, specified as an `N`-by-`1` vector.

Data Types: `double`

`Compounding` — Rate at which the input zero rates were compounded when annualized
`2` (default) | integer with value of `1`, `2`, `3`, `4`, `6`, `12`, `365`, or `-1`

(Optional) Rate at which the input zero rates were compounded when annualized, specified as a scalar integer value.

- If `Compounding` = `1`, `2`, `3`, `4`, `6`, `12`:

  `Disc = (1 + Z/F)^(-T)`, where `F` is the compounding frequency, `Z` is the zero rate, and `T` is the time in periodic units; for example, `T = F` is one year.
- If `Compounding` = `365`:

  `Disc = (1 + Z/F)^(-T)`, where `F` is the number of days in the basis year and `T` is a number of days elapsed computed by basis.
- If `Compounding` = `−1`:

  `Disc = exp(-T*Z)`, where `T` is time in years.

Data Types: `double`

`Basis` — Day-count basis
`0` (actual/actual) (default) | integer from `0` to `13`

(Optional) Day-count basis, specified as a scalar or an `N`-by-`1` vector using the following values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)

- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag
`1` (in effect) (default) | nonnegative integer `[0,1]`

(Optional) End-of-month rule flag, specified as a scalar or an `N`-by-`1` vector of end-of-month rules.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `logical`

Output Arguments

`Maturity` — Maturity dates corresponding to compounded rate quotes between `Settle` and time factors
serial date number

Maturity dates corresponding to compounded rate quotes between `Settle` and time factors, returned as a scalar or an `N`-by-`1` vector.

The `time2date` function is the inverse of `date2time`.

Version History

Introduced before R2006a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `time2date` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

treepath

Entries from node of recombining binomial tree

Syntax

```
Values = treepath(Tree,BranchList)
```

Description

`Values = treepath(Tree,BranchList)` extracts entries of a node of a recombining binomial tree. The node path is described by the sequence of branchings taken, starting at the root. The top branch is number one, the second-to-top is two, and so on. Set the branch sequence to zero to obtain the entries at the root node.

Examples

Extract Entries of a Node of a Recombining Binomial Tree

Create a BDT tree by loading the example file.

```
load deriv.mat;
FwdRates = treepath(BDTTree.FwdTree, [1 2 1])
```

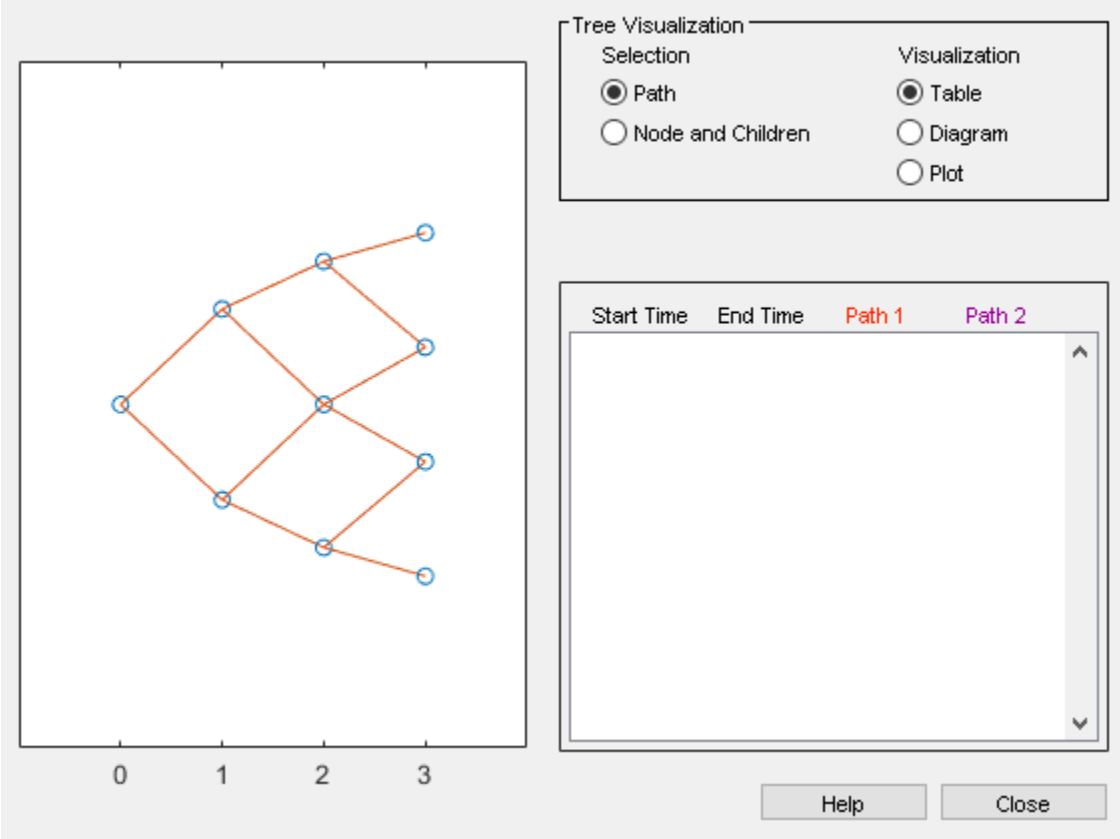
```
FwdRates = 4×1

    1.1000
    1.0979
    1.1377
    1.1183
```

This returns the rates at the tree nodes located by taking the up branch, then the down branch, and finally the up branch again.

You can visualize this with the `treeviewer` function.

```
treeviewer(BDTTree)
```



Input Arguments

Tree — Recombining binomial tree or trinomial tree

struct

Recombining binomial tree or trinomial tree specified as a struct that is created using one of the following functions:

- `hjmtree`
- `bdttree`
- `hwtree`
- `bktree`
- `crrtree`
- `eqptree`
- `lrtree`
- `cirtree`
- `stttree`
- `itttree`

Data Types: `struct`

`BranchList` — Number of paths by path length
matrix

Number of paths (`NUMPATHS`) by path length (`PATHLENGTH`), specified as a matrix containing the sequence of branchings.

Data Types: `double`

Output Arguments

`Values` — Retrieved entries of a recombining tree
matrix

Retrieved entries of a recombining tree, returned a number of values (`NUMVALS`)-by-`NUMPATHS` matrix.

Version History

Introduced before R2006a

treeshape

Shape of recombining binomial tree

Syntax

```
[NumLevels,NumPos,IsPriceTree] = treeshape(Tree)
```

Description

`[NumLevels,NumPos,IsPriceTree] = treeshape(Tree)` returns information on a recombining binomial tree's shape.

Examples

Determine Shape of Recombining Binomial Tree

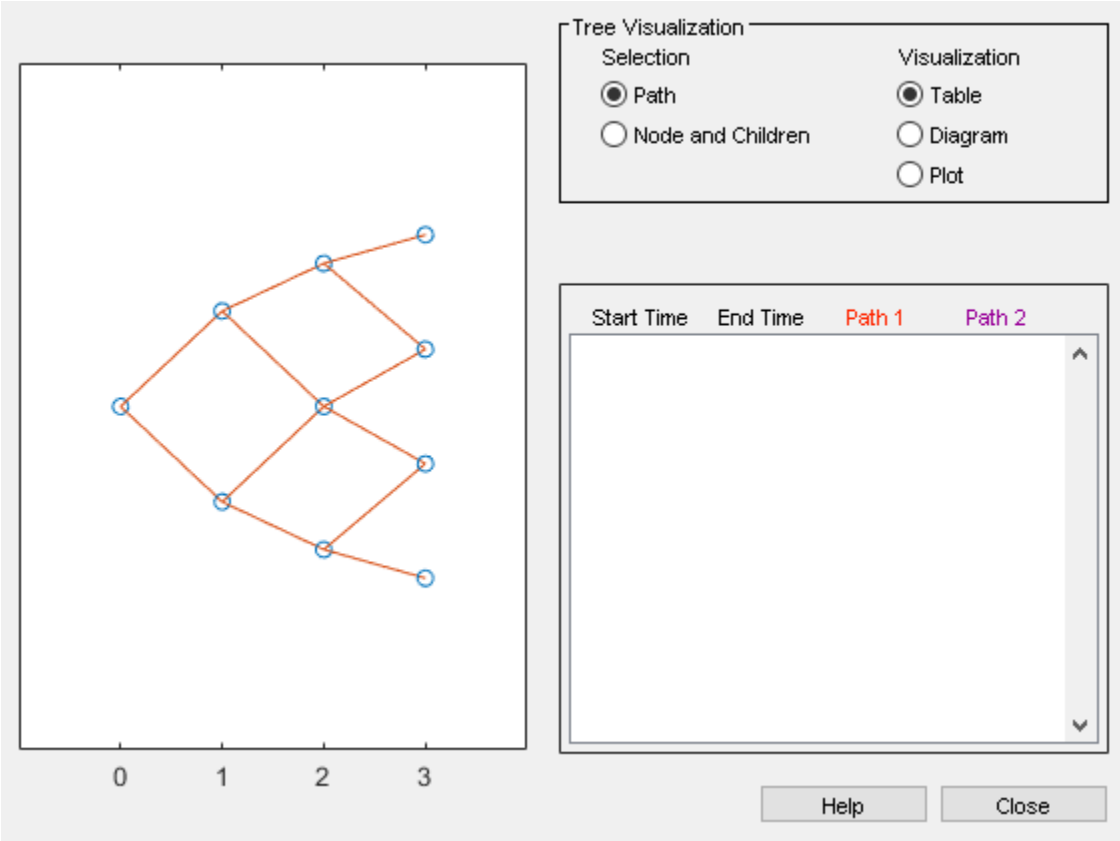
This example shows how to obtain information on a recombining binomial tree's shape.

Create a BDT tree by loading the example file.

```
load deriv.mat;
```

With `treeviewer` you can see the general shape of the BDT interest-rate tree.

```
treeviewer(BDTTree)
```



Use `treeshape` to display the shape of the binomial tree.

```
[NumLevels, NumPos, IsPriceTree] = treeshape(BDTTree.FwdTree)
```

```
NumLevels = 4
```

```
NumPos = 1×4

     1     1     1     1
```

```
IsPriceTree = logical
   0
```

Input Arguments

Tree — Recombining binomial tree

struct

Recombining binomial tree, specified as a struct that is created using one of the following functions:

- `hjmtree`
- `bdttree`
- `hwtree`

- `bktree`
- `cirtree`

Data Types: `struct`

Output Arguments

`NumLevels` — Number of time levels of tree
numeric

Number of time levels of tree, returned as a numeric.

`NumPos` — Length of the state vectors in each level
vector

Length of the state vectors in each level, returned as a `1`-by-`NUMLEVELS` vector.

`IsPriceTree` — Indicates if final horizontal branch is present in the tree
logical

Indicates if final horizontal branch is present in the tree, returned as a Boolean.

treeviewer

Tree information

Syntax

```
treeviewer(Tree)
treeviewer(PriceTree,InstSet)
treeviewer(CFTree,InstSet)
```

Description

`treeviewer(Tree)` displays an interest rate tree, stock price tree, or money-market tree.

`treeviewer(PriceTree,InstSet)` displays a tree of instrument prices.

If you provide the name of an instrument set (`InstSet`) and you have named the instruments using the field `Name`, the `treeviewer` display identifies the instrument being displayed with its name. (See Example 3 on page 11-1947 for a description.) If you do not provide the optional `InstSet` input argument, the instruments are identified by their sequence number in the instrument set. (See Example 6 on page 11-1950 for a description.)

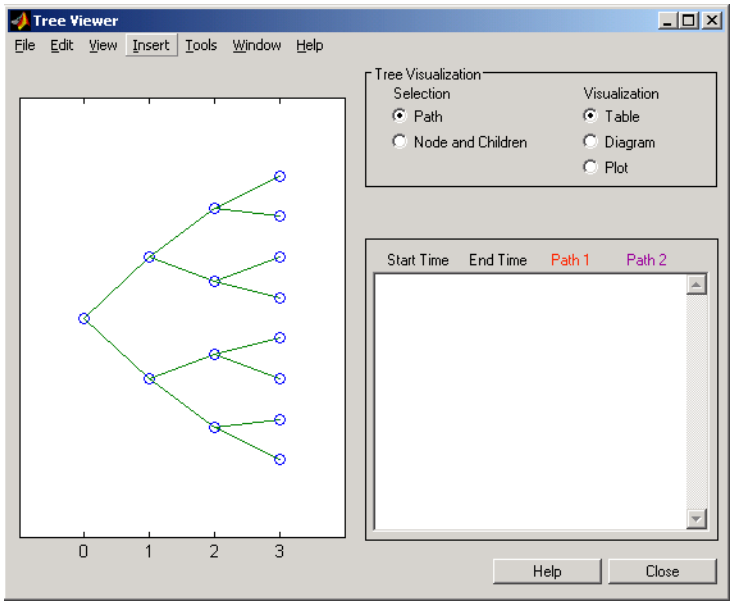
`treeviewer(CFTree,InstSet)` displays a cash flow tree that has been created with `swapbybdt` or `swapbyhjm`. If you provide the name of an instrument set (`InstSet`) containing cash flow names, the `treeviewer` display identifies the instrument being displayed with its name. (See Example 3 on page 11-1947 for a description.) If the optional `InstSet` argument is not present, the instruments are identified by their sequence number in the instrument set. See Example 6 on page 11-1950 for a description.)

Examples

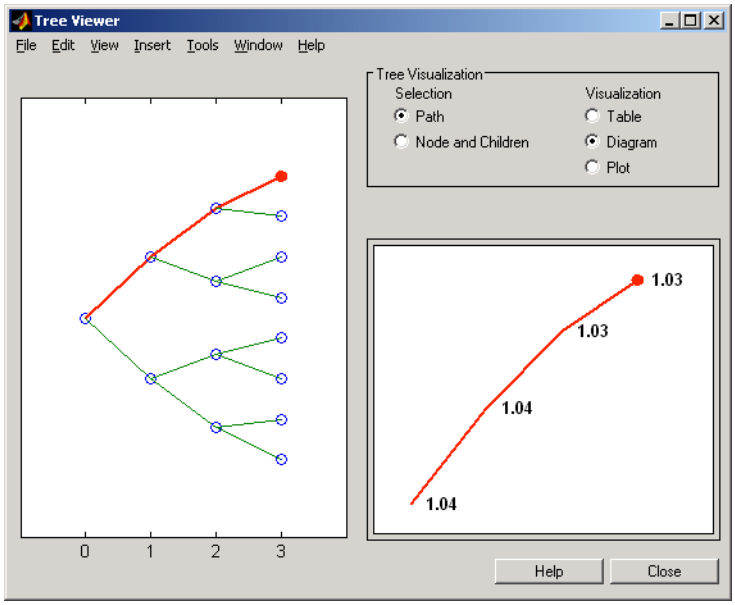
Display an HJM Interest-Rate Tree

```
load deriv.mat
treeviewer(HJMTree)
```

The `treeviewer` function displays the structure of an HJM tree in the left pane. The tree visualization in the right pane is blank.

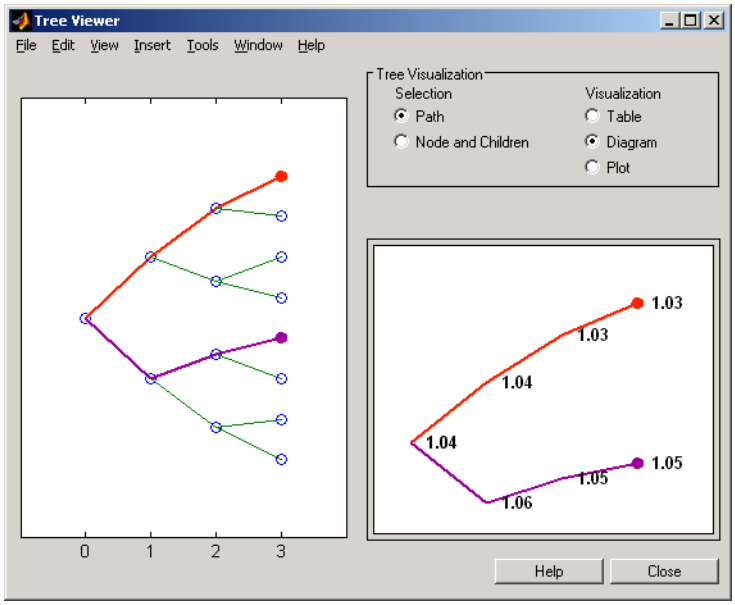


To visualize the actual interest-rate tree, go to the **Tree Visualization** pane and click**Path**(the default) and **Diagram**. Now, select the first path by clicking the last node (`t = 3`) of the upper branch.



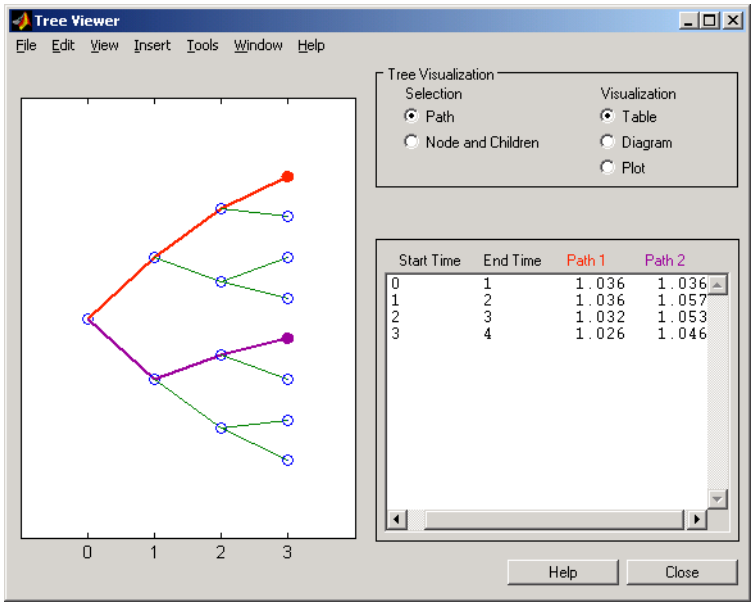
The entire upper path is highlighted in red.

To complete the process, select a second path by clicking the last node (`t = 3`) of another branch. The second path is highlighted in purple. The final display looks like this.

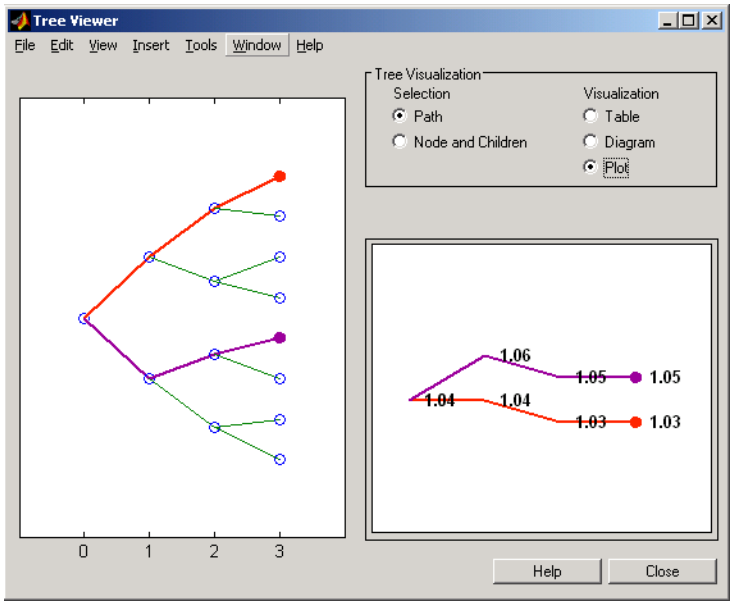


Alternative Forms of Display

The **Tree Visualization** pane allows you to select alternative ways to display tree data. For example, if you select **Path** and **Table** as your visualization choices, the final display above instead appears in tabular form.

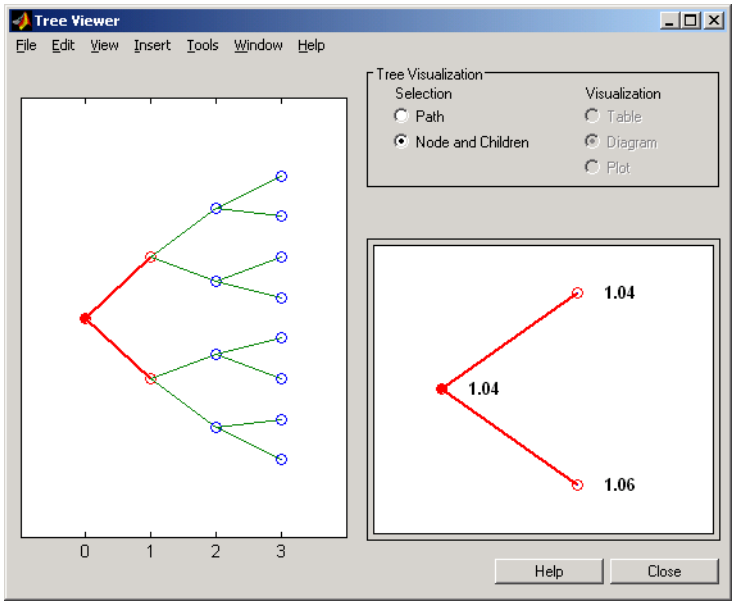


To see a plot of interest rates along the chosen branches, click **Path** and **Plot** in the **Tree Visualization** pane.



With **Plot** selected, rising interest rates are shown on the upper branch and declining interest rates on the lower.

Finally, if you clicked **Node and Children** under **Tree Visualization**, you restrict the data displayed to just the selected parent node and its children.

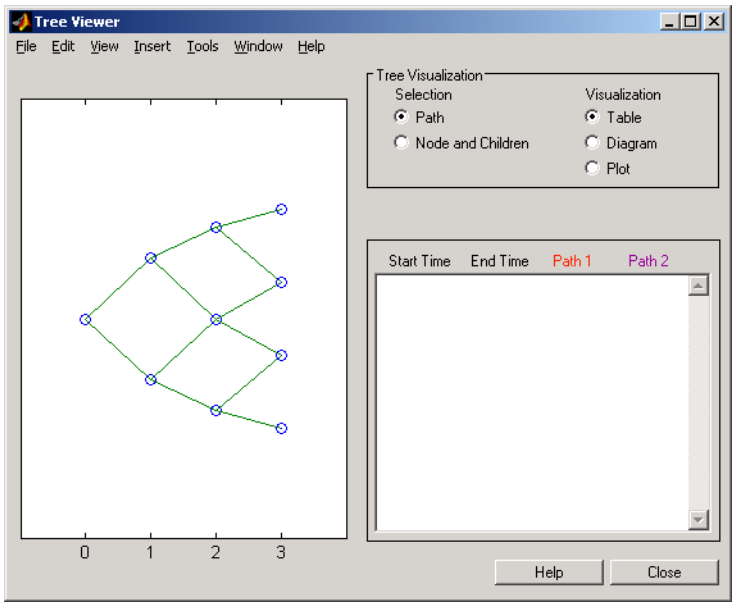


With **Node and Children** selected, the choices under **Visualization** are unavailable.

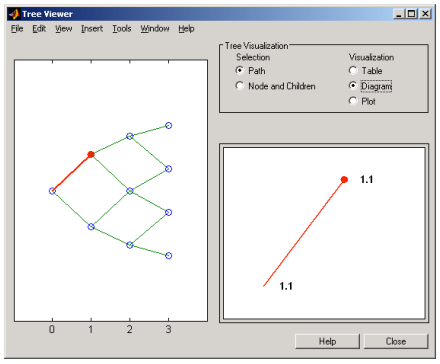
Display a BDT Interest-Rate Tree

```
load deriv.mat
treeviewer(BDTTree)
```

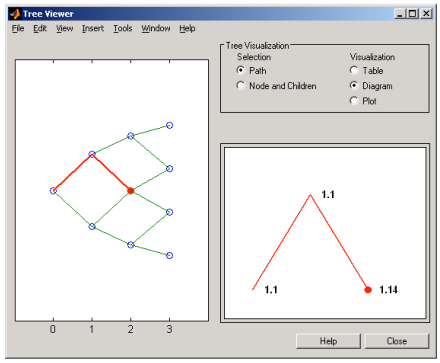
The `treeviewer` function displays the structure of a BDT tree in the left pane. The tree visualization in the right pane is blank.



To visualize the actual interest-rate tree, go to the **Tree Visualization** pane and click **Path** (the default) and **Diagram**. Now, select the first path by clicking the first node of the up branch (`t = 1`). Continue by clicking the down branch at the next node (`t = 2`). The two figures below show the treeviewer path diagrams for these selections.



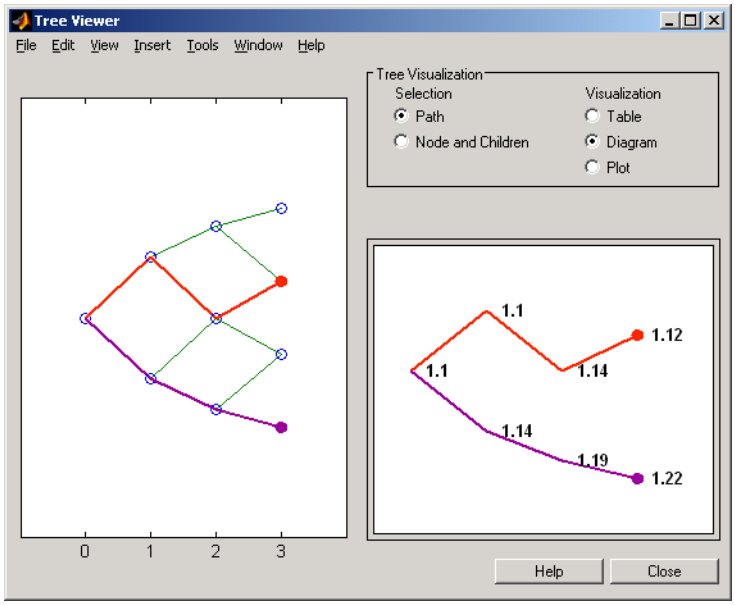
t = 1



t = 2

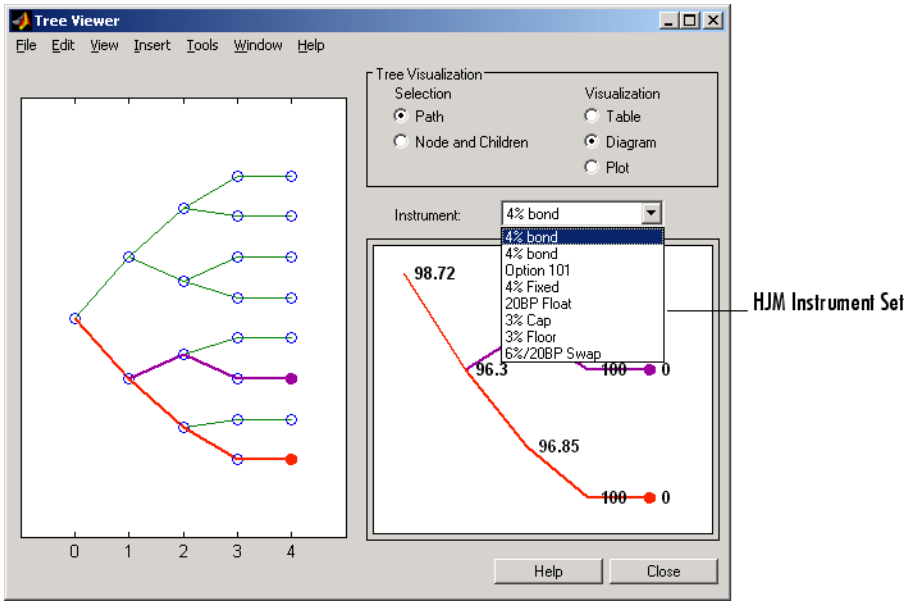
Continue clicking all nodes in succession until you reach the end of the branch. The entire path you have selected is highlighted in red.

Select a second path by clicking the first node of the lower branch (`t = 1`). Continue clicking lower nodes as you did on the first branch. The second branch is highlighted in purple. The final display looks like this.



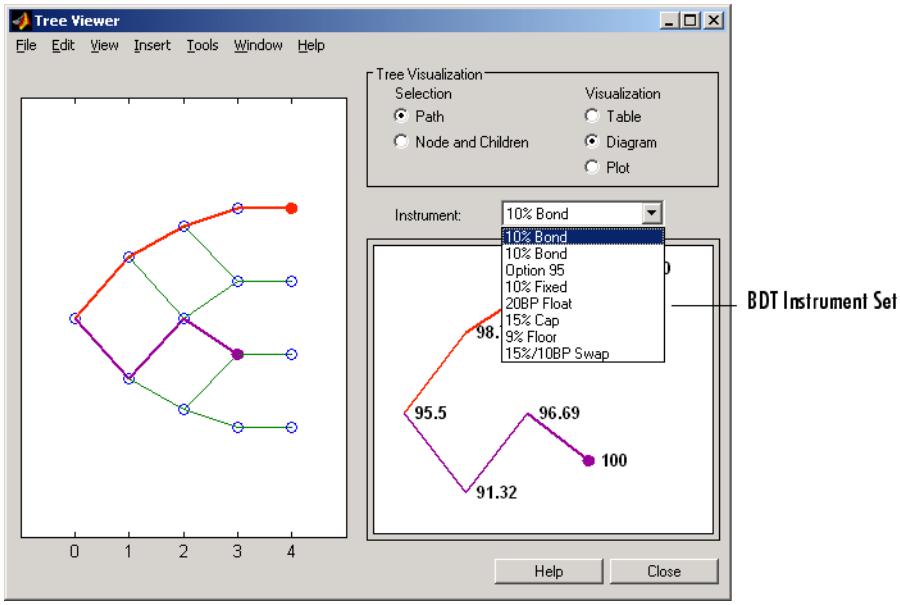
Display an HJM Price Tree for Named Instruments

```
load deriv.mat
[Price, PriceTree] = hjmprice(HJMTree, HJMInstSet);
treeviewer(PriceTree, HJMInstSet)
```



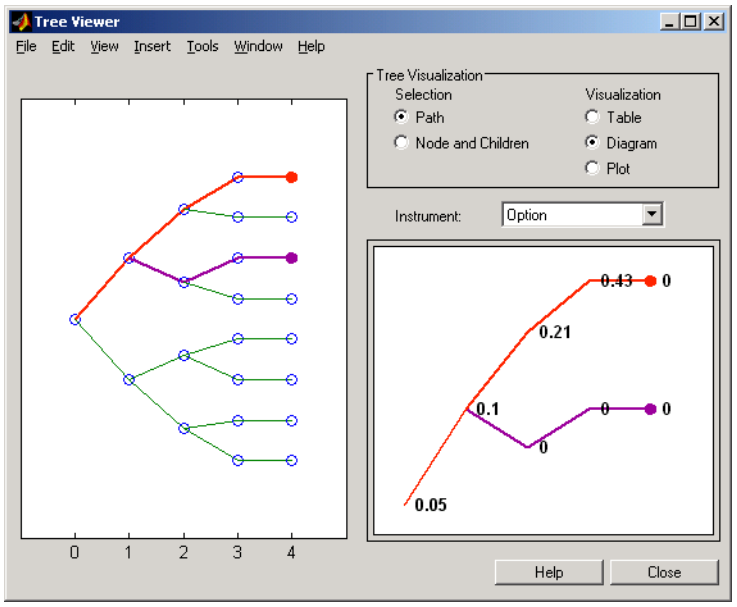
Display a BDT Price Tree for Named Instruments

```
load deriv.mat
[Price, PriceTree] = bdtprice(BDTTree, BDTInstSet);
treeviewer(PriceTree, BDTInstSet)
```



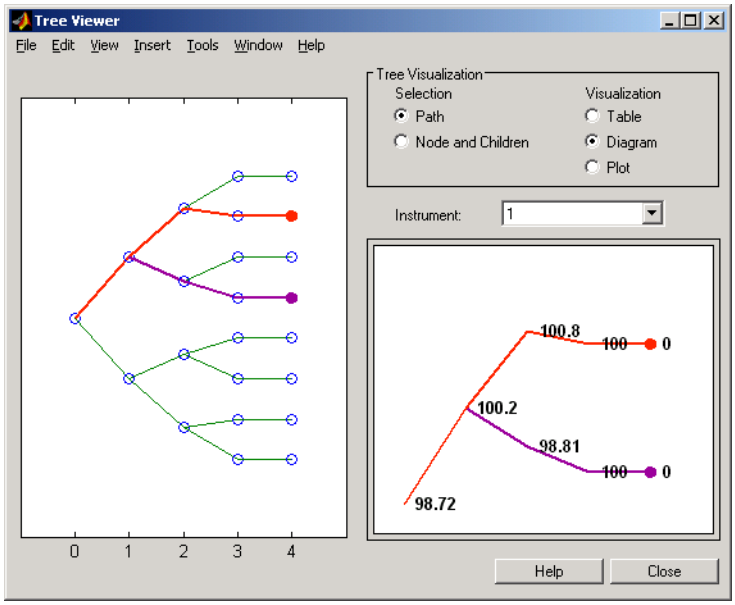
Display an HJM Price Tree with Renamed Instruments

```
load deriv.mat
[Price, PriceTree] = hjmprice(HJMTree, HJMInstSet);
Names = {'Bond1', 'Bond2', 'Option', 'Fixed','Float', 'Cap',...
'Floor', 'Swap'};
treeviewer(PriceTree, Names)
```



Display an HJM Price Tree Using Default Instrument Names (Numbers)

```
load deriv.mat
[Price, PriceTree] = hjmprice(HJMTree, HJMInstSet);
treeviewer(PriceTree)
```



Input Arguments

Tree — Interest-rate tree, stock price tree, or money-market tree

interest-rate tree structure | stock price tree structure | money-market tree structure

Interest-rate tree, stock price tree, or money-market tree, specified using the associated tree function.

Interest-rate trees:

- Black-Derman-Toy (`BDTTree`) obtained from `bdttree`
- Black-Karasinski (`BKTree`) obtained from `bktree`
- Heath-Jarrow-Morton (`HJMTree`) obtained from `hjmtree`
- Hull-White (`HWTree`) obtained from `hwtree`
- Cox-Ingersoll-Ross (`CIRTree`) obtained from `cirtree`

Money market trees:

- Black-Derman-Toy (`BDTMMktTree`) obtained from `mmktbybdt` for a money-market tree from a BDT interest-rate tree.
- Heath-Jarrow-Morton (`HJMMMktTree`) obtained from `mmktbyhjm` for a money-market tree from an HJM interest-rate tree.

Note Money market trees cannot be created from BK or HW interest-rate trees.

Stock price trees:

- Cox-Ross-Rubinstein (`CRRTree`) obtained from `crrtree`
- Implied Trinomial tree (`ITTTree`) obtained from `itttree`
- Standard Trinomial tree (`STTTree`) obtained from `sttree`

- Leisen-Reimer stock tree (`LRTree`) obtained from `lrtree`
- Equal probabilities (`EQPTree`) obtained from `eqptree`

Cash flow trees:

- Black-Derman-Toy (`BDTCFTree`) obtained as output from the swap function `swapbybdt`
- Heath-Jarrow-Morton (`HJMCFTree`) obtained as output from the swap function `swapbyhjm`

> **Note** For the function `swapbybdt`, which uses a recombining binomial tree, this structure contains only `NaN`s because cash flows cannot be accurately calculated at every tree node for floating-rate notes.

Data Types: `struct`

`PriceTree` — Tree structure of instrument prices
structure

Tree structure of instrument prices, specified as:

- Black-Derman-Toy (`BDTPriceTree`) obtained from the portfolio function `bdtprice` or the individual functions, such as `bondbybdt`, `capbybdt`, and so on.
- Black-Karasinski (`BKPriceTree`) obtained from the portfolio function `bkprice` or the individual functions, such as `bondbybk`, `capbybk`, and so on.
- Cox-Ingersoll-Ross (CIRPriceTree) obtained from the portfolio function `cirprice` or the individual functions, such as `bondbycir`, `capbycir`, and so on.
- Heath-Jarrow-Morton (`HJMPriceTree`) obtained from the portfolio function `hjmprice` or the individual functions, such as `bondbyhjm`, `capbyhjm`, and so on.
- Hull-White (`HWPriceTree`) obtained from the portfolio function `hwprice` or the individual functions, such as `bondbyhw`, `capbyhw`, and so on.
- Leisen-Reimer (`LRPriceTree`) obtained from the individual function `optstockbylr`.
- Cox-Ross-Rubinstein (`CRRPriceTree`) obtained from the portfolio function `crrprice` or the individual functions, such as `asianbycrr`, `barrierbycrr`, and so on.
- Equal probabilities (`EQPPriceTree`) obtained from the portfolio function `eqpprice` or the individual functions, such as `asianbyeqp`, `barrierbyeqp`, and so on.
- Implied Trinomial tree (`ITTPriceTree`) obtained from the portfolio function `ittprice` or the individual functions, such as `asianbyitt`, `barrierbyitt`, and so on.
- Standard trinomial tree (`STTPriceTree`) obtained from the portfolio function `sttprice` or the individual functions, such as `asianbystt`, `barrierbystt`, and so on.

Data Types: `struct`

`CFTree` — Tree of swap cash flows
structure

`CFTree` is a tree of swap cash flows, specified when you create cash flow trees by executing the Black-Derman-Toy (obtained as output from the swap function `swapbybdt`) and Heath-Jarrow-Morton (`swapbyhjm`) swap functions. (Black-Derman-Toy cash flow trees contain only `NaN`s.)

Data Types: `struct`

`InstSet` — Variable containing a collection of instruments whose prices or cash flows are contained in a tree
structure

(Optional) Variable containing a collection of instruments whose prices or cash flows are contained in a tree, specified using `instadd`. To display the names of the instruments, the field `Name` should exist in `InstSet`. If `InstSet` is not passed, `treeviewer` uses default instruments names (numbers) when displaying prices or cash flows.

Data Types: `struct`

More About

Treeviewer Conventions

`treeviewer` price tree diagrams follow the convention that increasing prices appear on the upper branch of a tree and, so, decreasing prices appear on the lower branch.

Conversely, for interest rate displays, *decreasing* interest rates appear on the upper branch (prices are rising) and *increasing* interest rates on the lower branch (prices are falling).

Using Treeviewer

`treeviewer` provides an interactive display of prices or interest rates.

The `treeviewer` display is activated by clicking the nodes along the price or interest rate path shown in the left pane when the function is called.

- For HJM trees, you select the endpoints of the path, and `treeviewer` displays all data from beginning to end.
- With recombining trees, such as BDT, BK, HW, and CIR you must click *each* node in succession from the beginning (`t = 1`) to the last node (`t = n`). Do not include the *root node*, the node at `t = 0`. If you do not click the nodes in the proper order, you are reminded with the message

  ```
  Parent of selected node must be selected.
  ```

Note The **Help** button is not available for `treeviewer` in MATLAB Online.

Version History

trintreepath

Entries from node of recombining trinomial tree

Syntax

```
Values = trintreepath(TrinTree,BranchList)
```

Description

`Values = trintreepath(TrinTree,BranchList)` extracts entries of a node of a recombining trinomial tree. The node path is described by the sequence of branchings taken, starting at the root. The top branch is number 1, the middle branch is 2, and the bottom branch is 3. Set the branch sequence to 0 to obtain the entries at the root node.

Examples

Extract Entries of a Node of a Recombining Trinomial Tree

Create a `HW` tree by loading the example file.

```
load deriv.mat;
FwdRates = trintreepath(HWTree, [1 2 3])
```

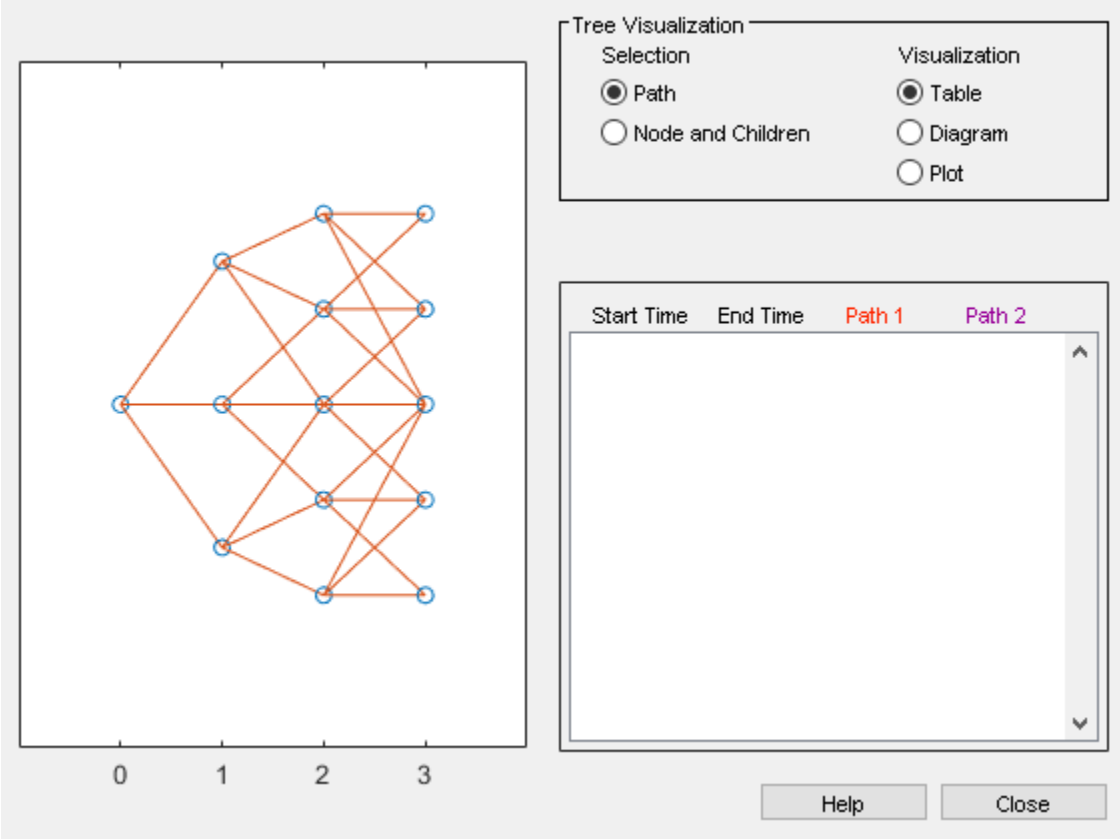
```
FwdRates = 4×1

    1.0279
    1.0528
    1.0652
    1.0591
```

This returns the rates at the tree nodes located by starting at 0, taking the up branch at the first node, the middle branch at the second node, and finally the bottom branch at the third node.

You can visualize this with the `treeviewer` function.

```
treeviewer(HWTree)
```



Input Arguments

`TrinTree` — Recombining price or interest-rate trinomial tree

struct

Recombining price or interest-rate trinomial tree, specified as a struct that is created using one of the following functions:

- `hjmtree`
- `bdttree`
- `hwtree`
- `bktree`
- `cirtree`

Data Types: `struct`

`BranchList` — Number of paths by path length

matrix

Number of paths (`NUMPATHS`) by path length (`PATHLENGTH`), specified as a matrix containing the sequence of branchings.

Data Types: `double`

Output Arguments

`Values` — Retrieved entries of a recombining tree

matrix

Retrieved entries of a recombining tree, returned a number of values (`NUMVALS`)-by-`NUMPATHS` matrix.

Version History

Introduced before R2006a

trintreeshape

Shape of recombining trinomial tree

Syntax

```
[NumLevels,NumPos,NumStates] = treeshape(TrinTree)
```

Description

`[NumLevels,NumPos,NumStates] = treeshape(TrinTree)` returns information on a recombining trinomial tree's shape.

Examples

Determine Shape of Recombining Trinomial Tree

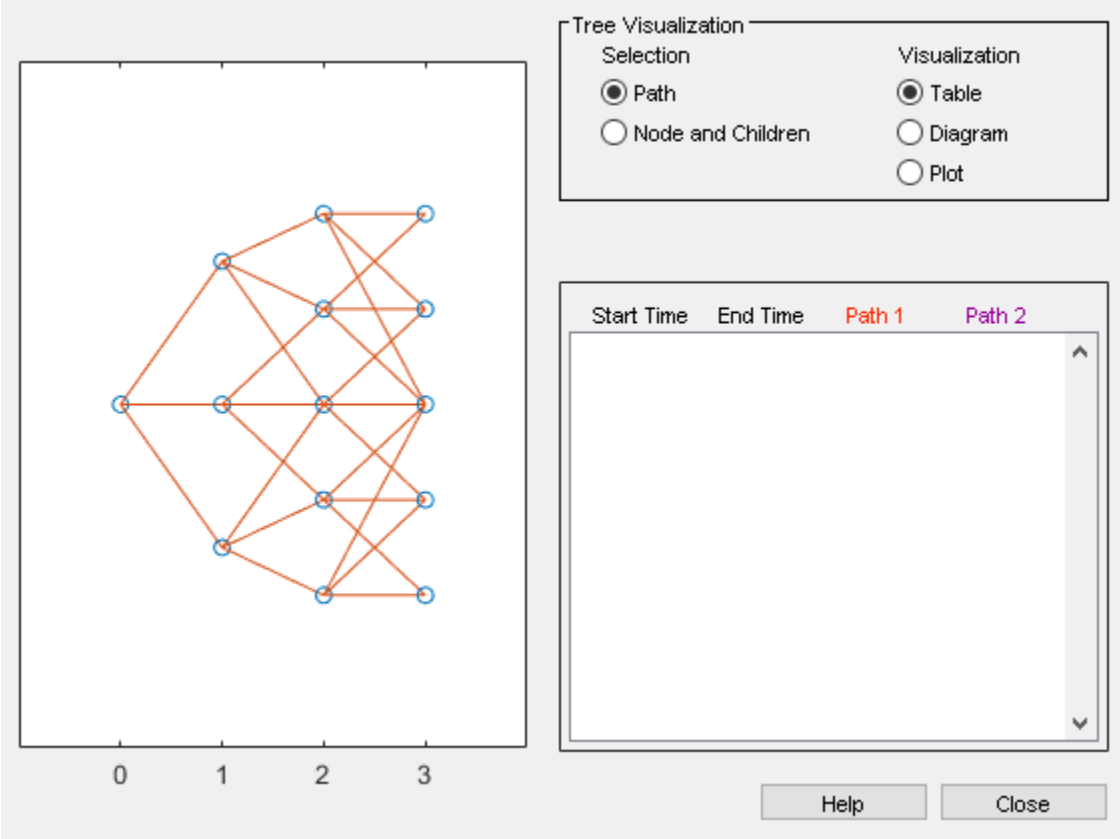
This example shows how to obtain information on a recombining trinomial tree's shape.

Create a `HW` tree by loading the example file.

```
load deriv.mat;
```

With `treeviewer` you can see the general shape of the `HW` interest-rate tree.

```
treeviewer(HWTree)
```



Use `trintreeshape` to display the shape of the binomial tree.

```
[NumLevels, NumPos, IsPriceTree] = trintreeshape(HWTree)
```

```
NumLevels = 4
```

```
NumPos = 1×4
```

```
     1     1     1     1
```

```
IsPriceTree = 1×4
```

```
     1     3     5     5
```

Input Arguments

`TrinTree` — Recombining price or interest-rate trinomial tree

struct

Recombining price or interest-rate trinomial tree, specified as a struct that is created using one of the following functions:

- `hjmtree`

- `bdttree`
- `hwtree`
- `bktree`
- `cirtree`

Data Types: `struct`

Output Arguments

`NumLevels` — Number of time levels of tree
numeric

Number of time levels of tree, returned as a numeric.

`NumPos` — Length of the state vectors in each level
vector

Length of the state vectors in each level, returned as a 1-by-`NUMLEVELS` vector.

`NumStates` — Number of state vectors in each level
vector

Number of state vectors in each level, returned as a 1-by-`NUMLEVELS` vector.

Version History

Introduced before R2006a

agencyoas

Determine option-adjusted spread of callable bond using Agency OAS model

Syntax

```
OAS = agencyoas(ZeroData,Price,CouponRate,Settle,Maturity,Vol,CallDate)
OAS = agencyoas( ___ ,Name,Value)
```

Description

`OAS = agencyoas(ZeroData,Price,CouponRate,Settle,Maturity,Vol,CallDate)` computes OAS of a callable bond given price using the Agency OAS model.

`OAS = agencyoas( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Compute the Agency OAS Value

This example shows how to compute the agency `OAS` value.

```
Settle = '20-Jan-2010';
ZeroRates = [.07 .164 .253 1.002 1.732 2.226 2.605 3.316 ...
3.474 4.188 4.902]'/100;
ZeroDates = daysadd(Settle,360*[.25 .5 1 2 3 4 5 7 10 20 30],1);
ZeroData = [ZeroDates ZeroRates];

Maturity = datetime(2013,12,30);
CouponRate = .022;
Price = 99.155;
Vol = .5117;
CallDate = datetime(2010,12,30);
OAS = agencyoas(ZeroData, Price, CouponRate, Settle, Maturity, Vol, CallDate)
```

```
OAS = 8.5837
```

Input Arguments

`ZeroData` — Zero curve

matrix

Zero curve, specified as an `numRates`-by-2 matrix where the first column is zero dates and the second column is the accompanying zero rates.

Data Types: `double`

`Price` — Prices

vector

Prices specified as an `numBonds`-by-`1` vector.

Data Types: `double`

`CouponRate` — Coupon rates
vector in decimals

Coupon rates, specified as an `numBonds`-by-`1` vector in decimals.

Data Types: `double`

`Settle` — Settlement date
datetime scalar | scalar string | date character vector

Settlement date, specified as a scalar datetime, string, date character vector .

Note The `Settle` date must be an identical settlement date for all the bonds and the zero curve.

To support existing code, `agencyoas` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date
datetime array | string array | date character vector

Maturity date, specified as a `numBonds`-by-`1` vector using datetime array, string array, or date character vectors.

To support existing code, `agencyoas` also accepts serial date numbers as inputs, but they are not recommended.

`Vol` — Volatilities
vector in decimals

Volatilities specified as a scalar or an `numBonds`-by-`1` vector in decimals. `Vol` is the volatility of interest rates corresponding to the time of the `CallDate`.

Data Types: `double`

`CallDate` — Call dates
datetime array | string array | date character vector

Call dates, specified as a scalar string or date character vector or an `numBonds`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `agencyoas` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `OAS = agencyoas(ZeroData,Price,CouponRate,Settle,Maturity,Vol,CallDate,'Basis',7,'Face',1000)`

`Basis` — Day-count basis
`0` (actual/actual) (default) | integer from `0` to `13`

Day-count basis, specified as the comma-separated pair consisting of `'Basis'` and a `N`-by-`1` vector using the following values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`CurveBasis` — Curve basis
`0` (actual/actual) (default) | integer from `0` to `13`

Curve basis, specified as the comma-separated pair consisting of `'CurveBasis'` and a `N`-by-`1` vector using the following values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)

- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`CurveCompounding` — Compounding frequency of the zero curve
2 (semiannual) (default) | possible values include: –1, 0, 1, 2, 3, 4, 6, 12.

Compounding frequency of the zero curve, specified as the comma-separated pair consisting of `'CurveCompounding'` and a `N`-by-`1` vector using the supported values: –1, 0, 1, 2, 3, 4, 6, and 12.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag
1 (in effect) (default) | nonnegative integer `[0,1]`

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer [0, 1] using a `N`-by-`1` vector.

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

`Face` — face value of bond
100 (default) | vector

Face value of bond, specified as the comma-separated pair consisting of `'Face'` and an `N`-by-`1` vector of numeric values.

Data Types: `double`

`FirstCouponDate` — Irregular first coupon date
if you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs (default) | datetime array | string array | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of `'FirstCouponDate'` and a scalar string or character vector or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `agencyoas` also accepts serial date numbers as inputs, but they are not recommended.

When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure.

`InterpMethod` — Interpolation method
`'linear'` (default) | `'cubic'`,`'pchip'`

Interpolation method, specified as the comma-separated pair consisting of `'InterpMethod'` and a `N`-by-`1` vector using a supported value. For more information on interpolation methods, see `interp1`.

Data Types: `char`

IssueDate — Bond issue date
if you do not specify an IssueDate, the cash flow payment dates are determined from other inputs (default) | datetime array | string array | date character vector

Bond issue date, specified as the comma-separated pair consisting of 'IssueDate' and scalar string or character vector or an N-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, agencyoas also accepts serial date numbers as inputs, but they are not recommended.

LastCouponDate — Irregular last coupon date
datetime array | string array | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a scalar string or character vector or a N-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, agencyoas also accepts serial date numbers as inputs, but they are not recommended.

In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date.

Period — Coupons per year
2 per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of 'Period' and an N-by-1 vector. Values for Period are 0, 1, 2, 3, 4, 6, and 12.

Data Types: double

StartDate — Forward starting date of payments
Settle date (default) | datetime array | string array | date character vector

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of 'StartDate' and a scalar string or character vector or an N-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, agencyoas also accepts serial date numbers as inputs, but they are not recommended.

If you do not specify StartDate, the effective start date is the Settle date.

Output Arguments

OAS — Option-adjusted spreads
matrix

Option-adjusted spreads, returned as an numBonds-by-1 matrix.

More About

Agency OAS Model

The BMA European Callable Securities Formula provides a standard methodology for computing price and option-adjusted spread for European Callable Securities (ECS).

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `agencyoas` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

agencyprice

Price callable bond using Agency OAS model

Syntax

```
Price = agencyprice(ZeroData,OAS,CouponRate,Settle,Maturity,Vol,CallDate)
Price = agencyprice( ___ ,Name,Value)
```

Description

`Price = agencyprice(ZeroData,OAS,CouponRate,Settle,Maturity,Vol,CallDate)` computes the price for a callable bond, given OAS, using the Agency OAS model.

`Price = agencyprice( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Compute the Agency Price

This example shows how to compute the agency `Price`.

```
Settle = '20-Jan-2010';
ZeroRates = [.07 .164 .253 1.002 1.732 2.226 2.605 3.316 ...
3.474 4.188 4.902]'/100;
ZeroDates = daysadd(Settle,360*[.25 .5 1 2 3 4 5 7 10 20 30],1);
ZeroData = [ZeroDates ZeroRates];

Maturity = datetime(2013,12,30);
CouponRate = .022;
OAS = 6.53/10000;
Vol = .5117;
CallDate = datetime(2010,12,30);
Price = agencyprice(ZeroData, OAS, CouponRate, Settle, Maturity, Vol, CallDate)
```

```
Price = 99.4212
```

Input Arguments

ZeroData — Zero curve

matrix

Zero curve, specified as an `numRates`-by-2 matrix where the first column is zero dates and the second column is the accompanying zero rates.

Data Types: `double`

OAS — Option-adjusted spreads

vector in decimals

Option-adjusted spreads, specified as an `numBonds`-by-`1` vector expressed as a decimal (that is, 50 basis points is entered as `.005`).

Data Types: `double`

`CouponRate` — Coupon rates
vector in decimals

Coupon rates, specified as an `numBonds`-by-`1` vector in decimals.

Data Types: `double`

`Settle` — Settlement date
datetime scalar | string scalar | date character vector

Settlement date, specified as a scalar datetime, string, or date character vector.

Note The `Settle` date must be an identical settlement date for all the bonds and the zero curve.

To support existing code, `agencyprice` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date
datetime array | scalar array | date character vector

Maturity date, specified as a scalar string or character vector or `numBonds`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `agencyprice` also accepts serial date numbers as inputs, but they are not recommended.

`Vol` — Volatilities
vector in decimals

Volatilities specified as a scalar or an `numBonds`-by-`1` vector in decimals. `Vol` is the volatility of interest rates corresponding to the time of the `CallDate`.

Data Types: `double`

`CallDate` — Call dates
datetime array | string array | date character vector

Call dates, specified as a scalar string or character vector or an `numBonds`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `agencyprice` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Price = agencyprice(ZeroData,OAS,CouponRate,Settle,Maturity,Vol,CallDate,'Basis',7,'Face',1000)`

`Basis` — Day-count basis
`0` (actual/actual) (default) | integer from `0` to `13`

Day-count basis, specified as the comma-separated pair consisting of `'Basis'` and a `N`-by-`1` vector using the following values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`CurveBasis` — Curve basis
`0` (actual/actual) (default) | integer from `0` to `13`

Curve basis, specified as the comma-separated pair consisting of `'CurveBasis'` and a `N`-by-`1` vector using the following values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)

- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`CurveCompounding` — Compounding frequency of the zero curve
2 (semiannual) (default) | possible values include: –1, 0, 1, 2, 3, 4, 6, 12.

Compounding frequency of the zero curve, specified as the comma-separated pair consisting of `'CurveCompounding'` and a N-by-1 vector using the supported values: –1, 0, 1, 2, 3, 4, 6, and 12.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag
1 (in effect) (default) | nonnegative integer `[0,1]`

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer [0, 1] using a N-by-1 vector with date character vectors or a datetime array.

- 0 = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

`Face` — face value of bond
100 (default) | vector

Face value of bond, specified as the comma-separated pair consisting of `'Face'` and an N-by-1 vector of numeric values.

Data Types: `double`

`FirstCouponDate` — Irregular first coupon date
if you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs (default) | datetime array | string array | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of `'FirstCouponDate'` and a scalar string or character vector or an NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, `agencyprice` also accepts serial date numbers as inputs, but they are not recommended.

When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure.

`InterpMethod` — Interpolation method
`'linear'` (default) | `'cubic'`,`'pchip'`

Interpolation method, specified as the comma-separated pair consisting of `'InterpMethod'` and a N-by-1 vector using a supported value. For more information on interpolation methods, see `interp1`.

Data Types: `char`

`IssueDate` — Bond issue date
if you do not specify an `IssueDate`, the cash flow payment dates are determined from other inputs (default) | datetime array | scalar array | date character vector

Bond issue date, specified as the comma-separated pair consisting of `'IssueDate'` and a scalar string or character vector or an `N`-by-`1` vector using a datetime array, string array, or date character vectors.

`LastCouponDate` — Irregular last coupon date
datetime array | string array | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a scalar string or character vector or an `N`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `agencyprice` also accepts serial date numbers as inputs, but they are not recommended.

In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date.

`Period` — Coupons per year
`2` per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of `'Period'` and an `N`-by-`1` vector. Values for `Period` are `0`, `1`, `2`, `3`, `4`, `6`, and `12`.

Data Types: `double`

`StartDate` — Forward starting date of payments
`Settle` date (default) | datetime array | string array | date character vector

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of `'StartDate'` and a scalar string or character vector or an `N`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `agencyprice` also accepts serial date numbers as inputs, but they are not recommended.

If you do not specify `StartDate`, the effective start date is the `Settle` date.

Output Arguments

`Price` — Prices
matrix

Prices returned as an `numBonds`-by-`1` matrix.

bkcall

Price European call option on bonds using Black model

Syntax

```
CallPrice = bkcall(Strike,ZeroData,Sigma,BondData,Settle,Expiry)
CallPrice = bkcall( ___ ,Period,Basis,EndMonthRule,InterpMethod,
StrikeConvention)
```

Description

`CallPrice = bkcall(Strike,ZeroData,Sigma,BondData,Settle,Expiry)` computes prices of European call options using Black's model.

`CallPrice = bkcall( ___ ,Period,Basis,EndMonthRule,InterpMethod, StrikeConvention)` adds optional input arguments for `Period`, `Basis`, `EndMonthRule`, `InterpMethod`, and `StrikeConvention`.

Examples

Price a European Call Option On Bonds Using the Black Model

This example shows how to price a European call option on bonds using the Black model. Consider a European call option on a bond maturing in 9.75 years. The underlying bond has a clean price of $935, a face value of $1000, and pays 10% semiannual coupons. Since the bond matures in 9.75 years, a $50 coupon will be paid in 3 months and again in 9 months. Also, assume that the annualized volatility of the forward bond price is 9%. Furthermore, suppose the option expires in 10 months and has a strike price of $1000, and that the annualized continuously compounded risk-free discount rates for maturities of 3, 9, and 10 months are 9%, 9.5%, and 10%, respectively.

```
% specify the option information
Settle       =  '15-Mar-2004';
Expiry       =  '15-Jan-2005'; % 10 months from settlement
Strike       =  1000;
Sigma        =  0.09;
Convention   =  [0 1]';

% specify the interest-rate environment
ZeroData     = [datenum('15-Jun-2004')  0.09   -1;  % 3 months
                datenum('15-Dec-2004')  0.095  -1;  % 9 months
                datenum(Expiry)         0.10   -1]; % 10 months

% specify the bond information
CleanPrice   =  935;
CouponRate   =  0.1;
Maturity     = '15-Dec-2013';  % 9.75 years from settlement
Face         =  1000;
BondData     = [CleanPrice CouponRate datenum(Maturity) Face];
Period       =  2;
Basis        =  1;
```

```
% call Black's model
CallPrices = bkcall(Strike, ZeroData, Sigma, BondData, Settle,...
Expiry, Period, Basis, [], [], Convention)

CallPrices = 2×1

    9.4873
    7.9686
```

When the strike price is the dirty price (`Convention = 0`), the call option value is $9.49. When the strike price is the clean price (`Convention = 1`), the call option value is $7.97.

Input Arguments

`Strike` — Strike price

numeric

Strike price, specified as a scalar numeric or an `NOPT`-by-`1` vector of strike prices.

Data Types: `double`

`ZeroData` — Zero rate information used to discount future cash flows

matrix

Zero rate information used to discount future cash flows, specified using a two-column (optionally three-column) matrix containing zero (spot) rate information used to discount future cash flows.

- Column 1 — Serial maturity date associated with the zero rate in the second column.
- Column 2 — Annualized zero rates, in decimal form, appropriate for discounting cash flows occurring on the date specified in the first column. All dates must occur after `Settle` (dates must correspond to future investment horizons) and must be in ascending order.
- Column 3 — (optional) Annual compounding frequency. Values are `1` (annual), `2` (semiannual, default), `3` (three times per year), `4` (quarterly), `6` (bimonthly), `12` (monthly), and `-1` (continuous).

If cash flows occur beyond the dates spanned by `ZeroData`, the input zero curve, the appropriate zero rate for discounting such cash flows is obtained by extrapolating the nearest rate on the curve (that is, if a cash flow occurs before the first or after the last date on the input zero curve, a flat curve is assumed).

In addition, you can use the method `getZeroRates` for an `IRDataCurve` object with a `Dates` property to create a vector of dates and data acceptable for `bkcall`. For more information, see “Converting an IRDataCurve or IRFunctionCurve Object” on page 9-30.

Data Types: `double`

`Sigma` — Annualized price volatilities required by Black model

numeric

Annualized price volatilities required by the Black model, specified as a scalar or an `NOPT`-by-`1` vector.

Data Types: `struct`

BondData — Characteristics of underlying bonds
vector

Characteristics of underlying bonds, specified as a row vector with three (optionally four) columns or NOPT-by-3 (optionally NOPT-by-4) matrix specifying characteristics of underlying bonds in the form:

```
[CleanPrice CouponRate Maturity Face]
```

- `CleanPrice` is the price excluding accrued interest.
- `CouponRate` is the decimal coupon rate.
- `Maturity` is the bond maturity date using a datetime format.
- `Face` is the face value of the bond. If unspecified, the face value is assumed to be 100.

Data Types: `double` | `datetime`

Settle — Settlement date
string scalar | date character vector | serial date number

Settlement date, specified as a scaler datetime, string, date character vector, or serial date number. `Settle` also represents the starting reference date for the input zero curve.

Data Types: `char` | `double` | `string`

Expiry — Option maturity date
string array | date character vector | serial date number

Option maturity date, specified as an NOPT-by-1 vector using a datetime array, string array, date character vectors, or serial date numbers.

Data Types: `char` | `string` | `double`

Period — Number of coupons per year for underlying bond
2 (semiannual) (default) | integer with value 0, 1, 2, 3, 4, 6, or 12

(Optional) Number of coupons per year for the underlying bond, specified as an integer with supported values of 0, 1, 2, 3, 4, 6, and 12.

Data Types: `double`

Basis — Day-count basis of underlying bonds
0 (actual/actual) (default) | integer from 0 to 13

(Optional) Day-count basis of underlying bonds, specified as a scalar or an NOPT-by-1 vector using the following values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)

- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag
`1` (in effect) (default) | nonnegative integer `[0,1]`

(Optional) End-of-month rule flag, specified as a scalar or an `NOPT`-by-`1` vector of end-of-month rules.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `logical`

`InterpMethod` — Zero curve interpolation method
`1` (linear interpolation) (default) | integer with value `0`, `1`, or `2`

(Optional) Zero curve interpolation method for cash flows that do not fall on a date found in the `ZeroData` spot curve, specified as a scalar integer. `InterpMethod` is used to interpolate the appropriate zero discount rate. Available interpolation methods are (`0`) nearest, (`1`) linear, and (`2`) cubic. For more information on interpolation methods, see `interp1`.

Data Types: `double`

`StrikeConvention` — Option contract strike price convention
`0` (default) | integer with value `0` or `1`

(Optional) Option contract strike price convention, specified as a scalar or an `NOPT`-by-`1` vector.

`StrikeConvention = 0` (default) defines the strike price as the cash (dirty) price paid for the underlying bond.

`StrikeConvention = 1` defines the strike price as the quoted (clean) price paid for the underlying bond. When evaluating Black's model, the accrued interest of the bond at option expiration is added to the input strike price.

Data Types: `double`

Output Arguments

`CallPrice` — Price for European call option on bonds derived from Black model
vector

Price for European call option on bonds derived from the Black model, returned as a `NOPT`-by-`1` vector.

Version History

Introduced before R2006a

bkcaplet

Price interest-rate caplet using Black model

Note `bkcaplet` has been removed. Use `capbyblk` instead.

Syntax

```
CapPrices = bkcaplet(CapData,FwdRates,ZeroPrice,Settle,StartDate,EndDate,Sigma)
```

Arguments

`CapData`	Number of caps (`NCAP`)-by-2 matrix containing cap rates and bases: `[CapRates Basis]`. Values for bases are: • 0 = actual/actual (default) • 1 = 30/360 (SIA) • 2 = actual/360 • 3 = actual/365 • 4 = 30/360 (BMA) • 5 = 30/360 (ISDA) • 6 = 30/360 (European) • 7 = actual/365 (Japanese) • 8 = actual/actual (ICMA) • 9 = actual/360 (ICMA) • 10 = actual/365 (ICMA) • 11 = 30/360E (ICMA) • 12 = actual/365 (ISDA) • 13 = BUS/252 For more information, see “Basis” on page 2-228.
`FwdRates`	Scalar or `NCAP`-by-1 vector containing forward rates in decimal. `FwdRates` accrue on the same basis as `CapRates`.
`ZeroPrice`	Scalar or `NCAP`-by-1 vector containing zero coupon prices with maturities corresponding to those of each cap in `CapData`, per $100 nominal value.
`Settle`	Scalar or `NCAP`-by-1 vector of identical elements containing settlement date of caplets.
`StartDate`	Scalar or `NCAP`-by-1 vector containing start dates of the caplets.
`EndDate`	Scalar or `NCAP`-by-1 vector containing maturity dates of caplets.

`Sigma`	Scalar or `NCAP`-by-`1` vector containing volatility of forward rates in decimal, corresponding to each caplet.

Description

`CapPrices = bkcaplet(CapData,FwdRates,ZeroPrice,Settle,StartDate,EndDate,Sigma)` computes the prices of interest-rate caplets for every $100 face value of principal.

Examples

Compute the Price of Interest-Rate Caplets for Every $100 Face Value of Principal

This example shows how to compute the price of interest-rate caplets for every $100 face value of principal. Given a notional amount of $1,000,000, compute the value of a caplet on October 15, 2002 that starts on October 15, 2003 and ends on January 15, 2004.

```
CapData = [0.08, 1];
FwdRates = 0.07;
ZeroPrice = 100*exp(-0.065*1.25);
Settle = datenum('15-Oct-2002');
BeginDates = datenum('15-Oct-2003');
EndDates = datenum('15-Jan-2004');
Sigma = 0.20;

% because the caplet is $100 notional, divide $1,000,000 by $100
Notional   = 1000000/100;

CapPrice = Notional*bkcaplet(CapData, FwdRates, ZeroPrice, ...
Settle, BeginDates, EndDates, Sigma)

Error using bkcaplet (line 117)
BKCAPLET has been removed. Use CAPBYBLK instead.
```

Version History

Introduced before R2006a

bkfloorlet

Price interest-rate floorlet using Black model

Note `bkfloorlet` has been removed. Use `floorbyblk` instead.

Syntax

```
FloorPrices = bkfloorlet(FloorData,FwdRates,ZeroPrice,Settle,StartDate,EndDate,Sigma)
```

Arguments

`FloorData`	Number of floors (`NFLR`)-by-2 matrix containing floor rates and bases: `[FloorRate Basis]`. Values for bases are: • 0 = actual/actual (default) • 1 = 30/360 (SIA) • 2 = actual/360 • 3 = actual/365 • 4 = 30/360 (BMA) • 5 = 30/360 (ISDA) • 6 = 30/360 (European) • 7 = actual/365 (Japanese) • 8 = actual/actual (ICMA) • 9 = actual/360 (ICMA) • 10 = actual/365 (ICMA) • 11 = 30/360E (ICMA) • 12 = actual/365 (ISDA) • 13 = BUS/252 For more information, see “Basis” on page 2-228.
`FwdRates`	Scalar or `NFLR`-by-`1` vector containing forward rates in decimal. `FwdRates` accrue on the same basis as `FloorRates`.
`ZeroPrice`	Scalar or `NFLR`-by-`1` vector containing zero coupon prices with maturities corresponding to those of each floor in `FloorData`, per $100 nominal value.
`Settle`	Scalar or `NFLR`-by-`1` vector of identical elements containing settlement date of floorlets.
`StartDate`	Scalar or `NFLR`-by-`1` vector containing start dates of the floorlets.
`EndDate`	Scalar or `NFLR`-by-`1` vector containing maturity dates of floorlets.

`Sigma`	Scalar or `NFLR`-by-`1` vector containing volatility of forward rates in decimal, corresponding to each floorlet.

Description

`FloorPrices = bkfloorlet(FloorData,FwdRates,ZeroPrice,Settle,StartDate,EndDate,Sigma)` computes the prices of interest-rate floorlets for every $100 of notional value.

Examples

Price an Interest-Rate Floorlet For Every $100 of Notional Value Using the Black Model

This example shows how to price an interest-rate floorlet for every $100 of notional value using the Black model. Given a notional amount of $1,000,000, compute the value of a floorlet on October 15, 2002 that starts on October 15, 2003 and ends on January 15, 2004.

```
FloorData = [0.08, 1];
FwdRates = 0.07;
ZeroPrice = 100*exp(-0.065*1.25);
Settle = datenum('15-Oct-2002');
BeginDates = datenum('15-Oct-2003');
EndDates = datenum('15-Jan-2004');
Sigma = 0.20;

% because floorlet is $100 notional, divide $1,000,000 by $100
Notional = 1000000/100;

FloorPrice = Notional*bkfloorlet(FloorData, FwdRates, ...
ZeroPrice, Settle, BeginDates, EndDates, Sigma)

Error using bkfloorlet (line 115)
BKFLOORLET has been removed. Use FLOORBYBLK instead.
```

bkput

Price European put option on bonds using Black model

Syntax

```
PutPrice = bkput(Strike,ZeroData,Sigma,BondData,Settle,Expiry)
PutPrice = bkput( ___ ,Period,Basis,EndMonthRule,InterpMethod,StrikeConvention)
```

Description

`PutPrice = bkput(Strike,ZeroData,Sigma,BondData,Settle,Expiry)` computes prices of European put options using a Black model.

`PutPrice = bkput( ___ ,Period,Basis,EndMonthRule,InterpMethod,StrikeConvention)` adds optional input arguments for `Period`, `Basis`, `EndMonthRule`, `InterpMethod`, and `StrikeConvention`.

Examples

Price European Put Options On Bonds Using the Black Model

This example shows how to price European put options on bonds using the Black model. Consider a European put option on a bond maturing in 10 years. The underlying bond has a clean price of $122.82, a face value of $100, and pays 8% semiannual coupons. Also, assume that the annualized volatility of the forward bond yield is 20%. Furthermore, suppose the option expires in 2.25 years and has a strike price of $115, and that the annualized continuously compounded risk free zero (spot) curve is flat at 5%. For a hypothetical settlement date of March 15, 2004, the following code illustrates the use of Black's model to duplicate the put prices in Example 22.2 of the Hull reference. In particular, it illustrates how to convert a broker's yield volatility to a price volatility suitable for Black's model.

```
% Specify the option information.
Settle       =  '15-Mar-2004';
Expiry       =  '15-Jun-2006';  % 2.25 years from settlement
Strike       =  115;
YieldSigma   =  0.2;
Convention   =  [0; 1];

% Specify the interest-rate environment. Since the
% zero curve is flat, interpolation into the curve always returns
% 0.05. Thus, the following curve is not unique to the solution.
ZeroData     = [datenum('15-Jun-2004') 0.05   -1;
                datenum('15-Dec-2004') 0.05   -1;
                datenum(Expiry)        0.05   -1];

% Specify the bond information.
CleanPrice   =  122.82;
CouponRate   =  0.08;
Maturity     = '15-Mar-2014';  % 10 years from settlement
Face         =  100;
```

```
BondData     = [CleanPrice CouponRate datenum(Maturity) Face];
Period       =  2;  % semiannual coupons
Basis        =  1;  % 30/360 day-count basis

% Convert a broker's yield volatility quote to a price volatility
% required by Black's model. To duplicate Example 22.2 in Hull,
% first compute the periodic (semiannual) yield to maturity from
% the clean bond price.
Yield  = bndyield(CleanPrice, CouponRate, Settle, Maturity,...
Period, Basis);

% Compute the duration of the bond at option expiration. Most
% fixed-income sensitivity analyses use the modified duration
% statistic to examine the impact of small changes in periodic
% yields on bond prices. However, Hull's example operates in
% continuous time (annualized instantaneous volatilities and
% continuously compounded zero yields for discounting coupons).
% To duplicate Hull's results, use the second output of BNDDURY,
% the Macaulay duration.
[Modified, Macaulay] = bnddury(Yield, CouponRate, Expiry,...
Maturity, Period, Basis);

% Convert the yield-to-maturity from a periodic to a
% continuous yield.
Yield  = Period .* log(1 + Yield./Period);

% Convert the yield volatility to a price volatility via
% Hull's Equation 22.6 (page 514).
PriceSigma = Macaulay .* Yield .* YieldSigma;

% Finally, call Black's model.
PutPrices  = bkput(Strike, ZeroData, PriceSigma, BondData,...
Settle, Expiry, Period, Basis, [], [], Convention)
```

```
PutPrices = 2×1

    1.7838
    2.4071
```

When the strike price is the dirty price (`Convention = 0`), the call option value is $1.78. When the strike price is the clean price (`Convention = 1`), the call option value is $2.41.

Input Arguments

`Strike` — Strike price

numeric

Strike price, specified as a scalar numeric or an `NOPT`-by-`1` vector of strike prices.

Data Types: `double`

`ZeroData` — Zero rate information used to discount future cash flows

matrix

Zero rate information used to discount future cash flows, specified using a two-column (optionally three-column) matrix containing zero (spot) rate information used to discount future cash flows.

- Column 1 — Serial maturity date associated with the zero rate in the second column.
- Column 2 — Annualized zero rates, in decimal form, appropriate for discounting cash flows occurring on the date specified in the first column. All dates must occur after `Settle` (dates must correspond to future investment horizons) and must be in ascending order.
- Column 3 — (optional) Annual compounding frequency. Values are `1` (annual), `2` (semiannual, default), `3` (three times per year), `4` (quarterly), `6` (bimonthly), `12` (monthly), and `-1` (continuous).

If cash flows occur beyond the dates spanned by `ZeroData`, the input zero curve, the appropriate zero rate for discounting such cash flows is obtained by extrapolating the nearest rate on the curve (that is, if a cash flow occurs before the first or after the last date on the input zero curve, a flat curve is assumed).

In addition, you can use the method `getZeroRates` for an `IRDataCurve` object with a `Dates` property to create a vector of dates and data acceptable for `bkput`. For more information, see “Converting an IRDataCurve or IRFunctionCurve Object” on page 9-30.

Data Types: `double`

`Sigma` — Annualized price volatilities required by Black model
numeric

Annualized price volatilities required by the Black model, specified as a scalar or an `NOPT`-by-`1` vector.

Data Types: `struct`

`BondData` — Characteristics of underlying bonds
vector

Characteristics of underlying bonds, specified as a row vector with three (optionally four) columns or `NOPT`-by-`3` (optionally `NOPT`-by-`4`) matrix specifying characteristics of underlying bonds in the form:

```
[CleanPrice CouponRate Maturity Face]
```

- `CleanPrice` is the price excluding accrued interest.
- `CouponRate` is the decimal coupon rate.
- `Maturity` is the bond maturity date using a serial date number, date character vector, or string.
- `Face` is the face value of the bond. If unspecified, the face value is assumed to be 100.

Data Types: `double` | `char` | `string`

`Settle` — Settlement date
string scalar | date character vector | serial date number

Settlement date, specified as a scalar string, date character vector, or serial date number. `Settle` also represents the starting reference date for the input zero curve.

Data Types: `char` | `double` | `string`

`Expiry` — Option maturity date
string array | date character vector | serial date number

Option maturity date, specified as an `NOPT`-by-`1` vector using a string array, date character vectors, or serial date numbers.

Data Types: `char` | `string` | `double`

`Period` — Number of coupons per year for underlying bond
2 (semiannual) (default) | integer with value `0`, `1`, `2`, `3`, `4`, `6`, or `12`

(Optional) Number of coupons per year for the underlying bond, specified as an integer with supported values of `0`, `1`, `2`, `3`, `4`, `6`, and `12`.

Data Types: `double`

`Basis` — Day-count basis of underlying bonds
`0` (actual/actual) (default) | integer from `0` to `13`

(Optional) Day-count basis of underlying bonds, specified as a scalar or an `NOPT`-by-`1` vector using the following values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag
`1` (in effect) (default) | nonnegative integer `[0,1]`

(Optional) End-of-month rule flag, specified as a scalar or an `NOPT`-by-`1` vector of end-of-month rules.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `logical`

`InterpMethod` — Zero curve interpolation method
`1` (linear interpolation) (default) | integer with value `0`, `1`, or `2`

(Optional) Zero curve interpolation method for cash flows that do not fall on a date found in the `ZeroData` spot curve, specified as a scalar integer. `InterpMethod` is used to interpolate the

appropriate zero discount rate. Available interpolation methods are (`0`) nearest, (`1`) linear, and (`2`) cubic. For more information on interpolation methods, see `interp1`.

Data Types: `double`

`StrikeConvention` — Option contract strike price convention
`0` (default) | integer with value `0` or `1`

(Optional) Option contract strike price convention, specified as a scalar or an `NOPT`-by-`1` vector.

`StrikeConvention = 0` (default) defines the strike price as the cash (dirty) price paid for the underlying bond.

`StrikeConvention = 1` defines the strike price as the quoted (clean) price paid for the underlying bond. When evaluating Black's model, the accrued interest of the bond at option expiration is added to the input strike price.

Data Types: `double`

Output Arguments

`PutPrice` — Price for European put option on bonds derived from Black model
vector

Price for European put option on bonds derived from the Black model, returned as a `NOPT`-by-`1` vector.

Version History

Introduced before R2006a

bndfutimprepo

Implied repo rates for bond future given price

Syntax

```
ImpRepo = bndfutimprep(Price,FutPrice,FutSettle,Delivery,ConvFactor,
CouponRate,Maturity)
ImpRepo = bndfutimprep( ___ ,Name,Value)
```

Description

`ImpRepo = bndfutimprep(Price,FutPrice,FutSettle,Delivery,ConvFactor, CouponRate,Maturity)` computes the implied repo rate for a bond future given the price of a bond, the bond properties, the price of the bond future, and the bond conversion factor. The default behavior is that the coupon reinvestment rate matches the repo rate. However, you can specify a separate reinvestment rate using optional inputs.

`ImpRepo = bndfutimprep( ___ ,Name,Value)` specifies options using one or more optional name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Compute the Repo Rate For a Bond Future

This example shows how to compute the repo rate for a bond future using the following data.

```
bndfutimprepo(129,98,datetime(2000,9,21),datetime(2000,12,29),1.3136,.0875,datetime(2020,8,15))
```

```
ans = 0.0584
```

Input Arguments

`Price` — Bond prices

vector

Bond prices, specified as an `numBonds`-by-`1` vector in decimals.

Data Types: `double`

`FutPrice` — Future prices

vector

Future prices, specified as an `numBonds`-by-`1` vector.

Data Types: `double` | `cell`

`FutSettle` — Future settlement dates

datetime array | string array | date character vector

Future settlement dates, specified as an `numBonds`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `bndfutimprepo` also accepts serial date numbers as inputs, but they are not recommended.

`Delivery` — Future delivery dates
datetime array | string array | date character vector

Future delivery dates, specified as an `numBonds`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `bndfutimprepo` also accepts serial date numbers as inputs, but they are not recommended.

`ConvFactor` — Bond conversion factors
vector

Bond conversion factors, specified as an `numBonds`-by-`1` vector. For more information, see `convfactor`.

Data Types: `double`

`CouponRate` — Coupon rates
vector

Coupon rates, specified as an `numBonds`-by-`1` vector of numeric decimals.

Data Types: `double`

`Maturity` — Maturity dates
datetime array | string array | date character vector

Maturity dates, specified as an `numBonds`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `bndfutimprepo` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `ImpRepo = bndfutimprepo(Price,FutPrice,FutSettle,Delivery,ConvFactor,CouponRate,Maturity,'Basis',5,'Face',1000,'Period',4)`

`Basis` — Day count basis
`0` (actual/actual) (default) | integer from `0` to `13`

Day count basis, specified as the comma-separated pair consisting of `'Basis'` and a scalar integer from `0` to `13`.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag for generating floorlet dates
`1` (in effect) (default) | scalar of nonnegative integer `[0,1]`

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a scalar with a nonnegative integer `[0, 1]`.

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

`Face` — Face value of the bond
`100` (default) | scalar numeric

Face value of the bond, specified as the comma-separated pair consisting of `'Face'` and a scalar numeric. `Face` has no impact on key rate duration.

Data Types: `double`

`FirstCouponDate` — Irregular first coupon date
if you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs (default) | datetime scalar | string scalar | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of `'FirstCouponDate'` and a scalar datetime, string, or date character vector.

To support existing code, `bndfutimprepo` also accepts serial date numbers as inputs, but they are not recommended.

When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure.

`IssueDate` — Bond issue date
if you do not specify an `IssueDate`, the cash flow payment dates are determined from other inputs (default) | datetime scalar | string scalar | date character vector

Bond issue date, specified as the comma-separated pair consisting of `'IssueDate'` and a scalar datetime, string, or date character vector.

To support existing code, `bndfutimprepo` also accepts serial date numbers as inputs, but they are not recommended.

`LastCouponDate` — Irregular last coupon date
datetime scalar | string scalar | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a scalar datetime, string, or date character vector.

To support existing code, `bndfutimprepo` also accepts serial date numbers as inputs, but they are not recommended.

In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date.

`Period` — Coupons per year
2 per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of `'Period'` and a scalar integer. Values for `Period` are `0`, `1`, `2`, `3`, `4`, `6`, and `12`.

Data Types: `double`

`ReinvestBasis` — Day count basis for reinvestment rate
identical to `RepoBasis` (default) | integer from `0` to `13`

Day count basis for the reinvestment rate, specified as the comma-separated pair consisting of `'ReinvestBasis'` and a scalar integer from `0` to `13`.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)

- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`ReinvestRate` — Underlying bond annual coupon
scalar decimal numeric

Underlying bond annual coupon, specified as the comma-separated pair consisting of `'ReinvestRate'` and a scalar decimal numeric.

Data Types: `double`

`RepoBasis` — Day count basis for repo rate
2 (actual/360) (default) | integer from `0` to `13`

Day count basis for repo rate, specified as the comma-separated pair consisting of `'RepoBasis'` and a scalar integer from `0` to `13`.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`StartDate` — Forward starting date of payments
`Settle` date (default) | datetime scalar | string scalar | date character vector

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of `'StartDate'` and a scalar datetime, string, or date character vector.

To support existing code, `bndfutimprepo` also accepts serial date numbers as inputs, but they are not recommended.

Output Arguments

`ImpRepo` — Implied repo rate
vector

Implied repo rate, or the repo rate that would produce the price input, returned as `numBonds`-by-1 vector.

Version History

Introduced in R2009b

Serial date numbers not recommended
Not recommended starting in R2022b

Although `bndfutimprepo` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

bndfutprice

Price bond future given repo rates

Syntax

```
[FutPrice,AccrInt] = bndfutprice(RepoRatePrice,FutSettle,Delivery,ConvFactor,
CouponRate,Maturity)
[FutPrice,AccrInt] = bndfutprice( ___ ,Name,Value)
```

Description

`[FutPrice,AccrInt] = bndfutprice(RepoRatePrice,FutSettle,Delivery,ConvFactor, CouponRate,Maturity)` computes the price of a bond futures contract for one or more bonds given a repo rate, and bond properties, including the bond conversion factor. The default behavior is that the coupon reinvestment rate matches the repo rate. However, you can specify a separate reinvestment rate using optional arguments.

`[FutPrice,AccrInt] = bndfutprice( ___ ,Name,Value)` specifies options using one or more optional name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Compute the Price For a Bond Future

This example shows how to compute the price for a bond future using the following data.

```
bndfutprice(.064, 129, datetime(2000,9,21),datetime(2000,12,29), 1.3136, .0875, datetime(2020,8,1
```

```
ans = 98.1516
```

Input Arguments

`RepoRate` — Repo rates

vector

Repo rates, specified as an `numBonds`-by-1 vector in decimals.

Data Types: `double`

`Price` — Bond prices

vector

Bond prices, specified as an `numBonds`-by-1 vector in decimals.

Data Types: `double`

`FutSettle` — Future settlement date

datetime array | string array | date character vector

Future settlement date, specified as an `numBonds`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `bndfutprice` also accepts serial date numbers as inputs, but they are not recommended.

`Delivery` — Future delivery dates
datetime array | string array | date character vector

Future delivery dates, specified as an `numBonds`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `bndfutprice` also accepts serial date numbers as inputs, but they are not recommended.

`ConvFactor` — Bond conversion factors
vector

Bond conversion factors, specified as an `numBonds`-by-`1` vector. For more information, see `convfactor`.

Data Types: `double`

`CouponRate` — Coupon rates
vector

Coupon rates, specified as an `numBonds`-by-`1` vector of numeric decimals.

Data Types: `double`

`Maturity` — Maturity dates
datetime array | string array | date character vector

Maturity dates, specified as an `numBonds`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `bndfutprice` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[FutPrice,AccrInt] = bndfutprice(RepoRate,Price,FutSettle,Delivery,ConvFactor,CouponRate,Maturity, 'Basis',5,'Face',1000,'Period',4)`

`Basis` — Day count basis
`0` (actual/actual) (default) | integer from `0` to `13`

Day count basis, specified as the comma-separated pair consisting of `'Basis'` and a scalar integer from `0` to `13`.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag for generating floorlet dates
`1` (in effect) (default) | scalar of nonnegative integer `[0,1]`

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a scalar with a nonnegative integer [`0`, `1`].

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

`IssueDate` — Bond issue date
if you do not specify an `IssueDate`, the cash flow payment dates are determined from other inputs (default) | datetime scalar | string scalar | date character vector

Bond issue date, specified as the comma-separated pair consisting of `'IssueDate'` and a scalar datetime, string, or date character vector.

To support existing code, `bndfutprice` also accepts serial date numbers as inputs, but they are not recommended.

`Face` — Face value of the bond
`100` (default) | scalar numeric

Face value of the bond, specified as the comma-separated pair consisting of `'Face'` and a scalar numeric. `Face` has no impact on key rate duration.

Data Types: `double`

`FirstCouponDate` — Irregular first coupon date
if you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs (default) | datetime scalar | string scalar | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of `'FirstCouponDate'` and a scalar datetime, string, or date character vector.

To support existing code, `bndfutprice` also accepts serial date numbers as inputs, but they are not recommended.

When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure.

`LastCouponDate` — Irregular last coupon date
datetime scalar | string scalar | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a scalar datetime, string, or date character vector.

To support existing code, `bndfutprice` also accepts serial date numbers as inputs, but they are not recommended.

In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date.

`Period` — Coupons per year
2 per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of `'Period'` and a scalar integer. Values for `Period` are `0`, `1`, `2`, `3`, `4`, `6`, and `12`.

Data Types: `double`

`ReinvestBasis` — Day count basis for reinvestment rate
identical to `RepoBasis` (default) | integer from `0` to `13`

Day count basis for the reinvestment rate, specified as the comma-separated pair consisting of `'ReinvestBasis'` and a scalar integer from `0` to `13`.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`ReinvestRate` — Underlying bond annual coupon
scalar decimal numeric

Underlying bond annual coupon, specified as the comma-separated pair consisting of `'ReinvestRate'` and a scalar decimal numeric.

Data Types: `double`

`RepoBasis` — Day count basis for repo rate
2 (actual/360) (default) | integer from `0` to `13`

Day count basis for repo rate, specified as the comma-separated pair consisting of `'RepoBasis'` and a scalar integer from `0` to `13`.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`StartDate` — Forward starting date of payments
`Settle` date (default) | datetime scalar | string scalar | date character vector

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of `'StartDate'` and a scalar datetime, string, or date character vector.

To support existing code, `bndfutprice` also accepts serial date numbers as inputs, but they are not recommended.

Output Arguments

`FutPrice` — Quoted futures price, per $100 notional
vector

Quoted futures price, per $100 notional, returned as `numBonds`-by-`1` vector.

`AccrInt` — Accrued interest due at delivery date, per $100 notional
vector

Accrued interest due at delivery date, per $100 notional, returned as `numBonds`-by-`1` vector.

Version History

Introduced in R2009b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `bndfutprice` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

bootstrap

Bootstrap interest-rate curve from market data

Syntax

```
DCurve = IRDataCurve.bootstrap(Type,Settle,InstrumentTypes,Instruments)
DCurve = IRDataCurve.bootstrap( ___ ,Name,Value)
```

Description

`DCurve = IRDataCurve.bootstrap(Type,Settle,InstrumentTypes,Instruments)` bootstraps an interest-rate curve from market data. The dates of the bootstrapped curve correspond to the maturity dates of the input instruments.

Note The `ratecurve` object and associated methods were introduced in R2020a as part of a new object-based framework in the Financial Instruments Toolbox which supports end-to-end workflows in instrument modeling and analysis. For more information, see `irbootstrap` and "Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments" on page 1-22.

`DCurve = IRDataCurve.bootstrap( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Use the bootstrap Method to Create an IRDataCurve Object

In this bootstrapping example, `InstrumentTypes`, `Instruments`, and a `Settle` date are defined:

```
InstrumentTypes = {'Deposit';'Deposit';...
'Futures';'Futures';'Futures';'Futures';'Futures';'Futures';...
'Swap';'Swap';'Swap';'Swap';};

Instruments = [datenum('08/10/2007'),datenum('09/17/2007'),.0532000; ...
datenum('08/10/2007'),datenum('11/17/2007'),.0535866; ...
datenum('08/08/2007'),datenum('19-Dec-2007'),9485; ...
datenum('08/08/2007'),datenum('19-Mar-2008'),9502; ...
datenum('08/08/2007'),datenum('18-Jun-2008'),9509.5; ...
datenum('08/08/2007'),datenum('17-Sep-2008'),9509; ...
datenum('08/08/2007'),datenum('17-Dec-2008'),9505.5; ...
datenum('08/08/2007'),datenum('18-Mar-2009'),9501; ...
datenum('08/08/2007'),datenum('08/08/2014'),.0530; ...
datenum('08/08/2007'),datenum('08/08/2019'),.0551; ...
datenum('08/08/2007'),datenum('08/08/2027'),.0565; ...
datenum('08/08/2007'),datenum('08/08/2037'),.0566];

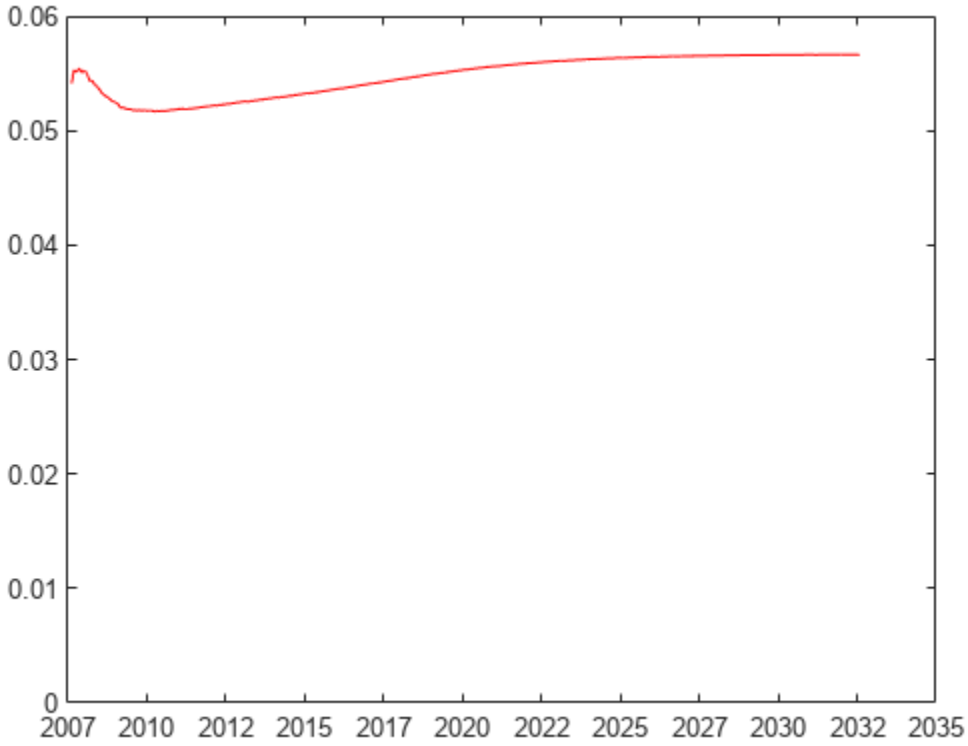
CurveSettle = datenum('08/10/2007');
```

Use the `bootstrap` method to create an `IRDataCurve` object.

```
bootModel = IRDataCurve.bootstrap('Forward', CurveSettle, ...
InstrumentTypes, Instruments,'InterpMethod','pchip');
```

To create the plot for the bootstrapped market data:

```
PlottingDates = (datenum('08/11/2007'):30:CurveSettle+365*25)';
plot(PlottingDates, getParYields(bootModel, PlottingDates),'r')
ylim([0 .06])
datetick
```



Use the `bootstrap` Method to Create an `IRDataCurve` Object That Includes Bonds

In this bootstrapping example, `InstrumentTypes`, `Instruments`, and a `Settle` date are defined:

```
CurveSettle = datenum('8-Mar-2010');

InstrumentTypes = {'Deposit';'Deposit';'Deposit';'Deposit';...
    'Futures';'Futures';'Futures';'Futures';'Swap';'Swap';'Bond';'Bond'};

Instruments = [datenum('8-Mar-2010'),datenum('8-Apr-2010'),.003; ...
    datenum('8-Mar-2010'),datenum('8-Jun-2010'),.005; ...
    datenum('8-Mar-2010'),datenum('8-Sep-2010'),.007; ...
    datenum('8-Mar-2010'),datenum('8-Mar-2011'),.009; ...
    datenum('8-Mar-2010'),datenum('18-Jun-2011'),9840; ...
    datenum('8-Mar-2010'),datenum('17-Sep-2011'),9820; ...
```

```
    datenum('8-Mar-2010'),datenum('17-Dec-2011'),9810; ...
    datenum('8-Mar-2010'),datenum('18-Mar-2012'),9800; ...
    datenum('8-Mar-2010'),datenum('8-Mar-2015'),.025; ...
    datenum('8-Mar-2010'),datenum('8-Mar-2020'),.035; ...
    datenum('8-Mar-2010'),datenum('8-Mar-2030'),99; ...
    datenum('8-Mar-2010'),datenum('8-Mar-2040'),101];
```

When bonds are used, `InstrumentCouponRate` must be specified:

```
InstrumentCouponRate = [zeros(10,1);.045;.05];
```

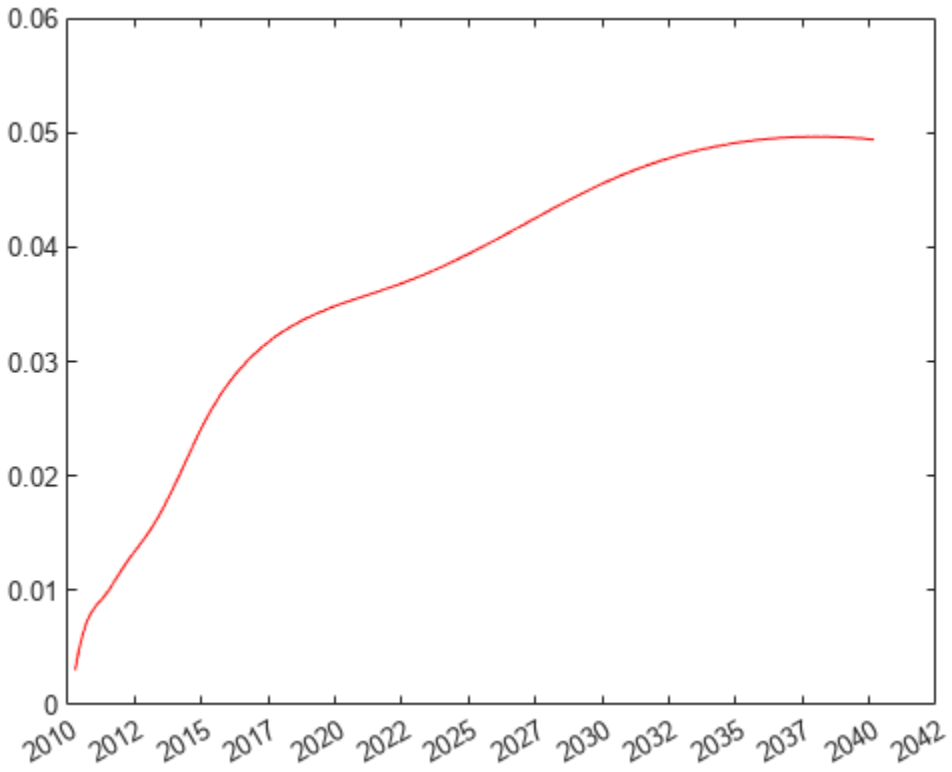
Note, for parameters that are only applicable to bonds (`InstrumentFirstCouponDate`, `InstrumentLastCouponDate`, `InstrumentIssueDate`, `InstrumentFace`) the entries for non-bond instruments (deposits and futures) are ignored.

Use the `bootstrap` method to create an `IRDataCurve` object.

```
bootModel = IRDataCurve.bootstrap('Forward', CurveSettle, ...
InstrumentTypes, Instruments,'InterpMethod','pchip',...
'InstrumentCouponRate',InstrumentCouponRate);
```

Create the plot for the bootstrapped market data.

```
PlottingDates = datemnth(CurveSettle,1:30*12);
plot(PlottingDates, getParYields(bootModel, PlottingDates),'r')
ylim([0 .06])
datetick
```



Use IRBootstrapOptionsObj with bootstrap for Negative Zero Interest-Rates

Use the `IRBootstrapOptionsObj` optional argument with the `bootstrap` method to allow for negative zero rates when solving for the swap zero points.

```
Settle = datenum('15-Mar-2015');
InstrumentTypes = {'Deposit';'Deposit';'Swap';'Swap';'Swap';'Swap';};

Instruments = [Settle,datenum('15-Jun-2015'),.001; ...
Settle,datenum('15-Dec-2015'),.0005; ...
Settle,datenum('15-Mar-2016'),-.001; ...
Settle,datenum('15-Mar-2017'),-0.0005; ...
Settle,datenum('15-Mar-2018'),.0017; ...
Settle,datenum('15-Mar-2020'),.0019];

irbo = IRBootstrapOptions('LowerBound',-1);

bootModel = IRDataCurve.bootstrap('zero', Settle, InstrumentTypes,...
    Instruments,'IRBootstrapOptions',irbo);

bootModel.getZeroRates(datemnth(Settle,1:60))
```

```
ans = 60×1

    0.0012
    0.0011
    0.0010
    0.0009
    0.0008
    0.0008
    0.0007
    0.0006
    0.0005
   -0.0000
      ⋮
```

Note that optional argument for `LowerBound` is set to `-1` for negative zero rates when solving the swap zero points.

Input Arguments

Type — Type of interest-rate curve bootstrapped from market instruments

character vector with value of `'zero'`, `'discount'`, or `'forward'`

Type of interest-rate curve bootstrapped from market instruments, specified by using a scalar character vector.

When using the `bootstrap`, the choice of the `Type` parameter can impact the curve construction because it will affect the type of data that will be interpolated on (that is, forward rates, zero rates, or discount factors) during the bootstrapping process. So curves that are bootstrapped using different `Type` parameters undergo different bootstrapping algorithms with different interpolation methods, and they can sometimes produce different results when using the “get” functions (for example, `getForwardRates`).

Data Types: char

Settle — Settle date of interest-rate curve
serial date number | character vector

Settle date of interest-rate curve, specified using a serial date number or date character vector.

Data Types: double | char

InstrumentTypes — Instrument types
cell array of character vectors with values of 'deposit', 'futures', 'swap', 'bond', and 'fra'

Instrument types, specified using an N-by-1 cell array (where N is the number of instruments) indicating what kind of instrument is in the Instruments matrix. Acceptable values are 'deposit', 'futures', 'swap', 'bond', and 'fra'.

Data Types: char | cell

Instruments — Instruments
matrix

Instruments, specified as an N-by-3 data matrix for Instruments where the first column is Settle date using a serial date number, the second column is Maturity using a serial date number, and the third column is the market quote. The market quote represents the following for each instrument:

- deposit: rate
- futures: price (for example, 9628.54)
- swap: rate
- bond: clean price
- fra: forward rate

Note Instruments input for fra and for futures are different. Specifically, the forward rate underlying a fra starts on the start date (column 1 of Instruments) and ends on the end date (column 2 of Instruments). While the forward rate underlying a futures contract starts on the maturity date of the futures contract and ends on a date *n* months after the futures maturity, where *n* is the periodicity of the futures contract.

Data Types: double

Name-Value Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: DCurve = IRDataCurve.bootstrap('Forward',CurveSettle,InstrumentTypes,Instruments,'InterpMethod','pchip')

Name-Value Pair Arguments for All Bond Instruments

Compounding — Compounding frequency per-year for IRDataCurve object
CurveObj.Compounding (default) | possible values include: –1, 0, 1, 2, 3, 4, 6, 12.

Compounding frequency per-year for the `IRDataCurve` object, specified as the comma-separated pair consisting of `'Compounding'` and a scalar numeric using one of the supported values:

- `-1` = Continuous compounding
- `0` = Simple interest (no compounding)
- `1` = Annual compounding
- `2` = Semiannual compounding
- `3` = Compounding three times per year
- `4` = Quarterly compounding
- `6` = Bimonthly compounding
- `12` = Monthly compounding

Data Types: `double`

`Basis` — Day count basis of the interest-rate curve
`0` (actual/actual) (default) | integer from `0` to `13`

Day count basis of the interest-rate curve, specified as the comma-separated pair consisting of `'Basis'` and a scalar integer.

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`InterpMethod` — Interpolation method
`'linear'` (default) | character vector with values of `'linear'`, `'cubic'`, `'pchip'`, or `'spline'`

Interpolation method, specified as the comma-separated pair consisting of `'InterpMethod'` and a scalar character vector. For more information on interpolation methods, see `interp1`.

Data Types: `char`

`IRBootstrapOptionsObj` — IRBootstrapOptions object
`[]` (default) | `IRBootstrapOptions` object

IRBootstrapOptions object, specified as the comma-separated pair consisting of `'IRBootstrapOptionsObj'` and an `IRBootstrapOptions` object previously created using `IRBootstrapOptions`.

Data Types: `object`

`DiscountCurve` — `RateSpec` for curve used to discount cash flows
`[]` (default) | `RateSpec` object

`RateSpec` for curve used to discount cash flows, specified as the comma-separated pair consisting of `'DiscountCurve'` and a `RateSpec` object previously created using `intenvset` or `toRateSpec`.

Data Types: `object`

Name-Value Pair Arguments for Each Bond Instrument

`InstrumentCouponRate` — Annual percentage rate to determine the coupons payable on an instrument
`[]` (default) | decimal

Annual percentage rate to determine the coupons payable on an instrument, specified as the comma-separated pair consisting of `'InstrumentCouponRate'` and a scalar decimal value.

Data Types: `double`

`InstrumentPeriod` — Coupons per year for the instrument
`2` (default) | numeric with value of `0`, `1`, `2`, `3`, `4`, `6`, and `12`

Coupons per year for the instrument, specified as the comma-separated pair consisting of `'InstrumentPeriod'` and a scalar numeric value.

Data Types: `double`

`InstrumentBasis` — Day-count basis of the instrument
`0` (actual/actual) (default) | integer from `0` to `13`

Day count basis of the instrument, specified as the comma-separated pair consisting of `'InstrumentBasis'` and a scalar integer.

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)

- 13 — BUS/252

Note `InstrumentBasis` distinguishes a bond instrument's `Basis` value from the interest-rate curve's `Basis` value.

For more information, see “Basis” on page 2-228.

Data Types: `double`

`InstrumentEndMonthRule` — End-of-month rule
`1` (default) | logical with value `0` or `1`

End-of-month rule, specified as the comma-separated pair consisting of `'InstrumentEndMonthRule'` and a logical value. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month.
- `1` = `set` rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.

Data Types: `logical`

`InstrumentIssueDate` — Instrument issue date
`[]` (default) | string scalar | date character vector | serial date number

Instrument issue date, specified as the comma-separated pair consisting of `'InstrumentIssueDate'` and a scalar string, data character vector, or serial date number.

Data Types: `char` | `double` | `string`

`InstrumentFirstCouponDate` — Date when a bond makes its first coupon payment
cash flow payment dates are determined from other inputs (default) | string scalar | date character vector | serial date number

Date when a bond makes its first coupon payment (used when bond has an irregular first coupon period), specified as the comma-separated pair consisting of `'InstrumentFirstCouponDate'` and a scalar string, date character vector, or serial date number. When `InstrumentFirstCouponDate` and `InstrumentLastCouponDate` are both specified, `InstrumentFirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `InstrumentFirstCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: `char` | `double` | `string`

`InstrumentLastCouponDate` — Last coupon date of a bond before the maturity date
cash flow payment dates are determined from other inputs (default) | string scalar | date character vector | serial date number

Last coupon date of a bond before the maturity date (used when bond has an irregular last coupon period), specified as the comma-separated pair consisting of `'InstrumentLastCouponDate'` and a scalar string, date character vector, or serial date number. In the absence of a specified `InstrumentFirstCouponDate`, a specified `InstrumentLastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `InstrumentLastCouponDate`, regardless of where it falls, and is followed only by the bond's

maturity cash flow date. If you do not specify a `InstrumentLastCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: `char` | `double` | `string` | `datetime`

`InstrumentFace` — Face or par value
`100` (default) | numeric

Face or par value, specified as the comma-separated pair consisting of `'InstrumentFace'` and a scalar numeric.

Data Types: `double`

Note When using `Instrument` name-value pairs, you can specify simple interest for an `Instrument` by specifying the `InstrumentPeriod` value as `0`. If `InstrumentBasis` and `InstrumentPeriod` are not specified for an `Instrument`, the following default values are used:

- `deposit` instrument uses `InstrumentBasis` as `2` (act/360) and `InstrumentPeriod` is `0` (simple interest).
- `futures` instrument uses `InstrumentBasis` as `2` (act/360) and `InstrumentPeriod` is `4` (quarterly).
- `swap` instrument uses `InstrumentBasis` as `2` (act/360) and `InstrumentPeriod` is `2`.
- `bond` instrument uses `InstrumentBasis` as `0` (act/act) and `InstrumentPeriod` is `2`.
- `FRA` instrument uses `InstrumentBasis` as `2` (act/360) and `InstrumentPeriod` is `4` (quarterly).

Output Arguments

`DCurve` — Interest-rate curve from market data
structure

Interest-rate curve from market data, returned as a structure.

Version History

Introduced in R2008b

cdsoptprice

Price payer and receiver credit default swap options

Syntax

```
[Payer,Receiver] = cdsoptprice(ZeroData,ProbData,Settle,OptionMaturity,
CDSMaturity,Strike,SpreadVol)
[Payer,Receiver] = cdsoptprice( ___ ,Name,Value)
```

Description

`[Payer,Receiver] = cdsoptprice(ZeroData,ProbData,Settle,OptionMaturity, CDSMaturity,Strike,SpreadVol)` computes the price of payer and receiver credit default swap options.

Note Alternatively, you can use the `CDSOption` object to price credit default swap options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Payer,Receiver] = cdsoptprice( ___ ,Name,Value)` computes the price of payer and receiver credit default swap options with additional options specified by one or more `Name,Value` pair arguments.

Examples

Obtain Payer and Receiver Values for a Credit Default Swap Option

Use `cdsoptprice` to generate `Payer` and `Receiver` values for a credit default swap option.

```
Settle = datenum('12-Jun-2012');
OptionMaturity = datenum('20-Sep-2012');
CDSMaturity = datenum('20-Sep-2017');
OptionStrike = 200;
SpreadVolatility = .4;

Zero_Time = [.5 1 2 3 4 5]';
Zero_Rate = [.5 .75 1.5 1.7 1.9 2.2]'/100;
Zero_Dates = daysadd(Settle,360*Zero_Time,1);
ZeroData = [Zero_Dates Zero_Rate];

Market_Time = [1 2 3 5 7 10]';
Market_Rate = [100 120 145 220 245 270]';
Market_Dates = daysadd(Settle,360*Market_Time,1);
MarketData = [Market_Dates Market_Rate];

ProbData = cdsbootstrap(ZeroData, MarketData, Settle);

[Payer,Receiver] = cdsoptprice(ZeroData, ProbData, Settle,...
OptionMaturity, CDSMaturity, OptionStrike, SpreadVolatility)
```

```
Payer = 223.5780

Receiver = 22.7460
```

Input Arguments

`ZeroData` — Zero rates

vector | `IRDataCurve` object

Zero rates, specified by using a `M`-by-2 vector of dates and zero rates or an `IRDataCurve` object of zero rates. For more information on an `IRDataCurve` object, see “Creating an IRDataCurve Object” on page 9-6..

Data Types: `double` | `object`

`ProbData` — Probability of default

array

Probability of default, specified as a `P`-by-2 array of dates and default probabilities.

Data Types: `double`

`Settle` — Settlement date

scalar for serial nonnegative date number | scalar for date character vector

Settlement date, specified as a scalar using a serial nonnegative date number or date character vector. `Settle` must be earlier than the `OptionMaturity` date.

Data Types: `double` | `char`

`OptionMaturity` — Option maturity dates

serial nonnegative date number | date character vector

Option maturity dates, specified as an `NINST`-by-1 vector using a serial nonnegative date number or date character vector.

Data Types: `double` | `char`

`CDSMaturity` — CDS maturity dates

serial nonnegative date number | date character vector

CDS maturity dates, specified as an `NINST`-by-1 vector using a serial nonnegative date number or date character vector.

Data Types: `double` | `char`

`Strike` — Option strikes in basis points

vector

Option strikes in basis points, specified as an `NINST`-by-1 vector.

Data Types: `double`

`SpreadVol` — Annualized credit spread volatilities

positive decimal

Annualized credit spread volatilities, specified an `NINST`-by-1 vector of positive decimals.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Payer,Receiver] = cdsoptprice(ZeroData,ProbData,Settle,OptionMaturity,CDSMaturity,OptionStrike, SpreadVolatility)`

`AdjustedForwardSpread` — Adjusted forward spread in basis points
unadjusted forward spread normally used for single-name CDS options (default) | vector

Adjusted forward spread in basis points, specified as the comma-separated pair consisting of `'AdjustedForwardSpread'` and an `NINST`-by-`1` vector.

Data Types: `double`

`Basis` — Day count basis
`0` (actual/actual) (default) | integer from `0` to `13`

Day count basis, specified as the comma-separated pair consisting of `'Basis'` and an `NINST`-by-`1` vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`BusinessDayConvention` — Business day conventions
`actual` (default) | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and a character vector or a `N`-by-`1` cell array of character vectors of

business day conventions. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (e.g. statutory holidays). Values are:

- `actual` — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- `follow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- `modifiedfollow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `previous` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- `modifiedprevious` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell`

`Knockout` — Indicator of knockout
`False` (default) | vector

Indicator of knockout, specified as the comma-separated pair consisting of `'Knockout'` and an `NINST`-by-`1` vector of boolean flags. If the credit default swaptions is a knockout, the flag is `True`, otherwise it is `False`.

Data Types: `logical`

`PayAccruedPremium` — Indicator of accrued premium
`True` (default) | vector

Indicator of accrued premium, specified as the comma-separated pair consisting of `'PayAccruedPremium'` and an `NINST`-by-`1` vector of boolean flags. If accrued premiums are paid upon default, the flag is `True`, otherwise it is `False`.

Data Types: `logical`

`Period` — Premiums per year of CDS
4 per year (default) | vector

Premiums per year of CDS, specified as the comma-separated pair consisting of `'Period'` and a `NINST`-by-`1` vector. Allowed values are `1`, `2`, `3`, `4`, `6`, and `12`.

Data Types: `double`

`RecoveryRate` — Recovery rates
`0.4` per year (default) | vector

Recovery rates, specified as the comma-separated pair consisting of `'RecoveryRate'` and a `NINST`-by-`1` vector of decimal values from `0` to `1`.

Data Types: `double`

`ZeroBasis` — Basis of zero curve
`0` (actual/actual) (default) | integer from `0` to `13`

Basis of zero curve, specified as the comma-separated pair consisting of `'ZeroBasis'` and an `NINST`-by-`1` vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`ZeroCompounding` — Compounding frequency of zero curve
2 (default) | integer with value of 1, 2, 3, 4, 6, 12, or -1

Compounding frequency of zero curve, specified as the comma-separated pair consisting of `'ZeroCompounding'` and an integer with one of the following allowed values:

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- −1 — Continuous compounding

Note When `ZeroData` is an `IRDataCurve` object, the arguments `ZeroCompounding` and `ZeroBasis` are implicit in `ZeroData` and are redundant inside this function. In that case, specify these optional arguments when constructing the `IRDataCurve` object before calling this function.

Data Types: `double`

Output Arguments

`Payer` — Payer swap options in `Basis` points
vector

Payer swap options in `Basis` points, returned as an `NINST`-by-`1` vector of prices.

`Receiver` — Receiver swap options in `Basis` points
vector

Receiver swap options in `Basis` points, returned as an `NINST`-by-`1` vector of prices.

More About

Credit Default Swap Option

A credit default swap (CDS) option, or credit default swaption, is a contract that provides the option holder with the right, but not the obligation, to enter into a credit default swap in the future.

CDS options can either be payer swaptions or receiver swaptions. In a payer swaption, the option holder has the right to enter into a CDS in which they are paying premiums and in a receiver swaption, the option holder is receiving premiums.

Algorithms

The payer and receiver credit default swap options are computed using the Black's model as described in O'Kane [1]:

$$V_{Pay(Knockout)} = RPV01(t, t_E, T)(F\Phi(d_1) - K\Phi(d_2))$$

$$V_{Rec(Knockout)} = RPV01(t, t_E, T)(K\Phi(-d_2) - F\Phi(-d_1))$$

$$d_1 = \frac{\ln\left(\frac{F}{K}\right) + \frac{1}{2}\sigma^2(t_E - t)}{\sigma\sqrt{t_E - t}}$$

$$d_2 = d_1 - \sigma\sqrt{t_E - t}$$

$$V_{Pay(Non-Knockout)} = V_{Pay(Knockout)} + FEP$$

$$V_{Pay(Non-Knockout)} = V_{Rec(Knockout)}$$

where

RPV01 is the risky present value of a basis point (see `cdsrpv01`).

Φ is the normal cumulative distribution function.

σ is the spread volatility.

t is the valuation date.

t_E is the option expiry date.

T is the CDS maturity date.

F is the forward spread (from option expiry to CDS maturity).

K is the strike spread.

FEP is the front-end protection (from option initiation to option expiry).

cmosched

Generate principal balance schedule for planned amortization class (PAC) or targeted amortization class (TAC) bond

Syntax

```
[BalanceSchedule,InitialBalance] = cmosched(Principal,Coupon,OriginalTerm,
TermRemaining,PrepaySpeed)
[BalanceSchedule,InitialBalance] = cmosched( ___ ,TranchePrincipal)
```

Description

`[BalanceSchedule,InitialBalance] = cmosched(Principal,Coupon,OriginalTerm, TermRemaining,PrepaySpeed)` generates a principal balance schedule for planned amortization class (PAC) bonds using two bands of Public Securities Association Prepayment Model (PSA) speeds or targeted amortization class (TAC) bonds using a single PSA speed.

`[BalanceSchedule,InitialBalance] = cmosched( ___ ,TranchePrincipal)` adds an optional argument for `TranchePrincipal`.

Examples

Calculate the Principal Balance Schedule for a CMO PAC Bond

Define the mortgage pool under consideration and generate a principal balance schedule for planned amortization class (PAC) bonds using two bands of PSA speeds.

```
Principal = 128687000;
GrossRate = 0.0648;
OriginalTerm = 360;
TermRemaining = 325;
PrepaySpeed = [300 525];
PacPrincipal = 100250000;

[BalanceSchedule, InitialBalance] ...
= cmosched(Principal, GrossRate, OriginalTerm, TermRemaining, ...
PrepaySpeed, PacPrincipal)
```

```
BalanceSchedule = 1×325
10^7 ×

    9.7996    9.5780    9.3602    9.1461    8.9357    8.7289    8.5257    8.3259    8.1296    7.9

InitialBalance = 100250000
```

Input Arguments

`Principal` — Principal of the underlying mortgage pool

numeric

Principal of the underlying mortgage pool, specified as a scalar numeric value.

Data Types: `double`

`Coupon` — Coupon rate of the underlying mortgage pool

decimal

Coupon rate of the underlying mortgage pool, specified as a scalar decimal value.

Data Types: `double`

`OriginalTerm` — Original term in months of the underlying mortgage pool

numeric

Original term in months of the underlying mortgage pool, specified as a scalar numeric value.

Data Types: `double`

`TermRemaining` — Terms remaining in months of the underlying mortgage pool

numeric

Terms remaining in months of the underlying mortgage pool, specified as a scalar numeric value.

Data Types: `double`

`PrepaySpeed` — PSA speed

matrix numeric | scalar numeric

PSA speed is specified as follows:

- For planned amortization class (PAC) bonds, PSA speed is specified as a 1-by-2 matrix, where the first element is the lower band and the second element is the upper band.
- For targeted amortization class (TAC) bonds, the PSA speed is specified as a scalar numeric value

Data Types: `double`

`TranchePrincipal` — Principal of the scheduled tranche

numeric

(Optional) Principal of the scheduled tranche, specified as a scalar numeric value. If `TranchePrincipal` is unspecified or empty `[]`, the principal of the scheduled tranche is assumed to be the sum of the payment schedule calculated from the PSA prepayment speeds.

Data Types: `double`

Output Arguments

`BalanceSchedule` — Number of terms remaining

matrix

Number of terms remaining, returned as a matrix of size 1-by-`NUMTERMS`, where `NUMTERMS` is the number of terms remaining. Each column contains the scheduled principal balance for the time period corresponding to the column number.

`InitialBalance` — Initial principal balance of the scheduled tranche
scalar

initial principal balance of the scheduled tranche, returned as a scalar numeric value.

More About

Planned Amortization Class (PAC) Bond

PAC bonds are a type of CMO bond and are designed to largely eliminate prepayment risk for investors.

They do this by transferring essentially all prepayment risk to other bonds in the CMO that are called support bonds.

Targeted Amortization Class (TAC) Bond

TAC bonds are analogous to PAC bonds, but are structured differently.

TAC bonds offer one-sided protection, shielding investors from high prepayment rates up to a specified PSA and do not protect against low prepayment rates.

cmoschedcf

Generate cash flows for scheduled collateralized mortgage obligation (CMO) using PAC or TAC model

Syntax

```
[Balance,Principal,Interest] = cmoschedcf(PrincipalPayments,TranchePrincipals
TrancheCoupons,BalanceSchedule)
```

Description

`[Balance,Principal,Interest] = cmoschedcf(PrincipalPayments,TranchePrincipals TrancheCoupons,BalanceSchedule)` generates cash flows for a scheduled CMO, such as the planned amortization class (PAC) or targeted amortization class (TAC), given the underlying mortgage pool payments (or payments from another CMO tranche). The output `Balances`, `Principal`, and `Interest` from this function can be used as input into `cmoseqcf` to further divide the PAC, TAC, or support dividing a tranche into sequential tranches.

Examples

Calculate Cash Flows for Each PAC Tranche

Define the mortgage pool under consideration for CMO structuring using `mbscfamounts` or `mbspassthrough`. Calculate the underlying mortgage cash flow, define the PAC schedule and CMO tranches, and calculate the cash flows for each tranche.

```
MortgagePrincipal = 1000000; % underlying mortgage
Coupon = 0.12;
Terms = 6; % months

[PrincipalBalance, MonthlyPayments, SchedPrincipalPayments, ...
InterestPayments, Prepayments] = ...
mbspassthrough(MortgagePrincipal, Coupon, Terms, Terms, 0, []);
PrincipalPayments = SchedPrincipalPayments.' + Prepayments.'
```

```
PrincipalPayments = 1×6
10^5 ×

    1.6255    1.6417    1.6582    1.6747    1.6915    1.7084
```

Calculate the PAC schedule for CMO using `cmosched`.

```
PrepaySpeed = [100 300];
[BalanceSchedule, InitialBalance] ...
= cmosched(MortgagePrincipal, Coupon, Terms, Terms, PrepaySpeed, [])
```

```
BalanceSchedule = 1×6
10^5 ×

```

```
InitialBalance = 9.9886e+05
```

Define CMO tranches.

```
TranchePrincipals = ...
[InitialBalance; MortgagePrincipal-InitialBalance];
TrancheCoupons = [0.12; 0.12];
```

Calculate cash flows for each tranche.

```
[Balance, Principal, Interest] = ...
cmoschedcf(PrincipalPayments, TranchePrincipals, ...
TrancheCoupons, BalanceSchedule)
```

```
Balance = 2×6
10^5 ×

    8.3631    6.7213    5.0632    3.3885    1.6970         0
    0.0114    0.0114    0.0114    0.0114    0.0114    0.0000

Principal = 2×6

Interest = 2×6
10^3 ×

    9.9886    8.3631    6.7213    5.0632    3.3885    1.6970
    0.0114    0.0114    0.0114    0.0114    0.0114    0.0114
```

Input Arguments

`PrincipalPayments` — Number of terms remaining for underlying principal payments

numeric matrix

Number of terms remaining for underlying principal payments, specified as a matrix of size 1-by-`NUMTERMS`, where `NUMTERMS` is the number of terms remaining. Each column contains the underlying principal payment for the time period corresponding to the row number. Calculate underlying principal payments using `mbscfamounts` or `mbspassthrough`. The underlying principal payments can also be outputs from other CMO cash flow functions.

Data Types: `double`

`TranchePrincipals` — Initial principal for the scheduled and the support tranche

numeric matrix

Initial principal for the scheduled and the support tranche, specified as a matrix of size 2-by-1.

Data Types: `double`

`TrancheCoupons` — Coupons for the schedule tranche and the support tranche

matrix of coupon values

Coupons for the schedule tranche and the support tranche, specified as a matrix of size 2-by-1 of coupon values. The weighted average coupon for the CMO should not exceed the coupon of the underlying mortgage.

Data Types: `double`

`BalanceSchedule` — Number of terms remaining for targeted balance
numeric matrix

Number of terms remaining for targeted balance, specified as a matrix of size 1-by-`NUMTERMS`, where `NUMTERMS` is the number of terms remaining. Each element represents the targeted balance schedule for the time period corresponding to that column.

Data Types: `double`

Output Arguments

`Balance` — Number of terms remaining and principal balances
matrix

Number of terms remaining and principal balances, returned as a matrix of size 2-by-`NUMTERMS`, where `NUMTERMS` is the number of terms remaining. The first row is the principal balances of the scheduled tranche, and the second row is the principal balances of the support tranche at the time period corresponding to the column.

`Principal` — Number of terms remaining and principal payments
matrix

Number of terms remaining and principal payments, returned as a matrix of size 2-by-`NUMTERMS`, where `NUMTERMS` is the number of terms remaining. The first row is the principal payments of the scheduled tranche, and the second row is the principal payments of the support tranche at the time period corresponding to the column.

`Interest` — Number of terms remaining and interest payments
scalar

Number of terms remaining and interest payments, returned as a matrix of size 2-by-`NUMTERMS`, where `NUMTERMS` is the number of terms remaining. The first row is the interest payments of the schedule tranche, and the second row is the interest payments of the support tranche at the time period corresponding to the column.

More About

Planned Amortization Class (PAC) Tranches

In a PAC CMO, there is a main tranche, known as the schedule tranche, and a support tranche.

The main purpose of a schedule tranche is to give investors in the PAC tranche a more certain cash flow.

Targeted Amortization Class (TAC) Tranches

TACs are like PACs, but principal payment is specified for only one prepayment rate.

If prepayment rates are higher or lower, then the principal payment to TAC holders are higher or lower accordingly.

Schedule and Support Tranche

The main purpose of a PAC tranche is to give investors in the PAC tranche a more certain cash flow.

The PAC tranche receives priority for receiving payments of principal and interest that gives investors in the PAC tranche a steadier income. If prepayments differ from what was expected, then the support tranche gets the variable portion of the payments. While income to the support tranche is more variable, it is also higher yielding. Estimates of the yield, average life, and lockout periods of the PAC tranche is more certain.

cmoseqcf

Generate cash flows for sequential collateralized mortgage obligation (CMO)

Syntax

```
[Balance,Principal,Interest] = cmoseqcf(PrincipalPayments,TranchePrincipals
TrancheCoupons)
[Balance,Principal,Interest] = cmoseqcf( ___ ,HasZ)
```

Description

`[Balance,Principal,Interest] = cmoseqcf(PrincipalPayments,TranchePrincipals TrancheCoupons)` generates cash flows for a sequential CMO without a Z-bond, given the underlying mortgage pool payments.

`[Balance,Principal,Interest] = cmoseqcf( ___ ,HasZ)` generates cash flows for a sequential CMO with a Z-bond, given the underlying mortgage pool payments, by adding an additional optional input for `HasZ`.

Examples

Calculate Cash Flows for a Sequential Collateralized Mortgage Obligation (CMO)

Define the mortgage pool under consideration for CMO structuring using `mbscfamounts` or `mbspassthrough` and calculate the cash flows with an A and B tranche for a sequential CMO.

```
MortgagePrincipal = 1000000;
Coupon = 0.12;
Terms = 6; % months

% Calculate underlying mortgage cash flows
[PrincipalBalance, MonthlyPayments, SchedPrincipalPayments, ...
InterestPayments, Prepayments] = ...
mbspassthrough(MortgagePrincipal, Coupon, Terms, Terms, 0, []);
PrincipalPayments = SchedPrincipalPayments.' + Prepayments.'
```

```
PrincipalPayments = 1×6

    5.0000    5.0000    5.0000    5.0000    3.3999    1.7084
```

Input Arguments

`PrincipalPayments` — Number of terms remaining for underlying principal payments

numeric matrix

Number of terms remaining for underlying principal payments, specified as a matrix of size 1-by-`NUMTERMS`, where `NUMTERMS` is the number of terms remaining. Each column contains the underlying principal payment for the time period corresponding to the row number. Calculate underlying principal payments using `mbscfamounts` or `mbspassthrough`. The underlying principal payments can also be outputs from other CMO cash flow functions.

Data Types: `double`

`TranchePrincipals` — Initial principal for each tranche

numeric matrix

Initial principal for each tranche, specified as a matrix of size `NUMTRANCHES`-by-1, where `NUMTRANCHES` is the number of tranches in the sequential CMO. Each element of the matrix represents the initial principal for each tranche. If the sequential CMO includes a Z-bond (`HasZ` is `true`), the last element of this matrix is the principal of the Z-bond.

Data Types: `double`

`TrancheCoupons` — Coupon for each tranche

matrix of coupon values

Coupon for each tranche, specified as a matrix of size `NUMTRANCHES`-by-1, where `NUMTRANCHES` is the number of tranches in the sequential CMO. Each element of the matrix represents the coupon for each tranche. If the sequential CMO includes a Z-bond (`HasZ` is `true`), the last element of this matrix is the coupon of the Z-bond. The weighted average coupon for the CMO should not exceed the coupon of the underlying mortgage.

Data Types: `double`

`HasZ` — Indicates that the sequential CMO contains a Z-bond

`false` (default) | `true` | `false`

(Optional) Indicates that the sequential CMO contains a Z-bond, specified as a Boolean (`true` or `false`). A value of `true` indicates that the sequential CMO contains a Z-bond, and the last element of `TranchePrincipals` and `TrancheCoupons` is treated as that of the Z-bond. A value of `false` indicates that there is no Z-bond in the sequential CMO, and the last element of `TranchePrincipals` and `TrancheCoupons` is treated as an ordinary tranche.

Data Types: `logical`

Output Arguments

`Balance` — Principal balance for time period and tranche

matrix

Principal balance for time period and tranche, returned as a matrix of size `NUMTRANCHES`-by-`NUMTERMS`, where `NUMTRANCHES` is the number of terms remaining and `NUMTRANCHES` is the number of tranches. Each element represents the principal balance at the time period corresponding to the column, and for the tranche corresponding to the row.

`Principal` — Principal payments for time period and tranche

matrix

Principal payments for time period and tranche, returned as a matrix of size `NUMTRANCHES`-by-`NUMTERMS`, where `NUMTRANCHES` is the number of terms remaining and `NUMTRANCHES` is the number of tranches. Each element represents the principal payments made at the time period corresponding to the column, and to the tranche corresponding to the row.

`Interest` — Interest payments for time period and tranche

matrix

Interest payments for time period and tranche, returned as a matrix of size `NUMTRANCHES`-by-`NUMTERMS`, where `NUMTRANCHES` is the number of terms remaining and `NUMTRANCHES` is the number of tranches. Each element represents the interest payments made at the time period corresponding to the column, and to the tranche corresponding to the row.

More About

Sequential Pay CMO

A sequential pay CMO involves tranches that pay off principal sequentially.

For example, consider the following case, where all principal from the underlying mortgage pool is repaid on tranche A first, then tranche B, then tranche C. Interest is paid on each tranche as long as the principal for the tranche has not been retired.

CMO Tranche

Tranche is a term often used to describe a specific class of bonds within an offering wherein each tranche offers varying degrees of risk to the investor.

Version History

Introduced in R2012a

convfactor

Bond conversion factors

Syntax

```
CF = convfactor(RefDate,Maturity,CouponRate)
CF = convfactor( ___ ,Name,Value)
```

Description

`CF = convfactor(RefDate,Maturity,CouponRate)` computes a conversion factor for a bond futures contract.

`CF = convfactor( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Compute the Conversion Factors For a Bond Futures Contract

This example shows how to calculate `CF`, given the following `RefDate`, `Maturity`, and `CouponRate`.

```
RefDate  = [datetime(2002,12,1);
               datetime(2003,3,1);
               datetime(2003,6,1);
               datetime(2003,9,1);
               datetime(2003,12,1);
               datetime(2003,9,1);
               datetime(2002,12,1);
               datetime(2003,6,1)];

Maturity = [datetime(2012,11,15);
               datetime(2012,8,15);
               datetime(2012,2,15);
               datetime(2011,2,15);
               datetime(2011,8,15);
               datetime(2010,8,15);
               datetime(2009,8,15);
               datetime(2010,2,15)];

CouponRate = [0.04; 0.04375; 0.04875; 0.05; 0.05; 0.0575; 0.06; 0.065];

CF = convfactor(RefDate, Maturity, CouponRate)
```

```
CF = 8×1

    0.8539
    0.8858
    0.9259
    0.9418
    0.9403
```

```
    0.9862
    1.0000
    1.0266
```

Compute the Conversion Factor For a German Bond

This example shows how to calculate `cf`, given the following `RefDate`, `Maturity`, and `CouponRate` for a German bond.

```
cf = convfactor(datetime(2009,3,10),datetime(2018,1,4), .04,.06,3)
```

```
cf = 0.8659
```

Input Arguments

`RefDate` — Reference dates
datetime array | string array | date character vector

Reference dates for which conversion factor is computed (usually the first day of delivery months), specified as an `N`-by-`1` vector using a datetime array, string array, or date character vectors

To support existing code, `convfactor` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date
datetime array | string array | date character vector

Maturity date, specified as a `N`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `convfactor` also accepts serial date numbers as inputs, but they are not recommended.

`CouponRate` — Annual coupon rates for underlying bond
vector in decimals

Annual coupon rates for underlying bond, specified as an `numBonds`-by-`1` vector in decimals.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `CF = convfactor(RefDate,Maturity,CouponRate,'Convention',2)`

`Convention` — Conversion factor convention
1 US Treasury bond (30-year) and Treasury note (10-year) futures contract (default) | integer from 1 to 5

Conversion factor convention, specified as the comma-separated pair consisting of `'Convention'` and a `N`-by-`1` vector using the following values:

- `1` = US Treasury bond (30-year) and Treasury note (10-year) futures contract
- `2` = US 2-year and 5-year Treasury note futures contract
- `3` = German Bobl, Bund, Buxl, and Schatz
- `4` = UK gilts
- `5` = Japanese Government Bonds (JGBs)

Data Types: `double`

`FirstCouponDate` — Irregular first coupon date
datetime array | string array | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of `'FirstCouponDate'` and a `N`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `convfactor` also accepts serial date numbers as inputs, but they are not recommended.

`RefYield` — Reference semiannual yield
`0.06` (6%) (default) | vector in decimals

Reference semiannual yield, specified as the comma-separated pair consisting of `'RefYield'` and an `N`-by-`1` vector in decimals.

Data Types: `double`

`StartDate` — Forward starting date of payments
datetime array | string array | date character vector

Forward starting date of payments, specified as the comma-separated pair consisting of `'StartDate'` and a `N`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `convfactor` also accepts serial date numbers as inputs, but they are not recommended.

Output Arguments

`CF` — Conversion factors against the 6% yield par-bond
vector

Conversion factors against the 6% yield par-bond, returned as an `N`-by-`1` vector.

More About

Conversion Factors

Conversion factors of US Treasury bonds and other government bonds are based on a bond yielding 6%.

Optionally, you can specify other types of bonds and yields using inputs for `RefYield` and `Convention`. For US Treasury bonds, verify the output of `convfactor` by comparing the output against the quotations provided by the Chicago Board of Trade (`https://www.cmegroup.com/company/cbot.html`).

For German bonds, verify the output of `convfactor` by comparing the output against the quotations provided by Eurex (`https://www.eurexchange.com`).

For UK Gilts, verify the output of `convfactor` by comparing the output against the quotations provided by Euronext (`https://www.euronext.com`).

For Japanese Government Bonds, verify the output of `convfactor` by comparing the output against the quotations provided by the Tokyo Stock Exchange (`https://www.jpx.co.jp/english/`).

Version History

Introduced in R2009b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `convfactor` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

fitFunction

Custom fit interest-rate curve object to bond market data

Syntax

```
CurveObj = fitFunction(Type,Settle,FunctionHandle,Instruments,
IRFitOptionsObj)
CurveObj = fitFunction( ___ ,Name,Value)
```

Description

`CurveObj = fitFunction(Type,Settle,FunctionHandle,Instruments, IRFitOptionsObj)` fits a bond to a custom fitting function.

`CurveObj = fitFunction( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Fit a Bond Using Custom Fitting Function

This example shows how to use `fitFunction` to custom fit a bond.

```
Settle = repmat(datenum('30-Apr-2008'),[6 1]);
Maturity = [datenum('07-Mar-2009');datenum('07-Mar-2011');...
datenum('07-Mar-2013');datenum('07-Sep-2016');...
datenum('07-Mar-2025');datenum('07-Mar-2036')];
CleanPrice = [100.1;100.1;100.8;96.6;103.3;96.3];
CouponRate = [0.0400;0.0425;0.0450;0.0400;0.0500;0.0425];
Instruments = [Settle Maturity CleanPrice CouponRate];
CurveSettle = datenum('30-Apr-2008');
OptOptions = optimoptions('lsqnonlin','display','iter');
functionHandle = @(t,theta) polyval(theta,t);

CustomModel = IRFunctionCurve.fitFunction('Zero', CurveSettle, ...
functionHandle,Instruments, ...
IRFitOptions([.05 .05 .05],'FitType','price',...
'OptOptions',OptOptions))
```

    36        148       0.0731652    6.32344e-08          0.063

Local minimum possible.

lsqnonlin stopped because the final change in the sum of squares relative to
its initial value is less than the value of the function tolerance.

CustomModel =
            Type: Zero
          Settle: 733528 (30-Apr-2008)
    Compounding: 2
           Basis: 0 (actual/actual)
```

Input Arguments

Type — Type of interest-rate curve

character vector with value of `'zero'`, `'forward'`, or `'discount'`

Type of interest-rate curve, specified by using a scalar character vector.

Data Types: `char`

Settle — Settle date of interest-rate curve

serial date number | date character vector

Settle date of interest-rate curve, specified using a scalar serial date number or date character vector.

Data Types: `double` | `char`

FunctionHandle — Function handle that defines the interest-rate curve

function handle

Function handle that defines the interest-rate curve, specified using a function handle. The function handle takes two numeric vectors (time-to-maturity and a vector of function coefficients) and returns one numeric output (interest rate or discount factor). For more information on defining a function handle, see the MATLAB Programming Fundamentals documentation.

Data Types: `function_handle`

`Instruments` — Instruments
matrix

Instruments, specified using an N-by-4 data matrix where the first column is `Settle` date using a serial date number, the second column is `Maturity` using a serial date number, the third column is the clean price, and the fourth column is a `CouponRate` for the bond.

Data Types: `double`

`IRFitOptionsObj` — IRFitOptions object
`IRFitOptions` object

`IRFitOptions` object, specified using previously created object using `IRFitOptions`.

Data Types: `object`

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `CurveObj = IRFunctionCurve.fitFunction('Zero',CurveSettle,functionHandle,Instruments,IRFitOptions([.05 .05 .05],'FitType','price','OptOptions',OptOptions))`

Name-Value Pair Arguments for All Bond Instruments

`Compounding` — Compounding frequency per-year for `IRFunctionCurve` object
`CurveObj.Compounding` (default) | possible values include: –1, 0, 1, 2, 3, 4, 6, 12.

Compounding frequency per-year for the `IRFunctionCurve` object, specified as the comma-separated pair consisting of `'Compounding'` and a scalar numeric using one of the supported values:

- `–1` = Continuous compounding
- `0` = Simple interest (no compounding)
- `1` = Annual compounding
- `2` = Semiannual compounding
- `3` = Compounding three times per year
- `4` = Quarterly compounding
- `6` = Bimonthly compounding
- `12` = Monthly compounding

Data Types: `double`

`Basis` — Day count basis of the bond

`0` (actual/actual) (default) | integer from `0` to `13`

Day count basis of the bond, specified as the comma-separated pair consisting of `'Basis'` and a scalar integer.

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

Name-Value Pair Arguments for Each Bond Instrument

`InstrumentPeriod` — Coupons per year for the bond

`2` (default) | numeric with value of `0`, `1`, `2`, `3`, `4`, `6`, and `12`

Coupons per year for the bond, specified as the comma-separated pair consisting of `'InstrumentPeriod'` and a scalar numeric value.

Data Types: `double`

`InstrumentBasis` — Day-count basis of the bond

`0` (actual/actual) (default) | integer from `0` to `13`

Day count basis of the bond, specified as the comma-separated pair consisting of `'InstrumentBasis'` and a scalar integer.

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)

- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

Note `InstrumentBasis` distinguishes a bond instrument's `Basis` value from the interest-rate curve's `Basis` value.

For more information, see “Basis” on page 2-228.

Data Types: `double`

`InstrumentEndMonthRule` — End-of-month rule
`1` (default) | logical with value `0` or `1`

End-of-month rule, specified as the comma-separated pair consisting of `'InstrumentEndMonthRule'` and a logical value. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month.
- `1` = `set` rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.

Data Types: `logical`

`InstrumentIssueDate` — Instrument issue date
`[]` (default) | serial date number | date character vector

Instrument issue date, specified as the comma-separated pair consisting of `'InstrumentIssueDate'` and a scalar serial date number or date character vector.

Data Types: `double` | `char`

`InstrumentFirstCouponDate` — Date when a bond makes its first coupon payment
cash flow payment dates are determined from other inputs (default) | serial date number | date character vector

Date when a bond makes its first coupon payment (used when bond has an irregular first coupon period), specified as the comma-separated pair consisting of `'InstrumentFirstCouponDate'` and a scalar serial date number or date character vector. When `InstrumentFirstCouponDate` and `InstrumentLastCouponDate` are both specified, `InstrumentFirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `InstrumentFirstCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: `double` | `char`

`InstrumentLastCouponDate` — Last coupon date of a bond before the maturity date
cash flow payment dates are determined from other inputs (default) | serial date number | date character vector

Last coupon date of a bond before the maturity date (used when bond has an irregular last coupon period), specified as the comma-separated pair consisting of `'InstrumentLastCouponDate'` and a scalar serial date number or date character vector. In the absence of a specified `InstrumentFirstCouponDate`, a specified `InstrumentLastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `InstrumentLastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `InstrumentLastCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: `double` | `char`

`InstrumentFace` — Face or par value
`100` (default) | numeric

Face or par value, specified as the comma-separated pair consisting of `'InstrumentFace'` and a scalar numeric.

Data Types: `double`

Note When using `Instrument` name-value pairs, you can specify simple interest for a bond by specifying the `InstrumentPeriod` value as `0`. If `InstrumentBasis` and `InstrumentPeriod` are not specified for a bond, the following default values are used: `InstrumentBasis` is `0` (act/act) and `InstrumentPeriod` is `2`.

Output Arguments

`CurveObj` — Curve model
structure

Curve model, returned as a structure.

Version History

Introduced in R2008b

fitNelsonSiegel

Fit Nelson-Siegel function to bond market data

Note `fitNelsonSiegel` for an `IRFunctionCurve` is not recommended. Use `fitNelsonSiegel` with a `parametercurve` object instead. For more information, see `fitNelsonSiegel`.

Syntax

```
CurveObj = IRFunctionCurve.fitNelsonSiegel(Type,Settle,Instruments)
CurveObj = IRFunctionCurve.fitNelsonSiegel(___,Name,Value)
```

Description

`CurveObj = IRFunctionCurve.fitNelsonSiegel(Type,Settle,Instruments)` fits a Nelson-Siegel function to market data for a bond.

`CurveObj = IRFunctionCurve.fitNelsonSiegel(___,Name,Value)` adds optional name-value pair arguments.

Examples

Use the Nelson-Siegel Function to Fit Bond Market Data

This example shows how to use the Nelson-Siegel function to fit bond market data.

```
Settle = repmat(datenum('30-Apr-2008'),[6 1]);
Maturity = [datenum('07-Mar-2009');datenum('07-Mar-2011');...
datenum('07-Mar-2013');datenum('07-Sep-2016');...
datenum('07-Mar-2025');datenum('07-Mar-2036')];

CleanPrice = [100.1;100.1;100.8;96.6;103.3;96.3];
CouponRate = [0.0400;0.0425;0.0450;0.0400;0.0500;0.0425];
Instruments = [Settle Maturity CleanPrice CouponRate];
PlottingPoints = datenum('07-Mar-2009'):180:datenum('07-Mar-2036');
Yield = bndyield(CleanPrice,CouponRate,Settle,Maturity);

NSModel = IRFunctionCurve.fitNelsonSiegel('Zero',datenum('30-Apr-2008'),Instruments);

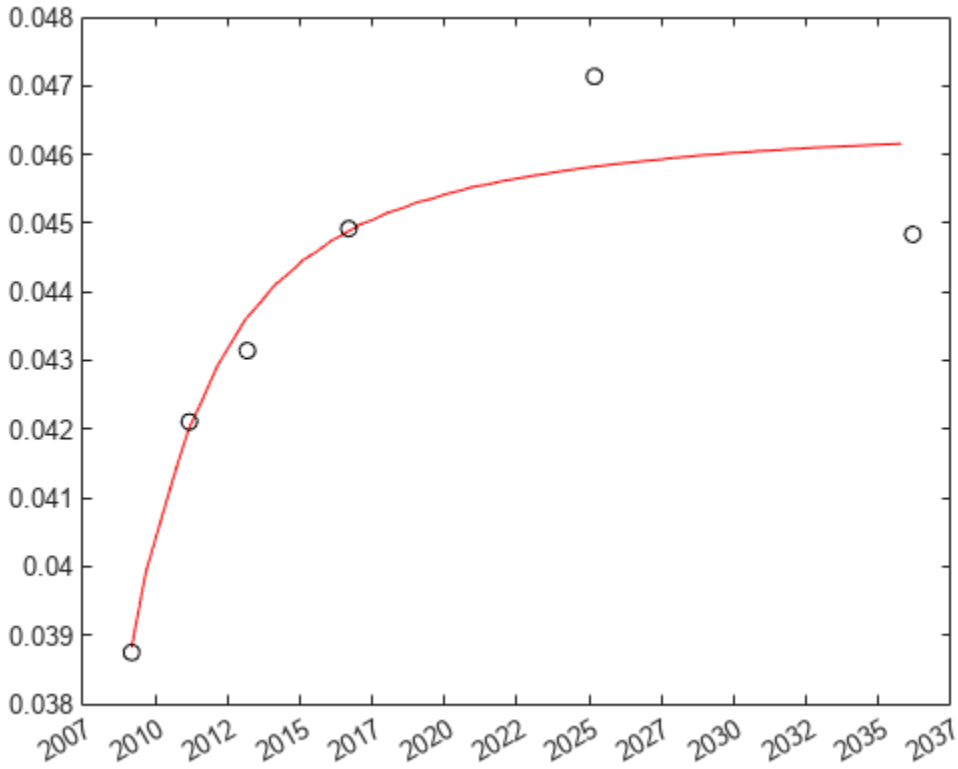
NSModel.Parameters
```

```
ans = 1×4

    4.6617   -1.0227   -0.3484    1.2386
```

```
% create the plot
plot(PlottingPoints, getParYields(NSModel, PlottingPoints),'r')
hold on
```

```
scatter(Maturity,Yield,'black')
datetick('x')
```



Input Arguments

Type — Type of interest-rate curve for a bond

character vector with value of `'zero'` or `'forward'`

Type of interest-rate curve for a bond, specified by using a scalar character vector.

Data Types: `char`

Settle — Settle date of interest-rate curve

serial date number | date character vector

Settle date of interest-rate curve, specified using a scalar serial date number or date character vector.

Data Types: `double` | `char`

Instruments — Instruments

matrix

Instruments, specified using an N-by-4 data matrix where the first column is `Settle` date using a serial date number, the second column is `Maturity` using a serial date number, the third column is the clean price, and the fourth column is a `CouponRate` for the bond.

Data Types: `double`

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `CurveObj = IRFunctionCurve.fitNelsonSiegel('Zero',datenum('30-Apr-2008'),Instruments)`

Name-Value Pair Arguments for All Bond Instruments

`Compounding` — Compounding frequency per-year for `IRFunctionCurve` object
`CurveObj.Compounding` (default) | possible values include: –1, 0, 1, 2, 3, 4, 6, 12.

Compounding frequency per-year for the `IRFunctionCurve` object, specified as the comma-separated pair consisting of `'Compounding'` and a scalar numeric using one of the supported values:

- `–1` = Continuous compounding
- `0` = Simple interest (no compounding)
- `1` = Annual compounding
- `2` = Semiannual compounding
- `3` = Compounding three times per year
- `4` = Quarterly compounding
- `6` = Bimonthly compounding
- `12` = Monthly compounding

Data Types: `double`

`Basis` — Day count basis of the interest-rate curve
`0` (actual/actual) (default) | integer from `0` to `13`

Day count basis of the interest-rate curve, specified as the comma-separated pair consisting of `'Basis'` and a scalar integer.

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)

- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`IRFitOptions` — IRFitOptions object

`IRFitOptions` object

`IRFitOptions` object, specified using previously created object using `IRFitOptions`. When using `IRFitOption`, the default `FitType` is `DurationWeightedPrice`. Duration weighted price refers to the form of the objective function that needs to be minimized to find the optimal Nelson-Siegel parameters. Specifically, this objective function minimizes using the following three algorithms:

- The difference between observed and model-predicted yields for each bond, `ObsY_`*i* – `PredY_`*i*
- The difference between observed and model-predicted prices for each bond, `ObsP_`*i* – `PredP_`*i*
- The difference between observed and model-predicted prices, weighted by the inverse of the duration of each bond (`ObsP_`*i* – `PredP_`*i*) / `D_`*i*. Weighting price by inverse duration converts the pricing errors into yield fitting errors, to a first approximation.

Data Types: `object`

Name-Value Pair Arguments for Each Bond Instrument

`InstrumentPeriod` — Coupons per year for the bond

2 (default) | numeric with value of `0`, `1`, `2`, `3`, `4`, `6`, and `12`

Coupons per year for the bond, specified as the comma-separated pair consisting of `'InstrumentPeriod'` and a scalar numeric value.

Data Types: `double`

`InstrumentBasis` — Day-count basis of the bond

`0` (actual/actual) (default) | integer from `0` to `13`

Day count basis of the bond, specified as the comma-separated pair consisting of `'InstrumentBasis'` and a scalar integer.

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)

- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

Note `InstrumentBasis` distinguishes a bond instrument's `Basis` value from the interest-rate curve's `Basis` value.

For more information, see “Basis” on page 2-228.

Data Types: `double`

`InstrumentEndMonthRule` — End-of-month rule
`1` (default) | logical with value `0` or `1`

End-of-month rule, specified as the comma-separated pair consisting of `'InstrumentEndMonthRule'` and a logical value. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month.
- `1` = `set` rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.

Data Types: `logical`

`InstrumentIssueDate` — Instrument issue date
`[]` (default) | serial date number | date character vector

Instrument issue date, specified as the comma-separated pair consisting of `'InstrumentIssueDate'` and a scalar serial date number or date character vector.

Data Types: `double` | `char`

`InstrumentFirstCouponDate` — Date when a bond makes its first coupon payment
cash flow payment dates are determined from other inputs (default) | serial date number | date character vector

Date when a bond makes its first coupon payment (used when bond has an irregular first coupon period), specified as the comma-separated pair consisting of `'InstrumentFirstCouponDate'` and a scalar serial date number or date character vector. When `InstrumentFirstCouponDate` and `InstrumentLastCouponDate` are both specified, `InstrumentFirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `InstrumentFirstCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: `double` | `char`

`InstrumentLastCouponDate` — Last coupon date of a bond before the maturity date
cash flow payment dates are determined from other inputs (default) | serial date number | date character vector

Last coupon date of a bond before the maturity date (used when bond has an irregular last coupon period), specified as the comma-separated pair consisting of `'InstrumentLastCouponDate'` and a

scalar serial date number or date character vector. In the absence of a specified `InstrumentFirstCouponDate`, a specified `InstrumentLastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `InstrumentLastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `InstrumentLastCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: `double` | `char`

`InstrumentFace` — Face or par value
`100` (default) | numeric

Face or par value, specified as the comma-separated pair consisting of `'InstrumentFace'` and a scalar numeric.

Data Types: `double`

Note When using `Instrument` name-value pairs, you can specify simple interest for a bond by specifying the `InstrumentPeriod` value as `0`. If `InstrumentBasis` and `InstrumentPeriod` are not specified for a bond, the following default values are used: `InstrumentBasis` is `0` (act/act) and `InstrumentPeriod` is `2`.

Output Arguments

`CurveObj` — Nelson-Siegel curve model
structure

Nelson-Siegel curve model, returned as a structure. After creating a Nelson-Siegel model, you can view the Nelson-Siegel model parameters using:

```
CurveObj.Parameters
```

where the order of parameters is [`Beta0`,`Beta1`,`Beta2`,`tau1`].

Algorithms

The Nelson-Siegel model proposes that the instantaneous forward curve can be modeled with the following:

$$f = \beta_0 + \beta_1 e^{\frac{-m}{\tau}} + \beta_2 \frac{m}{\tau} e^{\frac{-m}{\tau}}$$

This can be integrated to derive an equation for the zero curve (see [6] for more information on the equations and the derivation):

$$s = \beta_0 + (\beta_1 + \beta_2)\frac{\tau}{m}(1 - e^{\frac{-m}{\tau}}) - \beta_2 e^{\frac{-m}{\tau}}$$

See [1] for more information.

fitSmoothingSpline

Fit smoothing spline to bond market data

Syntax

```
CurveObj = IRFunctionCurve.fitSmoothingSpline(Type,Settle,Instruments,
Lambdafun)
CurveObj = IRFunctionCurve.fitSmoothingSpline( ___ ,Name,Value)
```

Description

`CurveObj = IRFunctionCurve.fitSmoothingSpline(Type,Settle,Instruments, Lambdafun)` fits a smoothing spline to market data for a bond.

Note You must have a license for Curve Fitting Toolbox software to use the `fitSmoothingSpline` method.

`CurveObj = IRFunctionCurve.fitSmoothingSpline( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Use a Smoothing Spline Function to Fit Market Data For a Bond

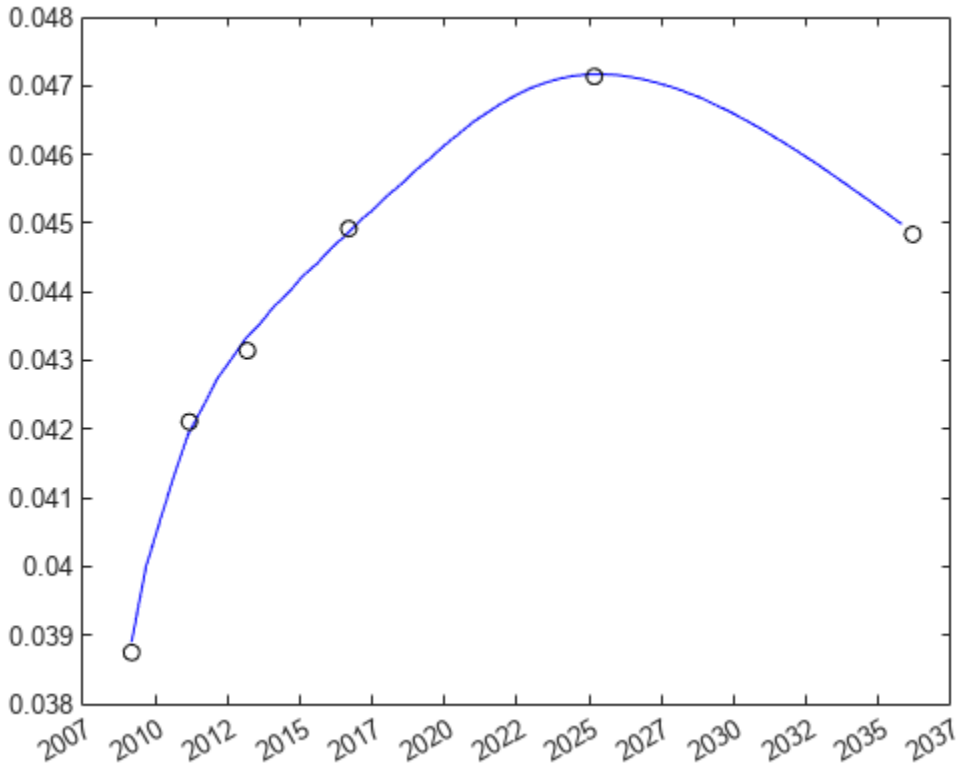
This example shows how to use a `fitSmoothingSpline` function to fit market data for a bond.

```
Settle = repmat(datenum('30-Apr-2008'),[6 1]);
Maturity = [datenum('07-Mar-2009');datenum('07-Mar-2011');...
datenum('07-Mar-2013');datenum('07-Sep-2016');...
datenum('07-Mar-2025');datenum('07-Mar-2036')];

CleanPrice = [100.1;100.1;100.8;96.6;103.3;96.3];
CouponRate = [0.0400;0.0425;0.0450;0.0400;0.0500;0.0425];
Instruments = [Settle Maturity CleanPrice CouponRate];
PlottingPoints = datenum('07-Mar-2009'):180:datenum('07-Mar-2036');
Yield = bndyield(CleanPrice,CouponRate,Settle,Maturity);

% Use the AUGKNT function to construct the knots for a cubic spline at
% every 5 years.
CustomKnots = augknt(0:5:30,4);
SmoothingModel = IRFunctionCurve.fitSmoothingSpline('Zero',datenum('30-Apr-2008'),...
Instruments,@(t) 1000,'knots', CustomKnots);

% Create the plot.
plot(PlottingPoints, getParYields(SmoothingModel, PlottingPoints),'b')
hold on
scatter(Maturity,Yield,'black')
datetick('x')
```



Fitting an `IRFunctionCurve` Object Using `fitSmoothingSpline` with Penalty Function

This example shows for to use `fitSmoothinSpline` function to fit the interest-rate curve and model the `Lambdafun` penalty function.

First, load the data.

```
load ukdata20080430
```

Convert the repo rates to be equivalent zero coupon bonds.

```
RepoCouponRate = repmat(0,size(RepoRates));
RepoPrice = bndprice(RepoRates, RepoCouponRate, RepoSettle, RepoMaturity);
```

Aggregate the data.

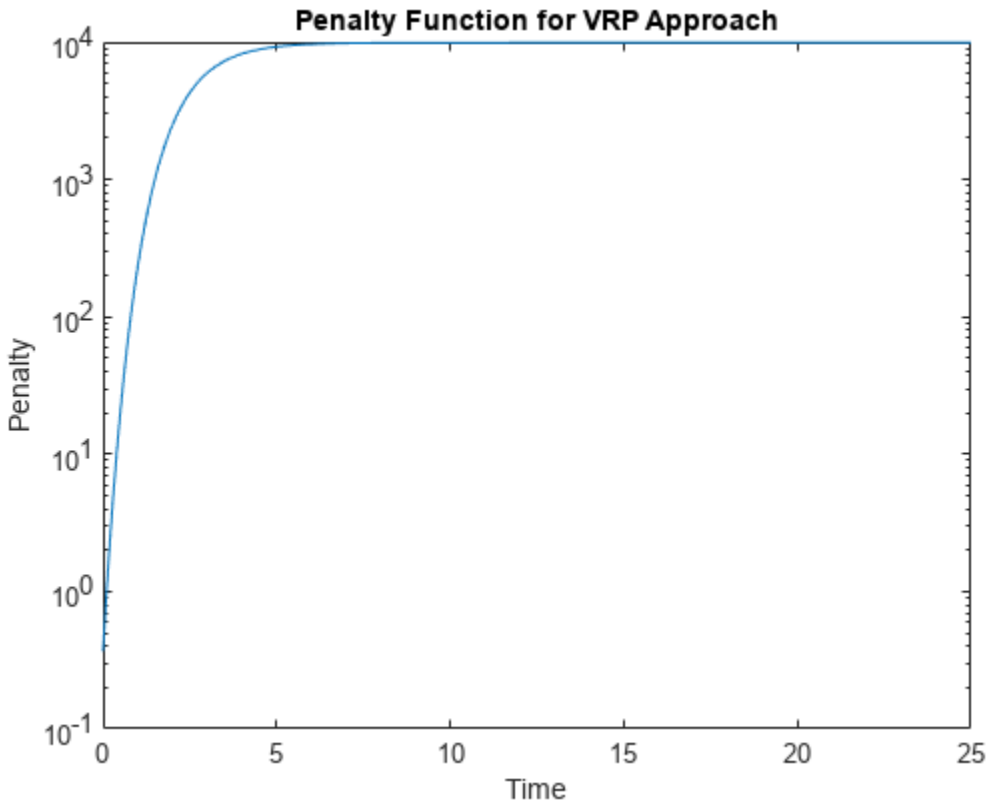
```
Settle = [RepoSettle;BondSettle];
Maturity = [RepoMaturity;BondMaturity];
CleanPrice = [RepoPrice;BondCleanPrice];
CouponRate = [RepoCouponRate;BondCouponRate];
Instruments = [Settle Maturity CleanPrice CouponRate];
InstrumentPeriod = [repmat(0,6,1);repmat(2,31,1)];
CurveSettle = datenum('30-Apr-2008');
```

Choose the parameters for the `Lambdafun` input argument.

```
L = 9.2;
S = -1;
mu = 1;
```

Define the `Lambdafun` penalty function.

```
lambdafun = @(t) exp(L - (L-S)*exp(-t/mu));
t = 0:.1:25;
y = lambdafun(t);
figure
semilogy(t,y);
title('Penalty Function for VRP Approach')
ylabel('Penalty')
xlabel('Time')
```



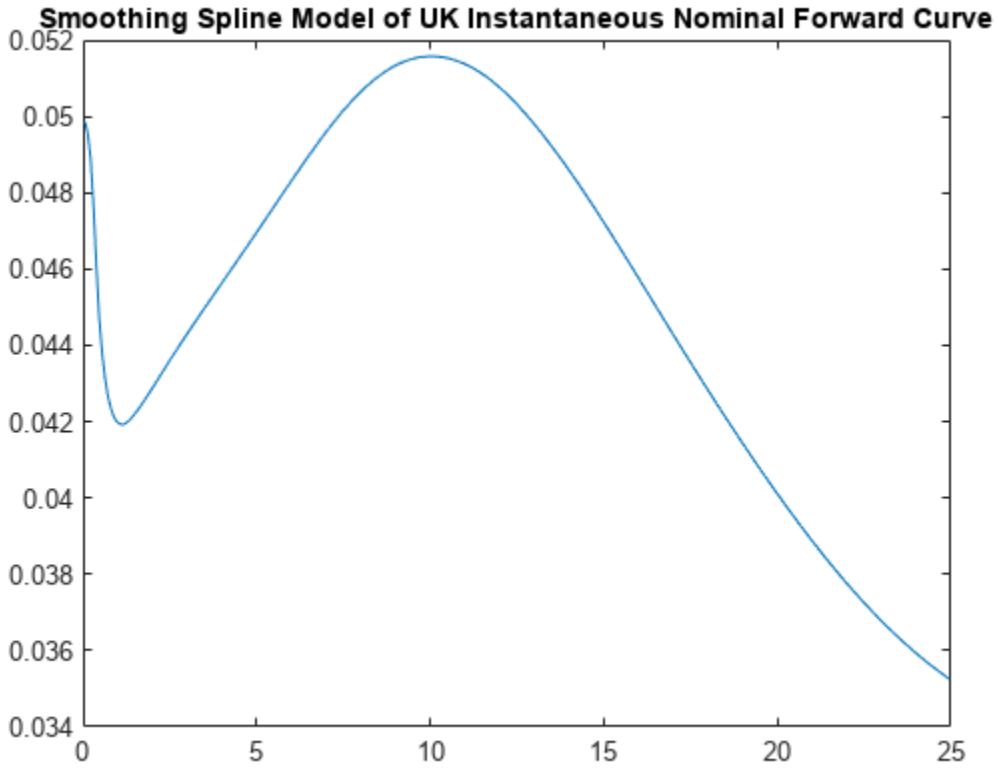
Use the `fitSmoothinSpline` function to fit the interest-rate curve and model the `Lambdafun` penalty function.

```
VRPModel = IRFunctionCurve.fitSmoothingSpline('Forward',CurveSettle,...
Instruments,lambdafun,'Compounding',-1, 'InstrumentPeriod',InstrumentPeriod)
```

```
VRPModel =
            Type: Forward
          Settle: 733528 (30-Apr-2008)
     Compounding: -1
           Basis: 0 (actual/actual)
```

Plot the smoothing spline interest-rate curve for the forward rates.

```
PlottingDates = CurveSettle+20:30:CurveSettle+365*25;
TimeToMaturity = yearfrac(CurveSettle,PlottingDates);
VRPForwardRates = getForwardRates(VRPModel, PlottingDates);
figure;plot(TimeToMaturity,VRPForwardRates)
title('Smoothing Spline Model of UK Instantaneous Nominal Forward Curve')
```



Input Arguments

Type — Type of interest-rate curve for a bond

character vector with value of `'zero'`, `'discount'`, or `'forward'`

Type of interest-rate curve for a bond, specified by using a scalar character vector.

Data Types: `char`

Settle — Settle date of interest-rate curve

serial date number | date character vector

Settle date of interest-rate curve, specified serial date number or date character vector.

Data Types: `double` | `char`

Instruments — Instruments

matrix

Instruments, specified using an N-by-4 data matrix where the first column is `Settle` date using a serial date number, the second column is `Maturity` using a serial date number, the third column is the clean price, and the fourth column is a `CouponRate` for the bond.

Data Types: `double`

`Lambdafun` — Penalty function
function handle

Penalty function, specified using a function handle. The penalty function that takes as its input time and returns a penalty value. The function handle for the penalty function takes one numeric input (time-to-maturity) and returns one numeric output (penalty to be applied to the curvature of the spline). For more information on defining a function handle, see the MATLAB Programming Fundamentals documentation.

Note The smoothing spline represents the forward curve. The spline is penalized for curvature by specifying a penalty function. This fit can only be done with a `FitType` of `DurationWeightedPrice`.

Data Types: `function_handle`

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `CurveObj = IRFunctionCurve.fitSmoothingSpline('Zero',datenum('30-Apr-2008'),Instruments,@(t) 1000,'knots',CustomKnots)`

Name-Value Pair Arguments for All Bond Instruments

`Compounding` — Compounding frequency per-year for `IRFunctionCurve` object
`CurveObj.Compounding` (default) | possible values include: –1, 0, 1, 2, 3, 4, 6, 12.

Compounding frequency per-year for the `IRFunctionCurve` object, specified as the comma-separated pair consisting of `'Compounding'` and a scalar numeric using one of the supported values:

- `–1` = Continuous compounding
- `0` = Simple interest (no compounding)
- `1` = Annual compounding
- `2` = Semiannual compounding
- `3` = Compounding three times per year
- `4` = Quarterly compounding
- `6` = Bimonthly compounding
- `12` = Monthly compounding

Data Types: `double`

Basis — Day count basis of the interest-rate curve

0 (actual/actual) (default) | integer from 0 to 13

Day count basis of the interest-rate curve, specified as the comma-separated pair consisting of `'Basis'` and a scalar integer.

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

Name-Value Pair Arguments for Each Bond Instrument

InstrumentPeriod — Coupons per year for the bond

2 (default) | numeric with value of 0, 1, 2, 3, 4, 6, and 12

Coupons per year for the bond, specified as the comma-separated pair consisting of `'InstrumentPeriod'` and a scalar numeric value.

Data Types: `double`

InstrumentBasis — Day-count basis of the bond

0 (actual/actual) (default) | integer from 0 to 13

Day count basis of the bond, specified as the comma-separated pair consisting of `'InstrumentBasis'` and a scalar integer.

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)

- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

Note `InstrumentBasis` distinguishes a bond instrument's `Basis` value from the interest-rate curve's `Basis` value.

For more information, see “Basis” on page 2-228.

Data Types: `double`

`InstrumentEndMonthRule` — End-of-month rule
`1` (default) | logical with value `0` or `1`

End-of-month rule, specified as the comma-separated pair consisting of `'InstrumentEndMonthRule'` and a logical value. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month.
- `1` = `set` rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.

Data Types: `logical`

`InstrumentIssueDate` — Instrument issue date
`[]` (default) | serial date number | date character vector

Instrument issue date, specified as the comma-separated pair consisting of `'InstrumentIssueDate'` and a scalar serial date number or date character vector.

Data Types: `double` | `char`

`InstrumentFirstCouponDate` — Date when a bond makes its first coupon payment
cash flow payment dates are determined from other inputs (default) | serial date number | date character vector

Date when a bond makes its first coupon payment (used when bond has an irregular first coupon period), specified as the comma-separated pair consisting of `'InstrumentFirstCouponDate'` and a scalar serial date number or date character vector. When `InstrumentFirstCouponDate` and `InstrumentLastCouponDate` are both specified, `InstrumentFirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `InstrumentFirstCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: `double` | `char`

`InstrumentLastCouponDate` — Last coupon date of a bond before the maturity date
cash flow payment dates are determined from other inputs (default) | serial date number | date character vector

Last coupon date of a bond before the maturity date (used when bond has an irregular last coupon period), specified as the comma-separated pair consisting of `'InstrumentLastCouponDate'` and a scalar serial date number or date character vector. In the absence of a specified `InstrumentFirstCouponDate`, a specified `InstrumentLastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `InstrumentLastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `InstrumentLastCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: `double` | `char`

`InstrumentFace` — Face or par value
`100` (default) | numeric

Face or par value, specified as the comma-separated pair consisting of `'InstrumentFace'` and a scalar numeric.

Data Types: `double`

Note When using `Instrument` name-value pairs, you can specify simple interest for a bond by specifying the `InstrumentPeriod` value as `0`. If `InstrumentBasis` and `InstrumentPeriod` are not specified for a bond, the following default values are used: `InstrumentBasis` is `0` (act/act) and `InstrumentPeriod` is `2`.

Output Arguments

`CurveObj` — Smoothing spline curve model
structure

Smoothing spline curve model, returned as a structure.

Algorithms

The term structure can be modeled with a spline — specifically, one way to model the term structure is by representing the forward curve with a cubic spline. To ensure that the spline is sufficiently smooth, a penalty is imposed relating to the curvature (second derivative) of the spline:

$$\sum_{i=1}^{N}[\frac{P_i - \hat{P}_i(f)}{D_i}]^2 + \int_0^M \lambda_t(m)[f''(m)]^2 dm$$

where the first term is the difference between the observed price P and the predicted price, $\widehat{P}$, (weighted by the bond's duration, D) summed over all bonds in our data set and the second term is the penalty term (where λ is a penalty function and f is the spline).

See [3], [4], [5] below.

There have been different proposals for the specification of the penalty function λ. One approach, advocated by [4], and currently used by the UK Debt Management Office, is a penalty function of the following form:

$$log(\lambda(m)) = L - (L - S)e^{\frac{-m}{k}}$$

fitSvensson

Fit Svensson function to bond market data

Note `fitSvensson` for an `IRFunctionCurve` is not recommended. Use `fitSvensson` with a `parametercurve` object instead. For more information, see `fitSvensson`.

Syntax

```
CurveObj = IRFunctionCurve.fitSvensson(Type,Settle,Instruments)
CurveObj = IRFunctionCurve.fitSvensson( ___ ,Name,Value)
```

Description

`CurveObj = IRFunctionCurve.fitSvensson(Type,Settle,Instruments)` fits the Svensson function to market data for a bond.

`CurveObj = IRFunctionCurve.fitSvensson( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Use a Svensson Function to Fit Bond Market Data

This example shows how to use a Svensson function to fit bond market data.

```
Settle = datenum('15-Apr-2014');
Maturity = datemnth(Settle,12*[1 2 3 5 7 10 20 30]');

CleanPrice = [100.1 100.1 100.2 99.0 101.8 99.2 101.7 100.2]';
CouponRate = [0.0200 0.0275 0.035 0.042 0.0475 0.0525 0.055 0.052]';
Instruments = [repmat(Settle,size(Maturity)) Maturity CleanPrice CouponRate];
PlottingPoints = datemnth(Settle,1:360);
Yield = bndyield(CleanPrice,CouponRate,Settle,Maturity);

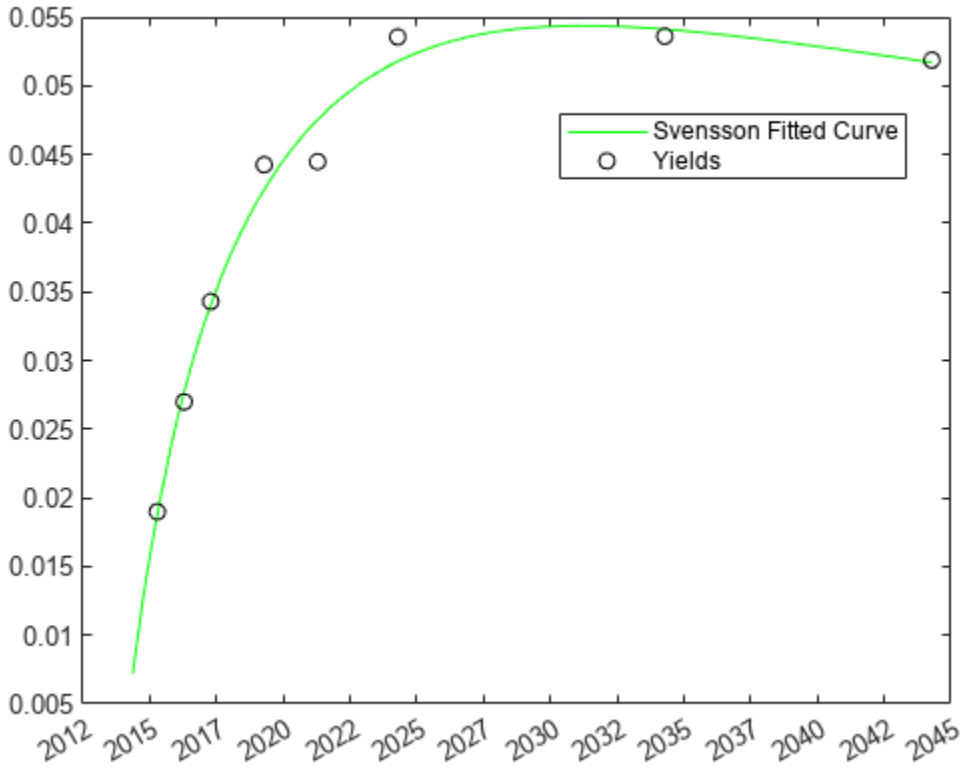
SvenssonModel = IRFunctionCurve.fitSvensson('Zero',Settle,Instruments);

SvenssonModel.Parameters
```

```
ans = 1×6

    1.8298   -1.2299    1.6316   12.3890    1.6982    8.9422
```

```
% create the plot
plot(PlottingPoints, getParYields(SvenssonModel, PlottingPoints),'g')
hold on
scatter(Maturity,Yield,'black')
datetick('x')
legend({'Svensson Fitted Curve','Yields'},'location','best')
```



Input Arguments

Type — Type of interest-rate curve for a bond

character vector with value of `'zero'` or `'forward'`

Type of interest-rate curve for a bond, specified by using a scalar character vector.

Data Types: `char`

Settle — Settle date of interest-rate curve

serial date number | date character vector

Settle date of interest-rate curve, specified using a scalar serial date number or date character vector.

Data Types: `double` | `char`

Instruments — Instruments

matrix

Instruments, specified using an N-by-4 data matrix where the first column is `Settle` date using a serial date number, the second column is `Maturity` using a serial date number, the third column is the clean price, and the fourth column is a `CouponRate` for the bond.

Data Types: `double`

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `CurveObj = IRFunctionCurve.fitSvensson('Zero',Settle,Instruments)`

Name-Value Pair Arguments for All Bond Instruments

`Compounding` — Compounding frequency per-year for `IRFunctionCurve` object
`CurveObj.Compounding` (default) | possible values include: –1, 0, 1, 2, 3, 4, 6, 12.

Compounding frequency per-year for the `IRFunctionCurve` object, specified as the comma-separated pair consisting of `'Compounding'` and a scalar numeric using one of the supported values:

- `-1` = Continuous compounding
- `0` = Simple interest (no compounding)
- `1` = Annual compounding
- `2` = Semiannual compounding
- `3` = Compounding three times per year
- `4` = Quarterly compounding
- `6` = Bimonthly compounding
- `12` = Monthly compounding

Data Types: `double`

`Basis` — Day count basis of the interest-rate curve
`0` (actual/actual) (default) | integer from `0` to `13`

Day count basis of the interest-rate curve, specified as the comma-separated pair consisting of `'Basis'` and a scalar integer.

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)

- 13 — BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`IRFitOptions` — IRFitOptions object
`IRFitOptions` object

`IRFitOptions` object, specified using previously created object using `IRFitOptions`.

Data Types: `object`

Name-Value Pair Arguments for Each Bond Instrument

`InstrumentPeriod` — Coupons per year for the bond
2 (default) | numeric with value of `0`, `1`, `2`, `3`, `4`, `6`, and `12`

Coupons per year for the bond, specified as the comma-separated pair consisting of `'InstrumentPeriod'` and a scalar numeric value.

Data Types: `double`

`InstrumentBasis` — Day-count basis of the bond
`0` (actual/actual) (default) | integer from `0` to `13`

Day count basis of the bond, specified as the comma-separated pair consisting of `'InstrumentBasis'` and a scalar integer.

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

Note `InstrumentBasis` distinguishes a bond instrument's `Basis` value from the interest-rate curve's `Basis` value.

For more information, see “Basis” on page 2-228.

Data Types: `double`

`InstrumentEndMonthRule` — End-of-month rule
`1` (default) | logical with value `0` or `1`

End-of-month rule, specified as the comma-separated pair consisting of `'InstrumentEndMonthRule'` and a logical value. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month.
- `1` = `set` rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.

Data Types: `logical`

`InstrumentIssueDate` — Instrument issue date
`[]` (default) | serial date number | date character vector

Instrument issue date, specified as the comma-separated pair consisting of `'InstrumentIssueDate'` and a scalar serial date number or date character vector.

Data Types: `double` | `char`

`InstrumentFirstCouponDate` — Date when a bond makes its first coupon payment
cash flow payment dates are determined from other inputs (default) | serial date number | date character vector

Date when a bond makes its first coupon payment (used when bond has an irregular first coupon period), specified as the comma-separated pair consisting of `'InstrumentFirstCouponDate'` and a scalar serial date number or date character vector. When `InstrumentFirstCouponDate` and `InstrumentLastCouponDate` are both specified, `InstrumentFirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `InstrumentFirstCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: `double` | `char`

`InstrumentLastCouponDate` — Last coupon date of a bond before the maturity date
cash flow payment dates are determined from other inputs (default) | serial date number | date character vector

Last coupon date of a bond before the maturity date (used when bond has an irregular last coupon period), specified as the comma-separated pair consisting of `'InstrumentLastCouponDate'` and a scalar serial date number or date character vector. In the absence of a specified `InstrumentFirstCouponDate`, a specified `InstrumentLastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `InstrumentLastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `InstrumentLastCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: `double` | `char`

`InstrumentFace` — Face or par value
`100` (default) | numeric

Face or par value, specified as the comma-separated pair consisting of `'InstrumentFace'` and a scalar numeric.

Data Types: `double`

Note When using `Instrument` name-value pairs, you can specify simple interest for a bond by specifying the `InstrumentPeriod` value as `0`. If `InstrumentBasis` and `InstrumentPeriod` are not specified for a bond, the following default values are used: `InstrumentBasis` is `0` (act/act) and `InstrumentPeriod` is `2`.

Output Arguments

`CurveObj` — Svensson curve model

structure

Svensson curve model, returned as a structure. After creating a Nelson-Siegel model, you can view the Nelson-Siegel model parameters using:

```
CurveObj.Parameters
```

where the order of parameters is [`Beta0`,`Beta1`,`Beta2`,`Beta3`,`tau1`,`tau2`].

Algorithms

A similar model to the Nelson-Siegel is the Svensson model, which adds two additional parameters to account for greater flexibility in the term structure. This model proposes that the forward rate can be modeled with the following form:

$$f = \beta_0 + \beta_1 e^{\frac{-m}{\tau_1}} + \beta_2 e^{\frac{-m}{\tau_1}} \frac{m}{\tau_1} + \beta_3 e^{\frac{-m}{\tau_2}} \frac{m}{\tau_2}$$

As above, this can be integrated to derive an equation for the zero curve:

$$s = \beta_0 + \beta_1 (1 - e^{\frac{-m}{\tau_1}})(-\frac{\tau_1}{m}) + \beta_2((1 - e^{\frac{-m}{\tau_1}})\frac{\tau_1}{m} - e^{\frac{m}{\tau_1}}) + \beta_3((1 - e^{\frac{-m}{\tau_2}})\frac{\tau_2}{m} - e^{\frac{m}{\tau_2}})$$

Version History

Introduced in R2008b

getDiscountFactors

Get discount factors for input dates for `IRDataCurve`

Syntax

```
F = getDiscountFactors(CurveObj,InpDates)
```

Description

`F = getDiscountFactors(CurveObj,InpDates)` computes discount factors for input dates for an `IRDataCurve` object.

Note The `ratecurve` object and the associated `discountfactors` were introduced in R2020a as part of a new object-based framework in the Financial Instruments Toolbox which supports end-to-end workflows in instrument modeling and analysis. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

Examples

Get Discount Factors For Input Dates for an IRDataCurve

This example shows how to get discount factors for input dates for an `IRDataCurve`.

```
CurveSettle = datetime(2016,3,2);
Data = [2.09 2.47 2.71 3.12 3.43 3.85 4.57 4.58]/100;
Dates = datemnth(CurveSettle,12*[1 2 3 5 7 10 20 30]);
irdc = IRDataCurve('Zero',CurveSettle,Dates,Data);
getDiscountFactors(irdc, CurveSettle+30:30:CurveSettle+720)
```

```
ans = 24×1

    0.9986
    0.9971
    0.9956
    0.9940
    0.9924
    0.9907
    0.9890
    0.9873
    0.9855
    0.9836
      ⋮
```

Input Arguments

CurveObj — Interest-rate curve object

object

Interest-rate curve object, specified by using `IRDataCurve`.

Data Types: `object`

`InpDates` — Input dates
datetime array | string array | date character vector

Input dates, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. The input dates must be after the `Settle` date of `IRDataCurve`.

To support existing code, `getDiscountFactors` also accepts serial date numbers as inputs, but they are not recommended.

Output Arguments

`F` — Discount factors
vector

Discount factors, returned as a vector.

Version History

Introduced in R2008b

Serial date numbers not recommended
Not recommended starting in R2022b

Although `getDiscountFactors` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

getDiscountFactors

Get discount factors for input dates for `IRFunctionCurve`

Syntax

```
F = getDiscountFactors(CurveObj,InpDates)
```

Description

`F = getDiscountFactors(CurveObj,InpDates)` computes discount factors for input dates for an `IRFunctionCurve` object.

Note The `parametercurve` object and the associated `discountfactors` were introduced in R2020a as part of a new object-based framework in the Financial Instruments Toolbox which supports end-to-end workflows in instrument modeling and analysis. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

Examples

Get Discount Factors for Input Dates For an IRFunctionCurve

This example shows how to get discount factors for input dates for an `IRFunctionCurve`.

```
irfc = IRFunctionCurve('Forward',today,@(t) polyval([-0.0001 0.003 0.02],t));
getDiscountFactors(irfc, today+30:30:today+720)
```

```
ans = 24×1

getForwardRates

Get forward rates for input dates for `IRDataCurve`

Syntax

```
F = getForwardRates(CurveObj,InpDates)
F = getForwardRates( ___ ,Name,Value)
```

Description

`F = getForwardRates(CurveObj,InpDates)` computes discount factors for input dates for an `IRDataCurve` object. `getForwardRates` returns discrete forward rates for the intervals input into this function. For example, running the following code:

```
getForwardRates(irdc, {Date1, Date2, Date3})
```

gives three forwards rates and the three tenors are: `[Settle, Date1]`, `[Date1, Date2]`, and `[Date2, Date3]`.

Note The `ratecurve` object and the associated `forwardrates` were introduced in R2020a as part of a new object-based framework in the Financial Instruments Toolbox which supports end-to-end workflows in instrument modeling and analysis. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`F = getForwardRates( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Get Forward Rates For Input Dates for an IRDataCurve

This example shows how to get forward rates for input dates for an `IRDataCurve`.

```
CurveSettle = datetime(2016,3,2);
Data = [2.09 2.47 2.71 3.12 3.43 3.85 4.57 4.58]/100;
Dates = datemnth(CurveSettle,12*[1 2 3 5 7 10 20 30]);
irdc = IRDataCurve('Zero',CurveSettle,Dates,Data);
getForwardRates(irdc, CurveSettle+30:30:CurveSettle+720)
```

```
ans = 24×1

    0.0174
    0.0180
    0.0187
    0.0193
    0.0199
    0.0205
    0.0212
    0.0218
    0.0224
```

```
    0.0230
      ⋮
```

Use getForwardRates to Compute the Five Year Forward Rate in Five Years Time

Use `getForwardRates` to compute the forward rate from the `Settle` date to 5 years from March 1, 2017 and then the forward rate for the period from 5 years to 10 years from March 1, 2017.

```
Data = [2.09 2.47 2.71 3.12 3.43 3.85 4.57 4.58]/100;
Dates = daysadd(736755,[360 2*360 3*360 5*360 7*360 10*360 20*360 30*360],1);
irdc = IRDataCurve('Zero',today,Dates,Data);
getForwardRates(irdc,datemnth(irdc.Settle,12*[5 10]))
```

```
ans = 2×1

    0.0389
    0.0461
```

The first element (`.0312`) is the forward rate from the `Settle` to 5 years from March 1, 2017. The second rate (`0.0458`) is the forward rate for the period from 5 years to 10 years from March 1, 2017, in other words, the 5-year forward rate 5 years from March 1, 2017.

Compute the Six Month Forward Rates in 1 Month, 2 Months and 3 Months

Use the following data to create an `IRDataCurve` object:

```
Data = [0.1 0.30 0.70 1.05 1.45 1.71 2.12 2.43 2.85 3.57]/100;
Settle = datetime(2016,8,8)
```

```
Settle = datetime
   08-Aug-2016
```

```
Dates = datemnth(Settle,[3 6 9 12*[1 2 3 5 7 10 20]]);
irdc = IRDataCurve('Zero',Settle,Dates,Data)
```

```
irdc =
             Type: Zero
           Settle: 736550 (08-Aug-2016)
      Compounding: 2
            Basis: 0 (actual/actual)
     InterpMethod: linear
            Dates: [10x1 double]
             Data: [10x1 double]
```

Compute the implied 6 month forward rates in 1 month, 2 months, and 3 months from the `Settle` date.

```
IntervalMonth = 6; % Interval for 6 month forward rates
FwdMonths = [1 2 3]'; % Starting in 1, 2, and 3 months from Settle
```

```
N = length(FwdMonths);
FwdRates_6M = zeros(N,1);

for k = 1:N
    FwdDates = datemnth(irdc.Settle, [FwdMonths(k) FwdMonths(k)+IntervalMonth]);
    f = getForwardRates(irdc,FwdDates);
    FwdRates_6M(k) = f(2);
end

[FwdMonths FwdRates_6M]

ans = 3×2

    1.0000    0.0050
    2.0000    0.0074
    3.0000    0.0101
```

Input Arguments

`CurveObj` — Interest-rate curve object

object

Interest-rate curve object, specified by using `IRDataCurve`.

Data Types: `object`

`InpDates` — Input dates

datetime array | string array | date character vector

Input dates, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. The input dates must be after the `Settle` date of `IRDataCurve`.

To support existing code, `getForwardRates` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `F = getForwardRates(irdc, CurveSettle+30:30:CurveSettle+720)`

`Compounding` — Compounding frequency per-year for forward rates

`CurveObj.Compounding` (default) | possible values include: `–1`, `0`, `1`, `2`, `3`, `4`, `6`, `12`.

Compounding frequency per-year for forward rates, specified as the comma-separated pair consisting of `'Compounding'` and a scalar numeric using one of the supported values:

- `–1` = Continuous compounding
- `0` = Simple interest (no compounding)

- 1 = Annual compounding
- 2 = Semiannual compounding
- 3 = Compounding three times per year
- 4 = Quarterly compounding
- 6 = Bimonthly compounding
- 12 = Monthly compounding

Data Types: double

Basis — Day count basis for the forward rates
0 (actual/actual) (default) | integer from 0 to 13

Day count basis for the forward rates, specified as the comma-separated pair consisting of 'Basis' and a scalar integer.

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-228.

Data Types: double

Output Arguments

F — Forward rates
vector

Forward rates, returned as a vector. getForwardRates returns forward rates corresponding to the periodicity of the dates input to getForwardRates. For example, where the dates are monthly, monthly forward rates are returned. The first element of the output is the forward rate from the Settle to one month, the second element is the forward rate from one month to two months, and so on.

Version History

Introduced in R2008b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `getForwardRates` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

“Mapping Financial Instruments Toolbox Curve Functions to Object-Based Framework” on page 1-95

getForwardRates

Get forward rates for input dates for `IRFunctionCurve`

Syntax

```
F = getForwardRates(CurveObj,InpDates)
F = getForwardRates( ___ ,Name,Value)
```

Description

`F = getForwardRates(CurveObj,InpDates)` computes discount factors for input dates for an `IRFunctionCurve` object. `getForwardRates` returns discrete forward rates for the intervals input into this function. For example, running the following code:

```
getForwardRates(irdc, {Date1, Date2, Date3})
```

gives three forwards rates and the three tenors are: `[Settle, Date1]`, `[Date1, Date2]`, and `[Date2, Date3]`.

Note The `parametercurve` object and the associated `forwardrates` were introduced in R2020a as part of a new object-based framework in the Financial Instruments Toolbox which supports end-to-end workflows in instrument modeling and analysis. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`F = getForwardRates( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Get Forward Rates For Input Dates For an IRFunctionCurve

This example shows how to get forward rates for input dates for an `IRFunctionCurve`.

```
irfc = IRFunctionCurve('Forward',today,@(t) polyval([-0.0001 0.003 0.02],t));
getForwardRates(irfc, today+30:30:today+720)
```

```
ans = 24×1

    0.0202
    0.0205
    0.0207
    0.0210
    0.0212
    0.0215
    0.0217
    0.0219
    0.0222
    0.0224
      ⋮
```

Compute the Implied 2-Year Forward Rates in 1 Year, 2 Years, 5 Years, and 10 Years

This example shows how to compute the implied 2-year forward rates in 1 year, 2 years, 5 years, and 10 years from the `Settle` date by using the `getForwardRates` method.

Use the following data for an `IRFunctionCurve` object that is created when using the `fitSvensson` method.

```
Settle = datenum('15-Apr-2014');
Maturity = datemnth(Settle,12*[1 2 3 5 7 10 20 30]');

CleanPrice = [100.1 100.1 100.2 99.0 101.8 99.2 101.7 100.2]';
CouponRate = [0.0200 0.0275 0.035 0.042 0.0475 0.0525 0.055 0.052]';
Instruments = [repmat(Settle,size(Maturity)) Maturity CleanPrice CouponRate];

SvenssonModel = IRFunctionCurve.fitSvensson('Zero',Settle,Instruments);
```

Compute the implied 2-year forward rates in 1 year, 2 years, 5 years, and 10 years from the `Settle` date.

```
IntervalMonth = 12.*2;         % Interval months for 2-year forward rates
FwdMonths = 12.*[1 2 5 10]';   % Starting in 1, 2, 5, and 10 years from Settle
N = length(FwdMonths);
FwdRates_2Y = zeros(N,1);

for k = 1:N
    FwdDates = datemnth(SvenssonModel.Settle, [FwdMonths(k) FwdMonths(k)+IntervalMonth]);
    f = getForwardRates(SvenssonModel,FwdDates);
    FwdRates_2Y(k) = f(2);
end

[FwdMonths FwdRates_2Y]
```

```
ans = 4×2

   12.0000    0.0418
   24.0000    0.0504
   60.0000    0.0620
  120.0000    0.0629
```

Input Arguments

`CurveObj` — Interest-rate curve object

object

Interest-rate curve object, specified by using `IRFunctionCurve`.

Data Types: `object`

`InpDates` — Input dates

datetime array | string array | date character vector

Input dates, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. The input dates must be after the `Settle` date of `IRFunctionCurve`.

To support existing code, `getForwardRates` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `F = getForwardRates(irfc, CurveSettle+30:30:CurveSettle+720)`

`Compounding` — Compounding frequency per-year for forward rates

`CurveObj.Compounding` (default) | possible values include: `–1`, `0`, `1`, `2`, `3`, `4`, `6`, `12`.

Compounding frequency per-year for forward rates, specified as the comma-separated pair consisting of `'Compounding'` and a scalar numeric using one of the supported values:

- `–1` = Continuous compounding
- `0` = Simple interest (no compounding)
- `1` = Annual compounding
- `2` = Semiannual compounding
- `3` = Compounding three times per year
- `4` = Quarterly compounding
- `6` = Bimonthly compounding
- `12` = Monthly compounding

Data Types: `double`

`Basis` — Day count basis for the forward rates

`0` (actual/actual) (default) | integer from `0` to `13`

Day count basis for the forward rates, specified as the comma-separated pair consisting of `'Basis'` and a scalar integer.

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)

- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

Output Arguments

F — Forward rates

vector

Forward rates, returned as a vector. `getForwardRates` returns forward rates corresponding to the periodicity of the dates input to `getForwardRates`. For example, where the dates are monthly, monthly forward rates are returned. The first element of the output is the forward rate from the `Settle` to one month, the second element is the forward rate from one month to two months, and so on.

Version History

Introduced in R2008b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `getForwardRates` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

getParYields

Get par yields for input dates for `IRDataCurve`

Syntax

```
F = getParYields(CurveObj,InpDates)
F = getParYields( ___ ,Name,Value)
```

Description

`F = getParYields(CurveObj,InpDates)` computes par yields for input dates for an `IRDataCurve` object.

`F = getParYields( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Get Par Yields For Input Dates For an `IRDataCurve`

This example shows how to get par yields for input dates for an `IRDataCurve`.

```
CurveSettle = datetime(2016,3,2);
Data = [2.09 2.47 2.71 3.12 3.43 3.85 4.57 4.58]/100;
Dates = datemnth(CurveSettle,12*[1 2 3 5 7 10 20 30]);
irdc = IRDataCurve('Zero',CurveSettle,Dates,Data);
getParYields(irdc, CurveSettle+30:30:CurveSettle+720)
```

```
ans = 24×1

```

Compute Par Yields From a Curve With Simple Interest Compounding

This example shows how set the compounding of an `IRDataCurve` to `Zero` (simple interest) and then compute par yields from that curve.

```
CurveSettle = datetime(2016,3,2);
Data = [2.09 2.47 2.71 3.12 3.43 3.85 4.57 4.58]/100;
```

```
Dates = datemnth(CurveSettle,12*[1 2 3 5 7 10 20 30]);
irdc = IRDataCurve('Zero',CurveSettle,Dates,Data,'Compounding',0);
SimpleInt = irdc.getParYields(Dates(1), 'Basis', 2, 'Compounding', 1)
```

```
SimpleInt = 0.0209
```

Input Arguments

`CurveObj` — Interest-rate curve object

object

Interest-rate curve object, specified by using `IRDataCurve`.

Data Types: `object`

`InpDates` — Input dates

datetime array | string array | date character vector

Input dates, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. The input dates must be after the `Settle` date of `IRDataCurve`.

To support existing code, `getParYields` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `F = getParYields(irdc, CurveSettle+30:30:CurveSettle+720)`

`Compounding` — Compounding frequency per-year for par yield rates

`CurveObj.Compounding` (default) | possible values include: `–1`, `0`, `1`, `2`, `3`, `4`, `6`, `12`.

Compounding frequency per-year for par yield rates, specified as the comma-separated pair consisting of `'Compounding'` and a scalar numeric using one of the supported values:

- `–1` = Continuous compounding
- `0` = Simple interest (no compounding)
- `1` = Annual compounding
- `2` = Semiannual compounding
- `3` = Compounding three times per year
- `4` = Quarterly compounding
- `6` = Bimonthly compounding
- `12` = Monthly compounding

Data Types: `double`

`Basis` — Day count basis for the par yield rates

`0` (actual/actual) (default) | integer from `0` to `13`

Day count basis for the par yield rates, specified as the comma-separated pair consisting of `'Basis'` and a scalar integer.

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

Output Arguments

F — Par yields

vector

Par yields, returned as a vector.

Version History

Introduced in R2008b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `getParYields` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");

Input Arguments

`CurveObj` — Interest-rate curve object

object

Interest-rate curve object, specified by using `IRFunctionCurve`.

Data Types: `object`

`InpDates` — Input dates

datetime array | string array | date character vector

Input dates, specified as an NINST-by-1 vector using a datetime array, string array, or date character vectors. The input dates must be after the Settle date of IRFunctionCurve.

To support existing code, getParYields also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: F = getParYields(irfc, CurveSettle+30:30:CurveSettle+720)

Compounding — Compounding frequency per-year for par yield rates

CurveObj.Compounding (default) | possible values include: –1, 0, 1, 2, 3, 4, 6, 12.

Compounding frequency per-year for par yield rates, specified as the comma-separated pair consisting of 'Compounding' and a scalar numeric using one of the supported values:

- –1 = Continuous compounding
- 0 = Simple interest (no compounding)
- 1 = Annual compounding
- 2 = Semiannual compounding
- 3 = Compounding three times per year
- 4 = Quarterly compounding
- 6 = Bimonthly compounding
- 12 = Monthly compounding

Data Types: double

Basis — Day count basis for the par yield rates

0 (actual/actual) (default) | integer from 0 to 13

Day count basis for the par yield rates, specified as the comma-separated pair consisting of 'Basis' and a scalar integer.

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)

- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

Output Arguments

F — Par yields

vector

Par yields, returned as a vector.

Version History

Introduced in R2008b

Serial date numbers not recommended

Not recommended starting in R2022b

getZeroRates

Get zero rates for input dates for `IRDataCurve`

Syntax

```
F = getZeroRates(CurveObj,InpDates)
F = getZeroRates( ___ ,Name,Value)
```

Description

`F = getZeroRates(CurveObj,InpDates)` computes zero rates for input dates for an `IRDataCurve` object.

Note The `ratecurve` object and the associated `zerorates` were introduced in R2020a as part of a new object-based framework in the Financial Instruments Toolbox which supports end-to-end workflows in instrument modeling and analysis. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`F = getZeroRates( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Get Zero Rates For Input Dates For an IRDataCurve

This example shows how to get zero rates for input dates for an `IRDataCurve`.

```
CurveSettle = datetime(2016,3,2);
Data = [2.09 2.47 2.71 3.12 3.43 3.85 4.57 4.58]/100;
Dates = datemnth(CurveSettle,12*[1 2 3 5 7 10 20 30]);
irdc = IRDataCurve('Zero',CurveSettle,Dates,Data);
getZeroRates(irdc, CurveSettle+30:30:CurveSettle+720)
```

```
ans = 24×1

    0.0193
    0.0196
    0.0199
    0.0202
      ⋮
```

Input Arguments

`CurveObj` — Interest-rate curve object

object

Interest-rate curve object, specified by using `IRDataCurve`.

Data Types: `object`

`InpDates` — Input dates

datetime array | string array | date character vector

Input dates, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. The input dates must be after the `Settle` date of `IRDataCurve`.

To support existing code, `getZeroRates` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `F = getZeroRates(irdc, CurveSettle+30:30:CurveSettle+720)`

`Compounding` — Compounding frequency per-year for zero rates

`CurveObj.Compounding` (default) | possible values include: `–1`, `0`, `1`, `2`, `3`, `4`, `6`, `12`.

Compounding frequency per-year for zero rates, specified as the comma-separated pair consisting of `'Compounding'` and a scalar numeric using one of the supported values:

- `–1` = Continuous compounding
- `0` = Simple interest (no compounding)
- `1` = Annual compounding
- `2` = Semiannual compounding
- `3` = Compounding three times per year
- `4` = Quarterly compounding
- `6` = Bimonthly compounding
- `12` = Monthly compounding

Data Types: `double`

`Basis` — Day count basis for the zero rates

`0` (actual/actual) (default) | integer from `0` to `13`

Day count basis for the zero rates, specified as the comma-separated pair consisting of `'Basis'` and a scalar integer.

- 0 — actual/actual

- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

Output Arguments

F — Zero rates

vector

Zero rates, returned as a vector.

Version History

Introduced in R2008b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `getZeroRates` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

```

Input Arguments

`CurveObj` — Interest-rate curve object

object

Interest-rate curve object, specified by using `IRFunctionCurve`.

Data Types: `object`

`InpDates` — Input dates

datetime array | string array | date character vector

Input dates, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. The input dates must be after the `Settle` date of `IRFunctionCurve`.

To support existing code, `getZeroRates` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `F = getZeroRates(irfc, CurveSettle+30:30:CurveSettle+720)`

`Compounding` — Compounding frequency per-year for zero rates

`CurveObj.Compounding` (default) | possible values include: `–1`, `0`, `1`, `2`, `3`, `4`, `6`, `12`.

Compounding frequency per-year for zero rates, specified as the comma-separated pair consisting of `'Compounding'` and a scalar numeric using one of the supported values:

- `–1` = Continuous compounding
- `0` = Simple interest (no compounding)
- `1` = Annual compounding
- `2` = Semiannual compounding
- `3` = Compounding three times per year
- `4` = Quarterly compounding
- `6` = Bimonthly compounding
- `12` = Monthly compounding

Data Types: `double`

`Basis` — Day count basis for the zero rates

`0` (actual/actual) (default) | integer from `0` to `13`

Day count basis for the zero rates, specified as the comma-separated pair consisting of `'Basis'` and a scalar integer.

- 0 — actual/actual

- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)

- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

Output Arguments

F — Zero rates

vector

Zero rates, returned as a vector.

Version History

Introduced in R2008b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `getZeroRates` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

IRBootstrapOptions

Construct specific options for bootstrapping interest-rate curve object

Description

Build an `IRBootstrapOptions` object using `IRBootstrapOptions`.

After creating an `IRBootstrapOptions` object, you can use the object with `bootstrap`.

For more detailed information on this workflow, see “Interest-Rate Curve Objects and Workflow” on page 9-2.

Creation

Syntax

```
IRBootstrapOptions_obj = IRBootstrapOptions(Name,Value)
```

Description

`IRBootstrapOptions_obj = IRBootstrapOptions(Name,Value)` sets properties on page 11-2089 and create the `IRBootstrapOptions` object to use with the `bootstrap` function. For example, `IRBootstrapOptions_obj = IRBootstrapOptions('LowerBound',-1)` creates an `IRBootstrapOptions` object. You can specify multiple name-value pair arguments.

Input Arguments

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `IRBootstrapOptions_obj = IRBootstrapOptions('LowerBound',-1)`

`ConvexityAdjustment` — Controls the convexity adjustment to interest rate futures
`[]` (default) | function handle | numeric vector

Controls the convexity adjustment to interest rate futures, specified as the comma-separated pair consisting of `'ConvexityAdjustment'` and a function handle or an `N`-by-`1` numeric vector.

The function handle that takes one numeric input (time-to-maturity) and returns one numeric output, `ConvexityAdjustment`. For more information on defining a function handle, see the MATLAB Programming Fundamentals documentation.

Alternatively, you can define `ConvexityAdjustment` as an `N`-by-`1` vector of values, where `N` is the number of interest-rate futures.

In either case, the `ConvexityAdjustment` is subtracted from the futures rate.

Data Types: `double` | `function_handle`

`UpperBound` — Upper bound for rates associated with bonds or swaps
`1` (default) | scalar numeric | numeric vector

Upper bound for rates associated with bonds or swaps, specified as the comma-separated pair consisting of `'UpperBound'` and a scalar numeric or an `N`-by-`1` vector where `N` is the number of swaps and bonds. By default, `UpperBound` is `1`. Specify an upper bound that is greater than `1` when bootstrapping a discount curve.

Data Types: `double`

`LowerBound` — Lower bound for rates associated with bonds or swaps
`0` (default) | scalar numeric | numeric vector

Lower bound for rates associated with bonds or swaps, specified as the comma-separated pair consisting of `'LowerBound'` and a scalar numeric or an `N`-by-`1` vector where `N` is the number of swaps and bonds. By default, `LowerBound` is `0`.

Data Types: `double`

Properties

`ConvexityAdjustment` — Controls the convexity adjustment to interest rate futures
`[]` (default) | function handle | numeric vector

This property is read-only.

Controls the convexity adjustment to interest rate futures, returned as a function handle or an `N`-by-`1` numeric vector.

Data Types: `double` | `function_handle`

`UpperBound` — Upper bound for rates associated with bonds or swaps
`1` (default) | scalar numeric | numeric vector

Upper bound for rates associated with bonds or swaps, returned as a scalar numeric or an `N`-by-`1` vector.

Data Types: `double`

`LowerBound` — Lower bound for rates associated with bonds or swaps
`0` (default) | scalar numeric | numeric vector

Lower bound for rates associated with bonds or swaps, returned as a scalar numeric or an `N`-by-`1` vector.

Data Types: `double`

Object Functions

bootstrap Bootstrap interest-rate curve from market data

Examples

Create IRBootstrapOptionsObj to Use With the bootstrap Method

Set the `ConvexityAdjustment` to control interest-rate futures.

```
mybootoptions = IRBootstrapOptions('ConvexityAdjustment',repmat(.005,10,1))
```

```
mybootoptions =
  IRBootstrapOptions with properties:

    ConvexityAdjustment: [10x1 double]
             LowerBound: 0
             UpperBound: 1
```

Use `mybootoptions` as the optional argument, `IRBootstrapOptionsObj`, to use with the `bootstrap` method.

Create an IRBootstrapOptionsObj to Use With Negative Zero Interest-Rates

Use an `IRBootstrapOptionsObj` optional argument with the `bootstrap` method to allow for negative zero rates when solving the swap zero points.

```
Settle = datenum('15-Mar-2015');
InstrumentTypes = {'Deposit';'Deposit';'Swap';'Swap';'Swap';'Swap';};

Instruments = [Settle,datenum('15-Jun-2015'),.001; ...
Settle,datenum('15-Dec-2015'),.0005; ...
Settle,datenum('15-Mar-2016'),-.001; ...
Settle,datenum('15-Mar-2017'),-0.0005; ...
Settle,datenum('15-Mar-2018'),.0017; ...
Settle,datenum('15-Mar-2020'),.0019];

irbo = IRBootstrapOptions('LowerBound',-1);

bootModel = IRDataCurve.bootstrap('zero', Settle, InstrumentTypes,...
    Instruments,'IRBootstrapOptions',irbo);

bootModel.getZeroRates(datemnth(Settle,1:60))
```

```
ans = 60×1

    0.0012
    0.0011
    0.0010
    0.0009
    0.0008
    0.0008
    0.0007
    0.0006
    0.0005
   -0.0000
      ⋮
```

Note that `IRBootstrapOptions` optional argument for `LowerBound` is set to `-1` for negative zero rates when solving the swap zero points.

Version History

Introduced in R2008b

IRDataCurve

Construct interest-rate curve object from dates and data

Description

Build an `IRDataCurve` object using `IRDataCurve`.

After creating an `IRDataCurve` object, you can use the associated object functions:

Object Function	Description
`getForwardRates`	Returns forward rates for input dates.
`getZeroRates`	Returns zero rates for input dates.
`getDiscountFactors`	Returns discount factors for input dates.
`getParYields`	Returns par yields for input dates.
`toRateSpec`	Converts to be a `RateSpec` object; this structure is identical to the `RateSpec` produced by the function `intenvset`.
`bootstrap`	Bootstraps an interest rate curve from market data.

For more detailed information on this workflow, see “Interest-Rate Curve Objects and Workflow” on page 9-2.

Creation

Syntax

```
IRDataCurve_obj = IRDataCurve(Type,Settle,Dates,Data)
IRDataCurve_obj = IRDataCurve( ___ ,Name,Value)
```

Description

`IRDataCurve_obj = IRDataCurve(Type,Settle,Dates,Data)` sets properties on page 11-2094 and creates an `IRDataCurve` object.

Note The `ratecurve` object was introduced in R2020a as part of a new object-based framework in the Financial Instruments Toolbox which supports end-to-end workflows in instrument modeling and analysis. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22. While `IRDataCurve` can be used for building and analyzing yield curves, `ratecurve` provides that functionality, but it is also seamlessly integrated with instrument pricing functionality. For example, the `ratecurve` can be used to price instruments (`Discount`) and the `irbootstrap` function takes as inputs an array of instrument objects.

`IRDataCurve_obj = IRDataCurve( ___ ,Name,Value)` sets optional properties on page 11-2094 using name-value pairs and any of the arguments in the previous syntax. For example,

`IRDataCurve_obj = IRDataCurve('Zero',CurveSettle,Dates,Data,'Compounding',4,'Basis',4)` creates an `IRDataCurve` object for a zero curve. You can specify multiple name-value pair arguments.

Input Arguments

Type — Type of interest-rate curve

string with value `"zero"`, `"forward"`, or `"discount"` | character vector with value `'zero'`, `'forward'`, or `'discount'`

Type of interest-rate curve, specified as a scalar string or character vector for one of the supported types.

Data Types: `char` | `string`

Settle — Settlement date for the curve

datetime scalar | string scalar | date character vector

Settlement date for the curve, specified as a scalar datetime, string, or date character vector.

To support existing code, `IRDataCurve` also accepts serial date numbers as inputs, but they are not recommended.

Dates — Dates corresponding to rate data

datetime array | string array | date character vector

Dates corresponding to the rate data, specified as datetime array, string array, or a vector of date character vectors.

To support existing code, `IRDataCurve` also accepts serial date numbers as inputs, but they are not recommended.

Data — Interest-rate data for curve object

numeric vector

Interest-rate data for curve object, specified as a numeric vector.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `IRDataCurve_obj = IRDataCurve('Zero',CurveSettle,Dates,Data,'Compounding',4,'Basis',4)`

Compounding — Compounding frequency for curve

`-1` (default) | possible values include: `–1`, `0`, `1`, `2`, `3`, `4`, `6`, `12`.

Compounding frequency for the curve, specified as the comma-separated pair consisting of `'Compounding'` and a scalar numeric using the supported values: `–1`, `0`, `1`, `2`, `3`, `4`, `6`, or `12`.

Note Simple interest can be specified by setting the `Compounding` value as `0` and is supported for "zero" and "discount" curve types only (not supported for "forward" curves).

Data Types: `double`

`Basis` — Day count basis of interest-rate curve
`0` (actual/actual) (default) | integer from `0` to `13`

Day count basis of interest-rate curve, specified as the comma-separated pair consisting of `'Basis'` and a scalar integer.

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see "Basis" on page 2-228.

Data Types: `double`

`InterpMethod` — Interpolation method
`'linear'` (default) | character vector

Interpolation method, specified as the comma-separated pair consisting of `'InterpMethod'` and a character vector or string for one of the following values:

- `'linear'` — Linear interpolation (default)
- `'constant'` — Piecewise constant interpolation.
- `'pchip'` — Piecewise cubic Hermite interpolation.
- `'spline'` — Cubic spline interpolation

Data Types: `char` | `string`

Properties

Type — Type of interest-rate curve
string with value `"zero"`, `"forward"`, or `"discount"`

This property is read-only.

Instrument type, returned as a string.

Data Types: `string`

`Settle` — Settlement date

datetime

This property is read-only.

Settlement date, returned as a datetime.

Data Types: `datetime`

`Dates` — Dates corresponding to rate data

numeric vector

This property is read-only.

Dates corresponding to rate data, returned as a numeric vector.

Data Types: `double`

`Data` — Interest-rate data for the curve object

numeric

This property is read-only.

Interest-rate data for the curve object, returned as a numeric vector.

Data Types: `double`

`Compounding` — Compounding frequency for curve

`-1` (default) | possible values include: –1, `0`, 1, 2, 3, 4, 6, 12.

This property is read-only.

Compounding frequency for curve, returned as a scalar numeric.

Data Types: `double`

`Basis` — Day count basis

`0` (actual/actual) (default) | integer from `0` to `13`

This property is read-only.

Day count basis, returned as a scalar integer.

Data Types: `double`

`InterpMethod` — Interpolation method

`'linear'` (default) | character vector

This property is read-only.

Interpolation method, returned as a scalar character vector.

Data Types: `char`

Object Functions

getForwardRates	Get forward rates for input dates for IRDataCurve
getZeroRates	Get zero rates for input dates for IRDataCurve
getDiscountFactors	Get discount factors for input dates for IRDataCurve
getParYields	Get par yields for input dates for IRDataCurve
toRateSpec	Convert IRDataCurve object to RateSpec
bootstrap	Bootstrap interest-rate curve from market data

Examples

Create IRDataCurve Object

This example shows how to create an `IRDataCurve` object for an interest-rate curve.

Define the type of interest-rate curve, `Settle` date, `Dates`, and `Data`.

```
CurveSettle = datetime(2016,3,2);
Data = [2.09 2.47 2.71 3.12 3.43 3.85 4.57 4.58]/100;
Dates = datemnth(CurveSettle,12*[1 2 3 5 7 10 20 30]);
```

Use `IRDataCurve` to create an `IRDataCurve` object.

```
irdc = IRDataCurve('Zero',CurveSettle,Dates,Data,'Compounding',4,'Basis',4)
```

```
irdc =
             Type: Zero
           Settle: 736391 (02-Mar-2016)
      Compounding: 4
            Basis: 4 (30/360 (PSA))
     InterpMethod: linear
            Dates: [8x1 double]
             Data: [8x1 double]
```

Version History

Introduced in R2008b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `IRDataCurve` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

IRFitOptions

Construct specific options for fitting interest-rate curve object

Description

Build an `IRFitOptions` object using `IRFitOptions`.

After creating an `IRFitOptions` object, you can use the object with `fitFunction`.

For more detailed information on this workflow, see “Interest-Rate Curve Objects and Workflow” on page 9-2.

Creation

Syntax

```
IRFitOptions_obj = IRFitOptions(InitialGuess)
IRFitOptions_obj = IRFitOptions( ___ ,Name,Value)
```

Description

`IRFitOptions_obj = IRFitOptions(InitialGuess)` sets properties on page 11-2099 and create the `IRFitOptions` object with an initial guess or with an initial guess and bounds.

`IRFitOptions_obj = IRFitOptions( ___ ,Name,Value)` sets optional properties on page 11-2099 using name-value pairs and any of the arguments in the previous syntax. For example, `IRFitOptions_obj = IRFitOptions([7 2 1 0],'FitType','yield')` creates an `IRFitOptions` object to use with `fitFunction` when building a custom fitting function. You can specify multiple name-value pair arguments.

Input Arguments

`InitialGuess` — Initial guess for the parameters of the curve function
vector

Initial guess for the parameters of the curve function, specified as vector of values for the starting point of the optimization.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `IRFitOptions_obj = IRFitOptions([7 2 1 0],'FitType','yield')`

`FitType` — Minimize by in curve fitting process
`'DurationWeightedPrice'` (default) | character vector with value of `'DurationWeightedPrice'`, `'Price'`, or `'Yield'`

Minimize by in curve fitting process, specified as the comma-separated pair consisting of `'FitType'` and a character vector.

Data Types: `char`

`UpperBound` — Upper bound for parameters of curve function
`[]` (default) | numeric

Upper bound for parameters of the curve function, specified as the comma-separated pair consisting of `'UpperBound'` and a scalar numeric.

Data Types: `double`

`LowerBound` — Lower bound for parameters of curve function
`[]` (default) | numeric

Lower bound for parameters of the curve function, specified as the comma-separated pair consisting of `'LowerBound'` and a scalar numeric.

Data Types: `double`

`OptOptions` — Optimization parameters
`[]` (default) | structure

Optimization parameters, specified as the comma-separated pair consisting of `'OptOptions'` and a structure defined by using `optimoptions` (`optimset` is also supported).

Data Types: `struct`

Properties

`FitType` — Minimize by in curve fitting process
`'DurationWeightedPrice'` (default) | character vector with value of `'DurationWeightedPrice'`, `'Price'`, or `'Yield'`

This property is read-only.

Minimize by in curve fitting process, returned as a character vector.

Data Types: `char`

`InitialGuess` — Initial guess for the parameters of the curve function
vector

This property is read-only.

Initial guess for the parameters of the curve function, returned as a vector.

Data Types: `double`

`UpperBound` — Upper bound for parameters of curve function
`[]` (default) | numeric

This property is read-only.

Upper bound for parameters of the curve function, returned as a scalar numeric.

Data Types: `double`

`LowerBound` — Lower bound for parameters of curve function
`[]` (default) | numeric

This property is read-only.

Lower bound for parameters of the curve function, returned as a scalar numeric.

Data Types: `double`

`OptOptions` — Optimization parameters
`[]` (default) | structure

This property is read-only.

Optimization parameters, returned as a structure defined by using `optimoptions` (`optimset` is also supported).

Data Types: `struct`

`A` — Inequality constraint for parameters
`[]` (default) | numeric

This property is read-only.

Inequality constraint for parameters, returned as a scalar numeric.

Data Types: `double`

`b` — Inequality constraint for parameters
`[]` (default) | numeric

This property is read-only.

Inequality constraint for parameters, returned as a scalar numeric.

Data Types: `double`

`OptimFunction` — Optimization function used to fit function
`lsqnonlin` (default) | `lsqnonlin` or `fmincon`

This property is read-only.

Optimization function used to fit function, returned as `lsqnonlin` or `fmincon`.

Data Types: `char`

Object Functions

fitFunction Custom fit interest-rate curve object to bond market data

Examples

Create IRFitOptions Object

This example shows how to create an `IRFitOptions` object with a `'yield'` `FitType`.

```
myfitoptions = IRFitOptions([7 2 1 0],'FitType','yield')
```

```
myfitoptions =
  IRFitOptions with properties:

          FitType: 'yield'
     InitialGuess: [7 2 1 0]
       UpperBound: []
       LowerBound: []
       OptOptions: []
                A: []
                b: []
    OptimFunction: 'lsqnonlin'
```

Version History

Introduced in R2008b

IRFunctionCurve

Construct interest-rate curve object from function handle or function and fit to market data

Description

Build a `IRFunctionCurve` object using `IRFunctionCurve`.

After you create an `IRFunctionCurve` object, you can fit the bond using the following functions.

Object Function	Description
`getForwardRates`	Returns forward rates for input dates.
`getZeroRates`	Returns zero rates for input dates.
`getDiscountFactors`	Returns discount factors for input dates.
`getParYields`	Returns par yields for input dates.
`toRateSpec`	Converts to be a `RateSpec` object. This `RateSpec` structure is identical to the `RateSpec` produced by the function `intenvset`.

Alternatively, you can create an `IRFunctionCurve` object using the following methods.

Method	Description
`fitNelsonSiegel`	Fits a Nelson-Siegel function to market data.
`fitSvensson`	Fits a Svensson function to market data.
`fitSmoothingSpline`	Fits a smoothing spline function to market data.
`fitFunction`	Fits a custom function to market data.

For more detailed information on this workflow, see “Interest-Rate Curve Objects and Workflow” on page 9-2.

Creation

Syntax

```
IRFunctionCurve_obj = IRFunctionCurve(Type,Settle,FunctionHandle)
IRFunctionCurve_obj = IRFunctionCurve( ___ ,Name,Value)
```

Description

`IRFunctionCurve_obj = IRFunctionCurve(Type,Settle,FunctionHandle)` creates an interest-rate curve object directly by specifying a function handle and sets properties on page 11-2104 and creates an `IRFunctionCurve` object. .

`IRFunctionCurve_obj = IRFunctionCurve( ___ ,Name,Value)` sets properties on page 11-2104 using optional name-value pairs and any of the arguments in the previous syntax. For example,

`IRFunctionCurve_obj = IRFunctionCurve('Forward',today,@(t) polyval([-0.0001 0.003 0.02],t))` creates an `IRFunctionCurve` object for a forward curve. You can specify multiple name-value pair arguments.

Input Arguments

Type — Type of interest-rate curve

string with value `"zero"`, `"forward"`, or `"discount"` | character vector with value `'zero'`, `'forward'`, or `'discount'`

Type of interest-rate curve, specified as a scalar string or character vector for one of the supported types.

Data Types: `char` | `string`

Settle — Settlement date for the curve

datetime scalar | string scalar | date character vector

Settlement date for the curve, specified as a scalar datetime, string, or date character vector.

To support existing code, `IRFunctionCurve` also accepts serial date numbers as inputs, but they are not recommended.

FunctionHandle — Dates corresponding to rate data

function handle

Dates corresponding to the rate data, specified as a function handle. The function handle requires one numeric input (time-to-maturity) and returns one numeric output (interest rate or discount factor). For more information on creating a function handle, see “Create Function Handle”.

Data Types: `function_handle`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `IRFunctionCurve_obj = IRFunctionCurve('Forward',today,@(t) polyval([-0.0001 0.003 0.02],t))`

Compounding — Compounding frequency per-year for curve

`-1` (default) | possible values include: –1, `0`, 1, 2, 3, 4, 6, 12.

Compounding frequency per-year for the curve, specified as the comma-separated pair consisting of `'Compounding'` and a scalar numeric using the supported values: –1, `0`, 1, 2, 3, 4, 6, or 12.

Data Types: `double`

Basis — Day count basis of the bond

`0` (actual/actual) (default) | integer from `0` to 13

Day count basis of the bond, specified as the comma-separated pair consisting of `'Basis'` and a scalar integer.

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Parameters` — Curve parameters
`[ ]` (default) | numeric

Curve parameters, specified as the comma-separated pair consisting of `'Parameters'` and a numeric value.

Data Types: `double`

Properties

Type — Type of interest-rate curve
string with value `"zero"`, `"forward"`, or `"discount"`

This property is read-only.

Instrument type, returned as a string.

Data Types: `string`

`Settle` — Settlement date for the curve
datetime

This property is read-only.

Settlement date for the curve, returned as a datetime.

Data Types: `datetime`

`FunctionHandle` — Dates corresponding to rate data
function handle

This property is read-only.

Function handle that defines the interest-rate curve, returned as a scalar function handle.

Data Types: `function_handle`

`Compounding` — Compounding frequency per-year for curve
`-1` (default) | possible values include: –1, `0`, 1, 2, 3, 4, 6, 12.

This property is read-only.

Compounding frequency per-year for curve, returned as a scalar numeric.

Data Types: `double`

`Basis` — Day count basis of the bond
`0` (actual/actual) (default) | integer from `0` to `13`

This property is read-only.

Day count basis of the bond, returned as a scalar integer.

Data Types: `double`

`Parameters` — Curve parameters
`[ ]` (default) | numeric

This property is read-only.

Curve parameters, returned as a numeric value.

Data Types: `double`

Object Functions

getForwardRates	Get forward rates for input dates for IRFunctionCurve
getZeroRates	Get zero rates for input dates for IRFunctionCurve
getDiscountFactors	Get discount factors for input dates for IRFunctionCurve
getParYields	Get par yields for input dates for IRFunctionCurve
toRateSpec	Convert IRFunctionCurve object to RateSpec

Examples

Create IRFunctionCurve Object

This example shows how to create an `IRFunctionCurve` object for a forward interest-rate curve.

```
irfc = IRFunctionCurve('Forward',today,@(t) polyval([-0.0001 0.003 0.02],t))
```

```
irfc =
            Type: Forward
          Settle: 738764 (31-Aug-2022)
    Compounding: 2
           Basis: 0 (actual/actual)
```

Version History

Introduced in R2008b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `IRFunctionCurve` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

liborduration

Duration of LIBOR-based interest-rate swap

Syntax

```
[PayFixDuration,GetFixDuration] = liborduration(SwapFixRate,Tenor,Settle)
```

Description

`[PayFixDuration,GetFixDuration] = liborduration(SwapFixRate,Tenor,Settle)` computes the duration of LIBOR-based interest-rate swaps.

Examples

Compute the Duration of LIBOR-Based Interest-Rate Swaps

This example shows how to compute the duration of LIBOR-based interest-rate swaps using the following data.

```
SwapFixRate = 0.0383;
Tenor = 7;
Settle = datetime(2002,10,11);

[PayFixDuration GetFixDuration] = liborduration(SwapFixRate,...
Tenor, Settle)
```

```
PayFixDuration = -4.7567

GetFixDuration = 4.7567
```

Input Arguments

`SwapFixRate` — Par swap fixed rate

vector in decimals

Par swap fixed rate (quarterly compounded), specified as an `N`-by-`1` vector in decimals. The Basis should be actual/360.

Data Types: `double`

`Tenor` — Swap tenor in years

vector

Swap tenor in years, specified as a `N`-by-`1` vector. Fractional numbers are rounded upward.

Data Types: `double`

`Settle` — Settlement date

vector

Settlement date, specified as an N-by-1 vector using serial date numbers.

Data Types: double

Output Arguments

PayFixDuration — Modified duration, in years, for the pay-fix side of the swap
vector

Modified duration, in years, for the pay-fix side of the swap, returned as a N-by-1 vector.

GetFixDuration — Modified duration, in years, for the receive-fix side of the swap
vector

Modified duration, in years, for the receive-fix side of the swap, returned as a N-by-1 vector.

Version History

Introduced before R2006a

liborfloat2fixed

Compute par fixed-rate of swap given 3-month LIBOR data

Syntax

```
[FixedSpec,ForwardDates,ForwardRates] = liborfloat2fixed(ThreeMonthRates,
Settle,Tenor)
Price = liborprice( ___ ,StartDate,Interpolation,ConvexAdj,RateParam,InArrears,
Sigma,FixedCompound,FixedBasis)
```

Description

`[FixedSpec,ForwardDates,ForwardRates] = liborfloat2fixed(ThreeMonthRates, Settle,Tenor)` computes forward rates, dates, and the swap fixed rate.

Note The `liborfloat2fixed` function assumes that floating-rate observations occur quarterly on the third Wednesday of a delivery month. The first delivery month is the month of the first third Wednesday after `Settle`. Floating-side payments occur on the third-month anniversaries of observation dates. Fixed payments start on the same date as the first floating payment, and recur on the same date as the first-coupon date (on anniversary months).

`Price = liborprice( ___ ,StartDate,Interpolation,ConvexAdj,RateParam,InArrears, Sigma,FixedCompound,FixedBasis)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

Examples

Compute the Par Fixed-Rate of a Swap Given 3-Month LIBOR Data

This example shows how to compute the par fixed-rate of a swap given 3-month LIBOR data. Use the supplied `EDdata.xls` file as input to a `liborfloat2fixed` computation.

```
[EDFutData, textdata] = xlsread('EDdata.xls');
Settle                = datetime(2002,10,15);
Tenor                 = 2;

[FixedSpec, ForwardDates, ForwardRates] =...
liborfloat2fixed(EDFutData(:,1:3), Settle, Tenor)
```

```
FixedSpec = struct with fields:
      Coupon: 0.0222
      Settle: '16-Oct-2002'
    Maturity: '16-Oct-2004'
      Period: 4
       Basis: 1

ForwardDates = 8×1
```

```
      731505
      731596
      731687
      731778
      731869
      731967
      732058
      732149

ForwardRates = 8×1

    0.0177
    0.0166
    0.0170
    0.0188
    0.0214
    0.0248
    0.0279
    0.0305
```

Input Arguments

`ThreeMonthRates` — Three-month Eurodollar futures data or forward rate agreement data

matrix

Three-month Eurodollar futures data or forward rate agreement data, specified as an `N`-by-3 matrix in the form of `[month year IMMQuote]`. A forward rate agreement stipulates that a certain interest rate applies to a certain principal amount for a given future time period. The floating rate is assumed to compound quarterly and to accrue on an actual/360 basis.

Data Types: `double`

`Settle` — Settlement date of fixed-rate of swap

datetime scalar | string scalar | date character vector

Settlement date of fixed-rate of swap, specified as a scalar datetime, string, or date character vector.

To support existing code, `liborfloat2fixed` also accepts serial date numbers as inputs, but they are not recommended.

`Tenor` — Life of the swap contract

scalar integer

Life of the swap contract, specified as a scalar integer.

Data Types: `double`

`StartDate` — Reference date for valuation of forward swap

`Settle` (default) | datetime scalar | string scalar | date character vector

(Optional) Reference date for valuation of forward swap, specified as a scalar datetime, string, or date character vector. This in effect allows forward swap valuation.

To support existing code, `liborfloat2fixed` also accepts serial date numbers as inputs, but they are not recommended.

`Interpolation` — Interpolation method to determine applicable forward rate for months when no Eurodollar data is available
`'linear'` (1) (default) | scalar integer with value of `0`, `1`, or `2`

(Optional) Interpolation method to determine applicable forward rate for months when no Eurodollar data is available, specified as a scalar numeric with values of:

- `0` is `'nearest'`
- `1` is `'linear'`
- `2` is `'cubic'`

.

Data Types: `double`

`ConvexAdj` — Indicates whether futures/forward convexity adjustment is required
`0` (off) (default) | scalar logical with a value of `0` or `1`

(Optional) Indicates whether futures/forward convexity adjustment is required, specified as a scalar logical. Use `ConvexAdj` for forward rate adjustments when those rates are taken from Eurodollar futures data.

Data Types: `logical`

`RateParam` — Short-rate model's parameters (Hull-White)
`[0.05 0.015]` (default) | vector

(Optional) Short-rate model's parameters (Hull-White), specified a 1-by-2 vector to denote the parameters `[a S]`, where the short-rate process is:
$dr = [\theta(t) - ar]dt + Sdz$.

Data Types: `double`

`InArrears` — Indicates whether the swap is in arrears
`0` (off) (default) | scalar logical with a value of `0` or `1`

(Optional) Indicates whether the swap is in arrears, specified as a scalar logical.

Data Types: `logical`

`Sigma` — Overall annual volatility of caplets
scalar numeric

(Optional) Overall annual volatility of caplets, specified as a scalar numeric.

Data Types: `double`

`FixedCompound` — Compounding or frequency of payment on the fixed side
4 (quarterly) (default) | scalar numeric with possible values of 1, 2,4, or 12

(Optional) Compounding or frequency of payment on the fixed side, specified as a scalar numeric with one of the following possible values:

- 1 is annual
- 2 is semiannual
- 4 is quarterly
- 12 is monthly

Data Types: double

FixedBasis — Basis of the fixed side
0 (actual/actual) (default) | scalar numeric

(Optional) Basis of the fixed side, specified as a scalar numeric using one of the supported values:.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)

For more information, see “Basis” on page 2-228.

Data Types: double

Output Arguments

FixedSpec — Structure of the fixed-rate side of the swap
structure

Structure of the fixed-rate side of the swap, returned as a structure with the following fields:

- Coupon: Par-swap rate
- Settle: Start date
- Maturity: End date
- Period: Frequency of payment
- Basis: Accrual basis

ForwardDates — Dates corresponding to ForwardRates
numeric

Dates corresponding to `ForwardRates`, returned as datetime numbers. All of the dates are third Wednesdays of the month, spread three months apart. The first element is the third Wednesday immediately after `Settle`.

`ForwardRates` — Forward rates corresponding to the forward dates
numeric

Forward rates corresponding to the forward dates, quarterly compounded, and on the actual/360 basis, returned as numeric decimal values.

Version History

Introduced before R2006a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `liborfloat2fixed` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

liborprice

Price swap given swap rate

Syntax

```
Price = liborprice(ThreeMonthRates,Settle,Tenor,SwapRate)
Price = liborprice( ___ ,StartDate,Interpolation,ConvexAdj,RateParam,InArrears,
Sigma,FixedCompound,FixedBasis)
```

Description

`Price = liborprice(ThreeMonthRates,Settle,Tenor,SwapRate)` computes the price per $100 notional value of a swap given the swap rate. A positive result indicates that fixed side is more valuable than the floating side.

`Price = liborprice( ___ ,StartDate,Interpolation,ConvexAdj,RateParam,InArrears, Sigma,FixedCompound,FixedBasis)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

Examples

Compute the Price Per $100 Notional Value of a Swap Given the Swap Rate

This example shows that a swap paying the par swap rate has a value of `0`.

```
% load the input data
[EDFutData, textdata] = xlsread('EDdata.xls');
Settle = datetime(2002,10,15);
Tenor = 2;

% compute the fixed rate from the Eurodollar data
FixedSpec = liborfloat2fixed(EDFutData(:,1:3), Settle, Tenor)
```

```
FixedSpec = struct with fields:
      Coupon: 0.0222
      Settle: '16-Oct-2002'
    Maturity: '16-Oct-2004'
      Period: 4
       Basis: 1
```

```
% compute the price of a par swap
Price = liborprice(EDFutData(:,1:3), Settle, Tenor, FixedSpec.Coupon)
```

```
Price = 3.4694e-15
```

`Price` is effectively equal to 0.

Input Arguments

`ThreeMonthRates` — Three-month Eurodollar futures data or forward rate agreement data

matrix

Three-month Eurodollar futures data or forward rate agreement data, specified as an `N`-by-`3` matrix in the form of `[month year IMMQuote]`. A forward rate agreement stipulates that a certain interest rate applies to a certain principal amount for a given future time period. The floating rate is assumed to compound quarterly and to accrue on an actual/360 basis.

Data Types: `double`

`Settle` — Settlement date of fixed-rate of swap

datetime scalar | string scalar | date character vector

Settlement date of fixed-rate of swap, specified as a scalar datetime, string, or date character vector.

To support existing code, `liborprice` also accepts serial date numbers as inputs, but they are not recommended.

`Tenor` — Life of the swap contract

scalar integer

Life of the swap contract, specified as a scalar integer.

Data Types: `double`

`SwapRate` — Swap rate

scalar decimal

Swap rate, specified as a scalar decimal.

Data Types: `double`

`StartDate` — Reference date for valuation of forward swap

`Settle` (default) | datetime scalar | string scalar | date character vector

(Optional) Reference date for valuation of forward swap, specified as a scalar datetime, string, or date character vector. This in effect allows forward swap valuation.

To support existing code, `liborprice` also accepts serial date numbers as inputs, but they are not recommended.

`Interpolation` — Interpolation method to determine applicable forward rate for months when no Eurodollar data is available

`'linear'` (`1`) (default) | scalar integer with value of `0`, `1`, or `2`

(Optional) Interpolation method to determine applicable forward rate for months when no Eurodollar data is available, specified as a scalar numeric with values of:

- `0` is `'nearest'`
- `1` is `'linear'`
- `2` is `'cubic'`

.

Data Types: `double`

`ConvexAdj` — Indicates whether futures/forward convexity adjustment is required
`0` (off) (default) | scalar logical with a value of `0` or `1`

(Optional) Indicates whether futures/forward convexity adjustment is required, specified as a scalar logical. Use `ConvexAdj` for forward rate adjustments when those rates are taken from Eurodollar futures data.

Data Types: `logical`

`RateParam` — Short-rate model's parameters (Hull-White)
`[0.05 0.015]` (default) | vector

(Optional) Short-rate model's parameters (Hull-White), specified a 1-by-2 vector to denote the parameters `[a S]`, where the short-rate process is:
$dr = [\theta(t) - ar]dt + Sdz$.

Data Types: `double`

`InArrears` — Indicates whether the swap is in arrears
`0` (off) (default) | scalar logical with a value of `0` or `1`

(Optional) Indicates whether the swap is in arrears, specified as a scalar logical.

Data Types: `logical`

`Sigma` — Overall annual volatility of caplets
scalar numeric

(Optional) Overall annual volatility of caplets, specified as a scalar numeric.

Data Types: `double`

`FixedCompound` — Compounding or frequency of payment on the fixed side
4 (quarterly) (default) | scalar numeric with possible values of 1, 2,4, or 12

(Optional) Compounding or frequency of payment on the fixed side, specified as a scalar numeric with one of the following possible values:

- 1 is annual
- 2 is semiannual
- 4 is quarterly
- 12 is monthly

Data Types: `double`

`FixedBasis` — Basis of the fixed side
`0` (actual/actual) (default) | scalar numeric

(Optional) Basis of the fixed side, specified as a scalar numeric using one of the supported values:.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360

- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)

For more information, see “Basis” on page 2-228.

Data Types: `double`

Output Arguments

`Price` — Present value of the difference between floating and fixed-rate sides of the swap per $100 notional

numeric

Present value of the difference between floating and fixed-rate sides of the swap per $100 notional, returned as a numeric value.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `liborprice` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

mbscfamounts

Cash flow and time mapping for mortgage pool

Syntax

```
[CFlowAmounts,CFlowDates,TFactors,Factors,Payment,Principal,Interest,
Prepayment] = mbscfamounts(Settle,Maturity,IssueDate,GrossRate)
[CFlowAmounts,CFlowDates,TFactors,Factors,Payment,Principal,Interest,
Prepayment] = mbscfamounts( ___ ,CouponRate,Delay,PrepaySpeed,PrepayMatrix)
```

Description

`[CFlowAmounts,CFlowDates,TFactors,Factors,Payment,Principal,Interest, Prepayment] = mbscfamounts(Settle,Maturity,IssueDate,GrossRate)` computes cash flows between `Settle` and `Maturity` dates, the corresponding time factors in months from `Settle` and the mortgage factor (the fraction of loan principal outstanding).

Note Unlike `mbspassthrough`, `mbscfamounts` does not accept an original balance amount as an input. `mbscfamounts` assumes an original balance of 1.

`[CFlowAmounts,CFlowDates,TFactors,Factors,Payment,Principal,Interest, Prepayment] = mbscfamounts( ___ ,CouponRate,Delay,PrepaySpeed,PrepayMatrix)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

Examples

Calculate Cash Flow Amounts and Dates, Time Factors, and Mortgage Factors for a Single Mortgage

Given a mortgage with the following characteristics, compute the cash flow amounts and dates, the time factors, and the mortgage factors.

Define the mortgage characteristics.

```
Settle      = datetime(2002,4,17);
Maturity    = datetime(2030,1,1);
IssueDate   = datetime(2000,1,1);
GrossRate   = 0.08125;
CouponRate  = 0.075;
Delay       = 14;
PrepaySpeed = 100;
```

Use `mbscfamonts` to evaluate the mortgage.

```
[CFlowAmounts, CFLowDates, TFactors, Factors] = ...
mbscfamounts(Settle, Maturity, IssueDate, GrossRate, ...
CouponRate, Delay, PrepaySpeed)
```

```
CFlowAmounts = 1×334

   -0.0033    0.0118    0.0120    0.0121    0.0120    0.0119    0.0119    0.0118    0.0117    0.0

CFLowDates = 1×334

      731323      731337      731368      731398      731429      731460      731490      731521

TFactors = 1×334

         0    0.9333    1.9333    2.9333    3.9333    4.9333    5.9333    6.9333    7.9333    8.9

Factors = 1×334

    1.0000    0.9944    0.9887    0.9828    0.9769    0.9711    0.9653    0.9595    0.9538    0.9
```

The result is contained in four 334-element row vectors.

Compute Cash Flow Amounts and Dates, Time Factors, and Mortgage Factors for a Mortgage Portfolio

Given a portfolio of mortgage-backed securities, use `mbscfamounts` to compute the cash flows and other factors from the portfolio.

Define characteristics for a mortgage portfolio.

```
Settle   = [datetime(2000,1,13) ; datetime(2002,4,17) ; datetime(2002,5,17)];
Maturity    = datetime(2030,1,1);
IssueDate   = datetime(2000,1,1);
GrossRate   = 0.08125;
CouponRate  = [0.075; 0.07875; 0.0775];
Delay       = 14;
PrepaySpeed = 100;
```

Use `mbscfamonts` to evaluate the mortgage.

```
[CFlowAmounts, CFlowDates, TFactors, Factors] = ...
mbscfamounts(Settle, Maturity, IssueDate, GrossRate, ...
CouponRate, Delay, PrepaySpeed)
```

```
CFlowAmounts = 3×361

   -0.0025    0.0071    0.0072    0.0074    0.0076    0.0077    0.0079    0.0080    0.0082    0.0
   -0.0035    0.0121    0.0123    0.0124    0.0123    0.0122    0.0122    0.0121    0.0120    0.0
   -0.0034    0.0122    0.0123    0.0123    0.0122    0.0121    0.0121    0.0120    0.0119    0.0

CFlowDates = 3×361

      730498      730517      730546      730577      730607      730638      730668      730699
      731323      731337      731368      731398      731429      731460      731490      731521
```

```
      731353      731368      731398      731429      731460      731490      731521      731551

TFactors = 3×361

         0    1.0667    2.0667    3.0667    4.0667    5.0667    6.0667    7.0667    8.0667    9.0
         0    0.9333    1.9333    2.9333    3.9333    4.9333    5.9333    6.9333    7.9333    8.9
         0    0.9333    1.9333    2.9333    3.9333    4.9333    5.9333    6.9333    7.9333    8.9

Factors = 3×361

    1.0000    0.9992    0.9982    0.9970    0.9957    0.9942    0.9925    0.9907    0.9887    0.9
    1.0000    0.9944    0.9887    0.9828    0.9769    0.9711    0.9653    0.9595    0.9538    0.9
    1.0000    0.9942    0.9883    0.9824    0.9766    0.9707    0.9649    0.9592    0.9534    0.9
```

Each output is a 3-by-361 element matrix padded with `NaN`'s wherever elements are missing.

Calculate Payment, Principal, Interest, and Prepayment for a Single Mortgage

Given a mortgage with the following characteristics, compute payments, principal, interest, and prepayment.

Define the mortgage characteristics.

```
Settle      = datetime(2002,4,17);
Maturity    = datetime(2030,1,1);
IssueDate   = datetime(2000,1,1);
GrossRate   = 0.08125;
CouponRate  = 0.075;
Delay       = 14;
PrepaySpeed = 100;
```

Use `mbscfamonts` to evaluate the mortgage.

```
[Payment, Principal, Interest, Prepayment] = ...
mbscfamounts(Settle, Maturity, IssueDate, GrossRate, ...
CouponRate, Delay, PrepaySpeed)
```

```
Payment = 1×334

```

Input Arguments

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date, specified as an `NMBS`-by-1 vector using a datetime array, string array, or date character vectors. `Settle` must be earlier than `Maturity`.

To support existing code, `mbscfamounts` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as an `NMBS`-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, `mbscfamounts` also accepts serial date numbers as inputs, but they are not recommended.

`IssueDate` — Issue date

datetime array | string array | date character vector

Issue date, specified as an `NMBS`-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, `mbscfamounts` also accepts serial date numbers as inputs, but they are not recommended.

`GrossRate` — Gross coupon rate (including fees)

vector of decimal values

Gross coupon rate (including fees), specified as an `NMBS`-by-1 vector of decimal values.

Data Types: `double`

`CouponRate` — Net coupon rate

`GrossRate` (default) | vector of decimal values

(Optional) Net coupon rate, specified as an `NMBS`-by-1 vector of decimal values.

Data Types: `double`

`Delay` — Delay (in days) between payment from homeowner and receipt by bondholder

`0` (no delay between payment and receipt) (default) | vector

(Optional) Delay (in days) between payment from homeowner and receipt by bondholder, specified as an `NMBS`-by-1 vector.

Data Types: `double`

`PrepaySpeed` — Speed relative to PSA standard

`0` (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an NMBS-by-1 vector. The PSA standard is 100.

Note Set the PrepaySpeed to [] if you input a customized PrepayMatrix.

Data Types: double

PrepayMatrix — Customized prepayment vector
matrix

(Optional) Customized prepayment vector, specified as a NaN-padded matrix of size max(TermRemaining)-by-NMBS. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

Note Use PrepayMatrix only when PrepaySpeed is unspecified.

Data Types: double

Output Arguments

CFlowAmounts — Cash flow amounts
matrix

Cash flows starting from Settle through end of the last month (Maturity), returned as a NMBS-by-P matrix.

CFlowDates — Cash flow dates
matrix

Cash flow dates (including at Settle), returned as a NMBS-by-P matrix.

TFactors — Time factors
matrix

Time factors (in months from Settle), returned as a NMBS-by-P matrix.

Factors — Mortgage factors (the fraction of the balance still outstanding at the end of each month)
matrix

Mortgage factors (the fraction of the balance still outstanding at the end of each month), returned as a NMBS-by-P matrix.

Payment — Total monthly payment
matrix

Total monthly payment, returned as a NMBS-by-P matrix.

Principal — Principal portion of the payment
matrix

Principal portion of the payment, returned as a NMBS-by-P matrix.

`Interest` — Interest portion of the payment
matrix

Interest portion of the payment, returned as a `NMBS`-by-`P` matrix.

`Prepayment` — Unscheduled payment of principal
matrix

Unscheduled payment of principal, returned as a `NMBS`-by-`P` matrix.

Version History

Introduced in R2012a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `mbscfamounts` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

mbsconvp

Convexity of mortgage pool given price

Syntax

```
Convexity = mbsconvp(Price,Settle,Maturity,IssueDate,GrossRate)
Convexity = mbsconvp( ___ ,CouponRate,Delay,PrepaySpeed,PrepayMatrix)
```

Description

`Convexity = mbsconvp(Price,Settle,Maturity,IssueDate,GrossRate)` computes mortgage-backed security convexity, given time information, price at settlement, and optionally, a prepayment model.

`Convexity = mbsconvp( ___ ,CouponRate,Delay,PrepaySpeed,PrepayMatrix)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

Examples

Compute a Mortgage-Backed Security Convexity

This example shows how to compute a mortgage-backed security convexity, given a mortgage-backed security with the following characteristics.

```
Price      = 101;
Settle     = '15-Apr-2002';
Maturity   = '1 Jan 2030';
IssueDate  = '1-Jan-2000';
GrossRate  = 0.08125;
CouponRate = 0.075;
Delay = 14;
Speed = 100;

Convexity = mbsconvp(Price, Settle, Maturity, IssueDate,...
GrossRate, CouponRate, Delay, Speed)

Convexity = 71.6299
```

Input Arguments

`Price` — Clean price for every $100 face value

vector

Clean price for every $100 face value, specified as an `NMBS`-by-`1` vector.

Data Types: `double`

Settle — Settlement dates
vector

Settlement dates, specified as an NMBS-by-1 vector of serial date numbers or a cell array of character vectors.

Data Types: double | cell

Maturity — Maturity dates
vector

Maturity dates, specified as an NMBS-by-1 vector of serial date numbers or a cell array of character vectors.

Data Types: double | cell

IssueDate — Issue dates
vector

Maturity dates, specified as an NMBS-by-1 vector of serial date numbers or a cell array of character vectors.

Data Types: double | cell

GrossRate — Gross coupon rate (including fees)
vector

Gross coupon rate (including fees), specified as an NMBS-by-1 vector of numeric decimals.

Data Types: double

CouponRate — Net coupon rate
GrossRate (default) | vector

(Optional) Net coupon rate, specified as an NMBS-by-1 vector of numeric decimals.

Data Types: double

Delay — Delay in days
0 (no delay) (default) | vector

(Optional) Delay in days, specified as an NMBS-by-1 vector.

Data Types: double

PrepaySpeed — Speed relative to PSA standard
0 (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an NMBS-by-1 vector. The PSA standard is 100.

Note Set the PrepaySpeed to [] if you input a customized PrepayMatrix.

Data Types: double

PrepayMatrix — Customized prepayment vector
matrix

(Optional) Customized prepayment vector, specified as a `NaN`-padded matrix of size `max(TermRemaining)`-by-`NMBS`. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

Note Use `PrepayMatrix` only when `PrepaySpeed` is unspecified.

Data Types: `double`

Output Arguments

`Convexity` — Periodic convexity of mortgage pool

scalar numeric

Periodic convexity of mortgage pool, returned as a scalar numeric.

Version History

Introduced before R2006a

mbsconvy

Convexity of mortgage pool given yield

Syntax

```
Convexity = mbsconvy(Yield,Settle,Maturity,IssueDate,GrossRate)
Convexity = mbsconvy( ___ ,CouponRate,Delay,PrepaySpeed,PrepayMatrix)
```

Description

`Convexity = mbsconvy(Yield,Settle,Maturity,IssueDate,GrossRate)` computes mortgage-backed security convexity, given time information, semiannual mortgage yield, and optionally, a prepayment model.

`Convexity = mbsconvy( ___ ,CouponRate,Delay,PrepaySpeed,PrepayMatrix)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

Examples

Compute the Convexity of a Mortgage Pool Given Yield

This example shows how to compute the convexity of mortgage pool given yield for a mortgage-backed security with the following characteristics.

```
Yield      = 0.07125;
Settle     = '15-Apr-2002';
Maturity   = '1 Jan 2030';
IssueDate  = '1-Jan-2000';
GrossRate  = 0.08125;
Speed      = 100;
CouponRate = 0.075;
Delay = 14;

Convexity = mbsconvy(Yield, Settle, Maturity, IssueDate, ...
GrossRate, CouponRate, Delay, Speed)

Convexity = 72.8263
```

Input Arguments

`Yield` — Mortgage yield, compounded monthly

vector

Mortgage yield, compounded monthly, specified as an `NMBS`-by-`1` vector in decimals.

Data Types: `double`

`Settle` — Settlement dates
vector

Settlement dates, specified as an `NMBS`-by-`1` vector of serial date numbers or a cell array of character vectors. `Settle` must be earlier than `Maturity`.

Data Types: `double` | `cell`

`Maturity` — Maturity dates
vector

Maturity dates, specified as an `NMBS`-by-`1` vector of serial date numbers or a cell array of character vectors.

Data Types: `double` | `cell`

`IssueDate` — Issue dates
vector

Maturity dates, specified as an `NMBS`-by-`1` vector of serial date numbers or a cell array of character vectors.

Data Types: `double` | `cell`

`GrossRate` — Gross coupon rate (including fees)
vector

Gross coupon rate (including fees), specified as an `NMBS`-by-`1` vector of numeric decimals.

Data Types: `double`

`CouponRate` — Net coupon rate
`GrossRate` (default) | vector

(Optional) Net coupon rate, specified as an `NMBS`-by-`1` vector of numeric decimals.

Data Types: `double`

`Delay` — Delay in days
`0` (no delay) (default) | vector

(Optional) Delay in days, specified as an `NMBS`-by-`1` vector.

Data Types: `double`

`PrepaySpeed` — Speed relative to PSA standard
`0` (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an `NMBS`-by-`1` vector. The PSA standard is `100`.

Note Set the `PrepaySpeed` to `[]` if you input a customized `PrepayMatrix`.

Data Types: `double`

`PrepayMatrix` — Customized prepayment vector
matrix

(Optional) Customized prepayment vector, specified as a `NaN`-padded matrix of size `max(TermRemaining)`-by-`NMBS`. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

Note Use `PrepayMatrix` only when `PrepaySpeed` is unspecified.

Data Types: `double`

Output Arguments

`Convexity` — Periodic convexity of mortgage pool

scalar numeric

Periodic convexity of mortgage pool, returned as a scalar numeric.

Version History

Introduced before R2006a

mbsdurp

Duration of mortgage pool given price

Syntax

```
[YearDuration,ModDuration] = mbsdurp(Price,Settle,Maturity,IssueDate,
GrossRate)
[YearDuration,ModDuration] = mbsdurp( ___ ,CouponRate,Delay,PrepaySpeed,
PrepayMatrix)
```

Description

`[YearDuration,ModDuration] = mbsdurp(Price,Settle,Maturity,IssueDate, GrossRate)` computes the mortgage-backed security Macaulay (`YearDuration`) in years and modified (`ModDuration`) durations in years, given time information, price at settlement, and optionally, a prepayment model.

`[YearDuration,ModDuration] = mbsdurp( ___ ,CouponRate,Delay,PrepaySpeed, PrepayMatrix)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

Examples

Find the Duration of a Mortgage Pool

This example shows how to find the duration of mortgage pool given a mortgage-backed security with the following characteristics.

```
Price = 101;
Settle = datenum('15-Apr-2002');
Maturity = datenum('1 Jan 2030');
IssueDate = datenum('1-Jan-2000');
GrossRate = 0.08125;
CouponRate = 0.075;;
Delay = 14;
Speed = 100;

[YearDuration, ModDuration] = mbsdurp(Price, Settle, Maturity,...
IssueDate, GrossRate, CouponRate, Delay, Speed)
```

```
YearDuration = 6.4380

ModDuration = 6.2080
```

Input Arguments

`Price` — Clean price for every $100 face of issue

vector

Clean price for every $100 face of issue, specified as an NMBS-by-1 vector.

Data Types: double

Settle — Settlement dates
vector

Settlement dates, specified as an NMBS-by-1 vector of serial date numbers or a cell array of character vectors. Settle must be earlier than Maturity.

Data Types: double | cell

Maturity — Maturity dates
vector

Maturity dates, specified as an NMBS-by-1 vector of serial date numbers or a cell array of character vectors.

Data Types: double | cell

IssueDate — Issue dates
vector

Maturity dates, specified as an NMBS-by-1 vector of serial date numbers or a cell array of character vectors.

Data Types: double | cell

GrossRate — Gross coupon rate (including fees)
vector

Gross coupon rate (including fees), specified as an NMBS-by-1 vector of numeric decimals.

Data Types: double

CouponRate — Net coupon rate
GrossRate (default) | vector

(Optional) Net coupon rate, specified as an NMBS-by-1 vector of numeric decimals.

Data Types: double

Delay — Delay in days
0 (no delay) (default) | vector

(Optional) Delay in days, specified as an NMBS-by-1 vector.

Data Types: double

PrepaySpeed — Speed relative to PSA standard
0 (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an NMBS-by-1 vector. The PSA standard is 100.

Note Set the PrepaySpeed to [] if you input a customized PrepayMatrix.

Data Types: double

`PrepayMatrix` — Customized prepayment vector
matrix

(Optional) Customized prepayment vector, specified as a `NaN`-padded matrix of size `max(TermRemaining)`-by-`NMBS`. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

Note Use `PrepayMatrix` only when `PrepaySpeed` is unspecified.

Data Types: `double`

Output Arguments

`YearDuration` — Macaulay duration in years
scalar numeric

Macaulay duration in years, returned as a scalar numeric.

`ModDuration` — Modified duration in years
scalar numeric

Modified duration in years, returned as a scalar numeric.

Version History

Introduced before R2006a

mbsdury

Duration of mortgage pool given yield

Syntax

```
[YearDuration,ModDuration] = mbsdury(Yield,Settle,Maturity,IssueDate,
GrossRate)
[YearDuration,ModDuration] = mbsdury( ___ ,CouponRate,Delay,PrepaySpeed,
PrepayMatrix)
```

Description

`[YearDuration,ModDuration] = mbsdury(Yield,Settle,Maturity,IssueDate, GrossRate)` computes the mortgage-backed security Macaulay (`YearDuration`) in years and modified (`ModDuration`) durations in years, given time information, yield to maturity, and optionally, a prepayment model.

`[YearDuration,ModDuration] = mbsdury( ___ ,CouponRate,Delay,PrepaySpeed, PrepayMatrix)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

Examples

Find the Duration of a Mortgage Pool Given the Yield

This example shows how to find the duration of mortgage pool given a mortgage-backed security with the following characteristics.

```
Yield = 0.07298413;
Settle = '15-Apr-2002';
Maturity = '1 Jan 2030';
IssueDate = '1-Jan-2000';
GrossRate = 0.08125;
Speed = 100;
CouponRate = 0.075;
Delay = 14;

[YearDuration, ModDuration] = mbsdury(Yield, Settle, Maturity,...
IssueDate, GrossRate, CouponRate, Delay, Speed)
```

```
YearDuration = 6.4380
```

```
ModDuration = 6.2080
```

Input Arguments

`Yield` — Mortgage yield, compounded monthly

vector

Mortgage yield, compounded monthly, specified as an NMBS-by-1 vector in decimals.

Data Types: double

Settle — Settlement dates
vector

Settlement dates, specified as an NMBS-by-1 vector of serial date numbers or a cell array of character vectors. Settle must be earlier than Maturity.

Data Types: double | cell

Maturity — Maturity dates
vector

Maturity dates, specified as an NMBS-by-1 vector of serial date numbers or a cell array of character vectors.

Data Types: double | cell

IssueDate — Issue dates
vector

Maturity dates, specified as an NMBS-by-1 vector of serial date numbers or a cell array of character vectors.

Data Types: double | cell

GrossRate — Gross coupon rate (including fees)
vector

Gross coupon rate (including fees), specified as an NMBS-by-1 vector of numeric decimals.

Data Types: double

CouponRate — Net coupon rate
GrossRate (default) | vector

(Optional) Net coupon rate, specified as an NMBS-by-1 vector of numeric decimals.

Data Types: double

Delay — Delay in days
0 (no delay) (default) | vector

(Optional) Delay in days, specified as an NMBS-by-1 vector.

Data Types: double

PrepaySpeed — Speed relative to PSA standard
0 (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an NMBS-by-1 vector. The PSA standard is 100.

Note Set the PrepaySpeed to [] if you input a customized PrepayMatrix.

Data Types: double

PrepayMatrix — Customized prepayment vector
matrix

(Optional) Customized prepayment vector, specified as a NaN-padded matrix of size max(TermRemaining)-by-NMBS. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

Note Use PrepayMatrix only when PrepaySpeed is unspecified.

Data Types: double

Output Arguments

YearDuration — Macaulay duration in years
scalar numeric

Macaulay duration in years, returned as a scalar numeric.

ModDuration — Modified duration in years
scalar numeric

Modified duration in years, returned as a scalar numeric.

Version History

Introduced before R2006a

mbsnoprepay

End-of-month mortgage cash flows and balances without prepayment

Syntax

```
[Balance,Interest,Payment,Principal] = mbsnoprepay(OriginalBalance,GrossRate,
Term)
```

Description

`[Balance,Interest,Payment,Principal] = mbsnoprepay(OriginalBalance,GrossRate, Term)` computes end-of-month mortgage balance, interest payments, principal payments, and cash flow payments with zero prepayment rate.

`mbsnoprepay` returns amortizing cash flows and balances over a specified term with no prepayment. When the lengths of pass-throughs are not the same, MATLAB software pads the shorter ones with `NaN`.

Examples

Compute an Amortization Schedule from Mortgage Pools

Given mortgage pools with the following characteristics, compute an amortization schedule.

```
OriginalBalance = 400000000;
CouponRate = 0.08125;
Term = [357; 355]; % Three- and five-month old mortgage pools.

[Balance, Interest, Payment, Principal] = mbsnoprepay(OriginalBalance, CouponRate, Term)
```

      ⋮
```

Input Arguments

`OriginalBalance` — Original face value in dollars

vector

Original face value in dollars, specified as a table or an `NUMOBS`-by-1 matrix.

Data Types: `double`

`GrossRate` — Gross coupon rate (including fees)

vector of decimal values

Gross coupon rate (including fees), specified as an `NUMOBS`-by-1 vector of decimal values.

Data Types: `double`

`Term` — Term of the mortgage in months
vector

Term of the mortgage in months, specified as an `NUMOBS`-by-`1` vector.

Data Types: `double`

Output Arguments

`Balance` — End-of-month balances over the life of the pass-through
vector

End-of-month balances over the life of the pass-through, returned as a `Term`-by-`1` vector.

`Interest` — End-of-month interest payments over the life of the pass-through
vector

End-of-month interest payments over the life of the pass-through, returned as a `Term`-by-`1` vector.

`Payment` — End-of-month payments over the life of the pass-through
vector

End-of-month payments over the life of the pass-through, returned as a `Term`-by-`1` vector.

`Principal` — All scheduled end-of-month principal payments over the life of the pass-through
vector

All scheduled end-of-month principal payments over the life of the pass-through, returned as a `Term`-by-`1` vector.

mbsoas2price

Price given option-adjusted spread

Syntax

```
Price = mbsoas2price(ZeroCurve,OAS,Settle,Maturity,IssueDate,GrossRate)
Price = mbsoas2price( ___ ,CouponRate,Delay,Interpolation,PrepaySpeed,
PrepayMatrix)
```

Description

`Price = mbsoas2price(ZeroCurve,OAS,Settle,Maturity,IssueDate,GrossRate)` computes the clean price of a pass-through security for each $100 face value of outstanding principal.

`Price = mbsoas2price( ___ ,CouponRate,Delay,Interpolation,PrepaySpeed, PrepayMatrix)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

Examples

Compute the Theoretical Price of a Mortgage Pool

Given an option-adjusted spread, a spot curve, and a prepayment assumption, compute theoretical price of a mortgage pool. First, create the bonds matrix:

```
Bonds = [datenum('11/21/2002')  0        100  0  2  1;
         datenum('02/20/2003')  0        100  0  2  1;
         datenum('07/31/2004')  0.03     100  2  3  1;
         datenum('08/15/2007')  0.035    100  2  3  1;
         datenum('08/15/2012')  0.04875  100  2  3  1;
         datenum('02/15/2031')  0.05375  100  2  3  1];
```

Choose a settlement date.

```
Settle = datenum('20-Aug-2002');
```

Assume the following clean prices for the bonds:

```
Prices =  [ 98.97467;
            98.58044;
           100.10534;
            98.18054;
           101.38136;
            99.25411];
```

Use the following formula to compute spot compounding for the bonds:

```
SpotCompounding = 2*ones(size(Prices));
```

Compute the zero curve.

```
[ZeroRatesP, CurveDatesP] = zbtprice(Bonds, Prices, Settle);
ZeroCurve = [CurveDatesP, ZeroRatesP, SpotCompounding]
```

```
ZeroCurve = 6×3
10^5 ×

    7.3154    0.0000    0.0000
    7.3163    0.0000    0.0000
    7.3216    0.0000    0.0000
    7.3327    0.0000    0.0000
    7.3510    0.0000    0.0000
    7.4185    0.0000    0.0000
```

Assign the following parameters:

```
OAS           = [26.0502; 28.6348; 31.2222];
Maturity      = datenum('02-Jan-2030');
IssueDate     = datenum('02-Jan-2000');
GrossRate     = 0.08125;
CouponRate    = 0.075;
Delay         = 14;
Interpolation = 1;
PrepaySpeed   = [0 50 100];
```

Calculate the theoretical price from the option-adjusted spread.

```
Price = mbsoas2price(ZeroCurve, OAS, Settle, Maturity, ...
IssueDate, GrossRate, CouponRate, Delay, Interpolation, ...
PrepaySpeed)
```

```
Price = 3×1

  124.7133
  120.9534
  118.0698
```

Input Arguments

ZeroCurve — Zero curve

matrix

Zero curve, specified as a three-column matrix, where:

- Column 1 is dates using serial date numbers.
- Column 2 is spot rates with maturities corresponding to the dates in Column 1, in decimal (for example, 0.075).
- Column 3 is the compounding value of the rates in Column 2. (This is the agency spot rate on the settlement date.) Allowable compounding values are: 1 (annual), 2 (semiannual, 3 (three times per year), 4 (quarterly), 6 (bimonthly), 12 (monthly), and -1 (continuous).

For example:

```
[datenum('11/21/2002')  0        100  0  2  1;
 datenum('02/20/2003')  0        100  0  2  1;
```

```
 datenum('07/31/2004')  0.03     100  2  3  1;
 datenum('08/15/2007')  0.035    100  2  3  1;
 datenum('08/15/2012')  0.04875  100  2  3  1;
 datenum('02/15/2031')  0.05375  100  2  3  1];
```

Data Types: `double` | `cell`

`OAS` — Option-adjusted spreads
vector

Option-adjusted spreads, in basis points, specified as an `NMBS`-by-1 vector.

Data Types: `double`

`Settle` — Settlement date
serial date number | date character vector

Settlement date, specified as an `NMBS`-by-1 vector using serial date numbers or date character vectors. `Settle` must be earlier than `Maturity`.

Data Types: `double` | `char`

`Maturity` — Maturity date
serial date number | date character vector

Maturity date, specified as an `NMBS`-by-1 vector using serial date numbers or date character vectors.

Data Types: `double` | `char`

`IssueDate` — Issue date
serial date number | date character vector

Issue date, specified as an `NMBS`-by-1 vector using serial date numbers or date character vectors.

Data Types: `double` | `char`

`GrossRate` — Gross coupon rate (including fees)
vector of decimal values

Gross coupon rate (including fees), specified as an `NMBS`-by-1 vector of decimal values.

Data Types: `double`

`CouponRate` — Net coupon rate
`GrossRate` (default) | vector of decimal values

(Optional) Net coupon rate, specified as an `NMBS`-by-1 vector of decimal values.

Data Types: `double`

`Delay` — Delay (in days) between payment from homeowner and receipt by bondholder
`0` (no delay between payment and receipt) (default) | vector

(Optional) Delay (in days) between payment from homeowner and receipt by bondholder, specified as an `NMBS`-by-1 vector.

Data Types: `double`

`Interpolation` — Interpolation method to compute the corresponding spot rates for the bond's cash flow
`1` (linear) (default) | vector

(Optional) Interpolation method to compute the corresponding spot rates for the bond's cash flow, specified as an `NMBS`-by-`1` vector. Available methods are (`0`) nearest, (`1`) linear, and (`2`) cubic spline. For more information on the supported interpolation methods, see `interp1`.

Data Types: `double`

`PrepaySpeed` — Speed relative to PSA standard
`0` (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an `NMBS`-by-`1` vector. The PSA standard is `100`.

Note Set the `PrepaySpeed` to `[]` if you input a customized `PrepayMatrix`.

Data Types: `double`

`PrepayMatrix` — Customized prepayment vector
matrix

(Optional) Customized prepayment vector, specified as a `NaN`-padded matrix of size `max(TermRemaining)`-by-`NMBS`. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

Note Use `PrepayMatrix` only when `PrepaySpeed` is unspecified.

Data Types: `double`

Output Arguments

`Price` — Clean price of passthrough per $100 face of principal outstanding
vector

Clean price of passthrough per $100 face of principal outstanding, returned as a `NMBS`-by-`1` vector.

Version History

Introduced before R2006a

mbsoas2yield

Yield given option-adjusted spread

Syntax

```
[MYield,BEMBSYield] = mbsoas2yield(ZeroCurve,OAS,Settle,Maturity,IssueDate,
GrossRate)
[MYield,BEMBSYield] = mbsoas2yield( ___ ,CouponRate,Delay,Interpolation,
PrepaySpeed,PrepayMatrix)
```

Description

`[MYield,BEMBSYield] = mbsoas2yield(ZeroCurve,OAS,Settle,Maturity,IssueDate, GrossRate)` computes the mortgage and bond-equivalent yields of a pass-through security.

`[MYield,BEMBSYield] = mbsoas2yield( ___ ,CouponRate,Delay,Interpolation, PrepaySpeed,PrepayMatrix)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

Examples

Compute the Theoretical Yield to Maturity of a Mortgage Pool

Given an option-adjusted spread, a spot curve, and a prepayment assumption, compute the theoretical yield to maturity of a mortgage pool. First, create the bonds matrix:

```
Bonds = [datenum('11/21/2002')  0        100  0  2  1;
         datenum('02/20/2003')  0        100  0  2  1;
         datenum('07/31/2004')  0.03     100  2  3  1;
         datenum('08/15/2007')  0.035    100  2  3  1;
         datenum('08/15/2012')  0.04875  100  2  3  1;
         datenum('02/15/2031')  0.05375  100  2  3  1];
```

Choose a settlement date.

```
Settle = datenum('20-Aug-2002');
```

Assume the following clean prices for the bonds:

```
Prices =  [ 98.97467;
            98.58044;
           100.10534;
            98.18054;
           101.38136;
            99.25411];
```

Use the following formula to compute spot compounding for the bonds:

```
SpotCompounding = 2*ones(size(Prices));
```

Compute the zero curve.

```
[ZeroRatesP, CurveDatesP] = zbtprice(Bonds, Prices, Settle);
ZeroCurve = [CurveDatesP, ZeroRatesP, SpotCompounding]
```

```
ZeroCurve = 6×3
10^5 ×

    0.0513
    0.0499

BEMBSYield = 3×1

    0.0533
    0.0518
    0.0504
```

Input Arguments

ZeroCurve — Zero curve

matrix

Zero curve, specified as a three-column matrix, where:

- Column 1 is dates using serial date numbers.
- Column 2 is spot rates with maturities corresponding to the dates in Column 1, in decimal (for example, 0.075).

- Column 3 is the compounding value of the rates in Column 2. (This is the agency spot rate on the settlement date.) Allowable compounding values are: 1 (annual), 2 (semiannual, 3 (three times per year), 4 (quarterly), 6 (bimonthly), 12 (monthly), and -1 (continuous).

For example:

```
[datenum('11/21/2002')  0        100  0  2  1;
 datenum('02/20/2003')  0        100  0  2  1;
 datenum('07/31/2004')  0.03     100  2  3  1;
 datenum('08/15/2007')  0.035    100  2  3  1;
 datenum('08/15/2012')  0.04875  100  2  3  1;
 datenum('02/15/2031')  0.05375  100  2  3  1];
```

Data Types: `double` | `cell`

`OAS` — Option-adjusted spreads
vector

Option-adjusted spreads, in basis points, specified as an `NMBS`-by-1 vector.

Data Types: `double`

`Settle` — Settlement date
serial date number | date character vector

Settlement date, specified as an `NMBS`-by-1 vector using serial date numbers or date character vectors. `Settle` must be earlier than `Maturity`.

Data Types: `double` | `char`

`Maturity` — Maturity date
serial date number | date character vector

Maturity date, specified as an `NMBS`-by-1 vector using serial date numbers or date character vectors.

Data Types: `double` | `char`

`IssueDate` — Issue date
serial date number | date character vector

Issue date, specified as an `NMBS`-by-1 vector using serial date numbers or date character vectors.

Data Types: `double` | `char`

`GrossRate` — Gross coupon rate (including fees)
vector of decimal values

Gross coupon rate (including fees), specified as an `NMBS`-by-1 vector of decimal values.

Data Types: `double`

`CouponRate` — Net coupon rate
`GrossRate` (default) | vector of decimal values

(Optional) Net coupon rate, specified as an `NMBS`-by-1 vector of decimal values.

Data Types: `double`

`Delay` — Delay (in days) between payment from homeowner and receipt by bondholder
`0` (no delay between payment and receipt) (default) | vector

(Optional) Delay (in days) between payment from homeowner and receipt by bondholder, specified as an `NMBS`-by-`1` vector.

Data Types: `double`

`Interpolation` — Interpolation method to compute the corresponding spot rates for the bond's cash flow
`1` (linear) (default) | vector

(Optional) Interpolation method to compute the corresponding spot rates for the bond's cash flow, specified as an `NMBS`-by-`1` vector. Available methods are (`0`) nearest, (`1`) linear, and (`2`) cubic spline. For more information on the supported interpolation methods, see `interp1`.

Data Types: `double`

`PrepaySpeed` — Speed relative to PSA standard
`0` (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an `NMBS`-by-`1` vector. The PSA standard is `100`.

Note Set the `PrepaySpeed` to `[]` if you input a customized `PrepayMatrix`.

Data Types: `double`

`PrepayMatrix` — Customized prepayment vector
matrix

(Optional) Customized prepayment vector, specified as a `NaN`-padded matrix of size `max(TermRemaining)`-by-`NMBS`. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

Note Use `PrepayMatrix` only when `PrepaySpeed` is unspecified.

Data Types: `double`

Output Arguments

`MYield` — Yield to maturity of the mortgage-backed security
vector

Yield to maturity of the mortgage-backed security, returned as a `NMBS`-by-`1` vector. This yield is compounded monthly (12 times a year).

`BEMBSYield` — Bond equivalent yield of the mortgage-backed security
vector

Bond equivalent yield of the mortgage-backed security, returned as a `NMBS`-by-`1` vector. This yield is compounded semiannually (two times a year).

mbspassthrough

Mortgage pool cash flows and balances with prepayment

Syntax

```
[Balance,Payment,Principal,Interest,Prepayment] = mbspassthrough(
OriginalBalance,GrossRate,OriginalTerm)
[Balance,Payment,Principal,Interest,Prepayment] = mbspassthrough( ___ ,
TermRemaining,PrepaySpeed,PrepayMatrix)
```

Description

`[Balance,Payment,Principal,Interest,Prepayment] = mbspassthrough( OriginalBalance,GrossRate,OriginalTerm)` calculates mortgage pool cash flows and balances with prepayments.

If a standard (PSA) prepayment is specified, "aging" is applied to standard prepayment vector. Aging is the same amount as the age of the pool (`OriginalTerm` - `TermRemaining`).

`[Balance,Payment,Principal,Interest,Prepayment] = mbspassthrough( ___ , TermRemaining,PrepaySpeed,PrepayMatrix)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

Examples

Compute the Cash Flow of Principal, Interest, and Prepayment of a Pass-Through Security

This example shows how to compute the cash flows and balances of a 3-month old mortgage pool with original term of 360 months, assuming a prepayment speed of 100.

```
OriginalBalance = 100000;
GrossRate = 0.08125;
OriginalTerm = 360;
TermRemaining = 357;
PrepaySpeed = 100;

[Balance, Payment, Principal, Interest, Prepayment] =...
mbspassthrough(OriginalBalance, GrossRate, OriginalTerm,...
TermRemaining, PrepaySpeed)

Input Arguments

`OriginalBalance` — Original balance value in dollars

vector

Original balance value in dollars (balance at the beginning of each `TermRemaining`), specified as an `NMBS`-by-`1` vector.

Data Types: `double`

`GrossRate` — Gross coupon rate (including fees)

vector of decimal values

Gross coupon rate (including fees), specified as an `NMBS`-by-`1` vector of decimal values.

Data Types: `double`

`OriginalTerm` — Term of the mortgage in months

vector

Term of the mortgage in months, specified as an `NMBS`-by-`1` vector.

Data Types: `double`

`TermRemaining` — Number of full months between settlement and maturity

`OriginalTerm` (default) | vector

(Optional) Number of full months between settlement and maturity, specified as an `NMBS`-by-`1` vector. For this argument, "full months" means not including fractional first term (if there is one).

Data Types: `double`

`PrepaySpeed` — Speed relative to PSA standard

`0` (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an `NMBS`-by-`1` vector. The PSA standard is `100`.

Note Set the `PrepaySpeed` to `[]` if you input a customized `PrepayMatrix`.

Data Types: `double`

`PrepayMatrix` — Customized prepayment vector

matrix

(Optional) Customized prepayment vector, specified as a `NaN`-padded matrix of size `max(TermRemaining)`-by-`NMBS`. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

Note Use `PrepayMatrix` only when `PrepaySpeed` is unspecified.

Data Types: `double`

Output Arguments

`Balance` — Principal balance at end of month

vector

Principal balance at end of month, returned as a `TermRemaining`-by-`1` vectors of end-of-month values.

`Payment` — Total monthly payment

vector

Total monthly payment, returned as a `TermRemaining`-by-`1` vectors of end-of-month values.

`Principal` — Principal portion of the payment

vector

Principal portion of the payment, returned as a `TermRemaining`-by-`1` vectors of end-of-month values.

`Interest` — Interest portion of the payment

vector

Interest portion of the payment, returned as a `TermRemaining`-by-`1` vectors of end-of-month values.

`Prepayment` — Unscheduled principal payment

vector

Unscheduled principal payment, returned as a `TermRemaining`-by-`1` vectors of end-of-month values.

mbsprice

Mortgage-backed security price given yield

Syntax

```
[Price,AccrInt] = mbsprice(Yield,Settle,Maturity,IssueDate,GrossRate)
[Price,AccrInt] = mbsprice( ___ CouponRate,Delay,PrepaySpeed,PrepayMatrix)
```

Description

`[Price,AccrInt] = mbsprice(Yield,Settle,Maturity,IssueDate,GrossRate)` computes a mortgage-backed security price, given time information and mortgage yield at settlement.

`[Price,AccrInt] = mbsprice( ___ CouponRate,Delay,PrepaySpeed,PrepayMatrix)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

Examples

Determine the Mortgage-Backed Security Price Given the Yield

This example shows how to determine the mortgage-backed security price given a mortgage-backed security with the following characteristics.

```
Yield = 0.0725;
Settle = datetime(2002,4,15);
Maturity = datetime(2030,1,1);
IssueDate = datetime(2000,1,1);
GrossRate = 0.08125;
CouponRate = 0.075;
Delay = 14;
Speed = 100;

[Price AccrInt] = mbsprice(Yield, Settle, Maturity, IssueDate,...
GrossRate, CouponRate, Delay, Speed)

Price = 101.3147

AccrInt = 0.2917
```

Determine the Mortgage-Backed Security Price Using a Customized `PrePaytMatrix`

This example shows how to determine the mortgage-backed security price, given a mortgage-backed security, and `PrePaytMatrix` with the following characteristics:

```
Yield = 0.0725;
Settle = datetime(2002,4,15);
Maturity = datetime(2030,1,1);
```

```
IssueDate = datetime(2000,1,1);
GrossRate = 0.08125;
PrepayMatrix = 0.005*ones(360,1);

[Price AccrInt] = mbsprice(Yield, Settle, Maturity, IssueDate,...
GrossRate, PrepayMatrix)
```

      ⋮
```

Input Arguments

`Yield` — Mortgage yield compounded monthly

vector of decimal values

Mortgage yield compounded monthly, specified as an `NMBS`-by-`1` vector using decimal values.

Data Types: `double`

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date, specified as an `NMBS`-by-`1` vector using a datetime array, string array, or date character vectors. `Settle` must be earlier than `Maturity`.

To support existing code, `mbsprice` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as an NMBS-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, mbsprice also accepts serial date numbers as inputs, but they are not recommended.

IssueDate — Issue date
datetime array | string array | date character vector

Issue date, specified as an NMBS-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, mbsprice also accepts serial date numbers as inputs, but they are not recommended.

GrossRate — Gross coupon rate (including fees)
vector of decimal values

Gross coupon rate (including fees), specified as an NMBS-by-1 vector of decimal values.

Data Types: double

CouponRate — Net coupon rate
GrossRate (default) | vector of decimal values

(Optional) Net coupon rate, specified as an NMBS-by-1 vector of decimal values.

Data Types: double

Delay — Delay (in days) between payment from homeowner and receipt by bondholder
0 (no delay between payment and receipt) (default) | vector

(Optional) Delay (in days) between payment from homeowner and receipt by bondholder, specified as an NMBS-by-1 vector.

Data Types: double

PrepaySpeed — Speed relative to PSA standard
0 (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an NMBS-by-1 vector. The PSA standard is 100.

Note Set the PrepaySpeed to [] if you input a customized PrepayMatrix.

Data Types: double

PrepayMatrix — Customized prepayment vector
matrix

(Optional) Customized prepayment vector, specified as a NaN-padded matrix of size max(TermRemaining)-by-NMBS. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

Note Use PrepayMatrix only when PrepaySpeed is unspecified.

Data Types: `double`

Output Arguments

`Price` — Clean price for every $100 face value of the securities

vector

Clean price for every $100 face value of the securities, returned as a `NMBS`-by-`1` vector.

`AccrInt` — Accrued interest of the mortgage-backed securities

vector

Accrued interest of the mortgage-backed securities, returned as a `NMBS`-by-`1` vector.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `mbsprice` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

mbsprice2oas

Option-adjusted spread given price

Syntax

```
OAS = mbsprice2oas(ZeroCurve,Price,Settle,Maturity,IssueDate,GrossRate)
OAS = mbsprice2oas( ___ ,CouponRate,Delay,Interpolation,PrepaySpeed,
PrepayMatrix)
```

Description

`OAS = mbsprice2oas(ZeroCurve,Price,Settle,Maturity,IssueDate,GrossRate)` computes the option-adjusted spread in basis points.

`OAS = mbsprice2oas( ___ ,CouponRate,Delay,Interpolation,PrepaySpeed, PrepayMatrix)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

Examples

Calculate the Option-Adjusted Spread of a 30-Year Fixed-Rate Mortgage

Calculate the option-adjusted spread of a 30-year fixed-rate mortgage with about a 28-year weighted average maturity remaining, given assumptions of 0, 50, and 100 PSA prepayments. First, create the bonds matrix:

```
Bonds = [datenum('11/21/2002')  0        100  0  2  1;
         datenum('02/20/2003')  0        100  0  2  1;
         datenum('07/31/2004')  0.03     100  2  3  1;
         datenum('08/15/2007')  0.035    100  2  3  1;
         datenum('08/15/2012')  0.04875  100  2  3  1;
         datenum('02/15/2031')  0.05375  100  2  3  1];
```

Choose a settlement date.

```
Settle = datenum('20-Aug-2002');
```

Assume the following clean prices for the bonds:

```
Prices =  [ 98.97467;
            98.58044;
           100.10534;
            98.18054;
           101.38136;
            99.25411];
```

Use the following formula to compute spot compounding for the bonds:

```
SpotCompounding = 2*ones(size(Prices));
```

Compute the zero curve.

```
[ZeroRatesP, CurveDatesP] = zbtprice(Bonds, Prices, Settle);
ZeroCurve = [CurveDatesP, ZeroRatesP, SpotCompounding]
```

```
ZeroCurve = 6×3
10^5 ×

    7.3154    0.0000    0.0000
    7.3163    0.0000    0.0000
    7.3216    0.0000    0.0000
    7.3327    0.0000    0.0000
    7.3510    0.0000    0.0000
    7.4185    0.0000    0.0000
```

Assign the following parameters:

```
Price         = 95;
Maturity      = datenum('02-Jan-2030');
IssueDate     = datenum('02-Jan-2000');
GrossRate     = 0.08125;
CouponRate    = 0.075;
Delay         = 14;
Interpolation = 1;
PrepaySpeed   = [0; 50; 100];
Interpolation = 1;
```

Compute the option-adjusted spread.

```
OAS = mbsprice2oas(ZeroCurve, Price, Settle, Maturity, ...
IssueDate, GrossRate, CouponRate, Delay, Interpolation, ...
PrepaySpeed)
```

```
OAS = 3×1

   26.0508
   28.6355
   31.2232
```

Input Arguments

ZeroCurve — Zero curve

matrix

Zero curve, specified as a three-column matrix, where:

- Column 1 is dates using datetimes.
- Column 2 is spot rates with maturities corresponding to the dates in Column 1, in decimal (for example, 0.075).
- Column 3 is the compounding value of the rates in Column 2. (This is the agency spot rate on the settlement date.) Allowable compounding values are: 1 (annual), 2 (semiannual, 3 (three times per year), 4 (quarterly), 6 (bimonthly), 12 (monthly), and -1 (continuous).

For example:

```
[datetime(2003,1,1)  0.0154  12;
 datetime(2004,1,1)  0.0250  12;
```

```
 ......
 datetime(2020,1,1)  0.0675   2];
```

Data Types: `datetime` | `cell`

`Price` — Clean price for every $100 face value of bond issue
vector

Clean price for every $100 face value of bond issue, specified as an `NMBS`-by-`1` vector.

Data Types: `double`

`Settle` — Settlement date
string array | date character vector | serial date number

Settlement date, specified as an `NMBS`-by-`1` vector using a string array, date character vectors, or serial date numbers. `Settle` must be earlier than `Maturity`.

Data Types: `double` | `char` | `string`

`Maturity` — Maturity date
string array | date character vector | serial date number

Maturity date, specified as an `NMBS`-by-`1` vector using a string array, date character vectors, or serial date numbers.

Data Types: `double` | `char` | `string`

`IssueDate` — Issue date
datetime array | string array | date character vector | serial date number

Issue date, specified as an `NMBS`-by-`1` vector using a string array, date character vectors, or serial date numbers.

Data Types: `double` | `char` | `string`

`GrossRate` — Gross coupon rate (including fees)
vector of decimal values

Gross coupon rate (including fees), specified as an `NMBS`-by-`1` vector of decimal values.

Data Types: `double`

`CouponRate` — Net coupon rate
`GrossRate` (default) | vector of decimal values

(Optional) Net coupon rate, specified as an `NMBS`-by-`1` vector of decimal values.

Data Types: `double`

`Delay` — Delay (in days) between payment from homeowner and receipt by bondholder
`0` (no delay between payment and receipt) (default) | vector

(Optional) Delay (in days) between payment from homeowner and receipt by bondholder, specified as an `NMBS`-by-`1` vector.

Data Types: `double`

`Interpolation` — Interpolation method to compute the corresponding spot rates for the bond's cash flow
`1` (linear) (default) | vector

(Optional) Interpolation method to compute the corresponding spot rates for the bond's cash flow, specified as an `NMBS`-by-`1` vector. Available methods are (`0`) nearest, (`1`) linear, and (`2`) cubic spline. For more information on the supported interpolation methods, see `interp1`.

Data Types: `double`

`PrepaySpeed` — Speed relative to PSA standard
`0` (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an `NMBS`-by-`1` vector. The PSA standard is `100`.

Note Set the `PrepaySpeed` to `[]` if you input a customized `PrepayMatrix`.

Data Types: `double`

`PrepayMatrix` — Customized prepayment vector
matrix

(Optional) Customized prepayment vector, specified as a `NaN`-padded matrix of size `max(TermRemaining)`-by-`NMBS`. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

Note Use `PrepayMatrix` only when `PrepaySpeed` is unspecified.

Data Types: `double`

Output Arguments

`OAS` — Zero volatility OAS
vector

Zero volatility OAS, in basis point (bp), returned as a `NMBS`-by-`1` vector.

Version History
Introduced before R2006a

mbsprice2speed

Implied PSA prepayment speeds given price

Syntax

```
[ImpSpdOnPrc,ImpSpdOnDur,ImpSpdOnCnv] = mbsprice2speed(Price,Settle,Maturity,
IssueDate,GrossRate,PrepayMatrix)
[ImpSpdOnPrc,ImpSpdOnDur,ImpSpdOnCnv] = mbsprice2speed( ___ ,CouponRate,Delay)
```

Description

`[ImpSpdOnPrc,ImpSpdOnDur,ImpSpdOnCnv] = mbsprice2speed(Price,Settle,Maturity, IssueDate,GrossRate,PrepayMatrix)` computes PSA prepayment speeds implied by pool prices and projected (user-defined) prepayment vectors. The calculated PSA speed produces the same price, modified duration, or modified convexity, depending upon the output requested.

`[ImpSpdOnPrc,ImpSpdOnDur,ImpSpdOnCnv] = mbsprice2speed( ___ ,CouponRate,Delay)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

Examples

Compute PSA Prepayment Speeds

This example shows how to compute the equivalent PSA benchmark prepayment speeds for a mortgage pool with the following characteristics and prepayment matrix.

```
Price        = 101;
Settle       = datetime(2000,1,1);
Maturity     = datetime(2030,1,1);
IssueDate    = datetime(2000,1,1);
GrossRate    = 0.08125;
PrepayMatrix = 0.005*ones(360,1);
CouponRate   = 0.075;
Delay        = 14;

[ImpSpdOnPrc, ImpSpdOnDur, ImpSpdOnCnv] = ...
mbsprice2speed(Price,Settle, Maturity, IssueDate, ...
GrossRate, PrepayMatrix, CouponRate, Delay)

ImpSpdOnPrc = 118.5980

ImpSpdOnDur = 118.3946

ImpSpdOnCnv = 109.5115
```

Input Arguments

`Price` — Clean price for every $100 face value

vector

Clean price for every $100 face value, specified as an `NMBS`-by-`1` vector.

Data Types: `double`

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date, specified as an `NMBS`-by-`1` vector using a datetime array, string array, or date character vectors. `Settle` must be earlier than `Maturity`.

To support existing code, `mbsprice2speed` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as an `NMBS`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `mbsprice2speed` also accepts serial date numbers as inputs, but they are not recommended.

`IssueDate` — Issue date

datetime array | string array | date character vector

Issue date, specified as an `NMBS`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `mbsprice2speed` also accepts serial date numbers as inputs, but they are not recommended.

`GrossRate` — Gross coupon rate (including fees)

vector of decimal values

Gross coupon rate (including fees), specified as an `NMBS`-by-`1` vector of decimal values.

Data Types: `double`

`PrepayMatrix` — Customized prepayment vector

matrix

Customized prepayment vector, specified as a `NaN`-padded matrix of size `max(TermRemaining)`-by-`NMBS`. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

Note Use `PrepayMatrix` only when `PrepaySpeed` is unspecified.

Data Types: `double`

`CouponRate` — Net coupon rate
`GrossRate` (default) | vector of decimal values

(Optional) Net coupon rate, specified as an `NMBS`-by-`1` vector of decimal values.

Data Types: `double`

`Delay` — Delay (in days) between payment from homeowner and receipt by bondholder
`0` (no delay between payment and receipt) (default) | vector

(Optional) Delay (in days) between payment from homeowner and receipt by bondholder, specified as an `NMBS`-by-`1` vector.

Data Types: `double`

Output Arguments

`ImpSpdOnPrc` — Equivalent PSA benchmark prepayment speed for the pass-through to carry the same price
vector

Equivalent PSA benchmark prepayment speed for the pass-through to carry the same price, returned as a `NMBS`-by-`1` vector.

`ImpSpdOnDur` — Equivalent PSA benchmark prepayment speed for the pass-through to carry the same modified duration
vector

Equivalent PSA benchmark prepayment speed for the pass-through to carry the same modified duration, returned as a `NMBS`-by-`1` vector.

`ImpSpdOnCnv` — Equivalent PSA benchmark prepayment speed for the pass-through to carry the same modified convexity
vector

Equivalent PSA benchmark prepayment speed for the pass-through to carry the same modified convexity, returned as a `NMBS`-by-`1` vector.

Version History

Introduced before R2006a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `mbsprice2speed` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

mbswal

Weighted average life of mortgage pool

Syntax

```
WAL = mbswal(Settle,Maturity,IssueDate,GrossRate)
WAL = mbswal( ___ CouponRate,Delay,PrepaySpeed,PrepayMatrix)
```

Description

`WAL = mbswal(Settle,Maturity,IssueDate,GrossRate)` computes the weighted average life, in number of years, of a mortgage pool, as measured from the settlement date.

`WAL = mbswal( ___ CouponRate,Delay,PrepaySpeed,PrepayMatrix)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

Examples

Determine the Weighted Average Life of a Mortgage Pool

This example shows how to determine the weighted average life of a mortgage pool, given a pass-through security with the following characteristics.

```
Settle = datetime(2002,4,15);
Maturity = datetime(2030,1,1);
IssueDate = datetime(2000,1,1);
GrossRate = 0.08125;
CouponRate = 0.075;
Delay = 14;
Speed = 100;

WAL = mbswal(Settle, Maturity, IssueDate, GrossRate, ...
CouponRate, Delay, Speed)
```

```
WAL = 10.5477
```

Input Arguments

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date, specified as an NMBS-by-1 vector using a datetime array, string array, or date character vectors. `Settle` must be earlier than `Maturity`.

To support existing code, `mbswal` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as an NMBS-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, mbswal also accepts serial date numbers as inputs, but they are not recommended.

IssueDate — Issue date
datetime array | string array | date character vector

Issue date, specified as an NMBS-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, mbswal also accepts serial date numbers as inputs, but they are not recommended.

GrossRate — Gross coupon rate (including fees)
vector of decimal values

Gross coupon rate (including fees), specified as an NMBS-by-1 vector of decimal values.

Data Types: double

CouponRate — Net coupon rate
GrossRate (default) | vector of decimal values

(Optional) Net coupon rate, specified as an NMBS-by-1 vector of decimal values.

Data Types: double

Delay — Delay (in days) between payment from homeowner and receipt by bondholder
0 (no delay between payment and receipt) (default) | vector

(Optional) Delay (in days) between payment from homeowner and receipt by bondholder, specified as an NMBS-by-1 vector.

Data Types: double

PrepaySpeed — Speed relative to PSA standard
0 (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an NMBS-by-1 vector. The PSA standard is 100.

Note Set the PrepaySpeed to [] if you input a customized PrepayMatrix.

Data Types: double

PrepayMatrix — Customized prepayment vector
matrix

(Optional) Customized prepayment vector, specified as a NaN-padded matrix of size max(TermRemaining)-by-NMBS. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

Note Use PrepayMatrix only when PrepaySpeed is unspecified.

Data Types: `double`

Output Arguments

`WAL` — Weighted Average Life of MBS, in number of years

vector

Weighted Average Life (WAL) of MBS, in number of years, returned as a `NMBS`-by-`1` vector.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `mbswal` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

mbsyield

Mortgage-backed security yields given price

Syntax

```
[MYield,BEMBSYield] = mbsyield(Price,Settle,Maturity,IssueDate,GrossRate)
[MYield,BEMBSYield] = mbsyield( ___ CouponRate,Delay,PrepaySpeed,PrepayMatrix)
```

Description

`[MYield,BEMBSYield] = mbsyield(Price,Settle,Maturity,IssueDate,GrossRate)` computes a mortgage-backed security yield to maturity and the bond equivalent yield, given time information, and price at settlement.

`[MYield,BEMBSYield] = mbsyield( ___ CouponRate,Delay,PrepaySpeed,PrepayMatrix)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

Examples

Determine a Mortgage-Backed Security Yield Given the Price

This example shows how to determine the mortgage-backed security yield, given a mortgage-backed security with the following characteristics.

```
Price = 102;
Settle = datetime(2002,4,15);
Maturity = datetime(2030,1,1);
IssueDate = datetime(2000,1,1);
GrossRate = 0.08125;
CouponRate = 0.075;
Delay = 14;
Speed = 100;

[MYield, BEMBSYield] = mbsyield(Price, Settle, Maturity, ...
IssueDate, GrossRate, CouponRate, Delay,  Speed)

MYield = 0.0715

BEMBSYield = 0.0725
```

Determine Multiple Mortgage-Backed Securities Yields Given the Price

This example shows how to determine multiple mortgage-backed securities yields, given a portfolio of mortgage-backed securities with the following characteristics.

```
Price = 102;
Settle = [datetime(2000,2,13) ; datetime(2002,4,17) ; datetime(2002,5,17) ; datetime(2000,1,13)]
```

```
Maturity  = datetime(2030,1,1);
IssueDate = datetime(2000,1,1);
GrossRate = 0.08125;
CouponRate = [0.075; 0.07875; 0.0775; 0.08125];
Delay = 14;
Speed = 100;

[MYield, BEMBSYield] = mbsyield(Price, Settle, Maturity,...
IssueDate, GrossRate, CouponRate, Delay,  Speed)
```

```
MYield = 4×1

    0.0717
    0.0751
    0.0739
    0.0779

BEMBSYield = 4×1

    0.0728
    0.0763
    0.0750
    0.0791
```

Input Arguments

`Price` — Clean price for every $100 face value

vector

Clean price for every $100 face value, specified as an NMBS-by-1 vector.

Data Types: `double`

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date, specified as an NMBS-by-1 vector using a datetime array, string array, or date character vectors. `Settle` must be earlier than `Maturity`.

To support existing code, `mbsyield` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as an NMBS-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, `mbsyield` also accepts serial date numbers as inputs, but they are not recommended.

`IssueDate` — Issue date

datetime array | string array | date character vector

Issue date, specified as an NMBS-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, `mbsyield` also accepts serial date numbers as inputs, but they are not recommended.

`GrossRate` — Gross coupon rate (including fees)
vector of decimal values

Gross coupon rate (including fees), specified as an NMBS-by-1 vector of decimal values.

Data Types: `double`

`CouponRate` — Net coupon rate
`GrossRate` (default) | vector of decimal values

(Optional) Net coupon rate, specified as an NMBS-by-1 vector of decimal values.

Data Types: `double`

`Delay` — Delay (in days) between payment from homeowner and receipt by bondholder
`0` (no delay between payment and receipt) (default) | vector

(Optional) Delay (in days) between payment from homeowner and receipt by bondholder, specified as an NMBS-by-1 vector.

Data Types: `double`

`PrepaySpeed` — Speed relative to PSA standard
`0` (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an NMBS-by-1 vector. The PSA standard is `100`.

Note Set the `PrepaySpeed` to `[]` if you input a customized `PrepayMatrix`.

Data Types: `double`

`PrepayMatrix` — Customized prepayment vector
matrix

(Optional) Customized prepayment vector, specified as a NaN-padded matrix of size `max(TermRemaining)`-by-NMBS. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

Note Use `PrepayMatrix` only when `PrepaySpeed` is unspecified.

Data Types: `double`

Output Arguments

`MYield` — Yield to maturity of the mortgage-backed security
vector

Yield to maturity of the mortgage-backed security, returned as a `NMBS`-by-`1` vector. This yield is compounded monthly (12 times a year).

`BEMBSYield` — Bond equivalent yield of the mortgage-backed security
vector

Bond equivalent yield of the mortgage-backed security, returned as a `NMBS`-by-`1` vector. This yield is compounded semiannually (two times a year).

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `mbsyield` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

mbsyield2oas

Option-adjusted spread given yield

Syntax

```
OAS = mbsyield2oas(ZeroCurve,Yield,Settle,Maturity,IssueDate,GrossRate)
OAS = mbsyield2oas( ___ ,CouponRate,Delay,Interpolation,PrepaySpeed,
PrepayMatrix)
```

Description

`OAS = mbsyield2oas(ZeroCurve,Yield,Settle,Maturity,IssueDate,GrossRate)` computes option-adjusted spread in basis points.

`OAS = mbsyield2oas( ___ ,CouponRate,Delay,Interpolation,PrepaySpeed, PrepayMatrix)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

Examples

Calculate the Option-Adjusted Spread of a 30-Year Fixed-Rate Mortgage Pool

Calculate the option-adjusted spread of a 30-year, fixed-rate mortgage pool with about 28-year weighted average maturity left, given assumptions of 0, 50, and 100 PSA prepayments. First, create the bonds matrix:

```
Bonds = [datenum('11/21/2002')  0        100  0  2  1;
         datenum('02/20/2003')  0        100  0  2  1;
         datenum('07/31/2004')  0.03     100  2  3  1;
         datenum('08/15/2007')  0.035    100  2  3  1;
         datenum('08/15/2012')  0.04875  100  2  3  1;
         datenum('02/15/2031')  0.05375  100  2  3  1];
```

Choose a settlement date.

```
Settle = datenum('20-Aug-2002');
```

Assume the following clean prices for the bonds:

```
Prices =  [ 98.97467;
            98.58044;
           100.10534;
            98.18054;
           101.38136;
            99.25411];
```

Use the following formula to compute spot compounding for the bonds:

```
SpotCompounding = 2*ones(size(Prices));
```

Compute the zero curve.

```
[ZeroRatesP, CurveDatesP] = zbtprice(Bonds, Prices, Settle);
ZeroCurve = [CurveDatesP, ZeroRatesP, SpotCompounding]
```

```
ZeroCurve = 6×3
10^5 ×

    7.3154    0.0000    0.0000
    7.3163    0.0000    0.0000
    7.3216    0.0000    0.0000
    7.3327    0.0000    0.0000
    7.3510    0.0000    0.0000
    7.4185    0.0000    0.0000
```

Assign the following parameters:

```
Price         = 95;
Maturity      = datenum('02-Jan-2030');
IssueDate     = datenum('02-Jan-2000');
GrossRate     = 0.08125;
CouponRate    = 0.075;
Delay         = 14;
Interpolation = 1;
PrepaySpeed   = [0 50 100];
```

Compute the yield, and from the yield, compute the option-adjusted spread.

```
[mbsyld, beyld] = mbsyield(Price, Settle, ...
Maturity, IssueDate, GrossRate, CouponRate, Delay, PrepaySpeed);

OAS = mbsyield2oas(ZeroCurve, mbsyld, Settle, ...
Maturity, IssueDate, GrossRate, CouponRate, Delay, ...
Interpolation, PrepaySpeed)
```

```
OAS = 3×1

   26.0508
   28.6355
   31.2232
```

Input Arguments

`ZeroCurve` — Zero curve

matrix

Zero curve, specified as a three-column matrix, where:

- Column 1 is serial date numbers.
- Column 2 is spot rates with maturities corresponding to the dates in Column 1, in decimal (for example, 0.075).
- Column 3 is the compounding value of the rates in Column 2. (This is the agency spot rate on the settlement date.) Allowable compounding values are: 1 (annual), 2 (semiannual, 3 (three times per year), 4 (quarterly), 6 (bimonthly), 12 (monthly), and -1 (continuous).

For example:

```
[datenum('1-Jan-2003')  0.0154  12;
 datenum('1-Jan-2004')  0.0250  12;
 ......
 datenum('1-Jan-2020')  0.0675   2];
```

Data Types: `double` | `char` | `cell`

`Yield` — Mortgage yield, compounded monthly
vector in decimals

Mortgage yield, compounded monthly, specified as an `NMBS`-by-`1` vector in decimals.

Data Types: `double`

`Settle` — Settlement date
serial date number | date character vector

Settlement date, specified as an `NMBS`-by-`1` vector using serial date numbers or date character vectors. `Settle` must be earlier than `Maturity`.

Data Types: `double` | `char`

`Maturity` — Maturity date
serial date number | date character vector

Maturity date, specified as an `NMBS`-by-`1` vector using serial date numbers or date character vectors.

Data Types: `double` | `char`

`IssueDate` — Issue date
serial date number | date character vector

Issue date, specified as an `NMBS`-by-`1` vector using serial date numbers or date character vectors.

Data Types: `double` | `char`

`GrossRate` — Gross coupon rate (including fees)
vector of decimal values

Gross coupon rate (including fees), specified as an `NMBS`-by-`1` vector of decimal values.

Data Types: `double`

`CouponRate` — Net coupon rate
`GrossRate` (default) | vector of decimal values

(Optional) Net coupon rate, specified as an `NMBS`-by-`1` vector of decimal values.

Data Types: `double`

`Delay` — Delay (in days) between payment from homeowner and receipt by bondholder
`0` (no delay between payment and receipt) (default) | vector

(Optional) Delay (in days) between payment from homeowner and receipt by bondholder, specified as an `NMBS`-by-`1` vector.

Data Types: `double`

`Interpolation` — Interpolation method to compute the corresponding spot rates for the bond's cash flow
`1` (linear) (default) | vector

(Optional) Interpolation method to compute the corresponding spot rates for the bond's cash flow, specified as an `NMBS`-by-`1` vector. Available methods are (`0`) nearest, (`1`) linear, and (`2`) cubic spline. For more information on the supported interpolation methods, see `interp1`.

Data Types: `double`

`PrepaySpeed` — Speed relative to PSA standard
`0` (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an `NMBS`-by-`1` vector. The PSA standard is `100`.

Note Set the `PrepaySpeed` to `[]` if you input a customized `PrepayMatrix`.

Data Types: `double`

`PrepayMatrix` — Customized prepayment vector
matrix

(Optional) Customized prepayment vector, specified as a `NaN`-padded matrix of size `max(TermRemaining)`-by-`NMBS`. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

Note Use `PrepayMatrix` only when `PrepaySpeed` is unspecified.

Data Types: `double`

Output Arguments

`OAS` — Zero volatility OAS
vector

Zero volatility OAS, in basis point (bp), returned as a `NMBS`-by-`1` vector.

Version History
Introduced before R2006a

mbsyield2speed

Implied PSA prepayment speeds given yield

Syntax

```
[ImpSpdOnPrc,ImpSpdOnDur,ImpSpdOnCnv] = mbsyield2speed(Yield,Settle,Maturity,
IssueDate,GrossRate,PrepayMatrix)
[ImpSpdOnPrc,ImpSpdOnDur,ImpSpdOnCnv] = mbsyield2speed( ___ ,CouponRate,Delay)
```

Description

`[ImpSpdOnPrc,ImpSpdOnDur,ImpSpdOnCnv] = mbsyield2speed(Yield,Settle,Maturity, IssueDate,GrossRate,PrepayMatrix)` computes PSA prepayment speeds implied by pool yields and projected (user-defined) prepayment vectors. The calculated PSA speed produces the same yield, modified duration, or modified convexity, depending upon the output requested.

`[ImpSpdOnPrc,ImpSpdOnDur,ImpSpdOnCnv] = mbsyield2speed( ___ ,CouponRate,Delay)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

Examples

Compute PSA Prepayment Speeds

Calculate the equivalent PSA benchmark prepayment speeds for a security with these characteristics and prepayment matrix.

```
Yield        = 0.065;
Settle       = datetime(2000,1,1);
Maturity     = datetime(2030,1,1);
IssueDate    = datetime(2000,1,1);
GrossRate    = 0.08125;
PrepayMatrix = 0.005*ones(360,1);
CouponRate   = 0.075;
Delay        = 14;

[ImpSpdOnYld, ImpSpdOnDur, ImpSpdOnCnv] = ...
mbsyield2speed(Yield, Settle, Maturity, IssueDate, GrossRate, ...
PrepayMatrix, CouponRate, Delay)

ImpSpdOnYld = 117.7644

ImpSpdOnDur = 116.7436

ImpSpdOnCnv = 108.3309
```

Input Arguments

`Yield` — Mortgage yield, compounded monthly

vector in decimals

Mortgage yield, compounded monthly, specified as an `NMBS`-by-`1` vector in decimals.

Data Types: `double`

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date, specified as an `NMBS`-by-`1` vector using a datetime array, string array, or date character vectors. `Settle` must be earlier than `Maturity`.

To support existing code, `mbsyield2speed` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as an `NMBS`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `mbsyield2speed` also accepts serial date numbers as inputs, but they are not recommended.

`IssueDate` — Issue date

datetime array | string array | date character vector

Issue date, specified as an `NMBS`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `mbsyield2speed` also accepts serial date numbers as inputs, but they are not recommended.

`GrossRate` — Gross coupon rate (including fees)

vector of decimal values

Gross coupon rate (including fees), specified as an `NMBS`-by-`1` vector of decimal values.

Data Types: `double`

`PrepayMatrix` — Customized prepayment vector

matrix

Customized prepayment vector, specified as a `NaN`-padded matrix of size `max(TermRemaining)`-by-`NMBS`. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

Note Use `PrepayMatrix` only when `PrepaySpeed` is unspecified.

Data Types: `double`

`CouponRate` — Net coupon rate
`GrossRate` (default) | vector of decimal values

(Optional) Net coupon rate, specified as an `NMBS`-by-`1` vector of decimal values.

Data Types: `double`

`Delay` — Delay (in days) between payment from homeowner and receipt by bondholder
`0` (no delay between payment and receipt) (default) | vector

(Optional) Delay (in days) between payment from homeowner and receipt by bondholder, specified as an `NMBS`-by-`1` vector.

Data Types: `double`

Output Arguments

`ImpSpdOnPrc` — Equivalent PSA benchmark prepayment speed for the pass-through to carry the same price
vector

Equivalent PSA benchmark prepayment speed for the pass-through to carry the same price, returned as a `NMBS`-by-`1` vector.

`ImpSpdOnDur` — Equivalent PSA benchmark prepayment speed for the pass-through to carry the same modified duration
vector

Equivalent PSA benchmark prepayment speed for the pass-through to carry the same modified duration, returned as a `NMBS`-by-`1` vector.

`ImpSpdOnCnv` — Equivalent PSA benchmark prepayment speed for the pass-through to carry the same modified convexity
vector

Equivalent PSA benchmark prepayment speed for the pass-through to carry the same modified convexity, returned as a `NMBS`-by-`1` vector.

Version History

Introduced before R2006a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `mbsyield2speed` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

psaspeed2default

Benchmark default

Syntax

```
[ADRPSA,MDRPSA] = psaspeed2default(DefaultSpeed)
```

Description

`[ADRPSA,MDRPSA] = psaspeed2default(DefaultSpeed)` computes the benchmark default on the performing balance of mortgage-backed securities per PSA benchmark speed.

Examples

Compute the Benchmark Default Rates on the Performing Balance of Mortgage-Backed Securities Per PSA Benchmark Speed

This example shows how to compute the benchmark default rates on the performing balance of mortgage-backed securities per PSA benchmark speed, given a mortgage-backed security with annual speed set at the PSA default benchmark.

```
DefaultSpeed = 100;

[ADRPSA, MDRPSA] = psaspeed2default(DefaultSpeed)
```

```
ADRPSA = 360×1

Input Arguments

`DefaultSpeed` — Annual speed relative to the benchmark

vector in decimals

Annual speed relative to the benchmark, specified as an `NDEF`-by-`1` vector. The PSA benchmark is `100`.

Data Types: `double`

Output Arguments

`ADRPSA` — PSA default rate

vector

PSA default rate, returned as a `360`-by-`NDEF` vector in decimals.

`MDRPSA` — PSA monthly default rate

vector

PSA monthly default rate, returned as a `360`-by-`NDEF` vector in decimals.

psaspeed2rate

Single monthly mortality rate given PSA speed

Syntax

```
[CPRPSA,SMMPSA] = psaspeed2rate(PSASpeed)
```

Description

`[CPRPSA,SMMPSA] = psaspeed2rate(PSASpeed)` calculates vectors of PSA prepayments, each containing 360 prepayment elements, to represent the 360 months in a 30-year mortgage pool.

Examples

Compute the Prepayment and Mortality Rates

This example shows how to compute the prepayment and mortality rates, given a mortgage-backed security with annual speed set at the PSA default benchmark.

```
PSASpeed = [100 200];

[CPRPSA, SMMPSA]= psaspeed2rate(PSASpeed)
```

```
CPRPSA = 360×2

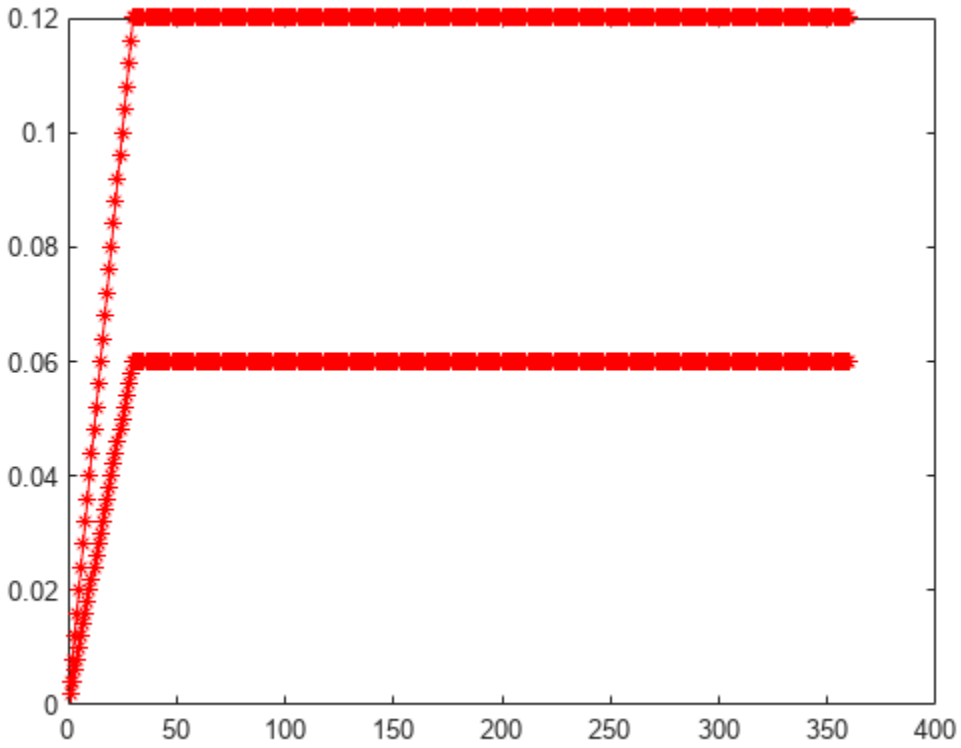
    0.0017    0.0034
      ⋮
```

```
% view the plot of the output
psaspeed2rate(PSASpeed)
```



Input Arguments

PSASpeed — Annual speed relative to the benchmark

vector in decimals

Annual speed relative to the benchmark, specified as any value > `0` using an `NSPD`-by-`1` vector. The PSA benchmark is `100`.

Data Types: `double`

Output Arguments

CPRPSA — PSA conditional prepayment rate

vector

PSA conditional prepayment rate, returned as a `360`-by-`NSPD` vector in decimals.

SMMPSA — PSA single monthly mortality rate

vector

PSA monthly default rate, returned as a `360`-by-`NSPD` vector in decimals.

stepcpncfamounts

Cash flow amounts and times for bonds and stepped coupons

Syntax

```
[CFlows,CDates,CTimes] = stepcpncfamounts(Settle,Maturity,ConvDates,
CouponRates)
[CFlows,CDates,CTimes] = stepcpncfamounts( ___ ,Period,Basis,EndMonthRule,Face)
```

Description

`[CFlows,CDates,CTimes] = stepcpncfamounts(Settle,Maturity,ConvDates, CouponRates)` returns matrices of cash flow amounts, cash flow dates, and time factors for a portfolio of `NUMBONDS` stepped-coupon bonds.

`[CFlows,CDates,CTimes] = stepcpncfamounts( ___ ,Period,Basis,EndMonthRule,Face)` adds additional optional arguments.

Examples

Generate Stepped Cash Flows for Three Different Bonds

This example generates stepped cash flows for three different bonds, all paying interest semiannually. The life span of the bonds is about 18–19 years each:

- Bond A has two conversions, but the first one occurs on the settlement date and immediately expires.
- Bond B has three conversions, with conversion dates exactly on the coupon dates.
- Bond C has three conversions, with some conversion dates not on the coupon dates. It has the longest maturity. This case illustrates that only cash flows for full periods after conversion dates are affected, as illustrated here:

The following table illustrates the interest-rate characteristics of this bond portfolio.

Bond A Dates	Bond A Rates	Bond B Dates	Bond B Rates	Bond C Dates	Bond C Rates
Settle (02-Aug-92)	7.5%	Settle (02-Aug-92)	7.5%	Settle (02-Aug-92)	2.5%
First Conversion (02-Aug-92)	8.875%	First Conversion (15-Jun-97))	8.875%	First Conversion (14-Jun-97))	5.0%
Second Conversion (15-Jun-03)	9.25%	Second Conversion (15-Jun-01)	9.25%	Second Conversion (14-Jun-01)	7.5%
Maturity (15-Jun-10)	NaN	Third Conversion (15-Jun-05)	10.0%	Third Conversion (14-Jun-05)	10.0%
		Maturity (15-Jun-10)	NaN	Maturity (15-Jun-11)	NaN

Define the bond specifications.

```
Settle   = datenum('02-Aug-1992');

ConvDates = [datenum('02-Aug-1992'), datenum('15-Jun-2003'),...
             nan;
            datenum('15-Jun-1997'), datenum('15-Jun-2001'),...
            datenum('15-Jun-2005');
            datenum('14-Jun-1997'), datenum('14-Jun-2001'),...
            datenum('14-Jun-2005')];

Maturity = [datenum('15-Jun-2010');
            datenum('15-Jun-2010');
            datenum('15-Jun-2011')];

CouponRates = [0.075 0.08875 0.0925 nan;
               0.075 0.08875 0.0925 0.1;
               0.025 0.05    0.0750 0.1];
Basis = 1;
Period = 2;
EndMonthRule = 1;
Face = 100;
```

Use `stepcpncfamounts` to compute cash flows and timings.

```
[CFlows, CDates, CTimes] = stepcpncfamounts(Settle, Maturity, ConvDates, CouponRates)
```

```
CFlows = 3×39

         0    0.7377    1.7377    2.7377    3.7377    4.7377    5.7377    6.7377    7.7377    8.7
         0    0.7377    1.7377    2.7377    3.7377    4.7377    5.7377    6.7377    7.7377    8.7
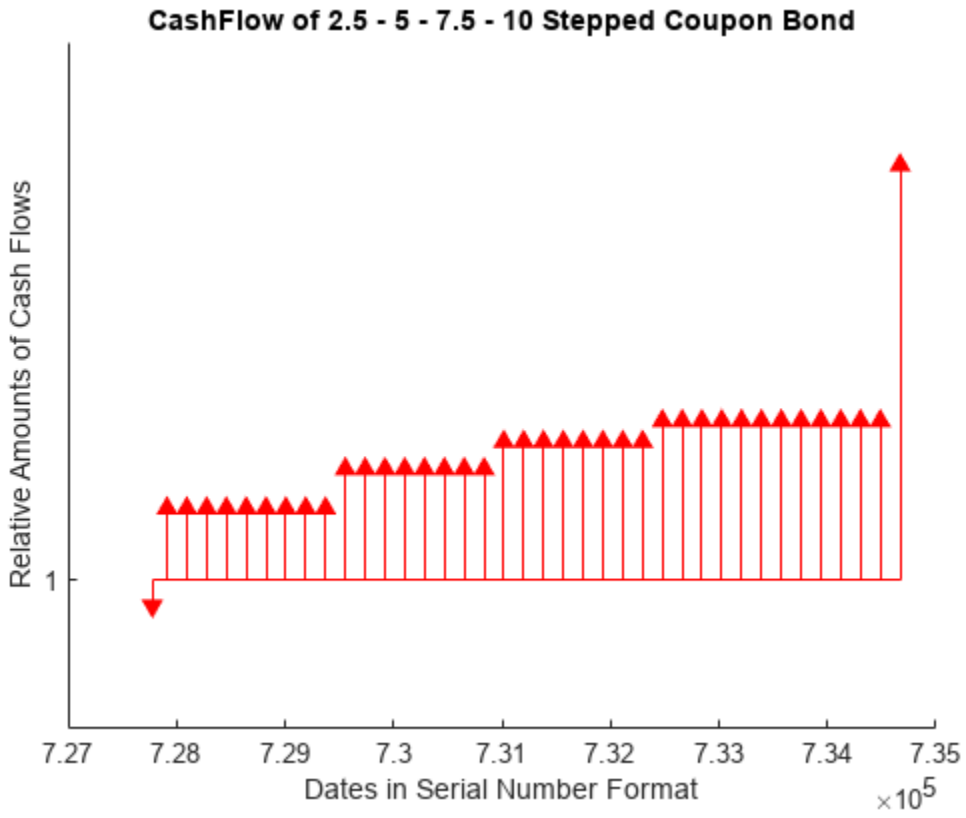
```

Visualize the third bond's cash flows (2.5 - 5 - 7.5 - 10) using the `cfplot` function.

```
cfplot(CDates(3,:),CFlows(3,:));
xlabel('Dates in Serial Number Format')
ylabel('Relative Amounts of Cash Flows')
title('CashFlow of 2.5 - 5 - 7.5 - 10 Stepped Coupon Bond')
```



Input Arguments

`Settle` — Settlement date

serial date number | date character vector

Settlement date, specified either as a scalar or `NSTP`-by-`1` vector using serial date numbers or date character vectors.

`Settle` must be earlier than `Maturity`.

Data Types: `double` | `char`

`Maturity` — Maturity date

serial date number | date character vector

Maturity date, specified as a scalar or an `NSTP`-by-`1` vector using serial date numbers or date character vectors that represent the maturity date for each bond.

Data Types: `double` | `char` | `string` | `datetime`

`ConvDates` — Conversion dates

serial date number | date character vector

Conversion dates, specified as a `NSTP`-by-max(`NCONV`) matrix using serial date numbers or date character vectors containing conversion dates after `Settle`. The size of the matrix is equal to the number of instruments by the maximum number of conversions. Fill unspecified entries with `NaN`.

Data Types: `double` | `char`

`CouponRates` — Bond coupon rate
positive decimal value

Bond coupon rate, specified as an `NSTP`-by-max(`NCONV+1`) matrix containing coupon rates for each bond in the portfolio in decimal form. The matrix size is equal to the number of instruments by maximum number of conversions + 1. First column of this matrix contains rates applicable between `Settle` and the first conversion date (date in the first column of `ConvDates`). Fill unspecified entries with `NaN`

`ConvDates` has the same number of rows as `CouponRates` to reflect the same number of bonds. However, `ConvDates` has one less column than `CouponRates`. This situation is illustrated by

```
Settle---------ConvDate1-----------ConvDate2------------Maturity

        Rate1               Rate2                Rate3
```

Data Types: `double`

`Period` — Coupons per year
2 per year (default) | vector

(Optional) Coupons per year, specified as an `NSTP`-by-`1` vector. Values for `Period` are `1`, `2`, `3`, `4`, `6`, and `12`.

Data Types: `double`

`Basis` — Day-count basis
`0` (actual/actual) (default) | integer from `0` to `13`

(Optional) Day-count basis of each instrument, specified as an `NSTP`-by-`1` vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

EndMonthRule — End-of-month rule flag for generating dates when Maturity is end-of-month date for month having 30 or fewer days
1 (in effect) (default) | nonnegative integer [0,1]

(Optional) End-of-month rule flag for generating dates when Maturity is an end-of-month date for a month having 30 or fewer days, specified for each bond as a nonnegative integer [0, 1] using a NSTP-by-1 vector.

- 0 = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: logical

Face — Face value
100 (default) | vector of nonnegative values

(Optional) Face value, specified for each bond as an NSTP-by-1 vector of nonnegative face values.

Data Types: double

Output Arguments

CFlows — Cash flow amounts
vector

Cash flow amounts, returned as a vector where the first entry in each row vector is the (negative) accrued interest due at settlement. If no accrued interest is due, the first column is zero.

CDates — Cash flow dates
vector

Cash flow dates, returned as vector in serial date number form. At least two columns are always present: one for settlement and one for maturity.

CTimes — Time factor
vector

Time factor for the SIA semiannual price/yield conversion, returned as a vector. The SIA semi-annual price/yield conversion is DiscountFactor = (1 + Yield/2).^(-TFactor). Time factors are in units of semiannual coupon periods. For ISMA conventions: DiscountFactor = (1 + Yield).^(-TFactor). Time factors are in units of annual coupon periods. In computing time factors, use SIA actual/actual conventions for all time factor calculations.

Note For bonds with fixed coupons, use cfamounts. If you use a fixed-coupon bond with stepcpncfamounts, MATLAB software generates an error.

stepcpnprice

Price bond with stepped coupons

Syntax

```
[Price,AccruedInterest] = stepcpnprice(Yield,Settle,Maturity,ConvDates,
CouponRates)
[Price,AccruedInterest] = stepcpnprice( ___ ,Period,Basis,EndMonthRule,Face)
```

Description

`[Price,AccruedInterest] = stepcpnprice(Yield,Settle,Maturity,ConvDates, CouponRates)` computes the price of bonds with stepped coupons given the yield to maturity. The function supports any number of conversion dates.

`[Price,AccruedInterest] = stepcpnprice( ___ ,Period,Basis,EndMonthRule,Face)` adds additional optional arguments.

Examples

Compute Bond Prices with Stepped Coupons

Compute the price and accrued interest due on a portfolio of stepped-coupon bonds having a yield of 7.221%, given three conversion scenarios:

- Bond A has two conversions, the first one falling on the settle date and immediately expiring.
- Bond B has three conversions, with conversion dates exactly on the coupon dates.
- Bond C has three conversions, with one or more conversion dates not on coupon dates. This case illustrates that only cash flows for full periods after conversion dates are affected, as illustrated below:

The following table illustrates the interest-rate characteristics of this bond portfolio.

Bond A Dates	Bond A Rates	Bond B Dates	Bond B Rates	Bond C Dates	Bond C Rates
Settle (02-Aug-92)	7.5%	Settle (02-Aug-92)	7.5%	Settle (02-Aug-92)	7.5%
First Conversion (02-Aug-92)	8.875%	First Conversion (15-Jun-97)	8.875%	First Conversion (14-Jun-97)	8.875%
Second Conversion (15-Jun-03)	9.25%	Second Conversion (15-Jun-01)	9.25%	Second Conversion (14-Jun-01)	9.25%
Maturity (15-Jun-10)	NaN	Third Conversion (15-Jun-05)	10.0%	Third Conversion (14-Jun-05)	10.0%
		Maturity (15-Jun-10)	NaN	Maturity (15-Jun-10)	NaN

Define the specifications for the bonds.

```
Yield = 0.07221;
Settle   = datenum('02-Aug-1992');
```

```
ConvDates = [datenum('02-Aug-1992'), datenum('15-Jun-2003'),...
             nan;
            datenum('15-Jun-1997'), datenum('15-Jun-2001'),...
            datenum('15-Jun-2005');
            datenum('14-Jun-1997'), datenum('14-Jun-2001'),...
            datenum('14-Jun-2005')];
Maturity = datenum('15-Jun-2010');

CouponRates = [0.075 0.08875 0.0925 nan;
               0.075 0.08875 0.0925 0.1;
               0.075 0.08875 0.0925 0.1];
Basis = 1;
Period = 2;
EndMonthRule = 1;
Face = 100;
```

Use `stepcpnprice` to compute the bond prices with stepped coupons.

```
[Price, AccruedInterest] = stepcpnprice(Yield, Settle, Maturity, ConvDates, CouponRates, Period,
```

```
Price = 3×1

  117.3874
  113.4387
  114.1759

AccruedInterest = 3×1

    1.1587
    0.9792
    0.9792
```

Input Arguments

`Yield` — Yield to maturity

numeric

Yield to maturity, specified as a scalar or `NUMBONDS`-by-1 vector of numeric values.

Data Types: `double`

`Settle` — Settlement date

serial date number | date character vector

Settlement date, specified either as a scalar or `NUMBONDS`-by-1 vector using serial date numbers or date character vectors.

`Settle` must be earlier than `Maturity`.

Data Types: `double` | `char`

`Maturity` — Maturity date

serial date number | date character vector

Maturity date, specified as a scalar or an NUMBONDS-by-1 vector using serial date numbers or date character vectors that represent the maturity date for each bond.

Data Types: double | char

ConvDates — Conversion dates
serial date number | date character vector

Conversion dates, specified as a NSTP-by-max(NCONV) matrix using serial date numbers or date character vectors that contain conversion dates after Settle. The size of the matrix is equal to the number of instruments by the maximum number of conversions. Fill unspecified entries with NaN.

Data Types: double | char

CouponRates — Bond coupon rate
positive decimal value

Bond coupon rate, specified as an NSTP-by-max(NCONV+1) matrix containing coupon rates for each bond in the portfolio in decimal form. The matrix size is equal to the number of instruments by maximum number of conversions + 1. First column of this matrix contains rates applicable between Settle and the first conversion date (date in the first column of ConvDates). Fill unspecified entries with NaN

ConvDates has the same number of rows as CouponRates to reflect the same number of bonds. However, ConvDates has one less column than CouponRates. This situation is illustrated by

```
Settle---------ConvDate1-----------ConvDate2------------Maturity

        Rate1               Rate2                Rate3
```

Data Types: double

Period — Coupons per year
2 per year (default) | vector

(Optional) Coupons per year, specified as an NUMBONDS-by-1 vector. Values for Period are 1, 2, 3, 4, 6, and 12.

Data Types: double

Basis — Day-count basis
0 (actual/actual) (default) | integer from 0 to 13

(Optional) Day-count basis of each instrument, specified as an NUMBONDS-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)

- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month having 30 or fewer days
`1` (in effect) (default) | nonnegative integer `[0,1]`

(Optional) End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month having 30 or fewer days, specified for each bond as a nonnegative integer [`0`, `1`] using a `NUMBONDS`-by-`1` vector.

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

Face — Face value
`100` (default) | vector of nonnegative values

(Optional) Face value, specified for each bond as an `NUMBONDS`-by-`1` vector of nonnegative face values.

Data Types: `double`

Output Arguments

`Price` — Clean price
vector

Clean price, returned as a `NUMBONDS`-by-`1` vector.

Note For bonds with fixed coupons, use `bndprice`. If you use a fixed-coupon bond with `stepcpnprice`, you receive the error: `incorrect number of inputs`.

`AccruedInterest` — Accrued interest payable at settlement dates
vector

accrued interest payable at settlement dates, returned as a `NUMBONDS`-by-`1` vector.

Version History

Introduced before R2006a

stepcpnyield

Yield to maturity of bond with stepped coupons

Syntax

```
Yield = stepcpnyield(Price,Settle,Maturity,ConvDates,CouponRates)
Yield = stepcpnyield( ___ ,Period,Basis,EndMonthRule,Face)
```

Description

`Yield = stepcpnyield(Price,Settle,Maturity,ConvDates,CouponRates)` computes the yield to maturity of bonds with stepped coupons given the price. The function supports any number of conversion dates.

`Yield = stepcpnyield( ___ ,Period,Basis,EndMonthRule,Face)` adds additional optional arguments.

Examples

Compute Yield to Maturity for Bonds with Stepped Coupons

Find the yield to maturity of three stepped-coupon bonds of known price, given three conversion scenarios:

- Bond A has two conversions, the first one falling on the settle date and immediately expiring.
- Bond B has three conversions, with conversion dates exactly on the coupon dates.
- Bond C has three conversions, with one or more conversion dates not on coupon dates. This case illustrates that only cash flows for full periods after conversion dates are affected, as illustrated below.

The following table illustrates the interest-rate characteristics of this bond portfolio.

Bond A Dates	Bond A Rates	Bond B Dates	Bond B Rates	Bond C Dates	Bond C Rates
Settle (02-Aug-92)	7.5%	Settle (02-Aug-92)	7.5%	Settle (02-Aug-92)	7.5%
First Conversion (02-Aug-92)	8.875%	First Conversion (15-Jun-97)	8.875%	First Conversion (14-Jun-97)	8.875%
Second Conversion (15-Jun-03)	9.25%	Second Conversion (15-Jun-01)	9.25%	Second Conversion (14-Jun-01)	9.25%
Maturity (15-Jun-10)	NaN	Third Conversion (15-Jun-05)	10.0%	Third Conversion (14-Jun-05)	10.0%
		Maturity (15-Jun-10)	NaN	Maturity (15-Jun-10)	NaN

Define the specifications for the bonds.

```
format long
Price = [117.3824; 113.4339; 113.4339];
```

```
Settle = datenum('02-Aug-1992');

ConvDates = [datenum('02-Aug-1992'), datenum('15-Jun-2003'), nan;
datenum('15-Jun-1997'), datenum('15-Jun-2001'), datenum('15-Jun-2005');
datenum('14-Jun-1997'), datenum('14-Jun-2001'), datenum('14-Jun-2005')];

Maturity = datenum('15-Jun-2010');

CouponRates = [0.075 0.08875 0.0925 nan;
               0.075 0.08875 0.0925 0.1;
               0.075 0.08875 0.0925 0.1];
Basis = 1;
Period = 2;
EndMonthRule = 1;
Face = 100;
```

Use `stepcpnyield` to compute the yield to maturity for the bonds with stepped coupons.

```
Yield = stepcpnyield(Price, Settle, Maturity, ConvDates, CouponRates, Period, Basis, EndMonthRule
```

```
Yield = 3×1

   0.072214402049150
   0.072214267800360
   0.072864799557221
```

Input Arguments

`Price` — Price of bond

numeric

Price of bond, specified as a scalar or `NUMBONDS`-by-1 vector of numeric values.

Data Types: `double`

`Settle` — Settlement date

serial date number | date character vector

Settlement date, specified either as a scalar or `NUMBONDS`-by-1 vector using serial date numbers or date character vectors.

`Settle` must be earlier than `Maturity`.

Data Types: `double` | `char`

`Maturity` — Maturity date

serial date number | date character vector

Maturity date, specified as a scalar or an `NUMBONDS`-by-1 vector using serial date numbers or date character vectors that represent the maturity date for each bond.

Data Types: `double` | `char`

`ConvDates` — Conversion dates

serial date number | date character vector

Conversion dates, specified as a NSTP-by-max(NCONV) matrix using serial date numbers or date character vectors that contain conversion dates after `Settle`. The size of the matrix is equal to the number of instruments by the maximum number of conversions. Fill unspecified entries with `NaN`.

Data Types: `double` | `char`

`CouponRates` — Bond coupon rate
positive decimal value

Bond coupon rate, specified as an NSTP-by-max(NCONV+1) matrix containing coupon rates for each bond in the portfolio in decimal form. The matrix size is equal to the number of instruments by maximum number of conversions + 1. First column of this matrix contains rates applicable between `Settle` and the first conversion date (date in the first column of `ConvDates`). Fill unspecified entries with `NaN`

`ConvDates` has the same number of rows as `CouponRates` to reflect the same number of bonds. However, `ConvDates` has one less column than `CouponRates`. This situation is illustrated by

```
Settle---------ConvDate1-----------ConvDate2------------Maturity

        Rate1              Rate2                Rate3
```

Data Types: `double`

`Period` — Coupons per year
2 per year (default) | vector

(Optional) Coupons per year, specified as an NUMBONDS-by-1 vector. Values for `Period` are `1`, `2`, `3`, `4`, `6`, and `12`.

Data Types: `double`

`Basis` — Day-count basis
`0` (actual/actual) (default) | integer from `0` to `13`

(Optional) Day-count basis of each instrument, specified as an NUMBONDS-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month having 30 or fewer days
`1` (in effect) (default) | nonnegative integer `[0,1]`

(Optional) End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month having 30 or fewer days, specified for each bond as a nonnegative integer [`0`, `1`] using a `NUMBONDS`-by-`1` vector.

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

Face — Face value
`100` (default) | vector of nonnegative values

(Optional) Face value, specified for each bond as an `NUMBONDS`-by-`1` vector of nonnegative face values.

Data Types: `double`

Output Arguments

`Yield` — Yield to maturity
vector

Yield to maturity, returned as a `NUMBONDS`-by-`1` vector in decimal form.

Note For bonds with fixed coupons, use `bndyield`. You receive the error `incorrect number of inputs` if you use a fixed-coupon bond with `stepcpnyield`.

Version History

Introduced before R2006a

tfutbyprice

Future prices of Treasury bonds given spot price

Syntax

```
[QtdFutPrice,AccrInt] = tfutbyprice(SpotCurve,Price,SettleFut,MatFut,
ConvFactor,CouponRate,Maturity)
[QtdFutPrice,AccrInt] = tfutbyprice( ___ ,Interpolation)
```

Description

`[QtdFutPrice,AccrInt] = tfutbyprice(SpotCurve,Price,SettleFut,MatFut, ConvFactor,CouponRate,Maturity)` computes future prices of Treasury notes and bonds given the spot price.

In addition, you can use the Financial Instruments Toolbox method `getZeroRates` for an `IRDataCurve` object with a `Dates` property to create a vector of dates and data acceptable for `tfutbyprice`. For more information, see “Converting an IRDataCurve or IRFunctionCurve Object” on page 9-30.

Note Alternatively, you can use the `BondFuture` object to price bond future instruments. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[QtdFutPrice,AccrInt] = tfutbyprice( ___ ,Interpolation)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

Examples

Determine the Future Prices of Treasury Bonds Given the Spot Price

This example shows how to determine the future price of two Treasury bonds based upon a spot rate curve constructed from data for November 14, 2002.

```
% construct spot curve from Nov 14, data
Bonds = [datenum('02/13/2003'),        0;
         datenum('05/15/2003'),        0;
         datenum('10/31/2004'),  0.02125;
         datenum('11/15/2007'),     0.03;
         datenum('11/15/2012'),     0.04;
         datenum('02/15/2031'),  0.05375];

Yields  = [1.20; 1.25; 1.86; 2.99; 4.02; 4.93]/100;

Settle = datenum('11/15/2002');

[ZeroRates, CurveDates] = ...
zbtyield(Bonds, Yields, Settle);
```

```
SpotCurve  = [CurveDates, ZeroRates];

% calculate a particular bond's future quoted price
RefDate    = [datenum('1-Dec-2002'); datenum('1-Mar-2003')];
MatFut     = [datenum('15-Dec-2002'); datenum('15-Mar-2003')];
Maturity   = [datenum('15-Aug-2009');datenum('15-Aug-2010')];
CouponRate = [0.06;0.0575];
ConvFactor = convfactor(RefDate, Maturity, CouponRate);
Price = [114.416; 113.171];
Interpolation = 1;

[QtdFutPrice, AccrInt] = tfutbyprice(SpotCurve, Price, Settle, ...
MatFut, ConvFactor, CouponRate, Maturity, Interpolation)
```

```
QtdFutPrice = 2×1

  114.0409
  113.4029

AccrInt = 2×1

    1.9891
    0.4448
```

Input Arguments

SpotCurve — Treasury spot curve

matrix

Treasury spot curve, specified as a number of futures using one of the following forms:

- NFUT-by-2 matrix in the form of `[SpotDates SpotRates]` and these spot rates must be quoted as semiannual compounding (2) when the third column is not supplied.
- NFUT-by-3 matrix in the form of `[SpotDates SpotRates Compounding]`, where allowed `Compounding` values for the third column are −1, 1, 2 (default), 3, 4, and 12, where −1 is continuous compounding.

Data Types: `double`

Price — Prices of Treasury bonds or notes per $100 notional at settlement date

scalar numeric | vector

Prices of Treasury bonds or notes per $100 notional at settlement date, specified as a scalar numeric or an NINST-by-1 vector. Use `bndprice` for theoretical value of bond.

Data Types: `double`

SettleFut — Settlement date of futures contract

serial date number | date character vector

Settlement date of futures contract, specified as a scalar or an NINST-by-1 vector using serial date numbers or date character vectors.

Data Types: `double` | `char`

`MatFut` — Maturity dates (or anticipated delivery dates) of futures contract
serial date number | date character vector

Maturity dates (or anticipated delivery dates) of futures contract, specified as a scalar or an `NINST`-by-`1` vector using serial date numbers or character vectors.

Data Types: `double` | `char`

`ConvFactor` — Conversion factor
numeric

Conversion factor, specified using `convfactor`.

Data Types: `double` | `char` | `cell`

`CouponRate` — Underlying bond annual coupon
scalar numeric in decimal | vector in decimals

Underlying bond annual coupon, specified as a scalar numeric decimal or an `NINST`-by-`1` vector of decimals.

Data Types: `double`

`Maturity` — Underlying bond maturity date
serial date number | date character vector

Underlying bond maturity date, specified as a scalar or an `NINST`-by-`1` vector using serial date numbers or date character vectors.

Data Types: `double` | `char`

`Interpolation` — Interpolation method to compute the corresponding spot rates for the bond's cash flow
`1` (linear) (default) | vector

(Optional) Interpolation method to compute the corresponding spot rates for the bond's cash flow, specified as an `NMBS`-by-`1` vector. Available methods are (`0`) nearest, (`1`) linear, and (`2`) cubic spline. For more information on the supported interpolation methods, see `interp1`.

Data Types: `double`

Output Arguments

`QtdFutPrice` — Quoted futures price, per $100 notional
vector

Quoted futures price, per $100 notional, returned as a `NINST`-by-`1` vector.

`AccrInt` — Accrued Interest due at delivery date, per $100 notional
vector

Accrued Interest due at delivery date, per $100 notional, returned as a `NINST`-by-`1` vector.

“Treasury Bills Defined”

tfutbyyield

Future prices of Treasury bonds given current yield

Syntax

```
[QtdFutPrice,AccrInt] = tfutbyyield(SpotCurve,Yield,SettleFut,MatFut,
ConvFactor,CouponRate,Maturity)
[QtdFutPrice,AccrInt] = tfutbyyield( ___ ,Interpolation)
```

Description

`[QtdFutPrice,AccrInt] = tfutbyyield(SpotCurve,Yield,SettleFut,MatFut, ConvFactor,CouponRate,Maturity)` computes prices of Treasury bond futures given a spot curve and bond yields at settlement.

In addition, you can use the Financial Instruments Toolbox method `getZeroRates` for an `IRDataCurve` object with a `Dates` property to create a vector of dates and data acceptable for `tfutbyyield`. For more information, see “Converting an IRDataCurve or IRFunctionCurve Object” on page 9-30.

`[QtdFutPrice,AccrInt] = tfutbyyield( ___ ,Interpolation)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

Examples

Determine Future Prices of Treasury Bonds Given the Current Yield

This example shows how to determine the future price of two Treasury bonds based upon a spot rate curve constructed from data for November 14, 2002.

```
% construct spot curve from Nov 14, data
Bonds = [datenum('02/13/2003'),        0;
         datenum('05/15/2003'),        0;
         datenum('10/31/2004'),  0.02125;

  114.0416
  113.4034

AccrInt = 2×1

    1.9891
    0.4448
```

Input Arguments

SpotCurve — Treasury spot curve

matrix

Treasury spot curve, specified as a number of futures using one of the following forms:

- NFUT-by-2 matrix in the form of `[SpotDates SpotRates]` and these spot rates must be quoted as semiannual compounding (2) when the third column is not supplied.
- NFUT-by-3 matrix in the form of `[SpotDates SpotRates Compounding]`, where allowed `Compounding` values for the third column are −1, 1, 2 (default), 3, 4, and 12, where −1 is continuous compounding.

Data Types: `double`

Yield — Yield to maturities at settlement date

scalar numeric | vector

Yield to maturities at settlement date, specified as a scalar numeric or an NINST-by-1 vector. Use `bndyield` for theoretical value of bond yield.

Data Types: `double`

SettleFut — Settlement date of futures contract

serial date number | date character vector

Settlement date of futures contract, specified as a scalar or an NINST-by-1 vector using serial date numbers or date character vectors.

Data Types: `double` | `char`

MatFut — Maturity dates (or anticipated delivery dates) of futures contract

serial date number | date character vector

Maturity dates (or anticipated delivery dates) of futures contract, specified as a scalar or an `NINST`-by-`1` vector using serial date numbers or character vectors.

Data Types: `double` | `char`

`ConvFactor` — Conversion factor
numeric

Conversion factor, specified using `convfactor`.

Data Types: `double` | `char` | `cell`

`CouponRate` — Underlying bond annual coupon
scalar numeric in decimal | vector in decimals

Underlying bond annual coupon, specified as a scalar numeric decimal or an `NINST`-by-`1` vector of decimals.

Data Types: `double`

`Maturity` — Underlying bond maturity date
serial date number | date character vector

Underlying bond maturity date, specified as a scalar or an `NINST`-by-`1` vector using serial date numbers or date character vectors.

Data Types: `double` | `char`

`Interpolation` — Interpolation method to compute the corresponding spot rates for the bond's cash flow
`1` (linear) (default) | vector

(Optional) Interpolation method to compute the corresponding spot rates for the bond's cash flow, specified as an `NMBS`-by-`1` vector. Available methods are (`0`) nearest, (`1`) linear, and (`2`) cubic spline. For more information on the supported interpolation methods, see `interp1`.

Data Types: `double`

Output Arguments

`QtdFutPrice` — Quoted futures price, per $100 notional
vector

Quoted futures price, per $100 notional, returned as a `NINST`-by-`1` vector.

`AccrInt` — Accrued Interest due at delivery date, per $100 notional
vector

Accrued Interest due at delivery date, per $100 notional, returned as a `NINST`-by-`1` vector.

Topics

tfutimprepo

Implied repo rates for Treasury bond future given price

Syntax

```
ImpliedRepo = tfutimprepo(ReinvestData,Price,QtdFutPrice,Settle,MatFut,
ConvFactor,CouponRate,Maturity)
```

Description

`ImpliedRepo = tfutimprepo(ReinvestData,Price,QtdFutPrice,Settle,MatFut, ConvFactor,CouponRate,Maturity)` computes the implied repo rate that prevents arbitrage of Treasury bond futures, given the clean price at the settlement and delivery dates.

Examples

Compute the Implied Repo Rates for Treasury Bond Futures Given the Price

This example shows how to compute the implied repo rate given the following set of data.

```
ReinvestData = [0.018  3];
Price = [114.4160; 113.1710];
QtdFutPrice = [114.1201; 113.7090];
Settle = datetime(2002,11,15);
MatFut = [datetime(2002,12,15) ; datetime(2003,3,15)];
ConvFactor = [1; 0.9854];
CouponRate = [0.06; 0.0575];
Maturity = [datetime(2009,8,15) ; datetime(2010,8,15)];

ImpliedRepo = tfutimprepo(ReinvestData, Price, QtdFutPrice, ...
Settle, MatFut, ConvFactor, CouponRate, Maturity)
```

```
ImpliedRepo = 2×1

    0.0200
    0.0200
```

Input Arguments

`ReinvestData` — Reinvestment of intervening coupons

matrix

Reinvestment of intervening coupons, specified as a number of futures `NFUT`-by-2 matrix of rates and bases in the form of `[ReinvestRate ReinvestBasis]`.

`ReinvestRate` is the simple reinvestment rate, in decimal. Specify `ReinvestBasis` as `0` = not reinvested, `2` = actual/360, or `3` = actual/365.

Data Types: `double`

`Price` — Current bond price per $100 notional
scalar numeric | vector

Current bond price per $100 notional, specified as a scalar numeric or an `NINST`-by-`1` vector.

Data Types: `double`

`QtdFutPrice` — Quoted bond futures price per $100 notional
scalar numeric | vector

Quoted bond futures price per $100 notional, specified as a scalar numeric or an `NINST`-by-`1` vector.

Data Types: `double`

`Settle` — Settlement/valuation date of futures contract
datetime array | string array | date character vector

Settlement/valuation date of futures contract, specified as a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `tfutimprepo` also accepts serial date numbers as inputs, but they are not recommended.

`MatFut` — Maturity dates (or anticipated delivery dates) of futures contract
datetime array | string array | date character vector

Maturity dates (or anticipated delivery dates) of futures contract, specified as a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `tfutimprepo` also accepts serial date numbers as inputs, but they are not recommended.

`ConvFactor` — Conversion factor
numeric

Conversion factor, specified using `convfactor`.

Data Types: `double` | `char` | `cell`

`CouponRate` — Underlying bond annual coupon
scalar numeric in decimal | vector in decimals

Underlying bond annual coupon, specified as a scalar numeric decimal or an `NINST`-by-`1` vector of decimals.

Data Types: `double`

`Maturity` — Underlying bond maturity date
datetime array | string array | date character vector

Underlying bond maturity date, specified as a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `tfutimprepo` also accepts serial date numbers as inputs, but they are not recommended.

Output Arguments

`ImpliedRepo` — Implied annual repo rate with an actual/360 basis
vector in decimals

Implied annual repo rate (in decimals) with an actual/360 basis, returned as a `NINST`-by-`1` vector.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `tfutimprepo` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

tfutpricebyrepo

Calculates Treasury bond futures price given the implied repo rates

Syntax

```
[QtdFutPrice,AccrInt] = tfutpricebyrepo(RepoData,ReinvestData,Price,Settle,
MatFut,ConvFactor,CouponRate,Maturity)
```

Description

`[QtdFutPrice,AccrInt] = tfutpricebyrepo(RepoData,ReinvestData,Price,Settle,MatFut,ConvFactor,CouponRate,Maturity)` computes the theoretical futures bond price given the settlement price, the repo/funding rates, and the reinvestment rate.

Examples

Compute Treasury Bond Futures Price Given the Implied Repo Rates

This example shows how to compute the quoted futures price and accrued interest due on the target delivery date, given the following data.

```
RepoData     = [0.020  2];
ReinvestData = [0.018  3];
Price        = [114.416; 113.171];
Settle       = datetime(2002,11,15);
MatFut       = [datetime(2002,12,15) ; datetime(2003,3,15)];
ConvFactor   = [1 ; 0.9854];
CouponRate   = [0.06;0.0575];
Maturity     = [datetime(2009,8,15) ; datetime(2010,8,15)];

[QtdFutPrice AccrInt] = tfutpricebyrepo(RepoData, ...
ReinvestData, Price, Settle, MatFut, ConvFactor, CouponRate, ...
Maturity)
```

```
QtdFutPrice = 2×1

  114.1201
  113.7090

AccrInt = 2×1

    1.9891
    0.4448
```

Input Arguments

RepoData — Simple term repo/funding rates

matrix

Simple term repo/funding rates, specified as a number of futures `NFUT`-by-`2` matrix of rates in decimal and their bases in the form of `[RepoRate RepoBasis]`.

Specify `RepoBasis` as `2` = actual/360 or `3` = actual/365.

Data Types: `double`

`ReinvestData` — Reinvestment of intervening coupons
matrix

Reinvestment of intervening coupons, specified as a number of futures `NFUT`-by-`2` matrix of rates and bases in the form of `[ReinvestRate ReinvestBasis]`.

`ReinvestRate` is the simple reinvestment rate, in decimal. Specify `ReinvestBasis` as `0` = not reinvested, `2` = actual/360, or `3` = actual/365.

Data Types: `double`

`Price` — Current bond price per $100 notional
scalar numeric | vector

Current bond price per $100 notional, specified as a scalar numeric or an `NINST`-by-`1` vector.

Data Types: `double`

`Settle` — Settlement/valuation date of futures contract
datetime array | string array | date character vector

Settlement/valuation date of futures contract, specified as a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `tfutpricebyrepo` also accepts serial date numbers as inputs, but they are not recommended.

`MatFut` — Maturity dates (or anticipated delivery dates) of futures contract
datetime array | string array | date character vector

Maturity dates (or anticipated delivery dates) of futures contract, specified as a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `tfutpricebyrepo` also accepts serial date numbers as inputs, but they are not recommended.

`ConvFactor` — Conversion factor
numeric

Conversion factor, specified using `convfactor`.

Data Types: `double` | `char` | `cell`

`CouponRate` — Underlying bond annual coupon
scalar numeric in decimal | vector in decimals

Underlying bond annual coupon, specified as a scalar numeric decimal or an `NINST`-by-`1` vector of decimals.

Data Types: `double`

`Maturity` — Underlying bond maturity date
datetime array | string array | date character vector

Underlying bond maturity date, specified as a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `tfutpricebyrepo` also accepts serial date numbers as inputs, but they are not recommended.

Output Arguments

`QtdFutPrice` — Quoted futures price, per $100 notional
vector

Quoted futures price, per $100 notional, returned as a `NINST`-by-`1` vector.

`AccrInt` — Accrued Interest due at delivery date, per $100 notional
vector

Accrued Interest due at delivery date, per $100 notional, returned as a `NINST`-by-`1` vector.

Version History

tfutyieldbyrepo

Calculates Treasury bond futures yield given the implied repo rates

Syntax

```
FwdYield = tfutyieldbyrepo(RepoData,ReinvestData,Yield,Settle,MatFut,
ConvFactor,CouponRate,Maturity)
```

Description

`FwdYield = tfutyieldbyrepo(RepoData,ReinvestData,Yield,Settle,MatFut, ConvFactor,CouponRate,Maturity)` computes the theoretical futures bond yield given the settlement yield, the repo/funding rate, and the reinvestment rate.

Examples

Compute the Treasury Bond Futures Yield Given the Implied Repo Rates

This example shows how to compute the quoted futures bond yield, given the following data.

```
RepoData     = [0.020  2];
ReinvestData = [0.018  3];
Yield        = [0.0215; 0.0257];
Settle       = datetime(2002,11,15);
MatFut       = [datetime(2002,12,15) ; datetime(2003,3,15)];
ConvFactor   = [1; 0.9854];
CouponRate   = [0.06; 0.0575];
Maturity     = [datetime(2009,8,15) ; datetime(2010,8,15)];

FwdYield = tfutyieldbyrepo(RepoData, ReinvestData, Yield,...
    Settle, MatFut, ConvFactor, CouponRate, Maturity)
```

```
FwdYield = 2×1

    0.0221
    0.0282
```

Input Arguments

RepoData — Simple term repo/funding rates

matrix

Simple term repo/funding rates, specified as a number of futures `NFUT`-by-2 matrix of rates in decimal and their bases in the form of `[RepoRate RepoBasis]`.

Specify `RepoBasis` as 2 = actual/360 or 3 = actual/365.

Data Types: `double`

`ReinvestData` — Reinvestment of intervening coupons
matrix

Reinvestment of intervening coupons, specified as a number of futures `NFUT`-by-`2` matrix of rates and bases in the form of `[ReinvestRate ReinvestBasis]`.

`ReinvestRate` is the simple reinvestment rate, in decimal. Specify `ReinvestBasis` as `0` = not reinvested, `2` = actual/360, or `3` = actual/365.

Data Types: `double`

`Yield` — Yield to maturity of Treasury bonds per $100 notional at `Settle`
scalar numeric | vector

Yield to maturity of Treasury bonds per $100 notional at `Settle`, specified as a scalar numeric or an `NINST`-by-`1` vector.

Data Types: `double`

`Settle` — Settlement/valuation date of futures contract
datetime array | string array | date character vector

Settlement/valuation date of futures contract, specified as a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `tfutyieldbyrepo` also accepts serial date numbers as inputs, but they are not recommended.

`MatFut` — Maturity dates (or anticipated delivery dates) of futures contract
datetime array | string array | date character vector

Maturity dates (or anticipated delivery dates) of futures contract, specified as a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `tfutyieldbyrepo` also accepts serial date numbers as inputs, but they are not recommended.

`ConvFactor` — Conversion factor
numeric

Conversion factor, specified using `convfactor`.

Data Types: `double` | `char` | `cell`

`CouponRate` — Underlying bond annual coupon
scalar numeric in decimal | vector in decimals

Underlying bond annual coupon, specified as a scalar numeric decimal or an `NINST`-by-`1` vector of decimals.

Data Types: `double`

`Maturity` — Underlying bond maturity date
datetime array | string array | date character vector

Underlying bond maturity date, specified as a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `tfutyieldbyrepo` also accepts serial date numbers as inputs, but they are not recommended.

Output Arguments

`FwdYield` — Forward yield to maturity compounded semiannually

vector in decimals

Forward yield to maturity, in decimals, compounded semiannually, returned as a `NINST`-by-`1` vector.

toRateSpec

Convert `IRDataCurve` object to `RateSpec`

Syntax

```
F = toRateSpec(CurveObj,InpDates)
```

Description

`F = toRateSpec(CurveObj,InpDates)` computes `RateSpec` object for input dates for an `IRDataCurve` object. The `RateSpec` object that is identical to the `RateSpec` structure created by the function `intenvset`.

Examples

Convert an IRDataCurve Object to a RateSpec

This example shows how to convert an `IRDataCurve` object to a `RateSpec`. First, an `IRDataCurve` object is created using the function `IRDataCurve` constructor with `Dates` and `Data`, then this object is converted to a `RateSpec` structure using the `toRateSpec` method.

```
CurveSettle = datetime(2016,3,2);
Data = [2.09 2.47 2.71 3.12 3.43 3.85 4.57 4.58]/100;
Dates = datemnth(CurveSettle,12*[1 2 3 5 7 10 20 30]);
irdc = IRDataCurve('Forward',CurveSettle,Dates,Data);
toRateSpec(irdc, CurveSettle+30:30:CurveSettle+365)
```

```
ans = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 2
             Disc: [12x1 double]
            Rates: [12x1 double]
         EndTimes: [12x1 double]
       StartTimes: [12x1 double]
         EndDates: [12x1 double]
       StartDates: 736391
    ValuationDate: 736391
            Basis: 0
     EndMonthRule: 1
```

Input Arguments

CurveObj — Interest-rate curve object

object

Interest-rate curve object, specified by using `IRDataCurve`.

Data Types: `object`

`InpDates` — Input dates
datetime array | string array | date character vector

Input dates, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. The input dates must be after the `Settle` date of `IRDataCurve`.

To support existing code, `toRateSpec` also accepts serial date numbers as inputs, but they are not recommended.

Output Arguments

`F` — Rate spec
object

Rate spec, returned as an object. The `RateSpec` object that is identical to the `RateSpec` structure created by the function `intenvset`.

Alternatively, you can convert the `RateSpec` object to a `ratecurve` object (see “Convert RateSpec to a ratecurve Object” on page 1-49) and then use the Financial Instruments Toolbox object-based framework for pricing instruments.

Version History

Introduced in R2008b

Serial date numbers not recommended
Not recommended starting in R2022b

Although `toRateSpec` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

toRateSpec

Convert `IRFunctionCurve` object to `RateSpec`

Syntax

```
F = toRateSpec(CurveObj,InpDates)
```

Description

`F = toRateSpec(CurveObj,InpDates)` computes `RateSpec` object for input dates for an `IRFunctionCurve` object. The `RateSpec` object that is identical to the `RateSpec` structure created by the function `intenvset`.

Examples

Convert an `IRFunctionCurve` Object to a `RateSpec`

This example shows how to convert an `IRFunctionCurve` object to a `RateSpec`. First, an `IRFunctionCurve` object is created using the function `IRFunctionCurve` constructor, then a `RateSpec` structure is created using the `toRateSpec` method.

```
irfc = IRFunctionCurve('Forward',today,@(t) polyval([-0.0001 0.003 0.02],t));
toRateSpec(irfc, today+30:30:today+365)
```

```
ans = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 2
             Disc: [12x1 double]
            Rates: [12x1 double]
         EndTimes: [12x1 double]
       StartTimes: [12x1 double]
         EndDates: [12x1 double]
       StartDates: 738764
    ValuationDate: 738764
            Basis: 0
     EndMonthRule: 1
```

Input Arguments

`CurveObj` — Interest-rate curve object

object

Interest-rate curve object, specified by using `IRFunctionCurve`.

Data Types: `object`

`InpDates` — Input dates

datetime array | string array | date character vector

Input dates, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. The input dates must be after the `Settle` date of `IRFunctionCurve`.

To support existing code, `toRateSpec` also accepts serial date numbers as inputs, but they are not recommended.

Output Arguments

F — Rate spec

object

Rate spec, returned as an object. The `RateSpec` object that is identical to the `RateSpec` structure created by the function `intenvset`.

Alternatively, you can convert the `RateSpec` object to a `ratecurve` object (see “Convert RateSpec to a ratecurve Object” on page 1-49) and then use the Financial Instruments Toolbox object-based framework for pricing instruments.

Version History

Introduced in R2008b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `toRateSpec` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

zeroprice

Price zero-coupon instruments given yield

Syntax

```
Price = zeroprice(Yield,Settle,Maturity)
Price = zeroprice( ___ ,Period,Basis,EndMonthRule)
```

Description

`Price = zeroprice(Yield,Settle,Maturity)` prices zero-coupon instruments given a yield. `zeroprice` calculates the prices for a portfolio of general short and long-term zero-coupon instruments given the yield of reference bonds. In other words, if the zero-coupon computed with this yield is used to discount the reference bond, the value of that reference bond is equal to its price.

`Price = zeroprice( ___ ,Period,Basis,EndMonthRule)` adds optional arguments for `Period`, `Basis`, and `EndMonthRule`.

Examples

Compute the Price of a Short-Term Zero-Coupon Instrument

This example shows how to compute the price of a short-term zero-coupon instrument.

```
Settle = datetime(1993,6,24);
Maturity = datetime(1993,11,1);
Period = 2;
Basis = 0;
Yield = 0.04;

Price = zeroprice(Yield, Settle, Maturity, Period, Basis)
```

```
Price = 98.6066
```

Compute the Prices of a Portfolio of Two Zero-Coupon Instruments

This example shows how to compute the prices of a portfolio of two zero-coupon instruments, one short-term, and the other long-term.

```
Settle = datetime(1993,6,24);
Maturity = [datetime(1993,11,1) ; datetime(2024,1,15)];
Basis = [0; 1];
Yield = [0.04; 0.1];

Price = zeroprice(Yield, Settle, Maturity, [], Basis)
```

```
Price = 2×1
```

```
   98.6066
    5.0697
```

Input Arguments

`Yield` — Reference bond yield

scalar | vector

Reference bond yield, specified as a scalar or a `NZERO`-by-`1` vector.

Data Types: `double`

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date, specified as a `NZERO`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `zeroprice` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as a `NZERO`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `zeroprice` also accepts serial date numbers as inputs, but they are not recommended.

`Period` — Number of coupons in one year

`2` (semiannual) (default) | vector of positive integers from the set `[1,2,3,4,6,12]`

(Optional) Number of coupons in one year, specified as a positive integer for the values `1,2,4,6,12` in a `NZERO`-by-`1` vector.

Data Types: `double`

`Basis` — Day-count basis of bond

`0` (actual/actual) (default) | vector of positive integers of the set `[1...13]`

(Optional) Day-count basis of the bond, specified as a positive integer using a `NZERO`-by-`1` vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)

- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag
1 (in effect) (default) | nonnegative integer with value of `0` or `1`

(Optional) End-of-month rule flag, specified as a nonnegative integer with a value of `0` or `1` using a `NZERO`-by-`1` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `double`

Output Arguments

`Price` — Price for each zero-coupon instrument
vector

Price for each zero-coupon instrument (per $100 notional), returned as a column vector.

Algorithms

To compute the price when `Period` is `1` or `0` for the quasi-coupon periods to redemption, `zeroprice` uses the formula

$$Price = \frac{RV}{1 + \left(\frac{DSR}{E} \times \frac{Y}{M}\right)}$$

.

Quasi-coupon periods are the coupon periods that would exist if the bond were paying interest at a rate other than zero.

When there is more than one quasi-coupon period to the redemption date, `zeroprice` uses the formula

$$Price = \frac{RV}{\left(1 + \frac{Y}{M}\right)^{Nq - 1 + \frac{DSC}{E}}}$$

.

The elements of the equations are defined as follows.

Variable	Definition
DSC	Number of days from settlement date to next quasi-coupon date as if the security paid periodic interest.
DSR	Number of days from settlement date to the redemption date (call date, put date, and so on).
E	Number of days in quasi-coupon period.
M	Number of quasi-coupon periods per year (standard for the particular security involved).
Nq	Number of quasi-coupon periods between settlement date and redemption date. If this number contains a fractional part, raise it to the next whole number.
Price	Dollar price per $100 par value.
RV	Redemption value.
Y	Annual yield (decimal) when held to redemption.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `zeroprice` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

zeroyield

Yield of zero-coupon instruments given price

Syntax

```
Yield = zeroyield(Price,Settle,Maturity)
Yield = zeroyield( ___ ,Period,Basis,EndMonthRule)
```

Description

`Yield = zeroyield(Price,Settle,Maturity)` computes the yield of zero-coupon instruments given price. `zeroyield` calculates the bond-equivalent yield for a portfolio of general short and long-term zero-coupon instruments given the price of the instruments. In other words, if the zero-coupon computed with this yield is used to discount the reference bond, the value of that reference bond is equal to its price

`Yield = zeroyield( ___ ,Period,Basis,EndMonthRule)` adds optional arguments for `Period`, `Basis`, and `EndMonthRule`.

Examples

Compute the Yield of a Short-Term Zero-Coupon Instrument

This example shows how to compute the yield of a short-term zero-coupon instrument.

```
Settle   = datetime(1993,6,24);
Maturity = datetime(1993,11,1);
Basis    = 0;
Price    = 95;

Yield = zeroyield(Price, Settle, Maturity, [], Basis)
```

```
Yield = 0.1490
```

Compute the Yield of a Short-Term Zero-Coupon Instrument Using a Day-Count Basis of 30/360 (SIA)

This example shows how to compute the yield of a short-term zero-coupon instrument using a day-count basis of 30/360 (SIA).

```
Settle   = datetime(1993,6,24);
Maturity = datetime(1993,11,1);
Basis    = 1;
Price    = 95;

Yield = zeroyield(Price, Settle, Maturity, [], Basis)
```

```
Yield = 0.1492
```

Compute the Yield of a Long-Term Zero-Coupon Instrument

This example shows how to compute the yield of a long-term zero-coupon instrument.

```
Settle   = datetime(1993,6,24);
Maturity = datetime(2024,6,15);
Basis    = 0;
Price    = 9;

Yield = zeroyield(Price, Settle, Maturity, [], Basis)
```

```
Yield = 0.0793
```

Input Arguments

`Price` — Reference bond price

scalar | vector

Reference bond price, specified as a scalar or a `NZERO`-by-`1` vector.

Data Types: `double`

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date, specified as a `NZERO`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `zeroyield` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as a `NZERO`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `zeroyield` also accepts serial date numbers as inputs, but they are not recommended.

`Period` — Number of coupons in one year

`2` (semiannual) (default) | vector of positive integers from the set `[1,2,3,4,6,12]`

(Optional) Number of coupons in one year, specified as a positive integer for the values `1,2,4,6,12` in a `NZERO`-by-`1` vector.

Data Types: `double`

`Basis` — Day-count basis of bond

`0` (actual/actual) (default) | vector of positive integers of the set `[1...13]`

(Optional) Day-count basis of the bond, specified as a positive integer using a `NZERO`-by-`1` vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Note When the `Maturity` date is fewer than 182 days away and the `Basis` is `actual/365`, the `zeroyield` uses a simple-interest algorithm. If `Maturity` is more than 182 days away, `zeroyield` uses present value calculations.

When the `Basis` is `actual/360`, the simple interest algorithm gives the money-market yield for short (1–6 months to maturity) Treasury bills.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag
`1` (in effect) (default) | nonnegative integer with value of `0` or `1`

(Optional) End-of-month rule flag, specified as a nonnegative integer with a value of `0` or `1` using a `NZERO`-by-`1` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `double`

Output Arguments

`Yield` — Bond-equivalent yield for each zero-coupon instrument
vector

Bond-equivalent yield for each zero-coupon instrument, returned as a column vector.

Algorithms

To compute the yield when there is zero or one quasi-coupon period to redemption, `zeroyield` uses the formula

$$Yield = \left(\frac{RV - P}{P}\right) \times \left(\frac{M \times E}{DSR}\right)$$

.

Quasi-coupon periods are the coupon periods which would exist if the bond was paying interest at a rate other than zero. The first term calculates the yield on invested dollars. The second term converts this yield to a per annum basis.

When there is more than one quasi-coupon period to the redemption date, `zeroyield` uses the formula

$$Yield = \left(\left(\frac{RV}{P}\right)^{\frac{1}{Nq - 1 + \frac{DSC}{E}}} - 1\right) \times M$$

The elements of the equations are defined as follows.

Variable	Definition
DSC	Number of days from the settlement date to next quasi-coupon date as if the security paid periodic interest.
DSR	Number of days from the settlement date to redemption date (call date, put date, and so on).
E	Number of days in quasi-coupon period.
M	Number of quasi-coupon periods per year (standard for the particular security involved).
Nq	Number of quasi-coupon periods between the settlement date and redemption date. If this number contains a fractional part, raise it to the next whole number.
P	Dollar price per $100 par value.
RV	Redemption value.
Yield	Annual yield (decimal) when held to redemption.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `zeroyield` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

touchbybls

Price one-touch and no-touch binary options using Black-Scholes option pricing model

Syntax

```
Price = touchybls(RateSpec,StockSpec,Settle,Maturity,BarrierSpec,Barrier,
Payoff)
```

Description

`Price = touchybls(RateSpec,StockSpec,Settle,Maturity,BarrierSpec,Barrier, Payoff)` calculates one-touch and no-touch binary options using the Black-Scholes option pricing model.

Note Alternatively, you can use the `Touch` object to price one touch options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

Examples

Price a One-Touch Option

Compute the price of a one-touch option using the following data:

```
AssetPrice = 105;
Rate = 0.1;
Volatility = 0.2;
Settle = datetime(2018,1,1);
Maturity = datetime(2018,6,1);
```

Define the `RateSpec` using `intenvset`.

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, 'EndDates', ...
Maturity, 'Rates', Rate, 'Compounding', -1);
```

Define the `StockSpec` using `stockspec`.

```
DividendType = "Continuous";
DividendYield = Rate - 0.1;
StockSpec = stockspec(Volatility, AssetPrice, DividendType, DividendYield);
```

Calculate the price of a one-touch binary option.

```
BarrierSpec = "OT";
Barrier = 100;
Payoff = 15;

Price = touchbybls(RateSpec, StockSpec, Settle, Maturity, BarrierSpec, Barrier, Payoff)
```

```
Price = 9.4102
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities, the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

Settle — Settlement or trade date

datetime array | string array | date character vector

Settlement or trade date for the touch option, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `touchbybls` also accepts serial date numbers as inputs, but they are not recommended.

Maturity — Maturity date

datetime array | string array | date character vector

Maturity date for the touch option, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `touchbybls` also accepts serial date numbers as inputs, but they are not recommended.

BarrierSpec — Barrier option type

character vector with values `'OT'` or `'NT'`

Barrier option type, specified as an `NINST`-by-`1` cell array of character vectors with the following values:

- `'OT'` — One-touch

  The one-touch option provides a payoff if the underlying asset ever trades at or beyond the `Barrier` level. Otherwise, the `Payoff` is zero.

- `'NT'` — No-touch

  The no-touch option provides a `Payoff` if the underlying asset never trades at or beyond the `Barrier` level. Otherwise, the `Payoff` is zero.

Data Types: `char` | `cell`

`Barrier` — Barrier value
numeric

Barrier value, specified as an `NINST`-by-`1` matrix of numeric values.

Data Types: `double`

`Payoff` — Payoff value
numeric

Payoff value, specified as an `NINST`-by-`1` matrix of numeric values.

Note The payoff value is calculated for the point in time that the `Barrier` value is reached. The payoff is either cash or nothing. If a no-touch option is specified using the `BarrierSpec`, the payoff is at the `Maturity` of the option.

Data Types: `double`

Output Arguments

`Price` — Expected prices for one-touch options
matrix

Expected prices for one-touch options at time 0, returned as an `NINST`-by-`1` matrix.

More About

Touch and No-Touch Options

The one-touch and no-touch options provide a payoff if the underlying spot either ever or never trades at or beyond the barrier level. Otherwise, the payoff is zero.

Only two outcomes are possible with a one-touch option if a trader holds the contract all the way through expiration:

- The target price (`Barrier`) is reached and the trader collects the full premium.
- The target price (`Barrier`) is not reached and the trader loses the amount originally paid to open the trade.

Version History

Introduced in R2019b

Serial date numbers not recommended
Not recommended starting in R2022b

Although `touchbybls` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

touchsensbybls

Calculate price or sensitivities for one-touch and no-touch binary options using Black-Scholes option pricing model

Syntax

```
PriceSens = touchsensbybls(RateSpec,StockSpec,Settle,Maturity,BarrierSpec,
Barrier,Payoff)
PriceSens = touchsensbybls( ___ ,Name,Value)
```

Description

`PriceSens = touchsensbybls(RateSpec,StockSpec,Settle,Maturity,BarrierSpec, Barrier,Payoff)` calculates the price and sensitivities for one-touch and no-touch binary options using the Black-Scholes option pricing model.

Note Alternatively, you can use the `Touch` object to calculate price or sensitivities for one touch options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`PriceSens = touchsensbybls( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Calculate the Price and Sensitivities for a One-Touch Option

Compute the price and sensitivities for a one-touch option using the following data:

```
AssetPrice = 105;
Rate = 0.1;
Volatility = 0.2;
Settle = datetime(2018,1,1);
Maturity = datetime(2018,6,1);
```

Define the `RateSpec` using `intenvset`.

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, 'EndDates', ...
Maturity, 'Rates', Rate, 'Compounding', -1);
```

Define the `StockSpec` using `stockspec`.

```
DividendType = "Continuous";
DividendYield = Rate - 0.1;
StockSpec = stockspec(Volatility, AssetPrice, DividendType, DividendYield);
```

Define the sensitivities.

```
OutSpec = {'price', 'delta', 'gamma'};
```

Calculate the price and sensitivities for a one-touch binary option.

```
BarrierSpec = "OT";
Barrier = 100;
Payoff = 15;

[Price, Delta, Gamma] = touchsensbybls(RateSpec, StockSpec, Settle, Maturity, BarrierSpec, Barrie

Price = 9.4102

Delta = -0.9415

Gamma = 0.0685
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities, the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

Settle — Settlement or trade date

datetime array | string array | date character vector

Settlement or trade date for the touch option, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `touchsensbybls` also accepts serial date numbers as inputs, but they are not recommended.

Maturity — Maturity date

datetime array | string array | date character vector

Maturity date for the touch option, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `touchsensbybls` also accepts serial date numbers as inputs, but they are not recommended.

BarrierSpec — Barrier option type

character vector with values `'OT'` or `'NT'`

Barrier option type, specified as an NINST-by-1 cell array of character vectors with the following values:

- 'OT' — One-touch. The one-touch option provides a payoff if the underlying spot ever trades at or beyond the Barrier level and the payoff is zero otherwise.
- 'NT' — No-touch. The no-touch option provides a Payoff if the underlying spot ever never trades at or beyond the Barrier level and the Payoff is zero otherwise.

Data Types: char | cell

Barrier — Barrier value
numeric

Barrier value, specified as an NINST-by-1 matrix of numeric values.

Data Types: double

Payoff — Payoff value
numeric

Payoff value, specified as an NINST-by-1 matrix of numeric values.

Note The payoff value is calculated for the point in time that the Barrier value is reached. The payoff is either cash or nothing. If a no-touch option is specified using the BarrierSpec, the payoff is at the Maturity of the option.

Data Types: double

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: Price = touchsensbybls(RateSpec,StockSpec,Settle,Maturity,BarrierSpec,Barrier,Payoff, 'OutSpec','Delta')

OutSpec — Define outputs
{'Price'} (default) | character vector with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All' | cell array of character vectors with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and an NOUT- by-1 or a 1-by-NOUT cell array of character vectors with possible values of 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'.

OutSpec = {'All'} specifies that the output is Delta, Gamma, Vega, Lambda, Rho, Theta, and Price, in that order. This is the same as specifying OutSpec to include each sensitivity.

Example: OutSpec = {'delta','gamma','vega','lambda','rho','theta','price'}

Data Types: char | cell

Output Arguments

`PriceSens` — Expected prices or sensitivities for one-touch options

matrix

Expected prices at time 0 or sensitivities (defined using `OutSpec`) for one-touch options, returned as an `NINST`-by-`1` matrix.

More About

Touch and No-Touch Options

The one-touch and no-touch options provide a payoff if the underlying spot either ever or never trades at or beyond the barrier level. Otherwise, the payoff is zero.

Only two outcomes are possible with a one-touch option if a trader holds the contract all the way through expiration:

- The target price (`Barrier`) is reached and the trader collects the full premium.
- The target price (`Barrier`) is not reached and the trader loses the amount originally paid to open the trade.

Version History

Introduced in R2019b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `touchsensbybls` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

dbltouchbybls

Price double one-touch and double no-touch binary options using Black-Scholes option pricing model

Syntax

```
Price = dbltouchbybls(RateSpec,StockSpec,Settle,Maturity,BarrierSpec,Barrier,
Payoff)
```

Description

`Price = dbltouchbybls(RateSpec,StockSpec,Settle,Maturity,BarrierSpec,Barrier, Payoff)` calculates double one-touch and double no-touch binary options using Black-Scholes option pricing model.

Note Alternatively, you can use the `DoubleTouch` object to price double touch options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

Examples

Price a Double No-Touch Option

Compute the price of a double no-touch option using the following data:

```
AssetPrice = 105;
Rate = 0.1;
Volatility = 0.2;
Settle = datetime(2018,1,1);
Maturity = datetime(2018,6,1);
```

Define the `RateSpec` using `intenvset`.

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, 'EndDates', ...
Maturity, 'Rates', Rate, 'Compounding', -1);
```

Define the `StockSpec` using `stockspec`.

```
DividendType = "Continuous";
DividendYield = Rate - 0.03;
StockSpec = stockspec(Volatility, AssetPrice, DividendType, DividendYield);
```

Calculate the price of a double no-touch binary option.

```
BarrierSpec = "DNT";
Barrier = [120 80];
Payoff = 10;

Price = dbltouchbybls(RateSpec, StockSpec, Settle, Maturity, BarrierSpec, Barrier, Payoff)
```

```
Price = 6.3082
```

Input Arguments

`RateSpec` — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

`StockSpec` — Stock specification for underlying asset

structure

Stock specification for the underlying asset, specified by the `StockSpec` obtained from `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities, the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

`Settle` — Settlement or trade date

datetime array | string array | date character vector

Settlement or trade date for the double touch option, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `dbltouchbybls` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date for the double touch option, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `dbltouchbybls` also accepts serial date numbers as inputs, but they are not recommended.

`BarrierSpec` — Double barrier option type

cell array of character vectors with values of `'DOT'` or `'DNT'` | string array with values of `"DOT"` or `"DNT"`

Double barrier option type, specified as an `NINST`-by-`1` cell array of character vectors or string array with the following values:

- `'DOT'` — Double one-touch. The double one-touch option defines two `Barrier` levels. A double one-touch option provides a `Payoff` if the underlying asset ever touches either the upper or lower `Barrier` levels.
- `'DNT'` — Double no-touch. The double no-touch option defines two `Barrier` levels. A double no-touch option provides a `Payoff` if the underlying asset ever never touches either the upper or lower `Barrier` levels.

Data Types: `char` | `cell` | `string`

`Barrier` — Double barrier value

numeric

Double barrier value, specified as an `NINST`-by-`2` matrix of numeric values, where the first column is Upper Barrier(1)(UB) and the second column is Lower Barrier(2)(LB). Barrier(1) must be greater than Barrier(2).

Data Types: `double`

`Payoff` — Payoff value

numeric

Payoff value, specified as an `NINST`-by-`1` matrix of numeric values, where each element is a `1`-by-`2` vector in which the first column is Barrier(1)(UB) and the second column is Barrier(2)(LB). Barrier(1) must be greater than Barrier(2).

Note The payoff value is calculated for the point in time that the `Barrier` value is reached. The payoff is either cash or nothing. If you specify a double no-touch option using `BarrierSpec`, the payoff is at the `Maturity` of the option.

Data Types: `double`

Output Arguments

`Price` — Expected prices for double one-touch options

matrix

Expected prices for double one-touch options at time 0, returned as an `NINST`-by-`1` matrix.

More About

Double One-Touch and Double No-Touch Options

Double one-touch options and double no-touch options work the same way as one-touch options, except that there are two barriers.

A double one-touch or double no-touch option provides a payoff if the underlying spot either ever or never touches either the upper or lower `Barrier` levels. If neither barrier level is breached prior to expiration, the option expires worthless and the trader loses all the premium paid to the broker for setting up the trade. For example, if the current USD/EUR rate is 1.15, and the trader believes that this rate will change significantly over the next 15 days, the trader can use a double one-touch option with barriers at 1.10 and 1.20. The trader can profit if the rate moves beyond either of the two barriers.

Version History

Introduced in R2019b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `dbltouchbybls` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

dbltouchsensbybls

Calculate prices and sensitivities for double one-touch and double no-touch binary options using Black-Scholes option pricing model

Syntax

```
PriceSens = dbltouchsensbybls(RateSpec,StockSpec,Settle,Maturity,BarrierSpec,
Barrier,Payoff)
PriceSens = dbltouchsensbybls( ___ ,Name,Value)
```

Description

`PriceSens = dbltouchsensbybls(RateSpec,StockSpec,Settle,Maturity,BarrierSpec, Barrier,Payoff)` calculates prices and sensitivities for double one-touch and double no-touch binary options using the Black-Scholes option pricing model.

Note Alternatively, you can use the `DoubleTouch` object to calculate price or sensitivities for double touch options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`PriceSens = dbltouchsensbybls( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Calculate the Price and Sensitivities for a Double No-Touch Option

Compute the price and sensitivities for a double no-touch option using the following data:

```
AssetPrice = 105;
Rate = 0.1;
Volatility = 0.2;
Settle = datetime(2018,1,1);
Maturity = datetime(2018,6,1);
```

Define the `RateSpec` using `intenvset`.

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, 'EndDates', ...
Maturity, 'Rates', Rate, 'Compounding', -1);
```

Define the `StockSpec` using `stockspec`.

```
DividendType = "Continuous";
DividendYield = Rate - 0.03;
StockSpec = stockspec(Volatility, AssetPrice, DividendType, DividendYield);
```

Define the sensitivities.

```
OutSpec = {'price', 'delta', 'gamma'};
```

Calculate the price and sensitivities for a double no-touch binary option.

```
BarrierSpec = "DNT";
Barrier = [120 80];
Payoff = 10;

[Price, Delta, Gamma] = dbltouchsensbybls(RateSpec, StockSpec, Settle, Maturity, BarrierSpec, Ba

Price = 6.3082

Delta = -0.2770

Gamma = -0.0311
```

Input Arguments

`RateSpec` — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

`StockSpec` — Stock specification for underlying asset

structure

Stock specification for the underlying asset, specified by the `StockSpec` obtained from `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities, the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

`Settle` — Settlement or trade date

datetime array | string array | date character vector

Settlement or trade date for the double touch option, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `dbltouchsensbybls` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date for the double touch option, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `dbltouchsensbybls` also accepts serial date numbers as inputs, but they are not recommended.

`BarrierSpec` — Double barrier option type

cell array of character vectors with values of `'DOT'` or `'DNT'` | string array with values of `"DOT"` or `"DNT"`

Double barrier option type, specified as an NINST-by-1 cell array of character vectors or string array with the following values:

- 'DOT' — Double one-touch. The double one-touch option defines two Barrier levels. A double one-touch option provides a Payoff if the underlying asset ever touches either the upper or lower Barrier levels.
- 'DNT' — Double no-touch. The double no-touch option defines two Barrier levels. A double no-touch option provides a Payoff if the underlying asset ever never touches either the upper or lower Barrier levels.

Data Types: char | cell | string

Barrier — Double barrier value
numeric

Double barrier value, specified as an NINST-by-2 matrix of numeric values, where the first column is Upper Barrier(1)(UB) and the second column is Lower Barrier(2)(LB). Barrier(1) must be greater than Barrier(2).

Data Types: double

Payoff — Payoff value
numeric

Payoff value, specified as an NINST-by-1 matrix of numeric values, where each element is a 1-by-2 vector in which the first column is Barrier(1)(UB) and the second column is Barrier(2)(LB). Barrier(1) must be greater than Barrier(2).

Note The payoff value is calculated for the point in time that the Barrier value is reached. The payoff is either cash or nothing. If you specify a double no-touch option using BarrierSpec, the payoff is at the Maturity of the option.

Data Types: double

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: PriceSens = dbltouchsensbybls(RateSpec,StockSpec,OptSpec,Strike,Settle,Maturity,BarrierSpec,Barrier,'OutSpec','Delta')

OutSpec — Define outputs
{'Price'} (default) | character vector with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All' | cell array of character vectors with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All' | string array with values "Price", "Delta", "Gamma", "Vega", "Lambda", "Rho", "Theta", and "All"

Define outputs, specified as the comma-separated pair consisting of `'OutSpec'` and an `NOUT`- by-`1` or a `1`-by-`NOUT` cell array of character vectors with possible values of `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`.

`OutSpec = {'All'}` specifies that the output is `Delta`, `Gamma`, `Vega`, `Lambda`, `Rho`, `Theta`, and `Price`, in that order. This is the same as specifying `OutSpec` to include each sensitivity.

Example: `OutSpec = {'delta','gamma','vega','lambda','rho','theta','price'}`

Data Types: `char` | `cell`

Output Arguments

`PriceSens` — Expected prices or sensitivities for double one-touch options

matrix

Expected prices at time 0 or sensitivities (defined using `OutSpec`) for double one-touch options, returned as an `NINST`-by-`1` matrix.

More About

Double One-Touch and Double No-Touch Options

Double one-touch options and double no-touch options work the same way as one-touch options, except that there are two barriers.

A double one-touch or double no-touch option provides a payoff if the underlying spot either ever or never touches either the upper or lower `Barrier` levels. If neither barrier level is breached prior to expiration, the option expires worthless and the trader loses all the premium paid to the broker for setting up the trade. For example, if the current USD/EUR rate is 1.15, and the trader believes that this rate will change significantly over the next 15 days, the trader can use a double one-touch option with barriers at 1.10 and 1.20. The trader can profit if the rate moves beyond either of the two barriers.

Version History

fininstrument

Create specified instrument object type

Syntax

```
Instrument = fininstrument(InstrumentType,Name,Value)
```

Description

`Instrument = fininstrument(InstrumentType,Name,Value)` creates an instrument object for one or more instruments specified by the `InstrumentType` and specifies options using one or more name-value pair arguments. The available name-value pair arguments depend on the `InstrumentType` you specify.

For more information on the workflow for creating an instrument object, a model object, and a pricer object, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods, see “Choose Instruments, Models, and Pricers” on page 1-53.

Examples

Use `fininstrument` to Create `OptionEmbeddedFixedBond` Instrument

Use `fininstrument` to create an `OptionEmbeddedFixedBond` instrument object.

```
CallDates = datetime(2025,9,15) + calyears([0 1 2]');
CallStrikes = [101 103 105]';
CallSchedule = timetable(CallDates,CallStrikes);
OptionEmbedFixedBOption = fininstrument("OptionEmbeddedFixedBond",'Maturity',"15-Sep-2031",'Coupo
```

```
OptionEmbedFixedBOption =
  OptionEmbeddedFixedBond with properties:

                 CouponRate: 0.0300
                     Period: 1
                      Basis: 0
                EndMonthRule: 1
                   Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                    Holidays: NaT
                   IssueDate: NaT
              FirstCouponDate: NaT
               LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 15-Sep-2031
                   CallDates: [3x1 datetime]
                    PutDates: [0x1 datetime]
                CallSchedule: [3x1 timetable]
```

```
      PutSchedule: [0x0 timetable]
CallExerciseStyle: "bermudan"
 PutExerciseStyle: [0x0 string]
             Name: "option_embedded_fixedbond"
```

Input Arguments

`InstrumentType` — Type of instrument

character vector | string

Type of instrument, specified as a scalar string or character vector.

Use these options for interest-rate instruments:

- `"Deposit"` — For more information, see `Deposit`.
- `"FRA"` — For more information, see `FRA`.
- `"FixedBond"` — For more information, see `FixedBond`.
- `"FixedBondOption"` — For more information, see `FixedBondOption`.
- `"FloatBond"` — For more information, see `FloatBond`.
- `"FloatBondOption"` — For more information, see `FloatBondOption`.
- `"OptionEmbeddedFixedBond"` — For more information, see `OptionEmbeddedFixedBond`.
- `"OptionEmbeddedFloatBond"` — For more information, see `OptionEmbeddedFloatBond`.
- `"Swap"` — For more information, see `Swap`.
- `"Cap"` — For more information, see `Cap`.
- `"Floor"` — For more information, see `Floor`.
- `"Swaption"` — For more information, see `Swaption`.
- `"STIRFuture"` — For more information, see `STIRFuture`.
- `"OISFuture"` — For more information, see `OISFuture`.
- `"OvernightIndexSwap"` — For more information, see `OvernightIndexedSwap`.
- `"BondFuture"` — For more information, see `BondFuture`.

Use these options for inflation instruments:

- `"InflationBond"` — For more information, see `InflationBond`.
- `"YearYearInflationSwap"` — For more information, see `YearYearInflationSwap`.
- `"ZeroCouponInflationSwap"` — For more information, see `ZeroCouponInflationSwap`.
- `"ConvertibleBond"` — For more information, see `ConvertibleBond`.

Use these options for equity, commodity, FX, or energy instruments:

- `"Vanilla"` — For more information, see `Vanilla`.
- `"Lookback"` — For more information, see `Lookback`.
- `"PartialLookback"` — For more information, see `PartialLookback`.
- `"Barrier"` — For more information, see `Barrier`.

- `"DoubleBarrier"` — For more information, see `DoubleBarrier`.
- `"Asian"` — For more information, see `Asian`.
- `"Spread"` — For more information, see `Spread`.
- `"VarianceSwap"` — For more information, see `VarianceSwap`.
- `"Touch"` — For more information, see `Touch`.
- `"DoubleTouch"` — For more information, see `DoubleTouch`.
- `"Cliquet"` — For more information, see `Cliquet`.
- `"Binary"` — For more information, see `Binary`.
- `"CommodityFuture"` — For more information, see `CommodityFuture`.
- `"EquityIndexFuture"` — For more information, see `EquityIndexFuture`.
- `"FXFuture"` — For more information, see `FXFuture`.
- `"ConvertibleBond"` — For more information, see `ConvertibleBond`.

Use these options for credit derivative instruments:

- `"CDS"` — For more information, see `CDS`.
- `"CDSOption"` — For more information, see `CDSOption`.

Data Types: `string` | `char`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Instrument = fininstrument("Cap",Name,Value)`

The available name-value pair arguments depend on the value you specify for `InstrumentType`.

Name-Value Pair Arguments for Interest-Rate Instruments

- `Deposit` — For more information, see “Deposit Name-Value Pair Arguments” on page 11-2994.
- `FRA` — For more information, see “FRA Name-Value Pair Arguments” on page 11-2835.
- `FixedBond` — For more information, see “FixedBond Name-Value Pair Arguments” on page 11-2750.
- `FixedBondOption` — For more information, see “FixedBondOption Name-Value Pair Arguments” on page 11-2770.
- `FloatBond` — For more information, see “FloatBond Name-Value Pair Arguments” on page 11-2786.
- `FloatBondOption` — For more information, see “FloatBondOption Name-Value Pair Arguments” on page 11-2804.
- `OptionEmbeddedFixedBond` — For more information, see “OptionEmbeddedFixedBond Name-Value Pair Arguments” on page 11-2860.
- `OptionEmbeddedFloatBond` — For more information, see “OptionEmbeddedFloatBond Name-Value Pair Arguments” on page 11-2884.

- `Swap` — For more information, see “Swap Name-Value Pair Arguments” on page 11-2917.
- `Cap` — For more information, see “Cap Name-Value Pair Arguments” on page 11-2710.
- `Floor` — For more information, see “Floor Name-Value Pair Arguments” on page 11-2818.
- `Swaption` — For more information, see “Swaption Name-Value Pair Arguments” on page 11-2946.
- `STIRFuture` — For more information, see “STIRFuture Name-Value Arguments” on page 11-2506.
- `OvernightIndexedSwap` — For more information, see “OvernightIndexedSwap Name-Value Arguments” on page 11-2529.
- `OISFuture` — For more information, see “OISFuture Name-Value Pair Arguments” on page 11-2495.
- `BondFuture` — For more information, see “BondFuture Name-Value Arguments” on page 11-3003.
- `ConvertibleBond` — For more information, see “ConvertibleBond Name-Value Pair Arguments” on page 11-2553.

Name-Value Pair Arguments for Inflation Instruments

- `InflationBond` — For more information, see “InflationBond Name-Value Pair Arguments” on page 11-2569.
- `YearYearInflationSwap` — For more information, see “YearYearInflationSwap Name-Value Pair Arguments” on page 11-2582.
- `ZeroCouponInflationSwap` — For more information, see “ZeroCouponInflationSwap Name-Value Pair Arguments” on page 11-2592.

Name-Value Pair Arguments for Equity Instruments

“Choose Instruments, Models, and Pricers” on page 1-53

finmodel

Create specified model object type

Syntax

```
Model = finmodel(ModelType,Name,Value)
```

Description

`Model = finmodel(ModelType,Name,Value)` creates a `Model` object based on `ModelType` creates a model object specified by `ModelType` and specifies model options using one or more name-value pair arguments.

For more information on the workflow for creating an instrument object, a model object, and a pricer object, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods, see “Choose Instruments, Models, and Pricers” on page 1-53.

Examples

Use `finmodel` to Create SABR Model

Use `finmodel` to create a SABR model object.

```
SabrModel = finmodel("SABR",'Alpha',0.032,'Beta',0.04, 'Rho', .08, 'Nu', 0043,'Shift',0.002)
```

```
SabrModel =
  SABR with properties:

             Alpha: 0.0320
              Beta: 0.0400
               Rho: 0.0800
                Nu: 43
             Shift: 0.0020
    VolatilityType: "black"
```

Input Arguments

`ModelType` — Model type

character vector | string

Model type, specified as a scalar string or character vector.

These options are available for interest-rate instruments:

- `"Black"` — For more information, see `Black`.
- `"HullWhite"` — For more information, see `HullWhite`.
- `"BlackKarasinski"` — For more information, see `BlackKarasinski`.
- `"BlackDermanToy"` — For more information, see `BlackDermanToy`.
- `"Normal"` — For more information, see `Normal`.
- `"SABR"` — For more information, see `SABR`.
- `"BraceGatarekMusiela"` — For more information, see `BraceGatarekMusiela`.
- `"SABRBraceGatarekMusiela"` — For more information, see `SABRBraceGatarekMusiela`.
- `"LinearGaussian2F"` — For more information, see `LinearGaussian2F`.

These options are available for equity instruments:

- `"BlackScholes"` — For more information, see `BlackScholes`.
- `"Bachelier"` — For more information, see `Bachelier`.
- `"Heston"` — For more information, see `Heston`.
- `"Bates"` — For more information, see `Bates`.
- `"Merton"` — For more information, see `Merton`.
- `"Dupire"` — For more information, see `Dupire`.

These options are available for credit derivative instruments:

- `"CDSBlack"` — For more information, see `CDSBlack`.

Data Types: `string` | `char`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Model = finmodel("Black",Name,Value)`

The available name-value pair arguments depend on the value you specify for `ModelType`.

Name-Value Pair Arguments for Interest-Rate Models

- `Black` — For more information, see “Black Name-Value Pair Arguments” on page 11-3048.
- `HullWhite` — For more information, see “HullWhite Name-Value Pair Arguments” on page 11-3115.
- `BlackKarasinski` — For more information, see “BlackKarasinski Name-Value Pair Arguments” on page 11-3096.
- `BlackDermanToy` — For more information, see “BlackDermanToy Name-Value Pair Arguments” on page 11-3103.
- `Normal` — For more information, see “Normal Name-Value Pair Arguments” on page 11-3125.
- `Sabr` — For more information, see “SABR Name-Value Pair Arguments” on page 11-3139

- `BraceGatarekMusiela` — For more information, see “BraceGatarekMusiela Name-Value Arguments” on page 11-3065

- `LinearGaussian2F` — For more information, see “LinearGaussian2F Name-Value Arguments” on page 11-3090

Name-Value Pair Arguments for Equity Models

- `BlackScholes` — For more information, see “BlackScholes Name-Value Pair Arguments” on page 11-3057.
- `Bachelier` — For more information, see “Bachelier Name-Value Pair Arguments” on page 11-3130.
- `Heston` — For more information, see “Heston Name-Value Pair Arguments” on page 11-3108.
- `Bates` — For more information, see “Bates Name-Value Pair Arguments” on page 11-3040.
- `Merton` — For more information, see “Merton Name-Value Pair Arguments” on page 11-3119.
- `Dupire` — For more information, see “Dupire Name-Value Pair Arguments” on page 11-3133.

Name-Value Pair Arguments for Credit Derivative Models

- `CDSBlack` — For more information, see “CDSBlack Name-Value Pair Arguments” on page 11-3052.

Output Arguments

`Model` — Model

model object

Model, returned as a model object.

finpricer

Create pricing method

Syntax

```
Pricer = finpricer(PricerType,Name,Value)
```

Description

`Pricer = finpricer(PricerType,Name,Value)` creates a `Pricer` object based on `PricerType` creates a pricer object and specifies pricing options using one or more name-value pair arguments. The available name-value pair arguments depend on the `PricerType` you specify.

For more information on the workflow for creating an instrument object, a model object, and a pricer object, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods, see “Choose Instruments, Models, and Pricers” on page 1-53.

Examples

Use `finpricer` to Create `ConzeViswanathan` Pricer

This example shows the workflow to create a `BlackScholes` model and `ratecurve` object to use with a `ConzeViswanathan` pricing method.

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',.358)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.3580
    Correlation: 1
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2020,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2020
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `ConzeViswanathan` Pricer Object

Use `finpricer` to create a `ConzeViswanathan` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPrice',950,
```

```
outPricer =
  ConzeViswanathan with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 950
    DividendValue: 2.5000
     DividendType: "continuous"
```

Input Arguments

`PricerType` — Pricer type

character vector | string

Pricer type, specified as a scalar string or character vector.

These options are available for interest-rate instruments:

- `"Discount"` — For more information, see `Discount`.
- `"Future"` — For more information, see `Future`.
- `"IRTree"` — For more information, see `IRTree`.
- `"IRMonteCarlo"` — For more information, see `IRMonteCarlo`.
- `"HullWhite"` — For more information, see `HullWhite`.
- `"Analytic"` — The `"Analytic"` pricer can be any one of the following types of pricing methods:
  - `SABR` — For more information, see `SABR`.
  - `Normal` — For more information, see `Normal`.
  - `Black` — For more information, see `Black`.

These options are available for inflation instruments:

- `"Inflation"` — For more information, see `Inflation`.

These options are available for equity instruments:

- `"Analytic"` — The `"Analytic"` pricer can be any one of the following types of pricing methods:
  - `BlackScholes` — For more information, see `BlackScholes`.
  - `IkedaKunitomo` — For more information, see `IkedaKunitomo`.
  - `HeynenKat` — For more information, see `HeynenKat`.
  - `Heston` — For more information, see `Heston`.
  - `Levy` — For more information, see `Levy`.
  - `KemnaVorst` — For more information, see `KemnaVorst`.
  - `TurnbullWakeman` — For more information, see `TurnbullWakeman`.
  - `ConzeViswanathan` — For more information, see `ConzeViswanathan`.
  - `GoldmanSosinGatto` — For more information, see `GoldmanSosinGatto`.
  - `RollGeskeWhaley` — For more information, see `RollGeskeWhaley`.
  - `Rubinstein` — For more information, see `Rubinstein`.
  - `Kirk` — For more information, see `Kirk`.
  - `BjerksundStensland` — For more information, see `BjerksundStensland`.
- `"AssetTree"` — For more information, see `AssetTree`.
- `"AssetMonteCarlo"` — For more information, see `AssetMonteCarlo`.
- `"FiniteDifference"` — For more information, see `FiniteDifference`.
- `"FFT"` — For more information, see `FFT`.
- `"NumericalIntegration"` — For more information, see `NumericalIntegration`.
- `"VannaVolga"` — For more information, see `VannaVolga`.
- `"ReplicatingVarianceSwap"` — For more information, see `ReplicatingVarianceSwap`.
- `"Future"` — For more information, see `Future`.

These options are available for credit derivative instruments:

- `"Credit"` — For more information, see `Credit`.
- `"Analytic"` — The `"Analytic"` pricer can be any one of the following types of pricing methods:
  - `CDSBlack` — For more information, see `CDSBlack`.

Data Types: `string` | `char`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Pricer = finpricer("Black",Name,Value)`

Depending on the `PricerType`, the associated name-value pair arguments are different.

Name-Value Pair Arguments for Interest-Rate Pricers

- `IRTree` — For more information, see “IRTree Name-Value Pair Arguments” on page 11-3288.
- `IRMonteCarlo` — For more information, see “IRMonteCarlo Name-Value Arguments” on page 11-3276.
- `Black` — For more information, see “Black Name-Value Pair Arguments” on page 11-3199.
- `HullWhite` — For more information, see “HullWhite Name-Value Pair Arguments” on page 11-3272.
- `Normal` — For more information, see “Normal Name-Value Pair Arguments” on page 11-3332.
- `Sabr` — For more information, see “SABR Name-Value Pair Arguments” on page 11-3342.
- `Discount` — For more information, see “Discount Name-Value Pair Arguments” on page 11-3244.
- `Future` — For more information, see “Future Name-Value Pair Arguments” on page 11-3248.

Name-Value Pair Arguments for Inflation Pricers

- `Inflation` — For more information, see “Inflation Name-Value Pair Arguments” on page 11-2602.

Name-Value Pair Arguments for Equity Pricers

- `AssetTree` — For more information, see “AssetTree Name-Value Pair Arguments” on page 11-3302.
- `FiniteDifference` — For more information, see “FiniteDifference Name-Value Pair Arguments” on page 11-3347.

- `FFT` — For more information, see “FFT Name-Value Pair Arguments” on page 11-3252.
- `NumericalIntegration` — For more information, see “NumericalIntegration Name-Value Pair Arguments” on page 11-3230.
- `VannaVolga` — For more information, see “Required VannaVolga Name-Value Pair Arguments” on page 11-3170.
- `ReplicatingVarianceSwap` — For more information, see “ReplicatingVarianceSwap Name-Value Pair Arguments” on page 11-3183.
- `Future` — For more information, see “Future Name-Value Pair Arguments” on page 11-3248.

Name-Value Pair Arguments for Credit Derivative Pricers

- `Credit` — For more information, see “Credit Name-Value Pair Arguments” on page 11-3216.
- `CDSBlack` — For more information, see “CDSBlack Name-Value Pair Arguments” on page 11-3221.

Output Arguments

`Pricer` — Pricer

pricer object

Pricer, returned as a pricer object.

Version History

Introduced in R2020a

irbootstrap

Bootstrap interest-rate curve from market data

Syntax

```
outCurve = irbootstrap(BootInstruments,Settle)
outCurve = irbootstrap( ___ ,Name,Value)
```

Description

`outCurve = irbootstrap(BootInstruments,Settle)` creates a data structure for storing interest-rate term structure data. The `outCurve` output is a `ratecurve` object.

`outCurve = irbootstrap( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to any of the input argument combinations in the previous syntax. For example, `OutCurve = irbootstrap(Settle,BootInstruments,'Type',"zero",'Compounding',2,'Basis',5,'InterpMethod',"cubic")` bootstraps a zero curve from `BootInstruments`.

Examples

Bootstrap `ratecurve` Object from Market Data

Define Deposit and Swap Parameters

```
Settle = datetime(2018,3,21);
DepRates = [.0050769 .0054934 .0061432 .0072388 .0093263]';
DepTimes = [1 2 3 6 12]';
DepDates = datemnth(Settle,DepTimes);
nDeposits = length(DepTimes);

SwapRates = [.0112597 0;.0128489 0;.0138917 0;.0146135 0;.0151175 0;...
      .0155184 0;.0158536 0;.0161435 0];
SwapTimes = (2:9)';
SwapDates = datemnth(Settle,12*SwapTimes);
nSwaps = length(SwapTimes);

nInst = nDeposits + nSwaps;
```

Create a Vector of Market Swap Instruments

Use `fininstrument` to create a vector of market `Deposit` and `Swap` instrument objects.

```
BootInstruments(nInst,1) = fininstrument.FinInstrument;
for ii=1:length(DepDates)
     BootInstruments(ii) = fininstrument("deposit",'Maturity',DepDates(ii),'Rate',DepRates(ii))
end

for ii=1:length(SwapDates)
     BootInstruments(ii+nDeposits) = fininstrument("swap",'Maturity',SwapDates(ii),'LegRate',[Sw
end
```

Create `ratecurve` Object for Zero-Rate Curve

Use `irbootstrap` to create a `ratecurve` object for the zero-rate curve.

```
ZeroCurve = irbootstrap(BootInstruments,Settle)
```

```
ZeroCurve =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [13x1 datetime]
               Rates: [13x1 double]
              Settle: 21-Mar-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create Zero Curve Using `DiscountCurve` Input

This example shows how to create a `ratecurve` object using `irbootstrap` with `Deposit` and `Swap` instruments and a `DiscountCurve` for discounting cash flows.

```
Settle = datetime(2021,4,15);
crvDates = Settle + [calmonths([1 2 3 6]) calyears([1 2 3 5 7 10 20 30])]';
crvRates = [0.0004 0.0004 0.0005 0.0006 0.0008 0.0018 0.0037 0.0088 0.013 0.0165 0.022 0.0233]';
DiscountCurve = ratecurve("zero",Settle,crvDates,crvRates);

DepRates = [0.002 0.0021 0.0023 0.0024 .0028]';
DepDates = Settle + calmonths([1 2 3 6 12]');

SwapRates = [0.0041 0;0.0057 0;0.017 0;0.0193 0;0.024 0;0.027 0];
SwapTimes = [2 3 5 10 20 30]';
SwapDates = datemnth(Settle,12*SwapTimes);

BootInstruments = [fininstrument("deposit","Maturity",DepDates,"Rate",DepRates); ...
    fininstrument("swap","Maturity",SwapDates,"LegRate",SwapRates)];

ZeroCurve = irbootstrap(BootInstruments,Settle,'DiscountCurve',DiscountCurve)
```

```
ZeroCurve =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [11x1 datetime]
               Rates: [11x1 double]
              Settle: 15-Apr-2021
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Bootstrap ratecurve Object from BootInstruments for OIS Futures and Overnight Indexed Swaps

Create a `BootInstruments` variable as an input argument to `irbootstrap` to create a ratecurve object. The `BootInstruments` variable has `OISFuture` instrument objects for one-month SOFR Futures and three-month SOFR Futures, and an `OvernightIndexedSwap` instrument object.

Create Instruments

Use `fininstrument` to create an `OISFuture` instrument object for one-month SOFR Futures.

```
Settle = datetime(2021,3,4);
HFDates = datetime(2021,3,1) + caldays(0:3)';
HistFixing = timetable(HFDates,[0.02;0.04;0.04;0.02]);

% Data from the following: https://www.cmegroup.com/trading/interest-rates/stir/one-month-sofr_qu
Prices_1M = [99.97 99.96 99.95]';
Maturity_1M = lbusdate(2021,[3 4 5]',[],[],'datetime');
StartDate_1M = fbusdate(2021,[3 4 5]',[],[],'datetime');
FutInstruments_1M = fininstrument("OISFuture","Maturity",Maturity_1M ,"QuotedPrice",Prices_1M,"St
    'HistoricalFixing',HistFixing,'Name',"1MonthSOFRFuture")
```

```
FutInstruments_1M=3×1 object
  3x1 OISFuture array with properties:

    QuotedPrice
    Method
    Basis
    StartDate
    Maturity
    Notional
    BusinessDayConvention
    Holidays
    ProjectionCurve
    HistoricalFixing
    Name
```

Use `fininstrument` to create an `OISFuture` instrument object for three-month SOFR Futures.

```
% Data from the following: https://www.cmegroup.com/trading/interest-rates/stir/three-month-sofr_
Prices_3M = [99.92 99.895 99.84 99.74]';
Dates_3M_Maturity = thirdwednesday([6 9 12 3]',[2021 2021 2021 2022]','datetime');
Dates_3M_Start = thirdwednesday([3 6 9 12]',2021,'datetime');
FutInstruments_3M = fininstrument("OISFuture","Maturity",Dates_3M_Maturity,...
    "QuotedPrice",Prices_3M,"StartDate",Dates_3M_Start,'HistoricalFixing',HistFixing,'Name',"3Mon
```

Use `fininstrument` to create an `OvernightIndexedSwap` instrument object.

```
SOFRSwapRates = [.0023 0;.0064 0;.013 0;.017 0;.0175 0];
SOFRSwapTimes = [3 5 10 20 30];
SOFRSwapDates = datemnth(Settle,12*SOFRSwapTimes)';
SOFRSwapInstruments = fininstrument("OvernightIndexedSwap","Maturity",SOFRSwapDates,"LegRate",SOF
```

```
SOFRSwapInstruments=5×1 object
  5x1 OvernightIndexedSwap array with properties:
```

```
    LegRate
    LegType
    Reset
    Basis
    Notional
    HistoricalFixing
    ResetOffset
    ProjectionCurve
    BusinessDayConvention
    Holidays
    EndMonthRule
    StartDate
    Maturity
    Name
```

Define `BootInstruments` for the three types of instruments.

```
BootInstruments = [FutInstruments_1M;FutInstruments_3M;SOFRSwapInstruments]
```

```
BootInstruments=12×1 object
  12x1 heterogeneous FinInstrument (OISFuture, OvernightIndexedSwap) array with properties:

    Name
```

Create `ratecurve` Object

Use `irbootstrap` to create a `ratecurve` object.

```
SOFRCurve = irbootstrap(BootInstruments,Settle)
```

```
SOFRCurve =
  ratecurve with properties:

                Type: "zero"
       Compounding: -1
             Basis: 0
             Dates: [12x1 datetime]
             Rates: [12x1 double]
            Settle: 04-Mar-2021
      InterpMethod: "linear"
   ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

Bootstrap `ratecurve` Object from `STIRFuture`, `Deposit`, and `Swap` `BootInstruments`

Create `BootInstruments` for multiple `Deposit`, `STIRFuture`, and `Swap` instruments and then use `irbootstrap` to create and display a `ratecurve` object.

Create Instruments

Use `fininstrument` to create a `Deposit` instrument object.

```
Settle = datetime(2021,6,15);
DepRates = [0.0016 0.0017 .00175]';
```

```
DepDates = Settle + calmonths([1 2 3]');

Deposits = fininstrument("Deposit","Maturity",DepDates,"Rate",DepRates,'Name',"deposit_instrumen

Deposits=3×1 object
  3x1 Deposit array with properties:

    Rate
    Period
    Basis
    Maturity
    Principal
    BusinessDayConvention
    Holidays
    Name
```

Use `fininstrument` to create a `STIRFuture` instrument object.

```
FutureRates = [0.002 0.0025 0.0035]';
FutMat = [datetime(2021,9,15) datetime(2021,12,15) datetime(2022,3,16)]';
FutEndDates = [datetime(2021,12,15) datetime(2022,3,15) datetime(2022,6,15)]';

Futures = fininstrument("STIRFuture","Maturity",FutMat,"RateEndDate",FutEndDates,"QuotedPrice",10

Futures=3×1 object
  3x1 STIRFuture array with properties:

    QuotedPrice
    Basis
    RateEndDate
    Maturity
    Notional
    BusinessDayConvention
    Holidays
    ProjectionCurve
    Name
```

Use `fininstrument` to create a `Swap` instrument object.

```
SwapRates = [.0063 0;.0108 0;.013 0;.015 0;0.017 0;.018 0;0.019 0];
SwapTimes = [2 5 7 10 15 20 30]';
SwapDates = datemnth(Settle,12*SwapTimes);

Swaps = fininstrument("Swap","Maturity",SwapDates,"LegRate",SwapRates,'Name',"swap_instrument")

Swaps=7×1 object
  7x1 Swap array with properties:

    LegRate
    LegType
    Reset
    Basis
    Notional
    LatestFloatingRate
    ResetOffset
    DaycountAdjustedCashFlow
    ProjectionCurve
```

```
    BusinessDayConvention
    Holidays
    EndMonthRule
    StartDate
    Maturity
    Name
```

Define `BootInstruments` for the three instruments.

```
BootInstruments = [Deposits;Futures;Swaps];
```

Create `ratecurve` Object Using `irbootstrap`

Use `irbootstrap` to create a `ratecurve` object.

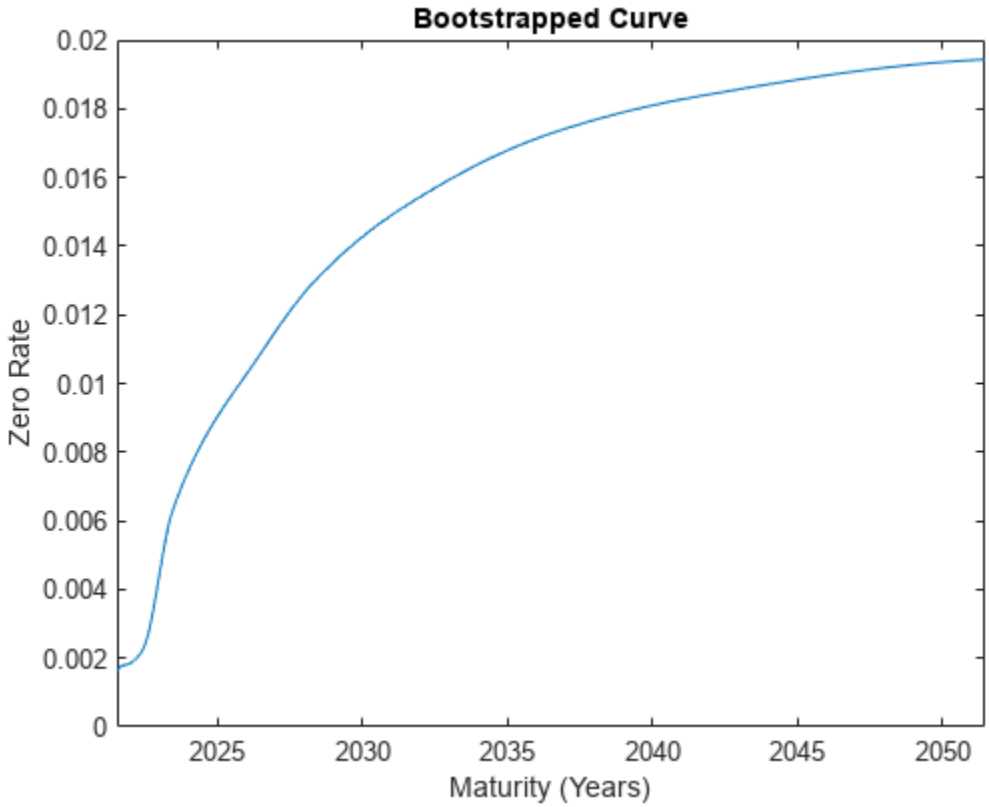
```
ConvexityAdj = (1:3)'/10000;
ZeroCurve = irbootstrap(BootInstruments,Settle,'ConvexityAdjustment',ConvexityAdj,'InterpMethod'
```

```
ZeroCurve =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [13x1 datetime]
               Rates: [13x1 double]
              Settle: 15-Jun-2021
        InterpMethod: "pchip"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Plot Bootstrapped Curve

```
PlottingDates = Settle + calmonths(1:360);
plot(PlottingDates,zerorates(ZeroCurve,PlottingDates))
xlabel('Maturity (Years)')
ylabel('Zero Rate')
title('Bootstrapped Curve')
```



Input Arguments

`BootInstruments` — Collection of instruments

array of instrument objects

Collection of instruments, specified as an array of instrument objects. The collection of instruments can include `Deposit`, `Swap`, `FRA`, `STIRFuture`, `OISFuture`, and `OvernightIndexedSwap` instruments.

Data Types: `object`

`Settle` — Settlement date

datetime scalar | string scalar | date character vector

Settlement date, specified as a scalar datetime, string, or date character vector.

To support existing code, `irbootstrap` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `OutCurve = irbootstrap(Settle,BootInstruments,'Type',"zero",'Compounding',2,'Basis',5,'InterpMethod',"cubic")`

Type — Type of interest-rate curve
`"zero"` (default) | string with value `"discount"`, `"forward"`, or `"zero"` | character vector with value `'discount'`, `'forward'`, or `'zero'`

Type of interest-rate curve, specified as the comma-separated pair consisting of `'Type'` and a scalar string or character vector.

Note When you use `irbootstrap`, the value you specify for `Type` can impact the curve construction because it affects the type of data that is interpolated on (that is, forward rates, zero rates, or discount factors) during the bootstrapping process.

Data Types: `char` | `string`

`Compounding` — Compounding frequency
`Compounding` for the `ratecurve` object (default) | possible values include: `–1`, `0`, `1`, `2`, `3`, `4`, `6`, `12`.

Compounding frequency, specified as the comma-separated pair consisting of `'Compounding'` and a scalar numeric using the supported values: `–1`, `0`, `1`, `2`, `3`, `4`, `6`, or `12`.

Data Types: `double`

`Basis` — Day-count basis
`0` (actual/actual) (default) | integer from `0` to `13`

Day-count basis, specified as the comma-separated pair consisting of `'Basis'` and a scalar integer.

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`InterpMethod` — Interpolation method
`"linear"` (default) | string with value `"linear"`, `"cubic"`, `"next"`, `"previous"`, `"pchip"`, `"v5cubic"`, `"makima"`, or `"spline"` | character vector with value `'linear'`, `'cubic'`, `'next'`, `'previous'`, `'pchip'`, `'v5cubic'`, `'makima'`, or `'spline'`

Interpolation method, specified as the comma-separated pair consisting of `'InterpMethod'` and a scalar string or character vector using a supported value. For more information on interpolation methods, see `interp1`.

Data Types: `char` | `string`

`ShortExtrapMethod` — Extrapolation method for data before first data
`"next"` (default) | string with value `"linear"`, `"next"`, `"previous"`, `"pchip"`, `"cubic"`,`"v5cubic"`, `"makima"`, or `"spline"` | character vector with value `'linear'`, `'next'`, `'previous'`, `'pchip'`, `'cubic'`,`'v5cubic'`, `'makima'`, or `'spline'`

Extrapolation method for data before first data, specified as the comma-separated pair consisting of `'ShortExtrapMethod'` and a scalar string or character vector using a supported value. For more information on interpolation methods, see `interp1`.

Data Types: `char` | `string`

`LongExtrapMethod` — Extrapolation method for data after last data
`"previous"` (default) | string with value `"linear"`, `"next"`, `"previous"`, `"pchip"`, `"cubic"`,`"v5cubic"`, `"makima"`, or `"spline"` | character vector with value `'linear'`, `'next'`, `'previous'`, `'pchip'`, `'cubic'`,`'v5cubic'`, `'makima'`, or `'spline'`

Extrapolation method for data after last data, specified as the comma-separated pair consisting of `'LongExtrapMethod'` and a scalar string or character vector using a supported value. For more information on interpolation methods, see `interp1`.

Data Types: `char` | `string`

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve.empty` (default) | scalar `ratecurve` object

`ratecurve` object for discounting cash flows, specified as the comma-separated pair consisting of `'DiscountCurve'` and the name of a previously created `ratecurve` object.

Data Types: `object`

`ConvexityAdjustment` — Convexity adjustment for `STIRFuture` instrument
`0` (default) | numeric vector

Convexity adjustment for one or more `STIRFuture` instruments, specified as the comma-separated pair consisting of `'ConvexityAdjustment'` and an `NFutures`-by-`1` vector of numeric values.

Note You can only use `ConvexityAdjustment` when using `irbootstrap` with a `STIRFuture` instrument. Also, the length of the `ConvexityAdjustment` vector must match the number of `STIRFuture` instruments.

Data Types: `double`

Output Arguments

`outCurve` — Rate curve

`ratecurve` object

Rate curve, returned as a `ratecurve` object. The object has the following properties:

- `Type`
- `Settle`
- `Compounding`
- `Basis`
- `Dates`
- `Rates`
- `InterpMethod`
- `ShortExtrapMethod`
- `LongExtrapMethod`

Version History

Introduced in R2020a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `irbootstrap` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

fitNelsonSiegel

Fit Nelson-Siegel model to bond market data

Syntax

```
outCurve = fitNelsonSiegel(Settle,Instruments,CleanPrice)
```

Description

`outCurve = fitNelsonSiegel(Settle,Instruments,CleanPrice)` fits a Nelson-Siegel model to bond data.

Examples

Fit Nelson-Siegel Model to Bond Market Data

Define the bond data and use `fininstrument` to create `FixedBond` instrument objects.

```
 Settle = datetime(2017,9,15);
  Maturity = [datetime(2019,9,15);datetime(2021,9,15);...
      datetime(2023,9,15);datetime(2026,9,7);...
      datetime(2035,9,15);datetime(2047,9,15)];

  CleanPrice = [100.1;100.1;100.8;96.6;103.3;96.3];
  CouponRate = [0.0400;0.0425;0.0450;0.0400;0.0500;0.0425];

  nInst = numel(CouponRate);
Bonds(nInst,1) = fininstrument.FinInstrument;
for ii=1:nInst
    Bonds(ii) = fininstrument("FixedBond",'Maturity',Maturity(ii),...
        'CouponRate',CouponRate(ii));
end
```

Use `fitNelsonSiegel` to create a `parametercurve` object.

```
NSModel = fitNelsonSiegel(Settle,Bonds,CleanPrice)
```

```
Local minimum possible.

lsqnonlin stopped because the final change in the sum of squares relative to
its initial value is less than the value of the function tolerance.

NSModel =
  parametercurve with properties:

              Type: "zero"
            Settle: 15-Sep-2017
       Compounding: -1
             Basis: 0
    FunctionHandle: @(t)fitF(Params,t)
        Parameters: [3.5246e-08 0.0363 0.0900 16.5823]
```

Input Arguments

`Settle` — Settlement date

datetime scalar | string scalar | date character vector

Settlement date, specified as a scalar datetime, string, or date character vector.

To support existing code, `fitNelsonSiegel` also accepts serial date numbers as inputs, but they are not recommended.

`Instruments` — Bond instrument objects

array

Bond instrument objects, specified as an array of bond instruments objects.

Data Types: `object`

`CleanPrice` — Observed market prices

vector

Observed market prices, specified as a vector.

Data Types: `double`

Output Arguments

`outCurve` — Fitted Nelson-Siegel model

`parametercurve` object

Fitted Nelson-Siegel model, returned as a `parametercurve` object.

Version History

Introduced in R2020a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `fitNelsonSiegel` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```

“Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22
“Choose Instruments, Models, and Pricers” on page 1-53

price

Package: `finpricer.analytic`

Compute price for interest-rate, equity, or credit derivative instrument with `Analytic` pricer

Syntax

```
[Price,PriceResult] = price(inpPricer,inpInstrument)
[Price,PriceResult] = price( ___ ,inpSensitivity)
```

Description

`[Price,PriceResult] = price(inpPricer,inpInstrument)` computes the instrument price and related pricing information based on the pricing object `inpPricer` and the instrument object `inpInstrument`.

The `Analytic` pricer supports the following pricer objects:

- `BjerksundStensland`
- `IkedaKunitomo`
- `Black`
- `BlackScholes`
- `CDSBlack`
- `ConzeViswanathan`
- `GoldmanSosinGatto`
- `HeynenKat`
- `HullWhite`
- `Heston`
- `KemnaVorst`
- `Kirk`
- `Levy`
- `Normal`
- `RollGeskeWhaley`
- `Rubinstein`
- `SABR`
- `TurnbullWakeman`

`[Price,PriceResult] = price( ___ ,inpSensitivity)` adds an optional argument to specify sensitivities.

Examples

Use Bjerksund-Stensland Pricer and Black-Scholes Model to Price Spread Instrument

This example shows the workflow to price a European exercise `Spread` instrument when you use a `BlackScholes` model and a `BjerksundStensland` pricing method.

Create Spread Instrument Object

Use `fininstrument` to create a `Spread` instrument object.

```
SpreadOpt = fininstrument("Spread",'Strike',5,'ExerciseDate',datetime(2021,9,15),'OptionType',"pu
```

```
SpreadOpt =
  Spread with properties:

       OptionType: "put"
           Strike: 5
    ExerciseStyle: "european"
     ExerciseDate: 15-Sep-2021
             Name: "spread_option"
```

Create BlackScholes Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',[0.2,0.1])
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: [0.2000 0.1000]
    Correlation: [2x2 double]
```

Create ratecurve Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                 Type: "zero"
          Compounding: -1
                Basis: 12
                Dates: 15-Sep-2023
                Rates: 0.0350
               Settle: 15-Sep-2018
         InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create BjerksundStensland Pricer Object

Use finpricer to create a BjerksundStensland pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPrice',[100
```

```
outPricer =
  BjerksundStensland with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: [100 105]
    DividendValue: [0.0900 0.1700]
     DividendType: "continuous"
```

Price Spread Instrument

Use price to compute the price and sensitivities for the Spread instrument.

```
[Price, outPR] = price(outPricer,SpreadOpt,["all"])
```

```
Price = 7.0596
```

```
outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×7 table
    Price            Delta                    Gamma                    Lambda                Vega
    _____    ____________________    ____________________    ____________________    ____________
    7.0596    -0.23249     0.27057    0.0069887    0.0055319    -3.2932     3.8327    41.938
```

Use Rubinstein Pricer and Black-Scholes Model to Price the Absolure Return for Cliquet Instruments

This example shows the workflow to price the absolute return for three Cliquet instruments when you use a BlackScholes model and a Rubinstein pricing method.

Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,Basis=12)
```

```
myRC =
  ratecurve with properties:
```

```
                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `Cliquet` Instrument Object

Use `fininstrument` to create a `Cliquet` instrument object for three Cliquet instruments.

```
ResetDates = Settle + years(0:0.25:1);
CliquetOpt = fininstrument("Cliquet",ResetDates=ResetDates,InitialStrike=[140;150;160],ExerciseS
```

```
CliquetOpt=3×1 object
  3x1 Cliquet array with properties:

    OptionType
    ExerciseStyle
    ResetDates
    LocalCap
    LocalFloor
    GlobalCap
    GlobalFloor
    ReturnType
    InitialStrike
    Name
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",Volatility=0.28)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.2800
    Correlation: 1
```

Create `Rubinstein` Pricer Object

Use `finpricer` to create a `Rubinstein` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",DiscountCurve=myRC,Model=BlackScholesModel,SpotPrice=135,Divide
```

```
outPricer =
  Rubinstein with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
```

```
        SpotPrice: 135
    DividendValue: 0.0250
     DividendType: "continuous"
```

Price Cliquet Instruments

Use `price` to compute the price and sensitivities for the three `Cliquet` instruments.

```
[Price, outPR] = price(outPricer,CliquetOpt,"all")
```

```
Price = 3×1

   28.1905
   25.3226
   23.8168

outPR=3×1 object
  3x1 priceresult array with properties:

```

Input Arguments

`inpPricer` — Pricer object

`BjerksundStensland` object | `IkedaKunitomo` object | `Black` object | `BlackScholes` object | `CDSBlack` object | `ConzeViswanathan` object | `GoldmanSosinGatto` object | `HeynenKat` object | `HullWhite` object | `Heston` object | `KemnaVorst` object | `Kirk` object | `Levy` object | `Normal` object | `Rubinstein` object | `RollGeskeWhaley` object | `SABR` object | `TurnbullWakeman` object

Pricer object (previously created using `finpricer`), specified as a scalar. The supported pricer objects are:

- `BjerksundStensland`
- `IkedaKunitomo`
- `Black`
- `BlackScholes`
- `CDSBlack`
- `ConzeViswanathan`
- `GoldmanSosinGatto`
- `HeynenKat`
- `HullWhite`
- `Heston`
- `KemnaVorst`
- `Kirk`
- `Levy`
- `Normal`
- `RollGeskeWhaley`
- `SABR`
- `Rubinstein`
- `TurnbullWakeman`

Data Types: `object`

`inpInstrument` — Instrument object
`Cap` object | `Floor` object | `Swaption` object | `Vanilla` object | `Lookback` object | `PartialLookback` object | `Barrier` object | `DoubleBarrier` object | `Asian` object | `Spread` object | `Cliquet` object | `VarianceSwap` object | `CDSOption` object

Instrument object (previously created using `fininstrument`), specified as a scalar or a vector.

The supported instrument objects using a scalar or vector are:

- `Cap`
- `Floor`
- `Swaption`
- `Vanilla`
- `Lookback`
- `PartialLookback`
- `Barrier`
- `DoubleBarrier`
- `Asian`
- `Cliquet`
- `Spread`
- `CDSOption`

The supported instrument object using a scalar is:

- `VarianceSwap`

Data Types: `object`

`inpSensitivity` — List of sensitivities to compute
`[ ]` (default) | string array with values dependent on pricer object | cell array of character vectors with values dependent on pricer object

(Optional) List of sensitivities to compute, specified as a `NOUT`-by-`1` or a `1`-by-`NOUT` cell array of character vectors or string array.

The supported sensitivities depend on the pricing method.

`inpPricer` Object	Supported Sensitivities
`BjerksundStensland`	`{'delta','gamma','vega', 'theta','rho','price','lambda'}`
`IkedaKunitomo`	`{'delta','gamma','vega','theta','rho', 'price','lambda'}`
`Black`	`'price'`
`BlackScholes`	`{'delta','gamma','vega','theta','rho', 'price','lambda'}`
`CDSBlack`	`'price'`
`ConzeViswanathan`	`{'delta','gamma','vega','theta','rho', 'price','lambda}'`
`GoldmanSosinGatto`	`{'delta','gamma','vega','theta','rho', 'price','lambda}'`
`HeynenKat`	`{'delta','gamma','vega','theta','rho', 'price','lambda}'`
`HullWhite`	`'price'`
`Heston`	`'price'`
`KemnaVorst`	`{'delta','gamma','vega','theta','rho', 'price','lambda'}`
`Kirk`	`{'delta','gamma','vega','theta','rho', 'price','lambda'}`
`Levy`	`{'delta','gamma','vega','theta','rho', 'price','lambda'}`
`Normal`	`'price'`
`RollGeskeWhaley`	`{'delta','gamma','vega','theta','rho', 'price','lambda'}`
`Rubinstein`	`{'delta','gamma','vega','theta','rho', 'price','lambda'}`
`SABR`	`'price'`
`TurnbullWakeman`	`{'delta','gamma','vega','theta','rho', 'price',}`

`inpSensitivity = {'All'}` or `inpSensitivity = ["All"]` specifies that all sensitivities for the pricing method are returned. This is the same as specifying `inpSensitivity` to include each sensitivity.

Example: `inpSensitivity = ["delta","gamma","vega","lambda","rho","theta","price"]`

Data Types: `cell` | `string`

Output Arguments

`Price` — Instrument price
numeric

Instrument price, returned as a numeric.

`PriceResult` — Price result
`PriceResult` object

Price result, returned as a `PriceResult` object. The object has the following fields:

- `PriceResult.Results` — Table of results that includes sensitivities (if you specify `inpSensitivity`)
- `PriceResult.PricerData` — Structure for pricer data

> **Note** When pricing a `VarianceSwap`, `PriceResult.FairVariance` is returned.

Note The `inpPricer` options that do not support sensitivities do not return a `PriceResult`. For example, there is no `PriceResult` returned for when using a `Black`, `CDSBlack`, `HullWhite`, `Normal`, `Heston`, or `SABR` pricing method.

Version History

Introduced in R2020a

price

Package: `finpricer`

Compute price for equity instrument with `VannaVolga` pricer

Syntax

```
[Price,PriceResult] = price(inpPricer,inpInstrument)
[Price,PriceResult] = price( ___ ,inpSensitivity)
```

Description

`[Price,PriceResult] = price(inpPricer,inpInstrument)` computes the instrument price and related pricing information based on the pricing object `inpPricer` and the instrument object `inpInstrument`.

`[Price,PriceResult] = price( ___ ,inpSensitivity)` adds an optional argument to specify sensitivities.

Examples

TBD

Input Arguments

`inpPricer` — Pricer object
`VannaVolga` object

Pricer object, specified as a scalar `VannaVolga` pricer object. Use `finpricer` to create the `VannaVolga` pricer object.

Data Types: `object`

`inpInstrument` — Instrument object
`Vanilla` object | `Barrier` object | `DoubleBarrier` object | `Touch` object

Instrument object, specified as a scalar or vector of `Vanilla`, `Barrier`, `DoubleBarrier`, `Touch`, or `DoubleTouch` instrument objects. Use `fininstrument` to create the `Vanilla`, `Barrier`, `DoubleBarrier`, `Touch`, or `DoubleTouch`instrument objects.

Data Types: `object`

`inpSensitivity` — List of sensitivities to compute
`[ ]` (default) | string array with values `"Price"`, `"Delta"`, `"Gamma"`, `"Vega"`, `"Rho"`, `"Theta"`, `'Lambda'`, and `"All"` | cell array of character vectors with values `'Price'`, `'Delta'`, `'Gamma'`, `'Lambda'`, `'Vega'`, `'Rho'`, `'Theta'`, and `'All'`

(Optional) List of sensitivities to compute, specified as a `NOUT`-by-`1` or a `1`-by-`NOUT` cell array of character vectors or string array with supported values.

`inpSensitivity = {'All'}` or `inpSensitivity = ["All"]` specifies that the output is `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'Price'`. This is the same as specifying `inpSensitivity` to include each sensitivity.

Example: `inpSensitivity = {'delta','gamma','vega','rho','lambda','theta','price'}`

The sensitivities supported depend on the `inpInstrument`.

inpInstrument	Supported Sensitivities
`Vanilla`,	`'delta','gamma','vega','rho','lambda', 'theta','price'`
`Barrier`	`'delta','gamma','vega','rho','lambda', 'theta','price'`
`DoubleBarrier`	`'delta','gamma','vega','rho','lambda', 'theta','price'`
`Touch`	`'delta','gamma','vega','rho','lambda', 'theta','price'`
`DoubleTouch`	`'delta','gamma','vega','rho','lambda', 'theta','price'`

Data Types: `string` | `cell`

Output Arguments

`Price` — Instrument price

numeric

Instrument price, returned as a numeric.

`PriceResult` — Price result

`PriceResult` object

Price result, returned as a `PriceResult` object. The object has the following fields:

- `PriceResult.Results` — Table of results that includes sensitivities (if you specify `inpSensitivity`)
- `PriceResult.PricerData` — Structure for pricer data
- `PriceResult.PricerData.Overhedge` — TBD

Version History

Introduced in R2020b

price

Package: `finpricer`

Compute price for equity instrument with `AssetMonteCarlo` pricer

Syntax

```
[Price,PriceResult] = price(inpPricer,inpInstrument)
[Price,PriceResult] = price( ___ ,inpSensitivity)
```

Description

`[Price,PriceResult] = price(inpPricer,inpInstrument)` computes the equity instrument price and related pricing information based on the pricing object `inpPricer` and the instrument object `inpInstrument`.

`[Price,PriceResult] = price( ___ ,inpSensitivity)` adds an optional argument to specify sensitivities. Use this syntax with the input argument combination in the previous syntax.

Examples

Price Touch Instrument Using Heston Model and Asset Monte Carlo Pricer

This example shows the workflow to price a `Touch` instrument when you use a `Heston` model and an `AssetMonteCarlo` pricing method.

Create Touch Instrument Object

Use `fininstrument` to create a `Touch` instrument object.

```
TouchOpt = fininstrument("Touch",'ExerciseDate',datetime(2022,9,15),'BarrierValue',110,'PayoffVa
```

```
TouchOpt =
  Touch with properties:

    ExerciseDate: 15-Sep-2022
    BarrierValue: 110
     PayoffValue: 140
     BarrierType: "ot"
      PayoffType: "expiry"
            Name: "touch_option"
```

Create Heston Model Object

Use `finmodel` to create a `Heston` model object.

```
HestonModel = finmodel("Heston",'V0',0.032,'ThetaV',0.1,'Kappa',0.003,'SigmaV',0.2,'RhoSV',0.9)
```

```
HestonModel =
  Heston with properties:
```

```
        V0: 0.0320
    ThetaV: 0.1000
     Kappa: 0.0030
    SigmaV: 0.2000
     RhoSV: 0.9000
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
        Compounding: -1
              Basis: 12
              Dates: 15-Sep-2023
              Rates: 0.0350
             Settle: 15-Sep-2018
       InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `AssetMonteCarlo` Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo",'DiscountCurve',myRC,"Model",HestonModel,'SpotPrice',112
```

```
outPricer =
  HestonMonteCarlo with properties:

      DiscountCurve: [1x1 ratecurve]
          SpotPrice: 112
    SimulationDates: 15-Sep-2022
          NumTrials: 1000
      RandomNumbers: []
              Model: [1x1 finmodel.Heston]
       DividendType: "continuous"
      DividendValue: 0
```

Price Touch Instrument

Use `price` to compute the price and sensitivities for the `Touch` instrument.

```
[Price, outPR] = price(outPricer,TouchOpt,["all"])
```

```
Price = 63.5247
```

```
outPR =
  priceresult with properties:

       Results: [1x8 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×8 table
    Price      Delta     Gamma     Lambda       Rho       Theta      Vega     VegaLT
    _____    ________    _____    ________    ________    _____    _____    _____

    63.525    -7.2363    1.0541    -12.758    -320.21    3.5527    418.94    8.1498
```

Input Arguments

inpPricer — Pricer object

`AssetMonteCarlo` object

Pricer object, specified as a previously created `AssetMonteCarlo` pricer object. Create the pricer object using `finpricer`.

Data Types: `object`

inpInstrument — Instrument object

`Vanilla` object | `Barrier` object | `Lookback` object | `Asian` object | `DoubleBarrier` object | `Spread` object | `Touch` object | `DoubleTouch` object | `Cliquet` object | `Binary` object

Instrument object, specified as a scalar or vector of previously created instrument objects. Create the instrument objects using `fininstrument`. The following instrument objects are supported:

- `Vanilla`
- `Lookback`
- `Barrier`
- `Asian`
- `Spread`
- `DoubleBarrier`
- `Cliquet`
- `Binary`
- `Touch`
- `DoubleTouch`

Data Types: `object`

inpSensitivity — List of sensitivities to compute

`[ ]` (default) | string array with values dependent on pricer object | cell array of character vectors with values dependent on pricer object

(Optional) List of sensitivities to compute, specified as an `NOUT`-by-`1` or `1`-by-`NOUT` cell array of character vectors or string array.

The supported sensitivities depend on the pricing method.

inpInstrument Object	Supported Sensitivities
Vanilla	{'delta','gamma','vega', 'theta','rho','price','lambda'}
Lookback	{'delta','gamma','vega','theta','rho', 'price','lambda'}
Barrier	{'delta','gamma','vega','theta','rho', 'price','lambda'}
Asian	{'delta','gamma','vega','theta','rho', 'price','lambda'}
Spread	{'delta','gamma','vega','theta','rho', 'price','lambda}'
DoubleBarrier	{'delta','gamma','vega','theta','rho', 'price','lambda}'
Cliquet	{'delta','gamma','vega','theta','rho', 'price','lambda}'
Binary	{'delta','gamma','vega','theta','rho', 'price','lambda'}
Touch	{'delta','gamma','vega','theta','rho', 'price','lambda'}
DoubleTouch	{'delta','gamma','vega','theta','rho', 'price','lambda'}

`inpSensitivity = {'All'}` or `inpSensitivity = ["All"]` specifies that all sensitivities for the pricing method are returned. This is the same as specifying `inpSensitivity` to include each sensitivity.

Example: `inpSensitivity = ["delta","gamma","vega","lambda","rho","theta","price"]`

Data Types: `cell` | `string`

Output Arguments

`Price` — Instrument price

numeric

Instrument price, returned as a numeric.

`PriceResult` — Price result

`PriceResult` object

Price result, returned as a `PriceResult` object. The object has the following fields:

- `PriceResult.Results` — Table of results that includes sensitivities (if you specify `inpSensitivity`)
- `PriceResult.PricerData` — Structure for pricer data

Note The `inpPricer` options that do not support sensitivities do not return a `PriceResult`. For example, there is no `PriceResult` returned for when you use a `Black`, `CDSBlack`, `HullWhite`, `Normal`, or SABR pricing method.

Version History

Introduced in R2020b

price

Package: `finpricer`

Compute price for interest-rate instrument with `IRMonteCarlo` pricer

Syntax

```
[Price,PriceResult] = price(inpPricer,inpInstrument)
[Price,PriceResult] = price( ___ ,inpSensitivity)
```

Description

`[Price,PriceResult] = price(inpPricer,inpInstrument)` computes the interest-rate instrument price and related pricing information based on the pricing object `inpPricer` and the instrument object `inpInstrument`.

`[Price,PriceResult] = price( ___ ,inpSensitivity)` adds an optional argument to specify sensitivities. Use this syntax with the input argument combination in the previous syntax.

Examples

Price Fixed Bond Instrument Using Hull-White Model and IRMonteCarlo Pricer

This example shows the workflow to price a `FixedBond` instrument when using a `HullWhite` model and an `IRMonteCarlo` pricing method.

Create FixedBond Instrument Object

Use `fininstrument` to create a `FixedBond` instrument object.

```
FixB = fininstrument("FixedBond","Maturity",datetime(2022,9,15),"CouponRate",0.05,'Name',"fixed_b
```

```
FixB =
  FixedBond with properties:

                 CouponRate: 0.0500
                     Period: 2
                      Basis: 0
                EndMonthRule: 1
                  Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                   Holidays: NaT
                  IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 15-Sep-2022
                        Name: "fixed_bond"
```

Create HullWhite Model Object

Use finmodel to create a HullWhite model object.

```
HullWhiteModel = finmodel("HullWhite",'Alpha',0.32,'Sigma',0.49)
```

```
HullWhiteModel =
  HullWhite with properties:

    Alpha: 0.3200
    Sigma: 0.4900
```

Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2019,1,1);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 01-Jan-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create IRMonteCarlo Pricer Object

Use finpricer to create an IRMonteCarlo pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("IRMonteCarlo",'Model',HullWhiteModel,'DiscountCurve',myRC,'SimulationDates
```

```
outPricer =
  HWMonteCarlo with properties:

          NumTrials: 1000
      RandomNumbers: []
      DiscountCurve: [1x1 ratecurve]
    SimulationDates: [01-Jul-2019    01-Jan-2020    01-Jan-2021    ...    ]
              Model: [1x1 finmodel.HullWhite]
```

Price FixedBond Instrument

Use price to compute the price and sensitivities for the FixedBond instrument.

```
[Price,outPR] = price(outPricer,FixB,["all"])

Price = 115.0303

outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: [1x1 struct]

outPR.Results

ans=1×4 table
    Price      Delta     Gamma     Vega
    _____    ________    _____    ____

    115.03    -397.13    1430.4     0
```

Input Arguments

`inpPricer` — Pricer object

`IRMonteCarlo` object

Pricer object, specified as a previously created `IRMonteCarlo` pricer object. Create the pricer object using `finpricer`.

Data Types: `object`

`inpInstrument` — Instrument object

`Cap` object | `Floor` object | `Swaption` object | `Swap` object | `FixedBond` object | `OptionEmbeddedFixedBond` object | `OptionEmbeddedFloatBond` object | `FixedBondOption` object | `FloatBond` object | `FloatBondOption` object

Instrument object, specified as scalar or a vector of previously created instrument objects. Create the instrument objects using `fininstrument`. The following instrument objects are supported:

- `Cap`
- `Floor`
- `Swap`
- `Swaption`
- `FixedBond`
- `OptionEmbeddedFixedBond`
- `FixedBondOption`
- `FloatBond`
- `FloatBondOption`
- `OptionEmbeddedFloatBond`

Data Types: `object`

`inpSensitivity` — List of sensitivities to compute
`[ ]` (default) | string array with values dependent on pricer object | cell array of character vectors with values dependent on pricer object

(Optional) List of sensitivities to compute, specified as an `NOUT`-by-`1` or `1`-by-`NOUT` cell array of character vectors or string array.

The supported sensitivities depend on the pricing method.

inpInstrument	Supported Sensitivities
`Cap`	`{'delta','gamma','vega','price'}` (`'vega'` not supported when using `SABRBraceGatarekMusiela` model with the `IRMonteCarlo` pricer.)
`Floor`	`{'delta','gamma','vega','price'}` (`'vega'` not supported when using `SABRBraceGatarekMusiela` model with the `IRMonteCarlo` pricer.)
`Swap`	`{'delta','gamma','vega','price'}`
`Swaption`	`{'delta','gamma','vega','price'}`
`FixedBond`	`{'delta','gamma','vega','price'}` (`'vega'` not supported when using `SABRBraceGatarekMusiela` model with the `IRMonteCarlo` pricer.)
`OptionEmbeddedFixedBond`	`{'delta','gamma','vega','price'}` (`'vega'` not supported when using `SABRBraceGatarekMusiela` model with the `IRMonteCarlo` pricer.)
`FixedBondOption`	`{'delta','gamma','vega','price'}` (`'vega'` not supported when using `SABRBraceGatarekMusiela` model with the `IRMonteCarlo` pricer.)
`FloatBond`	`{'delta','gamma','vega','price'}` (`'vega'` not supported when using `SABRBraceGatarekMusiela` model with the `IRMonteCarlo` pricer.)
`FloatBondOption`	`{'delta','gamma','vega','price'}` (`'vega'` not supported when using `SABRBraceGatarekMusiela` model with the `IRMonteCarlo` pricer.)
`OptionEmbeddedFloatBond`	`{'delta','gamma','vega','price'}` (`'vega'` not supported when using `SABRBraceGatarekMusiela` model with the `IRMonteCarlo` pricer.)

`inpSensitivity = 'All'` or `inpSensitivity = "All"` specifies that all sensitivities for the pricing method are returned. This is the same as specifying `inpSensitivity` to include each sensitivity.

Example: `inpSensitivity = ["delta","gamma","vega","price"]`

Data Types: `cell` | `string`

Output Arguments

`Price` — Instrument price

numeric

Instrument price, returned as a numeric.

`PriceResult` — Price result

`PriceResult` object

Price result, returned as a `PriceResult` object. The object has the following fields:

- `PriceResult.Results` — Table of results that includes sensitivities (if you specify `inpSensitivity`)
- `PriceResult.PricerData` — Structure for pricer data

Version History

Introduced in R2021b

price

Package: `finpricer`

Compute price for interest-rate instrument with `IRTree` pricer

Syntax

```
[Price,PriceResult] = price(inpPricer,inpInstrument)
[Price,PriceResult] = price( ___ ,inpSensitivity)
```

Description

`[Price,PriceResult] = price(inpPricer,inpInstrument)` computes the instrument price and related pricing information based on the pricing object `inpPricer` and the instrument object `inpInstrument`.

`[Price,PriceResult] = price( ___ ,inpSensitivity)` adds an optional argument to specify sensitivities.

Examples

Use Hull-White Tree Pricer and Hull-White Model to Price FixedBondOption Instrument

This example shows the workflow to price a `FixedBondOption` instrument when you use a `HullWhite` model and an `IRTree` pricing method.

Create FixedBond Instrument Object

Use `fininstrument` to create a `FixedBond` instrument object as the underlying bond.

```
BondInst = fininstrument("FixedBond",'Maturity',datetime(2029,9,15),'CouponRate',0.025,'Period',
```

```
BondInst =
  FixedBond with properties:

                  CouponRate: 0.0250
                      Period: 1
                       Basis: 0
                EndMonthRule: 1
                   Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                    Holidays: NaT
                   IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 15-Sep-2029
                        Name: "fixed_bond_instrument"
```

Create FixedBondOption Instrument Object

Use `fininstrument` to create a `FixedBondOption` instrument object.

```
FixedBOption = fininstrument("FixedBondOption",'ExerciseDate',datetime(2025,9,15),'Strike',98,'Bo
```

```
FixedBOption =
  FixedBondOption with properties:

       OptionType: "call"
    ExerciseStyle: "european"
     ExerciseDate: 15-Sep-2025
           Strike: 98
             Bond: [1x1 fininstrument.FixedBond]
             Name: "fixed_bond_option_instrument"
```

Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2019,9,15);
Type = 'zero';
ZeroTimes = [calyears([1:10])]';
ZeroRates = [0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307 0.0310]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create HullWhite Model Object

Use `finmodel` to create a `HullWhite` model object.

```
HullWhiteModel = finmodel("HullWhite",'Alpha',0.01,'Sigma',0.05)
```

```
HullWhiteModel =
  HullWhite with properties:

    Alpha: 0.0100
    Sigma: 0.0500
```

Create IRTree Pricer Object

Use `finpricer` to create an `IRTree` pricer object and use the `ratecurve` object with the `'DiscountCurve'` name-value pair argument.

```
HWTreePricer = finpricer("irtree",'Model',HullWhiteModel,'DiscountCurve',myRC,'TreeDates',ZeroDa
```

```
HWTreePricer =
  HWBKTree with properties:

             Tree: [1x1 struct]
        TreeDates: [10x1 datetime]
            Model: [1x1 finmodel.HullWhite]
    DiscountCurve: [1x1 ratecurve]
```

```
HWTreePricer.Tree
```

```
ans = struct with fields:
        tObs: [0 1 1.9973 2.9945 3.9918 4.9918 5.9891 6.9863 7.9836 8.9836]
        dObs: [15-Sep-2019    15-Sep-2020    15-Sep-2021    ...    ]
      CFlowT: {1x10 cell}
       Probs: {1x9 cell}
     Connect: {1x9 cell}
     FwdTree: {1x10 cell}
    RateTree: {1x10 cell}
```

Price FixedBondOption Instrument

Use `price` to compute the price and sensitivities for the `FixedBondOption` instrument.

```
[Price, outPR] = price(HWTreePricer,FixedBOption,["all"])
```

```
Price = 11.1739
```

```
outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×4 table
    Price      Delta     Gamma      Vega
    ______    _______    ______    ______

    11.174    -272.19    3667.6    243.09
```

Input Arguments

inpPricer — Pricer object

IRTree object

Pricer object, specified as a scalar `IRTree` pricer object. Use `finpricer` to create the `IRTree` pricer object.

Data Types: `object`

`inpInstrument` — Instrument object
`Cap` object | `Floor` object | `Swaption` object | `FixedBond` object | `OptionEmbeddedFixedBond` object | `OptionEmbeddedFloatBond` object | `FixedBondOption` object | `FloatBond` object | `FloatBondOption` object

Instrument object, specified as scalar or a vector of previously created instrument objects. Create the instrument objects using `fininstrument`. The following instrument objects are supported:

- `Cap`
- `Floor`
- `Swaption`
- `FixedBond`
- `OptionEmbeddedFixedBond`
- `FixedBondOption`
- `FloatBond`
- `FloatBondOption`
- `OptionEmbeddedFloatBond`

Data Types: `object`

`inpSensitivity` — List of sensitivities to compute
`[ ]` (default) | string array with values `"Price"`, `"Delta"`, `"Gamma"`, `"Vega"`, and `"All"` | cell array of character vectors with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, and `'All'`

(Optional) List of sensitivities to compute, specified as a `NOUT`-by-`1` or a `1`-by-`NOUT` cell array of character vectors or string array with possible values of `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, and `'All'`.

`inpSensitivity = {'All'}` or `inpSensitivity = ["All"]` specifies that the output is `'Delta'`, `'Gamma'`, `'Vega'`, and `'Price'`. This is the same as specifying `inpSensitivity` to include each sensitivity.

The sensitivities supported depend on the `inpInstrument`.

inpInstrument	Supported Sensitivities
`Cap`	`{'delta','gamma','vega','price'}`
`Floor`	`{'delta','gamma','vega','price'}`
`Swaption`	`{'delta','gamma','vega','price'}`
`FixedBond`	`{'delta','gamma','vega','price'}`
`OptionEmbeddedFixedBond`	`{'delta','gamma','vega','price'}`
`FixedBondOption`	`{'delta','gamma','vega','price'}`
`FloatBond`	`{'delta','gamma','vega','price'}`
`FloatBondOption`	`{'delta','gamma','vega','price'}`
`OptionEmbeddedFloatBond`	`{'delta','gamma','vega','price'}`

Note Sensitivities are calculated based on yield shifts of 1 basis point, where the ShiftValue = 1/10000. All sensitivities are returned as dollar sensitivities. To find the per-dollar sensitivities, divide the sensitivities by their respective instrument price.

Example: `inpSensitivity = {'delta','gamma','vega','price'}`

Data Types: `string` | `cell`

Output Arguments

`Price` — Instrument price

numeric

Instrument price, returned as a numeric.

`PriceResult` — Price result

`PriceResult` object

Price result, returned as a `PriceResult` object. The object has the following fields:

- `PriceResult.Results` — Table of results that includes sensitivities (if you specify `inpSensitivity`)
- `PriceResult.PricerData` — Structure for pricer data that depends on the instrument that is being priced

  `FixedBond`, `FloatBond`, `FixedBondOption`, and `OptionEmbeddedFixedBond` have the following shared fields for `PriceResult.PricerData.PriceTree`:

  - `tObs` contains the observation times.
  - `Connect` contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are `NumNodes` elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicates where the down branch connects to.

The following additional fields for `PriceResult.PricerData.PriceTree` depend on the instrument type:

- `PTree` contains the clean prices.
- `AITree` contains the accrued interest.
- `Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.
- `dObs` contains the date of each level of the tree.
- `CFlowT` is a cell array with as many elements as levels of the tree. Each cell array element contains the time factors (`tObs`) corresponding to its level of the tree and those levels ahead of it.
- `FwdTree` contains the forward spot rate from one node to the next. The forward spot rate is defined as the inverse of the discount factor.
- `ExTree` contains the exercise indicator arrays. Each element of the cell array is an array containing `1`'s where an option is exercised and `0`'s where it isn't.
- `ProbTree` contains the probability of reaching each node from root node.

- `ExProbTree` contains the exercise probabilities. Each element in the cell array is an array containing `0`'s where there is no exercise, or the probability of reaching that node where exercise happens.
- `ExProbsByTreeLevel` is an array with each row holding the exercise probability for a given option at each tree observation time.

A `FixedBond` instrument has these additional fields within `PriceResult.PricerData.PriceTree`:

- `PTree`
- `AITree`
- `Probs`.

A `FloatBond` instrument has these additional fields within `PriceResult.PricerData.PriceTree`:

- `dObs`
- `CFlowT`
- `Probs`
- `FwdTree`

A `FixedBondOption` instrument has these additional fields within `PriceResult.PricerData.PriceTree`:

- `PTree`
- `Probs`
- `ExTree`

A `OptionEmbeddedFixedBond` instrument has these additional fields within `PriceResult.PricerData.PriceTree`:

- `PTree`
- `ExTree`
- `ProbTree`
- `ExProbTree`
- `ExProbsByTreeLevel`

The following table displays the `PriceResult.PricerData.PriceTree` fields related to each instrument.

PriceResult.PricerData.PriceTree Fields	**FixedBond**	**FloatBond**	**FixedBondOption**	**OptionEmbeddedFixedBond**
`tObs`	✓	✓	✓	✓
`Connect`	✓	✓	✓	✓
`PTree`	✓	No	✓	✓
`AITree`	✓	No	No	No
`Probs`	✓	✓	✓	No

PriceResult.PricerData.PriceTree Fields	FixedBond	FloatBond	FixedBondOption	OptionEmbeddedFixedBond
dObs	No	✓	No	No
CFlowT	No	✓	No	No
FwdTree	No	✓	✓	✓
ExTree	No	No	✓	✓
ProbTree	No	No	No	✓
ExProbTree	No	No	No	✓
ExProbsByTreeLevel	No	No	No	✓

price

Package: `finpricer`

Compute price for equity instrument with `AssetTree` pricer

Syntax

```
[Price,PriceResult] = price(inpPricer,inpInstrument)
[Price,PriceResult] = price( ___ ,inpSensitivity)
```

Description

`[Price,PriceResult] = price(inpPricer,inpInstrument)` computes the equity instrument price and related pricing information based on the pricing object `inpPricer` and the instrument object `inpInstrument`.

`[Price,PriceResult] = price( ___ ,inpSensitivity)` adds an optional argument to specify sensitivities in addition to the required arguments in the previous syntax.

Examples

Use Leisen-Reimer Tree Pricer and Black-Scholes Model to Price Vanilla Instrument

This example shows the workflow to price a `Vanilla` instrument when you use a `BlackScholes` model and an `AssetTree` pricing method.

Create `Vanilla` Instrument Object

Use `fininstrument` to create a `Vanilla` instrument object.

```
VanillaOpt = fininstrument("Vanilla",'ExerciseDate',datetime(2019,5,1),'Strike',29,'OptionType','
```

```
VanillaOpt =
  Vanilla with properties:

       OptionType: "put"
    ExerciseStyle: "european"
     ExerciseDate: 01-May-2019
           Strike: 29
             Name: "vanilla_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.25)
```

```
BlackScholesModel =
  BlackScholes with properties:
```

```
     Volatility: 0.2500
    Correlation: 1
```

Create ratecurve Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,1,1);
Maturity = datetime(2020,1,1);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',1)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 1
               Dates: 01-Jan-2020
               Rates: 0.0350
              Settle: 01-Jan-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create AssetTree Pricer Object

Use `finpricer` to create an `AssetTree` pricer object for an LR equity tree and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
LRPricer = finpricer("AssetTree",'DiscountCurve',myRC,'Model',BlackScholesModel,'SpotPrice',30,'
```

```
LRPricer =
  LRTree with properties:

    InversionMethod: PP1
             Strike: 30
               Tree: [1x1 struct]
         NumPeriods: 15
              Model: [1x1 finmodel.BlackScholes]
      DiscountCurve: [1x1 ratecurve]
          SpotPrice: 30
       DividendType: "continuous"
      DividendValue: 0
          TreeDates: [02-Feb-2018 08:00:00    06-Mar-2018 16:00:00    ...    ]
```

Price Vanilla Instrument

Use `price` to compute the price and sensitivities for the `Vanilla` instrument.

```
[Price, outPR] = price(LRPricer,VanillaOpt,"all")
```

```
Price = 2.2542
```

```
outPR =
  priceresult with properties:
```

```
       Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta       Gamma       Vega      Lambda      Rho       Theta
    ______    ________    ________    ______    ______    _______    ________

    2.2542    -0.33628    0.044039    12.724    -4.469    -16.433    -0.76073
```

Use Standard Trinomial Tree Pricer and Black-Scholes Model to Price Vanilla Instrument

This example shows the workflow to price a `Vanilla` instrument when you use a `BlackScholes` model and an `AssetTree` pricing method for a Standard Trinomial (STT) tree.

Create `Vanilla` Instrument Object

Use `fininstrument` to create a `Vanilla` instrument object.

```
VanillaOpt = fininstrument("Vanilla",'ExerciseDate',datetime(2019,5,1),'Strike',29,'OptionType','
```

```
VanillaOpt =
  Vanilla with properties:

       OptionType: "put"
    ExerciseStyle: "european"
     ExerciseDate: 01-May-2019
           Strike: 29
             Name: "vanilla_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.25)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.2500
    Correlation: 1
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,1,1);
Maturity = datetime(2020,1,1);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',1)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 1
               Dates: 01-Jan-2020
               Rates: 0.0350
              Settle: 01-Jan-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create AssetTree Pricer Object

Use `finpricer` to create an `AssetTree` pricer object for an Standard Trinomial equity tree and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
STTPricer = finpricer("AssetTree",'DiscountCurve',myRC,'Model',BlackScholesModel,'SpotPrice',30,
```

```
STTPricer =
  STTree with properties:

            Tree: [1x1 struct]
       NumPeriods: 15
           Model: [1x1 finmodel.BlackScholes]
    DiscountCurve: [1x1 ratecurve]
        SpotPrice: 30
     DividendType: "continuous"
    DividendValue: 0
        TreeDates: [02-Feb-2018 08:00:00    06-Mar-2018 16:00:00    ...    ]
```

Price Vanilla Instrument

Use `price` to compute the price and sensitivities for the `Vanilla` instrument.

```
[Price, outPR] = price(STTPricer,VanillaOpt,"all")
```

```
Price = 2.2826
```

```
outPR =
  priceresult with properties:

      Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta      Gamma      Vega     Lambda       Rho       Theta
    ______    _______    ________    _____    _______    _______    ________
```

```
    2.2826    -0.2592    0.030949    12.51    -3.8981    -16.516    -0.73845
```

Input Arguments

`inpPricer` — Pricer object

`AssetTree` object

Pricer object, specified as a scalar `AssetTree` pricer object. Use `finpricer` to create the `AssetTree` pricer object.

Data Types: `object`

`inpInstrument` — Instrument object

`Vanilla` object | `Barrier` object | `Asian` object | `Lookback` object

Instrument object, specified as a scalar or vector of previously created instrument objects. Create the instrument objects using `fininstrument`. The following instrument objects are supported:

- `Vanilla`
- `Lookback`
- `Barrier`
- `Asian`

Data Types: `object`

`inpSensitivity` — List of sensitivities to compute

`[ ]` (default) | string array with values `"Price"`, `"Delta"`, `"Gamma"`, `"Vega"`, `"Theta"`, `"Rho"`, `"Lambda"`, and `"All"` | cell array of character vectors with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Theta'`, `'Rho'`, `'Lambda'`, and `'All'`

(Optional) List of sensitivities to compute, specified as an `NOUT`-by-`1` or a `1`-by-`NOUT` cell array of character vectors or string array with possible values of `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Theta'`, `'Rho'`, `'Lambda'`, and `'All'`.

`inpSensitivity = {'All'}` or `inpSensitivity = ["All"]` specifies that the output is `'Delta'`, `'Gamma'`, `'Vega'`, `'Theta'`, `'Rho'`, `'Lambda'`, and `'Price'`. Using this syntax is the same as specifying `inpSensitivity` to include each sensitivity.

inpInstrument	Supported Sensitivities
`Asian`	`{'delta','gamma','vega','theta','rho','lambda','price'}`
`Barrier`	`{'delta','gamma','vega','theta','rho','lambda','price'}`
`Lookback`	`{'delta','gamma','vega','theta','rho','lambda','price'}`
`Vanilla`	`{'delta','gamma','vega','theta','rho','lambda','price'}`

Note Sensitivities are calculated based on yield shifts of 1 basis point, where the ShiftValue = 1/10000. All sensitivities are returned as dollar sensitivities. To find the per-dollar sensitivities, divide the sensitivities by their respective instrument price.

Example: `inpSensitivity = {'delta','gamma','vega','price'}`

Data Types: `string` | `cell`

Output Arguments

`Price` — Instrument price

numeric

Instrument price, returned as a numeric.

`PriceResult` — Price result

`PriceResult` object

Price result, returned as a `PriceResult` object. The object has the following fields:

- `PriceResult.Results` — Table of results that includes sensitivities (if you specify `inpSensitivity`)
- `PriceResult.PricerData` — Structure for pricer data that depends on the instrument that is being priced

  `Asian` and `Lookback` have an empty (`[]`) `PricerData` field because the pricing functions for these instruments cannot unambiguously assign a price to any node but the root node.

  `Vanilla` and `Barrier` have the following shared fields for `PriceResult.PricerData.PriceTree`:

  - `PTree` contains the clean prices.
  - `ExTree` contains the exercise indicator arrays. Each element of the cell array is an array where `1` indicates that an option is exercised and `0` indicates that an option is not exercised.
  - `dObs` contains the date of each level of the tree.
  - `tObs` contains the observation times.
  - `Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.

Version History

Introduced in R2021a

price

Package: finpricer

Compute price for credit derivative instrument with Credit pricer

Syntax

```
[Price,PriceResult] = price(inpPricer,inpInstrument)
```

Description

[Price,PriceResult] = price(inpPricer,inpInstrument) computes the instrument price and related pricing information based on the pricing object inpPricer and the instrument object inpInstrument.

Examples

Use Credit Pricer and Default Probability Curve to Price CDS Instrument

This example shows the workflow to price a CDS instrument when you use a defprobcurve model and a Credit pricing method.

Create CDS Instrument Object

Use fininstrument to create a CDS instrument object.

```
CDS = fininstrument("cds",'Maturity',datetime(2027,9,20),'ContractSpread', 50,'Name',"CDS_instru
```

```
CDS =
  CDS with properties:

           ContractSpread: 50
                 Maturity: 20-Sep-2027
                   Period: 4
                    Basis: 2
              RecoveryRate: 0.4000
    BusinessDayConvention: "actual"
                 Holidays: NaT
        PayAccruedPremium: 1
                 Notional: 10000000
                     Name: "CDS_instrument"
```

Create defprobcurve Object

Create a defprobcurve object using defprobcurve.

```
Settle = datetime(2017, 9, 20);
DefProbTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
DefaultProbabilities = [0.005 0.007 0.01 0.015 0.026 0.04 0.077 0.093 0.15 0.20]';
ProbDates = Settle + DefProbTimes;
DefaultProbCurve = defprobcurve(Settle,ProbDates,DefaultProbabilities)
```

```
DefaultProbCurve =
  defprobcurve with properties:

                  Settle: 20-Sep-2017
                   Basis: 2
                   Dates: [10x1 datetime]
    DefaultProbabilities: [10x1 double]
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates)
```

```
ZeroCurve =
  ratecurve with properties:

                 Type: "zero"
          Compounding: -1
                Basis: 0
                Dates: [10x1 datetime]
                Rates: [10x1 double]
               Settle: 20-Sep-2017
         InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `Credit` Pricer Object

Use `finpricer` to create a `Credit` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
CDSpricer = finpricer("credit",'DiscountCurve',ZeroCurve,'DefaultProbabilityCurve',DefaultProbCu
```

```
CDSpricer =
  Credit with properties:

              DiscountCurve: [1x1 ratecurve]
                   TimeStep: 10
    DefaultProbabilityCurve: [1x1 defprobcurve]
```

Price CDS Instrument

Use `price` to compute the price for the `CDS` instrument.

```
outPrice = price(CDSpricer, CDS)
```

```
outPrice = 6.9363e+04
```

Input Arguments

`inpPricer` — Pricer object

`Credit` pricer object

Pricer object, specified as a scalar `Credit` pricer object. Use `finpricer` to create the `Credit` pricer object.

Data Types: `object`

`inpInstrument` — Instrument object
`CDS` object

Instrument object, specified as a scalar or vector of previously created `CDS` instrument objects. Use `fininstrument` to create `CDS` instrument objects.

Data Types: `object`

Output Arguments

`Price` — Instrument price
numeric

Instrument price, returned as a numeric.

`PriceResult` — Price result
`PriceResult` object

Price result, returned as a `PriceResult` object. The object has the following fields:

- `PriceResult.Results` — Table of results that includes the `CDS` price and accrued premium
- `PriceResult.PricerData` — Structure that includes the premium leg payment dates, times, and cash flows

price

Package: `finpricer`

Compute price for interest-rate instrument with `Discount` pricer

Syntax

```
[Price,PriceResult] = price(inpPricer,inpInstrument)
[Price,PriceResult] = price( ___ ,inpSensitivity)
```

Description

`[Price,PriceResult] = price(inpPricer,inpInstrument)` computes the instrument price and related pricing information based on the pricing object `inpPricer` and the instrument object `inpInstrument`.

`[Price,PriceResult] = price( ___ ,inpSensitivity)` adds an optional argument to specify sensitivities.

Examples

Use Discount Pricer and ratecurve to Price Swap Instrument

This example shows the workflow to price a `Swap` instrument when using a `ratecurve` and a `Discount` pricing method.

Create ratecurve Object

Create a `ratecurve` object using `ratecurve` for the underlying interest-rate curve for the `Swap` instrument.

```
Settle = datetime(2022,1,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
       Compounding: -1
             Basis: 0
             Dates: [10x1 datetime]
             Rates: [10x1 double]
            Settle: 15-Jan-2022
      InterpMethod: "linear"
  ShortExtrapMethod: "next"
```

```
     LongExtrapMethod: "previous"
```

Create Swap Instrument Object

Use `fininstrument` to create a `Swap` instrument object.

```
SwapOpt = fininstrument("Swap",'Maturity',datetime(2027,1,15),'LegRate',[0.024 0.015],'LegType',
```

```
SwapOpt =
  Swap with properties:

                    LegRate: [0.0240 0.0150]
                    LegType: ["fixed"    "float"]
                      Reset: [2 2]
                      Basis: [0 0]
                   Notional: 100
          LatestFloatingRate: [NaN NaN]
                 ResetOffset: [0 0]
    DaycountAdjustedCashFlow: [0 0]
             ProjectionCurve: [1x2 ratecurve]
       BusinessDayConvention: ["actual"    "actual"]
                   Holidays: NaT
                EndMonthRule: [1 1]
                   StartDate: NaT
                    Maturity: 15-Jan-2027
                        Name: "swap_instrument"
```

Create `Discount` Pricer Object

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("Discount", 'DiscountCurve',myRC)
```

```
outPricer =
  Discount with properties:

    DiscountCurve: [1x1 ratecurve]
```

Price Swap Instrument

Use `price` to compute the price and sensitivities for the `Swap` instrument.

```
[Price, outPR] = price(outPricer, SwapOpt,["all"])
```

```
Price = -1.3834
```

```
outPR =
  priceresult with properties:

       Results: [1x2 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×2 table
     Price       DV01
    _______    ________

    -1.3834    0.048336
```

Input Arguments

`inpPricer` — Pricer object

`Discount` pricer object

Pricer object, specified as a scalar `Discount` pricer object. Use `finpricer` to create the `Discount`pricer object.

Data Types: `object`

`inpInstrument` — Instrument object

`Deposit` object | `FixedBond` object | `FloatBond` object | `FRA` object | `Swap` object | `OISFuture` object | `STIRFuture` object | `OvernightIndexedSwap` object

Instrument object, specified as a scalar or vector for `Deposit`, `FixedBond`, `FloatBond`, `FRA`, `Swap`, `STIRFuture`, `OISFuture`, or `OvernightIndexedSwap` instrument objects. Use `fininstrument` to create the `Deposit`, `FixedBond`, `FloatBond`, `FRA`, `Swap`, `STIRFuture`, `OISFuture`, or `OvernightIndexedSwap` instrument objects.

Data Types: `object`

`inpSensitivity` — List of sensitivities to compute

`[ ]` (default) | string array of character vector with values `"Price"`, `"DV01"`, and `"All"` | cell array of character vectors with values `'Price'`, `'DV01'`, and `'All'`

(Optional) List of sensitivities to compute, specified as a `NOUT`-by-`1` or a `1`-by-`NOUT` cell array of character vectors or string array with possible values of `'Price'` and `'DV01'`.

`inpSensitivity = {'All'}` or `inpSensitivity = ["All"]` specifies that the output is `Price` and `DV01`. This is the same as specifying `inpSensitivity` to include each sensitivity.

The sensitivities supported depend on the `inpInstrument`.

inpInstrument	Supported Sensitivities
`Deposit`	`{'DV01','price'}`
`FixedBond`	`{'DV01','price'}`
`FloatBond`	`{'DV01','price'}`
`FRA`	`{'DV01','price'}`
`Swap`	`{'DV01','price'}`
`STIRFuture`	`{'DV01','price'}`
`OISFuture`	`{'DV01','price'}`
`OvernightIndexedSwap`	`{'DV01','price'}`

Example: `inpSensitivity = {'DV01','price'}`

Data Types: `cell` | `string`

Output Arguments

`Price` — Instrument price
numeric

Instrument price, returned as a numeric.

`PriceResult` — Price result
`PriceResult` object

Price result, returned as an object. The object has the following fields:

- `PriceResult.Results` — Table of results that includes sensitivities (if you specify `inpSensitivity`)
- `PriceResult.PricerData` — Structure for pricer data

Version History

Introduced in R2020a

price

Package: `finpricer`

Compute price for interest-rate instrument with `Future` pricer

Syntax

```
[Price,PriceResult] = price(inpPricer,inpInstrument)
```

Description

`[Price,PriceResult] = price(inpPricer,inpInstrument)` computes the instrument price and related pricing information based on the pricing object `inpPricer` and the instrument object `inpInstrument`.

The `price` function computes the value of the futures contract for the party that is long (not short) for the underlying asset, assuming the contract is held until maturity like a forward contract. If the price is negative for the party that is long, then the value is positive for the other party that is short. If the price is positive for the party that is long, then the value is negative for the other party that is short.

Examples

Use `Future` Pricer and `ratecurve` to Price `BondFuture` Instrument

This example shows the workflow to price a `BondFuture` instrument when you use a `ratecurve` object and a `Future` pricing method.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2022,3,1);
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates,Compounding=2);
```

Create Underlying `FixedBond` Instrument Object

Use `fininstrument` to create a `FixedBond` instrument object.

```
FixB = fininstrument("FixedBond",Maturity=datetime(2032,9,1),CouponRate=0.05,Name="fixed_bond_ins
```

```
FixB =
  FixedBond with properties:

                 CouponRate: 0.0500
                     Period: 2
                      Basis: 0
                EndMonthRule: 1
```

```

                        Name: "fixed_bond_instrument"
```

Create BondFuture Instrument Object

Use `fininstrument` to create a `BondFuture` instrument object.

```
BondFut = fininstrument("BondFuture",Maturity=datetime(2022,9,1),QuotedPrice=86,Bond=FixB,Convers
```

```
BondFut =
  BondFuture with properties:

            Maturity: 01-Sep-2022
         QuotedPrice: 86
                Bond: [1x1 fininstrument.FixedBond]
    ConversionFactor: 1.4300
            Notional: 100000
                Name: "bondfuture_instrument"
```

Create Future Pricer Object

Use `finpricer` to create a `Future` pricer object and use the `ratecurve` object with the `DiscountCurve` name-value argument.

```
outPricer = finpricer("Future",DiscountCurve=ZeroCurve,SpotPrice=125)
```

```
outPricer =
  Future with properties:

    DiscountCurve: [1x1 ratecurve]
        SpotPrice: 125
```

Price BondFuture Instrument

Use `price` to compute the price and price result for the `BondFuture` instrument.

```
[Price,outPR] = price(outPricer,BondFut)
```

```
Price = -151.9270
```

```
outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×4 table
     Price     FairDeliveryPrice    FairFuturePrice    AccruedInterest
    _______    _________________    _______________    _______________

    -151.93       1.2283e+05            85.893                0
```

Input Arguments

`inpPricer` — Pricer object

`Future` pricer object

Pricer object, specified as a scalar `Future` pricer object. Use `finpricer` to create the `Future` pricer object.

Data Types: `object`

`inpInstrument` — Instrument object

`BondFuture` object | `CommodityFuture` object | `EquityIndexFuture` object | `FXFuture` object

Instrument object, specified as a scalar or vector for `BondFuture`, `CommodityFuture`, `FXFuture`, or `EquityIndexFuture` instrument objects. Use `fininstrument` to create these instrument objects.

Data Types: `object`

Output Arguments

`Price` — Instrument price

numeric

Instrument price, returned as a numeric.

`PriceResult` — Price result

`PriceResult` object

Price result, returned as an object. The `PriceResult.Results` is a table of results that includes `Price`, `FairDeliveryPrice`, `FairFuturePrice`, and `AccruedInterest`.

Version History

Introduced in R2022a

price

Package: `finpricer`

Compute price for equity instrument with FFT pricer

Syntax

```
[Price,PriceResult] = price(inpPricer,inpInstrument)
[Price,PriceResult] = price( ___ ,inpSensitivity)
```

Description

`[Price,PriceResult] = price(inpPricer,inpInstrument)` computes the instrument price and related pricing information based on the pricing object `inpPricer` and the instrument object `inpInstrument`.

`[Price,PriceResult] = price( ___ ,inpSensitivity)` adds an optional argument to specify sensitivities.

Examples

Use FFT Pricer and Heston Model to Price Vanilla Instrument

This example shows the workflow to price a `Vanilla` instrument when you use a `Heston` model and an FFT pricing method.

Create `Vanilla` Instrument Object

Use `fininstrument` to create a `Vanilla` instrument object.

```
VanillaOpt = fininstrument("Vanilla",'ExerciseDate',datetime(2022,9,15),'Strike',105,'ExerciseSty
```

```
VanillaOpt =
  Vanilla with properties:

       OptionType: "call"
    ExerciseStyle: "european"
     ExerciseDate: 15-Sep-2022
           Strike: 105
             Name: "vanilla_option"
```

Create `Heston` Model Object

Use `finmodel` to create a `Heston` model object.

```
HestonModel = finmodel("Heston",'V0',0.032,'ThetaV',0.1,'Kappa',0.003,'SigmaV',0.2,'RhoSV',0.9)
```

```
HestonModel =
  Heston with properties:
```

```
        V0: 0.0320
    ThetaV: 0.1000
     Kappa: 0.0030
    SigmaV: 0.2000
     RhoSV: 0.9000
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
        Compounding: -1
              Basis: 12
              Dates: 15-Sep-2023
              Rates: 0.0350
             Settle: 15-Sep-2018
       InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create FFT Pricer Object

Use `finpricer` to create an FFT pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("fft",'DiscountCurve',myRC,'Model',HestonModel,'SpotPrice',100,'Characteris
```

```
outPricer =
  FFT with properties:

                  Model: [1x1 finmodel.Heston]
          DiscountCurve: [1x1 ratecurve]
              SpotPrice: 100
           DividendType: "continuous"
          DividendValue: 0
                 NumFFT: 8192
    CharacteristicFcnStep: 0.2000
          LogStrikeStep: 0.0038
      CharacteristicFcn: @characteristicFcnHeston
          DampingFactor: 1.5000
             Quadrature: "simpson"
        VolRiskPremium: 0
             LittleTrap: 1
```

Price `Vanilla` Instrument

Use `price` to compute the price and sensitivities for the `Vanilla` instrument.

```
[Price, outPR] = price(outPricer,VanillaOpt,["all"])

Price = 14.7545

outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: []

outPR.Results

ans=1×7 table
    Price      Delta      Gamma       Theta       Rho       Vega     VegaLT
    _____    _______    _________    ________    ______    ______    ______

    14.754    0.44868    0.021649    -0.20891    120.45    88.192    1.3248
```

Input Arguments

`inpPricer` — Pricer object

FFT object

Pricer object, specified as a scalar `FFT` pricer object. Use `finpricer` to create the `FFT` pricer object.

Data Types: `object`

`inpInstrument` — Instrument object

`Vanilla` object

Instrument object, specified as a scalar or vector of `Vanilla` instrument objects. Use `fininstrument` to create `Vanilla` instrument objects.

Data Types: `object`

`inpSensitivity` — List of sensitivities to compute

`[ ]` (default) | string array with values `"Price"`, `"Delta"`, `"Gamma"`, `"Vega"`, `"Rho"`, `"Theta"`, `"Vegalt"`, and `"All"` | cell array of character vectors with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Rho'`, `'Theta'`, `'Vegalt'`, and `'All'`

(Optional) List of sensitivities to compute, specified as a `NOUT`-by-`1` or a `1`-by-`NOUT` cell array of character vectors or string array with possible values of `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Rho'`, `'Theta'`, `'Vegalt'`, and `'All'`.

Note For a `Vanilla` instrument using a `Heston` model, `'Vegalt'` is not supported.

`inpSensitivity = {'All'}` or `inpSensitivity = ["All"]` specifies that the output is `'Delta'`, `'Gamma'`, `'Vega'`, `'Rho'`, `'Theta'`, `'Vegalt'`, and `'Price'`. This is the same as specifying `inpSensitivity` to include each sensitivity.

Example: `inpSensitivity = {'delta','gamma','vega','rho','theta','vegalt','price'}`

Data Types: `string` | `cell`

Output Arguments

`Price` — Instrument price
numeric

Instrument price, returned as a numeric.

`PriceResult` — Price result
`PriceResult` object

Price result, returned as a `PriceResult` object. The object has the following fields:

- `PriceResult.Results` — Table of results that includes sensitivities (if you specify `inpSensitivity`)
- `PriceResult.PricerData` — Structure for pricer data

Version History

Introduced in R2020a

price

Package: `finpricer`

Compute price for equity instrument with `FiniteDifference` pricer

Syntax

```
[Price,PriceResult] = price(inpPricer,inpInstrument)
[Price,PriceResult] = price( ___ ,inpSensitivity)
```

Description

`[Price,PriceResult] = price(inpPricer,inpInstrument)` computes the instrument price and related pricing information based on the pricing object `inpPricer` and the instrument object `inpInstrument`.

`[Price,PriceResult] = price( ___ ,inpSensitivity)` adds an optional argument to specify sensitivities.

Examples

Use Finite Difference Pricer and Black-Scholes Model to Price Barrier Instrument

This example shows the workflow to price a `Barrier` instrument when you use a `BlackScholes` model and a `FiniteDifference` pricing method.

Create `Barrier` Instrument Object

Use `fininstrument` to create a `Barrier` instrument object.

```
BarrierOpt = fininstrument("Barrier",'Strike',105,'ExerciseDate',datetime(2019,1,1),'OptionType'
```

```
BarrierOpt =
  Barrier with properties:

       OptionType: "call"
           Strike: 105
      BarrierType: "do"
     BarrierValue: 40
           Rebate: 0
    ExerciseStyle: "american"
     ExerciseDate: 01-Jan-2019
             Name: "barrier_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.30)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.3000
    Correlation: 1
```

Create ratecurve Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,1,1);
Maturity = datetime(2023,1,1);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',1)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 1
               Dates: 01-Jan-2023
               Rates: 0.0350
              Settle: 01-Jan-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create FiniteDifference Pricer Object

Use `finpricer` to create a `FiniteDifference` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("FiniteDifference",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPri
```

```
outPricer =
  FiniteDifference with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 100
    GridProperties: [1x1 struct]
      DividendType: "continuous"
     DividendValue: 0
```

Price Barrier Instrument

Use `price` to compute the price and sensitivities for the `Barrier` instrument.

```
[Price, outPR] = price(outPricer,BarrierOpt,["all"])
```

```
Price = 11.3230
```

```
outPR =
  priceresult with properties:
```

```
       Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta     Gamma     Lambda     Theta      Rho       Vega
    _____    ________    _____    _______    ______    ______    ______

    11.323    0.54126    0.0132    4.7802    -7.4408    42.766    39.627
```

Input Arguments

`inpPricer` — Pricer object

`FiniteDifference` object

Pricer object, specified as a scalar `FiniteDifference` pricer object. Use `finpricer` to create the `FiniteDifference` pricer object.

Data Types: `object`

`inpInstrument` — Instrument object

`Vanilla` object | `Barrier` object | `DoubleBarrier` object | `ConvertibleBond` object

Instrument object, specified as a scalar or vector of `Vanilla`, `Barrier`, `DoubleBarrier`, or `ConvertibleBond` instrument objects. Use `fininstrument` to create the `Vanilla`, `Barrier`, `DoubleBarrier`, or `ConvertibleBond` instrument objects.

Data Types: `object`

`inpSensitivity` — List of sensitivities to compute

`[ ]` (default) | string array with values `"Price"`, `"Delta"`, `"Gamma"`, `"Vega"`, `"Rho"`, `"Theta"`, `"Lambda"`, `"Vegalt"`, and `"All"` | cell array of character vectors with values `'Price'`, `'Delta'`, `'Gamma'`, `'Lambda'`, `'Vegalt'`, `'Vega'`, `'Rho'`, `'Theta'`, and `'All'`

(Optional) List of sensitivities to compute, specified as a `NOUT`-by-`1` or a `1`-by-`NOUT` cell array of character vectors or string array with supported values.

`inpSensitivity = {'All'}` or `inpSensitivity = ["All"]` specifies that the output is `'Delta'`, `'Gamma'`, `'Vega'`, `'Vegalt'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'Price'`. This is the same as specifying `inpSensitivity` to include each sensitivity.

Note When you price a `Barrier` or `ConvertibleBond` instruments using a `BlackScholes` model, `'Vegalt'` is not supported.

Example: `inpSensitivity = {'delta','gamma','vega','vegalt','rho','lambda','theta','price'}`

The sensitivities supported depend on the `inpInstrument`.

inpInstrument	Supported Sensitivities
`Vanilla`,	`'delta','gamma','vega','vegalt','rho','lambda','theta','price'`
`Barrier`	`'delta','gamma','vega','rho','lambda','theta','price'`
`DoubleBarrier`	`'delta','gamma','vega','vegalt','rho','lambda','theta','price'`
`ConvertibleBond`	`'delta','gamma','vega','rho','lambda','theta','price'`

Data Types: `string` | `cell`

Output Arguments

`Price` — Instrument price
numeric

Instrument price, returned as a numeric.

`PriceResult` — Price result
`PriceResult` object

Price result, returned as a `PriceResult` object. The object has the following fields:

- `PriceResult.Results` — Table of results that includes sensitivities (if you specify `inpSensitivity`)
- `PriceResult.PricerData` — Structure for pricer data

Version History

Introduced in R2020a

price

Package: `finpricer`

Compute price for equity instrument with `NumericalIntegration` pricer

Syntax

```
[Price,PriceResult] = price(inpPricer,inpInstrument)
[Price,PriceResult] = price( ___ ,inpSensitivity)
```

Description

`[Price,PriceResult] = price(inpPricer,inpInstrument)` computes the instrument price and related pricing information based on the pricing object `inpPricer` and the instrument object `inpInstrument`.

`[Price,PriceResult] = price( ___ ,inpSensitivity)` adds an optional argument to specify sensitivities.

Examples

Use Numerical Integration Pricer and Merton Model to Price Vanilla Instrument

This example shows the workflow to price a `Vanilla` instrument when you use a `Merton` model and a `NumericalIntegration` pricing method.

Create `Vanilla` Instrument Object

Use `fininstrument` to create a `Vanilla` instrument object.

```
VanillaOpt = fininstrument("Vanilla",'ExerciseDate',datetime(2020,3,15),'ExerciseStyle',"europea
```

```
VanillaOpt =
  Vanilla with properties:

       OptionType: "call"
    ExerciseStyle: "european"
     ExerciseDate: 15-Mar-2020
           Strike: 105
             Name: "vanilla_option"
```

Create `Merton` Model Object

Use `finmodel` to create a `Merton` model object.

```
MertonModel = finmodel("Merton",'Volatility',0.45,'MeanJ',0.02,'JumpVol',0.07,'JumpFreq',0.09)
```

```
MertonModel =
  Merton with properties:
```

```
    Volatility: 0.4500
         MeanJ: 0.0200
       JumpVol: 0.0700
      JumpFreq: 0.0900
```

Create ratecurve Object

Create a flat `ratecurve` object using `ratecurve`.

```
myRC = ratecurve('zero',datetime(2019,9,15),datetime(2020,3,15),0.02)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: 15-Mar-2020
               Rates: 0.0200
              Settle: 15-Sep-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create NumericalIntegration Pricer Object

Use `finpricer` to create a `NumericalIntegration` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("numericalintegration",'Model',MertonModel,'DiscountCurve',myRC,'SpotPrice
```

```
outPricer =
  NumericalIntegration with properties:

               Model: [1x1 finmodel.Merton]
       DiscountCurve: [1x1 ratecurve]
           SpotPrice: 100
        DividendType: "continuous"
       DividendValue: 0.0100
              AbsTol: 0.5000
              RelTol: 0.4000
     IntegrationRange: [1.0000e-09 Inf]
    CharacteristicFcn: @characteristicFcnMerton76
            Framework: "lewis2001"
       VolRiskPremium: 0.9000
           LittleTrap: 0
```

Price Vanilla Instrument

Use `price` to compute the price and sensitivities for the `Vanilla` instrument.

```
[Price, outPR] = price(outPricer,VanillaOpt,["all"])
```

```
Price = 10.7325
```

```
outPR =
  priceresult with properties:
```

```
       Results: [1x6 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×6 table
    Price     Delta      Gamma       Theta      Rho       Vega
    ______    ______    _________    _______    ______    ______

    10.732    0.5058    0.012492    -12.969    19.815    27.954
```

Input Arguments

`inpPricer` — Pricer object

`NumericalIntegration` object

Pricer object, specified as a scalar `NumericalIntegration` pricer object. Use `finpricer` to create the `NumericalIntegration` pricer object.

Data Types: `object`

`inpInstrument` — Instrument object

`Vanilla` object

Instrument object, specified as a scalar or vector of `Vanilla` instrument objects. Use `fininstrument` to create `Vanilla` instrument objects.

Data Types: `object`

`inpSensitivity` — List of sensitivities to compute

`[ ]` (default) | string array with values `"Price"`, `"Delta"`, `"Gamma"`, `"Vega"`, `"Rho"`, `"Theta"`, `"Vegalt"`, and `"All"` | cell array of character vectors with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Rho'`, `'Theta'`, `'Vegalt'`, and `'All'`

(Optional) List of sensitivities to compute, specified as a `NOUT`-by-`1` or a `1`-by-`NOUT` cell array of character vectors or string array with possible values of `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Rho'`, `'Theta'`, `'Vegalt'`, and `'All'`.

Note `'Vegalt'` is not supported when you price a `Vanilla` option with a `Merton` model.

`inpSensitivity = {'All'}` or `inpSensitivity = ["All"]` specifies that the output is `'Delta'`, `'Gamma'`, `'Vega'`, `'Rho'`, `'Theta'`, `'Vegalt'`, and `'Price'`. This is the same as specifying `inpSensitivity` to include each sensitivity.

Example: `inpSensitivity = {'delta','gamma','vega','rho','theta','vegalt','price'}`

Data Types: `string` | `cell`

Output Arguments

`Price` — Instrument price
numeric

Instrument price, returned as a numeric.

`PriceResult` — Price result
`PriceResult` object

Price result, returned as an object. The `PriceResult` object. The object has the following fields:

- `PriceResult.Results` — Table of results that includes sensitivities (if you specify `inpSensitivity`)
- `PriceResult.PricerData` — Structure for pricer data

Version History

Introduced in R2020a

price

Package: `finpricer`

Compute price for equity instrument with `ReplicatingVarianceSwap` pricer

Syntax

```
[Price,PriceResult] = price(inpPricer,inpInstrument)
[Price,PriceResult] = price( ___ ,inpSensitivity)
```

Description

`[Price,PriceResult] = price(inpPricer,inpInstrument)` computes the instrument price and related pricing information based on the pricing object `inpPricer` and the instrument object `inpInstrument`.

`[Price,PriceResult] = price( ___ ,inpSensitivity)` adds an optional argument to specify sensitivities.

Examples

Use Replicating Variance Swap Pricer and `ratecurve` to Price Variance Swap Instrument

This example shows the workflow to price a `VarianceSwap` instrument when you use a `ratecurve` and a `ReplicatingVarianceSwap` pricing method.

Create `VarianceSwap` Instrument Object

Use `fininstrument` to create a `VarianceSwap` instrument object.

```
VarianceSwapInst = fininstrument("VarianceSwap",'Maturity',datetime(2021,5,1),'Notional',150,'Sta
```

```
VarianceSwapInst =
  VarianceSwap with properties:

            Notional: 150
    RealizedVariance: 0.0500
              Strike: 0.1000
           StartDate: 01-May-2020
            Maturity: 01-May-2021
                Name: "variance_swap_instrument"
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2020, 9, 15);
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
Basis = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates,'Basis',Basis)
```

```
ZeroCurve =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 1
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2020
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create ReplicatingVarianceSwap Pricer Object

Use `finpricer` to create a `ReplicatingVarianceSwap` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
Strike = (50:5:135)';
Volatility = [.49;.45;.42;.38;.34;.31;.28;.25;.23;.21;.2;.21;.21;.22;.23;.24;.25;.26];
VolatilitySmile = table(Strike, Volatility);
SpotPrice = 100;
CallPutBoundary = 100;

outPricer =  finpricer("ReplicatingVarianceSwap",'DiscountCurve', ZeroCurve, 'VolatilitySmile', V
'SpotPrice', SpotPrice, 'CallPutBoundary', CallPutBoundary)
```

```
outPricer =
  ReplicatingVarianceSwap with properties:

     DiscountCurve: [1x1 ratecurve]
      InterpMethod: "linear"
    VolatilitySmile: [18x2 table]
         SpotPrice: 100
    CallPutBoundary: 100
```

Price VarianceSwap Instrument

Use `price` to compute the price and fair variance for the `VarianceSwap` instrument.

```
[Price, outPR] = price(outPricer,VarianceSwapInst,["all"])
```

```
Price = 8.1997
```

```
outPR =
  priceresult with properties:

      Results: [1x2 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×2 table
    Price     FairVariance
```

```
    ______    ____________

    8.1997      0.21701
```

```
outPR.PricerData.ReplicatingPortfolio
```

```
ans=19×6 table
    CallPut    Strike    Volatility      Weight       Value     Contribution
    _______    ______    __________    __________    _______    ____________

    "put"        50         0.49        0.0064038    0.39164      0.002508
    "put"        55         0.45        0.0052877    0.49353     0.0026097
    "put"        60         0.42        0.0044402    0.67329     0.0029895
    "put"        65         0.38        0.0037814    0.80343     0.0030381

      ⋮
```

Input Arguments

`inpPricer` — Pricer object

`ReplicatingVarianceSwap` object

Pricer object, specified as a scalar `ReplicatingVarianceSwap` pricer object. Use `finpricer` to create the `ReplicatingVarianceSwap` pricer object.

Data Types: `object`

`inpInstrument` — Instrument object

`VarianceSwap` object

Instrument object, specified as a scalar `VarianceSwap` instrument object. Use `fininstrument` to create the `VarianceSwap` instrument object.

Data Types: `object`

`inpSensitivity` — List of sensitivities to compute

`[ ]` (default) | string array with values `"Price"` and `"All"` | cell array of character vectors with values `'Price'` and `'All'`

(Optional) List of sensitivities to compute, specified as an `NOUT`-by-`1` or `1`-by-`NOUT` cell array of character vectors or string array with possible values of `'Price'` and `'All'`.

`inpSensitivity = {'All'}` or `inpSensitivity = ["All"]` specifies that the output is `'Price'`. This is the same as specifying `inpSensitivity` to include each sensitivity.

Example: `inpSensitivity = {'price'}`

Data Types: `string` | `cell`

Output Arguments

`Price` — Instrument price
numeric

Instrument price, returned as a numeric.

`PriceResult` — Price result
`PriceResult` object

Price result, returned as a `PriceResult` object. The object has the following fields:

- `PriceResult.Results` — Table of results that includes:
  - `Price` — Numeric scalar swap price value
  - `FairVariance` — Numeric fair variance in decimals
- `PriceResult.PricerData.ReplicatingPortfolio` — Table containing pricer data

pricePortfolio

Compute price and sensitivities for portfolio of instruments

Syntax

```
[PortPrice,InstPrice,PortSens,InstSens] = pricePortfolio(inPort)
```

Description

`[PortPrice,InstPrice,PortSens,InstSens] = pricePortfolio(inPort)` calculates the price and sensitivities for a portfolio of instruments that is previously created using `finportfolio`.

Examples

Price Portfolio of Heterogeneous Instruments

Use `finportfolio` and `pricePortfolio` to create and price a portfolio containing a `FixedBond` instrument and an American `Vanilla` option instrument.

Create `FixedBond` Instrument Object

Use `fininstrument` to create a `FixedBond` instrument object.

```
FixB = fininstrument("FixedBond",'Maturity',datetime(2022,9,15),'CouponRate',0.05,'Name',"fixed_
```

```
FixB =
  FixedBond with properties:

                 CouponRate: 0.0500
                     Period: 2
                      Basis: 0
                EndMonthRule: 1
                   Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                    Holidays: NaT
                   IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 15-Sep-2022
                        Name: "fixed_bond"
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
```

```
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)

myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `Discount` Pricer Object for `FixedBond` Instrument

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
FBPricer = finpricer("Discount",'DiscountCurve',myRC)

FBPricer =
  Discount with properties:

    DiscountCurve: [1x1 ratecurve]
```

Create `Vanilla` Instrument Object

Use `fininstrument` to create an American `Vanilla` instrument object.

```
Maturity = datetime(2023,9,15);
AmericanOpt = fininstrument("Vanilla",'ExerciseDate',Maturity,'Strike',120,'ExerciseStyle',"amer

AmericanOpt =
  Vanilla with properties:

       OptionType: "call"
    ExerciseStyle: "american"
     ExerciseDate: 15-Sep-2023
           Strike: 120
             Name: "vanilla_option"
```

Create `BlackScholes` Model Object for `Vanilla` Instrument

Use `finmodel` to create a `BlackScholes` model object.

```
BSModel = finmodel("BlackScholes",'Volatility',0.12)

BSModel =
  BlackScholes with properties:

     Volatility: 0.1200
```

```
    Correlation: 1
```

Create BjerksundStensland Pricer Object for Vanilla Instrument

Use `finpricer` to create an analytic pricer object for the `BjerksundStensland` pricing method and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
BJSPricer = finpricer("analytic",'Model',BSModel,'DiscountCurve',myRC,'SpotPrice',100,'DividendVa
```

```
BJSPricer =
  BjerksundStensland with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 100
    DividendValue: 0.0200
     DividendType: "continuous"
```

Add the Instruments to a finportfolio Object

Create a `finportfolio` object using `finportfolio` and add the two instruments with their associated pricers to the portfolio.

```
f1 = finportfolio([AmericanOpt,FixB],[BJSPricer,FBPricer])
```

```
f1 =
  finportfolio with properties:

    Instruments: [2x1 fininstrument.FinInstrument]
        Pricers: [2x1 finpricer.FinPricer]
    PricerIndex: [2x1 double]
       Quantity: [2x1 double]
```

Price Portfolio

Use `pricePortfolio` to compute the price and sensitivities for the portfolio and the instruments in the portfolio.

```
[PortPrice,InstPrice,PortSens,InstSens] = pricePortfolio(f1)
```

```
PortPrice = 119.1665

InstPrice = 2×1

    3.1912
  115.9753

PortSens=1×8 table
    Price      DV01       Delta      Gamma       Lambda     Vega      Theta       Rho
    ______    _______    _______    ________    ______    ______    ________    _____

    119.17    0.04295    0.23188    0.011522    7.2661    65.454    -0.81408    86.71

```

Price Portfolio of Bond and Bond Option Instruments

This example shows the workflow to create and price a portfolio of bond and bond option instruments. You can use `finportfolio` and `pricePortfolio` to price `FixedBond`, `FixedBondOption`, `OptionEmbeddedFixedBond`, and `FloatBond` instruments using an `IRTree` pricing method.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018, 1, 1);
 ZeroTimes = calyears(1:4)';
 ZeroRates = [0.035; 0.042147; 0.047345; 0.052707];
 ZeroDates = Settle + ZeroTimes;
 Compounding = 1;
 ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates, "Compounding",Compounding)
```

```
ZeroCurve =
  ratecurve with properties:

                Type: "zero"
         Compounding: 1
               Basis: 0
               Dates: [4x1 datetime]
               Rates: [4x1 double]
              Settle: 01-Jan-2018
        InterpMethod: "linear"
   ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

Create Bond and Option Instruments

Use `fininstrument` to create a `FixedBond`, `FixedBondOption`, `OptionEmbeddedFixedBond`, and `FloatBond` instrument objects.

```
CDates = datetime([2020,1,1 ; 2022,1,1]);
CRates = [.0425; .0750];
CouponRate = timetable(CDates,CRates);
Maturity = datetime(2022,1,1);
Period = 1;

% Vanilla FixedBond
VBond = fininstrument("FixedBond",'Maturity',Maturity,'CouponRate',0.0425,'Period',Period,'Name'
```

```
VBond =
  FixedBond with properties:

                 CouponRate: 0.0425
```

```
                    Period: 1
                     Basis: 0
                EndMonthRule: 1
                   Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                    Holidays: NaT
                   IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 01-Jan-2022
                        Name: "vanilla_fixed"
```

```
 % Stepped coupon bond
SBond = fininstrument("FixedBond",'Maturity',Maturity,'CouponRate',CouponRate,'Period',Period,'Na

SBond =
  FixedBond with properties:

                CouponRate: [2x1 timetable]
                    Period: 1
                     Basis: 0
                EndMonthRule: 1
                   Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                    Holidays: NaT
                   IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 01-Jan-2022
                        Name: "stepped_coupon_bond"
```

```
% FloatBond
Spread = 0;
Reset = 1;
Float = fininstrument("FloatBond",'Maturity',Maturity,'Spread',Spread,'Reset', Reset,...
                      'ProjectionCurve',ZeroCurve,'Name',"floatbond")

Float =
  FloatBond with properties:

                    Spread: 0
            ProjectionCurve: [1x1 ratecurve]
                ResetOffset: 0
                      Reset: 1
                      Basis: 0
                EndMonthRule: 1
                   Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
          LatestFloatingRate: NaN
                    Holidays: NaT
                   IssueDate: NaT
             FirstCouponDate: NaT
```

```
               LastCouponDate: NaT
                    StartDate: NaT
                     Maturity: 01-Jan-2022
                         Name: "floatbond"
```

```
% Call option
Strike = 100;
ExerciseDates = datetime(2020,1,1);
OptionType ='call';
Period = 1;
CallOption = fininstrument("FixedBondOption",'Strike',Strike,'ExerciseDate',ExerciseDates,...
                  'OptionType',OptionType,'ExerciseStyle',"american",'Bond', VBond,'Name',"fixe
```

```
CallOption =
  FixedBondOption with properties:

       OptionType: "call"
    ExerciseStyle: "american"
     ExerciseDate: 01-Jan-2020
           Strike: 100
             Bond: [1x1 fininstrument.FixedBond]
             Name: "fixed_bond_option"
```

```
% Option for embedded bond (callable bond)
CDates = datetime([2020,1,1 ; 2022,1,1]);
CRates = [.0425; .0750];
CouponRate = timetable(CDates,CRates);
StrikeOE = [100; 100];
ExerciseDatesOE = [datetime(2020,1,1); datetime(2021,1,1)];
CallSchedule =  timetable(ExerciseDatesOE,StrikeOE,'VariableNames',{'Strike Schedule'});
CallableBond = fininstrument("OptionEmbeddedFixedBond", 'Maturity',Maturity,...
                             'CouponRate',CouponRate,'Period', Period, ...
                             'CallSchedule',CallSchedule,'Name',"option_embedded_fixedbond")
```

```
CallableBond =
  OptionEmbeddedFixedBond with properties:

                 CouponRate: [2x1 timetable]
                     Period: 1
                      Basis: 0
                EndMonthRule: 1
                  Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                    Holidays: NaT
                   IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 01-Jan-2022
                   CallDates: [2x1 datetime]
                    PutDates: [0x1 datetime]
                CallSchedule: [2x1 timetable]
                 PutSchedule: [0x0 timetable]
           CallExerciseStyle: "american"
            PutExerciseStyle: [0x0 string]
```

```
    Name: "option_embedded_fixedbond"
```

Create HullWhite Model

Use `finmodel` to create a `HullWhite` model object.

```
VolCurve = 0.01;
AlphaCurve = 0.1;

HWModel = finmodel("hullwhite",'alpha',AlphaCurve,'sigma',VolCurve)
```

```
HWModel =
  HullWhite with properties:

    Alpha: 0.1000
    Sigma: 0.0100
```

Create IRTree Pricer for HullWhite Model

Use `finpricer` to create an `IRTree` pricer object for a `HullWhite` model and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
HWTreePricer = finpricer("IRTree",'Model',HWModel,'DiscountCurve',ZeroCurve,'TreeDates',ZeroDates
```

```
HWTreePricer =
  HWBKTree with properties:

            Tree: [1x1 struct]
       TreeDates: [4x1 datetime]
           Model: [1x1 finmodel.HullWhite]
   DiscountCurve: [1x1 ratecurve]
```

Create finportfolio Object and Add Callable Bond Instrument

Create a `finportfolio` object with the vanilla bond, stepped coupon bond, float bond, and the call option.

```
myportfolio = finportfolio([VBond,SBond,Float,CallOption],HWTreePricer, [1,2,2,1])
```

```
myportfolio =
  finportfolio with properties:

    Instruments: [4x1 fininstrument.FinInstrument]
        Pricers: [1x1 finpricer.irtree.HWBKTree]
    PricerIndex: [4x1 double]
       Quantity: [4x1 double]
```

Use `addInstrument` to add the callable bond instrument to the existing portfolio.

```
myportfolio = addInstrument(myportfolio,CallableBond,HWTreePricer,1)
```

```
myportfolio =
  finportfolio with properties:

    Instruments: [5x1 fininstrument.FinInstrument]
```

```
        Pricers: [1x1 finpricer.irtree.HWBKTree]
    PricerIndex: [5x1 double]
       Quantity: [5x1 double]
```

```
myportfolio.PricerIndex
```

```
ans = 5×1

     1
     1
     1
     1
     1
```

The `PricerIndex` property has a length equal to the length of instrument objects in the `finportfolio` object and stores the index of which pricer is used for each instrument object. In this case, because there is only one pricer, each instrument must use that pricer.

Price Portfolio

Use `pricePortfolio` to compute the price and sensitivities for the portfolio and the bond and option instruments in the portfolio.

```
format bank
[PortPrice,InstPrice,PortSens,InstSens] = pricePortfolio(myportfolio)
```

```
PortPrice =
        600.55

InstPrice = 5×1

         96.59
        204.14
        200.00

```

Input Arguments

`inPort` — Portfolio object

`finportfolio` object

Portfolio object, previously created using `finportfolio`.

Data Types: `object`

Output Arguments

`PortPrice` — Price of portfolio of instruments

numeric

Price of the portfolio of instruments, returned as a numeric.

`InstPrice` — Instrument prices

numeric

Instrument prices, returned as a numeric.

`PortSens` — Portfolio sensitivities

numeric

Portfolio sensitivities, returned as a numeric.

`InstSens` — Instrument sensitivities

numeric

Instrument sensitivities, returned as a numeric.

Version History

Introduced in R2020a

addInstrument

Add instrument to portfolio of instruments

Syntax

```
outPort = addInstrument(inPort,inInst)
outPort = addInstrument(inPort,inInst,inPricer)
outPort = addInstrument( ___ ,inQuant)
```

Description

`outPort = addInstrument(inPort,inInst)` adds the instrument `inInst` to a portfolio `inPort` of instruments previously created using `finportfolio`.

`outPort = addInstrument(inPort,inInst,inPricer)` adds the instrument `inInst` and the associated pricer `inPricer` to a portfolio `inPort` of instruments previously created using `finportfolio`.

`outPort = addInstrument( ___ ,inQuant)` optionally specifies the number (`inQuant`) of added instruments. Use this syntax with any of the input argument combinations in previous syntaxes.

Examples

Add Instruments to Portfolio

Use `finportfolio` to create an empty portfolio and then use `addInstrument` to add instruments to the portfolio.

Create `FixedBond` Instrument Objects

Use `fininstrument` to create two `FixedBond` instrument objects.

```
FixB1 = fininstrument("FixedBond", 'Maturity',datetime(2022,9,15),'CouponRate',0.045,'Name',"fixe
```

```
FixB1 =
  FixedBond with properties:

                 CouponRate: 0.0450
                     Period: 2
                      Basis: 0
                EndMonthRule: 1
                  Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                   Holidays: NaT
                  IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 15-Sep-2022
```

```
                        Name: "fixed_bond1"
```

```
FixB2 = fininstrument("FixedBond", 'Maturity',datetime(2022,9,15),'CouponRate',0.035,'Name',"fixe
```

```
FixB2 =
  FixedBond with properties:

                  CouponRate: 0.0350
                      Period: 2
                       Basis: 0
                EndMonthRule: 1
                   Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                    Holidays: NaT
                   IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 15-Sep-2022
                        Name: "fixed_bond2"
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = "zero";
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `Discount` Pricer Object for `FixedBond` Instruments

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
DiscountPricer = finpricer("Discount", 'DiscountCurve',myRC)
```

```
DiscountPricer =
  Discount with properties:
```

```
    DiscountCurve: [1x1 ratecurve]
```

Add Instruments to `finportfolio` Object

Create an empty `finportfolio` object using `finportfolio` and then use `addInstrument` to put the `FixedBond` instruments into the portfolio.

```
f1 = finportfolio;
f1 = addInstrument(f1,FixB1)
```

```
f1 =
  finportfolio with properties:

    Instruments: [1x1 fininstrument.FixedBond]
        Pricers: [0x1 finpricer.FinPricer]
    PricerIndex: NaN
       Quantity: 1

f1 = addInstrument(f1,FixB2)
```

```
f1 =
  finportfolio with properties:

    Instruments: [2x1 fininstrument.FixedBond]
        Pricers: [0x1 finpricer.FinPricer]
    PricerIndex: [2x1 double]
       Quantity: [2x1 double]
```

Set Pricer for Portfolio

Use `setPricer` to set the pricer for the portfolio and then use `pricePortfolio` to calculate the price and sensitivities for the instruments in the portfolio.

```
f1 = setPricer(f1,DiscountPricer,[1,2])
```

```
f1 =
  finportfolio with properties:

    Instruments: [2x1 fininstrument.FixedBond]
        Pricers: [1x1 finpricer.Discount]
    PricerIndex: [2x1 double]
       Quantity: [2x1 double]

[PortPrice,InstPrice,PortSens,InstSens] = pricePortfolio(f1)
```

```
PortPrice = 224.0834

InstPrice = 2×1

  114.0085
  110.0749

PortSens=1×2 table
    Price       DV01
```

```
    ______    ________

    224.08    0.084139

InstSens=2×2 table
                    Price       DV01
                    ______    ________

    fixed_bond1     114.01     0.04251
    fixed_bond2     110.07    0.041629
```

Add Multiple Instruments to Portfolio

Use `finportfolio` to create an empty portfolio and then use `addInstrument` to add multiple instruments to the portfolio.

Create FixedBond Instrument Objects

Use `fininstrument` to create two `FixedBond` instrument objects each with two instruments.

```
FixB1 = fininstrument("FixedBond", 'Maturity',datetime([2022,9,15 ; 2022,10,15]),'CouponRate',0.0
```

```
FixB1=2×1 object
  2x1 FixedBond array with properties:

    CouponRate
    Period
    Basis
    EndMonthRule
    Principal
    DaycountAdjustedCashFlow
    BusinessDayConvention
    Holidays
    IssueDate
    FirstCouponDate
    LastCouponDate
    StartDate
    Maturity
    Name
```

```
FixB2 = fininstrument("FixedBond", 'Maturity',datetime([2022,11,15 ; 2022,12,15]),'CouponRate',0
```

```
FixB2=2×1 object
  2x1 FixedBond array with properties:

    CouponRate
    Period
    Basis
    EndMonthRule
    Principal
    DaycountAdjustedCashFlow
    BusinessDayConvention
    Holidays
    IssueDate
```

```
    FirstCouponDate
    LastCouponDate
    StartDate
    Maturity
    Name
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2020,9,15);
Type = "zero";
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2020
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `Discount` Pricer Object for `FixedBond` Instruments

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
DiscountPricer = finpricer("Discount", 'DiscountCurve',myRC)
```

```
DiscountPricer =
  Discount with properties:

    DiscountCurve: [1x1 ratecurve]
```

Add Instruments to `finportfolio` Object

Create an empty `finportfolio` object using `finportfolio` and then use `addInstrument` to put the `FixedBond` instruments into the portfolio.

```
f1 = finportfolio;
f1 = addInstrument(f1,FixB1(1))
```

```
f1 =
  finportfolio with properties:

    Instruments: [1x1 fininstrument.FixedBond]
        Pricers: [0x1 finpricer.FinPricer]
```

```
    PricerIndex: NaN
       Quantity: 1

f1 = addInstrument(f1,FixB1(2))

f1 =
  finportfolio with properties:

    Instruments: [2x1 fininstrument.FixedBond]
        Pricers: [0x1 finpricer.FinPricer]
    PricerIndex: [2x1 double]
       Quantity: [2x1 double]

f1 = addInstrument(f1,FixB2(1))

f1 =
  finportfolio with properties:

    Instruments: [3x1 fininstrument.FixedBond]
        Pricers: [0x1 finpricer.FinPricer]
    PricerIndex: [3x1 double]
       Quantity: [3x1 double]

f1 = addInstrument(f1,FixB2(2))

f1 =
  finportfolio with properties:

    Instruments: [4x1 fininstrument.FixedBond]
        Pricers: [0x1 finpricer.FinPricer]
    PricerIndex: [4x1 double]
       Quantity: [4x1 double]
```

Set Pricer for Portfolio

Use `setPricer` to set the pricer for the portfolio and then use `pricePortfolio` to calculate the prices and sensitivities for the instruments in the portfolio.

```
f1 = setPricer(f1,DiscountPricer,[1,2,3,4])

f1 =
  finportfolio with properties:

    Instruments: [4x1 fininstrument.FixedBond]
        Pricers: [1x1 finpricer.Discount]
    PricerIndex: [4x1 double]
       Quantity: [4x1 double]

[PortPrice,InstPrice,PortSens,InstSens] = pricePortfolio(f1)

PortPrice = 428.2788

InstPrice = 4×1

  107.7226
```

Input Arguments

`inPort` — `finportfolio` object

`finportfolio` object

`finportfolio` object, specified as a scalar `finportfolio` object.

Data Types: `object`

`inInst` — Instrument object to add to portfolio

scalar instrument object

Instrument object to add to portfolio, specified as a scalar instrument object that is previously created using `fininstrument`.

Note If the instrument object for `inInst` is a vector of instruments, you must use `addInstrument` to add each instrument separately.

Data Types: `object`

`inPricer` — Pricer object associated with an added instrument object

scalar pricer object | array of pricer objects

Pricer object associated with an added instrument object, specified as a scalar pricer object or an array of pricer objects that are previously created using `finpricer`.

Data Types: `object`

`inQuant` — Number of added instruments

1 (default) | positive or negative numeric

Number of instruments, specified as a scalar numeric. Use a positive value for a long position and a negative value for a short position.

Data Types: `double`

Output Arguments

`outPort` — Updated `finportfolio` object
`finportfolio` object

Updated `finportfolio`, returned as a `finportfolio` object.

Version History

Introduced in R2020a

removeInstrument

Remove instrument from portfolio of instruments

Syntax

```
outPort = removeInstrument(inPort,inInst)
```

Description

`outPort = removeInstrument(inPort,inInst)` removes an instrument object (`inInst`) from a portfolio of instruments (`inPort`) previously created using `finportfolio`.

Examples

Remove Instrument From a Portfolio

Use `addInstrument` to add instruments to an empty portfolio and then remove an instrument from the portfolio using `removeInstrument`.

Create FixedBond Instrument Objects

Use `fininstrument` to create two `FixedBond` instrument objects.

```
FixB1 = fininstrument("FixedBond", 'Maturity',datetime(2022,9,15),'CouponRate',0.045,'Name',"fixe
```

```
FixB1 =
  FixedBond with properties:

                 CouponRate: 0.0450
                     Period: 2
                      Basis: 0
                EndMonthRule: 1
                  Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"

                   IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 15-Sep-2022
                        Name: "fixed_bond1"
```

```
FixB2 = fininstrument("FixedBond", 'Maturity',datetime(2022,9,15),'CouponRate',0.035,'Name',"fixe
```

```
FixB2 =
  FixedBond with properties:

                 CouponRate: 0.0350
                     Period: 2
```

```
                    Basis: 0
             EndMonthRule: 1
                Principal: 100
  DaycountAdjustedCashFlow: 0
     BusinessDayConvention: "actual"
                 Holidays: NaT
                IssueDate: NaT
          FirstCouponDate: NaT
           LastCouponDate: NaT
                StartDate: NaT
                 Maturity: 15-Sep-2022
                     Name: "fixed_bond2"
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2018
        InterpMethod: "linear"
   ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

Create `Discount` Pricer Object for `FixedBond` Instruments

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
DiscountPricer = finpricer("Discount",'DiscountCurve',myRC)
```

```
DiscountPricer =
  Discount with properties:

    DiscountCurve: [1x1 ratecurve]
```

Add Instruments to `finportfolio` Object

Create an empty `finportflio` object using `finportfolio` and then use `addInstrument` to add the two `FixedBond` instruments to the portfolio.

```
f1 = finportfolio;
f1 = addInstrument(f1,FixB1)

f1 =
  finportfolio with properties:

    Instruments: [1x1 fininstrument.FixedBond]
        Pricers: [0x1 finpricer.FinPricer]
    PricerIndex: NaN
       Quantity: 1

f1 = addInstrument(f1,FixB2)

f1 =
  finportfolio with properties:

    Instruments: [2x1 fininstrument.FixedBond]
        Pricers: [0x1 finpricer.FinPricer]
    PricerIndex: [2x1 double]
       Quantity: [2x1 double]
```

Remove Instrument from `finportfolio` Object

Use `removeInstrument` to remove the first `FixedBond` instrument from the portfolio.

```
f1 = removeInstrument(f1,1)

f1 =
  finportfolio with properties:

    Instruments: [1x1 fininstrument.FixedBond]
        Pricers: [0x1 finpricer.FinPricer]
    PricerIndex: NaN
       Quantity: 1
```

Set Pricer for Portfolio

Use `setPricer` to set the `Discount` pricer for the portfolio and then use `pricePortfolio` to calculate the price and sensitivities for the single instrument in the portfolio.

```
f1 = setPricer(f1,DiscountPricer)

f1 =
  finportfolio with properties:

    Instruments: [1x1 fininstrument.FixedBond]
        Pricers: [1x1 finpricer.Discount]
    PricerIndex: 1
       Quantity: 1

[PortPrice,InstPrice,PortSens,InstSens] = pricePortfolio(f1)

PortPrice = 110.0749

InstPrice = 110.0749
```

```
PortSens=1×2 table
    Price       DV01
    ______    ________

    110.07    0.041629

InstSens=1×2 table
                   Price       DV01
                   ______    ________

    fixed_bond2    110.07    0.041629
```

Input Arguments

`inPort` — `finportfolio` object

`finportfolio` object

`finportfolio` object, specified as a scalar `finportfolio` object.

Data Types: `object`

`inInst` — Instrument to remove from `finportfolio` object

instrument object | index | string for the instrument object `'Name'` property

Instrument to remove from `finportfolio` object, specified as a scalar instrument object, string for the instrument object `'Name'` property, or index value for the position of instrument in the `finportfolio` object.

Data Types: `object` | `double` | `string`

Output Arguments

`outPort` — Updated `finportfolio` object

`finportfolio` object

Updated `finportfolio`, returned as a `finportfolio` object.

Version History

Introduced in R2020a

“Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22
“Choose Instruments, Models, and Pricers” on page 1-53

setPricer

Set pricer for `finportfolio` object

Syntax

```
outPort = setPricer(inPort,inPricer,Index)
```

Description

`outPort = setPricer(inPort,inPricer,Index)` sets a specified pricer for the previously created `finportfolio` object.

Examples

Set Pricer for Portfolio Containing Instruments

Use `finportfolio` to create a portfolio of instruments and then use `setPricer` to set the pricer for the portfolio.

Create `FixedBond` Instrument Objects

Use `fininstrument` to create two `FixedBond` instrument objects.

```
FixB1 = fininstrument("FixedBond",'Maturity',datetime(2022,9,15),'CouponRate',0.045,'Name',"fixe
```

```
FixB1 =
  FixedBond with properties:

                 CouponRate: 0.0450
                     Period: 2
                      Basis: 0
                EndMonthRule: 1
                  Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                    Holidays: NaT
                   IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 15-Sep-2022
                        Name: "fixed_bond1"
```

```
FixB2 = fininstrument("FixedBond",'Maturity',datetime(2022,9,15),'CouponRate',0.035,'Name',"fixe
```

```
FixB2 =
  FixedBond with properties:

                 CouponRate: 0.0350
                     Period: 2
```

```
                    Basis: 0
             EndMonthRule: 1
                Principal: 100
DaycountAdjustedCashFlow: 0
   BusinessDayConvention: "actual"
                 Holidays: NaT
                IssueDate: NaT
          FirstCouponDate: NaT
           LastCouponDate: NaT
                StartDate: NaT
                 Maturity: 15-Sep-2022
                     Name: "fixed_bond2"
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2018
        InterpMethod: "linear"
   ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

Create `Discount` Pricer Object for `FixedBond` Instruments

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
DiscountPricer = finpricer("Discount",'DiscountCurve',myRC)
```

```
DiscountPricer =
  Discount with properties:

    DiscountCurve: [1x1 ratecurve]
```

Add Instruments to `finportfolio` Object

Create a `finportflio` object using `finportfolio` and use `addInstrument` to put the `FixedBond` instruments in the portfolio.

```
f1 = finportfolio;
f1 = addInstrument(f1,FixB1)

f1 =
  finportfolio with properties:

    Instruments: [1x1 fininstrument.FixedBond]
        Pricers: [0x1 finpricer.FinPricer]
    PricerIndex: NaN
       Quantity: 1

f1 = addInstrument(f1,FixB2)

f1 =
  finportfolio with properties:

    Instruments: [2x1 fininstrument.FixedBond]
        Pricers: [0x1 finpricer.FinPricer]
    PricerIndex: [2x1 double]
       Quantity: [2x1 double]
```

Set Pricer for Portfolio

Use `setPricer` to set the pricer for the portfolio and then use `pricePortfolio` to calculate the price and sensitivities for the instruments in the portfolio.

```
f1 = setPricer(f1,DiscountPricer,[1,2])

f1 =
  finportfolio with properties:

    Instruments: [2x1 fininstrument.FixedBond]
        Pricers: [1x1 finpricer.Discount]
    PricerIndex: [2x1 double]
       Quantity: [2x1 double]

[PortPrice,InstPrice,PortSens,InstSens] = pricePortfolio(f1)

PortPrice = 224.0834

InstPrice = 2×1

  114.0085
  110.0749

PortSens=1×2 table
    Price       DV01
    ______    ________

    224.08    0.084139

InstSens=2×2 table
                   Price       DV01
                   ______    ________
```

```
fixed_bond1    114.01     0.04251
fixed_bond2    110.07    0.041629
```

Input Arguments

`inPort` — Portfolio

`finportfolio` object

Portfolio, specified using a previously created `finportfolio` object.

Data Types: `object`

`inPricer` — Pricer object to set for an instrument in a `finportfolio` object

object

Pricer object to set for an instrument in a `finportfolio` object, specified using a previously created pricer object with `finpricer`.

Data Types: `object`

`Index` — Index to instruments in `finportfolio` object

numeric

Index to instruments in the `finportfolio` object, specified as a numeric value.

Data Types: `double`

Output Arguments

`outPort` — Updated portfolio

`finportfolio` object

Updated portfolio, returned as an `finportfolio` object.

Version History

Introduced in R2020a

Topics

“Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22
“Choose Instruments, Models, and Pricers” on page 1-53

cashflows

Package: `fininstrument`

Compute cash flow for `FixedBond`, `FloatBond`, `Swap`, `FRA`, `STIRFuture`, `OISFuture`, `OvernightIndexedSwap`, or `Deposit` instrument

Syntax

```
CF = cashflows(InstrumentObject,Settle)
```

Description

`CF = cashflows(InstrumentObject,Settle)` computes cash flow for a `Deposit`, `FRA`, ,`Swap`, `STIRFuture`, `OISFuture`, `FixedBond`, `OvernightIndexedSwap`, or `FloatBond` instrument object.

Examples

Calculate Cash Flow for FRA Instrument

This example shows the workflow to price a `FRA` (forward rate agreement) instrument and then use `cashflows` to determine the cash flow for the `FRA` instrument.

Create FRA Instrument Object

Use `fininstrument` to create a `FRA` instrument object.

```
FRAObj = fininstrument("FRA",'StartDate',datetime(2020,9,15),'Maturity',datetime(2022,9,15),'Rate
```

```
FRAObj =
  FRA with properties:

                     Rate: 0.1750
                    Basis: 2
                StartDate: 15-Sep-2020
                 Maturity: 15-Sep-2022
                Principal: 100
    BusinessDayConvention: "actual"
                 Holidays: NaT
                     Name: ""
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = "zero";
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `Discount` Pricer Object

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object with the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("Discount", 'DiscountCurve',myRC)
```

```
outPricer =
  Discount with properties:

    DiscountCurve: [1x1 ratecurve]
```

Price FRA Instrument

Use `price` to compute the price and sensitivities for the FRA instrument.

```
[Price, outPR] = price(outPricer, FRAObj,["all"])
```

```
Price = 34.1757
```

```
outPR =
  priceresult with properties:

       Results: [1x2 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×2 table
    Price      DV01
    ______    _______

    34.176    0.01368
```

Use `cashflows` for the FRA instrument with a `Settle` date of `15-Dec-2021`. The specified `Settle` date must be before the instrument `Maturity` date.

```
CF = cashflows(FRAObj,datetime(2021,12,15))
```

```
CF= 1×1timetable
       Time         CFA
    ___________    ______
```

```
    15-Sep-2022    35.486
```

Calculate Cash Flow for OIS Future Instrument

This example shows the workflow to price an `OISFuture` instrument and then use `cashflows` to calculate the cashflow for the `OISFuture` instrument.

Create ratecurve Object

Create a `ratecurve` object using `ratecurve` for the underlying interest-rate curve for the `STIRFuture` instrument.

```
Settle = datetime(2019,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `OISFuture` Instrument Object

Use `fininstrument` to create an `OISFuture` instrument object.

```
OISFuture = fininstrument("OISFuture",'Maturity',datetime(2022,12,15),'QuotedPrice',99.5,'StartDa
```

```
OISFuture =
  OISFuture with properties:

             QuotedPrice: 99.5000
                  Method: "compound"
                   Basis: 2
               StartDate: 15-Sep-2022
                Maturity: 15-Dec-2022
                Notional: 90
    BusinessDayConvention: "actual"
                Holidays: NaT
          ProjectionCurve: [1x1 ratecurve]
        HistoricalFixing: [0x0 timetable]
                    Name: "ois_future_instrument"
```

Create Discount Pricer Object

Use finpricer to create a Discount pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("Discount",'DiscountCurve',myRC)
```

```
outPricer =
  Discount with properties:

    DiscountCurve: [1x1 ratecurve]
```

Price OISFuture Instrument

Use price to compute the price and sensitivities for the OISFuture instrument.

```
[Price, outPR] = price(outPricer,OISFuture,["all"])
```

```
Price = 2.6543

outPR =
  priceresult with properties:

       Results: [1x2 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×2 table
    Price        DV01
    ______    __________

    2.6543    -0.0013589
```

Use cashflows to calculate the cash flow for the OISFuture instrument with a Settle date of 15-Sep-2022. The specified Settle date must be before the instrument Maturity date.

```
CF = cashflows(OISFuture,datetime(2022,9,15))
```

```
CF= 1×1timetable
       Time          CFA
    ___________    ______

    15-Dec-2022    2.7225
```

Calculate Cash Flow for Multiple FRA Instruments

This example shows the workflow to price multiple FRA (forward rate agreement) instruments and then use cashflows to determine the cash flow for each of the FRA instruments.

Create FRA Instrument Object

Use fininstrument to create a FRA instrument object for three FRA instruments.

```
FRAObj = fininstrument("FRA",'StartDate',datetime([2020,9,15 ; 2020,10,15 ; 2020,11,15]),'Maturi
```

```
FRAObj=3×1 object
  3x1 FRA array with properties:

    Rate
    Basis
    StartDate
    Maturity
    Principal
    BusinessDayConvention
    Holidays
    Name
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = "zero";
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `Discount` Pricer Object

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object with the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("Discount", 'DiscountCurve',myRC)
```

```
outPricer =
  Discount with properties:

    DiscountCurve: [1x1 ratecurve]
```

Price FRA Instruments

Use `price` to compute the prices and sensitivities for the three FRA instrument.

```
[Price, outPR] = price(outPricer, FRAObj,["all"])
```

```
Price = 3×1

   34.1757
   34.1207
   34.0627

outPR=1×3 object
  1x3 priceresult array with properties:

    Results
    PricerData

outPR.Results

```

Use `cashflows` for the three `FRA` instruments with a `Settle` date of April 15, 2022. The specified `Settle` date must be before the instrument `Maturity` date.

```
CF = cashflows(FRAObj(1),datetime(2022,4,15))

CF= 1×1timetable
       Time          CFA
    ___________    ______

    15-Sep-2022    35.486

CF = cashflows(FRAObj(2),datetime(2022,4,15))

CF= 1×1timetable
       Time          CFA
    ___________    ______

    15-Oct-2022    35.486

CF = cashflows(FRAObj(3),datetime(2022,4,15))
```

```
CF= 1×1timetable
       Time          CFA
    ____________    ______

    15-Nov-2022    35.486
```

Calculate Cash Flow for FixedBond Instrument

This example shows the workflow to price a `FixedBond` instrument and then use `cashflows` to calculate the cash flow for the `FixedBond` instrument.

Create FixedBond Instrument Object

Use `fininstrument` to create a `FixedBond` instrument object.

```
FixB = fininstrument("FixedBond",'Maturity',datetime(2022,9,15),'CouponRate',0.05,'Period',4,'Bas
```

```
FixB =
  FixedBond with properties:

                 CouponRate: 0.0500
                     Period: 4
                      Basis: 7
                EndMonthRule: 1
                   Principal: 1000
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "follow"
                   Holidays: NaT
                  IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 15-Sep-2022
                        Name: "fixed_bond_instrument"
```

Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
        Compounding: -1
              Basis: 0
              Dates: [10x1 datetime]
              Rates: [10x1 double]
```

```
              Settle: 15-Sep-2018
          InterpMethod: "linear"
     ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"
```

Create `Discount` Pricer Object

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("Discount",'DiscountCurve',myRC)
```

```
outPricer =
  Discount with properties:

    DiscountCurve: [1x1 ratecurve]
```

Price `FixedBond` Instrument

Use `price` to compute the price and sensitivities for the `FixedBond` instrument.

```
[Price, outPR] = price(outPricer, FixB,["all"])
```

```
Price = 1.1600e+03
```

```
outPR =
  priceresult with properties:

       Results: [1x2 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×2 table
    Price     DV01
    _____    _______

    1160     0.42712
```

Use `cashflows` to calculate the cash flow for the `FixedBond` instrument for any specified `Settle` date before the instrument `Maturity` date.

```
CF = cashflows(FixB,datetime(2021,9,15))
```

```
CF=5×1 timetable
       Time         Var1
    ____________    ______

    15-Sep-2021        0
    15-Dec-2021      12.5
    15-Mar-2022      12.5
    15-Jun-2022      12.5
```

```
15-Sep-2022    1012.5
```

Input Arguments

`InstrumentObject` — Instrument object

`Deposit` object | `FixedBond` object | `FloatBond` object | `Swap` object | `STIRFuture` object | `OISFuture` object | `OvernightIndexedSwap` object | `FRA` object

Instrument object, specified using a previously created instrument object for one of the following: `Deposit`, `FixedBond`, `FloatBond`, `Swap`, `STIRFuture`, `OISFuture`, `OvernightIndexedSwap`, or `FRA`.

Note If the `InstrumentObject` is a vector of instruments, you must use `cashflows` separately with each instrument.

Data Types: `object`

`Settle` — Settlement date for instrument cash flow

datetime scalar | string scalar | date character vector

Settlement date for instrument cash flow, specified as a scalar datetime, string, or date character vector.

Note The `Settle` date you specify must be before the `Maturity` date for the `Deposit`, `FixedBond`, `FloatBond`, `Swap`, `STIRFuture`, `OISFuture`,`OvernightIndexedSwap`, or `FRA` instrument.

To support existing code, `cashflows` also accepts serial date numbers as inputs, but they are not recommended.

Output Arguments

`CF` — Cash flow

timetable

Cash flow, returned as a timetable.

Version History

Introduced in R2020a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `cashflows` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

cashsettle

Package: `fininstrument`

Compute cash settlement for `BondFuture`, `CommodityFuture`, `EquityIndexFuture`, or `FXFuture` instrument

Syntax

```
outCS = cashsettle(InstrumentObject,SpotPrice,DiscountCurve)
```

Description

`outCS = cashsettle(InstrumentObject,SpotPrice,DiscountCurve)` computes the cash settlement for a `BondFuture`, `CommodityFuture`, `FXFuture`, or `EquityIndexFuture` instrument object.

Examples

Compute Cash Settlement for `BondFuture` Instrument

This example shows the workflow to price a `BondFuture` instrument and then use `cashsettle` to compute the cash settlement amount for the `BondFuture` instrument.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2022,3,1);
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates,Compounding=2);
```

Create Underlying `FixedBond` Instrument Object

Use `fininstrument` to create a `FixedBond` instrument object.

```
FixB = fininstrument("FixedBond",Maturity=datetime(2032,9,1),CouponRate=0.05,Name="fixed_bond_ins
```

```
FixB =
  FixedBond with properties:

                 CouponRate: 0.0500
                     Period: 2
                      Basis: 0
                EndMonthRule: 1
                   Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                    Holidays: NaT
                   IssueDate: NaT
```

```
              FirstCouponDate: NaT
               LastCouponDate: NaT
                    StartDate: NaT
                     Maturity: 01-Sep-2032
                         Name: "fixed_bond_instrument"
```

Create BondFuture Instrument Object

Use `fininstrument` to create a `BondFuture` instrument object.

```
BondFut = fininstrument("BondFuture",Maturity=datetime(2022,9,1),QuotedPrice=86,Bond=FixB,Convers
```

```
BondFut =
  BondFuture with properties:

           Maturity: 01-Sep-2022
        QuotedPrice: 86
               Bond: [1x1 fininstrument.FixedBond]
    ConversionFactor: 1.4300
           Notional: 100000
               Name: "bondfuture_instrument"
```

Create Future Pricer Object

Use `finpricer` to create a `Future` pricer object and use the `ratecurve` object with the `DiscountCurve` name-value argument.

```
outPricer = finpricer("Future",DiscountCurve=ZeroCurve,SpotPrice=125)
```

```
outPricer =
  Future with properties:

    DiscountCurve: [1x1 ratecurve]
        SpotPrice: 125
```

Price BondFuture Instrument

Use `price` to compute the price and price result for the `BondFuture` instrument.

```
[Price,outPR] = price(outPricer,BondFut)
```

```
Price = -151.9270

outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×4 table
     Price     FairDeliveryPrice    FairFuturePrice    AccruedInterest
    _______    _________________    _______________    _______________
```

```
    -151.93       1.2283e+05            85.893                0
```

Compute Cash Settlement Amount

Use `cashsettle` with the `BondFuture` instrument to compute the cash settlement.

```
SpotPrice = 125; % Clean spot price for $100 face value of underlying bond.
outCS = cashsettle(BondFut,SpotPrice,ZeroCurve)
```

```
outCS= 1×1timetable
       Time        CashSettleAmount
    ___________    ________________

    01-Sep-2022        -152.33
```

Compute Cash Settlement for Multiple FXFuture Instruments

This example shows the workflow to price multiple `FXFuture` instruments and then use `cashsettle` to compute the cash settlement amount for the `FXFuture` instruments.

Create `ratecurve` Objects

Create `ratecurve` objects using `ratecurve` for the foreign and domestic zero curves.

```
% Define Foreign Zero Curve
Settle = datetime(2022, 3, 1);
ForeignZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ForeignZeroRates = [0.0031 0.0035 0.0047 0.0058 0.0062 0.0093 0.0128 0.0182 0.0223 0.0285]';
ForeignZeroDates = Settle + ForeignZeroTimes;
ForeignRC = ratecurve('zero', Settle, ForeignZeroDates, ForeignZeroRates);

% Define Domestic Zero Curve
DomesticZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
DomesticZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
DomesticZeroDates = Settle + DomesticZeroTimes;
DomesticRC = ratecurve('zero', Settle, DomesticZeroDates, DomesticZeroRates);
```

Create FXFuture Instrument Object

Use `fininstrument` to create a `FXFuture` instrument object for three FX Future instruments.

```
FXFut = fininstrument("FXFuture",Maturity=datetime([2022,9,1 ; 2022,10,1 ; 2022,11,1]),QuotedPric
```

```
FXFut=3×1 object
  3x1 FXFuture array with properties:

    Maturity
    QuotedPrice
    ForeignRateCurve
    Notional
    Name
```

Create Future Pricer Object

Use `finpricer` to create a `Future` pricer object and use the `ratecurve` object with the `DiscountCurve` name-value argument.

```
outPricer = finpricer("Future",DiscountCurve=DomesticRC,SpotPrice=0.79)
```

```
outPricer =
  Future with properties:

    DiscountCurve: [1x1 ratecurve]
        SpotPrice: 0.7900
```

Price FXFuture Instruments

Use `price` to compute the prices and price results for the `FXFuture` instrument.

```
[Price,outPR] = price(outPricer,FXFut)
```

```
Price = 3×1
10^4 ×

    0.2162
   -0.5789
   -1.3732

outPR=1×3 object
  1x3 priceresult array with properties:

    01-Nov-2022         -13781
```

Input Arguments

`InstrumentObject` — Instrument object
`BondFuture` object | `CommodityFuture` object | `EquityIndexFuture` object | `FXFuture` object

Instrument object, specified using a previously created instrument object for one of the following: `BondFuture`, `CommodityFuture`, `FXFuture`, or `EquityIndexFuture`.

Note If `InstrumentObject` is a vector of instruments, you must use `cashsettle` separately with each instrument.

Data Types: `object`

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

`ratecurve` object for discounting cash flows, specified using the name of a previously created `ratecurve` object.

Data Types: `object`

`SpotPrice` — Quoted spot price for underlying asset to be delivered
numeric

Quoted spot price for underlying asset to be delivered, specified using a numeric value that depends on the type of future instrument being priced:

- `BondFuture` instrument — Clean spot price quoted for $100 face value of underlying bond
- `CommodityFuture` instrument — Spot price for underlying commodity quantity specified in contract
- `EquityIndexFuture` instrument — Spot equity index value
- `FXFuture` instrument — Spot price quoted in domestic currency for one unit of foreign currency

Data Types: `double`

Output Arguments

`outCS` — Cash settlement
timetable

Cash settlement, returned as a timetable.

fairdelivery

Package: `fininstrument`

Compute fair delivery price of underlying asset for `BondFuture`, `CommodityFuture`, `EquityIndexFuture`, or `FXFuture` instrument

Syntax

```
[FairDeliveryPrice,FairFuturePrice,AccruedInterest] = fairdelivery(
InstrumentObject,SpotPrice,DiscountCurve)
```

Description

`[FairDeliveryPrice,FairFuturePrice,AccruedInterest] = fairdelivery( InstrumentObject,SpotPrice,DiscountCurve)` computes the fair delivery price of the underlying asset for a `BondFuture`, `CommodityFuture`, `FXFuture`, or `EquityIndexFuture` instrument object.

Examples

Compute Fair Delivery Price of Underlying Bond for `BondFuture` Instrument

This example shows the workflow to price a `BondFuture` instrument and then use `fairdelivery` to compute the fair delivery price for the underlying `FixedBond`.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2022,3,1);
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates,Compounding=2);
```

Create Underlying `FixedBond` Instrument Object

Use `fininstrument` to create a `FixedBond` instrument object.

```
FixB = fininstrument("FixedBond",Maturity=datetime(2032,9,1),CouponRate=0.05,Name="fixed_bond_ins
```

```
FixB =
  FixedBond with properties:

                 CouponRate: 0.0500
                     Period: 2
                      Basis: 0
                EndMonthRule: 1

            LastCouponDate: NaT
                 StartDate: NaT
                  Maturity: 01-Sep-2032
                      Name: "fixed_bond_instrument"
```

Create BondFuture Instrument Object

Use `fininstrument` to create a `BondFuture` instrument object.

```
BondFut = fininstrument("BondFuture",Maturity=datetime(2022,9,1),QuotedPrice=86,Bond=FixB,Convers
```

```
BondFut =
  BondFuture with properties:

            Maturity: 01-Sep-2022
         QuotedPrice: 86
                Bond: [1x1 fininstrument.FixedBond]
    ConversionFactor: 1.4300
            Notional: 100000
                Name: "bondfuture_instrument"
```

Create Future Pricer Object

Use `finpricer` to create a `Future` pricer object and use the `ratecurve` object with the `DiscountCurve` name-value argument.

```
outPricer = finpricer("Future",DiscountCurve=ZeroCurve,SpotPrice=125)
```

```
outPricer =
  Future with properties:

    DiscountCurve: [1x1 ratecurve]
        SpotPrice: 125
```

Price BondFuture Instrument

Use `price` to compute the price and price result for the `BondFuture` instrument.

```
[Price,outPR] = price(outPricer,BondFut)
```

```
Price = -151.9270

outPR =

    -151.93       1.2283e+05            85.893                0
```

Compute Fair Delivery Price

Use `fairdelivery` with the `BondFuture` instrument to compute the fair delivery price for the underlying `FixedBond`.

```
SpotPrice = 125; % Clean spot price for $100 face value of underlying bond.
[FairDeliveryPrice,FairFuturePrice,AccruedInterest] = fairdelivery(BondFut,SpotPrice,ZeroCurve)
```

```
FairDeliveryPrice = 1.2283e+05

FairFuturePrice = 85.8935

AccruedInterest = 0
```

Compute Fair Delivery Price for Multiple FXFuture Instruments

This example shows the workflow to price multiple `FXFuture` instruments and then use `fairdelivery` to compute the fair delivery price for the `FXFuture` instruments.

Create ratecurve Objects

Create `ratecurve` objects using `ratecurve` for the foreign and domestic zero curves.

```
% Define Foreign Zero Curve
Settle = datetime(2022, 3, 1);
ForeignZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ForeignZeroRates = [0.0031 0.0035 0.0047 0.0058 0.0062 0.0093 0.0128 0.0182 0.0223 0.0285]';
ForeignZeroDates = Settle + ForeignZeroTimes;
ForeignRC = ratecurve('zero', Settle, ForeignZeroDates, ForeignZeroRates);

% Define Domestic Zero Curve
DomesticZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
DomesticZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
DomesticZeroDates = Settle + DomesticZeroTimes;
DomesticRC = ratecurve('zero', Settle, DomesticZeroDates, DomesticZeroRates);
```

Create FXFuture Instrument Object

Use `fininstrument` to create a `FXFuture` instrument object for three FX Future instruments.

```
FXFut = fininstrument("FXFuture",Maturity=datetime([2022,9,1 ; 2022,10,1 ; 2022,11,1]),QuotedPric
```

```
FXFut=3×1 object
  3x1 FXFuture array with properties:

    Maturity
    QuotedPrice
    ForeignRateCurve
    Notional
    Name
```

Create Future Pricer Object

Use `finpricer` to create a `Future` pricer object and use the `ratecurve` object with the `DiscountCurve` name-value argument.

```
outPricer = finpricer("Future",DiscountCurve=DomesticRC,SpotPrice=0.79)
```

```
outPricer =
  Future with properties:

    DiscountCurve: [1x1 ratecurve]
        SpotPrice: 0.7900
```

Price FXFuture Instruments

Use `price` to compute the prices and price results for the `FXFuture` instrument.

```
[Price,outPR] = price(outPricer,FXFut)
```

```
Price = 3×1

Compute Fair Delivery for FXFuture Instruments

Use `fairdelivery` with the `FXFuture` instruments to compute the fair delivery price for the `FXFuture` instruments.

```
SpotPrice = 0.79; % Quoted in domestic currency for one unit of foreign currency
[FairDeliveryPrice,FairFuturePrice,AccruedInterest] = fairdelivery(FXFut(1),SpotPrice,DomesticRC)

FairDeliveryPrice = 1.5817e+05

FairFuturePrice = 0.7908

AccruedInterest = 0

[FairDeliveryPrice,FairFuturePrice,AccruedInterest] = fairdelivery(FXFut(2),SpotPrice,DomesticRC)

FairDeliveryPrice = 1.5819e+05

FairFuturePrice = 0.7910

AccruedInterest = 0

[FairDeliveryPrice,FairFuturePrice,AccruedInterest] = fairdelivery(FXFut(3),SpotPrice,DomesticRC)

FairDeliveryPrice = 1.5822e+05

FairFuturePrice = 0.7911

AccruedInterest = 0
```

Input Arguments

`InstrumentObject` — Instrument object

`BondFuture` object | `CommodityFuture` object | `EquityIndexFuture` object | `FXFuture` object

Instrument object, specified using a previously created instrument object for one of the following: `BondFuture`, `CommodityFuture`, `FXFuture`, or `EquityIndexFuture`.

Note If the `InstrumentObject` is a vector of instruments, you must use `fairdelivery` separately with each instrument.

Data Types: `object`

`SpotPrice` — Quoted spot price for underlying asset to be delivered

numeric

Quoted spot price for underlying asset to be delivered, specified as `SpotPrice` and a numeric value that depends on the type of future instrument being priced:

- `BondFuture` instrument — Clean spot price quoted for $100 face value of underlying bond
- `CommodityFuture` instrument — Spot price for underlying commodity quantity specified in contract
- `EquityIndexFuture` instrument — Spot equity index value
- `FXFuture` instrument — Spot price quoted in domestic currency for one unit of foreign currency

Data Types: `double`

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

`ratecurve` object for discounting cash flows, specified as `DiscountCurve` and the name of a previously created `ratecurve` object.

Data Types: `object`

Output Arguments

`FairDeliveryPrice` — Fair delivery price for underlying asset
numeric

Fair delivery price for underlying asset, returned as a numeric. Depending on `InstrumentObject`, the `FairDeliveryPrice` output is defined:

- `BondFuture` instrument — Fair delivery price (full cash price) for underlying bond
- `CommodityFuture` instrument — Fair delivery price for underlying commodity
- `EquityIndexFuture` instrument — Fair delivery price for equity index future
- `FXFuture` instrument — Fair delivery price for FX future in domestic currency

`FairFuturePrice` — Fair future price (clean price) for $100 face value
numeric

Fair future price (clean price) for 100 face value, returned as a numeric. Depending on `InstrumentObject`, the `FairFuturePrice` output is defined:

- `BondFuture` instrument — Fair future price (clean price) for $100 face value
- `CommodityFuture` instrument — Fair future price
- `EquityIndexFuture` instrument — Fair future price
- `FXFuture` instrument — Fair future price in domestic currency for one unit of foreign currency

`AccruedInterest` — Accrued interest at delivery
numeric

Accrued interest at delivery, returned as a numeric. Depending on `InstrumentObject`, the `AccruedInterest` output is defined:

- `BondFuture` instrument — Accrued interest at delivery for $100 face value
- `CommodityFuture` instrument — Accrued interest at delivery
- `EquityIndexFuture` instrument — Accrued interest at delivery
- `FXFuture` instrument — Accrued interest at delivery

setCallExercisePolicy

Package: `fininstrument`

Set call exercise policy for `OptionEmbeddedFixedBond`, `OptionEmbeddedFloatBond`, or `ConvertibleBond` instrument

Syntax

```
UpdatedInstrumentObject = setCallExercisePolicy(InstrumentObject,
exerciseSchedule,exerciseStyle)
```

Description

`UpdatedInstrumentObject = setCallExercisePolicy(InstrumentObject, exerciseSchedule,exerciseStyle)` sets the call exercise policy for a `OptionEmbeddedFixedBond`, `OptionEmbeddedFloatBond`, or `ConvertibleBond` instrument object.

Examples

Set Call Exercise Policy for Option Embedded Fixed Bond Instrument

This example shows how to use `setCallExercisePolicy` to maintain consistency between the exercise schedule and exercise style when using a `OptionEmbeddedFixedBond` instrument object.

Create `OptionEmbeddedFixedBond` Instrument Object

Use `fininstrument` to create an `OptionEmbeddedFixedBond` instrument object with different exercise styles.

```
Maturity = datetime(2024,1,1);
Strike = [100;100];
ExerciseDates = [datetime(2020,1,1); datetime(2024,1,1)];
Period = 1;
CallSchedule =  timetable(ExerciseDates,Strike,'VariableNames',{'Strike Schedule'});

CallableBond = fininstrument("OptionEmbeddedFixedBond",'Maturity',Maturity,...
                             'CouponRate',0.025,'Period',Period, ...
                             'CallSchedule',CallSchedule)
```

```
CallableBond =
  OptionEmbeddedFixedBond with properties:

                 CouponRate: 0.0250
                     Period: 1
                      Basis: 0
                EndMonthRule: 1
                   Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
```

```
                 Holidays: NaT
                IssueDate: NaT

                 PutDates: [0x1 datetime]
             CallSchedule: [2x1 timetable]
              PutSchedule: [0x0 timetable]
        CallExerciseStyle: "american"
         PutExerciseStyle: [0x0 string]
                     Name: ""
```

Set the Exercise Style to Bermudan

Use `setCallExercisePolicy` to define the `CallExerciseStyle` as `Bermudan`.

```
CallableBond = setCallExercisePolicy(CallableBond, CallSchedule, "Bermudan")
```

```
CallableBond =
  OptionEmbeddedFixedBond with properties:

                CouponRate: 0.0250
                    Period: 1
                     Basis: 0
               EndMonthRule: 1
                  Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"

                  IssueDate: NaT
            FirstCouponDate: NaT
             LastCouponDate: NaT
                  StartDate: NaT
                   Maturity: 01-Jan-2024
                  CallDates: [2x1 datetime]
                   PutDates: [0x1 datetime]
               CallSchedule: [2x1 timetable]
                PutSchedule: [0x0 timetable]
          CallExerciseStyle: "bermudan"
           PutExerciseStyle: [0x0 string]
                       Name: ""
```

Use `setCallExercisePolicy` to modify Call`Schedule` and continue using a Bermudan exercise style.

```
Strike = [100; 101;102;103];
ExerciseDates = [datetime(2018,1,1);datetime(2020,1,1);datetime(2022,1,1);datetime(2024,1,1)];

CallSchedule =  timetable(ExerciseDates,Strike,'VariableNames',{'Strike Schedule'});

CallableBond = setCallExercisePolicy(CallableBond, CallSchedule)
```

```
CallableBond =
  OptionEmbeddedFixedBond with properties:
```

```
                CouponRate: 0.0250
                    Period: 1
                     Basis: 0
               EndMonthRule: 1
                  Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                   Holidays: NaT
                  IssueDate: NaT
            FirstCouponDate: NaT
             LastCouponDate: NaT
                  StartDate: NaT
                   Maturity: 01-Jan-2024
                  CallDates: [4x1 datetime]
                   PutDates: [0x1 datetime]
               CallSchedule: [4x1 timetable]
                PutSchedule: [0x0 timetable]
          CallExerciseStyle: "bermudan"
           PutExerciseStyle: [0x0 string]
                       Name: ""
```

Set Call Exercise Policy for Specific Option Embedded Fixed Bond Instrument

This example shows how to use `setCallExercisePolicy` to maintain consistency between the exercise schedule and exercise style when using a `OptionEmbeddedFixedBond` instrument object with three `OptionEmbeddedFixedBond` instruments.

Create `OptionEmbeddedFixedBond` Instrument Object

Use `fininstrument` to create an `OptionEmbeddedFixedBond` instrument object for three Option Embedded Fixed Bond instruments with `American` exercise styles.

```
Maturity = datetime([2024,1,1 ; 2024,4,1 ; 2024,8,1]);
Strike = [100;100];
ExerciseDates = [datetime(2020,1,1); datetime(2024,1,1)];
Period = 1;
CallSchedule =  timetable(ExerciseDates,Strike,'VariableNames',{'Strike Schedule'});

CallableBond = fininstrument("OptionEmbeddedFixedBond",'Maturity',Maturity,...
                             'CouponRate',0.025,'Period',Period, ...
                             'CallSchedule',CallSchedule)
```

```
CallableBond=3×1 object
  3x1 OptionEmbeddedFixedBond array with properties:

    CouponRate
    Period
    Basis
    EndMonthRule
    Principal
    DaycountAdjustedCashFlow
    BusinessDayConvention
    Holidays
    IssueDate
    FirstCouponDate
```

```
    LastCouponDate
    StartDate
    Maturity
    CallDates
    PutDates
    CallSchedule
    PutSchedule
    CallExerciseStyle
    PutExerciseStyle
    Name

CallableBond.CallExerciseStyle

ans =
"american"

ans =
"american"

ans =
"american"
```

The `CallExerciseStyle` is `"American"` because the `fininstrument` syntax does not contain a `CallExercideStyle` specification and there are two exercise dates defined in the `CallSchedule`.

Set the Exercise Style to Bermudan

Use `setCallExercisePolicy` to define the `CallExerciseStyle` as `Bermudan` for the second (`CallableBond(2)`) instrument.

```
CallableBond(2) = setCallExercisePolicy(CallableBond(2), CallSchedule, "Bermudan")

CallableBond=3×1 object
  3x1 OptionEmbeddedFixedBond array with properties:

    CouponRate
    Period
    Basis
    EndMonthRule
    Principal
    DaycountAdjustedCashFlow
    BusinessDayConvention
    Holidays
    IssueDate
    FirstCouponDate
    LastCouponDate
    StartDate
    Maturity
    CallDates
    PutDates
    CallSchedule
    PutSchedule
    CallExerciseStyle
    PutExerciseStyle
    Name

CallableBond.CallExerciseStyle
```

```
ans =
"american"

ans =
"bermudan"

ans =
"american"
```

Use `setCallExercisePolicy` to modify Call`Schedule` and continue using a `Bermudan` exercise style.

```
Strike = [100; 101;102;103];
ExerciseDates = [datetime(2018,1,1);datetime(2020,1,1);datetime(2022,1,1);datetime(2024,1,1)];

CallSchedule =  timetable(ExerciseDates,Strike,'VariableNames',{'Strike Schedule'});

CallableBond(2) = setCallExercisePolicy(CallableBond(2), CallSchedule)

CallableBond=3×1 object
  3x1 OptionEmbeddedFixedBond array with properties:

    CouponRate
    Period
    Basis
    EndMonthRule
    Principal
    DaycountAdjustedCashFlow
    BusinessDayConvention
    Holidays
    IssueDate
    FirstCouponDate
    LastCouponDate
    StartDate
    Maturity
    CallDates
    PutDates
    CallSchedule
    PutSchedule
    CallExerciseStyle
    PutExerciseStyle
    Name

CallableBond.CallExerciseStyle

ans =
"american"

ans =
"bermudan"
```

```
ans =
"american"
```

Input Arguments

`InstrumentObject` — Instrument object
`OptionEmbeddedFixedBond` object | `OptionEmbeddedFloatBond` object | `ConvertibleBond` object

Instrument object, specified as a previously created `OptionEmbeddedFixedBond`, `OptionEmbeddedFloatBond`, or `ConvertibleBond` object instrument object.

Note If the `OptionEmbeddedFixedBond`, `OptionEmbeddedFloatBond`, or `ConvertibleBond` instrument object is a vector of instruments, you must use `setCallExercisePolicy` separately with each instrument.

Data Types: `object`

`exerciseSchedule` — Call exercise schedule
timetable

Call exercise schedule, specified as a timetable. The timetable must contain both the `exerciseDate` value and `Strike` information.

Data Types: `timetable`

`exerciseStyle` — Call option exercise style
`"American"` (default) | string with value `"European"`, `"American"`, or `"Bermudan"` | character vector with value `'European'`, `'American'`, or `'Bermudan'`

Call option exercise style, specified as a scalar string or character vector.

Data Types: `string` | `char`

Output Arguments

`UpdatedInstrumentObject` — Updated instrument
object

Updated instrument, returned as an object.

Version History

Introduced in R2020b

setPutExercisePolicy

Package: `fininstrument`

Set put exercise policy for `OptionEmbeddedFixedBond`, `OptionEmbeddedFloatBond`, or `ConvertibleBond` instrument

Syntax

```
UpdatedInstrumentObject = setPutExercisePolicy(InstrumentObject,
exerciseSchedule,exerciseStyle)
```

Description

`UpdatedInstrumentObject = setPutExercisePolicy(InstrumentObject, exerciseSchedule,exerciseStyle)` sets the put exercise policy for an `OptionEmbeddedFixedBond`, `OptionEmbeddedFloatBond`, or `ConvertibleBond` instrument object.

Examples

Set Put Exercise Policy for Option Embedded Fixed Bond Instrument

This example shows how to use `setPutExercisePolicy` to maintain consistency between the exercise schedule and exercise style when using a `OptionEmbeddedFixedBond` instrument object.

Create `OptionEmbeddedFixedBond` Instrument Object

Use `fininstrument` to create an `OptionEmbeddedFixedBond` instrument object with different exercise styles.

```
Maturity = datetime(2024,1,1);
Strike = [100;100];
ExerciseDates = [datetime(2020,1,1); datetime(2024,1,1)];
Period = 1;
PutSchedule =  timetable(ExerciseDates,Strike,'VariableNames',{'Strike Schedule'});

PuttableBond = fininstrument("OptionEmbeddedFixedBond",'Maturity',Maturity,...
                             'CouponRate',0.025,'Period',Period, ...
                             'PutSchedule',PutSchedule)
```

```
PuttableBond =
  OptionEmbeddedFixedBond with properties:

                 CouponRate: 0.0250
                     Period: 1
                      Basis: 0
                EndMonthRule: 1
                   Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
```

               CallSchedule: [0x0 timetable]
                PutSchedule: [4x1 timetable]
          CallExerciseStyle: [0x0 string]
           PutExerciseStyle: "bermudan"
                       Name: ""
```

Set Put Exercise Policy for Specific Option Embedded Fixed Bond Instrument

This example shows how to use `setPutExercisePolicy` to maintain consistency between the exercise schedule and exercise style when using a `OptionEmbeddedFixedBond` instrument object with three `OptionEmbeddedFixedBond` instruments.

Create `OptionEmbeddedFixedBond` Instrument Object

Use `fininstrument` to create an `OptionEmbeddedFixedBond` instrument object for three Option Embedded Fixed Bond instruments with `American` exercise styles.

```
Maturity = datetime([2024,1,1 ; 2024,4,1 ; 2024,8,1]);
Strike = [100;100];
ExerciseDates = [datetime(2020,1,1); datetime(2024,1,1)];
Period = 1;
PutSchedule =  timetable(ExerciseDates,Strike,'VariableNames',{'Strike Schedule'});

PuttableBond = fininstrument("OptionEmbeddedFixedBond",'Maturity',Maturity,...
                             'CouponRate',0.025,'Period',Period, ...
                             'PutSchedule',PutSchedule)
```

```
PuttableBond=3×1 object
  3x1 OptionEmbeddedFixedBond array with properties:

    CouponRate
    Period
    Basis
    EndMonthRule
    Principal
    DaycountAdjustedCashFlow
    BusinessDayConvention
    Holidays
    IssueDate
    FirstCouponDate
```

```
    LastCouponDate
    StartDate
    Maturity
    CallDates
    PutDates
    CallSchedule
    PutSchedule
    CallExerciseStyle
    PutExerciseStyle
    Name

PuttableBond.PutExerciseStyle

ans =
"american"

ans =
"american"

ans =
"american"
```

The `PutExerciseStyle` is `"American"` because the `fininstrument` syntax does not contain a `PutExercideStyle` specification and there are two exercise dates defined in the `PutSchedule`.

Set Exercise Style to Bermudan

Use `setPutExercisePolicy` to define `PutExerciseStyle` as `Bermudan` for the second (`PuttableBond(2)`) instrument.

```
PuttableBond(2) = setPutExercisePolicy(PuttableBond(2), PutSchedule, "Bermudan")

PuttableBond=3×1 object
  3x1 OptionEmbeddedFixedBond array with properties:

    CouponRate
    Period
    Basis
    EndMonthRule
    Principal
    DaycountAdjustedCashFlow
    BusinessDayConvention
    Holidays
    IssueDate
    FirstCouponDate
    LastCouponDate
    StartDate
    Maturity
    CallDates
    PutDates
    CallSchedule
    PutSchedule
    CallExerciseStyle
    PutExerciseStyle
    Name

PuttableBond.PutExerciseStyle
```

```
ans =
"american"

ans =
"bermudan"

ans =
"american"
```

Use `setPutExercisePolicy` to modify `PutSchedule` and continue using a `Bermudan` exercise style.

```
Strike = [100; 101;102;103];
ExerciseDates = [datetime(2018,1,1);datetime(2020,1,1);datetime(2022,1,1);datetime(2024,1,1)];

PutSchedule =  timetable(ExerciseDates,Strike,'VariableNames',{'Strike Schedule'});

PuttableBond(2) = setPutExercisePolicy(PuttableBond(2), PutSchedule)

PuttableBond=3×1 object
  3x1 OptionEmbeddedFixedBond array with properties:

    CouponRate
    Period
    Basis
    EndMonthRule
    Principal
    DaycountAdjustedCashFlow
    BusinessDayConvention
    Holidays
    IssueDate
    FirstCouponDate
    LastCouponDate
    StartDate
    Maturity
    CallDates
    PutDates
    CallSchedule
    PutSchedule
    CallExerciseStyle
    PutExerciseStyle
    Name

PuttableBond.PutExerciseStyle

ans =
"american"

ans =
"bermudan"
```

```
ans =
"american"
```

Input Arguments

`InstrumentObject` — Instrument object
`OptionEmbeddedFixedBond` object | `OptionEmbeddedFloatBond` object | `ConvertibleBond` object

Instrument object, specified using a previously created `OptionEmbeddedFixedBond`, `OptionEmbeddedFloatBond`, or `ConvertibleBond` instrument object.

Note If the `OptionEmbeddedFixedBond`, `OptionEmbeddedFloatBond`, or `ConvertibleBond` instrument object is a vector of instruments, you must use `setCallExercisePolicy` separately with each instrument.

Data Types: `object`

`exerciseSchedule` — Put exercise schedule
timetable

Put exercise schedule, specified as a timetable. The timetable must contain both the `exerciseDate` value and `Strike` information.

Data Types: `timetable`

`exerciseStyle` — Put option exercise style
`"American"` (default) | string with value `"European"`, `"American"`, or `"Bermudan"` | character vector with value `'European'`, `'American'`, or `'Bermudan'`

Put option exercise style, specified as a scalar string or character vector.

Data Types: `string` | `char`

Output Arguments

`UpdatedInstrumentObject` — Updated instrument
object

Updated instrument, returned as an object.

Version History

Introduced in R2020b

setExercisePolicy

Package: `fininstrument`

Set exercise policy for `FixedBondOption`, `FloatBondOption`, or `Vanilla` instrument

Syntax

```
UpdatedInstrumentObject = setExercisePolicy(InstrumentObject,exerciseDate,
Strike,exerciseStyle)
```

Description

`UpdatedInstrumentObject = setExercisePolicy(InstrumentObject,exerciseDate, Strike,exerciseStyle)` sets the exercise policy for a `FixedBondOption`, `FloatBondOption`, or `Vanilla` instrument object.

Examples

Set Exercise Policy for Fixed Bond Option Instrument

This example shows how to use `setExercisePolicy` to maintain consistency between the exercise schedule and exercise style when using a `FixedBondOption` instrument.

Create FixedBond Instrument Object

Use `fininstrument` to create a `FixedBond` instrument object as the underlying bond.

```
BondInst = fininstrument("FixedBond",'Maturity',datetime(2029,9,15),'CouponRate',.021,'Period',1
```

Create FixedBondOption Instrument Object

Use `fininstrument` to create a callable `FixedBondOption` instrument object with a European exercise.

```
FixedBOption = fininstrument("FixedBondOption",'ExerciseDate',datetime(2025,9,15),'Strike',98,'Bo
```

```
FixedBOption =
  FixedBondOption with properties:

       OptionType: "call"
    ExerciseStyle: "european"
     ExerciseDate: 15-Sep-2025
           Strike: 98
             Bond: [1x1 fininstrument.FixedBond]
             Name: "fixed_bond_option"
```

Set the Exercise Style to American

Use `setExercisePolicy` to define `ExerciseStyle` as `American`.

```
FixedBOption = setExercisePolicy(FixedBOption,datetime(2025,9,15),98,"American")
```

```
FixedBOption =
  FixedBondOption with properties:

       OptionType: "call"
    ExerciseStyle: "american"
     ExerciseDate: 15-Sep-2025
           Strike: 98
             Bond: [1x1 fininstrument.FixedBond]
             Name: "fixed_bond_option"
```

Set Exercise Policy for a Specific Fixed Bond Option Instrument

This example shows how to use `setExercisePolicy` to maintain consistency between the exercise schedule and exercise style when using a `FixedBondOption` instrument object with three Fixed Bond instruments.

Create `FixedBond` Instrument Object

Use `fininstrument` to create a `FixedBond` instrument object as the underlying bond.

```
BondInst = fininstrument("FixedBond",'Maturity',datetime(2029,9,15),'CouponRate',.021,'Period',1
```

Create `FixedBondOption` Instrument Object

Use `fininstrument` to create a callable `FixedBondOption` instrument object for three Fixed Bond Option instruments with European exercises.

```
FixedBOption = fininstrument("FixedBondOption",'ExerciseDate',datetime([2025,9,15 ; 2025,10,15 ;
```

```
FixedBOption=3×1 object
  3x1 FixedBondOption array with properties:

    OptionType
    ExerciseStyle
    ExerciseDate
    Strike
    Bond
    Name
```

Set the Exercise Style to American

Use `setExercisePolicy` to define `ExerciseStyle` as `American` for the second (`FixedBOption(2)`) instrument.

```
FixedBOption(2) = setExercisePolicy(FixedBOption(2),datetime(2025,9,15),98,"American")
```

```
FixedBOption=3×1 object
  3x1 FixedBondOption array with properties:

    OptionType
    ExerciseStyle
    ExerciseDate
    Strike
```

```
    Bond
    Name

FixedBOption(2).ExerciseStyle

ans =
"american"

FixedBOption.ExerciseStyle

ans =
"european"

ans =
"american"

ans =
"european"
```

Input Arguments

`InstrumentObject` — Instrument object

`FixedBondOption` object | `FloatBondOption` object | `Vanilla` object

Instrument object, specified using a previously created `FixedBondOption`, `FloatBondOption`, or `Vanilla` instrument object.

Note If the `FixedBondOption`, `FloatBondOption`, or `Vanilla` instrument object is a vector of instruments, you must use `setExercisePolicy` separately with each instrument.

Data Types: `object`

`exerciseDate` — Exercise date

datetime

Exercise date, specified as a scalar datetime.

Data Types: `datetime`

`Strike` — Strike

numeric

Strike, specified as a scalar numeric.

Data Types: `double`

`exerciseStyle` — Option exercise style

`"American"` (default) | string with value `"European"`, `"American"`, or `"Bermudan"` | character vector with value `'European'`, `'American'`, or `'Bermudan'`

Option exercise style, specified as a scalar string or character vector.

Data Types: `string` | `char`

Output Arguments

`UpdatedInstrumentObject` — Updated instrument object
object

Updated instrument object, returned as an object.

parswaprate

Package: `fininstrument`

Compute par swap rate for `Swap` instrument

Syntax

```
outRate = parswaprate(SwapObject,inCurve)
```

Description

`outRate = parswaprate(SwapObject,inCurve)` computes a par swap rate for a `Swap` instrument object.

Examples

Compute Par Swap Rate for Vanilla Swap Instrument Using ratecurve and Discount Pricer

This example shows the workflow to compute the par swap rate for a vanilla `Swap` instrument when you use a `ratecurve` and a `Discount` pricing method.

Create ratecurve Object

Create a `ratecurve` object using `ratecurve` for the underlying interest-rate curve for the `Swap` instrument.

```
Settle = datetime(2018,3,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Mar-2018
        InterpMethod: "linear"
   ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

Create Swap Instrument Object

Use `fininstrument` to create a vanilla `Swap` instrument object.

```
Swap = fininstrument("Swap",'Maturity',datetime(2020,9,15),'LegRate',[0.022 0.019 ],'LegType',["
```

```
Swap =
  Swap with properties:

                     LegRate: [0.0220 0.0190]
                     LegType: ["float"    "fixed"]
                       Reset: [2 2]
                       Basis: [0 0]
                    Notional: 100
           LatestFloatingRate: [NaN NaN]
                  ResetOffset: [0 0]
      DaycountAdjustedCashFlow: [0 0]
               ProjectionCurve: [1x2 ratecurve]
         BusinessDayConvention: ["actual"    "actual"]
                     Holidays: NaT
                 EndMonthRule: [1 1]
                    StartDate: NaT
                     Maturity: 15-Sep-2020
                         Name: "swap_instrument"
```

Create `Discount` Pricer Object

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("Discount", 'DiscountCurve',myRC)
```

```
outPricer =
  Discount with properties:

    DiscountCurve: [1x1 ratecurve]
```

Price `Swap` Instrument

Use `price` to compute the price and sensitivities for the vanilla `Swap` instrument.

```
[Price, outPR] = price(outPricer, Swap,["all"])
```

```
Price = 2.4066
```

```
outPR =
  priceresult with properties:

       Results: [1x2 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×2 table
    Price       DV01
    ______    _________

    2.4066    -0.024499
```

Compute the par swap rate using `parswaprate`.

```
outRate = parswaprate(Swap,myRC)
```

```
outRate = 0.0287
```

Compute Par Swap Rate for Multiple Vanilla Swap Instruments Using ratecurve and Discount Pricer

This example shows the workflow to compute the par swap rate for multiple vanilla `Swap` instruments when you use a `ratecurve` and a `Discount` pricing method.

Create ratecurve Object

Create a `ratecurve` object using `ratecurve` for the underlying interest-rate curve for the `Swap` instrument.

```
Settle = datetime(2019,4,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Apr-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create Swap Instrument Object

Use `fininstrument` to create a vanilla `Swap` instrument object for three Swap instruments.

```
Swap = fininstrument("Swap",'Maturity',datetime([2020,4,15 ; 2021,4,15 ; 2024,4,15]),'LegRate',[0
```

```
Swap=3×1 object
  3x1 Swap array with properties:

    LegRate
    LegType
    Reset
    Basis
    Notional
    LatestFloatingRate
    ResetOffset
    DaycountAdjustedCashFlow
    ProjectionCurve
    BusinessDayConvention
    Holidays
```

```
    EndMonthRule
    StartDate
    Maturity
    Name
```

Create `Discount` Pricer Object

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("Discount", 'DiscountCurve',myRC)
```

```
outPricer =
  Discount with properties:

    DiscountCurve: [1x1 ratecurve]
```

Price Swap Instruments

Use `price` to compute the prices and sensitivities for the vanilla `Swap` instruments.

```
[Price, outPR] = price(outPricer, Swap,["all"])
```

```
Price = 3×1

    0.8473
    1.8067
    7.2322

outPR=1×3 object
  1x3 priceresult array with properties:

    Results
    PricerData
```

```
outPR.Results
```

```
ans=1×2 table
     Price        DV01
    _______    __________

    0.84728    -0.0099228

ans=1×2 table
    Price       DV01
    ______    _________

    1.8067    -0.019656

ans=1×2 table
    Price       DV01
    ______    ________
```

```
    7.2322    -0.04664
```

Compute the par swap rate for each of the three Swap instruments using `parswaprate`.

```
outRate = parswaprate(Swap(1),myRC)
```

```
outRate = 0.0275
```

```
outRate = parswaprate(Swap(2),myRC)
```

```
outRate = 0.0281
```

```
outRate = parswaprate(Swap(3),myRC)
```

```
outRate = 0.0338
```

Input Arguments

`SwapObject` — Swap object
`Swap` object

Swap object, specified using a previously created `Swap` instrument object.

Note If the `SwapObject` is a vector of instruments, you must use `parswaprate` separately with each instrument.

Data Types: `object`

`inCurve` — Rate curve
`ratecurve` object

Rate curve, specified as a previously created `ratecurve` object.

Data Types: `object`

Output Arguments

`outRate` — Par swap rate
decimal

Par swap rate, returned as a decimal.

More About

Par Swap Rate

The par swap rate is the rate that renders a swap value equal to zero.

In other words, the par swap rate is the value of the fixed rate that gives the swap a zero present value, or the fixed rate that makes the value of both legs equal (that is, the value of the fixed leg and the value of the floating leg).

Version History

Introduced in R2020b

volatilities

Package: `finpricer.analytic`

Compute implied volatilities when using SABR pricer

Syntax

```
outVolatilities = volatilities(inpPricer,ExerciseDate,ForwardValue,Strike)
```

Description

`outVolatilities = volatilities(inpPricer,ExerciseDate,ForwardValue,Strike)` computes implied volatilities for a `Swaption` instrument when you use a SABR pricer.

Examples

Compute Implied Volatilities for Swaption Instrument

This example shows the workflow to compute implied volatilities for a `Swaption` Instrument.

Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
ValuationDate = datetime(2016,3,5);
ZeroDates = datemnth(ValuationDate,[1 2 3 6 9 12*[1 2 3 4 5 6 7 8 9 10 12]])';
ZeroRates = [-0.33 -0.28 -0.24 -0.12 -0.08 -0.03 0.015 0.028 ...
             0.033 0.042 0.056 0.095 0.194 0.299 0.415 0.525]'/100;
Compounding = 1;
ZeroCurve = ratecurve("zero",ValuationDate,ZeroDates,ZeroRates,'Compounding',Compounding)
```

```
ZeroCurve =
  ratecurve with properties:

                Type: "zero"
         Compounding: 1
               Basis: 0
               Dates: [16x1 datetime]
               Rates: [16x1 double]
              Settle: 05-Mar-2016
        InterpMethod: "linear"
   ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

Create SABR Model Object

Use `finmodel` to create a SABR model object.

```
Alpha = 0.0135;
Beta = 0.5;
```

```
Rho = 0.4654;
Nu = 0.4957;
Shift = 0.008;

SABRModel = finmodel("SABR",'Alpha',Alpha,'Beta',Beta,'Rho',Rho,'Nu',Nu,'Shift',Shift)
```

```
SABRModel =
  SABR with properties:

            Alpha: 0.0135
             Beta: 0.5000
              Rho: 0.4654
               Nu: 0.4957
            Shift: 0.0080
    VolatilityType: "black"
```

Create SABR Pricer Object

Use `finpricer` to create a SABR pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
SABRPricer = finpricer("Analytic", 'Model', SABRModel,'DiscountCurve', ZeroCurve)
```

```
SABRPricer =
  SABR with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.SABR]
```

Compute Implied Volatilities

Use `volatilities` to compute the implied volatilities for a `Swaption` instrument.

```
SwaptionExerciseDate = datetime(2017,3,5);
ForwardValue = 0.0007;
StrikeGrid = [-0.5; -0.25; -0.125; 0; 0.125; 0.25; 0.5; 1.0; 1.5]/100;
MarketStrikes = ForwardValue + StrikeGrid;

outVolatilities = volatilities(SABRPricer, SwaptionExerciseDate, ForwardValue, MarketStrikes)
```

```
outVolatilities = 9×1

    0.2132
    0.1500
    0.1409
    0.1474
    0.1609
    0.1752
    0.2004
    0.2372
```

```
    0.2627
```

Input Arguments

`inpPricer` — SABR pricer
SABR pricer object

SABR pricer, specified as a previously created SABR pricer object.

Data Types: `object`

`ExerciseDate` — Option exercise date
datetime scalar | string scalar | date character vector

Option exercise date, specified as a scalar datetime, string, or date character vector.

To support existing code, `volatilities` also accepts serial date numbers as inputs, but they are not recommended.

`ForwardValue` — Forward swap rate
decimal

Forward swap rate, specified as a scalar decimal.

Data Types: `object`

`Strike` — Strike rate
decimal

Strike rate, specified as a scalar decimal.

Data Types: `double`

Output Arguments

`outVolatilities` — Output volatilities
numeric

Output volatilities, returned as a numeric.

Version History

Introduced in R2020b

Serial date numbers not recommended
Not recommended starting in R2022b

Although `volatilities` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

fitSvensson

Fit Svensson model to bond market data

Syntax

```
outCurve = fitSvensson(Settle,Instruments,CleanPrice)
```

Description

`outCurve = fitSvensson(Settle,Instruments,CleanPrice)` fits a Svensson model to bond data.

Examples

Fit Svensson Model to Bond Market Data

Define the bond data and use `fininstrument` to create `FixedBond` instrument objects.

```
 Settle = datetime(2017,9,15);
  Maturity = [datetime(2019,9,15);datetime(2021,9,15);...
      datetime(2023,9,15);datetime(2026,9,7);...
      datetime(2035,9,15);datetime(2047,9,15)];

  CleanPrice = [100.1;100.1;100.8;96.6;103.3;96.3];
  CouponRate = [0.0400;0.0425;0.0450;0.0400;0.0500;0.0425];

nInst = numel(CouponRate);
Bonds(nInst,1) = fininstrument.FinInstrument;
for ii=1:nInst
    Bonds(ii) = fininstrument("FixedBond",'Maturity',Maturity(ii),...
        'CouponRate',CouponRate(ii));
end
```

Use `fitSvensson` to create a `parametercurve` object.

```
SvenModel = fitSvensson(Settle,Bonds,CleanPrice)
```

```
Local minimum possible.

lsqnonlin stopped because the final change in the sum of squares relative to
its initial value is less than the value of the function tolerance.

SvenModel =
  parametercurve with properties:

             Type: "zero"
           Settle: 15-Sep-2017
      Compounding: -1
            Basis: 0
   FunctionHandle: @(t)fitF(Params,t)
       Parameters: [3.3043e-08 0.0197 0.0624 0.1391 1.3563 11.7741]
```

Input Arguments

`Settle` — Settlement date

datetime scalar | string scalar | date character vector

Settlement date, specified as a scalar datetime, string, or date character vector.

To support existing code, `fitSvensson` also accepts serial date numbers as inputs, but they are not recommended.

`Instruments` — Bond instrument objects

array

Bond instrument objects, specified as an array of bond instrument objects.

Data Types: `object`

`CleanPrice` — Observed market prices

vector

Observed market prices, specified as a vector.

Data Types: `double`

Output Arguments

`outCurve` — Fitted Svensson model

object

Fitted Svensson model, returned as a `parametercurve` object.

Version History

Introduced in R2020a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `fitSvensson` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

discountfactors

Calculate discount factors for a `ratecurve` object

Syntax

```
outDF = discountfactors(obj,inpDates)
```

Description

`outDF = discountfactors(obj,inpDates)` calculates the discount factors for a `ratecurve` object.

Examples

Calculate Discount Factors for a ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2019,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates,'Compounding',2,'Basis',5,'InterpMethod',"pch
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: 2
               Basis: 5
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2019
        InterpMethod: "pchip"
   ShortExtrapMethod: "linear"
    LongExtrapMethod: "pchip"
```

Compute the discount factors using `discountfactors`.

```
CurveSettle = datetime(2019,9,15);
outRates = discountfactors(myRC,CurveSettle+30:30:CurveSettle+720)
```

```
outRates = 1×24

    0.9996    0.9992    0.9988    0.9983    0.9979    0.9974    0.9970    0.9965    0.9961    0.9
```

Input Arguments

`obj` — `ratecurve` object

`ratecurve` object

`ratecurve` object, specified using a previously created `ratecurve` object.

Data Types: `object`

`inpDates` — Input dates

datetime array | string array | date character vector

Input dates, specified as a scalar or an `NPOINTS`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `discountfactors` also accepts serial date numbers as inputs, but they are not recommended.

Output Arguments

`outDF` — Discount factors

numeric

Discount factors, returned as a numeric.

Version History

Introduced in R2020a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `discountfactors` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

forwardrates

Calculate forward rates for `ratecurve` object

Syntax

```
outRates = forwardrates(obj,startDates,endDates)
outRates = forwardrates( ___ ,inpComp,inpBasis)
```

Description

`outRates = forwardrates(obj,startDates,endDates)` calculates forward rates for the `ratecurve` object (`obj`) based on the `startDates` and `endDates`.

`outRates = forwardrates( ___ ,inpComp,inpBasis)` optionally specifies the input compounding frequency (`inpComp`) and the input day-count basis (`inpBasis`) in addition to any of the input argument combinations in the previous syntax.

Examples

Calculate Forward Rates for `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2019,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates,'Compounding',2,'Basis',5,'InterpMethod',"pchi
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: 2
               Basis: 5
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2019
        InterpMethod: "pchip"
   ShortExtrapMethod: "linear"
    LongExtrapMethod: "pchip"
```

Compute the forward rates using `forwardrates`.

```
outRates = forwardrates(myRC,datetime(2019,12,15),datetime(2021,9,15),6,7)
```

```
outRates = 0.0062
```

Input Arguments

`obj` — `ratecurve` object

`ratecurve` object

`ratecurve` object, specified using a previously created `ratecurve` object.

Data Types: `object`

`startDates` — Start dates of interval to discount over

datetime array | string array | date character vector

Start dates of the interval to discount over, specified as a scalar or an `NPOINTS`-by-`1` vector using a datetime array, string array, or date character vectors. `startDates` must be earlier than `endDates`.

To support existing code, `forwardrates` also accepts serial date numbers as inputs, but they are not recommended.

`endDates` — Maturity dates ending interval to discount over

datetime array | string array | date character vector

Maturity dates ending the interval to discount over, specified as a scalar or an `NPOINTS`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `forwardrates` also accepts serial date numbers as inputs, but they are not recommended.

`inpComp` — Input compounding frequency

`Compounding` for the `ratecurve` object (default) | possible values include: `–1`, `0`, `1`, `2`, `3`, `4`, `6`, `12`.

(Optional) Input compounding frequency, specified as a scalar numeric using one of the supported values: `–1`, `0`, `1`, `2`, `3`, `4`, `6`, or `12`.

Data Types: `double`

`inpBasis` — Input day-count basis

`0` (actual/actual) (default) | integer from `0` to `13`

(Optional) Input day-count basis, specified as a scalar integer.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)

- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

Output Arguments

`outRates` — Forward rates

numeric

Forward rates, returned as a numeric.

Version History

Introduced in R2020a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `forwardrates` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

zerorates

Calculate zero rates for `ratecurve` object

Syntax

```
outRates = zerorates(obj,inpDates)
outRates = zerorates( ___ ,inpComp,inpBasis)
```

Description

`outRates = zerorates(obj,inpDates)` computes zero rates for the `ratecurve` object (`obj`) based on `inpDates`.

`outRates = zerorates( ___ ,inpComp,inpBasis)` optionally specifies the input compounding frequency (`inpComp`) and the input day-count basis (`inpBasis`) in addition to any of the input argument combinations in the previous syntax.

Examples

Calculate Zero Rates for `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2019,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates,'Compounding',2,'Basis',5,'InterpMethod',"pchi
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: 2
               Basis: 5
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2019
        InterpMethod: "pchip"
    ShortExtrapMethod: "linear"
     LongExtrapMethod: "pchip"
```

Compute the zero rates using `zerorates`.

```
CurveSettle = datetime(2019,9,15);
outRates = zerorates(myRC,CurveSettle+30:30:CurveSettle+720)
```

```
outRates = 1×24
```

```
    0.0049    0.0050    0.0050    0.0051    0.0051    0.0052    0.0052    0.0053    0.0053    0.0
```

Input Arguments

`obj` — `ratecurve` object

`ratecurve` object

`ratecurve` object, specified using a previously created `ratecurve` object.

Data Types: `object`

`inpDates` — Input dates

datetime array | string array | date character vector

Input dates, specified as a scalar or an `NPOINTS`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `zerorates` also accepts serial date numbers as inputs, but they are not recommended.

`inpComp` — Input compounding frequency

`Compounding` for the `ratecurve` object (default) | possible values include: `–1`, `0`, `1`, `2`, `3`, `4`, `6`, `12`.

(Optional) Input compounding frequency, specified as a scalar numeric using one of the supported values: `–1`, `0`, `1`, `2`, `3`, `4`, `6`, or `12`.

Data Types: `double`

`inpBasis` — Input day-count basis

`0` (actual/actual) (default) | integer from `0` to `13`

(Optional) Input day-count basis, specified as a scalar integer.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

Output Arguments

`outRates` — Zero rates

numeric

Zero rates, returned as a numeric.

Version History

Introduced in R2020a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `zerorates` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

discountfactors

Calculate discount factors for `parametercurve` object

Syntax

```
outDF = discountfactors(obj,inpDates)
```

Description

`outDF = discountfactors(obj,inpDates)` calculates the discount factors for a `parametercurve` object.

Examples

Calculate Discount Factors for parametercurve Object

Create a `parametercurve` object using `parametercurve`.

```
PCobj = parametercurve('zero',datetime(2019,9,15),@(t)polyval([-0.0001 0.003 0.02],t),'Compoundi
```

```
PCobj =
  parametercurve with properties:

             Type: "zero"
           Settle: 15-Sep-2019
      Compounding: 4
            Basis: 5
    FunctionHandle: @(t)polyval([-0.0001,0.003,0.02],t)
        Parameters: [-1.0000e-04 0.0030 0.0200]
```

Compute the discount factors using `discountfactors`.

```
CurveSettle = datetime(2019,9,15);
outDF = discountfactors(PCobj,CurveSettle+30:30:CurveSettle+720)
```

```
outDF = 1×24

    0.9983    0.9967    0.9949    0.9932    0.9914    0.9895    0.9876    0.9857    0.9838    0.9
```

Input Arguments

obj — parametercurve object

`parametercurve` object

`parametercurve` object, specified as a previously created `parametercurve` object.

Data Types: `object`

`inpDates` — Input dates
datetime array | string array | date character vector

Input dates, specified as a scalar or an `NPOINTS`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `discountfactors` also accepts serial date numbers as inputs, but they are not recommended.

Output Arguments

`outDF` — Discount factors
numeric

Discount factors, returned as a numeric.

Version History

Introduced in R2020a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `discountfactors` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

forwardrates

Calculate forward rates for `parametercurve` object

Syntax

```
outRates = forwardrates(obj,startDates,endDates)
outRates = forwardrates( ___ ,inpComp,inpBasis)
```

Description

`outRates = forwardrates(obj,startDates,endDates)` computes forward rates for the `parametercurve` object (`obj`) based on `startDates` and `endDates`.

`outRates = forwardrates( ___ ,inpComp,inpBasis)` specifies options in addition to any of the input argument combinations in the previous syntax.

Examples

Calculate Forward Rates for `parametercurve` Object

Create a `parametercurve` object using `parametercurve`.

```
PCobj = parametercurve('zero',datetime(2019,9,15),@(t)polyval([-0.0001 0.003 0.02],t),'Compoundi
```

```
PCobj =
  parametercurve with properties:

              Type: "zero"
            Settle: 15-Sep-2019
       Compounding: 4
             Basis: 5
    FunctionHandle: @(t)polyval([-0.0001,0.003,0.02],t)
        Parameters: [-1.0000e-04 0.0030 0.0200]
```

Compute the forward rates using `forwardrates`.

```
CurveSettle = datetime(2019,9,15);
outRates = forwardrates(PCobj,datetime(2019,12,15),datetime(2020,9,15),6,7)
```

```
outRates = 0.0236
```

Input Arguments

`obj` — `parametercurve` object

`parametercurve` object

`parametercurve` object, specified as a previously created `parametercurve` object.

Data Types: `object`

`startDates` — Start dates of interval to discount over
datetime array | string array | date character vector

Start dates of the interval to discount over, specified as a scalar or an `NPOINTS`-by-`1` vector using a datetime array, string array, or date character vectors. `startDates` must be earlier than `endDates`.

To support existing code, `forwardrates` also accepts serial date numbers as inputs, but they are not recommended.

`endDates` — Maturity dates ending the interval to discount over
datetime array | string array | date character vector

Maturity dates ending the interval to discount over, specified as a scalar or an `NPOINTS`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `forwardrates` also accepts serial date numbers as inputs, but they are not recommended.

`inpComp` — Input compounding frequency
`Compounding` for the `parametercurve` object (default) | possible values include: `–1`, `0`, `1`, `2`, `3`, `4`, `6`, `12`.

(Optional) Input compounding frequency, specified as a scalar numeric using one of the supported values: `–1`, `0`, `1`, `2`, `3`, `4`, `6`, or `12`.

Data Types: `double`

`inpBasis` — Input day-count basis
`0` (actual/actual) (default) | integer from `0` to `13`

(Optional) Input day-count basis, specified as a scalar integer.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

Output Arguments

`outRates` — Forward rates
numeric

Forward rates, returned as a numeric.

Version History

Introduced in R2020a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `forwardrates` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

zerorates

Calculate zero rates for `parametercurve` object

Syntax

```
outRates = zerorates(obj,inpDates)
outRates = zerorates( ___ ,inpComp,inpBasis)
```

Description

`outRates = zerorates(obj,inpDates)` computes zero rates for the `parametercurve` object (`obj`) based on `inpDates`.

`outRates = zerorates( ___ ,inpComp,inpBasis)` specifies options in addition to any of the input argument combinations in the previous syntax.

Examples

Calculate Zero Rates for `parametercurve` Object

Create a `parametercurve` object using `parametercurve`.

```
PCobj = parametercurve('zero',datetime(2019,9,15),@(t)polyval([-0.0001 0.003 0.02],t),'Compoundi
```

```
PCobj =
  parametercurve with properties:

             Type: "zero"
           Settle: 15-Sep-2019
      Compounding: 4
            Basis: 5
   FunctionHandle: @(t)polyval([-0.0001,0.003,0.02],t)
       Parameters: [-1.0000e-04 0.0030 0.0200]
```

Compute the zero rates using `zerorates`.

```
CurveSettle = datetime(2019,9,15);
outRates = zerorates(PCobj,CurveSettle+30:30:CurveSettle+720)
```

```
outRates = 1×24

    0.0202    0.0205    0.0207    0.0210    0.0212    0.0215    0.0217    0.0219    0.0222    0.0
```

Input Arguments

`obj` — `parametercurve` object

`parametercurve` object

parametercurve object, specified as a previously created parametercurve object.

Data Types: object

inpDates — Input dates
datetime array | string array | date character vector

Input dates, specified as a scalar or an NPOINTS-by-1 vector using a datetime array, string array, or date character vectors. StartDates must be earlier than EndDates.

To support existing code, zerorates also accepts serial date numbers as inputs, but they are not recommended.

inpComp — Input compounding frequency
Compounding for the parametercurve object (default) | possible values include: –1, 0, 1, 2, 3, 4, 6, 12.

(Optional) Input compounding frequency, specified as a scalar numeric using one of the supported values: –1, 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

inpBasis — Input day-count basis
0 (actual/actual) (default) | integer from 0 to 13

(Optional) Input day-count basis, specified as a scalar integer.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: double

Output Arguments

outRates — Zero rates
numeric

Zero rates, returned as a numeric.

Version History

Introduced in R2020a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `zerorates` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

Topics

“Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22
“Choose Instruments, Models, and Pricers” on page 1-53

finportfolio

Create a `finportfolio` object

Description

Create a `finportfolio` object for a collection of instrument objects.

After creating instruments, models, and pricer objects, use `finportfolio` to create a `finportfolio` object for a collection of instruments. For more detailed information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
finportfolio_obj = finportfolio
finportfolio_obj = finportfolio(inInstruments)
finportfolio_obj = finportfolio(inInstruments,inPricers)
finportfolio_obj = finportfolio( ___ ,inQuant)
```

Description

`finportfolio_obj = finportfolio` creates an empty `finportfolio` object.

`finportfolio_obj = finportfolio(inInstruments)` creates a `finportfolio` object containing the instrument objects `inInstruments`.

`finportfolio_obj = finportfolio(inInstruments,inPricers)` creates a `finportfolio` object containing the instrument objects `inInstruments` and the pricer objects `inPricers`.

`finportfolio_obj = finportfolio( ___ ,inQuant)` optionally sets the `inQuant` property which specifies the number of instruments. Use this syntax with any of the input argument combinations in previous syntaxes to set the properties on page 11-2437 for the `finportfolio` object. For example, `finportfolio_obj = finportfolio([CapObj,FloorObj,SwaptionObj], [BlackPricerObj,NormalPricerObj,SabrPricerObj])` creates a `finportfolio` object that contains instrument and pricer objects.

Input Arguments

`inInstruments` — Instrument objects in the portfolio
scalar Instrument object | array of Instrument objects

Instrument objects in the portfolio, specified as a scalar Instrument object or an array of Instrument objects.

Data Types: `object`

`inPricers` — Pricer objects in the portfolio
scalar Pricer object | array of Pricer objects

Pricer objects in the portfolio, specified as a scalar Pricer object or an array of Pricer objects.

Data Types: `object`

`inQuant` — Number of instruments
positive or negative numeric | array of positive or negative numerics

Number of instruments, specified as a scalar numeric or an `NINST`-by-`1` array of numeric values. Use a positive value for long positions and a negative value for short positions.

Data Types: `double`

Properties

`Instruments` — Instrument objects in the portfolio
scalar instrument object | array of instrument objects

Instrument objects in the portfolio, returned as a scalar instrument object or an array of instrument objects.

Data Types: `struct`

`Pricers` — Pricer objects in the portfolio
scalar pricer object | array of pricer objects

Pricer objects in the portfolio, returned as a scalar pricer object or an array of pricer objects.

Data Types: `struct`

`PricerIndex` — Mapping of instrument objects to pricer objects in the portfolio
numeric

This property is read-only.

Mapping of instrument objects to pricer objects in the portfolio, returned as numeric.

`PricerIndex` has a length equal to the number of instrument objects in the `finportfolio` object and stores an index of which pricer is used for each instrument object.

Data Types: `struct`

`Quantity` — Number of instruments
numeric

Number of instruments, returned as a scalar numeric or numeric array.

Data Types: `double`

Object Functions

pricePortfolio	Compute price and sensitivities for portfolio of instruments

addInstrument	Add instrument to portfolio of instruments
removeInstrument	Remove instrument from portfolio of instruments
setPricer	Set pricer for finportfolio object

Examples

Price Portfolio of Heterogeneous Instruments

Use `finportfolio` and `pricePortfolio` to create and price a portfolio containing a `FixedBond` instrument and an American `Vanilla` option instrument.

Create `FixedBond` Instrument Object

Use `fininstrument` to create a `FixedBond` instrument object.

```
FixB = fininstrument("FixedBond",'Maturity',datetime(2022,9,15),'CouponRate',0.05,'Name',"fixed_b
```

```
FixB =
  FixedBond with properties:

                 CouponRate: 0.0500
                     Period: 2
                      Basis: 0
                EndMonthRule: 1
                   Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                    Holidays: NaT
                   IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 15-Sep-2022
                        Name: "fixed_bond"
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
        Compounding: -1
              Basis: 0
              Dates: [10x1 datetime]
              Rates: [10x1 double]
```

```
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `Discount` Pricer Object for `FixedBond` Instrument

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
FBPricer = finpricer("Discount",'DiscountCurve',myRC)
```

```
FBPricer =
  Discount with properties:

    DiscountCurve: [1x1 ratecurve]
```

Create `Vanilla` Instrument Object

Use `fininstrument` to create an American `Vanilla` instrument object.

```
Maturity = datetime(2023,9,15);
AmericanOpt = fininstrument("Vanilla",'ExerciseDate',Maturity,'Strike',120,'ExerciseStyle',"amer
```

```
AmericanOpt =
  Vanilla with properties:

       OptionType: "call"
    ExerciseStyle: "american"
     ExerciseDate: 15-Sep-2023
           Strike: 120
             Name: "vanilla_option"
```

Create `BlackScholes` Model Object for `Vanilla` Instrument

Use `finmodel` to create a `BlackScholes` model object.

```
BSModel = finmodel("BlackScholes",'Volatility',0.12)
```

```
BSModel =
  BlackScholes with properties:

     Volatility: 0.1200
    Correlation: 1
```

Create `BjerksundStensland` Pricer Object for `Vanilla` Instrument

Use `finpricer` to create an analytic pricer object for the `BjerksundStensland` pricing method and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
BJSPricer = finpricer("analytic",'Model',BSModel,'DiscountCurve',myRC,'SpotPrice',100,'DividendVa
```

```
BJSPricer =
  BjerksundStensland with properties:
```

```
    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 100
    DividendValue: 0.0200
     DividendType: "continuous"
```

Add the Instruments to a `finportfolio` Object

Create a `finportfolio` object using `finportfolio` and add the two instruments with their associated pricers to the portfolio.

```
f1 = finportfolio([AmericanOpt,FixB],[BJSPricer,FBPricer])
```

```
f1 =
  finportfolio with properties:

    Instruments: [2x1 fininstrument.FinInstrument]
        Pricers: [2x1 finpricer.FinPricer]
    PricerIndex: [2x1 double]
       Quantity: [2x1 double]
```

Price Portfolio

Use `pricePortfolio` to compute the price and sensitivities for the portfolio and the instruments in the portfolio.

```
[PortPrice,InstPrice,PortSens,InstSens] = pricePortfolio(f1)
```

```
PortPrice = 119.1665

InstPrice = 2×1

    3.1912
  115.9753

PortSens=1×8 table
    Price      DV01       Delta      Gamma      Lambda     Vega      Theta       Rho

                       Price      DV01       Delta      Gamma      Lambda     Vega      Theta
                       ______    _______    _______    ________    ______    ______    ________

    vanilla_option     3.1912       NaN     0.23188    0.011522    7.2661    65.454    -0.81408
    fixed_bond         115.98    0.04295        NaN         NaN       NaN       NaN         NaN
```

Price Portfolio of Bond and Bond Option Instruments

This example shows the workflow to create and price a portfolio of bond and bond option instruments. You can use `finportfolio` and `pricePortfolio` to price `FixedBond`,

`FixedBondOption`, `OptionEmbeddedFixedBond`, and `FloatBond` instruments using an `IRTree` pricing method.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018, 1, 1);
 ZeroTimes = calyears(1:4)';
 ZeroRates = [0.035; 0.042147; 0.047345; 0.052707];
 ZeroDates = Settle + ZeroTimes;
 Compounding = 1;
 ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates, "Compounding",Compounding)
```

```
ZeroCurve =
  ratecurve with properties:

                Type: "zero"
         Compounding: 1
               Basis: 0
               Dates: [4x1 datetime]
               Rates: [4x1 double]
              Settle: 01-Jan-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create Bond and Option Instruments

Use `fininstrument` to create a `FixedBond`, `FixedBondOption`, `OptionEmbeddedFixedBond`, and `FloatBond` instrument objects.

```
CDates = datetime([2020,1,1 ; 2022,1,1]);
CRates = [.0425; .0750];
CouponRate = timetable(CDates,CRates);
Maturity = datetime(2022,1,1);
Period = 1;

% Vanilla FixedBond
VBond = fininstrument("FixedBond",'Maturity',Maturity,'CouponRate',0.0425,'Period',Period,'Name'
```

```
VBond =
  FixedBond with properties:

                CouponRate: 0.0425
                    Period: 1
                     Basis: 0
               EndMonthRule: 1
                  Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                   Holidays: NaT
                  IssueDate: NaT
            FirstCouponDate: NaT
             LastCouponDate: NaT
                  StartDate: NaT
                   Maturity: 01-Jan-2022
```

```
                        Name: "vanilla_fixed"

 % Stepped coupon bond
SBond = fininstrument("FixedBond",'Maturity',Maturity,'CouponRate',CouponRate,'Period',Period,'Na

SBond =
  FixedBond with properties:

                 CouponRate: [2x1 timetable]
                     Period: 1
                      Basis: 0
                EndMonthRule: 1
                  Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                   Holidays: NaT
                  IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 01-Jan-2022
                        Name: "stepped_coupon_bond"

% FloatBond
Spread = 0;
Reset = 1;
Float = fininstrument("FloatBond",'Maturity',Maturity,'Spread',Spread,'Reset', Reset,...
                      'ProjectionCurve',ZeroCurve,'Name',"floatbond")

Float =
  FloatBond with properties:

                     Spread: 0
             ProjectionCurve: [1x1 ratecurve]
                 ResetOffset: 0
                       Reset: 1
                       Basis: 0
                EndMonthRule: 1
                  Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
          LatestFloatingRate: NaN
                   Holidays: NaT
                  IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 01-Jan-2022
                        Name: "floatbond"

% Call option
Strike = 100;
ExerciseDates = datetime(2020,1,1);
OptionType ='call';
Period = 1;
```

```
CallOption = fininstrument("FixedBondOption",'Strike',Strike,'ExerciseDate',ExerciseDates,...
                  'OptionType',OptionType,'ExerciseStyle',"american",'Bond', VBond,'Name',"fixed
```

```
CallOption =
  FixedBondOption with properties:

       OptionType: "call"
    ExerciseStyle: "american"
     ExerciseDate: 01-Jan-2020
           Strike: 100
             Bond: [1x1 fininstrument.FixedBond]
             Name: "fixed_bond_option"
```

```
% Option for embedded bond (callable bond)
CDates = datetime([2020,1,1 ; 2022,1,1]);
CRates = [.0425; .0750];
CouponRate = timetable(CDates,CRates);
StrikeOE = [100; 100];
ExerciseDatesOE = [datetime(2020,1,1); datetime(2021,1,1)];
CallSchedule =  timetable(ExerciseDatesOE,StrikeOE,'VariableNames',{'Strike Schedule'});
CallableBond = fininstrument("OptionEmbeddedFixedBond", 'Maturity',Maturity,...
                             'CouponRate',CouponRate,'Period', Period, ...
                             'CallSchedule',CallSchedule,'Name',"option_embedded_fixedbond")
```

```
CallableBond =
  OptionEmbeddedFixedBond with properties:

                 CouponRate: [2x1 timetable]
                     Period: 1
                      Basis: 0
                EndMonthRule: 1
                  Principal: 100
   DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
                   Holidays: NaT
                  IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 01-Jan-2022
                  CallDates: [2x1 datetime]
                   PutDates: [0x1 datetime]
                CallSchedule: [2x1 timetable]
                 PutSchedule: [0x0 timetable]
          CallExerciseStyle: "american"
           PutExerciseStyle: [0x0 string]
                       Name: "option_embedded_fixedbond"
```

Create `HullWhite` Model

Use `finmodel` to create a `HullWhite` model object.

```
VolCurve = 0.01;
AlphaCurve = 0.1;

HWModel = finmodel("hullwhite",'alpha',AlphaCurve,'sigma',VolCurve)
```

```
HWModel =
  HullWhite with properties:

    Alpha: 0.1000
    Sigma: 0.0100
```

Create IRTree Pricer for HullWhite Model

Use `finpricer` to create an `IRTree` pricer object for a `HullWhite` model and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
HWTreePricer = finpricer("IRTree",'Model',HWModel,'DiscountCurve',ZeroCurve,'TreeDates',ZeroDates
```

```
HWTreePricer =
  HWBKTree with properties:

            Tree: [1x1 struct]
       TreeDates: [4x1 datetime]
           Model: [1x1 finmodel.HullWhite]
   DiscountCurve: [1x1 ratecurve]
```

Create finportfolio Object and Add Callable Bond Instrument

Create a `finportfolio` object with the vanilla bond, stepped coupon bond, float bond, and the call option.

```
myportfolio = finportfolio([VBond,SBond,Float,CallOption],HWTreePricer, [1,2,2,1])
```

```
myportfolio =
  finportfolio with properties:

    Instruments: [4x1 fininstrument.FinInstrument]
        Pricers: [1x1 finpricer.irtree.HWBKTree]
    PricerIndex: [4x1 double]
       Quantity: [4x1 double]
```

Use `addInstrument` to add the callable bond instrument to the existing portfolio.

```
myportfolio = addInstrument(myportfolio,CallableBond,HWTreePricer,1)
```

```
myportfolio =
  finportfolio with properties:

    Instruments: [5x1 fininstrument.FinInstrument]
        Pricers: [1x1 finpricer.irtree.HWBKTree]
    PricerIndex: [5x1 double]
       Quantity: [5x1 double]
```

```
myportfolio.PricerIndex
```

```
ans = 5×1

     1
     1
     1
```

```
     1
     1
```

The `PricerIndex` property has a length equal to the length of instrument objects in the `finportfolio` object and stores the index of which pricer is used for each instrument object. In this case, because there is only one pricer, each instrument must use that pricer.

Price Portfolio

Use `pricePortfolio` to compute the price and sensitivities for the portfolio and the bond and option instruments in the portfolio.

```
format bank
[PortPrice,InstPrice,PortSens,InstSens] = pricePortfolio(myportfolio)
```

```
PortPrice =
        600.55

InstPrice = 5×1

         96.59
        204.14
        200.00
          0.05
         99.77

PortSens=1×4 table
    Price      Delta       Gamma      Vega
    _______    ________    _______    _______

    600.55    -1297.48    5759.65    -63.40

InstSens=5×4 table
                                Price      Delta      Gamma      Vega
                                _____    ________    _______    _____

    vanilla_fixed                96.59    -344.81    1603.49     -0.00
    stepped_coupon_bond         204.14    -725.96    3364.60      0.00
    floatbond                   200.00       0.00      -0.00     -0.00
    fixed_bond_option             0.05      -3.69      24.15     12.48
    option_embedded_fixedbond    99.77    -223.03     767.41    -75.88
```

Price Portfolio of Multiple Instances of Heterogeneous Instruments

Use `finportfolio` and `pricePortfolio` to create and price a portfolio containing three `FixedBond` instruments and three American `Vanilla` option instruments.

Create FixedBond Instrument Object

Use `fininstrument` to create a `FixedBond` instrument object for three Fixed Bond instruments.

```
FixB = fininstrument("FixedBond",'Maturity',datetime([2022,9,15 ; 2022,10,15 ; 2022,11,15]),'Coup
```

```
FixB=3×1 object
  3x1 FixedBond array with properties:

    CouponRate
    Period
    Basis
    EndMonthRule
    Principal
    DaycountAdjustedCashFlow
    BusinessDayConvention
    Holidays
    IssueDate
    FirstCouponDate
    LastCouponDate
    StartDate
    Maturity
    Name
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `Discount` Pricer Object for `FixedBond` Instruments

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
FBPricer = finpricer("Discount",'DiscountCurve',myRC)
```

```
FBPricer =
  Discount with properties:

    DiscountCurve: [1x1 ratecurve]
```

Create Vanilla Instrument Object

Use `fininstrument` to create an American `Vanilla` instrument object for three Vanilla instruments.

```
Maturity = datetime([2023,9,15 ; 2023,10,15 ; 2023,11,15]);
AmericanOpt = fininstrument("Vanilla",'ExerciseDate',Maturity,'Strike',120,'ExerciseStyle',"amer
```

```
AmericanOpt=3×1 object
  3x1 Vanilla array with properties:

    OptionType
    ExerciseStyle
    ExerciseDate
    Strike
    Name
```

Create BlackScholes Model Object for Vanilla Instruments

Use `finmodel` to create a `BlackScholes` model object.

```
BSModel = finmodel("BlackScholes",'Volatility',0.12)
```

```
BSModel =
  BlackScholes with properties:

     Volatility: 0.1200
    Correlation: 1
```

Create BjerksundStensland Pricer Object for Vanilla Instruments

Use `finpricer` to create an analytic pricer object for the `BjerksundStensland` pricing method and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
BJSPricer = finpricer("analytic",'Model',BSModel,'DiscountCurve',myRC,'SpotPrice',100,'DividendVa
```

```
BJSPricer =
  BjerksundStensland with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 100
    DividendValue: 0.0200
     DividendType: "continuous"
```

Add the Instruments to a finportfolio Object

Create a `finportfolio` object using `finportfolio` and add the six instruments with their associated pricers to the portfolio.

```
f1 = finportfolio([AmericanOpt;FixB],[BJSPricer, BJSPricer, BJSPricer, FBPricer, FBPricer, FBPric
```

```
f1 =
  finportfolio with properties:

    Instruments: [6x1 fininstrument.FinInstrument]
```

```
        Pricers: [6x1 finpricer.FinPricer]
    PricerIndex: [6x1 double]
       Quantity: [6x1 double]
```

Price Portfolio

Use `pricePortfolio` to compute the price and sensitivities for the portfolio and the instruments in the portfolio.

```
[PortPrice,InstPrice,PortSens,InstSens] = pricePortfolio(f1)
```

```
PortPrice = 358.4108

InstPrice = 6×1

    3.1912

ratecurve

Create `ratecurve` object for interest-rate curve from dates and data

Description

Build a `ratecurve` object using `ratecurve`.

After creating a `ratecurve` object, you can use the associated object functions `forwardrates`, `discountfactors`, and `zerorates`.

Note If you have the `RateSpec` obtained previously from `intenvset` or `toRateSpec` for an `IRDataCurve` or `toRateSpec` for an `IRFunctionCurve`, refer to "Convert RateSpec to a ratecurve Object" on page 1-49.

To price a `Swap`, `FixedBond`, `FloatBond`, `FRA`, or `Deposit` instrument, you must create a `ratecurve` object and then create `Discount` pricer object.

For more detailed information on this workflow, see "Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments" on page 1-22.

For more information on the available instruments, models, and pricing methods, see "Choose Instruments, Models, and Pricers" on page 1-53.

Creation

Syntax

```
ratecurve_obj = ratecurve(Type,Settle,Dates,Rates)
ratecurve_obj = ratecurve( ___ ,Name,Value)
```

Description

`ratecurve_obj = ratecurve(Type,Settle,Dates,Rates)` creates a `ratecurve` object.

`ratecurve_obj = ratecurve( ___ ,Name,Value)` creates a `ratecurve` object using name-value pairs and any of the arguments in the previous syntax. For example, `myRC = ratecurve("zero",Settle,ZeroDates,ZeroRates,'Compounding',2,'Basis',5,'InterpMethod',"pchip",'ShortExtrapMethod',"linear",'LongExtrapMethod',"cubic")` creates a `ratecurve` object for a zero curve. You can specify multiple name-value pair arguments.

Input Arguments

Type — Type of interest-rate curve
string with value `"zero"`, `"forward"`, or `"discount"` | character vector with value `'zero'`, `'forward'`, or `'discount'`

Type of interest-rate curve, specified as a string or character vector for one of the supported types.

Data Types: `char` | `string`

`Settle` — Settlement date
datetime scalar | string scalar | date character vector

Settlement date, specified as a scalar datetime, string, or date character vector.

To support existing code, `ratecurve` also accepts serial date numbers as inputs, but they are not recommended.

If you use a date character vector or string, the format must be recognizable by `datetime` because the `Settle` property is stored as a datetime.

`Dates` — Dates corresponding to rate data
datetime array | string array | date character vector

Dates corresponding to the rate data, specified as vector using a datetime array, string array, or date character vectors.

To support existing code, `ratecurve` also accepts serial date numbers as inputs, but they are not recommended.

If you use a date character vectors or strings, the format must be recognizable by `datetime` because the `Dates` property is stored as a datetime.

`Rates` — Interest-rate data for the curve
numeric

Interest-rate data for the curve, specified as a scalar numeric.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `myRC = ratecurve("zero",Settle,ZeroDates,ZeroRates,'Compounding',2,'Basis',5,'InterpMethod',"pchip",'ShortExtrapMethod',"linear",'LongExtrapMethod',"cubic")`

`Compounding` — Compounding frequency
`-1` (default) | possible values include: –1, `0`, `1`, `2`, `3`, `4`, `6`, or `12`.

Compounding frequency, specified as the comma-separated pair consisting of `'Compounding'` and a scalar numeric using the supported values: –1, `0`, `1`, `2`, `3`, `4`, `6`, or `12`.

Data Types: `double`

`Basis` — Day count basis
`0` (actual/actual) (default) | integer from `0` to `13`

Day count basis, specified as the comma-separated pair consisting of `'Basis'` and a scalar integer.

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`InterpMethod` — Interpolation method
`"linear"` (default) | string with value `"linear"`, `"cubic"`, `"next"`, `"previous"`, `"pchip"`, `"v5cubic"`, `"makima"`, or `"spline"` | character vector with value `'linear'`, `'cubic'`, `'next'`, `'previous'`, `'pchip'`, `'v5cubic'`, `'makima'`, or `'spline'`

Interpolation method, specified as the comma-separated pair consisting of `'InterpMethod'` and a scalar string or character vector using a supported value. For more information on interpolation methods, see `interp1`.

Data Types: `char` | `string`

`ShortExtrapMethod` — Extrapolation method for data before first data
`"next"` (default) | string with value `"linear"`, `"next"`, `"previous"`, `"pchip"`, `"cubic"`,`"v5cubic"`, `"makima"`, or `"spline"` | character vector with value `'linear'`, `'next'`, `'previous'`, `'pchip'`, `'cubic'`,`'v5cubic'`, `'makima'`, or `'spline'`

Extrapolation method for data before first data, specified as the comma-separated pair consisting of `'ShortExtrapMethod'` and a scalar string or character vector using a supported value. For more information on interpolation methods, see `interp1`.

Data Types: `char` | `string`

`LongExtrapMethod` — Extrapolation method for data after last data
`"previous"` (default) | string with value `"linear"`, `"next"`, `"previous"`, `"pchip"`, `"cubic"`,`"v5cubic"`, `"makima"`, or `"spline"` | character vector with value `'linear'`, `'next'`, `'previous'`, `'pchip'`, `'cubic'`,`'v5cubic'`, `'makima'`, or `'spline'`

Extrapolation method for data after last data, specified as the comma-separated pair consisting of `'LongExtrapMethod'` and a scalar string or character vector using a supported value. For more information on interpolation methods, see `interp1`.

Data Types: `char` | `string`

Properties

`Type` — Type of interest-rate curve
string with value `"zero"`, `"forward"`, or `"discount"`

Type of interest-rate curve, returned as a string.

Data Types: `string`

`Compounding` — Compounding frequency
`-1` (default) | possible values include: –1, `0`, 1, 2, 3, 4, 6, or 12.

Compounding frequency, returned as a scalar numeric.

Data Types: `double`

`Basis` — Day count basis
`0` (actual/actual) (default) | integer from `0` to `13`

Day count basis of the instrument, returned as a scalar integer.

Data Types: `double`

`Dates` — Dates corresponding to rate data
datetime

Dates corresponding to the rate data, returned as a datetime.

Data Types: `datetime`

`Rates` — Rates corresponding to dates data
vector

Rates corresponding to dates data, returned as vector.

Data Types: `datetime`

`Settle` — Settlement date
datetime

Settlement date, returned as a datetime.

Data Types: `datetime`

`InterpMethod` — Interpolation method
`"linear"` (default) | string with value `"linear"`, `"cubic"`, `"next"`, `"previous"`, `"pchip"`, `"v5cubic"`, `"makima"`, or `"spline"`

Interpolation method, returned as a scalar string.

Data Types: `string`

`ShortExtrapMethod` — Short extrapolation method
`"next"` (default) | string with value `"linear"`, `"next"`, `"previous"`, `"pchip"`, `"cubic"`,`"v5cubic"`, `"makima"`, or `"spline"`

Short extrapolation method, returned as a scalar string.

Data Types: `string`

LongExtrapMethod — Long extrapolation method
`"previous"` (default) | string with value `"linear"`, `"next"`, `"previous"`, `"pchip"`, `"cubic"`,`"v5cubic"`, `"makima"`, or `"spline"`

Log extrapolation method, returned as a scalar string.

Data Types: `string`

Object Functions

forwardrates	Calculate forward rates for ratecurve object
discountfactors	Calculate discount factors for a ratecurve object
zerorates	Calculate zero rates for ratecurve object
irbootstrap	Bootstrap interest-rate curve from market data

Examples

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = "zero";
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve("zero",Settle,ZeroDates,ZeroRates,'Compounding',2,'Basis',5,'InterpMethod',"pchi
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: 2
               Basis: 5
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2018
        InterpMethod: "pchip"
   ShortExtrapMethod: "linear"
    LongExtrapMethod: "cubic"
```

Version History

Introduced in R2020a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `ratecurve` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

inflationcurve

Create `inflationcurve` object for interest-rate curve from dates and data

Description

Build an `inflationcurve` object using `inflationcurve`.

After creating a `inflationcurve` object, you can use the associated object function `indexvalues`.

To price an `InflationBond`, `YearYearInflationSwap`, or `ZeroCouponInflationSwap` instrument, you must create an `inflationcurve` object and then create an `Inflation` pricer object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
inflationcurve_obj = inflationcurve(Dates,InflationIndexValues)
inflationcurve_obj = inflationcurve( ___ ,Name,Value)
```

Description

`inflationcurve_obj = inflationcurve(Dates,InflationIndexValues)` creates an `inflationcurve` object.

`inflationcurve_obj = inflationcurve( ___ ,Name,Value)` creates an `inflationcurve` object using name-value pairs and any of the arguments in the previous syntax. For example, `myInflationCurve = inflationcurve(InflationDates,InflationIndexValues,'Basis',4)` creates an `inflationcurve` object. You can specify multiple name-value pair arguments.

Input Arguments

`Dates` — Dates corresponding to `InflationIndexValues`
datetime array | serial date number | cell array of date character vectors | date string array

Dates corresponding to `InflationIndexValues`, specified as a datetime array, serial date numbers, cell array of date character vectors, or date string array. The first date is the base date.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `Dates` property is stored as a datetime.

Data Types: `double` | `char` | `cell` | `string` | `datetime`

`InflationIndexValues` — Inflation index values for the curve

vector of positive values

Inflation index values for the curve, specified as a vector of positive values. The first value is the base index value.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `myInflationCurve = inflationcurve(InflationDates,InflationIndexValues,'Basis',4)`

`Basis` — Day count basis

`0` (actual/actual) (default) | integer from `0` to `13`

Day count basis, specified as the comma-separated pair consisting of `'Basis'` and a scalar integer.

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Seasonality` — Seasonal adjustment rates

12-by-1 vector of `0`s (no seasonality) (default) | decimal

Seasonal adjustment rates, specified as the comma-separated pair consisting of `'Seasonality'` and a 12-by-1 vector in decimals for each month ordered from January to December. The rates are annualized and continuously compounded seasonal rates that are internally corrected to add to `0`.

Data Types: `double`

Properties

`Basis` — Day count basis
`0` (actual/actual) (default) | integer from `0` to `13`

Day count basis of the instrument, returned as a scalar integer.

Data Types: `double`

`Dates` — Dates corresponding to `InflationIndexValues`
datetime

Dates corresponding to `InflationIndexValues`, returned as a datetime array.

Data Types: `datetime`

`InflationIndexValues` — Inflation index values for the curve
vector

Inflation index values for the curve, returned as vector.

Data Types: `double`

`ForwardInflationRates` — Forward inflation rates
vector

Forward inflation rates, returned as vector.

Data Types: `double`

`Seasonality` — Seasonal adjustment rates
vector

Seasonal adjustment rates, returned as a 12-by-1 vector.

Data Types: `double`

Object Functions

indexvalues Calculate index values for inflationcurve object

Examples

Create `inflationcurve` Object

Create an `inflationcurve` object using `inflationcurve`.

```
BaseDate = datetime(2020, 9, 20);
InflationTimes = [0 calyears([1 2 3 4 5 7 10 20 30])]';
InflationIndexValues = [100 102 103.5 105 106.8 108.2 111.3 120.1 130.4 150.2]';
InflationDates = BaseDate + InflationTimes;

myInflationCurve = inflationcurve(InflationDates,InflationIndexValues)
```

```
myInflationCurve =
  inflationcurve with properties:
```

```
                Basis: 0
                Dates: [10x1 datetime]
 InflationIndexValues: [10x1 double]
ForwardInflationRates: [9x1 double]
          Seasonality: [12x1 double]
```

Algorithms

Build an inflation curve from a series of breakeven zero-coupon inflation swap (ZCIS) rates:

$I(0, T_{1Y}) = I(T_0)($1

$I(0, T_{2Y}) = I(T_0)($1

$I(0, T_{3Y}) = I(T_0)($1

...

$I(0, T_i) = I(T_0)($1

where

- $I(0, T_i)$ is the breakeven inflation index reference number for maturity date T_i.
- $I(T_0)$ is the base inflation index value for the starting date T_0.
- $b(0; T_0, T_i)$ is the breakeven inflation rate for the ZCIS maturing on T_i.

The ZCIS rates typically have maturities that increase in whole number of years. So the inflation curve is built on an annual basis. From the annual basis inflation curve, the annual unadjusted (that is, not seasonally adjusted) forward inflation rates are computed as follows:

$$f_i = \frac{1}{(T_i - T_{i-1})} \log\left(\frac{I(0, T_i)}{I(0, T_{i-1})}\right)$$

The unadjusted forward inflation rates are used for interpolating and also for incorporating seasonality to the inflation curve.

For monthly periods that are not a whole number of years, seasonal adjustments can be made to reflect seasonal patterns of inflation within the year. These 12 monthly seasonal adjustments are annualized and they add up to zero to ensure that the cumulative seasonal adjustments are reset to zero every year.

$$I(0, T_i) = I(T_0)\exp\left(\int_{T_0}^{T_i} f(u)du\right)\exp\left(\int_{T_0}^{T_i} s(u)du\right)$$

$$I(0, T_i) = I(0, T_{i-1})\exp((T_i - T_{i-1})(f_i + s_i))$$

where

- $I(0, T_i)$ is the breakeven inflation index reference number.
- $I(0, T_{i-1})$ is the previous inflation reference number.

- f_i is the annual unadjusted forward inflation rate.
- s_i is the annualized seasonal component for the period $[T_{i-1}, T_i]$.

The first year seasonal adjustment may need special treatment, because typically, the breakeven inflation reference number of the first month is already known. If that is the case, the unadjusted forward inflation rate for the first year needs to be recomputed for the remaining 11 months.

indexvalues

Calculate index values for `inflationcurve` object

Syntax

```
outIndexValues = indexvalues(inpInflationCurve,inpDates)
```

Description

`outIndexValues = indexvalues(inpInflationCurve,inpDates)` calculates the inflation index values for the `inflationcurve` object (`inpInflationCurve`) based on the Inflation index end dates (`inpDates`).

Examples

Calculate Index Values for `inflationcurve` Object

Create an inflation`curve` object using `inflationcurve`.

```
BaseDate = datetime(2020,9,20);
InflationTimes = [0 calyears([1 2 3 4 5 7 10 20 30])]';
InflationIndexValues = [100 102 103.5 105 106.8 108.2 111.3 120.1 130.4 150.2]';
InflationDates = BaseDate + InflationTimes;
myInflationCurve = inflationcurve(InflationDates,InflationIndexValues);
```

Compute the index values using `indexvalues`.

```
outIndexValues = indexvalues(myInflationCurve,datetime(2023,9,20))
```

```
outIndexValues = 105
```

Input Arguments

`inpInflationCurve` — Inflation curve

`inflationcurve` object

Inflation curve, specified using a previously created `inflationcurve` object.

Data Types: `object`

`inpDates` — Inflation index end dates

datetime array | string array | date character vector

Inflation index end dates, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `indexvalues` also accepts serial date numbers as inputs, but they are not recommended.

Output Arguments

`outIndexValues` — Output inflation index values
numeric

Output inflation index values, returned as a numeric.

Version History

Introduced in R2021a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `indexvalues` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

inflationbuild

Build inflation curve from market zero-coupon inflation swap rates

Syntax

```
InflationCurve = inflationbuild(BaseDate,BaseIndexValue,ZCISDates,ZCISRates)
myInflationCurve = inflationbuild( ___ ,Name,Value)
```

Description

`InflationCurve = inflationbuild(BaseDate,BaseIndexValue,ZCISDates,ZCISRates)` builds an inflation curve from market zero-coupon inflation swap (ZCIS) rates. The `InflationCurve` output is an `inflationcurve` object.

`myInflationCurve = inflationbuild( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to any of the input argument combinations in the previous syntax. For example, `myInflationCurve = inflationbuild(BaseDate,BaseIndexValue,ZCISDates,ZCISRates,'Seasonality',SeasonalRates)` builds an `inflationcurve` object from market zero ZCIS dates and rates.

Examples

Build Inflation Curve from Zero-Coupon Inflation Swap Rates

This example shows the workflow to build an `inflationcurve` object from zero-coupon inflation swap (ZCIS) rates using `inflationbuild`.

Define the inflation curve parameters.

```
BaseDate = datetime(2020,9,20);
BaseIndexValue = 100;
ZCISTimes = [calyears([1 2 3 4 5 7 10 20 30])]';
ZCISRates = [0.51 0.65 0.87 0.92 0.95 1.42 1.75 2.03 2.54]'./100;
ZCISDates = BaseDate + ZCISTimes;
SeasonalRates = [-0.19 -0.09 -0.04 0.1 0.16 0.11 0.26 0.17 -0.07 -0.08 -0.14 -0.19]'./100;
```

Use `inflationbuild` to create an `inflationcurve` object.

```
myInflationCurve = inflationbuild(BaseDate,BaseIndexValue,ZCISDates,ZCISRates,'Seasonality',Seaso
```

```
myInflationCurve =
  inflationcurve with properties:

                    Basis: 0
                    Dates: [10x1 datetime]
     InflationIndexValues: [10x1 double]
    ForwardInflationRates: [9x1 double]
              Seasonality: [12x1 double]
```

Input Arguments

`BaseDate` — Base date of inflation curve

datetime scalar | string scalar | date character vector

Base date of inflation curve, specified as a scalar datetime, string, or data character vector.

To support existing code, `inflationbuild` also accepts serial date numbers as inputs, but they are not recommended.

`BaseIndexValue` — Base index value of inflation curve

numeric

Base index value of inflation curve, specified as a scalar numeric.

Data Types: `double`

`ZCISDates` — Market ZCIS maturity dates minus lag

datetime array | string array | date character vector

Market ZCIS maturity dates minus lag, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `inflationbuild` also accepts serial date numbers as inputs, but they are not recommended.

`ZCISRates` — Market ZCIS rates

decimal

Market ZCIS rates, specified as an `NINST`-by-`1` vector of decimals.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `myInflationCurve = inflationbuild(BaseDate,BaseIndexValue,ZCISDates,ZCISRates,'Seasonality',SeasonalRates)`

`Basis` — Day count basis

`0` (actual/actual) (default) | integer from `0` to `13`

Day count basis, specified as the comma-separated pair consisting of `'Basis'` and a scalar integer.

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365

- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Seasonality` — Seasonal adjustment rates
`12`-by-`1` vector of `0`s (no seasonality) (default) | decimal

Seasonal adjustment rates, specified as the comma-separated pair consisting of `'Seasonality'` and a `12`-by-`1` vector in decimals for each month ordered from January to December. The rates are annualized and continuously compounded seasonal rates that are internally corrected to add to `0`.

Data Types: `double`

`FirstMonthIndex` — First month inflation index
`[]` (not known) (default) | positive numeric

First month inflation index, specified as the comma-separated pair consisting of `'FirstMonthIndex'` and a positive numeric.

Data Types: `double`

Output Arguments

`InflationCurve` — Inflation curve
`inflationcurve` object

Inflation curve, returned as an `inflationcurve` object. The object has the following properties:

- `Basis`
- `Dates`
- `InflationIndexValues`
- `ForwardInflationRates`
- `Seasonality`

Algorithms

Build an inflation curve from a series of breakeven zero-coupon inflation swap (ZCIS) rates:

$$I(0,T_{1Y}) = I(T_0)(^1$$

$$I(0,T_{2Y}) = I(T_0)(^1$$

$$I(0,T_{3Y}) = I(T_0)(^1$$

...

$$I(0,T_i) = I(T_0)(^1$$

where

- $I(0,T_i)$ is the breakeven inflation index reference number for maturity date T_i.
- $I(T_0)$ is the base inflation index value for the starting date T_0.
- $b(0;T_0,T_i)$ is the breakeven inflation rate for the ZCIS maturing on T_i.

The ZCIS rates typically have maturities that increase in whole number of years, so the inflation curve is built on an annual basis. From the annual basis inflation curve, the annual unadjusted (that is, not seasonally adjusted) forward inflation rates are computed as follows:

$$f_i = \frac{1}{(T_i - T_{i-1})}\log\left(\frac{I(0,T_i)}{I(0,T_{i-1})}\right)$$

The unadjusted forward inflation rates are used for interpolating and also for incorporating seasonality to the inflation curve.

For monthly periods that are not a whole number of years, seasonal adjustments can be made to reflect seasonal patterns of inflation within the year. These 12 monthly seasonal adjustments are annualized and they add up to zero to ensure that the cumulative seasonal adjustments are reset to zero every year.

$$I(0,T_i) = I(T_0)\exp\left(\int_{T_0}^{T_i} f(u)du\right)\exp\left(\int_{T_0}^{T_i} s(u)du\right)$$

$$I(0,T_i) = I(0,T_{i-1})\exp((T_i - T_{i-1})(f_i + s_i))$$

where

- $I(0,T_i)$ is the breakeven inflation index reference number.
- $I(0,T_{i-1})$ is the previous inflation reference number.
- f_i is the annual unadjusted forward inflation rate.
- s_i is the annualized seasonal component for the period $[T_{i-1},T_i]$.

The first year seasonal adjustment may need special treatment because, typically, the breakeven inflation reference number of the first month is already known. If that is the case, the unadjusted forward inflation rate for the first year needs to be recomputed for the remaining 11 months.

Version History

Introduced in R2021a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `inflationbuild` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

```

Description

[Price,PriceResult] = price(inpPricer,inpInstrument) computes the instrument price and related pricing information based on the pricing object inpPricer and the instrument object inpInstrument.

[Price,PriceResult] = price(___ ,inpSensitivity) adds an optional argument to specify sensitivities.

Examples

Use Inflation Pricer and inflationcurve to Price Inflation Bond Instrument

This example shows the workflow to price an InflationBond instrument when you use an inflationcurve object and an Inflation pricing method.

Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2021,1,15);
Type = "zero";
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
ZeroCurve =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Jan-2021
        InterpMethod: "linear"
   ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

Create `inflationcurve` Object

Create an `inflationcurve` object using `inflationcurve`.

```
BaseDate = datetime(2020,10,1);
InflationTimes = [0 calyears([1 2 3 4 5 7 10 20 30])]';
InflationIndexValues = [100 102 103.5 105 106.8 108.2 111.3 120.1 130.4 150.2]';
InflationDates = BaseDate + InflationTimes;
myInflationCurve = inflationcurve(InflationDates,InflationIndexValues)
```

```
myInflationCurve =
  inflationcurve with properties:

                   Basis: 0
                   Dates: [10x1 datetime]
     InflationIndexValues: [10x1 double]
    ForwardInflationRates: [9x1 double]
              Seasonality: [12x1 double]
```

Create `InflationBond` Instrument Object

Use `fininstrument` to create an `InflationBond` instrument object.

```
IssueDate = datetime(2021,1,1);
Maturity = datetime(2026,1,1);
CouponRate = 0.02;

InflationBond = fininstrument("InflationBond",'IssueDate',IssueDate,'Maturity',Maturity,'CouponRa
```

```
InflationBond =
  InflationBond with properties:

                  CouponRate: 0.0200
                      Period: 2
                       Basis: 0
                   Principal: 100
    DaycountAdjustedCashFlow: 0
                         Lag: 3
       BusinessDayConvention: "actual"
                    Holidays: NaT
                EndMonthRule: 1
                   IssueDate: 01-Jan-2021
             FirstCouponDate: NaT
              LastCouponDate: NaT
                    Maturity: 01-Jan-2026
                        Name: "inflation_bond_instrument"
```

Create `Inflation` Pricer Object

Use `finpricer` to create an `Inflation` pricer object and use the `ratecurve` object with the `'DiscountCurve'` name-value pair argument and the `inflationcurve` object with the `'InflationCurve'` name-value pair argument.

```
outPricer = finpricer("Inflation",'DiscountCurve',ZeroCurve,'InflationCurve',myInflationCurve)
```

```
outPricer =
  Inflation with properties:
```

```
     DiscountCurve: [1x1 ratecurve]
    InflationCurve: [1x1 inflationcurve]
```

Price `InflationBond` Instrument

Use `price` to compute the price and sensitivities for the `InflationBond` instrument.

```
[Price,outPR] = price(outPricer,InflationBond)
```

```
Price = 112.1856

outPR =
  priceresult with properties:

       Results: [1x1 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=table
    Price
    ______

    112.19
```

Input Arguments

`inpPricer` — Pricer object
`Inflation` pricer object

Pricer object, specified as a scalar `Inflation` pricer object. Use `finpricer` to create the `Inflation` pricer object.

Data Types: `object`

`inpInstrument` — Instrument object
`ZeroCouponInflationSwap` object | `YearYearInflationSwap` object | `InflationBond` object

Instrument object, specified as a scalar or vector of `InflationBond`, `YearYearInflationSwap`, or `ZeroCouponInflationSwap` instrument objects. Use `fininstrument` to create the `InflationBond`, `YearYearInflationSwap`, or `ZeroCouponInflationSwap` instrument objects.

Data Types: `object`

`inpSensitivity` — List of sensitivities to compute
`[ ]` (default) | string array with values `"Price"` and `"All"` | cell array of character vectors with values `'Price'` and `'All'`

(Optional) List of sensitivities to compute, specified as an `NOUT`-by-`1` or `1`-by-`NOUT` cell array of character vectors or string array with possible values of `'Price'` and `'All'`.

`inpSensitivity = {'All'}` or `inpSensitivity = ["All"]` specifies that the output is `'Price'`. This option is the same as specifying `inpSensitivity` to include each sensitivity.

Example: `inpSensitivity = {'price'}`

Data Types: `string` | `cell`

Output Arguments

`Price` — Instrument price

numeric

Instrument price, returned as a numeric.

`PriceResult` — Price result

`PriceResult` object

Price result, returned as an object. The object has the following fields:

- `PriceResult.Results` — Table of results
- `PriceResult.PricerData` — Structure for pricer data

Version History

Introduced in R2021a

inflationCashflows

Package: fininstrument

Compute cash flows for InflationBond instrument

Syntax

```
outCF = inflationCashflows(inpInstrumentObject,Settle,inpInflationCurve)
```

Description

outCF = inflationCashflows(inpInstrumentObject,Settle,inpInflationCurve) computes cash flows for an InflationBond instrument object.

Examples

Price Inflation Bond Instrument Using inflationcurve and Inflation Pricer and Compute Cash Flows

This example shows the workflow to price an InflationBond instrument when you use an inflationcurve object and an Inflation pricing method. The cash flows for the InflationBond instrument are computed using inflationCashflows.

Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2021,1,15);
Type = "zero";
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
ZeroCurve =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Jan-2021
        InterpMethod: "linear"
   ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

Create inflationcurve Object

Create an inflationcurve object using inflationcurve.

```
BaseDate = datetime(2020,10,1);
InflationTimes = [0 calyears([1 2 3 4 5 7 10 20 30])]';
InflationIndexValues = [100 102 103.5 105 106.8 108.2 111.3 120.1 130.4 150.2]';
InflationDates = BaseDate + InflationTimes;
myInflationCurve = inflationcurve(InflationDates,InflationIndexValues)
```

```
myInflationCurve =
  inflationcurve with properties:

                   Basis: 0
                   Dates: [10x1 datetime]
     InflationIndexValues: [10x1 double]
    ForwardInflationRates: [9x1 double]
              Seasonality: [12x1 double]
```

Create `InflationBond` Instrument Object

Use `fininstrument` to create an `InflationBond` instrument object.

```
IssueDate = datetime(2021,1,1);
Maturity = datetime(2026,1,1);
CouponRate = 0.02;

InflationBond = fininstrument("InflationBond",'IssueDate',IssueDate,'Maturity',Maturity,'CouponRa
```

```
InflationBond =
  InflationBond with properties:

                 CouponRate: 0.0200
                     Period: 2
                      Basis: 0
                  Principal: 100
    DaycountAdjustedCashFlow: 0
                        Lag: 3
       BusinessDayConvention: "actual"
                    Holidays: NaT
                EndMonthRule: 1
                   IssueDate: 01-Jan-2021
             FirstCouponDate: NaT
              LastCouponDate: NaT
                    Maturity: 01-Jan-2026
                        Name: "inflation_bond_instrument"
```

Create `Inflation` Pricer Object

Use `finpricer` to create an `Inflation` pricer object and use the `ratecurve` object with the `'DiscountCurve'` name-value pair argument and the `inflationcurve` object with the `'InflationCurve'` name-value pair argument.

```
outPricer = finpricer("Inflation",'DiscountCurve',ZeroCurve,'InflationCurve',myInflationCurve)
```

```
outPricer =
  Inflation with properties:

     DiscountCurve: [1x1 ratecurve]
    InflationCurve: [1x1 inflationcurve]
```

Price InflationBond Instrument

Use price to compute the price and sensitivities for the InflationBond instrument.

```
[Price,outPR] = price(outPricer,InflationBond)
```

```
Price = 112.1856

outPR =
  priceresult with properties:

       Results: [1x1 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=table
    Price
    ______

    112.19
```

Compute Cash Flows for InflationBond Instrument

Use inflationCashflows to compute the cash flows for the InflationBond instrument.

```
outCF = inflationCashflows(InflationBond,datetime(2021,1,15),myInflationCurve)
```

```
outCF=11×1 timetable
       Time        InflationCFAmounts

Price Multiple Inflation Bond Instruments Using inflationcurve and Inflation Pricer and Compute Cash Flows

This example shows the workflow to price multiple InflationBond instruments when you use an inflationcurve object and an Inflation pricing method. The cash flows for the InflationBond instruments are computed using inflationCashflows.

Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2021,1,15);
Type = "zero";
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
ZeroCurve =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Jan-2021
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `inflationcurve` Object

Create an `inflationcurve` object using `inflationcurve`.

```
BaseDate = datetime(2019,8,1);
InflationTimes = [0 calyears([1 2 3 4 5 7 10 20 30])]';
InflationIndexValues = [100 102 103.5 105 106.8 108.2 111.3 120.1 130.4 150.2]';
InflationDates = BaseDate + InflationTimes;
myInflationCurve = inflationcurve(InflationDates,InflationIndexValues)
```

```
myInflationCurve =
  inflationcurve with properties:

                   Basis: 0
                   Dates: [10x1 datetime]
    InflationIndexValues: [10x1 double]
    ForwardInflationRates: [9x1 double]
              Seasonality: [12x1 double]
```

Create `InflationBond` Instrument Object

Use `fininstrument` to create an `InflationBond` instrument object for three Inflation Bond instruments.

```
IssueDate = datetime([2020,1,1 ; 2019,12,1 ; 2019,11,1]);
Maturity = datetime([2026,1,1 ; 2026,2,1 ; 2026,3,1]);
CouponRate = 0.02;

InflationBond = fininstrument("InflationBond",'IssueDate',IssueDate,'Maturity',Maturity,'CouponRa
```

```
InflationBond=3×1 object
  3x1 InflationBond array with properties:

    CouponRate
    Period
    Basis
    Principal
```

```
    DaycountAdjustedCashFlow
    Lag
    BusinessDayConvention
    Holidays
    EndMonthRule
    IssueDate
    FirstCouponDate
    LastCouponDate
    Maturity
    Name
```

Create `Inflation` Pricer Object

Use `finpricer` to create an `Inflation` pricer object and use the `ratecurve` object with the `'DiscountCurve'` name-value pair argument and the `inflationcurve` object with the `'InflationCurve'` name-value pair argument.

```
outPricer = finpricer("Inflation",'DiscountCurve',ZeroCurve,'InflationCurve',myInflationCurve)
```

```
outPricer =
  Inflation with properties:

     DiscountCurve: [1x1 ratecurve]
    InflationCurve: [1x1 inflationcurve]
```

Price `InflationBond` Instruments

Use `price` to compute the prices and sensitivities for the `InflationBond` instruments.

```
[Price,outPR] = price(outPricer,InflationBond)
```

```
Price = 3×1

  113.6829
  113.9533
  114.2316

outPR=1×3 object
  1x3 priceresult array with properties:

    Results
    PricerData
```

```
outPR.Results
```

```
ans=table
    Price
    ______

    113.68

```

Input Arguments

`inpInstrumentObject` — Instrument object

`InflationBond` object

Instrument object, specified using a previously created instrument object for an `InflationBond`.

Note If the `inpInstrumentObject` is a vector of instruments, you must use `inflationCashflows` separately with each instrument.

Data Types: `object`

`Settle` — Settlement date for instrument cash flow

datetime scalar | string scalar | date character vector

Settlement date for instrument cash flow, specified as a scalar datetime, string, or date character vector.

Note The `Settle` date you specify must be before the `Maturity` date for the `InflationBond` instrument.

To support existing code, `inflationCashflows` also accepts serial date numbers as inputs, but they are not recommended.

`inpInflationCurve` — Inflation curve

`inflationcurve` object

Inflation curve, specified using a previously created inflation curve object using `inflationcurve`.

Data Types: `object`

Output Arguments

`outCF` — Output cash flow

timetable

Output cash flow, returned as a timetable.

Version History

Introduced in R2021a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `inflationCashflows` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

inflationCashflows

Package: fininstrument

Compute cash flows for YearYearInflationSwap instrument

Syntax

```
outCF = inflationCashflows(inpInstrumentObject,Settle,inpInflationCurve)
```

Description

outCF = inflationCashflows(inpInstrumentObject,Settle,inpInflationCurve) computes cash flows for an YearYearInflationSwap instrument object.

Examples

Price Year-on-Year Inflation-Indexed Swap Instrument Using inflationcurve and Inflation Pricer and Compute Cash Flows

This example shows the workflow to price a YearYearInflationSwap instrument when you use an inflationcurve object and an Inflation pricing method. Then use inflationCashflows to compute the cash flows for the YearYearInflationSwap instrument.

Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2021,1,15);
Type = "zero";
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
ZeroCurve =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Jan-2021
        InterpMethod: "linear"
   ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

Create inflationcurve Object

Create an inflationcurve object using inflationcurve.

```
BaseDate = datetime(2020,10,1);
InflationTimes = [0 calyears([1 2 3 4 5 7 10 20 30])]';
InflationIndexValues = [100 102 103.5 105 106.8 108.2 111.3 120.1 130.4 150.2]';
InflationDates = BaseDate + InflationTimes;
myInflationCurve = inflationcurve(InflationDates,InflationIndexValues)
```

```
myInflationCurve =
  inflationcurve with properties:

                   Basis: 0
                   Dates: [10x1 datetime]
     InflationIndexValues: [10x1 double]
    ForwardInflationRates: [9x1 double]
              Seasonality: [12x1 double]
```

Create YearYearInflationSwap Instrument Object

Use `fininstrument` to create a `YearYearInflationSwap` instrument object.

```
Maturity = datetime(2025,1,1);
FixedInflationRate = 0.015;
Notional = 2000;

YYInflationSwap = fininstrument("YearYearInflationSwap",'Maturity',Maturity,'FixedInflationRate'
```

```
YYInflationSwap =
  YearYearInflationSwap with properties:

              Notional: 2000
    FixedInflationRate: 0.0150
                 Basis: 0
                   Lag: 3
              Maturity: 01-Jan-2025
                  Name: "YYInflationSwap_instrument"
```

Create Inflation Pricer Object

Use `finpricer` to create an `Inflation` pricer object and use the `ratecurve` object with the `'DiscountCurve'` name-value pair argument and the `inflationcurve` object with the `'InflationCurve'` name-value pair argument.

```
outPricer = finpricer("Inflation",'DiscountCurve',ZeroCurve,'InflationCurve',myInflationCurve)
```

```
outPricer =
  Inflation with properties:

     DiscountCurve: [1x1 ratecurve]
    InflationCurve: [1x1 inflationcurve]
```

Price YearYearInflationSwap Instrument

Use `price` to compute the price and sensitivities for the `YearYearInflationSwap` instrument.

```
[Price,outPR] = price(outPricer,YYInflationSwap,"all")
```

```
Price = 12.5035
```

```
outPR =
  priceresult with properties:

       Results: [1x1 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=table
    Price
    ______

    12.504
```

Compute Cash Flows for YearYearInflationSwap Instrument

Use `inflationCashflows` to compute the cash flows for the `YearYearInflationSwap` instrument.

```
outCF = inflationCashflows(YYInflationSwap,datetime(2021,1,15),myInflationCurve)
```

```
outCF=4×2 timetable
       Time        Var1     Var2
    ___________    ____    ______

    01-Jan-2022    -30         40
    01-Jan-2023    -30     29.412
    01-Jan-2024    -30     28.986
    01-Jan-2025    -30     34.286
```

Price Multiple Year-on-Year Inflation-Indexed Swap Instruments Using `inflationcurve` and Inflation Pricer and Compute Cash Flows

This example shows the workflow to price multiple `YearYearInflationSwap` instrument when you use an `inflationcurve` object and an `Inflation` pricing method. Then use `inflationCashflows` to compute the cash flows for the `YearYearInflationSwap` instruments.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2021,1,15);
Type = "zero";
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
ZeroCurve =
  ratecurve with properties:

                Type: "zero"
       Compounding: -1
             Basis: 0
```

```
                Dates: [10x1 datetime]
                Rates: [10x1 double]
               Settle: 15-Jan-2021
         InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `inflationcurve` Object

Create an `inflationcurve` object using `inflationcurve`.

```
BaseDate = datetime(2019,10,1);
InflationTimes = [0 calyears([1 2 3 4 5 7 10 20 30])]';
InflationIndexValues = [100 102 103.5 105 106.8 108.2 111.3 120.1 130.4 150.2]';
InflationDates = BaseDate + InflationTimes;
myInflationCurve = inflationcurve(InflationDates,InflationIndexValues)
```

```
myInflationCurve =
  inflationcurve with properties:

                    Basis: 0
                    Dates: [10x1 datetime]
     InflationIndexValues: [10x1 double]
    ForwardInflationRates: [9x1 double]
              Seasonality: [12x1 double]
```

Create `YearYearInflationSwap` Instrument Object

Use `fininstrument` to create a `YearYearInflationSwap` instrument object for three Year-on-Year Inflation-Indexed Swap instruments.

```
Maturity = datetime([2024,1,1 ; 2024,11,1 ; 2024,12,1]);
FixedInflationRate = 0.015;
Notional = [20000 ; 30000 ; 40000];

YYInflationSwap = fininstrument("YearYearInflationSwap",'Maturity',Maturity,'FixedInflationRate'
```

```
YYInflationSwap=3×1 object
  3x1 YearYearInflationSwap array with properties:

    Notional
    FixedInflationRate
    Basis
    Lag
    Maturity
    Name
```

Create `Inflation` Pricer Object

Use `finpricer` to create an `Inflation` pricer object and use the `ratecurve` object with the `'DiscountCurve'` name-value pair argument and the `inflationcurve` object with the `'InflationCurve'` name-value pair argument.

```
outPricer = finpricer("Inflation",'DiscountCurve',ZeroCurve,'InflationCurve',myInflationCurve)
```

```
outPricer =
  Inflation with properties:
```

```
     DiscountCurve: [1x1 ratecurve]
    InflationCurve: [1x1 inflationcurve]
```

Price YearYearInflationSwap Instruments

Use `price` to compute the prices and sensitivities for the `YearYearInflationSwap` instruments.

```
[Price,outPR] = price(outPricer,YYInflationSwap,"all")
```

```
Price = 3×1

   26.0701
   18.1540
    1.3201

outPR=1×3 object
  1x3 priceresult array with properties:

    Results
    PricerData
```

```
outPR.Results
```

```
ans=table
    Price
    _____

    26.07

ans=table
    Price
    ______

    18.154

ans=table
    Price
    ______

    1.3201
```

Compute Cash Flows for YearYearInflationSwap Instruments

Use `inflationCashflows` to compute the cash flows for the `YearYearInflationSwap` instruments.

```
outCF = inflationCashflows(YYInflationSwap(1),datetime(2021,1,15),myInflationCurve)
```

```
outCF=3×2 timetable
       Time        Var1     Var2
    ___________    ____    ______
```

```
    01-Jan-2022    -300    294.12
    01-Jan-2023    -300    289.86
    01-Jan-2024    -300    342.86
```

```
outCF = inflationCashflows(YYInflationSwap(2),datetime(2021,1,15),myInflationCurve)
```

```
outCF=4×2 timetable
       Time        Var1     Var2
    ___________    ____    ______

    01-Nov-2021    -450    467.39
    01-Nov-2022    -450    435.85
    01-Nov-2023    -450    500.98
    01-Nov-2024    -450    413.63
```

```
outCF = inflationCashflows(YYInflationSwap(3),datetime(2021,1,15),myInflationCurve)
```

```
outCF=4×2 timetable
       Time        Var1     Var2
    ___________    ____    ______

    01-Dec-2021    -600    605.42
    01-Dec-2022    -600    580.41
    01-Dec-2023    -600    676.99
    01-Dec-2024    -600     537.7
```

Input Arguments

`inpInstrumentObject` — Instrument object

`YearYearInflationSwap` object

Instrument object, specified using a previously created instrument object for a `YearYearInflationSwap`.

Note If the `inpInstrumentObject` is a vector of instruments, you must use `inflationCashflows` separately with each instrument.

Data Types: `object`

`Settle` — Settlement date for instrument cash flow

datetime scalar | string scalar | date character vector

Settlement date for instrument cash flow, specified as a scalar datetime, string, or date character vector.

Note The `Settle` date you specify must be before the `Maturity` date for the `YearYearInflationSwap` instrument.

To support existing code, `inflationCashflows` also accepts serial date numbers as inputs, but they are not recommended.

`inpInflationCurve` — Inflation curve
`inflationcurve` object

Inflation curve, specified using a previously created inflation curve object using `inflationcurve`.

Data Types: `object`

Output Arguments

`outCF` — Output cash flow
timetable

Output cash flow, returned as a timetable.

Version History

Introduced in R2021a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `inflationCashflows` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

inflationCashflows

Package: `fininstrument`

Compute cash flows for `ZeroCouponInflationSwap` instrument

Syntax

```
outCF = inflationCashflows(inpInstrumentObject,Settle,inpInflationCurve)
```

Description

`outCF = inflationCashflows(inpInstrumentObject,Settle,inpInflationCurve)` computes cash flows for a `ZeroCouponInflationSwap` instrument object.

Examples

Price Zero-Coupon Inflation Swap Instrument Using `inflationcurve` and Inflation Pricer and Compute Cash Flow

This example shows the workflow to price a `ZeroCouponInflationSwap` instrument when you use an `inflationcurve` object and an `Inflation` pricing method. Then use `inflationCashflows` to compute the cash flow for the `ZeroCouponInflationSwap` instrument.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2021,1,15);
Type = "zero";
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
ZeroCurve =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Jan-2021
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `inflationcurve` Object

Create an `inflationcurve` object using `inflationcurve`.

```
BaseDate = datetime(2020, 10, 1);
InflationTimes = [0 calyears([1 2 3 4 5 7 10 20 30])]';
InflationIndexValues = [100 102 103.5 105 106.8 108.2 111.3 120.1 130.4 150.2]';
InflationDates = BaseDate + InflationTimes;
myInflationCurve = inflationcurve(InflationDates,InflationIndexValues)
```

```
myInflationCurve =
  inflationcurve with properties:

                   Basis: 0
                   Dates: [10x1 datetime]
     InflationIndexValues: [10x1 double]
    ForwardInflationRates: [9x1 double]
              Seasonality: [12x1 double]
```

Create ZeroCouponInflationSwap Instrument Object

Use `fininstrument` to create a `ZeroCouponInflationSwap` instrument object.

```
StartDate = datetime(2021,1,1);
Maturity = datetime(2022,10,1);
FixedInflationRate = 0.015;
Notional = 2000;

ZCInflationSwap = fininstrument("ZeroCouponInflationSwap",'StartDate',StartDate,'Maturity',Matur
```

```
ZCInflationSwap =
  ZeroCouponInflationSwap with properties:

             Notional: 2000
    FixedInflationRate: 0.0150
                Basis: 0
                  Lag: 3
            StartDate: 01-Jan-2021
             Maturity: 01-Oct-2022
                 Name: "zero_coupon_inflation_swap_instrument"
```

Create Inflation Pricer Object

Use `finpricer` to create an `Inflation` pricer object and use the `ratecurve` object with the `'DiscountCurve'` name-value pair argument and the `inflationcurve` object with the `'InflationCurve'` name-value pair argument.

```
outPricer = finpricer("Inflation",'DiscountCurve',ZeroCurve,'InflationCurve',myInflationCurve)
```

```
outPricer =
  Inflation with properties:

     DiscountCurve: [1x1 ratecurve]
    InflationCurve: [1x1 inflationcurve]
```

Price ZeroCouponInflationSwap Instrument

Use `price` to compute the price and sensitivities for the `ZeroCouponInflationSwap` instrument.

```
[Price,outPR] = price(outPricer,ZCInflationSwap,"all")
```

```
Price = 9.5675

outPR =
  priceresult with properties:

       Results: [1x1 table]
    PricerData: []
```

```
outPR.Results

ans=table
    Price
    ______

    9.5675
```

Compute Cash Flow for ZeroCouponInflationSwap Instrument

Use `inflationCashflows` to compute the cash flow for the `ZeroCouponInflationSwap` instrument.

```
outCF = inflationCashflows(ZCInflationSwap,datetime(2021,1,1),myInflationCurve)

outCF=1×2 timetable
       Time         Var1       Var2
    ____________    _______    ______

    01-Oct-2022    -52.732    62.397
```

Price Multiple Zero-Coupon Inflation Swap Instruments Using `inflationcurve` and Inflation Pricer and Compute Cash Flow

This example shows the workflow to price multiple `ZeroCouponInflationSwap` instruments when you use an `inflationcurve` object and an `Inflation` pricing method. Then use `inflationCashflows` to compute the cash flow for the `ZeroCouponInflationSwap` instruments.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2021,12,15);
Type = "zero";
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve('zero',Settle,ZeroDates,ZeroRates)

ZeroCurve =
  ratecurve with properties:

                Type: "zero"
        Compounding: -1
              Basis: 0
              Dates: [10x1 datetime]
```

```
                Rates: [10x1 double]
               Settle: 15-Dec-2021
         InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `inflationcurve` Object

Create an `inflationcurve` object using `inflationcurve`.

```
BaseDate = datetime(2020, 10, 1);
InflationTimes = [0 calyears([1 2 3 4 5 7 10 20 30])]';
InflationIndexValues = [100 102 103.5 105 106.8 108.2 111.3 120.1 130.4 150.2]';
InflationDates = BaseDate + InflationTimes;
myInflationCurve = inflationcurve(InflationDates,InflationIndexValues)
```

```
myInflationCurve =
  inflationcurve with properties:

                   Basis: 0
                   Dates: [10x1 datetime]
    InflationIndexValues: [10x1 double]
   ForwardInflationRates: [9x1 double]
             Seasonality: [12x1 double]
```

Create `ZeroCouponInflationSwap` Instrument Object

Use `fininstrument` to create a `ZeroCouponInflationSwap` instrument object for three Zero-Coupon Inflation Swap instruments.

```
StartDate = datetime([2021,5,1 ; 2021,6,1 ; 2021,7,1]);
Maturity = datetime([2022,10,1 ; 2022,11,1 ;2022,12,1]);
FixedInflationRate = 0.015;
Notional = [20000 ; 30000 ; 40000];

ZCInflationSwap = fininstrument("ZeroCouponInflationSwap",'StartDate',StartDate,'Maturity',Matur
```

```
ZCInflationSwap=3×1 object
  3x1 ZeroCouponInflationSwap array with properties:

    Notional
    FixedInflationRate
    Basis
    Lag
    StartDate
    Maturity
    Name
```

Create `Inflation` Pricer Object

Use `finpricer` to create an `Inflation` pricer object and use the `ratecurve` object with the `'DiscountCurve'` name-value pair argument and the `inflationcurve` object with the `'InflationCurve'` name-value pair argument.

```
outPricer = finpricer("Inflation",'DiscountCurve',ZeroCurve,'InflationCurve',myInflationCurve)
```

```
outPricer =
  Inflation with properties:

     DiscountCurve: [1x1 ratecurve]
    InflationCurve: [1x1 inflationcurve]
```

Price ZeroCouponInflationSwap Instruments

Use `price` to compute the prices and sensitivities for the `ZeroCouponInflationSwap` instruments.

```
[Price,outPR] = price(outPricer,ZCInflationSwap,"all")
```

```
Price = 3×1

   59.4576
   80.6037
   89.4137

outPR=1×3 object
  1x3 priceresult array with properties:

    Results
    PricerData

Input Arguments

`inpInstrumentObject` — Instrument object

`ZeroCouponInflationSwap` object

Instrument object, specified using a previously created instrument object for a `ZeroCouponInflationSwap`.

Note If the `inpInstrumentObject` is a vector of instruments, you must use `inflationCashflows` separately with each instrument.

Data Types: `object`

`Settle` — Settlement date for instrument cash flow

datetime scalar | string scalar | date character vector

Settlement date for instrument cash flow, specified as a scalar datetime, string, or date character vector.

Note The `Settle` date you specify must be before the `Maturity` date for the `ZeroCouponInflationSwap` instrument.

To support existing code, `inflationCashflows` also accepts serial date numbers as inputs, but they are not recommended.

`inpInflationCurve` — Inflation curve

`inflationcurve` object

Inflation curve, specified using a previously created inflation curve object using `inflationcurve`.

Data Types: `object`

Output Arguments

`outCF` — Output cash flow

timetable

Output cash flow, returned as a timetable.

Version History

Introduced in R2021a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `inflationCashflows` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

OISFuture

`OISFuture` instrument object

Description

Create and price an `OISFuture` instrument object for one or more one-month or three-month future instruments using this workflow:

1. Use `fininstrument` to create an `OISFuture` instrument object for one or more OIS Future instruments.
2. Use `ratecurve` to specify an interest-rate model for the `OISFuture` instrument object.
3. Use `finpricer` to specify a `Discount` pricing method for one or more `OISFuture` instruments.

Create an `OISFuture` instrument object for one or more OIS futures instruments to use in curve construction using this workflow:

1. Use `fininstrument` to create an `OISFuture` instrument object for one or more OIS future instruments.
2. Use `irbootstrap` to create an interest-rate curve (`ratecurve`) for one or more `OISFuture` instruments.

For more information on these workflows, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for an `OISFuture` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
OISFutureInst = fininstrument(InstrumentType,QuotedPrice=OIS_quoted_price,
Maturity=maturity_date,StartDate=start_date)
OISFutureInst = fininstrument( ___ ,Name=Value)
```

Description

`OISFutureInst = fininstrument(InstrumentType,QuotedPrice=OIS_quoted_price, Maturity=maturity_date,StartDate=start_date)` creates an `OISFuture` instrument object for one or more OIS future instruments by specifying `InstrumentType`, `QuotedPrice`, `Maturity`, and `StartDate`.

The `OISFuture` instrument supports many alternative reference rate (ARR) securities that are compliant with standards from the International Organization of Securities Commissions (IOSCO). For example, ARRs like SOFR, EONIA, SONIA, SARON, and TONAR focus on risk-free rate or near risk-free rates based on transactions of overnight funding.

`OISFutureInst = fininstrument( ___ ,Name=Value)` sets optional properties on page 11-2498 using additional name-value arguments in addition to the required arguments in the previous syntax. For example, `OISFutureInst = fininstrument("OISFuture",QuotedPrice=99.5,Maturity=datetime(2022,12,15),StartDate=datetime(2022,9,15))` creates an OIS future instrument. You can specify multiple name-value arguments.

Input Arguments

`InstrumentType` — Instrument type

string with value `"OISFuture"` | string array with values of `"OISFuture"` | character vector with value `'OISFuture'` | cell array of character vectors with values of `'OISFuture'`

Instrument type, specified as a string with the value of `"OISFuture"`, a character vector with the value of `'OISFuture'`, an `NINST`-by-`1` string array with values of `"OISFuture"`, or an `NINST`-by-`1` cell array of character vectors with values of `'OISFuture'`.

Data Types: `char` | `cell` | `string`

`OISFuture` Name-Value Pair Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `OISFutureInst = fininstrument("OISFuture",QuotedPrice=99.5,Maturity=datetime(2022,12,15),StartDate=datetime(2022,9,15))`

Required `OISFuture` Name-Value Arguments

`QuotedPrice` — OIS future quoted price

scalar numeric | numeric decimal

OIS future quoted price, specified as `QuotedPrice` and a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`Maturity` — OIS future maturity date

datetime array | string array | date character vector

OIS future maturity date, specified as `Maturity` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `OISFuture` also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `Maturity` property is stored as a datetime.

`StartDate` — OIS future underlying rate end date

datetime array | string array | date character vector

OIS future underlying rate end date, specified as `StartDate` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `OISFuture` also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `StartDate` property is stored as a datetime.

Optional OISFuture Name-Value Arguments

`Method` — Computation method
`"Compound"` (default) | string with value `"Compound"` or `"Average"` | string array with values of `"Compound"` or `"Average"` | character vector with value `'Compound'` or `'Average'` | cell array of character vectors with values of `'Compound'` or `'Average'`

Computation method, specified as `Method` and a scalar character vector or string or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `cell` | `char` | `string`

`Basis` — Day count basis
`2` (actual/360) (default) | scalar integer from `0` to `13` | vector of integers from `0` to `13`

Day count basis, specified as `Basis` and a scalar integer or an `NINST`-by-`1` vector of integers for the following:

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Notional` — Notional principal amount
`100` (default) | scalar numeric | numeric vector

Notional principal amount, specified as `Notional` and a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`BusinessDayConvention` — Business day convention for cash flow dates
`"actual"` (default) | string | string array | character vector | cell array of character vectors

Business day convention for cash flow dates, specified as `BusinessDayConvention` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- `"actual"` — Nonbusiness days are effectively ignored. Cash flows that fall on nonbusiness days are assumed to be distributed on the actual date.
- `"follow"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- `"modifiedfollow"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day. However, if the following business day is in a different month, the previous business day is adopted instead.
- `"previous"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- `"modifiedprevious"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However, if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell` | `string`

`Holidays` — Holidays used in computing business days
`NaT` (default) | datetime array | string array | date character vector

Holidays used in computing business days, specified as `Holidays` and dates using an `NINST`-by-`1` vector of a datetime array, string array, or date character vectors. For example:

```
H = holidays(datetime('today'),datetime(2025,12,15));
OISFutureInst = fininstrument("OISFuture",Maturity=datetime(2022,12,15),QuotedPrice=99.5,Exercise
```

To support existing code, `OISFuture` also accepts serial date numbers as inputs, but they are not recommended.

`ProjectionCurve` — Projection curve used to price OIS future
`ratecurve.empty` (default) | `ratecurve` object | vector of `ratecurve` objects

Projection curve used to price OIS future, specified as `ProjectionCurve` and a scalar `ratecurve` object or an `NINST`-by-`1` vector of `ratecurve` objects. These objects must be created using `ratecurve`. Use this optional input if the forward curve is different from the discount curve.

Data Types: `object`

`HistoricalFixing` — Historical fixing for `OISFuture`
`timetable.empty` (default) | timetable

Historical fixing for `OISFuture`, specified as `HistoricalFixing` and a timetable.

Data Types: `timetable`

`Name` — User-defined name for instrument
`""` (default) | string | character vector

User-defined name for the instrument, specified as `Name` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

Properties

`QuotedPrice` — OIS future quoted price
scalar numeric | numeric vector

OIS future quoted price, returned as a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`Maturity` — OIS future maturity date
datetime | vector of datetimes

OIS future maturity date, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`StartDate` — OIS future underlying end date
datetime | vector of datetimes

OIS future underlying end date, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`Method` — Computation method
`"Compound"` (default) | string with value `"Compound"` or `"Average"` | string array with values of `"Compound"` or `"Average"`

Computation method, returned as a string or an `NINST`-by-`1` string array.

Data Types: `string`

`Basis` — Day count basis
`0` (actual/actual) (default) | scalar integer from `0` to `13` | vector of integers from `0` to `13`

Day count basis, returned as a scalar integer or an `NINST`-by-`1` vector of integers.

Data Types: `double`

`Notional` — Notional principal amount
`100` (default) | scalar numeric | numeric vector

Notional principal amount, returned as a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`BusinessDayConvention` — Business day convention for cash flows
`"actual"` (default) | scalar string | string array

Business day convention for cash flows, returned as a scalar string or an `NINST`-by-`1` string array.

Data Types: `string`

`Holidays` — Holidays used in computing business days
`NaT` (default) | datetimes

Holidays used in computing business days, returned as an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`ProjectionCurve` — Projection curve used to price OIS future
`ratecurve.empty` (default) | `ratecurve` object | vector of `ratecurve` objects

Projection curve used to price OIS future, returned as a scalar `ratecurve` object or an `NINST`-by-`1` vector of `ratecurve` objects.

Data Types: `object`

`HistoricalFixing` — Historical fixing for `OISFuture`
`timetable.empty` (default) | timetable

Historical fixing for `OISFuture`, returned as a timetable.

Data Types: `timetable`

`Name` — User-defined name for instrument
`""` (default) | string | string array

User-defined name for the instrument, returned as a string or an `NINST`-by-`1` string array.

Data Types: `string`

Object Functions

cashflows	Compute cash flow for FixedBond, FloatBond, Swap, FRA, STIRFuture, OISFuture, OvernightIndexedSwap, or Deposit instrument

Examples

Price SOFR Future Using `ratecurve` and Discount Pricer

This example shows the workflow to price an `OISFuture` instrument for a one-month SOFR future when you use a `ratecurve` object and a `Discount` pricing method.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve` for the underlying interest-rate curve for the `OISFuture` instrument.

```
Settle = datetime(2021,1,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
       Compounding: -1
             Basis: 0
```

```
                Dates: [10x1 datetime]
                Rates: [10x1 double]
               Settle: 15-Jan-2021
         InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `OISFuture` Instrument Object

Use `fininstrument` to create an `OISFuture` instrument object for a one-month SOFR future.

```
HFDates = datetime(2021,3,1) + caldays(0:3)';
HistFixing = timetable(HFDates,[0.02;0.04;0.04;0.02]);

% Data from the following: https://www.cmegroup.com/trading/interest-rates/stir/one-month-sofr_qu
Prices_1M = 99.97;
Maturity_1M = lbusdate(2021,3,[],[],'datetime');
StartDate_1M = fbusdate(2021,3,[],[],'datetime');
FutInstrument_1M = fininstrument("OISFuture",Maturity=Maturity_1M ,QuotedPrice=Prices_1M,StartDat
    HistoricalFixing=HistFixing,Name="1MonthSOFRFuture")
```

```
FutInstrument_1M =
  OISFuture with properties:

             QuotedPrice: 99.9700
                  Method: "average"
                   Basis: 2
               StartDate: 01-Mar-2021
                Maturity: 31-Mar-2021
                Notional: 100
    BusinessDayConvention: "actual"
                Holidays: NaT
          ProjectionCurve: [0x0 ratecurve]
         HistoricalFixing: [4x1 timetable]
                     Name: "1MonthSOFRFuture"
```

Create `Discount` Pricer Object

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("Discount",DiscountCurve=myRC)
```

```
outPricer =
  Discount with properties:

    DiscountCurve: [1x1 ratecurve]
```

Price `OISFuture` Instrument for SOFR Future

Use `price` to compute the price and sensitivities for the `OISFuture` instrument for a one-month SOFR future.

```
[Price,outPR] = price(outPricer,FutInstrument_1M,["all"])
```

```
Price = 0.0408
```

```
outPR =
  priceresult with properties:

       Results: [1x2 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×2 table
     Price        DV01
    _______    ___________

    0.04079    -0.00083163
```

Price Multiple SOFR Futures Using `ratecurve` and Discount Pricer

This example shows the workflow to price multiple `OISFuture` instruments for one-month SOFR futures and three-month SOFR futures when you use a `ratecurve` object and a `Discount` pricing method.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve` for the underlying interest-rate curve for the `OISFuture` instruments.

```
Settle = datetime(2019,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `OISFuture` Instrument Objects for SOFR Futures

Use `fininstrument` to create an `OISFuture` instrument object for one-month SOFR futures.

```
HFDates = datetime(2021,3,1) + caldays(0:3)';
HistFixing = timetable(HFDates,[0.02;0.04;0.04;0.02]);

% Data from the following: https://www.cmegroup.com/trading/interest-rates/stir/one-month-sofr_qu
```

```
Prices_1M = [99.97 99.96 99.95]';
Maturity_1M = lbusdate(2021,[3 4 5]',[],[],'datetime');
StartDate_1M = fbusdate(2021,[3 4 5]',[],[],'datetime');
FutInstruments_1M = fininstrument("OISFuture",Maturity=Maturity_1M ,QuotedPrice=Prices_1M,StartDa
    HistoricalFixing=HistFixing,Name="1MonthSOFRFuture")
```

```
FutInstruments_1M=3×1 object
  3x1 OISFuture array with properties:

    QuotedPrice
    Method
    Basis
    StartDate
    Maturity
    Notional
    BusinessDayConvention
    Holidays
    ProjectionCurve
    HistoricalFixing
    Name
```

Use `fininstrument` to create an `OISFuture` instrument object for three-month SOFR futures.

```
% Data from the following: https://www.cmegroup.com/trading/interest-rates/stir/three-month-sofr_
Prices_3M = [99.92 99.895 99.84 99.74]';
Dates_3M_Maturity = thirdwednesday([6 9 12 3]',[2021 2021 2021 2022]','datetime');
Dates_3M_Start = thirdwednesday([3 6 9 12]',2021,'datetime');
FutInstruments_3M = fininstrument("OISFuture",Maturity=Dates_3M_Maturity, ...
    QuotedPrice=Prices_3M,StartDate=Dates_3M_Start,HistoricalFixing=HistFixing,Name="3MonthSOFRFu
```

```
FutInstruments_3M=4×1 object
  4x1 OISFuture array with properties:

    QuotedPrice
    Method
    Basis
    StartDate
    Maturity
    Notional
    BusinessDayConvention
    Holidays
    ProjectionCurve
    HistoricalFixing
    Name
```

Create `Discount` Pricer Object

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("Discount",DiscountCurve=myRC)
```

```
outPricer =
  Discount with properties:

    DiscountCurve: [1x1 ratecurve]
```

Price OISFuture Instruments for SOFR Futures

Use `price` to compute the prices for the `OISFuture` instruments for one-month and three-month SOFR futures.

```
Price = price(outPricer,[FutInstruments_1M ; FutInstruments_3M])
```

```
Price = 7×1

    0.0527
    0.0509
    0.0439
    0.1511
    0.1520
    0.1791
    0.1687
```

More About

OIS Future

An OIS future is a futures contract that has an overnight index swap as the underlying asset.

To support the LIBOR transition, the `OISFuture` instrument supports the adoption of alternative reference rates (ARR) like SOFR, EONIA, SONIA, SARON, and TONAR. The ARRs replace the LIBOR benchmark, which underpins many loans, mortgages, bonds, and interest-rate derivatives.

The secured overnight financing rate (SOFR) ARR tracks the overnight effective federal funds rate (which is a benchmark of the US short-term interest rate market). SOFR is becoming the benchmark rate for dollar-denominated derivatives and loans. Other countries have sought their own alternative rates, such as SONIA and EONIA. In the US, SOFR futures mature in three months and the start dates for an SOFR future coincide with international money market (IMM) expiration dates. The SOFR futures trade on maturity dates of money market futures and money market futures options, which are set by futures and options exchanges. These dates are always the third Wednesday of the last month of the quarter (March, June, September, December). You can determine these third Wednesday dates using `thirdwednesday`.

Version History

Introduced in R2021b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `OISFuture` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

STIRFuture

`STIRFuture` instrument object

Description

Create and price a `STIRFuture` instrument object for one or more STIR future instruments using this workflow:

1. Use `fininstrument` to create a `STIRFuture` instrument object for one or more STIR future instruments.
2. Use `ratecurve` to specify an interest-rate model for the `STIRFuture` instrument object.
3. Use `finpricer` to specify a `Discount` pricing method for one or more `STIRFuture` instruments.

Create a `STIRFuture` instrument object for one or more STIR future instruments to use in curve construction using this workflow:

1. Use `fininstrument` to create a `STIRFuture` instrument object for one or more STIR future instruments.
2. Use `irbootstrap` to create an interest-rate curve (`ratecurve`) for one or more `STIRFuture` instruments. In addition, you can use the `irbootstrap` optional name-value input argument `ConvexityAdjustment` to specify a convexity adjustment for the `STIRFuture` instruments.

For more information on these workflows, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a `STIRFuture` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
STIRFutureInst = fininstrument(InstrumentType,QuotedPrice=quoted_stir_price,
Maturity=maturity_date,RateEndDate=rate_end_date)
STIRFutureInst = fininstrument( ___ ,Name=Value)
```

Description

`STIRFutureInst = fininstrument(InstrumentType,QuotedPrice=quoted_stir_price, Maturity=maturity_date,RateEndDate=rate_end_date)` creates a `STIRFuture` object for one or more STIR future instruments by specifying `InstrumentType`, `QuotedPrice`, `Maturity`, and `EndDate`.

`STIRFutureInst = fininstrument( ___ ,Name=Value)` sets optional properties on page 11-2508 using additional name-value arguments in addition to the required arguments in the previous syntax. For example, `STIRFutureInst =`

`fininstrument("STIRFuture",QuotedPrice=99.5,Maturity=datetime(2022,12,15),RateEndDate=datetime(2022,6,15))` creates a STIR future instrument. You can specify multiple name-value arguments.

Input Arguments

`InstrumentType` — Instrument type

string with value `"STIRFuture"` | string array with values of `"STIRFuture"` | character vector with value `'STIRFuture'` | cell array of character vectors with values of `'STIRFuture'`

Instrument type, specified as a string with the value of `"STIRFuture"`, a character vector with the value of `'STIRFuture'`, an `NINST`-by-`1` string array 'with values of `"STIRFuture"`, or an `NINST`-by-`1` cell array of character vectors with values of `'STIRFuture'`.

Data Types: `char` | `cell` | `string`

`STIRFuture` Name-Value Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `STIRFutureInst = fininstrument("STIRFuture",QuotedPrice=99.5,Maturity=datetime(2022,12,15),RateEndDate=datetime(2022,6,15))`

Required `STIRFuture` Name-Value Arguments

`QuotedPrice` — STIR future quoted price

scalar numeric | numeric vector

STIR future quoted price, specified as `QuotedPrice` and a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`Maturity` — STIR future maturity date

datetime array | string array | date character vector

STIR future maturity date, specified as `Maturity` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `STIRFuture` also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `Maturity` property is stored as a datetime.

`RateEndDate` — STIR future underlying rate end date

datetime array | string array | date character vector

STIR future underlying rate end date, specified as `RateEndDate` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `STIRFuture` also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `RateEndDate` property is stored as a datetime.

Optional STIRFuture Name-Value Arguments

`Basis` — Day count basis
`0` (actual/actual) (default) | scalar integer from `0` to `13` | vector of integers from `0` to `13`

Day count basis, specified as `Basis` and a scalar integer or an `NINST`-by-`1` vector of integers for the following:

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Notional` — Notional principal amount
`100` (default) | scalar numeric | numeric vector

Notional principal amount, specified as `Notional` and a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`BusinessDayConvention` — Business day convention for cash flow dates
`"actual"` (default) | string | string array | character vector | cell array of character vectors

Business day convention for cash flow dates, specified as `BusinessDayConvention` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- `"actual"` — Nonbusiness days are effectively ignored. Cash flows that fall on nonbusiness days are assumed to be distributed on the actual date.
- `"follow"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.

- `"modifiedfollow"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day. However, if the following business day is in a different month, the previous business day is adopted instead.
- `"previous"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- `"modifiedprevious"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However, if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell` | `string`

`Holidays` — Holidays used in computing business days
`NaT` (default) | datetime array | string array | date character vector

Holidays used in computing business days, specified as `Holidays` and dates using an `NINST`-by-`1` vector of a datetime array, string array, or date character vectors. For example:

```
H = holidays(datetime('today'),datetime(2025,12,15));
STIRFutureInst = fininstrument("STIRFuture",Maturity=datetime(2022,12,15),QuotedPrice=99.5,Exerci
```

To support existing code, `STIRFuture` also accepts serial date numbers as inputs, but they are not recommended.

`ProjectionCurve` — Projection curve used to price STIR future
`ratecurve.empty` (default) | `ratecurve` object | vector of `ratecurve` objects

Projection curve used to price STIR future, specified as `ProjectionCurve` and a scalar `ratecurve` object or an `NINST`-by-`1` vector of `ratecurve` objects. These objects must be created using `ratecurve`. Use this optional input if the forward curve is different from the discount curve.

Data Types: `object`

`Name` — User-defined name for instrument
`""` (default) | string | character vector

User-defined name for the instrument, specified as `Name` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

Properties

`QuotedPrice` — STIR future quoted price
scalar numeric | numeric vector

STIR Future quoted price, returned as a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`Maturity` — STIR future maturity date
datetime | vector of datetimes

STIR future maturity date, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`RateEndDate` — STIR future underlying rate end date
datetime | vector of datetimes

STIR future underlying rate end date, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`Basis` — Day count basis
`0` (actual/actual) (default) | scalar integer from `0` to `13` | vector of integers from `0` to `13`

Day count basis, returned as a scalar integer or an `NINST`-by-`1` vector of integers.

Data Types: `double`

`Notional` — Notional principal amount
`100` (default) | scalar numeric | numeric vector

Notional principal amount, returned as a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`BusinessDayConvention` — Business day convention for cash flow dates
`"actual"` (default) | scalar string | string array

Business day convention for cash flow dates, returned as a scalar string or an `NINST`-by-`1` string array.

Data Types: `string`

`Holidays` — Holidays used in computing business days
`NaT` (default) | datetimes

Holidays used in computing business days, returned as an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`ProjectionCurve` — Projection curve used to price STIR future
`ratecurve.empty` (default) | `ratecurve` object | vector of `ratecurve` objects

Projection curve used to price STIR future, returned as a scalar `ratecurve` object or an `NINST`-by-`1` vector of `ratecurve` objects.

Data Types: `object`

`Name` — User-defined name for instrument
`""` (default) | string | string array

User-defined name for the instrument, returned as a string or an `NINST`-by-`1` string array.

Data Types: `string`

Object Functions

cashflows	Compute cash flow for FixedBond, FloatBond, Swap, FRA, STIRFuture, OISFuture, OvernightIndexedSwap, or Deposit instrument

Examples

Price STIR Future Instrument Using `ratecurve` and Discount Pricer

This example shows the workflow to price a `STIRFuture` instrument when you use a `ratecurve` object and a `Discount` pricing method.

Create ratecurve Object

Create a `ratecurve` object using `ratecurve` for the underlying interest-rate curve for the `STIRFuture` instrument.

```
Settle = datetime(2019,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `STIRFuture` Instrument Object

Use `fininstrument` to create a `STIRFuture` instrument object.

```
STIRFuture = fininstrument("STIRFuture",Maturity=datetime(2022,9,15),QuotedPrice=99.5,RateEndDate
```

```
STIRFuture =
  STIRFuture with properties:

             QuotedPrice: 99.5000
                   Basis: 2
             RateEndDate: 15-Dec-2022
                Maturity: 15-Sep-2022
                Notional: 500
    BusinessDayConvention: "actual"
                Holidays: NaT
          ProjectionCurve: [0x0 ratecurve]
                     Name: "stir_future_instrument"
```

Create `Discount` Pricer Object

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("Discount",DiscountCurve=myRC)
```

```
outPricer =
  Discount with properties:

    DiscountCurve: [1x1 ratecurve]
```

Price `STIRFuture` Instrument

Use `price` to compute the price and sensitivities for the `STIRFuture` instrument.

```
[Price, outPR] = price(outPricer,STIRFuture,["all"])
```

```
Price = 97.3030

outPR =
  priceresult with properties:

       Results: [1x2 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×2 table
    Price       DV01
    ______    ________

    97.303    0.041513
```

Price Multiple STIR Future Instruments Using `ratecurve` and Discount Pricer

This example shows the workflow to price multiple `STIRFuture` instruments when you use a `ratecurve` object and a `Discount` pricing method.

Create ratecurve Object

Create a `ratecurve` object using `ratecurve` for the underlying interest-rate curve for the `STIRFuture` instrument.

```
Settle = datetime(2019,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:
```

```
                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create STIRFuture Instrument Object

Use `fininstrument` to create a `STIRFuture` instrument object for three STIR future instruments.

```
STIRFuture = fininstrument("STIRFuture",Maturity=datetime([2022,4,15 ; 2022,5,15 ; 2022,6,15]),Qu
```

```
STIRFuture=3×1 object
  3x1 STIRFuture array with properties:

    QuotedPrice
    Basis
    RateEndDate
    Maturity
    Notional
    BusinessDayConvention
    Holidays
    ProjectionCurve
    Name
```

Create Discount Pricer Object

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("Discount",DiscountCurve=myRC)
```

```
outPricer =
  Discount with properties:

    DiscountCurve: [1x1 ratecurve]
```

Price STIRFuture Instruments

Use `price` to compute the prices for the `STIRFuture` instruments.

```
Price = price(outPricer,STIRFuture)
```

```
Price = 3×1

   98.2155
   98.8120
```

```
    97.6983
```

More About

STIR Future

A STIR future is a short-term interest-rate future.

A STIR future is a cash settled derivative contract on a specified term interest rate paid on a notional deposit. The price of a STIR future is quoted as 100.00 minus the rate of interest, meaning there is an inverse relationship between the direction in which the underlying interest rate is expected to move and the value of the contract.

Version History

Introduced in R2021b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `STIRFuture` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

Cliquet

`Cliquet` instrument object

Description

Create and price a `Cliquet` instrument object for one or more Cliquet instruments using this workflow:

1. Use `fininstrument` to create a `Cliquet` instrument object for one or more Cliquet instruments.
2. Use `finmodel` to specify a `BlackScholes`, `Bates`, `Merton`, or `Heston` model for the `Cliquet` instrument object.
3. Choose a pricing method.
   - When using a `BlackScholes` model, use `finpricer` to specify a `Rubinstein` pricing method for one or more `Cliquet` instruments.
   - When using a `BlackScholes`, `Heston`, `Bates`, or `Merton` model, use `finpricer` to specify an `AssetMonteCarlo` pricing method for one or more `Cliquet` instruments.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a `Cliquet` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
CliquetOpt = fininstrument(InstrumentType,ResetDates=reset_dates)
CliquetOpt = fininstrument( ___ ,Name=Value)
```

Description

`CliquetOpt = fininstrument(InstrumentType,ResetDates=reset_dates)` creates a `Cliquet` instrument object for one or more Cliquet instruments by specifying `InstrumentType` and sets properties on page 11-2517 using the required name-value argument for `ResetDates`.

`CliquetOpt = fininstrument( ___ ,Name=Value)` sets optional properties on page 11-2517 using additional name-value arguments in addition to the required arguments in the previous syntax. For example, `CliquetOpt = fininstrument("Cliquet",ResetDates=ResetDates,Name="Cliquet_option")` creates a `Cliquet` option. You can specify multiple name-value arguments.

Input Arguments

`InstrumentType` — Instrument type

string with value `"Cliquet"` | string array with values of `"Cliquet"` | character vector with value `'Cliquet'` | cell array of character vectors with values of `'Cliquet'`

Instrument type, specified as a string with the value of `"Cliquet"`, a character vector with the value of `'Cliquet'`, an `NINST`-by-`1` string array with values of `"Cliquet"`, or an `NINST`-by-`1` cell array of character vectors with values of `'Cliquet'`.

Data Types: `char` | `cell` | `string`

`Cliquet` Name-Value Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `CliquetOpt = fininstrument("Cliquet",ResetDates=ResetDates,Name="Cliquet_option")`

Required Cliquet Name-Value Arguments

`ResetDates` — Reset dates when option strike is set

vector of datetimes

Reset dates when option strike is set, specified as `ResetDates` and a `1`-by-`NumDates` vector of datetimes. The last element corresponds to the maturity date of the `Cliquet` option.

A cliquet option is a path-dependent, exotic option that periodically settles and then resets its strike price at the level of the underlying asset at the time of settlement. The reset of the strike price is not conditional to the value of the underlying asset at the reset date.

Data Types: `datetime`

Optional Cliquet Name-Value Arguments

`OptionType` — Option type

`"call"` (default) | string with value `"call"` or `"put"` | string array with values of `"call"` or `"put"` | character vector with value `'call'` or `'put'` | cell array of character vectors with values of `'call'` or `'put'`

Option type, specified as `OptionType` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `string`

`ExerciseStyle` — Option exercise style

`"European"` (default) | string with value `"European"` | string array with values of `"European"` | character vector with value `'European'` | cell array of character vectors with values of `'European'`

Option exercise style, specified as `ExerciseStyle` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `string` | `char`

ReturnType — Return calculation type
"absolute" (default) | string with value "absolute" or "relative" | string array with values of "absolute" or "relative" | character vector with value 'absolute' or 'relative' | cell array of character vectors with values of 'absolute' or 'relative'

Option type, specified as ReturnType and a scalar string or character vector or an NINST-by-1 cell array of character vectors or string array.

Data Types: char | string

InitialStrike — Original strike price used for first reset date
0 (default) | nonnegative numeric | vector of nonnegative numeric

Original strike price used for first reset date, specified as InitialStrike and a scalar nonnegative numeric value or an NINST-by-1 vector of nonnegative numeric values.

Data Types: double

LocalCap — Local cap
inf (default) | nonnegative numeric | vector of nonnegative numeric

Local cap, specified as LocalCap and a scalar nonnegative numeric value or an NINST-by-1 vector of nonnegative numeric values.

Data Types: double

LocalFloor — Local floor
0 (default) | nonnegative numeric | vector of nonnegative numeric

Local floor, specified as LocalFloor and a scalar nonnegative numeric value or an NINST-by-1 vector of nonnegative numeric values.

Data Types: double

GlobalCap — Global cap
inf (default) | nonnegative numeric | vector of nonnegative numeric

Global cap, specified as GlobalCap and a scalar nonnegative numeric value or an NINST-by-1 vector of nonnegative numeric values.

Data Types: double

GlobalFloor — Global floor
0 (default) | nonnegative numeric | vector of nonnegative numeric

Global floor, specified as GlobalFloor and a scalar nonnegative numeric value or an NINST-by-1 vector of nonnegative numeric values.

Data Types: double

Name — User-defined name for instrument
" " (default) | string | string array | character vector | cell array of character vectors

User-defined name for one or more instruments, specified as Name and a scalar string or character vector or an NINST-by-1 cell array of character vectors or string array.

Data Types: char | cell | string

Properties

`ResetDates` — Reset dates when option strike is set
vector of datetimes

Reset dates when option strike is set, returned as a 1-by-`NumDates` vector of datetimes.

Data Types: `datetime`

`OptionType` — Option type
`"call"` (default) | string with value `"call"` or `"put"`

Option type, returned as a scalar string.

Data Types: `string`

`ReturnType` — Return calculation type
`"absolute"` (default) | string with value `"absolute"` or `"relative"`

Option type, returned as a scalar string.

Data Types: `string`

`InitialStrike` — Original strike price used for first reset date
`0` (default) | nonnegative numeric |

Original strike price used for first reset date, returned as a scalar nonnegative numeric value.

Data Types: `double`

`ExerciseStyle` — Option exercise style
`"European"` (default) | string with value `"European"`

Option exercise style, returned as a scalar string.

Data Types: `string`

`LocalCap` — Local cap
`inf` (default) | nonnegative numeric

Local cap, returned as a scalar nonnegative numeric value.

Data Types: `double`

`LocalFloor` — Local floor
`0` (default) | nonnegative numeric

Local floor, returned as a scalar nonnegative numeric value.

Data Types: `double`

`GlobalCap` — Global cap
`inf` (default) | nonnegative numeric

Global cap, returned as a scalar nonnegative numeric value.

Data Types: `double`

`GlobalFloor` — Global floor
`0` (default) | nonnegative numeric

Global floor, returned as a scalar nonnegative numeric value.

Data Types: `double`

`Name` — User-defined name for instrument
`" "` (default) | string | string array

User-defined name for the instrument, returned as a scalar string or an `NINST`-by-`1` string array.

Data Types: `string`

Examples

Price Absolute Return for Cliquet Instrument Using a Black-Scholes Model and Asset Monte Carlo Pricer

This example shows the workflow to price the absolute return for a `Cliquet` instrument when you use a `BlackScholes` model and an `AssetMonteCarlo` pricing method.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2020,1,1);
Date = datetime(2021,1,1);
Rates = 0.10;
Basis = 1;
ZeroCurve = ratecurve('zero',Settle,Date,Rates,Basis=Basis)
```

```
ZeroCurve =
  ratecurve with properties:

                Type: "zero"
        Compounding: -1
              Basis: 1
              Dates: 01-Jan-2021
              Rates: 0.1000
             Settle: 01-Jan-2020
       InterpMethod: "linear"
  ShortExtrapMethod: "next"
   LongExtrapMethod: "previous"
```

Create `Cliquet` Instrument Object

Use `fininstrument` to create a `Cliquet` instrument object.

```
ResetDates =  Settle + years(0:0.25:1);
CliquetOpt = fininstrument("Cliquet",ResetDates=ResetDates,Name="cliquet_option")
```

```
CliquetOpt =
  Cliquet with properties:

      OptionType: "call"
```

```
    ExerciseStyle: "european"
       ResetDates: [01-Jan-2020 00:00:00    01-Apr-2020 07:27:18    ...    ]
         LocalCap: Inf
       LocalFloor: 0
        GlobalCap: Inf
      GlobalFloor: 0
       ReturnType: "absolute"
    InitialStrike: NaN
             Name: "cliquet_option"
```

Create BlackScholes Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",Volatility=0.1)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.1000
    Correlation: 1
```

Create AssetMonteCarlo Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo",DiscountCurve=ZeroCurve,Model=BlackScholesModel,SpotPrice
```

```
outPricer =
  GBMMonteCarlo with properties:

      DiscountCurve: [1x1 ratecurve]
          SpotPrice: 100
    SimulationDates: [02-Jan-2020    03-Jan-2020    04-Jan-2020    ...    ]
          NumTrials: 1000
      RandomNumbers: []
              Model: [1x1 finmodel.BlackScholes]
       DividendType: "continuous"
      DividendValue: 0
```

Price Cliquet Instrument

Use `price` to compute the price and sensitivities for the `Cliquet` instrument.

```
[Price, outPR] = price(outPricer,CliquetOpt,"all")
```

```
Price = 13.1885
```

```
outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta       Gamma        Lambda     Rho      Theta     Vega
    ______    ________    ___________    ______    ______    _____    ______

    13.189    0.13189    1.2434e-14       1       59.019      0      66.068
```

Price Relative Return for Cliquet Instrument Using a Black-Scholes Model and Asset Monte Carlo Pricer

This example shows the workflow to price a `Cliquet` instrument when you use a `BlackScholes` model and an `AssetMonteCarlo` pricing method. This example demonstrates how variations in caps and floors affect option prices on European Cliquet options.

This example uses three 1-year call cliquet options with quarterly observation dates. The first Cliquet option has no caps or floors, the second Cliquet option has a local floor, and the third Cliquet option has a local cap and a local floor.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2020,01,01);
Dates = datetime(2021,01,01);
Rate = 0.035;
Compounding = -1;
ZeroCurve = ratecurve('zero',Settle,Dates,Rate,Compounding=Compounding)
```

```
ZeroCurve =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: 01-Jan-2021
               Rates: 0.0350
              Settle: 01-Jan-2020
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BSModel = finmodel("BlackScholes",Volatility=0.20)
```

```
BSModel =
  BlackScholes with properties:

     Volatility: 0.2000
    Correlation: 1
```

Create Cliquet Instrument Objects with Quarterly Observation Dates

Use `fininstrument` to create the first `Cliquet` instrument object with no caps or floors.

```
ResetDates = Settle + years(0:0.25:1);

Cliquet = fininstrument("Cliquet",ResetDates=ResetDates,ReturnType="relative",LocalFloor="-inf",
```

```
Cliquet =
  Cliquet with properties:

       OptionType: "call"
    ExerciseStyle: "european"
       ResetDates: [01-Jan-2020 00:00:00    01-Apr-2020 07:27:18    ...    ]
         LocalCap: Inf
       LocalFloor: -Inf
        GlobalCap: Inf
      GlobalFloor: -Inf
       ReturnType: "relative"
    InitialStrike: NaN
             Name: "Vanilla_Cliquet"
```

Use `fininstrument` to create the second `Cliquet` instrument object with a local floor of 0%.

```
LFCliquet = fininstrument("Cliquet",ResetDates=ResetDates,ReturnType="relative",GlobalFloor="-in
```

```
LFCliquet =
  Cliquet with properties:

       OptionType: "call"
    ExerciseStyle: "european"
       ResetDates: [01-Jan-2020 00:00:00    01-Apr-2020 07:27:18    ...    ]
         LocalCap: Inf
       LocalFloor: 0
        GlobalCap: Inf
      GlobalFloor: -Inf
       ReturnType: "relative"
    InitialStrike: NaN
             Name: "LFCliquet"
```

Use `fininstrument` to create the third `Cliquet` instrument object with a local cap of 7% and a local floor of 0%.

```
LocalCap = 0.07;
LFLCCliquet = fininstrument("Cliquet",ResetDates=ResetDates,ReturnType="relative",LocalCap=Local
```

```
LFLCCliquet =
  Cliquet with properties:

       OptionType: "call"
    ExerciseStyle: "european"
       ResetDates: [01-Jan-2020 00:00:00    01-Apr-2020 07:27:18    ...    ]
         LocalCap: 0.0700
       LocalFloor: 0
        GlobalCap: Inf
      GlobalFloor: -Inf
       ReturnType: "relative"
```

```
    InitialStrike: NaN
             Name: "LFLCCLiquet"
```

Create AssetMonteCarlo Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
SpotPrice = 100;
NumTrials =  5000;
MCPricer = finpricer("AssetMonteCarlo",DiscountCurve=ZeroCurve,Model=BSModel,...
                     SpotPrice=SpotPrice,SimulationDates=[Settle+years(0:0.25:1),Settle+calmonths
```

```
MCPricer =
  GBMMonteCarlo with properties:

      DiscountCurve: [1x1 ratecurve]
          SpotPrice: 100
    SimulationDates: [01-Jan-2020 00:00:00    01-Feb-2020 00:00:00    ...    ]
          NumTrials: 5000
      RandomNumbers: []
              Model: [1x1 finmodel.BlackScholes]
       DividendType: "continuous"
      DividendValue: 0
```

Price Cliquet Instruments

Use `price` to compute the prices for the three `Cliquet` instruments.

```
Price = price(MCPricer,[Cliquet;LFCliquet;LFLCCliquet])
```

```
Price = 3×1

    0.0337
    0.1717
    0.1042
```

The underlying asset has good and poor performances when simulating Cliquet option returns. You can observe the effect of caps and floors on these performances when computing the payoff of the three Cliquet instruments:

- The first Cliquet option has no local floor, so it picks up all the poor performances. Since there is no local cap, none of the returns are capped for this Cliquet option.
- The price of the second Cliquet option is higher than the price of the first Cliquet option. The effect of the local floor on the second Cliquet option is that none of the performances below 0% are considered.
- The price of the third Cliquet option is lower than the price of the second Cliquet option because of the capped performances (returns above 7% are not considered), but it is higher than the price of the first Cliquet option with no local floor, since poor performances below 0% are not considered.

Price Multiple Cliquet Instruments Using Black-Scholes Model and Rubinstein Pricer

This example shows the workflow to price multiple `Cliquet` instruments when you use a `BlackScholes` model and a `Rubinstein` pricing method.

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,Basis=12)
```

```
myRC =
  ratecurve with properties:

                 Type: "zero"
          Compounding: -1
                Basis: 12
                Dates: 15-Sep-2023
                Rates: 0.0350
               Settle: 15-Sep-2018
         InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `Cliquet` Instrument Object

Use `fininstrument` to create a `Cliquet` instrument object for three Cliquet instruments.

```
ResetDates = Settle + years(0:0.25:1);
CliquetOpt = fininstrument("Cliquet",ResetDates=ResetDates,InitialStrike=[140;150;160],ExerciseS
```

```
CliquetOpt=3×1 object
  3x1 Cliquet array with properties:

    OptionType
    ExerciseStyle
    ResetDates
    LocalCap
    LocalFloor
    GlobalCap
    GlobalFloor
    ReturnType
    InitialStrike
    Name
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",Volatility=0.28)
```

```
BlackScholesModel =
  BlackScholes with properties:
```

```
     Volatility: 0.2800
    Correlation: 1
```

Create Rubinstein Pricer Object

Use `finpricer` to create a `Rubinstein` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",DiscountCurve=myRC,Model=BlackScholesModel,SpotPrice=135,Divider
```

```
outPricer =
  Rubinstein with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 135
    DividendValue: 0.0250
     DividendType: "continuous"
```

Price Cliquet Instruments

Use `price` to compute the prices and sensitivities for the three `Cliquet` instruments.

```
[Price, outPR] = price(outPricer,CliquetOpt,"all")
```

```
Price = 3×1

   28.1905
   25.3226
   23.8168

outPR=3×1 object
  3x1 priceresult array with properties:

    Results
    PricerData
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta      Gamma      Lambda     Vega      Rho      Theta

```

More About

Cliquet Option

A cliquet option, also called a "ratchet option," is a series of at-the-money (ATM) options, either puts or calls, where each successive option becomes active when the previous one expires.

A cliquet option is a series of forward start options, all related to each other. Each forward start option represents the advance purchase of a put, or call, option with an at-the-money strike price to be determined at a later date, typically when the option becomes active. A forward start option becomes active at a specified date in the future. The premium is paid in advance, while the time to expiration and the underlying security are established at the time the forward start option is purchased.

For example, a comparison of a European cliquet with a European vanilla option illustrates the behavior of a cliquet option. Assume that a cliquet call and put option has these characteristics:

```
Underlying index = FTST 100 index
Settle = June 19, 2019
Maturity = June 19, 2022
Intial Strike = 3000
% Assume that the underlying asset has the following values at these ResetDates:
ResetDate(1) = Strike = 3300
ResetDate(2) = Strike = 2700
ResetDate(3) = Strike = 2900
Local floor = 0
```

Assume that a vanilla call and put option has these characteristics:

```
Underlying index = FTST 100 index
Settle = June 19, 2019
Maturity = June 19, 2022
Strike = 3000
```

A three-year cliquet call on the FTST with annual resets is a series of three annual at-the-money spot calls. The initial strike is set at 3000. If at the end of year 1, the FTST closes at 3300, the first call matures in-the-money and the holder makes $300 in profit on the one-year start call. The call strike for year 2 is then reset at 3300. If at the end of year 2, the FTST closes at 2700, the call will expire worthless. The call strike for year 3 is then reset at 2700. If at the end of year 3 the underlying asset is trading at 2900, the call matures in-the-money and the holder makes a profit of $200. In summary, the holder has locked $500 in profit.

Year	Strike	Payoff at End of Each Year
1	$3000	$300
2	$3300	$0
3	$2700	$200

On the other hand, a three-year call vanilla option with a strike of 3000 will expire worthless.

A three-year cliquet put on the FTST with annual resets is a series of three annual at-the-money spot puts. The initial strike is set at 3000. If at the end of year 1, the FTST closes at 3300, the first put expires worthless. The put strike for year 2 is then reset at 3300. If at the end of year 2, the FTST closes at 2700, the put matures in-the-money and the holder makes $600 in profit on the second-year start put. The put strike for year 3 is then reset at 2700. If at the end of year 3 the underlying asset is trading at 2900, the put matures worthless. In summary, the holder has locked $600 in profit.

Year	Strike	Payoff at End of Each Year
1	$3000	0
2	$3300	$600
3	$2700	0

On the other hand, a three-year vanilla put option with a strike of $3000 will expire in-the-money with a $100 profit.

Algorithms

A cliquet option is constructed as a series of forward start options. The premium and observation (reset) dates are set in advance and its payoff depends on the returns of the underlying asset at given observation or reset dates. This return can be based in terms of absolute or relative returns. The return during the period [*Tn*-1, *Tn*] is defined as follows:

$$R_n = \begin{Bmatrix} \frac{S_{T_n} - S_{T_{n-1}}}{S_{T_{n-1}}} relative\ return \\ S_{T_n} - S_{T_{n-1}} absolute\ return \end{Bmatrix}$$

Where $n = 1,\ldots,Nobs$ and *Nobs* is the number of observations (reset dates) during the life of the contract, *Sn* is the price of the underlying asset at observation time *n*.

Since the cliquet instrument is built as a series of forward start options, then its payoff is the sum of the returns:

$$\text{Payoff cliquet} = \sum_{i=1}^{n} (Ri)$$

Depending on the underlying asset performance, there would be positive and negative returns, and the presence of caps and floors play a big role in the payoff and price of the cliquet instrument.

If a local cap (LC) and a local floor (LF) of the individual returns are considered, then the payoff of the cliquet option is the sum of the returns, capped and floored by LC and LF, at every observation time *tn*:

$$\text{LCLFCliquetPayoff} = \sum_{i=1}^{n} \max(LF, \min(LC, Ri))$$

At maturity, the sum of these modified local returns might also be globally capped and floored. If a global cap (GC) and a global floor (GF) are also considered, the cliquet option has a final payoff of:

$$\text{GCGFCliquetPayoff} = \max\left[GF, \min(GC, \textstyle\sum_{i=1}^{n} \max(\text{LF}, \min(\text{LC}, \text{RI}))\right]$$

In this case the total sum of all the cliquets is now globally capped and floored.

There are two popular cliquets in the market, the globally capped and locally floored cliquet (GCLF) and the globally floored and locally capped cliquet (GFLC). Their payoffs are defined as follows:

$$\text{GCLFCliquetPayoff} = \min(GC, \sum_{i=1}^{n} \max(LF, Ri))$$

$$\text{GFLCCliquetPayoff} = \max(GF, \sum_{i=1}^{n} \min(LF, Ri))$$

In summary, the payoff of a cliquet instrument is the sum of the capped and floored returns.

OvernightIndexedSwap

`OvernightIndexedSwap` instrument object

Description

Create and price an `OvernightIndexedSwap` instrument object for one or more Overnight Indexed Swap (OIS) instruments using this workflow:

1. Use `fininstrument` to create an `OvernightIndexedSwap` instrument object for one or more OIS instruments.
2. Use `ratecurve` to specify a curve model for the `OvernightIndexedSwap` instrument object.
3. Use `finpricer` to specify a `Discount` pricing method for one or more `OvernightIndexedSwap` instruments when using a `ratecurve` object.

Create an `OvernightIndexedSwap` instrument object for one or more OIS instruments to use in curve construction using this workflow:

1. Use `fininstrument` to create an `OvernightIndexedSwap` instrument object for one or more OIS instruments.
2. Use `irbootstrap` to create an interest-rate curve (`ratecurve`) for one or more `OvernightIndexedSwap` instruments.

For more information on these workflows, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for an `OvernightIndexedSwap` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
OvernightIndexedSwapInst = fininstrument(InstrumentType,
Maturity=maturity_date,LegRate=leg_rate)
OvernightIndexedSwapInst = fininstrument( ___ ,Name=Value)
```

Description

`OvernightIndexedSwapInst = fininstrument(InstrumentType, Maturity=maturity_date,LegRate=leg_rate)` creates a `OvernightIndexedSwap` object for one or more OIS instruments by specifying `InstrumentType` and sets the properties on page 11-2533 for the required name-value arguments `Maturity` and `LegRate`. The `OvernightIndexedSwap` instrument supports vanilla Overnight Indexed Swaps, amortizing Overnight Indexed Swaps, and forward Overnight Indexed Swaps.

`OvernightIndexedSwapInst = fininstrument( ___ ,Name=Value)` sets optional properties on page 11-2533 using additional name-value arguments in addition to the required arguments in the

previous syntax. For example, `OvernightIndexedSwapInst = fininstrument("OvernightIndexedSwap",Maturity=datetime(2019,1,30),LegRate=[0.06 0.12],LegType=["fixed","fixed"],Basis=1,Notional=100,StartDate=datetime(2018,1,30),DaycountAdjustedCashFlow=true,BusinessDayConvention="follow",ProjectionCurve=ratecurve,Name="overnight_indexed_swap_instrument")` creates an `OvernightIndexedSwap` instrument with a maturity of January 30, 2019. You can specify multiple name-value arguments.

Input Arguments

`InstrumentType` — Instrument type

string with value `"OvernigntIndexedSwap"` | string array with values of `"OvernigntIndexedSwap"` | character vector with value `'OvernigntIndexedSwap'` | cell array of character vectors with values of `'OvernigntIndexedSwap'`

Instrument type, specified as a string with the value of `"OvernigntIndexedSwap"`, a character vector with the value of `'OvernigntIndexedSwap'`, an `NINST`-by-`1` string array with values of `"OvernigntIndexedSwap"`, or an `NINST`-by-`1` cell array of character vectors with values of `'OvernigntIndexedSwap'`.

Data Types: `char` | `cell` | `string`

`OvernightIndexedSwap` Name-Value Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `OvernightIndexedSwapInst = fininstrument("OvernightIndexedSwap",Maturity=datetime(2019,1,30),LegRate=[0.06 0.12],LegType=["fixed","fixed"],Basis=1,Notional=100,StartDate=datetime(2018,1,30),DaycountAdjustedCashFlow=true,BusinessDayConvention="follow",ProjectionCurve=ratecurve,Name="overnight_indexed_swap_instrument")`

Required `OvernightIndexedSwap` Name-Value Arguments

`Maturity` — Swap maturity date

datetime array | string array | date character vector

Swap maturity date, specified as `Maturity` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `OvernightIndexedSwap` also accepts serial date numbers as inputs, but they are not recommended.

If you use date characters vector or strings, the format must be recognizable by `datetime` because the `Maturity` property is stored as a datetime.

`LegRate` — Leg rate in decimal values

matrix

Leg rate in decimal values, specified as `LegRate` and a `NINST`-by-`2` matrix. Each row can be defined as one of the following:

- `[CouponRate Spread]` (fixed-float)
- `[Spread CouponRate]` (float-fixed)
- `[CouponRate CouponRate]` (fixed-fixed)
- `[Spread Spread]` (float-float)

`CouponRate` is the decimal annual rate. `Spread` is the number of basis points in decimals over the reference rate. The first column represents the receiving leg, while the second column represents the paying leg.

Data Types: `double`

Optional OvernightIndexedSwap Name-Value Arguments

`LegType` — `OvernightIndexedSwap` leg type
`["fixed","float"]` for each instrument (default) | cell array of character vectors with values `{'fixed','fixed'}`, `{'fixed','float'}`, `{'float','fixed'}`, or `{'float','float'}` | string array with values `["fixed","fixed"]`, `["fixed","float"]`, `["float","fixed"]`, or `["float","float"]`

`OvernightIndexedSwap` leg type, specified as `LegType` and a cell array of character vectors or a string array with the supported values. The `LegType` defines the interpretation of the values entered in `LegRate`.

Data Types: `cell` | `string`

`ProjectionCurve` — Rate curve for projecting floating cash flows
`ratecurve.empty` (default) | scalar `ratecurve` object | vector of `ratecurve` objects

Rate curve for projecting floating cash flows, specified as `ProjectionCurve` and a scalar `ratecurve` object or an `NINST`-by-`1` vector of `ratecurve` objects. You must create this object using `ratecurve`. Use this optional input if the forward curve is different from the discount curve.

Data Types: `object`

`Reset` — Frequency of payments per year
`[2 2]` (default) | numeric value of `0`, `1`, `2`, `3`, `4`, `6`, or `12` | matrix

Frequency of payments per year, specified as `Reset` and a scalar or a `NINST`-by-`2` matrix if `Reset` is different for each leg) with one of the following values: `0`, `1`, `2`, `3`, `4`, `6`, or `12`.

Data Types: `double`

`Basis` — Day count basis representing the basis for each leg
`[0 0]` (actual/actual) (default) | integer from `0` to `13`

Day count basis representing the basis for each leg, specified as `Basis` and a `NINST`-by-`1` matrix (or `NINST`-by-`2` matrix if `Basis` is different for each leg).

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)

- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Notional` — Notional principal amount
`100` (default) | scalar numeric | numeric vector

Notional principal amount, specified as `Notional` and a scalar numeric or an `NINST`-by-`1` numeric vector.

`Notional` accepts a scalar for a principal amount (or a `NINST`-by-`2` matrix if `Notional` is different for each leg).

Data Types: `double`

`HistoricalFixing` — Historical fixing data
`timetable.empty` (default) | timetable

Historical fixing data, specified as `HistoricalFixing` and a timetable.

Note If you are creating one or more `OvernightIndexedSwap` instruments and use a timetable, the timetable specification applies to all of the `OvernightIndexedSwap` instruments. `HistoricalFixing` does not accept an `NINST`-by-`1` cell array of timetables as input.

Data Types: `timetable`

`ResetOffset` — Lag in rate setting
`[0 0]` (default) | vector

Lag in rate setting, specified as `ResetOffset` and a `NINST`-by-`2` matrix.

Data Types: `double`

`BusinessDayConvention` — Business day conventions
`"actual"` (default) | string | string array | character vector | cell array of character vectors

Business day conventions, specified as `BusinessDayConvention` and string (or `NINST`-by-`2` string array if `BusinessDayConvention` is different for each leg) or a character vector (or `NINST`-by-`2` cell array of character vectors if `BusinessDayConvention` is different for each leg). The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- `"actual"` — Nonbusiness days are effectively ignored. Cash flows that fall on nonbusiness days are assumed to be distributed on the actual date.
- `"follow"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- `"modifiedfollow"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day. However, if the following business day is in a different month, the previous business day is adopted instead.
- `"previous"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- `"modifiedprevious"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However, if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell` | `string`

`Holidays` — Holidays used in computing business days
`NaT` (default) | datetime array | string array | date character vector

Holidays used in computing business days, specified as `Holidays` and dates using an `NINST`-by-`1` vector of a datetime array, string array, or date character vectors. For example:

```
H = holidays(datetime('today'),datetime(2025,12,15));
OvernightIndexedSwapInst = fininstrument("OvernightIndexedSwap",Maturity=datetime(2025,12,15),Leg
```

To support existing code, `OvernightIndexedSwap` also accepts serial date numbers as inputs, but they are not recommended.

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month with 30 or fewer days
`[true true]` (in effect) (default) | logical with value of `true` or `false`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month with 30 or fewer days, specified as `EndMonthRule` and a logical value of `true` or `false` using a `NINST`-by-`1` matrix (or `NINST`-by-`2` matrix if `EndMonthRule` is different for each leg).

- If you set `EndMonthRule` to `false`, the software ignores the rule, meaning that a payment date is always the same numerical day of the month.
- If you set `EndMonthRule` to `true`, the software sets the rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

`StartDate` — Date `OvernightIndexedSwap` starts payments
`Settle` date (default) | datetime array | string array | date character vector

Date `OvernightIndexedSwap` starts payments, specified as `StartDate` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `OvernightIndexedSwap` also accepts serial date numbers as inputs, but they are not recommended.

Use `StartDate` to price a forward `OvernightIndexedSwap`, that is, an `OvernightIndexedSwap` that starts at a future date.

If you use a date character vector or string, the format must be recognizable by `datetime` because the `StartDate` property is stored as a datetime.

`Name` — User-defined name for instrument
`" "` (default) | string | string array | character vector | cell array of character vectors

User-defined name for the instrument, specified as `Name` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

Properties

`Maturity` — Maturity date
scalar datetime | vector of datetimes

Maturity date, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`LegRate` — Leg rate
matrix

Leg rate, returned as a `NINST`-by-`2` matrix of decimal values, with each row defined as one of the following:

- `[CouponRate Spread]` (fixed-float)
- `[Spread CouponRate]` (float-fixed)
- `[CouponRate CouponRate]` (fixed-fixed)
- `[Spread Spread]` (float-float)

Data Types: `double`

`LegType` — Leg type
`["fixed","float"]` for each instrument (default) | string array with values `["fixed","fixed"]`, `["fixed","float"]`, `["float","fixed"]`, or `["float","float"]`

Leg type, returned as a string array with the values `["fixed","fixed"]`, `["fixed","float"]`, `["float","fixed"]`, or `["float","float"]`.

Data Types: `string`

`ProjectionCurve` — Rate curve used in generating future cash flows
`ratecurve.empty` (default) | scalar `ratecurve` object | vector of `ratecurve` objects

Rate curve used in projecting the future cash flows, returned as a `ratecurve` object or an `NINST`-by-`1` vector of `ratecurve` objects.

Data Types: `object`

`Reset` — Reset frequency per year for each swap
`[2 2]` (default) | vector

Reset frequency per year for each swap, returned as an 1-by-2 matrix.

Data Types: `double`

Basis — Day count basis
`[0 0]` (actual/actual) (default) | integer from `0` to `13`

Day count basis, returned as an 1-by-2 matrix.

Data Types: `double`

ResetOffset — Lag in rate setting
`[0 0]` (default) | matrix

Lag in rate setting, returned as an `NINST`-by-2 matrix.

Data Types: `double`

Notional — Notional principal amount
`100` (default) | scalar numeric | numeric vector

Notional principal amount, returned as a scalar numeric or an `NINST`-by-1 numeric vector.

Data Types: `double`

HistoricalFixing — Historical fixing data
`timetable.empty` (default) | timetable

Historical fixing data, returned as a timetable.

Data Types: `timetable`

BusinessDayConvention — Business day conventions
`"actual"` (default) | string | string array

Business day conventions, returned as a string or a `NINST`-by-2 string array if `BusinessDayConvention` is different for each leg.

Data Types: `char` | `cell` | `string`

Holidays — Holidays used in computing business days
`NaT` (default) | datetimes

Holidays used in computing business days, returned as an `NINST`-by-1 vector of datetimes.

Data Types: `datetime`

EndMonthRule — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month with 30 or fewer days
`[true true]` (in effect) (default) | logical with value of `true` or `false` | vector of logicals with values of `true` or `false`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month with 30 or fewer days, returned as an `NINST`-by-1 matrix (or `NINST`-by-2 matrix if `EndMonthRule` is different for each leg).

Data Types: `logical`

StartDate — Date `OvernightIndexedSwap` starts payments
`Settle` date (default) | scalar datetime | vector of datetimes

Date `OvernightIndexedSwap` starts payments, returned as a scalar datetime or an `NINST`-by-1 vector of datetimes.

Data Types: `datetime`

`Name` — User-defined name for instrument
`""` (default) | string | string array

User-defined name for the instrument, returned as a scalar string or an `NINST`-by-`1` string array.

Data Types: `string`

Object Functions

cashflows	Compute cash flow for FixedBond, FloatBond, Swap, FRA, STIRFuture, OISFuture, OvernightIndexedSwap, or Deposit instrument

Examples

Price Overnight Indexed Swap Instrument Using `ratecurve` and Discount Pricer

This example shows the workflow to price an `OvernightIndexedSwap` instrument when you use a `ratecurve` object and a `Discount` pricing method.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve` for the underlying interest-rate curve for the `OvernightIndexedSwap` instrument.

```
Settle = datetime(2019,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2019
        InterpMethod: "linear"
   ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

Create `OvernightIndexedSwap` Instrument Object

Use `fininstrument` to create an `OvernightIndexedSwap` instrument object.

```
OvernightIndexedSwap = fininstrument("OvernightIndexedSwap",Maturity=datetime(2022,9,15),LegRate=
```

```
OvernightIndexedSwap =
  OvernightIndexedSwap with properties:
```

```
                 LegRate: [0.0220 0.0190]
                 LegType: ["float"    "fixed"]
                   Reset: [2 2]
                   Basis: [0 0]
                Notional: 100
         HistoricalFixing: [0x0 timetable]
              ResetOffset: [0 0]
           ProjectionCurve: [1x1 ratecurve]
    BusinessDayConvention: ["actual"    "actual"]
                 Holidays: NaT
             EndMonthRule: [1 1]
                StartDate: NaT
                 Maturity: 15-Sep-2022
                     Name: "overnight_swap_instrument"
```

Create `Discount` Pricer Object

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("Discount",DiscountCurve=myRC)
```

```
outPricer =
  Discount with properties:

    DiscountCurve: [1x1 ratecurve]
```

Price `OvernightIndexedSwap` Instrument

Use `price` to compute the price and sensitivities for the `OvernightIndexedSwap` instrument.

```
[Price, outPR] = price(outPricer,OvernightIndexedSwap,["all"])
```

```
Price = 3.0226
```

```
outPR =
  priceresult with properties:

       Results: [1x2 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×2 table
    Price       DV01
    ______    ________

    3.0226    -0.02915
```

Price Multiple Overnight Indexed Swap Instruments Using `ratecurve` and Discount Pricer

This example shows the workflow to price multiple `OvernightIndexedSwap` instruments when you use a `ratecurve` object and a `Discount` pricing method.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve` for the underlying interest-rate curve for the `OvernightIndexedSwap` instrument.

```
Settle = datetime(2020,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2020
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `OvernightIndexedSwap` Instrument Object

Use `fininstrument` to create an `OvernightIndexedSwap` instrument object for three Overnight Indexed Swap instruments.

```
OvernightIndexedSwap = fininstrument("OvernightIndexedSwap",Maturity=datetime([2022,9,15 ; 2023,9
```

```
OvernightIndexedSwap=3×1 object
  3x1 OvernightIndexedSwap array with properties:

    LegRate
    LegType
    Reset
    Basis
    Notional
    HistoricalFixing
    ResetOffset
    ProjectionCurve
    BusinessDayConvention
    Holidays
    EndMonthRule
    StartDate
    Maturity
    Name
```

Create `Discount` Pricer Object

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("Discount",DiscountCurve=myRC)
```

```
outPricer =
  Discount with properties:

    DiscountCurve: [1x1 ratecurve]
```

Price OvernightIndexedSwap Instruments

Use `price` to compute the prices for the `OvernightIndexedSwap` instruments.

```
Price = price(outPricer,OvernightIndexedSwap)
```

```
Price = 3×1

   -0.7832
   -0.7336
   -0.2178
```

More About

Overnight Indexed Swap

An Overnight Indexed Swap (OIS) is an interest-rate swap over some fixed term where the periodic floating payment is based on a return calculated from a daily compound interest investment.

The overnight indexed swap denotes an interest-rate swap involving the overnight rate being exchanged for a fixed interest rate. An overnight indexed swap uses an overnight rate index such as the federal funds rate as the underlying rate for the floating leg, while the fixed leg is set at a rate agreed on by both parties.

Version History

Introduced in R2021b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `OvernightIndexedSwap` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

PartialLookback

`PartialLookback` instrument

Description

Create and price a `PartialLookback` instrument object for one or more Partial Lookback instruments using this workflow:

1. Use `fininstrument` to create a `PartialLookback` instrument object for one or more Partial Lookback instruments.
2. Use `finmodel` to specify a `BlackScholes`, `Heston`, `Bates`, or `Merton` model for the `PartialLookback` instrument object.
3. Choose a pricing method.
   - When using a `BlackScholes` model, use `finpricer` to specify a `HeynenKat` pricing method for one or more `PartialLookback` instruments.
   - When using a `BlackScholes`, `Heston`, `Bates`, or `Merton` model, use `finpricer` to specify an `AssetMonteCarlo` pricing method for one or more `PartialLookback` instruments.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a `PartialLookback` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
PartialLookbackObj = fininstrument(InstrumentType,ExerciseDate=exercise_date,
Strike=strike_value,MonitorDate=monitor_date)
PartialLookbackObj = fininstrument( ___ ,Name=Value)
```

Description

`PartialLookbackObj = fininstrument(InstrumentType,ExerciseDate=exercise_date, Strike=strike_value,MonitorDate=monitor_date)` creates a `PartialLookback` object for one or more Partial Lookback instruments by specifying `InstrumentType` and sets the properties on page 11-2543 for the required name-value arguments `Strike`, `ExerciseDate`, and `MonitorDate`.

The `PartialLookback` instrument supports fixed-strike and floating-strike partial lookback options. To compute the value of a floating-strike partial lookback option, the `Strike` must be specified as `NaN`. For more information on a `PartialLookback` instrument, see “More About” on page 11-2550.

`PartialLookbackObj = fininstrument( ___ ,Name=Value)` sets optional

properties on page 11-2543 using additional name-value arguments in addition to the required arguments in the previous syntax. For example, `LookbackObj =`

`fininstrument("Lookback",Strike=100,ExerciseDate=datetime(2022,1,30),MonitorDate=datetime(2021,1,30),OptionType="put",ExerciseStyle="European",Name="partial_lookback_option")` creates a `PartialLookback` put option with an European exercise. You can specify multiple name-value arguments.

Input Arguments

`InstrumentType` — Instrument type

string with value `"PartialLookback"` | string array with values of `"PartialLookback"` | character vector with value `'PartialLookback'` | cell array of character vectors with values of `'PartialLookback'`

Instrument type, specified as a string with the value of `"PartialLookback"`, a character vector with the value of `'PartialLookback'`, an `NINST`-by-`1` string array with values of `"PartialLookback"`, or an `NINST`-by-`1` cell array of character vectors with values of `'PartialLookback'`.

Data Types: `char` | `cell` | `string`

`PartialLookback` Name-Value Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `LookbackObj = fininstrument("Lookback",Strike=100,ExerciseDate=datetime(2022,1,30),MonitorDate=datetime(2021,1,30),OptionType="put",ExerciseStyle="European",Name="partial_lookback_option")`

Required Lookback Name-Value Arguments

`Strike` — Option strike price value

nonnegative numeric | vector of nonnegative values | `NaN`

Option strike price value, specified as `Strike` and a scalar nonnegative numeric or an `NINST`-by-`1` vector of nonnegative values for a fixed-strike `PartialLookback` option. For a floating-strike partial lookback option, specify `Strike` as a `NaN` or an `NINST`-by-`1` vector of `NaN`s.

Data Types: `double`

`ExerciseDate` — Option exercise date

datetime array | string array | date character vector

Option exercise date, specified as `ExerciseDate` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

Note For a European option, there is only one `ExerciseDate` on the option expiry date.

To support existing code, `PartialLookback` also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `ExerciseDate` property is stored as a datetime.

`MonitorDate` — Predetermined lookback monitoring date
datetime array | string array | date character vector

Predetermined lookback monitoring date, specified as `MonitorDate` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

- For a fixed-strike partial lookback, the monitoring period is [`MonitorDate`, `ExerciseDate`]. The `MonitorDate` is the start date for a fixed-strike partial lookback option.
- For a floating-strike partial lookback, the monitoring period is [`Settle`, `MonitorDate`], where `Settle` is < `MonitorDate` < `ExerciseDate`. The `MonitorDate` is the end date for a floating-strike partial lookback option.

To support existing code, `PartialLookback` also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `ExerciseDate` property is stored as a datetime.

Optional PartialLookback Name-Value Arguments

`OptionType` — Option type
`"call"` (default) | string with value `"call"` or `"put"` | string array with values `"call"` or `"put"` | character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Option type, specified as `OptionType` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

`ExerciseStyle` — Option exercise style
`"European"` (default) | string with value `"European"` or `"American"` | string array with values `"European"` or `"American"` | character vector with value `'European'` or `'American'` | cell array of character vectors with values `'European'` or `'American'`

Option exercise style, specified as `ExerciseStyle` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `string` | `cell` | `char`

`AssetMinMax` — Maximum or minimum underlying asset price
`NaN` where `SpotPrice` of the underlying asset is used (default) | scalar numeric | numeric vector

Maximum or minimum underlying asset price, specified as `AssetMinMax` and a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`StrikeScaler` — Degree of partiality for floating-strike partial lookback
`1` (default) | scalar numeric | numeric vector

Degree of partiality for a floating-strike partial lookback, specified as `StrikeScaler` and a scalar numeric or an `NINST`-by-`1` numeric vector. The `StrikeScaler` value indicates the percentage of the `Strike` that is fixed above or below the `AssetMinMax` value.

- For a call floating-strike partial lookback, the `StrikeScaler` is ≥ 1.

- For a put floating-strike partial lookback, 0 < `StrikeScaler` ≤ 1.

Data Types: `double`

`Name` — User-defined name for instrument
`" "` (default) | string | string array | character vector | cell array of character vectors

User-defined name for one of more instruments, specified as `Name` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

Properties

`Strike` — Option strike price value
nonnegative numeric | vector of nonnegative values

Option strike price value, returned as a scalar nonnegative numeric or an `NINST`-by-`1` vector of nonnegative values.

Data Types: `double`

`ExerciseDate` — Option exercise date
datetime | vector of datetimes

Option exercise date, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`MonitorDate` — Predetermined lookback monitoring date
datetime | vector of datetimes

Predetermined monitoring date, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`OptionType` — Option type
`"call"` (default) | string with value `"call"` or `"put"` | string array with values `"call"` or `"put"`

Option type, returned as a scalar string or an `NINST`-by-`1` string array with values of `"call"` or `"put"`.

Data Types: `string`

`ExerciseStyle` — Option exercise style
`"European"` (default) | string with value `"European"` or `"American"` | string array with value `"European"` or `"American"`

Option exercise style, returned as a scalar string or an `NINST`-by-`1` string array with values of `"European"` or `"American"`.

Data Types: `string`

`AssetMinMax` — Maximum or minimum underlying asset price
`NaN` where `SpotPrice` of the underlying asset is used (default) | scalar numeric | numeric vector

Maximum or minimum underlying asset price, returned as a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`StrikeScaler` — Degree of partiality for partial floating-strike lookback
1 (default) | scalar numeric | numeric vector

Degree of partiality for partial floating-strike lookback, returned as a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`Name` — User-defined name for instrument
`" "` (default) | string | string array

User-defined name for the instrument, returned as an `NINST`-by-`1` string array.

Data Types: `string`

Examples

Price Partial Lookback Instrument Using Black-Scholes Model and Heynen-Kat Pricer

This example shows the workflow to price a floating-strike `PartialLookback` instrument when you use a `BlackScholes` model and a `HeynenKat` pricing method.

Create `PartialLookback` Instrument Object

Use `fininstrument` to create an `PartialLookback` instrument object.

```
PartialLookbackOpt = fininstrument("PartialLookback",ExerciseDate=datetime(2022,9,15),Strike=NaN
```

```
PartialLookbackOpt =
  PartialLookback with properties:

     MonitorDate: 15-Sep-2021
    StrikeScaler: 0.7500
      OptionType: "put"
          Strike: NaN
     AssetMinMax: 98
   ExerciseStyle: "european"
    ExerciseDate: 15-Sep-2022
            Name: "partial_lookback_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",Volatility=0.32)
```

```
BlackScholesModel =
  BlackScholes with properties:

    Volatility: 0.3200
   Correlation: 1
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,Basis=12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `HeynenKat` Pricer Object

Use `finpricer` to create a `HeynenKat` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",Model=BlackScholesModel,DiscountCurve=myRC,SpotPrice=100,Divide
```

```
outPricer =
  HeynenKat with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 100
    DividendValue: 0.0500
     DividendType: "continuous"
```

Price `PartialLookback` Instrument

Use `price` to compute the price and sensitivities for the `PartialLookback` instrument.

```
[Price, outPR] = price(outPricer,PartialLookbackOpt,["all"])
```

```
Price = 24.8148
```

```
outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta      Gamma      Lambda     Vega      Theta       Rho
```

```
    ______    _______    ________    ______    ______    _______    _______

    24.815    0.27297    0.012438     1.1      131.33    -5.0942    -193.51
```

Price Multiple Partial Lookback Instruments Using Black-Scholes Model and Heynen-Kat Pricer

This example shows the workflow to price multiple floating-strike `PartialLookback` instruments when you use a `BlackScholes` model and a `HeynenKat` pricing method.

Create `PartialLookback` Instrument Object

Use `fininstrument` to create an `PartialLookback` instrument object for three Partial Lookback instruments.

```
PartialLookbackOpt = fininstrument("PartialLookback",ExerciseDate=datetime([2022,9,15 ; 2022,10,1
```

```
PartialLookbackOpt=3×1 object
  3x1 PartialLookback array with properties:

    MonitorDate
    StrikeScaler
    OptionType
    Strike
    AssetMinMax
    ExerciseStyle
    ExerciseDate
    Name
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",Volatility=0.32)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.3200
    Correlation: 1
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,Basis=12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
```

```
       Compounding: -1
             Basis: 12
             Dates: 15-Sep-2023
             Rates: 0.0350
            Settle: 15-Sep-2018
      InterpMethod: "linear"
ShortExtrapMethod: "next"
 LongExtrapMethod: "previous"
```

Create HeynenKat Pricer Object

Use `finpricer` to create a `HeynenKat` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",Model=BlackScholesModel,DiscountCurve=myRC,SpotPrice=100,Divider
```

```
outPricer =
  HeynenKat with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 100
    DividendValue: 0.0500
     DividendType: "continuous"
```

Price PartialLookback Instruments

Use `price` to compute the prices and sensitivities for the `PartialLookback` instruments.

```
[Price, outPR] = price(outPricer,PartialLookbackOpt,["all"])
```

```
Price = 3×1

   24.8148
   25.2306
   25.6545

outPR=3×1 object
  3x1 priceresult array with properties:

    Results
    PricerData
```

```

Price Partial Lookback Instrument Using Heston Model and Asset Monte-Carlo Pricer

This example shows the workflow to price a fixed-strike `PartialLookback` instrument when you use a `Heston` model and an `AssetMonteCarlo` pricing method.

Create `PartialLookback` Instrument Object

Use `fininstrument` to create an `PartialLookback` instrument object.

```
PartialLookbackOpt = fininstrument("PartialLookback",ExerciseDate=datetime(2022,9,15),Strike=102
```

```
PartialLookbackOpt =
  PartialLookback with properties:

     MonitorDate: 15-Sep-2021
     StrikeScaler: 1
       OptionType: "call"
           Strike: 102
      AssetMinMax: NaN
    ExerciseStyle: "european"
     ExerciseDate: 15-Sep-2022
             Name: "partial_lookback_option"
```

Create `Heston` Model Object

Use `finmodel` to create a `Hestone` model object.

```
HestonModel = finmodel("Heston",V0=0.032,ThetaV=0.1,Kappa=0.003,SigmaV=0.2,RhoSV=-0.9)
```

```
HestonModel =
  Heston with properties:

        V0: 0.0320
    ThetaV: 0.1000
     Kappa: 0.0030
    SigmaV: 0.2000
     RhoSV: -0.9000
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
```

```
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,Basis=12)

myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `AssetMonteCarlo` Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo",DiscountCurve=myRC,Model=HestonModel,SpotPrice=100,simula

outPricer =
  HestonMonteCarlo with properties:

      DiscountCurve: [1x1 ratecurve]
          SpotPrice: 100
    SimulationDates: [15-Oct-2018    15-Nov-2018    15-Dec-2018    ...    ]
          NumTrials: 1000
      RandomNumbers: []
              Model: [1x1 finmodel.Heston]
       DividendType: "continuous"
      DividendValue: 0
```

Price `PartialLookback` Instrument

Use `price` to compute the price and sensitivities for the `PartialLookback` instrument.

```
[Price, outPR] = price(outPricer,PartialLookbackOpt,["all"])

Price = 19.9479

outPR =
  priceresult with properties:

       Results: [1x8 table]
    PricerData: [1x1 struct]

outPR.Results

ans=1×8 table
    Price      Delta       Gamma      Lambda     Rho      Theta     Vega     VegaLT
    _____    _______    _________    ______    _____    ______    _____    ______
```

```
    19.948    0.93159    0.0084898    4.6701    283.87    1.9218    48.04    2.666
```

More About

Partial Lookback Option

A partial lookback option gives the investor the right to exercise the option with the highest (or lowest) price of the underling asset during the partial lookback period.

Partial lookback options are called fractional lookback options because:

- The extreme values (*Smax* and *Smin*) are monitored during a subset of the lives of the options
- Only a fraction of the floating-strike values are in effect

For the latter, the factor λ (lambda) is introduced. The λ factor, represented by the optional name-value argument `StrikeScaler`, is a constant and enables the creation of the fractional floating-strike lookback option where the strike is fixed at some percentage above or below the actual extreme values (*Smax* and *Smin*).

- For calls when $\lambda \geq 1$, the call floating strike increases
- For puts when $0 \leq \lambda \leq 1$, the put floating strike decreases

Financial Instruments Toolbox software supports two types of partial lookback options: fixed and floating. The fixed-strike partial lookback option is similar to a standard fixed-strike lookback option, but the lookback period starts at a predetermined date (*T*) after the settlement date of the option. The payoff for this options is

- *Max*(0, *Smax* - *K*) for a call
- *Max*(0, *K* -*Smin*) for a put

where

Smax is the maximum value of underlying asset during the monitoring period.

Smin is the minimum value of underlying asset during the monitoring period.

K is the strike price.

The floating-strike partial lookback option is similar to a standard floating-strike lookback option, but the lookback period starts at settle and ends at a predetermined date(*T*) before expiration.

The payoff for this options is

- *Max*(0, *S* - λ × *Smin*) for a call
- *Max*(0, λ × *Smax* - *S*) for a put

where

Smax is the maximum value of underlying asset during the monitoring period.

Smin is the minimum value of underlying asset during the monitoring period.

K is the strike price.

S is the price of underlying asset.

λ, represented by `StrikeScaler`, is the degree of partiality.

Version History

Introduced in R2021b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `PartialLookback` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

ConvertibleBond

`ConvertibleBond` instrument object

Description

Create and price a `ConvertibleBond` instrument object for one of more Convertible Bond instruments using this workflow:

1. Use `fininstrument` to create a `ConvertibleBond` instrument object for one of more Convertible Bond instruments.
2. Use `finmodel` to specify a `BlackScholes` model for the `ConvertibleBond` instrument object.
3. Use `finpricer` to specify a `FiniteDifference` pricing method for one or more `ConvertibleBond` instruments.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a `ConvertibleBond` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
ConvertibleBondObj = fininstrument(InstrumentType,'
CouponRate',couponrate_value,'Maturity',maturity_date,'
ConversionRatio',conversion_ratio_value)
ConvertibleBondObj = fininstrument( ___ ,Name,Value)
```

Description

`ConvertibleBondObj = fininstrument(InstrumentType,'CouponRate',couponrate_value,'Maturity',maturity_date,'ConversionRatio',conversion_ratio_value)` creates a `ConvertibleBond` object for one of more Convertible Bond instruments by specifying `InstrumentType` and sets the properties on page 11-2558 for the required name-value pair arguments `CouponRate`, `Maturity`, and `ConversionRatio`.

`ConvertibleBondObj = fininstrument( ___ ,Name,Value)` sets optional properties on page 11-2558 using name-value pair arguments in addition to the required arguments in the previous syntax. For example, `ConvertibleBondObj = fininstrument("ConvertibleBond",'CouponRate',CouponRate,'Maturity',Maturity,'ConversionRatio',ConvRatio,'Period',Period,'Spread',Spread,'CallSchedule',CallSchedule,'CallExerciseStyle',"american")` creates an `ConvertibleBond` instrument with an American exercise and a call schedule. You can specify multiple name-value pair arguments.

Input Arguments

`InstrumentType` — Instrument type

string with value `"ConvertibleBond"` | string array with values of `"ConvertibleBond"` | character vector with value `'ConvertibleBond'` | cell array of character vectors with values of `'ConvertibleBond'`

Instrument type, specified as a string with the value of `"ConvertibleBond"`, a character vector with the value of `'ConvertibleBond'`, an `NINST`-by-`1` string array with values of `"ConvertibleBond"`, or an `NINST`-by-`1` cell array of character vectors with values of `'ConvertibleBond'`.

Data Types: `char` | `cell` | `string`

`ConvertibleBond` Name-Value Pair Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `ConvertibleBondObj = fininstrument("ConvertibleBond",'CouponRate',CouponRate, 'Maturity',Maturity,'ConversionRatio',ConvRatio,'Period',Period,'Spread',Spread,'CallSchedule',CallSchedule,'CallExerciseStyle',"american")`

Required `ConvertibleBond` Name-Value Pair Arguments

`CouponRate` — Coupon rate for `ConvertibleBond` object

scalar decimal | decimal vector | timetable

Coupon rate for the `ConvertibleBond` object, specified as the comma-separated pair consisting of `'CouponRate'` as a scalar decimal or an `NINST`-by-`1` vector of decimals for an annual rate or a timetable where the first column is dates and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Note If you are creating one or more `ConvertibleBond` instruments and use a timetable, the timetable specification applies to all of the `ConvertibleBond` instruments. `CouponRate` does not accept an `NINST`-by-`1` cell array of timetables as input.

Data Types: `double` | `timetable`

`Maturity` — Maturity date for `ConvertibleBond` object

datetime array | string array | date character vector

Maturity date for the `ConvertibleBond` object, specified as the comma-separated pair consisting of `'Maturity'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `ConvertibleBond` also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `Maturity` property is stored as a datetime.

`ConversionRatio` — Number of shares convertible from one bond
scalar numeric | numeric vector | timetable

Number of shares convertible from one bond, specified as the comma-separated pair consisting of `'ConversionRatio'` and a scalar numeric or an `NINST`-by-`1` numeric vector or a timetable where the first column is dates and the second column is associated ratios. The date in the first column indicates the last day that the conversion ratio is valid.

Note If you are creating one or more `ConvertibleBond` instruments and use a timetable, the timetable specification applies to all of the `ConvertibleBond` instruments. `ConversionRatio` does not accept an `NINST`-by-`1` cell array of timetables as input.

Data Types: `double` | `timetable`

Optional ConvertibleBond Name-Value Pair Arguments

`Spread` — Number of basis points over the reference rate
`0` (default) | scalar numeric | numeric vector

Number of basis points over the reference rate, specified as the comma-separated pair consisting of `'Spread'` and a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`CallSchedule` — Call schedule
`[ ]` (default) | timetable

Call schedule, specified as the comma-separated pair consisting of `'CallSchedule'` and a timetable of call dates and strikes.

If you use a date character vector or date string for the dates in this timetable, the format must be recognizable by `datetime` because the `CallSchedule` property is stored as a datetime.

Note For the `ConvertibleBond` instrument, you can use a `CallSchedule` with a `CallExerciseStyle` and a `PutSchedule` with a `PutExerciseStyle` simultaneously.

Data Types: `timetable`

`CallExerciseStyle` — Call option exercise style
`"European"` (default) | string with value `"European"`, `"American"`, or `"Bermudan"` | string array with values of `"European"`, `"American"`, or `"Bermudan"` | character vector with value `'European'`, `'American'`, or `'Bermudan'` | cell array of character vectors with values of `'European'`, `'American'`, or `'Bermudan'`

Call option exercise style, specified as the comma-separated pair consisting of `'CallExerciseStyle'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `string` | `char` | `cell`

`PutSchedule` — Put schedule
`[ ]` (default) | timetable

Put schedule, specified as the comma-separated pair consisting of `'PutSchedule'` and a timetable of call dates and strikes.

If you use a date character vector or date string for dates in this timetable, the format must be recognizable by `datetime` because the `PutSchedule` property is stored as a datetime.

Note For he `ConvertibleBond` instrument, you can use a `CallSchedule` with a `CallExerciseStyle` and a `PutSchedule` with a `PutExerciseStyle` simultaneously.

Data Types: `timetable`

`PutExerciseStyle` — Put option exercise style
`"European"` (default) | string with value `"European"`, `"American"`, or `"Bermudan"` | string array with values of `"European"`, `"American"`, or `"Bermudan"` | character vector with value `'European'`, `'American'`, or `'Bermudan'` | cell array of character vectors with values of `'European'`, `'American'`, or `'Bermudan'`

Put option exercise style, specified as the comma-separated pair consisting of `'PutExerciseStyle'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `string` | `cell` | `char`

`Period` — Frequency of payments per year
`2` (default) | integer | vector of integers

Frequency of payments per year, specified as the comma-separated pair consisting of `'Period'` and a scalar integer or an `NINST`-by-`1` vector of integers. Possible values for `Period` are `1`, `2`, `3`, `4`, `6`, and `12`.

Data Types: `double`

`Basis` — Day count basis
`0` (actual/actual) (default) | integer from `0` to `13` | vector of integers from `0` to `13`

Day count basis, specified as the comma-separated pair consisting of `'Basis'` and scalar integer or an `NINST`-by-`1` vector of integers using the following values:

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)

- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amount or principal value schedule
`100` (default) | scalar numeric | numeric vector | timetable

Notional principal amount or principal value schedule, specified as the comma-separated pair consisting of `'Principal'` and a scalar numeric or `NINST`-by-`1` numeric vector or a timetable.

`Principal` accepts a `timetable`, where the first column is dates and the second column is the associated notional principal value. The date indicates the last day that the principal value is valid.

Data Types: `double` | `timetable`

`DaycountAdjustedCashFlow` — Flag indicating whether cash flow adjusts for day count convention
`false` (default) | value of `true` or `false`

Flag indicating whether cash flow adjusts for the day count convention, specified as the comma-separated pair consisting of `'DaycountAdjustedCashFlow'` and a scalar logical or an `NINST`-by-`1` vector of logicals with values of `true` or `false`.

Data Types: `logical`

`BusinessDayConvention` — Business day conventions
`"actual"` (default) | string | string array | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Possible values are:

- `"actual"` — Nonbusiness days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- `"follow"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- `"modifiedfollow"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `"previous"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- `"modifiedprevious"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell` | `string`

`Holidays` — Holidays used in computing business days
`NaT` (default) | datetime array | string array | date character vector

Holidays used in computing business days, specified as the comma-separated pair consisting of `'Holidays'` and dates using an `NINST`-by-`1` vector of a datetime array, string array, or date character vectors. An example follows.

```
H = holidays(datetime('today'),datetime(2025,12,15));
ConvertibleBondObj = fininstrument("ConvertibleBond",'CouponRate',0.34,'Maturity',datetime(2025,1
'ConversionRatio',ConvRatio,'CallSchedule',schedule,'CallExerciseStyle',"american",'Holidays',H)
```

To support existing code, `ConvertibleBond` also accepts serial date numbers as inputs, but they are not recommended.

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month with 30 or fewer days
`true` (in effect) (default) | value of `true` or `false`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month with 30 or fewer days, specified as the comma-separated pair consisting of `'EndMonthRule'` and a scalar logical value or an `NINST`-by-`1` vector of logical values of `true` or `false`.

- If you set `EndMonthRule` to `false`, the software ignores the rule, meaning that a payment date is always the same numerical day of the month.
- If you set `EndMonthRule` to `true`, the software sets the rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

`IssueDate` — Bond issue date
`NaT` (default) | datetime array | string array | date character vector

Bond issue date, specified as the comma-separated pair consisting of `'IssueDate'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `ConvertibleBond` also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `IssueDate` property is stored as a datetime.

`FirstCouponDate` — Irregular first coupon date
`NaT` (default) | datetime array | string array | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of `'FirstCouponDate'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `ConvertibleBond` also accepts serial date numbers as inputs, but they are not recommended.

When you specify both `FirstCouponDate` and `LastCouponDate`, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `FirstCouponDate` property is stored as a datetime.

`LastCouponDate` — Irregular last coupon date
`NaT` (default) | datetime array | string array | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a scalar or an `NINST`-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, `ConvertibleBond` also accepts serial date numbers as inputs, but they are not recommended.

If you specify `LastCouponDate` but not `FirstCouponDate`, `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify `LastCouponDate`, the cash flow payment dates are determined from other inputs.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `LastCouponDate` property is stored as a datetime.

`StartDate` — Forward starting date of payments
`NaT` (default) | datetime array | string array | date character vector

Forward starting date of payments, specified as the comma-separated pair consisting of `'StartDate'` and a scalar or an `NINST`-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, `ConvertibleBond` also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `StartDate` property is stored as a datetime.

`Name` — User-defined name for instrument
`"  "` (default) | string | character vector

User-defined name for one of more instruments, specified as the comma-separated pair consisting of `'Name'` and a scalar string or character vector or an `NINST`-by-1 cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

Properties

`CouponRate` — Coupon annual rate
scalar decimal | decimal vector | timetable

Coupon annual rate, returned as a scalar decimal or an `NINST`-by-1 or timetable.

Data Types: `double` | `timetable`

`Maturity` — Maturity date
datetime | vector of datetimes

Maturity date, returned as a scalar datetime or an `NINST`-by-1 vector of datetimes.

Data Types: `datetime`

`ConversionRatio` — Number of shares convertible from one bond
scalar numeric | numeric vector | timetable

Number of shares convertible from one bond, returned as a scalar numeric or an `NINST`-by-`1` numeric vector an a timetable.

Data Types: `double` | `timetable`

`Spread` — Number of basis points over the reference rate
scalar numeric | numeric vector

Number of basis points over the reference rate, returned as a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`CallSchedule` — Call schedule
timetable

Call schedule, returned as a timetable.

Data Types: `timetable`

`PutSchedule` — Put schedule
timetable

Put schedule, returned as a timetable.

Data Types: `timetable`

`Period` — Coupons per year
`2` (default) | integer | vector of integers

Coupons per year, returned as a scalar integer or an `NINST`-by-`1` vector of integers.

Data Types: `double`

`Basis` — Day count basis
`0` (actual/actual) (default) | integer from `0` to `13` | vector of integers from `0` to `13`

Day count basis, returned as a scalar integer or an `NINST`-by-`1` vector of integers.

Data Types: `double`

`Principal` — Notional principal amount or principal value schedule
`100` (default) | scalar numeric | numeric vector | timetable

Notional principal amount or principal value schedule, returned as a scalar numeric or an `NINST`-by-`1` numeric vector or a timetable.

Data Types: `timetable` | `double`

`DaycountAdjustedCashFlow` — Flag indicating whether cash flow adjusts for day count convention
`false` (default) | value of `true` or `false`

Flag indicating whether cash flow adjusted for day count convention, returned as scalar logical or an NINST-by-1 vector of logicals with values of `true` or `false`.

Data Types: `logical`

`BusinessDayConvention` — Business day conventions
`"actual"` (default) | string | string array

Business day conventions, returned as a scalar string or an NINST-by-1 string array.

Data Types: `string`

`Holidays` — Holidays used in computing business days
`NaT` (default) | datetime | vector of datetimes

Holidays used in computing business days, returned as datetimes or an NINST-by-1 vector of datetimes.

Data Types: `datetime`

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month with 30 or fewer days
`true` (in effect) (default) | value of `true` or `false`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month with 30 or fewer days, returned as a scalar logical or an NINST-by-1 vector of logicals.

Data Types: `logical`

`IssueDate` — Bond issue date
`NaT` (default) | datetime | vector of datetimes

Bond issue date, returned as a scalar datetime or an NINST-by-1 vector of datetimes.

Data Types: `datetime`

`FirstCouponDate` — Irregular first coupon date
`NaT` (default) | datetime | vector of datetimes

Irregular first coupon date, returned as a scalar datetime or an NINST-by-1 vector of datetimes.

Data Types: `datetime`

`LastCouponDate` — Irregular last coupon date
`NaT` (default) | datetime | vector of datetimes

Irregular last coupon date, returned as a scalar datetime or an NINST-by-1 vector of datetimes.

Data Types: `datetime`

`StartDate` — Forward starting date of payments
`NaT` (default) | datetime | vector of datetimes

Forward starting date of payments, returned as a scalar datetime or an NINST-by-1 vector of datetimes.

Data Types: `datetime`

`CallExerciseStyle` — Call option exercise style
`"European"` (default) | string with value `"European"`, `"American"`, or `"Bermuda"` | string array with values of `"European"`, `"American"`, or `"Bermuda"`

This property is read-only.

Call option exercise style, returned as a scalar string or `NINST`-by-`1` string array with values of `"European"`, `"American"`, or `"Bermuda"`.

Data Types: `string`

`PutExerciseStyle` — Put option exercise style
`"European"` (default) | string with value `"European"`, `"American"`, or `"Bermuda"` | string array with values of `"European"`, `"American"`, or `"Bermuda"`

This property is read-only.

Put option exercise style, returned as a scalar string or an `NINST`-by-`1` string array with values of `"European"`, `"American"`, or `"Bermuda"`.

Data Types: `string`

`Name` — User-defined name for instrument
`"  "` (default) | string | string array

User-defined name for the instrument, returned as a scalar string or an `NINST`-by-`1` string array.

Data Types: `string`

Object Functions

setCallExercisePolicy	Set call exercise policy for OptionEmbeddedFixedBond, OptionEmbeddedFloatBond, or ConvertibleBond instrument
setPutExercisePolicy	Set put exercise policy for OptionEmbeddedFixedBond, OptionEmbeddedFloatBond, or ConvertibleBond instrument

Examples

Price Convertible Bond Instrument Using Black-Scholes Model and Finite Difference Pricer

This example shows the workflow to price a `ConvertibleBond` instrument when you use a `BlackScholes` model and a `FiniteDifference` pricing method.

Create `ConvertibleBond` Instrument Object

Use `fininstrument` to create a `ConvertibleBond` instrument object.

```
CouponRate = 0;
Maturity = datetime(2014,10,1);
ConvRatio = 2;
Period = 1;
Spread = 0.05;

CallExDates = datetime(2014,10,1);
CallStrike = 115;
CallSchedule = timetable(CallExDates, CallStrike);
```

```
ConvBond = fininstrument("ConvertibleBond",'CouponRate',CouponRate,'Maturity',Maturity,'Conversio
```

```
ConvBond =
  ConvertibleBond with properties:

                CouponRate: 0
           ConversionRatio: 2
                    Spread: 0.0500
                    Period: 1
                     Basis: 0
              EndMonthRule: 1
                 Principal: 100
  DaycountAdjustedCashFlow: 0
     BusinessDayConvention: "actual"
                  Holidays: NaT
                  Maturity: 01-Oct-2014
                 IssueDate: NaT
           FirstCouponDate: NaT
            LastCouponDate: NaT
                 StartDate: NaT
              CallSchedule: [1x1 timetable]
               PutSchedule: [0x0 timetable]
         CallExerciseStyle: "american"
          PutExerciseStyle: [0x0 string]
                      Name: "Convertible_Bond"
```

Create BlackScholes Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
AssetPrice = 50;
Volatility = 0.3;

BSModel = finmodel("BlackScholes",'Volatility',Volatility)
```

```
BSModel =
  BlackScholes with properties:

    Volatility: 0.3000
   Correlation: 1
```

Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
StartDate = datetime(2014,1,1);
EndDate = datetime(2015,1,1);
Rate = 0.1;

ZeroCurve = ratecurve('zero',StartDate,EndDate,Rate,'Compounding',-1,'Basis',1)
```

```
ZeroCurve =
  ratecurve with properties:

            Type: "zero"
     Compounding: -1
```

```
                Basis: 1
                Dates: 01-Jan-2015
                Rates: 0.1000
               Settle: 01-Jan-2014
         InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create FiniteDifference Pricer Object

Use `finpricer` to create a `FiniteDifference` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("FiniteDifference",'Model',BSModel,'SpotPrice',AssetPrice,'DiscountCurve',Z
```

```
outPricer =
  FiniteDifference with properties:

     DiscountCurve: [1x1 ratecurve]
             Model: [1x1 finmodel.BlackScholes]
         SpotPrice: 50
    GridProperties: [1x1 struct]
      DividendType: "continuous"
     DividendValue: 0
```

Price ConvertibleBond Instrument

Use `price` to compute the price and sensitivities for the `ConvertibleBond` instrument.

```
[Price, outPR] = price(outPricer,ConvBond,"all")
```

```
Price = 104.3812

outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×7 table
    Price     Delta      Gamma     Lambda      Theta       Rho       Vega
    ______    ______    _______    _______    _______    _______    ______

    104.38    1.3012    0.04195    0.62329    0.72984    -21.883    17.947
```

Price Multiple Convertible Bond Instruments Using Black-Scholes Model and Finite Difference Pricer

This example shows the workflow to price multiple `ConvertibleBond` instruments when you use a `BlackScholes` model and a `FiniteDifference` pricing method.

Create ConvertibleBond Instrument Object

Use `fininstrument` to create a `ConvertibleBond` instrument object for three Convertible Bond instruments.

```
ConvRatio = 2;
Period = 1;
Spread = 0.05;

CallExDates = datetime(2014,10,1);
CallStrike = 115;
CallSchedule = timetable(CallExDates, CallStrike);

ConvBond = fininstrument("ConvertibleBond",'CouponRate',[0 ; 0.1 ; 0.2],'Maturity',datetime([201
```

```
ConvBond=3×1 object
  3x1 ConvertibleBond array with properties:

    CouponRate
    ConversionRatio
    Spread
    Period
    Basis
    EndMonthRule
    Principal
    DaycountAdjustedCashFlow
    BusinessDayConvention
    Holidays
    Maturity
    IssueDate
    FirstCouponDate
    LastCouponDate
    StartDate
    CallSchedule
    PutSchedule
    CallExerciseStyle
    PutExerciseStyle
    Name
```

Create BlackScholes Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
AssetPrice = 50;
Volatility = 0.3;

BSModel = finmodel("BlackScholes",'Volatility',Volatility)
```

```
BSModel =
  BlackScholes with properties:

     Volatility: 0.3000
    Correlation: 1
```

Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
StartDate = datetime(2014,1,1);
EndDate = datetime(2015,1,1);
Rate = 0.1;

ZeroCurve = ratecurve('zero',StartDate,EndDate,Rate,'Compounding',-1,'Basis',1)
```

```
ZeroCurve =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 1
               Dates: 01-Jan-2015
               Rates: 0.1000
              Settle: 01-Jan-2014
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `FiniteDifference` Pricer Object

Use `finpricer` to create a `FiniteDifference` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("FiniteDifference",'Model',BSModel,'SpotPrice',AssetPrice,'DiscountCurve',Z
```

```
outPricer =
  FiniteDifference with properties:

     DiscountCurve: [1x1 ratecurve]
             Model: [1x1 finmodel.BlackScholes]
         SpotPrice: 50
    GridProperties: [1x1 struct]
      DividendType: "continuous"
     DividendValue: 0
```

Price `ConvertibleBond` Instruments

Use `price` to compute the prices and sensitivities for the `ConvertibleBond` instruments.

```
[Price, outPR] = price(outPricer,ConvBond,"all")
```

```
Price = 3×1

  104.3812
  198.3288
  298.3014

outPR=3×1 object
  3x1 priceresult array with properties:

    Results
    PricerData
```

```
outPR.Results
```

```
ans=1×7 table
    Price     Delta      Gamma      Lambda      Theta       Rho       Vega
    ______    _______    ________   ________    ________    _______    ______

    104.38    1.3012     0.04195    0.62329     0.72984     -21.883    17.947

ans=1×7 table
    Price     Delta      Gamma        Lambda     Theta       Rho           Vega
    ______    ______    ___________   _______    _______    ___________    ___________

    198.33      4       1.7053e-13    1.0084     300.82     2.8422e-10     2.8422e-10

ans=1×7 table
    Price     Delta       Gamma        Lambda     Theta         Rho           Vega
    ______    ______    ___________    _______    _______    ____________    ____________

    298.3       6       -1.7053e-13    1.0057     277.96     -1.7053e-09     -5.6843e-10
```

More About

Convertible Bond

A convertible bond is a financial instrument that combines equity and debt features.

A convertible bond is a bond with the embedded option to turn it into a fixed number of shares. The holder of a convertible bond has the right, but not the obligation, to exchange the convertible security for a predetermined number of equity shares at a preset price. The debt component is derived from the coupon payments and the principal. The equity component is provided by the conversion feature.

Convertible bonds have several defining features:

- Coupon — Coupons in convertible bonds are typically lower than coupons in vanilla bonds since investors are willing to take the lower coupon for the opportunity to participate in the company stock via the conversion.
- Maturity — Most convertible bonds are issued with long-stated maturities. Short-term maturity convertible bonds usually do not have call or put provisions.
- Conversion ratio — Conversion ratio is the number of shares that the holder of the convertible bond receives from exercising the call option of the convertible bond. The conversion ratio is the par value of the convertible bond divided by the conversion price of equity.

  For example, a conversion ratio of 25 means a bond can be exchanged for 25 shares of stock. This also implies a conversion price of $40 (1000/25). This, $40, is the price at which the owner would buy the shares. This can be expressed as a ratio or as the conversion price and is specified in the contract along with other provisions.
- Option type:
  - Callable convertible: Convertible bond that is callable by the issuer. The issuer of the bond forces conversion, removing the advantage that conversion is at the discretion of the bondholder. Upon call, the bondholder can either convert the bond or redeem the bond at the call price. This option enables the issuer to control the price of the convertible bond and if necessary refinance the debt with a new, cheaper bond.

- Puttable convertible: Convertible bond with a put feature that allows the bondholder to sell back the bond at a premium on a specific date. This option protects the holder against rising interest rates by reducing the year to maturity.

Tips

After creating a `ConvertibleBond` object, you can modify the `CallSchedule` and `CallExerciseStyle` using `setCallExercisePolicy`. You can modify the `PutSchedule` and `PutExerciseStyle` values using `setPutExercisePolicy`.

Version History

Introduced in R2021a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `ConvertibleBond` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

InflationBond

`InflationBond` instrument object

Description

Create and price an `InflationBond` instrument object for one or more Inflation Bond instruments using this workflow:

1. Use `fininstrument` to create an `InflationBond` instrument object for one or more Inflation Bond instruments.
2. Use `ratecurve` to specify an interest-rate model for the `InflationBond` instrument object.
3. Use `inflationcurve` to specify an inflation curve model for the `InflationBond` instrument object.
4. Use `finpricer` to specify an `Inflation` pricing method for one or more `InflationBond` instruments.
5. Use `inflationCashflows` to compute cash flows for each one of the `InflationBond` instruments.

For more detailed information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for an `InflationBond` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
InflationBond = fininstrument(InstrumentType,'CouponRate',couponrate_value,'
Maturity',maturity_date)
InflationBond = fininstrument( ___ ,Name,Value)
```

Description

`InflationBond = fininstrument(InstrumentType,'CouponRate',couponrate_value,'Maturity',maturity_date)` creates an `InflationBond` object for one or more Inflation Bond instruments by specifying `InstrumentType` and sets the properties on page 11-2573 for the required name-value pair arguments `CouponRate` and `Maturity`.

`InflationBond = fininstrument( ___ ,Name,Value)` sets optional properties on page 11-2573 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `InflationBond = fininstrument("InflationBond",'Maturity',Maturity,'CouponRate',CouponRate,'IssueDate',IssueDate)` creates a `InflationBond` option.

Input Arguments

`InstrumentType` — Instrument type

string with value `"InflationBond"` | string array with values of `"InflationBond"` | character vector with value `'InflationBond'` | cell array of character vectors with values of `'InflationBond'`

Instrument type, specified as a string with the value of `"InflationBond"`, a character vector with the value of `'InflationBond'`, an `NINST`-by-`1` string array with values of `"InflationBond"`, or an `NINST`-by-`1` cell array of character vectors with values of `'InflationBond'`.

Data Types: `char` | `cell` | `string`

`InflationBond` Name-Value Pair Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `InflationBond = fininstrument("InflationBond",'Maturity',Maturity,'CouponRate',CouponRate,'IssueDate',IssueDate)`

Required InflationBond Name-Value Pair Arguments

`CouponRate` — `InflationBond` coupon rate

scalar decimal | vector of decimals

`InflationBond` coupon rate, specified as the comma-separated pair consisting of `'CouponRate'` and a scalar decimal or an `NINST`-by-`1` vector of decimals for an annual rate.

Data Types: `double`

`Maturity` — `InflationBond` maturity date

datetime array | string array | date character vector

`InflationBond` maturity date, specified as the comma-separated pair consisting of `'Maturity'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `InflationBond` also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `Maturity` property is stored as a datetime.

Optional InflationBond Name-Value Pair Arguments

`Period` — Frequency of payments per year

`2` (default) | scalar numeric with value of `0`, `1`, `2`, `3`, `4`, `6`, or `12` | numeric vector with values of `0`, `1`, `2`, `3`, `4`, `6`, or `12`

Frequency of payments, specified as the comma-separated pair consisting of `'Period'` and a scalar integer or an `NINST`-by-`1` vector of integers. Values for `Period` are `1`, `2`, `3`, `4`, `6`, or `12`.

Data Types: `double`

Basis — Day count basis
0 (actual/actual) (default) | scalar integer from 0 to 13 | vector of integers from 0 to 13

Day count basis, specified as the comma-separated pair consisting of 'Basis' and scalar integer or an NINST-by-1 vector of integers using the following values:

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-228.

Data Types: double

Principal — Initial principal amount
100 (default) | scalar numeric | numeric vector

Initial principal amount, specified as the comma-separated pair consisting of 'Principal' and a scalar numeric or an NINST-by-1 numeric vector.

Data Types: double

DaycountAdjustedCashFlow — Flag indicating whether cash flow adjusts for day count convention
false (default) | scalar logical value of true or false | vector of logical values of true or false

Flag indicating whether cash flow is adjusted by day count convention, specified as the comma-separated pair consisting of 'DaycountAdjustedCashFlow' and a scalar logical or an NINST-by-1 vector of logicals with values of true or false.

Data Types: logical

IssueDate — Bond issue date
NaT (default) | datetime array | string array | date character vector

Bond issue date, specified as the comma-separated pair consisting of 'IssueDate' and a scalar or an NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, InflationBond also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `IssueDate` property is stored as a datetime.

`Lag` — Indexation lag in months
3 (default) | scalar numeric | numeric vector

Indexation lag in months, specified as the comma-separated pair consisting of `'Lag'` and a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`BusinessDayConvention` — Business day conventions for cash flow dates
`"actual"` (default) | string | string array | character vector | cell array of character vectors

Business day conventions for cash flow dates, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- `"actual"` — Nonbusiness days are effectively ignored. Cash flows that fall on nonbusiness days are assumed to be distributed on the actual date.
- `"follow"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- `"modifiedfollow"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day. However, if the following business day is in a different month, the previous business day is adopted instead.
- `"previous"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- `"modifiedprevious"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However, if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell` | `string`

`Holidays` — Holidays used in computing business days
`NaT` (default) | datetime array | string array | date character vector

Holidays used in computing business days, specified as the comma-separated pair consisting of `'Holidays'` and dates using an `NINST`-by-`1` vector of a datetime array, string array, or date character vectors. For example:

```
H = holidays(datetime('today'),datetime(2025,12,15));
InflationBondObj = fininstrument("InflationBond",'CouponRate',0.34,'Maturity',datetime(2025,12,15
```

To support existing code, `InflationBond` also accepts serial date numbers as inputs, but they are not recommended.

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month with 30 or fewer days
`true` (in effect) (default) | scalar logical values of `true` or `false` | vector of logical values with `true` or `false`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month with 30 or fewer days, specified as the comma-separated pair consisting of `'EndMonthRule'` and a scalar logical value or an `NINST`-by-`1` vector of logical values of `true` or `false`.

- If you set `EndMonthRule` to `false`, the software ignores the rule, meaning that a payment date is always the same numerical day of the month.
- If you set `EndMonthRule` to `true`, the software sets the rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

`FirstCouponDate` — Irregular first coupon date
`NaT` (default) | datetime array | string array | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of `'FirstCouponDate'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `InflationBond` also accepts serial date numbers as inputs, but they are not recommended.

When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `FirstCouponDate` property is stored as a datetime.

`LastCouponDate` — Irregular last coupon date
`NaT` (default) | datetime array | string array | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `InflationBond` also accepts serial date numbers as inputs, but they are not recommended.

If you specify `LastCouponDate` but not `FirstCouponDate`, `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify `LastCouponDate`, the cash flow payment dates are determined from other inputs.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `LastCouponDate` property is stored as a datetime.

`Name` — User-defined name for instrument
`''` (default) | string | string array | character vector | cell array of character vectors

User-defined name for one of more instruments, specified as the comma-separated pair consisting of `'Name'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

Properties

`CouponRate` — `InflationBond` coupon annual rate
scalar decimal | vector of decimals

`InflationBond` coupon annual rate, returned as a scalar decimal or an `NINST`-by-`1` vector of decimals.

Data Types: `double`

`Maturity` — `InflationBond` maturity date
datetime | vector of datetimes

`InflationBond` maturity date, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`Period` — Frequency of payments per year
`2` (default) | scalar integer | vector of integers

Frequency of payments per year, returned as a scalar integer or an `NINST`-by-`1` vector of integers.

Data Types: `double`

`Basis` — Day count basis
`0` (actual/actual) (default) | scalar integer from `0` to `13` | vector of integers from `0` to `13`

Day count basis, returned as a scalar integer or an `NINST`-by-`1` vector of integers.

Data Types: `double`

`Principal` — Initial principal amount
`100` (default) | scalar numeric | numeric vector

Initial principal amount, returned as a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`DaycountAdjustedCashFlow` — Flag indicating whether cash flow adjusts for day count convention
`false` (default) | scalar logical value of `true` or `false` | vector of logical values with `true` or `false`

Flag indicating whether cash flow adjusts for day count convention, returned as scalar logical or an `NINST`-by-`1` vector of logicals with values of `true` or `false`.

Data Types: `logical`

`IssueDate` — Bond issue date
`NaT` (default) | datetime | vector of datetimes

Bond issue date, returned as a datetime or an `NINST`-by-`1` datetime vector.

Data Types: `datetime`

`Lag` — Indexation lag in months
`3` (default) | scalar numeric | numeric vector

Indexation lag in months, returned as a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`BusinessDayConvention` — Business day conventions
`"actual"` (default) | string | string array

Business day conventions, returned as a scalar string or an `NINST`-by-`1` string array.

Data Types: `string`

`Holidays` — Holidays used in computing business days
`NaT` (default) | datetimes

Holidays used in computing business days, returned as an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month with 30 or fewer days
`true` (in effect) (default) | scalar logical value of `true` or `false` | vector of logicals with value of `true` or `false`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month having 30 or fewer days, returned as a scalar logical or an `NINST`-by-`1` vector of logicals.

Data Types: `logical`

`FirstCouponDate` — Irregular first coupon date
`NaT` (default) | datetime | vector of datetimes

Irregular first coupon date, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`LastCouponDate` — Irregular last coupon date
`NaT` (default) | datetime | vector of datetimes

Irregular last coupon date, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`Name` — User-defined name for instrument
`" "` (default) | string | string array

User-defined name for the instrument, returned as a scalar string or an `NINST`-by-`1` string array.

Data Types: `string`

inflationCashflows Compute cash flows for InflationBond instrument

Examples

Price Inflation Bond Instrument Using `inflationcurve` and Inflation Pricer

This example shows the workflow to price an `InflationBond` instrument when you use an `inflationcurve` and an `Inflation` pricing method.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2021,1,15);
Type = "zero";
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
ZeroCurve =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Jan-2021
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `inflationcurve` Object

Create an `inflationcurve` object using `inflationcurve`.

```
BaseDate = datetime(2020,10,1);
InflationTimes = [0 calyears([1 2 3 4 5 7 10 20 30])]';
InflationIndexValues = [100 102 103.5 105 106.8 108.2 111.3 120.1 130.4 150.2]';
InflationDates = BaseDate + InflationTimes;
myInflationCurve = inflationcurve(InflationDates,InflationIndexValues)
```

```
myInflationCurve =
  inflationcurve with properties:

                   Basis: 0
                   Dates: [10x1 datetime]
    InflationIndexValues: [10x1 double]
    ForwardInflationRates: [9x1 double]
              Seasonality: [12x1 double]
```

Create `InflationBond` Instrument Object

Use `fininstrument` to create an `InflationBond` instrument object.

```
IssueDate = datetime(2021,1,1);
Maturity = datetime(2026,1,1);
CouponRate = 0.02;

InflationBond = fininstrument("InflationBond", 'IssueDate', IssueDate, 'Maturity', Maturity, 'Cou
```

```
InflationBond =
  InflationBond with properties:

                 CouponRate: 0.0200
```

```
                    Period: 2
                     Basis: 0
                 Principal: 100
    DaycountAdjustedCashFlow: 0
                       Lag: 3
       BusinessDayConvention: "actual"
                   Holidays: NaT
              EndMonthRule: 1
                 IssueDate: 01-Jan-2021
           FirstCouponDate: NaT
            LastCouponDate: NaT
                  Maturity: 01-Jan-2026
                      Name: "inflation_bond_instrument"
```

Create `Inflation` Pricer Object

Use `finpricer` to create an `Inflation` pricer object and use the `ratecurve` object with the `'DiscountCurve'` name-value pair argument and the `inflationcurve` object with the `'InflationCurve'` name-value pair argument.

```
outPricer = finpricer("Inflation",'DiscountCurve',ZeroCurve,'InflationCurve',myInflationCurve)
```

```
outPricer =
  Inflation with properties:

     DiscountCurve: [1x1 ratecurve]
    InflationCurve: [1x1 inflationcurve]
```

Price `InflationBond` Instrument

Use `price` to compute the price and sensitivities for the `InflationBond` instrument.

```
[Price, outPR] = price(outPricer, InflationBond)
```

```
Price = 112.1856

outPR =
  priceresult with properties:

       Results: [1x1 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=table
    Price
    ______

    112.19
```

Price Multiple Inflation Bond Instruments Using `inflationcurve` and Inflation Pricer

This example shows the workflow to price multiple `InflationBond` instruments when you use an `inflationcurve` and an `Inflation` pricing method.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2020,1,15);
Type = "zero";
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
ZeroCurve =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Jan-2020
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `inflationcurve` Object

Create an `inflationcurve` object using `inflationcurve`.

```
BaseDate = datetime(2019,8,1);
InflationTimes = [0 calyears([1 2 3 4 5 7 10 20 30])]';
InflationIndexValues = [100 102 103.5 105 106.8 108.2 111.3 120.1 130.4 150.2]';
InflationDates = BaseDate + InflationTimes;
myInflationCurve = inflationcurve(InflationDates,InflationIndexValues)
```

```
myInflationCurve =
  inflationcurve with properties:

                   Basis: 0
                   Dates: [10x1 datetime]
     InflationIndexValues: [10x1 double]
    ForwardInflationRates: [9x1 double]
              Seasonality: [12x1 double]
```

Create `InflationBond` Instrument Object

Use `fininstrument` to create an `InflationBond` instrument object for three Inflation Bond instruments.

```
IssueDate = datetime([2020,1,1 ; 2019,12,1 ; 2019,11,1]);
Maturity = datetime([2026,1,1 ; 2026,2,1 ; 2026,3,1]);
CouponRate = 0.02;
```

```
InflationBond = fininstrument("InflationBond", 'IssueDate', IssueDate, 'Maturity', Maturity, 'Cou

InflationBond=3×1 object
  3x1 InflationBond array with properties:

    CouponRate
    Period
    Basis
    Principal
    DaycountAdjustedCashFlow
    Lag
    BusinessDayConvention
    Holidays
    EndMonthRule
    IssueDate
    FirstCouponDate
    LastCouponDate
    Maturity
    Name
```

Create `Inflation` Pricer Object

Use `finpricer` to create an `Inflation` pricer object and use the `ratecurve` object with the `'DiscountCurve'` name-value pair argument and the `inflationcurve` object with the `'InflationCurve'` name-value pair argument.

```
outPricer = finpricer("Inflation",'DiscountCurve',ZeroCurve,'InflationCurve',myInflationCurve)

outPricer =
  Inflation with properties:

     DiscountCurve: [1x1 ratecurve]
    InflationCurve: [1x1 inflationcurve]
```

Price `InflationBond` Instruments

Use `price` to compute the prices and sensitivities for the `InflationBond` instruments.

```
[Price, outPR] = price(outPricer, InflationBond)

Price = 3×1

  112.8769
  113.1022
  113.3434

outPR=1×3 object
  1x3 priceresult array with properties:

    Results
    PricerData

outPR.Results
```

```
ans=table
    Price
    ______

    112.88

ans=table
    Price
    _____

    113.1

ans=table
    Price
    ______

    113.34
```

More About

Inflation-Indexed Bond

An inflation-indexed bond is a security that guarantees a return higher than the rate of inflation if it is held to maturity. Inflation-indexed securities link their capital appreciation, or coupon payments, to inflation rates

Algorithms

To price an inflation-indexed bond, use an inflation curve and a nominal discount curve (model-free approach), where the cash flows are discounted using the nominal discount curve.

$$I(0,T)P_n(0,T) = I(0)P_r(0,T)$$

$$B_{TIPS}(0,T_M) = \frac{1}{I(T_0)}\sum_{i=1}^{M} cI(0)P_r(0,T_i) + FI(0)P_r(0,T_M)$$

$$= \frac{1}{I(T_0)}\sum_{i=1}^{M} cI(0,T_i)P_n(0,T_i) + FI(0,T_M)P_n(0,T_M)$$

where

- P_n is the nominal zero-coupon bond price.
- P_r is the real zero-coupon bond price.
- k is the fixed inflation rate.
- $I(0,T)$ is the breakeven inflation index for period $(0,T)$.
- $I(0)$ is the inflation index at $(t = 0)$.
- $I(T_0)$ is the base inflation index at the issue date $(t = T_0)$.
- $B_{TIPS}(0,T_M)$ is the inflation-indexed bond price.
- $I(T_{i-1})$ is the inflation index at the start date with some lag (for example, three months).

- *C* is the coupon.
- *F* is the face value.

Version History

Introduced in R2021a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `InflationBond` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

YearYearInflationSwap

`YearYearInflationSwap` instrument object

Description

Create and price a `YearYearInflationSwap` instrument object for one or more Year-on-Year Inflation-Indexed Swap instruments using this workflow:

1. Use `fininstrument` to create a `YearYearInflationSwap` instrument object for one or more Year-on-Year Inflation-Indexed Swap instruments.
2. Use `ratecurve` to specify an interest-rate model for the `YearYearInflationSwap` instrument object.
3. Use `inflationcurve` to specify an inflation curve model.
4. Use `finpricer` to specify an `Inflation` pricing method for one or more `YearYearInflationSwap` instruments.
5. Use `inflationCashflows` to compute cash flows for each one of the `YearYearInflationSwap` instruments.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a `YearYearInflationSwap` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
YYInflationSwap = fininstrument(InstrumentType,'Maturity',maturity_date,'
Notional',notional_value,'FixedInflationRate',inflation_rate)
YYInflationSwap = fininstrument( ___ ,Name,Value)
```

Description

`YYInflationSwap = fininstrument(InstrumentType,'Maturity',maturity_date,'Notional',notional_value,'FixedInflationRate',inflation_rate)` creates a `YearYearInflationSwap` object for one or more Year-on-Year Inflation-Indexed Swap instruments by specifying `InstrumentType` and sets the properties on page 11-2583 for the required name-value pair arguments `Maturity`, `Notional`, and `FixedInflationRate`.

`YYInflationSwap = fininstrument( ___ ,Name,Value)` sets optional properties on page 11-2583 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `YYInflationSwap = fininstrument("YearYearInflationSwap",'Maturity',Maturity,'FixedInflationRate',FixedInflationRate,'Notional',Notional,'Basis',4,'Lag',4)` creates a `YearYearInflationSwap` option. You can specify multiple name-value pair arguments.

Input Arguments

`InstrumentType` — Instrument type

string with value `"YearYearInflationSwap"` | string array with values of `"YearYearInflationSwap"` | character vector with value `'YearYearInflationSwap'` | cell array of character vectors with values of `'YearYearInflationSwap'`

Instrument type, specified as a string with the value of `"YearYearInflationSwap"`, a character vector with the value of `'YearYearInflationSwap'`, an `NINST`-by-`1` string array with values of `"YearYearInflationSwap"`, or an `NINST`-by-`1` cell array of character vectors with values of `'YearYearInflationSwap'`.

Data Types: `char` | `cell` | `string`

`YearYearInflationSwap` Name-Value Pair Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `YYInflationSwap = fininstrument("YearYearInflationSwap",'Maturity',Maturity,'FixedInflationRate',FixedInflationRate,'Notional',Notional,'Basis',4,'Lag',4)`

Required YearYearInflationSwap Name-Value Pair Arguments

`Maturity` — Swap maturity date

datetime array | string array | date character vector

Swap maturity date, specified as the comma-separated pair consisting of `'Maturity'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `YearYearInflationSwap` also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `Maturity` property is stored as a datetime.

`Notional` — Notional amount

scalar numeric | numeric decimal

Notional amount, specified as the comma-separated pair consisting of `'Notional'` and a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`FixedInflationRate` — Inflation rate

scalar decimal | vector of decimals

Inflation rate, specified as the comma-separated pair consisting of `'FixedInflationRate'` and a scalar decimal or an `NINST`-by-`1` vector of decimals.

Data Types: `double`

Optional YearYearInflationSwap Name-Value Pair Arguments

`Basis` — Day count basis for the fixed leg
`0` (actual/actual) (default) | scalar integer from `0` to `13` | vector of integers from `0` to `13`

Day count basis for the fixed leg, specified as the comma-separated pair consisting of `'Basis'` and a scalar integer or an `NINST`-by-`1` vector of integers for the following:

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Lag` — Indexation lag in months
`3` (default) | scalar numeric | numeric vector

Indexation lag in months, specified as the comma-separated pair consisting of `'Lag'` and a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`Name` — User-defined name for instrument
`" "` (default) | string | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of `'Name'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

Properties

`Maturity` — Swap maturity date
scalar datetime | vector of datetimes

Swap maturity date, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`Notional` — Notional amount
scalar numeric | numeric vector

Notional amount, returned as a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`FixedInflationRate` — Inflation rate
scalar decimal | vector of decimals

Inflation rate, returned as a scalar decimal or an `NINST`-by-`1` vector of decimals.

Data Types: `double`

`Basis` — Day count basis for fixed leg
`0` (actual/actual) (default) | scalar integer from `0` to `13` | vector of integers from `0` to `13`

Day count basis for fixed leg, returned as a scalar integer or an `NINST`-by-`1` vector of integers.

Data Types: `double`

`Lag` — Indexation lag in months
`3` (default) | scalar numeric | numeric vector

Indexation lag in months, returned as a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`Name` — User-defined name for instrument
`" "` (default) | scalar string | string array

User-defined name for the instrument, returned as a scalar string or an `NINST`-by-`1` string array.

Data Types: `string`

Examples

Price Year-on-Year Inflation-Indexed Swap Instrument Using `inflationcurve` and Inflation Pricer

This example shows the workflow to price a `YearYearInflationSwap` instrument when you use an `inflationcurve` object and an `Inflation` pricing method.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2021,1,15);
Type = "zero";
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
```

```
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve('zero',Settle,ZeroDates,ZeroRates)

ZeroCurve =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Jan-2021
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `inflationcurve` Object

Create an `inflationcurve` object using `inflationcurve`.

```
BaseDate = datetime(2020,10,1);
InflationTimes = [0 calyears([1 2 3 4 5 7 10 20 30])]';
InflationIndexValues = [100 102 103.5 105 106.8 108.2 111.3 120.1 130.4 150.2]';
InflationDates = BaseDate + InflationTimes;
myInflationCurve = inflationcurve(InflationDates,InflationIndexValues)

myInflationCurve =
  inflationcurve with properties:

                   Basis: 0
                   Dates: [10x1 datetime]
     InflationIndexValues: [10x1 double]
    ForwardInflationRates: [9x1 double]
              Seasonality: [12x1 double]
```

Create `YearYearInflationSwap` Instrument Object

Use `fininstrument` to create a `YearYearInflationSwap` instrument object.

```
Maturity = datetime(2025,1,1);
FixedInflationRate = 0.015;
Notional = 2000;

YYInflationSwap = fininstrument("YearYearInflationSwap",'Maturity',Maturity,'FixedInflationRate'

YYInflationSwap =
  YearYearInflationSwap with properties:

             Notional: 2000
    FixedInflationRate: 0.0150
                Basis: 0
                  Lag: 3
             Maturity: 01-Jan-2025
                 Name: "YYInflationSwap_instrument"
```

Create Inflation Pricer Object

Use finpricer to create an Inflation pricer object and use the ratecurve object with the 'DiscountCurve' name-value pair argument and the inflationcurve object with the 'InflationCurve' name-value pair argument.

```
outPricer = finpricer("Inflation",'DiscountCurve',ZeroCurve,'InflationCurve',myInflationCurve)
```

```
outPricer =
  Inflation with properties:

     DiscountCurve: [1x1 ratecurve]
    InflationCurve: [1x1 inflationcurve]
```

Price YearYearInflationSwap Instrument

Use price to compute the price and sensitivities for the YearYearInflationSwap instrument.

```
[Price,outPR] = price(outPricer,YYInflationSwap,"all")
```

```
Price = 12.5035
```

```
outPR =
  priceresult with properties:

       Results: [1x1 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=table
    Price
    ______

    12.504
```

Price Multiple Year-on-Year Inflation-Indexed Swap Instruments Using inflationcurve and Inflation Pricer

This example shows the workflow to price multiple YearYearInflationSwap instruments when you use an inflationcurve object and an Inflation pricing method.

Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2021,1,15);
Type = "zero";
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
ZeroCurve =
  ratecurve with properties:
```

```
                Type: "zero"
        Compounding: -1
              Basis: 0
              Dates: [10x1 datetime]
              Rates: [10x1 double]
             Settle: 15-Jan-2021
       InterpMethod: "linear"
  ShortExtrapMethod: "next"
   LongExtrapMethod: "previous"
```

Create `inflationcurve` Object

Create an `inflationcurve` object using `inflationcurve`.

```
BaseDate = datetime(2019,10,1);
InflationTimes = [0 calyears([1 2 3 4 5 7 10 20 30])]';
InflationIndexValues = [100 102 103.5 105 106.8 108.2 111.3 120.1 130.4 150.2]';
InflationDates = BaseDate + InflationTimes;
myInflationCurve = inflationcurve(InflationDates,InflationIndexValues)
```

```
myInflationCurve =
  inflationcurve with properties:

                   Basis: 0
                   Dates: [10x1 datetime]
    InflationIndexValues: [10x1 double]
   ForwardInflationRates: [9x1 double]
             Seasonality: [12x1 double]
```

Create `YearYearInflationSwap` Instrument Object

Use `fininstrument` to create a `YearYearInflationSwap` instrument object for three Year-on-Year Inflation-Indexed Swap instruments.

```
Maturity = datetime([2024,1,1 ; 2024,11,1 ; 2024,12,1]);
FixedInflationRate = 0.015;
Notional = [20000 ; 30000 ; 40000];

YYInflationSwap = fininstrument("YearYearInflationSwap",'Maturity',Maturity,'FixedInflationRate'
```

```
YYInflationSwap=3×1 object
  3x1 YearYearInflationSwap array with properties:

    Notional
    FixedInflationRate
    Basis
    Lag
    Maturity
    Name
```

Create `Inflation` Pricer Object

Use `finpricer` to create an `Inflation` pricer object and use the `ratecurve` object with the `'DiscountCurve'` name-value pair argument and the `inflationcurve` object with the `'InflationCurve'` name-value pair argument.

```
outPricer = finpricer("Inflation",'DiscountCurve',ZeroCurve,'InflationCurve',myInflationCurve)
```

```
outPricer =
  Inflation with properties:

     DiscountCurve: [1x1 ratecurve]
    InflationCurve: [1x1 inflationcurve]
```

Price YearYearInflationSwap Instruments

Use `price` to compute the prices and sensitivities for the `YearYearInflationSwap` instruments.

```
[Price,outPR] = price(outPricer,YYInflationSwap,"all")
```

```
Price = 3×1

   26.0701
   18.1540
    1.3201

outPR=1×3 object
  1x3 priceresult array with properties:

    Results
    PricerData
```

```
outPR.Results
```

```
ans=table
    Price
    _____

    26.07

ans=table

    ______

    18.154

ans=table
    Price
    ______

    1.3201
```

More About

Year-on-Year Inflation-Indexed Swap

A year-on-year inflation-indexed swap is a financial contract where, at the end of each accrual period, one party (the inflation receiver) pays a fixed-rate coupon and receives a floating payment linked to a specific inflation index from the other party (the inflation payer).

Algorithms

To price a year-on-year inflation-indexed swap (YYIIS), use an inflation curve and a nominal discount curve (model-free approach), where the cash flows are discounted using the nominal discount curve.

Cash flows for each year $t = \{T_1,...,T_i,...,T_M\}$:

$$FixedLeg = N \times k \times \Delta t_{fixed}$$

$$InflationLeg = N \times \left[\frac{I(T_i)}{I(T_i - 1)} - 1\right] \times \Delta t_{inflation}$$

where

- N is the reference notional of the swap.
- k is the fixed inflation rate.
- Δt_{fixed} is the fixed leg fraction for the period.
- $\Delta t_{inflation}$ is the inflation leg fraction for the period.
- $I(T_i)$ is the inflation index at the period end date with some lag (for example, three months).
- $I(T_{i\text{-}1})$ is the inflation index at the start date with some lag (for example, three months).

Version History

Introduced in R2021a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `YearYearInflationSwap` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

ZeroCouponInflationSwap

`ZeroCouponInflationSwap` instrument object

Description

Create and price a `ZeroCouponInflationSwap` instrument object for one or more Zero-Coupon Inflation Swap instruments using this workflow:

1. Use `fininstrument` to create a `ZeroCouponInflationSwap` instrument object for one or more Zero-Coupon Inflation Swap instruments.
2. Use `ratecurve` to specify an interest-rate model for the `ZeroCouponInflationSwap` instrument object.
3. Use `inflationcurve` to specify an inflation curve model.
4. Use `finpricer` to specify an `Inflation` pricing method for one or more `ZeroCouponInflationSwap` instruments.
5. Use `inflationCashflows` to compute cash flows for each one of the `ZeroCouponInflationSwap` instruments.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a `ZeroCouponInflationSwap` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
ZCInflationSwap = fininstrument(InstrumentType,'Maturity',maturity_date,'
Notional',notional_value,'FixedInflationRate',inflation_rate)
ZCInflationSwap = fininstrument( ___ ,Name,Value)
```

Description

`ZCInflationSwap = fininstrument(InstrumentType,'Maturity',maturity_date,'Notional',notional_value,'FixedInflationRate',inflation_rate)` creates a `ZeroCouponInflationSwap` object for one or more Zero-Coupon Inflation Swap instruments by specifying `InstrumentType` and sets the properties on page 11-2594 for the required name-value pair arguments `Maturity`, `Notional`, and `FixedInflationRate`.

`ZCInflationSwap = fininstrument( ___ ,Name,Value)` sets optional properties on page 11-2594 using name-value pairs in addition to the required arguments in the previous syntax. For example, `ZCInflationSwap = fininstrument("ZeroCouponInflationSwap", 'Maturity',Maturity,'Notional',Notional,'FixedInflationRate',FixedInflationRate,'StartDate',StartDate)` creates a `ZeroCouponInflationSwap` instrument. You can specify multiple name-value pair arguments.

Input Arguments

`InstrumentType` — Instrument type

string with value `"ZeroCouponInflationSwap"` | string array with values of `"ZeroCouponInflationSwap"` | character vector with value `'ZeroCouponInflationSwap'` | cell array of character vectors with values of `'ZeroCouponInflationSwap'`

Instrument type, specified as a string with the value of `"ZeroCouponInflationSwap"`, a character vector with the value of `'ZeroCouponInflationSwap'`, an `NINST`-by-`1` string array with values of `"ZeroCouponInflationSwap"`, or an `NINST`-by-`1` cell array of character vectors with values of `'ZeroCouponInflationSwap'`.

Data Types: `char` | `cell` | `string`

`ZeroCouponInflationSwap` Name-Value Pair Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `ZCInflationSwap = fininstrument("ZeroCouponInflationSwap", 'Maturity',Maturity,'Notional',Notional,'FixedInflationRate',FixedInflationRate,'StartDate',StartDate)`

Required `ZeroCouponInflationSwap` Name-Value Pair Arguments

`Maturity` — Swap maturity date

datetime array | string array | date character vector

Swap maturity date, specified as the comma-separated pair consisting of `'Maturity'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `ZeroCouponInflationSwap` also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `Maturity` property is stored as a datetime.

`Notional` — Notional amount

scalar numeric | numeric vector

Notional amount, specified as the comma-separated pair consisting of `'Notional'` and a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`FixedInflationRate` — Inflation rate

decimal | vector of decimals

Inflation rate, specified as the comma-separated pair consisting of `'FixedInflationRate'` and a scalar decimal or an `NINST`-by-`1` vector of decimals.

Data Types: `double`

Optional ZeroCouponInflationSwap Name-Value Pair Arguments

`StartDate` — Date swap starts

`Settle` date (default) | datetime array | string array | date character vector

Date swap starts, specified as the comma-separated pair consisting of `'StartDate'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. If not specified, when pricing the `ZeroCouponInflationSwap` instrument, the `Inflation` pricer uses the `Settle` date of the `DiscountCurve` as the `StartDate`.

To support existing code, `ZeroCouponInflationSwap` also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `StartDate` property is stored as a datetime.

`Basis` — Day count basis for the fixed leg

`0` (actual/actual) (default) | scalar integer from `0` to `13` | vector of integers from `0` to `13`

Day count basis for the fixed leg, specified as the comma-separated pair consisting of `'Basis'` and a scalar integer or an `NINST`-by-`1` vector of integers for the following:

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Lag` — Indexation lag in months

`3` (default) | scalar numeric | numeric vector

Indexation lag in months, specified as the comma-separated pair consisting of `'Lag'` and a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`Name` — User-defined name for instrument

`" "` (default) | string | string array | character vector | cell array of character vectors

User-defined name for the instrument, specified as the comma-separated pair consisting of `'Name'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

Properties

`Maturity` — Swap maturity date
scalar datetime | vector of datetimes

Swap maturity date, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`Notional` — Notional amount
scalar numeric | numeric vector

Notional amount, returned as a scalar numeric or an `NINST`-by-`1` vector of decimals.

Data Types: `double`

`FixedInflationRate` — Inflation rate
scalar decimal | vector of decimals

Inflation rate, returned as a scalar decimal or an `NINST`-by-`1` vector of decimals.

Data Types: `double`

`StartDate` — Date swap starts
`Settle` date (default) | scalar datetime | vector of datetimes

Date swap starts, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`Basis` — Day count basis for fixed leg
`0` (actual/actual) (default) | scalar integer from `0` to `13` | vector of integers from `0` to `13`

Day count basis for fixed leg, returned as a scalar integer or an `NINST`-by-`1` vector of integers.

Data Types: `double`

`Lag` — Indexation lag in months
`3` (default) | scalar numeric | numeric vector

Indexation lag in months, returned as a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`Name` — User-defined name for instrument
`" "` (default) | string

User-defined name for the instrument, returned as a string or an `NINST`-by-`1` string array.

Data Types: `string`

Object Functions

inflationCashflows Compute cash flows for ZeroCouponInflationSwap instrument

Examples

Price Zero Coupon Inflation Swap Instrument Using `inflationcurve` and Inflation Pricer

This example shows the workflow to price a `ZeroCouponInflationSwap` instrument when you use an `inflationcurve` object and an `Inflation` pricing method.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2021,1,15);
Type = "zero";
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
ZeroCurve =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Jan-2021
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `inflationcurve` Object

Create an `inflationcurve` object using `inflationcurve`.

```
BaseDate = datetime(2020, 10, 1);
InflationTimes = [0 calyears([1 2 3 4 5 7 10 20 30])]';
InflationIndexValues = [100 102 103.5 105 106.8 108.2 111.3 120.1 130.4 150.2]';
InflationDates = BaseDate + InflationTimes;
myInflationCurve = inflationcurve(InflationDates,InflationIndexValues)
```

```
myInflationCurve =
  inflationcurve with properties:

                   Basis: 0
                   Dates: [10x1 datetime]
     InflationIndexValues: [10x1 double]
    ForwardInflationRates: [9x1 double]
              Seasonality: [12x1 double]
```

Create ZeroCouponInflationSwap Instrument Object

Use `fininstrument` to create a `ZeroCouponInflationSwap` instrument object.

```
StartDate = datetime(2021,1,1);
Maturity = datetime(2022,10,1);
FixedInflationRate = 0.015;
Notional = 2000;

ZCInflationSwap = fininstrument("ZeroCouponInflationSwap",'StartDate',StartDate,'Maturity',Matur
```

```
ZCInflationSwap =
  ZeroCouponInflationSwap with properties:

             Notional: 2000
    FixedInflationRate: 0.0150
                Basis: 0
                  Lag: 3
            StartDate: 01-Jan-2021
             Maturity: 01-Oct-2022
                 Name: "zero_coupon_inflation_swap_instrument"
```

Create Inflation Pricer Object

Use `finpricer` to create an `Inflation` pricer object and use the `ratecurve` object with the `'DiscountCurve'` name-value pair argument and the `inflationcurve` object with the `'InflationCurve'` name-value pair argument.

```
outPricer = finpricer("Inflation",'DiscountCurve',ZeroCurve,'InflationCurve',myInflationCurve)
```

```
outPricer =
  Inflation with properties:

     DiscountCurve: [1x1 ratecurve]
    InflationCurve: [1x1 inflationcurve]
```

Price ZeroCouponInflationSwap Instrument

Use `price` to compute the price and sensitivities for the `ZeroCouponInflationSwap` instrument.

```
[Price,outPR] = price(outPricer,ZCInflationSwap,"all")
```

```
Price = 9.5675

outPR =
  priceresult with properties:

       Results: [1x1 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=table
    Price
    ______
```

```
    9.5675
```

Price Multiple Zero Coupon Inflation Swap Instruments Using `inflationcurve` and Inflation Pricer

This example shows the workflow to price multiple `ZeroCouponInflationSwap` instruments when you use an `inflationcurve` object and an `Inflation` pricing method.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2021,12,15);
Type = "zero";
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
ZeroCurve =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Dec-2021
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `inflationcurve` Object

Create an `inflationcurve` object using `inflationcurve`.

```
BaseDate = datetime(2020, 10, 1);
InflationTimes = [0 calyears([1 2 3 4 5 7 10 20 30])]';
InflationIndexValues = [100 102 103.5 105 106.8 108.2 111.3 120.1 130.4 150.2]';
InflationDates = BaseDate + InflationTimes;
myInflationCurve = inflationcurve(InflationDates,InflationIndexValues)
```

```
myInflationCurve =
  inflationcurve with properties:

                   Basis: 0
                   Dates: [10x1 datetime]
    InflationIndexValues: [10x1 double]
   ForwardInflationRates: [9x1 double]
             Seasonality: [12x1 double]
```

Create `ZeroCouponInflationSwap` Instrument Object

Use `fininstrument` to create a `ZeroCouponInflationSwap` instrument object.

```
StartDate = datetime([2021,5,1 ; 2021,6,1 ; 2021,7,1]);
Maturity = datetime([2022,10,1 ; 2022,11,1 ;2022,12,1]);
FixedInflationRate = 0.015;
Notional = [20000 ; 30000 ; 40000] ;

ZCInflationSwap = fininstrument("ZeroCouponInflationSwap",'StartDate',StartDate,'Maturity',Matur
```

```
ZCInflationSwap=3×1 object
  3x1 ZeroCouponInflationSwap array with properties:

    Notional
    FixedInflationRate
    Basis
    Lag
    StartDate
    Maturity
    Name
```

Create `Inflation` Pricer Object

Use `finpricer` to create an `Inflation` pricer object and use the `ratecurve` object with the `'DiscountCurve'` name-value pair argument and the `inflationcurve` object with the `'InflationCurve'` name-value pair argument.

```
outPricer = finpricer("Inflation",'DiscountCurve',ZeroCurve,'InflationCurve',myInflationCurve)
```

```
outPricer =
  Inflation with properties:

     DiscountCurve: [1x1 ratecurve]
    InflationCurve: [1x1 inflationcurve]
```

Price `ZeroCouponInflationSwap` Instruments

Use `price` to compute the prices and sensitivities for the `ZeroCouponInflationSwap` instruments.

```
[Price,outPR] = price(outPricer,ZCInflationSwap,"all")
```

```
Price = 3×1

   59.4576
   80.6037
   89.4137

outPR=1×3 object
  1x3 priceresult array with properties:

ans=table
    Price
    _____

    89.414
```

More About

Zero Coupon Inflation Swap

A zero coupon inflation swap is a type of derivative in which a fixed-rate payment on a notional amount is exchanged for a payment at the rate of inflation.

Algorithms

To price a zero-coupon inflation-indexed swap (ZCIS), use an inflation curve and a nominal discount curve (model-free approach), where the cash flows are discounted using the nominal discount curve.

Cash flows at maturity $t = T_M$:

$FixedLeg = N \times [(^1 - 1]$

$InflationLeg = N \times \left[\frac{I(T_M)}{I_0} - 1\right]$

where

- N is the reference notional of the swap.
- k is the fixed inflation rate.
- M is the number of years for the life of the swap.
- $I(T_M)$ is the inflation index at the maturity date with some lag (for example, three months).
- I_0 is the inflation index at the start date with some lag (for example, three months).

Version History

Introduced in R2021a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `ZeroCouponInflationSwap` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

Inflation

Create `Inflation` pricer object for `InflationBond`, `YearYearInflationSwap`, or `ZeroCouponInflationSwap` instrument using `inflationcurve` model

Description

Create and price an `InflationBond`, `YearYearInflationSwap`, or `ZeroCouponInflationSwap` instrument object with an `inflationcurve` model and an `Inflation` pricing method using this workflow:

1. Use `fininstrument` to create an `InflationBond`, `YearYearInflationSwap`, or `ZeroCouponInflationSwap` instrument object.
2. Use `inflationcurve` to specify an inflation curve object.
3. Create an interest-rate curve object using `ratecurve`.
4. Use `finpricer` to specify the `Inflation` pricer object for the `InflationBond`, `YearYearInflationSwap`, or `ZeroCouponInflationSwap` instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for an `InflationBond`, `YearYearInflationSwap`, or `ZeroCouponInflationSwap` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
InflationPricerObj = finpricer(PricerType,'DiscountCurve',ratecurve_obj,'
InflationCurve',inflationcurve_obj)
```

Description

`InflationPricerObj = finpricer(PricerType,'DiscountCurve',ratecurve_obj,'InflationCurve',inflationcurve_obj)` creates an `Inflation` pricer object by specifying `PricerType` and the required name-value pair arguments `DiscountCurve` and `InflationCurve` to set properties on page 11-2602 using name-value pairs. For example, `InflationPricerObj = finpricer("Inflation",'DiscountCurve',ZeroCurve,'InflationCurve',myInflationCurve)` creates an `Inflation` pricer object.

Input Arguments

`PricerType` — Pricer type

string with value `"Inflation"` | character vector with value `'Inflation'`

Pricer type, specified as a string with the value of `"Inflation"` or a character vector with the value of `'Inflation'`.

Data Types: `char` | `string`

`Inflation` Name-Value Pair Arguments

Specify required pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `InflationPricerObj = finpricer("Inflation",'DiscountCurve',ZeroCurve,'InflationCurve',myInflationCurve)`

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

`ratecurve` object for discounting cash flows, specified as the comma-separated pair consisting of `'DiscountCurve'` and the name of a previously created `ratecurve` object.

Data Types: `object`

`InflationCurve` — Inflation curve
`inflationcurve` object

Inflation curve, specified as the comma-separated pair consisting of `'InflationCurve'` and the name of the previously created `inflationcurve`.

Data Types: `object`

Properties

`DiscountCurve` — `ratecurve` object for discounting cash flows
object

`ratecurve` object for discounting cash flows, returned as a `ratecurve` object.

Data Types: `object`

`InflationCurve` — Inflation curve
`inflationcurve` object

Inflation curve, returned as an `inflationcurve` object.

Data Types: `object`

Object Functions

price Compute price for inflation instrument with Inflation pricer

Examples

Use Inflation Pricer and `inflationcurve` to Price Inflation Bond Instrument

This example shows the workflow to price an `InflationBond` instrument when you use an `inflationcurve` object and an `Inflation` pricing method.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2021,1,15);
Type = "zero";
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
ZeroCurve =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Jan-2021
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `inflationcurve` Object

Create an `inflationcurve` object using `inflationcurve`.

```
BaseDate = datetime(2020,10,1);
InflationTimes = [0 calyears([1 2 3 4 5 7 10 20 30])]';
InflationIndexValues = [100 102 103.5 105 106.8 108.2 111.3 120.1 130.4 150.2]';
InflationDates = BaseDate + InflationTimes;
myInflationCurve = inflationcurve(InflationDates,InflationIndexValues)
```

```
myInflationCurve =
  inflationcurve with properties:

                   Basis: 0
                   Dates: [10x1 datetime]
    InflationIndexValues: [10x1 double]
    ForwardInflationRates: [9x1 double]
              Seasonality: [12x1 double]
```

Create `InflationBond` Instrument Object

Use `fininstrument` to create an `InflationBond` instrument object.

```
IssueDate = datetime(2021,1,1);
Maturity = datetime(2026,1,1);
CouponRate = 0.02;

InflationBond = fininstrument("InflationBond",'IssueDate',IssueDate,'Maturity',Maturity,'CouponRa
```

```
InflationBond =
  InflationBond with properties:

                 CouponRate: 0.0200
```

```
                    Period: 2
                     Basis: 0
                 Principal: 100
    DaycountAdjustedCashFlow: 0
                       Lag: 3
       BusinessDayConvention: "actual"
                   Holidays: NaT

Create `Inflation` Pricer Object

Use `finpricer` to create an `Inflation` pricer object and use the `ratecurve` object with the `'DiscountCurve'` name-value pair argument and the `inflationcurve` object with the `'InflationCurve'` name-value pair argument.

```
outPricer = finpricer("Inflation",'DiscountCurve',ZeroCurve,'InflationCurve',myInflationCurve)
```

```
outPricer =
  Inflation with properties:

     DiscountCurve: [1x1 ratecurve]
    InflationCurve: [1x1 inflationcurve]
```

Price `InflationBond` Instrument

Use `price` to compute the price and sensitivities for the `InflationBond` instrument.

```
[Price,outPR] = price(outPricer,InflationBond)
```

```
Price = 112.1856

outPR =
  priceresult with properties:

       Results: [1x1 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=table
    Price
    ______

    112.19
```

Rubinstein

Create `Rubinstein` pricer object for `Cliquet` instrument using `BlackScholes` model

Description

Create and price a `Cliquet` instrument object with a `BlackScholes` model and a `Rubinstein` pricing method using this workflow:

1. Use `fininstrument` to create an `Cliquet` instrument object.
2. Use `finmodel` to specify a `BlackScholes` model for the `Cliquet` instrument object.
3. Use `finpricer` to specify a `Rubinstein` pricer object for the `Cliquet` instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for an `Cliquet` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
RubinsteinPricerObj = finpricer(PricerType,DiscountCurve=ratecurve_obj,
Model=model,SpotPrice=spotprice_value)
RubinsteinPricerObj = finpricer( ___ ,Name=Value)
```

Description

`RubinsteinPricerObj = finpricer(PricerType,DiscountCurve=ratecurve_obj, Model=model,SpotPrice=spotprice_value)` creates a `Rubinstein` pricer object by specifying `PricerType` and sets the properties on page 11-2608 for the required name-value arguments `DiscountCurve`, `Model`, and `SpotPrice`.

`RubinsteinPricerObj = finpricer( ___ ,Name=Value)` sets optional properties on page 11-3325 using additional name-value arguments in addition to the required arguments in the previous syntax. For example, `RubinsteinPricerObj = finpricer("Analytic",DiscountCurve=ratecurve_obj,Model=BSModel,SpotPrice=1000 ,DividendType="continuous",DividendValue=100,PricingMethod="Rubinstein")` creates a `Cliquet` pricer object.

Input Arguments

`PricerType` — Pricer type

string with value `"Analytic"` | character vector with value `'Analytic'`

Pricer type, specified as a string with the value of `"Analytic"` or a character vector with the value of `'Analytic'`.

Data Types: `string` | `char`

Rubinstein Name-Value Pair Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `RubinsteinPricerObj = finpricer("Analytic",DiscountCurve=ratecurve_obj,Model=BSModel,SpotPrice=1000,DividendType="continuous",DividendValue=100,PricingMethod="Rubinstein")`

Required Rubinstein Name-Value Arguments

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

`ratecurve` object for discounting cash flows, specified as `DiscountCurve` and the name of a previously created `ratecurve` object.

Note Specify a flat `ratecurve` object for `DiscountCurve`. If you use a nonflat `ratecurve` object, the software uses the rate in the `ratecurve` object at `Maturity` and assumes that the value is constant for the life of the equity option.

Data Types: `object`

`Model` — Model
`BlackScholes` model object

Model, specified as `Model` and the name of a previously created `BlackScholes` model object using `finmodel`.

Data Types: `object`

`SpotPrice` — Current price of underlying asset
nonnegative numeric

Current price of the underlying asset, specified as `SpotPrice` and a scalar nonnegative numeric.

Data Types: `double`

Optional Rubinstein Name-Value Arguments

`DividendType` — Dividend type
`"continuous"` (default) | string with value of `"continuous"` | character vector with value of `'continuous'`

Dividend type, specified as `DividendType` and a string or character vector for a continuous dividend yield.

Data Types: `char` | `string`

`DividendValue` — Dividend yield for underlying stock
`0` (default) | scalar numeric

Dividend yield for the underlying stock, specified as `DividendValue` and a scalar numeric.

Data Types: `double`

`PricingMethod` — Analytic pricing method
default pricer associated with `BlackScholes` model (default) | string with value `"Rubinstein"` | character vector with value `'Rubinstein'`

Analytic pricing method, specified as `PricingMethod` and a character vector or string.

Note The default pricing method for a `BlackScholes` model is a `BlackScholes` pricer.

Data Types: `double`

Properties

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

`ratecurve` object for discounting cash flows, returned as a `ratecurve` object.

Data Types: `object`

`Model` — Model
`BlackScholes` model object

Model, returned as a `BlackScholes` model object.

Data Types: `object`

`SpotPrice` — Current price of underlying asset
nonnegative numeric

Current price of the underlying asset, returned as a scalar nonnegative numeric.

Data Types: `double`

`DividendType` — Dividend type
`"continuous"` (default) | string with value of `"continuous"`

This property is read-only.

Dividend type, returned as a string.

Data Types: `string`

`DividendValue` — Dividend yield for underlying stock
`0` (default) | numeric

Dividend yield for the underlying stock, returned as a scalar numeric.

Data Types: `double`

`PricingMethod` — Analytic pricing method
default pricer associated with `BlackScholes` model (default) | string with value `"Rubinstein"`

Analytic pricing method, returned as a string.

Data Types: `string`

Object Functions

price Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

Examples

Use Rubinstein Pricer and Black-Scholes Model to Price the Absolure Return for Cliquet Instruments

This example shows the workflow to price the absolute return for three `Cliquet` instruments when you use a `BlackScholes` model and a `Rubinstein` pricing method.

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,Basis=12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
   ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

Create `Cliquet` Instrument Object

Use `fininstrument` to create a `Cliquet` instrument object for three Cliquet instruments.

```
ResetDates = Settle + years(0:0.25:1);
CliquetOpt = fininstrument("Cliquet",ResetDates=ResetDates,InitialStrike=[140;150;160],ExerciseS
```

```
CliquetOpt=3×1 object
  3x1 Cliquet array with properties:

    OptionType
    ExerciseStyle
    ResetDates
    LocalCap
    LocalFloor
    GlobalCap
    GlobalFloor
    ReturnType
    InitialStrike
```

```
    Name
```

Create BlackScholes Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",Volatility=0.28)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.2800
    Correlation: 1
```

Create Rubinstein Pricer Object

Use `finpricer` to create a `Rubinstein` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",DiscountCurve=myRC,Model=BlackScholesModel,SpotPrice=135,Divider
```

```
outPricer =
  Rubinstein with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 135
    DividendValue: 0.0250
     DividendType: "continuous"
```

Price Cliquet Instruments

Use `price` to compute the price and sensitivities for the three `Cliquet` instruments.

```
[Price, outPR] = price(outPricer,CliquetOpt,"all")
```

```
Price = 3×1

parametercurve

Create `parametercurve` object for storing interest-rate curve function

Description

Build a `parametercurve` object using `parametercurve`.

After creating a `parametercurve` object, you can use the associated object functions `discountfactors`, `zerorates`, `forwardrates`, `fitNelsonSiegel`, and `fitSvensson`.

For more detailed information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
parametercurve_obj = parametercurve(Type,Settle,FunctionHandle)
parametercurve_obj = parametercurve( ___ ,Name,Value)
```

Description

`parametercurve_obj = parametercurve(Type,Settle,FunctionHandle)` creates a `parametercurve` object.

`parametercurve_obj = parametercurve( ___ ,Name,Value)` sets properties on page 11-2614 using name-value pairs and any of the arguments in the previous syntax. For example, `parametercurve_obj = parametercurve('zero',datetime(2017,1,30),@(t)polyval([-0.0001 0.003 0.02],t),'Compounding',4,'Basis',5,'Parameters',[-0.0001 0.003 0.02])` creates a `parametercurve` object for a zero curve. You can specify multiple name-value pair arguments.

Input Arguments

Type — Type of interest-rate curve
string with value `"zero"`, `"forward"`, or `"discount"` | character vector with value `'zero'`, `'forward'`, or `'discount'`

Type of interest-rate curve, specified as a scalar string or character vector for one of the supported types.

Data Types: `char` | `string`

Settle — Settlement date for the curve
datetime scalar | string scalar | date character vector

Settlement date for the curve, specified as a scalar datetime, string, or date character vector.

To support existing code, `parametercurve` also accepts serial date numbers as inputs, but they are not recommended.

`FunctionHandle` — Dates corresponding to rate data

function handle

Dates corresponding to the rate data, specified as a function handle. The function handle requires one numeric input (time-to-maturity) and returns one numeric output (interest rate or discount factor). For more information on creating a function handle, see “Create Function Handle”.

Data Types: `function_handle`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example:
```
parametercurve_obj =
parametercurve('zero',datetime(2017,1,30),@(t)polyval([-0.0001 0.003
0.02],t),'Compounding',4,'Basis',5,'Parameters',[-0.0001 0.003 0.02])
```

`Compounding` — Compounding frequency for curve

`-1` (default) | possible values include: –1, `0`, `1`, `2`, `3`, `4`, `6`, `12`.

Compounding frequency for the curve, specified as the comma-separated pair consisting of `'Compounding'` and a scalar numeric using the supported values: –1, `0`, `1`, `2`, `3`, `4`, `6`, or `12`.

Data Types: `double`

`Basis` — Day count basis

`0` (actual/actual) (default) | integer from `0` to `13`

Day count basis, specified as the comma-separated pair consisting of `'Basis'` and a scalar integer.

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)

- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Parameters` — Curve parameters
`[ ]` (default) | numeric

Curve parameters, specified as the comma-separated pair consisting of `'Parameters'` and a numeric value.

Data Types: `double`

Properties

Type — Type of interest-rate curve
string with value `"zero"`, `"forward"`, or `"discount"`

Instrument type, returned as a string.

Data Types: `string`

`Settle` — Settlement date
datetime

Settlement date, returned as a datetime.

Data Types: `datetime`

`FunctionHandle` — Dates corresponding to rate data
function handle

Function handle that defines the interest-rate curve, returned as a scalar function handle.

Data Types: `function_handle`

`Compounding` — Compounding frequency for curve
`-1` (default) | possible values include: –1, `0`, `1`, `2`, `3`, `4`, `6`, `12`.

Compounding frequency for curve, returned as a scalar numeric.

Data Types: `double`

`Basis` — Day count basis
`0` (actual/actual) (default) | integer from `0` to `13`

Day count basis, returned as a scalar integer.

Data Types: `double`

`Parameters` — Curve parameters
`[ ]` (default) | numeric

Curve parameters, returned as a numeric value.

Data Types: `double`

Object Functions

discountfactors	Calculate discount factors for parametercurve object
zerorates	Calculate zero rates for parametercurve object
forwardrates	Calculate forward rates for parametercurve object
fitNelsonSiegel	Fit Nelson-Siegel model to bond market data
fitSvensson	Fit Svensson model to bond market data

Examples

Create `parametercurve` Object

Create a `parametercurve` object using `parametercurve`.

```
PCobj = parametercurve('zero',datetime(2019,9,15),@(t)polyval([-0.0001 0.003 0.02],t),'Compoundi
```

```
PCobj =
  parametercurve with properties:

              Type: "zero"
            Settle: 15-Sep-2019
       Compounding: 4
             Basis: 5
    FunctionHandle: @(t)polyval([-0.0001,0.003,0.02],t)
        Parameters: [-1.0000e-04 0.0030 0.0200]
```

Version History

Introduced in R2020a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `parametercurve` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

Topics

Asian

`Asian` instrument object

Description

Create and price an `Asian` instrument object for one ore more Asian instruments using this workflow:

1. Use `fininstrument` to create an `Asian` instrument object for one or more Asian instruments.
2. Use `finmodel` to specify a `BlackScholes`, `Heston`, `Bates`, or `Merton` model for the `Asian` instrument object.
3. Choose a pricing method.
   - When using a `BlackScholes` model, use `finpricer` to specify a `Levy`, `KemnaVorst`, `AssetTree`, or `TurnbullWakeman` pricing method for one or more `Asian` instruments.
   - When using a `BlackScholes`, `Heston`, `Bates`, or `Merton` model, use `finpricer` to specify an `AssetMonteCarlo` pricing method for one or more `Asian` instruments.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for an `Asian` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
AsianOpt = fininstrument(InstrumentType,'Strike',strike_price,'
ExerciseDate',exercise_date)
AsianOpt = fininstrument( ___ ,Name,Value)
```

Description

`AsianOpt = fininstrument(InstrumentType,'Strike',strike_price,'ExerciseDate',exercise_date)` creates an `Asian` instrument object for one or more Asian instruments by specifying `InstrumentType` and sets the properties on page 11-2620 for the required name-value pair arguments `Strike` and `ExerciseDate`.

The `Asian` instrument supports arithmetic and geometric, fixed-strike, and floating-strike Asian options.

`AsianOpt = fininstrument( ___ ,Name,Value)` sets optional properties on page 11-2620 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `AsianOpt = fininstrument("Asian",'Strike',100,'ExerciseDate',datetime(2019,1,30),'Option`

Type','put','ExerciseStyle','European','Name','asian_option') creates an Asian put option with an European exercise. You can specify multiple name-value pair arguments.

Input Arguments

InstrumentType — Instrument type

string with value "Asian" | string array with values of "Asian" | character vector with value 'Asian' | cell array of character vectors with values of 'Asian'

Instrument type, specified as a string with the value of "Asian", a character vector with the value of 'Asian', an NINST-by-1 string array with values of "Asian", or an NINST-by-1 cell array of character vectors with values of 'Asian'.

Data Types: string | char | cell

Asian Name-Value Pair Arguments

Specify required and optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: AsianOpt = fininstrument("Asian",'Strike',100,'ExerciseDate',datetime(2019,1,30),'OptionType','put','ExerciseStyle','European','Name','asian_option")

Required Asian Name-Value Pair Arguments

Strike — Option strike price value

nonnegative value | vector of nonnegative values

Option strike price value, specified as the comma-separated pair consisting of 'Strike' and a scalar nonnegative value or an NINST-by-1 vector of nonnegative values.

Data Types: double

ExerciseDate — Option exercise dates

datetime array | string array | date character vector

Option exercise date, specified as the comma-separated pair consisting of 'ExerciseDate' and a scalar or an NINST-by-1 vector using a datetime array, string array, or date character vectors.

Note For an Asian European option, there is only one ExerciseDate on the option expiry date.

To support existing code, Asian also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by datetime because the ExerciseDate property is stored as a datetime.

Optional Asian Name-Value Pair Arguments

`OptionType` — Option type
`"call"` (default) | string with value `"call"` or `"put"` | string array with values `"call"` or `"put"` | character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Option type, specified as the comma-separated pair consisting of `'OptionType'` and a scalar character vector or string or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `string` | `cell`

`ExerciseStyle` — Option exercise style
`"European"` (default) | string with value `"European"` | string array with a value `"European"` | character vector with value `'European'` | cell array of character vectors with a value `'European'`

Option exercise style, specified as the comma-separated pair consisting of `'ExerciseStyle'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `string` | `char` | `cell`

`AverageType` — Average type
`"arithmetic"` (default) | string with value `"arithmetic"` or `"geometric"` | string array with values `"arithmetic"` or `"geometric"` | character vector with value `'arithmetic'` or `'geometric'` | cell array of character vectors with values `'arithmetic'` or `'geometric'`

Average types, specified as the comma-separated pair consisting of `'AverageType'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array. Use `"arithmetic"` for an arithmetic average, or `"geometric"` for a geometric average.

Note When you use a `RollGeskeWhaley` pricer, the `AverageType` must be `"geometric"`.

Data Types: `char` | `cell` | `string`

`AveragePrice` — Average price of underlying asset
`0` (default) | scalar numeric | numeric vector

Average price of the underlying asset, specified as the comma-separated pair consisting of `'AveragePrice'` and a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`AverageStartDate` — Start date of averaging period
datetime array | string array | date character vector

Start date of averaging period, specified as the comma-separated pair consisting of `'AverageStartDate'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `Asian` also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `AverageStartDate` property is stored as a `datetime`.

Name — User-defined name for instrument
" " (default) | string | string array | character vector | cell array of character vectors

User-defined name for one of more instruments, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector or an NINST-by-1 cell array of character vectors or string array.

Data Types: char | cell | string

Properties

Strike — Option strike price value
nonnegative value | vector of nonnegative values

Option strike price value, returned as a scalar nonnegative value or an NINST-by-1 vector of nonnegative values.

Data Types: double

ExerciseDate — Option exercise date
datetime | vector of datetimes

Option exercise date, returned as a scalar datetime or an NINST-by-1 vector of datetimes.

Data Types: datetime

OptionType — Option type
"call" (default) | scalar string with value "call" or "put" | string array with values "call" or "put"

Option type, returned as a scalar string or an NINST-by-1 string array with the values of "call" or "put" .

Data Types: string

ExerciseStyle — Option exercise style
"European" (default) | scalar string with value "European" | string array with values "European"

Option exercise style, returned as a scalar string with the value "European" or NINST-by-1 string array.

Data Types: string

AverageType — Average type
"arithmetic" (default) | scalar string with value "arithmetic" or "geometric" | string array with value "arithmetic" or "geometric"

Average types, returned as a scalar string with the value "arithmetic" for arithmetic average or "geometric" for geometric average or an NINST-by-1 string array.

Data Types: string

AveragePrice — Average price of underlying asset at Settle
0 (default) | scalar numeric | numeric vector

Average price of underlying asset at Settle, returned as a scalar numeric or an NINST-by-1 numeric vector.

Data Types: `double`

`AverageStartDate` — Start date of averaging period
`NaT` (default) | datetime | vector of datetimes

Start date of averaging period, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`Name` — User-defined name for instrument
`" "` (default) | string | string array

User-defined name for the instrument, returned as a string or an `NINST`-by-`1` string array.

Data Types: `string`

Examples

Price Asian Instrument Using a Black-Scholes Model and Turnbull-Wakeman Pricer

This example shows the workflow to price a fixed-strike `Asian` instrument when you use a `BlackScholes` model and a `TurnbullWakeman` pricing method.

Create `Asian` Instrument Object

Use `fininstrument` to create an `Asian` instrument object.

```
AsianOpt = fininstrument("Asian",'ExerciseDate',datetime(2022,9,15),'Strike',1000,'OptionType',"
```

```
AsianOpt =
  Asian with properties:

          OptionType: "put"
              Strike: 1000
         AverageType: "arithmetic"
        AveragePrice: 0
    AverageStartDate: NaT
       ExerciseStyle: "european"
        ExerciseDate: 15-Sep-2022
                Name: "asian_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',.2)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.2000
    Correlation: 1
```

Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create TurnbullWakeman Pricer Object

Use finpricer to create a TurnbullWakeman pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic",'DiscountCurve',myRC,'Model',BlackScholesModel,'SpotPrice',1000
```

```
outPricer =
  TurnbullWakeman with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 1000
    DividendValue: 0
     DividendType: "continuous"
```

Price Asian Instrument

Use price to compute the price and sensitivities for the Asian instrument.

```
[Price, outPR] = price(outPricer,AsianOpt,["all"])
```

```
Price = 56.7068
```

```
outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta       Gamma      Lambda      Vega      Theta       Rho
```

```
    ______    _______    _________    _______    ______    _______    _______

    56.707    -0.3155    0.0014381    -5.5637    408.85    -2.9341    -832.53
```

Price Multiple Asian Instruments Using a Black-Scholes Model and Turnbull-Wakeman Pricer

This example shows the workflow to price multiple fixed-strike `Asian` instruments when you use a `BlackScholes` model and a `TurnbullWakeman` pricing method.

Create `Asian` Instrument Object

Use `fininstrument` to create an `Asian` instrument object for three Asian instruments.

```
AsianOpt = fininstrument("Asian",'ExerciseDate',datetime([2022,9,15; 2022,10,15; 2022,11,15]),'S
```

```
AsianOpt=3×1 object
  3x1 Asian array with properties:

    OptionType
    Strike
    AverageType
    AveragePrice
    AverageStartDate
    ExerciseStyle
    ExerciseDate
    Name
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',.2)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.2000
    Correlation: 1
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
        Compounding: -1
              Basis: 12
```

```
                Dates: 15-Sep-2023
                Rates: 0.0350
               Settle: 15-Sep-2018
         InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `TurnbullWakeman` Pricer Object

Use `finpricer` to create a `TurnbullWakeman` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'DiscountCurve',myRC,'Model',BlackScholesModel,'SpotPrice',1000,
```

```
outPricer =
  TurnbullWakeman with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 1000
    DividendValue: 0
     DividendType: "continuous"
```

Price `Asian` Instruments

Use `price` to compute the prices and sensitivities for the `Asian` instruments.

```
[Price, outPR] = price(outPricer,AsianOpt,["all"])
```

```
Price = 3×1
10^3 ×

    0.0567
    0.8023
    1.6624

outPR=3×1 object
  3x1 priceresult array with properties:

    Results
    PricerData
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta       Gamma       Lambda      Vega      Theta       Rho
    ______    ________    __________    _______    ______    _______    _______

    56.707    -0.3155    0.0014381    -5.5637    408.85    -2.9341    -832.53

ans=1×7 table
    Price      Delta        Gamma        Lambda      Vega      Theta       Rho
    ______    ________    __________    _______    ______    _______    _______
```

```
    802.32    -0.92568    7.9581e-05    -1.1537    20.935    44.139    -5206.3

ans=1×7 table

```

Price Asian Instrument Using a Black-Scholes Model and Asset Tree Pricer for CRR Binomial Tree

This example shows the workflow to price a fixed-strike `Asian` instrument when you use a `BlackScholes` model and an `AssetTree` pricing method for a Cox-Ross-Rubinstein (CRR) binomial tree.

Create `Asian` Instrument Object

Use `fininstrument` to create an `Asian` instrument object.

```
AsianOpt = fininstrument("Asian",'ExerciseDate',datetime(2022,9,15),'Strike',1000,'OptionType',"p
```

```
AsianOpt =
  Asian with properties:

          OptionType: "put"
              Strike: 1000
         AverageType: "arithmetic"
        AveragePrice: 0
    AverageStartDate: NaT
       ExerciseStyle: "european"
        ExerciseDate: 15-Sep-2022
                Name: "asian_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.2)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.2000
    Correlation: 1
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create AssetTree Pricer Object

Use `finpricer` to create an `AssetTree` pricer object for a CRR equity tree and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
NumPeriods = 15;
CRRPricer = finpricer("AssetTree",'DiscountCurve',myRC,'Model',BlackScholesModel,'SpotPrice',100
```

```
CRRPricer =
  CRRTree with properties:

            Tree: [1x1 struct]
       NumPeriods: 15
            Model: [1x1 finmodel.BlackScholes]
    DiscountCurve: [1x1 ratecurve]
        SpotPrice: 1000
     DividendType: "continuous"
    DividendValue: 0
        TreeDates: [21-Dec-2018 09:36:00    28-Mar-2019 19:12:00    ...    ]
```

```
CRRPricer.Tree
```

```
ans = struct with fields:
    Probs: [2x15 double]
    ATree: {1x16 cell}
     dObs: [15-Sep-2018 00:00:00    21-Dec-2018 09:36:00    ...    ]
     tObs: [0 0.2667 0.5333 0.8000 1.0667 1.3333 1.6000 1.8667 2.1333 ... ]
```

Price Asian Instrument

Use `price` to compute the price and sensitivities for the `Asian` instrument.

```
[Price, outPR] = price(CRRPricer,AsianOpt,["all"])
```

```
Price = 54.9225
```

```
outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta      Gamma      Vega      Lambda       Rho        Theta
    ______    ________    ______    ______    ________    ________    ________

    54.922    -0.32119    0.0581    393.85    -5.8481    -846.57    -2.4325
```

Price Asian Instrument Using a Black-Scholes Model and Asset Tree Pricer for Standard Trinomial Tree

This example shows the workflow to price a fixed-strike `Asian` instrument when you use a `BlackScholes` model and an `AssetTree` pricing method for a Standard Trinomial (STT) tree.

Create `Asian` Instrument Object

Use `fininstrument` to create an `Asian` instrument object.

```
AsianOpt = fininstrument("Asian",'ExerciseDate',datetime(2022,9,15),'Strike',1000,'OptionType',"p
```

```
AsianOpt =
  Asian with properties:

          OptionType: "put"
              Strike: 1000
         AverageType: "arithmetic"
        AveragePrice: 0
    AverageStartDate: NaT
       ExerciseStyle: "european"
        ExerciseDate: 15-Sep-2022
                Name: "asian_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.2)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.2000
    Correlation: 1
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:
```

```
                Type: "zero"
        Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create AssetTree Pricer Object

Use `finpricer` to create an `AssetTree` pricer object for a Standard Trinomial tree and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
NumPeriods = 15;
STTPricer = finpricer("AssetTree",'DiscountCurve',myRC,'Model',BlackScholesModel,'SpotPrice',100
```

```
STTPricer =
  STTree with properties:

            Tree: [1x1 struct]
       NumPeriods: 15
           Model: [1x1 finmodel.BlackScholes]
    DiscountCurve: [1x1 ratecurve]
        SpotPrice: 1000
     DividendType: "continuous"
    DividendValue: 0
        TreeDates: [21-Dec-2018 09:36:00    28-Mar-2019 19:12:00    ...    ]
```

```
STTPricer.Tree
```

```
ans = struct with fields:
    ATree: {1x16 cell}
    Probs: {1x15 cell}
     dObs: [15-Sep-2018 00:00:00    21-Dec-2018 09:36:00    ...    ]
     tObs: [0 0.2667 0.5333 0.8000 1.0667 1.3333 1.6000 1.8667 2.1333 ... ]
```

Price Asian Instrument

Use `price` to compute the price and sensitivities for the `Asian` instrument.

```
[Price, outPR] = price(STTPricer,AsianOpt,["all"])
```

```
Price = 54.2450
```

```
outPR =
  priceresult with properties:

      Results: [1x7 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta       Gamma       Vega      Lambda       Rho       Theta
```

```
    _____    ________    ________    _____    _______    _______    _______

    54.245    -0.32307    0.075269    390.55    -5.9558    -839.02    -2.4161
```

Price Asian Instrument for Foreign Exchange Using Black-Scholes Model and Levy Pricer

This example shows the workflow to price an `Asian` instrument for an arithmetic average currency option when you use a `BlackScholes` model and a `Levy` pricing method. Assume that the current exchange rate is $0.52 and has a volatility of 12% per annum. The annualized continuously compounded foreign risk-free rate is 8% per annum.

Create `Asian` Instrument Object

Use `fininstrument` to create an `Asian` instrument object.

```
AsianOpt = fininstrument("Asian",'ExerciseDate',datetime(2022,9,15),'Strike',0.65,'OptionType',"p
```

```
AsianOpt =
  Asian with properties:

         OptionType: "put"
             Strike: 0.6500
        AverageType: "arithmetic"
       AveragePrice: 0
   AverageStartDate: NaT
      ExerciseStyle: "european"
       ExerciseDate: 15-Sep-2022
               Name: "asian_fx_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
Sigma = .12;
BlackScholesModel = finmodel("BlackScholes",'Volatility',Sigma)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.1200
    Correlation: 1
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:
```

```
                Type: "zero"
        Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create Levy Pricer Object

Use `finpricer` to create a `Levy` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument. When you price currencies using an Asian instrument for an arithmetic average currency option, the `DividendType` must be `'continuous'` and `DividendValue` is the annualized risk-free interest rate in the foreign country.

```
ForeignRate = 0.08;
outPricer = finpricer("analytic",'DiscountCurve',myRC,'Model',BlackScholesModel,'SpotPrice',.52,
```

```
outPricer =
  Levy with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 0.5200
    DividendValue: 0.0800
     DividendType: "continuous"
```

Price Asian FX Instrument

Use `price` to compute the price and sensitivities for the `Asian` FX instrument.

```
[Price, outPR] = price(outPricer,AsianOpt,["all"])
```

```
Price = 0.1516

outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×7 table
     Price      Delta       Gamma      Lambda       Vega         Theta          Rho
    _______    ________    _______    _______    ________    __________    _______

    0.15161    -0.78532    0.37534    -2.6935    0.015668    -0.0038317    -1.3974
```

Price Asian Instrument Using a Black-Scholes Model and Asset Monte-Carlo Pricer

This example shows the workflow to price a fixed-strike `Asian` instrument when you use a `BlackScholes` model and an `AssetMonteCarlo` pricing method.

Create `Asian` Instrument Object

Use `fininstrument` to create an `Asian` instrument object.

```
AsianOpt = fininstrument("Asian",'ExerciseDate',datetime(2022,9,15),'Strike',1000,'OptionType',"p
```

```
AsianOpt =
  Asian with properties:

          OptionType: "put"
              Strike: 1000
         AverageType: "arithmetic"
        AveragePrice: 0
    AverageStartDate: NaT
       ExerciseStyle: "european"
        ExerciseDate: 15-Sep-2022
                Name: "asian_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.2)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.2000
    Correlation: 1
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create AssetMonteCarlo Pricer Object

Use finpricer to create an AssetMonteCarlo pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo",'DiscountCurve',myRC,"Model",BlackScholesModel,'SpotPrice
```

```
outPricer =
  GBMMonteCarlo with properties:

     DiscountCurve: [1x1 ratecurve]
         SpotPrice: 200
    SimulationDates: 15-Sep-2022
         NumTrials: 1000
     RandomNumbers: []
             Model: [1x1 finmodel.BlackScholes]
      DividendType: "continuous"
     DividendValue: 0
```

Price Asian Instrument

Use price to compute the price and sensitivities for the Asian instrument.

```
[Price, outPR] = price(outPricer,AsianOpt,["all"])
```

```
Price = 682.3365
```

```
outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta         Gamma         Lambda       Rho      Theta      Vega
    _____    ________    ___________    ________    _______    _____    _______

    682.34    -0.93511    -5.6843e-14    -0.27409    -3129.1    27.433    -1.2121
```

Price Asian Instrument Using a Merton Model and Asset Monte-Carlo Pricer

This example shows the workflow to price a fixed-strike Asian instrument when you use a Merton model and an AssetMonteCarlo pricing method.

Create Asian Instrument Object

Use fininstrument to create an Asian instrument object.

```
AsianOpt = fininstrument("Asian",'ExerciseDate',datetime(2022,9,15),'Strike',1000,'OptionType',"p
```

```
AsianOpt =
  Asian with properties:
```

```
          OptionType: "put"
              Strike: 1000
         AverageType: "arithmetic"
        AveragePrice: 0
    AverageStartDate: NaT
       ExerciseStyle: "european"
        ExerciseDate: 15-Sep-2022
                Name: "asian_option"
```

Create `Merton` Model Object

Use `finmodel` to create a `Merton` model object.

```
MertonModel = finmodel("Merton",'Volatility',0.45,'MeanJ',0.02,'JumpVol',0.07,'JumpFreq',0.09)
```

```
MertonModel =
  Merton with properties:

    Volatility: 0.4500
         MeanJ: 0.0200
       JumpVol: 0.0700
      JumpFreq: 0.0900
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `AssetMonteCarlo` Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo",'DiscountCurve',myRC,"Model",MertonModel,'SpotPrice',200
```

```
outPricer =
  MertonMonteCarlo with properties:
```

```
      DiscountCurve: [1x1 ratecurve]
          SpotPrice: 200
    SimulationDates: 15-Sep-2022
          NumTrials: 1000
      RandomNumbers: []
              Model: [1x1 finmodel.Merton]
       DividendType: "continuous"
      DividendValue: 0
```

Price Asian Instrument

Use `price` to compute the price and sensitivities for the `Asian` instrument.

```
[Price, outPR] = price(outPricer,AsianOpt,["all"])
```

```
Price = 682.8127

outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta      Gamma      Lambda       Rho       Theta      Vega
    _____    ________    _____    ________    ________    _____    _______

    682.81    -0.90665      0      -0.26556    -3110.3    25.98    19.316
```

More About

Asian Option

An Asian option is a path-dependent option with a payoff linked to the average value of the underlying asset during the life (or some part of the life) of the option.

Asian options are similar to lookback options in that there are two types of Asian options: fixed (average price option) and floating (average strike option). Fixed Asian options have a specified strike, while floating Asian options have a strike equal to the average value of the underlying asset over the life of the option. For more information, see “Asian Option” on page 3-34.

Version History

Introduced in R2020a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `Asian` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

Barrier

`Barrier` instrument object

Description

Create and price a `Barrier` instrument object for one or more Barrier instruments using this workflow:

1. Use `fininstrument` to create a `Barrier` instrument object for one or more Barrier instruments.
2. Use `finmodel` to specify a `BlackScholes`, `Heston`, `Bates`, or `Merton` model for the `Barrier` instrument object.
3. Choose a pricing method.
   - When using a `BlackScholes` model, use `finpricer` to specify a `BlackScholes`, `AssetTree`, or `VannaVolga` pricing method for one or more `Barrier` instruments.
   - When using a `BlackScholes`, `Heston`, `Bates`, or `Merton` model, use `finpricer` to specify an `AssetMonteCarlo` or `FiniteDifference` pricing method for one ore more `Barrier` instruments.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a `Barrier` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
BarrierOpt = fininstrument(InstrumentType,'Strike',strike_value,'
ExerciseDate',exercise_date,'BarrierValue',barrier_value)
BarrierOpt = fininstrument( ___ ,Name,Value)
```

Description

`BarrierOpt = fininstrument(InstrumentType,'Strike',strike_value,'ExerciseDate',exercise_date,'BarrierValue',barrier_value)` creates a `Barrier` instrument object for one or more Barrier instruments by specifying `InstrumentType` and sets the properties on page 11-2639 for the required name-value pair arguments `Strike`, `ExerciseDate`, and `BarrierValue`.

`BarrierOpt = fininstrument( ___ ,Name,Value)` sets optional properties on page 11-2639 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `BarrierOpt = fininstrument("Barrier",'Strike',100,'ExerciseDate',datetime(2019,1,30),'BarrierValue',110,'OptionType',"put",'ExerciseStyle',"European",'BarrierType',"DO`

",'Name',"barrier_option") creates a Barrier put option with an European exercise. You can specify multiple name-value pair arguments.

Input Arguments

InstrumentType — Instrument type

string with value "Barrier" | string with value "Barrier" | string array with values of "Barrier" | character vector with value 'Barrier' | cell array of character vectors with values of 'Barrier'

Instrument type, specified as a string with the value of "Barrier", a character vector with the value of 'Barrier', an NINST-by-1 string array with values "Barrier", or an NINST-by-1 cell array of character vectors with values of 'Barrier'.

Data Types: char | string | cell

Barrier Name-Value Pair Arguments

Specify required and optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: BarrierOpt = fininstrument("Barrier",'Strike',100,'ExerciseDate',datetime(2019,1,30),'BarrierValue',110,'OptionType',"put",'ExerciseStyle',"European",'BarrierType',"DO",'Name',"barrier_option")

Required Barrier Name-Value Pair Arguments

Strike — Option strike value

nonnegative value | vector of nonnegative values

Option strike value, specified as the comma-separated pair consisting of 'Strike' and a scalar nonnegative value or an NINST-by-1 vector of nonnegative values.

Data Types: double

ExerciseDate — Option exercise date

datetime array | string array | date character vector

Option exercise date, specified as the comma-separated pair consisting of 'ExerciseDate' and a scalar or an NINST-by-1 vector using a datetime array, string array, or date character vectors.

Note For a European option, there is only one ExerciseDate on the option expiry date.

To support existing code, Barrier also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by datetime because the ExerciseDate property is stored as a datetime.

BarrierValue — Barrier level

scalar numeric | numeric vector

Barrier level, specified as the comma-separated pair consisting of `'BarrierLevel'` and a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

Optional Barrier Name-Value Pair Arguments

`OptionType` — Option type
`"call"` (default) | string with value `"call"` or `"put"` | string array with values `"call"` or `"put"` | character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Option type, specified as the comma-separated pair consisting of `'OptionType'` and a scalar character vector or string or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

`ExerciseStyle` — Option exercise style
`"European"` (default) | string with value `"European"` or `"American"` | string array with values `"European"` or `"American"` | character vector with value `'European'` or `'American'` | cell array of character vectors with values `'European'` or `'American'`

Option exercise style, specified as the comma-separated pair consisting of `'ExerciseStyle'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Note For a `Barrier` option, the `BlackScholes` pricer supports only `"European"` exercise and the `FiniteDifference` pricer supports an `"American"` or `"European"` exercise.

Data Types: `string` | `char` | `cell`

`BarrierType` — Barrier option type
`"UO"` (default) | string with value `"UI"`, `"UO"`, `"DI"`, or `"DO"` | string array with values `"UI"`, `"UO"`, `"DI"`, or `"DO"` | character vector with value `'UI'`, `'UO'`, `'DI'`, or `'DO'` | cell array of character vectors with values `'UI'`, `'UO'`, `'DI'`, or `'DO'`

Barrier option type, specified as the comma-separated pair consisting of `'BarrierType'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array with one of the following values:

- `"UI"` — Up knock-in

  This option becomes effective when the price of the underlying asset passes above the barrier level. If the underlying asset goes above the barrier level during the life of the option, the option holder has the right, but not the obligation, to buy or sell (call or put) the underlying security at the strike price.
- `"UO"` — Up knock-out

  This option gives the option holder the right, but not the obligation, to buy or sell (call or put) the underlying security at the strike price as long as the underlying asset does not go above the barrier level during the life of the option. This option terminates when the price of the underlying security passes above the barrier level. If the spot price of the underlying asset reaches or exceeds the barrier level with an up-and-out option, the rebate is paid.
- `"DI"` — Down knock-in

This option becomes effective when the price of the underlying stock passes below the barrier level. If the underlying security goes below the barrier level during the life of the option, the option holder has the right, but not the obligation, to buy or sell (call or put) the underlying security at the strike price. With a down-and-in option, the rebate is paid if the spot price of the underlying does not reach the barrier level during the life of the option. Note that a `Barrier` instrument using the `FiniteDifference` pricer does not support American knock-in barrier options.

- `"DO"` — Down knock-up

  This option gives the option holder the right, but not the obligation, to buy or sell (call or put) the underlying asset at the strike price as long as the underlying asset does not go below the barrier level during the life of the option. This option terminates when the price of the underlying security passes below the barrier level. If the option is worthless when it expires, the option holder receives a rebate amount.

Option	Barrier Type	Payoff If Barrier Crossed	Payoff If Barrier Not Crossed
Call or Put	Down knock-out	Worthless	Standard Call or Put
Call or Put	Down knock-in	Call or Put	Worthless
Call or Put	Up knock-out	Worthless	Standard Call or Put
Call or Put	Up knock-in	Standard Call or Put	Worthless

Data Types: `char` | `cell` | `string`

`Rebate` — Rebate value
`0` (default) | scalar numeric | numeric vector

Rebate value, specified as the comma-separated pair consisting of `'Rebate'` and a scalar numeric or an `NINST`-by-`1` numeric vector.

- For knock-in options, the `Rebate` is paid at expiry.
- For knock-out options, the `Rebate` is paid when `BarrierValue` is reached.

Data Types: `double`

`Name` — User-defined name for instrument
`" "` (default) | string | string array | character vector | cell array of character vectors

User-defined name for the instrument, specified as the comma-separated pair consisting of `'Name'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

Properties

`Strike` — Option strike value
nonnegative value | vector of nonnegative values

Option strike value, returned as a scalar nonnegative value or an `NINST`-by-`1` vector of nonnegative values.

Data Types: `double`

`ExerciseDate` — Option exercise date
datetime | vector of datetimes

Option exercise date, returned as a datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`OptionType` — Option type
`"call"` (default) | string with value `"call"` or `"put"` | string array with values `"call"` or `"put"`

Option type, returned as a scalar string or an `NINST`-by-`1` string array with the values of `"call"` or `"put"`.

Data Types: `string`

`ExerciseStyle` — Option exercise style
`"European"` (default) | string with value `"European"` or `"American"` | string array with values `"European"` or `"American"`

Option exercise style, returned as a scalar string or `NINST`-by-`1` string array with the values of `"European"` or `"American"`.

Data Types: `string`

`BarrierSpec` — Barrier option type
`"UO"` European (default) | string with value `"UI"`, `"UO"`, `"DI"`, or `"DO"` | string array with values `"UI"`, `"UO"`, `"DI"`, or `"DO"`

Barrier option type, returned as a scalar string or `NINST`-by-`1` string array with the values of `"UI"`, `"UO"`, `"DI"`, or `"DO"`.

Data Types: `string`

`BarrierValue` — Barrier level
scalar numeric | numeric vector

Barrier level, returned as a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`Rebate` — Rebate value
`0` (default) | scalar numeric | numeric vector

Rebate value, returned as a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`Name` — User-defined name for instrument
`" "` (default) | string | string array

User-defined name for the instrument, returned as a string or an `NINST`-by-`1` string array.

Data Types: `string`

Examples

Price Barrier Instrument Using Black-Scholes Model and Finite Difference Pricer

This example shows the workflow to price an `Barrier` instrument when you use a `BlackScholes` model and a `FiniteDifference` pricing method.

Create `Barrier` Instrument Object

Use `fininstrument` to create an `Barrier` instrument object.

```
BarrierOpt = fininstrument("Barrier",'Strike',45,'ExerciseDate',datetime(2019,1,1),'OptionType','
```

```
BarrierOpt =
  Barrier with properties:

       OptionType: "call"
           Strike: 45
      BarrierType: "do"
     BarrierValue: 40
           Rebate: 0
    ExerciseStyle: "american"
     ExerciseDate: 01-Jan-2019
             Name: "barrier_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.30)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.3000
    Correlation: 1
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,1,1);
Maturity = datetime(2023,1,1);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',1)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
        Compounding: -1
              Basis: 1
              Dates: 01-Jan-2023
              Rates: 0.0350
             Settle: 01-Jan-2018
       InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create FiniteDifference Pricer Object

Use finpricer to create a FiniteDifference pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("FiniteDifference",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPri
```

```
outPricer =
  FiniteDifference with properties:

     DiscountCurve: [1x1 ratecurve]
             Model: [1x1 finmodel.BlackScholes]
         SpotPrice: 50
    GridProperties: [1x1 struct]
      DividendType: "continuous"
     DividendValue: 0
```

Price Barrier Instrument

Use price to compute the price and sensitivities for the Barrier instrument.

```
[Price, outPR] = price(outPricer,BarrierOpt,["all"])
```

```
Price = 8.5014

outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta       Gamma       Lambda     Theta      Rho       Vega
    ______    _______    _________    ______    _______    ______    ______

    8.5014    0.85673    0.0057199    5.0388    -1.8461    26.238    6.1837
```

Price Multiple Barrier Instruments Using Black-Scholes Model and Finite Difference Pricer

This example shows the workflow to price multiple Barrier instruments when you use a BlackScholes model and a FiniteDifference pricing method.

Create Barrier Instrument Object

Use fininstrument to create an Barrier instrument object for three Barrier instruments.

```
BarrierOpt = fininstrument("Barrier",'Strike',45,'ExerciseDate',datetime([2019,1,1; 2019,2,1 ; 20
```

```
BarrierOpt=3×1 object
  3x1 Barrier array with properties:

    OptionType
```

```
    Strike
    BarrierType
    BarrierValue
    Rebate
    ExerciseStyle
    ExerciseDate
    Name
```

Create BlackScholes Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.30)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.3000
    Correlation: 1
```

Create ratecurve Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,1,1);
Maturity = datetime(2023,1,1);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',1)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 1
               Dates: 01-Jan-2023
               Rates: 0.0350
              Settle: 01-Jan-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create FiniteDifference Pricer Object

Use `finpricer` to create a `FiniteDifference` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("FiniteDifference",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPric
```

```
outPricer =
  FiniteDifference with properties:

     DiscountCurve: [1x1 ratecurve]
             Model: [1x1 finmodel.BlackScholes]
         SpotPrice: 50
    GridProperties: [1x1 struct]
```

```
      DividendType: "continuous"
     DividendValue: 0
```

Price Barrier Instruments

Use `price` to compute the prices and sensitivities for the `Barrier` instruments.

```
[Price, outPR] = price(outPricer,BarrierOpt,["all"])
```

```
Price = 3×1

    8.5014
    9.7112
    9.9901

outPR=3×1 object
  3x1 priceresult array with properties:

    Results
    PricerData
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta       Gamma       Lambda     Theta      Rho       Vega
    _____    ________    _________    ______    ________    _____    ______

    8.5014    0.85673    0.0057199    5.0388    -1.8461    26.238    6.1837

ans=1×7 table
    Price      Delta       Gamma       Lambda     Theta      Rho       Vega
    _____    ________    _________    ______    ________    _____    ______

    9.7112    0.73186    0.020793     3.7681    -3.2754    29.014    16.885

ans=1×7 table
    Price      Delta       Gamma       Lambda     Theta      Rho       Vega

    9.9901    0.7296     0.020326     3.6516    -3.2151    30.872    17.803
```

Price Barrier Instrument Using Black-Scholes Model and Asset Tree Pricer for EQP Binomial Tree

This example shows the workflow to price an `Barrier` instrument when you use a `BlackScholes` model and an `AssetTree` pricing method using an Equal Probability (EQP) tree.

Create Barrier Instrument Object

Use `fininstrument` to create an `Barrier` instrument object.

```
BarrierOpt = fininstrument("Barrier",'Strike',45,'ExerciseDate',datetime(2019,1,1),'OptionType','
```

```
BarrierOpt =
  Barrier with properties:

       OptionType: "call"
           Strike: 45
      BarrierType: "do"
     BarrierValue: 40
           Rebate: 0
    ExerciseStyle: "american"
     ExerciseDate: 01-Jan-2019
             Name: "barrier_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.30)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.3000
    Correlation: 1
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,1,1);
Maturity = datetime(2023,1,1);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',1)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 1
               Dates: 01-Jan-2023
               Rates: 0.0350
              Settle: 01-Jan-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `AssetTree` Pricer Object

Use `finpricer` to create an `AssetTree` pricer object with an EQP equity tree and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
NumPeriods = 15;
EQPPricer = finpricer("AssetTree",'DiscountCurve',myRC,'Model',BlackScholesModel,'SpotPrice',1000
```

```
EQPPricer =
  EQPTree with properties:
```

```
            Tree: [1x1 struct]
       NumPeriods: 15
            Model: [1x1 finmodel.BlackScholes]
    DiscountCurve: [1x1 ratecurve]
        SpotPrice: 1000
     DividendType: "continuous"
    DividendValue: 0
        TreeDates: [25-Jan-2018 08:00:00    18-Feb-2018 16:00:00    ...    ]
```

```
EQPPricer.Tree
```

```
ans = struct with fields:
    Probs: [2x15 double]
    ATree: {1x16 cell}
     dObs: [01-Jan-2018 00:00:00    25-Jan-2018 08:00:00    ...    ]

Price `Barrier` Instrument

Use `price` to compute the price and sensitivities for the `Barrier` instrument.

```
[Price, outPR] = price(EQPPricer,BarrierOpt,["all"])
```

```
Price = 956.5478
```

```
outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×7 table

Price Barrier Instrument Using Black-Scholes Model and Asset Tree Pricer for Standard Trinomial Tree

This example shows the workflow to price an `Barrier` instrument when you use a `BlackScholes` model and an `AssetTree` pricing method using a Standard Trinomial (STT) tree.

Create `Barrier` Instrument Object

Use `fininstrument` to create an `Barrier` instrument object.

```
BarrierOpt = fininstrument("Barrier",'Strike',45,'ExerciseDate',datetime(2019,1,1),'OptionType','
```

```
BarrierOpt =
  Barrier with properties:

       OptionType: "call"
           Strike: 45
      BarrierType: "do"
     BarrierValue: 40
           Rebate: 0
    ExerciseStyle: "american"
     ExerciseDate: 01-Jan-2019
             Name: "barrier_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.30)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.3000
    Correlation: 1
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,1,1);
Maturity = datetime(2023,1,1);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',1)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
       Compounding: -1
             Basis: 1
             Dates: 01-Jan-2023
             Rates: 0.0350
            Settle: 01-Jan-2018
      InterpMethod: "linear"
  ShortExtrapMethod: "next"
```

```
     LongExtrapMethod: "previous"
```

Create AssetTree Pricer Object

Use `finpricer` to create an `AssetTree` pricer object with a Standard Trinomial (STT) equity tree and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
NumPeriods = 15;
STTPricer = finpricer("AssetTree",'DiscountCurve',myRC,'Model',BlackScholesModel,'SpotPrice',1000
```

```
STTPricer =
  STTree with properties:

             Tree: [1x1 struct]
       NumPeriods: 15
            Model: [1x1 finmodel.BlackScholes]
    DiscountCurve: [1x1 ratecurve]
        SpotPrice: 1000
     DividendType: "continuous"
    DividendValue: 0
        TreeDates: [25-Jan-2018 08:00:00    18-Feb-2018 16:00:00    ...    ]
```

```
STTPricer.Tree
```

```
ans = struct with fields:
    ATree: {1x16 cell}
    Probs: {1x15 cell}
     dObs: [01-Jan-2018 00:00:00    25-Jan-2018 08:00:00    ...    ]
     tObs: [0 0.0667 0.1333 0.2000 0.2667 0.3333 0.4000 0.4667 0.5333 ... ]
```

Price Barrier Instrument

Use `price` to compute the price and sensitivities for the `Barrier` instrument.

```
[Price, outPR] = price(STTPricer,BarrierOpt,["all"])
```

```
Price = 956.5444
```

```
outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×7 table
    Price     Delta       Gamma          Vega       Lambda     Rho       Theta
    ______    _____    ___________    _________    ______    ______    _______

    956.54      1      -1.9331e-17    -0.20023    1.0454    44.112    -1.514
```

```
outPR.PricerData.PriceTree
```

```
ans = struct with fields:
     PTree: {1x16 cell}
```

```
    ExTree: {1x16 cell}
      tObs: [0 0.0667 0.1333 0.2000 0.2667 0.3333 0.4000 0.4667 0.5333 ... ]
      dObs: [01-Jan-2018    25-Jan-2018    18-Feb-2018    ...    ]
     Probs: {1x15 cell}
```

Price Barrier Instrument Using Black-Scholes Model and Asset Monte-Carlo Pricer

This example shows the workflow to price an `Barrier` instrument when you use a `BlackScholes` model and a `AssetMonteCarlo` pricing method.

Create `Barrier` Instrument Object

Use `fininstrument` to create an `Barrier` instrument object.

```
BarrierOpt = fininstrument("Barrier",'Strike',45,'ExerciseDate',datetime(2019,1,1),'OptionType','
```

```
BarrierOpt =
  Barrier with properties:

       OptionType: "call"
           Strike: 45
      BarrierType: "do"
     BarrierValue: 40
           Rebate: 0
    ExerciseStyle: "american"
     ExerciseDate: 01-Jan-2019
             Name: "barrier_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.30)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.3000
    Correlation: 1
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,1,1);
Maturity = datetime(2023,1,1);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',1)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
          Compounding: -1
```

```
                Basis: 1
                Dates: 01-Jan-2023
                Rates: 0.0350
               Settle: 01-Jan-2018
         InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create AssetMonteCarlo Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo",'DiscountCurve',myRC,"Model",BlackScholesModel,'SpotPrice
```

```
outPricer =
  GBMMonteCarlo with properties:

      DiscountCurve: [1x1 ratecurve]
          SpotPrice: 200
    SimulationDates: 01-Jan-2019
          NumTrials: 1000
      RandomNumbers: []
              Model: [1x1 finmodel.BlackScholes]
       DividendType: "continuous"
      DividendValue: 0
```

Price Barrier Instrument

Use `price` to compute the price and sensitivities for the `Barrier` instrument.

```
[Price, outPR] = price(outPricer,BarrierOpt,["all"])
```

```
Price = 156.6270
```

```
outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×7 table
    Price     Delta        Gamma        Lambda     Rho     Theta     Vega
    ______    ______    ___________    ______    _____    _____    _______

    156.63    1.0004    -7.6028e-12    1.2774    43.45      0      0.67904
```

Price Barrier Instrument Using Heston Model and Asset Monte-Carlo Pricer

This example shows the workflow to price an `Barrier` instrument when you use a `Heston` model and an `AssetMonteCarlo` pricing method.

Create `Barrier` Instrument Object

Use `fininstrument` to create an `Barrier` instrument object.

```
BarrierOpt = fininstrument("Barrier",'Strike',45,'ExerciseDate',datetime(2019,1,1),'OptionType','
```

```
BarrierOpt =
  Barrier with properties:

       OptionType: "call"
           Strike: 45
      BarrierType: "do"
     BarrierValue: 40
           Rebate: 0
    ExerciseStyle: "american"
     ExerciseDate: 01-Jan-2019
             Name: "barrier_option"
```

Create `Heston` Model Object

Use `finmodel` to create a `Heston` model object.

```
HestonModel = finmodel("Heston",'V0',0.032,'ThetaV',0.1,'Kappa',0.003,'SigmaV',0.2,'RhoSV',0.9)
```

```
HestonModel =
  Heston with properties:

         V0: 0.0320
    ThetaV: 0.1000
     Kappa: 0.0030
    SigmaV: 0.2000
     RhoSV: 0.9000
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,1,1);
Maturity = datetime(2023,1,1);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',1)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 1
               Dates: 01-Jan-2023
               Rates: 0.0350
              Settle: 01-Jan-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create AssetMonteCarlo Pricer Object

Use finpricer to create an AssetMonteCarlo pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo",'DiscountCurve',myRC,"Model",HestonModel,'SpotPrice',200
```

```
outPricer =
  HestonMonteCarlo with properties:

     DiscountCurve: [1x1 ratecurve]
         SpotPrice: 200
    SimulationDates: 01-Jan-2019
         NumTrials: 1000
     RandomNumbers: []
             Model: [1x1 finmodel.Heston]
      DividendType: "continuous"
     DividendValue: 0
```

Price Barrier Instrument

Use price to compute the price and sensitivities for the Barrier instrument.

```
[Price, outPR] = price(outPricer,BarrierOpt,["all"])
```

```
Price = 156.9962

outPR =
  priceresult with properties:

       Results: [1x8 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×8 table
    Price    Delta       Gamma       Lambda     Rho     Theta     Vega      VegaLT
    _____    _____    __________    ______    _____    _____    ______    _________

     157     1.0022    -1.08e-12     1.2768    43.45      0      2.7882    0.0013677
```

More About

Barrier Option

A barrier option has not only a strike price but also a barrier level and sometimes a rebate.

The payoff for this type of option depends on whether the underlying asset crosses the predetermined trigger value (barrier level), indicated by BarrierValue, during the life of the option. If the option cannot be exercised because the barrier level either has or has not been reached, a fixed rebate amount is paid. For more information, see “Barrier Option” on page 3-20.

Version History

Introduced in R2020a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `Barrier` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

DoubleBarrier

`DoubleBarrier` instrument object

Description

Create and price a `DoubleBarrier` instrument object for one of more Double Barrier instruments using this workflow:

1. Use `fininstrument` to create a `DoubleBarrier` instrument object for one of more Double Barrier instruments.
2. Use `finmodel` to specify a `BlackScholes`, `Heston`, `Bates`, or `Merton` model for the `DoubleBarrier` instrument object.
3. Choose a pricing method.
   - When using a `BlackScholes` model, use `finpricer` to specify an `IkedaKunitomo` or `VannaVolga` pricing method for one or more `DoubleBarrier` instruments.
   - When using a `BlackScholes`, `Heston`, `Bates`, or `Merton` model, use `finpricer` to specify a `FiniteDifference` or an `AssetMonteCarlo` pricing method for one or more `DoubleBarrier` instruments.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a `DoubleBarrier` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
DoubleBarrierOpt = fininstrument(InstrumentType,'Strike',strike_value,'
ExerciseDate',exercise_date,'BarrierValue',barrier_value)
DoubleBarrierOpt = fininstrument( ___ ,Name,Value)
```

Description

`DoubleBarrierOpt = fininstrument(InstrumentType,'Strike',strike_value,'ExerciseDate',exercise_date,'BarrierValue',barrier_value)` creates a `DoubleBarrier` instrument object for one of more Double Barrier instruments by specifying `InstrumentType` and sets properties on page 11-2657 using the required name-value pair arguments `Strike`, `ExerciseDate`, and `BarrierValue`.

`DoubleBarrierOpt = fininstrument( ___ ,Name,Value)` sets optional properties on page 11-2657 using additional name-value pair arguments in addition to the required arguments in the previous syntax. For example, `DoubleBarrierOpt = fininstrument("DoubleBarrier",'Strike',100,'ExerciseDate',datetime(2019,1,30),'BarrierValue',110,'OptionType',"put",'ExerciseStyle',"European",'BarrierTyp`

e',"DKI",'Name',"doublebarrier_option") creates a DoubleBarrier put option with a European exercise. You can specify multiple name-value pair arguments.

Input Arguments

InstrumentType — Instrument type

string with value "DoubleBarrier" | string array with values of "DoubleBarrier" | character vector with value 'DoubleBarrier' | cell array of character vectors with values of 'DoubleBarrier'

Instrument type, specified as a string with the value of "DoubleBarrier", a character vector with the value of 'DoubleBarrier', an NINST-by-1 string array with values of "DoubleBarrier", or an NINST-by-1 cell array of character vectors with values of 'DoubleBarrier'.

Data Types: char | cell | string

DoubleBarrier Name-Value Pair Arguments

Specify required and optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: DoubleBarrierOpt = fininstrument("DoubleBarrier",'Strike',100,'ExerciseDate',datetime(2019,1,30),'BarrierValue',110,'OptionType',"put",'ExerciseStyle',"European",'BarrierType',"DKI",'Name',"doublebarrier_option")

Required DoubleBarrier Name-Value Pair Arguments

Strike — Option strike value

nonnegative value | vector of nonnegative values

Option strike price value, specified as the comma-separated pair consisting of 'Strike' and a scalar nonnegative value or an NINST-by-1 vector of nonnegative values.

Data Types: double

ExerciseDate — Option exercise date

datetime array | string array | date character vector

Option exercise date, specified as the comma-separated pair consisting of 'ExerciseDate' and a scalar or an NINST-by-1 vector using a datetime array, string array, or date character vectors.

Note For a European option, there is only one ExerciseDate value on the option expiry date.

To support existing code, DoubleBarrier also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by datetime because the ExerciseDate property is stored as a datetime.

BarrierValue — Double barrier value

numeric

Double barrier value, specified as the comma-separated pair consisting of 'BarrierValue' and an NINST-by-1 matrix of numeric values, where each element is a 1-by-2 vector where the first column is Barrier(1)(UB) and the second column is Barrier(2)(LB). Barrier(1) must be greater than Barrier(2).

Data Types: double

Optional DoubleBarrier Name-Value Pair Arguments

OptionType — Option type

"call" (default) | string with value "call" or "put" | string array with values "call" or "put" | character vector with value 'call' or 'put' | cell array of character vectors with values 'call' or 'put'

Option type, specified as the comma-separated pair consisting of 'OptionType' and a scalar string or character vector or an NINST-by-1 cell array of character vectors or string array.

Data Types: char | cell | string

ExerciseStyle — Option exercise style

"European" (default) | string with value "European" or "American" | string array with values "European" or "American" | character vector with value 'European' or 'American' | cell array of character vectors with values 'European' or 'American'

Option exercise style, specified as the comma-separated pair consisting of 'ExerciseStyle' and a scalar string or character vector or an NINST-by-1 cell array of character vectors or string array.

Note For a DoubleBarrier option, the IkedaKunitomo pricer supports only a "European" exercise and the FiniteDifference pricer supports an "American" or "European" exercise.

Data Types: string | cell | char

BarrierType — Double barrier type

"DKO" (default) | string with value of "DKI" or "DKO" | string array with values of "DKI" or "DKO" | character vector with value of 'DKI' or 'DKO' | cell array of character vectors with values of 'DKI' or 'DKO'

Double barrier type, specified as the comma-separated pair consisting of 'BarrierType' and a scalar character vector or string or an NINST-by-1 cell array of character vectors or string array with one of the following values:

- 'DKI' — Double knock-in

  The 'DKI' option becomes effective when the price of the underlying asset reaches one of the barriers. It gives the option holder the right but not the obligation to buy or sell the underlying security at the strike price, if the underlying asset goes above or below the barrier levels during the life of the option.

- 'DKO' — Double knock-out

  The 'DKO' option gives the option holder the right but not the obligation to buy or sell the underlying security at the strike price, as long as the underlying asset remains between the barrier levels during the life of the option. This option terminates when the price of the underlying asset passes one of the barriers.

Option	Barrier Type	Payoff If Any Barrier Crossed	Payoff If Barriers Not Crossed
Call/Put	Double Knock-in	Standard Call/Put	Worthless
Call/Put	Double Knock-out	Worthless	Standard Call/Put

Data Types: `char` | `cell` | `string`

`Rebate` — Barrier rebate
`[0 0]` (default) | numeric

Barrier rebate, specified as the comma-separated pair consisting of `'Rebate'` and a numeric matrix.

- For knock-in options, the `Rebate` is paid at expiry.
- For knock-out options, the `Rebate` is paid if the Upper Barrier(1)(UB) is hit and the second value is paid if the Lower Barrier(2)(LB) is hit.

Data Types: `double`

`Name` — User-defined name for instrument
`" "` (default) | string | string array | character vector | cell array of character vectors

User-defined name for the instrument, specified as the comma-separated pair consisting of `'Name'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

Properties

`Strike` — Option strike price value
nonnegative value | vector of nonnegative values

Option strike price value, returned as a scalar nonnegative value or an `NINST`-by-`1` vector of nonnegative values.

Data Types: `double`

`ExerciseDate` — Option exercise date
datetime | vector of datetimes

Option exercise date, returned as a datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`BarrierValue` — Double barrier value
numeric

Double barrier value, returned as a numeric matrix.

Data Types: `double`

`OptionType` — Option type
`"call"` (default) | string with value `"call"` or `"put"` | string array with values `"call"` or `"put"`

Option type, returned as a scalar string or an NINST-by-1 string array with the values `"call"` or `"put"`.

Data Types: `string`

`ExerciseStyle` — Option exercise style
`"European"` (default) | string with value `"European"` or `"American"` | string array with values `"European"` or `"American"`

Option exercise style, returned as a scalar string or an NINST-by-1 string array with the values of `"European"` or `"American"`.

Data Types: `string`

`BarrierType` — Double barrier type
`"DKO"` (default) | string with value of `"DKI"` or `"DKO"` | string array with values of `"DKI"` or `"DKO"`

Double barrier type, returned as a scalar string or an NINST-by-1 string array with the values of `"DKI"` or `"DKO"`.

Data Types: `string`

`Rebate` — Barrier rebate
`[0 0]` (default) | numeric

Barrier rebate, returned as a numeric matrix.

Data Types: `double`

`Name` — User-defined name for instrument
`" "` (default) | string | string array

User-defined name for the instrument, returned as a scalar string or an NINST-by-1 string array.

Data Types: `string`

Examples

Price Double Barrier Instrument Using Black-Scholes Model and Finite Difference Pricer

This example shows the workflow to price an `DoubleBarrier` instrument when you use a `BlackScholes` model and a `FiniteDifference` pricing method.

Create `DoubleBarrier` Instrument Object

Use `fininstrument` to create a `DoubleBarrier` instrument object.

```
DoubleBarrierOpt = fininstrument("DoubleBarrier",'Strike',75,'ExerciseDate',datetime(2019,1,1),'
```

```
DoubleBarrierOpt =
  DoubleBarrier with properties:

       OptionType: "call"
           Strike: 75
     BarrierValue: [110 80]
    ExerciseStyle: "american"
     ExerciseDate: 01-Jan-2019
```

```
      BarrierType: "dko"
           Rebate: [0 0]
             Name: "doublebarrier_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.30)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.3000
    Correlation: 1
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,1,1);
Maturity = datetime(2023,1,1);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',1)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 1
               Dates: 01-Jan-2023
               Rates: 0.0350
              Settle: 01-Jan-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `FiniteDifference` Pricer Object

Use `finpricer` to create a `FiniteDifference` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("FiniteDifference",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPric
```

```
outPricer =
  FiniteDifference with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 100
    GridProperties: [1x1 struct]
      DividendType: "continuous"
     DividendValue: 0
```

Price DoubleBarrier Instrument

Use `price` to compute the price and sensitivities for the `DoubleBarrier` instrument.

```
[Price, outPR] = price(outPricer,DoubleBarrierOpt,["all"])
```

```
Price = 25

outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×7 table
    Price    Delta    Gamma    Lambda      Theta       Rho    Vega
    _____    _____    _____    ______    __________    ___    ____

     25        1        0        4       2.2737e-13     0      0
```

Price Multiple Double Barrier Instruments Using Black-Scholes Model and Finite Difference Pricer

This example shows the workflow to price multiple `DoubleBarrier` instruments when you use a `BlackScholes` model and a `FiniteDifference` pricing method.

Create DoubleBarrier Instrument Object

Use `fininstrument` to create a `DoubleBarrier` instrument object for three Double Barrier instruments.

```
DoubleBarrierOpt = fininstrument("DoubleBarrier",'Strike',[75 ; 85 ; 95],'ExerciseDate',datetime
```

```
DoubleBarrierOpt=3×1 object
  3x1 DoubleBarrier array with properties:

    OptionType
    Strike
    BarrierValue
    ExerciseStyle
    ExerciseDate
    BarrierType
    Rebate
    Name
```

Create BlackScholes Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.30)
```

```
BlackScholesModel =
  BlackScholes with properties:
```

```
     Volatility: 0.3000
    Correlation: 1
```

Create ratecurve Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,1,1);
Maturity = datetime(2023,1,1);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',1)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
        Compounding: -1
               Basis: 1
               Dates: 01-Jan-2023
               Rates: 0.0350
              Settle: 01-Jan-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create FiniteDifference Pricer Object

Use `finpricer` to create a `FiniteDifference` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("FiniteDifference",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPric
```

```
outPricer =
  FiniteDifference with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 100
    GridProperties: [1x1 struct]
      DividendType: "continuous"
     DividendValue: 0
```

Price DoubleBarrier Instruments

Use `price` to compute the prices and sensitivities for the `DoubleBarrier` instruments.

```
[Price, outPR] = price(outPricer,DoubleBarrierOpt,["all"])
```

```
Price = 3×1

   25.0000
   15.6821
    7.8957
```

```
outPR=3×1 object
  3x1 priceresult array with properties:

    Results
    PricerData
```

```
outPR.Results
```

```
ans=1×7 table
    Price    Delta    Gamma    Lambda      Theta       Rho    Vega
    _____    _____    _____    _______    __________    ___    ____

     25        1        0        4       2.2737e-13     0      0
```

```
ans=1×7 table
    Price     Delta      Gamma      Lambda     Theta      Rho      Vega
    ______    ______    _______    ______    _______    _____    _______

    15.682    0.7196    0.28626    4.5887    0.88484    6.467    -6.3778
```

```
ans=1×7 table
    Price      Delta       Gamma       Lambda      Theta       Rho       Vega
    ______    _______    __________    ______    _________    ______    _______

    7.8957    0.36913    -0.0020435    4.675     -0.057311    4.3022    -6.9367
```

Price Double Barrier Instrument Using a Heston Model and Asset Monte Carlo Pricer

This example shows the workflow to price a `DoubleBarrier` instrument when you use a `Heston` model and an `AssetMonteCarlo` pricing method.

Create `DoubleBarrier` Instrument Object

Use `fininstrument` to create a `DoubleBarrier` instrument object.

```
DoubleBarrierOpt = fininstrument("DoubleBarrier",'Strike',75,'ExerciseDate',datetime(2020,9,15),
```

```
DoubleBarrierOpt =
  DoubleBarrier with properties:

       OptionType: "call"
           Strike: 75
     BarrierValue: [110 80]
    ExerciseStyle: "american"
     ExerciseDate: 15-Sep-2020
      BarrierType: "dko"
           Rebate: [0 0]
             Name: "doublebarrier_option"
```

Create `Heston` Model Object

Use `finmodel` to create a `Heston` model object.

```
HestonModel = finmodel("Heston",'V0',0.032,'ThetaV',0.1,'Kappa',0.003,'SigmaV',0.2,'RhoSV',0.9)
```

```
HestonModel =
  Heston with properties:

       V0: 0.0320
    ThetaV: 0.1000
     Kappa: 0.0030
    SigmaV: 0.2000
     RhoSV: 0.9000
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
        Compounding: -1
              Basis: 12
              Dates: 15-Sep-2023
              Rates: 0.0350
             Settle: 15-Sep-2018
       InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `AssetMonteCarlo` Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo",'DiscountCurve',myRC,"Model",HestonModel,'SpotPrice',102
```

```
outPricer =
  HestonMonteCarlo with properties:

     DiscountCurve: [1x1 ratecurve]
         SpotPrice: 102
    SimulationDates: 15-Sep-2020
          NumTrials: 1000
      RandomNumbers: []
              Model: [1x1 finmodel.Heston]
       DividendType: "continuous"
      DividendValue: 0
```

Price `DoubleBarrier` Instrument

Use `price` to compute the price and sensitivities for the `DoubleBarrier` instrument.

```
[Price, outPR] = price(outPricer,DoubleBarrierOpt,["all"])

Price = 32.6351

outPR =
  priceresult with properties:

      Results: [1x8 table]
    PricerData: [1x1 struct]

outPR.Results

ans=1×8 table
    Price        Delta          Gamma          Lambda         Rho       Theta      Vega        VegaLT
    _____    ___________    ___________    ___________    _______    ______    _______    ________

    32.635    -0.00089196    -0.0025511    -0.0027878    -76.828    1.1334    -0.2616    -0.00298
```

Price Double Barrier Instrument Using a Black-Scholes Model and Asset Monte Carlo Pricer

This example shows the workflow to price a `DoubleBarrier` instrument when you use a `BlackScholes` model and an `AssetMonteCarlo` pricing method.

Create `DoubleBarrier` Instrument Object

Use `fininstrument` to create a `DoubleBarrier` instrument object.

```
DoubleBarrierOpt = fininstrument("DoubleBarrier",'Strike',100,'ExerciseDate',datetime(2020,8,15),

DoubleBarrierOpt =
  DoubleBarrier with properties:

       OptionType: "call"
           Strike: 100
     BarrierValue: [110 80]
    ExerciseStyle: "american"
     ExerciseDate: 15-Aug-2020
      BarrierType: "dko"
           Rebate: [0 0]
             Name: "doublebarrier_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes","Volatility",.3)

BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.3000
    Correlation: 1
```

Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```
Settle = datetime(2017,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
        Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2017
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create AssetMonteCarlo Pricer Object

Use finpricer to create an AssetMonteCarlo pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
ExerciseDate = datetime(2020,08,15);
Settle = datetime(2017,09,15);
outPricer = finpricer("AssetMonteCarlo","DiscountCurve",myRC,"Model",BlackScholesModel,'SpotPrice
```

Price DoubleBarrier Instrument

Use price to compute the price and sensitivities for the DoubleBarrier instrument.

```
[Price, outPR] = price(outPricer,DoubleBarrierOpt,["all"])
```

```
Price = 6.9667

outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta       Gamma       Lambda      Rho       Theta      Vega
    ______    _______    _________    ______    _______    ______    _______

    6.9667    0.26875    -0.096337    3.8576    0.39855    9.5406    -1.2907
```

Price DoubleBarrier Instrument Using Black-Scholes Model and IkedaKunitomo Pricer

This example shows the workflow to price a `DoubleBarrier` instrument when you use a `BlackScholes` model and an `IkedaKunitomo` pricing method.

Create `DoubleBarrier` Instrument Object

Use `fininstrument` to create a `DoubleBarrier` instrument object.

```
DoubleBarrierOpt = fininstrument("DoubleBarrier",'Strike',100,'ExerciseDate',datetime(2020,8,15),
```

```
DoubleBarrierOpt =
  DoubleBarrier with properties:

      OptionType: "call"
          Strike: 100
     BarrierValue: [110 80]
    ExerciseStyle: "european"
     ExerciseDate: 15-Aug-2020
      BarrierType: "dko"
           Rebate: [0 0]
             Name: "doublebarrier_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes","Volatility",.3)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.3000
    Correlation: 1
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2017,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2017
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create IkedaKunitomo Pricer Object

Use `finpricer` to create an `IkedaKunitomo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("Analytic","DiscountCurve",myRC,"Model",BlackScholesModel,'SpotPrice',100,
```

```
outPricer =
  IkedaKunitomo with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 100
    DividendValue: 0.0290
     DividendType: "continuous"
        Curvature: [0.0300 -0.0300]
```

Price DoubleBarrier Instrument

Use `price` to compute the price and sensitivities for the `DoubleBarrier` instrument.

```
[Price, outPR] = price(outPricer,DoubleBarrierOpt,["all"])
```

```
Price = 5.6848e-04

outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×7 table
      Price          Delta          Gamma        Lambda        Vega          Theta           Rho
    __________    ___________    ___________    _______    _________    _________    ____________

    0.00056848    -3.7713e-05    -4.2071e-06    -6.6339    -0.031332    0.0008912    -0.00035113
```

Price Double Barrier Instrument Using Black-Scholes Model and Vanna Volga Pricer

This example shows the workflow to price a `DoubleBarrier` instrument when you use a `BlackScholes` model and a `VannaVolga` pricing method.

Create DoubleBarrier Instrument Object

Use `fininstrument` to create a `DoubleBarrier` instrument object.

```
DoubleBarrierOpt = fininstrument("DoubleBarrier",'Strike',100,'ExerciseDate',datetime(2020,8,15),
```

```
DoubleBarrierOpt =
  DoubleBarrier with properties:

       OptionType: "call"
```

```
          Strike: 100
     BarrierValue: [110 80]
    ExerciseStyle: "european"
     ExerciseDate: 15-Aug-2020
      BarrierType: "dko"
           Rebate: [0 0]
             Name: "doublebarrier_option"
```

Create BlackScholes Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes","Volatility",0.02)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.0200
    Correlation: 1
```

Create ratecurve Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2019,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create VannaVolga Pricer Object

Use `finpricer` to create a `VannaVolga` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
VolRR = -0.0045;
VolBF = 0.0037;
RateF = 0.0210;
outPricer = finpricer("VannaVolga","DiscountCurve",myRC,"Model",BlackScholesModel,'SpotPrice',100
```

```
outPricer =
  VannaVolga with properties:

    DiscountCurve: [1x1 ratecurve]
```

```
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 100
     DividendType: "continuous"
    DividendValue: 0.0210
     VolatilityRR: -0.0045
     VolatilityBF: 0.0037
```

Price DoubleBarrier Instrument

Use `price` to compute the price and sensitivities for the `DoubleBarrier` instrument.

```
[Price, outPR] = price(outPricer,DoubleBarrierOpt,["all"])
```

```
Price = 1.6450
```

```
outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×7 table
    Price     Delta     Gamma     Lambda     Vega      Theta      Rho
    _____    _______    ______    ______    ______    _______    ______

    1.645    0.82818    75.662    50.346    14.697    -1.3145    74.666
```

More About

Double Barrier Option

A double barrier option is similar to the standard single barrier option except that they have two barrier levels: a lower barrier (LB) and an upper barrier (UB).

The payoff for a double barrier option depends on whether the underlying asset remains between the barrier levels during the life of the option. Double barrier options are less expensive than single barrier options as the probability of being knocked out is higher. Because of this, double barrier options allow investors to achieve reduction in the option premiums and match an investor’s belief about the future movement of the underlying price process.

There are two types of double barrier options:

- Double knock-in

  This option becomes effective when the price of the underlying asset reaches one of the barriers. It gives the option holder the right but not the obligation to buy or sell the underlying security at the strike price, if the underlying asset goes above or below the barrier levels during the life of the option.
- Double knock-out

  This option gives the option holder the right but not the obligation to buy or sell the underlying security at the strike price, as long as the underlying asset remains between the barrier levels

during the life of the option. This option terminates when the price of the underlying asset passes one of the barriers.

The payoff for this type of option depends on whether the underlying asset crosses the predetermined trigger value (barrier level), indicated by `BarrierValue`, during the life of the option. If the option cannot be exercised because the barrier level either has or has not been reached, a fixed rebate amount is paid. For more information, see “Double Barrier Option” on page 3-21.

Tips

After creating an `DoubleBarrier` instrument object with an `ExerciseStyle` set to `"American"`, you can modify the `ExerciseStyle` property to change it to `"European"` using dot notation.

```
DoubleBarrier.ExerciseStyle = "European"
```

Because a European option has a scalar `Strike` and `ExerciseDate` value and an American option has a 2-element vector for `Strike` and `ExerciseDate` values, when you change to `ExerciseStyle` from `"American"` to `"European"`, the `Strike` and `ExerciseDate` values become the last element in the 2-element vector for the `Strike` and `ExerciseDate` values.

Version History

Introduced in R2020b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `DoubleBarrier` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

“Supported Exercise Styles” on page 1-62

Touch

`Touch` instrument object

Description

Create and price a `Touch` instrument object for one or more Touch instruments using this workflow:

1. Use `fininstrument` to create a `Touch` instrument object for one or more Touch instruments.
2. Use `finmodel` to specify a `BlackScholes`, `Bates`, `Merton`, or `Heston` model for the `Touch` instrument object.
3. Choose a pricing method.
   - When using a `BlackScholes` model, use `finpricer` to specify a `BlackScholes` or a `VannaVolga` pricing method for one or more `Barrier` instruments.
   - When using a `BlackScholes`, `Heston`, `Bates`, or `Merton` model, use `finpricer` to specify an `AssetMonteCarlo` pricing method for one or more `Touch` instruments.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a `Touch` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
TouchOpt = fininstrument(InstrumentType,'ExerciseDate',exercise_date,'
BarrierValue',barrier_value,'PayoffValue',payoff_value)
TouchOpt = fininstrument( ___ ,Name,Value)
```

Description

`TouchOpt = fininstrument(InstrumentType,'ExerciseDate',exercise_date,'BarrierValue',barrier_value,'PayoffValue',payoff_value)` creates a `Touch` instrument object for one or more Touch instruments by specifying `InstrumentType` and sets properties on page 11-2673 using the required name-value pair arguments `ExerciseDate`, `BarrierValue`, and `PayoffValue`.

`TouchOpt = fininstrument( ___ ,Name,Value)` sets optional properties on page 11-2673 using additional name-value pair arguments in addition to the required arguments in the previous syntax. For example, `TouchOpt = fininstrument("Touch",'ExerciseDate',datetime(2019,1,30),'BarrierValue',110,'PayoffValue',130,'BarrierType',"OT",'PayoffType',"Expiry",'Name',"Touch_option")` creates a `Touch` option with an expiry payoff type. You can specify multiple name-value pair arguments.

Input Arguments

`InstrumentType` — Instrument type

string with value `"Touch"` | string array with values of `"Touch"` | character vector with value `'Touch'` | cell array of character vectors with values of `'Touch'`

Instrument type, specified as a string with the value of `"Touch"`, a character vector with the value of `'Touch'`, an `NINST`-by-`1` string array with values of `"Touch"`, or an `NINST`-by-`1` cell array of character vectors with values of `'Touch'`.

Data Types: `char` | `cell` | `string`

`Touch` Name-Value Pair Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `TouchOpt = fininstrument("Touch",'ExerciseDate',datetime(2019,1,30),'BarrierValue',110,'PayoffValue',130,'BarrierType',"OT",'PayoffType',"Expiry",'Name',"Touch_option")`

Required `Touch` Name-Value Pair Arguments

`ExerciseDate` — Option exercise date

datetime array | string array | date character vector

Option exercise date, specified as the comma-separated pair consisting of `'ExerciseDate'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `Touch` also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `ExerciseDate` property is stored as a datetime.

`BarrierValue` — Barrier level

scalar numeric | numeric vector

Barrier level, specified as the comma-separated pair consisting of `'BarrierValue'` and a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`PayoffValue` — Option payoff value

scalar numeric | numeric vector

Option payoff value, specified as the comma-separated pair consisting of `'PayoffValue'` and a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

Optional Touch Name-Value Pair Arguments

`BarrierType` — Barrier type
`"OT"` (default) | string with value `"OT"` or `"NT"` | string array with values `"OT"` or `"NT"` | character vector with value `'OT'` or `'NT'` | cell array of character vectors with values `'OT'` or `'NT'`

Barrier type, specified as the comma-separated pair consisting of `'BarrierType'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array with one of the following values:

- `'OT'` — One-touch

  The one-touch option provides a payoff if the underlying asset ever trades at or beyond the `BarrierValue`. Otherwise, the `PayoffValue` is zero.
- `'NT'` — No-touch

  The no-touch option provides a payoff if the underlying asset never trades at or beyond the `BarrierValue`. Otherwise, the `PayoffValue` is zero.

Data Types: `char` | `cell` | `string`

`PayoffType` — Payoff type
`"Hit"` (default) | string with value `"Hit"` or `"Expiry"` | string array with values `"Hit"` or `"Expiry"` | character vector with value `'Hit'` or `'Expiry'` | cell array of character vectors with values `'Hit'` or `'Expiry'`

Payoff type, specified as the comma-separated pair consisting of `'PayoffType'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array. You can specify `"Expiry"` only when you specify `'OT'` as the `BarrierType`.

Note When you use a `BlackScholes` pricer, only the `"Hit"` `PayoffType` is supported.

Data Types: `char` | `cell` | `string`

`Name` — User-defined name for instrument
`" "` (default) | string | string array | character vector | cell array of character vectors

User-defined name for one of more instruments, specified as the comma-separated pair consisting of `'Name'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

Properties

`ExerciseDate` — Option exercise date
datetime | vector of datetimes

Option exercise date, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`BarrierValue` — Barrier level
scalar numeric | numeric vector

Barrier level, returned as a scalar numeric or an NINST-by-1 numeric vector.

Data Types: double

PayoffValue — Option payoff
scalar numeric | numeric vector

Option payoff, returned as a scalar numeric or an NINST-by-1 numeric vector.

Data Types: double

BarrierType — Barrier type
"OT" (default) | string with value "OT" or "NT" | string array with values "OT" or "NT"

Barrier type, returned as a scalar string or an NINST-by-1 string array.

Data Types: string

PayoffType — Payoff type
"Hit" (default) | string with value "Hit" or "Expiry" | string array with values "Hit" or "Expiry"

Option type, returned as a scalar string or an NINST-by-1 string array.

Data Types: string

Name — User-defined name for instrument
" " (default) | string | string array

User-defined name for the instrument, returned as a scalar string or an NINST-by-1 string array.

Data Types: string

Examples

Price Touch Instrument Using a Black-Scholes Model and Asset Monte Carlo Pricer

This example shows the workflow to price a Touch instrument when you use a BlackScholes model and an AssetMonteCarlo pricing method.

Create Touch Instrument Object

Use fininstrument to create a Touch instrument object.

```
TouchOpt = fininstrument("Touch",'ExerciseDate',datetime(2022,9,15),'BarrierValue',100,'PayoffVa
```

```
TouchOpt =
  Touch with properties:

    ExerciseDate: 15-Sep-2022
    BarrierValue: 100
     PayoffValue: 110
     BarrierType: "ot"
      PayoffType: "expiry"
            Name: "touch_option"
```

Create BlackScholes Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',.2)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.2000
    Correlation: 1
```

Create ratecurve Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create AssetMonteCarlo Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo",'DiscountCurve',myRC,"Model",BlackScholesModel,'SpotPrice
```

```
outPricer =
  GBMMonteCarlo with properties:

      DiscountCurve: [1x1 ratecurve]
          SpotPrice: 102
    SimulationDates: 15-Sep-2022
          NumTrials: 1000
      RandomNumbers: []
              Model: [1x1 finmodel.BlackScholes]
       DividendType: "continuous"
      DividendValue: 0
```

Price Touch Instrument

Use `price` to compute the price and sensitivities for the `Touch` instrument.

```
[Price, outPR] = price(outPricer,TouchOpt,["all"])

Price = 91.1862

outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: [1x1 struct]

outPR.Results

ans=1×7 table
    Price      Delta      Gamma      Lambda       Rho      Theta      Vega
    _____    ________    _________    _______    _______    _____    _____

    91.186    -2.1825    0.038281    -2.4413    -415.45    2.7374    35.998
```

Price Multiple Touch Instruments Using Black-Scholes Model and Black-Scholes Pricer

This example shows the workflow to price multiple `Touch` instruments when you use a `BlackScholes` model and a `BlackScholes` pricing method.

Create Touch Instrument Object

Use `fininstrument` to create a `Touch` instrument object for three Touch instruments.

```
TouchOpt = fininstrument("Touch",'ExerciseDate',datetime([2022,9,15 ; 2022,10,15 ; 2022,11,15]),

TouchOpt=3×1 object
  3x1 Touch array with properties:

    ExerciseDate
    BarrierValue
    PayoffValue
    BarrierType
    PayoffType
    Name
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.28)

BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.2800
    Correlation: 1
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                 Type: "zero"
          Compounding: -1
                Basis: 12
                Dates: 15-Sep-2023
                Rates: 0.0350
               Settle: 15-Sep-2018
         InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create BlackScholes Pricer Object

Use `finpricer` to create a `BlackScholes` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'DiscountCurve',myRC,'Model',BlackScholesModel,'SpotPrice',135,
```

```
outPricer =
  BlackScholes with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 135
    DividendValue: 0.0450
     DividendType: "continuous"
```

Price Touch Instruments

Use `price` to compute the prices and sensitivities for the `Touch` instruments.

```
[Price, outPR] = price(outPricer,TouchOpt,["all"])
```

```
Price = 3×1

  136.5553
   99.8742
   63.6835

outPR=3×1 object
  3x1 priceresult array with properties:

    Results
    PricerData
```

```
outPR.Results
```

```
ans=1×7 table
    Price     Delta      Gamma      Lambda     Vega     Theta       Rho
```

```
    ______    ______    _________    ______    ______    ______    _______

    136.56    2.2346    0.005457    2.2092    30.812    3.9013    -465.89

ans=1×7 table
    Price     Delta      Gamma       Lambda     Vega       Theta         Rho
    ______    ______    _________    ______    ______    _________    _______

    99.874    1.8197    0.008319    2.4597    120.98    0.0043188    -138.47

ans=1×7 table
    Price     Delta       Gamma       Lambda     Vega      Theta       Rho
    ______    ______    _________    ______    ______    _______    ______

    63.683    1.3221    0.0099462    2.8028    182.58    -3.0963    72.793
```

Price Touch Instrument Using Heston Model and Asset Monte Carlo Pricer

This example shows the workflow to price a `Touch` instrument when you use a `Heston` model and an `AssetMonteCarlo` pricing method.

Create Touch Instrument Object

Use `fininstrument` to create a `Touch` instrument object.

```
TouchOpt = fininstrument("Touch",'ExerciseDate',datetime(2022,9,15),'BarrierValue',110,'PayoffVa
```

```
TouchOpt =
  Touch with properties:

    ExerciseDate: 15-Sep-2022
    BarrierValue: 110
     PayoffValue: 140
     BarrierType: "ot"
      PayoffType: "expiry"
            Name: "touch_option"
```

Create Heston Model Object

Use `finmodel` to create a `Heston` model object.

```
HestonModel = finmodel("Heston",'V0',0.032,'ThetaV',0.1,'Kappa',0.003,'SigmaV',0.2,'RhoSV',0.9)
```

```
HestonModel =
  Heston with properties:

        V0: 0.0320
    ThetaV: 0.1000
     Kappa: 0.0030
    SigmaV: 0.2000
     RhoSV: 0.9000
```

Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create AssetMonteCarlo Pricer Object

Use finpricer to create an AssetMonteCarlo pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo",'DiscountCurve',myRC,"Model",HestonModel,'SpotPrice',112
```

```
outPricer =
  HestonMonteCarlo with properties:

      DiscountCurve: [1x1 ratecurve]
          SpotPrice: 112
    SimulationDates: 15-Sep-2022
          NumTrials: 1000
      RandomNumbers: []
              Model: [1x1 finmodel.Heston]
       DividendType: "continuous"
      DividendValue: 0
```

Price Touch Instrument

Use price to compute the price and sensitivities for the Touch instrument.

```
[Price, outPR] = price(outPricer,TouchOpt,["all"])
```

```
Price = 63.5247
```

```
outPR =
  priceresult with properties:

       Results: [1x8 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×8 table
    Price      Delta      Gamma      Lambda       Rho       Theta      Vega      VegaLT
    ______    ________    ______    ________    ________    ______    ______    ______

    63.525    -7.2363    1.0541    -12.758    -320.21    3.5527    418.94    8.1498
```

Price Touch Instrument Using Black-Scholes Model and Black-Scholes Pricer

This example shows the workflow to price a `Touch` instrument when you use a `BlackScholes` model and a `BlackScholes` pricing method.

Create Touch Instrument Object

Use `fininstrument` to create a `Touch` instrument object.

```
TouchOpt = fininstrument("Touch",'ExerciseDate',datetime(2022,9,15),'BarrierValue',140,'PayoffVa
```

```
TouchOpt =
  Touch with properties:

    ExerciseDate: 15-Sep-2022
    BarrierValue: 140
     PayoffValue: 170
     BarrierType: "ot"
      PayoffType: "expiry"
            Name: "touch_option"
```

Create BlackScholes Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.28)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.2800
    Correlation: 1
```

Create ratecurve Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
       Compounding: -1
             Basis: 12
```

```
                Dates: 15-Sep-2023
                Rates: 0.0350
               Settle: 15-Sep-2018
         InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create BlackScholes Pricer Object

Use `finpricer` to create a `BlackScholes` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'DiscountCurve',myRC,'Model',BlackScholesModel,'SpotPrice',135,
```

```
outPricer =
  BlackScholes with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 135
    DividendValue: 0.0450
     DividendType: "continuous"
```

Price Touch Instrument

Use `price` to compute the price and sensitivities for the `Touch` instrument.

```
[Price, outPR] = price(outPricer,TouchOpt,["all"])
```

```
Price = 136.5553

outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×7 table
    Price     Delta      Gamma      Lambda     Vega     Theta       Rho
    ______    ______    _________    ______    ______    ______    _______

    136.56    2.2346    0.005457    2.2092    30.812    3.9013    -465.89
```

More About

Touch Option

A touch option (also known as a binary barrier option or American digital) is a path-dependent option in which the existence and payment of the options depend on the movement of the underlying spot through their option life.

The one-touch (no-touch) option provides a payoff if the underlying spot ever (never) trades at or beyond the barrier level and otherwise it is zero. For more information, see “One-Touch and Double One-Touch Options” on page 3-30.

Version History

Introduced in R2020b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `Touch` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

DoubleTouch

`DoubleTouch` instrument object

Description

Create and price a `DoubleTouch` instrument object for one of more Double Touch instruments using this workflow:

1. Use `fininstrument` to create a `DoubleTouch` instrument object for one of more Double Touch instruments.
2. Use `finmodel` to specify a `BlackScholes`, `Bates`, `Merton`, or `Heston` model for the `DoubleTouch` instrument object.
3. Choose a pricing method.
   - When using a `BlackScholes` model, use `finpricer` to specify a `BlackScholes` or `VannaVolga` pricing method for one or more `DoubleTouch` instruments.
   - When using a `BlackScholes`, `Heston`, `Bates`, or `Merton` model, use `finpricer` to specify an `AssetMonteCarlo` pricing method for one or more `DoubleTouch` instruments.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a `DoubleTouch` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
DoubleTouchOpt = fininstrument(InstrumentType,'ExerciseDate',exercise_date,'
BarrierValue',barrier_value,'PayoffValue',payoff_value)
DoubleTouchOpt = fininstrument( ___ ,Name,Value)
```

Description

`DoubleTouchOpt = fininstrument(InstrumentType,'ExerciseDate',exercise_date,'BarrierValue',barrier_value,'PayoffValue',payoff_value)` creates a `DoubleTouch` object for one of more Double Touch instruments by specifying `InstrumentType` and sets properties on page 11-2686 using the required name-value pair arguments `ExerciseDate`, `BarrierValue`, and `PayoffValue`.

`DoubleTouchOpt = fininstrument( ___ ,Name,Value)` sets optional properties on page 11-2686 using additional name-value pair arguments in addition to the required arguments in the previous syntax. For example, `DoubleTouchOpt = fininstrument("DoubleTouch",'Strike',100,'ExerciseDate',datetime(2019,1,30),'BarrierValue',110,'PayoffValue',150,'BarrierType',"DOT",'PayoffType',"Expiry"`

,'Name',"DoubleTouch_option") creates a DoubleTouch option with a payoff type of Expiry. You can specify multiple name-value pair arguments.

Input Arguments

InstrumentType — Instrument type

string with value "DoubleTouch" | string array with values of "DoubleTouch" | character vector with value 'DoubleTouch' | cell array of character vectors with values of 'DoubleTouch'

Instrument type, specified as a string with the value of "DoubleTouch", a character vector with the value of 'DoubleTouch', an NINST-by-1 string array with values of "DoubleTouch", or an NINST-by-1 cell array of character vectors with values of 'DoubleTouch'.

Data Types: char | cell | string

DoubleTouch Name-Value Pair Arguments

Specify required and optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: DoubleTouchOpt = fininstrument("DoubleTouch",'Strike',100,'ExerciseDate',datetime(2019,1,30),'BarrierValue',110,'OptionType',"put",'ExerciseStyle',"European",'BarrierType',"DO",'Name',"DoubleTouch_option")

Required DoubleTouch Name-Value Pair Arguments

ExerciseDate — Option exercise date

datetime array | string array | date character vector

Option exercise date, specified as the comma-separated pair consisting of 'ExerciseDate' and a scalar or an NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, DoubleTouch also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by datetime because the ExerciseDate property is stored as a datetime.

BarrierValue — Option barrier levels

numeric

Option barrier levels, specified as the comma-separated pair consisting of 'BarrierValue' and an NINST-by-2 matrix of numeric values, where the first column is Upper Barrier(1)(UB) and the second column is Lower Barrier(2)(LB). Barrier(1) must be greater than Barrier(2).

Data Types: double

PayoffValue — Payoff value

numeric

Payoff value, specified as the comma-separated pair consisting of 'PayoffValue' and an NINST-by-1 matrix of numeric values, where each element is a 1-by-2 vector in which the first column is Barrier(1)(UB) and the second column is Barrier(2)(LB). Barrier(1) must be greater than Barrier(2).

Note The payoff value is calculated for the point in time that the `BarrierValue` is reached. The payoff is either cash or nothing. If you specify a double no-touch option using `BarrierType`, the payoff is at the maturity of the option.

Data Types: `double`

Optional DoubleTouch Name-Value Pair Arguments

`BarrierType` — Double barrier type

`"DOT"` (default) | string with value `"DOT"`, `"DNT"`, `"UNT-LOT"`, or `"UOT-LNT"` | string array with values `"DOT"`, `"DNT"`, `"UNT-LOT"`, or `"UOT-LNT"` | character vector with value `'DOT'`, `'DNT'`, `'UNT-LOT'`, or `'UOT-LNT'` | cell array of character vectors with values `'DOT'`, `'DNT'`, `'UNT-LOT'`, or `'UOT-LNT'`

Double barrier type, specified as the comma-separated pair consisting of `'BarrierType'` and a string or character vector or an `NINST`-by-`1` cell array of character vectors or string array with one of the following values:

- `'DOT'` — Double one-touch. The double one-touch option defines two `BarrierValue` values. A double one-touch option provides a `PayoffValue` if the underlying asset ever touches either the upper or lower `BarrierValue` values.
- `'DNT'` — Double no-touch. The double no-touch option defines two `BarrierValue` values. A double no-touch option provides a `PayoffValue` if the underlying asset ever never touches either the upper or lower `BarrierValue` values.
- `'UNT-LOT'` — Upper `BarrierValue` is No Touch and Lower `BarrierValue` is one Touch.
- `'UOT-LNT'` — Upper `BarrierValue` is One Touch and Lower `BarrierValue` is No Touch.

Data Types: `char` | `cell` | `string`

`PayoffType` — Payoff type

`"Hit"` (default) | string with value `"Hit"` or `"Expiry"` | string arrays with values `"Hit"` or `"Expiry"` | character vector with value `'Hit'` or `'Expiry'` | cell array of character vectors with values `'Hit'` or `'Expiry'`

Payoff type, specified as the comma-separated pair consisting of `'PayoffType'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array. You cannot use specify `"Expiry"` when using a `BarrierType` of `'DNT'`.

Note When you use a `BlackScholes` pricer, only the `"Expiry"` `PayoffType` is supported.

Data Types: `char` | `cell` | `string`

`Name` — User-defined name for instrument

`" "` (default) | string | string array | character vector | cell array of character vectors

User-defined name for the instrument, specified as the comma-separated pair consisting of `'Name'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

Properties

`ExerciseDate` — Option exercise date
datetime | vector of datetimes

Option exercise date, returned as a datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`BarrierValue` — Barrier level
numeric

Barrier level, returned as a numeric matrix.

Data Types: `double`

`PayoffValue` — Option payoff
numeric

Option payoff, returned as a numeric matrix.

Data Types: `double`

`BarrierType` — Double barrier type
`"DOT"` (default) | string with value `"DOT"`, `"DNT"`, `"UNT-LOT"`, or `"UOT-LNT"` | string array with values `"DOT"`, `"DNT"`, `"UNT-LOT"`, or `"UOT-LNT"`

Double barrier type, returned as a scalar string or an `NINST`-by-`1` string array.

Data Types: `string`

`PayoffType` — Payoff type
`"Hit"` (default) | string with value `"Hit"` or `"Expiry"` | string array with values `"Hit"` or `"Expiry"`

Option type, returned as a string or an `NINST`-by-`1` string array.

Data Types: `string`

`Name` — User-defined name for instrument
`" "` (default) | string | string array

User-defined name for the instrument, returned as a string or an `NINST`-by-`1` string array.

Data Types: `string`

Examples

Price Double Touch Instrument Using a Black-Scholes Model and Asset Monte Carlo Pricer

This example shows the workflow to price a `DoubleTouch` instrument when you use a `BlackScholes` model and an `AssetMonteCarlo` pricing method.

Create `DoubleTouch` Instrument Object

Use `fininstrument` to create a `DoubleTouch` instrument object.

```
DoubleTouchOpt = fininstrument("DoubleTouch",'ExerciseDate',datetime(2022,9,15),'BarrierValue',[1
```

```
DoubleTouchOpt =
  DoubleTouch with properties:

    ExerciseDate: 15-Sep-2022
    BarrierValue: [110 90]
     PayoffValue: 50
     BarrierType: "dot"
      PayoffType: "expiry"
            Name: "doubletouch_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',.2)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.2000
    Correlation: 1
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `AssetMonteCarlo` Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo",'DiscountCurve',myRC,"Model",BlackScholesModel,'SpotPrice
```

```
outPricer =
  GBMMonteCarlo with properties:
```

```
      DiscountCurve: [1x1 ratecurve]
          SpotPrice: 102
    SimulationDates: 15-Sep-2022
          NumTrials: 1000
      RandomNumbers: []
              Model: [1x1 finmodel.BlackScholes]
       DividendType: "continuous"
      DividendValue: 0
```

Price DoubleTouch Instrument

Use `price` to compute the price and sensitivities for the `DoubleTouch` instrument.

```
[Price, outPR] = price(outPricer,DoubleTouchOpt,["all"])
```

```
Price = 43.3860

outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×7 table
    Price       Delta        Gamma       Lambda       Rho       Theta      Vega
    _____    _________    _________    ________    _______    ______    ______

    43.386    0.0043916    0.0018346    0.010325    -173.28    1.4722    1.8176
```

Price Multiple Double Touch Instruments Using a Black-Scholes Model and Black-Scholes Pricer

This example shows the workflow to price multiple `DoubleTouch` instruments when you use a `BlackScholes` model and a `BlackScholes` pricing method.

Create DoubleTouch Instrument Object

Use `fininstrument` to create a `DoubleTouch` instrument object for three Double Touch instruments.

```
DoubleTouchOpt = fininstrument("DoubleTouch",'ExerciseDate',datetime([2022,9,15 ; 2022,10,15 ; 20
```

```
DoubleTouchOpt=3×1 object
  3x1 DoubleTouch array with properties:

    ExerciseDate
    BarrierValue
    PayoffValue
    BarrierType
    PayoffType
    Name
```

Create BlackScholes Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.28)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.2800
    Correlation: 1
```

Create ratecurve Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
        Compounding: -1
              Basis: 12
              Dates: 15-Sep-2023
              Rates: 0.0350
             Settle: 15-Sep-2018
       InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create BlackScholes Pricer Object

Use `finpricer` to create a `BlackScholes` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'DiscountCurve',myRC,'Model',BlackScholesModel,'SpotPrice',100,
```

```
outPricer =
  BlackScholes with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 100
    DividendValue: 0.0450
     DividendType: "continuous"
```

Price DoubleTouch Instruments

Use `price` to compute the prices and sensitivities for the `DoubleTouch` instruments.

```
[Price, outPR] = price(outPricer,DoubleTouchOpt,["all"])
```

```
Price = 3×1

   52.6903
   66.9920
   67.7447

outPR=3×1 object
  3x1 priceresult array with properties:

    Results
    PricerData
```

```
outPR.Results
```

```

    67.745    -4.4624    -0.0053149    -6.5871    -1.7318      0      -46.135
```

Price Double Touch Instrument Using a Bates Model and Asset Monte Carlo Pricer

This example shows the workflow to price a `DoubleTouch` instrument when you use a `Bates` model and an `AssetMonteCarlo` pricing method.

Create `DoubleTouch` Instrument Object

Use `fininstrument` to create a `DoubleTouch` instrument object.

```
DoubleTouchOpt = fininstrument("DoubleTouch",'ExerciseDate',datetime(2022,9,15),'BarrierValue',[1
```

```
DoubleTouchOpt =
  DoubleTouch with properties:

    ExerciseDate: 15-Sep-2022
    BarrierValue: [115 95]
     PayoffValue: 40
     BarrierType: "dot"
      PayoffType: "expiry"
            Name: "doubletouch_option"
```

Create Bates Model Object

Use `finmodel` to create a `Bates` model object.

```
BatesModel = finmodel("Bates",'V0',0.032,'ThetaV',0.1,'Kappa',0.003,'SigmaV',0.2,'RhoSV',0.9,'Mea
```

```
BatesModel =
  Bates with properties:

          V0: 0.0320
      ThetaV: 0.1000
       Kappa: 0.0030
      SigmaV: 0.2000
       RhoSV: 0.9000
       MeanJ: 0.1100
     JumpVol: 0.0230
    JumpFreq: 0.0200
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `AssetMonteCarlo` Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo",'DiscountCurve',myRC,"Model",BatesModel,'SpotPrice',102,
```

```
outPricer =
  BatesMonteCarlo with properties:

      DiscountCurve: [1x1 ratecurve]
          SpotPrice: 102
    SimulationDates: 15-Sep-2022
          NumTrials: 1000
      RandomNumbers: []
              Model: [1x1 finmodel.Bates]
       DividendType: "continuous"
```

```
      DividendValue: 0
```

Price DoubleTouch Instrument

Use `price` to compute the price and sensitivities for the `DoubleTouch` instrument.

```
[Price, outPR] = price(outPricer,DoubleTouchOpt,["all"])
```

```
Price = 34.7743

outPR =
  priceresult with properties:

       Results: [1x8 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×8 table
    Price     Delta    Gamma    Lambda      Rho       Theta     Vega     VegaLT
    ______    _____    _____    ______    _______    ______    ____    ______

    34.774      0        0        0       -139.07    1.2179     0        0
```

Price Double Touch Instrument Using a Black-Scholes Model and Black-Scholes Pricer

This example shows the workflow to price a `DoubleTouch` instrument when you use a `BlackScholes` model and a `BlackScholes` pricing method.

Create DoubleTouch Instrument Object

Use `fininstrument` to create a `DoubleTouch` instrument object.

```
DoubleTouchOpt = fininstrument("DoubleTouch",'ExerciseDate',datetime(2022,9,15),'BarrierValue',[1
```

```
DoubleTouchOpt =
  DoubleTouch with properties:

    ExerciseDate: 15-Sep-2022
    BarrierValue: [115 95]
     PayoffValue: 70
     BarrierType: "unt-lot"
      PayoffType: "expiry"
            Name: "doubletouch_option"
```

Create BlackScholes Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.28)
```

```
BlackScholesModel =
  BlackScholes with properties:
```

```
     Volatility: 0.2800
    Correlation: 1
```

Create ratecurve Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create BlackScholes Pricer Object

Use `finpricer` to create a `BlackScholes` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'DiscountCurve',myRC,'Model',BlackScholesModel,'SpotPrice',100,
```

```
outPricer =
  BlackScholes with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 100
    DividendValue: 0.0450
     DividendType: "continuous"
```

Price DoubleTouch Instrument

Use `price` to compute the price and sensitivities for the `DoubleTouch` instrument.

```
[Price, outPR] = price(outPricer,DoubleTouchOpt,["all"])
```

```
Price = 52.6903
```

```
outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×7 table
    Price     Delta       Gamma        Lambda      Vega      Theta      Rho
    _____    ________    ___________    _______    _______    _____    ________

    52.69    -3.4708    -0.0041339    -6.5871    -1.3469      0       -35.883
```

More About

Double Touch Option

Double touch and double no-touch options work the same way as a `Touch` option, but have two barriers.

Double touch and double no-touch option provides a payoff if the underlying spot ever (never) touches either the upper or lower barriers levels. For more information, see “One-Touch and Double One-Touch Options” on page 3-30.

Version History

Introduced in R2020b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `DoubleTouch` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

“Supported Exercise Styles” on page 1-62

Binary

`Binary` instrument object

Description

Create and price a `Binary` instrument object for one or more Binary instruments using this workflow:

1. Use `fininstrument` to create a `Binary` instrument object for one or more Binary instruments.
2. Use `finmodel` to specify a `BlackScholes` or `Bachelier` model for the `Binary` instrument object.
3. Choose a pricing method.
   - When using a `BlackScholes` model, use `finpricer` to specify a `BlackScholes` or `AssetMonteCarlo` pricing method for one or more `Binary` instruments.
   - When using a `Bachelier` model, use `finpricer` to specify an `AssetMonteCarlo` pricing method for one or more `Binary` instruments.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a `Binary` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
BinaryOpt = fininstrument(InstrumentType,'Strike',strike_value,'
ExerciseDate',exercise_date,'PayoffValue',payoff_value)
BinaryOpt = fininstrument( ___ ,Name,Value)
```

Description

`BinaryOpt = fininstrument(InstrumentType,'Strike',strike_value,'ExerciseDate',exercise_date,'PayoffValue',payoff_value)` creates a `Binary` instrument object for one or more Binary instruments by specifying `InstrumentType` and sets properties on page 11-2697 using the required name-value pair arguments `Strike`, `ExerciseDate`, and `PayoffValue`.

`BinaryOpt = fininstrument( ___ ,Name,Value)` sets optional properties on page 11-2697 using additional name-value pair arguments in addition to the required arguments in the previous syntax. For example, `BinaryOpt = fininstrument("Binary",'Strike',100,'ExerciseDate',datetime(2019,1,30),'PayoffValue',110,'OptionType',"put",'Name',"binary_option")` creates a `Binary` put option with a `PayoffValue` of 110. You can specify multiple name-value pair arguments.

Input Arguments

`InstrumentType` — Instrument type

string with value `"Binary"` | string array with values of `"Binary"` | character vector with value `'Binary'` | cell array of character vectors with values of `'Binary'`

Instrument type, specified as a string with the value of `"Binary"`, a character vector with the value of `'Binary'`, an `NINST`-by-`1` string array with values of `"Binary"`, or an `NINST`-by-`1` cell array of character vectors with values of `'Binary'`.

Data Types: `char` | `cell` | `string`

`Binary` Name-Value Pair Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `BinaryOpt = fininstrument("Binary",'Strike',100,'ExerciseDate',datetime(2019,1,30),'PayoffValue',110,'OptionType',"put",'Name',"binary_option")`

Required Binary Name-Value Pair Arguments

`Strike` — Option strike price value

nonnegative value | vector of nonnegative values

Option strike price value, specified as the comma-separated pair consisting of `'Strike'` and a scalar nonnegative value or an `NINST`-by-`1` vector of nonnegative values.

Data Types: `double`

`ExerciseDate` — Option exercise date

datetime array | string array | date character vector

Option exercise date, specified as the comma-separated pair consisting of `'ExerciseDate'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `Binary` also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `ExerciseDate` property is stored as a datetime.

`PayoffValue` — Option payoff value

scalar numeric | numeric vector

Option payoff value, specified as the comma-separated pair consisting of `'PayoffValue'` and a scalar numeric value or an `NINST`-by-`1` numeric vector.

Data Types: `double`

Optional Binary Name-Value Pair Arguments

`OptionType` — Option type
`"call"` (default) | string with value `"call"` or `"put"` | string array with values `"call"` or `"put"` | character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Option type, specified as the comma-separated pair consisting of `'OptionType'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

`ExerciseStyle` — Option exercise style
`"European"` (default) | string with value `"European"` | string array with a value `"European"` | character vector with value `'European'` | cell array of character vectors with a value `'European'`

Option exercise style, specified as the comma-separated pair consisting of `'ExerciseStyle'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `string` | `char` | `cell`

`Name` — User-defined name for instrument
`" "` (default) | string | string array | character vector | cell array of character vectors

User-defined name for the instrument, specified as the comma-separated pair consisting of `'Name'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

Properties

`Strike` — Option strike price value
nonnegative value | nonnegative value | vector of nonnegative values

Option strike price value, returned as a scalar nonnegative value or an `NINST`-by-`1` vector of nonnegative values.

Data Types: `double`

`ExerciseDate` — Option exercise date
datetime | vector of datetimes

Option exercise date, returned as a datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`PayoffValue` — Option payoff value
scalar numeric | numeric vector

Option payoff value, returned as a scalar numeric value or an `NINST`-by-`1` vector of numeric values.

Data Types: `double`

`OptionType` — Option type
`"call"` (default) | string with value `"call"` or `"put"` | string array with values `"call"` or `"put"`

Option type, returned as a scalar string or an NINST-by-1 string array with the values of "call" or "put".

Data Types: string

ExerciseStyle — Option exercise style
"European" (default) | string with value "European" | string array with values "European"

This property is read-only.

Option exercise style, returned as a scalar string or an NINST-by-1 string array with the value of "European".

Data Types: string

Name — User-defined name for instrument
" " (default) | string | string array

User-defined name for the instrument, returned as a scalar string or an NINST-by-1 string array.

Data Types: string

Examples

Price Binary Instrument Using Black-Scholes Model and Asset Monte Carlo Pricer

This example shows the workflow to price a Binary instrument when you use a BlackScholes model and an AssetMonteCarlo pricing method.

Create Binary Instrument Object

Use fininstrument to create a Binary instrument object.

```
BinaryOpt = fininstrument("Binary",'ExerciseDate',datetime(2022,9,15),'Strike',1000,'PayoffValue
```

```
BinaryOpt =
  Binary with properties:

       OptionType: "put"
     ExerciseDate: 15-Sep-2022
           Strike: 1000
      PayoffValue: 130
    ExerciseStyle: "european"
             Name: "binary_option"
```

Create BlackScholes Model Object

Use finmodel to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',.2)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.2000
```

```
    Correlation: 1
```

Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create AssetMonteCarlo Pricer Object

Use finpricer to create an AssetMonteCarlo pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo",'DiscountCurve',myRC,"Model",BlackScholesModel,'SpotPrice
```

```
outPricer =
  GBMMonteCarlo with properties:

      DiscountCurve: [1x1 ratecurve]
          SpotPrice: 102
    SimulationDates: 15-Sep-2022
          NumTrials: 1000
      RandomNumbers: []
              Model: [1x1 finmodel.BlackScholes]
       DividendType: "continuous"
      DividendValue: 0
```

Price Binary Instrument

Use price to compute the price and sensitivities for the Binary instrument.

```
[Price, outPR] = price(outPricer,BinaryOpt,["all"])
```

```
Price = 113.0166
```

```
outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×7 table
    Price     Delta     Gamma     Lambda      Rho       Theta     Vega
    ______    _____     _____     ______    _______    ______    ____

    113.02      0         0         0       -451.98    3.9582     0
```

Price Multiple Binary Instruments Using Black-Scholes Model and Black-Scholes Pricer

This example shows the workflow to price multiple `Binary` instruments when you use a `BlackScholes` model and a `BlackScholes` pricing method.

Create `Binary` Instrument Object

Use `fininstrument` to create a `Binary` instrument object with three Binary instruments.

```
BinaryOpt = fininstrument("Binary",'ExerciseDate',datetime([2022,9,15 ; 2022,10,15 ; 2022,11,15])
```

```
BinaryOpt=3×1 object
  3x1 Binary array with properties:

    OptionType
    ExerciseDate
    Strike
    PayoffValue
    ExerciseStyle
    Name
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.28)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.2800
    Correlation: 1
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
```

```
          Compounding: -1
                Basis: 12
                Dates: 15-Sep-2023
                Rates: 0.0350
               Settle: 15-Sep-2018
         InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create BlackScholes Pricer Object

Use `finpricer` to create a `BlackScholes` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'DiscountCurve',myRC,'Model',BlackScholesModel,'SpotPrice',800,
```

```
outPricer =
  BlackScholes with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 800
    DividendValue: 0.0450
     DividendType: "continuous"
```

Price Binary Instruments

Use `price` to compute the prices and sensitivities for the `Binary` instruments.

```
[Price, outPR] = price(outPricer,BinaryOpt,["all"])
```

```
Price = 3×1

   87.4005
  109.9703
  111.9328

outPR=3×1 object
  3x1 priceresult array with properties:

    Results
    PricerData
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta         Gamma        Lambda      Vega      Theta       Rho
    _____    _________    ___________    _______    _______    ______    _______

    87.4     -0.075973    -3.1264e-05    -0.6954    -23.084    3.2599    -592.61

ans=1×7 table
    Price       Delta         Gamma         Lambda       Vega       Theta       Rho
    ______    _________    ___________    ________    _______    ______    _______
```

```
    109.97    -0.014137    -4.4054e-05    -0.10284    -32.196    4.8405    -495.01

ans=1×7 table

```

Price Binary Instrument Using Merton Model and Asset Monte Carlo Pricer

This example shows the workflow to price a `Binary` instrument when you use a `Merton` model and an `AssetMonteCarlo` pricing method.

Create `Binary` Instrument Object

Use `fininstrument` to create a `Binary` instrument object.

```
BinaryOpt = fininstrument("Binary",'ExerciseDate',datetime(2022,9,15),'Strike',1000,'PayoffValue
```

```
BinaryOpt =
  Binary with properties:

       OptionType: "put"
     ExerciseDate: 15-Sep-2022
           Strike: 1000
      PayoffValue: 130
    ExerciseStyle: "european"
             Name: "binary_option"
```

Create `Merton` Model Object

Use `finmodel` to create a `Merton` model object.

```
MertonModel = finmodel("Merton",'Volatility',0.45,'MeanJ',0.02,'JumpVol',0.07,'JumpFreq',0.09)
```

```
MertonModel =
  Merton with properties:

    Volatility: 0.4500
         MeanJ: 0.0200
       JumpVol: 0.0700
      JumpFreq: 0.0900
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `AssetMonteCarlo` Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo",'DiscountCurve',myRC,"Model",MertonModel,'SpotPrice',102
```

```
outPricer =
  MertonMonteCarlo with properties:

      DiscountCurve: [1x1 ratecurve]
          SpotPrice: 102
    SimulationDates: 15-Sep-2022
          NumTrials: 1000
      RandomNumbers: []
              Model: [1x1 finmodel.Merton]
       DividendType: "continuous"
      DividendValue: 0
```

Price `Binary` Instrument

Use `price` to compute the price and sensitivities for the `Binary` instrument.

```
[Price, outPR] = price(outPricer,BinaryOpt,["all"])
```

```
Price = 112.4515
```

```
outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×7 table
    Price     Delta     Gamma     Lambda      Rho       Theta      Vega
    _____     _____     _____     ______    _______     ______     ____

    112.45      0         0         0       -449.72     3.9384      0
```

Price Binary Instrument Using Bachelier Model and Asset Monte Carlo Pricer

This example shows the workflow to price a `Binary` instrument when you use a `Bachelier` model and an `AssetMonteCarlo` pricing method.

Create `Binary` Instrument Object

Use `fininstrument` to create a `Binary` instrument object.

```
BinaryOpt = fininstrument("Binary",'ExerciseDate',datetime(2022,9,15),'Strike',1000,'PayoffValue
```

```
BinaryOpt =
  Binary with properties:

       OptionType: "put"
     ExerciseDate: 15-Sep-2022
           Strike: 1000
      PayoffValue: 130
    ExerciseStyle: "european"
             Name: "binary_option"
```

Create `Bachelier` Model Object

Use `finmodel` to create a `Bachelier` model object.

```
BachelierModel = finmodel("Bachelier",'Volatility',.2)
```

```
BachelierModel =
  Bachelier with properties:

     Volatility: 0.2000
    Correlation: 1
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                 Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create AssetMonteCarlo Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo",'DiscountCurve',myRC,"Model",BachelierModel,'SpotPrice',1
```

```
outPricer =
  BachelierMonteCarlo with properties:

     DiscountCurve: [1x1 ratecurve]
         SpotPrice: 102
    SimulationDates: 15-Sep-2022
         NumTrials: 1000
     RandomNumbers: []
             Model: [1x1 finmodel.Bachelier]
      DividendType: "continuous"
     DividendValue: 0
```

Price Binary Instrument

Use `price` to compute the price and sensitivities for the `Binary` instrument.

```
[Price, outPR] = price(outPricer,BinaryOpt,["all"])
```

```
Price = 113.0166
```

```
outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×7 table
    Price     Delta    Gamma    Lambda      Rho      Theta     Vega
    ______    _____    _____    ______    ________    ______    ____

    113.02      0        0        0       -451.98    3.9582     0
```

Price Binary Instrument Using Black-Scholes Model and Black-Scholes Pricer

This example shows the workflow to price a `Binary` instrument when you use a `BlackScholes` model and a `BlackScholes` pricing method.

Create Binary Instrument Object

Use `fininstrument` to create a `Binary` instrument object.

```
BinaryOpt = fininstrument("Binary",'ExerciseDate',datetime(2022,9,15),'Strike',1000,'PayoffValue
```

```
BinaryOpt =
  Binary with properties:
```

```
       OptionType: "put"
     ExerciseDate: 15-Sep-2022
           Strike: 1000
      PayoffValue: 130
    ExerciseStyle: "european"
             Name: "binary_option"
```

Create BlackScholes Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.28)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.2800
    Correlation: 1
```

Create ratecurve Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create BlackScholes Pricer Object

Use `finpricer` to create a `BlackScholes` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'DiscountCurve',myRC,'Model',BlackScholesModel,'SpotPrice',800,
```

```
outPricer =
  BlackScholes with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 800
    DividendValue: 0.0450
```

```
     DividendType: "continuous"
```

Price Binary Instrument

Use `price` to compute the price and sensitivities for the `Binary` instrument.

```
[Price, outPR] = price(outPricer,BinaryOpt,["all"])
```

```
Price = 87.4005
```

```
outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta         Gamma        Lambda      Vega      Theta       Rho
    _____    _________    ___________    _______    _______    ______    _______

    87.4     -0.075973    -3.1264e-05    -0.6954    -23.084    3.2599    -592.61
```

More About

Binary Option

A binary option is where the buyer receives a payout or loses their investment, depending on whether the option expires in the money.

Binary options depend on the outcome of a "yes or no" proposition, hence the name "binary." Binary options have an expiry date and/or time. At the time of expiry, the price of the underlying asset must be on the correct side of the strike price (based on the trade taken) for the trader to make a profit.

A binary option automatically exercises, meaning the gain or loss on the trade is automatically credited or debited to the trader's account when the option expires.

Version History

Introduced in R2020b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `Binary` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

Cap

`Cap` instrument object

Description

Create and price a `Cap` instrument object for one or more Cap instruments using this workflow:

1. Use `fininstrument` to create a `Cap` instrument object for one or more Cap instruments.
2. Use `finmodel` to specify a `HullWhite`, `BlackKarasinski`, `BlackDermanToy`, `Black`, `Normal`, `BraceGatarekMusiela`, `SABRBraceGatarekMusiela`, or `LinearGaussian2F` model for the `Cap` instrument object.
3. Choose a pricing method.
   - When using a `HullWhite`, `BlackKarasinski`, `BlackDermanToy`, `Black`, or `Normal` model, use `finpricer` for pricing one or more `Cap` instruments and specify:
     - A `Normal` pricer when using a `Normal` model.
     - A `Black` pricer when using a `Black` model.
     - A `HullWhite` pricer when using a `HullWhite` model.
     - An `IRTree` pricer when using a `BlackKarasinski` or `BlackDermanToy` model.
   - When using a `HullWhite`, `BlackKarasinski`, `BraceGatarekMusiela`, `SABRBraceGatarekMusiela`, or `LinearGaussian2F` model, use `finpricer` to specify an `IRMonteCarlo` pricing method for one or more `Cap` instruments.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a `Cap` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
CapOpt = fininstrument(InstrumentType,'Strike',strike_value,'
Maturity',maturity_date)
CapOpt = fininstrument( ___ ,Name,Value)
```

Description

`CapOpt = fininstrument(InstrumentType,'Strike',strike_value,'Maturity',maturity_date)` creates a `Cap` object for one or more Cap instruments by specifying `InstrumentType` and sets the properties on page 11-2713 for the required name-value pair arguments `Strike` and `Maturity`.

The `Cap` instrument supports vanilla and amortizing caps.

`CapOpt = fininstrument( ___ ,Name,Value)` sets optional properties on page 11-2713 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `CapOpt = fininstrument("Cap",'Strike',0.65,'Maturity',datetime(2019,1,30),'Reset',4,'Principal',100,'ResetOffset',1,'Basis',1,'DaycountAdjustedCashFlow',true,'BusinessDayConvention',"follow",'ProjectionCurve',ratecurve_object,'Name',"cap_option")` creates a `Cap` option with a strike of 0.65. You can specify multiple name-value pair arguments.

Input Arguments

`InstrumentType` — Instrument type

string with value `"Cap"` | string array with values of `"Cap"` | character vector with value `'Cap'` | cell array of character vectors with values of `'Cap'`

Instrument type, specified as a string with the value of `"Cap"`, a character vector with the value of `'Cap'`, an `NINST`-by-1 string array with values of `"Cap"`, or an `NINST`-by-1 cell array of character vectors with values of `'Cap'`.

Data Types: `char` | `cell` | `string`

Cap Name-Value Pair Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `CapOpt = fininstrument("Cap",'Strike',0.65,'Maturity',datetime(2019,1,30),'Reset',4,'Principal',100,'ResetOffset',1,'Basis',1,'DaycountAdjustedCashFlow',true,'BusinessDayConvention',"follow",'ProjectionCurve',ratecurve_object,'Name',"cap_option")`

Required Cap Name-Value Pair Arguments

`Strike` — Cap strike price

nonnegative decimal | vector of nonnegative decimals

Cap strike price, specified as the comma-separated pair consisting of `'Strike'` and a scalar nonnegative decimal value or an `NINST`-by-1 nonnegative numeric vector.

Data Types: `double`

`Maturity` — Cap maturity date

datetime array | string array | date character vector

Cap maturity date, specified as the comma-separated pair consisting of `'ExerciseDate'` and a scalar or an `NINST`-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, `Cap` also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `Maturity` property is stored as a datetime.

Optional Cap Name-Value Pair Arguments

`Reset` — Reset frequency payments per year
`1` (default) | numeric with value of `0`, `1`, `2`, `3`, `4`, `6`, or `12` | numeric vector with values of `0`, `1`, `2`, `3`, `4`, `6`, or `12`

Reset frequency payments per year, specified as the comma-separated pair consisting of `'Reset'` and a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`Basis` — Day count basis
`0` (actual/actual) (default) | integer from `0` to `13` | vector of integers from `0` to `13`

Day count basis, specified as the comma-separated pair consisting of `'Basis'` and a scalar integer or an `NINST`-by-`1` vector of integers with the following values:

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Principal amount or principal value schedule
`100` (default) | scalar numeric | numeric vector | timetable

Principal amount or principal value schedule, specified as the comma-separated pair consisting of `'Principal'` and a scalar numeric or an `NINST`-by-`1` numeric vector or a timetable.

`Principal` accepts a `timetable`, where the first column is dates and the second column is its associated principal value. The date indicates the last day that the principal value is valid.

Note If you are creating one or more `Cap` instruments and use a timetable, the timetable specification applies to all of the `Cap` instruments. `Principal` does not accept an `NINST`-by-`1` cell array of timetables as input.

Data Types: `double` | `timetable`

ResetOffset — Lag in rate setting
0 (default) | scalar numeric | numeric vector

Lag in rate setting, specified as the comma-separated pair consisting of 'ResetOffset' and a scalar numeric or an NINST-by-1 numeric vector.

Data Types: double

DaycountAdjustedCashFlow — Flag to adjust cash flows based on actual period day count
false (default) | value of true or false | vector of values of true or false

Flag to adjust cash flows based on the actual period day count, specified as the comma-separated pair consisting of 'DaycountAdjustedCashFlow' and a scalar or an NINST-by-1 vector with values of true or false.

Data Types: logical

BusinessDayConvention — Business day conventions
"actual" (default) | string | string array | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of 'BusinessDayConvention' and a scalar string or character vector or an NINST-by-1 cell array of character vectors or string array for a business day convention. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- "actual" — Nonbusiness days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- "follow" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- "modifiedfollow" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day. However, if the following business day is in a different month, the previous business day is adopted instead.
- "previous" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- "modifiedprevious" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However, if the previous business day is in a different month, the following business day is adopted instead.

Data Types: char | cell | string

Holidays — Holidays used in computing business days
NaT (default) | datetime array | string array | date character vector

Holidays used in computing business days, specified as the comma-separated pair consisting of 'Holidays' and dates using an NINST-by-1 vector of a datetime array, string array, or date character vectors. For example:

```
H = holidays(datetime('today'),datetime(2025,12,15));
CapOpt = fininstrument("Cap",'Strike',100,'Maturity',datetime(2025,12,15),'Holidays',H)
```

To support existing code, Cap also accepts serial date numbers as inputs, but they are not recommended.

`ProjectionCurve` — Rate curve used in generating future cash flows
`ratecurve.empty` (default) | `ratecurve` object | vector of `ratecurve` objects

Rate curve used in projecting the future cash flows, specified as the comma-separated pair consisting of `'ProjectionCurve'` and a scalar `ratecurve` object or an `NINST`-by-`1` vector of `ratecurve` objects. These objects must be created using `ratecurve`. Use this optional input if the forward curve is different from the discount curve.

Data Types: `object`

`Name` — User-defined name for instrument
`" "` (default) | string | string array | character vector | cell array of character vectors

User-defined name for one of more instruments, specified as the comma-separated pair consisting of `'Name'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

Properties

`Strike` — Option strike price value
nonnegative value | vector of nonnegative values

Option strike price value, returned as a scalar nonnegative value or an `NINST`-by-`1` vector of nonnegative values.

Data Types: `double`

`Maturity` — Cap maturity date
datetime | vector of datetimes

Cap maturity date, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`Reset` — Reset frequency payments per year
`1` (default) | scalar numeric | numeric vector

Reset frequency payments per year, returned as a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`Basis` — Day count basis
`0` (actual/actual) (default) | integer from `0` to `13` | vector of integers from `0` to `13`

Day count basis, returned as a scalar integer or an `NINST`-by-`1` vector of integers.

Data Types: `double`

`Principal` — Principal amount or principal value schedule
`100` (default) | scalar numeric | numeric vector | timetable

Principal amount or principal value schedule, returned as a scalar numeric or an `NINST`-by-`1` numeric vector for principal amounts or a timetable for a principal value schedule.

Data Types: `double` | `timetable`

ResetOffset — Lag in rate setting
0 (default) | scalar numeric | numeric vector

Lag in rate setting, returned as a scalar numeric or an NINST-by-1 numeric vector.

Data Types: double

DaycountAdjustedCashFlow — Flag to adjust cash flows based on actual period day count
false (default) | value of true or false | vector of values of true or false

Flag to adjust cash flows based on the actual period day count, returned as a scalar logical or an NINST-by-1 vector with values of true or false.

Data Types: logical

BusinessDayConvention — Business day conventions
"actual" (default) | string | string array

Business day conventions, returned as a scalar string or an NINST-by-1 string array.

Data Types: string

Holidays — Holidays used in computing business days
NaT (default) | vector of datetimes

Holidays used in computing business days, returned as an NINST-by-1 vector of datetimes.

Data Types: datetime

ProjectionCurve — Rate curve used in generating future cash flows
ratecurve.empty (default) | ratecurve object | vector of ratecurve objects

Rate curve used in projecting the future cash flows, returned as a scalar ratecurve object or an NINST-by-1 vector of ratecurve objects.

Data Types: object

Name — User-defined name for instrument
" " (default) | string | string array

User-defined name for the instrument, returned as a scalar string or an NINST-by-1 string array.

Data Types: string

Examples

Price Vanilla Cap Instrument Using Hull-White Model and Hull-White Pricer

This example shows the workflow to price a vanilla Cap instrument when using a HullWhite model and a HullWhite pricing method.

Create Cap Instrument Object

Use fininstrument to create a Cap instrument object.

```
CapOpt = fininstrument("Cap",'Strike',0.02,'Maturity',datetime(2019,1,30),'Reset',4,'Principal',1
```

```
CapOpt =
  Cap with properties:

                     Strike: 0.0200
                   Maturity: 30-Jan-2019
                ResetOffset: 0
                      Reset: 4
                      Basis: 8
                  Principal: 100
             ProjectionCurve: [0x0 ratecurve]
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                    Holidays: NaT
                        Name: "cap_option"
```

Create HullWhite Model Object

Use `finmodel` to create a `HullWhite` model object.

```
HullWhiteModel = finmodel("HullWhite",'Alpha',0.62,'Sigma',0.99)
```

```
HullWhiteModel =
  HullWhite with properties:

    Alpha: 0.6200
    Sigma: 0.9900
```

Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create HullWhite Pricer Object

Use `finpricer` to create a `HullWhite` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'Model',HullWhiteModel,'DiscountCurve',myRC)

outPricer =
  HullWhite with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.HullWhite]
```

Price Cap Instrument

Use `price` to compute the price for the `Cap` instrument.

```
Price = price(outPricer,CapOpt)

Price = 2.9366
```

Price Multiple Vanilla Cap Instruments Using Hull-White Model and Hull-White Pricer

This example shows the workflow to price multiple vanilla `Cap` instruments when using a `HullWhite` model and a `HullWhite` pricing method.

Create Cap Instrument Object

Use `fininstrument` to create a `Cap` instrument object for three Cap instruments.

```
CapOpt = fininstrument("Cap",'Strike',0.02,'Maturity',datetime([2019,1,30 ; 2019,2,30 ; 2019,3,30

CapOpt=3×1 object
  3x1 Cap array with properties:

    Strike
    Maturity
    ResetOffset
    Reset
    Basis
    Principal
    ProjectionCurve
    DaycountAdjustedCashFlow
    BusinessDayConvention
    Holidays
    Name
```

Create `HullWhite` Model Object

Use `finmodel` to create a `HullWhite` model object.

```
HullWhiteModel = finmodel("HullWhite",'Alpha',0.62,'Sigma',0.99)

HullWhiteModel =
  HullWhite with properties:

    Alpha: 0.6200
    Sigma: 0.9900
```

Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create HullWhite Pricer Object

Use finpricer to create a HullWhite pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic",'Model',HullWhiteModel,'DiscountCurve',myRC)
```

```
outPricer =
  HullWhite with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.HullWhite]
```

Price Cap Instruments

Use price to compute the prices for the Cap instruments.

```
Price = price(outPricer,CapOpt)
```

```
Price = 3×1

    2.9366
    7.4694
   17.7915
```

Price Vanilla Cap Instrument Using Normal Model and Normal Pricer

This example shows the workflow to price a vanilla Cap instrument when you use a Normal model and a Normal pricing method.

Create ratecurve Object

Create a ratecurve object using ratecurve for the underlying interest-rate curve for the cap instrument.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create Cap Instrument Object

Use fininstrument to create a Cap instrument object.

```
CapOpt = fininstrument("Cap",'Maturity',datetime(2022,9,15),'Strike',0.04,'ProjectionCurve',myRC)
```

```
CapOpt =
  Cap with properties:

                    Strike: 0.0400
                  Maturity: 15-Sep-2022
               ResetOffset: 0
                     Reset: 1
                     Basis: 0
                 Principal: 100
            ProjectionCurve: [1x1 ratecurve]
   DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
                  Holidays: NaT
                      Name: ""
```

Create Normal Model Object

Use finmodel to create a Normal model object.

```
NormalModel = finmodel("Normal",'Volatility',0.01)
```

```
NormalModel =
  Normal with properties:
```

```
    Volatility: 0.0100
```

Create Normal Pricer Object

Use `finpricer` to create a `Normal` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'DiscountCurve',myRC,'Model',NormalModel)
```

```
outPricer =
  Normal with properties:

    DiscountCurve: [1x1 ratecurve]
            Shift: 0
            Model: [1x1 finmodel.Normal]
```

Price Cap Instrument

Use `price` to compute the price for the `Cap` instrument.

```
[Price, outPR] = price(outPricer, CapOpt)
```

```
Price = 0.0701
```

```
outPR =
  priceresult with properties:

       Results: [1x1 table]
    PricerData: []
```

Price Amortizing Cap Instrument Using Black Model and Black Pricer

This example shows the workflow to price an amortizing `Cap` instrument when you use a `Black` model and a `Black` pricing method.

Create Cap Instrument Object

Use `fininstrument` to create an amortizing `Cap` instrument object.

```
CADates = [datetime(2020,9,1) ; datetime(2023,9,1)];
CAPrincipal = [100; 85];
Principal = timetable(CADates,CAPrincipal);

CapOpt = fininstrument("Cap",'Maturity',datetime(2023,9,1),'Strike',0.015,'Principal',Principal,
```

```
CapOpt =
  Cap with properties:

                    Strike: 0.0150
                  Maturity: 01-Sep-2023
               ResetOffset: 0
                     Reset: 1
                     Basis: 0
                 Principal: [2x1 timetable]
```

```
           ProjectionCurve: [0x0 ratecurve]
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                    Holidays: NaT
                        Name: "cap_amortizing_option"
```

Create Black Model Object

Use `finmodel` to create a `Black` model object.

```
BlackModel = finmodel("Black",'Volatility',0.2)
```

```
BlackModel =
  Black with properties:

    Volatility: 0.2000
         Shift: 0
```

Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,1);
Type = 'zero';
ZeroTimes = [calyears([1 2 3 4 5 7 10])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates);
```

Create Black Pricer Object

Use `finpricer` to create a `Black` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'Model',BlackModel,'DiscountCurve',myRC)
```

```
outPricer =
  Black with properties:

           Model: [1x1 finmodel.Black]
    DiscountCurve: [1x1 ratecurve]
```

Price Cap Instrument

Use `price` to compute the price for the `Cap` instrument.

```
Price = price(outPricer,CapOpt)
```

```
Price = 0.3897
```

Price Vanilla Cap Instrument Using Hull-White Model and IRTree Pricer

This example shows the workflow to price a vanilla `Cap` instrument when using a `HullWhite` model and an `IRTree` pricing method.

Create Cap Instrument Object

Use `fininstrument` to create a `Cap` instrument object.

```
CapOpt = fininstrument("Cap",'Strike',0.02,'Maturity',datetime(2020,1,30),'Reset',4,'Principal',1
```

```
CapOpt =
  Cap with properties:

                     Strike: 0.0200
                   Maturity: 30-Jan-2020
                ResetOffset: 0
                      Reset: 4
                      Basis: 8
                  Principal: 100
             ProjectionCurve: [0x0 ratecurve]
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                   Holidays: NaT
                       Name: "cap_option"
```

Create `HullWhite` Model Object

Use `finmodel` to create a `HullWhite` model object.

```
HullWhiteModel = finmodel("HullWhite",'Alpha',0.01,'Sigma',0.10)
```

```
HullWhiteModel =
  HullWhite with properties:

    Alpha: 0.0100
    Sigma: 0.1000
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
       Compounding: -1
             Basis: 0
             Dates: [10x1 datetime]
             Rates: [10x1 double]
            Settle: 15-Sep-2018
      InterpMethod: "linear"
    ShortExtrapMethod: "next"
```

```
     LongExtrapMethod: "previous"
```

Create IRTree Pricer Object

Use `finpricer` to create an `IRTree` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
CFdates = cfdates(Settle, CapOpt.Maturity, CapOpt.Reset, CapOpt.Basis);
outPricer = finpricer("IRTree",'Model',HullWhiteModel,'DiscountCurve',myRC,'TreeDates',CFdates')
```

```
outPricer =
  HWBKTree with properties:

            Tree: [1x1 struct]
       TreeDates: [6x1 datetime]
           Model: [1x1 finmodel.HullWhite]
   DiscountCurve: [1x1 ratecurve]
```

Price Cap Instrument

Use `price` to compute the price and sensitivities for the `Cap` instrument.

```
[Price, outPR] = price(outPricer,CapOpt,["all"])
```

```
Price = 2.7733

outPR =
  priceresult with properties:

      Results: [1x4 table]
   PricerData: [1x1 struct]

outPR.Results

ans=1×4 table
    Price     Delta      Gamma      Vega
    ______    ______    _______    ______

    2.7733    28.932    -49.227    31.655
```

Price Cap Instrument Using LinearGaussian2F Model and IRMonteCarlo Pricer

This example shows the workflow to price a `Cap` instrument when using a `LinearGaussian2F` model and an `IRMonteCarlo` pricing method.

Create Cap Instrument Object

Use `fininstrument` to create a `Cap` instrument object.

```
CapOpt = fininstrument("Cap","Maturity",datetime(2022,9,15),'Strike',0.01,'Reset',2,'Name',"cap_
```

```
CapOpt =
  Cap with properties:
```

```
                    Strike: 0.0100
                  Maturity: 15-Sep-2022
               ResetOffset: 0
                     Reset: 2
                     Basis: 0
                 Principal: 100
            ProjectionCurve: [0x0 ratecurve]
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                  Holidays: NaT
                      Name: "cap_option"
```

Create LinearGaussian2F Model Object

Use `finmodel` to create a `LinearGaussian2F` model object.

```
LinearGaussian2FModel = finmodel("LinearGaussian2F",'Alpha1',0.07,'Sigma1',0.01,'Alpha2',0.5,'Sig
```

```
LinearGaussian2FModel =
  LinearGaussian2F with properties:

        Alpha1: 0.0700
        Sigma1: 0.0100
        Alpha2: 0.5000
        Sigma2: 0.0060
    Correlation: -0.7000
```

Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2019,1,1);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
          Compounding: -1
                Basis: 0
                Dates: [10x1 datetime]
                Rates: [10x1 double]
              Settle: 01-Jan-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create IRMonteCarlo Pricer Object

Use `finpricer` to create an `IRMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("IRMonteCarlo",'Model',LinearGaussian2FModel,'DiscountCurve',myRC,'Simulati
```

```
outPricer =
  G2PPMonteCarlo with properties:

          NumTrials: 1000
      RandomNumbers: []
      DiscountCurve: [1x1 ratecurve]
    SimulationDates: [01-Jul-2019    01-Jan-2020    01-Jan-2021    ...    ]
              Model: [1x1 finmodel.LinearGaussian2F]
```

Price Cap Instrument

Use `price` to compute the price and sensitivities for the `Cap` instrument.

```
[Price,outPR] = price(outPricer,CapOpt,["all"])
```

```
Price = 1.2156

outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×4 table
    Price     Delta     Gamma          Vega
    ______    ______    _____    _______________

    1.2156    131.37    11048    126.5    -157.38
```

More About

Cap

A cap is a contract that includes a guarantee that sets the maximum interest rate the holder pays, based on an otherwise floating interest rate.

The payoff for a cap is: max(*CurrentRate* − *CapRate*, 0)

For more information, see “Cap” on page 2-12.

Version History

Introduced in R2020a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `Cap` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

CDS

CDS instrument object

Description

Create and price a CDS instrument object for one or more CDS instruments using this workflow:

1. Use fininstrument to create a CDS instrument object for one or more CDS instruments.
2. Use defprobcurve to specify a default probability curve for the CDS instrument object.
3. Use finpricer to specify a Credit pricing method for one or more CDS instruments.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a CDS instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
CDSobj = fininstrument(InstrumentType,'Maturity',maturity_date,'
ContractSpread',contractspread_value)
CDSobj = fininstrument( ___ ,Name,Value)
```

Description

`CDSobj = fininstrument(InstrumentType,'Maturity',maturity_date,'ContractSpread',contractspread_value)` creates a CDS object for one or more CDS instruments by specifying InstrumentType and sets the properties on page 11-2729 for the required name-value pair arguments Maturity and ContractSpread.

`CDSobj = fininstrument( ___ ,Name,Value)` sets optional properties on page 11-2729 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `CDSobj = fininstrument("CDS",'Maturity',datetime(2019,1,30),'ContractSpread',200,'Period',4,'Basis',5,'BusinessDayConvention','follow','Name',"cds_instrument")` creates a CDS instrument with contract spread of 200. You can specify multiple name-value pair arguments.

Input Arguments

InstrumentType — Instrument type

string with value "CDS" | string array with values of "CDS" | character vector with value 'CDS' | cell array of character vectors with values of 'CDS'

Instrument type, specified as a string with the value of "CDS", a character vector with the value of 'CDS', an NINST-by-1 string array with values of "CDS", or an NINST-by-1 cell array of character vectors with values of 'CDS'.

Data Types: char | cell | string

CDS Name-Value Pair Arguments

Specify required and optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: CDSobj = fininstrument("CDS",'Maturity',datetime(2019,1,30),'ContractSpread',200,'Period',4,'Basis',5,'BusinessDayConvention',"follow",'Name',"cds_instrument")

Required CDS Name-Value Pair Arguments

Maturity — Maturity date
datetime array | string array | date character vector

Maturity date, specified as the comma-separated pair consisting of 'Maturity' and a scalar or an NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, CDS also accepts serial date numbers as inputs, but they are not recommended.

If you use date characters vector or strings, the format must be recognizable by datetime because the Maturity property is stored as a datetime.

ContractSpread — Contract spreads expressed in basis points
scalar numeric | numeric vector

Contract spreads expressed in basis points, specified as the comma-separated pair consisting of 'ContractSpread' and a scalar numeric or an NINST-by-1 numeric vector.

Data Types: double

Optional CDS Name-Value Pair Argument

Period — Premium payments per year
4 (default) | scalar numeric with value of 1, 2, 3, 4, 6, 12 | numeric vector with values of 1, 2, 3, 4, 6, 12

Premium payments per year, specified as the comma-separated pair consisting of 'Period' and a scalar numeric or an NINST-by-1 numeric vector with values of 1, 2, 3, 4, 6, or 12.

Data Types: double

Basis — Day count basis
0 (actual/actual) (default) | scalar of positive integers of the set [1...13] | vector of positive integers of the set [1...13]

Day count basis, specified as the comma-separated pair consisting of 'Basis' and a scalar positive integer or an NINST-by-1vector of positive integers using the following values:

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`BusinessDayConvention` — Business day convention for cash flow dates
`"actual"` (default) | string | string array | character vector | cell array of character vectors

Business day conventions for cash flow dates, specified as the comma-separated pair consisting of `'BusDayConvention'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- `"actual"` — Nonbusiness days are effectively ignored. Cash flows that fall on nonbusiness days are assumed to be distributed on the actual date.
- `"follow"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- `"modifiedfollow"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day. However, if the following business day is in a different month, the previous business day is adopted instead.
- `"previous"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- `"modifiedprevious"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However, if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell` | `string`

`PayAccruedPremium` — Flag for accrued premiums
`true` (default) | scalar value of `true` or `false` | vector with values of `true` or `false`

Flag for accrued premiums, specified as the comma-separated pair consisting of `'PayAccruedPremium'` and a scalar Boolean flag or an `NINST`-by-`1` vector of Boolean flags that are `true` if accrued premiums are paid upon default and `false` otherwise.

Data Types: `logical`

`RecoveryRate` — Recovery rate
`0.4` (default) | scalar decimal | vector of decimals

Recovery rate, specified as the comma-separated pair consisting of `'RecoveryRate'` and a scalar decimal or an `NINST`-by-`1` vector of decimals from `0` to `1`.

Data Types: `double`

`Notional` — Contract notional value
`100` (default) | scalar positive integer | vector of positive integers

Contract notional value, specified as the comma-separated pair consisting of `'Notional'` and a scalar positive integer or an `NINST`-by-`1` vector of positive integers.

Data Types: `double`

`Holidays` — Holidays used in computing business days
`NaT` (default) | datetimes | cell array of character vectors | date string array

Holidays used in computing business days, specified as the comma-separated pair consisting of `'Holidays'` and dates using an `NINST`-by-`1` vector of datetimes, cell array of date character vectors, or date string array. For example:

```
H = holidays(datetime('today'),datetime(2025,12,15));
CDSobj = fininstrument("CDS",'Maturity',datetime(2025,12,15),'ContractSpread',200,'Holidays',H)
```

To support existing code, `CDS` also accepts serial date numbers as inputs, but they are not recommended.

`Name` — User-defined name for instrument
`" "` (default) | string | string array | character vector | cell array of character vectors

User-defined name for one of more instruments, specified as the comma-separated pair consisting of `'Name'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

Properties

`Maturity` — Maturity date
datetime | vector of datetimes

Maturity date, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`ContractSpread` — Contract spreads expressed in basis points
scalar numeric | numeric vector

Contract spreads expressed in basis points, returned as a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`Period` — Premium payments per year
`4` (default) | scalar numeric with value of `1`, `2`, `3`, `4`, `6` or `12` | numeric vector with values of `1`, `2`, `3`, `4`, `6` or `12`

Premium payments per year, returned as a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`Basis` — Day count basis
`0` (actual/actual) (default) | scalar positive integers of the set `[1...13]` | vector of positive integers of the set `[1...13]`

Day count basis, returned as a scalar positive integer or an `NINST`-by-`1` vector of positive integers.

Data Types: `double`

`BusinessDayConvention` — Business day convention for cash flow dates
`"actual"` (default) | string | string array

Business day conventions for cash flow dates, returned as a scalar string or an `NINST`-by-`1` string array.

Data Types: `string`

`PayAccruedPremium` — Flag for accrued premiums
`true` (default) | scalar value `true` or `false` | vector of values `true` or `false`

Flag for accrued premiums, returned as a scalar Boolean flag or an `NINST`-by-`1` vector of Boolean flags.

Data Types: `logical`

`RecoveryRate` — Recovery rate
`0.4` (default) | scalar decimal | vector of decimals

Recovery rate, returned as a scalar decimal or an `NINST`-by-`1` vector of decimals.

Data Types: `double`

`Notional` — Contract notional value
`100` (default) | scalar positive integer | vector of positive integers

Contract notional value, returned as a scalar positive integer or an `NINST`-by-`1` vector of positive integers.

Data Types: `double`

`Holidays` — Holidays used in computing business days
`NaT` (default) | datetimes

Holidays used in computing business days, returned as an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`Name` — User-defined name for instrument
`" "` (default) | string | string array

User-defined name for the instrument, returned as a string or an `NINST`-by-`1` string array.

Data Types: `string`

Examples

Price CDS Instrument Using Default Probability Curve and Credit Pricer

This example shows the workflow to price a `CDS` instrument when you use a `defprobcurve` model and a `Credit` pricing method.

Create `CDS` Instrument Object

Use `fininstrument` to create a `CDS` instrument object.

```
CDS = fininstrument("CDS",'Maturity',datetime(2021,9,15),'ContractSpread',15,'Notional',20000,'Pe
```

```
CDS =
  CDS with properties:

          ContractSpread: 15
                Maturity: 15-Sep-2021
                  Period: 4
                   Basis: 3
            RecoveryRate: 0.4000
    BusinessDayConvention: "follow"
                Holidays: NaT
        PayAccruedPremium: 1
                Notional: 20000
                    Name: "CDS_instrument"
```

Create `defprobcurve` Object

Create a `defprobcurve` object using `defprobcurve`.

```
Settle = datetime(2020,9,20);
DefProbTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
DefaultProbabilities = [0.005 0.007 0.01 0.015 0.026 0.04 0.077 0.093 0.15 0.20]';
ProbDates = Settle + DefProbTimes;
DefaultProbCurve = defprobcurve(Settle,ProbDates,DefaultProbabilities,'Basis',5)
```

```
DefaultProbCurve =
  defprobcurve with properties:

                 Settle: 20-Sep-2020
                  Basis: 5
                  Dates: [10x1 datetime]
    DefaultProbabilities: [10x1 double]
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2020,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
```

```
ZeroDates = Settle + ZeroTimes;
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2020
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `Credit` Pricer Object

Use `finpricer` to create a `Credit` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("credit",'DefaultProbabilityCurve',DefaultProbCurve,'DiscountCurve',myRC)
```

```
outPricer =
  Credit with properties:

             DiscountCurve: [1x1 ratecurve]
                  TimeStep: 10
    DefaultProbabilityCurve: [1x1 defprobcurve]
```

Price `CDS` Instrument

Use `price` to compute the price for the `CDS` instrument.

```
Price = price(outPricer,CDS)
```

```
Price = 52.7426
```

Price Multiple `CDS` Instruments Using Default Probability Curve and Credit Pricer

This example shows the workflow to price multiple `CDS` instruments when you use a `defprobcurve` model and a `Credit` pricing method.

Create `CDS` Instrument Object

Use `fininstrument` to create a `CDS` instrument object for three CDS instruments.

```
CDS = fininstrument("CDS",'Maturity',datetime([2021,9,15 ; 2021,10,15 ; 2021,11,15]),'ContractSp
```

```
CDS=3×1 object
  3x1 CDS array with properties:

    ContractSpread
    Maturity
    Period
```

```
    Basis
    RecoveryRate
    BusinessDayConvention
    Holidays
    PayAccruedPremium
    Notional
    Name
```

Create `defprobcurve` Object

Create a `defprobcurve` object using `defprobcurve`.

```
Settle = datetime(2020,9,20);
DefProbTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
DefaultProbabilities = [0.005 0.007 0.01 0.015 0.026 0.04 0.077 0.093 0.15 0.20]';
ProbDates = Settle + DefProbTimes;
DefaultProbCurve = defprobcurve(Settle,ProbDates,DefaultProbabilities,'Basis',5)
```

```
DefaultProbCurve =
  defprobcurve with properties:

                 Settle: 20-Sep-2020
                  Basis: 5
                  Dates: [10x1 datetime]
    DefaultProbabilities: [10x1 double]
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2020,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2020
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `Credit` Pricer Object

Use `finpricer` to create a `Credit` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("credit",'DefaultProbabilityCurve',DefaultProbCurve,'DiscountCurve',myRC)
```

```
outPricer =
  Credit with properties:

             DiscountCurve: [1x1 ratecurve]
                  TimeStep: 10
    DefaultProbabilityCurve: [1x1 defprobcurve]
```

Price CDS Instruments

Use `price` to compute the prices for the `CDS` instruments.

```
Price = price(outPricer,CDS)
```

```
Price = 3×1

   52.7426
   80.2945
  108.0357
```

Version History

Introduced in R2020a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `CDS` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

CDSOption

`CDSOption` instrument object

Description

Create and price a `CDSOption` instrument object for one or more CDS Option instruments using this workflow:

1. Use `fininstrument` to create a `CDSOption` instrument object for one or more CDS Option instruments. By default, this creates a single-name CDS option. You can create a CDS index option by specifying the optional name-value argument `AdjustedForwardSpread`.
2. Use `finmodel` to specify a `CDSBlack` model for the `CDSoption` instrument object.
3. Use `finpricer` to specify a `CDSBlack` pricing method for one or more `CDSoption` instruments.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods using a `CDSoption` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
CDSOptionObj = fininstrument(InstrumentType,'ExerciseDate',exercise_date,'
Strike',strike_value,'CDS',cds_obj)
CDSOptionObj = fininstrument( ___ ,Name,Value)
```

Description

`CDSOptionObj = fininstrument(InstrumentType,'ExerciseDate',exercise_date,'Strike',strike_value,'CDS',cds_obj)` creates a `CDSOption` object for one or more CDS Option instruments by specifying `InstrumentType` and sets the properties on page 11-2737 for the required name-value pair arguments `ExerciseDate`, `Strike`, and `CDS`.

`CDSOptionObj = fininstrument( ___ ,Name,Value)` sets optional properties on page 11-2737 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `CDSOptionObj = fininstrument("CDSoption",'ExerciseDate',datetime(2019,1,30),'Strike',500,'CDS',cds_object,'Name',"cdsoption_instrument")` creates a `CDSOption` instrument for a single-name CDS option with a strike of 500. You can specify multiple name-value pair arguments.

Input Arguments

`InstrumentType` — Instrument type

string with value `"CDSoption"` | string array with values of `"CDSoption"` | character vector with value `'CDSoption'` | cell array of character vectors with values of `'CDSoption'`

Instrument type, specified as a string with the value of "CDSoption", a character vector with the value of 'CDSoption', an NINST-by-1 string array with values of "CDSoption", or an NINST-by-1 cell array of character vectors with values of 'CDSoption'.

Data Types: char | cell | string

CDSOption Name-Value Pair Arguments

Specify required and optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: CDSOptionObj = fininstrument("CDSoption",'ExerciseDate',datetime(2019,1,30),'Strike',500,'CDS',cds_object,'Name',"cdsoption_instrument")

Required CDSOption Name-Value Pair Arguments

ExerciseDate — Option exercise date
datetime array | string array | date character vector

Option exercise date, specified as the comma-separated pair consisting of 'ExerciseDate' and a scalar or an NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, CDSOption also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by datetime because the ExerciseDate property is stored as a datetime.

Strike — Option strike price
scalar nonnegative numeric | vector of nonnegative numeric

Option strike price, specified as the comma-separated pair consisting of 'Strike' and a scalar nonnegative numeric or an NINST-by-1 vector of nonnegative numeric.

Data Types: double

CDS — CDS object
CDS object | vector of CDS objects

CDS object, specified as the comma-separated pair consisting of 'CDS' and a scalar CDS object or an NINST-by-1 vector of CDS objects.

Data Types: object

Optional CDSOption Name-Value Pair Argument

OptionType — Option type
"call" (default) | string with value "call" or "put" | string array with values of "call" or "put" | character vector with value 'call' or 'put' | cell array of character vectors with values of 'call' or 'put'

Option type, specified as the comma-separated pair consisting of 'OptionType' and a scalar string or character vector or an NINST-by-1 cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

`Knockout` — Flag indicating if option is knockout type
`false` (default) | scalar logical with value `true` or `false` | vector of logicals with values of `true` or `false`

Flag indicating if option is knockout type, specified as the comma-separated pair consisting of `'Knockout'` and a scalar logical or an `NINST`-by-`1` vector of logical values.

Data Types: `logical`

`AdjustedForwardSpread` — Adjusted forward spread (in basis points) for pricing CDS index option
`NaN` (single-name CDS option) (default) | scalar numeric | numeric vector

Adjusted forward spread (in basis points) for pricing a CDS index option, specified as the comma-separated pair consisting of `'AdjustedForwardSpread'` and a scalar numeric or an `NINST`-by-`1` numeric vector. For more information on using `'AdjustedForwardSpread'` when pricing a CDS index option, see “Price CDS Index Options Using CDS Black Model and CDS Black Pricer” on page 11-2742.

Data Types: `double`

`Name` — User-defined name for instrument
`" "` (default) | string | string array | character vector | cell array of character vectors

User-defined name for one of more instruments, specified as the comma-separated pair consisting of `'Name'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

Properties

`ExerciseDate` — Option exercise date
datetime | vector of datetimes

Option exercise date, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`Strike` — Option strike price
scalar nonnegative numeric | vector of nonnegative numeric

Option strike price, returned as a scalar nonnegative numeric or an `NINST`-by-`1` vector of nonnegative numeric values.

Data Types: `double`

`CDS` — `CDS` object
`CDS` object | vector of `CDS` objects

`CDS` object, returned as a scalar `CDS` object or an `NINST`-by-`1` vector of CDS objects.

Data Types: `object`

OptionType — Definition of option
"call" (default) | string with value "call" or "put" | string array with values of "call" or "put"

Definition of option, returned as a scalar string or an NINST-by-1 string array with values of "call" or "put".

Data Types: string

Knockout — Flag indicating if option is knockout type
false (default) | scalar logical with value true or false | vector of logicals with values of true or false

Flag indicating if option is knockout type, returned as a scalar logical or an NINST-by-1 vector of logicals.

Data Types: logical

AdjustedForwardSpread — Adjusted forward spread (in basis points) for pricing CDS index option
NaN (single-name CDS option) (default) | scalar numeric | numeric vector

Adjusted forward spread (in basis points) for pricing a CDS index option, returned as a scalar numeric or an NINST-by-1 numeric vector.

Data Types: double

Name — User-defined name for instrument
" " (default) | string | string array

User-defined name for the instrument, returned as a scalar string or an NINST-by-1 string array.

Data Types: string

Examples

Price CDS Option Instrument Using CDS Black Model and CDS Black Pricer

This example shows the workflow to price a CDSOption instrument for a single-name CDS option when you use a CDSBlack model and a CDSBlack pricing method.

Create CDS Instrument Object

Use fininstrument to create the underlying CDS instrument object.

```
CDSOpt = fininstrument("CDS",'Maturity',datetime(2021,9,15),'ContractSpread',150,'Notional',100,
```

```
CDSOpt =
  CDS with properties:

          ContractSpread: 150
                Maturity: 15-Sep-2021
                  Period: 4
                   Basis: 2
            RecoveryRate: 0.4000
    BusinessDayConvention: "actual"
                Holidays: NaT
```

```
        PayAccruedPremium: 1
                 Notional: 100
                     Name: "CDS_option"
```

Create defprobcurve Object

Create a `defprobcurve` object using `defprobcurve`.

```
Settle = datetime(2020,9,20);
DefProbTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
DefaultProbabilities = [0.005 0.007 0.01 0.015 0.026 0.04 0.077 0.093 0.15 0.20]';
ProbDates = Settle + DefProbTimes;
DefaultProbCurve = defprobcurve(Settle,ProbDates,DefaultProbabilities,'Basis',5)
```

```
DefaultProbCurve =
  defprobcurve with properties:

                  Settle: 20-Sep-2020
                   Basis: 5
                   Dates: [10x1 datetime]
    DefaultProbabilities: [10x1 double]
```

Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2020,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                 Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2020
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create CDSOption Instrument Object

Use `fininstrument` to create a `CDSOption` instrument object for a single-name CDS option.

```
CDSOptionInst = fininstrument("CDSOption",'ExerciseDate',datetime(2021,8,15),'Strike',20,'CDS',CD
```

```
CDSOptionInst =
  CDSOption with properties:

              OptionType: "put"
```

```
                Strike: 20
             Knockout: 1
    AdjustedForwardSpread: NaN
            ExerciseDate: 15-Aug-2021
                     CDS: [1x1 fininstrument.CDS]
                    Name: "CDSOption_option"
```

Create CDSBlack Model Object

Use `finmodel` to create a `CDSBlack` model object.

```
CDSBlackModel = finmodel("CDSBlack",'SpreadVolatility',.2)
```

```
CDSBlackModel =
  CDSBlack with properties:

    SpreadVolatility: 0.2000
```

Create CDSBlack Pricer Object

Use `finpricer` to create a `CDSBlack` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'Model',CDSBlackModel,'DefaultProbabilityCurve',DefaultProbCurve
```

```
outPricer =
  CDSBlack with properties:

                      Model: [1x1 finmodel.CDSBlack]
              DiscountCurve: [1x1 ratecurve]
    DefaultProbabilityCurve: [1x1 defprobcurve]
```

Price CDSOption Instrument

Use `price` to compute the price for the `CDSOption` instrument for a single-name CDS option.

```
Price = price(outPricer,CDSOptionInst)
```

```
Price = 3.3016e-04
```

Price Multiple CDS Option Instruments Using CDS Black Model and CDS Black Pricer

This example shows the workflow to price multiple `CDSOption` instruments when you use a `CDSBlack` model and a `CDSBlack` pricing method.

Create CDS Instrument Object

Use `fininstrument` to create the underlying `CDS` instrument object for three CDS Option instruments.

```
CDSOpt = fininstrument("CDS",'Maturity',datetime([2021,9,15 ; 2021,10,15 ; 2021,11,15]),'Contract
```

```
CDSOpt=3×1 object
  3x1 CDS array with properties:
```

```
    ContractSpread
    Maturity
    Period
    Basis
    RecoveryRate
    BusinessDayConvention
    Holidays
    PayAccruedPremium
    Notional
    Name
```

Create `defprobcurve` Object

Create a `defprobcurve` object using `defprobcurve`.

```
Settle = datetime(2020,9,20);
DefProbTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
DefaultProbabilities = [0.005 0.007 0.01 0.015 0.026 0.04 0.077 0.093 0.15 0.20]';
ProbDates = Settle + DefProbTimes;
DefaultProbCurve = defprobcurve(Settle,ProbDates,DefaultProbabilities,'Basis',5)
```

```
DefaultProbCurve =
  defprobcurve with properties:

                 Settle: 20-Sep-2020
                  Basis: 5
                  Dates: [10x1 datetime]
    DefaultProbabilities: [10x1 double]
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2020,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
       Compounding: -1
             Basis: 0
             Dates: [10x1 datetime]
             Rates: [10x1 double]
            Settle: 15-Sep-2020
      InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create CDSOption Instrument Object

Use `fininstrument` to create a `CDSOption` instrument object for three single-name CDS options.

```
CDSOptionInst = fininstrument("CDSOption",'ExerciseDate',datetime(2021,8,15),'Strike',20,'CDS',CD
```

```
CDSOptionInst=3×1 object
  3x1 CDSOption array with properties:

    OptionType
    Strike
    Knockout
    AdjustedForwardSpread
    ExerciseDate
    CDS
    Name
```

Create CDSBlack Model Object

Use `finmodel` to create a `CDSBlack` model object.

```
CDSBlackModel = finmodel("CDSBlack",'SpreadVolatility',.2)
```

```
CDSBlackModel =
  CDSBlack with properties:

    SpreadVolatility: 0.2000
```

Create CDSBlack Pricer Object

Use `finpricer` to create a `CDSBlack` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'Model',CDSBlackModel,'DefaultProbabilityCurve',DefaultProbCurve
```

```
outPricer =
  CDSBlack with properties:

                     Model: [1x1 finmodel.CDSBlack]
             DiscountCurve: [1x1 ratecurve]
    DefaultProbabilityCurve: [1x1 defprobcurve]
```

Price CDSOption Instruments

Use `price` to compute the prices for the three `CDSOption` instruments.

```
Price = price(outPricer,CDSOptionInst)
```

```
Price = 3×1

    0.0003
    0.0384
    0.5941
```

Price CDS Index Options Using CDS Black Model and CDS Black Pricer

This example shows the workflow to use a `CDSOption` instrument to price CDS index options when you use a `CDSBlack` model and a `CDSBlack` pricing method.

Set Up Data for CDS Index

```
% CDS index and option data
Recovery = .4;
Basis = 2;
Period = 4;
CDSMaturity = datetime(2017,6,20);
ContractSpread = 100;
IndexSpread = 140;
BusDayConvention = 'follow';
Settle = datetime(2012,4,13);
OptionMaturity = datetime(2012,6,20);
OptionStrike = 140;
SpreadVolatility = .69;
```

Create `ratecurve` Object for Zero Curve Using `irbootstrap`

Create `ratecurve` object for a zero curve using `irbootstrap`.

```
% Zero curve data
DepRates = [0.004111 0.00563 0.00757 0.01053]';
DepTimes = calmonths([1 2 3 6]');
DepDates = Settle + DepTimes;
nDeposits = length(DepTimes);

SwapRates = [0.01387 0.01035 0.01145 0.01318 0.01508 0.01700 0.01868 ...
    0.02012 0.02132 0.02237 0.02408 0.02564 0.02612 0.02524]';
SwapTimes = calyears([1 2 3 4 5 6 7 8 9 10 12 15 20 30]');
SwapDates = Settle + SwapTimes;
nSwaps = length(SwapTimes);

nInst = nDeposits + nSwaps;

BootInstruments(nInst,1) = fininstrument.FinInstrument;
for ii=1:length(DepDates)
    BootInstruments(ii) = fininstrument("deposit","Maturity",DepDates(ii),"Rate",DepRates(ii));
end

for ii=1:length(SwapDates)
    BootInstruments(ii+nDeposits) = fininstrument("swap","Maturity",SwapDates(ii),"LegRate",[Swa
end

ZeroCurve = irbootstrap(BootInstruments,Settle)
```

```
ZeroCurve =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [18x1 datetime]
               Rates: [18x1 double]
              Settle: 13-Apr-2012
```

```
         InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Bootstrap Default Probability Curve

Use `defprobstrip` to bootstrap default probability curve assuming a flat index spread.

```
ProbDates = datemnth(OptionMaturity,(0:5*12)');
MarketCDSInstruments = fininstrument("cds", ...
    'ContractSpread', ContractSpread, 'Maturity', CDSMaturity);
DefaultProbCurve = defprobstrip(ZeroCurve, MarketCDSInstruments, IndexSpread, 'ProbDates', ProbDa
```

```
DefaultProbCurve =
  defprobcurve with properties:

                 Settle: 13-Apr-2012
                  Basis: 2
                  Dates: [61x1 datetime]
    DefaultProbabilities: [61x1 double]
```

Compute Spot and Forward RPV01s

Compute the spot and forward RPV01s using `cdsrpv01`.

```
ProbData = [datenum(DefaultProbCurve.Dates) DefaultProbCurve.DefaultProbabilities];

% RPV01(t,T)
RPV01_CDSMaturity = cdsrpv01(ZeroCurve,ProbData,Settle,CDSMaturity)
```

```
RPV01_CDSMaturity = 4.7853
```

```
% RPV01(t,t_E,T)
RPV01_OptionExpiryForward = cdsrpv01(ZeroCurve,ProbData,Settle,CDSMaturity,...
    'StartDate',OptionMaturity)
```

```
RPV01_OptionExpiryForward = 4.5972
```

```
% RPV01(t,t_E) = RPV01(t,T) - RPV01(t,t_E,T)
RPV01_OptionExpiry = RPV01_CDSMaturity - RPV01_OptionExpiryForward
```

```
RPV01_OptionExpiry = 0.1882
```

Compute Spot Spreads

Compute the spot spreads using `cdsspread`.

```
% S(t,t_E)
Spread_OptionExpiry = cdsspread(ZeroCurve,ProbData,Settle,OptionMaturity,...
    'Period',Period,'Basis',Basis,'BusDayConvention',BusDayConvention,...
    'PayAccruedPremium',true,'recoveryrate',Recovery)
```

```
Spread_OptionExpiry = 139.8995
```

```
% S(t,T)
Spread_CDSMaturity = cdsspread(ZeroCurve,ProbData,Settle,CDSMaturity,...
    'Period',Period,'Basis',Basis,'BusDayConvention',BusDayConvention,...
    'PayAccruedPremium',true,'recoveryrate',Recovery)
```

```
Spread_CDSMaturity = 139.9999
```

Compute Forward Spread

Compute the forward spread using the spot spreads and RPV01s.

```
% F = S(t,t_E,T)
ForwardSpread = (Spread_CDSMaturity.*RPV01_CDSMaturity - Spread_OptionExpiry.*RPV01_OptionExpiry
```

```
ForwardSpread = 140.0040
```

Compute Front-End Protection

Compute the front-end protection (FEP).

```
FEP = 10000*(1-Recovery)*ZeroCurve.discountfactors(OptionMaturity)*DefaultProbCurve.DefaultProba
```

```
FEP = 26.3108
```

Compute Adjusted Forward Spread

Compute the adjusted forward spread to use when creating an `CDSOption` instrument.

```
AdjustedForwardSpread = ForwardSpread + FEP./RPV01_OptionExpiryForward
```

```
AdjustedForwardSpread = 145.7273
```

Compute CDS Option Prices with Adjusted Forward Spread

Use `fininstrument` to create the underlying `CDS` instrument object for the two CDS Option instruments.

```
CDS = fininstrument("cds",'ContractSpread', ContractSpread, 'Maturity', CDSMaturity)
```

```
CDS =
  CDS with properties:

          ContractSpread: 100
                Maturity: 20-Jun-2017
                  Period: 4
                   Basis: 2
            RecoveryRate: 0.4000
    BusinessDayConvention: "actual"
                Holidays: NaT
        PayAccruedPremium: 1
                Notional: 10000000
                    Name: ""
```

Use `fininstrument` to create a `CDSOption` instrument for two CDS index option instruments.

```
CDSCallOption = fininstrument("cdsoption", 'Strike', OptionStrike, ...
    'ExerciseDate', OptionMaturity, 'OptionType', 'call', 'CDS', CDS, ...
    'Knockout',true, 'AdjustedForwardSpread', AdjustedForwardSpread)
```

```
CDSCallOption =
  CDSOption with properties:

              OptionType: "call"
                  Strike: 140
```

```
                Knockout: 1
    AdjustedForwardSpread: 145.7273
             ExerciseDate: 20-Jun-2012
                      CDS: [1x1 fininstrument.CDS]
                     Name: ""
```

```
CDSPutOption = fininstrument("cdsoption", 'Strike', OptionStrike, ...
    'ExerciseDate', OptionMaturity, 'OptionType', 'put', 'CDS', CDS, ...
    'Knockout',true, 'AdjustedForwardSpread', AdjustedForwardSpread)
```

```
CDSPutOption =
  CDSOption with properties:

               OptionType: "put"
                   Strike: 140
                Knockout: 1
    AdjustedForwardSpread: 145.7273
             ExerciseDate: 20-Jun-2012
                      CDS: [1x1 fininstrument.CDS]
                     Name: ""
```

Create CDSBlack Model Object

Use `finmodel` to create a `CDSBlack` model object.

```
CDSOptionModel = finmodel("cdsblack",'SpreadVolatility',SpreadVolatility)
```

```
CDSOptionModel =
  CDSBlack with properties:

    SpreadVolatility: 0.6900
```

Create CDSBlack Pricer Object

Use `finpricer` to create a `CDSBlack` pricer object and use the `ratecurve` object for the zero curve for the `'DiscountCurve'` name-value pair argument.

```
CDSOptionpricer = finpricer("analytic",'Model',CDSOptionModel,'DiscountCurve',ZeroCurve,'DefaultI
```

```
CDSOptionpricer =
  CDSBlack with properties:

                     Model: [1x1 finmodel.CDSBlack]
             DiscountCurve: [1x1 ratecurve]
    DefaultProbabilityCurve: [1x1 defprobcurve]
```

Price CDS Index Options

Use `price` to compute the price for the two CDS index options.

```
outPrice = price(CDSOptionpricer, [CDSCallOption;CDSPutOption]);
fprintf('    Payer: %.0f   Receiver: %.0f  \n',outPrice(1),outPrice(2));
```

```
Payer: 92   Receiver: 66
```

More About

Credit Default Swap Option

A credit default swap (CDS) option, or credit default swaption, is a contract that provides the option holder with the right, but not the obligation, to enter into a credit default swap in the future.

CDS options can be either payer swaptions or receiver swaptions. In a payer swaption, the option holder has the right to enter into a CDS in which they are paying premiums, and in a receiver swaption, the option holder is receiving premiums.

A CDS option can be a single-name CDS option or CDS index option. When pricing a CDS index option , use the optional name-value argument `AdjustedForwardSpread`. Unlike a single-name CDS, a CDS portfolio index contains multiple credits. When one or more of the credits default, the corresponding contingent payments are made to the protection buyer but the contract still continues with reduced coupon payments. Considering the fact that the CDS index option does not cancel when some of the underlying credits default before expiry, one might attempt to price CDS index options using the Black's model for non-knockout single-name CDS option. However, Black's model in this form is not appropriate for pricing CDS index options because it does not capture the exercise decision correctly when the strike spread (K) is very high, nor does it ensure put-call parity when (K) is not equal to the contractual spread (O'Kane, 2008).

However, with the appropriate modifications, Black's model for single-name CDS options used with a `CDSOption` instrument and `CDSBlack` pricer can provide a good approximation for CDS index options. While there are some variations in the way the Black's model is modified for CDS index options, they usually involve adjusting the forward spread F, the strike spread K, or both. Here we describe the approach of adjusting the forward spread only. In the Black's model for single-name CDS options, the forward spread F is defined as:

$$F = S(t, t_E, T) = \frac{S(t, T)RPV01(t, T) - S(t, t_E)RPV01(t, t_E)}{RPV01(t, t_E, T)}$$

where

S is the spread.

RPV01 is the risky present value of a basis point (see `cdsrpv01`).

t is the valuation date.

t_E is the option expiry date.

T is the CDS maturity date.

To capture the exercise decision correctly for CDS index options, we use the knockout form of the Black's model and adjust the forward spread to incorporate the *FEP* (front end protection) as follows:

$$F_{Adj} = F + \frac{FEP}{RPV01(t, t_E, T)}$$

with *FEP* defined as

$$FEP = (1 - R)Z(t, t_E)(1 - Q(t, t_E))$$

where

R is the recovery rate.

Z is the discount factor.

Q is the survival probability.

In the `CDSOption` object, forward spread adjustment can be made with the `AdjustedForwardSpread` name-value argument. When computing the adjusted forward spread, you can compute the spreads using `cdsspread` and the RPV01s using `cdsrpv01`.

Version History

Introduced in R2020a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `CDSOption` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

FixedBond

`FixedBond` instrument object

Description

Create and price a `FixedBond` instrument object for one of more Fixed Bond instruments using this workflow:

1. Use `fininstrument` to create a `FixedBond` instrument object for one of more Fixed Bond instruments.
2. Use `ratecurve` to specify a curve model for the `FixedBond` instrument object or use a `HullWhite`, `BlackKarasinski`, `BlackDermanToy`, `BraceGatarekMusiela`, `SABRBraceGatarekMusiela`, or `LinearGaussian2F` model.
3. Choose a pricing method.
   - When using a `ratecurve` use `finpricer` to specify a `Discount` pricing method for one or more `FixedBond` instruments.
   - When using a `HullWhite`, `BlackKarasinski`, or `BlackDermanToy` model, use `finpricer` to specify an `IRTree` pricing method for one or more `FixedBond` instruments.
   - When using a `HullWhite`, `BlackKarasinski`, `BraceGatarekMusiela`, `SABRBraceGatarekMusiela`, or `LinearGaussian2F` model, use `finpricer` to specify an `IRMonteCarlo` pricing method for one or more `FixedBond` instruments.

For more detailed information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a `FixedBond` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
FixedBondObj = fininstrument(InstrumentType,'CouponRate',couponrate_value,'
Maturity',maturity_date)
FixedBondObj = fininstrument( ___ ,Name,Value)
```

Description

`FixedBondObj = fininstrument(InstrumentType,'CouponRate',couponrate_value,'Maturity',maturity_date)` creates a `FixedBond` object for one of more Fixed Bond instruments by specifying `InstrumentType` and sets the properties on page 11-2754 for the required name-value pair arguments `CouponRate` and `Maturity`.

The `FixedBond` instrument supports a vanilla bond, a stepped coupon bond, and an amortizing bond. For more information, see “More About” on page 11-2767.

`FixedBondObj = fininstrument( ___ ,Name,Value)` sets optional properties on page 11-2754 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `FixedBondObj = fininstrument("FixedBond",'CouponRate',0.034,'Maturity',datetime(2019,1,30),'Period',4,'Basis',1,'Principal',100,'FirstCouponDate',datetime(2016,1,30),'EndMonthRule',true,'Name',"fixedbond_instrument")` creates a `FixedBond` option with a coupon rate of 0.34 and a maturity of January 30, 2019. You can specify multiple name-value pair arguments.

Input Arguments

`InstrumentType` — Instrument type

string with value `"Fixedbond"` | string array with values of `"Fixedbond"` | character vector with value `'FixedBond'` | cell array of character vectors with values of `'FixedBond'`

Instrument type, specified as a string with the value of `"FixedBond"`, a character vector with the value of `'FixedBond'`, an `NINST`-by-`1` string array with values of `"FixedBond"`, or an `NINST`-by-`1` cell array of character vectors with values of `'FixedBond'`.

Data Types: `char` | `cell` | `string`

`FixedBond` Name-Value Pair Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `FixedBondObj = fininstrument("FixedBond",'CouponRate',0.034,'Maturity',datetime(2019,1,30),'Period',4,'Basis',1,'Principal',100,'FirstCouponDate',datetime(2016,1,30),'EndMonthRule',true,'Name',"fixedbond_instrument")`

Required `FixedBond` Name-Value Pair Arguments

`CouponRate` — `FixedBond` coupon rate

scalar decimal | vector of decimals | timetable

`FixedBond` coupon rate, specified as the comma-separated pair consisting of `'CouponRate'` and a scalar decimal or an `NINST`-by-`1` vector of decimals for an annual rate or a timetable where the first column is dates and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Note If you are creating one or more `FixedBond` instruments and use a timetable, the timetable specification applies to all of the `FixedBond` instruments. `CouponRate` does not accept an `NINST`-by-`1` cell array of timetables as input.

Data Types: `double` | `timetable`

`Maturity` — `FixedBond` maturity date

datetime array | string array | date character vector

`FixedBond` maturity date, specified as the comma-separated pair consisting of `'Maturity'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `FixedBond` also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `Maturity` property is stored as a datetime.

Optional FixedBond Name-Value Pair Arguments

`Period` — Frequency of payments per year

`2` (default) | scalar numeric value of `0`, `1`, `2`, `3`, `4`, `6`, or `12` | numeric vector with values of `0`, `1`, `2`, `3`, `4`, `6`, or `12`

Frequency of payments, specified as the comma-separated pair consisting of `'Period'` and a scalar integer or an `NINST`-by-`1` vector of integers. Values for `Period` are `1`, `2`, `3`, `4`, `6`, or `12`.

Data Types: `double`

`Basis` — Day count basis

`0` (actual/actual) (default) | scalar integer from `0` to `13` | vector of integers from `0` to `13`

Day count basis, specified as the comma-separated pair consisting of `'Basis'` and scalar integer or an `NINST`-by-`1` vector of integers using the following values:

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Principal amount or principal value schedule

`100` (default) | scalar numeric | numeric vector | timetable

Principal amount or principal value schedule, specified as the comma-separated pair consisting of `'Principal'` and a scalar numeric or an `NINST`-by-`1` numeric vector or a timetable.

`Principal` accepts a `timetable`, where the first column is dates and the second column is the associated notional principal value. The date indicates the last day that the principal value is valid.

Note If you are creating one or more `FixedBond` instruments and use a timetable, the timetable specification applies to all of the `FixedBond` instruments. `Principal` does not accept an `NINST`-by-`1` cell array of timetables as input.

Data Types: `double` | `timetable`

`DaycountAdjustedCashFlow` — Flag indicating whether cash flow adjusts for day count convention
`false` (default) | scalar logical value of `true` or `false` | vector of logical values of `true` or `false`

Flag indicating whether cash flow is adjusted by day count convention, specified as the comma-separated pair consisting of `'DaycountAdjustedCashFlow'` and a scalar logical or an `NINST`-by-`1` vector of logicals with values of `true` or `false`.

Data Types: `logical`

`BusinessDayConvention` — Business day conventions for cash flow dates
`"actual"` (default) | string | string array | character vector | cell array of character vectors

Business day conventions for cash flow dates, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- `"actual"` — Nonbusiness days are effectively ignored. Cash flows that fall on nonbusiness days are assumed to be distributed on the actual date.
- `"follow"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- `"modifiedfollow"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day. However, if the following business day is in a different month, the previous business day is adopted instead.
- `"previous"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- `"modifiedprevious"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However, if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell` | `string`

`Holidays` — Holidays used in computing business days
`NaT` (default) | datetime array | string array | date character vector

Holidays used in computing business days, specified as the comma-separated pair consisting of `'Holidays'` and dates using an `NINST`-by-`1` vector of a datetime array, string array, or date character vectors. For example:

```
H = holidays(datetime('today'),datetime(2025,12,15));
FixedBondObj = fininstrument("FixedBond",'CouponRate',0.34,'Maturity',datetime(2025,12,15),'Holi
```

To support existing code, `FixedBond` also accepts serial date numbers as inputs, but they are not recommended.

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month with 30 or fewer days
`true` (in effect) (default) | scalar logical value of `true` or `false` | vector of logical values of `true` or `false`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month with 30 or fewer days, specified as the comma-separated pair consisting of `'EndMonthRule'` and a scalar logical value or an `NINST`-by-`1` vector of logicals with values of `true` or `false`.

- If you set `EndMonthRule` to `false`, the software ignores the rule, meaning that a payment date is always the same numerical day of the month.
- If you set `EndMonthRule` to `true`, the software sets the rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

`IssueDate` — Bond issue date
`NaT` (default) | datetime array | string array | date character vector

Bond issue date, specified as the comma-separated pair consisting of `'IssueDate'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `FixedBond` also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `IssueDate` property is stored as a datetime.

`FirstCouponDate` — Irregular first coupon date
`NaT` (default) | datetime array | string array | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of `'FirstCouponDate'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `FixedBond` also accepts serial date numbers as inputs, but they are not recommended.

When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `FirstCouponDate` property is stored as a datetime.

`LastCouponDate` — Irregular last coupon date
`NaT` (default) | datetime array | string array | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, FixedBond also accepts serial date numbers as inputs, but they are not recommended.

If you specify LastCouponDate but not FirstCouponDate, LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify LastCouponDate, the cash flow payment dates are determined from other inputs.

If you use date character vectors or strings, the format must be recognizable by datetime because the LastCouponDate property is stored as a datetime.

StartDate — Forward starting date of payments
NaT (default) | datetime array | string array | date character vector

Forward starting date of payments, specified as the comma-separated pair consisting of 'StartDate' and a scalar or an NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, FixedBond also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by datetime because the StartDate property is stored as a datetime.

Name — User-defined name for instrument
" " (default) | string | string array | character vector | cell array of character vectors

User-defined name for one of more instruments, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector or an NINST-by-1 cell array of character vectors or string array.

Data Types: char | cell | string

Properties

CouponRate — FixedBond coupon annual rate
scalar decimal | vector of decimals | timetable

FixedBond coupon annual rate, returned as a scalar decimal or an NINST-by-1 vector of decimals or a timetable.

Data Types: double | timetable

Maturity — FixedBond maturity date
scalar datetime | vector of datetimes

FixedBond maturity date, returned as a scalar datetime or NINST-by-1 vector of datetimes.

Data Types: datetime

Period — Frequency of payments per year
2 (default) | scalar integer | vector of integers

Frequency of payments per year, returned as a scalar integer or an NINST-by-1 vector of integers.

Data Types: double

`Basis` — Day count basis
`0` (actual/actual) (default) | scalar integer from `0` to `13` | vector of integers from `0` to `13`

Day count basis, returned as a scalar integer or an `NINST`-by-`1` vector of integers.

Data Types: `double`

`Principal` — Principal amount or principal value schedules
`100` (default) | scalar numeric | numeric vector | timetable

Principal amount or principal value schedules, returned as a scalar numeric or an `NINST`-by-`1` numeric vector or a timetable.

Data Types: `double`

`DaycountAdjustedCashFlow` — Flag indicating whether cash flow adjusts for day count convention
`false` (default) | scalar logical value of `true` or `false` | vector of logicals with values of `true` or `false`

Flag indicating whether cash flow adjusts for day count convention, returned as scalar logical or an `NINST`-by-`1` vector of logicals with values of `true` or `false`.

Data Types: `logical`

`BusinessDayConvention` — Business day conventions
`"actual"` (default) | string | string array

Business day conventions, returned as a scalar string or an `NINST`-by-`1` string array.

Data Types: `string`

`Holidays` — Holidays used in computing business days
`NaT` (default) | datetimes

Holidays used in computing business days, returned as an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month with 30 or fewer days
`true` (in effect) (default) | scalar logical value of `true` or `false` | vector of logicals with values of `true` or `false`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month having 30 or fewer days, returned as a scalar logical or an `NINST`-by-`1` vector of logical values.

Data Types: `logical`

`IssueDate` — Bond issue date
`NaT` (default) | datetime | vector of datetimes

Bond issue date, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`FirstCouponDate` — Irregular first coupon date
`NaT` (default) | datetime | vector of datetimes

Irregular first coupon date, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`LastCouponDate` — Irregular last coupon date
`NaT` (default) | datetime | vector of datetimes

Irregular last coupon date, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`StartDate` — Forward starting date of payments
`NaT` (default) | datetime | vector of datetimes

Forward starting date of payments, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`Name` — User-defined name for instrument
`" "` (default) | string | string array

User-defined name for the instrument, returned as a scalar string or an `NINST`-by-`1` string array.

Data Types: `string`

Object Functions

cashflows	Compute cash flow for FixedBond, FloatBond, Swap, FRA, STIRFuture, OISFuture, OvernightIndexedSwap, or Deposit instrument

Examples

Price Vanilla Fixed Bond Instrument Using `ratecurve` and Discount Pricer

This example shows the workflow to price a vanilla `FixedBond` instrument when you use a `ratecurve` and a `Discount` pricing method.

Create `FixedBond` Instrument Object

Use `fininstrument` to create a `FixedBond` instrument object.

```
FixB = fininstrument("FixedBond",'Maturity',datetime(2022,9,15),'CouponRate',0.021,'Period',2,'Ba
```

```
FixB =
  FixedBond with properties:

                 CouponRate: 0.0210
                     Period: 2
                      Basis: 1
                EndMonthRule: 1
                   Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                    Holidays: NaT
                   IssueDate: NaT
             FirstCouponDate: NaT
```

```
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 15-Sep-2022
                        Name: "fixed_bond_instrument"
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `Discount` Pricer Object

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object with the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("Discount",'DiscountCurve',myRC)
```

```
outPricer =
  Discount with properties:

    DiscountCurve: [1x1 ratecurve]
```

Price `FixedBond` Instrument

Use `price` to compute the price and sensitivities for the `FixedBond` instrument.

```
[Price, outPR] = price(outPricer, FixB,["all"])
```

```
Price = 104.5679
```

```
outPR =
  priceresult with properties:

       Results: [1x2 table]
    PricerData: []
```

```
outPR.Results

ans=1×2 table
    Price       DV01
    ______    ________

    104.57    0.040397
```

Price Multiple Vanilla Fixed Bond Instruments Using ratecurve and Discount Pricer

This example shows the workflow to price multiple vanilla FixedBond instruments when you use a ratecurve and a Discount pricing method.

Create FixedBond Instrument Object

Use fininstrument to create a FixedBond instrument object for three Fixed Bond instruments.

```
FixB = fininstrument("FixedBond",'Maturity',datetime([2022,9,15 ; 2022,10,15 ; 2022,11,15]),'Coup

FixB=3×1 object
  3x1 FixedBond array with properties:

    CouponRate
    Period
    Basis
    EndMonthRule
    Principal
    DaycountAdjustedCashFlow
    BusinessDayConvention
    Holidays
    IssueDate
    FirstCouponDate
    LastCouponDate
    StartDate
    Maturity
    Name
```

Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)

myRC =
  ratecurve with properties:

                Type: "zero"
        Compounding: -1
               Basis: 0
```

```
                Dates: [10x1 datetime]
                Rates: [10x1 double]
               Settle: 15-Sep-2018
         InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `Discount` Pricer Object

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object with the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("Discount",'DiscountCurve',myRC)
```

```
outPricer =
  Discount with properties:

    DiscountCurve: [1x1 ratecurve]
```

Price `FixedBond` Instruments

Use `price` to compute the prices and sensitivities for the `FixedBond` instruments.

```
[Price, outPR] = price(outPricer, FixB,["all"])
```

```
Price = 3×1

  104.5679
  261.4498
  522.9174

outPR=1×3 object
  1x3 priceresult array with properties:

    Results
    PricerData
```

```
outPR.Results
```

```
ans=1×2 table
    Price       DV01
    ______    ________

    104.57    0.040397

ans=1×2 table
    Price     DV01
    ______    _____

    261.45    0.103

ans=1×2 table
    Price      DV01
```

```
    ______    _______

    522.92    0.21013
```

Price Stepped Fixed Bond Instrument Using `ratecurve` and Discount Pricer

This example shows the workflow to price a stepped `FixedBond` instrument when you use a `ratecurve` and a `Discount` pricing method.

Create `FixedBond` Instrument Object

Use `fininstrument` to create a stepped `FixedBond` instrument object.

```
Maturity = datetime(2024,1,1);
Period = 1;
CDates = datetime([2020,1,1 ; 2024,1,1]);
CRates = [.025; .03];
CouponRate = timetable(CDates,CRates);

SBond = fininstrument("FixedBond",'Maturity',Maturity,'CouponRate',CouponRate,'Period',Period)
```

```
SBond =
  FixedBond with properties:

                 CouponRate: [2x1 timetable]
                     Period: 1
                      Basis: 0
                EndMonthRule: 1
                  Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                    Holidays: NaT
                   IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 01-Jan-2024
                        Name: ""
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,1,1);
ZeroTimes = calyears(1:10)';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
Compounding = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates, "Compounding",Compounding)
```

```
ZeroCurve =
  ratecurve with properties:

                Type: "zero"
         Compounding: 1
```

```
                Basis: 0
                Dates: [10x1 datetime]
                Rates: [10x1 double]
               Settle: 01-Jan-2018
         InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `Discount` Pricer Object

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object with the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("Discount",'DiscountCurve',ZeroCurve)
```

```
outPricer =
  Discount with properties:

    DiscountCurve: [1x1 ratecurve]
```

Price `FixedBond` Instrument

Use `price` to compute the price and sensitivities for the vanilla `FixedBond` instrument.

```
[Price, outPR] = price(outPricer, SBond,["all"])
```

```
Price = 109.6218
```

```
outPR =
  priceresult with properties:

Price Amortizing Fixed Bond Instrument Using `ratecurve` and Discount Pricer

This example shows the workflow to price a amortizing `FixedBond` instrument when you use a `ratecurve` and a `Discount` pricing method.

Create `FixedBond` Instrument Object

Use `fininstrument` to create a amortizing `FixedBond` instrument object.

```
Maturity = datetime(2024,1,1);
Period = 1;
```

```
ADates = datetime([2020,1,1 ; 2024,1,1]);
APrincipal = [100; 85];
Principal = timetable(ADates,APrincipal);
Bondamort = fininstrument("FixedBond",'Maturity',Maturity,'CouponRate',0.025,'Period',Period,'Pr
```

```
Bondamort =
  FixedBond with properties:

                 CouponRate: 0.0250
                     Period: 1
                      Basis: 0
                EndMonthRule: 1
                   Principal: [2x1 timetable]
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                    Holidays: NaT
                   IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 01-Jan-2024
                        Name: ""
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,1,1);
ZeroTimes = calyears(1:10)';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
Compounding = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates, "Compounding",Compounding);
```

Create `Discount` Pricer Object

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("Discount",'DiscountCurve',ZeroCurve)
```

```
outPricer =
  Discount with properties:

    DiscountCurve: [1x1 ratecurve]
```

Price `FixedBond` Instrument

Use `price` to compute the price and sensitivities for the vanilla `FixedBond` instrument.

```
[Price, outPR] = price(outPricer,Bondamort,["all"])
```

```
Price = 107.1273
```

```
outPR =
  priceresult with properties:
```

```
       Results: [1x2 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×2 table
    Price       DV01
    ______    ________

    107.13    0.054279
```

Price Fixed Bond Instrument Using Hull-White Model and IRMonteCarlo Pricer

This example shows the workflow to price a `FixedBond` instrument when using a `HullWhite` model and an `IRMonteCarlo` pricing method.

Create `FixedBond` Instrument Object

Use `fininstrument` to create a `FixedBond` instrument object.

```
FixB = fininstrument("FixedBond","Maturity",datetime(2022,9,15),"CouponRate",0.05,'Name',"fixed_
```

```
FixB =
  FixedBond with properties:

                  CouponRate: 0.0500
                      Period: 2
                       Basis: 0
                 EndMonthRule: 1
                    Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                    Holidays: NaT
                   IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 15-Sep-2022
                        Name: "fixed_bond"
```

Create `HullWhite` Model Object

Use `finmodel` to create a `HullWhite` model object.

```
HullWhiteModel = finmodel("HullWhite",'Alpha',0.32,'Sigma',0.49)
```

```
HullWhiteModel =
  HullWhite with properties:

    Alpha: 0.3200
    Sigma: 0.4900
```

Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2019,1,1);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 01-Jan-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create IRMonteCarlo Pricer Object

Use finpricer to create an IRMonteCarlo pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("IRMonteCarlo",'Model',HullWhiteModel,'DiscountCurve',myRC,'SimulationDates
```

```
outPricer =
  HWMonteCarlo with properties:

          NumTrials: 1000
      RandomNumbers: []
      DiscountCurve: [1x1 ratecurve]
    SimulationDates: [01-Jul-2019    01-Jan-2020    01-Jan-2021    ...    ]
              Model: [1x1 finmodel.HullWhite]
```

Price FixedBond Instrument

Use price to compute the price and sensitivities for the FixedBond instrument.

```
[Price,outPR] = price(outPricer,FixB,["all"])
```

```
Price = 115.0303
```

```
outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×4 table
    Price      Delta     Gamma     Vega
    ______    _______    ______    ____

    115.03    -397.13    1430.4     0
```

Price FixedBond Instrument Using a Hull-White Model and IRTree Pricer

This example shows the workflow to price a `FixedBond` instrument when using a `HullWhite` model and a IRTree pricing method.

Create FixedBond Instrument Object

Use `fininstrument` to create a `FixedBond` instrument object.

```
FixB = fininstrument("FixedBond","Maturity",datetime(2029,9,15),"CouponRate",.05,"Period",1,"Name
```

```
FixB =
  FixedBond with properties:

                 CouponRate: 0.0500
                     Period: 1
                      Basis: 0
                EndMonthRule: 1
                   Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                    Holidays: NaT
                   IssueDate: NaT
              FirstCouponDate: NaT
               LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 15-Sep-2029
                        Name: "fixed_bond_instrument"
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2019,9,15);
Type = "zero";
ZeroTimes = [calyears([1:10])]';
ZeroRates = [0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307 0.0310]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                 Type: "zero"
          Compounding: -1
                Basis: 0
                Dates: [10x1 datetime]
                Rates: [10x1 double]
```

```
              Settle: 15-Sep-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create HullWhite Model Object

Use `finmodel` to create a `HullWhite` model object.

```
HullWhiteModel = finmodel("hullwhite",'Alpha',0.052,'Sigma',0.34)
```

```
HullWhiteModel =
  HullWhite with properties:

    Alpha: 0.0520
    Sigma: 0.3400
```

Create IRTree Pricer Object

Use `finpricer` to create an `IRTree` pricer object and use the `ratecurve` object with the `'DiscountCurve'` name-value pair argument.

```
HWTreePricer = finpricer("irtree","model",HullWhiteModel,"DiscountCurve",myRC,"TreeDates",ZeroDa
```

```
HWTreePricer =
  HWBKTree with properties:

            Tree: [1x1 struct]
       TreeDates: [10x1 datetime]
           Model: [1x1 finmodel.HullWhite]
   DiscountCurve: [1x1 ratecurve]
```

```
HWTreePricer.Tree
```

```
ans = struct with fields:
        tObs: [0 1 1.9973 2.9945 3.9918 4.9918 5.9891 6.9863 7.9836 8.9836]
        dObs: [15-Sep-2019    15-Sep-2020    15-Sep-2021    ...    ]
      CFlowT: {1x10 cell}
       Probs: {1x9 cell}
     Connect: {1x9 cell}
     FwdTree: {1x10 cell}
    RateTree: {1x10 cell}
```

Price FixedBond Instrument

Use `price` to compute the price and sensitivities for the `FixedBond` instrument.

```
[Price, outPR] = price(HWTreePricer, FixB,["all"])
```

```
Price = 117.9440
```

```
outPR =
  priceresult with properties:

       Results: [1x4 table]
```

```
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```

More About

Fixed-Rate Note

A fixed-rate note is a long-term debt security with a preset interest rate and maturity, by which the interest must be paid.

The principal might or might not be paid at maturity. In Financial Instruments Toolbox, the principal is always paid at maturity. For more information, see “Fixed-Rate Note” on page 2-9.

Vanilla Bond

A vanilla coupon bond is a security representing an obligation to repay a borrowed amount at a designated time and to make periodic interest payments until that time.

The issuer of a bond makes the periodic interest payments until the bond matures. At maturity, the issuer pays to the holder of the bond the principal amount owed (face value) and the last interest payment.

Stepped Coupon Bond

A step-up bond and a step-down bond are debt securities with a predetermined coupon structure over time.

With these instruments, coupons increase (step up) or decrease (step down) at specific times during the life of the bond.

Bond with an Amortization Schedule

An amortized bond is treated as an asset, with the discount amount being amortized to interest expense over the life of the bond.

Version History

Introduced in R2020a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `FixedBond` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

FixedBondOption

`FixedBondOption` instrument object

Description

Create and price a `FixedBondOption` instrument object for one or more Fixed Bond Option instruments using this workflow:

1. Use `fininstrument` to create a `FixedBondOption` instrument object for one or more Fixed Bond Option instruments.
2. Use `finmodel` to specify a `HullWhite`, `BlackKarasinski`, `BlackDermanToy`, `BraceGatarekMusiela`, `SABRBraceGatarekMusiela`, or `LinearGaussian2F` model for the `FixedBondOption` instrument object.
3. Choose a pricing method.
   - When using a `HullWhite`, `BlackKarasinski`, or `BlackDermanToy` model, use `finpricer` to specify an `IRTree` pricing method for one or more `FixedBondOption` instruments.
   - When using a `HullWhite`, `BlackKarasinski`, `BraceGatarekMusiela`, `SABRBraceGatarekMusiela`, or `LinearGaussian2F` model, use `finpricer` to specify an `IRMonteCarlo` pricing method for one or more `FixedBondOption` instruments.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a `FixedBondOption` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
FixedBondOptionObj = fininstrument(InstrumentType,'Strike',strike_value,'
ExerciseDate',exercise_date,'Bond',bond_obj)
FixedBondOptionObj = fininstrument( ___ ,Name,Value)
```

Description

`FixedBondOptionObj = fininstrument(InstrumentType,'Strike',strike_value,'ExerciseDate',exercise_date,'Bond',bond_obj)` creates a `FixedBondOption` object for one or more Fixed Bond Option instruments by specifying `InstrumentType` and sets the properties on page 11-2771 for the required name-value pair arguments `Strike`, `ExerciseDate`, and `Bond`.

The `FixedBondOption` instrument supports a European or American option. For more information, see “More About” on page 11-2783.

`FixedBondOptionObj = fininstrument( ___ ,Name,Value)` sets optional properties on page 11-2771 using additional name-value pairs in addition to the required arguments in the previous

syntax. For example, `FixedBondOptionObj = fininstrument("FixedBondOption",'Strike',100,'ExerciseDate',datetime(2019,1,30),'Bond',bond_obj,'OptionType','put','ExerciseStyle',"American",'Name',"fixed_bond_option")` creates a `FixedBondOption` instrument with a strike of 100 and an American exercise. You can specify multiple name-value pair arguments.

Input Arguments

`InstrumentType` — Instrument type

string with value `"FixedBondOption"` | string array with values of `"FixedBondOption"` | character vector with value `'FixedBondOption'` | cell array of character vectors with values of `'FixedBondOption'`

Instrument type, specified as a string with the value of `"FixedBondOption"`, a character vector with the value of `'FixedBondOption'`, an `NINST`-by-`1` string array with values of `"FixedBondOption"`, or an `NINST`-by-`1` cell array of character vectors with values of `'FixedBondOption'`.

Data Types: `char` | `cell` | `string`

`FixedBondOption` Name-Value Pair Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `FixedBondOptionObj = fininstrument("FixedBondOption",'Strike',100,'ExerciseDate',datetime(2019,1,30),'Bond',bond_obj,'OptionType','put','ExerciseStyle',"American",'Name',"fixed_bond_option")`

Required FixedBondOption Name-Value Pair Arguments

`Strike` — Option strike value

scalar nonnegative numeric | nonnegative numeric vector

Option strike value, specified as the comma-separated pair consisting of `'Strike'` and a scalar nonnegative numeric or an `NINST`-by-`1` nonnegative numeric vector.

Data Types: `double`

`ExerciseDate` — Option exercise date

datetime array | string array | date character vector | serial date number

Option exercise date, specified as the comma-separated pair consisting of `'ExerciseDate'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, date character vectors, or serial date numbers.

- For a European option, there is only one `ExerciseDate` on the option expiry date.
- For a Bermudan option, there is a `1`-by-`NSTRIKES` vector of exercise dates.
- For an American option, the option can be exercised between `Settle` of the `ratecurve` and the single listed `ExerciseDate`.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `ExerciseDate` property is stored as a `datetime`.

Data Types: `double` | `char` | `string` | `datetime`

`Bond` — Underlying `FixedBond` instrument
`FixedBond` object | vector of `FixedBond` objects

Underlying `FixedBond` instrument, specified as the comma-separated pair consisting of `'Bond'` and a scalar `FixedBond` object or an `NINST`-by-`1` vector of `FixedBond` objects.

Data Types: `object`

Optional FixedBondOption Name-Value Pair Arguments

`OptionType` — Option type
`"call"` (default) | string with value `"call"` or `"put"` | string array with values of `"call"` or `"put"` | character vector with value `'call'` or `'put'` | cell array of character vectors with values of `'call'` or `'put'`

Option type, specified as the comma-separated pair consisting of `'OptionType'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

`ExerciseStyle` — Option exercise style
`"European"` (default) | string with value `"European"`, `"American"`, or `"Bermudan"` | string array with values of `"European"`, `"American"`, or `"Bermudan"` | character vector with value `'European'`, `'American'`, or `'Bermudan'` | cell array of character vectors with values of `'European'`, `'American'`, or `'Bermudan'`

Option exercise style, specified as the comma-separated pair consisting of `'ExerciseStyle'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array with values of `"European"`, `"American"`, or `"Bermudan"`.

Data Types: `string` | `cell` | `char`

`Name` — User-defined name for instrument
`"  "` (default) | string | string array | character vector | cell array of character vectors

User-defined name for one of more instruments, specified as the comma-separated pair consisting of `'Name'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

Properties

`Strike` — Option strike value
scalar nonnegative numeric | vector of nonnegative numeric

Option strike value, returned as a scalar nonnegative numeric or an `NINST`-by-`1` numeric vector of nonnegative values.

Data Types: `double`

`ExerciseDate` — Option exercise date
scalar datetime | vector of datetimes

Option exercise date, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`OptionType` — Option type
`"call"` (default) | scalar string with value `"call"` or `"put"` | string array with values of `"call"` or `"put"`

Option type, returned as a scalar string or an `NINST`-by-`1` string array with values of `"call"` or `"put"`.

Data Types: `string`

`ExerciseStyle` — Option exercise style
`"European"` (default) | scalar string with value `"European"`, `"American"` | string array with values of `"European"`, `"American"`

Option exercise style, returned as a scalar string or an `NINST`-by-`1` string array with values of `"European"` or `"American"`.

Data Types: `string`

`Bond` — Underlying `FixedBond` instrument
scalar `FixedBond` object | vector of `FixedBond` objects

Underlying `FixedBond` instrument, returned as a scalar `FixedBond` object or an `NINST`-by-`1` vector of `FixedBond` objects.

Data Types: `object`

`Name` — User-defined name for instrument
`"  "` (default) | scalar string | string array

User-defined name for the instrument, returned as a scalar string or an `NINST`-by-`1` string array.

Data Types: `string`

Examples

Price a FixedBondOption Instrument Using Hull-White Model and Hull-White Tree Pricer

This example shows the workflow to price a `FixedBondOption` instrument when you use a `HullWhite` model and an `IRTree` pricing method.

Create `FixedBond` Instrument Object

Use `fininstrument` to create a `FixedBond` instrument object as the underlying bond.

```
BondInst = fininstrument("FixedBond",'Maturity',datetime(2029,9,15),'CouponRate',.021,'Period',1
```

```
BondInst =
  FixedBond with properties:

                  CouponRate: 0.0210
```

```
                    Period: 1
                     Basis: 0
               EndMonthRule: 1
                  Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                    Holidays: NaT
                   IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 15-Sep-2029
                        Name: "bond_instrument"
```

Create `FixedBondOption` Instrument Objects

Use `fininstrument` to create three callable `FixedBondOption` instrument objects with European, American, and Bermudan exercise.

```
FixedBOptionEuro = fininstrument("FixedBondOption",'ExerciseDate',datetime(2025,9,15),'Strike',98
```

```
FixedBOptionEuro =
  FixedBondOption with properties:

       OptionType: "call"
    ExerciseStyle: "european"
     ExerciseDate: 15-Sep-2025
           Strike: 98
             Bond: [1x1 fininstrument.FixedBond]
             Name: "fixed_bond_option_european"
```

```
FixedBOptionAmerican = fininstrument("FixedBondOption",'ExerciseDate',datetime(2025,9,15),'Strike
```

```
FixedBOptionAmerican =
  FixedBondOption with properties:

       OptionType: "call"
    ExerciseStyle: "american"
     ExerciseDate: 15-Sep-2025
           Strike: 98
             Bond: [1x1 fininstrument.FixedBond]
             Name: "fixed_bond_option_american"
```

```
FixedBOptionBermudan = fininstrument("FixedBondOption",'ExerciseDate',[datetime(2025,9,15) , date
```

```
FixedBOptionBermudan =
  FixedBondOption with properties:

       OptionType: "call"
    ExerciseStyle: "bermudan"
     ExerciseDate: [15-Sep-2025    15-Nov-2025]
           Strike: [98 1000]
             Bond: [1x1 fininstrument.FixedBond]
             Name: "fixed_bond_option_bermudan"
```

Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2019,9,15);
Type = 'zero';
ZeroTimes = [calyears([1:10])]';
ZeroRates = [0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307 0.0310]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create a HullWhite Model Object

Use finmodel to create a HullWhite model object.

```
HullWhiteModel = finmodel("HullWhite",'Alpha',0.01,'Sigma',0.05)
```

```
HullWhiteModel =
  HullWhite with properties:

    Alpha: 0.0100
    Sigma: 0.0500
```

Create IRTree Pricer Object

Use finpricer to create an IRTree pricer object and use the ratecurve object with the 'DiscountCurve' name-value pair argument.

```
HWTreePricer = finpricer("IRTree",'Model',HullWhiteModel,'DiscountCurve',myRC,'TreeDates',ZeroDa
```

```
HWTreePricer =
  HWBKTree with properties:

             Tree: [1x1 struct]
        TreeDates: [10x1 datetime]
            Model: [1x1 finmodel.HullWhite]
    DiscountCurve: [1x1 ratecurve]
```

```
HWTreePricer.Tree
```

```
ans = struct with fields:
        tObs: [0 1 1.9973 2.9945 3.9918 4.9918 5.9891 6.9863 7.9836 8.9836]
```

```
        dObs: [15-Sep-2019    15-Sep-2020    15-Sep-2021    ...    ]
      CFlowT: {1x10 cell}
       Probs: {1x9 cell}
     Connect: {1x9 cell}
     FwdTree: {1x10 cell}
    RateTree: {1x10 cell}
```

Price FixedBondOption Instruments

Use `price` to compute the price and sensitivities for the two `FixedBondOption` instruments.

```
[Price, outPR] = price(HWTreePricer,FixedBOptionEuro,["all"])
```

```
Price = 10.7571

outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×4 table
    Price      Delta     Gamma      Vega
    _____    ________    _____    _____

    10.757    -178.78    2207.3    308.87
```

```
[Price, outPR] = price(HWTreePricer,FixedBOptionAmerican,["all"])
```

```
Price = 19.2984

outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×4 table
    Price      Delta     Gamma      Vega
    _____    ________    _____    _____

    19.298    -459.06    4977.1    437.32
```

```
[Price, outPR] = price(HWTreePricer,FixedBOptionBermudan,["all"])
```

```
Price = 10.7571

outPR =
  priceresult with properties:

       Results: [1x4 table]
```

```
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×4 table
    Price      Delta     Gamma      Vega
    ______    _______    ______    ______

    10.757    -178.78    2207.3    308.87
```

Price Multiple Fixed Bond Option Instruments Using Hull-White Model and Hull-White Tree Pricer

This example shows the workflow to price multiple `FixedBondOption` instruments when you use a `HullWhite` model and an `IRTree` pricing method.

Create FixedBond Instrument Object

Use `fininstrument` to create a `FixedBond` instrument object as the underlying bond.

```
BondInst = fininstrument("FixedBond",'Maturity',datetime(2029,9,15),'CouponRate',.021,'Period',1
```

```
BondInst =
  FixedBond with properties:

                 CouponRate: 0.0210
                     Period: 1
                      Basis: 0
                EndMonthRule: 1
                   Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                    Holidays: NaT
                   IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 15-Sep-2029
                        Name: "bond_instrument"
```

Create FixedBondOption Instrument Objects

Use `fininstrument` to create a `FixedBondOption` instrument object with European exercise for three Fixed Bond Option instruments.

```
FixedBOptionEuro = fininstrument("FixedBondOption",'ExerciseDate',datetime([2025,9,15 ; 2025,10,1
```

```
FixedBOptionEuro=3×1 object
  3x1 FixedBondOption array with properties:

    OptionType
    ExerciseStyle
    ExerciseDate
    Strike
```

```
    Bond
    Name
```

Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2019,9,15);
Type = 'zero';
ZeroTimes = [calyears([1:10])]';
ZeroRates = [0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307 0.0310]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create a HullWhite Model Object

Use finmodel to create a HullWhite model object.

```
HullWhiteModel = finmodel("HullWhite",'Alpha',0.01,'Sigma',0.05)
```

```
HullWhiteModel =
  HullWhite with properties:

    Alpha: 0.0100
    Sigma: 0.0500
```

Create IRTree Pricer Object

Use finpricer to create an IRTree pricer object and use the ratecurve object with the 'DiscountCurve' name-value pair argument.

```
HWTreePricer = finpricer("IRTree",'Model',HullWhiteModel,'DiscountCurve',myRC,'TreeDates',ZeroDa
```

```
HWTreePricer =
  HWBKTree with properties:

            Tree: [1x1 struct]
       TreeDates: [10x1 datetime]
           Model: [1x1 finmodel.HullWhite]
    DiscountCurve: [1x1 ratecurve]
```

```
HWTreePricer.Tree
```

```
ans = struct with fields:
        tObs: [0 1 1.9973 2.9945 3.9918 4.9918 5.9891 6.9863 7.9836 8.9836]
        dObs: [15-Sep-2019    15-Sep-2020    15-Sep-2021    ...    ]
      CFlowT: {1x10 cell}
       Probs: {1x9 cell}
     Connect: {1x9 cell}
     FwdTree: {1x10 cell}
    RateTree: {1x10 cell}
```

Price FixedBondOption Instruments

Use `price` to compute the prices and sensitivities for the `FixedBondOption` instruments.

```
[Price, outPR] = price(HWTreePricer,FixedBOptionEuro,["all"])
```

```
Price = 3×1

   10.7571
   10.2111
    9.6508

outPR=3×1 object
  3x1 priceresult array with properties:

    Results
    PricerData
```

```
outPR.Results
```

```
ans=1×4 table
    Price      Delta     Gamma      Vega
    _______    _______    _______    _______

    10.757    -178.78    2207.3    308.87

ans=1×4 table
    Price      Delta     Gamma      Vega
    _______    _______    _______    _______

    10.211    -173.94    2168.8    300.36

ans=1×4 table
    Price      Delta     Gamma      Vega
    _______    _______    _______    _______

    9.6508    -168.87    2127.8    291.34
```

Price a FixedBondOption Instrument on a Stepped FixedBond Using Hull-White Model and Hull-White Tree Pricer

This example shows the workflow to price a `FixedBondOption` instrument on a stepped `FixedBond` instrument when you use a `HullWhite` model and an `IRTree` pricing method.

Create Stepped FixedBond Instrument Object

Use `fininstrument` to create a stepped `FixedBond` instrument object as the underlying bond.

```
Maturity = datetime(2027,1,1);
Period = 1;
CDates = datetime([2022,1,1 ; 2027,1,1]);
CRates = [.022; .027];
CouponRate = timetable(CDates,CRates);

SBond = fininstrument("FixedBond",'Maturity',Maturity,'CouponRate',CouponRate,'Period',Period,'Na
```

```
SBond =
  FixedBond with properties:

                 CouponRate: [2x1 timetable]
                     Period: 1
                      Basis: 0
               EndMonthRule: 1
                  Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                   Holidays: NaT
                  IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 01-Jan-2027
                        Name: "stepped_bond_instrument"
```

Create FixedBondOption Instrument Object

Use `fininstrument` to create a `FixedBondOption` instrument object with European exercise.

```
FixedBOption = fininstrument("FixedBondOption",'ExerciseDate',datetime(2026,1,1),'Strike',90,'Bo
```

```
FixedBOption =
  FixedBondOption with properties:

       OptionType: "call"
    ExerciseStyle: "european"
     ExerciseDate: 01-Jan-2026
           Strike: 90
             Bond: [1x1 fininstrument.FixedBond]
             Name: "fixed_bond_option_european"
```

Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,1,1);
ZeroTimes = calyears(1:10)';
ZeroRates = [0.0055 0.0063 0.0071 0.0083 0.0099 0.0131 0.0178 0.0262 0.0343 0.0387]';
ZeroDates = Settle + ZeroTimes;
Compounding = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates, "Compounding",Compounding);
```

Create HullWhite Model Object

Use finmodel to create a HullWhite model object.

```
VolCurve = 0.15;
AlphaCurve = 0.03;

HWModel = finmodel("HullWhite",'Alpha',AlphaCurve,'Sigma',VolCurve)
```

```
HWModel =
  HullWhite with properties:

    Alpha: 0.0300
    Sigma: 0.1500
```

Create IRTree Pricer Object

Use finpricer to create an IRTree pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
HWTreePricer = finpricer("IRTree",'Model',HWModel,'DiscountCurve',ZeroCurve,'TreeDates',ZeroDates
```

```
HWTreePricer =
  HWBKTree with properties:

            Tree: [1x1 struct]
       TreeDates: [10x1 datetime]
           Model: [1x1 finmodel.HullWhite]
   DiscountCurve: [1x1 ratecurve]
```

```
HWTreePricer.Tree
```

```
ans = struct with fields:
        tObs: [0 1 2 3.0027 4.0027 5.0027 6.0027 7.0055 8.0055 9.0055]
        dObs: [01-Jan-2018    01-Jan-2019    01-Jan-2020    ...    ]
      CFlowT: {1x10 cell}
       Probs: {1x9 cell}
     Connect: {1x9 cell}
     FwdTree: {1x10 cell}
    RateTree: {1x10 cell}
```

Price FixedBondOption Instrument

Use price to compute the price and sensitivities for the FixedBondOption instrument.

```
[Price, outPR] = price(HWTreePricer,FixedBOption,"all")
```

```
Price = 12.2717
```

```
outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×4 table
    Price     Delta     Gamma      Vega
    _____    _____    _____    _____

    12.272    -130.1    1438.4    100.91
```

Price Fixed Bond Option Instrument Using Hull-White Model and IRMonteCarlo Pricer

This example shows the workflow to price a `FixedBondOption` instrument when using a `HullWhite` model and an `IRMonteCarlo` pricing method.

Create `FixedBond` Instrument Object

Use `fininstrument` to create a `FixedBond` instrument object as the underlying bond.

```
BondInst = fininstrument("FixedBond",'Maturity',datetime(2022,9,15),'CouponRate',.021,'Period',1
```

```
BondInst =
  FixedBond with properties:

                 CouponRate: 0.0210
                     Period: 1
                      Basis: 0
                EndMonthRule: 1
                   Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                    Holidays: NaT
                   IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 15-Sep-2022
                        Name: "bond_instrument"
```

Create `FixedBondOption` Instrument Object

Use `fininstrument` to create a `FixedBondOption` instrument object.

```
FixedBOptionEuro = fininstrument("FixedBondOption",'ExerciseDate',datetime(2020,3,15),'Strike',98
```

```
FixedBOptionEuro =
  FixedBondOption with properties:

       OptionType: "call"
    ExerciseStyle: "european"
     ExerciseDate: 15-Mar-2020
           Strike: 98
             Bond: [1x1 fininstrument.FixedBond]
             Name: "fixed_bond_option_european"
```

Create `HullWhite` Model Object

Use `finmodel` to create a `HullWhite` model object.

```
HullWhiteModel = finmodel("HullWhite",'Alpha',0.32,'Sigma',0.49)
```

```
HullWhiteModel =
  HullWhite with properties:

    Alpha: 0.3200
    Sigma: 0.4900
```

Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2019,1,1);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 01-Jan-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create IRMonteCarlo Pricer Object

Use `finpricer` to create an `IRMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("IRMonteCarlo",'Model',HullWhiteModel,'DiscountCurve',myRC,'SimulationDates
```

```
outPricer =
  HWMonteCarlo with properties:

          NumTrials: 1000
      RandomNumbers: []
      DiscountCurve: [1x1 ratecurve]
    SimulationDates: [15-Mar-2019    15-Sep-2019    15-Mar-2020    ...    ]
              Model: [1x1 finmodel.HullWhite]
```

Price FixedBondOption Instrument

Use `price` to compute the price and sensitivities for the `FixedBondOption` instrument.

```
[Price,outPR] = price(outPricer,FixedBOptionEuro,["all"])
```

```
Price = 24.0750
```

```
outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×4 table
    Price      Delta     Gamma      Vega
    _____    _______    _____    _____

    24.075    -166.42    1456.2    20.329
```

More About

Bond Option

A bond option gives the holder the right to sell a bond back to the issuer (put) or to redeem a bond from its current owner (call) at a specific price and on a specific date.

The `FixedBondOption` instrument supports two types of put and call options on bonds:

- American option — An option that you exercise any time until its expiration date.
- European option — An option that you exercise only on its expiration date.

For more information, see “Bond Options” on page 2-6.

Tips

After creating a `FixedBondOption` instrument object, you can use `setExercisePolicy` to change the size of the options. For example, if you have the following instrument:

```
FixedBOption = fininstrument("FixedBondOption",'ExerciseDate',datetime(2022,9,15),'Strike',98,'Bo
```

To modify the `FixedBondOption` instrument's size by changing the `ExerciseStyle` from `"European"` to `"American"`, use `setExercisePolicy`:

```
FixedBOption = setExercisePolicy(FixedBOption,[datetime(2021,1,1) datetime(2022,1,1)],100,'Americ
```

Version History

Introduced in R2020a

FloatBond

`FloatBond` instrument object

Description

Create and price a `FloatBond` instrument object using this workflow:

1. Use `fininstrument` to create a `FloatBond` instrument object.
2. Use `ratecurve` to specify a curve model for the `FloatBond` instrument or use a `HullWhite`, `BlackKarasinski`, `BlackDermanToy`, `BraceGatarekMusiela`, `SABRBraceGatarekMusiela`, or `LinearGaussian2F` model.
3. Choose a pricing method.
   - When using a `ratecurve`, use `finpricer` to specify a `Discount` pricing method for one or more `FloatBond` instruments.
   - When using a `HullWhite`, `BlackKarasinski`, or `BlackDermanToy` model, use `finpricer` to specify an `IRTree` pricing method for one or more `FloatBond` instruments.
   - When using a `HullWhite`, `BlackKarasinski`, `BraceGatarekMusiela`, `SABRBraceGatarekMusiela`, or `LinearGaussian2F` model, use `finpricer` to specify an `IRMonteCarlo` pricing method for one or more `FloatBond` instruments.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a `FloatBond` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
FloatBondObj = fininstrument(InstrumentType,'Spread',spread_value,'
Maturity',maturity_date)
FloatBondObj = fininstrument( ___ ,Name,Value)
```

Description

`FloatBondObj = fininstrument(InstrumentType,'Spread',spread_value,'Maturity',maturity_date)` creates a `FloatBond` object by specifying `InstrumentType` and sets the properties on page 11-2790 for the required name-value pair arguments `Spread` and `Maturity`.

The `FloatBond` instrument supports a vanilla floating rate note and an amortizing floating rate note. For more information, see “Floating-Rate Note” on page 11-2801.

`FloatBondObj = fininstrument( ___ ,Name,Value)` sets optional properties on page 11-2790 using additional name-value pairs in addition to the required arguments in the previous syntax. For

example, `FloatBondObj = fininstrument("FloatBond",'Spread',0.6,'Maturity',datetime(2019,1,30),'Basis',1,'Principal',100,'FirstCouponDate',datetime(2016,1,30),'EndMonthRule',true,'Name',"float_bond_instrument")` creates a `FloatBond` instrument with a spread of 0.6 and a maturity of January 30, 2019. You can specify multiple name-value pair arguments.

Input Arguments

`InstrumentType` — Instrument type

string with value `"FloatBond"` | string array with values of `"FloatBond"` | character vector with value `'FloatBond'` | cell array of character vectors with values of `'FloatBond'`

Instrument type, specified as a string with the value of `"FloatBond"`, a character vector with the value of `'FloatBond'`, an `NINST`-by-`1` string array with values of `"FloatBond"`, or an `NINST`-by-`1` cell array of character vectors with values of `'FloatBond'`.

Data Types: `char` | `cell` | `string`

`FloatBond` Name-Value Pair Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `FloatBondObj = fininstrument("FloatBond",'Spread',0.6,'Maturity',datetime(2019,1,30),'Basis',1,'Principal',100,'FirstCouponDate',datetime(2016,1,30),'EndMonthRule',true,'Name',"float_bond_instrument")`

Required `FloatBond` Name-Value Pair Arguments

`Spread` — Decimal value over the reference rate

scalar nonnegative decimal | vector of nonnegative decimals

Decimal value over the reference rate, specified as the comma-separated pair consisting of `'Spread'` and a scalar nonnegative decimal or an `NINST`-by-`1` vector of nonnegative decimals.

Data Types: `double`

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as the comma-separated pair consisting of `'Maturity'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `FloatBond` also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `Maturity` property is stored as a datetime.

Optional `FloatBond` Name-Value Pair Arguments

`Reset` — Frequency of payments per year

2 (default) | scalar integer | vector of integers

Frequency of payments per year, specified as the comma-separated pair consisting of `'Reset'` and a scalar integer or an `NINST`-by-`1` vector of integers. Values for `Reset` are: `1`, `2`, `3`, `4`, `6`, or `12`.

Data Types: `double`

`Basis` — Day count basis
`[0 0]` (actual/actual) (default) | scalar integer from `0` to `13` | vector of integers from `0` to `13`

Day count basis, specified as the comma-separated pair consisting of `'Basis'` and a scalar integer or an `NINST`-by-`1` using the following values:

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Principal amount or principal value schedule
`100` (default) | scalar numeric | numeric vector | timetable

Notional principal amount or principal value schedule, specified as the comma-separated pair consisting of `'Principal'` and a scalar numeric or an `NINST`-by-`1` numeric vector or a timetable.

`Principal` accepts a `timetable`, where the first column is dates and the second column is the associated notional principal value. The date indicates the last day that the principal value is valid.

Note If you are creating one or more `FloatBond` instruments and use a timetable, the timetable specification applies to all of the `FloatBond` instruments. `Principal` does not accept an `NINST`-by-`1` cell array of timetables as input.

Data Types: `double` | `timetable`

`ProjectionCurve` — Rate curve for projecting floating cash flows
`ratecurve.empty` (default) | scalar `ratecurve` object | vector of `ratecurve` objects

Rate curve for projecting floating cash flows, specified as the comma-separated pair consisting of `'ProjectionCurve'` and a scalar `ratecurve` object or an `NINST`-by-`1` vector of `ratecurve` objects. You must create this object using `ratecurve`.

Data Types: `object`

`ResetOffset` — Lag in rate setting
`0` (default) | scalar numeric | numeric vector

Lag in rate setting, specified as the comma-separated pair consisting of `'ResetOffset'` and a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`LatestFloatingRate` — Latest floating rate
`[]` (default) | scalar decimal | vector of decimals

Latest floating rate for the `FloatBond` object, specified as the comma-separated pair consisting of `'LatestFloatingRate'` and a scalar decimal or an `NINST`-by-`1` vector of decimals.

Data Types: `double`

`DaycountAdjustedCashFlow` — Flag to adjust cash flows based on actual period day count
`false` (default) | scalar logical value of `true` or `false` | vector of logical values with `true` or `false`

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of `'DaycountAdjustedCashFlow'` and a scalar logical or an `NINST`-by-`1` vector of logicals with values of `true` or `false`.

Data Types: `logical`

`BusinessDayConvention` — Business day conventions
`"actual"` (default) | string | string array | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- `"actual"` — Nonbusiness days are effectively ignored. Cash flows that fall on nonbusiness days are assumed to be distributed on the actual date.
- `"follow"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- `"modifiedfollow"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `"previous"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- `"modifiedprevious"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell` | `string`

`Holidays` — Holidays used in computing business days
`NaT` (default) | datetime array | string array | date character vector

Holidays used in computing business days, specified as the comma-separated pair consisting of `'Holidays'` and dates using an `NINST`-by-`1` vector of a datetime array, string array, or date character vectors. For example:

```
H = holidays(datetime('today'),datetime(2025,12,15));
FloatBondObj = fininstrument("floatbond",'Spread',100,'Maturity',datetime(2025,12,15),'Holidays',
```

To support existing code, `FloatBond` also accepts serial date numbers as inputs, but they are not recommended.

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month with 30 or fewer days
`true` (in effect) (default) | scalar logical with value of `true` or `false` | vector of logicals with values of `true` or `false`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month with 30 or fewer days, specified as the comma-separated pair consisting of `'EndMonthRule'` and a scalar logical or an `NINST`-by-`1` vector of logicals with values of `true` or `false`.

- If you set `EndMonthRule` to `false`, the software ignores the rule, meaning that a payment date is always the same numerical day of the month.
- If you set `EndMonthRule` to `true`, the software sets the rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

`IssueDate` — Bond issue date
`NaT` (default) | datetime array | string array | date character vector

Bond issue date, specified as the comma-separated pair consisting of `'IssueDate'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `FloatBond` also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `IssueDate` property is stored as a datetime.

`FirstCouponDate` — Irregular first coupon date
`NaT` (default) | datetime array | string array | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of `'FirstCouponDate'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `FloatBond` also accepts serial date numbers as inputs, but they are not recommended.

When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `FirstCouponDate` property is stored as a datetime.

`LastCouponDate` — Irregular last coupon date
`NaT` (default) | datetime array | string array | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `FloatBond` also accepts serial date numbers as inputs, but they are not recommended.

If you specify `LastCouponDate` but not `FirstCouponDate`, `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify `LastCouponDate`, the cash flow payment dates are determined from other inputs.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `LastCouponDate` property is stored as a datetime.

`StartDate` — Forward starting date of payments
`NaT` (default) | datetime array | string array | date character vector

Forward starting date of payments, specified as the comma-separated pair consisting of `'StartDate'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `FloatBond` also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `StartDate` property is stored as a datetime.

`Name` — User-defined name for instrument
`" "` (default) | string | string array | character vector | cell array of character vectors

User-defined name for one of more instruments, specified as the comma-separated pair consisting of `'Name'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

Properties

`Spread` — Number of basis points over the reference rate
scalar nonnegative numeric | nonnegative numeric vector

Number of basis points over the reference rate, returned as a scalar nonnegative numeric or an `NINST`-by-`1` nonnegative numeric vector.

Data Types: `double`

`Maturity` — Maturity date
datetime | vector of datetimes

Maturity date, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`Reset` — Frequency of payment per year
`1` (default) | scalar integer | vector of integers

Coupons per year, returned as a scalar integer or an `NINST`-by-`1` vector of integers.

Data Types: `double`

`Basis` — Day count basis
`0` (actual/actual) (default) | scalar integer from `0` to `13` | vector of integers from `0` to `13`

Day count basis, returned as a scalar integer or an `NINST`-by-`1` vector of integers.

Data Types: `double`

`Principal` — Notional principal amount or principal value schedules
`100` (default) | scalar numeric | numeric vector | timetable

Notional principal amount or principal value schedules, returned as a scalar numeric or an `NINST`-by-`1` numeric vector or a timetable.

Data Types: `timetable` | `double`

`ProjectionCurve` — Rate curve used in generating future cash flows
`ratecurve.empty` (default) | scalar `ratecurve` object | vector of `ratecurve` objects

Rate curve to be used in projecting the future cash flows, returned as a scalar `ratecurve` object or an `NINST`-by-`1` vector of `ratecurve` objects.

Data Types: `object`

`ResetOffset` — Lag in rate setting
`0` (default) | scalar numeric | numeric vector

Lag in rate setting, returned as a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`LatestFloatingRate` — Latest floating rate for `FloatBond`
`[ ]` (default) | scalar decimal | vector of decimals

Latest floating rate for `FloatBond`, returned as a scalar decimal or an `NINST`-by-`1` vector of decimals.

Data Types: `double`

`DaycountAdjustedCashFlow` — Flag to adjust cash flows based on actual period day count
`false` (default) | scalar logical value of `true` or `false` | vector of logical values with `true` or `false`

Flag to adjust cash flows based on actual period day count, returned as scalar logical or an `NINST`-by-`1` vector of logicals with values of `true` or `false`.

Data Types: `logical`

`BusinessDayConvention` — Business day conventions
`"actual"` (default) | scalar string | string array

Business day conventions, returned as a scalar string or an `NINST`-by-`1` string array.

Data Types: string

Holidays — Holidays used in computing business days
NaT (default) | datetimes

Holidays used in computing business days, returned as an NINST-by-1 vector of datetimes.

Data Types: datetime

EndMonthRule — End-of-month rule flag for generating dates when Maturity is end-of-month date for month with 30 or fewer days
true (in effect) (default) | scalar logical with value of true or false | vector of logicals with values of true or false

End-of-month rule flag for generating dates when Maturity is an end-of-month date for a month with 30 or fewer days, returned as a scalar logical or an NINST-by-1 vector of logical values.

Data Types: logical

IssueDate — Bond issue date
NaT (default) | datetime | vector of datetimes

Bond issue date, returned as a scalar datetime or an NINST-by-1 vector of datetimes.

Data Types: datetime

FirstCouponDate — Irregular first coupon date
NaT (default) | datetime | vector of datetimes

Irregular first coupon date, returned as a scalar datetime or an NINST-by-1 vector of datetimes.

Data Types: datetime

LastCouponDate — Irregular last coupon date
NaT (default) | datetime | vector of datetimes

Irregular last coupon date, returned as a scalar datetime or an NINST-by-1 vector of datetimes.

Data Types: datetime

StartDate — Forward starting date of payments
NaT (default) | datetime | vector of datetimes

Forward starting date of payments, returned as a scalar datetime or an NINST-by-1 vector of datetimes.

Data Types: datetime

Name — User-defined name for instrument
" " (default) | string | string array

User-defined name for the instrument, returned as a string or an NINST-by-1 string array.

Data Types: string

Object Functions

cashflows — Compute cash flow for FixedBond, FloatBond, Swap, FRA, STIRFuture, OISFuture, OvernightIndexedSwap, or Deposit instrument

Examples

Price Vanilla Float Bond Instrument Using `ratecurve` and Discount Pricer

This example shows the workflow to price a vanilla `FloatBond` instrument when you use a `ratecurve` and a `Discount` pricing method.

Create `FloatBond` Instrument Object

Use `fininstrument` to create a vanilla `FloatBond` instrument object.

```
FloatB = fininstrument("FloatBond",'Maturity',datetime(2022,9,15),'Spread',0.025,'Reset',2,'Basis
```

```
FloatB =
  FloatBond with properties:

                     Spread: 0.0250
            ProjectionCurve: [0x0 ratecurve]
                ResetOffset: 0
                      Reset: 2
                      Basis: 1
               EndMonthRule: 0
                  Principal: 100
   DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
         LatestFloatingRate: NaN
                   Holidays: NaT
                  IssueDate: NaT
            FirstCouponDate: NaT
             LastCouponDate: NaT
                  StartDate: NaT
                   Maturity: 15-Sep-2022
                       Name: "float_bond_instrument"
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
        Compounding: -1
```

```
                Basis: 0
                Dates: [10x1 datetime]
                Rates: [10x1 double]
               Settle: 15-Sep-2018
         InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `Discount` Pricer Object

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("Discount",'DiscountCurve',myRC)
```

```
outPricer =
  Discount with properties:

    DiscountCurve: [1x1 ratecurve]
```

Price `FloatBond` Instrument

Use `price` to compute the price and sensitivities for the vanilla `FloatBond` instrument.

```
[Price, outPR] = price(outPricer, FloatB,["all"])
```

```
Price = 109.8322
```

```
outPR =
  priceresult with properties:

       Results: [1x2 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×2 table
    Price       DV01
    ______    _________

    109.83    0.0021981
```

Price Multiple Vanilla Float Bond Instruments Using `ratecurve` and Discount Pricer

This example shows the workflow to price multiple vanilla `FloatBond` instruments when you use a `ratecurve` and a `Discount` pricing method.

Create `FloatBond` Instrument Object

Use `fininstrument` to create a vanilla `FloatBond` instrument object for three Float Bond instruments.

```
FloatB = fininstrument("FloatBond",'Maturity',datetime([2022,9,15 ; 2022,9,15 ; 2022,9,15]),'Spre
```

```
FloatB=3×1 object
  3x1 FloatBond array with properties:

    Spread
    ProjectionCurve
    ResetOffset
    Reset
    Basis
    EndMonthRule
    Principal
    DaycountAdjustedCashFlow
    BusinessDayConvention
    LatestFloatingRate
    Holidays
    IssueDate
    FirstCouponDate
    LastCouponDate
    StartDate
    Maturity
    Name
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2018
        InterpMethod: "linear"
   ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

Create `Discount` Pricer Object

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("Discount",'DiscountCurve',myRC)
```

```
outPricer =
  Discount with properties:
```

```
    DiscountCurve: [1x1 ratecurve]
```

Price FloatBond Instruments

Use `price` to compute the prices and sensitivities for the vanilla `FloatBond` instruments.

```
[Price, outPR] = price(outPricer, FloatB,["all"])
```

```
Price = 3×1

  109.8322
  219.6644
  329.4965

outPR=1×3 object
  1x3 priceresult array with properties:

    Results
    PricerData
```

```
outPR.Results
```

```
ans=1×2 table
    Price       DV01
    ______    _________

    109.83    0.0021981

ans=1×2 table
    Price       DV01
    ______    _________

    219.66    0.0043961

ans=1×2 table
    Price      DV01
    _____    _________

    329.5    0.0065942
```

Price Amortizing Float Bond Instrument Using `ratecurve` and Discount Pricer

This example shows the workflow to price an amortizing `FloatBond` instrument when you use a `ratecurve` and a `Discount` pricing method.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,1,1);
ZeroTimes = calyears(1:10)';
```

```
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
Compounding = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates, "Compounding",Compounding);
```

Create FloatBond Instrument Object

Use `fininstrument` to create an amortizing `FloatBond` instrument object.

```
Maturity = datetime(2024,1,1);
Spread = 0.02;
Reset = 1;
ADates = datetime([2020,1,1 ; 2024,1,1]);
APrincipal = [100; 80];
Principal = timetable(ADates,APrincipal);
Floatamort = fininstrument("FloatBond",'Maturity',Maturity,'Spread',Spread,'Reset',Reset,'Projec
```

```
Floatamort =
  FloatBond with properties:

                     Spread: 0.0200
            ProjectionCurve: [1x1 ratecurve]
                ResetOffset: 0
                      Reset: 1
                      Basis: 0
               EndMonthRule: 1
                  Principal: [2x1 timetable]
   DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
         LatestFloatingRate: NaN
                   Holidays: NaT
                  IssueDate: NaT
            FirstCouponDate: NaT
             LastCouponDate: NaT
                  StartDate: NaT
                   Maturity: 01-Jan-2024
                       Name: ""
```

Create Discount Pricer Object

Use `finpricer` to create an `Discount` pricer object and use the `ratecurve` object with the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("Discount",'DiscountCurve',ZeroCurve)
```

```
outPricer =
  Discount with properties:

    DiscountCurve: [1x1 ratecurve]
```

Price FloatBond Instrument

Use `price` to compute the price and sensitivities for the vanilla `FloatBond` instrument.

```
[Price, outPR] = price(outPricer,Floatamort,["all"])
```

```
Price = 110.1101
```

```
outPR =
  priceresult with properties:

       Results: [1x2 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×2 table
    Price       DV01
    ______    _________

    110.11    0.0033187
```

Price Float Bond Instrument Using Hull-White Model and IRMonteCarlo Pricer

This example shows the workflow to price a `FloatBond` instrument when using a `HullWhite` model and an `IRMonteCarlo` pricing method.

Create `FloatBond` Instrument Object

Use `fininstrument` to create a `FloatBond` instrument object.

```
FloatB = fininstrument("FloatBond",'Maturity',datetime(2022,9,15),'Spread',0.025,'Reset',2,'Basis
```

```
FloatB =
  FloatBond with properties:

                     Spread: 0.0250
            ProjectionCurve: [0x0 ratecurve]
                ResetOffset: 0
                      Reset: 2
                      Basis: 1
               EndMonthRule: 0
                  Principal: 100
   DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
         LatestFloatingRate: NaN
                   Holidays: NaT
                  IssueDate: NaT
            FirstCouponDate: NaT
             LastCouponDate: NaT
                  StartDate: NaT
                   Maturity: 15-Sep-2022
                       Name: "float_bond_instrument"
```

Create `HullWhite` Model Object

Use `finmodel` to create a `HullWhite` model object.

```
HullWhiteModel = finmodel("HullWhite",'Alpha',0.32,'Sigma',0.49)
```

```
HullWhiteModel =
  HullWhite with properties:
```

```
    Alpha: 0.3200
    Sigma: 0.4900
```

Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2019,1,1);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 01-Jan-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create IRMonteCarlo Pricer Object

Use `finpricer` to create an `IRMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("IRMonteCarlo",'Model',HullWhiteModel,'DiscountCurve',myRC,'SimulationDates
```

```
outPricer =
  HWMonteCarlo with properties:

          NumTrials: 1000
      RandomNumbers: []
      DiscountCurve: [1x1 ratecurve]
    SimulationDates: [01-Jul-2019    01-Jan-2020    01-Jan-2021    ...    ]
              Model: [1x1 finmodel.HullWhite]
```

Price FloatBond Instrument

Use `price` to compute the price and sensitivities for the `FloatBond` instrument.

```
[Price,outPR] = price(outPricer,FloatB,["all"])
```

```
Price = 109.1227
```

```
outPR =
  priceresult with properties:
```

```
       Results: [1x4 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×4 table
    Price      Delta     Gamma     Vega
    ______    _______    ______    ____

    109.12    -19.033    50.224     0
```

Price Vanilla FloatBond Instrument Using a Hull-White Model and IRTree Pricer

This example shows the workflow to price a vanilla `FloatBond` instrument when using a `HullWhite` model and an IRTree pricing method.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,1,1);
ZeroTimes = calyears(1:10)';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
Compounding = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates, "Compounding",Compounding);
```

Create FloatBond Instrument Object

Use `fininstrument` to create a vanilla `FloatdBond` instrument object.

```
Spread = 0.03;
Reset = 1;
Maturity = datetime(2024,1,1);
Period = 1;
Float = fininstrument("FloatBond",'Maturity',Maturity,'Spread',Spread,'Reset',Reset,'ProjectionCu
```

```
Float =
  FloatBond with properties:

                     Spread: 0.0300
            ProjectionCurve: [1x1 ratecurve]
                ResetOffset: 0
                      Reset: 1
                      Basis: 0
               EndMonthRule: 1
                  Principal: 100
   DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
         LatestFloatingRate: NaN
                   Holidays: NaT
                  IssueDate: NaT
            FirstCouponDate: NaT
             LastCouponDate: NaT
                  StartDate: NaT
```

```
                Maturity: 01-Jan-2024
                    Name: ""
```

Create HullWhite Model Object

Use `finmodel` to create a `HullWhite` model object.

```
VolCurve = 0.01;
AlphaCurve = 0.1;

HWModel = finmodel("HullWhite",'alpha',AlphaCurve,'sigma',VolCurve);
```

Create IRTree Pricer Object

Use `finpricer` to create an `IRTree` pricer object and use the `ratecurve` object with the `'DiscountCurve'` name-value pair argument.

```
HWTreePricer = finpricer("IRTree",'Model',HWModel,'DiscountCurve',ZeroCurve,'TreeDates',ZeroDates
```

```
HWTreePricer =
  HWBKTree with properties:

             Tree: [1x1 struct]
        TreeDates: [10x1 datetime]
            Model: [1x1 finmodel.HullWhite]
    DiscountCurve: [1x1 ratecurve]
```

Price FloatBond Instrument

Use `price` to compute the price and sensitivities for the vanilla `FloatBond` instrument.

```
[Price, outPR] = price(HWTreePricer,Float,["all"])
```

```
Price = 117.4686

outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×4 table
    Price      Delta     Gamma     Vega
    ______    _______    ______    ____

    117.47    -60.007    315.09     0
```

More About

Floating-Rate Note

A floating-rate note is a security like a bond, but the interest rate of the note is reset periodically, relative to a reference index rate, to reflect fluctuations in market interest rates.

Version History

Introduced in R2020a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `FloatBond` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

FloatBondOption

`FloatBondOption` instrument object

Description

Create and price a `FloatBondOption` instrument object for one or more Float Bond Option instruments using this workflow:

1. Use `fininstrument` to create an `FloatBondOption` instrument object for one or more Float Bond Option instruments.
2. Use `finmodel` to specify a `HullWhite`, `BlackKarasinski`, `BlackDermanToy`, `BraceGatarekMusiela`, `SABRBraceGatarekMusiela`, or `LinearGaussian2F` model for the `FloatBondOption` instrument object.
3. Choose a pricing method.
   - When using a `HullWhite`, `BlackKarasinski`, or `BlackDermanToy` model, use `finpricer` to specify an `IRTree` pricing method for one or more `FloatBondOption` instruments.
   - When using a `HullWhite`, `BlackKarasinski`, `BraceGatarekMusiela`, `SABRBraceGatarekMusiela`, or `LinearGaussian2F` model, use `finpricer` to specify an `IRMonteCarlo` pricing method for one or more `FloatBondOption` instruments.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods `FloatBondOption` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
FloatBondOptionObj = fininstrument(InstrumentType,'Strike',strike_value,'
ExerciseDate',exercise_date,'Bond',bond_obj)
FloatBondOptionObj = fininstrument( ___ ,Name,Value)
```

Description

`FloatBondOptionObj = fininstrument(InstrumentType,'Strike',strike_value,'ExerciseDate',exercise_date,'Bond',bond_obj)` creates a `FloatBond` object for one or more Float Bond Option instruments by specifying `InstrumentType` and sets properties on page 11-2805 using the required name-value pair arguments `Strike`, `ExerciseDate`, and `Bond`.

`FloatBondOptionObj = fininstrument( ___ ,Name,Value)` sets optional properties on page 11-2805 using additional name-value pair arguments in addition to the required arguments in the previous syntax. For example, `FloatBondOptionObj = fininstrument("FloatBondOption",'Strike',100,'ExerciseDate',datetime(2019,1,30),'Bond',bond_obj,'OptionType','put','ExerciseStyle',"american",'Name',"floa`

t_bond_option") creates a FloatBondOption instrument with a strike of 100 and an American exercise. You can specify multiple name-value pair arguments.

Input Arguments

InstrumentType — Instrument type

string with value "FloatBondOption" | string array with values of "FloatBondOption" | character vector with value 'FloatBondOption' | cell array of character vectors with values of 'FloatBondOption'

Instrument type, specified as a string with the value of "FloatBondOption", a character vector with the value of 'FloatBondOption', an NINST-by-1 string array with values of "FloatBondOption", or an NINST-by-1 cell array of character vectors with values of 'FloatBondOption'.

Data Types: char | cell | string

FloatBondOption Name-Value Pair Arguments

Specify required and optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: FloatBondOptionObj = fininstrument("FloatBondOption",'Strike',100,'ExerciseDate',datetime(2019,1,30),'Bond',bond_obj,'OptionType','put','ExerciseStyle',"american",'Name',"float_bond_option")

Required FloatBondOption Name-Value Pair Arguments

Strike — Option strike value

nonnegative value | vector of nonnegative values

Option strike value, specified as the comma-separated pair consisting of 'Strike' and a scalar nonnegative value or an NINST-by-1 vector of nonnegative values.

Data Types: double

ExerciseDate — Option exercise dates

datetime array | string array | date character vector

Option exercise date, specified as the comma-separated pair consisting of 'ExerciseDate' and a scalar or an NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, FloatBondOption also accepts serial date numbers as inputs, but they are not recommended.

- For a European option, there is only one ExerciseDate on the option expiry date.
- For a Bermudan option, there is a 1-by-NSTRIKES vector of exercise dates.
- For an American option, the option can be exercised between ValuationDate of the stock tree and the single listed ExerciseDate.

If you use date character vectors or strings, the format must be recognizable by datetime because the Maturity property is stored as a datetime.

Bond — Underlying float bond
`FloatBond` object | vector of `FloatBond` objects

Underlying float bond, specified as the comma-separated pair consisting of `'Bond'` and the name of a `FloatBond` object or an `NINST`-by-`1` vector of `FloatBond` objects.

Data Types: `object`

Optional FloatBondOption Name-Value Pair Arguments

`OptionType` — Definition of option
`"call"` (default) | string with value `"call"` or `"put"` | string array with values of `"call"` or `"put"` | character vector with value `'call'` or `'put'` | cell array of character vectors with values of `'call'` or `'put'`

Definition of option, specified as the comma-separated pair consisting of `'OptionType'` and a scalar character vector or a string or an `NINST`-by-`1` cell array of character vectors or string array using `'call'` or `'put'`.

Data Types: `char` | `cell` | `string`

`ExerciseStyle` — Option type
`"European"` (default) | string with value `"European"`, `"American"`, or `"Bermudan"` | string array with values of `"European"`, `"American"`, or `"Bermudan"` | character vector with value `'European'`, `'American'`, or `'Bermudan'` | cell array of character vectors with values of `'European'`, `'American'`, or `'Bermudan'`

Option type, specified as the comma-separated pair consisting of `'ExerciseStyle'` and a scalar character vector or string or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `string` | `cell` | `char`

`Name` — User-defined name for instrument
`" "` (default) | string | string array | character vector | cell array of character vectors

User-defined name for one of more instruments, specified as the comma-separated pair consisting of `'Name'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

Properties

`InstrumentType` — Instrument type
string with value `"FloatBondOption"` | string array with values of `"FloatBondOption"`

Instrument type, returned as a scalar string or an `NINST`-by-`1` string array.

Data Types: `string`

`Strike` — Option strike value
nonnegative value | nonnegative value

Option strike value, returned as a scalar nonnegative value or an `NINST`-by-`1` vector of nonnegative values.

Data Types: `double`

ExerciseDate — Option exercise date
datetime | vector of datetimes

Option exercise date, returned as a scalar datetime or an NINST-by-1 vector of datetimes.

Data Types: datetime

OptionType — Definition of option
"call" (default) | string with value "call" or "put" | string array with values of "call" or "put"

Definition of option, returned as a scalar string or an NINST-by-1 string array.

Data Types: string

ExerciseStyle — Option type
"European" (default) | string with value "European", "American", or "Bermudan" | string array with values of "European", "American", or "Bermudan"

Option type, returned as a scalar string or an NINST-by-1 string array.

Data Types: string

Bond — Underlying float bond
FloatBond object | vector of FloatBond objects

Underlying float bond, returned as a scalar FloatBond object or an NINST-by-1 vector of FloatBond objects.

Data Types: object

Name — User-defined name for instrument
" " (default) | string | string array

User-defined name for the instrument, returned as a scalar string or an NINST-by-1 string array.

Data Types: string

Object Functions

Examples

Price a Float Bond Option Instrument Using Hull-White Model and IRTree Pricer

This example shows the workflow to price a FloatBondOption instrument when you use a HullWhite model and an IRTree pricing method.

Create FloatBond Instrument Object

Use fininstrument to create a FloatBond instrument object as the underlying bond.

```
BondInst = fininstrument("FloatBond",'Maturity',datetime(2030,9,15),'Spread',0.021,'Name',"bond_
```

```
BondInst =
  FloatBond with properties:
```

```
                    Spread: 0.0210
              ProjectionCurve: [0x0 ratecurve]
                  ResetOffset: 0
                        Reset: 2
                        Basis: 0
                 EndMonthRule: 1
                    Principal: 100
      DaycountAdjustedCashFlow: 0
         BusinessDayConvention: "actual"
            LatestFloatingRate: NaN
                     Holidays: NaT
                    IssueDate: NaT
              FirstCouponDate: NaT
               LastCouponDate: NaT
                    StartDate: NaT
                     Maturity: 15-Sep-2030
                         Name: "bond_instrument"
```

Create `FloatBondOption` Instrument Objects

Use `fininstrument` to create three callable `FloatBondOption` instrument objects with European, American, and Bermudan exercise.

```
FloatBOptionEuro = fininstrument("FloatBondOption",'ExerciseDate',datetime(2029,9,15),'Strike',98
```

```
FloatBOptionEuro =
  FloatBondOption with properties:

       OptionType: "call"
    ExerciseStyle: "european"
     ExerciseDate: 15-Sep-2029
           Strike: 98
             Bond: [1x1 fininstrument.FloatBond]
             Name: "float_bond_option_european"
```

```
FloatBOptionAmerican = fininstrument("FloatBondOption",'ExerciseDate',datetime(2029,9,15),'Strike
```

```
FloatBOptionAmerican =
  FloatBondOption with properties:

       OptionType: "call"
    ExerciseStyle: "american"
     ExerciseDate: 15-Sep-2029
           Strike: 98
             Bond: [1x1 fininstrument.FloatBond]
             Name: "float_bond_option_american"
```

```
FloatBOptionBermudan = fininstrument("FloatBondOption",'ExerciseDate',[datetime(2025,9,15) , date
```

```
FloatBOptionBermudan =
  FloatBondOption with properties:

       OptionType: "call"
    ExerciseStyle: "bermudan"
     ExerciseDate: [15-Sep-2025    15-Sep-2029]
           Strike: [98 100]
```

```
              Bond: [1x1 fininstrument.FloatBond]
              Name: "float_bond_option_bermudan"
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2024,9,15);
Type = 'zero';
ZeroTimes = [calyears([1:10])]';
ZeroRates = [0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307 0.0310]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2024
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create a `HullWhite` Model Object

Use `finmodel` to create a `HullWhite` model object.

```
HullWhiteModel = finmodel("HullWhite",'Alpha',0.01,'Sigma',0.05)
```

```
HullWhiteModel =
  HullWhite with properties:

    Alpha: 0.0100
    Sigma: 0.0500
```

Create `IRTree` Pricer Object

Use `finpricer` to create an `IRTree` pricer object and use the `ratecurve` object with the `'DiscountCurve'` name-value pair argument.

```
CFdates = cfdates(Settle, BondInst.Maturity, BondInst.Reset, BondInst.Basis);
HWTreePricer = finpricer("IRTree",'Model',HullWhiteModel,'DiscountCurve',myRC,'TreeDates',CFdates
```

```
HWTreePricer =
  HWBKTree with properties:

             Tree: [1x1 struct]
        TreeDates: [12x1 datetime]
            Model: [1x1 finmodel.HullWhite]
    DiscountCurve: [1x1 ratecurve]
```

```
HWTreePricer.Tree

ans = struct with fields:
        tObs: [0 0.4959 1 1.4959 2 2.4959 3 3.4986 4.0027 4.4986 5.0027 ... ]
        dObs: [15-Sep-2024    15-Mar-2025    15-Sep-2025    ...    ]
      CFlowT: {1x12 cell}
       Probs: {1x11 cell}
     Connect: {1x11 cell}
     FwdTree: {1x12 cell}
    RateTree: {1x12 cell}
```

Price FixedBondOption Instruments

Use `price` to compute the price and sensitivities for the two `FixedBondOption` instruments.

```
[Price, outPR] = price(HWTreePricer,FloatBOptionEuro,["all"])

Price = 3.8040

outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: [1x1 struct]

outPR.Results

ans=1×4 table
    Price     Delta     Gamma        Vega
    _____    _______    ______    ___________

    3.804    -20.465    110.75    -2.6645e-11

[Price, outPR] = price(HWTreePricer,FloatBOptionAmerican,["all"])

Price = 14.1700

outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: [1x1 struct]

outPR.Results

ans=1×4 table
    Price     Delta     Gamma     Vega
    _____    _______    ______    ____

    14.17    -38.981    160.87     0

[Price, outPR] = price(HWTreePricer,FloatBOptionBermudan,["all"])

Price = 12.0676
```

```
outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×4 table
    Price      Delta     Gamma        Vega
    ______    _______    ______    ___________

    12.068    -39.402    161.55    -2.8422e-10
```

Price Multiple Float Bond Option Instruments Using Hull-White Model and IRTree Pricer

This example shows the workflow to price multiple `FloatBondOption` instruments when you use a `HullWhite` model and an `IRTree` pricing method.

Create FloatBond Instrument Object

Use `fininstrument` to create a `FloatBond` instrument object as the underlying bond.

```
BondInst = fininstrument("FloatBond",'Maturity',datetime(2030,9,15),'Spread',0.021,'Name',"bond_
```

```
BondInst =
  FloatBond with properties:

                     Spread: 0.0210
            ProjectionCurve: [0x0 ratecurve]
                ResetOffset: 0
                      Reset: 2
                      Basis: 0
               EndMonthRule: 1
                  Principal: 100
   DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
         LatestFloatingRate: NaN
                   Holidays: NaT
                  IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 15-Sep-2030
                        Name: "bond_instrument"
```

Create FloatBondOption Instrument Objects

Use `fininstrument` to create a `FloatBondOption` instrument object with European exercise for three Float Bond Option instruments.

```
FloatBOptionEuro = fininstrument("FloatBondOption",'ExerciseDate',datetime([2030,9,15 ; 2029,09,
```

```
FloatBOptionEuro=3×1 object
  3x1 FloatBondOption array with properties:
```

```
    OptionType
    ExerciseStyle
    ExerciseDate
    Strike
    Bond
    Name
```

Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2024,9,15);
Type = 'zero';
ZeroTimes = [calyears([1:10])]';
ZeroRates = [0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307 0.0310]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2024
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create a HullWhite Model Object

Use `finmodel` to create a `HullWhite` model object.

```
HullWhiteModel = finmodel("HullWhite",'Alpha',0.01,'Sigma',0.05)
```

```
HullWhiteModel =
  HullWhite with properties:

    Alpha: 0.0100
    Sigma: 0.0500
```

Create IRTree Pricer Object

Use `finpricer` to create an `IRTree` pricer object and use the `ratecurve` object with the `'DiscountCurve'` name-value pair argument.

```
CFdates = cfdates(Settle, BondInst.Maturity, BondInst.Reset, BondInst.Basis);
HWTreePricer = finpricer("IRTree",'Model',HullWhiteModel,'DiscountCurve',myRC,'TreeDates',CFdates
```

```
HWTreePricer =
  HWBKTree with properties:
```

```
            Tree: [1x1 struct]
       TreeDates: [12x1 datetime]
           Model: [1x1 finmodel.HullWhite]
    DiscountCurve: [1x1 ratecurve]
```

```
HWTreePricer.Tree
```

```
ans = struct with fields:
        tObs: [0 0.4959 1 1.4959 2 2.4959 3 3.4986 4.0027 4.4986 5.0027 ... ]
        dObs: [15-Sep-2024    15-Mar-2025    15-Sep-2025    ...    ]
      CFlowT: {1x12 cell}
       Probs: {1x11 cell}
     Connect: {1x11 cell}
     FwdTree: {1x12 cell}
    RateTree: {1x12 cell}
```

Price FixedBondOption Instruments

Use `price` to compute the prices and sensitivities for the `FixedBondOption` instruments.

```
[Price, outPR] = price(HWTreePricer,FloatBOptionEuro,["all"])
```

```
Price = 3×1

    1.8081
    2.8617
    3.9097
```

```
outPR=3×1 object
  3x1 priceresult array with properties:

    Results
    PricerData
```

```
outPR.Results
```

```
ans=1×4 table
    Price      Delta     Gamma        Vega
    _____    _______    _____    __________

    1.8081    -10.854    65.153    4.4409e-12
```

```
ans=1×4 table
    Price      Delta     Gamma        Vega
    _____    _______    _____    __________

    2.8617    -15.751    87.167    -1.7764e-11
```

```
ans=1×4 table
    Price      Delta     Gamma        Vega
    _____    _______    _____    __________
```

```
    3.9097    -20.493    108.64    -7.1054e-11
```

Price Float Bond Option Instrument Using Hull-White Model and IRMonteCarlo Pricer

This example shows the workflow to price a `FloatdBondOption` instrument when using a `HullWhite` model and an `IRMonteCarlo` pricing method.

Create `FloatBond` Instrument Object

Use `fininstrument` to create a `FloatBond` instrument object as the underlying bond.

```
BondInst = fininstrument("FloatBond",'Maturity',datetime(2030,9,15),'Spread',0.021,'Name',"bond_
```

```
BondInst =
  FloatBond with properties:

                    Spread: 0.0210
            ProjectionCurve: [0x0 ratecurve]
                ResetOffset: 0
                      Reset: 2
                      Basis: 0
               EndMonthRule: 1
                  Principal: 100
   DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
         LatestFloatingRate: NaN
                   Holidays: NaT
                  IssueDate: NaT
            FirstCouponDate: NaT
             LastCouponDate: NaT
                  StartDate: NaT
                   Maturity: 15-Sep-2030
                       Name: "bond_instrument"
```

Create `FloatBondOption` Instrument Object

Use `fininstrument` to create a `FloatBondOption` instrument object.

```
FloatBOptionEuro = fininstrument("FloatBondOption",'ExerciseDate',datetime(2020,3,15),'Strike',98
```

```
FloatBOptionEuro =
  FloatBondOption with properties:

      OptionType: "call"
    ExerciseStyle: "european"
     ExerciseDate: 15-Mar-2020
           Strike: 98
             Bond: [1x1 fininstrument.FloatBond]
             Name: "float_bond_option_european"
```

Create `HullWhite` Model Object

Use `finmodel` to create a `HullWhite` model object.

```
HullWhiteModel = finmodel("HullWhite",'Alpha',0.32,'Sigma',0.49)
```

```
HullWhiteModel =
  HullWhite with properties:

    Alpha: 0.3200
    Sigma: 0.4900
```

Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2019,1,1);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 01-Jan-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create IRMonteCarlo Pricer Object

Use `finpricer` to create an `IRMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("IRMonteCarlo",'Model',HullWhiteModel,'DiscountCurve',myRC,'SimulationDates
```

```
outPricer =
  HWMonteCarlo with properties:

          NumTrials: 1000
      RandomNumbers: []
      DiscountCurve: [1x1 ratecurve]
    SimulationDates: [15-Mar-2019    15-Sep-2019    15-Mar-2020    ...    ]
              Model: [1x1 finmodel.HullWhite]
```

Price FloatBondOption Instrument

Use `price` to compute the price and sensitivities for the `FloatBondOption` instrument.

```
[Price,outPR] = price(outPricer,FloatBOptionEuro,["all"])
```

```
Price = 18.2369
```

```
outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×4 table
    Price      Delta     Gamma     Vega
    _____    ________    _____    _____

    18.237    -104.22    788.7    -13.949
```

More About

Floating-Rate Note Option

A floating-rate note option gives the option holder the right to sell the option back to the issuer (put) or to redeem an option (call) at a specific price and on a specific date.

Financial Instruments Toolbox supports three types of put and call options on bonds:

- American option — An option that you exercise any time until its expiration date
- European option — An option that you exercise only on its expiration date
- Bermuda option — A Bermuda option resembles a hybrid of American and European options; you can only exercise it on predetermined dates, usually monthly

For more information, see “Bond Options” on page 2-6.

Tips

After creating a `FloatBondOption` instrument object, you can use `setExercisePolicy` to change the size of the options. For example, consider the following instrument:

```
FloatBOption = fininstrument("FloatBondOption",'ExerciseDate',datetime(2029,9,15),'Strike',98,'Bo
```

To modify the size of the `FloatBondOption` instrument object by changing the `ExerciseStyle` from `"European"` to `"American"`, use `setExercisePolicy`:

```
FloatBOption = setExercisePolicy(FloatBOption,[datetime(2021,1,1) datetime(2022,1,1)],100,'Americ
```

Version History

Introduced in R2020a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `FloatBondOption` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

Topics
“Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22
“Choose Instruments, Models, and Pricers” on page 1-53

Floor

`Floor` instrument object

Description

Create and price a `Floor` instrument object for one of more Floor instruments using this workflow:

1. Use `fininstrument` to create a `Floor` instrument object for one of more Floor instruments.
2. Use `finmodel` to specify a `HullWhite`, `BlackKarasinski`, `BlackDermanToy`, `Black`, `Normal`, `BraceGatarekMusiela`, `SABRBraceGatarekMusiela`, or `LinearGaussian2F` model for the `Floor` instrument object.
3. Choose a pricing method.
   - When using a `HullWhite`, `BlackKarasinski`, `BlackDermanToy`, `Black`, or `Normal` model, use `finpricer` for pricing one or more `Floor` instruments and specify:
     - A `Normal` pricer when using a `Normal` model.
     - A `Black` pricer when using a `Black` model.
     - A `HullWhite` pricer when using a `HullWhite` model.
     - An `IRTree` pricer when using a `BlackKarasinski` or `BlackDermanToy` model.
   - When using a `HullWhite`, `BlackKarasinski`, `BraceGatarekMusiela`, `SABRBraceGatarekMusiela`, or `LinearGaussian2F` model, use `finpricer` to specify an `IRMonteCarlo` pricing method for one or more `Floor` instruments.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a `Floor` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
FloorOpt = fininstrument(InstrumentType,'Strike',strike_value,'
Maturity',maturity_date)
FloorOpt = fininstrument( ___ ,Name,Value)
```

Description

`FloorOpt = fininstrument(InstrumentType,'Strike',strike_value,'Maturity',maturity_date)` creates a `Floor` object for one of more Floor instruments by specifying `InstrumentType` and sets the properties on page 11-2821 for the required name-value pair arguments`Strike` and `Maturity`.

The `Floor` instrument supports vanilla and amortizing floors.

`FloorOpt = fininstrument( ___ ,Name,Value)` sets optional properties on page 11-2821 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `FloorOpt = fininstrument("floor",'Strike',100,'Maturity',datetime(2019,1,30),'Reset',4,'Principal',100,'ResetOffset',1,'Basis',4,'DaycountAdjustedCashFlow',true,'BusinessDayConvention',"follow",'ProjectionCurve',ratecurve_object,'Name',"floor_option")` creates a `Floor` instrument with a strike of 100 and a maturity of January 30, 2019. You can specify multiple name-value pair arguments.

Input Arguments

`InstrumentType` — Instrument type

string with value `"Floor"` | string array with values of `"Floor"` | character vector with value `'Floor'` | cell array of character vectors with values of `'Floor'`

Instrument type, specified as a string with the value of `"Floor"`, a character vector with the value of `'Floor'`, an `NINST`-by-`1` string array with values of `"Floor"`, or an `NINST`-by-`1` cell array of character vectors with values of `'Floor'`.

Data Types: `char` | `cell` | `string`

`Floor` Name-Value Pair Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `FloorOpt = fininstrument("floor",'Strike',100,'Maturity',datetime(2019,1,30),'Reset',4,'Principal',100,'ResetOffset',1,'Basis',4,'DaycountAdjustedCashFlow',true,'BusinessDayConvention',"follow",'ProjectionCurve',ratecurve_object,'Name',"floor_option")`

Required `Floor` Name-Value Pair Arguments

`Strike` — Option strike price value

scalar nonnegative decimal | vector of nonnegative decimals

Option strike price value, specified as the comma-separated pair consisting of `'Strike'` and a scalar nonnegative decimal or an `NINST`-by-`1` vector of nonnegative decimals.

Data Types: `double`

`Maturity` — Floor maturity date

datetime array | string array | date character vector

Floor maturity date, specified as the comma-separated pair consisting of `'ExerciseDate'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `Floor` also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `Maturity` property is stored as a datetime.

Optional Floor Name-Value Pair Arguments

`Reset` — Reset frequency payments per year

`1` (default) | scalar numeric with value of `0`, `1`, `2`, `3`, `4`, `6`, or `12` | numeric vector with values of `0`, `1`, `2`, `3`, `4`, `6`, or `12`

Reset frequency payments per year, specified as the comma-separated pair consisting of `'Reset'` and a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`Basis` — Day count basis

`0` (actual/actual) (default) | scalar integer from `0` to `13` | vector of integers from `0` to `13`

Day count basis, specified as the comma-separated pair consisting of `'Basis'` and a scalar integer or an `NINST`-by-`1` vector of integers with the following values:

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Principal amount or principal value schedule

`100` (default) | scalar numeric | numeric vector | timetable

Principal amount or principal value schedule, specified as the comma-separated pair consisting of `'Principal'` and a scalar numeric or an `NINST`-by-`1` numeric vector or a timetable.

`Principal` accepts a `timetable`, where the first column is dates and the second column is its associated principal value. The date indicates the last day that the principal value is valid.

Note If you are creating one or more `Floor` instruments and use a timetable, the timetable specification applies to all of the `Floor` instruments. `Principal` does not accept an `NINST`-by-`1` cell array of timetables as input.

Data Types: `double` | `timetable`

ResetOffset — Lag in rate setting
0 (default) | scalar numeric | numeric vector

Lag in rate setting, specified as the comma-separated pair consisting of 'ResetOffset' and a scalar numeric or an NINST-by-1 numeric vector.

Data Types: double

DaycountAdjustedCashFlow — Flag to adjust cash flows based on actual period day count
false (default) | scalar logical value of true or false | vector of logical values of true or false

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of 'DaycountAdjustedCashFlow' and a scalar logical or an NINST-by-1 vector of logicals with values of true or false.

Data Types: logical

BusinessDayConvention — Business day conventions
"actual" (default) | string | string array | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of 'BusinessDayConvention' and a scalar string or character vector or an NINST-by-1 cell array of character vector or string array for a business day convention. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- "actual" — Nonbusiness days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- "follow" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- "modifiedfollow" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day. However, if the following business day is in a different month, the previous business day is adopted instead.
- "previous" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- "modifiedprevious" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However, if the previous business day is in a different month, the following business day is adopted instead.

Data Types: char | cell | string

Holidays — Holidays used in computing business days
NaT (default) | datetime array | string array | date character vector

Holidays used in computing business days, specified as the comma-separated pair consisting of 'Holidays' and dates using an NINST-by-1 vector of a datetime array, string array, or date character vectors. For example:

```
H = holidays(datetime('today'),datetime(2025,12,15));
FloorOpt = fininstrument("floor",'Strike',100,'Maturity',datetime(2025,12,15),'Holidays',H)
```

To support existing code, Floor also accepts serial date numbers as inputs, but they are not recommended.

`ProjectionCurve` — Rate curve used in generating future cash flows
`ratecurve.empty` (default) | `ratecurve` object | vector of `ratecurve` objects

Rate curve used in projecting the future cash flows, specified as the comma-separated pair consisting of `'ProjectionCurve'` and a scalar `ratecurve` object or an `NINST`-by-`1` vector of `ratecurve` objects. This object is created using `ratecurve`. Use this optional input if the forward curve is different from the discount curve.

Data Types: `object`

`Name` — User-defined name for instrument
`" "` (default) | string | string array | character vector | cell array of character vectors

User-defined name for one of more instruments, specified as the comma-separated pair consisting of `'Name'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

Properties

`Strike` — Option strike price value
scalar nonnegative | vector of nonnegative values

Option strike price value, returned as a scalar nonnegative numeric or an `NINST`-by-`1` vector of nonnegative values.

Data Types: `double`

`Maturity` — Floor maturity date
scalar datetime | vector of datetimes

Floor maturity date, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`Reset` — Reset frequency payments per year
`1` (default) | scalar numeric | numeric vector

Reset frequency payments per year, returned as a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`Basis` — Day count basis
`0` (actual/actual) (default) | scalar integer from `0` to `13` | vector of integers from `0` to `13`

Day count basis, returned as a scalar integer or an `NINST`-by-`1` vector of integers.

Data Types: `double`

`Principal` — Principal amount or principal value schedule
`100` (default) | scalar numeric | numeric vector | timetable

Principal amount or principal value schedule, returned as a scalar numeric or an `NINST`-by-`1` numeric vector for principal amount or a timetable for a principal value schedule.

Data Types: `double` | `timetable`

ResetOffset — Lag in rate setting
0 (default) | scalar numeric | numeric vector

Lag in rate setting, returned as a scalar numeric or an NINST-by-1 numeric vector.

Data Types: double

DaycountAdjustedCashFlow — Flag to adjust cash flows based on actual period day count
false (default) | scalar logical value of true or false | vector of logical values of true or false

Flag to adjust cash flows based on actual period day count, returned as a scalar logical or an NINST-by-1 vector of logical values with values of true or false.

Data Types: logical

BusinessDayConvention — Business day conventions
"actual" (default) | string | string array

Business day conventions, returned as a scalar string or an NINST-by-1 string array.

Data Types: string

Holidays — Holidays used in computing business days
NaT (default) | datetimes

Holidays used in computing business days, returned as an NINST-by-1 vector of datetimes.

Data Types: datetime

ProjectionCurve — Rate curve used in generating future cash flows
ratecurve.empty (default) | scalar ratecurve object | vector of ratecurve objects

Rate curve used in projecting the future cash flows, returned as a scalar ratecurve object or an NINST-by-1 vector of ratecurve objects.

Data Types: object

Name — User-defined name for instrument
" " (default) | string | string array

User-defined name for the instrument, returned as a scalar string or an NINST-by-1 string array.

Data Types: string

Examples

Price Vanilla Floor Instrument Using Black Model and Black Pricer

This example shows the workflow to price a vanilla Floor instrument when you use a Black model and a Black pricing method.

Create ratecurve Object

Create a ratecurve object using ratecurve for the underlying interest-rate curve for the floor instrument.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `Floor` Instrument Object

Use `fininstrument` to create a `Floor` instrument object.

```
FloorOpt = fininstrument("Floor",'Maturity',datetime(2022,9,15),'Strike',0.03,'ProjectionCurve',r
```

```
FloorOpt =
  Floor with properties:

                    Strike: 0.0300
                  Maturity: 15-Sep-2022
               ResetOffset: 0
                     Reset: 1
                     Basis: 0
                 Principal: 100
            ProjectionCurve: [1x1 ratecurve]
   DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
                  Holidays: NaT
                      Name: ""
```

Create `Black` Model Object

Use `finmodel` to create a `Black` model object.

```
BlackModel = finmodel("Black",'Volatility',0.2)
```

```
BlackModel =
  Black with properties:

    Volatility: 0.2000
         Shift: 0
```

Create Black Pricer Object

Use `finpricer` to create a `Black` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
 outPricer = finpricer("analytic",'DiscountCurve',myRC,'Model',BlackModel)
```

```
outPricer =
  Black with properties:

            Model: [1x1 finmodel.Black]
    DiscountCurve: [1x1 ratecurve]
```

Price Floor Instrument

Use `price` to compute the price for the `Floor` instrument.

```
[Price, outPR] = price(outPricer,FloorOpt)
```

```
Price = 8.0878
```

```
outPR =
  priceresult with properties:

       Results: [1x1 table]
    PricerData: []
```

Price Multiple Vanilla Floor Instruments Using Black Model and Black Pricer

This example shows the workflow to price multiple vanilla `Floor` instruments when you use a `Black` model and a `Black` pricing method.

Create ratecurve Object

Create a `ratecurve` object using `ratecurve` for the underlying interest-rate curve for the `floor` instrument.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
        Compounding: -1
              Basis: 0
              Dates: [10x1 datetime]
              Rates: [10x1 double]
             Settle: 15-Sep-2018
       InterpMethod: "linear"
```

```
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create Floor Instrument Object

Use `fininstrument` to create a `Floor` instrument object for three Florr instruments.

```
FloorOpt = fininstrument("Floor",'Maturity',datetime([2022,9,15 ; 2022,9,15 ; 2022,9,15]),'Strike
```

```
FloorOpt=3×1 object
  3x1 Floor array with properties:

    Strike
    Maturity
    ResetOffset
    Reset
    Basis
    Principal
    ProjectionCurve
    DaycountAdjustedCashFlow
    BusinessDayConvention
    Holidays
    Name
```

Create Black Model Object

Use `finmodel` to create a `Black` model object.

```
BlackModel = finmodel("Black",'Volatility',0.2)
```

```
BlackModel =
  Black with properties:

    Volatility: 0.2000
         Shift: 0
```

Create Black Pricer Object

Use `finpricer` to create a `Black` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
 outPricer = finpricer("analytic",'DiscountCurve',myRC,'Model',BlackModel)
```

```
outPricer =
  Black with properties:

              Model: [1x1 finmodel.Black]
    DiscountCurve: [1x1 ratecurve]
```

Price Floor Instruments

Use `price` to compute the prices for the `Floor` instruments.

```
[Price, outPR] = price(outPricer,FloorOpt)
```

```
Price = 3×1

    8.0878
   12.0033
   15.9263

outPR=3×1 object
  3x1 priceresult array with properties:

    Results
    PricerData
```

Price Vanilla Floor Instrument Using Hull-White Model and Hull-White Pricer

This example shows the workflow to price a vanilla `Floor` instrument when you use a `HullWhite` model and a `HullWhite` pricing method.

Create `Floor` Instrument Object

Use `fininstrument` to create a `Floor` instrument object.

```
FloorOpt = fininstrument("Floor",'Strike',0.039,'Maturity',datetime(2019,1,30),'Reset',4,'Princi
```

```
FloorOpt =
  Floor with properties:

                     Strike: 0.0390
                   Maturity: 30-Jan-2019
                ResetOffset: 0
                      Reset: 4
                      Basis: 12
                  Principal: 100
             ProjectionCurve: [0x0 ratecurve]
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                   Holidays: NaT
                       Name: "floor_option"
```

Create `HullWhite` Model Object

Use `finmodel` to create a `HullWhite` model object.

```
HullWhiteModel = finmodel("HullWhite",'Alpha',0.032,'Sigma',0.04)
```

```
HullWhiteModel =
  HullWhite with properties:

    Alpha: 0.0320
    Sigma: 0.0400
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `HullWhite` Pricer Object

Use `finpricer` to create a `HullWhite` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'Model',HullWhiteModel,'DiscountCurve',myRC)
```

```
outPricer =
  HullWhite with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.HullWhite]
```

Price `Floor` Instrument

Use `price` to compute the price for the `Floor` instrument.

```
Price = price(outPricer,FloorOpt)
```

```
Price = 1.2676
```

Price Amortizing Floor Instrument Using Black Model and Black Pricer

This example shows the workflow to price an amortizing `Floor` instrument when you use a `Black` model and a `Black` pricing method.

Create `Floor` Instrument Object

Use `fininstrument` to create an amortizing `Floor` instrument object.

```
CADates = datetime([2020,9,1 ; 2023,9,1]);
CAPrincipal = [100; 85];
Principal = timetable(CADates,CAPrincipal);
```

```
FloorOpt = fininstrument("Floor",'Maturity',datetime(2023,9,1),'Strike',0.015,'Principal',Princi
```

```
FloorOpt =
  Floor with properties:

                     Strike: 0.0150
                   Maturity: 01-Sep-2023
                ResetOffset: 0
                      Reset: 1
                      Basis: 0
                  Principal: [2x1 timetable]
             ProjectionCurve: [0x0 ratecurve]
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                   Holidays: NaT
                       Name: "floor_amortizing_option"
```

Create Black Model Object

Use `finmodel` to create a `Black` model object.

```
BlackModel = finmodel("Black",'Volatility',0.2)
```

```
BlackModel =
  Black with properties:

    Volatility: 0.2000
         Shift: 0
```

Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,1);
Type = 'zero';
ZeroTimes = [calyears([1 2 3 4 5 7 10])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates);
```

Create Black Pricer Object

Use `finpricer` to create a `Black` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'Model',BlackModel,'DiscountCurve',myRC)
```

```
outPricer =
  Black with properties:

            Model: [1x1 finmodel.Black]
    DiscountCurve: [1x1 ratecurve]
```

Price Floor Instrument

Use price to compute the price for the Floor instrument.

```
Price = price(outPricer,FloorOpt)
```

```
Price = 3.0030
```

Price Vanilla Floor Instrument Using Hull-White Model and IRTree Pricer

This example shows the workflow to price a vanilla Floor instrument when using a HullWhite model and an IRTree pricing method.

Create Floor Instrument Object

Use fininstrument to create a Floor instrument object.

```
FloorOpt = fininstrument("Floor",'Strike',0.03,'Maturity',datetime(2020,1,30),'Reset',4,'Principa
```

```
FloorOpt =
  Floor with properties:

                    Strike: 0.0300
                  Maturity: 30-Jan-2020
               ResetOffset: 0
                     Reset: 4
                     Basis: 8
                 Principal: 100
            ProjectionCurve: [0x0 ratecurve]
   DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
                  Holidays: NaT
                      Name: "floor_option"
```

Create HullWhite Model Object

Use finmodel to create a HullWhite model object.

```
HullWhiteModel = finmodel("HullWhite",'Alpha',0.01,'Sigma',0.10)
```

```
HullWhiteModel =
  HullWhite with properties:

    Alpha: 0.0100
    Sigma: 0.1000
```

Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create IRTree Pricer Object

Use `finpricer` to create an `IRTree` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
CFdates = cfdates(Settle, FloorOpt.Maturity, FloorOpt.Reset, FloorOpt.Basis);
outPricer = finpricer("IRTree",'Model',HullWhiteModel,'DiscountCurve',myRC,'TreeDates',CFdates')
```

```
outPricer =
  HWBKTree with properties:

            Tree: [1x1 struct]
       TreeDates: [6x1 datetime]
           Model: [1x1 finmodel.HullWhite]
    DiscountCurve: [1x1 ratecurve]
```

Price Floor Instrument

Use `price` to compute the price and sensitivities for the `Floor` instrument.

```
[Price, outPR] = price(outPricer,FloorOpt,["all"])
```

```
Price = 5.7821
```

```
outPR =
  priceresult with properties:

      Results: [1x4 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×4 table
    Price      Delta     Gamma      Vega
    ______    _______    ______    ______

    5.7821    -110.54    141.45    31.821
```

Price Floor Instrument Using BraceGatarekMusiela Model and IRMonteCarlo Pricer

This example shows the workflow to price a `Floor` instrument when using a `BraceGatarekMusiela` model and an `IRMonteCarlo` pricing method.

Create Floor Instrument Object

Use `fininstrument` to create a `Floor` instrument object.

```
FloorOpt = fininstrument("Floor","Maturity",datetime(2022,9,15),'Strike',0.05,'Reset',1,'Name',"
```

```
FloorOpt =
  Floor with properties:

                    Strike: 0.0500
                  Maturity: 15-Sep-2022
               ResetOffset: 0
                     Reset: 1
                     Basis: 0
                 Principal: 100
            ProjectionCurve: [0x0 ratecurve]
   DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
                  Holidays: NaT
                      Name: "floor_option"
```

Create BraceGatarekMusiela Model Object

Use `finmodel` to create a `BraceGatarekMusiela` model object.

```
BGMVolFunc = @(a,t) (a(1)*t + a(2)).*exp(-a(3)*t) + a(4);
BGMVolParams = [.3 -.02 .7 .14];
numRates = 20;
VolFunc(1:numRates-1) = {@(t) BGMVolFunc(BGMVolParams,t)};
Beta = .08;
CorrFunc = @(i,j,Beta) exp(-Beta*abs(i-j));
Correlation = CorrFunc(meshgrid(1:numRates-1)',meshgrid(1:numRates-1),Beta);
BGM = finmodel("BraceGatarekMusiela",'Volatility',VolFunc,'Correlation',Correlation,'Period',1);
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2019,1,1);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
        Compounding: -1
              Basis: 0
              Dates: [9x1 datetime]
```

```
               Rates: [9x1 double]
              Settle: 01-Jan-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create IRMonteCarlo Pricer Object

Use `finpricer` to create an `IRMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("IRMonteCarlo",'Model',BGM,'DiscountCurve',myRC,'SimulationDates',ZeroDates
```

```
outPricer =
  BGMMonteCarlo with properties:

         NumTrials: 1000
      RandomNumbers: []
      DiscountCurve: [1x1 ratecurve]
    SimulationDates: [01-Jul-2019    01-Jan-2020    01-Jan-2021    ...    ]
              Model: [1x1 finmodel.BraceGatarekMusiela]
```

Price Floor Instrument

Use `price` to compute the price and sensitivities for the `Floor` instrument.

```
[Price,outPR] = price(outPricer,FloorOpt,["all"])
```

```
Price = 14.7975

outPR =
  priceresult with properties:

       Results: [1x3 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×3 table
    Price      Delta     Gamma
    ______    _______    ______

    14.797    -398.43    1399.5
```

More About

Floor

A floor is a contract that includes a guarantee setting the minimum interest rate received by the holder, based on an otherwise floating interest rate.

The payoff for a floor is: max(*FloorRate* − *CurrentRate*, 0)

Version History

Introduced in R2020a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `Floor` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

FRA

FRA instrument object

Description

Create and price a FRA (forward rate agreement) instrument object for one or more FRA instruments using this workflow:

1. Use `fininstrument` to create a FRA instrument object for one or more FRA instruments.
2. Use `ratecurve` to specify an interest-rate model for the FRA instrument object.
3. Use `finpricer` to specify a `Discount` pricing method for one or more FRA instruments.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a FRA instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
FRAObj = fininstrument(InstrumentType,'StartDate',start_date,'
Maturity',maturity_date,'Rate',rate_value)
FRAObj = fininstrument( ___ ,Name,Value)
```

Description

`FRAObj = fininstrument(InstrumentType,'StartDate',start_date,'Maturity',maturity_date,'Rate',rate_value)` creates a FRA object for one or more FRA instruments by specifying `InstrumentType` and sets the properties on page 11-2837 for the required name-value pair arguments `StartDate`, `Maturity`, and `Rate`. For more information on a FRA instrument, see “More About” on page 11-2842.

`FRAObj = fininstrument( ___ ,Name,Value)` sets optional properties on page 11-2837 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `FRAObj = fininstrument("FRA",'StartDate',datetime(2016,1,30),'Maturity',datetime(2019,1,30),'Rate',0.025,'Principal',100,'Basis',1,'BusinessDayConvention',"follow",'Name',"FRA_instrument")` creates a FRA instrument with a principal of 100 and a maturity of January 30, 2019. You can specify multiple name-value pair arguments.

Input Arguments

`InstrumentType` — Instrument type

string with value `"FRA"` | string array with values of `"FRA"` | character vector with value `'FRA'` | cell array of character vectors with values of `'FRA'`

Instrument type, specified as a string with the value of "FRA", a character vector with the value of 'FRA', an NINST-by-1 string array with values of "FRA", or an NINST-by-1 cell array of character vectors with values of 'FRA'.

Data Types: char | cell | string

FRA Name-Value Pair Arguments

Specify required and optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: FRAObj = fininstrument("FRA",'StartDate',datetime(2016,1,30),'Maturity',datetime(2019,1,30),'Rate',0.025,'Principal',100,'Basis',1,'BusinessDayConvention',"follow",'Name',"FRA_instrument")

Required FRA Name-Value Pair Arguments

StartDate — FRA start date

datetime array | string array | date character vector

FRA start date, specified as the comma-separated pair consisting of 'StartDate' and a scalar or an NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, FRA also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by datetime because the StartDate property is stored as a datetime.

Maturity — FRA maturity date

datetime array | string array | date character vector

FRA maturity date, specified as the comma-separated pair consisting of 'Maturity' and a scalar or an NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, FRA also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by datetime because the Maturity property is stored as a datetime.

Rate — FRA coupon rate

scalar decimal | vector of decimals

FRA coupon rate, specified as the comma-separated pair consisting of 'Rate' and a scalar decimal or an NINST-by-1 vector of decimals.

Data Types: double

Optional FRA Name-Value Pair Arguments

Basis — Day count basis

0 (actual/actual) (default) | scalar integer from 0 to 13 | vector of integers from 0 to 13

Day count basis, specified as the comma-separated pair consisting of `'Basis'` and scalar value or an `NINST`-by-`1` vector of integers from the following:

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Principal amount
`100` (default) | scalar numeric | numeric vector

Principal amount, specified as the comma-separated pair consisting of `'Principal'` and a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`BusinessDayConvention` — Business day convention
`"actual"` (default) | string | string array | character vector | cell array of character vectors

Business day convention, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- `"actual"` — Nonbusiness days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- `"follow"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- `"modifiedfollow"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `"previous"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.

- `"modifiedprevious"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell` | `string`

`Holidays` — Holidays used in computing business days
`NaT` (default) | datetime array | string array | date character vector

Holidays used in computing business days, specified as the comma-separated pair consisting of `'Holidays'` and dates using an `NINST`-by-`1` vector of a datetime array, string array, or date character vectors. For example:

```
H = holidays(datetime('today'),datetime(2025,12,15));
FRAObj = fininstrument("FRA",'StartDate',datetime(2016,1,30),'Maturity',datetime(2025,12,15),'Ra
```

To support existing code, `FRA` also accepts serial date numbers as inputs, but they are not recommended.

`Name` — User-defined name for instrument
`"  "` (default) | string | string array | character vector | cell array of character vectors

User-defined name for one of more instruments, specified as the comma-separated pair consisting of `'Name'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

Properties

`StartDate` — FRA start date
scalar datetime | vector of datetimes

FRA start date, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`Maturity` — FRA maturity date
scalar datetime | vector of datetimes

FRA maturity date, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`Rate` — FRA coupon rate
scalar decimal | vector of decimals

FRA coupon rate, returned as a scalar decimal or an `NINST`-by-`1` vector of decimals.

Data Types: `double`

`Basis` — Day count basis
`[0 0]` (actual/actual) (default) | scalar integer from `0` to `13` | vector of integers from `0` to `13`

Day count basis, returned as a scalar integer or an `NINST`-by-`1` vector of integers.

Data Types: `double`

`Principal` — Principal amount
`100` (default) | scalar numeric | numeric vector

Principal amount, returned as a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`BusinessDayConvention` — Business day convention
`"actual"` (default) | scalar string | string array

Business day convention, returned as a scalar string or an `NINST`-by-`1` string array.

Data Types: `string`

`Holidays` — Holidays used in computing business days
`NaT` (default) | datetimes

Holidays used in computing business days, returned as an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`Name` — User-defined name for instrument
`" "` (default) | scalar string | string array

User-defined name for the instrument, returned as a scalar string or an `NINST`-by-`1` string array.

Data Types: `string`

Object Functions

cashflows	Compute cash flow for FixedBond, FloatBond, Swap, FRA, STIRFuture, OISFuture, OvernightIndexedSwap, or Deposit instrument

Examples

Price FRA Instrument Using `ratecurve` and Discount Pricer

This example shows the workflow to price a FRA (forward rate agreement) instrument when you use a `ratecurve` and a `Discount` pricing method.

Create FRA Instrument Object

Use `fininstrument` to create a FRA instrument object.

```
FRAObj = fininstrument("FRA",'StartDate',datetime(2020,9,15),'Maturity',datetime(2022,9,15),'Rate
```

```
FRAObj =
  FRA with properties:

                     Rate: 0.0175
                    Basis: 2
                StartDate: 15-Sep-2020
                 Maturity: 15-Sep-2022
                Principal: 100
    BusinessDayConvention: "actual"
                 Holidays: NaT
```

```
                    Name: ""
```

Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
        Compounding: -1
              Basis: 0
              Dates: [10x1 datetime]
              Rates: [10x1 double]
             Settle: 15-Sep-2018
       InterpMethod: "linear"
  ShortExtrapMethod: "next"
   LongExtrapMethod: "previous"
```

Create Discount Pricer Object

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("Discount",'DiscountCurve',myRC)
```

```
outPricer =
  Discount with properties:

    DiscountCurve: [1x1 ratecurve]
```

Price FRA Instrument

Use `price` to compute the price and sensitivities for the FRA instrument.

```
[Price, outPR] = price(outPricer, FRAObj,["all"])
```

```
Price = 3.4176
```

```
outPR =
  priceresult with properties:

      Results: [1x2 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×2 table
    Price       DV01
    ______    ________

    3.4176    0.001368
```

Price Multiple FRA Instruments Using ratecurve and Discount Pricer

This example shows the workflow to price multiple FRA (forward rate agreement) instruments when you use a `ratecurve` and a `Discount` pricing method.

Create FRA Instrument Object

Use `fininstrument` to create a FRA instrument object for three FRA instruments.

```
FRAObj = fininstrument("FRA",'StartDate',datetime([2020,9,15 ; 2020,10,15 ; 2020,11,15]),'Maturi
```

```
FRAObj=3×1 object
  3x1 FRA array with properties:

    Rate
    Basis
    StartDate
    Maturity
    Principal
    BusinessDayConvention
    Holidays
    Name
```

Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `Discount` Pricer Object

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("Discount",'DiscountCurve',myRC)
```

```
outPricer =
  Discount with properties:

    DiscountCurve: [1x1 ratecurve]
```

Price FRA Instruments

Use `price` to compute the prices and sensitivities for the FRA instruments.

```
[Price, outPR] = price(outPricer, FRAObj,["all"])
```

```
Price = 3×1

    3.4176
    3.4121
    3.4063

outPR=1×3 object
  1x3 priceresult array with properties:

    Results
    PricerData
```

```
outPR.Results
```

```
ans=1×2 table
    Price       DV01
    ______    ________

    3.4176    0.001368

ans=1×2 table
    Price       DV01
    ______    _________

    3.4121    0.0013938

ans=1×2 table
    Price       DV01
    ______    _________
```

```
    3.4063    0.0014204
```

More About

FRA Instrument

A FRA (forward rate agreement) instrument is an over-the-counter contract between parties that determines the rate of interest to be paid on an agreed upon date in the future.

The FRA determines the rates to be used along with the termination date and notional value. FRAs are cash-settled with the payment based on the net difference between the interest rate of the contract and the floating rate in the market, called the reference rate. The notional amount is not exchanged, but is rather a cash amount based on the rate differentials and the notional value of the contract.

Version History

Introduced in R2020a

Serial date numbers not recommended

Not recommended starting in R2022b

Although FRA supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

Lookback

`Lookback` instrument

Description

Create and price a `Lookback` instrument object for one or more Lookback instruments using this workflow:

1. Use `fininstrument` to create a `Lookback` instrument object for one or more Lookback instruments.
2. Use `finmodel` to specify a `BlackScholes`, `Heston`, `Bates`, or `Merton` model for the `Lookback` instrument object.
3. Choose a pricing method.
   - When using a `BlackScholes` model, use `finpricer` to specify a `ConzeViswanathan`, `AssetTree`, or `GoldmanSosinGatto` pricing method for one or more `Lookback` instruments.
   - When using a `BlackScholes`, `Heston`, `Bates`, or `Merton` model, use `finpricer` to specify an `AssetMonteCarlo` pricing method for one or more `Lookback` instruments.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a `Lookback` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
LookbackObj = fininstrument(InstrumentType,'Strike',strike_value,'
ExerciseDate',exercise_date)
LookbackObj = fininstrument( ___ ,Name,Value)
```

Description

`LookbackObj = fininstrument(InstrumentType,'Strike',strike_value,'ExerciseDate',exercise_date)` creates a `Lookback` object for one or more Lookback instruments by specifying `InstrumentType` and sets the properties on page 11-2845 for the required name-value pair arguments `Strike` and `ExerciseDate`.

The `Lookback` instrument supports fixed-strike and floating-strike lookback options. For more information on a `Lookback` instrument, see “More About” on page 11-2858.

`LookbackObj = fininstrument( ___ ,Name,Value)` sets optional properties on page 11-2845 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `LookbackObj =`

`fininstrument("Lookback",'Strike',100,'ExerciseDate',datetime(2019,1,30),'OptionType',"put",'ExerciseStyle',"European",'Name',"lookback_option")` creates a `Lookback` put option with an European exercise. You can specify multiple name-value pair arguments.

Input Arguments

`InstrumentType` — Instrument type

string with value `"Lookback"` | string array with values of `"Lookback"` | character vector with value `'Lookback'` | cell array of character vectors with values of `'Lookback'`

Instrument type, specified as a string with the value of `"Lookback"`, a character vector with the value of `'Lookback'`, an `NINST`-by-`1` string array with values `"Lookback"`, or an `NINST`-by-`1` cell array of character vectors with values of `'Lookback'`.

Data Types: `char` | `cell` | `string`

Lookback Name-Value Pair Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `LookbackObj = fininstrument("Lookback",'Strike',100,'ExerciseDate',datetime(2019,1,30),'OptionType',"put",'ExerciseStyle',"European",'Name',"lookback_option")`

Required Lookback Name-Value Pair Arguments

`Strike` — Option strike price value

nonnegative numeric | vector of nonnegative values | `NaN`

Option strike price value, specified as the comma-separated pair consisting of `'Strike'` and a scalar nonnegative numeric value or an `NINST`-by-`1` vector of nonnegative values for a fixed-strike `Lookback` option. For a floating-strike `Lookback` option, specify `'Strike'` as a `NaN` or an `NINST`-by-`1` vector of `NaN`s.

Note Use the `ConzeViswanathan` pricer for a fixed strike `Lookback` option and use the `GoldmanSosinGatto` pricer for a floating strike `Lookback` option.

Data Types: `double`

`ExerciseDate` — Option exercise date

datetime array | string array | date character vector

Option exercise date, specified as the comma-separated pair consisting of `'ExerciseDate'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

Note For a European option, there is only one `ExerciseDate` on the option expiry date.

To support existing code, `Lookback` also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `ExerciseDate` property is stored as a datetime.

Optional Lookback Name-Value Pair Arguments

`OptionType` — Option type
`"call"` (default) | string with value `"call"` or `"put"` | string array with values `"call"` or `"put"` | character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Option type, specified as the comma-separated pair consisting of `'OptionType'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

`ExerciseStyle` — Option exercise style
`"European"` (default) | string with value `"European"` or `"American"` | string array with values `"European"` or `"American"` | character vector with value `'European'` or `'American'` | cell array of character vectors with values `'European'` or `'American'`

Option exercise style, specified as the comma-separated pair consisting of `'ExerciseStyle'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `string` | `cell` | `char`

`AssetMinMax` — Maximum or minimum underlying asset price
`NaN` where `SpotPrice` of the underlying asset is used (default) | scalar numeric | numeric vector

Maximum or minimum underlying asset price, specified as the comma-separated pair consisting of `'AssetMinMax'` and a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`Name` — User-defined name for instrument
`"  "` (default) | string | string array | character vector | cell array of character vectors

User-defined name for one of more instruments, specified as the comma-separated pair consisting of `'Name'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

Properties

`Strike` — Option strike price value
nonnegative numeric | vector of nonnegative values

Option strike price value, returned as a scalar nonnegative numeric or an `NINST`-by-`1` vector of nonnegative values.

Data Types: `double`

`ExerciseDate` — Option exercise date
datetime | vector of datetimes

Option exercise date, returned as a datetime or an NINST-by-1 vector of datetimes.

Data Types: datetime

OptionType — Option type
"call" (default) | string with value "call" or "put" | string array with values "call" or "put"

Option type, returned as a scalar string or an NINST-by-1 string array with the values of "call" or "put".

Data Types: string

ExerciseStyle — Option exercise style
"European" (default) | string with value "European" or "American" | string array with values "European" or "American"

Option exercise style, returned as a scalar string or an NINST-by-1 string array with values of "European" or "American".

Data Types: string

AssetMinMax — Maximum or minimum underlying asset price
NaN where SpotPrice of the underlying asset is used (default) | scalar numeric | numeric vector

Maximum or minimum underlying asset price, returned as a scalar numeric or an NINST-by-1 numeric vector.

Data Types: double

Name — User-defined name for instrument
" " (default) | string | string array

User-defined name for the instrument, returned as a string or an NINST-by-1 string array.

Data Types: string

Examples

Price Lookback Instrument Using a Black-Scholes Model and Conze-Viswanathan Pricer

This example shows the workflow to price a LookBack instrument when you use a BlackScholes model and a ConzeViswanathan pricing method.

Create Lookback Instrument Object

Use fininstrument to create a Lookback instrument object.

```
LookbackOpt = fininstrument("Lookback",'Strike',105,'ExerciseDate',datetime(2022,9,15),'OptionTy
```

```
LookbackOpt =
  Lookback with properties:

       OptionType: "put"
           Strike: 105
      AssetMinMax: NaN
    ExerciseStyle: "european"
     ExerciseDate: 15-Sep-2022
```

```
             Name: "lookback_option"
```

Create BlackScholes Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.2)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.2000
    Correlation: 1
```

Create ratecurve Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create ConzeViswanathan Pricer Object

Use `finpricer` to create a `ConzeViswanathan` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic","Model",BlackScholesModel,"DiscountCurve",myRC,"SpotPrice",100,'
```

```
outPricer =
  ConzeViswanathan with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 100
    DividendValue: 0.2500
     DividendType: "continuous"
```

Price Lookback Instrument

Use `price` to compute the price and sensitivities for the `Lookback` instrument.

```
[Price, outPR] = price(outPricer,LookbackOpt,["all"])

Price = 57.8786

outPR =
  priceresult with properties:

      Results: [1x7 table]
    PricerData: []

outPR.Results

ans=1×7 table
    Price      Delta      Gamma      Lambda      Vega      Theta       Rho
    _____    ________    _____    ________    ______    _______    _______

    57.879    -0.33404      0      -0.57714    32.587    -5.1863    -350.41
```

Price Multiple Lookback Instruments Using a Black-Scholes Model and Conze-Viswanathan Pricer

This example shows the workflow to price multiple `LookBack` instrument when you use a `BlackScholes` model and a `ConzeViswanathan` pricing method.

Create Lookback Instrument Object

Use `fininstrument` to create a `Lookback` instrument object for three Lookback instruments.

```
LookbackOpt = fininstrument("Lookback",'Strike',[105 ; 120; 140],'ExerciseDate',datetime([2022,9

LookbackOpt=3×1 object
  3x1 Lookback array with properties:

    OptionType
    Strike
    AssetMinMax
    ExerciseStyle
    ExerciseDate
    Name
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.2)

BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.2000
    Correlation: 1
```

Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create ConzeViswanathan Pricer Object

Use finpricer to create a ConzeViswanathan pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic","Model",BlackScholesModel,"DiscountCurve",myRC,"SpotPrice",100,'
```

```
outPricer =
  ConzeViswanathan with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 100
    DividendValue: 0.2500
     DividendType: "continuous"
```

Price Lookback Instruments

Use price to compute the prices and sensitivities for the Lookback instruments.

```
[Price, outPR] = price(outPricer,LookbackOpt,["all"])
```

```
Price = 3×1

   57.8786
   71.3008
   88.9673

outPR=3×1 object
  3x1 priceresult array with properties:

    Results
    PricerData
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta      Gamma      Lambda      Vega      Theta       Rho
    _____    ________    _____    ________    ______    _______    _______

    57.879    -0.33404      0       -0.57714    32.587    -5.1863    -350.41

Price Lookback Instrument Using a Black-Scholes Model and Asset Tree Pricer for LR Binomial Tree

This example shows the workflow to price a `LookBack` instrument when you use an `BlackScholes` model and an `AssetTree` pricing method using a Leisen-Reimer (LR) binomial tree.

Create Lookback Instrument Object

Use `fininstrument` to create a `Lookback` instrument object.

```
LookbackOpt = fininstrument("Lookback",'Strike',105,'ExerciseDate',datetime(2022,9,15),'OptionTy
```

```
LookbackOpt =
  Lookback with properties:

       OptionType: "put"
           Strike: 105
      AssetMinMax: NaN
    ExerciseStyle: "european"
     ExerciseDate: 15-Sep-2022
             Name: "lookback_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.2)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.2000
```

```
    Correlation: 1
```

Create ratecurve Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create AssetTree Pricer Object

Use `finpricer` to create an `AssetTree` pricer object for a LR equity tree and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
NumPeriods = 15;
LRPricer = finpricer("AssetTree",'DiscountCurve',myRC,'Model',BlackScholesModel,'SpotPrice',150,
```

```
LRPricer =
  LRTree with properties:

    InversionMethod: PP1
             Strike: 150
               Tree: [1x1 struct]
        NumPeriods: 15
              Model: [1x1 finmodel.BlackScholes]
      DiscountCurve: [1x1 ratecurve]
          SpotPrice: 150
       DividendType: "continuous"
      DividendValue: 0
          TreeDates: [21-Dec-2018 09:36:00    28-Mar-2019 19:12:00    ...    ]
```

```
LRPricer.Tree
```

```
ans = struct with fields:
    Probs: [2x15 double]
    ATree: {1x16 cell}
     dObs: [15-Sep-2018 00:00:00    21-Dec-2018 09:36:00    ...    ]
     tObs: [0 0.2667 0.5333 0.8000 1.0667 1.3333 1.6000 1.8667 2.1333 ... ]
```

Price Lookback Instrument

Use `price` to compute the price and sensitivities for the `Lookback` instrument.

```
[Price, outPR] = price(LRPricer,LookbackOpt,["all"])
```

```
Price = 3.9412
```

```
outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta        Gamma        Vega     Lambda       Rho        Theta
    _____    ________    _________    _____    _______    _______    _______

    3.9412    -0.13312    -0.011131    67.684    -5.0757    -73.857    -1.0383
```

Price Lookback Instrument Using a Black-Scholes Model and Asset Tree Pricer for Standard Trinomial Tree

This example shows the workflow to price a `LookBack` instrument when you use an `BlackScholes` model and an `AssetTree` pricing method using a Standard Trinomial (STT) tree.

Create Lookback Instrument Object

Use `fininstrument` to create a `Lookback` instrument object.

```
LookbackOpt = fininstrument("Lookback",'Strike',105,'ExerciseDate',datetime(2022,9,15),'OptionTy
```

```
LookbackOpt =
  Lookback with properties:

      OptionType: "put"
          Strike: 105
     AssetMinMax: NaN
    ExerciseStyle: "european"
     ExerciseDate: 15-Sep-2022
             Name: "lookback_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.2)
```

```
BlackScholesModel =
  BlackScholes with properties:

    Volatility: 0.2000
```

```
    Correlation: 1
```

Create ratecurve Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create AssetTree Pricer Object

Use `finpricer` to create an `AssetTree` pricer object for a Standard Trinomial (STT) equity tree and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
NumPeriods = 15;
STTPricer = finpricer("AssetTree",'DiscountCurve',myRC,'Model',BlackScholesModel,'SpotPrice',150
```

```
STTPricer =
  STTree with properties:

            Tree: [1x1 struct]
       NumPeriods: 15
            Model: [1x1 finmodel.BlackScholes]
    DiscountCurve: [1x1 ratecurve]
        SpotPrice: 150
     DividendType: "continuous"
    DividendValue: 0
        TreeDates: [21-Dec-2018 09:36:00    28-Mar-2019 19:12:00    ...    ]
```

```
STTPricer.Tree
```

```
ans = struct with fields:
    ATree: {1x16 cell}
    Probs: {1x15 cell}
     dObs: [15-Sep-2018 00:00:00    21-Dec-2018 09:36:00    ...    ]
     tObs: [0 0.2667 0.5333 0.8000 1.0667 1.3333 1.6000 1.8667 2.1333 ... ]
```

Price Lookback Instrument

Use `price` to compute the price and sensitivities for the `Lookback` instrument.

```
[Price, outPR] = price(STTPricer,LookbackOpt,["all"])

Price = 3.3392

outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: []

outPR.Results

ans=1×7 table
    Price      Delta         Gamma         Vega      Lambda       Rho        Theta
    _____    _________    ___________    ______    _______    ________    _______

    3.3392    -0.15942    -1.0596e-11    63.886    -7.1613    -68.263    -1.0254
```

Price Lookback Instrument Using a Black-Scholes Model and Asset Monte-Carlo Pricer

This example shows the workflow to price a `LookBack` instrument when you use a `BlackScholes` model and an `AssetMonetCarlo` pricing method.

Create Lookback Instrument Object

Use `fininstrument` to create a `Lookback` instrument object.

```
LookbackOpt = fininstrument("Lookback",'Strike',105,'ExerciseDate',datetime(2022,9,15),'OptionTy

LookbackOpt =
  Lookback with properties:

       OptionType: "put"
           Strike: 105
      AssetMinMax: NaN
    ExerciseStyle: "european"
     ExerciseDate: 15-Sep-2022
             Name: "lookback_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.2)

BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.2000
    Correlation: 1
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `AssetMonteCarlo` Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo",'DiscountCurve',myRC,"Model",BlackScholesModel,'SpotPrice
```

```
outPricer =
  GBMMonteCarlo with properties:

     DiscountCurve: [1x1 ratecurve]
         SpotPrice: 200
    SimulationDates: 15-Sep-2022
         NumTrials: 1000
     RandomNumbers: []
             Model: [1x1 finmodel.BlackScholes]
      DividendType: "continuous"
     DividendValue: 0
```

Price Lookback Instrument

Use `price` to compute the price and sensitivities for the `Lookback` instrument.

```
[Price, outPR] = price(outPricer,LookbackOpt,["all"])
```

```
Price = 1.8553

outPR =
  priceresult with properties:

      Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×7 table
    Price       Delta        Gamma       Lambda       Rho       Theta       Vega
    ______    _________    __________    _______    _______    ________    ______
```

```
    1.8553    -0.040442    0.00062792    -4.3596    -39.426    -0.71345    42.311
```

Price Lookback Instrument Using a Bates Model and Asset Monte-Carlo Pricer

This example shows the workflow to price a `LookBack` instrument when you use a `Bates` model and an `AssetMonetCarlo` pricing method.

Create Lookback Instrument Object

Use `fininstrument` to create a `Lookback` instrument object.

```
LookbackOpt = fininstrument("Lookback",'Strike',105,'ExerciseDate',datetime(2022,9,15),'OptionTy
```

```
LookbackOpt =
  Lookback with properties:

       OptionType: "put"
           Strike: 105
      AssetMinMax: NaN
    ExerciseStyle: "european"
     ExerciseDate: 15-Sep-2022
             Name: "lookback_option"
```

Create Bates Model Object

Use `finmodel` to create a `Bates` model object.

```
BatesModel = finmodel("Bates",'V0',0.032,'ThetaV',0.1,'Kappa',0.003,'SigmaV',0.2,'RhoSV',0.9,'Mea
```

```
BatesModel =
  Bates with properties:

          V0: 0.0320
      ThetaV: 0.1000
       Kappa: 0.0030
      SigmaV: 0.2000
       RhoSV: 0.9000
       MeanJ: 0.1100
     JumpVol: 0.0230
    JumpFreq: 0.0200
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:
```

```
                Type: "zero"
        Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `AssetMonteCarlo` Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo",'DiscountCurve',myRC,"Model",BatesModel,'SpotPrice',100,
```

```
outPricer =
  BatesMonteCarlo with properties:

      DiscountCurve: [1x1 ratecurve]
          SpotPrice: 100
    SimulationDates: 15-Sep-2022
          NumTrials: 1000
      RandomNumbers: []
              Model: [1x1 finmodel.Bates]
       DividendType: "continuous"
      DividendValue: 0
```

Price Lookback Instrument

Use `price` to compute the price and sensitivities for the `Lookback` instrument.

```
[Price, outPR] = price(outPricer,LookbackOpt,["all"])
```

```
Price = 7.2577
```

```
outPR =
  priceresult with properties:

       Results: [1x8 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×8 table
    Price      Delta      Gamma     Lambda       Rho        Theta       Vega      VegaLT
    ______    _______    _____    _______    _______    _________    ______    _______
```

```
    7.2577    -0.84025      0      -11.577    -29.025    -0.027666    30.748    0.68416
```

More About

Lookback Option

A lookback option is a path-dependent option based on the maximum or minimum value the underlying asset achieves during the entire life of the option.

Financial Instruments Toolbox software supports two types of lookback options: fixed and floating. Fixed lookback options have a specified strike price, while floating lookback options have a strike price determined by the asset path. For more information, see “Lookback Option” on page 3-39.

Version History

Introduced in R2020a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `Lookback` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

OptionEmbeddedFixedBond

`OptionEmbeddedFixedBond` instrument object

Description

Create and price a `OptionEmbeddedFixedBond` instrument object for one or more Option Embedded Fixed Bond instruments using this workflow:

1. Use `fininstrument` to create an `OptionEmbeddedFixedBond` instrument object for one or more Option Embedded Fixed Bond instruments.
2. use `finmodel` to specify a `HullWhite`, `BlackKarasinski`, `BlackDermanToy`, `BraceGatarekMusiela`, `SABRBraceGatarekMusiela`, or `LinearGaussian2F` model for the `OptionEmbeddedFixedBond` instrument object.
3. Choose a pricing method.
   - When using a `HullWhite`, `BlackKarasinski`, or `BlackDermanToy` model, use `finpricer` to specify an `IRTree` pricing method for one or more `OptionEmbeddedFixedBond` instruments.
   - When using a `HullWhite`, `BlackKarasinski`, `BraceGatarekMusiela`, `SABRBraceGatarekMusiela`, or `LinearGaussian2F` model, use `finpricer` to specify an `IRMonteCarlo` pricing method for one or more `OptionEmbeddedFixedBond` instruments.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for an `OptionEmbeddedFixedBond` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
OptionEmbeddedFixedBondObj = fininstrument(InstrumentType,'
CouponRate',couponrate_value,'Maturity',maturity_date,'
CallSchedule',call_schedule_value)
OptionEmbeddedFixedBondObj = fininstrument(InstrumentType,'
CouponRate',couponrate_value,'Maturity',maturity_date,'
PutSchedule',put_schedule_value)
OptionEmbeddedFixedBondObj = fininstrument( ___ ,Name,Value)
```

Description

`OptionEmbeddedFixedBondObj = fininstrument(InstrumentType,'CouponRate',couponrate_value,'Maturity',maturity_date,'CallSchedule',call_schedule_value)` creates a `OptionEmbeddedFixedBond` object for one

or more Option Embedded Fixed Bond instruments by specifying `InstrumentType` and sets the properties on page 11-2866 for the required name-value pair arguments `CouponRate`, `Maturity`, and `CallSchedule`.

The `OptionEmbeddedFixedBond` instrument supports a vanilla bond with embedded option, stepped coupon bond with embedded option, and an amortizing bond with embedded option. For more information, see "More About" on page 11-2881.

`OptionEmbeddedFixedBondObj = fininstrument(InstrumentType,'CouponRate',couponrate_value,'Maturity',maturity_date,'PutSchedule',put_schedule_value)` creates a `OptionEmbeddedFixedBond` object for one or more Option Embedded Fixed Bond instruments by specifying `InstrumentType` and sets the properties on page 11-2866 for the required name-value pair arguments `CouponRate`, `Maturity`, and `PutSchedule`.

`OptionEmbeddedFixedBondObj = fininstrument(___,Name,Value)` sets optional properties on page 11-2866 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `OptionEmbeddedFixedBondObj = fininstrument("OptionEmbeddedFixedBond",'CouponRate',0.034,'Maturity',datetime(2019,1,30),'Period',2,'Basis',1,'Principal',100,'CallSchedule',schedule,'CallExerciseStyle',"American",'Name',"optionembeddedfixedbond_instrument")` creates an `OptionEmbeddedFixedBond` instrument with an American exercise and a call schedule. You can specify multiple name-value pair arguments.

Input Arguments

`InstrumentType` — Instrument type

string with value `"OptionEmbeddedFixedBond"` | string array with values of `"OptionEmbeddedFixedBond"` | character vector with value `'OptionEmbeddedFixedBond'` | cell array of character vectors with values of `'OptionEmbeddedFixedBond'`

Instrument type, specified as a string with the value of `"OptionEmbeddedFixedBond"`, a character vector with the value of `'OptionEmbeddedFixedBond'`, an `NINST`-by-`1` string array with values of `"OptionEmbeddedFixedBond"`, or an `NINST`-by-`1` cell array of character vectors with values of `'OptionEmbeddedFixedBond'`.

Data Types: `char` | `cell` | `string`

`OptionEmbeddedFixedBond` Name-Value Pair Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `OptionEmbeddedFixedBondObj = fininstrument("OptionEmbeddedFixedBond",'CouponRate',0.034,'Maturity',datetime(2019,1,30),'Period',2,'Basis',1,'Principal',100,'CallSchedule',schedule,'CallExerciseStyle',"American",'Name',"optionembeddedfixedbond_instrument")`

Required `OptionEmbeddedFixedBond` Name-Value Pair Arguments

`CouponRate` — Coupon rate for `OptionEmbeddedFixedBond`

scalar decimal | vector of decimals | timetable

Coupon rate for `OptionEmbeddedFixedBond`, specified as the comma-separated pair consisting of `'CouponRate'` as a scalar decimal or an `NINST`-by-`1` vector of decimals for an annual rate or a timetable where the first column is dates and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Note If you are creating one or more `OptionEmbeddedFixedBond` instruments and use a timetable, the timetable specification applies to all of the `OptionEmbeddedFixedBond` instruments. `CouponRate` does not accept an `NINST`-by-`1` cell array of timetables as input.

Data Types: `double` | `timetable`

`Maturity` — Maturity date for `OptionEmbeddedFixedBond`
datetime array | string array | date character vector

Maturity date for `OptionEmbeddedFixedBond`, specified as the comma-separated pair consisting of `'Maturity'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `OptionEmbeddedFixedBond` also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `Maturity` property is stored as a datetime.

`CallSchedule` — Call schedule
timetable

Call schedule, specified as the comma-separated pair consisting of `'CallSchedule'` and a timetable of call dates and strikes.

If you use a date character vector or date string for the dates in this timetable, the format must be recognizable by `datetime` because the `CallSchedule` property is stored as a datetime.

Note The `OptionEmbeddedFixedBond` instrument supports either `CallSchedule` and `CallExerciseStyle` or `PutSchedule` and `PutExerciseStyle`, but not both.

If you are creating one or more `OptionEmbeddedFixedBond` instruments and use a timetable, the timetable specification applies to all of the `OptionEmbeddedFixedBond` instruments. `CallSchedule` does not accept an `NINST`-by-`1` cell array of timetables as input.

Data Types: `timetable`

`PutSchedule` — Call schedule
timetable

Put schedule, specified as the comma-separated pair consisting of `'PutSchedule'` and a timetable of call dates and strikes.

If you use a date character vector or date string for dates in this timetable, the format must be recognizable by `datetime` because the `PutSchedule` property is stored as a datetime.

Note The `OptionEmbeddedFixedBond` instrument supports either `CallSchedule` and `CallExerciseStyle` or `PutSchedule` and `PutExerciseStyle`, but not both.

If you are creating one or more `OptionEmbeddedFixedBond` instruments and use a timetable, the timetable specification applies to all of the `OptionEmbeddedFixedBond` instruments. `PutSchedule` does not accept an `NINST`-by-`1` cell array of timetables as input.

Data Types: `timetable`

Optional OptionEmbeddedFixedBond Name-Value Pair Arguments

`Period` — Frequency of payments per year

2 (default) | scalar integer | vector of integers

Frequency of payments per year, specified as the comma-separated pair consisting of `'Period'` and a scalar integer or an `NINST`-by-`1` vector of integers. Values for `Period` are: `1`, `2`, `3`, `4`, `6`, and `12`.

Data Types: `double`

`CallExerciseStyle` — Call option exercise style

`"European"` (default) | string with value `"European"`, `"American"`, or `"Bermudan"` | string array with value `"European"`, `"American"`, or `"Bermudan"` | character vector with value `'European'`, `'American'`, or `'Bermudan'` | cell array of character vectors with values of `'European'`, `'American'`, or `'Bermudan'`

Call option exercise style, specified as the comma-separated pair consisting of `'CallExerciseStyle'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Note The `CallSchedule` is a timetable of call dates and strikes. If you do not specify a `CallExerciseStyle`, then based on the `CallSchedule` specification, a default value of `CallExerciseStyle` is assigned as follows:

- If there is one exercise date in the `CallSchedule`, then the `CallExerciseStyle` is an `"European"`.
- If there are two exercise dates in the `CallSchedule`, then the `CallExerciseStyle` is an `"American"` with a start date and maturity.
- If there are more than two exercise dates in the `CallSchedule`, then the `CallExerciseStyle` is an `"Bermudan"`.

If the you define a `CallExerciseStyle` and this is not consistent with what you have specified in the `CallSchedule`, you receive an error message.

Data Types: `string` | `cell` | `char`

`PutExerciseStyle` — Put option exercise style

`"European"` (default) | string with value `"European"`, `"American"`, or `"Bermudan"` | string array with value `"European"`, `"American"`, or `"Bermudan"` | character vector with value `'European'`, `'American'`, or `'Bermudan'` | cell array of character vectors with values of `'European'`, `'American'`, or `'Bermudan'`

Put option exercise style, specified as the comma-separated pair consisting of `'PutExerciseStyle'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Note The `PutSchedule` is a timetable of call dates and strikes. If you do not specify a `PutExerciseStyle`, then based on the `PutSchedule` specification, a default value of `PutExerciseStyle` is assigned as follows:

- If there is one exercise date in the `PutSchedule`, then the `PutExerciseStyle` is an `"European"`.
- If there are two exercise dates in the `PutSchedule`, then the `PutExerciseStyle` is an `"American"` with a start date and maturity.
- If there are more than two exercise dates in the `PutSchedule`, then the `PutExerciseStyle` is an `"Bermudan"`.

If the you define a `PutExerciseStyle` and this is not consistent with what you have specified in the `PutSchedule`, you receive an error message.

Data Types: `string` | `cell` | `char`

`Basis` — Day count basis
`0` (actual/actual) (default) | scalar integer from `0` to `13` | vector of integers from `0` to `13`

Day count basis, specified as the comma-separated pair consisting of `'Basis'` and scalar integer or an `NINST`-by-`1` vector of integers using the following values:

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amount or principal value schedule
`100` (default) | scalar numeric | numeric vector | timetable

Notional principal amount or principal value schedule, specified as the comma-separated pair consisting of `'Principal'` and a scalar numeric or an `NINST`-by-`1` numeric vector or a timetable.

`Principal` accepts a `timetable`, where the first column is dates and the second column is the associated notional principal value. The date indicates the last day that the principal value is valid.

Note If you are creating one or more `OptionEmbeddedFixedBond` instruments and use a timetable, the timetable specification applies to all of the `OptionEmbeddedFixedBond` instruments. `Principal` does not accept an `NINST`-by-`1` cell array of timetables as input.

Data Types: `double` | `timetable`

`DaycountAdjustedCashFlow` — Flag indicating whether cash flow adjusts for day count convention
`false` (default) | scalar logical value of `true` or `false` | vector of logicals with values of `true` or `false`

Flag indicating whether cash flow adjusts for day count convention, specified as the comma-separated pair consisting of `'DaycountAdjustedCashFlow'` and a scalar logical or an `NINST`-by-`1` vector of logicals with values of `true` or `false`.

Data Types: `logical`

`BusinessDayConvention` — Business day conventions
`"actual"` (default) | string | string array | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- `"actual"` — Nonbusiness days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- `"follow"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- `"modifiedfollow"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `"previous"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- `"modifiedprevious"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell` | `string`

`Holidays` — Holidays used in computing business days
`NaT` (default) | datetime array | string array | date character vector

Holidays used in computing business days, specified as the comma-separated pair consisting of `'Holidays'` and dates using an `NINST`-by-`1` vector of a datetime array, string array, or date character vectors. For example:

```
H = holidays(datetime('today'),datetime(2025,12,15));
OptionEmbeddedFixedBondObj = fininstrument("OptionEmbeddedFixedBond",'CouponRate',0.34,'Maturity
'CallSchedule',schedule,'CallExerciseStyle',"american",'Holidays',H)
```

To support existing code, `OptionEmbeddedFixedBond` also accepts serial date numbers as inputs, but they are not recommended.

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month with 30 or fewer days

`true` (in effect) (default) | scalar logical value of `true` or `false` | vector of logicals with values of `true` or `false`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month with 30 or fewer days, specified as the comma-separated pair consisting of `'EndMonthRule'` and a scalar logical or an `NINST`-by-`1` vector of logicals with values of `true` or `false`.

- If you set `EndMonthRule` to `false`, the software ignores the rule, meaning that a payment date is always the same numerical day of the month.
- If you set `EndMonthRule` to `true`, the software sets the rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

`IssueDate` — Bond issue date

`NaT` (default) | datetime array | string array | date character vector

Bond issue date, specified as the comma-separated pair consisting of `'IssueDate'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `OptionEmbeddedFixedBond` also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `IssueDate` property is stored as a datetime.

`FirstCouponDate` — Irregular first coupon date

`NaT` (default) | datetime array | string array | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of `'FirstCouponDate'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `OptionEmbeddedFixedBond` also accepts serial date numbers as inputs, but they are not recommended.

When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

If you use date character vectors or date strings, the format must be recognizable by `datetime` because the `FirstCouponDate` property is stored as a datetime.

`LastCouponDate` — Irregular last coupon date
`NaT` (default) | datetime array | string array | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `OptionEmbeddedFixedBond` also accepts serial date numbers as inputs, but they are not recommended.

If you specify `LastCouponDate` but not `FirstCouponDate`, `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify `LastCouponDate`, the cash flow payment dates are determined from other inputs.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `LastCouponDate` property is stored as a datetime.

`StartDate` — Forward starting date of payments
`NaT` (default) | datetime array | string array | date character vector

Forward starting date of payments, specified as the comma-separated pair consisting of `'StartDate'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `OptionEmbeddedFixedBond` also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `StartDate` property is stored as a datetime.

`Name` — User-defined name for instrument
`"  "` (default) | string | string array | character vector | cell array of character vectors

User-defined name for the instrument, specified as the comma-separated pair consisting of `'Name'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

Properties

`CouponRate` — Coupon annual rate
scalar decimal | timetable | vector of decimals

Coupon annual rate, returned as a scalar decimal or an `NINST`-by-`1` vector of decimals or a timetable.

Data Types: `double` | `timetable`

`Maturity` — Maturity date
scalar datetime | vector of datetimes

Maturity date, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`CallSchedule` — Call schedule
timetable

Call schedule, returned as a timetable.

Data Types: `datetime`

`PutSchedule` — Call schedule
timetable

Put schedule, returned as a timetable.

Data Types: `datetime`

`Period` — Coupons per year
`2` (default) | scalar integer | vector of integers

Coupons per year, returned as a scalar integer or an `NINST`-by-`1` vector of integers.

Data Types: `double`

`Basis` — Day count basis
`0` (actual/actual) (default) | scalar integer from `0` to `13` | vector of integers from `0` to `13`

Day count basis, returned as a scalar integer or an `NINST`-by-`1` vector of integers.

Data Types: `double`

`Principal` — Notional principal amount or principal value schedule
`100` (default) | scalar numeric | numeric vector | timetable

Notional principal amount or principal value schedule, returned as a scalar numeric or an `NINST`-by-`1` numeric vector or a timetable.

Data Types: `timetable` | `double`

`DaycountAdjustedCashFlow` — Flag indicating whether cash flow adjusts for day count convention
`false` (default) | scalar logical value of `true` or `false` | vector of logical values of `true` or `false`

Flag indicating whether cash flow adjusted for day count convention, returned as scalar logical or an `NINST`-by-`1` vector of logicals with values of `true` or `false`.

Data Types: `logical`

`BusinessDayConvention` — Business day conventions
`"actual"` (default) | string | string array

Business day conventions, returned as a string or an `NINST`-by-`1` string array.

Data Types: `string`

`Holidays` — Holidays used in computing business days
`NaT` (default) | datetimes

Holidays used in computing business days, returned as an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

EndMonthRule — End-of-month rule flag for generating dates when Maturity is end-of-month date for month with 30 or fewer days
`true` (in effect) (default) | scalar logical value of `true` or `false` | vector of logical values of `true` or `false`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month with 30 or fewer days, returned as a scalar logical or an `NINST`-by-`1` vector of logicals.

Data Types: `logical`

IssueDate — Bond issue date
`NaT` (default) | scalar datetime | vector of datetimes

Bond issue date, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

FirstCouponDate — Irregular first coupon date
`NaT` (default) | datetime | vector of datetimes

Irregular first coupon date, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

LastCouponDate — Irregular last coupon date
`NaT` (default) | scalar datetime | vector of datetimes

Irregular last coupon date, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

StartDate — Forward starting date of payments
`NaT` (default) | scalar datetime | vector of datetimes

Forward starting date of payments, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

CallExerciseStyle — Call option exercise style
`"European"` (default) | string with value `"European"`, `"American"`, or `"Bermuda"` | string array with values of `"European"`, `"American"`, or `"Bermuda"`

This property is read-only.

Call option exercise style, returned as a scalar string or an `NINST`-by-`1` string array with values of `"European"`, `"American"`, or `"Bermuda"`.

Data Types: `string`

PutExerciseStyle — Put option exercise style
`"European"` (default) | string with value `"European"`, `"American"`, or `"Bermuda"` | string array with values of `"European"`, `"American"`, or `"Bermuda"`

This property is read-only.

Put option exercise style, returned as a scalar string or an `NINST`-by-`1` string array with values of `"European"`, `"American"`, or `"Bermuda"`.

Data Types: `string`

Name — User-defined name for instrument
`" "` (default) | string | string array

User-defined name for the instrument, returned as a string or an `NINST`-by-`1` string array.

Data Types: `string`

Object Functions

setCallExercisePolicy	Set call exercise policy for OptionEmbeddedFixedBond, OptionEmbeddedFloatBond, or ConvertibleBond instrument
setPutExercisePolicy	Set put exercise policy for OptionEmbeddedFixedBond, OptionEmbeddedFloatBond, or ConvertibleBond instrument

Examples

Price Option Embedded Fixed Bond Instruments Using Hull-White Model and IRTree Pricer

This example shows the workflow to price American, European, and Bermudan exercise styles for three callable `OptionEmbeddedFixedBond` instruments when you use a `HullWhite` model and an `IRTree` pricing method.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,1,1);
ZeroTimes = calyears(1:10)';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
Compounding = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates, "Compounding",Compounding);
```

Create `OptionEmbeddedFixedBond` Instrument Objects

Use `fininstrument` to create three `OptionEmbeddedFixedBond` instrument objects with the different exercise styles.

```
Maturity = datetime(2024,1,1);

% Option embedded bond (Bermudan callable bond)
Strike = [100; 100];
ExerciseDates = [datetime(2020,1,1); datetime(2024,1,1)];
Period = 1;
CallSchedule =  timetable(ExerciseDates,Strike,'VariableNames',{'Strike Schedule'});

CallableBondBermudan = fininstrument("OptionEmbeddedFixedBond",'Maturity',Maturity,...
                                'CouponRate',0.025,'Period',Period, ...
                                'CallSchedule',CallSchedule,'CallExerciseStyle', "bermudan")
```

```
CallableBondBermudan =
  OptionEmbeddedFixedBond with properties:

                  CouponRate: 0.0250
```

```
                    Period: 1
                     Basis: 0
                EndMonthRule: 1
                   Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                    Holidays: NaT
                   IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 01-Jan-2024
                   CallDates: [2x1 datetime]
                    PutDates: [0x1 datetime]
                CallSchedule: [2x1 timetable]
                 PutSchedule: [0x0 timetable]
           CallExerciseStyle: "bermudan"
            PutExerciseStyle: [0x0 string]
                        Name: ""
```

```
% Option embedded bond (American callable bond)
Strike = 100;
ExerciseDates = datetime(2024,1,1);
CallSchedule =  timetable(ExerciseDates,Strike,'VariableNames',{'Strike Schedule'});
Period = 1;

CallableBondAmerican = fininstrument("OptionEmbeddedFixedBond",'Maturity',Maturity,...
                              'CouponRate',0.025,'Period', Period, ...
                              'CallSchedule',CallSchedule,'CallExerciseStyle',"american")
```

```
CallableBondAmerican =
  OptionEmbeddedFixedBond with properties:

                CouponRate: 0.0250
                    Period: 1
                     Basis: 0
                EndMonthRule: 1
                   Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                    Holidays: NaT
                   IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 01-Jan-2024
                   CallDates: 01-Jan-2024
                    PutDates: [0x1 datetime]
                CallSchedule: [1x1 timetable]
                 PutSchedule: [0x0 timetable]
           CallExerciseStyle: "american"
            PutExerciseStyle: [0x0 string]
                        Name: ""
```

```
% Option embedded bond (European callable bond)
Strike = 100;
ExerciseDates = datetime(2024,1,1);
```

```
CallSchedule =  timetable(ExerciseDates,Strike,'VariableNames',{'Strike Schedule'});
Period = 1;

CallableBondEuropean = fininstrument("OptionEmbeddedFixedBond",'Maturity',Maturity,...
                                'CouponRate',0.025,'Period',Period, ...
                                'CallSchedule',CallSchedule)
```

```
CallableBondEuropean =
  OptionEmbeddedFixedBond with properties:

                 CouponRate: 0.0250
                     Period: 1
                      Basis: 0
                EndMonthRule: 1
                   Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                    Holidays: NaT
                   IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 01-Jan-2024
                   CallDates: 01-Jan-2024
                    PutDates: [0x1 datetime]
                CallSchedule: [1x1 timetable]
                 PutSchedule: [0x0 timetable]
           CallExerciseStyle: "european"
            PutExerciseStyle: [0x0 string]
                        Name: ""
```

Create `HullWhite` Model Object

Use `finmodel` to create a `HullWhite` model object.

```
VolCurve = 0.01;
AlphaCurve = 0.1;

HWModel = finmodel("HullWhite",'alpha',AlphaCurve,'sigma',VolCurve);
```

Create `IRTree` Pricer Object

Use `finpricer` to create an `IRTree` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
HWTreePricer = finpricer("IRTree",'Model',HWModel,'DiscountCurve',ZeroCurve,'TreeDates',ZeroDates
```

```
HWTreePricer =
  HWBKTree with properties:

            Tree: [1x1 struct]
       TreeDates: [10x1 datetime]
           Model: [1x1 finmodel.HullWhite]
   DiscountCurve: [1x1 ratecurve]
```

Price OptionEmbeddedFixedBond Instruments

Use `price` to compute the price and sensitivities for the three `OptionEmbeddedFixedBond` instruments.

```
[Price, outPR] = price(HWTreePricer,CallableBondBermudan,["all"])
```

```
Price = 103.2729

outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×4 table
    Price      Delta     Gamma      Vega
    _____    _______    _____    _______

    103.27    -290.33    1375.9    -148.28
```

```
[Price, outPR] = price(HWTreePricer,CallableBondAmerican,["all"])
```

```
Price = 100

outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×4 table
    Price    Delta    Gamma    Vega
    _____    _____    _____    ____

     100       0        0       0
```

```
[Price, outPR] = price(HWTreePricer,CallableBondEuropean,["all"])
```

```
Price = 107.7023

outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×4 table
    Price     Delta     Gamma     Vega
```

```
    _____    ________    _______    ____

    107.7    -602.56     4086.4      0
```

Price Multiple Option Embedded Fixed Bond Instruments Using Hull-White Model and IRTree Pricer

This example shows the workflow to price multiple callable `OptionEmbeddedFixedBond` instruments with Bermudan exercise styles when you use a `HullWhite` model and an `IRTree` pricing method.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,1,1);
ZeroTimes = calyears(1:10)';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
Compounding = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates, "Compounding",Compounding);
```

Create `OptionEmbeddedFixedBond` Instrument Objects

Use `fininstrument` to create an `OptionEmbeddedFixedBond` instrument object for three Option Embedded Fixed Bond instuments.

```
Maturity = datetime([2025,1,1 ; 2026,1,1 ; 2027,1,1]);

% Option embedded bond (Bermudan callable bond)
Strike = [100 ; 200 ; 300];
ExerciseDates = datetime([2022,1,1 ; 2023,1,1 ; 2024,1,1]);
CallSchedule =  timetable(ExerciseDates,Strike,'VariableNames',{'Strike Schedule'});
Period = 1;

CallableBondBermudan = fininstrument("OptionEmbeddedFixedBond",'Maturity',Maturity,...
                                'CouponRate',0.025,'Period', Period, ...
                                'CallSchedule',CallSchedule,'CallExerciseStyle',"Bermudan")
```

```
CallableBondBermudan=3×1 object
  3x1 OptionEmbeddedFixedBond array with properties:

    CouponRate
    Period
    Basis
    EndMonthRule
    Principal
    DaycountAdjustedCashFlow
    BusinessDayConvention
    Holidays
    IssueDate
    FirstCouponDate
    LastCouponDate
    StartDate
    Maturity
```

```
    CallDates
    PutDates
    CallSchedule
    PutSchedule
    CallExerciseStyle
    PutExerciseStyle
    Name
```

When you create multiple `OptionEmbeddedFixedBond` instruments and use a timetable for `CallSchedule`, the timetable specification applies to all of the `OptionEmbeddedFixedBond` instruments. The `CallSchedule` input argument does not accept an `NINST`-by-`1` cell array of timetables as input.

Create `HullWhite` Model Object

Use `finmodel` to create a `HullWhite` model object.

```
VolCurve = 0.01;
AlphaCurve = 0.1;

HWModel = finmodel("HullWhite",'alpha',AlphaCurve,'sigma',VolCurve);
```

Create `IRTree` Pricer Object

Use `finpricer` to create an `IRTree` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
HWTreePricer = finpricer("IRTree",'Model',HWModel,'DiscountCurve',ZeroCurve,'TreeDates',ZeroDates
```

```
HWTreePricer =
  HWBKTree with properties:

             Tree: [1x1 struct]
        TreeDates: [10x1 datetime]
            Model: [1x1 finmodel.HullWhite]
    DiscountCurve: [1x1 ratecurve]
```

Price `OptionEmbeddedFixedBond` Instruments

Use `price` to compute the prices and sensitivities for the `OptionEmbeddedFixedBond` instruments.

```
[Price, outPR] = price(HWTreePricer,CallableBondBermudan,["all"])
```

```
Price = 3×1

  104.5001
  102.0649
   97.6664

outPR=3×1 object
  3x1 priceresult array with properties:

Price Option Embedded Fixed Bond Option Instrument Using Hull-White Model and IRMonteCarlo Pricer

This example shows the workflow to price an `OptionEmbeddedFixedBondOption` instrument when using a `HullWhite` model and an `IRMonteCarlo` pricing method.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2019,1,1);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)

myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 01-Jan-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create OptionEmbeddedFixedBondOption Instrument Object

Use `fininstrument` to create an `OptionEmbeddedFixedBondOption` instrument object.

```
% Option embedded bond (European callable bond)
Maturity = datetime(2022,9,15);
Strike = 100;
ExerciseDates = datetime(2024,1,1);
CallSchedule = timetable(datetime(2020,3,15), 50);
Period = 1;

CallableBondEuropean = fininstrument("OptionEmbeddedFixedBond",'Maturity',Maturity,...
                                     'CouponRate',0.025,'Period',Period, ...
                                     'CallSchedule',CallSchedule)
```

```
CallableBondEuropean =
  OptionEmbeddedFixedBond with properties:

                  CouponRate: 0.0250
                      Period: 1
                       Basis: 0
                EndMonthRule: 1
                   Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                    Holidays: NaT
                   IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 15-Sep-2022
                   CallDates: 15-Mar-2020
                    PutDates: [0x1 datetime]
                CallSchedule: [1x1 timetable]
                 PutSchedule: [0x0 timetable]
           CallExerciseStyle: "european"
            PutExerciseStyle: [0x0 string]
                        Name: ""
```

Create HullWhite Model Object

Use `finmodel` to create a `HullWhite` model object.

```
HullWhiteModel = finmodel("HullWhite",'Alpha',0.32,'Sigma',0.49)
```

```
HullWhiteModel =
  HullWhite with properties:

    Alpha: 0.3200
    Sigma: 0.4900
```

Create IRMonteCarlo Pricer Object

Use `finpricer` to create an `IRMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("IRMonteCarlo",'Model',HullWhiteModel,'DiscountCurve',myRC,'SimulationDates
```

```
outPricer =
  HWMonteCarlo with properties:

         NumTrials: 1000
      RandomNumbers: []
      DiscountCurve: [1x1 ratecurve]
    SimulationDates: [15-Mar-2019    15-Sep-2019    15-Mar-2020    ...    ]
              Model: [1x1 finmodel.HullWhite]
```

Price `OptionEmbeddedFixedBondOption` Instrument

Use `price` to compute the price and sensitivities for the `OptionEmbeddedFixedBondOption` instrument.

```
[Price,outPR] = price(outPricer,CallableBondEuropean,["all"])
```

```
Price = 58.1882

outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×4 table
    Price      Delta     Gamma     Vega
    _____    _______    _____    _____

    58.188    -125.43    356.04    18.24
```

Price OptionEmbeddedFixedBond Instrument and Obtain Exercise Probabilities Using Black-Karasinski Model and IRTree Pricer

This example shows the workflow to price a callable `OptionEmbeddedFixedBond` instrument and obtain the exercise probabilities when you use a `BlackKarasinski` model and an `IRTree` pricing method.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018, 1, 1);
ZeroTimes = calyears(1:4)';
ZeroRates = [0.035; 0.042147; 0.047345; 0.052707];
ZeroDates = Settle + ZeroTimes;
Compounding = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates, "Compounding",Compounding)
```

```
ZeroCurve =
  ratecurve with properties:

                Type: "zero"
```

```
          Compounding: 1
                Basis: 0
                Dates: [4x1 datetime]
                Rates: [4x1 double]
               Settle: 01-Jan-2018
         InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `OptionEmbeddedFixedBond` Instrument Object

Use `fininstrument` to create an `OptionEmbeddedFixedBond` instrument object with an American exercise style.

```
CouponRate = 0.0425;
Strike = [95; 98];
ExerciseDates = [datetime(2021,1,1); datetime(2022,1,1)];
Maturity = datetime(2022,1,1);
Period = 1;
CallSchedule =  timetable(ExerciseDates,Strike,'VariableNames',{'Strike Schedule'});
CallableBond = fininstrument("OptionEmbeddedFixedBond", 'Maturity',Maturity,...
                             'CouponRate',CouponRate,'Period', Period, ...
                             'CallSchedule',CallSchedule,...
                             'CallExerciseStyle', "American",...
                             'Name',"MyCallableBond")
```

```
CallableBond =
  OptionEmbeddedFixedBond with properties:

                CouponRate: 0.0425
                    Period: 1
                     Basis: 0
               EndMonthRule: 1
                  Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                    Holidays: NaT
                   IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 01-Jan-2022
                   CallDates: [2x1 datetime]
                    PutDates: [0x1 datetime]
                CallSchedule: [2x1 timetable]
                 PutSchedule: [0x0 timetable]
           CallExerciseStyle: "american"
            PutExerciseStyle: [0x0 string]
                        Name: "MyCallableBond"
```

Create `BlackKarasinski` Model Object

Use `finmodel` to create a `BlackKarasinski` model object.

```
VolCurve = 0.01;
AlphaCurve = 0.1;
BKModel = finmodel("BlackKarasinski",'alpha',AlphaCurve,'sigma',VolCurve)
```

```
BKModel =
  BlackKarasinski with properties:

    Alpha: 0.1000
    Sigma: 0.0100
```

Create IRTree Pricer Object

Use `finpricer` to create an `IRTree` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
BKTreePricer = finpricer("IRTree",'Model',BKModel,'DiscountCurve',ZeroCurve,'TreeDates',ZeroDates
```

```
BKTreePricer =
  HWBKTree with properties:

            Tree: [1x1 struct]
       TreeDates: [4x1 datetime]
           Model: [1x1 finmodel.BlackKarasinski]
   DiscountCurve: [1x1 ratecurve]
```

Price OptionEmbeddedFixedBond Instrument

Use `price` to compute the price and sensitivities for the `OptionEmbeddedFixedBond` instrument.

```
[Price,  PriceResults]= price(BKTreePricer, CallableBond)
```

```
Price = 92.5235

PriceResults =
  priceresult with properties:

      Results: [1x1 table]
   PricerData: [1x1 struct]
```

Examine the output `PriceResults.PricerData.PriceTree.ExTree`, which contains the exercise indicator arrays. In the cell array, a `1` indicates an exercised option and a `0` indicates an unexercised option.

```
PriceResults.PricerData.PriceTree.ExTree{5}
```

```
ans = 1x7 logical array

   1   1   1   1   1   1   1
```

No options are exercised.

```
PriceResults.PricerData.PriceTree.ExTree{4}
```

```
ans = 1x7 logical array

   0   0   0   0   0   0   0
```

The instrument is exercised at all nodes.

```
PriceResults.PricerData.PriceTree.ExTree{3}
```

```
ans = 1x5 logical array
```

```
   0   0   0   0   0
```

No options are exercised.

```
PriceResults.PricerData.PriceTree.ExTree{2}
```

```
ans = 1x3 logical array
```

```
   0   0   0
```

No options are exercised.

View the probability of reaching each node from the root node using `PriceResults.PricerData.PriceTree.ProbTree`.

```
PriceResults.PricerData.PriceTree.ProbTree{2}
```

```
ans = 1×3
```

```
    0.1667    0.6667    0.1667
```

```
PriceResults.PricerData.PriceTree.ProbTree{3}
```

```
ans = 1×5
```

```
    0.0203    0.2206    0.5183    0.2206    0.0203
```

```
PriceResults.PricerData.PriceTree.ProbTree{4}
```

```
ans = 1×7
```

```
    0.0018    0.0395    0.2370    0.4433    0.2370    0.0395    0.0018
```

```
PriceResults.PricerData.PriceTree.ProbTree{5}
```

```
ans = 1×7
```

```
    0.0018    0.0395    0.2370    0.4433    0.2370    0.0395    0.0018
```

View the exercise probabilities using `PriceResults.PricerData.PriceTree.ExProbTree`. `PriceResults.PricerData.PriceTree.ExProbTree` contains the exercise probabilities. Each element in the cell array is an array containing `0`'s where there is no exercise, or the probability of reaching that node where exercise happens.

```
PriceResults.PricerData.PriceTree.ExProbTree{5}
```

```
ans = 1×7
```

```
    0.0018    0.0395    0.2370    0.4433    0.2370    0.0395    0.0018
```

```
PriceResults.PricerData.PriceTree.ExProbTree{4}
```

```
ans = 1×7

     0     0     0     0     0     0     0
```

```
PriceResults.PricerData.PriceTree.ExProbTree{3}
```

```
ans = 1×5

     0     0     0     0     0
```

```
PriceResults.PricerData.PriceTree.ExProbTree{2}
```

```
ans = 1×3

     0     0     0
```

View the exercise probabilities at each tree level using `PriceResults.PricerData.PriceTree.ExProbsByTreeLevel`. `PriceResults.PricerData.PriceTree.ExProbsByTreeLevel` is an array in which each row holds the exercise probability for a given option at each tree observation time.

```
PriceResults.PricerData.PriceTree.ExProbsByTreeLevel
```

```
ans = 1×5

         0         0         0         0    1.0000
```

More About

Vanilla Bond with Embedded Option

A vanilla coupon bond is a security representing an obligation to repay a borrowed amount at a designated time and to make periodic interest payments until that time.

The issuer of a bond makes the periodic interest payments until the bond matures. At maturity, the issuer pays to the holder of the bond the principal amount owed (face value) and the last interest payment. A vanilla bond with an embedded option is where an option contract has an underlying asset of a vanilla bond.

Stepped Coupon Bond with Callable and Puttable Features

A step-up bond and step-down bond is a debt security with a predetermined coupon structure over time.

With these instruments, coupons increase (step up) or decrease (step down) at specific times during the life of the bond. Stepped coupon bonds can have options features (call and puts).

Amortizing Callable and Puttable Bond

An amortizing callable bond or amortizing puttable bond work under a scheduled `Principal`.

An amortizing callable bond gives the issuer the right to call back the bond, but instead of paying the `Principal` amount at maturity, it repays part of the principal along with the coupon payments. An amortizing puttable bond, repays part of the principal along with the coupon payments and gives the bondholder the right to sell the bond back to the issuer.

Tips

After creating an `OptionEmbeddedFixedBond` object, you can modify the `CallSchedule` and `CallExerciseStyle` using `setCallExercisePolicy`. Or, you can modify the `PutSchedule` and `PutExerciseStyle` values using `setPutExercisePolicy`.

Version History

Introduced in R2020a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `OptionEmbeddedFixedBond` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

OptionEmbeddedFloatBond

`OptionEmbeddedFloatBond` instrument object

Description

Create and price a `OptionEmbeddedFloatBond` instrument object for one or more Option Embedded Float Bond instruments using this workflow:

1. Use `fininstrument` to create an `OptionEmbeddedFloatBond` instrument object for one or more Option Embedded Float Bond instruments.
2. Use `finmodel` to specify a `HullWhite`, `BlackKarasinski`, `BlackDermanToy`, `BraceGatarekMusiela`, `SABRBraceGatarekMusiela`, or `LinearGaussian2F` model for the `OptionEmbeddedFloatBond` instrument object.
3. Choose a pricing method.
   - When using a `HullWhite`, `BlackKarasinski`, or `BlackDermanToy` model, use `finpricer` to specify an `IRTree` pricing method for one or more `OptionEmbeddedFloatBond` instruments.
   - When using a `HullWhite`, `BlackKarasinski`, `BraceGatarekMusiela`, `SABRBraceGatarekMusiela`, or `LinearGaussian2F` model, use `finpricer` to specify an `IRMonteCarlo` pricing method for one or more `OptionEmbeddedFloatBond` instruments.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for an `OptionEmbeddedFloatBond` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
OptionEmbeddedFloatBondObj = fininstrument(InstrumentType,'
Spread',spread_value,'Maturity',maturity_date,'
CallSchedule',call_schedule_value)
OptionEmbeddedFloatBondObj = fininstrument(InstrumentType,'
Spread',spread_value,'Maturity',maturity_date,'
PutSchedule',put_schedule_value)
OptionEmbeddedFloatBondObj = fininstrument( ___ ,Name,Value)
```

Description

`OptionEmbeddedFloatBondObj = fininstrument(InstrumentType,'Spread',spread_value,'Maturity',maturity_date,'CallSchedule',call_schedule_value)` creates a `OptionEmbeddedFloatBond` object for one

or more Option Embedded Float Bond instruments by specifying `InstrumentType` and the required name-value pair arguments `Spread`, `Maturity`, and `CallSchedule` sets the properties on page 11-2890 using required name-value pair arguments.

`OptionEmbeddedFloatBond` supports vanilla bonds with embedded options, stepped coupon bonds with embedded options and amortizing bonds with embedded options.

`OptionEmbeddedFloatBondObj = fininstrument(InstrumentType,'Spread',spread_value,'Maturity',maturity_date,'PutSchedule',put_schedule_value)` creates a `OptionEmbeddedFloatBond` object for one or more Option Embedded Float Bond instruments by specifying `InstrumentType` and the required name-value pair arguments `Spread`, `Maturity`, and `PutSchedule` sets the properties on page 11-2890 using required name-value pair arguments.

`OptionEmbeddedFloatBondObj = fininstrument( ___ ,Name,Value)` sets optional properties on page 11-2890 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `OptionEmbeddedFloatBondObj = fininstrument("OptionEmbeddedFloatBond",'Spread',0.01,'Maturity',datetime(2019,1,30),'Period',4,'Basis',5,'Principal',1000,'FirstCouponDate',datetime(2016,1,30),'EndMonthRule',1,'CallSchedule',schedule,'CallExerciseStyle',"american",'ProjectionCurve',ratecurve_obj,'Name',"optionembeddedfloatbond")`. You can specify multiple name-value pairs.

Input Arguments

`InstrumentType` — Instrument type

string with value `"OptionEmbeddedFloatBond"` | string array with values of `"OptionEmbeddedFloatBond"` | character vector with value `'OptionEmbeddedFloatBond'` | cell array of character vectors with values of `'OptionEmbeddedFloatBond'`

Instrument type, specified as a string with the value of `"OptionEmbeddedFloatBond"`, a character vector with the value of `'OptionEmbeddedFloatBond'`, an `NINST`-by-`1` string array with values of `"OptionEmbeddedFloatBond"`, or an `NINST`-by-`1` cell array of character vectors with values of `'OptionEmbeddedFloatBond'`.

Data Types: `char` | `cell` | `string`

`OptionEmbeddedFloatBond` Name-Value Pair Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `OptionEmbeddedFloatBondObj = fininstrument("OptionEmbeddedFloatBond",'Spread',0.01,'Maturity',datetime(2019,1,30),'Period',4,'Basis',5,'Principal',1000,'FirstCouponDate',datetime(2016,1,30),'EndMonthRule',1,'CallSchedule',schedule,'CallExerciseStyle',"american",'ProjectionCurve',ratecurve_obj,'Name',"optionembeddedfloatbond")`

Required `OptionEmbeddedFloatBond` Name-Value Pair Arguments

`Spread` — Number of basis points over the reference rate

nonnegative numeric | vector of nonnegative numeric

Number of basis points over the reference rate, specified as the comma-separated pair consisting of `'Spread'` and a scalar nonnegative numeric or an `NINST`-by-`1` vector of nonnegative numeric.

Data Types: `double`

`Maturity` — Maturity date
datetime array | string array | date character vector

Maturity date, specified as the comma-separated pair consisting of `'Maturity'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `OptionEmbeddedFloatBond` also accepts serial date numbers as inputs, but they are not recommended.

`CallSchedule` — Call schedule
timetable

Call schedule, specified as the comma-separated pair consisting of `'CallSchedule'` and a timetable of call dates and strikes.

If you use a date character vector or date string for the dates in this timetable, the format must be recognizable by `datetime` because the `CallSchedule` property is stored as a datetime.

Note The `OptionEmbeddedFloatBond` instrument supports either `CallSchedule` and `CallExerciseStyle` or `PutSchedule` and `PutExerciseStyle`, but not both.

If you are creating one or more `OptionEmbeddedFloatBond` instruments and use a timetable, the timetable specification applies to all of the `OptionEmbeddedFloatBond` instruments. `CallSchedule` does not accept an `NINST`-by-`1` cell array of timetables as input.

Data Types: `timetable`

`PutSchedule` — Call schedule
timetable

Put schedule, specified as the comma-separated pair consisting of `'PutSchedule'` and a timetable of call dates and strikes.

If you use a date character vector or date string for dates in this timetable, the format must be recognizable by `datetime` because the `PutSchedule` property is stored as a datetime.

Note The `OptionEmbeddedFloatBond` instrument supports either `CallSchedule` and `CallExerciseStyle` or `PutSchedule` and `PutExerciseStyle`, but not both.

If you are creating one or more `OptionEmbeddedFloatBond` instruments and use a timetable, the timetable specification applies to all of the `OptionEmbeddedFloatBond` instruments. `PutSchedule` does not accept an `NINST`-by-`1` cell array of timetables as input.

Data Types: `timetable`

Optional OptionEmbeddedFloatBond Name-Value Pair Arguments

Reset — Frequency of payments per year
2 (default) | scalar integer | vector of integers

Frequency of payments per year, specified as the comma-separated pair consisting of `'Reset'` and a scalar integer or an `NINST`-by-1 vector of integers. Values for `Reset` are: 1, 2, 3, 4, 6, and 12.

Data Types: `double`

CallExerciseStyle — Call option exercise style
`"European"` (default) | string with value `"European"`, `"American"`, or `"Bermudan"` | string array with values of `"European"`, `"American"`, or `"Bermudan"` | character vector with value `'European'`, `'American'`, or `'Bermudan'` | cell array of character vectors with values of `'European'`, `'American'`, or `'Bermudan'`

Call option exercise style, specified as the comma-separated pair consisting of `'CallExerciseStyle'` and a scalar string or character vector or an `NINST`-by-1 cell array of character vectors or string array.

Note The `CallSchedule` is a timetable of call dates and strikes. If you do not specify a `CallExerciseStyle`, then based on the `CallSchedule` specification, a default value of `CallExerciseStyle` is assigned as follows:

- If there is one exercise date in the `CallSchedule`, then the `CallExerciseStyle` is an `"European"`.
- If there are two exercise dates in the `CallSchedule`, then the `CallExerciseStyle` is an `"American"` with a start date and maturity.
- If there are more than two exercise dates in the `CallSchedule`, then the `CallExerciseStyle` is an `"Bermudan"`.

If the you define a `CallExerciseStyle` and this is not consistent with what you have specified in the `CallSchedule`, you receive an error message.

Data Types: `string` | `cell` | `char`

PutExerciseStyle — Put option exercise style
`"European"` (default) | string with value `"European"`, `"American"`, or `"Bermudan"` | string array with values of `"European"`, `"American"`, or `"Bermudan"` | character vector with value `'European'`, `'American'`, or `'Bermudan'` | cell array of character vectors with values of `'European'`, `'American'`, or `'Bermudan'`

Put option exercise style, specified as the comma-separated pair consisting of `'PutExerciseStyle'` and a scalar string or character vector or an `NINST`-by-1 cell array of character vectors or string array.

Note The `PutSchedule` is a timetable of call dates and strikes. If you do not specify a `PutExerciseStyle`, then based on the `PutSchedule` specification, a default value of `PutExerciseStyle` is assigned as follows:

- If there is one exercise date in the `PutSchedule`, then the `PutExerciseStyle` is an `"European"`.

- If there are two exercise dates in the `PutSchedule`, then the `PutExerciseStyle` is an `"American"` with a start date and maturity.
- If there are more than two exercise dates in the `PutSchedule`, then the `PutExerciseStyle` is an `"Bermudan"`.

If the you define a `PutExerciseStyle` and this is not consistent with what you have specified in the `PutSchedule`, you receive an error message.

Data Types: `string` | `cell` | `char`

`Basis` — Day count basis
`0` (actual/actual) (default) | scalar integer from `0` to `13` | vector of integers from `0` to `13`

Day count basis, specified as the comma-separated pair consisting of `'Basis'` and scalar integer or an `NINST`-by-`1` vector of integers using the following values:

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amount or principal value schedule
`100` (default) | scalar numeric | numeric vector | timetable

Notional principal amount or principal value schedule, specified as the comma-separated pair consisting of `'Principal'` and a scalar numeric or an `NINST`-by-`1` numeric vector or a timetable.

`Principal` accepts a `timetable`, where the first column is dates and the second column is the associated notional principal value. The date indicates the last day that the principal value is valid.

Note If you are creating one or more `OptionEmbeddedFloatBond` instruments and use a timetable, the timetable specification applies to all of the `OptionEmbeddedFloatBond` instruments. `Principal` does not accept an `NINST`-by-`1` cell array of timetables as input.

Data Types: `double` | `timetable`

`DaycountAdjustedCashFlow` — Flag indicating whether cash flow adjusts for day count convention
`false` (default) | scalar logical value of `true` or `false` | vector of logicals with values of `true` or `false`

Flag indicating whether cash flow adjusts for day count convention, specified as the comma-separated pair consisting of `'DaycountAdjustedCashFlow'` and a scalar logical or an `NINST`-by-`1` vector of logicals with values of `true` or `false`.

Data Types: `logical`

`BusinessDayConvention` — Business day conventions
`"actual"` (default) | string | string array | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- `"actual"` — Nonbusiness days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- `"follow"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- `"modifiedfollow"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `"previous"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- `"modifiedprevious"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell` | `string`

`Holidays` — Holidays used in computing business days
`NaT` (default) | datetime array | string array | date character vector

Holidays used in computing business days, specified as the comma-separated pair consisting of `'Holidays'` and dates using an `NINST`-by-`1` vector of a datetime array, string array, or date character vectors. For example:

```
H = holidays(datetime('today'),datetime(2025,12,15));
OptionEmbeddedFixedBondObj = fininstrument("OptionEmbeddedFixedBond",'CouponRate',0.34,'Maturity
'CallSchedule',schedule,'CallExerciseStyle',"american",'Holidays',H)
```

To support existing code, `OptionEmbeddedFloatBond` also accepts serial date numbers as inputs, but they are not recommended.

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month with 30 or fewer days
`true` (in effect) (default) | scalar logical value of `true` or `false` | vector of logicals with values of `true` or `false`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month with 30 or fewer days, specified as the comma-separated pair consisting of `'EndMonthRule'` and a scalar logical or an `NINST`-by-`1` vector of logicals values of `true` or `false`.

- If you set `EndMonthRule` to `false`, the software ignores the rule, meaning that a payment date is always the same numerical day of the month.
- If you set `EndMonthRule` to `true`, the software sets the rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

`IssueDate` — Bond issue date
`NaT` (default) | datetime array | string array | date character vector

Bond issue date, specified as the comma-separated pair consisting of `'IssueDate'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `OptionEmbeddedFloatBond` also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `IssueDate` property is stored as a datetime.

`FirstCouponDate` — Irregular first coupon date
`NaT` (default) | datetime array | string array | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of `'FirstCouponDate'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `OptionEmbeddedFloatBond` also accepts serial date numbers as inputs, but they are not recommended.

When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `FirstCouponDate` property is stored as a datetime.

`LastCouponDate` — Irregular last coupon date
`NaT` (default) | datetime array | string array | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `OptionEmbeddedFloatBond` also accepts serial date numbers as inputs, but they are not recommended.

If you specify `LastCouponDate` but not `FirstCouponDate`, `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at `LastCouponDate`,

regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify `LastCouponDate`, the cash flow payment dates are determined from other inputs.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `LastCouponDate` property is stored as a datetime.

`StartDate` — Forward starting date of payments
`NaT` (default) | datetime array | string array | date character vector

Forward starting date of payments, specified as the comma-separated pair consisting of `'StartDate'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `OptionEmbeddedFloatBond` also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `StartDate` property is stored as a datetime.

`Name` — User-defined name for instrument
`" "` (default) | string | string array | character vector | cell array of character vectors

User-defined name for the instrument, specified as the comma-separated pair consisting of `'Name'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

Properties

`Spread` — Number of basis points over the reference rate
scalar nonnegative numeric | vector of nonnegative numeric

Number of basis points over the reference rate, returned as a scalar nonnegative numeric or an `NINST`-by-`1` vector of nonnegative numeric values.

Data Types: `double`

`Maturity` — Maturity date
scalar datetime | vector of datetimes

Maturity date, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`CallSchedule` — Call schedule
timetable

Call schedule, returned as a timetable.

Data Types: `cell` | `datetime`

`PutSchedule` — Call schedule
timetable

Put schedule, returned as a timetable.

Data Types: `cell` | `datetime`

`Reset` — Frequency of payments per year
`2` (default) | scalar integer | vector of integers

Frequency of payments per year, returned as a scalar integer or an `NINST`-by-`1` vector of integers.

Data Types: `double`

`Basis` — Day count basis
`0` (actual/actual) (default) | scalar integer from `0` to `13` | vector of integers from `0` to `13`

Day count basis, returned as a scalar integer or an `NINST`-by-`1` vector of integers.

Data Types: `double`

`Principal` — Notional principal amount or principal value schedule
`100` (default) | scalar numeric | numeric vector | timetable

Notional principal amount or principal value schedule, returned as a scalar numeric or an `NINST`-by-`1` numeric vector or a timetable.

Data Types: `timetable` | `double`

`DaycountAdjustedCashFlow` — Flag indicating whether cash flow adjusts for day count convention
`false` (default) | scalar logical value of `true` or `false` | vector of logicals with values of `true` or `false`

Flag indicating whether cash flow adjusted for day count convention, returned as scalar logical or an `NINST`-by-`1` vector of logicals with values of `true` or `false`.

Data Types: `logical`

`BusinessDayConvention` — Business day conventions
`"actual"` (default) | string | string array

Business day conventions, returned as a string or an `NINST`-by-`1` string array.

Data Types: `string`

`Holidays` — Holidays used in computing business days
`NaT` (default) | datetimes

Holidays used in computing business days, returned as an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month with 30 or fewer days
`true` (in effect) (default) | scalar logical value of `true` or `false` | vector of logicals with values of `true` or `false`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month with 30 or fewer days, returned as a scalar logical or an `NINST`-by-`1` vector of logicals.

Data Types: `logical`

`IssueDate` — Bond issue date
`NaT` (default) | scalar datetime | vector of datetimes

Bond issue date, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`FirstCouponDate` — Irregular first coupon date
`NaT` (default) | scalar datetime | vector of datetimes

Irregular first coupon date, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`LastCouponDate` — Irregular last coupon date
`NaT` (default) | scalar datetime | vector of datetimes

Irregular last coupon date, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`StartDate` — Forward starting date of payments
`NaT` (default) | scalar datetime

Forward starting date of payments, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`CallExerciseStyle` — Call option exercise style
`"European"` (default) | string with value `"European"`, `"American"`, or `"Bermudan"` | string array with values of `"European"`, `"American"`, or `"Bermudan"`

This property is read-only.

Call option exercise style, returned as a string or an `NINST`-by-`1` string array with values of `"European"`, `"American"`, or `"Bermudan"`.

Data Types: `string`

`PutExerciseStyle` — Put option exercise style
`"European"` (default) | string with value `"European"`, `"American"`, or `"Bermudan"` | string array with values of `"European"`, `"American"`, or `"Bermudan"`

This property is read-only.

Put option exercise style, returned as a string or an `NINST`-by-`1` string array with values of `"European"`, `"American"`, or `"Bermudan"`.

Data Types: `string`

`Name` — User-defined name for instrument
`"  "` (default) | string | string array

User-defined name for the instrument, returned as a string or an `NINST`-by-`1` string array.

Data Types: `string`

Object Functions

setCallExercisePolicy	Set call exercise policy for OptionEmbeddedFixedBond, OptionEmbeddedFloatBond, or ConvertibleBond instrument
setPutExercisePolicy	Set put exercise policy for OptionEmbeddedFixedBond, OptionEmbeddedFloatBond, or ConvertibleBond instrument

Examples

Price Option Embedded Float Bond Instruments Using Hull-White Model and IRTree Pricer

This example shows the workflow to price American, European, and Bermudan exercise styles for three callable `OptionEmbeddedFloatBond` instruments when you use a `HullWhite` model and an `IRTree` pricing method.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,1,1);
ZeroTimes = calyears(1:10)';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
Compounding = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates, "Compounding",Compounding);
```

Create `OptionEmbeddedFloatBond` Instrument Objects

Use `fininstrument` to create three `OptionEmbeddedFloatBond` instrument objects with different exercise styles.

```
Maturity = datetime(2024,1,1);

% Option embedded float bond (Bermudan callable bond)
Strike = [100; 100];
ExerciseDates = [datetime(2020,1,1); datetime(2024,1,1)];
Reset = 1;
CallSchedule =  timetable(ExerciseDates,Strike,'VariableNames',{'Strike Schedule'});

CallableBondBermudan = fininstrument("OptionEmbeddedFloatBond",'Maturity',Maturity,...
                              'Spread',0.025,'Reset',Reset, ...
                              'CallSchedule',CallSchedule,'CallExerciseStyle', "bermudan")
```

```
CallableBondBermudan =
  OptionEmbeddedFloatBond with properties:

                    Spread: 0.0250
            ProjectionCurve: [0x0 ratecurve]
                ResetOffset: 0
                      Reset: 1
                      Basis: 0
               EndMonthRule: 1
                  Principal: 100
   DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
                   Holidays: NaT
```

```
                IssueDate: NaT
            FirstCouponDate: NaT
             LastCouponDate: NaT
                StartDate: NaT
                 Maturity: 01-Jan-2024
                CallDates: [2x1 datetime]
                 PutDates: [0x1 datetime]
              CallSchedule: [2x1 timetable]
               PutSchedule: [0x0 timetable]
          CallExerciseStyle: "bermudan"
           PutExerciseStyle: [0x0 string]
                       Name: ""
```

```
% Option embedded float bond (American callable bond)
Strike = 100;
ExerciseDates = datetime(2024,1,1);
CallSchedule =  timetable(ExerciseDates,Strike,'VariableNames',{'Strike Schedule'});
Reset = 1;

CallableBondAmerican = fininstrument("OptionEmbeddedFloatBond",'Maturity',Maturity,...
                              'Spread',0.025,'Reset', Reset, ...
                              'CallSchedule',CallSchedule,'CallExerciseStyle',"american")
```

```
CallableBondAmerican =
  OptionEmbeddedFloatBond with properties:

                    Spread: 0.0250
            ProjectionCurve: [0x0 ratecurve]
                ResetOffset: 0
                      Reset: 1
                      Basis: 0
                EndMonthRule: 1
                  Principal: 100
   DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
                   Holidays: NaT
                IssueDate: NaT
            FirstCouponDate: NaT
             LastCouponDate: NaT
                StartDate: NaT
                 Maturity: 01-Jan-2024
                CallDates: 01-Jan-2024
                 PutDates: [0x1 datetime]
              CallSchedule: [1x1 timetable]
               PutSchedule: [0x0 timetable]
          CallExerciseStyle: "american"
           PutExerciseStyle: [0x0 string]
                       Name: ""
```

```
% Option embedded float bond (European callable bond)
Strike = 100;
ExerciseDates = datetime(2024,1,1);
CallSchedule =  timetable(ExerciseDates,Strike,'VariableNames',{'Strike Schedule'});
Reset = 1;

CallableBondEuropean = fininstrument("OptionEmbeddedFloatBond",'Maturity',Maturity,...
```

```
                            'Spread',0.025,'Reset',Reset, ...
                            'CallSchedule',CallSchedule)

CallableBondEuropean =
  OptionEmbeddedFloatBond with properties:

                     Spread: 0.0250
            ProjectionCurve: [0x0 ratecurve]
                ResetOffset: 0
                      Reset: 1
                      Basis: 0
               EndMonthRule: 1
                  Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                   Holidays: NaT
                  IssueDate: NaT
            FirstCouponDate: NaT
             LastCouponDate: NaT
                  StartDate: NaT
                   Maturity: 01-Jan-2024
                  CallDates: 01-Jan-2024
                   PutDates: [0x1 datetime]
               CallSchedule: [1x1 timetable]
                PutSchedule: [0x0 timetable]
          CallExerciseStyle: "european"
           PutExerciseStyle: [0x0 string]
                       Name: ""
```

Create HullWhite Model Object

Use `finmodel` to create a `HullWhite` model object.

```
VolCurve = 0.01;
AlphaCurve = 0.1;

HWModel = finmodel("HullWhite",'alpha',AlphaCurve,'sigma',VolCurve);
```

Create IRTree Pricer Object

Use `finpricer` to create an `IRTree` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
HWTreePricer = finpricer("IRTree",'Model',HWModel,'DiscountCurve',ZeroCurve,'TreeDates',ZeroDates
```

```
HWTreePricer =
  HWBKTree with properties:

            Tree: [1x1 struct]
       TreeDates: [10x1 datetime]
           Model: [1x1 finmodel.HullWhite]
   DiscountCurve: [1x1 ratecurve]
```

Price OptionEmbeddedFixedBond Instruments

Use `price` to compute the price and sensitivities for the three `OptionEmbeddedFixedBond` instruments.

```
[Price, outPR] = price(HWTreePricer,CallableBondBermudan,["all"])

Price = 104.9598

outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: [1x1 struct]

outPR.Results

ans=1×4 table
    Price      Delta     Gamma     Vega
    _____    _______    _____    ____

    104.96    -7.3926    19.597     0

[Price, outPR] = price(HWTreePricer,CallableBondAmerican,["all"])

Price = 100

outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: [1x1 struct]

outPR.Results

ans=1×4 table
    Price    Delta    Gamma    Vega
    _____    _____    _____    ____

     100       0        0       0

[Price, outPR] = price(HWTreePricer,CallableBondEuropean,["all"])

Price = 114.5571

outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: [1x1 struct]

outPR.Results

ans=1×4 table
    Price      Delta     Gamma        Vega
    _____    _______    _____    __________

    114.56    -50.006    262.58    -2.8422e-10
```

Price Option Embedded Float Bond Option Instrument Using Hull-White Model and IRMonteCarlo Pricer

This example shows the workflow to price an `OptionEmbeddedFloatBondOption` instrument when using a `HullWhite` model and an `IRMonteCarlo` pricing method.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2019,1,1);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 01-Jan-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `OptionEmbeddedFloatBondOption` Instrument Object

Use `fininstrument` to create an `OptionEmbeddedFloatBondOption` instrument object.

```
% Option embedded float bond (European callable bond)
Maturity = datetime(2022,9,15);
Strike = 100;
ExerciseDates = datetime(2024,1,1);
CallSchedule = timetable(datetime(2020,3,15), 50);
Reset = 1;

CallableBondEuropean = fininstrument("OptionEmbeddedFloatBond",'Maturity',Maturity,...
                               'Spread',0.025,'Reset',Reset, ...
                               'CallSchedule',CallSchedule)
```

```
CallableBondEuropean =
  OptionEmbeddedFloatBond with properties:

                    Spread: 0.0250
            ProjectionCurve: [0x0 ratecurve]
                ResetOffset: 0
                      Reset: 1
                      Basis: 0
               EndMonthRule: 1
                  Principal: 100
    DaycountAdjustedCashFlow: 0
```

```
       BusinessDayConvention: "actual"
                    Holidays: NaT
                   IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 15-Sep-2022
                   CallDates: 15-Mar-2020
                    PutDates: [0x1 datetime]
                CallSchedule: [1x1 timetable]
                 PutSchedule: [0x0 timetable]
           CallExerciseStyle: "european"
            PutExerciseStyle: [0x0 string]
                        Name: ""
```

Create HullWhite Model Object

Use `finmodel` to create a `HullWhite` model object.

```
HullWhiteModel = finmodel("HullWhite",'Alpha',0.32,'Sigma',0.49)
```

```
HullWhiteModel =
  HullWhite with properties:

    Alpha: 0.3200
    Sigma: 0.4900
```

Create IRMonteCarlo Pricer Object

Use `finpricer` to create an `IRMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("IRMonteCarlo",'Model',HullWhiteModel,'DiscountCurve',myRC,'SimulationDates
```

```
outPricer =
  HWMonteCarlo with properties:

         NumTrials: 1000
      RandomNumbers: []
      DiscountCurve: [1x1 ratecurve]
    SimulationDates: [15-Mar-2019    15-Sep-2019    15-Mar-2020    ...    ]
              Model: [1x1 finmodel.HullWhite]
```

Price OptionEmbeddedFloatBondOption Instrument

Use `price` to compute the price and sensitivities for the `OptionEmbeddedFloatBondOption` instrument.

```
[Price,outPR] = price(outPricer,CallableBondEuropean,["all"])
```

```
Price = 51.3788
```

```
outPR =
  priceresult with properties:

       Results: [1x4 table]
```

```
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×4 table
    Price     Delta      Gamma      Vega
    ______    ______    _______    _______

    51.379    61.634    -81.051    -7.0508
```

Price Multiple Option Embedded Float Bond Instruments Using Hull-White Model and IRTree Pricer

This example shows the workflow to price multiple `OptionEmbeddedFloatBond` instruments with Bermudan exercise styles when you use a `HullWhite` model and an `IRTree` pricing method.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,1,1);
ZeroTimes = calyears(1:10)';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
Compounding = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates, "Compounding",Compounding);
```

Create `OptionEmbeddedFloatBond` Instrument Objects

Use `fininstrument` to create an `OptionEmbeddedFloatBond` instrument object for three Option Embedded Float Bond instruments with a `Bermudan` exercise style.

```
Maturity = datetime([2025,1,1 ; 2026,1,1 ; 2027,1,1]);

% Option embedded float bond (Bermudan callable bond)
Strike = [101 ; 102 ; 103];
ExerciseDates = datetime([2022,1,1 ; 2023,1,1 ; 2024,1,1]);
CallSchedule =  timetable(ExerciseDates,Strike,'VariableNames',{'Strike Schedule'});
Reset = 1;

CallableBondBermudan = fininstrument("OptionEmbeddedFloatBond",'Maturity',Maturity,...
                              'Spread',[0.001; 0.0015; 0.002],'Reset', Reset, ...
                              'CallSchedule',CallSchedule,'CallExerciseStyle',"bermudan")
```

```
CallableBondBermudan=3×1 object
  3x1 OptionEmbeddedFloatBond array with properties:

    Spread
    ProjectionCurve
    ResetOffset
    Reset
    Basis
    EndMonthRule
    Principal
    DaycountAdjustedCashFlow
```

```
    BusinessDayConvention
    Holidays
    IssueDate
    FirstCouponDate
    LastCouponDate
    StartDate
    Maturity
    CallDates
    PutDates
    CallSchedule
    PutSchedule
    CallExerciseStyle
    PutExerciseStyle
    Name
```

When you create multiple `OptionEmbeddedFloatBond` instruments and use a timetable for `CallSchedule`, the timetable specification applies to all of the `OptionEmbeddedFloatBond` instruments. The `CallSchedule` input argument does not accept an `NINST`-by-`1` cell array of timetables as input.

Create `HullWhite` Model Object

Use `finmodel` to create a `HullWhite` model object.

```
VolCurve = 0.01;
AlphaCurve = 0.1;

HWModel = finmodel("HullWhite",'alpha',AlphaCurve,'sigma',VolCurve);
```

Create `IRTree` Pricer Object

Use `finpricer` to create an `IRTree` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
HWTreePricer = finpricer("IRTree",'Model',HWModel,'DiscountCurve',ZeroCurve,'TreeDates',ZeroDates
```

```
HWTreePricer =
  HWBKTree with properties:

             Tree: [1x1 struct]
        TreeDates: [10x1 datetime]
            Model: [1x1 finmodel.HullWhite]
    DiscountCurve: [1x1 ratecurve]
```

Price `OptionEmbeddedFixedBond` Instruments

Use `price` to compute the prices and sensitivities for the three `OptionEmbeddedFixedBond` instruments.

```
[Price, outPR] = price(HWTreePricer,CallableBondBermudan,"all")
```

```
Price = 3×1

  100.6713
```

```
  101.1327
  101.6643

outPR=3×1 object
  3x1 priceresult array with properties:

    Results
    PricerData

outPR.Results

ans=1×4 table
    Price      Delta     Gamma       Vega
    _____    ________    _____    ___________

    100.67    -2.6133    15.33    -4.2633e-10

ans=1×4 table
    Price      Delta     Gamma        Vega
    _____    ________    ______    ___________

    101.13    -4.9053    31.676    -5.6843e-10

ans=1×4 table
    Price      Delta     Gamma       Vega

    101.66    -7.8748    55.171    -0.066246
```

More About

Floating-Rate Note with Embedded Options

A floating-rate note with an embedded option enables floating-rate notes to have early redemption features.

A floating-rate note with an embedded option gives investors or issuers the option to retire the outstanding principal prior to maturity. An embedded call option gives the right to retire the note prior to the maturity date (callable floater), and an embedded put option gives the right to sell the note back at a specific price (puttable floater).

For more information, see “Floating-Rate Note with Embedded Options” on page 2-11.

Tips

After creating an `OptionEmbeddedFixedBond` object, you can modify the `CallSchedule` and `CallExerciseStyle` using `setCallExercisePolicy`. Or, you can modify the `PutSchedule` and `PutExerciseStyle` values using `setPutExercisePolicy`.

Version History

Introduced in R2020a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `OptionEmbeddedFloatBond` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

Topics

“Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22

Spread

`Spread` instrument object

Description

Create and price a `Spread` instrument object for one or more Spread instruments using this workflow:

1. Use `fininstrument` to create a `Spread` instrument object for one or more Spread instruments.
2. Use `finmodel` to specify a `BlackScholes` or `Bachelier` model for the `Spread` instrument object.
3. Choose a pricing method.
   - When using a `BlackScholes` model, use `finpricer` to specify a `Kirk`, `BjerksundStensland`, or `AssetMonteCarlo` pricing method for one or more `Spread` instruments.
   - When using a `Bachelier` model, use `finpricer` to specify an `AssetMonteCarlo` pricing method for one or more `Spread` instruments.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a `Spread` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
SpreadObj = fininstrument(InstrumentType,'Strike',strike_value,'
ExerciseDate',exercise_date)
SpreadObj = fininstrument( ___ ,Name,Value)
```

Description

`SpreadObj = fininstrument(InstrumentType,'Strike',strike_value,'ExerciseDate',exercise_date)` creates a `Spread` object for one or more Spread instruments by specifying `InstrumentType` and sets the properties on page 11-2905 for the required name-value pair arguments `Strike` and `ExerciseDate`.

`SpreadObj = fininstrument( ___ ,Name,Value)` sets optional properties on page 11-2905 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `SpreadObj = fininstrument("Spread",'Strike',100,'ExerciseDate',datetime(2019,1,30),'OptionType',"put",'ExerciseStyle',"American",'Name',"spread_instrument")` creates a `Spread` put option with an American exercise. You can specify multiple name-value pair arguments.

Input Arguments

`InstrumentType` — Instrument type

string with value `"Spread"` | string array with values of `"Spread"` | character vector with value `'Spread'` | cell array of character vectors with values of `'Spread'`

Instrument type, specified as a string with the value of `"Spread"`, a character vector with the value of `'Spread'`, an `NINST`-by-`1` string array with values of `"Spread"`, or an `NINST`-by-`1` cell array of character vectors with values of `'Spread'`.

Data Types: `char` | `cell` | `string`

Spread Name-Value Pair Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `SpreadObj = fininstrument("Spread",'Strike',100,'ExerciseDate',datetime(2019,1,30),'OptionType',"put",'ExerciseStyle',"American",'Name',"spread_instrument")`

Required Spread Name-Value Pair Arguments

`Strike` — Option strike price value

nonnegative numeric | nonnegative numeric vector

Option strike price value, specified as the comma-separated pair consisting of `'Strike'` and a scalar nonnegative numeric or an `NINST`-by-`1` nonnegative numeric vector.

Data Types: `double`

`ExerciseDate` — Option exercise date

datetime array | string array | date character vector

Option exercise date, specified as the comma-separated pair consisting of `'ExerciseDate'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

Note For a European option, there is only one `ExerciseDate` on the option expiry date.

To support existing code, `Spread` also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `ExerciseDate` property is stored as a datetime.

Optional Spread Name-Value Pair Arguments

`OptionType` — Option type

`"call"` (default) | string with value `"call"` or `"put"` | string array with values of `"call"` or `"put"` | character vector with value `'call'` or `'put'` | cell array of character vectors with values of `'call'` or `'put'`

Option type, specified as the comma-separated pair consisting of `'OptionType'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

`ExerciseStyle` — Option exercise style
`"European"` (default) | string with value `"European"` | string array with values of `"European"` | character vector with value `'European'` | cell array of character vectors with values of `'European'`

Option exercise style, specified as the comma-separated pair consisting of `'ExerciseStyle'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `string` | `cell` | `char`

`Name` — User-defined name for instrument
`" "` (default) | string | string array | character vector | cell array of character vectors

User-defined name for one of more instruments, specified as the comma-separated pair consisting of `'Name'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

Properties

`Strike` — Option strike price value
nonnegative numeric | nonnegative numeric vector

Option strike price value, returned as a scalar nonnegative numeric or an `NINST`-by-`1` nonnegative numeric vector.

Data Types: `double`

`ExerciseDate` — Option exercise date
datetime | vector of datetimes

Option exercise date, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`OptionType` — Option type
`"call"` (default) | string with value `"call"` or `"put"` | string array with value `"call"` or `"put"`

Option type, returned as a scalar string or an `NINST`-by-`1` string array with values of `"call"` or `"put"`.

Data Types: `string`

`ExerciseStyle` — Option exercise style
`"European"` (default) | string with value `"European"` | string array with values of `"European"`

Option exercise style, returned as a string or an `NINST`-by-`1` string array with values of `"European"`.

Data Types: `string`

`Name` — User-defined name for instrument
`" "` (default) | string | string array

User-defined name for the instrument, returned as a scalar string or an `NINST`-by-`1` string array.

Data Types: `string`

Examples

Price Spread Instrument with European Option Using Black-Scholes Model and Bjerksund-Stensland Pricer

This example shows the workflow to price a `Spread` instrument with a European option when using a `BlackScholes` model and a `BjerksundStensland` pricing method.

Create Spread Instrument Object

Use `fininstrument` to create a `Spread` instrument object.

```
SpreadOpt = fininstrument("Spread",'Strike',105,'ExerciseDate',datetime(2021,9,15),'OptionType','
```

```
SpreadOpt =
  Spread with properties:

      OptionType: "put"
          Strike: 105
    ExerciseStyle: "european"
     ExerciseDate: 15-Sep-2021
             Name: "spread_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',[0.2,0.1])
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: [0.2000 0.1000]
    Correlation: [2x2 double]
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
       Compounding: -1
             Basis: 12
             Dates: 15-Sep-2023
```

```
              Rates: 0.0350
             Settle: 15-Sep-2018
       InterpMethod: "linear"
  ShortExtrapMethod: "next"
   LongExtrapMethod: "previous"
```

Create BjerksundStensland Pricer Object

Use finpricer to create a BjerksundStensland pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPrice',[103
```

```
outPricer =
  BjerksundStensland with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: [103 105]
    DividendValue: [0.0250 0.0280]
     DividendType: "continuous"
```

Price Spread Instrument

Use price to compute the price and sensitivities for the Spread instrument.

```
[Price, outPR] = price(outPricer,SpreadOpt,["all"])
```

```
Price = 95.9884
```

```
outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×7 table
    Price           Delta                  Gamma                  Lambda                Vega
    _____    ___________________    ___________________________    ____________________    ____

    95.988    -0.8916    0.90457    0.0021316    0.00048175    -0.95673    0.97064    13.582
```

Price Multiple Spread Instruments with European Option Using Black-Scholes Model and Bjerksund-Stensland Pricer

This example shows the workflow to price multiple Spread instruments with a European option when using a BlackScholes model and a BjerksundStensland pricing method.

Create Spread Instrument Object

Use fininstrument to create a Spread instrument object for three Spread instruments.

```
SpreadOpt = fininstrument("Spread",'Strike',[105 ; 120 ; 150],'ExerciseDate',datetime([2021,9,15
```

```
SpreadOpt=3×1 object
  3x1 Spread array with properties:

    OptionType
    Strike
    ExerciseStyle
    ExerciseDate
    Name
```

Create BlackScholes Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',[0.2,0.1])
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: [0.2000 0.1000]
    Correlation: [2x2 double]
```

Create ratecurve Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
        Compounding: -1
              Basis: 12
              Dates: 15-Sep-2023
              Rates: 0.0350
             Settle: 15-Sep-2018
       InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create BjerksundStensland Pricer Object

Use `finpricer` to create a `BjerksundStensland` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPrice',[103
```

```
outPricer =
  BjerksundStensland with properties:

    DiscountCurve: [1x1 ratecurve]
```

```
           Model: [1x1 finmodel.BlackScholes]
       SpotPrice: [103 160]
   DividendValue: [0.0250 0.0280]
    DividendType: "continuous"
```

Price Spread Instruments

Use `price` to compute the prices and sensitivities for the `Spread` instruments.

```
[Price, outPR] = price(outPricer,SpreadOpt,["all"])
```

```
Price = 3×1

  146.1732
  159.1989
  185.5513

Price Spread Instrument for a Commodity Using Black-Scholes Model and Analytic Pricers

This example shows the workflow to price a commodity `Spread` instrument when you use a `BlackScholes` model and `Kirk` and `BjerksundStensland` analytic pricing methods.

Understanding Crack Spread Options

In the petroleum industry, refiners are concerned about the difference between their input costs (crude oil) and output prices (refined products — gasoline, heating oil, diesel fuel, and so on). The

differential between these two underlying commodities is referred to as a *crack spread*. It represents the profit margin between crude oil and the refined products.

A *spread option* is an option on the spread where the holder has the right, but not the obligation, to enter into a spot or forward spread contract. Crack spread options are often used to protect against declines in the crack spread or to monetize volatility or price expectations on the spread.

Define the Commodity

Assume that current gasoline prices are strong, and you want to model a crack spread option strategy to protect the gasoline margin. A crack spread option strategy is used to maintain profits for the following season. The WTI crude oil futures are at $93.20 per barrel and RBOB gasoline futures contract are at $2.85 per gallon.

```
Strike = 20;
Rate = 0.05;

Settle = datetime(2020,1,1);
Maturity = datemnth(Settle,3);

% Price and volatility of RBOB gasoline
PriceGallon1 = 2.85;          % Dollars per gallon
Price1 = PriceGallon1 * 42;   % Dollars per barrel
Vol1 = 0.29;

% Price and volatility of WTI crude oil
Price2 = 93.20;         % Dollars per barrel
Vol2 = 0.36;

% Correlation between the prices of the commodities
Corr = 0.42;
```

Create Spread Instrument Object

Use `fininstrument` to create a `Spread` instrument object.

```
SpreadOpt = fininstrument("Spread", 'ExerciseDate', Maturity, 'Strike', Strike,'ExerciseStyle',"e
```

```
SpreadOpt =
  Spread with properties:

       OptionType: "call"
           Strike: 20
    ExerciseStyle: "european"
     ExerciseDate: 01-Apr-2020
             Name: "spread_instrument"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', [Vol1,Vol2], 'Correlation', [1 Corr; C
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
ZeroCurve = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 1);
```

Create BjerksundStensland Pricer Object

Use finpricer to create a BjerksundStensland pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
BJSPricer = finpricer("Analytic", 'Model', BlackScholesModel, 'SpotPrice', [Price1 , Price2], 'Di
```

Create Kirk Pricer Object

Use finpricer to create a Kirk pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
KirkPricer = finpricer("Analytic", 'Model', BlackScholesModel,'SpotPrice', [Price1 , Price2], 'Di
```

Price Spread Instrument Using BjerksundStensland and Kirk Analytic Pricing Methods

Use price to compute the price and sensitivities for the commodity Spread instrument.

```
[PriceKirk, outPR_Kirk] = price(KirkPricer, SpreadOpt, "all");
[PriceBJS,  outPR_BJS]  = price(BJSPricer,  SpreadOpt, "all");

[outPR_Kirk.Results; outPR_BJS.Results]
```

```
ans=2×7 table
    Price           Delta                 Gamma                 Lambda                Vega

Price Spread Instrument with American Option Using Black-Scholes Model and Asset Monte-Carlo Pricer

This example shows the workflow to price a Spread instrument with an American option when using a BlackScholes model and an AssetMonteCarlo pricing method.

Create Spread Instrument Object

Use fininstrument to create a Spread instrument object.

```
SpreadOpt = fininstrument("Spread",'Strike',100,'ExerciseDate',datetime(2021,9,15),'OptionType','
```

```
SpreadOpt =
  Spread with properties:

       OptionType: "put"
           Strike: 100
    ExerciseStyle: "american"
     ExerciseDate: 15-Sep-2021
             Name: "spread_option"
```

Create BlackScholes Model Object

Use finmodel to create a BlackScholes model object.

```
Corr = 0.42;
BlackScholesModel = finmodel("BlackScholes","Volatility",[0.3,0.1],"Correlation", [1 Corr;Corr 1]

BlackScholesModel =
  BlackScholes with properties:

     Volatility: [0.3000 0.1000]
    Correlation: [2x2 double]
```

Create ratecurve Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)

myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create AssetMonteCarlo Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo","DiscountCurve",myRC,"Model",BlackScholesModel,'SpotPrice

outPricer =
  GBMMonteCarlo with properties:

      DiscountCurve: [1x1 ratecurve]
          SpotPrice: [100 95]
    SimulationDates: 15-Sep-2021
          NumTrials: 1000
      RandomNumbers: []
              Model: [1x1 finmodel.BlackScholes]
       DividendType: ["continuous"    "continuous"]
      DividendValue: [0 0.0100]
```

Price Spread Instrument

Use `price` to compute the price and sensitivities for the `Spread` instrument.

```
[Price, outPR] = price(outPricer,SpreadOpt,["all"])
```

```
Price = 95

outPR =
  priceresult with properties:

      Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×7 table
    Price     Delta           Gamma                Lambda          Rho     Theta      Vega
    _____    ________    _________________    ____________________    ___    _____    _______

     95       -1     1    0    3.1492e-14     -1.0526           1     0       0       0    0
```

Price Spread Instrument with American Option Using Bachelier Model and Asset Monte-Carlo Pricer

This example shows the workflow to price a `Spread` instrument with an American option when using a `Bachelier` model and an `AssetMonteCarlo` pricing method.

Create Spread Instrument Object

Use `fininstrument` to create a `Spread` instrument object.

```
SpreadOpt = fininstrument("Spread",'Strike',100,'ExerciseDate',datetime(2021,9,15),'OptionType','
```

```
SpreadOpt =
  Spread with properties:

       OptionType: "put"
           Strike: 100
    ExerciseStyle: "american"
     ExerciseDate: 15-Sep-2021
             Name: "spread_option"
```

Create `Bachelier` Model Object

Use `finmodel` to create a `Bachelier` model object.

```
Corr = 0.42;
BachelierModel = finmodel("BlackScholes","Volatility",[0.3,0.1],"Correlation", [1 Corr;Corr 1])
```

```
BachelierModel =
  BlackScholes with properties:

     Volatility: [0.3000 0.1000]
    Correlation: [2x2 double]
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create AssetMonteCarlo Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo","DiscountCurve",myRC,"Model",BachelierModel,'SpotPrice',
```

```
outPricer =
  GBMMonteCarlo with properties:

     DiscountCurve: [1x1 ratecurve]
         SpotPrice: [100 95]
    SimulationDates: 15-Sep-2021
         NumTrials: 1000
     RandomNumbers: []
             Model: [1x1 finmodel.BlackScholes]
      DividendType: ["continuous"    "continuous"]
     DividendValue: [0 0.0100]
```

Price Spread Instrument

Use `price` to compute the price and sensitivities for the `Spread` instrument.

```
[Price, outPR] = price(outPricer,SpreadOpt,["all"])
```

```
Price = 95
```

```
outPR =
  priceresult with properties:

      Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×7 table
    Price     Delta          Gamma              Lambda          Rho     Theta     Vega
```

```
_____    ________    ______________    ___________________    ___    _____    _____

 95       -1     1    0    3.1492e-14    -1.0526           1     0       0       0    0
```

More About

Spread Option

A spread option is written on the difference of two underlying assets.

For example, a European call on the difference of two assets *X1* and *X2* has the following pay off at maturity:

$$\max(X1 - X2 - K, 0)$$

K is the strike price.

For more information, see “Spread Option” on page 3-30.

Version History

Introduced in R2020a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `Spread` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

Swap

Swap instrument object

Description

Create and price a Swap instrument object for one or more Swap instruments using this workflow:

1. Use fininstrument to create a Swap instrument object for one or more Swap instruments.
2. Use ratecurve to specify a curve model for the Swap instrument object or use finmodel to specify a HullWhite, BlackKarasinski, BlackDermanToy, or LinearGaussian2F model.
3. Choose a pricing method.
   - When using a ratecurve, use finpricer to specify a Discount pricing method
   - When using a HullWhite, BlackKarasinski, or BlackDermanToy model , use an IRTree pricing method for one or more Swap instruments.
   - When using a HullWhite, BlackKarasinski, or LinearGaussian2F model, use finpricer to specify an IRMonteCarlo pricing method for one or more Swap instruments.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a Swap instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
SwapInstrument = fininstrument(InstrumentType,'Maturity',maturity_date,'
LegRate',leg_rate)
SwapInstrument = fininstrument( ___ ,Name,Value)
```

Description

`SwapInstrument = fininstrument(InstrumentType,'Maturity',maturity_date,'LegRate',leg_rate)` creates a Swap object for one or more Swap instruments by specifying InstrumentType and sets the properties on page 11-2921 for the required name-value pair arguments Maturity and LegRate.

The Swap instrument supports vanilla swaps, amortizing swaps and forward swaps. You can use the Swap instrument for a single currency swap but not a cross-currency swap. For more information on a Swap instrument, see “More About” on page 11-2933.

`SwapInstrument = fininstrument( ___ ,Name,Value)` sets optional properties on page 11-2921 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, SwapInstrument =

```
fininstrument("Swap",'Maturity',datetime(2019,1,30),'LegRate',[0.06
0.12],'LegType',
["fixed","fixed"],'Basis',1,'Notional',100,'StartDate',datetime(2016,1,30),'D
aycountAdjustedCashFlow',true,'BusinessDayConvention',"follow",'ProjectionCur
ve',ratecurve,'Name',"swap_instrument")
```
creates a `Swap` option with a maturity of January 30, 2019. You can specify multiple name-value pair arguments.

Input Arguments

`InstrumentType` — Instrument type

string with value `"Swap"` | string array with values of `"Swap"` | character vector with value `'Swap'` | cell array of character vectors with values of `'Swap'`

Instrument type, specified as a string with the value of `"Swap"`, a character vector with the value of `'Swap'`, an `NINST`-by-`1` string array with values of `"Swap"`, or an `NINST`-by-`1` cell array of character vectors with values of `'Swap'`.

Data Types: `char` | `cell` | `string`

`Swap` Name-Value Pair Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `SwapInstrument =`
```
fininstrument("Swap",'Maturity',datetime(2019,1,30),'LegRate',[0.06
0.12],'LegType',
["fixed","fixed"],'Basis',1,'Notional',100,'StartDate',datetime(2016,1,30),'D
aycountAdjustedCashFlow',true,'BusinessDayConvention',"follow",'ProjectionCur
ve',ratecurve,'Name',"swap_instrument")
```

Required `Swap` Name-Value Pair Arguments

`Maturity` — Swap maturity date

datetime array | string array | date character vector

Swap maturity date, specified as the comma-separated pair consisting of `'Maturity'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `Swap` also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `Maturity` property is stored as a datetime.

`LegRate` — Leg rate in decimal values

matrix

Leg rate in decimal values, specified as the comma-separated pair consisting of `'LegRate'` and a `NINST`-by-`2` matrix. Each row can be defined as one of the following:

- `[CouponRate Spread]` (fixed-float)

- `[Spread CouponRate]` (float-fixed)
- `[CouponRate CouponRate]` (fixed-fixed)
- `[Spread Spread]` (float-float)

`CouponRate` is the decimal annual rate. `Spread` is the number of basis points in decimals over the reference rate. The first column represents the receiving leg, while the second column represents the paying leg.

Data Types: `double`

Optional Swap Name-Value Pair Arguments

LegType — Leg type
`["fixed","float"]` for each instrument (default) | cell array of character vectors with values `{'fixed','fixed'}`, `{'fixed','float'}`, `{'float','fixed'}`, or `{'float','float'}` | string array with values `["fixed","fixed"]`, `["fixed","float"]`, `["float","fixed"]`, or `["float","float"]`

Leg type, specified as the comma-separated pair consisting of `'LegType'` and a cell array of character vectors or a string array with the supported values. The `LegType` defines the interpretation of the values entered in `LegRate`.

Note When you specify a `Swap` instrument as the underlying asset for a `Swaption` instrument while using a `Normal`, `SABR`, `Black`, or `HullWhite` pricer, the `Swap` `LegType` must be `["fixed","float"]` or `["float","fixed"]`. You must also set the `ExerciseStyle` name-value pair argument of the associated `Swaption` instrument to `'European'`.

Data Types: `cell` | `string`

ProjectionCurve — Rate curve for projecting floating cash flows
`ratecurve.empty` (default) | scalar `ratecurve` object | vector of `ratecurve` objects

Rate curve for projecting floating cash flows, specified as the comma-separated pair consisting of `'ProjectionCurve'` and a scalar `ratecurve` object or an `NINST`-by-`1` vector of `ratecurve` objects. You must create this object using `ratecurve`. Use this optional input if the forward curve is different from the discount curve.

Data Types: `object`

Reset — Frequency of payments per year
`[2 2]` (default) | numeric value of `0`, `1`, `2`, `3`, `4`, `6`, or `12` | matrix

Frequency of payments per year, specified as the comma-separated pair consisting of `'Reset'` and scalar or a `NINST`-by-`2` matrix if `Reset` is different for each leg) with one of the following values: `0`, `1`, `2`, `3`, `4`, `6`, or `12`.

Data Types: `double`

Basis — Day count basis representing the basis for each leg
`[0 0]` (actual/actual) (default) | integer from `0` to `13`

Day count basis representing the basis for each leg, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-`1` matrix (or `NINST`-by-`2` matrix if `Basis` is different for each leg).

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Notional` — Notional principal amount or principal value schedule
`100` (default) | scalar numeric | numeric vector | timetable

Notional principal amount or principal value schedule, specified as the comma-separated pair consisting of `'Notional'` and a scalar numeric or an `NINST`-by-`1` numeric vector or a timetable. Use a scalar or vector for a vanilla `Swap` instrument and a timetable for an amortizing `Swap` instrument.

`Notional` accepts a scalar for a principal amount (or a `1`-by-`2` matrix if `Notional` is different for each leg) or a `timetable` for principal value schedules. For schedules, the first column of the timetable is dates and the second column is the associated notional principal value. The date indicates the last day that the principal value is valid.

Note If you are creating one or more `Swap` instruments and use a timetable, the timetable specification applies to all of the `Swap` instruments. `Notional` does not accept an `NINST`-by-`1` cell array of timetables as input.

Data Types: `timetable` | `double`

`LatestFloatingRate` — Latest floating rate for float legs
if not specified, then `ratecurve` must contain this information (default) | scalar numeric | vector

Latest floating rate for float legs, specified as the comma-separated pair consisting of `'LatestFloatingRate'` and a scalar numeric or an `NINST`-by-`1` numeric vector.

`LatestFloatingRate` is a `NINST`-by-`1` matrix (or `NINST`-by-`2` matrix if `LatestFloatingRate` is different for each leg).

Data Types: `double`

ResetOffset — Lag in rate setting
`[0 0]` (default) | vector

Lag in rate setting, specified as the comma-separated pair consisting of `'ResetOffset'` and a `NINST`-by-2 matrix.

Data Types: `double`

DaycountAdjustedCashFlow — Flag to adjust cash flows based on actual period day count
`false` (default) | logical value of `true` or `false` | vector of logical values of `true` or `false`

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of `'DaycountAdjustedCashFlow'` and a `NINST`-by-1 matrix (or `NINST`-by-2 matrix if `AdjustCashFlowsBasis` is different for each leg) of logicals with values of `true` or `false`.

Data Types: `logical`

BusinessDayConvention — Business day conventions
`"actual"` (default) | string | string array | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and string (or `NINST`-by-2 string array if `BusinessDayConvention` is different for each leg) or a character vector (or `NINST`-by-2 cell array of character vectors if `BusinessDayConvention` is different for each leg). The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- `"actual"` — Nonbusiness days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- `"follow"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- `"modifiedfollow"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day. However, if the following business day is in a different month, the previous business day is adopted instead.
- `"previous"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- `"modifiedprevious"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However, if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell` | `string`

Holidays — Holidays used in computing business days
`NaT` (default) | datetime array | string array | date character vector

Holidays used in computing business days, specified as the comma-separated pair consisting of `'Holidays'` and dates using an `NINST`-by-1 vector of datetimes, cell array of date character vectors, or date string array. For example:

```
H = holidays(datetime('today'),datetime(2025,12,15));
Swap = fininstrument("Swap",'Maturity',datetime(2025,12,15),'LegRate',[0.06 20],'Holidays',H)
```

To support existing code, `Swap` also accepts serial date numbers as inputs, but they are not recommended.

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month with 30 or fewer days
`[true true]` (in effect) (default) | logical with value of `true` or `false` | vector of logicals with values of `true` or `false`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month with 30 or fewer days, specified as the comma-separated pair consisting of `'EndMonthRule'` and a logical value of `true` or `false` using a `NINST`-by-`1` matrix (or `NINST`-by-`2` matrix if `EndMonthRule` is different for each leg).

- If you set `EndMonthRule` to `false`, the software ignores the rule, meaning that a payment date is always the same numerical day of the month.
- If you set `EndMonthRule` to `true`, the software sets the rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

`StartDate` — Date swap starts
`Settle` date (default) | datetime array | string array | date character vector

Date swap starts, specified as the comma-separated pair consisting of `'StartDate'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `Swap` also accepts serial date numbers as inputs, but they are not recommended.

Use `StartDate` to price a forward swap, that is, a swap that starts at a future date.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `StartDate` property is stored as a datetime.

`Name` — User-defined name for instrument
`" "` (default) | string | string array | character vector | cell array of character vectors

User-defined name for the instrument, specified as the comma-separated pair consisting of `'Name'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

Properties

`Maturity` — Maturity date
scalar datetime | vector of datetimes

Maturity date, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`LegRate` — Leg rate
matrix

Leg rate, returned as a `NINST`-by-`2` matrix of decimal values, with each row defined as one of the following:

- `[CouponRate Spread]` (fixed-float)
- `[Spread CouponRate]` (float-fixed)
- `[CouponRate CouponRate]` (fixed-fixed)
- `[Spread Spread]` (float-float)

Data Types: `double`

`LegType` — Leg type
`["fixed","float"]` for each instrument (default) | string array with values `["fixed","fixed"]`, `["fixed","float"]`, `["float","fixed"]`, or `["float","float"]`

Leg type, returned as a string array with the values `["fixed","fixed"]`, `["fixed","float"]`, `["float","fixed"]`, or `["float","float"]`.

Data Types: `string`

`ProjectionCurve` — Rate curve used in generating future cash flows
`ratecurve.empty` (default) | scalar `ratecurve` object | vector of `ratecurve` objects

Rate curve used in projecting the future cash flows, returned as a `ratecurve` object or an `NINST`-by-`1` vector of `ratecurve` objects.

Data Types: `object`

`Reset` — Reset frequency per year for each swap
`[2 2]` (default) | vector

Reset frequency per year for each swap, returned as a scalar or an `NINST`-by-`2` matrix.

Data Types: `double`

`Basis` — Day count basis
`[0 0]` (actual/actual) (default) | integer from `0` to `13`

Day count basis, returned as an `NINST`-by-`1` or an `NINST`-by-`2` matrix.

Data Types: `double`

`ResetOffset` — Lag in rate setting
`[0 0]` (default) | matrix

Lag in rate setting, returned as an `NINST`-by-`2` or an `NINST`-by-`2` matrix.

Data Types: `double`

`Notional` — Notional principal amount or principal value schedules
`100` (default) | scalar numeric | numeric vector | timetable

Notional principal amount, returned as a scalar numeric or an `NINST`-by-`1` numeric vector or a timetable.

Data Types: `double` | `timetable`

`LatestFloatingRate` — Rate for the next floating payment
if not specified, then `ratecurve` must contain this information (default) | scalar numeric | numeric vector

Rate for the next floating payment, set at the last reset date, returned as a scalar numeric or an `NINST`-by-1 numeric vector or `NINST`-by-2 if `LatestFloatingRate` is different for each leg.

Data Types: `double`

`DaycountAdjustedCashFlow` — Flag to adjust cash flows based on actual period day count
`false` (default) | logical value of `true` or `false` | vector of logical values of `true` or `false`

Flag to adjust cash flows based on actual period day count, returned as an `NINST`-by-1 matrix (or an `NINST`-by-2 matrix if `AdjustCashFlowsBasis` is different for each leg) of logicals with values of `true` or `false`.

Data Types: `logical`

`BusinessDayConvention` — Business day conventions
`"actual"` (default) | string | string array

Business day conventions, returned as a string or a `NINST`-by-2 string array if `BusinessDayConvention` is different for each leg.

Data Types: `char` | `cell` | `string`

`Holidays` — Holidays used in computing business days
`NaT` (default) | datetimes

Holidays used in computing business days, returned as an `NINST`-by-1 vector of datetimes.

Data Types: `datetime`

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month with 30 or fewer days
`[true true]` (in effect) (default) | logical with value of `true` or `false` | vector of logicals with values of `true` or `false`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month with 30 or fewer days, returned as an `NINST`-by-1 matrix (or `NINST`-by-2 matrix if `EndMonthRule` is different for each leg.

Data Types: `logical`

`StartDate` — Date swap starts
`Settle` date (default) | scalar datetime | vector of datetimes

Date swap starts, returned as a scalar datetime or an `NINST`-by-1 vector of datetimes.

Data Types: `datetime`

`Name` — User-defined name for instrument
`"  "` (default) | string | string array

User-defined name for the instrument, returned as a scalar string or an `NINST`-by-1 string array.

Data Types: `string`

Object Functions

cashflows	Compute cash flow for FixedBond, FloatBond, Swap, FRA, STIRFuture, OISFuture, OvernightIndexedSwap, or Deposit instrument

parswaprate Compute par swap rate for Swap instrument

Examples

Price Vanilla Swap Instrument Using ratecurve and Discount Pricer

This example shows the workflow to price a vanilla Swap instrument when you use a `ratecurve` and a `Discount` pricing method.

Create ratecurve Object

Create a `ratecurve` object using `ratecurve` for the underlying interest-rate curve for the Swap instrument.

```
Settle = datetime(2019,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create Swap Instrument Object

Use `fininstrument` to create a vanilla Swap instrument object.

```
Swap = fininstrument("Swap",'Maturity',datetime(2024,9,15),'LegRate',[0.022 0.019 ],'LegType',["
```

```
Swap =
  Swap with properties:

                   LegRate: [0.0220 0.0190]
                   LegType: ["float"    "fixed"]
                     Reset: [2 2]
                     Basis: [0 0]
                  Notional: 100
         LatestFloatingRate: [NaN NaN]
                ResetOffset: [0 0]
   DaycountAdjustedCashFlow: [0 0]
             ProjectionCurve: [1x2 ratecurve]
      BusinessDayConvention: ["actual"    "actual"]
                   Holidays: NaT
```

```
    EndMonthRule: [1 1]
       StartDate: NaT
        Maturity: 15-Sep-2024
            Name: "swap_instrument"
```

Create Discount Pricer Object

Use finpricer to create a Discount pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("Discount", 'DiscountCurve',myRC)
```

```
outPricer =
  Discount with properties:

    DiscountCurve: [1x1 ratecurve]
```

Price Swap Instrument

Use price to compute the price and sensitivities for the vanilla Swap instrument.

```
[Price, outPR] = price(outPricer, Swap,["all"])
```

```
Price = 7.2279
```

```
outPR =
  priceresult with properties:

       Results: [1x2 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×2 table
    Price       DV01
    ______    _________

    7.2279    -0.046631
```

Price Multiple Vanilla Swap Instruments Using ratecurve and Discount Pricer

This example shows the workflow to price multiple vanilla Swap instruments when you use a ratecurve and a Discount pricing method.

Create ratecurve Object

Create a ratecurve object using ratecurve for the underlying interest-rate curve for the Swap instrument.

```
Settle = datetime(2019,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
```

```
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)

myRC =
  ratecurve with properties:

                 Type: "zero"
          Compounding: -1
                Basis: 0
                Dates: [10x1 datetime]
                Rates: [10x1 double]
               Settle: 15-Sep-2019
         InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create Swap Instrument Object

Use `fininstrument` to create a vanilla `Swap` instrument object for three Swap instruments.

```
Swap = fininstrument("Swap",'Maturity',datetime([2024,9,15 ; 2025,9,15 ; 2026,9,15]),'LegRate',[0

Swap=3×1 object
  3x1 Swap array with properties:

    LegRate
    LegType
    Reset
    Basis
    Notional
    LatestFloatingRate
    ResetOffset
    DaycountAdjustedCashFlow
    ProjectionCurve
    BusinessDayConvention
    Holidays
    EndMonthRule
    StartDate
    Maturity
    Name
```

Create `Discount` Pricer Object

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("Discount", 'DiscountCurve',myRC)

outPricer =
  Discount with properties:

    DiscountCurve: [1x1 ratecurve]
```

Price Swap Instruments

Use `price` to compute the prices and sensitivities for the vanilla `Swap` instruments.

```
[Price, outPR] = price(outPricer, Swap,["all"])
```

```
Price = 3×1

    7.2279
    9.9725
   13.0798

outPR=1×3 object
  1x3 priceresult array with properties:

    Results
    PricerData
```

```
outPR.Results
```

```
ans=1×2 table
    Price       DV01
    ______    _________

    7.2279    -0.046631

ans=1×2 table
    Price       DV01
    ______    _________

    9.9725    -0.054393

ans=1×2 table
    Price      DV01
    _____    _________

    13.08    -0.061381
```

Price Amortizing Swap Instrument Using ratecurve and Discount Pricer

This example shows the workflow to price an amortizing `Swap` instrument when you use a `ratecurve` and a `Discount` pricing method.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve` for the underlying interest-rate curve for the `Swap` instrument.

```
Settle = datetime(2019,1,1);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
```

```
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)

myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 01-Jan-2019
        InterpMethod: "linear"
   ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

Create Swap Instrument Object

Use `fininstrument` to create an amortizing `Swap` instrument object.

```
Maturity = datetime(2024,1,1);
ADates = datetime([2020,1,1 ; 2024,1,1]);
APrincipal = [100; 85];
Notional = timetable(ADates,APrincipal);
Swap = fininstrument("Swap",'Maturity',Maturity,'LegRate',[0.035,0.01],'Reset',[1 1],'Notional',N

Swap =
  Swap with properties:

                   LegRate: [0.0350 0.0100]
                   LegType: ["fixed"    "float"]
                     Reset: [1 1]
                     Basis: [0 0]
                  Notional: [2x1 timetable]
         LatestFloatingRate: [NaN NaN]
                ResetOffset: [0 0]
   DaycountAdjustedCashFlow: [0 0]
             ProjectionCurve: [0x0 ratecurve]
      BusinessDayConvention: ["actual"    "actual"]
                   Holidays: NaT
              EndMonthRule: [1 1]
                 StartDate: NaT
                  Maturity: 01-Jan-2024
                      Name: "swap_instrument"
```

Create `Discount` Pricer Object

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("Discount", 'DiscountCurve',myRC)

outPricer =
  Discount with properties:
```

```
    DiscountCurve: [1x1 ratecurve]
```

Price Swap Instrument

Use `price` to compute the price and sensitivities for the amortizing `Swap` instrument.

```
[Price, outPR] = price(outPricer, Swap,["all"])

Price = 5.7183

outPR =
  priceresult with properties:

       Results: [1x2 table]
    PricerData: []

outPR.Results

ans=1×2 table
    Price       DV01
    ______    ________

    5.7183    0.044672
```

Price Vanilla Swap Instrument Using Hull-White Model and IRTree Pricer

This example shows the workflow to price a vanilla `Swap` instrument when you use a `HullWhite` model and an `IRTree` pricing method.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve` for the underlying interest-rate curve for the `Swap` instrument.

```
Settle = datetime(2020,1,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)

myRC =
  ratecurve with properties:

                Type: "zero"
       Compounding: -1
             Basis: 0
             Dates: [10x1 datetime]
             Rates: [10x1 double]
            Settle: 15-Jan-2020
      InterpMethod: "linear"
    ShortExtrapMethod: "next"
```

```
     LongExtrapMethod: "previous"
```

Create Swap Instrument Object

Use `fininstrument` to create a vanilla `Swap` instrument object.

```
LegType = ["float","fixed"];
Swap = fininstrument("Swap",'Maturity',datetime(2030,9,15),'LegRate',[0.022 0.019],'LegType',Leg
```

```
Swap =
  Swap with properties:

                     LegRate: [0.0220 0.0190]
                     LegType: ["float"    "fixed"]
                       Reset: [2 2]
                       Basis: [0 0]
                    Notional: 100
           LatestFloatingRate: [NaN NaN]
                  ResetOffset: [0 0]
    DaycountAdjustedCashFlow: [0 0]
             ProjectionCurve: [1x2 ratecurve]
       BusinessDayConvention: ["actual"    "actual"]
                    Holidays: NaT
                EndMonthRule: [1 1]
                   StartDate: NaT
                    Maturity: 15-Sep-2030
                        Name: "swap_instrument"
```

Create `HullWhite` Model Object

Use `finmodel` to create a `HullWhite` model object.

```
HullWhiteModel = finmodel("HullWhite",'Alpha',0.032,'Sigma',0.04)
```

```
HullWhiteModel =
  HullWhite with properties:

    Alpha: 0.0320
    Sigma: 0.0400
```

Compute Swap Instrument Cash Flow Dates

Use `cfdates` to compute the cash flows.

```
CFdates = cfdates(Settle, Swap.Maturity, Swap.Reset(1), Swap.Basis(1))
```

```
CFdates = 1x22 datetime
Columns 1 through 5

   15-Mar-2020   15-Sep-2020   15-Mar-2021   15-Sep-2021   15-Mar-2022

Columns 6 through 10

   15-Sep-2022   15-Mar-2023   15-Sep-2023   15-Mar-2024   15-Sep-2024

Columns 11 through 15
```

```
   15-Mar-2025   15-Sep-2025   15-Mar-2026   15-Sep-2026   15-Mar-2027

Columns 16 through 20

   15-Sep-2027   15-Mar-2028   15-Sep-2028   15-Mar-2029   15-Sep-2029

Columns 21 through 22

   15-Mar-2030   15-Sep-2030
```

Create IRTree Pricer Object

Use `finpricer` to create an `IRTree` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
HWTreePricer = finpricer("IRTree",'Model',HullWhiteModel,'DiscountCurve',myRC,'TreeDates',CFdates
```

```
HWTreePricer =
  HWBKTree with properties:

             Tree: [1x1 struct]
        TreeDates: [22x1 datetime]
            Model: [1x1 finmodel.HullWhite]
    DiscountCurve: [1x1 ratecurve]
```

Price Swap Instrument

Use `price` to compute the price and sensitivities for the vanilla `Swap` instrument.

```
[Price, outPR] = price(HWTreePricer, Swap,"all")
```

```
Price = 24.3727

outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×4 table
    Price     Delta      Gamma        Vega
    ______    ______    _______    __________

    24.373    820.67    -8790.5    8.5265e-10
```

Price Vanilla Swap Instrument Using LinearGaussian2F Model and IRMonteCarlo Pricer

This example shows the workflow to price a vanilla `Swap` instrument when using a `LinearGaussian2F` model and an `IRMonteCarlo` pricing method.

Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2020,1,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Jan-2020
        InterpMethod: "linear"
   ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

Create Swap Instrument Object

Use fininstrument to create a Swap instrument object.

```
LegType = ["float","fixed"];
Swap = fininstrument("Swap",'Maturity',datetime(2030,9,15),'LegRate',[0.022 0.019],'LegType',Leg
```

```
Swap =
  Swap with properties:

                   LegRate: [0.0220 0.0190]
                   LegType: ["float"    "fixed"]
                     Reset: [2 2]
                     Basis: [0 0]
                  Notional: 100
         LatestFloatingRate: [NaN NaN]
                ResetOffset: [0 0]
   DaycountAdjustedCashFlow: [0 0]
             ProjectionCurve: [1x2 ratecurve]
      BusinessDayConvention: ["actual"    "actual"]
                  Holidays: NaT
              EndMonthRule: [1 1]
                 StartDate: NaT
                  Maturity: 15-Sep-2030
                      Name: "swap_instrument"
```

Create LinearGaussian2F Model Object

Use finmodel to create a LinearGaussian2F model object.

```
LinearGaussian2FModel = finmodel("LinearGaussian2F",'Alpha1',0.07,'Sigma1',0.01,'Alpha2',0.5,'Sig
```

```
LinearGaussian2FModel =
  LinearGaussian2F with properties:

        Alpha1: 0.0700
        Sigma1: 0.0100
        Alpha2: 0.5000
        Sigma2: 0.0060
    Correlation: -0.7000
```

Create IRMonteCarlo Pricer Object

Use `finpricer` to create an `IRMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("IRMonteCarlo",'Model',LinearGaussian2FModel,'DiscountCurve',myRC,'Simulati
```

```
outPricer =
  G2PPMonteCarlo with properties:

         NumTrials: 1000
      RandomNumbers: []
      DiscountCurve: [1x1 ratecurve]
    SimulationDates: [15-Jul-2020    15-Jan-2021    15-Jan-2022    ...    ]
              Model: [1x1 finmodel.LinearGaussian2F]
```

Price Swap Instrument

Use `price` to compute the price and sensitivities for the `Swap` instrument.

```
[Price,outPR] = price(outPricer,Swap,["all"])
```

```
Price = 23.6657
```

```
outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×4 table
    Price     Delta      Gamma      Vega
    ______    ______    _______    ______

    23.666    819.11    -8748.9    0    0
```

More About

Swap

A swap is contract between two parties obligating the parties to exchange future cash flows.

A vanilla swap is composed of a floating-rate leg and a fixed-rate leg.

Swap with Amortization

A swap with an amortization schedule repays part of the principal (face value) along with the coupon payments.

A swap with an amortization schedule is used to manage interest-rate risk and serve as a cash flow management tool. For this particular type of swap, the notional amount decreases over time. This means that interest payments decrease not only on the floating leg but also on the fixed leg. Use the `Notional` name-value pair argument to support an amortization schedule.

Forward Swap

In a forward interest-rate swap, a fixed interest-rate loan is exchanged for a floating interest-rate loan at a future specified date.

The `StartDate` name-value pair argument supports the future date for the forward swap.

Version History

Introduced in R2020a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `Swap` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

VarianceSwap

`VarianceSwap` instrument object

Description

Create and price a `VarianceSwap` instrument object for one or more Variance Swap instruments using this workflow:

1. Use `fininstrument` to create a `VarianceSwap` instrument object for one or more Variance Swap instruments.
2. Use `ratecurve` to specify a curve model or use `finmodel` to specify a `Heston` model.
3. Choose a pricing method.
   - When using a curve model, use `finpricer` to specify a `ReplicatingVarianceSwap` pricing method for one or more `VarianceSwap` instruments.
   - When using a `Heston` model, use `finpricer` to specify a `Heston` pricing method for one or more `VarianceSwap` instruments.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a `VarianceSwap` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
VarianceSwapInstrument = fininstrument(InstrumentType,'
Maturity',maturity_date,'Notional',notional_value)
VarianceSwapInstrument = fininstrument( ___ ,Name,Value)
```

Description

`VarianceSwapInstrument = fininstrument(InstrumentType,'Maturity',maturity_date,'Notional',notional_value)` creates a `VarianceSwap` object for one or more Variance Swap instruments by specifying `InstrumentType` and sets properties on page 11-2937 using the required name-value pair arguments `Maturity` and `Notional`.

The `VarianceSwap` instrument supports the `ReplicatingVarianceSwap` and `Heston` pricing methods. For more information on the `VarianceSwap` instrument, see “More About” on page 11-2943.

`VarianceSwapInstrument = fininstrument( ___ ,Name,Value)` sets optional properties on page 11-2921 using additional name-value pair arguments in addition to the required arguments in the previous syntax. For example, `VarianceSwapInstrument = fininstrument("VarianceSwap",'Maturity',datetime(2019,1,30),'Notional',100,'S`

tartDate',datetime(2016,1,30),'RealizedVariance',0.02,'Strike',110,'Name',"varianceswap_instrument") creates a VarianceSwap option with a maturity date of January 30, 2019. You can specify multiple name-value pair arguments.

Input Arguments

InstrumentType — Instrument type

string with value "VarianceSwap" | string array with values of "VarianceSwap" | character vector with value 'VarianceSwap' | cell array of character vectors with values of 'VarianceSwap'

Instrument type, specified as a string with the value of "VarianceSwap", a character vector with the value of 'VarianceSwap', an NINST-by-1 string array with values of "VarianceSwap", or an NINST-by-1 cell array of character vectors with values of 'VarianceSwap'.

Data Types: char | cell | string

VarianceSwap Name-Value Pair Arguments

Specify required and optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: VarianceSwapInstrument = fininstrument("VarianceSwap",'Maturity',datetime(2019,1,30),'Notional',100,'StartDate',datetime(2016,1,30),'RealizedVariance',0.02,'Strike',110,'Name',"varianceswap_instrument")

Required VarianceSwap Name-Value Pair Arguments

Maturity — Variance swap maturity date

datetime array | string array | date character vector

Variance swap maturity date, specified as the comma-separated pair consisting of 'Maturity' and a scalar or an NINST-by-1 vector.

If you use date character vectors or strings, the format must be recognizable by datetime because the Maturity property is stored as a datetime.

To support existing code, VarianceSwap also accepts serial date numbers as inputs, but they are not recommended.

Notional — Notional amount

scalar numeric | numeric vector

Notional amount, specified as the comma-separated pair consisting of 'Notional' and a scalar numeric or an NINST-by-1 numeric vector.

Data Types: double

Optional VarianceSwap Name-Value Pair Arguments

StartDate — Start date

Settle date of the ratecurve (default) | datetime array | string array | date character vector

Start date, specified as the comma-separated pair consisting of `'StartDate'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `VarianceSwap` also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `ExerciseDate` property is stored as a datetime.

`RealizedVariance` — Realized variance
`0` (default) | scalar decimal | decimal vector

Realized variance, specified as the comma-separated pair consisting of `'RealizedVariance'` and a scalar decimal or an `NINST`-by-`1` vector of decimals.

Data Types: `double`

`Strike` — Strike variance
fair variance computed by pricer (default) | scalar decimal | decimal vector

Strike variance, specified as the comma-separated pair consisting of `'Strike'` and a scalar decimal or an `NINST`-by-`1` vector of decimals.

Data Types: `double`

`Name` — User-defined name for instrument
`" "` (default) | string | string array | character vector | cell array of character vectors

User-defined name for one of more instruments, specified as the comma-separated pair consisting of `'Name'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

Properties

`Maturity` — Maturity date
datetime | vector of datetimes

Maturity date, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`Notional` — Notional amount
scalar numeric | numeric vector

Notional amount, returned as a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`StartDate` — Start date
`Settle` date of the `ratecurve` (default) | datetime | vector of datetimes

Start date, returned as a scalar datetime or an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`RealizedVariance` — Realized variance
`0` (default) | scalar decimal | decimal vector

Realized variance, returned as a scalar decimal or an `NINST`-by-`1` decimal vector.

Data Types: `double`

`Strike` — Strike variance
fair variance computed by pricer (default) | scalar decimal | decimal vector

Strike variance, returned as a scalar decimal or an `NINST`-by-`1` decimal vector.

Data Types: `double`

`Name` — User-defined name for instrument
`" "` (default) | string | string array

User-defined name for the instrument, returned as a scalar string or an `NINST`-by-`1` string array.

Data Types: `string`

Object Functions

Examples

Price Variance Swap Instrument Using Heston Model and Heston Pricer

This example shows the workflow to price a `VarianceSwap` instrument when you use a `Heston` model and a `Heston` pricing method.

Create `VarianceSwap` Instrument Object

Use `fininstrument` to create a `VarianceSwap` instrument object.

```
VarianceSwapInst = fininstrument("VarianceSwap",'Maturity',datetime(2020,9,15),'Notional',100,'St
```

```
VarianceSwapInst =
  VarianceSwap with properties:

            Notional: 100
    RealizedVariance: 0.0200
              Strike: 0.0500
           StartDate: 15-Jun-2020
            Maturity: 15-Sep-2020
                Name: "variance_swap_instrument"
```

Create `Heston` Model Object

Use `finmodel` to create a `Heston` model object.

```
HestonModel = finmodel("Heston",'V0',0.06,'ThetaV',0.1,'Kappa',0.9,'SigmaV',0.7,'RhoSV',-.3)
```

```
HestonModel =
  Heston with properties:
```

```
        V0: 0.0600
    ThetaV: 0.1000
     Kappa: 0.9000
    SigmaV: 0.7000
     RhoSV: -0.3000
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2020, 1, 1);
ZeroTimes = calmonths(3);
ZeroRates = 0.05;
ZeroDates = Settle + ZeroTimes;
Basis = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates,'Basis',Basis)
```

```
ZeroCurve =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 1
               Dates: 01-Apr-2020
               Rates: 0.0500
              Settle: 01-Jan-2020
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `Heston` Pricer Object

Use `finpricer` to create a `Heston` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("Analytic",'DiscountCurve',ZeroCurve,'Model',HestonModel)
```

```
outPricer =
  Heston with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.Heston]
```

Price `VarianceSwap` Instrument

Use `price` to compute the price and fair variance for the `VarianceSwap` instrument.

```
[Price, outPR] = price(outPricer,VarianceSwapInst,["all"])
```

```
Price = 10.8321

outPR =
  priceresult with properties:

       Results: [1x2 table]
```

```
    PricerData: []
```

```
outPR.Results
```

```
ans=1×2 table
    Price     FairVariance
    ______    ____________

    10.832      0.07039
```

Price Multiple Variance Swap Instruments Using Heston Model and Heston Pricer

This example shows the workflow to price multiple `VarianceSwap` instrument when you use a `Heston` model and a `Heston` pricing method.

Create `VarianceSwap` Instrument Object

Use `fininstrument` to create a `VarianceSwap` instrument object for three Variance Swap instruments.

```
VarianceSwapInst = fininstrument("VarianceSwap",'Maturity',datetime([2020,9,15 ; 2020,9,15 ; 2020
```

```
VarianceSwapInst=3×1 object
  3x1 VarianceSwap array with properties:

    Notional
    RealizedVariance
    Strike
    StartDate
    Maturity
    Name
```

Create `Heston` Model Object

Use `finmodel` to create a `Heston` model object.

```
HestonModel = finmodel("Heston",'V0',0.06,'ThetaV',0.1,'Kappa',0.9,'SigmaV',0.7,'RhoSV',-.3)
```

```
HestonModel =
  Heston with properties:

        V0: 0.0600
    ThetaV: 0.1000
     Kappa: 0.9000
    SigmaV: 0.7000
     RhoSV: -0.3000
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2020, 1, 1);
ZeroTimes = calmonths(3);
```

```
ZeroRates = 0.05;
ZeroDates = Settle + ZeroTimes;
Basis = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates,'Basis',Basis)
```

```
ZeroCurve =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 1
               Dates: 01-Apr-2020
               Rates: 0.0500
              Settle: 01-Jan-2020
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `Heston` Pricer Object

Use `finpricer` to create a `Heston` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("Analytic",'DiscountCurve',ZeroCurve,'Model',HestonModel)
```

```
outPricer =
  Heston with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.Heston]
```

Price `VarianceSwap` Instruments

Use `price` to compute the prices and fair variance for the three `VarianceSwap` instruments.

```
% [Price, outPR] = price(outPricer,VarianceSwapInst,["all"])
% outPR.Results
```

Price Variance Swap Instrument Using `ratecurve` and Replicating Variance Swap Pricer

This example shows the workflow to price a `VarianceSwap` instrument when you use a `ratecurve` object and a `ReplicatingVarianceSwap` pricing method.

Create `VarianceSwap` Instrument Object

Use `fininstrument` to create a `VarianceSwap` instrument object.

```
VarianceSwapInst = fininstrument("VarianceSwap",'Maturity',datetime(2021,5,1),'Notional',150,'Sta
```

```
VarianceSwapInst =
  VarianceSwap with properties:

            Notional: 150
    RealizedVariance: 0.0500
```

```
            Strike: 0.1000
         StartDate: 01-May-2020
          Maturity: 01-May-2021
              Name: "variance_swap_instrument"
```

Create ratecurve Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2020, 9, 15);
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
Basis = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates,'Basis',Basis)
```

```
ZeroCurve =
  ratecurve with properties:

               Type: "zero"
       Compounding: -1
             Basis: 1
             Dates: [10x1 datetime]
             Rates: [10x1 double]
            Settle: 15-Sep-2020
      InterpMethod: "linear"
 ShortExtrapMethod: "next"
  LongExtrapMethod: "previous"
```

Create ReplicatingVarianceSwap Pricer Object

Use `finpricer` to create a `ReplicatingVarianceSwap` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
Strike = (50:5:135)';
Volatility = [.49;.45;.42;.38;.34;.31;.28;.25;.23;.21;.2;.21;.21;.22;.23;.24;.25;.26];
VolatilitySmile = table(Strike, Volatility);
SpotPrice = 100;
CallPutBoundary = 100;

outPricer =  finpricer("ReplicatingVarianceSwap",'DiscountCurve', ZeroCurve, 'VolatilitySmile', V
'SpotPrice', SpotPrice, 'CallPutBoundary', CallPutBoundary)
```

```
outPricer =
  ReplicatingVarianceSwap with properties:

    DiscountCurve: [1x1 ratecurve]
     InterpMethod: "linear"
 VolatilitySmile: [18x2 table]
       SpotPrice: 100
 CallPutBoundary: 100
```

Price VarianceSwap Instrument

Use `price` to compute the price and fair variance for the `VarianceSwap` instrument.

```
[Price, outPR] = price(outPricer,VarianceSwapInst,["all"])

Price = 8.1997

outPR =
  priceresult with properties:

       Results: [1x2 table]
    PricerData: [1x1 struct]

outPR.Results

ans=1×2 table
    Price     FairVariance
    ______    ____________

    8.1997      0.21701
```

More About

Variance Swap

A variance swap is a forward contract on the realized variance over time.

At expiration, the payoff of a variance swap is $(\sigma_R^2 - K_{\text{var}}) \times \text{N}$

Here:

σ^2_R is the realized variance of the underlying asset (for example a stock or equity index) over the life of the contract.

K_{var} is the strike (contractual) variance that is set at the beginning of the contract to make the starting value equal to zero.

N is the notional amount.

Version History

Introduced in R2020b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `VarianceSwap` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

Topics
“Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22
“Choose Instruments, Models, and Pricers” on page 1-53

Swaption

`Swaption` instrument object

Description

Create and price a `Swaption` instrument object for one or more Swaption instruments using this workflow:

1. Use `fininstrument` to create a `Swaption` instrument object for one or more Swaption instruments.
2. Use `finmodel` to specify a `HullWhite`, `BlackKarasinski`, `BlackDermanToy`, `Black`, `Normal`, `SABR`, or `LinearGaussian2F` model for the `Swaption` instrument object.
3. Choose a pricing method.
   - When using a `HullWhite`, `BlackKarasinski`, `BlackDermanToy`, `Black`, `Normal`, or `SABR` model, use `finpricer` for pricing one or more `Swaption` instruments and specify:
     - A `Normal` pricer when using a `Normal` model.
     - A `Black` pricer when using a `Black` model.
     - A `HullWhite` pricer when using a `HullWhite` model.
     - A `SABR` pricer when using a `SABR` model.
     - An `IRTree` pricer when using a `BlackKarasinski` or `BlackDermanToy` model.
   - When using a `HullWhite`, `BlackKarasinski`, or `LinearGaussian2F` model, use `finpricer` to specify an `IRMonteCarlo` pricing method for one or more `Swaption` instruments.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a `Swaption` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
SwaptionInstrument = fininstrument(InstrumentType,'Strike',strike_value,'
ExerciseDate',exercice_date)
SwaptionInstrument = fininstrument( ___ ,Name,Value)
```

Description

`SwaptionInstrument = fininstrument(InstrumentType,'Strike',strike_value,'ExerciseDate',exercice_date)` creates a `Swaption` object for one or more Swaption instruments by specifying `InstrumentType` and sets the properties on page 11-2947 for the

required name-value pair arguments `Strike` and `ExerciseDate`. For more information on a `Swaption` instrument, see “More About” on page 11-2963.

`SwaptionInstrument = fininstrument( ___ ,Name,Value)` sets optional properties on page 11-2947 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `SwaptionInstrument = fininstrument("Swaption",'Strike',0.67,'ExerciseDate',datetime(2019,1,30),'Swap',Swap_obj,'OptionType',"put",'ExerciseStyle',"European",'Name',"swaption_instrument")` creates a `Swaption` put instrument with a strike of 0.67 and an European exercise. You can specify multiple name-value pair arguments.

Input Arguments

`InstrumentType` — Instrument type

string with value `"Swaption"` | string array with values of `"Swaption"` | character vector with value `'Swaption'` | cell array of character vectors with values of `'Swaption'`

Instrument type, specified as a string with the value of `"Swaption"`, a character vector with the value of `'Swaption'`, an `NINST`-by-`1` string array with values of `"Swaption"`, or an `NINST`-by-`1` cell array of character vectors with values of `'Swaption'`.

Data Types: `char` | `cell` | `string`

`Swaption` Name-Value Pair Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `SwaptionInstrument = fininstrument("Swaption",'Strike',.67,'ExerciseDate',datetime(2019,1,30),'Swap',Swap_obj,'OptionType',"put",'ExerciseStyle',"European",'Name',"swaption_instrument")`

Required Swaption Name-Value Pair Arguments

`Strike` — Option strike value

scalar nonnegative decimal | vector of nonnegative decimals

Option strike value, specified as the comma-separated pair consisting of `'Strike'` and a scalar nonnegative decimal or an `NINST`-by-`1` vector of nonnegative decimals.

Data Types: `double`

`ExerciseDate` — Option exercise date

datetime array | string array | date character vector

Option exercise date, specified as the comma-separated pair consisting of `'ExerciseDate'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array,or date character vectors.

Note For a European option, there is only one `ExerciseDate` on the option expiry date.

To support existing code, `Swaption` also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `ExerciseDate` property is stored as a datetime.

`Swap` — Underlying `Swap` object
scalar `Swap` object | vector of `Swap` objects

Underlying `Swap` object, specified as the comma-separated pair consisting of `'Swap'` and a scalar `Swap` object or an `NINST`-by-`1` vector of `Swap` objects.

Data Types: `object`

Optional Swaption Name-Value Pair Arguments

`OptionType` — Option type
`"call"` (default) | string with values `"call"` or `"put"` | string array with values of `"call"` or `"put"` | character vector with value `'call'` or `'put'` | cell array of character vectors with values of `'call'` or `'put'`

Option type, specified as the comma-separated pair consisting of `'OptionType'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

`ExerciseStyle` — Option exercise style
`"European"` (default) | string with value `"European"` | string array with values of `"European"` | character vector with value `'European'` | cell array of character vectors with values of `"European"`

Option exercise style, specified as the comma-separated pair consisting of `'ExerciseStyle'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Note When you specify a `Swap` instrument as the underlying asset for a `Swaption` instrument and use a `Normal`, `SABR`, `Black`, or `HullWhite` pricer, the `Swap` instrument `LegType` must be `["fixed","float"]` or `["float","fixed"]` and the `Swaption` instrument `ExerciseStyle` must be `"European"`.

Data Types: `string` | `cell` | `char`

`Name` — User-defined name for instrument
`" "` (default) | string | string array | character vector | cell array of character vectors

User-defined name for the instrument, specified as the comma-separated pair consisting of `'Name'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

Properties

`Strike` — Option strike value
scalar nonnegative decimal | vector of nonnegative decimals

Option strike value, returned as a scalar nonnegative decimal or an NINST-by-1 vector of nonnegative decimals.

Data Types: double

ExerciseDate — Option exercise date
datetime | vector of datetimes

Option exercise date, returned as a scalar datetime or an NINST-by-1 vector of datetimes.

Data Types: datetime

Swap — Underlying Swap object
scalar Swap object | vector of Swap objects

Swap object, returned as a scalar Swap object or an NINST-by-1 vector of Swap objects.

Data Types: object

OptionType — Option type
"call" (default) | string with value "call" or "put" | string array with values of "call" or "put"

Option type, returned as a scalar string or an NINST-by-1 string array with a value of "call" or "put".

Data Types: string

ExerciseStyle — Option exercise style
"European" (default) | string with value "European" | string array with values of "European"

Option exercise style, returned as a scalar string or an NINST-by-1 string array with a value of "European".

Data Types: string

Name — User-defined name for instrument
" " (default) | string | string array

User-defined name for the instrument, returned as a string or an NINST-by-1 string array.

Data Types: string

Examples

Price Swaption Instrument Using SABR Model and SABR Pricer

This example shows the workflow to price a Swaption instrument when you use a SABR model and a SABR pricing method.

Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
```

```
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2018
        InterpMethod: "linear"
   ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

Create Swap Instrument Object

Use `fininstrument` to create the underlying `Swap` instrument object.

```
Swap = fininstrument("Swap",'Maturity',datetime(2027,3,15),'LegRate',[0 0],'LegType',...
    ["float","fixed"],'Notional',100,'StartDate',datetime(2022,3,15),'Name',"swap_instrument")
```

```
Swap =
  Swap with properties:

                   LegRate: [0 0]
                   LegType: ["float"    "fixed"]
                     Reset: [2 2]
                     Basis: [0 0]
                  Notional: 100
         LatestFloatingRate: [NaN NaN]
                ResetOffset: [0 0]
   DaycountAdjustedCashFlow: [0 0]
             ProjectionCurve: [0x0 ratecurve]
      BusinessDayConvention: ["actual"    "actual"]
                   Holidays: NaT
               EndMonthRule: [1 1]
                  StartDate: 15-Mar-2022
                   Maturity: 15-Mar-2027
                       Name: "swap_instrument"
```

Create Swaption Instrument Object

Use `fininstrument` to create a `Swaption` instrument object.

```
Swaption = fininstrument("Swaption",'Strike',0.02,'ExerciseDate',datetime(2022,3,15),'Swap',Swap
```

```
Swaption =
  Swaption with properties:

      OptionType: "call"
   ExerciseStyle: "european"
    ExerciseDate: 15-Mar-2022
          Strike: 0.0200
            Swap: [1x1 fininstrument.Swap]
```

```
              Name: "swaption_option"
```

Create SABR Model Object

Use `finmodel` to create a SABR model object.

```
SabrModel = finmodel("SABR",'Alpha',0.032,'Beta',0.04,'Rho',.08,'Nu',0.49,'Shift',0.002)
```

```
SabrModel =
  SABR with properties:

             Alpha: 0.0320
              Beta: 0.0400
               Rho: 0.0800
                Nu: 0.4900
             Shift: 0.0020
    VolatilityType: "black"
```

Create SABR Pricer Object

Use `finpricer` to create a SABR pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'Model',SabrModel,'DiscountCurve',myRC)
```

```
outPricer =
  SABR with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.SABR]
```

Price `Swaption` Instrument

Use `price` to compute the price for the `Swaption` instrument.

```
Price = price(outPricer,Swaption)
```

```
Price = 10.8558
```

Price Multiple Swaption Instruments Using SABR Model and SABR Pricer

This example shows the workflow to price multiple `Swaption` instrument when you use a SABR model and a SABR pricing method.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create Swap Instrument Object

Use `fininstrument` to create the underlying `Swap` instrument object.

```
Swap = fininstrument("Swap",'Maturity',datetime(2027,3,15),'LegRate',[0 0],'LegType',...
    ["float","fixed"],'Notional',100,'StartDate',datetime(2022,3,15),'Name',"swap_instrument")
```

```
Swap =
  Swap with properties:

                    LegRate: [0 0]
                    LegType: ["float"    "fixed"]
                      Reset: [2 2]
                      Basis: [0 0]
                   Notional: 100
          LatestFloatingRate: [NaN NaN]
                 ResetOffset: [0 0]
    DaycountAdjustedCashFlow: [0 0]
              ProjectionCurve: [0x0 ratecurve]
       BusinessDayConvention: ["actual"    "actual"]
                    Holidays: NaT
                EndMonthRule: [1 1]
                   StartDate: 15-Mar-2022
                    Maturity: 15-Mar-2027
                        Name: "swap_instrument"
```

Create Swaption Instrument Object

Use `fininstrument` to create a `Swaption` instrument object for three Swaption instruments.

```
Swaption = fininstrument("Swaption",'Strike',[0.02 ; 0.03 ; 0.04],'ExerciseDate',datetime([2022,3
```

```
Swaption=3×1 object
  3x1 Swaption array with properties:

    OptionType
    ExerciseStyle
    ExerciseDate
    Strike
    Swap
    Name
```

Create SABR Model Object

Use `finmodel` to create a SABR model object.

```
SabrModel = finmodel("SABR",'Alpha',0.032,'Beta',0.04,'Rho',.08,'Nu',0.49,'Shift',0.002)
```

```
SabrModel =
  SABR with properties:

             Alpha: 0.0320
              Beta: 0.0400
               Rho: 0.0800
                Nu: 0.4900
             Shift: 0.0020
    VolatilityType: "black"
```

Create SABR Pricer Object

Use `finpricer` to create a SABR pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'Model',SabrModel,'DiscountCurve',myRC)
```

```
outPricer =
  SABR with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.SABR]
```

Price Swaption Instruments

Use `price` to compute the prices for the `Swaption` instruments.

```
Price = price(outPricer,Swaption)
```

```
Price = 3×1

   10.8558
    9.0442
    7.4883
```

Price Swaption Instrument Using Black Model and Black Pricer

This example shows the workflow to price a `Swaption` instrument when you use a `Black` model and a `Black` pricing method.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
```

```
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                 Type: "zero"
          Compounding: -1
                Basis: 0
                Dates: [10x1 datetime]
                Rates: [10x1 double]
               Settle: 15-Sep-2018
         InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create Swap Instrument Object

Use `fininstrument` to create the underlying `Swap` instrument object.

```
Swap = fininstrument("Swap",'Maturity',datetime(2027,3,15),'LegRate',[0 0],'LegType',...
    ["float","fixed"],'Notional',100,'StartDate',datetime(2022,3,15),'Name',"swap_instrument")
```

```
Swap =
  Swap with properties:

                    LegRate: [0 0]
                    LegType: ["float"    "fixed"]
                      Reset: [2 2]
                      Basis: [0 0]
                   Notional: 100
          LatestFloatingRate: [NaN NaN]
                ResetOffset: [0 0]
    DaycountAdjustedCashFlow: [0 0]
             ProjectionCurve: [0x0 ratecurve]
       BusinessDayConvention: ["actual"    "actual"]
                    Holidays: NaT
                EndMonthRule: [1 1]
                   StartDate: 15-Mar-2022
                    Maturity: 15-Mar-2027
                        Name: "swap_instrument"
```

Create Swaption Instrument Object

Use `fininstrument` to create a `Swaption` instrument object.

```
Swaption = fininstrument("Swaption",'Strike',0.02,'ExerciseDate',datetime(2022,3,15),'Swap',Swap
```

```
Swaption =
  Swaption with properties:

       OptionType: "call"
    ExerciseStyle: "european"
     ExerciseDate: 15-Mar-2022
           Strike: 0.0200
             Swap: [1x1 fininstrument.Swap]
```

```
              Name: "swaption_option"
```

Create Black Model Object

Use `finmodel` to create a `Black` model object.

```
BlackModel = finmodel("Black",'Volatility',0.032,'Shift',0.002)
```

```
BlackModel =
  Black with properties:

    Volatility: 0.0320
         Shift: 0.0020
```

Create Black Pricer Object

Use `finpricer` to create a `Black` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'Model',BlackModel,'DiscountCurve',myRC)
```

```
outPricer =
  Black with properties:

            Model: [1x1 finmodel.Black]
    DiscountCurve: [1x1 ratecurve]
```

Price Swaption Instrument

Use `price` to compute the price for the `Swaption` instrument.

```
Price = price(outPricer,Swaption)
```

```
Price = 3.3116
```

Price Swaption Instrument Using Hull-White Model and IRTree Pricer

This example shows the workflow to price a `Swaption` instrument when you use a `HullWhite` model and an `IRTree` pricing method.

Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:
```

```
                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create Swap Instrument Object

Use `fininstrument` to create the underlying `Swap` instrument object.

```
Swap = fininstrument("Swap",'Maturity',datetime(2027,3,15),'LegRate',[0 0],'LegType',...
    ["float","fixed"],'Notional',100,'StartDate',datetime(2022,3,15),'Name',"swap_instrument")
```

```
Swap =
  Swap with properties:

                    LegRate: [0 0]
                    LegType: ["float"    "fixed"]
                      Reset: [2 2]
                      Basis: [0 0]
                   Notional: 100
         LatestFloatingRate: [NaN NaN]
                ResetOffset: [0 0]
    DaycountAdjustedCashFlow: [0 0]
             ProjectionCurve: [0x0 ratecurve]
       BusinessDayConvention: ["actual"    "actual"]
                   Holidays: NaT
               EndMonthRule: [1 1]
                  StartDate: 15-Mar-2022
                   Maturity: 15-Mar-2027
                       Name: "swap_instrument"
```

Create Swaption Instrument Object

Use `fininstrument` to create a `Swaption` instrument object.

```
Swaption = fininstrument("Swaption",'Strike',0.02,'ExerciseDate',datetime(2022,3,15),'Swap',Swap
```

```
Swaption =
  Swaption with properties:

       OptionType: "call"
    ExerciseStyle: "european"
     ExerciseDate: 15-Mar-2022
           Strike: 0.0200
             Swap: [1x1 fininstrument.Swap]
             Name: "swaption_option"
```

Create HullWhite Model Object

Use `finmodel` to create a `HullWhite` model object.

```
HullWhiteModel = finmodel("HullWhite",'Alpha',0.032,'Sigma',0.04)

HullWhiteModel =
  HullWhite with properties:

    Alpha: 0.0320
    Sigma: 0.0400
```

Create IRTree Pricer Object

Use `finpricer` to create an `IRTree` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("IRTree",'Model',HullWhiteModel,'DiscountCurve',myRC,'TreeDates',ZeroDates)

outPricer =
  HWBKTree with properties:

             Tree: [1x1 struct]
        TreeDates: [10x1 datetime]
            Model: [1x1 finmodel.HullWhite]
    DiscountCurve: [1x1 ratecurve]
```

Price Swaption Instrument

Use `price` to compute the price and sensitivities for the `Swaption` instrument.

```
[Price, outPR] = price(outPricer,Swaption,["all"])

Price = 14.6783

outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: [1x1 struct]

outPR.Results

ans=1×4 table
    Price     Delta      Gamma     Vega
    ______    ______    _______    _____

    14.678    142.29    -2263.2    321.8
```

Price Swaption Instrument Using LinearGaussian2F Model and IRMonteCarlo Pricer

This example shows the workflow to price a `Swaption` instrument when using a `LinearGaussian2F` model and an `IRMonteCarlo` pricing method.

Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2019,1,1);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 01-Jan-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create Swap Instrument Object

Use `fininstrument` to create the underlying `Swap` instrument object.

```
Swap = fininstrument("Swap",'Maturity',datetime(2022,1,1),'LegRate',[0.05,0.04],'Name',"swap_inst
```

```
Swap =
  Swap with properties:

                    LegRate: [0.0500 0.0400]
                    LegType: ["fixed"    "float"]
                      Reset: [2 2]
                      Basis: [0 0]
                   Notional: 100
          LatestFloatingRate: [NaN NaN]
                 ResetOffset: [0 0]
    DaycountAdjustedCashFlow: [0 0]
             ProjectionCurve: [0x0 ratecurve]
       BusinessDayConvention: ["actual"    "actual"]
                   Holidays: NaT
                EndMonthRule: [1 1]
                   StartDate: NaT
                    Maturity: 01-Jan-2022
                        Name: "swap_instrument"
```

Create Swaption Instrument Object

Use `fininstrument` to create a `Swaption` instrument object.

```
Swaption = fininstrument("Swaption",'Strike',0.02,'ExerciseDate',datetime(2021,7,1),'Swap',Swap,
```

```
Swaption =
  Swaption with properties:

       OptionType: "call"
    ExerciseStyle: "european"
```

```
     ExerciseDate: 01-Jul-2021
           Strike: 0.0200
             Swap: [1x1 fininstrument.Swap]
             Name: "swaption_option"
```

Create LinearGaussian2F Model Object

Use `finmodel` to create a `LinearGaussian2F` model object.

```
LinearGaussian2FModel = finmodel("LinearGaussian2F",'Alpha1',0.07,'Sigma1',0.01,'Alpha2',0.5,'Sig
```

```
LinearGaussian2FModel =
  LinearGaussian2F with properties:

         Alpha1: 0.0700
         Sigma1: 0.0100
         Alpha2: 0.5000
         Sigma2: 0.0060
    Correlation: -0.7000
```

Create IRMonteCarlo Pricer Object

Use `finpricer` to create an `IRMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
simDates = datetime(2019,7,1)+calmonths(0:6:30);
outPricer = finpricer("IRMonteCarlo",'Model',LinearGaussian2FModel,'DiscountCurve',myRC,'Simulati
```

```
outPricer =
  G2PPMonteCarlo with properties:

          NumTrials: 1000
      RandomNumbers: []
      DiscountCurve: [1x1 ratecurve]
    SimulationDates: [01-Jul-2019    01-Jan-2020    01-Jul-2020    ...    ]
              Model: [1x1 finmodel.LinearGaussian2F]
```

Price Swaption Instrument

Use `price` to compute the price and sensitivities for the `Swaption` instrument.

```
[Price,outPR] = price(outPricer,Swaption,["all"])
```

```
Price = 1.5065

outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×4 table
    Price     Delta     Gamma           Vega
```

```
    ______    ______    ______    _________________

    1.5065    44.746    -257.2    1.6729    -2.0015
```

Calibrate Shifted SABR Model Parameters for Swaption Instrument

Calibrate model parameters for a `Swaption` instrument when you use a SABR pricing method.

Load Market Data

```
% Zero curve
ValuationDate = datetime("5-Mar-2016", 'Locale', 'en_US');
ZeroDates = datemnth(ValuationDate,[1 2 3 6 9 12*[1 2 3 4 5 6 7 8 9 10 12]])';
ZeroRates = [-0.33 -0.28 -0.24 -0.12 -0.08 -0.03 0.015 0.028 ...
    0.033 0.042 0.056 0.095 0.194 0.299 0.415 0.525]'/100;
Compounding = 1;
ZeroCurve = ratecurve("zero",ValuationDate,ZeroDates,ZeroRates,'Compounding',Compounding)
```

```
ZeroCurve =
  ratecurve with properties:

                Type: "zero"
         Compounding: 1
               Basis: 0
               Dates: [16x1 datetime]
               Rates: [16x1 double]
              Settle: 05-Mar-2016
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

```
% Define the swaptions
SwaptionSettle = datetime("5-Mar-2016", 'Locale', 'en_US');
SwaptionExerciseDate = datetime("5-Mar-2017", 'Locale', 'en_US');
SwaptionStrikes = (-0.6:0.01:1.6)'/100; % Include negative strikes
SwapMaturity = datetime("5-Mar-2022", 'Locale', 'en_US'); % Maturity of underlying swap
OptSpec = 'call';
```

Compute Forward Swap Rate by Creating Swap Instrument

Use `fininstrument` to create a `Swap` instrument object.

```
LegRate = [0 0];
Swap = fininstrument("Swap", 'Maturity', SwapMaturity, 'LegRate', LegRate, "LegType",["fixed" "f
    "ProjectionCurve", ZeroCurve, "StartDate", SwaptionExerciseDate)
```

```
Swap =
  Swap with properties:

                   LegRate: [0 0]
                   LegType: ["fixed"    "float"]
                     Reset: [2 2]
                     Basis: [0 0]

         LatestFloatingRate: [NaN NaN]
```

```
              ResetOffset: [0 0]
    DaycountAdjustedCashFlow: [0 0]
             ProjectionCurve: [1x2 ratecurve]
       BusinessDayConvention: ["actual"    "actual"]
                    Holidays: NaT
                EndMonthRule: [1 1]
                   StartDate: 05-Mar-2017
                    Maturity: 05-Mar-2022
                        Name: ""
```

```
ForwardValue = parswaprate(Swap,ZeroCurve)
```

```
ForwardValue = 7.3271e-04
```

Load the Market Implied Volatility Data

The market swaption volatilities are quoted in terms of shifted Black volatilities with a `0.8` percent shift.

```
StrikeGrid = [-0.5; -0.25; -0.125; 0; 0.125; 0.25; 0.5; 1.0; 1.5]/100;
MarketStrikes = ForwardValue + StrikeGrid;
Shift = 0.008;  % 0.8 percent shift
MarketShiftedBlackVolatilities = [21.1; 15.3; 14.0; 14.6; 16.0; 17.7; 19.8; 23.9; 26.2]/100;
ATMShiftedBlackVolatility = MarketShiftedBlackVolatilities(StrikeGrid==0);
```

Calibrate Shifted SABR Model Parameters

The `Beta` parameter is predetermined at `0.5`. Use `volatilities` to compute the implied volatility.

```
Beta = 0.5;

% Calibrate Alpha, Rho, and Nu
objFun = @(X) MarketShiftedBlackVolatilities - volatilities(finpricer("Analytic", 'Model', ...
    finmodel("SABR", 'Alpha', X(1), 'Beta', Beta, 'Rho', X(2), 'Nu', X(3), 'Shift', Shift), ...
    'DiscountCurve', ZeroCurve), SwaptionExerciseDate, ForwardValue, MarketStrikes);

X = lsqnonlin(objFun, [0.5 0 0.5], [0 -1 0], [Inf 1 Inf]);

Local minimum possible.

lsqnonlin stopped because the final change in the sum of squares relative to
its initial value is less than the value of the function tolerance.

Alpha = X(1);
Rho = X(2);
Nu = X(3);
```

Create SABR Model Using the Calibrated Parameters

Use `finmodel` to create a SABR model object.

```
SABRModel = finmodel("SABR",'Alpha',Alpha,'Beta',Beta,'Rho',Rho,'Nu',Nu,'Shift',Shift)
```

```
SABRModel =
  SABR with properties:

             Alpha: 0.0135
```

```
             Beta: 0.5000
              Rho: 0.4654
               Nu: 0.4957
            Shift: 0.0080
    VolatilityType: "black"
```

Create SABR Pricer Using Calibrated SABR Model and Compute Volatilities

Use `finpricer` to create a SABR pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
SABRPricer = finpricer("Analytic", 'Model', SABRModel, 'DiscountCurve', ZeroCurve)
```

```
SABRPricer =
  SABR with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.SABR]
```

```
SABRShiftedBlackVolatilities = volatilities(SABRPricer, SwaptionExerciseDate, ForwardValue, Swapt
```

```
SABRShiftedBlackVolatilities = 221×1

    0.2978
    0.2911
    0.2848
    0.2787
    0.2729
    0.2673
    0.2620
    0.2568
    0.2518
    0.2470
      ⋮
```

```

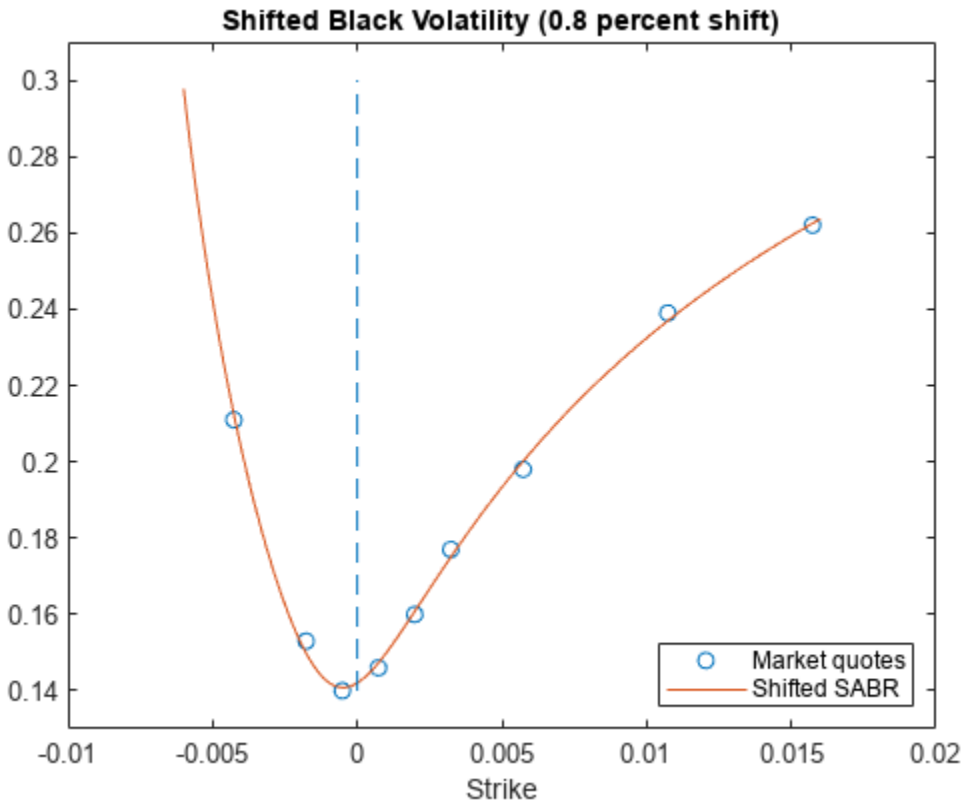
plot(MarketStrikes, MarketShiftedBlackVolatilities, 'o', ...
    SwaptionStrikes, SABRShiftedBlackVolatilities);
h = gca;
line([0,0],[min(h.YLim),max(h.YLim)],'LineStyle','--');
ylim([0.13 0.31])
xlabel('Strike');
legend('Market quotes','Shifted SABR', 'location', 'southeast');
title (['Shifted Black Volatility (',num2str(Shift*100),' percent shift)']);
```



Price Swaption Instruments Using Calibrated SABR Model and SABR Pricer

```
% Create swaption instruments
NumInst = length(SwaptionStrikes);
Swaptions(NumInst, 1) = fininstrument("Swaption", ...
    'Strike', SwaptionStrikes(1), 'ExerciseDate', SwaptionExerciseDate(1), 'Swap', Swap);
for k = 1:NumInst
    Swaptions(k) = fininstrument("Swaption", 'Strike', SwaptionStrikes(k), ...
        'ExerciseDate', SwaptionExerciseDate, 'Swap', Swap, 'OptionType', OptSpec);
end
Swaptions
```

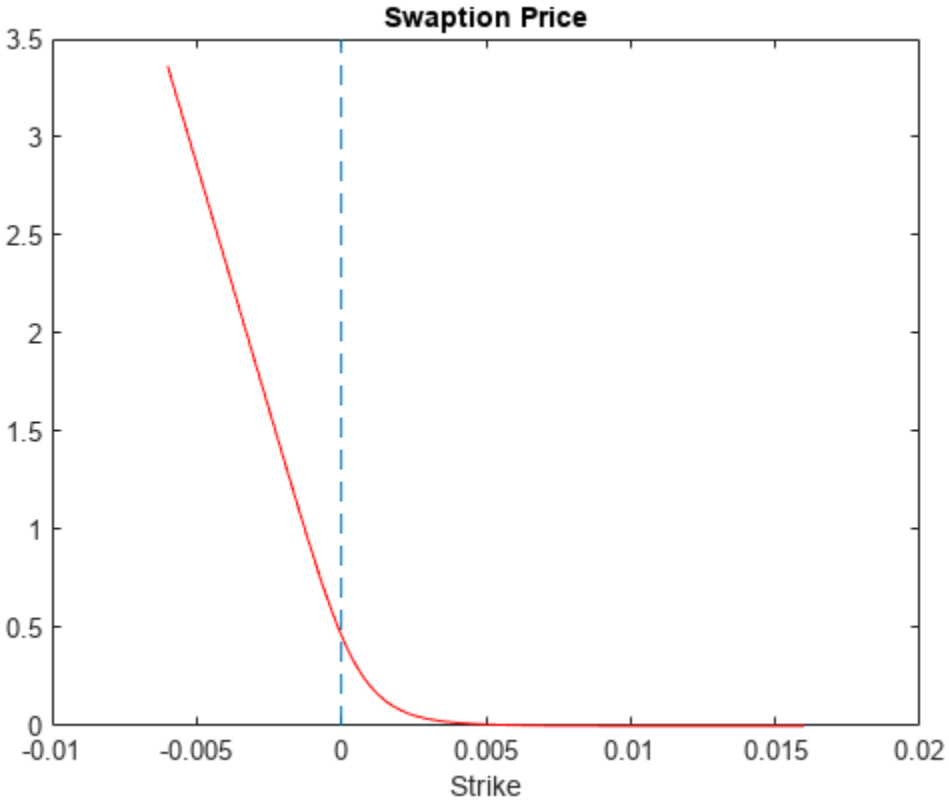
```
Swaptions=221×1 object
  16x1 Swaption array with properties:

    OptionType
    ExerciseStyle
    ExerciseDate
    Strike
    Swap
    Name
      ⋮
```

```
% Price swaptions using the SABR pricer
SwaptionPrices = price(SABRPricer,Swaptions);

figure;
```

```
plot(SwaptionStrikes, SwaptionPrices, 'r');
h = gca;
line([0,0],[min(h.YLim),max(h.YLim)],'LineStyle','--');
xlabel('Strike');
title ('Swaption Price');
```



More About

Call Swaption

A call swaption or payer swaption allows the option buyer to enter into an interest-rate swap in which the buyer of the option pays the fixed rate and receives the floating rate.

Put Swaption

A put swaption or receiver swaption allows the option buyer to enter into an interest-rate swap in which the buyer of the option receives the fixed rate and pays the floating rate.

Version History

Introduced in R2020a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `Swaption` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

Vanilla

`Vanilla` instrument object

Description

Create and price a `Vanilla` instrument object for one or more Vanilla instruments using this workflow:

1. Use `fininstrument` to create a `Vanilla` instrument object for one or more Vanilla instruments.
2. Use `finmodel` to specify a `BlackScholes`, `Bachelier`, `Heston`, `Bates`, `Merton`, or `Dupire` model for the `Vanilla` instrument object.
3. Choose a pricing method.
   - When using a `BlackScholes` model, use `finpricer` to specify a `FiniteDifference`, `BlackScholes`, `BjerksundStensland`, `RollGeskeWhaley`, `VannaVolga`, `AssetTree`, or `AssetMonteCarlo` pricing method for one or more `Vanilla` instruments.
   - When using a `Heston`, `Bates`, or `Merton` model, use `finpricer` to specify a `FiniteDifference`, `NumericalIntegration`, `FFT`, or `AssetMonteCarlo` pricing method for one or more `Vanilla` instruments.
   - When using a `Dupire` model, use `finpricer` to specify a `FiniteDifference` pricing method for one or more `Vanilla` instruments.
   - When using a `Bachelier` model, use `finpricer` to specify an `AssetMonteCarlo` pricing method for one or more `Vanilla` instruments.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a `Vanilla` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
VanillaObj = fininstrument(InstrumentType,'Strike',strike_value,'
ExerciseDate',exercise_date)
VanillaObj = fininstrument( ___ ,Name,Value)
```

Description

`VanillaObj = fininstrument(InstrumentType,'Strike',strike_value,'ExerciseDate',exercise_date)` creates a `Vanilla` object for one or more Vanilla instruments by specifying `InstrumentType` and sets the properties on page 11-2968 for the required name-value pair arguments `Strike` and `ExerciseDate`. For more information on a `Vanilla` instrument, see “More About” on page 11-2991.

`VanillaObj = fininstrument( ___ ,Name,Value)` sets optional properties on page 11-2968 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `VanillaObj = fininstrument("Vanilla",'Strike',100,'ExerciseDate',datetime(2019,1,30),'OptionType',"put",'ExerciseStyle',"American",'Name',"vanilla_instrument")` creates a `Vanilla` put option with an American exercise. You can specify multiple name-value pair arguments.

Input Arguments

`InstrumentType` — Instrument type

string with value `"Vanilla"` | string array with values of `"Vanilla"` | character vector with value `'Vanilla'` | cell array of character vectors with values of `'Vanilla'`

Instrument type, specified as a string with the value of `"Vanilla"`, a character vector with the value of `'Vanilla'`, an `NINST`-by-`1` string array with values of `"Vanilla"`, or an `NINST`-by-`1` cell array of character vectors with values of `'Vanilla'`.

Data Types: `char` | `cell` | `string`

`Vanilla` Name-Value Pair Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `VanillaObj = fininstrument("Vanilla",'Strike',100,'ExerciseDate',datetime(2019,1,30),'OptionType',"put",'ExerciseStyle',"American",'Name',"vanilla_instrument")`

Required Vanilla Name-Value Pair Arguments

`Strike` — Option strike price value

nonnegative numeric | nonnegative numeric vector

Option strike price value, specified as the comma-separated pair consisting of `'Strike'` and a scalar nonnegative numeric value or an `NINST`-by-`1` nonnegative numeric vector.

Note When using a `"Bermudan"` `ExerciseStyle` with a `FiniteDifference` pricer, the `Strike` is a vector.

Data Types: `double`

`ExerciseDate` — Option exercise date

datetime array | string array | date character vector

Option exercise date, specified as the comma-separated pair consisting of `'ExerciseDate'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

Note For a European option, there is only one `ExerciseDate` on the option expiry date.

When using a `"Bermudan"` `ExerciseStyle` with a `FiniteDifference` pricer, the `ExerciseDate` is a vector.

To support existing code, `Vanilla` also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `ExerciseDate` property is stored as a datetime.

Optional Vanilla Name-Value Pair Arguments

`OptionType` — Option type
`"call"` (default) | string with value `"call"` or `"put"` | string array with values of `"call"` or `"put"` | character vector with value `'call'` or `'put'` | cell array of character vectors with values of `'call'` or `'put'`

Option type, specified as the comma-separated pair consisting of `'OptionType'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Note When you use a `RollGeskeWhaley` pricer with a `Vanilla` option, `OptionType` must be `'call'`.

Data Types: `char` | `cell` | `string`

`ExerciseStyle` — Option exercise style
`"European"` (default) | string with value `"European"`, `"American"`, or `"Bermudan"` | string array with values of `"European"`, `"American"`, or `"Bermudan"` | character vector with value `'European'`, `'American'`, or `'Bermudan'` | cell array of character vectors with values of `'European'`, `'American'`, or `'Bermudan'`

Option exercise style, specified as the comma-separated pair consisting of `'ExerciseStyle'` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Note

- When you use a `BlackScholes` pricer with a `Vanilla` option, the `'American'` option type is not supported.
- When you use a `RollGeskeWhaley` or a `BjerksundStensland` pricer with a `Vanilla` option, you must specify an `'American'` option.
- When you use a `NumericalIntegration` pricer with a `Bates`, `Merton`, or `Heston` model for a `Vanilla` option, the `ExerciseStyle` must be `'European'`.
- When you use a `FFT` pricer with a `Bates`, `Merton`, or `Heston` model for a `Vanilla` option, the `ExerciseStyle` must be `'European'`.
- When you use an `AssetMonteCarlo` pricer with a `BlackScholes`, `Bates`, `Merton`, or `Heston` model for a `Vanilla` option, the `ExerciseStyle` can be `'American'`, `'European'`, or `'Bermudan'`.
- When you use a `FiniteDifference` pricer with a `BlackScholes`, `Bachelier`, `Dupire`, `Bates`, `Merton`, or `Heston` model for a `Vanilla` option, the `ExerciseStyle` can be `'American'`, `'European'`, or `'Bermudan'`.

For more information on `ExerciseStyle`, see “Supported Exercise Styles” on page 1-62.

Data Types: `string` | `cell` | `char`

Name — User-defined name for instrument
" " (default) | string | string array | character vector | cell array of character vectors

User-defined name for one of more instruments, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector or an NINST-by-1 cell array of character vectors or string array.

Data Types: char | cell | string

Properties

Strike — Option strike price value
nonnegative numeric | nonnegative numeric vector

Option strike price value, returned as a scalar nonnegative numeric or an NINST-by-1 nonnegative numeric vector.

Data Types: double

ExerciseDate — Option exercise date
datetime | vector of datetimes

Option exercise date, returned as a scalar datetime or an NINST-by-1 vector of datetimes.

Data Types: datetime

OptionType — Option type
"call" (default) | string with value "call" or "put" | string array with values of "call" or "put"

Option type, returned as a scalar string or an NINST-by-1 string array with values of "call" or "put".

Data Types: string

ExerciseStyle — Option type
"European" (default) | string with value "European", "American", or "Bermudan" | string array with values of "European", "American", or "Bermudan"

Option exercise style, returned as a scalar string or an NINST-by-1 string array with values of "European", "American", or "Bermudan".

Data Types: string

Name — User-defined name for instrument
" " (default) | string | string array

User-defined name for the instrument, returned as a scalar string or an NINST-by-1 string array.

Data Types: string

Object Functions

setExercisePolicy Set exercise policy for FixedBondOption, FloatBondOption, or Vanilla instrument

Examples

Price Vanilla Instrument Using Black-Scholes Model and Black-Scholes Pricer

This example shows the workflow to price a `Vanilla` instrument when you use a `BlackScholes` model and a `BlackScholes` pricing method.

Create `Vanilla` Instrument Object

Use `fininstrument` to create a `Vanilla` instrument object.

```
VanillaOpt = fininstrument("Vanilla",'ExerciseDate',datetime(2018,5,1),'Strike',29,'OptionType','
```

```
VanillaOpt =
  Vanilla with properties:

       OptionType: "put"
    ExerciseStyle: "european"
     ExerciseDate: 01-May-2018
           Strike: 29
             Name: "vanilla_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.25)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.2500
    Correlation: 1
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,1,1);
Maturity = datetime(2019,1,1);
Rate = 0.05;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',1)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
       Compounding: -1
             Basis: 1
             Dates: 01-Jan-2019
             Rates: 0.0500
            Settle: 01-Jan-2018
      InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create BlackScholes Pricer Object

Use `finpricer` to create a `BlackScholes` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'DiscountCurve',myRC,'Model',BlackScholesModel,'SpotPrice',30,'D
```

```
outPricer =
  BlackScholes with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 30
    DividendValue: 0.0450
     DividendType: "continuous"
```

Price Vanilla Instrument

Use `price` to compute the price and sensitivities for the `Vanilla` instrument.

```
[Price, outPR] = price(outPricer,VanillaOpt,["all"])
```

```
Price = 1.2046
```

```
outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta       Gamma      Lambda      Vega       Rho       Theta
    ______    ________    ________    _______    ______    _______    _______

    1.2046    -0.36943    0.086269    -9.3396    6.4702    -4.0959    -2.3107
```

Price Multiple Vanilla Instruments Using Black-Scholes Model and Black-Scholes Pricer

This example shows the workflow to price multiple `Vanilla` instrument when you use a `BlackScholes` model and a `BlackScholes` pricing method.

Create Vanilla Instrument Object

Use `fininstrument` to create a `Vanilla` instrument object for three Vanilla instruments.

```
VanillaOpt = fininstrument("Vanilla",'ExerciseDate',datetime([2018,5,1 ; 2018,6,1 ; 2018,7,1]),'S
```

```
VanillaOpt=3×1 object
  3x1 Vanilla array with properties:

    OptionType
    ExerciseStyle
```

```
    ExerciseDate
    Strike
    Name
```

Create BlackScholes Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.25)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.2500
    Correlation: 1
```

Create ratecurve Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,1,1);
Maturity = datetime(2019,1,1);
Rate = 0.05;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',1)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 1
               Dates: 01-Jan-2019
               Rates: 0.0500
              Settle: 01-Jan-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create BlackScholes Pricer Object

Use `finpricer` to create a `BlackScholes` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'DiscountCurve',myRC,'Model',BlackScholesModel,'SpotPrice',30,'D
```

```
outPricer =
  BlackScholes with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 30
    DividendValue: 0.0450
     DividendType: "continuous"
```

Price Vanilla Instruments

Use `price` to compute the prices and sensitivities for the `Vanilla` instruments.

```
[Price, outPR] = price(outPricer,VanillaOpt,["all"])
```

```
Price = 3×1

    1.2046
    7.9479
   38.9392

outPR=3×1 object
  3x1 priceresult array with properties:

    Results
    PricerData
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta       Gamma      Lambda      Vega       Rho       Theta

```

Price Vanilla Instrument Using Black-Scholes Model and Asset Tree Pricer for LR Binomial Tree

This example shows the workflow to price a `Vanilla` instrument when you use a `BlackScholes` model and an `AssetTree` pricing method using a Leisen-Reimer (LR) binomial tree.

Create Vanilla Instrument Object

Use `fininstrument` to create a `Vanilla` instrument object.

```
VanillaOpt = fininstrument("Vanilla",'ExerciseDate',datetime(2018,5,1),'Strike',29,'OptionType','
```

```
VanillaOpt =
  Vanilla with properties:
```

```
       OptionType: "put"
    ExerciseStyle: "european"
     ExerciseDate: 01-May-2018
           Strike: 29
             Name: "vanilla_option"
```

Create BlackScholes Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.25)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.2500
    Correlation: 1
```

Create ratecurve Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,1,1);
Maturity = datetime(2019,1,1);
Rate = 0.05;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',1)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 1
               Dates: 01-Jan-2019
               Rates: 0.0500
              Settle: 01-Jan-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create AssetTree Pricer Object

Use `finpricer` to create an `AssetTree` pricer object for a LR equity tree and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
NumPeriods = 15;
LRPricer = finpricer("AssetTree",'DiscountCurve',myRC,'Model',BlackScholesModel,'SpotPrice',50,'
```

```
LRPricer =
  LRTree with properties:

    InversionMethod: PP1
             Strike: 50
               Tree: [1x1 struct]
        NumPeriods: 15
```

```

Price Vanilla Instrument Using Black-Scholes Model and Asset Tree Pricer for Standard Trinomial Tree

This example shows the workflow to price a `Vanilla` instrument when you use a `BlackScholes` model and an `AssetTree` pricing method using a Standard Trinomial (STT) tree.

Create `Vanilla` Instrument Object

Use `fininstrument` to create a `Vanilla` instrument object.

```
VanillaOpt = fininstrument("Vanilla",'ExerciseDate',datetime(2018,5,1),'Strike',29,'OptionType','
```

```
VanillaOpt =
  Vanilla with properties:

       OptionType: "put"
    ExerciseStyle: "european"
     ExerciseDate: 01-May-2018
           Strike: 29
             Name: "vanilla_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.25)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.2500
    Correlation: 1
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,1,1);
Maturity = datetime(2019,1,1);
```

```
Rate = 0.05;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',1)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 1
               Dates: 01-Jan-2019
               Rates: 0.0500
              Settle: 01-Jan-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create AssetTree Pricer Object

Use `finpricer` to create an `AssetTree` pricer object for a Standard Trinomial (STT) equity tree and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
NumPeriods = 15;
STTPricer = finpricer("AssetTree",'DiscountCurve',myRC,'Model',BlackScholesModel,'SpotPrice',50,
```

```
STTPricer =
  STTree with properties:

            Tree: [1x1 struct]
       NumPeriods: 15
            Model: [1x1 finmodel.BlackScholes]
    DiscountCurve: [1x1 ratecurve]
        SpotPrice: 50
     DividendType: "continuous"
    DividendValue: 0
        TreeDates: [09-Jan-2018    17-Jan-2018    25-Jan-2018    ...    ]
```

```
STTPricer.Tree
```

```
ans = struct with fields:
    ATree: {1x16 cell}
    Probs: {1x15 cell}
     dObs: [01-Jan-2018    09-Jan-2018    17-Jan-2018    ...    ]
     tObs: [0 0.0222 0.0444 0.0667 0.0889 0.1111 0.1333 0.1556 0.1778 ... ]
```

Price Vanilla Instrument

Use `price` to compute the price and sensitivities for the `Vanilla` instrument.

```
[Price, outPR] = price(STTPricer,VanillaOpt,["all"])
```

```
Price = 6.3773e-05
```

```
outPR =
  priceresult with properties:

       Results: [1x7 table]
```

```
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×7 table
      Price          Delta          Gamma          Vega       Lambda         Rho           Theta
    __________    ___________    __________    _________    _______    ___________    _________

    ExTree: {1x16 cell}
      tObs: [0 0.0222 0.0444 0.0667 0.0889 0.1111 0.1333 0.1556 0.1778 ... ]
      dObs: [01-Jan-2018    09-Jan-2018    17-Jan-2018    ...    ]
     Probs: {1x15 cell}
```

```
outPR.PricerData.PriceTree.ExTree
```

```
ans=1×16 cell array
  Columns 1 through 4

    {[0]}    {[0 0 0]}    {[0 0 0 0 0]}    {[0 0 0 0 0 0 0]}

  Columns 5 through 7

    {[0 0 0 0 0 0 0 0 0]}    {[0 0 0 0 0 0 ... ]}    {[0 0 0 0 0 0 ... ]}

  Columns 8 through 10

    {[0 0 0 0 0 0 ... ]}    {[0 0 0 0 0 0 ... ]}    {[0 0 0 0 0 0 ... ]}

  Columns 11 through 13

    {[0 0 0 0 0 0 ... ]}    {[0 0 0 0 0 0 ... ]}    {[0 0 0 0 0 0 ... ]}

  Columns 14 through 16

    {[0 0 0 0 0 0 ... ]}    {[0 0 0 0 0 0 ... ]}    {[0 0 0 0 0 0 ... ]}
```

Price American Option for Vanilla Instrument Using Black-Scholes Model and Roll-Geske-Whaley Pricer

This example shows the workflow to price an American option for a `Vanilla` instrument when you use a `BlackScholes` model and a `RollGeskeWhaley` pricing method.

Create `Vanilla` Instrument Object

Use `fininstrument` to create a `Vanilla` instrument object.

```
VanillaOpt = fininstrument("Vanilla",'Strike',105,'ExerciseDate',datetime(2022,9,15),'OptionType
```

```
VanillaOpt =
  Vanilla with properties:

       OptionType: "call"
    ExerciseStyle: "american"
     ExerciseDate: 15-Sep-2022
           Strike: 105
             Name: "vanilla_option"
```

Create BlackScholes Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes","Volatility",0.2)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.2000
    Correlation: 1
```

Create ratecurve Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create RollGeskeWhaley Pricer Object

Use `finpricer` to create a `RollGeskeWhaley` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPrice',100,
```

```
outPricer =
  RollGeskeWhaley with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 100
```

```
    DividendValue: [1x1 timetable]
     DividendType: "cash"
```

Price Vanilla Instrument

Use `price` to compute the price and sensitivities for the `Vanilla` instrument.

```
[Price, outPR] = price(outPricer,VanillaOpt,["all"])
```

```
Price = 19.9066

outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta       Gamma       Lambda     Vega      Theta      Rho
    _____    ________    _________    ______    ______    _______    _____

    19.907    0.66568    0.0090971    3.344     72.804    -3.4537    186.68
```

Price a Vanilla Instrument for Foreign Exchange Using Black-Scholes Model and Black-Scholes Pricer

This example shows the workflow to price a `Vanilla` instrument for foreign exchange (FX) when you use a `BlackScholes` model and a `BlackScholes` pricing method. Assume that the current exchange rate is $0.52 and has a volatility of 12% per annum. The annualized continuously compounded foreign risk-free rate is 8% per annum.

Create Vanilla Instrument Object

Use `fininstrument` to create a `Vanilla` instrument object.

```
VanillaOpt = fininstrument("Vanilla",'ExerciseDate',datetime(2022,9,15),'Strike',.50,'OptionType
```

```
VanillaOpt =
  Vanilla with properties:

       OptionType: "put"
    ExerciseStyle: "european"
     ExerciseDate: 15-Sep-2022
           Strike: 0.5000
             Name: "vanilla_fx_option"
```

Create BlackScholes Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
Sigma = .12;
BlackScholesModel = finmodel("BlackScholes","Volatility",Sigma)

BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.1200
    Correlation: 1
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)

myRC =
  ratecurve with properties:

                Type: "zero"
        Compounding: -1
              Basis: 12
              Dates: 15-Sep-2023
              Rates: 0.0350
             Settle: 15-Sep-2018
       InterpMethod: "linear"
   ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

Create `BlackScholes` Pricer Object

Use `finpricer` to create a `BlackScholes` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument. When pricing currencies using a `Vanilla` instrument, the `DividendType` must be `'continuous'` and `DividendValue` is the annualized risk-free interest rate in the foreign country.

```
ForeignRate = 0.08;
outPricer = finpricer("analytic",'DiscountCurve',myRC,'Model',BlackScholesModel,'SpotPrice',.52,

outPricer =
  BlackScholes with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 0.5200
    DividendValue: 0.0800
     DividendType: "continuous"
```

Price `Vanilla` FX Instrument

Use `price` to compute the price and sensitivities for the `Vanilla` FX instrument.

```
[Price, outPR] = price(outPricer,VanillaOpt,["all"])
```

```
Price = 0.0738

outPR =
  priceresult with properties:

      Results: [1x7 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×7 table
     Price       Delta       Gamma      Lambda       Vega         Rho         Theta
    ________    ________    _______    ________    ________    ________    _________

    0.073778    -0.49349    2.0818     -4.7899     0.27021     -1.3216     -0.013019
```

Price American Option for Vanilla Instrument Using Black-Scholes Model and Asset Monte-Carlo Pricer

This example shows the workflow to price an American option for a `Vanilla` instrument when you use a `BlackScholes` model and an `AssetMonteCarlo` pricing method.

Create `Vanilla` Instrument Object

Use `fininstrument` to create a `Vanilla` instrument object.

```
VanillaOpt = fininstrument("Vanilla",'Strike',105,'ExerciseDate',datetime(2022,9,15),'OptionType
```

```
VanillaOpt =
  Vanilla with properties:

      OptionType: "call"
    ExerciseStyle: "american"
     ExerciseDate: 15-Sep-2022
           Strike: 105
             Name: "vanilla_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes","Volatility",0.2)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.2000
    Correlation: 1
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `AssetMonteCarlo` Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo",'DiscountCurve',myRC,"Model",BlackScholesModel,'SpotPrice
```

```
outPricer =
  GBMMonteCarlo with properties:

     DiscountCurve: [1x1 ratecurve]
         SpotPrice: 150
    SimulationDates: 15-Sep-2022
         NumTrials: 1000
     RandomNumbers: []
             Model: [1x1 finmodel.BlackScholes]
      DividendType: "continuous"
     DividendValue: 0
```

Price `Vanilla` Instrument

Use `price` to compute the price and sensitivities for the `Vanilla` instrument.

```
[Price, outPR] = price(outPricer,VanillaOpt,["all"])
```

```
Price = 61.2010

outPR =
  priceresult with properties:

      Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta       Gamma      Lambda     Rho       Theta      Vega
    ______    _______    _________    ______    ______    _______    ______
```

```
    61.201    0.93074    0.0027813    2.2812    313.95    -3.7909    41.626
```

Price American Option for Vanilla Instrument Using Heston Model and Asset Monte-Carlo Pricer

This example shows the workflow to price an American option for a `Vanilla` instrument when you use a `Heston` model and an `AssetMonteCarlo` pricing method.

Create `Vanilla` Instrument Object

Use `fininstrument` to create a `Vanilla` instrument object.

```
VanillaOpt = fininstrument("Vanilla",'Strike',105,'ExerciseDate',datetime(2022,9,15),'OptionType
```

```
VanillaOpt =
  Vanilla with properties:

       OptionType: "call"
    ExerciseStyle: "american"
     ExerciseDate: 15-Sep-2022
           Strike: 105
             Name: "vanilla_option"
```

Create `Heston` Model Object

Use `finmodel` to create a `Heston` model object.

```
HestonModel = finmodel("Heston",'V0',0.032,'ThetaV',0.07,'Kappa',0.003,'SigmaV',0.02,'RhoSV',0.09
```

```
HestonModel =
  Heston with properties:

         V0: 0.0320
    ThetaV: 0.0700
     Kappa: 0.0030
    SigmaV: 0.0200
     RhoSV: 0.0900
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
        Compounding: -1
              Basis: 12
```

```
                Dates: 15-Sep-2023
                Rates: 0.0350
               Settle: 15-Sep-2018
         InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create AssetMonteCarlo Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo",'DiscountCurve',myRC,"Model",HestonModel,'SpotPrice',150,
```

```
outPricer =
  HestonMonteCarlo with properties:

      DiscountCurve: [1x1 ratecurve]
          SpotPrice: 150
    SimulationDates: 15-Sep-2022
          NumTrials: 1000
      RandomNumbers: []
              Model: [1x1 finmodel.Heston]
       DividendType: "continuous"
      DividendValue: 0
```

Price Vanilla Instrument

Use `price` to compute the price and sensitivities for the `Vanilla` instrument.

```
[Price, outPR] = price(outPricer,VanillaOpt,["all"])
```

```
Price = 60.5637
```

```
outPR =
  priceresult with properties:

       Results: [1x8 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×8 table
    Price      Delta       Gamma       Lambda     Rho       Theta      Vega     VegaLT

    60.564    0.94774    0.0011954    2.3473    326.36    -3.7126    35.272    0.31155
```

Price Bermudan Option for Vanilla Instrument Using Black-Scholes Model and Finite Difference Pricer

This example shows the workflow to price a Bermudan option for a `Vanilla` instrument when you use a `BlackScholes` model and a `FiniteDifference` pricing method.

Create `Vanilla` Instrument Object

Use `fininstrument` to create a `Vanilla` instrument object.

```
VanillaOpt = fininstrument("Vanilla",'Strike',[110,120],'ExerciseDate',[datetime(2022,9,15) , dat
```

```
VanillaOpt =
  Vanilla with properties:

       OptionType: "call"
    ExerciseStyle: "bermudan"
     ExerciseDate: [15-Sep-2022    15-Sep-2023]
           Strike: [110 120]
             Name: "vanilla_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes","Volatility",0.2)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.2000
    Correlation: 1
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
       Compounding: -1
             Basis: 12
             Dates: 15-Sep-2023
             Rates: 0.0350
            Settle: 15-Sep-2018
      InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `FiniteDifference` Pricer Object

Use `finpricer` to create a `FiniteDifference` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("FiniteDifference",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPric
```

```
outPricer =
  FiniteDifference with properties:

     DiscountCurve: [1x1 ratecurve]
             Model: [1x1 finmodel.BlackScholes]
         SpotPrice: 100
    GridProperties: [1x1 struct]
      DividendType: "continuous"
     DividendValue: 0
```

Price `Vanilla` Instrument

Use `price` to compute the price and sensitivities for the `Vanilla` instrument.

```
[Price, outPR] = price(outPricer,VanillaOpt,["all"])
```

```
Price = 18.6797
```

```
outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×7 table
    Price     Delta       Gamma       Lambda     Theta      Rho       Vega
    _____    _______    _________    ______    _______    ______    ______

    18.68    0.62163    0.0091406    3.3278    -3.3154    184.31    83.162
```

Price Vanilla Instrument Using Heston Model and Multiple Different Pricers

This example shows the workflow to price a `Vanilla` instrument when you use a `Heston` model and various pricing methods.

Create `Vanilla` Instrument Object

Use `fininstrument` to create a `Vanilla` instrument object.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle,6);
Strike = 80;
VanillaOpt = fininstrument('Vanilla','ExerciseDate',Maturity,'Strike',Strike,'Name',"vanilla_opti
```

```
VanillaOpt =
  Vanilla with properties:

       OptionType: "call"
    ExerciseStyle: "european"
     ExerciseDate: 29-Dec-2017
           Strike: 80
             Name: "vanilla_option"
```

Create Heston Model Object

Use finmodel to create a Heston model object.

```
V0 = 0.04;
ThetaV = 0.05;
Kappa = 1.0;
SigmaV = 0.2;
RhoSV = -0.7;

HestonModel = finmodel("Heston",'V0',V0,'ThetaV',ThetaV,'Kappa',Kappa,'SigmaV',SigmaV,'RhoSV',Rho
```

```
HestonModel =
  Heston with properties:

        V0: 0.0400
    ThetaV: 0.0500
     Kappa: 1
    SigmaV: 0.2000
     RhoSV: -0.7000
```

Create ratecurve object

Create a ratecurve object using ratecurve.

```
Rate = 0.03;
ZeroCurve = ratecurve('zero',Settle,Maturity,Rate);
```

Create NumericalIntegration, FFT, and FiniteDifference Pricer Objects

Use finpricer to create a NumericalIntegration, FFT, and FiniteDifference pricer objects and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
SpotPrice = 80;
Strike = 80;
DividendYield = 0.02;

NIPricer = finpricer("NumericalIntegration",'Model', HestonModel,'SpotPrice',SpotPrice,'DiscountC
```

```
NIPricer =
  NumericalIntegration with properties:

               Model: [1x1 finmodel.Heston]
       DiscountCurve: [1x1 ratecurve]
           SpotPrice: 80
        DividendType: "continuous"
       DividendValue: 0.0200
              AbsTol: 1.0000e-10
              RelTol: 1.0000e-10
    IntegrationRange: [1.0000e-09 Inf]
   CharacteristicFcn: @characteristicFcnHeston
           Framework: "heston1993"
      VolRiskPremium: 0
          LittleTrap: 1
```

```
FFTPricer = finpricer("FFT",'Model',HestonModel, ...
    'SpotPrice',SpotPrice,'DiscountCurve',ZeroCurve, ...
    'DividendValue',DividendYield,'NumFFT',8192)

FFTPricer =
  FFT with properties:

                    Model: [1x1 finmodel.Heston]
            DiscountCurve: [1x1 ratecurve]
                SpotPrice: 80
             DividendType: "continuous"
            DividendValue: 0.0200
                   NumFFT: 8192
    CharacteristicFcnStep: 0.0100
            LogStrikeStep: 0.0767
        CharacteristicFcn: @characteristicFcnHeston
            DampingFactor: 1.5000
               Quadrature: "simpson"
          VolRiskPremium: 0
               LittleTrap: 1

FDPricer = finpricer("FiniteDifference",'Model',HestonModel,'SpotPrice',SpotPrice,'DiscountCurve

FDPricer =
  FiniteDifference with properties:

     DiscountCurve: [1x1 ratecurve]
             Model: [1x1 finmodel.Heston]
         SpotPrice: 80
    GridProperties: [1x1 struct]
      DividendType: "continuous"
     DividendValue: 0.0200
```

Price `Vanilla` Instrument

Use the following sensitivities when pricing the `Vanilla` instrument.

```
InpSensitivity = ["delta", "gamma", "theta", "rho", "vega", "vegalt"];
```

Use `price` to compute the price and sensitivities for the `Vanilla` instrument that uses the `NumericalIntegration` pricer.

```
[PriceNI,  outPR_NI]  = price(NIPricer,VanillaOpt,InpSensitivity)

PriceNI = 4.7007

outPR_NI =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: []
```

Use `price` to compute the price and sensitivities for the `Vanilla` instrument that uses the `FFT` pricer.

```
[PriceFFT, outPR_FFT] = price(FFTPricer,VanillaOpt,InpSensitivity)
```

```
PriceFFT = 4.7007

outPR_FFT =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: []
```

Use `price` to compute the price and sensitivities for the `Vanilla` instrument that uses the `FiniteDifference` pricer.

```
[PriceFD,  outPR_FD]  = price(FDPricer,VanillaOpt,InpSensitivity)

PriceFD = 4.7003

outPR_FD =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: [1x1 struct]
```

Aggregate the price results.

```
[outPR_NI.Results;outPR_FFT.Results;outPR_FD.Results]

ans=3×7 table
    Price      Delta      Gamma       Theta      Rho       Vega      VegaLT
    ______    _______    ________    _______    ______    ______    ______

    4.7007    0.57747     0.03392    -4.8474    20.805    17.028    5.2394
    4.7007    0.57747     0.03392    -4.8474    20.805    17.028    5.2394
    4.7003    0.57722    0.035254    -4.8483    20.801    17.046    5.2422
```

Compute Option Price Surfaces

Use the `price` function for the `NumericalIntegration` pricer and the `price` function for the `FFT` pricer to compute the prices for a range of `Vanilla` instruments.

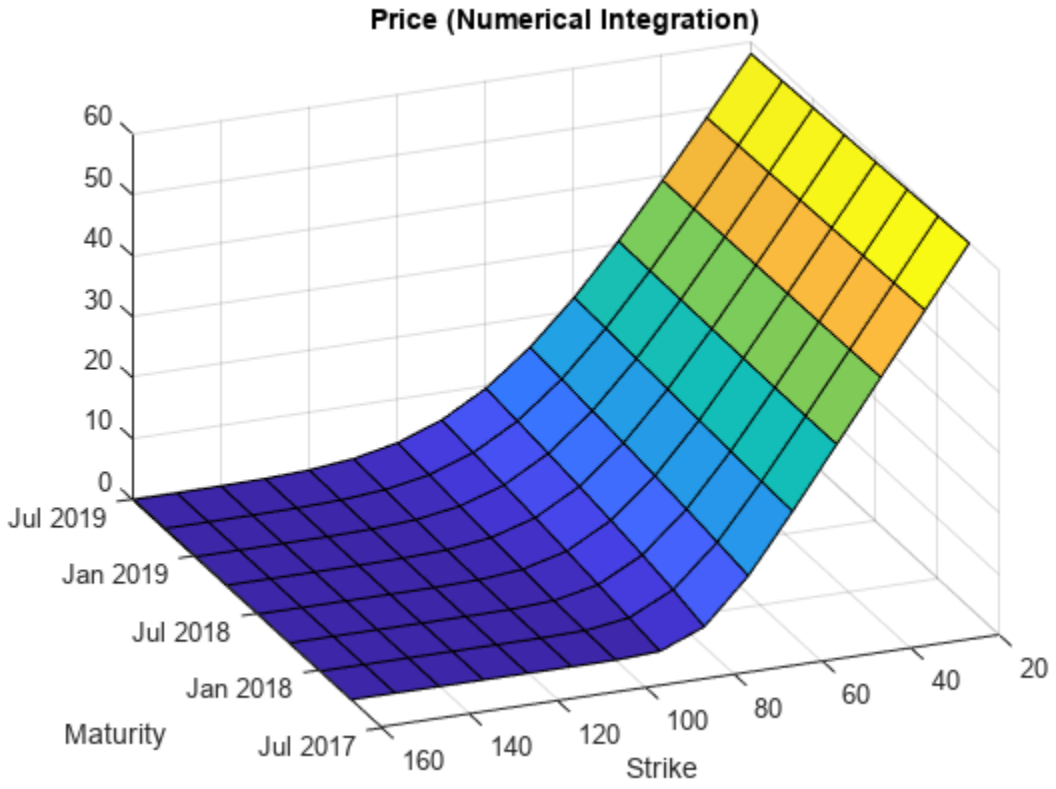
```
Maturities = datemnth(Settle,(3:3:24)');
NumMaturities = length(Maturities);
Strikes = (20:10:160)';
NumStrikes = length(Strikes);

[Maturities_Full,Strikes_Full] = meshgrid(Maturities,Strikes);

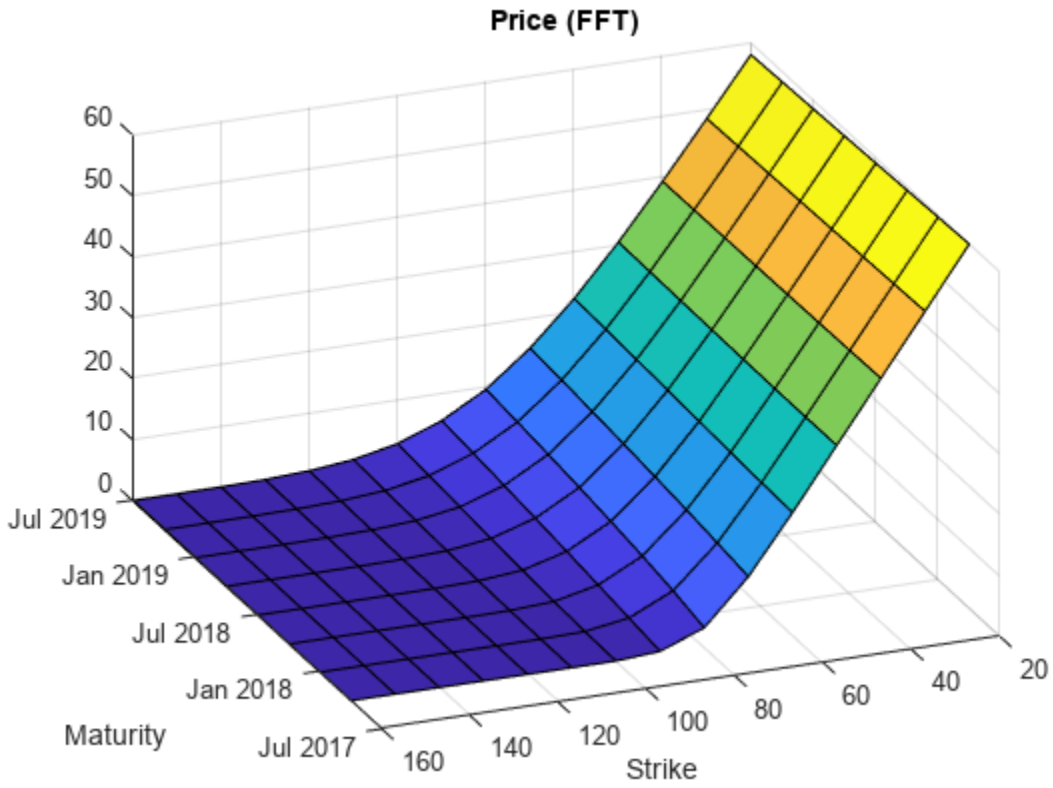
NumInst = numel(Strikes_Full);
VanillaOptions(NumInst, 1) = fininstrument("vanilla",...
    "ExerciseDate", Maturities_Full(1), "Strike", Strikes_Full(1));
for instidx=1:NumInst
    VanillaOptions(instidx) = fininstrument("vanilla",...
        "ExerciseDate", Maturities_Full(instidx), "Strike", Strikes_Full(instidx));
end

Prices_NI = price(NIPricer, VanillaOptions);
Prices_FFT = price(FFTPricer, VanillaOptions);
```

```
figure;
surf(Maturities_Full,Strikes_Full,reshape(Prices_NI,[NumStrikes,NumMaturities]));
title('Price (Numerical Integration)');
view(-112,34);
xlabel('Maturity')
ylabel('Strike')
```



```
figure;
surf(Maturities_Full,Strikes_Full,reshape(Prices_FFT,[NumStrikes,NumMaturities]));
title('Price (FFT)');
view(-112,34);
xlabel('Maturity')
ylabel('Strike')
```



More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

For more information, see “Vanilla Option” on page 3-27.

Tips

After creating a `Vanilla` instrument object, you can use `setExercisePolicy` to change the size of the options. For example, if you have the following instrument:

```
VanillaOpt = fininstrument("Vanilla",'ExerciseDate',datetime(2021,5,1),'Strike',29,'OptionType','
```

To modify the `Vanilla` instrument's size by changing the `ExerciseStyle` from `"European"` to `"American"`, use `setExercisePolicy`:

```
VanillaOpt = setExercisePolicy(VanillaOpt,[datetime(2021,1,1) datetime(2022,1,1)],100,'American')
```

Version History

Introduced in R2020a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `Vanilla` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

Deposit

`Deposit` instrument object

Description

Create and price a `Deposit` instrument object for one or more Deposit instruments using this workflow:

1. Use `fininstrument` to create a `Deposit` instrument object for one or more Deposit instruments.
2. Use `ratecurve` to specify an interest-rate model for the `Deposit` instrument object.
3. Use `finpricer` to specify a `Discount` pricing method for one or more `Deposit` instruments.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a `Deposit` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
DepositObj = fininstrument(InstrumentType,'Maturity',maturity_date,'
Rate',rate_value)
DepositObj = fininstrument( ___ ,Name,Value)
```

Description

`DepositObj = fininstrument(InstrumentType,'Maturity',maturity_date,'Rate',rate_value)` creates a `Deposit` object for one or more Deposit instruments by specifying `InstrumentType` and sets the properties on page 11-2996 for the required name-value pair arguments `Maturity` and `Rate`.

`DepositObj = fininstrument( ___ ,Name,Value)` sets optional properties on page 11-2996 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `DepositObj = fininstrument("Deposit",'Maturity',datetime(2019,1,30),'Rate',0.027,'Period',2,'Basis',1,'Principal',100,'BusinessDayConvention',"follow",'Name',"deposit_instrument")` creates a `Deposit` instrument with an interest rate of .027 and a maturity of January 30, 2019. You can specify multiple name-value pair arguments.

Input Arguments

`InstrumentType` — Instrument type

string with value `"Deposit"` | string array with values of `"Deposit"` | character vector with value `'Deposit'` | cell array of character vectors with values of `'Deposit'`

Instrument type, specified as a string with the value of "Deposit", a character vector with the value of 'Deposit', an NINST-by-1 string array with values of "Deposit", or an NINST-by-1 cell array of character vectors with values of 'Deposit'.

Data Types: char | string

Deposit Name-Value Pair Arguments

Specify required and optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: DepositObj = fininstrument("Deposit",'Maturity',datetime(2019,1,30),'Rate',0.027,'Period',2,'Basis',1,'Principal',100,'BusinessDayConvention',"follow",'Name',"deposit_instrument")

Required Deposit Name-Value Pair Arguments

Maturity — Maturity date
datetime array | string array | date character vector

Maturity date, specified as the comma-separated pair consisting of 'Maturity' and a scalar or an NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, Deposit also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by datetime because the Maturity property is stored as a datetime.

Rate — Deposit interest rate
scalar decimal | vector of decimals

Deposit interest rate, specified as the comma-separated pair consisting of 'Rate' and a scalar decimal or an NINST-by-1 vector of decimals.

Data Types: double

Optional Deposit Name-Value Pair Arguments

Period — Frequency of payments per year
1 (default) | scalar numeric value of 0, 1, 2, 3, 4, 6, or 12 | vector of numeric values of 0, 1, 2, 3, 4, 6, or 12

Frequency of payments per year, specified as the comma-separated pair consisting of 'Period' and scalar integer or an NINST-by-1 vector of integers. Values for Period are: 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

Basis — Day count basis
0 (actual/actual) (default) | scalar integer from 0 to 13 | vector of integers from 0 to 13

Day count basis, specified as the comma-separated pair consisting of 'Basis' and a scalar integer or an NINST-by-1 vector of integers using the following values:

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Principal amount
`100` (default) | scalar numeric | numeric vector

Principal amount, specified as the comma-separated pair consisting of `'Principal'` and a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`BusinessDayConvention` — Business day convention
`"actual"` (default) | string | string array | character vector | cell array of character vectors

Business day convention, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and a string or character vector or an `NINST`-by-`1` cell array of character vectors or string array. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- `"actual"` — Nonbusiness days are effectively ignored. Cash flows that fall on nonbusiness days are assumed to be distributed on the actual date.
- `"follow"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- `"modifiedfollow"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `"previous"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- `"modifiedprevious"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: char | cell | string

Holidays — Holidays used in computing business days
NaT (default) | datetime array | string array | date character vector

Holidays used in computing business days, specified as the comma-separated pair consisting of 'Holidays' and dates using an NINST-by-1 vector of a datetime array, string array, or date character vectors. For example:

```
H = holidays(datetime('today'),datetime(2025,12,15));
DepositObj = fininstrument("deposit",'Maturity',datetime(2025,12,15),'Rate',0.027,'Holidays',H)
```

To support existing code, Deposit also accepts serial date numbers as inputs, but they are not recommended.

Name — User-defined name for instrument
" " (default) | string | string array | character vector | cell array of character vectors

User-defined name for one of more instruments, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector or an NINST-by-1 cell array of character vectors or string array.

Data Types: char | cell | string

Properties

Maturity — Maturity date
datetime | vector of datetimes

Maturity date, returned as a scalar datetime or an NINST-by-1 vector of datetimes.

Data Types: datetime

Rate — Deposit interest rate
scalar decimal | vector of decimals

Deposit interest rate, returned as a scalar decimal or an NINST-by-1 vector of decimals.

Data Types: double

Period — Frequency of payments per year
1 (default) | scalar integer | vector of integers

Frequency of payments per year, returned as a scalar integer or an NINST-by-1 vector of integers.

Data Types: double

Basis — Day count basis
0 (actual/actual) (default) | scalar integer from 0 to 13 | vector of integers from 0 to 13

Day count basis, returned as a scalar integer or an NINST-by-1 vector of integers.

Data Types: double

Principal — Principal amount
100 (default) | scalar numeric | numeric vector

Principal amount, returned as a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`BusinessDayConvention` — Business day convention
`"actual"` (default) | scalar string | string array

Business day convention, returned as a scalar string or an `NINST`-by-`1` string array.

Data Types: `string`

`Holidays` — Holidays used in computing business days
`NaT` (default) | datetimes

Holidays used in computing business days, returned as an `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`Name` — User-defined name for instrument
`" "` (default) | string | string array

User-defined name for the instrument, returned as a scalar string or an `NINST`-by-`1` string array.

Data Types: `string`

Object Functions

Examples

Price Deposit Instrument Using `ratecurve` and Discount Pricer

This example shows the workflow to price a `Deposit` instrument when using a `ratecurve` and a `Discount` pricing method.

Create `Deposit` Instrument Object

Use `fininstrument` to create a `Deposit` instrument object.

```
DepositObj = fininstrument("Deposit",'Maturity',datetime(2019,3,15),'Rate',0.0195,'Period',2,'Bas
```

```
DepositObj =
  Deposit with properties:

                     Rate: 0.0195
                   Period: 2
                    Basis: 1
                 Maturity: 15-Mar-2019
                Principal: 100
    BusinessDayConvention: "actual"
                 Holidays: NaT
                     Name: "deposit_instrument"
```

Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2018
        InterpMethod: "linear"
   ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

Create Discount Pricer Object

Use finpricer to create a Discount pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("Discount", 'DiscountCurve',myRC)
```

```
outPricer =
  Discount with properties:

    DiscountCurve: [1x1 ratecurve]
```

Price Deposit Instrument

Use price to compute the price and sensitivities for the Deposit instrument.

```
[Price, outPR] = price(outPricer, DepositObj,["all"])
```

```
Price = 0.9725

outPR =
  priceresult with properties:

      Results: [1x2 table]
   PricerData: []
```

```
outPR.Results
```

```
ans=1×2 table
     Price        DV01
    _______    __________
```

```
    0.97249    4.8225e-05
```

Price Multiple Deposit Instruments Using `ratecurve` and Discount Pricer

This example shows the workflow to price multiple `Deposit` instruments when using a `ratecurve` and a `Discount` pricing method.

Create `Deposit` Instrument Object

Use `fininstrument` to create a `Deposit` instrument object for three Deposit instruments.

```
DepositObj = fininstrument("Deposit",'Maturity',datetime([2019,3,15 ; 2019,4,15 ; 2019,5,15]),'Ra
```

```
DepositObj=3×1 object
  3x1 Deposit array with properties:

    Rate
    Period
    Basis
    Maturity
    Principal
    BusinessDayConvention
    Holidays
    Name
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
        Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `Discount` Pricer Object

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("Discount", 'DiscountCurve',myRC)
```

```
outPricer =
  Discount with properties:

    DiscountCurve: [1x1 ratecurve]
```

Price `Deposit` Instruments

Use `price` to compute the prices and sensitivities for the `Deposit` instruments.

```
[Price, outPR] = price(outPricer, DepositObj,["all"])
```

```
Price = 3×1

    9.7249
   22.6807
   38.8632

outPR=1×3 object
  1x3 priceresult array with properties:

    Results
    PricerData
```

```
outPR.Results
```

```
ans=1×2 table
    Price        DV01
    ______    __________

    9.7249    0.00048225

ans=1×2 table
    Price       DV01
    ______    _________

    22.681    0.0013173

ans=1×2 table
    Price       DV01
    ______    _________
```

```
    38.863    0.0025767
```

More About

Deposit Instrument

A deposit instrument is an over-the-counter contract between banks for interbank lending.

Version History

Introduced in R2020a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `Deposit` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

“Choose Instruments, Models, and Pricers” on page 1-53

BondFuture

`BondFuture` instrument object

Description

Create and price a `BondFuture` instrument object for one or more Bond Future instruments using this workflow:

1. Use `fininstrument` to create a `BondFuture` instrument object for one or more Bond Future instruments.
2. Use `ratecurve` to specify a curve model for the `BondFuture` instrument object.
3. Use `finpricer` to specify a `Future` pricing method for one or more `BondFuture` instruments.
4. Use `cashsettle` to compute the cash settlement for the `BondFuture` instrument and `fairdelivery` to compute the fair delivery price for the underlying asset for the `BondFuture` instrument.

For more detailed information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a `BondFuture` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
BondFutureObj = fininstrument(InstrumentType,Maturity=maturity_value,
QuotedPrice=quoted_price,Bond=underlying_bond,
ConversionFactor=conversion_factor)
BondFutureObj = fininstrument( ___ ,Name=Value)
```

Description

`BondFutureObj = fininstrument(InstrumentType,Maturity=maturity_value, QuotedPrice=quoted_price,Bond=underlying_bond, ConversionFactor=conversion_factor)` creates a `BondFuture` object for one or more Bond Future instruments by specifying `InstrumentType` and sets the properties on page 11-3004 for the required name-value pair arguments `Maturity`, `QuotedPrice`, `Bond`, and `ConversionFactor`.

The `BondFuture` instrument supports bond futures such as Treasury bond futures, Eurobond futures, Japanese Government Bond (JGB) futures. For more information, see “Bond Futures” on page 11-3009

You can use bond futures for interest-rate futures and forwards. The main difference between forward and futures contracts:

- Forward contracts are private contracts between two parties, while futures contracts are more standardized and are traded on an exchange.
- Futures contracts are marked-to-market with corresponding settlement cash flows occurring on every trading day, while forward contract cash flows and deliveries do not occur until the maturity of the forward contract.

`BondFutureObj = fininstrument( ___ ,Name=Value)` sets optional properties on page 11-3004 using additional name-value arguments in addition to the required arguments in the previous syntax. For example, `BondFutureObj = fininstrument("BondFuture",Maturity=datetime(2022,9,1),QuotedPrice=86,Bond=myFixedBond,ConversionFactor=1.43,Name="bondfuture_instrument")` creates a `BondFuture` instrument. You can specify multiple name-value arguments.

Input Arguments

`InstrumentType` — Instrument type

string with value `"BondFuture"` | string array with values of `"BondFuture"` | character vector with value `'BondFuture'` | cell array of character vectors with values of `'BondFuture'`

Instrument type, specified as a string with the value of `"BondFuture"`, a character vector with the value of `'BondFuture'`, an `NINST`-by-`1` string array with values of `"BondFuture"`, or an `NINST`-by-`1` cell array of character vectors with values of `'BondFuture'`.

Data Types: `char` | `cell` | `string`

`BondFuture` Name-Value Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `BondFutureObj = fininstrument("BondFuture",Maturity=datetime(2022,9,1),QuotedPrice=86,SpotPrice=125,Bond=myFixedBond,ConversionFactor=1.43,Name="bondfuture_instrument")`

Required `BondFuture` Name-Value Arguments

`Maturity` — `BondFuture` maturity date

datetime array | string array | date character vector

`BondFuture` maturity date, specified as `Maturity` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array,or date character vectors.

To support existing code, `BondFuture` also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `Maturity` property is stored as a datetime.

`QuotedPrice` — `BondFuture` quoted price

scalar numeric | numeric vector

`BondFuture` quoted price, specified as `QuotedPrice` and a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

Bond — Underlying FixedBond instrument
FixedBond object | vector of FixedBond objects

Underlying FixedBond instrument, specified as a scalar FixedBond object or an NINST-by-1 vector of FixedBond objects.

Data Types: object

ConversionFactor — Conversion factor for underlying Bond
scalar numeric | numeric vector

Conversion factor for underlying Bond, specified as a scalar numeric or an NINST-by-1 numeric vector.

Data Types: double

Optional BondFuture Name-Value Arguments

Notional — Notional value
100000 (default) | scalar numeric | numeric vector

Notional value, specified as a scalar numeric or an NINST-by-1 vector.

Data Types: double

Name — User-defined name for instrument
" " (default) | string | string array | character vector | cell array of character vectors

User-defined name for one or more instruments, specified as Name and a scalar string, character vector, or an NINST-by-1 cell array of character vectors, or a string array.

Data Types: char | cell | string

Properties

Maturity — BondFuture maturity date
scalar datetime | vector of datetimes

BondFuture maturity date, returned as a scalar datetime or NINST-by-1 vector of datetimes.

Data Types: datetime

QuotedPrice — BondFuture quoted price
scalar numeric | numeric vector

BondFuture quoted price, returned as a scalar numeric or an NINST-by-1 numeric vector.

Data Types: double

Bond — Underlying FixedBond instrument
FixedBond object

Underlying FixedBond instrument, returned as a scalar FixedBond object or an NINST-by-1 vector of FixedBond objects.

Data Types: object

`ConversionFactor` — Conversion factor for underlying `Bond`

scalar numeric

Conversion factor for underlying `Bond`, returned as a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`Notional` — Notional value

`100000` (default) | scalar numeric | numeric vector

Notional value, returned as a scalar numeric or an `NINST`-by-`1` vector.

Data Types: `double`

`Name` — User-defined name for instrument

`""` (default) | string | string array

User-defined name for the instrument, returned as a scalar string or an `NINST`-by-`1` string array.

Data Types: `string`

Object Functions

cashsettle	Compute cash settlement for BondFuture, CommodityFuture, EquityIndexFuture, or FXFuture instrument
fairdelivery	Compute fair delivery price of underlying asset for BondFuture, CommodityFuture, EquityIndexFuture, or FXFuture instrument

Examples

Price `BondFuture` Instrument Using `ratecurve` and `Future` Pricer

This example shows the workflow to price a `BondFuture` instrument when you use a `ratecurve` object and a `Future` pricing method.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2022,3,1);
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates,Compounding=2);
```

Create Underlying `FixedBond` Instrument Object

Use `fininstrument` to create a `FixedBond` instrument object.

```
FixB = fininstrument("FixedBond",Maturity=datetime(2032,9,1),CouponRate=0.05,Name="fixed_bond_ins
```

```
FixB =
  FixedBond with properties:

                 CouponRate: 0.0500
```

```
                    Period: 2
                     Basis: 0
                EndMonthRule: 1
                   Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                    Holidays: NaT
                   IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 01-Sep-2032
                        Name: "fixed_bond_instrument"
```

Create BondFuture Instrument Object

Use `fininstrument` to create a `BondFuture` instrument object.

```
BondFut = fininstrument("BondFuture",Maturity=datetime(2022,9,1),QuotedPrice=86,Bond=FixB,Convers
```

```
BondFut =
  BondFuture with properties:

            Maturity: 01-Sep-2022
         QuotedPrice: 86
                Bond: [1x1 fininstrument.FixedBond]
    ConversionFactor: 1.4300
            Notional: 100000
                Name: "bondfuture_instrument"
```

Create Future Pricer Object

Use `finpricer` to create a `Future` pricer object and use the `ratecurve` object with the `DiscountCurve` name-value argument.

```
outPricer = finpricer("Future",DiscountCurve=ZeroCurve,SpotPrice=125)
```

```
outPricer =
  Future with properties:

    DiscountCurve: [1x1 ratecurve]
        SpotPrice: 125
```

Price BondFuture Instrument

Use `price` to compute the price and price result for the `BondFuture` instrument.

```
[Price,outPR] = price(outPricer,BondFut)
```

```
Price = -151.9270
```

```
outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×4 table
     Price     FairDeliveryPrice    FairFuturePrice    AccruedInterest
    _______    _________________    _______________    _______________

    -151.93       1.2283e+05            85.893                0
```

Price Multiple BondFuture Instruments Using ratecurve and Future Pricer

This example shows the workflow to price multiple `BondFuture` instruments when you use a `ratecurve` object and a `Future` pricing method.

Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2022,3,1);
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates,Compounding=2);
```

Create Underlying FixedBond Instrument Object

Use `fininstrument` to create a `FixedBond` instrument object.

```
FixB = fininstrument("FixedBond",Maturity=datetime(2032,9,1),CouponRate=0.05,Name="fixed_bond_ins
```

```
FixB =
  FixedBond with properties:

                 CouponRate: 0.0500
                     Period: 2
                      Basis: 0
                EndMonthRule: 1
                   Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                    Holidays: NaT
                   IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 01-Sep-2032
                        Name: "fixed_bond_instrument"
```

Create BondFuture Instrument Object

Use `fininstrument` to create a `BondFuture` instrument object for three Bond Future instruments.

```
BondFut = fininstrument("BondFuture",Maturity=datetime([2022,9,1 ; 2022,10,1 ; 2022,11,1]),Quote
```

```
BondFut=3×1 object
  3x1 BondFuture array with properties:
```

```
    Maturity
    QuotedPrice
    Bond
    ConversionFactor
    Notional
    Name
```

Create Future Pricer Object

Use `finpricer` to create a `Future` pricer object and use the `ratecurve` object with the `DiscountCurve` name-value argument.

```
outPricer = finpricer("Future",DiscountCurve=ZeroCurve,SpotPrice=125)
```

```
outPricer =
  Future with properties:

    DiscountCurve: [1x1 ratecurve]
        SpotPrice: 125
```

Price BondFuture Instruments

Use `price` to compute the prices and price results for the `BondFuture` instruments.

```
[Price,outPR] = price(outPricer,BondFut)
```

```
Price = 3×1
10^3 ×

   -0.1519
   -3.3603
   -6.5765

outPR=1×3 object
  1x3 priceresult array with properties:

    Results
    PricerData
```

```
outPR.Results
```

```
ans=1×4 table
     Price     FairDeliveryPrice    FairFuturePrice    AccruedInterest
    _______    _________________    _______________    _______________

    -151.93       1.2283e+05            85.893                0

ans=1×4 table
     Price     FairDeliveryPrice    FairFuturePrice    AccruedInterest
    _______    _________________    _______________    _______________

    -3360.3       1.2288e+05            85.643             0.41436
```

```
ans=1×4 table
     Price     FairDeliveryPrice    FairFuturePrice    AccruedInterest
    _______    _________________    _______________    _______________

    -6576.5       1.2294e+05            85.385             0.84254
```

More About

Bond Futures

A bond future is a financial derivatives that obligates the contract holder to purchase or sell a bond on a specified date at a predetermined price.

$$B_0 = (S_0 - I)/DiscountFactor$$

- B_0 — Full fair future cash price for $100 face value of deliverable bond
- S_0 — Full spot cash price for $100 face value of deliverable bond
- I — Present value of interest income for $100 face value for the life of the contract
- *DiscountFactor* — Discount factor to maturity of contract

$$FairFuturePrice = F_0 = (B_0 - AccruedInterest)/ConversionFactor$$
$$FairDeliveryPrice = B_0/100 \times Size$$

- F_0 — Clean fair future cash price for $100 face value
- B_0 — Full fair future cash price for $100 face value of the deliverable bond
- *ConversionFactor* — Conversion factor of the deliverable bond
- *AccruedInterest* — Accrued interest at delivery
- *Size* — Futures contract size

There are two workflows:

- The first workflow is to compute the discounted present value of the futures contract using `cashsettle` assuming it is held until maturity like a forward contract.

  $$f = (B_0 - K) \times DiscountFactor/100 \times Size$$

  - B_0 — Full fair future cash price for $100 face value of the delivery bond
  - K_0 — Full contractual delivery bond price for $100 face value of the deliverable bond
  - *DiscountFactor* — Discount factor to the maturity of the contract
  - *Size* — Futures contract size
- Since futures contracts are settled on every trading day, the second workflow is to use `fairdelivery` to compute the current fair delivery bond price B_0 of the futures contract, fair future price F_0, and the accrued interest to support marking to market.

  $$DelieveryBondPrice(B_0) = FairFuturePrice(F_0) \times ConversionFactor + AccruedInterest$$
  $$MarkToMarket = (ChangeinFuturePrice) \times (ContractSize)$$

  - B_0 — Full fair future cash price for $100 face value of the deliverable bond

- F_0 — Clean fair future price for $100 face value
- *ConversionFactor* — Conversion factor of the deliverable bond
- *AccruedInterest* — Accrued interest at delivery for $100 fave value

Version History

Introduced in R2022a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `BondFuture` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

“Choose Instruments, Models, and Pricers” on page 1-53

CommodityFuture

`CommodityFuture` instrument object

Description

Create and price a `CommodityFuture` instrument object for one or more Commodity Future instruments using this workflow:

1. Use `fininstrument` to create a `CommodityFuture` instrument object for one or more Commodity Future instruments.
2. Use `ratecurve` to specify a curve model for the `CommodityFuture` instrument object.
3. Use `finpricer` to specify a `Future` pricing method for one or more `CommodityFuture` instruments.
4. Use `cashsettle` to compute the cash settlement for the `CommodityFuture` instrument and `fairdelivery` to compute the fair delivery price for the underlying asset for the `CommodityFuture` instrument.

For more detailed information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a `CommodityFuture` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
CommodityFutureObj = fininstrument(InstrumentType,Maturity=maturity_value,
QuotedPrice=quoted_price)
CommodityFutureObj = fininstrument( ___ ,Name=Value)
```

Description

`CommodityFutureObj = fininstrument(InstrumentType,Maturity=maturity_value, QuotedPrice=quoted_price)` creates a `CommodityFuture` object for one of more Commodity Future instruments by specifying `InstrumentType` and sets the properties on page 11-3015 for the required name-value arguments `Maturity` and `QuotedPrice`.

You can use commodity futures for commodity futures and forwards. The main difference between forward and futures contracts:

- Forward contracts are private contracts between two parties, while futures contracts are more standardized and are traded on an exchange.
- Futures contracts are marked-to-market with corresponding settlement cash flows occurring on every trading day, while forward contract cash flows and deliveries do not occur until the maturity of the forward contract.

The CommodityFuture instrument supports oil, natural gas, gold, silver, and wheat, and other commodities. For more information, see “Commodity Future” on page 11-3019.

CommodityFutureObj = fininstrument(___ ,Name=Value) sets optional properties on page 11-3015 using additional name-value arguments in addition to the required arguments in the previous syntax. For example, CommodityFutureObj = fininstrument("CommodityFuture",Maturity=datetime(2022,9,1),QuotedPrice=68,StorageCost=1000,Income=500,PercentStorageCost=0.03,Name="commodity_future_instrument") creates a CommodityFuture. You can specify multiple name-value arguments.

Input Arguments

InstrumentType — Instrument type

string with value "CommodityFuture" | string array with values of "CommodityFuture" | character vector with value 'CommodityFuture' | cell array of character vectors with values of 'CommodityFuture'

Instrument type, specified as a string with the value of "CommodityFuture", a character vector with the value of 'CommodityFuture', an NINST-by-1 string array with values of "CommodityFuture", or an NINST-by-1 cell array of character vectors with values of 'CommodityFuture'.

Data Types: char | cell | string

CommodityFuture Name-Value Arguments

Specify required and optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: CommodityFutureObj = fininstrument("CommodityFuture",Maturity=datetime(2022,9,1), QuotedPrice=68,StorageCost=1000,Income=500,PercentStorageCost=0.03,Name="commodity_future_instrument")

Required CommodityFuture Name-Value Arguments

Maturity — CommodityFuture maturity date

datetime array | string array | date character vector

CommodityFuture maturity date, specified as Maturity and a scalar or an NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, CommodityFuture also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by datetime because the Maturity property is stored as a datetime.

QuotedPrice — CommodityFuture quoted price

scalar numeric | numeric vector

CommodityFuture quoted price, specified as QuotedPrice and a scalar numeric or an NINST-by-1 numeric vector.

Data Types: double

Optional CommodityFuture Name-Value Arguments

`StorageCost` — Present value of storage cost for life of contract
`0` (default) | scalar numeric | numeric vector

Present value of storage cost for the life of the contract, specified as `StorageCost` and a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`Income` — Present value of income for life of contract
`0` (default) | scalar numeric | numeric vector

Present value of income for the life of the contract, specified as `Income` and a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`PercentStorageCost` — Annualized percentage storage cost
`0` (default) | scalar decimal | vector of decimals

Annualized percentage storage cost, specified as `PercentStorageCost` and a scalar decimal or an `NINST`-by-`1` vector of decimals.

Data Types: `double`

`PercentStorageCostCompounding` — Compounding frequency for `PercentageStorageCost`
`-1` (continuous compounding) (default) | scalar integer with value of `-1`, `0`, `1`, `2`, `4`, `6`, or `12` | vector of integers with values `-1`, `0`, `1`, `2`, `4`, `6`, or `12`

Compounding frequency for `PercentageStorageCost`, specified as `PercentStorageCostCompounding` and a scalar integer or an `NINST`-by-`1` vector of integers.

Data Types: `double`

`PercentageStorageCostBasis` — Day count basis for `PercentStorageCost`
`0` (actual/actual) (default) | scalar integer from `0` to `13` | vector of integers from `0` to `13`

Day count basis for `PercentageStorageCost`, specified as `PercentageStorageCostBasis` and scalar integer or an `NINST`-by-`1` vector of integers using the following values:

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)

- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`ConvenienceYield` — Annualized convenience yield
`0` (default) | scalar decimal | vector of decimals

Annualized convenience yield, specified as `ConvenienceYield` and a scalar decimal or an `NINST`-by-`1` vector of decimals.

Data Types: `double`

`ConvenienceYieldCompounding` — Compounding frequency for `ConvenienceYield`
`1` (continuous compounding) (default) | scalar integer with value of `-1`, `0`, `1`, `2`, `4`, `6`, or `12` | vector of integers with values `-1`, `0`, `1`, `2`, `4`, `6`, or `12`

Compounding frequency for `ConvenienceYield`, specified as `ConvenienceYieldCompounding` and a scalar integer or an `NINST`-by-`1` vector of integers.

Data Types: `double`

`ConvenienceYieldBasis` — Day count basis for `ConvenienceYield`
`0` (actual/actual) (default) | scalar integer from `0` to `13` | vector of integers from `0` to `13`

Day count basis for `ConvenienceYield`, specified as `ConvenienceYieldBasis` and scalar integer or an `NINST`-by-`1` vector of integers using the following values:

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Name` — User-defined name for instrument
`""` (default) | string | string array | character vector | cell array of character vectors

User-defined name for one or more instruments, specified as `Name` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

Properties

`Maturity` — `CommodityFuture` maturity date
scalar datetime | vector of datetimes

`CommodityFuture` maturity date, returned as a scalar datetime or `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`QuotedPrice` — `CommodityFuture` quoted price
scalar numeric | numeric vector

`CommodityFuture` quoted price, returned as a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`StorageCost` — Present value of storage cost for life of contract
`0` (default) | scalar numeric | numeric vector

Present value of storage cost for the life of the contract, returned as a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`Income` — Present value of income for life of contract
`0` (default) | scalar numeric | numeric vector

Present value of income for the life of the contract, returned as an `NINST`-by-`1` numeric vector.

Data Types: `double`

`PercentStorageCost` — Annualized percentage storage cost
`0` (default) | scalar decimal | vector of decimals

Annualized percentage storage cost, returned as a scalar decimal or an `NINST`-by-`1` vector of decimals.

Data Types: `double`

`PercentStorageCostCompounding` — Compounding frequency for `PercentageStorageCost`
`-1` (continuous compounding) (default) | scalar integer with value of `-1`, `0`, `1`, `2`, `4`, `6`, or `12` | vector of integers with values `-1`, `0`, `1`, `2`, `4`, `6`, or `12`

Compounding frequency for `PercentageStorageCost`, returned as a scalar integer or an `NINST`-by-`1` vector of integers.

Data Types: `double`

`PercentageStorageCostBasis` — Day count basis for `PercentStorageCost`
`0` (actual/actual) (default) | scalar integer from `0` to `13` | vector of integers from `0` to `13`

Day count basis for `PercentageStorageCost`, returned as a scalar integer or an `NINST`-by-`1` vector of integers.

Data Types: `double`

`ConvenienceYield` — Annualized convenience yield
`0` (default) | scalar decimal | vector of decimals

Annualized convenience yield, returned as a scalar decimal or an `NINST`-by-`1` vector of decimals.

Data Types: `double`

`ConvenienceYieldCompounding` — Compounding frequency for `ConvenienceYield`
`1` (continuous compounding) (default) | scalar integer with value of `-1`, `0`, `1`, `2`, `4`, `6`, or `12` | vector of integers with values `-1`, `0`, `1`, `2`, `4`, `6`, or `12`

Compounding frequency for `ConvenienceYield`, returned as a scalar integer or an `NINST`-by-`1` vector of integers.

Data Types: `double`

`ConvenienceYieldBasis` — Day count basis for `ConvenienceYield`
`0` (actual/actual) (default) | scalar integer from `0` to `13` | vector of integers from `0` to `13`

Day count basis for `ConvenienceYield`, returned as a scalar integer or an `NINST`-by-`1` vector of integers.

Data Types: `double`

`Name` — User-defined name for instrument
`""` (default) | string | string array

User-defined name for the instrument, returned as a scalar string or an `NINST`-by-`1` string array.

Data Types: `string`

Object Functions

cashsettle	Compute cash settlement for BondFuture, CommodityFuture, EquityIndexFuture, or FXFuture instrument
fairdelivery	Compute fair delivery price of underlying asset for BondFuture, CommodityFuture, EquityIndexFuture, or FXFuture instrument

Examples

Price `CommodityFuture` Instrument Using `ratecurve` and `Future` Pricer

This example shows the workflow to price a `CommodityFuture` instrument when you use a `ratecurve` object and a `Future` pricing method.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2022,3,1);
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
```

```
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates,Compounding=2);
```

Create `CommodityFuture` Instrument Object

Use `fininstrument` to create a `CommodityFuture` instrument object.

```
CommodityFut = fininstrument("CommodityFuture",Maturity=datetime(2022,9,1),QuotedPrice=68,Storage
```

```
CommodityFut =
  CommodityFuture with properties:

                        Maturity: 01-Sep-2022
                    QuotedPrice: 68
                    StorageCost: 25
                         Income: 0
              PercentStorageCost: 0
    PercentStorageCostCompounding: -1
          PercentStorageCostBasis: 0
                ConvenienceYield: 0
      ConvenienceYieldCompounding: -1
            ConvenienceYieldBasis: 0
                           Name: "commodityfuture_instrument"
```

Create `Future` Pricer Object

Use `finpricer` to create a `Future` pricer object and use the `ratecurve` object with the `DiscountCurve` name-value argument.

```
outPricer = finpricer("Future",DiscountCurve=ZeroCurve,SpotPrice=66)
```

```
outPricer =
  Future with properties:

    DiscountCurve: [1x1 ratecurve]
        SpotPrice: 66
```

Price `CommodityFuture` Instrument

Use `price` to compute the price and price result for the `CommodityFuture` instrument.

```
[Price,outPR] = price(outPricer,CommodityFut)
```

```
Price = 23.1778

outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×4 table
    Price     FairDeliveryPrice    FairFuturePrice    AccruedInterest
```

```
    ______    _________________    _____________    _____________

    23.178         91.239              91.239              0
```

Price Multiple CommodityFuture Instruments Using ratecurve and Future Pricer

This example shows the workflow to price multiple `CommodityFuture` instruments when you use a `ratecurve` object and a `Future` pricing method.

Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2022,3,1);
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates,Compounding=2);
```

Create CommodityFuture Instrument Object

Use `fininstrument` to create a `CommodityFuture` instrument object for three Commodity Future instruments.

```
CommodityFut = fininstrument("CommodityFuture",Maturity=datetime([2022,9,1 ; 2022,10,1 ; 2022,11
```

```
CommodityFut=3×1 object
  3x1 CommodityFuture array with properties:

    Maturity
    QuotedPrice
    StorageCost
    Income
    PercentStorageCost
    PercentStorageCostCompounding
    PercentStorageCostBasis
    ConvenienceYield
    ConvenienceYieldCompounding
    ConvenienceYieldBasis
    Name
```

Create Future Pricer Object

Use `finpricer` to create a `Future` pricer object and use the `ratecurve` object with the `DiscountCurve` name-value argument.

```
outPricer = finpricer("Future",DiscountCurve=ZeroCurve,SpotPrice=66)
```

```
outPricer =
  Future with properties:

    DiscountCurve: [1x1 ratecurve]
        SpotPrice: 66
```

Price CommodityFuture Instruments

Use `price` to compute the prices and price results for the `CommodityFuture` instruments.

```
[Price,outPR] = price(outPricer,CommodityFut)
```

```
Price = 3×1

   24.0976
   22.2855
   20.4822

outPR=1×3 object
  1x3 priceresult array with properties:

    Results
    PricerData
```

```
outPR.Results
```

```
ans=1×4 table
    Price     FairDeliveryPrice    FairFuturePrice    AccruedInterest
    ______    _________________    _______________    _______________

    24.098         92.161              92.161                0

ans=1×4 table
    Price     FairDeliveryPrice    FairFuturePrice    AccruedInterest
    ______    _________________    _______________    _______________

    22.286         92.354              92.354                0

ans=1×4 table
    Price     FairDeliveryPrice    FairFuturePrice    AccruedInterest
    ______    _________________    _______________    _______________

    20.482         92.555              92.555                0
```

More About

Commodity Future

A commodity future contract is an agreement to buy or sell a predetermined amount of a commodity at a specific price on a specific date in the future.

In the commodity futures market, the underlying commodity has a standardized size and quality in the contract specification (for example, 1000 barrels of light sweet crude oil for WTI Crude Oil futures). During the life of the contract, the underlying commodity may have unit storage cost or unit income that occurs at specific times. It may also have percentage storage cost or convenience yield that is proportional to the price of the commodity.

$$F_0 = (S_0 + U - I)\exp(r + w - y)T$$

$$FairDeliveryPrice = F_0$$

- F_0 — Fair future price of commodity
- S_0 — Spot price of commodity
- U — Present value of storage cost for the life of the contract
- I — Present value of interest income for the life of the contract
- r — Continuously compounded zero rate
- w — Continuously compounded annualized percent storage cost
- y — Continuously compounded annualized convenience yield
- T — Time to maturity of contract

There are two workflows:

- The first workflow is to compute the discounted present value of the futures contract using `cashsettle` assuming it is held until maturity like a forward contract.

  $$f = (F_0 - K)\exp(-rT)Size = (F_0 - K) \times DiscountFactor \times Size$$

  - F_0 — Fair future price
  - K — Contractual price
  - r — Continuously compounded zero rate
  - T — Time to maturity of contract
- Since futures contracts are settled on every trading day, the second workflow is to use `fairdelivery` to compute the current fair delivery price of the futures contract to support marking to market.

  $$MarkToMarket = (ChangeinFuturePrice) \times (ContractSize)$$

Version History

Introduced in R2022a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `CommodityFuture` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

Topics
“Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22
“Choose Instruments, Models, and Pricers” on page 1-53

EquityIndexFuture

`EquityIndexFuture` instrument object

Description

Create and price an `EquityIndexFuture` instrument object for one or more Equity Index Future instruments using this workflow:

1. Use `fininstrument` to create an `EquityIndexFuture` instrument object for one or more Equity Index Future instruments.
2. Use `ratecurve` to specify a curve model for the `EquityIndexFuture` instrument object.
3. Use `finpricer` to specify a `Future` pricing method for one or more `EquityIndexFuture` instruments.
4. Use `cashsettle` to compute the cash settlement for the `EquityIndexFuture` instrument and `fairdelivery` to compute the fair delivery price for the underlying asset for the `EquityIndexFuture` instrument.

For more detailed information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for an `EquityIndexFuture` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
EquityIndexFutureObj = fininstrument(InstrumentType,Maturity=maturity_value,
QuotedPrice=quoted_price)
EquityIndexFutureObj = fininstrument( ___ ,Name=Value)
```

Description

`EquityIndexFutureObj = fininstrument(InstrumentType,Maturity=maturity_value, QuotedPrice=quoted_price)` creates an `EquityIndexFuture` object for one or more Equity Index Future instruments by specifying `InstrumentType` and sets the properties on page 11-3024 for the required name-value arguments `Maturity` and `QuotedPrice`.

The `EquityIndexFuture` instrument supports stock index futures such as NASDAQ 100 and Dow Jones index futures. For more information, see “Equity Index Futures” on page 11-3028.

`EquityIndexFutureObj = fininstrument( ___ ,Name=Value)` sets optional properties on page 11-3024 using additional name-value arguments in addition to the required arguments in the previous syntax. For example, `EquityIndexFutureObj = fininstrument("EquityIndexFuture",Maturity=datetime(2022,9,1),QuotedPrice=4800,Size=500,Name="equityindexfuture_instrument")` creates an `EquityIndexFuture` instrument. You can specify multiple name-value arguments.

Input Arguments

`InstrumentType` — Instrument type

string with value `"EquityIndexFuture"` | string array with values of `"EquityIndexFuture"` | character vector with value `'EquityIndexFuture'` | cell array of character vectors with values of `'EquityIndexFuture'`

Instrument type, specified as a string with the value of `"EquityIndexFuture"`, a character vector with the value of `'EquityIndexFuture'`, an `NINST`-by-`1` string array with values of `"EquityIndexFuture"`, or an `NINST`-by-`1` cell array of character vectors with values of `'EquityIndexFuture'`.

Data Types: `char` | `cell` | `string`

`EquityIndexFuture` Name-Value Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `EquityIndexFutureObj = fininstrument("EquityIndexFuture",Maturity=datetime(2022,9,1),QuotedPrice=4800,Size=500,Name="equityindexfuture_instrument")`

Required `EquityIndexFuture` Name-Value Arguments

`Maturity` — `EquityIndexFuture` maturity date

datetime array | string array | date character vector

`EquityIndexFuture` maturity date, specified as `Maturity` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `EquityIndexFuture` also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `Maturity` property is stored as a datetime.

`QuotedPrice` — `EquityIndexFuture` quoted delivery index price

scalar numeric | numeric vector

`EquityIndexFuture` quoted delivery index price, specified as `QuotedPrice` and a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

Optional `EquityIndexFuture` Name-Value Arguments

`Size` — Contract size multiplier

`250` (default) | scalar numeric | numeric vector

Contract size multiplier, specified as `Size` and a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`DividendYield` — Annualized dividend yield for life of contract

`0` (default) | scalar numeric | numeric vector

Annualized dividend yield for the life of the contract, specified as `DividendYield` and a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`DividendYieldCompounding` — Compounding frequency for `DividendYield`
`-1` (continuous compounding) (default) | scalar integer with value of `-1`, `0`, `1`, `2`, `4`, `6`, or `12` | vector of integers with values `-1`, `0`, `1`, `2`, `4`, `6`, or `12`

Compounding frequency for `DividendYield`, specified as `DividendYieldCompounding` and a scalar integer or an `NINST`-by-`1` vector of integers.

Data Types: `double`

`DividendYieldBasis` — Day count basis for `DividendYield`
`0` (actual/actual) (default) | scalar integer from `0` to `13` | vector of integers from `0` to `13`

Day count basis for `DividendYield`, specified as `DividendYieldBasis` and scalar integer or an `NINST`-by-`1` vector of integers using the following values:

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Name` — User-defined name for instrument
`""` (default) | string | string array | character vector | cell array of character vectors

User-defined name for one rf more instruments, specified as `Name` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

Properties

`Maturity` — `EquityIndexFuture` maturity date
scalar datetime | vector of datetimes

`EquityIndexFuture` maturity date, returned as a scalar datetime or `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`QuotedPrice` — `EquityIndexFuture` quoted price
scalar numeric | numeric vector

`EquityIndexFuture` quoted price, returned as a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`Size` — Contract size multiplier
`250` (default) | scalar numeric | numeric vector

Contract size multiplier, returned as a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`DividendYield` — Annualized dividend yield for life of contract
`0` (default) | scalar numeric | numeric vector

Annualized dividend yield for the life of the contract, returned as a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`DividendYieldCompounding` — Compounding frequency for `DividendYield`
`-1` (continuous compounding) (default) | scalar integer with value of `-1`, `0`, `1`, `2`, `4`, `6`, or `12` | vector of integers with values `-1`, `0`, `1`, `2`, `4`, `6`, or `12`

Compounding frequency for `DividendYield`, returned as a scalar integer or an `NINST`-by-`1` vector of integers.

Data Types: `double`

`DividendYieldBasis` — Day count basis for `DividendYield`
`0` (actual/actual) (default) | scalar integer from `0` to `13` | vector of integers from `0` to `13`

Day count basis for `DividendYield`, returned as a scalar integer or an `NINST`-by-`1` vector of integers.

Data Types: `double`

`Name` — User-defined name for instrument
`""` (default) | string | string array

User-defined name for the instrument, returned as a scalar string or an `NINST`-by-`1` string array.

Data Types: `string`

Object Functions

cashsettle	Compute cash settlement for BondFuture, CommodityFuture, EquityIndexFuture, or FXFuture instrument
fairdelivery	Compute fair delivery price of underlying asset for BondFuture, CommodityFuture, EquityIndexFuture, or FXFuture instrument

Examples

Price EquityIndexFuture Instrument Using ratecurve and Future Pricer

This example shows the workflow to price an `EquityIndexFuture` instrument when you use a `ratecurve` object and a `Future` pricing method.

Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2022,3,1);
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates,Compounding=2);
```

Create EquityIndexFuture Instrument Object

Use `fininstrument` to create an `EquityIndexFuture` instrument object.

```
EquityIndexFut = fininstrument("EquityIndexFuture",Maturity=datetime(2022,9,1),QuotedPrice=4800,I
```

```
EquityIndexFut =
  EquityIndexFuture with properties:

                  Maturity: 01-Sep-2022
               QuotedPrice: 4800
                      Size: 250
             DividendYield: 0.0300
   DividendYieldCompounding: -1
         DividendYieldBasis: 0
                      Name: "equityindexfuture_instrument"
```

Create Future Pricer Object

Use `finpricer` to create a `Future` pricer object and use the `ratecurve` object with the `DiscountCurve` name-value argument.

```
outPricer = finpricer("Future",DiscountCurve=ZeroCurve,SpotPrice=4460)
```

```
outPricer =
  Future with properties:

    DiscountCurve: [1x1 ratecurve]
        SpotPrice: 4460
```

Price EquityIndexFuture Instrument

Use `price` to compute the price and price result for the `EquityIndexFuture` instrument.

```
[Price,outPR] = price(outPricer,EquityIndexFut)
```

```
Price = -9.8598e+04

outPR =
  priceresult with properties:
```

```
       Results: [1x4 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×4 table
    Price     FairDeliveryPrice    FairFuturePrice    AccruedInterest
    ______    _________________    _______________    _______________

    -98598       1.1011e+06            4404.6                0
```

Price Multiple EquityIndexFuture Instruments Using ratecurve and Future Pricer

This example shows the workflow to price multiple `EquityIndexFuture` instruments when you use a `ratecurve` object and a `Future` pricing method.

Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2022,3,1);
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates,Compounding=2);
```

Create EquityIndexFuture Instrument Object

Use `fininstrument` to create an `EquityIndexFuture` instrument object for three Equity Index Future instruments.

```
EquityIndexFut = fininstrument("EquityIndexFuture",Maturity=datetime([2022,9,1 ; 2022,10,1 ; 202
```

```
EquityIndexFut=3×1 object
  3x1 EquityIndexFuture array with properties:

    Maturity
    QuotedPrice
    Size
    DividendYield
    DividendYieldCompounding
    DividendYieldBasis
    Name
```

Create Future Pricer Object

Use `finpricer` to create a `Future` pricer object and use the `ratecurve` object with the `DiscountCurve` name-value argument.

```
outPricer = finpricer("Future",DiscountCurve=ZeroCurve,SpotPrice=4460)
```

```
outPricer =
  Future with properties:
```

```
    DiscountCurve: [1x1 ratecurve]
        SpotPrice: 4460
```

Price EquityIndexFuture Instruments

Use `price` to compute the prices and price results for the `EquityIndexFuture` instruments.

```
[Price,outPR] = price(outPricer,EquityIndexFut)
```

```
Price = 3×1
10^5 ×

   -0.9860
   -1.5060
   -2.0262

outPR=1×3 object
  1x3 priceresult array with properties:

More About

Equity Index Futures

An equity index future is a "futures contract" on an equity index.

Equity index futures are cash settled contracts with the majority having quarterly expiration dates scheduled for the months of March, June, September, and December. In the equity index futures market, the underlying asset is an equity index (for example, S&P 500) multiplied by a size multiplier

that is standardized to each specific type of equity index future (for example, $250 for S&P 500 Future, and $50 for E-Mini S&P 500 Future). If the equity index has dividends, computing the fair future price requires the dividend yield for the life of the contract in addition to the interest rate.

$$F_0 = S_0\exp(r - q)T$$
$$FairDeliveryPrice = F_0 \times Size$$

- F_0 — Fair future price of equity index
- S_0 — Spot price of equity index
- r — Continuously compounded zero rate
- q — Continuously compounded annualized dividend yield
- T — Time to maturity of contract
- $Size$ — Size multiplier for equity index futures (for example, $250 for S&P 500 Future)

There are two workflows.

- The first workflow is to compute the discounted present value of the futures contract using `cashsettle` assuming it is held until maturity like a forward contract.

  $$f = (F_0 - K)\exp(-rT)Size = (F_0 - K) \times DiscountFactor \times Size$$

  - F_0 — Fair future price
  - K — Contractual price
  - r — Continuously compounded zero rate
  - T — Time to maturity of contract
- Since futures contracts are settled on every trading day, the second workflow is to use `fairdelivery` to compute the current fair delivery price of the futures contract to support marking to market.

  $$MarkToMarket = (ChangeinFuturePrice) \times (ContractSize)$$

Version History

Introduced in R2022a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `EquityIndexFuture` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

FXFuture

`FXFuture` instrument object

Description

Create and price an `FXFuture` instrument object for one or more FX Future instruments using this workflow:

1. Use `fininstrument` to create an `FXFuture` instrument object for one or more FX Future instruments.
2. Use `ratecurve` to specify a curve model for the `FXFuture` instrument object.
3. Use `finpricer` to specify a `Discount` pricing method for one or more `FXFuture` instruments.
4. Use `cashsettle` to compute the cash settlement for the `FXFuture` instrument and `fairdelivery` to compute the fair delivery price for the underlying asset for the `FXFuture` instrument.

For more detailed information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for an `FXFuture` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
FXFutureObj = fininstrument(InstrumentType,Maturity=maturity_value,
QuotedPrice=quoted_price,ForeignRateCurve=foreign_rate_curve)
FXFutureObj = fininstrument( ___ ,Name=Value)
```

Description

`FXFutureObj = fininstrument(InstrumentType,Maturity=maturity_value, QuotedPrice=quoted_price,ForeignRateCurve=foreign_rate_curve)` creates an `FXFuture` object for one or more FX Future instruments by specifying `InstrumentType` and sets the properties on page 11-3033 for the required name-value arguments `Maturity`, `QuotedPrice`, and `ForeignRateCurve`.

The `FXFuture` instrument supports currency pairs where the price is quoted in domestic currency for one unit of foreign currency. For more information, see “FXFuture” on page 11-3037.

`FXFutureObj = fininstrument( ___ ,Name=Value)` sets optional properties on page 11-3033 using additional name-value arguments in addition to the required arguments in the previous syntax. For example, `FXFutureObj = fininstrument("FXFuture",Maturity=datetime(2022,9,1),QuotedPrice=0.78,ForeignRateCurve=ForeignRC,Notional=200000,Name="fxfuture_instrument")` creates an `FXFuture`. You can specify multiple name-value arguments.

Input Arguments

`InstrumentType` — Instrument type

string with value `"FXFuture"` | string array with values of `"FXFuture"` | character vector with value `'FXFuture'` | cell array of character vectors with values of `'FXFuture'`

Instrument type, specified as a string with the value of `"FXFuture"`, a character vector with the value of `'FXFuture'`, an `NINST`-by-`1` string array with values of `"FXFuture"`, or an `NINST`-by-`1` cell array of character vectors with values of `'FXFuture'`.

Data Types: `char` | `cell` | `string`

`FXFuture` Name-Value Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `FXFutureObj = fininstrument("FXFuture",Maturity=datetime(2022,9,1),QuotedPrice=0.78,ForeignRateCurve=ForeignRC,Notional=200000,Name="fxfuture_instrument")`

Required `FXFuture` Name-Value Arguments

`Maturity` — `FXFuture` maturity date

datetime array | string array | date character vector

`FXFuture` maturity date, specified as `Maturity` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `FXFuture` also accepts serial date numbers as inputs, but they are not recommended.

If you use date character vectors or strings, the format must be recognizable by `datetime` because the `Maturity` property is stored as a datetime.

`QuotedPrice` — `FXFuture` delivery price quoted in domestic currency for one unit of foreign currency

scalar numeric | numeric vector

`FXFuture` delivery price quoted in domestic currency for one unit of foreign currency, specified as `QuotedPrice` and a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`ForeignRateCurve` — Rate curve object for foreign currency

`ratecurve` object

Rate curve object for foreign currency, specified as a scalar `ratecurve` object or an `NINST`-by-`1` vector of `ratecurve` objects.

Data Types: `object`

Optional `FXFuture` Name-Value Arguments

`Notional` — Notional in foreign currency

`100000` (default) | scalar numeric | numeric vector

Notional in foreign currency, specified as `Notional` and a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`Name` — User-defined name for instrument
`""` (default) | string | string array | character vector | cell array of character vectors

User-defined name for one or more instruments, specified as `Name` and a scalar string or character vector or an `NINST`-by-`1` cell array of character vectors or string array.

Data Types: `char` | `cell` | `string`

Properties

`Maturity` — `FXFuture` maturity date
scalar datetime | vector of datetimes

`FXFuture` maturity date, returned as a scalar datetime or `NINST`-by-`1` vector of datetimes.

Data Types: `datetime`

`QuotedPrice` — `FXFuture` quoted price
scalar numeric | numeric vector

`FXFuture` quoted price, returned as a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`ForeignRateCurve` — Rate curve object for foreign currency
`ratecurve` object

Rate curve object for foreign currency, returned as a scalar `ratecurve` object or an `NINST`-by-`1` vector of `ratecurve` objects.

Data Types: `object`

`Notional` — Notional in foreign currency
`100000` (default) | scalar numeric | numeric vector

Notional in foreign currency, returned as a scalar numeric or an `NINST`-by-`1` numeric vector.

Data Types: `double`

`Name` — User-defined name for instrument
`""` (default) | string | string array

User-defined name for the instrument, returned as a scalar string or an `NINST`-by-`1` string array.

Data Types: `string`

Object Functions

cashsettle	Compute cash settlement for BondFuture, CommodityFuture, EquityIndexFuture, or FXFuture instrument
fairdelivery	Compute fair delivery price of underlying asset for BondFuture, CommodityFuture, EquityIndexFuture, or FXFuture instrument

Examples

Price FXFuture Instrument Using ratecurve and Future Pricer

This example shows the workflow to price an FXFuture instrument when you use a ratecurve object and a Future pricing method.

Create ratecurve Objects

Create ratecurve objects using ratecurve for the foreign and domestic zero curves.

```
% Define Foreign Zero Curve
Settle = datetime(2022, 3, 1);
ForeignZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ForeignZeroRates = [0.0031 0.0035 0.0047 0.0058 0.0062 0.0093 0.0128 0.0182 0.0223 0.0285]';
ForeignZeroDates = Settle + ForeignZeroTimes;
ForeignRC = ratecurve('zero', Settle, ForeignZeroDates, ForeignZeroRates);

% Define Domestic Zero Curve
DomesticZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
DomesticZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
DomesticZeroDates = Settle + DomesticZeroTimes;
DomesticRC = ratecurve('zero', Settle, DomesticZeroDates, DomesticZeroRates);
```

Create FXFuture Instrument Object

Use fininstrument to create an FXFuture instrument object.

```
FXFut = fininstrument("FXFuture",Maturity=datetime(2022,9,1),QuotedPrice=0.78,ForeignRateCurve=Fo
```

```
FXFut =
  FXFuture with properties:

           Maturity: 01-Sep-2022
        QuotedPrice: 0.7800
    ForeignRateCurve: [1x1 ratecurve]
           Notional: 200000
               Name: "FXfuture_instrument"
```

Create Future Pricer Object

Use finpricer to create a Future pricer object and use the ratecurve object with the DiscountCurve name-value argument.

```
outPricer = finpricer("Future",DiscountCurve=DomesticRC,SpotPrice=0.79)
```

```
outPricer =
  Future with properties:

    DiscountCurve: [1x1 ratecurve]
        SpotPrice: 0.7900
```

Price FXFuture Instrument

Use price to compute the price and price result for the FXFuture instrument.

```
[Price,outPR] = price(outPricer,FXFut)

Price = 2.1617e+03

outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: []

outPR.Results

ans=1×4 table
    Price     FairDeliveryPrice    FairFuturePrice    AccruedInterest
    ______    _________________    _______________    _______________

    2161.7       1.5817e+05           0.79084                0
```

Price Multiple FXFuture Instruments Using ratecurve and Future Pricer

This example shows the workflow to price multiple FXFuture instruments when you use a ratecurve object and a Future pricing method.

Create ratecurve Objects

Create ratecurve objects using ratecurve for the foreign and domestic zero curves.

```
% Define Foreign Zero Curve
Settle = datetime(2022, 3, 1);
ForeignZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ForeignZeroRates = [0.0031 0.0035 0.0047 0.0058 0.0062 0.0093 0.0128 0.0182 0.0223 0.0285]';
ForeignZeroDates = Settle + ForeignZeroTimes;
ForeignRC = ratecurve('zero', Settle, ForeignZeroDates, ForeignZeroRates);

% Define Domestic Zero Curve
DomesticZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
DomesticZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
DomesticZeroDates = Settle + DomesticZeroTimes;
DomesticRC = ratecurve('zero', Settle, DomesticZeroDates, DomesticZeroRates);
```

Create FXFuture Instrument Object

Use fininstrument to create an FXFuture instrument object for three FX Future instruments.

```
FXFut = fininstrument("FXFuture",Maturity=datetime([2022,9,1 ; 2022,10,1 ; 2022,11,1]),QuotedPric

FXFut=3×1 object
  3x1 FXFuture array with properties:

    Maturity
    QuotedPrice
    ForeignRateCurve
    Notional
    Name
```

Create Future Pricer Object

Use `finpricer` to create a `Future` pricer object and use the `ratecurve` object with the `DiscountCurve` name-value argument.

```
outPricer = finpricer("Future",DiscountCurve=DomesticRC,SpotPrice=0.79)
```

```
outPricer =
  Future with properties:

    DiscountCurve: [1x1 ratecurve]
        SpotPrice: 0.7900
```

Price FXFuture Instruments

Use `price` to compute the prices and price results for the `FXFuture` instrument.

```
[Price,outPR] = price(outPricer,FXFut)
```

```
Price = 3×1
10^4 ×

    0.2162
   -0.5789
   -1.3732

outPR=1×3 object
  1x3 priceresult array with properties:

    Results
    PricerData
```

```
outPR.Results
```

```
ans=1×4 table
    Price     FairDeliveryPrice    FairFuturePrice    AccruedInterest
    ______    _________________    _______________    _______________

```

More About

FXFuture

An FXFuture is an exchange-traded currency derivative contract obligating the buyer and seller to transact at a set price and predetermined time.

In the FX futures market, the underlying asset is a currency pair (for example, price in domestic currency for one unit of foreign currency). Both the domestic currency interest rate and the foreign currency interest rate are required to compute the fair delivery price.

$$F_0 = S_0\exp(r_d - r_f)T$$
$$FairDeliveryPrice = F_0 \times Notional$$

- F_0 — Fair future price in domestic currency for one unit of foreign currency
- S_0 — Spot price in domestic currency for one unit of foreign currency
- r_d — Domestic currency continuously compounded zero rate
- r_f — Foreign currency continuously compounded zero rate
- T — Time to maturity of contract
- $Notional$ — Notional value of the contract in foreign currency

There are two workflows.

- The first workflow is to compute the discounted present value of the futures contract using `cashsettle` assuming it is held until maturity like a forward contract.

  $$f = (F_0 - K)\exp(-rT)Size = (F_0 - K) \times DiscountFactor \times Size$$

  - F_0 — Fair future price
  - K — Contractual price
  - r — Continuously compounded zero rate
  - T — Time to maturity of contract
- Since futures contracts are settled on every trading day, the second workflow is to use `fairdelivery` to compute the current fair delivery price of the futures contract to support marking to market.

  $$MarkToMarket = (ChangeinFuturePrice) \times (ContractSize)$$

Version History

Introduced in R2022a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `FXFuture` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

Bates

Create `Bates` model object for `Vanilla`, `Asian`, `Barrier`, `DoubleBarrier`, `Lookback`, `PartialLookback`, `Touch`, `DoubleTouch`, `Cliquet`, or `Binary` instrument

Description

Create and price a `Vanilla`, `Asian`, `Barrier`, `DoubleBarrier`, `Lookback`, `PartialLookback`, `Touch`, `DoubleTouch`, `Cliquet`, or `Binary` instrument object with a `Bates` model using this workflow:

1. Use `fininstrument` to create a `Vanilla`, `Barrier`, `Lookback`, `PartialLookback`, `Asian`, `DoubleBarrier`, `Cliquet`, `Binary`, `Touch`, or `DoubleTouch` instrument object.
2. Use `finmodel` to specify a `Bates` model object for the `Vanilla`, `Asian`, `Barrier`, `DoubleBarrier`, `Lookback`, `PartialLookback`, `Touch`, `DoubleTouch`, `Cliquet`, or `Binary` instrument object.
3. Use `finpricer` to specify a `FiniteDifference`, `NumericalIntegration`, or `FFT` pricing method for the `Vanilla` instrument object.

   Use `finpricer` to specify an `AssetMonteCarlo` pricing method for the `Vanilla`, `Asian`, `Barrier`, `DoubleBarrier`, `Lookback`, `PartialLookback`, `Touch`, `DoubleTouch`, `Cliquet`, or `Binary` instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a `Vanilla`, `Asian`, `Barrier`, `DoubleBarrier`, `Lookback`, `PartialLookback`, `Touch`, `DoubleTouch`, or `Binary` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
BatesObj = finmodel(ModelType,'V0',V0_value,'ThetaV',thetav_value,'
Kappa',kappa_value,'SigmaV',sigmav_value,'RhoSV',rhosv_value, '
MeanJ',meanj_value, 'JumpVol',jumpvol_value,'JumpFreq',jumpfreq_value)
```

Description

`BatesObj = finmodel(ModelType,'V0',V0_value,'ThetaV',thetav_value,'Kappa',kappa_value,'SigmaV',sigmav_value,'RhoSV',rhosv_value, 'MeanJ',meanj_value, 'JumpVol',jumpvol_value,'JumpFreq',jumpfreq_value)` creates an `Bates` object by specifying `ModelType` and the required name-value pair arguments `V0`, `ThetaV`, `Kappa`, `SigmaV`, `RhoSV`, `MeanJ`, `JumpVol`, and `JumpFreq`. The required name-value pair arguments set properties on page 11-3041. For example, `BatesObj = finmodel("Bates",'V0',0.032,'ThetaV',0.1,'Kappa',0.003,'SigmaV',0.2,'RhoSV',0.9,'MeanJ',0.11,'JumpVol',.023,'JumpFreq',0.02)` creates a `Bates` model object.

Input Arguments

ModelType — Model type

string with value "Bates" | character vector with value 'Bates'

Model type, specified as a string with the value of "Bates" or a character vector with the value of 'Bates'.

Data Types: char | string

Bates Name-Value Pair Arguments

Specify required pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: Bates = finmodel("Bates",'V0',0.032,'ThetaV',0.1,'Kappa',0.003,'SigmaV',0.2,'RhoSV',0.9,'MeanJ',0.11,'JumpVol',.023,'JumpFreq',0.02)

V0 — Initial variance of underlying asset

numeric

Initial variance of the underlying asset, specified as the comma-separated pair consisting of 'V0' and a scalar numeric value.

Data Types: double

ThetaV — Long-term variance of underlying asset

numeric

Long-term variance of the underlying asset, specified as the comma-separated pair consisting of 'ThetaV' and a scalar numeric value.

Data Types: double

Kappa — Mean revision speed for the variance of underlying asset

numeric

Mean revision speed for the underlying asset, specified as the comma-separated pair consisting of 'Kappa' and a scalar numeric value.

Data Types: double

SigmaV — Volatility of the variance of underlying asset

numeric

Volatility of the variance of the underlying asset, specified as the comma-separated pair consisting of 'SigmaV' and a scalar numeric value.

Data Types: double

RhoSV — Correlation between Weiner processes for underlying asset and its variance

numeric

Correlation between the Weiner processes for the underlying asset and its variance, specified as the comma-separated pair consisting of `'RhoSV'` and a scalar numeric value.

Data Types: `double`

`MeanJ` — Mean of the random percentage jump size
decimal

Mean of the random percentage jump size (*J*), specified as the comma-separated pair consisting of `'MeanJ'` and a scalar decimal value where `log`(1+*J*) is normally distributed with mean (`log`(1+`MeanJ`)-0.5*`JumpVol`^2) and the standard deviation `JumpVol`.

Data Types: `double`

`JumpVol` — Standard deviation of `log`(1+*J*)
decimal

Standard deviation of `log`(1+*J*), where `J` is the random percentage jump size, specified as the comma-separated pair consisting of `'JumpVol'` and a scalar decimal value.

Data Types: `double`

`JumpFreq` — Annual frequency of Poisson jump process
numeric

Annual frequency of the Poisson jump process, specified as the comma-separated pair consisting of `'JumpFreq'` and a scalar numeric value.

Data Types: `double`

Properties

`V0` — Initial variance of underlying asset
numeric

Initial variance of the underlying asset, returned as a scalar numeric value.

Data Types: `double`

`ThetaV` — Long-term variance of underlying asset
numeric

Long-term variance of the underlying asset, returned as a scalar numeric value.

Data Types: `double`

`Kappa` — Mean revision speed for the variance of underlying asset
numeric

Mean revision speed for the underlying asset, returned as a scalar numeric value.

Data Types: `double`

`SigmaV` — Volatility of the variance of underlying asset
numeric

Volatility of the variance of the underlying asset, returned as a scalar numeric value.

Data Types: `double`

`RhoSV` — Correlation between Weiner processes for underlying asset and its variance
numeric

Correlation between the Weiner processes for the underlying asset and its variance, returned as a scalar numeric value.

Data Types: `double`

`MeanJ` — Mean of the random percentage jump size
decimal

Mean of the random percentage jump size (*J*), returned as a scalar decimal value.

Data Types: `double`

`JumpVol` — Standard deviation of `log(1+J)`
decimal

Standard deviation of `log`(1+*J*), where `J` is the random percentage jump size, returned as a scalar decimal value.

Data Types: `double`

`JumpFreq` — Annual frequency of Poisson jump process
numeric

Annual frequency of the Poisson jump process, returned as a scalar numeric value.

Data Types: `double`

Examples

Use a Bates Model and Numerical Integration Pricer to Price Vanilla Instrument

This example shows the workflow to price a `Vanilla` instrument when you use a `Bates` model and a `NumericalIntegration` pricing method.

Create `Vanilla` Instrument Object

Use `fininstrument` to create a `Vanilla` instrument object.

```
VanillaOpt = fininstrument("Vanilla",'ExerciseDate',datetime(2022,9,15),'Strike',105,'OptionType
```

```
VanillaOpt =
  Vanilla with properties:

       OptionType: "put"
    ExerciseStyle: "european"
     ExerciseDate: 15-Sep-2022
           Strike: 105
             Name: "vanilla_option"
```

Create Bates Model Object

Use `finmodel` to create a `Bates` model object.

```
BatesModel = finmodel("Bates",'V0',0.032,'ThetaV',0.1,'Kappa',0.003,'SigmaV',0.2,'RhoSV',0.9,'Mea
```

```
BatesModel =
  Bates with properties:

          V0: 0.0320
      ThetaV: 0.1000
       Kappa: 0.0030
      SigmaV: 0.2000
       RhoSV: 0.9000
       MeanJ: 0.1100
     JumpVol: 0.0230
    JumpFreq: 0.0200
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `NumericalIntegration` Pricer Object

Use `finpricer` to create a `NumericalIntegration` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("numericalintegration",'DiscountCurve',myRC,'Model',BatesModel,'SpotPrice'
```

```
outPricer =
  NumericalIntegration with properties:

               Model: [1x1 finmodel.Bates]
       DiscountCurve: [1x1 ratecurve]
           SpotPrice: 100
        DividendType: "continuous"
       DividendValue: 0
              AbsTol: 1.0000e-10
              RelTol: 1.0000e-10
```

```
     IntegrationRange: [1.0000e-09 Inf]
    CharacteristicFcn: @characteristicFcnBates
            Framework: "heston1993"
       VolRiskPremium: 0
           LittleTrap: 1
```

Price `Vanilla` Instrument

Use `price` to compute the price and sensitivities for the `Vanilla` instrument.

```
[Price, outPR] = price(outPricer,VanillaOpt,["all"])
```

```
Price = 6.4007

outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta       Gamma      Theta      Rho       Vega      VegaLT
    ______    ________    ________    _____    _______    ______    ______

    6.4007    -0.53541    0.02006     1.106    -239.77    94.257    1.3059
```

Use Bates Model and Asset Monte-Carlo Pricer to Price Asian Instrument

This example shows the workflow to price a fixed-strike `Asian` instrument when you use a `Bates` model and an `AssetMonteCarlo` pricing method.

Create `Asian` Instrument Object

Use `fininstrument` to create an `Asian` instrument object.

```
AsianOpt = fininstrument("Asian",'ExerciseDate',datetime(2022,9,15),'Strike',100,'OptionType',"pu
```

```
AsianOpt =
  Asian with properties:

          OptionType: "put"
              Strike: 100
         AverageType: "arithmetic"
        AveragePrice: 0
    AverageStartDate: NaT
       ExerciseStyle: "european"
        ExerciseDate: 15-Sep-2022
                Name: "asian_option"
```

Create `Bates` Model Object

Use `finmodel` to create a `Bates` model object.

```
BatesModel = finmodel("Bates",'V0',0.032,'ThetaV',0.1,'Kappa',0.003,'SigmaV',0.02,'RhoSV',0.9,'Me

BatesModel =
  Bates with properties:

         V0: 0.0320
     ThetaV: 0.1000
      Kappa: 0.0030
     SigmaV: 0.0200
      RhoSV: 0.9000
      MeanJ: 0.1100
    JumpVol: 0.0230
   JumpFreq: 0.0200
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)

myRC =
  ratecurve with properties:

                Type: "zero"
       Compounding: -1
             Basis: 12
             Dates: 15-Sep-2023
             Rates: 0.0350
            Settle: 15-Sep-2018
      InterpMethod: "linear"
  ShortExtrapMethod: "next"
   LongExtrapMethod: "previous"
```

Create `AssetMonteCarlo` Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo",'DiscountCurve',myRC,"Model",BatesModel,'SpotPrice',80,'S

outPricer =
  BatesMonteCarlo with properties:

    DiscountCurve: [1x1 ratecurve]
        SpotPrice: 80
  SimulationDates: 15-Sep-2022
        NumTrials: 1000
    RandomNumbers: []
            Model: [1x1 finmodel.Bates]
     DividendType: "continuous"
    DividendValue: 0
```

Price Asian Instrument

Use `price` to compute the price and sensitivities for the `Asian` instrument.

```
[Price, outPR] = price(outPricer,AsianOpt,["all"])
```

```
Price = 14.5650
```

```
outPR =
  priceresult with properties:

       Results: [1x8 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×8 table
    Price      Delta       Gamma      Lambda       Rho       Theta      Vega     VegaLT
    ______    ________    ________    _______    _______    _______    ______    _______

    14.565    -0.72501    0.015172    -3.9822    -174.38    0.80043    26.545    0.25296
```

Black

Create `Black` model object for `Cap`, `Floor`, or `Swaption` instrument

Description

Create and price a `Cap`, `Floor`, or `Swaption` instrument object with a `Black` model using this workflow:

1. Use `fininstrument` to create a `Cap`, `Floor`, or`Swaption` instrument object.
2. Use `finmodel` to specify a `Black` model object for the `Cap`, `Floor`, or `Swaption` instrument object.
3. Use `finpricer` to specify a `Black` pricing method for the `Cap`, `Floor`, or `Swaption` instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a `Cap`, `Floor`, or `Swaption` instrument when using a `Black` model, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
BlackModelObj = finmodel(ModelType,'Volatility',volatility_value)
BlackModelObj = finmodel( ___ ,Name,Value)
```

Description

`BlackModelObj = finmodel(ModelType,'Volatility',volatility_value)` creates a `Black` model object by specifying `ModelType` and sets the properties on page 11-3048 for the required name-value pair argument `Volatility`. For more information on a `Black` model, see “More About” on page 11-3050 and “Algorithms” on page 11-3050.

`BlackModelObj = finmodel( ___ ,Name,Value)` sets optional properties on page 11-3048 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `BlackModelObj = finmodel("Black",'Volatility',0.032,'Shift',0.002)` creates a `Black` model object. You can specify multiple name-value pair arguments.

Input Arguments

`ModelType` — Model type
string with value `"Black"` | character vector with value `'Black'`

Model type, specified as a string with the value of `"Black"` or a character vector with the value of `'Black'`.

Data Types: `char` | `string`

Black Name-Value Pair Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `BlackModelObj = finmodel("Black",'Volatility',0.032,'Shift',0.002)`

Required Black Name-Value Pair Arguments

`Volatility` — Volatility value for the underlying asset
nonnegative numeric

Volatility value for the underlying asset, specified as the comma-separated pair consisting of `'Volatility'` and a scalar nonnegative numeric.

Data Types: `double`

Optional Black Name-Value Pair Argument

`Shift` — Shift in decimals for shifted Black model
`0` (no shift) (default) | positive decimal

Shift in decimals for the shifted Black model, specified as the comma-separated pair consisting of `'Shift'` and a scalar rate shift in positive decimals. Set this parameter to a positive rate shift in decimals to add a positive shift to the forward rate and strike, which effectively sets a negative lower bound for the forward rate. For example, a `Shift` value of `0.01` is equal to a 1% shift.

Data Types: `double`

Properties

`Volatility` — Volatility value
nonnegative numeric

Volatility value, returned as a scalar nonnegative numeric.

Data Types: `double`

`Shift` — Shift in decimals for shifted Black model
`0` (no shift) (default) | positive decimal

Shift in decimals for the shifted Black model, returned as a scalar rate shift in a positive decimal.

Data Types: `double`

Examples

Use Black Model and Black Pricer to Price Cap Instrument

This example shows the workflow to price a `Cap` instrument when you use a `Black` model and a `Black` pricing method.

Create Cap Instrument Object

Use `fininstrument` to create a `Cap` instrument object.

```
CapOpt = fininstrument("Cap",'Strike',.001,'Maturity',datetime(2019,1,30),'Reset',4,'Principal',1
```

```
CapOpt =
  Cap with properties:

                     Strike: 1.0000e-03
                   Maturity: 30-Jan-2019
                ResetOffset: 0
                      Reset: 4
                      Basis: 8
                  Principal: 100
             ProjectionCurve: [0x0 ratecurve]
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                   Holidays: NaT
                       Name: "cap_option"
```

Create Black Model Object

Use `finmodel` to create a `Black` model object.

```
BlackModel = finmodel("Black",'Volatility',0.032,'Shift',0.002)
```

```
BlackModel =
  Black with properties:

    Volatility: 0.0320
         Shift: 0.0020
```

Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
        Compounding: -1
              Basis: 0
              Dates: [10x1 datetime]
              Rates: [10x1 double]
             Settle: 15-Sep-2018
       InterpMethod: "linear"
    ShortExtrapMethod: "next"
```

```
     LongExtrapMethod: "previous"
```

Create Black Pricer Object

Use `finpricer` to create a `Black` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'Model',BlackModel,'DiscountCurve',myRC)
```

```
outPricer =
  Black with properties:

            Model: [1x1 finmodel.Black]
    DiscountCurve: [1x1 ratecurve]
```

Price Cap Instrument

Use `price` to compute the price for the `Cap` instrument.

```
Price = price(outPricer,CapOpt)
```

```
Price = 0.1575
```

More About

Shifted Black Model

The shifted Black model is the same as the Black model, except that it models the movements of (F + *Shift*) as the underlying asset, instead of F (which is the forward rate in the case of caplets).

This model allows negative rates, with a fixed negative lower bound defined by the amount of shift; that is, the zero lower bound of the Black model is shifted.

Algorithms

Black Model

$$dF = \sigma_{Black} F dw$$

$$call = e^{-\gamma T}[FN(d_1) - KN(d_2)]$$

$$put = e^{-\gamma T}[KN(-d_2) - FN(-d_1)]$$

$$d_1 = \frac{\ln\left(\frac{F}{K}\right) + \left(\frac{\sigma_B^2}{2}\right)T}{\sigma_B\sqrt{T}}, \quad d_2 = d_1 - \sigma_B\sqrt{T}$$

$$\sigma_B = \sigma_{Black}$$

Here, F is the forward value and K is the strike.

Shifted Black Model

$$dF = \sigma_{Shifted\_Black}(F + Shift)dw$$

$$call = e^{-\gamma T}[(F + Shift)N(d_{s1}) - (K + Shift)N(d_{s2})]$$

$$put = e^{-\gamma T}[(K + Shift)N(-d_{s2}) - (F + Shift)N(-d_{s1})]$$

$$d_{s1} = \frac{\ln\left(\frac{F + Shift}{K + Shift}\right) + \left(\frac{\sigma_{sB}{}^2}{2}\right)T}{\sigma_{sB}\sqrt{T}}, \quad d_{s2} = d_{s1} - \sigma_{sB}\sqrt{T}$$

$$\sigma_{sB} = \sigma_{Shifted\_Black}$$

Here, $F+Shift$ is the forward value and $K+Shift$ is the strike for the shifted version.

CDSBlack

Create CDSBlack model object for CDSOption instrument

Description

Create and price a CDSOption instrument object with a CDSBlack model using this workflow:

1. Use fininstrument to create a CDSOption instrument object.
2. Use finmodel to specify a CDSBlack model object for the CDSOption instrument object.
3. Use finpricer to specify a CDSBlack pricing method for the CDSOption instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a CDSOption instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
CDSBlackModelObj = finmodel(ModelType,'
SpreadVolatility',spreadvolatility_value)
```

Description

`CDSBlackModelObj = finmodel(ModelType,'SpreadVolatility',spreadvolatility_value)` creates a CDSBlack model object by specifying ModelType and the required name-value pair argument SpreadVolatility to set the properties on page 11-3053 using name-value pair arguments. For example, `CDSBlackModelObj = finmodel("CDSBlack",'SpreadVolatility',0.052)` creates a CDSBlack model object.

Input Arguments

ModelType — Model type

string with value `"CDSBlack"` | character vector with value `'CDSBlack'`

Model type, specified as a string with the value of `"CDSBlack"` or a character vector with the value of `'CDSBlack'`.

Data Types: `char` | `string`

CDSBlack Name-Value Pair Arguments

Specify required pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: `CDSBlackModelObj = finmodel("CDSBlack",'SpreadVolatility',0.052)`

`SpreadVolatility` — Spread volatility value
nonnegative numeric

Spread volatility value, specified as the comma-separated pair consisting of `'SpreadVolatility'` and a scalar nonnegative numeric.

Data Types: `double`

Properties

`SpreadVolatility` — Spread volatility value
nonnegative numeric

Spread volatility value, returned as a scalar nonnegative numeric.

Data Types: `double`

Examples

Use CDS Black Model and CDS Black Pricer to Price CDS Option Instrument

This example shows the workflow to price a `CDSOption` instrument when you use a `CDSBlack` model and a `CDSBlack` pricing method.

Create CDS Instrument Object

Use `fininstrument` to create a `CDS` instrument object as the underlying instrument.

```
CDS = fininstrument("CDS",'Maturity',datetime(2021,9,15),'ContractSpread',150,'Notional',100,'Nar
```

```
CDS =
  CDS with properties:

          ContractSpread: 150
                Maturity: 15-Sep-2021
                  Period: 4
                   Basis: 2
            RecoveryRate: 0.4000
    BusinessDayConvention: "actual"
                Holidays: NaT
        PayAccruedPremium: 1
                Notional: 100
                    Name: "CDS_instrument"
```

Create `defprobcurve` Object

Create a `defprobcurve` object using `defprobcurve`.

```
Settle = datetime(2020,9,20);
DefProbTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
DefaultProbabilities = [0.005 0.007 0.01 0.015 0.026 0.04 0.077 0.093 0.15 0.20]';
ProbDates = Settle + DefProbTimes;
DefaultProbCurve = defprobcurve(Settle,ProbDates,DefaultProbabilities,'Basis',5)
```

```
DefaultProbCurve =
  defprobcurve with properties:

                  Settle: 20-Sep-2020
                   Basis: 5
                   Dates: [10x1 datetime]
    DefaultProbabilities: [10x1 double]
```

Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2020,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2020
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create CDSOption Instrument Object

Use `fininstrument` to create a `CDSOption` instrument object.

```
CDSOptionInst = fininstrument("CDSOption",'ExerciseDate',datetime(2021,8,15),'Strike',20,'CDS',CD
```

```
CDSOptionInst =
  CDSOption with properties:

              OptionType: "put"
                  Strike: 20
               Knockout: 0
    AdjustedForwardSpread: NaN
            ExerciseDate: 15-Aug-2021
                     CDS: [1x1 fininstrument.CDS]
                    Name: "CDSOption_option"
```

Create CDSBlack Model Object

Use `finmodel` to create a `CDSBlack` model object.

```
CDSBlackModel = finmodel("CDSBlack",'SpreadVolatility',.2)
```

```
CDSBlackModel =
  CDSBlack with properties:
```

```
    SpreadVolatility: 0.2000
```

Create CDSBlack Pricer Object

Use `finpricer` to create a `CDSBlack` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'Model',CDSBlackModel,'DefaultProbabilityCurve',DefaultProbCurve
```

```
outPricer =
  CDSBlack with properties:

                      Model: [1x1 finmodel.CDSBlack]
              DiscountCurve: [1x1 ratecurve]
    DefaultProbabilityCurve: [1x1 defprobcurve]
```

Price CDSOption Instrument

Use `price` to compute the price for the `CDSOption` instrument.

```
Price = price(outPricer,CDSOptionInst)
```

```
Price = 3.3016e-04
```

Version History

Introduced in R2020a

BlackScholes

Create `BlackScholes` model object for an `Asian`, `Barrier`, `DoubleBarrier`, `Lookback`, `PartialLookback`, `Spread`, `Vanilla`, `Touch`, `DoubleTouch`, `Cliquet`, or `Binary` instrument

Description

Create and price a `Vanilla`, `Lookback`, `PartialLookback`, `Barrier`, `DoubleBarrier` `Asian`, `Spread`, `Touch`, `DoubleTouch`, `Cliquet`, or `Binary` instrument object with a `BlackScholes` model using this workflow:

1. Use `fininstrument` to create a `Vanilla`, `Lookback`, `PartialLookback`, `Barrier`, `Asian`, `Spread`, `DoubleBarrier`, `Cliquet`, `Binary`, `Touch`, or `DoubleTouch` instrument object.
2. Use `finmodel` to specify the `BlackScholes` model object for a `Vanilla`, `Lookback`, `PartialLookback`, `Barrier`, `DoubleBarrier`, `Asian`, `Spread`, `Touch`, `DoubleTouch`, `Cliquet`, or `Binary` instrument object.
3. Use `finpricer` to specify a supported pricing method. For more information on the available pricing methods for the `Vanilla`, `Lookback`, `PartialLookback`, `Barrier`, `DoubleBarrier`, `Asian`, `Spread`, `Touch`, `DoubleTouch`, `Cliquet`, or `Binary` instrument object when using a `BlackScholes` model, see “Choose Instruments, Models, and Pricers” on page 1-53.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a `Vanilla`, `Lookback`, `PartialLookback`, `Barrier`, `DoubleBarrier`, `Asian`, `Spread`, `Touch`, `DoubleTouch`, or `Binary` instrument when using a `BlackScholes` model, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
BlackScholesModelObj = finmodel(ModelType,'Volatility',volatility_value)
BlackScholesModelObj = finmodel( ___ ,Name,Value)
```

Description

`BlackScholesModelObj = finmodel(ModelType,'Volatility',volatility_value)` creates a `BlackScholes` model object by specifying `ModelType` and sets the properties on page 11-3057 for the required name-value pair argument `Volatility`.

`BlackScholesModelObj = finmodel( ___ ,Name,Value)` sets optional properties on page 11-3057 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `BlackScholesModelObj = finmodel("BlackScholes",'Volatility',0.032,'Correlation',Corr)` creates a `BlackScholes` model object. You can specify multiple name-value pair arguments.

Input Arguments

`ModelType` — Model type
string with value `"BlackScholes"` | character vector with value `'BlackScholes'`

Model type, specified as a string with the value of `"BlackScholes"` or a character vector with the value of `'BlackScholes'`.

Data Types: `char` | `string`

`BlackScholes` Name-Value Pair Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `BlackScholesModelObj = finmodel("BlackScholes",'Volatility',0.032,'Correlation',Corr)`

Required BlackScholes Name-Value Pair Arguments

`Volatility` — Volatility value
nonnegative numeric

Volatility value, specified as the comma-separated pair consisting of `'Volatility'` and a scalar nonnegative numeric.

Data Types: `double`

Optional BlackScholes Name-Value Pair Arguments

`Correlation` — Correlation between underlying asset prices
1 (default) | semidefinite matrix

Correlation between the underlying asset prices, specified as the comma-separated pair consisting of `'Correlation'` and a semidefinite matrix. For more information on creating a positive semidefinite matrix, see `nearcorr`.

Data Types: `double`

Properties

`Volatility` — Volatility value
nonnegative numeric

Volatility value, returned as a scalar nonnegative numeric.

Data Types: `double`

`Corrrelation` — Correlation between underlying assets
1 (default) | semi-definite matrix

Correlation between underlying assets, returned as a semi-definite matrix.

Data Types: `double`

Examples

Use Black-Scholes Model and Turnbull-Wakeman Pricer to Price Asian Instrument

This example shows the workflow to price an `Asian` instrument when you use a `BlackScholes` model and a `TurnbullWakeman` pricing method.

Create `Asian` Instrument Object

Use `fininstrument` to create an `Asian` instrument object.

```
AsianOpt = fininstrument("Asian",'ExerciseDate',datetime(2022,9,15),'Strike',105,'OptionType',"pu
```

```
AsianOpt =
  Asian with properties:

          OptionType: "put"
              Strike: 105
         AverageType: "arithmetic"
        AveragePrice: 0
    AverageStartDate: NaT
       ExerciseStyle: "european"
        ExerciseDate: 15-Sep-2022
                Name: "asian_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.28)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.2800
    Correlation: 1
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
        Compounding: -1
              Basis: 12
              Dates: 15-Sep-2023
              Rates: 0.0350
             Settle: 15-Sep-2018
```

```
         InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create TurnbullWakeman Pricer Object

Use `finpricer` to create a `TurnbulllWakeman` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPrice',100,
```

```
outPricer =
  TurnbullWakeman with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 100
    DividendValue: 0
     DividendType: "continuous"
```

Price Asian Instrument

Use `price` to compute the price and sensitivities for the `Asian` instrument.

```
[Price, outPR] = price(outPricer,AsianOpt,["all"])
```

```
Price = 11.2249

outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta       Gamma      Lambda      Vega       Theta       Rho
    _____    ________    ________    _______    _____    ________    ______

    11.225    -0.38072    0.01087    -3.3917    44.242    -0.5256    -116.88
```

Use Black-Scholes Model and Asset Monte-Carlo Pricer to Price DoubleBarrier Instrument

This example shows the workflow to price a `DoubleBarrier` instrument when you use a `BlackScholes` model and an `AssetMonteCarlo` pricing method.

Create DoubleBarrier Instrument Object

Use `fininstrument` to create a `DoubleBarrier` instrument object.

```
DoubleBarrierOpt = fininstrument("DoubleBarrier",'Strike',100,'ExerciseDate',datetime(2020,8,15),
```

```
DoubleBarrierOpt =
  DoubleBarrier with properties:

       OptionType: "call"
           Strike: 100
     BarrierValue: [110 80]
    ExerciseStyle: "american"
     ExerciseDate: 15-Aug-2020
      BarrierType: "dko"
           Rebate: [0 0]
             Name: "doublebarrier_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes","Volatility",.3)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.3000
    Correlation: 1
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2017,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
       Compounding: -1
             Basis: 12
             Dates: 15-Sep-2023
             Rates: 0.0350
            Settle: 15-Sep-2017
      InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `AssetMonetCarlo` Pricer Object

Use `finpricer` to create an `AssetMonetCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
ExerciseDate = datetime(2020,08,15);
Settle = datetime(2017,9,15);
outPricer = finpricer("AssetMonteCarlo","DiscountCurve",myRC,"Model",BlackScholesModel,'SpotPrice
```

Price DoubleBarrier Instrument

Use `price` to compute the price and sensitivities for the `DoubleBarrier` instrument.

```
[Price, outPR] = price(outPricer,DoubleBarrierOpt,["all"])
```

```
Price = 6.9667

outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta       Gamma       Lambda      Rho       Theta      Vega
    ______    _______    __________    ______    _______    ______    _______

    6.9667    0.26875    -0.096337    3.8576    0.39855    9.5406    -1.2907
```

Use Black-Scholes Model and Asset Tree Pricer to Price Vanilla Instrument

This example shows the workflow to price a `Vanilla` instrument when you use a `BlackScholes` model and an `AssetTree` pricing method.

Create Vanilla Instrument Object

Use `fininstrument` to create a `Vanilla` instrument object.

```
VanillaOpt = fininstrument("Vanilla",'ExerciseDate',datetime(2019,5,1),'Strike',29,'OptionType','
```

```
VanillaOpt =
  Vanilla with properties:

       OptionType: "put"
    ExerciseStyle: "european"
     ExerciseDate: 01-May-2019
           Strike: 29
             Name: "vanilla_option"
```

Create BlackScholes Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.25)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.2500
    Correlation: 1
```

Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```
Settle = datetime(2018,1,1);
Maturity = datetime(2020,1,1);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',1)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 1
               Dates: 01-Jan-2020
               Rates: 0.0350
              Settle: 01-Jan-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create AssetTree Pricer Object

Use finpricer to create an AssetTree pricer object for a LR equity tree and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
LRPricer = finpricer("AssetTree",'DiscountCurve',myRC,'Model',BlackScholesModel,'SpotPrice',30,'
```

```
LRPricer =
  LRTree with properties:

    InversionMethod: PP1
             Strike: 30
               Tree: [1x1 struct]
        NumPeriods: 15
              Model: [1x1 finmodel.BlackScholes]
      DiscountCurve: [1x1 ratecurve]
          SpotPrice: 30
       DividendType: "continuous"
      DividendValue: 0
          TreeDates: [02-Feb-2018 08:00:00    06-Mar-2018 16:00:00    ...    ]
```

Price Vanilla Instrument

Use price to compute the price and sensitivities for the Vanilla instrument.

```
[Price, outPR] = price(LRPricer,VanillaOpt,"all")
```

```
Price = 2.2542
```

```
outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta       Gamma       Vega     Lambda      Rho       Theta
    ______    ________    _________    ______    ______    _______    ________

    2.2542    -0.33628    0.044039    12.724    -4.469    -16.433    -0.76073
```

BraceGatarekMusiela

Create `BraceGatarekMusiela` model object for `Cap`, `Floor`, `FixedBond`, `FloatBond`, `FloatBondOption`, `FixedBondOption`, `OptionEmbeddedFixedBond`, or `OptionEmbeddedFloatBond` instrument

Description

Create and price a `Cap`, `Floor`, `FloatBond`, `FloatBondOption`, `FixedBond`, `FixedBondOption`, `OptionEmbeddedFixedBond`, or `OptionEmbeddedFloatBond` instrument object with a `BraceGatarekMusiela` model using this workflow:

1. Use `fininstrument` to create a `Cap`, `Floor`, `FixedBond`, `FloatBond`, `FloatBondOption` `FixedBondOption`, `OptionEmbeddedFixedBond`, or `OptionEmbeddedFloatBond` instrument object.
2. Use `finmodel` to specify a `BraceGatarekMusiela` model object for the `Cap`, `Floor`, `FixedBond`, `FloatBond`, `FloatBondOption`, `FixedBondOption`, `OptionEmbeddedFixedBond`, or `OptionEmbeddedFloatBond` instrument object.
3. Use `finpricer` to specify an `IRMonteCarlo` pricing method for a `Cap`, `Floor`, `FixedBond`, `FloatBond`, `FloatBondOption`, `FixedBondOption`, `OptionEmbeddedFixedBond`, or `OptionEmbeddedFloatBond` instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a `Cap`, `Floor`, `FixedBond`, `FloatBond`, `FloatBondOption`, `FixedBondOption`, `OptionEmbeddedFixedBond`, or `OptionEmbeddedFloatBond` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
BraceGatarekMusielaModelObj = finmodel(ModelType,Volatility=volatility_value,
Correlation=correlation_value)
BraceGatarekMusielaModelObj = finmodel( ___ ,Name=Value)
```

Description

`BraceGatarekMusielaModelObj = finmodel(ModelType,Volatility=volatility_value, Correlation=correlation_value)` creates a `BraceGatarekMusiela` model object by specifying `ModelType` and the required name-value arguments `Volatility` and `Correlation` to set the properties on page 11-3066.

`BraceGatarekMusielaModelObj = finmodel( ___ ,Name=Value)` sets optional properties on page 11-3066 using additional name-value arguments in addition to the required arguments in the previous syntax. For example, `BraceGatarekMusielaModelObj =`

`finmodel("BraceGatarekMusiela",Volatility=VolFunc,Correlation=Correlation,Period=1)` creates a `BraceGatarekMusiela` model object. You can specify multiple name-value arguments.

Input Arguments

`ModelType` — Model type

string with value `"BraceGatarekMusiela"` | character vector with value `'BraceGatarekMusiela'`

Model type, specified as a string with the value of `"BraceGatarekMusiela"` or a character vector with the value of `'BraceGatarekMusiela'`.

Data Types: `char` | `string`

`BraceGatarekMusiela` Name-Value Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `BraceGatarekMusielaModelObj = finmodel("BraceGatarekMusiela",Volatility=VolFunc,Correlation=Correlation,Period=1)`

`Volatility` — Volatility

function handle

Volatility, specified as `Volatility` and an (`NumRates-1`)-by-`1` cell array of function handles. Each function handle must take time as an input and return a scalar volatility.

Data Types: `double` | `cell`

`Correlation` — Correlation matrix

matrix

Correlation matrix, specified as `Correlation` and a (`NumRates-1`)-by-(`NumRates-1`) correlation matrix.

Data Types: `double`

Optional `BraceGatarekMusiela` Name-Value Arguments

`NumFactors` — Number of Brownian factors

`NaN` (default) | numeric

Number of Brownian factors, specified as `NumFactors` and a scalar numeric. The default is `NaN` which means that `NumFactors` is equal to the number of rates.

Data Types: `double`

`Period` — Period of forward rates

`2` (default) | numeric

Period of forward rates, specified as `Period` and a scalar numeric. The default is `2`, meaning forward rates are spaced at `0`, `.5`, `1`, `1.5`, and so on.

Data Types: `double`

Properties

`Volatility` — Volatility
function handle

Volatility, returned as a (`NumRates-1`)-by-`1` cell array of function handles.

Data Types: `double` | `cell`

`Correlation` — Correlation matrix
matrix

Correlation matrix, returned as a (`NumRates-1`)-by-(`NumRates-1`) correlation matrix.

Data Types: `double`

`NumFactors` — Number of Brownian factors
`NaN` (default) | numeric

Number of Brownian factors, returned as a scalar numeric.

Data Types: `double`

`Period` — Period of forward rates
`2` (default) | numeric

Period of forward rates, returned as a scalar numeric.

Data Types: `double`

Examples

Use BraceGatarekMusiela Model and IRMonteCarlo Pricer to Price Floor Instrument

This example shows the workflow to price a `Floor` instrument when using a `BraceGatarekMusiela` model and an `IRMonteCarlo` pricing method.

Create Floor Instrument Object

Use `fininstrument` to create a `Floor` instrument object.

```
FloorOpt = fininstrument("Floor",Maturity=datetime(2022,9,15),Strike=0.05,Reset=1,Name="floor_op
```

```
FloorOpt =
  Floor with properties:

                     Strike: 0.0500
                   Maturity: 15-Sep-2022
                ResetOffset: 0
                      Reset: 1
                      Basis: 0
                  Principal: 100
             ProjectionCurve: [0x0 ratecurve]
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                   Holidays: NaT
```

```
                        Name: "floor_option"
```

Create BraceGatarekMusiela Model Object

Use `finmodel` to create a `LinearGaussian2F` model object.

```
BGMVolFunc = @(a,t) (a(1)*t + a(2)).*exp(-a(3)*t) + a(4);
BGMVolParams = [.3 -.02 .7 .14];
numRates = 20;
VolFunc(1:numRates-1) = {@(t) BGMVolFunc(BGMVolParams,t)};
Beta = .08;
CorrFunc = @(i,j,Beta) exp(-Beta*abs(i-j));
Correlation = CorrFunc(meshgrid(1:numRates-1)',meshgrid(1:numRates-1),Beta);
BGM = finmodel("BraceGatarekMusiela",Volatility=VolFunc,Correlation=Correlation,Period=1);
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2019,1,1);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [9x1 datetime]
               Rates: [9x1 double]
              Settle: 01-Jan-2019
        InterpMethod: "linear"
   ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

Create `IRMonteCarlo` Pricer Object

Use `finpricer` to create an `IRMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("IRMonteCarlo",Model=BGM,DiscountCurve=myRC,SimulationDates=ZeroDates)
```

```
outPricer =
  BGMMonteCarlo with properties:

         NumTrials: 1000
     RandomNumbers: []
     DiscountCurve: [1x1 ratecurve]
   SimulationDates: [01-Jul-2019    01-Jan-2020    01-Jan-2021    ...    ]
             Model: [1x1 finmodel.BraceGatarekMusiela]
```

Price Floor Instrument

Use `price` to compute the price and sensitivities for the `Floor` instrument.

```
[Price,outPR] = price(outPricer,FloorOpt,["all"])
```

```
Price = 14.7975

outPR =
  priceresult with properties:

       Results: [1x3 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×3 table
    Price      Delta     Gamma
    _____    ________    _____

    14.797    -398.43    1399.5
```

More About

BraceGatarekMusiela Model

The BraceGatarekMusiela (BGM) model, also known as the LIBOR market model, is a financial model of interest rates.

The BGM model is based on the Heath-Jarrow-Morton (HJM) forward rate approach, it builds a process for LIBOR interest rates, assuming a conditional lognormal process for LIBOR. The BGM model is an interest-rate model that differs from short rate models in that it evolves a set of discrete forward rates.

Specifically, the lognormal BGM model specifies the following diffusion equation for each forward rate

$$\frac{dF_i(t)}{F_i} = -\mu_i dt + \sigma_i(t) dW_i$$

where:

W is an N-dimensional geometric Brownian motion with

$$dW_i(t) dW_j(t) = \rho_{ij}$$

The BGM model relates drifts of the forward rates based on no-arbitrage arguments. Specifically, under the Spot LIBOR measure, drifts are expressed as

$$\mu_i(t) = -\sigma_i(t) \sum_{j=q(t)}^{i} \frac{\tau_j \rho_{i,j} \sigma_j(t) F_j(t)}{1 + \tau_j F_j(t)}$$

where:

$\rho_{i,j}$ represents the input argument `Correlation`.

$\sigma_j(t)$ represents the input argument `Volatility`.

$F_j(t)$ represents the computation of the `ZeroCurve`.

τ_i is the time fraction associated with the i th forward rate.

q(t) is an index defined by the relation

$$T_{q(t)-1} < t < T_{q(t)}$$

and the Spot LIBOR numeraire is defined as

$$B(t) = P(t, T_{q(t)}) \prod_{n=0}^{q(t)-1} (1 + \tau_n F_n(T_n))$$

SABRBraceGatarekMusiela

Create SABRBraceGatarekMusiela model object for Cap, Floor, FixedBond, FloatBond, FloatBondOption, FixedBondOption, OptionEmbeddedFixedBond, or OptionEmbeddedFloatBond instrument

Description

Create and price a Cap, Floor, FloatBond, FloatBondOption, FixedBond, FixedBondOption, OptionEmbeddedFixedBond, or OptionEmbeddedFloatBond instrument object with a SABRBraceGatarekMusiela model using this workflow:

1. Use fininstrument to create a Cap, Floor, FixedBond, FloatBond, FloatBondOption FixedBondOption, OptionEmbeddedFixedBond, or OptionEmbeddedFloatBond instrument object.
2. Use finmodel to specify a SABRBraceGatarekMusiela model object for the Cap, Floor, FixedBond, FloatBond, FloatBondOption, FixedBondOption, OptionEmbeddedFixedBond, or OptionEmbeddedFloatBond instrument object.
3. Use finpricer to specify an IRMonteCarlo pricing method for a Cap, Floor, FixedBond, FloatBond, FloatBondOption, FixedBondOption, OptionEmbeddedFixedBond, or OptionEmbeddedFloatBond instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a Cap, Floor, FixedBond, FloatBond, FloatBondOption, FixedBondOption, OptionEmbeddedFixedBond, or OptionEmbeddedFloatBond instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
SABRBraceGatarekMusielaModelObj = finmodel(ModelType,Alpha=alpha_value,
Beta=beta_value,VolatilityofVolatility=volatilityofvolatility_value,
FwdFwdCorrelation=fwdfwdcorrelation_value,
VolVolCorrelation=volvolcorrelation_value)
```

Description

`SABRBraceGatarekMusielaModelObj = finmodel(ModelType,Alpha=alpha_value, Beta=beta_value,VolatilityofVolatility=volatilityofvolatility_value, FwdFwdCorrelation=fwdfwdcorrelation_value, VolVolCorrelation=volvolcorrelation_value)` creates a classic SABRBraceGatarekMusiela model object with null forward to volatility correlation by specifying ModelType and the required name-value arguments Alpha, Beta, VolatilityofVolatility, FwdFwdCorrelation, and VolVolCorrelation to set properties on page 11-3073 using name-

value arguments. For example, `SABRBraceGatarekMusielaModelObj = finmodel("SABRBraceGatarekMusiela",Alpha=Alpha,Beta=Beta,VolatilityofVolatility=VolVolFunc,FwdFwdCorrelation=FwdFwdCorrelation, VolVolCorrelation=VolVolCorrelation)` creates a classic `SABRBraceGatarekMusiela` model object with null forward to volatility correlation.

`SABRBraceGatarekMusielaModelObj = finmodel( ___ ,Name=Value)` sets optional properties on page 11-3073 using additional name-value arguments in addition to the required arguments in the previous syntax. You can specify multiple name-value arguments. For example, you can use name-value arguments to create the following variations of the `SABRBraceGatarekMusiela` model:

- To create a classic `SABRBraceGatarekMusiela` model object, use the `FwdVolCorrelation` name-value pair argument: `SABRBraceGatarekMusielaModelObj = finmodel("SABRBraceGatarekMusiela",Alpha=Alpha,Beta=Beta,VolatilityofVolatility=VolVolFunc,FwdFwdCorrelation=FwdFwdCorrelation,VolVolCorrelation=VolVolCorrelation,FwdVolCorrelation=FwdVolCorrelation)`
- To create a classic `SABRBraceGatarekMusiela` model object in Rebonato parametric form with null forward-to-volatility correlation, use the `Volatility` name-value pair argument: `SABRBraceGatarekMusielaModelObj = finmodel("SABRBraceGatarekMusiela",Alpha=Alpha,Beta=Beta,VolatilityofVolatility=VolVolFunc,Volatility=VolFunc,FwdFwdCorrelation=FwdFwdCorrelation,VolVolCorrelation=VolVolCorrelation)`
- To create a classic `SABRBraceGatarekMusiela` model object in Rebonato parametric form with `FwdVolCorrelation = CorrFunc(meshgrid(1:numRates-1)',meshgrid(1:numRates-1),.02)`, use the `Volatility` and `FwdVolCorrelation` name-value arguments: `SABRBraceGatarekMusielaModelObj = finmodel("SABRBraceGatarekMusiela",Alpha=Alpha,Beta=Beta,VolatilityofVolatility=VolVolFunc,Volatility=VolFunc,FwdFwdCorrelation=FwdFwdCorrelation,VolVolCorrelation=VolVolCorrelation)`

Input Arguments

`ModelType` — Model type

string with value `"SABRBraceGatarekMusiela"` | character vector with value `'SABRBraceGatarekMusiela'`

Model type, specified as a string with the value of `"SABRBraceGatarekMusiela"` or a character vector with the value of `'SABRBraceGatarekMusiela'`.

Data Types: `char` | `string`

`SABRBraceGatarekMusiela` Name-Value Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `SABRBraceGatarekMusielaModelObj = finmodel("SABRBraceGatarekMusiela",Alpha=Alpha,Beta=Beta,VolatilityofVolatility=VolVolFunc,FwdFwdCorrelation=FwdFwdCorrelation, VolVolCorrelation=VolVolCorrelation)`

`Alpha` — Initial SABR volatilities for each forward rate maturity

positive numeric

Initial SABR volatilities for each forward rate maturity, specified as `Alpha` and an (`NumRates-1`)-by-`1` vector of positive numeric values.

Data Types: `double`

`Beta` — SABR exponent parameters for each forward rate maturity
numeric between `0` and `1`

SABR exponent parameters for each forward rate maturity, specified as `Beta` and an (`NumRates-1`)-by-`1` vector of numeric values between `0` and `1`.

Data Types: `double`

`VolatilityofVolatility` — Variation in volatility
function handle

Variation in volatility, specified as `VolatilityofVolatility` and an (`NumRates-1`)-by-`1` cell array of function handles. Each function handle must take time as an input and return a scalar volatility of volatility that must be positive numeric.

Data Types: `double` | `cell`

`FwdFwdCorrelation` — Correlation matrix for forward rates
numeric between `-1` and `1`

Correlation matrix for forward rates, specified as `FwdFwdCorrelation` and a (`NumRates-1`)-by-(`NumRates-1`) correlation matrix.

Data Types: `double`

`VolVolCorrelation` — Correlation matrix for volatilities
numeric between `-1` and `1`

Correlation matrix for volatilities, specified as `VolVolFwdCorrelation` and an (`NumRates-1`)-by-(`NumRates-1`) correlation matrix.

Data Types: `double`

Optional SABRBraceGatarekMusiela Name-Value Arguments

`Volatility` — Volatility
simulate stochastic volatilities without volatility functions (default) | function handle

Volatility, specified as `Volatility` and an (`NumRates-1`)-by-`1` cell array of function handles. Specify these optional volatility function handles to use the Rebonato (2009) parametric form, which simulates stochastic volatilities with deterministic volatility functions and stochastic correction terms. Each function handle must take time as an input and return a scalar volatility that must be positive numeric.

Data Types: `double`

`FwdVolCorrelation` — Correlation matrix between forward rates and volatilities
(`NumRates-1`)-by-(`NumRates-1`) matrix of zeros (default) | numeric between `-1` and `1`

Correlation matrix between forward rates and volatilities, specified as `FwdVolCorrelation` and an (`NumRates-1`)-by-(`NumRates-1`) correlation matrix. The diagonal elements of the matrix are the SABR Rho parameters.

Data Types: `double`

`Period` — Period of forward rates
2 (default) | numeric

Period of forward rates, specified as `Period` and a scalar numeric. The default is `2`, meaning forward rates are spaced at `0`, `.5`, `1`, `1.5`, and so on.

Data Types: `double`

Properties

`Alpha` — Initial SABR volatilities for each forward rate maturity
positive numeric

Initial SABR volatilities for each forward rate maturity, returned as an `NumRates-1`-by-`1` vector of positive numeric values.

Data Types: `double`

`Beta` — SABR exponent parameters for each forward rate maturity
numeric between `0` and `1`

SABR exponent parameters for each forward rate maturity, returned as an `NumRates-1`-by-`1` vector of numeric values between `0` and `1`.

Data Types: `double`

`VolatilityofVolatility` — Variation in volatility
function handle

Variation in volatility, returned as an `NumRates-1`-by-`1` cell array of function handles.

Data Types: `double` | `cell`

`FwdFwdCorrelation` — Correlation matrix for forward rates
numeric between `-1` and `1`

Correlation matrix for forward rates, returned as an (`NumRates-1`)-by-(`NumRates-1`) correlation matrix.

Data Types: `double`

`VolVolCorrelation` — Correlation matrix for volatilities
numeric between `-1` and `1`

Correlation matrix for volatilities, returned as an (`NumRates-1`)-by-(`NumRates-1`) correlation matrix.

Data Types: `double`

`Volatility` — Volatility
simulate stochastic volatilities without volatility functions (default) | function handle

Volatility, returned as an `NumRates-1`-by-`1` cell array of function handles.

Data Types: `double`

FwdVolCorrelation — Correlation matrix between forward rates and volatilities
(NumRates-1)-by-(NumRates-1) matrix of zeros (default) | numeric between -1 and 1

Correlation matrix between forward rates and volatilities, returned as an (NumRates-1)-by-(NumRates-1) correlation matrix.

Data Types: double

Period — Period of forward rates
2 (default) | numeric

Period of forward rates, returned as a scalar numeric.

Data Types: double

Examples

Use SABR-BraceGatarekMusiela Model with Null Forward-Volatility Correlation and IRMonteCarlo Pricer to Price Cap Instrument

This example shows the workflow to price a Cap instrument when you use a SABRBraceGatarekMusiela model with null Forward-Volatility correlation and an IRMonteCarlo pricing method.

Create Cap Instrument Object

Use fininstrument to create a Cap instrument object.

```
CapOpt = fininstrument("Cap",Maturity=datetime(2021,7,1),Strike=0.035,Name="cap_option")
```

```
CapOpt =
  Cap with properties:

                    Strike: 0.0350
                  Maturity: 01-Jul-2021
               ResetOffset: 0
                     Reset: 1
                     Basis: 0
                 Principal: 100
            ProjectionCurve: [0x0 ratecurve]
   DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
                  Holidays: NaT
                      Name: "cap_option"
```

Create Classic SABRBraceGatarekMusiela Model Object with Null Forward-Volatility Correlation

Use finmodel to create a SABRBraceGatarekMusiela model object that is a classic SABR-BGM model with null Forward-Volatility correlation.

```
Alpha = [0.4;0.34;0.31;0.28];
Beta = [0.5;0.5;0.5;0.5];

SABRBGMVolVolFunc = @(a,t) (a(1)*t + a(2)).*exp(-a(3)*t) + a(4);
```

```
SABRBGMVolVolParams = [.3 -.02 .7 .14];

numRates = 5;
VolVolFunc(1:numRates-1,1) = {@(t) SABRBGMVolVolFunc(SABRBGMVolVolParams,t)};

CorrFunc = @(i,j,B) exp(-B*abs(i-j));
FwdFwdCorrelation = CorrFunc(meshgrid(1:numRates-1)',meshgrid(1:numRates-1),.08);
VolVolCorrelation = CorrFunc(meshgrid(1:numRates-1)',meshgrid(1:numRates-1),.04);

SABRBGM_NF = finmodel("SABRBraceGatarekMusiela",Alpha=Alpha,Beta=Beta,VolatilityofVolatility=Vol
```

```
SABRBGM_NF =
  SABRBraceGatarekMusiela with properties:

                   Period: 2
                    Alpha: [4x1 double]
                     Beta: [4x1 double]
               Volatility: {4x1 cell}
    VolatilityofVolatility: {4x1 cell}
         FwdFwdCorrelation: [4x4 double]
         VolVolCorrelation: [4x4 double]
         FwdVolCorrelation: [4x4 double]
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2019,1,1);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 01-Jan-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `IRMonteCarlo` Pricer Object

Use `finpricer` to create an `IRMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
simDates = datetime(2019,7,1)+calmonths(0:6:24);
outPricer = finpricer("IRMonteCarlo",Model=SABRBGM_NF,DiscountCurve=myRC,SimulationDates=simDates
```

```
outPricer =
  SABRBGMMonteCarlo with properties:
```

```
          NumTrials: 1000
      RandomNumbers: []
      DiscountCurve: [1x1 ratecurve]
    SimulationDates: [01-Jul-2019    01-Jan-2020    01-Jul-2020    ...    ]
              Model: [1x1 finmodel.SABRBraceGatarekMusiela]
```

Price Cap Instrument

Use `price` to compute the price and sensitivities for the `Cap` instrument.

```
[Price,outPR] = price(outPricer,CapOpt,["all"])
```

```
Price = 0.8867

outPR =
  priceresult with properties:

       Results: [1x3 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×3 table
    Price     Delta      Gamma
    ______    ______    _______

    0.8867    118.82    -9486.5
```

You can access the simulated interest-rate `Paths` in the `PricerData` output.

```
outPR.PricerData
```

```
ans = struct with fields:
    SimulationTimes: [6x1 timetable]
              Paths: [6x8x1000 double]
      RandomNumbers: [1x1 struct]
```

Use Classic SABR-BraceGatarekMusiela Model and IRMonteCarlo Pricer to Price Floor Instrument

This example shows the workflow to price a `Floor` instrument when you use a classic `SABRBraceGatarekMusiela` model and an `IRMonteCarlo` pricing method.

Create `Floor` Instrument Object

Use `fininstrument` to create a `Floor` instrument object.

```
FloorOpt = fininstrument("Floor",Maturity=datetime(2021,7,1),Strike=0.05,Reset=1,Name="floor_opti
```

```
FloorOpt =
  Floor with properties:
```

```
                    Strike: 0.0500
                  Maturity: 01-Jul-2021
               ResetOffset: 0
                     Reset: 1
                     Basis: 0
                 Principal: 100
           ProjectionCurve: [0x0 ratecurve]
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                  Holidays: NaT
                      Name: "floor_option"
```

Create Classic SABRBraceGatarekMusiela Model Object

Use `finmodel` to create a classic `SABRBraceGatarekMusiela` model object.

```
Alpha = [0.4;0.34;0.31;0.28];
Beta = [0.5;0.5;0.5;0.5];

SABRBGMVolVolFunc = @(a,t) (a(1)*t + a(2)).*exp(-a(3)*t) + a(4);
SABRBGMVolVolParams = [.3 -.02 .7 .14];

numRates = 5;
VolVolFunc(1:numRates-1,1) = {@(t) SABRBGMVolVolFunc(SABRBGMVolVolParams,t)};

CorrFunc = @(i,j,B) exp(-B*abs(i-j));
FwdFwdCorrelation = CorrFunc(meshgrid(1:numRates-1)',meshgrid(1:numRates-1),.08);
VolVolCorrelation = CorrFunc(meshgrid(1:numRates-1)',meshgrid(1:numRates-1),.04);
SABRRho = [0.0005;0.0006;0.0060;0.0055];
FwdVolCorrelation = diag(SABRRho);

SABRBGM_Classic = finmodel("SABRBraceGatarekMusiela",Alpha=Alpha,Beta=Beta,VolatilityofVolatility
```

```
SABRBGM_Classic =
  SABRBraceGatarekMusiela with properties:

                    Period: 2
                     Alpha: [4x1 double]
                      Beta: [4x1 double]
                Volatility: {4x1 cell}
    VolatilityofVolatility: {4x1 cell}
         FwdFwdCorrelation: [4x4 double]
         VolVolCorrelation: [4x4 double]
         FwdVolCorrelation: [4x4 double]
```

Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2019,1,1);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 01-Jan-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create IRMonteCarlo Pricer Object

Use `finpricer` to create an `IRMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
simDates = datetime(2019,7,1)+calmonths(0:6:24);
outPricer = finpricer("IRMonteCarlo",Model=SABRBGM_Classic,DiscountCurve=myRC,SimulationDates=sim
```

```
outPricer =
  SABRBGMMonteCarlo with properties:

          NumTrials: 1000
      RandomNumbers: []
      DiscountCurve: [1x1 ratecurve]
    SimulationDates: [01-Jul-2019    01-Jan-2020    01-Jul-2020    ...    ]
              Model: [1x1 finmodel.SABRBraceGatarekMusiela]
```

Price Floor Instrument

Use `price` to compute the price and sensitivities for the `Floor` instrument.

```
[Price,outPR] = price(outPricer,FloorOpt,["all"])
```

```
Price = 11.6086
```

```
outPR =
  priceresult with properties:

       Results: [1x3 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×3 table
    Price      Delta     Gamma
    ______    _______    _____

    11.609    -171.15    13201
```

You can access the simulated interest-rate `Paths` in the `PricerData` output.

```
outPR.PricerData
```

```
ans = struct with fields:
    SimulationTimes: [6x1 timetable]
              Paths: [6x8x1000 double]
      RandomNumbers: [1x1 struct]
```

Use SABR-BraceGatarekMusiela Model (Rebonato Parametric Form with Null Forward-Volatility Correlation) and IRMonteCarlo Pricer to Price Fixed Bond Instrument

This example shows the workflow to price a `FixedBond` instrument when you use a `SABRBraceGatarekMusiela` model in Rebonato parametric form with null Forward-Volatility correlation and an `IRMonteCarlo` pricing method.

Create FixedBond Instrument Object

Use `fininstrument` to create a `FixedBond` instrument object.

```
FixB = fininstrument("FixedBond",Maturity=datetime(2021,7,1),CouponRate=0.021,Period=2,Basis=1,P
```

```
FixB =
  FixedBond with properties:

                 CouponRate: 0.0210
                     Period: 2
                      Basis: 1
                EndMonthRule: 1
                   Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                    Holidays: NaT
                   IssueDate: NaT
              FirstCouponDate: NaT
               LastCouponDate: NaT
                    StartDate: NaT
                     Maturity: 01-Jul-2021
                         Name: "fixed_bond_instrument"
```

Create Rebonato Form with Null Forward-Volatility Correlation SABRBraceGatarekMusiela Model Object

Use `finmodel` to create a `SABRBraceGatarekMusiela` model object that is a SABR-BGM model in Rebonato parametric form with null Forward-Volatility correlation.

```
Alpha = [0.4;0.34;0.31;0.28];
Beta = [0.5;0.5;0.5;0.5];
numRates = 5;

SABRBGMVolVolFunc = @(a,t) (a(1)*t + a(2)).*exp(-a(3)*t) + a(4);
SABRBGMVolVolParams = [.3 -.02 .7 .14];

SABRBGMVolFunc = @(a,t) (a(1)*t + a(2)).*exp(-a(3)*t) + a(4);
SABRBGMVolParams = [.2 -.01 .8 .16];
VolFunc(1:numRates-1,1) = {@(t) SABRBGMVolFunc(SABRBGMVolParams,t)};

VolVolFunc(1:numRates-1,1) = {@(t) SABRBGMVolVolFunc(SABRBGMVolVolParams,t)};
```

```
CorrFunc = @(i,j,B) exp(-B*abs(i-j));
FwdFwdCorrelation = CorrFunc(meshgrid(1:numRates-1)',meshgrid(1:numRates-1),.08);
VolVolCorrelation = CorrFunc(meshgrid(1:numRates-1)',meshgrid(1:numRates-1),.04);

SABRBGM_Rebonato = finmodel("SABRBraceGatarekMusiela",Alpha=Alpha,Beta=Beta,VolatilityofVolatili
```

```
SABRBGM_Rebonato =
  SABRBraceGatarekMusiela with properties:

                   Period: 2
                    Alpha: [4x1 double]
                     Beta: [4x1 double]
               Volatility: {4x1 cell}
    VolatilityofVolatility: {4x1 cell}
         FwdFwdCorrelation: [4x4 double]
         VolVolCorrelation: [4x4 double]
         FwdVolCorrelation: [4x4 double]
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2019,1,1);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 01-Jan-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `IRMonteCarlo` Pricer Object

Use `finpricer` to create an `IRMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
simDates = datetime(2019,7,1)+calmonths(0:6:24);
outPricer = finpricer("IRMonteCarlo",Model=SABRBGM_Rebonato,DiscountCurve=myRC,SimulationDates=si
```

```
outPricer =
  SABRBGMMonteCarlo with properties:

          NumTrials: 1000
      RandomNumbers: []
```

```
      DiscountCurve: [1x1 ratecurve]
    SimulationDates: [01-Jul-2019    01-Jan-2020    01-Jul-2020    ...    ]
              Model: [1x1 finmodel.SABRBraceGatarekMusiela]
```

Price FixedBond Instrument

Use `price` to compute the price and sensitivities for the `FixedBond` instrument.

```
[Price,outPR] = price(outPricer,FixB,["all"])
```

```
Price = 103.5433

outPR =
  priceresult with properties:

       Results: [1x3 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×3 table
    Price     Delta     Gamma
    ______    ______    _____

    103.54    -253.5    628.2
```

You can access the simulated interest-rate `Paths` in the `PricerData` output.

```
outPR.PricerData
```

```
ans = struct with fields:
    SimulationTimes: [6x1 timetable]
              Paths: [6x8x1000 double]
      RandomNumbers: [1x1 struct]
```

Use SABR-BraceGatarekMusiela Model (Rebonato Parameteric Form) and IRMonteCarlo Pricer to Price Float Bond Instrument

This example shows the workflow to price a `FloatBond` instrument when you use a `SABRBraceGatarekMusiela` model in Rebonato parametric form and an `IRMonteCarlo` pricing method.

Create FloatBond Instrument Object

Use `fininstrument` to create a `FloatBond` instrument object.

```
FloatB = fininstrument("FloatBond",Maturity=datetime(2021,7,1),Spread=0.025,Reset=2,Basis=1,Princ
```

```
FloatB =
  FloatBond with properties:

                    Spread: 0.0250
            ProjectionCurve: [0x0 ratecurve]
```

```

```

Create Rebonato Form SABRBraceGatarekMusiela Model Object

Use `finmodel` to create a `SABRBraceGatarekMusiela` model object that is a SABR-BGM model in Rebonato parametric form.

```
Alpha = [0.4;0.34;0.31;0.28];
Beta = [0.5;0.5;0.5;0.5];
numRates = 5;

SABRBGMVolVolFunc = @(a,t) (a(1)*t + a(2)).*exp(-a(3)*t) + a(4);
SABRBGMVolVolParams = [.3 -.02 .7 .14];

SABRBGMVolFunc = @(a,t) (a(1)*t + a(2)).*exp(-a(3)*t) + a(4);
SABRBGMVolParams = [.2 -.01 .8 .16];
VolFunc(1:numRates-1,1) = {@(t) SABRBGMVolFunc(SABRBGMVolParams,t)};

VolVolFunc(1:numRates-1,1) = {@(t) SABRBGMVolVolFunc(SABRBGMVolVolParams,t)};

CorrFunc = @(i,j,B) exp(-B*abs(i-j));
FwdFwdCorrelation = CorrFunc(meshgrid(1:numRates-1)',meshgrid(1:numRates-1),.08);
VolVolCorrelation = CorrFunc(meshgrid(1:numRates-1)',meshgrid(1:numRates-1),.04);
SABRRho = [0.0005;0.0006;0.0060;0.0055];
FwdVolCorrelation = diag(SABRRho);

SABRBGM_Rebonato_param = finmodel("SABRBraceGatarekMusiela",Alpha=Alpha,Beta=Beta,VolatilityofVo
```

```
SABRBGM_Rebonato_param =
  SABRBraceGatarekMusiela with properties:

                   Period: 2
                    Alpha: [4x1 double]
                     Beta: [4x1 double]
               Volatility: {4x1 cell}
    VolatilityofVolatility: {4x1 cell}
         FwdFwdCorrelation: [4x4 double]
         VolVolCorrelation: [4x4 double]
         FwdVolCorrelation: [4x4 double]
```

Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2019,1,1);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 01-Jan-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create IRMonteCarlo Pricer Object

Use `finpricer` to create an `IRMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
simDates = datetime(2019,7,1)+calmonths(0:6:24);
outPricer = finpricer("IRMonteCarlo",Model=SABRBGM_Rebonato_param,DiscountCurve=myRC,SimulationDa
```

```
outPricer =
  SABRBGMMonteCarlo with properties:

          NumTrials: 1000
      RandomNumbers: []
      DiscountCurve: [1x1 ratecurve]
    SimulationDates: [01-Jul-2019    01-Jan-2020    01-Jul-2020    ...    ]
              Model: [1x1 finmodel.SABRBraceGatarekMusiela]
```

Price FloatBond Instrument

Use `price` to compute the price and sensitivities for the `FloatBond` instrument.

```
[Price,outPR] = price(outPricer,FloatB,["all"])
```

```
Price = 106.1830
```

```
outPR =
  priceresult with properties:

       Results: [1x3 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×3 table
    Price      Delta     Gamma
```

```
    ______    _______    ______

    106.18    -9.2496    16.927
```

You can access the simulated interest-rate `Paths` in the `PricerData` output.

```
outPR.PricerData
```

```
ans = struct with fields:
    SimulationTimes: [6x1 timetable]
              Paths: [6x8x1000 double]
      RandomNumbers: [1x1 struct]
```

More About

SABR-BGM Model

The SABR-BGM model combines the BGM model and the SABR model by introducing the SABR β_k exponent and the SABR volatility $\alpha_k(t)$ to the BGM forward rate SDE.

$$dF_k(t) = \mu_k(t)dt + \alpha_k {F_k}^{\beta_k}(t)dW_{F_k}(t)$$

$$d\alpha_k(t) = \eta_k(t)dt + \nu_k(t)\alpha_k(t)dW_{\alpha_k}(t)$$

$$\mu_k(t) = \alpha_k(t){F_k}^{\beta_k}(t) \sum_{\gamma(t)\le l\le k} \frac{\rho_{l,k}\tau_l\alpha_l(t){F_l}^{\beta_l}(t)}{1+\tau_l F_l(t)}dt$$

$$\eta_k(t) = \phi_{k,k}\nu_k(t)\alpha_k(t) \sum_{\gamma(t)\le l\le k} \frac{\rho_{l,k}\tau_l\alpha_l(t){F_l}^{\beta_l}(t)}{1+\tau_l F_l(t)}dt$$

$$T_{\gamma(t)-1} \le t < T_{\gamma(t)}$$

SABR-BGM Model

- The volatility-of-volatility function $\nu_k(t)$ is a deterministic function of time.
- The correlation matrix is $2N$-by-$2N$:

$$\mathbf{E}\left[dW_{F_k}(t)dW_{F_l}(t)\right] = \rho_{k,l}dt$$
$$\mathbf{E}\left[dW_{\alpha_k}(t)dW_{\alpha_l}(t)\right] = \omega_{k,l}dt$$
$$\mathbf{E}\left[dW_{F_k}(t)dW_{\alpha_l}(t)\right] = \phi_{k,l}dt$$
$$\phi_{k,k}dt = \rho_k dt$$

$$\Pi = \begin{bmatrix} \rho & \phi \\ \phi^T & \omega \end{bmatrix} = \begin{bmatrix} \rho_{1,1} & \cdots & \rho_{1,N} & \phi_{1,1} & \cdots & \phi_{1,N} \\ \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\ \rho_{N,1} & \cdots & \rho_{N,N} & \phi_{N,1} & \cdots & \phi_{N,N} \\ \phi_{1,1} & \cdots & \phi_{N,1} & \omega_{1,1} & \cdots & \omega_{1,N} \\ \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\ \phi_{1,N} & \cdots & \phi_{N,N} & \omega_{N,1} & \cdots & \omega_{N,N} \end{bmatrix}$$

$\rho_{k,l}$: Forward-Forward correlations (BGM)
$\omega_{k,l}$: Volatility-Volatility correlations
$\phi_{k,l}$: Forward-Volatility correlations
ρ_k: SABR Rho parameters

SABR-BGM Correlation Matrix

A special case of null (zero) Forward-Volatility correlations has some advantages:

- Sets the Forward-Volatility correlations $\varphi_{k,1}$ and the SABR Rho ρ_k to zero, which means fewer parameters to calibrate
- Still fits market data
- Gives lower variance and faster convergence in Monte Carlo simulation

SABR-BGM Model in Rebonato Parametric Form

To facilitate the calibration of the SABR-BGM model using market data, Rebonato et. al. (2009) introduced the parametric form.

In the parametric form, the SABR volatility $\alpha_k(t)$ is decomposed into a product of two components: the deterministic volatility function $g(T_{k-1} - t)$ and the stochastic correction term $s_k(t)$.

$$dF_k(t) = \mu_k(t)dt + \alpha_k {F_k}^{\beta_k}(t)dW_{F_k}(t)$$

$$d\alpha_k(t) = g(T_{k-1} - t)ds_k(t)$$

$$ds_k(t) = \eta_k(t)dt + h(T_{k-1} - t)s_k(t)dW_{S_k}(t)$$

$$\mu_k(t) = g(T_{k-1} - t)s_k(t){F_k}^{\beta_k}(t) \sum_{\gamma(t) \le l \le k} \frac{\rho_{l,k}\tau_l g(T_{l-1} - t)s_l(t){F_l}^{\beta_l}(t)}{1 + \tau_l F_l(t)} dt$$

$$\eta_k(t) = \phi_{k,k} h(T_{k-1} - t)s_k(t) \sum_{\gamma(t) \le l \le k} \frac{\rho_{l,k}\tau_l g(T_{l-1} - t)s_l(t){F_l}^{\beta_l}(t)}{1 + \tau_l F_l(t)} dt$$

$$T_{\gamma(t)-1} \le t < T_{\gamma(t)}$$

SABR-BGM Model in Rebonato Parametric Form

- The volatility function $g(T_{k-1} - t)$ is a deterministic function of time.
- The volatility-of-volatility function $h(T_{k-1} - t)$ is a deterministic function of time.
- The correlation matrix is $2N$-by-$2N$:

$$\mathbf{E}\left[dW_{F_k}(t)dW_{F_l}(t)\right] = \rho_{k,l}dt$$
$$\mathbf{E}\left[dW_{\alpha_k}(t)dW_{\alpha_l}(t)\right] = \omega_{k,l}dt$$
$$\mathbf{E}\left[dW_{F_k}(t)dW_{\alpha_l}(t)\right] = \phi_{k,l}dt$$
$$\phi_{k,k}dt = \rho_k dt$$

$$\Pi = \begin{bmatrix} \rho & \phi \\ \phi^T & \omega \end{bmatrix} = \begin{bmatrix} \rho_{1,1} & \cdots & \rho_{1,N} & \phi_{1,1} & \cdots & \phi_{1,N} \\ \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\ \rho_{N,1} & \cdots & \rho_{N,N} & \phi_{N,1} & \cdots & \phi_{N,N} \\ \phi_{1,1} & \cdots & \phi_{N,1} & \omega_{1,1} & \cdots & \omega_{1,N} \\ \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\ \phi_{1,N} & \cdots & \phi_{N,N} & \omega_{N,1} & \cdots & \omega_{N,N} \end{bmatrix}$$

$\rho_{k,l}$: Forward-Forward correlations (BGM)
$\omega_{k,l}$: Volatility-Volatility correlations
$\phi_{k,l}$: Forward-Volatility correlations
ρ_k: SABR Rho parameters

SABR-BGM Model in Rebonato Parametric Form Correlation Matrix

A special case of null (zero) Forward-Volatility correlations has some advantages:

- Sets the Forward-Volatility correlations $\varphi_{k,1}$ and the SABR Rho ρ_k to zero, which means fewer parameters to calibrate
- Still fits market data
- Gives lower variance and faster convergence in Monte Carlo simulation

LinearGaussian2F

Create `LinearGaussian2F` model object for `Cap`, `Floor`, `Swaption`, `Swap`, `FixedBond`, `FloatBond`, `FloatBondOption`, `FixedBondOption`, `OptionEmbeddedFixedBond`, or `OptionEmbeddedFloatBond` instrument

Description

Create and price a `Cap`, `Floor`, `Swaption`, `Swap`, `FloatBond`, `FloatBondOption`, `FixedBond`, `FixedBondOption`, `OptionEmbeddedFixedBond`, or `OptionEmbeddedFloatBond` instrument object with a `LinearGaussian2F` model using this workflow:

1. Use `fininstrument` to create a `Cap`, `Floor`, `Swaption`, `Swap`, `FixedBond`, `FloatBond`, `FloatBondOption` `FixedBondOption`, `OptionEmbeddedFixedBond`, or `OptionEmbeddedFloatBond` instrument object.
2. Use `finmodel` to specify a `LinearGaussian2F` model object for the `Cap`, `Floor`, `Swaption`, `Swap`, `FixedBond`, `FloatBond`, `FloatBondOption`, `FixedBondOption`, `OptionEmbeddedFixedBond`, or `OptionEmbeddedFloatBond` instrument object.
3. Use `finpricer` to specify an `IRMonteCarlo` pricing method for a `Cap`, `Floor`, `Swaption`, `Swap`, `FixedBond`, `FloatBond`, `FloatBondOption`, `FixedBondOption`, `OptionEmbeddedFixedBond`, or `OptionEmbeddedFloatBond` instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a `Cap`, `Floor`, `Swaption`, `Swap`, `FixedBond`, `FloatBond`, `FloatBondOption`, `FixedBondOption`, `OptionEmbeddedFixedBond`, or `OptionEmbeddedFloatBond` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
LinearGaussian2FModelObj = finmodel(ModelType,Alpha1=alpha1_value,
Sigma1=sigma1_value,Alpha2=alpha2_value,Sigma2=sigma2_value,
Correlation=correlation_value)
```

Description

`LinearGaussian2FModelObj = finmodel(ModelType,Alpha1=alpha1_value, Sigma1=sigma1_value,Alpha2=alpha2_value,Sigma2=sigma2_value, Correlation=correlation_value)` creates a `LinearGaussian2F` model object by specifying `ModelType` and the required name-value arguments for `Alpha1`, `Sigma1`, `Alpha2`, `Sigma2` and `Correlation` to set properties on page 11-3091 using name-value pair arguments. For example, `LinearGaussian2FModelObj = finmodel("LinearGaussian2F",Alpha1=0.07,Sigma1=0.01,Alpha2=0.5,Sigma2=0.006,Correlation=-0.7)` creates a `LinearGaussian2F` model object.

Input Arguments

`ModelType` — Model type

string with value `"LinearGaussian2F"` | character vector with value `'LinearGaussian2F'`

Model type, specified as a string with the value of `"LinearGaussian2F"` or a character vector with the value of `'LinearGaussian2F'`.

Data Types: `char` | `string`

`LinearGaussian2F` Name-Value Arguments

Specify required pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `LinearGaussian2FModelObj = finmodel("LinearGaussian2F",Alpha1=0.07,Sigma1=0.01,Alpha2=0.5,Sigma2=0.006,Correlation=-0.7)`

`Alpha1` — Positive mean reversion value for first factor

scalar numeric | timetable

Positive mean reversion value for first factor, specified as `Alpha1` and a scalar numeric or timetable.

Data Types: `double` | `timetable`

`Sigma1` — Positive volatility for first factor

scalar numeric | timetable

Positive volatility for first factor, specified as `Sigma1` and a scalar numeric or timetable.

Data Types: `double` | `timetable`

`Alpha2` — Positive mean reversion value for second factor

numeric | timetable

Positive mean reversion value for the second factor, specified as `Alpha2` and a scalar numeric or timetable.

Data Types: `double` | `timetable`

`Sigma2` — Positive volatility for second factor

numeric | timetable

Positive volatility for second factor, specified as `Sigma2` and a scalar numeric or timetable.

Data Types: `double` | `timetable`

`Correlation` — Scalar correlation of factors

numeric

Scalar correlation of factors, specified as `Correlation` and a scalar numeric.

Data Types: `double`

Properties

`Alpha1` — Positive mean reversion for first factor
numeric | timetable

Positive mean reversion for first factor, returned as a scalar numeric or timetable.

Data Types: `double`

`Sigma1` — Positive volatility for first factor
numeric | timetable

Positive volatility for first factor, returned as a scalar numeric value or timetable.

Data Types: `double`

`Alpha2` — Positive mean reversion value for second factor
numeric | timetable

Positive mean reversion value for second factor, returned as a scalar numeric or timetable.

Data Types: `double`

`Sigma2` — Positive volatility for second factor
numeric | timetable

Positive volatility for second factor, returned as a scalar numeric value or timetable.

Data Types: `double` | `timetable`

`Correlation` — Scalar correlation of factors
numeric

Scalar correlation of factors, returned as a scalar numeric value.

Data Types: `double`

Examples

Use LinearGaussian2F Model and IRMonteCarlo Pricer to Price Cap Instrument

This example shows the workflow to price a `Cap` instrument when using a `LinearGaussian2F` model and an `IRMonteCarlo` pricing method.

Create Cap Instrument Object

Use `fininstrument` to create a `Cap` instrument object.

```
CapOpt = fininstrument("Cap",Maturity=datetime(2022,9,15),Strike=0.01,Reset=2,Name="cap_option")
```

```
CapOpt =
  Cap with properties:

                    Strike: 0.0100
                  Maturity: 15-Sep-2022
               ResetOffset: 0
```

```
                    Reset: 2
                    Basis: 0
                Principal: 100
          ProjectionCurve: [0x0 ratecurve]
  DaycountAdjustedCashFlow: 0
     BusinessDayConvention: "actual"
                 Holidays: NaT
                     Name: "cap_option"
```

Create LinearGaussian2F Model Object

Use `finmodel` to create a `LinearGaussian2F` model object.

```
LinearGaussian2FModel = finmodel("LinearGaussian2F",Alpha1=0.07,Sigma1=0.01,Alpha2=0.5,Sigma2=0.0
```

```
LinearGaussian2FModel =
  LinearGaussian2F with properties:

        Alpha1: 0.0700
        Sigma1: 0.0100
        Alpha2: 0.5000
        Sigma2: 0.0060
   Correlation: -0.7000
```

Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2019,1,1);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

               Type: "zero"
       Compounding: -1
             Basis: 0
             Dates: [10x1 datetime]
             Rates: [10x1 double]
            Settle: 01-Jan-2019
      InterpMethod: "linear"
   ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

Create IRMonteCarlo Pricer Object

Use `finpricer` to create an `IRMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("IRMonteCarlo",Model=LinearGaussian2FModel,DiscountCurve=myRC,SimulationDat
```

```
outPricer =
  G2PPMonteCarlo with properties:

         NumTrials: 1000
      RandomNumbers: []
      DiscountCurve: [1x1 ratecurve]
    SimulationDates: [01-Jul-2019    01-Jan-2020    01-Jan-2021    ...    ]
              Model: [1x1 finmodel.LinearGaussian2F]
```

Price Cap Instrument

Use `price` to compute the price and sensitivities for the `Cap` instrument.

```
[Price,outPR] = price(outPricer,CapOpt,["all"])
```

```
Price = 1.2156

outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×4 table
    Price     Delta     Gamma          Vega
    ______    ______    _____    _______________

    1.2156    131.37    11048    126.5    -157.38
```

More About

LinearGaussian2F Model

The LinearGaussian2F two-factor additive Gaussian interest-rate model.

Specifically, the LinearGaussian2F model is defined using the following equations:

$$r(t) = x(t) + y(t) + \phi(t)$$

$$dx(t) = -a(t)x(t)dt + \sigma(t)dW_1(t), x(0) = 0$$

$$dy(t) = -b(t)y(t)dt + \eta(t)dW_2(t), y(0) = 0$$

where $dW_1(t)dW_2(t) = \rho dt$ is a two-dimensional Brownian motion with correlation ρ, and ϕ is a function chosen to match the initial zero curve.

BlackKarasinski

Create `BlackKarasinski` model object for a `Cap`, `FloorSwaption`, `Swap`, `FloatBond`, `FixedBond`, `FixedBondOption`, `FloatBondOption`, `OptionEmbeddedFixedBond`, or `OptionEmbeddedFloatBond` instrument

Description

Create and price a `Cap`, `Floor`, `Swaption`, `Swap`, `FloatBond`, `FixedBond`, `FixedBondOption`, `FloatBondOption`, `OptionEmbeddedFixedBond`, or `OptionEmbeddedFloatBond` instrument object with a `BlackKarasinski` model using this workflow:

1. Use `fininstrument` to create a `Cap`, `Floor`, `Swaption`, `Swap`, `FloatBond`, `FixedBond`, `FixedBondOption`, `FloatBondOption`, `OptionEmbeddedFixedBond`, or `OptionEmbeddedFloatBond` instrument object.
2. Use `finmodel` to specify a `BlackKarasinski` model object for the `Cap`, `Floor`, `Swaption`, `Swap`, `FixedBond`, `FloatBond`, `FixedBondOption`, `FloatBondOption`, `OptionEmbeddedFixedBond`, or `OptionEmbeddedFloatBond` instrument object.
3. Use `finpricer` to specify a `IRTree` or `IRMonteCarlo` pricing method for the `Cap`, `Floor`, `Swaption`, `SwapFixedBond`, `FloatBond`, `FixedBondOption` or `OptionEmbeddedFixedBond` instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a `Cap`, `FloorSwaption`, `Swap`, `FixedBond`, `FloatBond`, `FixedBondOption`, `FloatBondOption`, `OptionEmbeddedFixedBond`, or `OptionEmbeddedFloatBond` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
BlackKarasinskiModelObj = finmodel(ModelType,'Alpha',alpha_value,'
Sigma',sigma_value)
```

Description

`BlackKarasinskiModelObj = finmodel(ModelType,'Alpha',alpha_value,'Sigma',sigma_value)` creates a `BlackKarasinski` model object by specifying `ModelType` and the required name-value pair arguments `Alpha` and `Sigma` to set the properties on page 11-3096. For example, `BlackKarasinskiModelObj = finmodel("BlackKarasinski",'Alpha',0.052,'Sigma',0.34)` creates a `BlackKarasinski` model object.

Input Arguments

ModelType — Model type

string with value "BlackKarasinski" | character vector with value 'BlackKarasinski'

Model type, specified as a string with the value of "BlackKarasinski" or a character vector with the value of 'BlackKarasinski'.

Data Types: char | string

BlackKarasinski Name-Value Pair Arguments

Specify required and optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: BlackKarasinskiModelObj = finmodel("BlackKarasinski",'Alpha',0.052,'Sigma',0.34)

Alpha — Mean reversion speed

numeric | timetable

Mean reversion speed, specified as the comma-separated pair consisting of 'Alpha' and a scalar numeric value or timetable.

Alpha accepts a timetable, where the first column is dates and the second column is the associated Alpha value.

Data Types: double | timetable

Sigma — Volatility

numeric | timetable

Volatility, specified as the comma-separated pair consisting of 'Sigma' and a scalar numeric value or timetable.

Sigma accepts a timetable, where the first column is dates and the second column is the associated Sigma value.

Data Types: double | timetable

Properties

Alpha — Mean reversion speed

numeric

Mean reversion speed, returned as a scalar numeric value or timetable.

Data Types: double | timetable

Sigma — Volatility

numeric

Volatility, returned as a scalar numeric value or timetable.

Data Types: double | timetable

Examples

Use Black-Karasinski Model and Black-Karasinski Tree Pricer to Price FixedBondOption Instrument

This example shows the workflow to price a `FixedBondOption` instrument when you use a `BlackKarasinski` model and an `IRTree` pricing method.

Create FixedBond Instrument Object

Use `fininstrument` to create a `FixedBond` instrument object as the underlying bond.

```
BondInst = fininstrument("FixedBond",'Maturity',datetime(2029,9,15),'CouponRate',.024,'Principal
```

```
BondInst =
  FixedBond with properties:

                 CouponRate: 0.0240
                     Period: 1
                      Basis: 1
                EndMonthRule: 1
                   Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                    Holidays: NaT
                   IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 15-Sep-2029
                        Name: "fixed_bond"
```

Create FixedBondOption Instrument Object

Use `fininstrument` to create a `FixedBondOption` instrument object.

```
FixedBOption = fininstrument("FixedBondOption",'ExerciseDate',datetime(2025,9,15),'Strike',800,'
```

```
FixedBOption =
  FixedBondOption with properties:

       OptionType: "put"
    ExerciseStyle: "american"
     ExerciseDate: 15-Sep-2025
           Strike: 800
             Bond: [1x1 fininstrument.FixedBond]
             Name: "fixed_bond_option"
```

Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2019,9,15);
Type = 'zero';
ZeroTimes = [calyears([1:10])]';
```

```
ZeroRates = [0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307 0.0310]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates, 'Basis',5)

myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 5
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create BlackKarasinski Model Object

Use `finmodel` to create a `BlackKarasinski` model object.

```
BlackKarasinskiModel = finmodel("BlackKarasinski",'Alpha',0.02,'Sigma',0.34)

BlackKarasinskiModel =
  BlackKarasinski with properties:

    Alpha: 0.0200
    Sigma: 0.3400
```

Create IRTree Pricer Object

Use `finpricer` to create an `IRTree` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
BKTreePricer = finpricer("IRTree",'Model',BlackKarasinskiModel,'DiscountCurve',myRC,'TreeDates',Z

BKTreePricer =
  HWBKTree with properties:

             Tree: [1x1 struct]
        TreeDates: [10x1 datetime]
            Model: [1x1 finmodel.BlackKarasinski]
    DiscountCurve: [1x1 ratecurve]

BKTreePricer.Tree

ans = struct with fields:
        tObs: [0 1 2 3 4 5 6 7 8 9]
        dObs: [15-Sep-2019    15-Sep-2020    15-Sep-2021    ...    ]
      CFlowT: {1x10 cell}
       Probs: {1x9 cell}
     Connect: {1x9 cell}
     FwdTree: {1x10 cell}
    RateTree: {1x10 cell}
```

Price FixedBondOption Instrument

Use `price` to compute the price and sensitivities for the `FixedBondOption` instrument.

```
[Price, outPR] = price(BKTreePricer,FixedBOption,["all"])
```

```
Price = 705.2729

outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×4 table
    Price     Delta      Gamma        Vega
    ______    ______    _______    ___________

    705.27    844.75    -8084.8    -1.1369e-09
```

Use Black-Karasinski Model and IRMonteCarlo Pricer to Price Fixed Bond Instrument

This example shows the workflow to price a `FixedBond` instrument when using a `BlackKarasinski` model and an `IRMonteCarlo` pricing method.

Create FixedBond Instrument Object

Use `fininstrument` to create a `FixedBond` instrument object.

```
FixB = fininstrument("FixedBond",Maturity=datetime(2022,9,15),CouponRate=0.05,Name="fixed_bond")
```

```
FixB =
  FixedBond with properties:

                 CouponRate: 0.0500
                     Period: 2
                      Basis: 0
                EndMonthRule: 1
                  Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                   Holidays: NaT
                  IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 15-Sep-2022
                        Name: "fixed_bond"
```

Create BlackKarasinski Model Object

Use `finmodel` to create a `BlackKarasinski` model object.

```
BlackKarasinskiModel = finmodel("BlackKarasinski",'Alpha',0.02,'Sigma',0.34)
```

```
BlackKarasinskiModel =
  BlackKarasinski with properties:

    Alpha: 0.0200
    Sigma: 0.3400
```

Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2019,1,1);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 01-Jan-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create IRMonteCarlo Pricer Object

Use `finpricer` to create an `IRMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("IRMonteCarlo",Model=BlackKarasinskiModel,DiscountCurve=myRC,SimulationDate
```

```
outPricer =
  BKMonteCarlo with properties:

          NumTrials: 1000
      RandomNumbers: []
      DiscountCurve: [1x1 ratecurve]
    SimulationDates: [15-Mar-2019    15-Sep-2019    15-Mar-2020    ...    ]
              Model: [1x1 finmodel.BlackKarasinski]
```

Price FixedBond Instrument

Use `price` to compute the price for the `FixedBond` instrument.

```
[Price,outPR] = price(outPricer,FixB,["all"])
```

```
Price = 113.3046
```

```
outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×4 table
    Price     Delta     Gamma      Vega
    _____    _______    ______    ______

    113.3    -310.39    -26741    2.0294
```

BlackDermanToy

Create BlackDermanToy model object for a Cap, Floor, Swaption, Swap, FloatBond, FixedBond, FixedBondOption, FloatBondOption, OptionEmbeddedFixedBond, or OptionEmbeddedFloatBond instrument

Description

Create and price a Cap, Floor, Swaption, Swap, FloatBond, FixedBond, FixedBondOption, FloatBondOption, OptionEmbeddedFixedBond, or OptionEmbeddedFloatBond instrument object with a BlackDermanToy model using this workflow:

1. Use fininstrument to create a Cap, Floor, Swaption, Swap, FloatBond, FixedBond, FixedBondOption, FloatBondOption, OptionEmbeddedFixedBond, or OptionEmbeddedFloatBond instrument object.
2. Use finmodel to specify a BlackDermanToy model object for the Cap, Floor, Swaption, Swap, FixedBond, FloatBond, FixedBondOption, FloatBondOption, OptionEmbeddedFixedBond, or OptionEmbeddedFloatBond instrument object.
3. Use finpricer to specify an IRTree pricing method for the Cap, Floor, Swaption, Swap, FixedBond, FloatBond, FixedBondOption, OptionEmbeddedFixedBond, or OptionEmbeddedFloatBond instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a Cap, Floor, Swaption, Swap, FixedBond, FloatBond, FixedBondOption, FloatBondOption, OptionEmbeddedFixedBond, or OptionEmbeddedFloatBond instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
BlackDermanToyModelObj = finmodel(ModelType,Sigma=sigma_value)
```

Description

BlackDermanToyModelObj = finmodel(ModelType,Sigma=sigma_value) creates a BlackDermanToy model object by specifying ModelType and the required name-value pair argument Sigma to set the properties on page 11-3103. For example, BlackDermanToyModelObj = finmodel("BlackDermanToy",Sigma=0.34) creates a BlackDermanToy model object with a Sigma volatility of .34.

Input Arguments

ModelType — Model type
string with value "BlackDermanToy" | character vector with value 'BlackDermanToy'

Model type, specified as a string with the value of `"BlackDermanToy"` or a character vector with the value of `'BlackDermanToy'`.

Data Types: `char` | `string`

`BlackDermanToy` Name-Value Pair Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `BlackDermanToyModelObj = finmodel("BlackDermanToy",Sigma=0.34)`

`Sigma` — Positive volatility
numeric | timetable

Positive volatility, specified as `Sigma` and a scalar numeric value or timetable.

`Sigma` accepts a `timetable`, where the first column is dates and the second column is the associated `Sigma` value.

Data Types: `double` | `timetable`

Properties

`Sigma` — Positive volatility
numeric

Positive volatility, returned as a scalar numeric value or timetable.

Data Types: `double` | `timetable`

Examples

Use Black-Derman-Toy Model and BlackDermanToy Tree Pricer to Price FixedBondOption Instrument

This example shows the workflow to price a `FixedBondOption` instrument when you use a `BlackDermanToy` model and an `IRTree` pricing method.

Create `FixedBond` Instrument Object

Use `fininstrument` to create a `FixedBond` instrument object as the underlying bond.

```
BondInst = fininstrument("FixedBond",Maturity=datetime(2029,9,15),CouponRate=.024,Principal=100,I
```

```
BondInst =
  FixedBond with properties:

                 CouponRate: 0.0240
                     Period: 1
                      Basis: 1
               EndMonthRule: 1
                  Principal: 100
```

```
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                    Holidays: NaT
                   IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 15-Sep-2029
                        Name: "fixed_bond"
```

Create `FixedBondOption` Instrument Object

Use `fininstrument` to create a `FixedBondOption` instrument object.

```
FixedBOption = fininstrument("FixedBondOption",ExerciseDate=datetime(2025,9,15),Strike=80,Bond=Bo
```

```
FixedBOption =
  FixedBondOption with properties:

       OptionType: "put"
    ExerciseStyle: "american"
     ExerciseDate: 15-Sep-2025
           Strike: 80
             Bond: [1x1 fininstrument.FixedBond]
             Name: "fixed_bond_option"
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2019,9,15);
Type = 'zero';
ZeroTimes = [calyears(1:10)]';
ZeroRates = [0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307 0.0310]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates,Basis=5)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 5
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `BlackDermanToy` Model Object

Use `finmodel` to create a `BlackDermanToy` model object.

```
BlackDermanToyModel = finmodel("BlackDermanToy",Sigma=0.14)
```

```
BlackDermanToyModel =
  BlackDermanToy with properties:

    Sigma: 0.1400
```

Create IRTree Pricer Object

Use `finpricer` to create an `IRTree` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
BKTreePricer = finpricer("IRTree",Model=BlackDermanToyModel,DiscountCurve=myRC,TreeDates=ZeroDate
```

```
BKTreePricer =
  BDTTree with properties:

             Tree: [1x1 struct]
        TreeDates: [10x1 datetime]
            Model: [1x1 finmodel.BlackDermanToy]
    DiscountCurve: [1x1 ratecurve]
```

```
BKTreePricer.Tree
```

```
ans = struct with fields:
        tObs: [0 1 2 3 4 5 6 7 8 9]
        dObs: [15-Sep-2019    15-Sep-2020    15-Sep-2021    ...    ]
     FwdTree: {1x10 cell}
    RateTree: {1x10 cell}
```

Price FixedBondOption Instrument

Use `price` to compute the price and sensitivities for the `FixedBondOption` instrument.

```
[Price, outPR] = price(BKTreePricer,FixedBOption,"all")
```

```
Price = 0.5153
```

```
outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×4 table
     Price     Delta      Gamma      Vega
    _______    ______    _______    ______

    0.51526    106.21    -1973.8    15.402
```

Heston

Create `Heston` model object for `Vanilla`, `Asian`, `Barrier`, `DoubleBarrier`, `Lookback`, `PartialLookback`, `VarianceSwap`, `Touch`, `DoubleTouch`, `Cliquet`, or `Binary` instrument

Description

Create and price a `Vanilla`, `Asian`, `Barrier`, `DoubleBarrier`, `Lookback`, `PartialLookback`, `VarianceSwap`, `Touch`, `DoubleTouch`, `Cliquet`, or `Binary` instrument object with a `Heston` model using this workflow:

1. Use `fininstrument` to create a `Vanilla`, `Barrier`, `Lookback`, `PartialLookback`, `Asian`, `DoubleBarrier`, `VarianceSwap`, `Binary`, `Touch`, `Cliquet`, or `DoubleTouch` instrument object.
2. Use `finmodel` to specify a `Heston` model object for the `Vanilla`, `Asian`, `Barrier`, `DoubleBarrier`, `Lookback`, `PartialLookback`, `VarianceSwap`, `Touch`, `DoubleTouch`, `Cliquet`, or `Binary` instrument object.
3. Use `finpricer` to specify a `FiniteDifference`, `NumericalIntegration`, or `FFT` pricing method for the `Vanilla` instrument object.

   Use `finpricer` to specify an `AssetMonteCarlo` pricing method for the `Vanilla`, `Asian`, `BarrierDoubleBarrier`, `Lookback`, `PartialLookback`, `VarianceSwap`, `Touch`, `DoubleTouch`, `Cliquet`, or `Binary` instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a `Vanilla`, `AsianBarrier`, `DoubleBarrier`, `Lookback`, `PartialLookback`, `VarianceSwap`, `Touch`, `DoubleTouch`, or `Binary` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
HestonModelObj = finmodel(ModelType,'V0'v0_value,'ThetaV',thetav_value,'
Kappa',kappa_value,'SigmaV',sigmav_value,'RhoSV',rhosv_value)
```

Description

`HestonModelObj = finmodel(ModelType,'V0'v0_value,'ThetaV',thetav_value,'Kappa',kappa_value,'SigmaV',sigmav_value,'RhoSV',rhosv_value)` creates a `Black` model object by specifying `ModelType` and the required name-value pair arguments `V0`, `ThetaV`, `Kappa`, `SigmaV`, and `RhoSV` to set properties on page 11-3109 using required name-value pair arguments. For example, `HestonModelObj = finmodel("Heston",'V0',0.032,'ThetaV',0.1,'Kappa',0.003,'SigmaV',0.2,'RhoSV',0.9)` creates a `Heston` model object.

Input Arguments

`ModelType` — Model type

string with value `"Heston"` | character vector with value `'Heston'`

Model type, specified as a string with the value of `"Heston"` or a character vector with the value of `'Heston'`.

Data Types: `char` | `string`

`Heston` Name-Value Pair Arguments

Specify required pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `HestonModelObj = finmodel("Heston",'V0',0.032,'ThetaV',0.1,'Kappa',0.003,'SigmaV',0.2,'RhoSV', 0.9)`

`V0` — Initial variance of underlying asset

numeric

Initial variance of the underlying asset, specified as the comma-separated pair consisting of `'V0'` and a scalar numeric value.

Data Types: `double`

`ThetaV` — Long-term variance of underlying asset

numeric

Long-term variance of the underlying asset, specified as the comma-separated pair consisting of `'ThetaV'` and a scalar numeric value.

Data Types: `double`

`Kappa` — Mean revision speed for the variance of underlying asset

numeric

Mean revision speed for the underlying asset, specified as the comma-separated pair consisting of `'Kappa'` and a scalar numeric value.

Data Types: `double`

`SigmaV` — Volatility of the variance of underlying asset

numeric

Volatility of the variance of the underlying asset, specified as the comma-separated pair consisting of `'SigmaV'` and a scalar numeric value.

Data Types: `double`

`RhoSV` — Correlation between Weiner processes for underlying asset and its variance

numeric

Correlation between the Weiner processes for the underlying asset and its variance, specified as the comma-separated pair consisting of `'RhoSV'` and a scalar numeric value.

Data Types: `double`

Properties

`V0` — Initial variance of underlying asset

numeric

Initial variance of the underlying asset, returned as a scalar numeric value.

Data Types: `double`

`ThetaV` — Long-term variance of underlying asset

numeric

Long-term variance of the underlying asset, returned as a scalar numeric value.

Data Types: `double`

`Kappa` — Mean revision speed for the variance of underlying asset

numeric

Mean revision speed for the underlying asset, returned as a scalar numeric value.

Data Types: `double`

`SigmaV` — Volatility of the variance of underlying asset

numeric

Volatility of the variance of the underlying asset, returned as a scalar numeric value.

Data Types: `double`

`RhoSV` — Correlation between Weiner processes for underlying asset and its variance

numeric

Correlation between the Weiner processes for the underlying asset and its variance, returned as a scalar numeric value.

Data Types: `double`

Examples

Use Heston Model and FFT Pricer to Price Vanilla Instrument

This example shows the workflow to price a `Vanilla` instrument when you use a `Heston` model and an `FFT` pricing method.

Create `Vanilla` Instrument Object

Use `fininstrument` to create a `Vanilla` instrument object.

```
VanillaOpt = fininstrument("Vanilla",'ExerciseDate',datetime(2022,9,15),'Strike',105,'ExerciseSty
```

```
VanillaOpt =
  Vanilla with properties:

       OptionType: "call"
    ExerciseStyle: "european"
     ExerciseDate: 15-Sep-2022
           Strike: 105
             Name: "vanilla_option"
```

Create Heston Model Object

Use `finmodel` to create a `Heston` model object.

```
HestonModel = finmodel("Heston",'V0',0.032,'ThetaV',0.1,'Kappa',0.003,'SigmaV',0.2,'RhoSV',0.9)
```

```
HestonModel =
  Heston with properties:

        V0: 0.0320
    ThetaV: 0.1000
     Kappa: 0.0030
    SigmaV: 0.2000
     RhoSV: 0.9000
```

Create ratecurve Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create FFT Pricer Object

Use `finpricer` to create an FFT pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("FFT",'DiscountCurve',myRC,'Model',HestonModel,'SpotPrice',100,'Characteris
```

```
outPricer =
  FFT with properties:
```

```
                  Model: [1x1 finmodel.Heston]
          DiscountCurve: [1x1 ratecurve]
              SpotPrice: 100
           DividendType: "continuous"
          DividendValue: 0
                 NumFFT: 8192
    CharacteristicFcnStep: 0.2000
          LogStrikeStep: 0.0038
      CharacteristicFcn: @characteristicFcnHeston
          DampingFactor: 1.5000
             Quadrature: "simpson"
        VolRiskPremium: 0
             LittleTrap: 1
```

Price `Vanilla` Instrument

Use `price` to compute the price and sensitivities for the `Vanilla` instrument.

```
[Price, outPR] = price(outPricer,VanillaOpt,["all"])
```

```
Price = 14.7545

outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta      Gamma       Theta       Rho       Vega     VegaLT
    _____    _______    ________    ________    ______    ______    ______

    14.754    0.44868    0.021649    -0.20891    120.45    88.192    1.3248
```

Use Heston Model and Asset Monte-Carlo Pricer to Price Lookback Instrument

This example shows the workflow to price a `LookBack` instrument when you use a `Heston` model and an `AssetMonetCarlo` pricing method.

Create Lookback Instrument Object

Use `fininstrument` to create a `Lookback` instrument object.

```
LookbackOpt = fininstrument("Lookback",'Strike',105,'ExerciseDate',datetime(2022,9,15),'OptionTy
```

```
LookbackOpt =
  Lookback with properties:

       OptionType: "put"
           Strike: 105
      AssetMinMax: NaN
    ExerciseStyle: "american"
```

```
     ExerciseDate: 15-Sep-2022
             Name: "lookback_option"
```

Create Heston Model Object

Use `finmodel` to create a `Heston` model object.

```
HestonModel = finmodel("Heston",'V0',0.032,'ThetaV',0.1,'Kappa',0.003,'SigmaV',0.08,'RhoSV',0.9)
```

```
HestonModel =
  Heston with properties:

        V0: 0.0320
    ThetaV: 0.1000
     Kappa: 0.0030
    SigmaV: 0.0800
     RhoSV: 0.9000
```

Create ratecurve Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create AssetMonteCarlo Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo",'DiscountCurve',myRC,"Model",HestonModel,'SpotPrice',90,
```

```
outPricer =
  HestonMonteCarlo with properties:

      DiscountCurve: [1x1 ratecurve]
          SpotPrice: 90
    SimulationDates: 15-Sep-2022
          NumTrials: 1000
      RandomNumbers: []
              Model: [1x1 finmodel.Heston]
```

```
       DividendType: "continuous"
      DividendValue: 0
```

Price Lookback Instrument

Use `price` to compute the price and sensitivities for the `Lookback` instrument.

```
[Price, outPR] = price(outPricer,LookbackOpt,["all"])
```

```
Price = 21.9733
```

```
outPR =
  priceresult with properties:

       Results: [1x8 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×8 table
    Price      Delta      Gamma     Lambda       Rho        Theta      Vega      VegaLT
    ______    ________    _____    ________    ________    ________    ______    ______

    21.973    -0.7701       0       -3.1542    -215.94     0.28812    99.825    1.447

HullWhite

Create HullWhite model object for Cap, Floor, Swaption, Swap, FixedBond, FloatBond, FloatBondOption, FixedBondOption, OptionEmbeddedFixedBond, or OptionEmbeddedFloatBond instrument

Description

Create and price a Cap, Floor, Swaption, Swap, FloatBond, FloatBondOption, FixedBond, FixedBondOption, OptionEmbeddedFixedBond, or OptionEmbeddedFloatBond instrument object with a HullWhite model using this workflow:

1. Use fininstrument to create a Cap, Floor, Swaption, Swap, FixedBond, FloatBond, FloatBondOption FixedBondOption, OptionEmbeddedFixedBond, or OptionEmbeddedFloatBond instrument object.
2. Use finmodel to specify a HullWhite model object for the Cap, Floor, Swaption, Swap, FixedBond, FloatBond, FloatBondOption, FixedBondOption, OptionEmbeddedFixedBond, or OptionEmbeddedFloatBond instrument object.
3. Use finpricer to specify a HullWhite pricing method for a Cap, Floor, or Swaption instrument object and use an IRTree or IRMonteCarlo pricing method for the Cap, Floor, Swaption, Swap, FixedBond, FloatBond, FloatBondOption, FixedBondOption, OptionEmbeddedFixedBond, or OptionEmbeddedFloatBond instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a Cap, Floor, Swaption, Swap, FixedBond, FloatBond, FloatBondOption, FixedBondOption, OptionEmbeddedFixedBond, or OptionEmbeddedFloatBond instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
HullWhiteModelObj = finmodel(ModelType,'Alpha'alpha_value,'
Sigma',sigma_value)
```

Description

`HullWhiteModelObj = finmodel(ModelType,'Alpha'alpha_value,'Sigma',sigma_value)` creates a HullWhite model object by specifying ModelType and the required name-value pair argumentsAlpha and Sigma to set properties on page 11-3115 using name-value pair arguments. For example, `HullWhiteModelObj = finmodel("HullWhite",'Alpha',0.052,'Sigma',0.34)` creates a HullWhite model object.

Input Arguments

`ModelType` — Model type
string with value `"HullWhite"` | character vector with value `'HullWhite'`

Model type, specified as a string with the value of `"HullWhite"` or a character vector with the value of `'HullWhite'`.

Data Types: `char` | `string`

`HullWhite` Name-Value Pair Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `HullWhiteModelObj = finmodel("HullWhite",'Alpha',0.052,'Sigma',0.34)`

`Alpha` — Mean reversion speed
numeric

Mean reversion speed, specified as the comma-separated pair consisting of `'Alpha'` and a scalar numeric or timetable.

`Alpha` accepts a `timetable`, where the first column is dates and the second column is the associated `Alpha` value.

Data Types: `double` | `timetable`

`Sigma` — Volatility
numeric | timetable

Volatility, specified as the comma-separated pair consisting of `'Sigma'` and a scalar numeric or timetable.

`Sigma` accepts a `timetable`, where the first column is dates and the second column is the associated `Sigma` value.

Data Types: `double` | `timetable`

Properties

`Alpha` — Mean reversion speed
numeric

Mean reversion speed, returned as a scalar numeric or timetable.

Data Types: `double` | `timetable`

`Sigma` — Volatility
numeric | timetable

Volatility, returned as a scalar numeric value or timetable.

Data Types: `double` | `timetable`

Examples

Use Hull-White Model and Hull-White Pricer to Price Floor Instrument

This example shows the workflow to price a `Floor` instrument when you use a `HullWhite` model and a `HullWhite` pricing method.

Create `Floor` Instrument Object

Use `fininstrument` to create a `Floor` instrument object.

```
FloorOpt = fininstrument("Floor",'Strike',0.045,'Maturity',datetime(2019,1,30),'Reset',4,'Princi
```

```
FloorOpt =
  Floor with properties:

                     Strike: 0.0450
                   Maturity: 30-Jan-2019
                ResetOffset: 0
                      Reset: 4
                      Basis: 1
                  Principal: 100
             ProjectionCurve: [0x0 ratecurve]
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                   Holidays: NaT
                       Name: "floor_option"
```

Create `HullWhite` Model Object

Use `finmodel` to create a `HullWhite` model object.

```
HullWhiteModel = finmodel("HullWhite",'Alpha',0.032,'Sigma',0.04)
```

```
HullWhiteModel =
  HullWhite with properties:

    Alpha: 0.0320
    Sigma: 0.0400
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:
```

```
                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `HullWhite` Pricer Object

Use `finpricer` to create a `HullWhite` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'Model',HullWhiteModel,'DiscountCurve',myRC)
```

```
outPricer =
  HullWhite with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.HullWhite]
```

Price `Floor` Instrument

Use `price` to compute the price for the `Floor` instrument.

```
Price = price(outPricer,FloorOpt)
```

```
Price = 1.4917
```

Merton

Create Merton model object for Vanilla, Asian, Barrier, DoubleBarrier, Lookback, PartialLookback, OneTouch, DoubleTouch, Cliquet, or Binary instrument

Description

Create and price a Vanilla, Asian, Barrier, DoubleBarrier, Lookback, PartialLookback, Touch, DoubleTouch, Cliquet, or Binary instrument object with a Merton model using this workflow:

1. Use fininstrument to create a Vanilla, Barrier, Lookback, PartialLookback, Asian, DoubleBarrier, Binary, Touch, Cliquet, or DoubleTouch instrument object.
2. Use finmodel to specify a Merton model object for the Vanilla, Asian, Barrier, DoubleBarrier, Lookback, PartialLookback, Touch, DoubleTouch, Cliquet, or Binary instrument object.
3. Use finpricer to specify a FiniteDifference, NumericalIntegration, or FFT pricing method for the Vanilla instrument object.

   Use finpricer to specify an AssetMonteCarlo pricing method for the Vanilla, Asian, BarrierDoubleBarrier, Lookback, PartialLookback, Touch, DoubleTouch, Cliquet, or Binary instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a Vanilla, Asian, Barrier, DoubleBarrier, Lookback, PartialLookback, Touch, DoubleTouch, or Binary instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
MertonModelObj = finmodel(ModelType,'Volatility',volatility_value,'
MeanJ',meanj_value,'JumpVol',jumpvol_value,'JumpFreq',jumpfreq_value)
```

Description

`MertonModelObj = finmodel(ModelType,'Volatility',volatility_value,'MeanJ',meanj_value,'JumpVol',jumpvol_value,'JumpFreq',jumpfreq_value)` creates a Merton model object by specifying ModelType and the required name-value pair arguments MeanJ, JumpVol, and JumpFreq to set properties on page 11-3120 using name-value pair arguments. For example, `MertonModelObj = finmodel("Merton",'Volatility',0.03,'MeanJ',0.22,'JumpVol',0.007,'JumpFreq',0.009)` creates a Merton model object.

Input Arguments

`ModelType` — Model type

string with value `"Merton"` | character vector with value `'Merton'`

Model type, specified as a string with the value of `"Merton"` or a character vector with the value of `'Merton'`.

Data Types: `char` | `string`

`Merton` Name-Value Pair Arguments

Specify required pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `MertonModelObj = finmodel("Merton",'Volatility',0.03,'MeanJ',0.22,'JumpVol',0.007,'JumpFreq',0.009)`

`Volatility` — Volatility value for the underlying asset

nonnegative numeric

Volatility value for the underlying asset, specified as the comma-separated pair consisting of `'Volatility'` and a scalar nonnegative numeric.

Data Types: `double`

`MeanJ` — Mean of the random percentage jump size

decimal

Mean of the random percentage jump size (J), specified as the comma-separated pair consisting of `'MeanJ'` and a scalar decimal value, where `log`(1+J) is normally distributed with mean (`log`(1+`MeanJ`)-0.5*`JumpVol`^2) and the standard deviation `JumpVol`.

Data Types: `double`

`JumpVol` — Standard deviation of `log`(1+J)

decimal

Standard deviation of `log`(1+J), where `J` is the random percentage jump size, specified as the comma-separated pair consisting of `'JumpVol'` and a scalar decimal value.

Data Types: `double`

`JumpFreq` — Annual frequency of Poisson jump process

numeric

Annual frequency of the Poisson jump process, specified as the comma-separated pair consisting of `'JumpFreq'` and a scalar numeric value.

Data Types: `double`

Properties

`Volatility` — Volatility value
nonnegative numeric

Volatility value, returned as a scalar nonnegative numeric.

Data Types: `double`

`MeanJ` — Mean of the random percentage jump size
decimal

Mean of the random percentage jump size (*J*), returned as a scalar decimal value.

Data Types: `double`

`JumpVol` — Standard deviation of `log(1+J)`
decimal

Standard deviation of `log`(1+*J*), where `J` is the random percentage jump size, returned as a scalar decimal value.

Data Types: `double`

`JumpFreq` — Annual frequency of Poisson jump process
numeric

Annual frequency of the Poisson jump process, returned as a scalar numeric value.

Data Types: `double`

Examples

Use Merton Model and Numerical Integration Pricer to Price Vanilla Instrument

This example shows the workflow to price a `Vanilla` instrument when you use a `Merton` model and a `NumericalIntegration` pricing method.

Create `Vanilla` Instrument Object

Use `fininstrument` to create a `Vanilla` instrument object.

```
VanillaOpt = fininstrument("Vanilla",'ExerciseDate',datetime(2022,9,15),'Strike',105,'OptionType
```

```
VanillaOpt =
  Vanilla with properties:

       OptionType: "put"
    ExerciseStyle: "european"
     ExerciseDate: 15-Sep-2022
           Strike: 105
             Name: "vanilla_option"
```

Create `Merton` Model Object

Use `finmodel` to create a `Merton` model object.

```
MertonModel = finmodel("Merton",'Volatility',0.45,'MeanJ',0.02,'JumpVol',0.07,'JumpFreq',0.09)

MertonModel =
  Merton with properties:

    Volatility: 0.4500
         MeanJ: 0.0200
       JumpVol: 0.0700
      JumpFreq: 0.0900
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)

myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `NumericalIntegration` Pricer Object

Use `finpricer` to create a `NumericalIntegration` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("numericalintegration",'DiscountCurve',myRC,'Model',MertonModel,'SpotPrice

outPricer =
  NumericalIntegration with properties:

                Model: [1x1 finmodel.Merton]
        DiscountCurve: [1x1 ratecurve]
            SpotPrice: 100
         DividendType: "continuous"
        DividendValue: 0.4500
               AbsTol: 0.5000
               RelTol: 0.0400
     IntegrationRange: [1.0000e-09 Inf]
    CharacteristicFcn: @characteristicFcnMerton76
            Framework: "lewis2001"
       VolRiskPremium: 0.0900
           LittleTrap: 0
```

Price Vanilla Instrument

Use price to compute the price and sensitivities for the Vanilla instrument.

```
[Price, outPR] = price(outPricer,VanillaOpt,["all"])
```

```
Price = 75.1139

outPR =
  priceresult with properties:

       Results: [1x6 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×6 table
    Price      Delta        Gamma         Theta       Rho       Vega
    _____    ________    __________    _______    _______    _____

    75.114    -0.15305    0.00025732    -3.9836    -361.67    4.6317
```

Use Merton Model and Asset Monte-Carlo Pricer to Price Binary Instrument

This example shows the workflow to price a Binary instrument when you use a Merton model and an AssetMonteCarlo pricing method.

Create Binary Instrument Object

Use fininstrument to create an Binary instrument object.

```
BinaryOpt = fininstrument("Binary",'ExerciseDate',datetime(2022,9,15),'Strike',100,'PayoffValue'
```

```
BinaryOpt =
  Binary with properties:

      OptionType: "put"
    ExerciseDate: 15-Sep-2022
          Strike: 100
     PayoffValue: 130
   ExerciseStyle: "european"
            Name: "binary_option"
```

Create Merton Model Object

Use finmodel to create a Merton model object.

```
MertonModel = finmodel("Merton",'Volatility',0.25,'MeanJ',0.02,'JumpVol',0.07,'JumpFreq',0.09)
```

```
MertonModel =
  Merton with properties:

    Volatility: 0.2500
         MeanJ: 0.0200
```

```
       JumpVol: 0.0700
      JumpFreq: 0.0900
```

Create ratecurve Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create AssetMonetCarlo Pricer Object

Use `finpricer` to create an `AssetMonetCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo",'DiscountCurve',myRC,"Model",MertonModel,'SpotPrice',102
```

```
outPricer =
  MertonMonteCarlo with properties:

     DiscountCurve: [1x1 ratecurve]
         SpotPrice: 102
    SimulationDates: 15-Sep-2022
         NumTrials: 1000
     RandomNumbers: []
             Model: [1x1 finmodel.Merton]
      DividendType: "continuous"
     DividendValue: 0
```

Price Binary Instrument

Use `price` to compute the price and sensitivities for the `Binary` instrument.

```
[Price, outPR] = price(outPricer,BinaryOpt,["all"])
```

```
Price = 53.1178
```

```
outPR =
  priceresult with properties:

       Results: [1x7 table]
```

```
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta     Gamma     Lambda       Rho      Theta     Vega
    ______    _______    _____    ________    _______    ______    ____

    53.118    -0.4432      0      -0.85106    -212.43    1.8604     0
```

Normal

Create `Normal` model object for `Cap`, `Floor`, or `Swaption` instrument

Description

Create and price a `Cap`, `Floor`, or `Swaption` instrument object with a `Normal` model using this workflow:

1. Use `fininstrument` to create a `Cap`, `Floor`, or `Swaption` instrument object.
2. Use `finmodel` to specify a `Normal` model object for the `Cap`, `Floor`, or `Swaption` instrument object.
3. Use `finpricer` to specify a `Normal` pricing method for the `Cap`, `Floor`, or `Swaption` instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a `Cap`, `Floor`, or `Swaption` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
NormalModelObj = finmodel(ModelType,'Volatility',volatility_value)
```

Description

`NormalModelObj = finmodel(ModelType,'Volatility',volatility_value)` creates a `Normal` model object by specifying `ModelType` and the required name-value pair argument `Volatility` to set properties on page 11-3126 using name-value pair arguments. For example, `NormalModelObj = finmodel("Normal",'Volatility',0.063)` creates a `Normal` model object.

Input Arguments

`ModelType` — Model type

string with value `"Normal"` | character vector with value `'Normal'`

Model type, specified as a string with the value of `"Normal"` or a character vector with the value of `'Normal'`.

Data Types: `char` | `string`

`Normal` Name-Value Pair Arguments

Specify required pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `NormalModelObj = finmodel("Normal",'Volatility',0.063)`

`Volatility` — Volatility value
nonnegative numeric

Volatility value, specified as the comma-separated pair consisting of `'Volatility'` and a scalar nonnegative numeric.

Data Types: `double`

Properties

`Volatility` — Volatility value
nonnegative numeric

Volatility value, returned as a scalar nonnegative numeric.

Data Types: `double`

Examples

Use Normal Model and Normal Pricer to Price Cap Instrument

This example shows the workflow to price a `Cap` instrument when you use a `Normal` model and a `Normal` pricing method.

Create Cap Instrument Object

Use `fininstrument` to create a `Cap` instrument object.

```
CapOpt = fininstrument("Cap",'Strike',0.51,'Maturity',datetime(2019,6,25),'Reset',4,'Principal',1
```

```
CapOpt =
  Cap with properties:

                     Strike: 0.5100
                   Maturity: 25-Jun-2019
                ResetOffset: 0
                      Reset: 4
                      Basis: 8
                  Principal: 100
             ProjectionCurve: [0x0 ratecurve]
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                   Holidays: NaT
                       Name: "cap_option"
```

Create `Normal` Model Object

Use `finmodel` to create a `Normal` model object.

```
NormalModel = finmodel("normal",'Volatility',0.063)
```

```
NormalModel =
  Normal with properties:

    Volatility: 0.0630
```

Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create Normal Pricer Object

Use finpricer to create a Normal pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic",'Model',NormalModel,'DiscountCurve',myRC)
```

```
outPricer =
  Normal with properties:

    DiscountCurve: [1x1 ratecurve]
            Shift: 0
            Model: [1x1 finmodel.Normal]
```

Price Cap Instrument

Use price to compute the price for the Cap instrument.

```
Price = price(outPricer,CapOpt)
```

```
Price = 9.3325e-30
```

Version History

Introduced in R2020a

Bachelier

Create `Bachelier` model object for `Vanilla`, `Spread`, or `Binary` instrument

Description

Create and price a `Vanilla`, `Spread`, or `Binary` instrument object with a `Bachelier` model using this workflow:

1. Use `fininstrument` to create a `Vanilla`, `Spread`, or `Binary` instrument object.
2. Use `finmodel` to specify a `Bachelier` model object for the `Vanilla`, `Spread`, or `Binary` instrument object.
3. Use `finpricer` to specify an `AssetMonteCarlo` pricing method for the `Vanilla`, `Spread`, or `Binary` instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a `Vanilla`, `Spread`, or `Binary` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
BachelierModelObj = finmodel(ModelType,'Volatility',volatility_value)
BachelierModelObj = finmodel(ModelType,Name,Value)
```

Description

`BachelierModelObj = finmodel(ModelType,'Volatility',volatility_value)` creates a `Bachelier` model object by specifying `ModelType` and the required name-value pair argument `Volatility` to set properties on page 11-3130 using name-value pair arguments. For example, `BachelierModelObj = finmodel("Bachelier",'Volatility',0.063)` creates a `Bachelier` model object.

`BachelierModelObj = finmodel(ModelType,Name,Value)` sets optional properties on page 11-3048 using an additional name-value pair argument in addition to the required arguments in the previous syntax. For example, `BachelierModelObj = finmodel("Bachelier",'Volatility',0.063,'Correlation',Corr)` creates a `Bachelier` model object with a specified `Correlation` value.

Input Arguments

`ModelType` — Model type

string with value `"Bachelier"` | character vector with value `'Bachelier'`

Model type, specified as a string with the value `"Bachelier"` or a character vector with the value `'Bachelier'`.

Data Types: `char` | `string`

Bachelier Name-Value Pair Arguments

Specify required pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `BachelierModelObj = finmodel("Bachelier",'Volatility',0.063,'Correlation',Corr)`

`Volatility` — Volatility value
nonnegative numeric

Volatility value, specified as the comma-separated pair consisting of `'Volatility'` and a scalar nonnegative numeric.

Data Types: `double`

`Correlation` — Correlation for underlying assets
1 (default) | positive semidefinite matrix

Correlation for the underlying assets, specified as the comma-separated pair consisting of `'Correlation'` and a positive semidefinite matrix. For more information on creating a positive semidefinite matrix, see `nearcorr`.

Data Types: `double`

Properties

`Volatility` — Volatility value
nonnegative numeric

Volatility value, returned as a scalar nonnegative numeric.

Data Types: `double`

`Correlation` — Correlation for underlying assets
1 (default) | positive semidefinite matrix

Correlation for the underlying assets, returned as a matrix.

Data Types: `double`

Examples

Use Bachelier Model and Asset Monte-Carlo Pricer to Price American Option for Vanilla Instrument

This example shows the workflow to price an American option for a `Vanilla` instrument when you use a `Bachelier` model and an `AssetMonteCarlo` pricing method.

Create `Vanilla` Instrument Object

Use `fininstrument` to create a `Vanilla` instrument object.

```
VanillaOpt = fininstrument("Vanilla",'Strike',105,'ExerciseDate',datetime(2022,9,15),'OptionType
```

```
VanillaOpt =
  Vanilla with properties:

       OptionType: "call"
    ExerciseStyle: "american"
     ExerciseDate: 15-Sep-2022
           Strike: 105
             Name: "vanilla_option"
```

Create `Bachelier` Model Object

Use `finmodel` to create a `Bachelier` model object.

```
BachelierModel = finmodel("Bachelier","Volatility",0.2)
```

```
BachelierModel =
  Bachelier with properties:

     Volatility: 0.2000
    Correlation: 1
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
       Compounding: -1
             Basis: 12
             Dates: 15-Sep-2023
             Rates: 0.0350
            Settle: 15-Sep-2018
      InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `AssetMonteCarlo` Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo",'DiscountCurve',myRC,"Model",BachelierModel,'SpotPrice',
```

```
outPricer =
  BachelierMonteCarlo with properties:

     DiscountCurve: [1x1 ratecurve]
         SpotPrice: 150
    SimulationDates: 15-Sep-2022
         NumTrials: 1000
     RandomNumbers: []
             Model: [1x1 finmodel.Bachelier]
      DividendType: "continuous"
     DividendValue: 0
```

Price `Vanilla` Instrument

Use `price` to compute the price and sensitivities for the `Vanilla` instrument.

```
[Price, outPR] = price(outPricer,VanillaOpt,"all")
```

```
Price = 57.3776
```

```
outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta       Gamma        Lambda     Rho       Theta        Vega
    _______    _______    ___________    _______    _______    _______    ___________

    57.378     0.99107    -1.579e-14     2.5909     291.94     -2.5576    -2.1316e-10
```

Dupire

Create `Dupire` model object for local volatility for `Vanilla` instrument

Description

Create and price a `Vanilla` instrument object with a `Dupire` model using this workflow:

1. Use `fininstrument` to create a `Vanilla` instrument object.
2. Use `finmodel` to specify a `Dupire` model object for the `Vanilla` instrument object.
3. Use `finpricer` to specify a `FiniteDifference` pricing method for the `Vanilla` instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a `Vanilla` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
DupireObj = finmodel(ModelType,'ImpliedVolData',impliedvoldata_value)
```

Description

`DupireObj = finmodel(ModelType,'ImpliedVolData',impliedvoldata_value)` creates a `Dupire` model object by specifying `ModelType` and the required name-value pair argument `ImpliedVolData` to set properties on page 11-3134 using name-value pair arguments. For example, `DupireObj = finmodel("Dupire",'ImpliedVolData',voldata_table)` creates a `Dupire` model object.

Input Arguments

`ModelType` — Model type

string with value `"Dupire"` | character vector with value `'Dupire'`

Model type, specified as the string with the value `"Dupire"` or the character vector with the value `'Dupire'`.

Data Types: `char` | `string`

`Dupire` Name-Value Pair Arguments

Specify required pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `DupireObj = finmodel("Dupire",'ImpliedVolData',voldata_table)`

`ImpliedVolData` — Table of maturity dates, strike or exercise prices, and corresponding implied volatilities
table

Table of maturity dates, strike or exercise prices, and their corresponding implied volatilities, specified as the comma-separated pair consisting of `'ImpliedVolData'` and an `NVOL`-by-3 table.

Data Types: `table`

Properties

`ImpliedVolData` — Table of maturity dates, strike or exercise prices, and corresponding implied volatilities
table

Table of maturity dates, strike or exercise prices, and corresponding implied volatilities, returned as an `NVOL`-by-3 table.

Data Types: `table`

Examples

Use Dupire Model and Finite Difference Pricer to Price Vanilla Instrument

This example shows the workflow to price a `Vanilla` instrument when you use a `Dupire` model and a `FiniteDifference` pricing method.

Create `Vanilla` Instrument Object

Use `fininstrument` to create a `Vanilla` instrument object.

```
VanillaOpt = fininstrument("Vanilla",'ExerciseDate',datetime(2020,1,1),'Strike',105,'ExerciseSty
```

```
VanillaOpt =
  Vanilla with properties:

       OptionType: "call"
    ExerciseStyle: "american"
     ExerciseDate: 01-Jan-2020
           Strike: 105
             Name: "vanilla_option"
```

Create `Dupire` Model Object

Define the implied volatility surface data.

```
AssetPrice = 590;
Maturity = ["06-Mar-2018" "05-Jun-2018" "12-Sep-2018" "10-Dec-2018" "01-Jan-2019" ...
"02-Jul-2019" "01-Jan-2020" "01-Jan-2021" "01-Jan-2022" "01-Jan-2023"];
Maturity = repmat(Maturity,10,1);
Maturity = Maturity(:);
```

```
ExercisePrice = AssetPrice.*[0.85 0.90 0.95 1.00 1.05 1.10 1.15 1.20 1.30 1.40];
ExercisePrice = repmat(ExercisePrice,1,10)';

ImpliedVol = [...
    0.190; 0.168; 0.133; 0.113; 0.102; 0.097; 0.120; 0.142; 0.169; 0.200; ...
    0.177; 0.155; 0.138; 0.125; 0.109; 0.103; 0.100; 0.114; 0.130; 0.150; ...
    0.172; 0.157; 0.144; 0.133; 0.118; 0.104; 0.100; 0.101; 0.108; 0.124; ...
    0.171; 0.159; 0.149; 0.137; 0.127; 0.113; 0.106; 0.103; 0.100; 0.110; ...
    0.171; 0.159; 0.150; 0.138; 0.128; 0.115; 0.107; 0.103; 0.099; 0.108; ...
    0.169; 0.160; 0.151; 0.142; 0.133; 0.124; 0.119; 0.113; 0.107; 0.102; ...
    0.169; 0.161; 0.153; 0.145; 0.137; 0.130; 0.126; 0.119; 0.115; 0.111; ...
    0.168; 0.161; 0.155; 0.149; 0.143; 0.137; 0.133; 0.128; 0.124; 0.123; ...
    0.168; 0.162; 0.157; 0.152; 0.148; 0.143; 0.139; 0.135; 0.130; 0.128; ...
    0.168; 0.164; 0.159; 0.154; 0.151; 0.147; 0.144; 0.140; 0.136; 0.132];

ImpliedVolData = table(Maturity, ExercisePrice, ImpliedVol);
```

Use `finmodel` to create a `Dupire` model object.

```
DupireModel = finmodel("Dupire",'ImpliedVolData',ImpliedVolData)
```

```
DupireModel =
  Dupire with properties:

    ImpliedVolData: [100x3 table]
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,1,1);
Maturity = datetime(2020,9,1);
Rate = 0.06;
myRC = ratecurve('zero',Settle,Maturity,Rate)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
       Compounding: -1
             Basis: 0
             Dates: 01-Sep-2020
             Rates: 0.0600
            Settle: 01-Jan-2018
      InterpMethod: "linear"
  ShortExtrapMethod: "next"
   LongExtrapMethod: "previous"
```

Create `FiniteDifference` Pricer Object

Use `finpricer` to create a `FiniteDifference` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("FiniteDifference",'Model',DupireModel,'DiscountCurve',myRC,'SpotPrice',100
```

```
outPricer =
  FiniteDifference with properties:
```

```
     DiscountCurve: [1x1 ratecurve]
             Model: [1x1 finmodel.Dupire]
         SpotPrice: 100
    GridProperties: [1x1 struct]
      DividendType: "continuous"
     DividendValue: 0.0262
```

Price `Vanilla` Instrument

Use `price` to compute the price and sensitivities for the `Vanilla` instrument.

```
[Price, outPR] = price(outPricer,VanillaOpt,["all"])

Price = 15.5930

outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results

ans=1×7 table
    Price      Delta       Gamma       Lambda     Theta      Rho      Vega
    _____    ________    _________    ______    ________    _____    _____

    15.593    0.55004    0.0091484    3.5275    -3.3431    78.792    49.33
```

More About

Local Volatility Model

A local volatility model treats volatility as a function both of the current asset level and of time.

The local volatility can be estimated by using the Dupire formula [2]:

$$\sigma_{loc}^2(K,\tau) = \frac{\sigma_{imp}^2 + 2\tau\sigma_{imp}\frac{\partial\sigma_{imp}}{\partial\tau} + 2(\tau - d)K\tau\sigma_{imp}\frac{\partial\sigma_{imp}}{\partial K}}{\left(1 + Kd_1\sqrt{\tau}\frac{\partial\sigma_{imp}}{\partial K}\right)^2 + K^2\tau\sigma_{imp}\left(\frac{\partial^2\sigma_{imp}}{\partial K^2} - d_1\sqrt{\tau}\left(\frac{\partial\sigma_{imp}}{\partial K}\right)^2\right)}$$

$$d_1 = \frac{\ln(S_0/K) + \left((\tau - d) + \sigma_{imp}^2/2\right)\tau}{\sigma_{imp}\sqrt{\tau}}$$

SABR

Create SABR model object for Swaption instrument

Description

Create and price a Swaption instrument object with a SABR model using this workflow:

1. Use fininstrument to create a Swaption instrument object.
2. Use finmodel to specify a SABR model object for the Swaption instrument object.
3. Use finpricer to specify a SABR pricing method for the Swaption instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a Swaption instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
SabrModelObj = finmodel(ModelType,'Alpha',alpha_value,'Beta',beta_value,'
Rho',rho_value,'Nu',nu_value)
SabrModelObj = finmodel(___,Name,Value)
```

Description

SabrModelObj = finmodel(ModelType,'Alpha',alpha_value,'Beta',beta_value,'Rho',rho_value,'Nu',nu_value) creates a SABR model object by specifying ModelType and sets the properties on page 11-3140 for the required name-value pair arguments Alpha, Beta, Rho, and Nu.

SabrModelObj = finmodel(___,Name,Value) sets optional properties on page 11-3140 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, SabrModelObj = finmodel("SABR",'Alpha',0.22,'Beta',0.007,'Rho',0.009,'Nu',0.03,'Shift',0.002,'VolatilityType',"black") creates a SABR model object. You can specify multiple name-value pair arguments.

Input Arguments

ModelType — Model type

string with value "SABR" | character vector with value 'SABR'

Model type, specified as a string with the value of "SABR" or a character vector with the value of 'SABR'.

Data Types: char | string

SABR Name-Value Pair Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `SabrModelObj = finmodel("SABR",'Alpha',0.22,'Beta',0.007,'Rho',0.009,'Nu',0.03,'Shift',0.002,'VolatilityType',"black")`

Required SABR Name-Value Pair Arguments

`Alpha` — Current SABR volatility
scalar numeric

Current SABR volatility, specified as the comma-separated pair consisting of `'Alpha'` and a scalar numeric.

Data Types: `double`

`Beta` — SABR constant elasticity of variance (CEV) exponent
scalar numeric

SABR constant elasticity of variance (CEV) exponent, specified as the comma-separated pair consisting of `'Beta'` and a scalar numeric.

Note Set the `Beta` parameter to `0` to allow a negative `ForwardValue` and `Strike`.

Data Types: `double`

`Rho` — Correlation between forward value and volatility
scalar numeric

Correlation between the forward value and volatility, specified as the comma-separated pair consisting of `'Rho'` and a scalar numeric.

Data Types: `double`

`Nu` — Volatility of volatility
scalar numeric

Volatility of volatility, specified as the comma-separated pair consisting of `'Nu'` and a scalar numeric.

Data Types: `double`

Optional SABR Name-Value Pair Arguments

`Shift` — Shift in decimals for shifted SABR model
`0` (no shift) (default) | scalar positive decimal

Shift in decimals for the shifted SABR model (to be used with the shifted Black model), specified as the comma-separated pair consisting of `'Shift'` and a scalar positive decimal value. For example, a `Shift` value of `0.01` is equal to a 1% positive shift.

Note If you set `VolatilityType` to `'normal'`, the `Shift` value must be `0`.

Data Types: `double`

`VolatilityType` — Model used by the implied volatility sigma
`"black"` (default) | string with value `"black"` or `"normal"` | character vector with value `'black'` or `'normal'`

Model used by the implied volatility sigma, specified as the comma-separated pair consisting of `'VolatilityType'` and a scalar string or character vector.

Note The value of `VolatilityType` affects the interpretation of the implied volatility ("sigma").

- If you set `VolatilityType` to `'black'` (default), “sigma” can be either implied Black (no shift) or implied shifted Black volatility.
- If you set `VolatilityType` to `'normal'`, “sigma” is the implied Normal (Bachelier) volatility and you must also set `Shift` to zero.

Data Types: `char` | `string`

Properties

`Alpha` — Current SABR volatility
scalar numeric

Current SABR volatility, returned as a scalar numeric.

Data Types: `double`

`Beta` — SABR constant elasticity of variance (CEV) exponent
scalar numeric

SABR constant elasticity of variance (CEV) exponent, returned as a scalar numeric.

Data Types: `double`

`Rho` — Correlation between forward value and volatility
scalar numeric

Correlation between forward value and volatility, returned as a scalar numeric.

Data Types: `double`

`Nu` — Volatility of volatility
scalar numeric

Volatility of volatility, returned as a scalar numeric.

Data Types: `double`

`Shift` — Shift in decimals for shifted SABR model
`0` (no shift) (default) | scalar positive decimal

Shift in decimals for the shifted SABR model (to be used with the Shifted Black model), returned as a scalar positive decimal value.

Data Types: `double`

`VolatilityType` — Model used by the implied volatility sigma
`"black"` (default) | string with value `"black"` or `"normal"`

Model used by the implied volatility sigma, returned as a string with a value of `"black"` or `"normal"`.

Data Types: `string`

Examples

Use SABR Model and SABR Pricer to Price Swaption Instrument

This example shows the workflow to price a `Swaption` instrument when you use a SABR model and a SABR pricing method.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2018
        InterpMethod: "linear"
   ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

Create `Swap` Instrument Object

Use `fininstrument` to create the underlying `Swap` instrument object.

```
Swap = fininstrument("Swap",'Maturity',datetime(2023,1,30),'LegRate',[0.018 0.24],'LegType',["fi
```

```
Swap =
  Swap with properties:

                    LegRate: [0.0180 0.2400]
                    LegType: ["fixed"    "float"]
```

```
                    Reset: [2 2]
                    Basis: [5 5]
                 Notional: 1000
       LatestFloatingRate: [NaN NaN]
              ResetOffset: [0 0]
  DaycountAdjustedCashFlow: [1 1]
           ProjectionCurve: [1x2 ratecurve]
     BusinessDayConvention: ["follow"    "follow"]
                 Holidays: NaT
              EndMonthRule: [1 1]
                 StartDate: 30-Mar-2020
                  Maturity: 30-Jan-2023
                      Name: "swap_instrument"
```

Create Swaption Instrument Object

Use `fininstrument` to create a `Swaption` instrument object.

```
Swaption = fininstrument("swaption",'Strike',0.25,'ExerciseDate',datetime(2021,7,30),'Swap',Swap
```

```
Swaption =
  Swaption with properties:

      OptionType: "put"
  ExerciseStyle: "european"
   ExerciseDate: 30-Jul-2021
         Strike: 0.2500
           Swap: [1x1 fininstrument.Swap]
           Name: "swaption_instrument"
```

Create SABR Model Object

Use `finmodel` to create a SABR model object.

```
SabrModel = finmodel("SABR",'Alpha',0.032,'Beta',0.04, 'Rho', .08, 'Nu', 0.49,'Shift',0.002)
```

```
SabrModel =
  SABR with properties:

           Alpha: 0.0320
            Beta: 0.0400
             Rho: 0.0800
              Nu: 0.4900
           Shift: 0.0020
  VolatilityType: "black"
```

Create SABR Pricer Object

Use `finpricer` to create a SABR pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'Model',SabrModel,'DiscountCurve',myRC)
```

```
outPricer =
  SABR with properties:
```

```
    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.SABR]
```

Price `Swaption` Instrument

Use `price` to compute the price for the `Swaption` instrument.

```
Price = price(outPricer,Swaption)
```

```
Price = 55.8596
```

Version History

Introduced in R2020a

AssetMonteCarlo

Create `AssetMonteCarlo` pricer object for equity instruments using `BlackScholes`, `Merton`, `Heston`, or `Bates` model

Description

Create and price a `Vanilla`, `Barrier`, `Lookback`, `PartialLookback`, `Asian`, `Spread`, `DoubleBarrier`, `Cliquet`, `Touch`, `DoubleTouch`, `Binary` instrument object with a `BlackScholes`, `Bachelier`, `Merton`, `Heston`, or `Bates` model and a `AssetMonteCarlo` pricing method using this workflow:

1. Use `fininstrument` to create a `Vanilla`, `Barrier`, `Lookback`, `PartialLookback`, `Asian`, `Spread`, `DoubleBarrier`, `Cliquet`, `Binary`, `Touch`, or `DoubleTouch` instrument object.
2. Use `finmodel` to specify a `BlackScholes` model for the `Vanilla`, `Barrier`, `Lookback`, `PartialLookback`, `Asian`, `Spread`, `DoubleBarrier`, `Cliquet`, `Touch`, `DoubleTouch`, or `Binary` instrument object.

   Use `finmodel` to specify a `Bachelier` model for the `Vanilla`, `Spread` or `Binary` instrument object.

   Use `finmodel` to specify a `Merton`, `Bates`, or `Heston` model for the `Vanilla`, `Barrier`, `Lookback`, `PartialLookback`, `Asian`, `DoubleBarrier`, `Touch`, `DoubleTouch`, `Cliquet`, or `Binary` instrument object.
3. Use `finpricer` to specify an `AssetMonteCarlo` pricer object for the `Vanilla`, `Barrier`, `Lookback`, `PartialLookback`, `Asian`, `Spread`, `DoubleBarrier`, `Cliquet`, `Touch`, `DoubleTouch`, or `Binary` instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for `Vanilla`, `Barrier`, `Lookback`, `PartialLookback`, `Asian`, `Spread`, `DoubleBarrier`, `Cliquet`, `Touch`, `DoubleTouch`, or `Binary` instruments, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
AssetMonteCarloPricerObj = finpricer(PricerType,'Model',model,'
DiscountCurve',ratecurve_obj,'SpotPrice',spotprice_value,'
SimulationDates',simulation_dates)
AssetMonteCarloPricerObj = finpricer( ___ ,Name,Value)
```

Description

```
AssetMonteCarloPricerObj = finpricer(PricerType,'Model',model,'
DiscountCurve',ratecurve_obj,'SpotPrice',spotprice_value,'
```

`SimulationDates',simulation_dates)` creates a `AssetMonteCarlo` pricer object by specifying `PricerType` and sets the properties on page 11-3147 using the required name-value pair arguments `Model`, `DiscountCurve`, `SpotPrice`, and `SimulationDates`.

`AssetMonteCarloPricerObj = finpricer( ___ ,Name,Value)` sets optional properties on page 11-3147 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `AssetMonteCarloPricerObj = finpricer("assetmontecarlo",'Model',BSModel,'DiscountCurve',ratecurve_obj,'SpotPrice',1000,'SimulationDates',[datetime(2018,1,30); datetime(2019,1,30)],'NumTrials',500,'DividendType','continuous','DividendValue',0.3)` creates an `AssetMonteCarlo` pricer object using a `BlackScholes` model. You can specify multiple name-value pair arguments.

Input Arguments

`PricerType` — Pricer type

string with value `"AssetMonteCarlo"` | character vector with value `'AssetMonteCarlo'`

Pricer type, specified as a string with the value `"AssetMonteCarlo"` or a character vector with the value `'AssetMonteCarlo'`.

Data Types: `char` | `string`

`AssetMonteCarlo` Name-Value Pair Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `AssetMonteCarloPricerObj = finpricer("assetmontecarlo",'Model',BSModel,'DiscountCurve',ratecurve_obj,'SpotPrice',1000,'SimulationDates',[datetime(2018,1,30); datetime(2019,1,30)],'NumTrials',500,'DividendType','continuous','DividendValue',0.3)`

Required AssetMonteCarlo Name-Value Pair Arguments

`Model` — Model

`BlackScholes` object | `Merton` object | `Bates` object | `Heston` object

Model, specified as the comma-separated pair consisting of `'Model'` and the name of a previously created `BlackScholes`, `Merton`, `Bates`, or `Heston` model object. Create the model object using `finmodel`.

Data Types: `object`

`DiscountCurve` — `ratecurve` object for discounting cash flows

`ratecurve` object

`ratecurve` object for discounting cash flows, specified as the comma-separated pair consisting of `'DiscountCurve'` and the name of a previously created `ratecurve` object.

Note Specify a flat `ratecurve` object for `DiscountCurve`. If you use a nonflat `ratecurve` object, the software uses the rate in the `ratecurve` object at `Maturity` and assumes that the value is constant for the life of the equity option.

Data Types: `object`

`SpotPrice` — Current price of underlying asset
nonnegative numeric | positive or negative numeric when using `Bachelier` model

Current price of the underlying asset, specified as the comma-separated pair consisting of `'SpotPrice'` and a scalar nonnegative numeric or scalar positive or negative numeric when using `Bachelier` model.

Note If you use a `Vanilla`, `Binary`, or `Spread` instrument with a `Bachelier` model, the `SpotPrice` can be a negative numeric value.

Data Types: `double`

`SimulationDates` — Simulation dates
`[ ]` (default) | datetime array | string array | date character vector

Simulation dates, specified as the comma-separated pair consisting of `'SimulationDates'` and a scalar or a vector using a datetime array, string array, or date character vectors.

To support existing code, `AssetMonteCarlo` also accepts serial date numbers as inputs, but they are not recommended.

Optional AssetMonteCarlo Name-Value Pair Arguments

`NumTrials` — Simulation trials
`1000` (default) | scalar

Simulation trials, specified as the comma-separated pair consisting of `'NumTrials'` and a scalar number of independent sample paths.

Data Types: `double`

`RandomNumbers` — Dependent random variates
`[ ]` (default) | structure

Dependent random variates, specified as the comma-separated pair consisting of `'RandomNumbers'` and an `NSimulationDates`-by-`NBrownians`-by-`NTrials` 3D time series array. The 3D time series array has the following fields:

- `Z` — `NSimulationDates`-by-`NBrownians`-by-`NTrials` 3D time series array of dependent random variates used to generate the Brownian motion vector (that is, Wiener processes) that drive the simulation.
- `N` — `NSimulationDates`-by-`NBrownians`-by-`NTrials` 3D time series array of dependent random variates used as the number of jumps.
- `SizeJ` — `NSimulationDates`-by-`NBrownians`-by-`NTrials` 3D time series array of dependent random variates used as the jump sizes.

Note `BlackScholes` and `Heston` models only require `Z` field.

Data Types: `struct`

`DividendType` — Stock dividend type
`"continuous"` (default) | string with value `"cash"` or `"continuous"` | character vector with value `'cash'` or `'continuous'`

Stock dividend type, specified as the comma-separated pair consisting of `'DividendType'` and a character vector or string. `DividendType` must be either `"cash"` for actual dollar dividends or `"continuous"` for a continuous dividend yield.

Data Types: `char` | `string`

`DividendValue` — Dividend yield or dividend schedule for underlying stock
`0` (default) | scalar numeric | timetable

Dividend yield for the underlying stock, specified as the comma-separated pair consisting of `'DividendValue'` and a scalar numeric for a dividend yield or a timetable for a dividend schedule.

Note Specify a scalar if `DividendType` is `"continuous"` and a timetable if `DividendType` is `"cash"`.

Data Types: `double` | `timetable`

Properties

`Model` — Model
object

Model, returned as an object.

Data Types: `object`

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

This property is read-only.

`ratecurve` object for discounting cash flows, returned as a `ratecurve` object.

Data Types: `object`

`SpotPrice` — Current price of underlying asset
nonnegative numeric | positive or negative numeric when using `Bachelier` model

Current price of underlying asset, returned as a scalar nonnegative numeric or a scalar positive or negative numeric when using `Bachelier` model.

Data Types: `double`

`SimulationDates` — Simulation dates
datetime

Simulation dates, returned as a datetime array.

Data Types: `datetime`

`NumTrials` — Simulation trials
`1000` (default) | scalar

Simulation trials, returned as a scalar number of independent sample paths.

Data Types: `double`

`RandomNumbers` — Dependent random variates
`[ ]` (default) | structure

Dependent random variates, returned as an `NSimulationDates`-by-`NBrownians`-by-`NTrials` 3D time series array.

Data Types: `struct`

`EarlyExerciseFunction` — Calculation for early exercise premium
`@longstaffschwartz_cubic` (default) | function handle

Calculation for the early exercise premium, returned as a scalar function handle. The default `@longstaffschwartz_cubic` uses the Longstaff-Schwartz least squares method.

Data Types: `function_handle`

`DividendType` — Dividend type
`"continuous"` (default) | string with value `"cash"` or `"continuous"`

This property is read-only.

Dividend type, returned as a string. `DividendType` is either `"cash"` for actual dollar dividends or `"continuous"` for a continuous dividend yield.

Data Types: `string`

`DividendValue` — Dividend yield or dividend schedule for underlying stock
`0` (default) | scalar nonnegative numeric | timetable

Dividend yield or dividend schedule for the underlying stock, returned as a scalar numeric for a dividend yield or a timetable for a dividend schedule.

Data Types: `double` | `timetable`

price Compute price for equity instrument with AssetMonteCarlo pricer

Examples

Use Asset Monte-Carlo Pricer and Black-Scholes Model to Price Double Barrier Instrument

This example shows the workflow to price a `DoubleBarrier` instrument when you use a `BlackScholes` model and an `AssetMonteCarlo` pricing method.

Create DoubleBarrier Instrument Object

Use `fininstrument` to create a `DoubleBarrier` instrument object.

```
DoubleBarrierOpt = fininstrument("DoubleBarrier",'Strike',100,'ExerciseDate',datetime(2020,8,15),
```

```
DoubleBarrierOpt =
  DoubleBarrier with properties:

       OptionType: "call"
           Strike: 100
     BarrierValue: [110 80]
    ExerciseStyle: "american"
     ExerciseDate: 15-Aug-2020
      BarrierType: "dko"
           Rebate: [0 0]
             Name: "doublebarrier_option"
```

Create BlackScholes Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes","Volatility",0.3)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.3000
    Correlation: 1
```

Create ratecurve Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2017,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                 Type: "zero"
          Compounding: -1
                Basis: 12
                Dates: 15-Sep-2023
                Rates: 0.0350
               Settle: 15-Sep-2017
         InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create AssetMonteCarlo Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
ExerciseDate = datetime(2020,08,15);
Settle = datetime(2017,9,15);
outPricer = finpricer("AssetMonteCarlo","DiscountCurve",myRC,"Model",BlackScholesModel,'SpotPrice
```

Price DoubleBarrier Instrument

Use `price` to compute the price and sensitivities for the `DoubleBarrier` instrument.

```
[Price, outPR] = price(outPricer,DoubleBarrierOpt,"all")
```

```
Price = 6.9667

outPR =
  priceresult with properties:

      Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta       Gamma       Lambda      Rho       Theta      Vega
    ______    _______    _________    ______    _______    ______    _______

    6.9667    0.26875    -0.096337    3.8576    0.39855    9.5406    -1.2907
```

Use Asset Monte-Carlo Pricer and Heston Model to Price Asian Instrument

This example shows the workflow to price a fixed-strike `Asian` instrument when you use a `Heston` model and an `AssetMonteCarlo` pricing method.

Create Asian Instrument Object

Use `fininstrument` to create an `Asian` instrument object.

```
AsianOpt = fininstrument("Asian",'ExerciseDate',datetime(2022,9,15),'Strike',100,'OptionType',"pu
```

```
AsianOpt =
  Asian with properties:

         OptionType: "put"
             Strike: 100
        AverageType: "arithmetic"
       AveragePrice: 0
    AverageStartDate: NaT
       ExerciseStyle: "european"
        ExerciseDate: 15-Sep-2022
                Name: "asian_option"
```

Create Heston Model Object

Use `finmodel` to create a `Heston` model object.

```
HestonModel = finmodel("Heston",'V0',0.032,'ThetaV',0.1,'Kappa',0.003,'SigmaV',0.02,'RhoSV',0.9)
```

```
HestonModel =
  Heston with properties:

       V0: 0.0320
    ThetaV: 0.1000
     Kappa: 0.0030
    SigmaV: 0.0200
     RhoSV: 0.9000
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
        Compounding: -1
              Basis: 12
              Dates: 15-Sep-2023
              Rates: 0.0350
             Settle: 15-Sep-2018
       InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `AssetMonteCarlo` Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo",'DiscountCurve',myRC,"Model",HestonModel,'SpotPrice',80,
```

```
outPricer =
  HestonMonteCarlo with properties:

     DiscountCurve: [1x1 ratecurve]
         SpotPrice: 80
    SimulationDates: [15-Oct-2018    15-Nov-2018    15-Dec-2018    ...    ]
         NumTrials: 1000
     RandomNumbers: []
             Model: [1x1 finmodel.Heston]
      DividendType: "continuous"
     DividendValue: 0
```

Price `Asian` Instrument

Use `price` to compute the price and sensitivities for the `Asian` instrument.

```
[Price, outPR] = price(outPricer,AsianOpt,"all")
```

```
Price = 14.7999

outPR =
  priceresult with properties:

      Results: [1x8 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×8 table
    Price     Delta       Gamma       Lambda       Rho       Theta      Vega     VegaLT
    _____    ________    ________    _______    _______    _______    ______    _______

    14.8     -0.71073    0.023453    -3.8418    -173.12    0.61794    27.992    0.15319
```

Use Asset Monte-Carlo Pricer and Bachelier Model to Price American Option for Vanilla Instrument

This example shows the workflow to price an American option for a `Vanilla` instrument when you use a `Bachelier` model and an `AssetMonteCarlo` pricing method.

Create `Vanilla` Instrument Object

Use `fininstrument` to create a `Vanilla` instrument object.

```
VanillaOpt = fininstrument("Vanilla",'Strike',105,'ExerciseDate',datetime(2022,9,15),'OptionType
```

```
VanillaOpt =
  Vanilla with properties:

      OptionType: "call"
    ExerciseStyle: "american"
     ExerciseDate: 15-Sep-2022
           Strike: 105
             Name: "vanilla_option"
```

Create `Bachelier` Model Object

Use `finmodel` to create a `Bachelier` model object.

```
BachelierModel = finmodel("Bachelier","Volatility",0.2)
```

```
BachelierModel =
  Bachelier with properties:

     Volatility: 0.2000
    Correlation: 1
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `AssetMonteCarlo` Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo",'DiscountCurve',myRC,"Model",BachelierModel,'SpotPrice',1
```

```
outPricer =
  BachelierMonteCarlo with properties:

      DiscountCurve: [1x1 ratecurve]
          SpotPrice: 150
    SimulationDates: 15-Sep-2022
          NumTrials: 1000
      RandomNumbers: []
              Model: [1x1 finmodel.Bachelier]
       DividendType: "continuous"
      DividendValue: 0
```

Price `Vanilla` Instrument

Use `price` to compute the price and sensitivities for the `Vanilla` instrument.

```
[Price, outPR] = price(outPricer,VanillaOpt,["all"])
```

```
Price = 57.3776

outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta       Gamma       Lambda     Rho       Theta        Vega
    ______    _______    __________    ______    ______    _______    __________
```

```
    57.378    0.99107    -1.579e-14    2.5909    291.94    -2.5576    -2.1316e-10
```

Use Asset Monte-Carlo Pricer and Bachelier Model to Price Binary Instrument With Underlying Negative Value

This example shows the workflow to price a `Binary` instrument with an underlying negatively valued asset when you use a `Bachelier` model and an `AssetMonteCarlo` pricing method.

Create `Binary` Instrument Object

Use `fininstrument` to create a `Binary` instrument object.

```
BinaryOpt = fininstrument("Binary",'ExerciseDate',datetime(2022,9,15),'Strike',15,'PayoffValue',1
```

```
BinaryOpt =
  Binary with properties:

       OptionType: "put"
     ExerciseDate: 15-Sep-2022
           Strike: 15
      PayoffValue: 13
    ExerciseStyle: "european"
             Name: "binary_option"
```

Create `Bachelier` Model Object

Use `finmodel` to create a `Bachelier` model object.

```
BachelierModel = finmodel("Bachelier","Volatility",0.2)
```

```
BachelierModel =
  Bachelier with properties:

     Volatility: 0.2000
    Correlation: 1
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
        Compounding: -1
              Basis: 12
              Dates: 15-Sep-2023
              Rates: 0.0350
```

```
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create AssetMonteCarlo Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument. Note that when using a Bachelier model with a Vanilla, Binary, or Spread instrument, the `SpotPrice` can be a positive or negative numeric value.

```
outPricer = finpricer("AssetMonteCarlo",'DiscountCurve',myRC,"Model",BachelierModel,'SpotPrice',
```

```
outPricer =
  BachelierMonteCarlo with properties:

      DiscountCurve: [1x1 ratecurve]
          SpotPrice: -6
    SimulationDates: 15-Sep-2022
          NumTrials: 1000
      RandomNumbers: []
              Model: [1x1 finmodel.Bachelier]
       DividendType: "continuous"
      DividendValue: 0
```

Price Binary Instrument

Use `price` to compute the price and sensitivities for the `Binary` instrument.

```
[Price, outPR] = price(outPricer,BinaryOpt,["all"])
```

```
Price = 11.3017

outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×7 table
    Price     Delta    Gamma    Lambda      Rho       Theta      Vega
    ______    _____    _____    ______    _______    _______    ____

    11.302      0        0        0       -45.198    0.39582     0
```

Version History

Introduced in R2020b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `AssetMonteCarlo` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

HeynenKat

Create `HeynenKat` pricer object for `PartialLookback` instrument using `BlackScholes` model

Description

Create and price a `PartialLookback` instrument object with a `BlackScholes` model and a `HeynenKat` pricing method using this workflow:

1. Use `fininstrument` to create a `PartialLookback` instrument object.
2. Use `finmodel` to specify a `BlackScholes` model for the `PartialLookback` instrument object.
3. Use `finpricer` to specify a `HeynenKat` pricer object for the `PartialLookback` instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for an `PartialLookback` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
HeynenKatPricerObj = finpricer(PricerType,DiscountCurve=ratecurve_obj,
Model=model,SpotPrice=spotprice_value)
HeynenKatPricerObj = finpricer(___,Name=Value)
```

Description

`HeynenKatPricerObj = finpricer(PricerType,DiscountCurve=ratecurve_obj, Model=model,SpotPrice=spotprice_value)` creates a `HeynenKat` pricer object by specifying `PricerType` and sets the properties on page 11-3159 for the required name-value arguments `DiscountCurve`, `Model`, and `SpotPrice`.

`HeynenKatPricerObj = finpricer(___,Name=Value)` to set optional properties on page 11-3159 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `HeynenKatPricerObj = finpricer("Analytic",DiscountCurve=ratecurve_obj,Model=BSModel,SpotPrice=1000,DividendType="continuous",DividendValue=100,PricingMethod="HeynenKat")` creates a `HeynenKat` pricer object.

Input Arguments

`PricerType` — Pricer type

string with value `"Analytic"` | character vector with value `'Analytic'`

Pricer type, specified as a string with the value of `"Analytic"` or a character vector with the value of `'Analytic'`.

Data Types: `char` | `string`

HeynenKat Name-Value Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `HeynenKatPricerObj = finpricer("Analytic",DiscountCurve=ratecurve_obj,Model=BSModel,SpotPrice=1000,DividendType="continuous",DividendValue=100,PricingMethod="HeynenKat")`

Required HeynenKat Name-Value Arguments

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

`ratecurve` object for discounting cash flows, specified as `DiscountCurve` and the name of the previously created `ratecurve` object.

Note Specify a flat `ratecurve` object for `DiscountCurve`. If you use a nonflat `ratecurve` object, the software uses the rate in the `ratecurve` object at `Maturity` and assumes that the value is constant for the life of the equity option.

Data Types: `object`

`Model` — Model
`BlackScholes` model object

Model, specified as `Model` and the name of a previously created `BlackScholes` model object using `finmodel`.

Data Types: `object`

`SpotPrice` — Current price of underlying asset
nonnegative numeric

Current price of the underlying asset, specified as `SpotPrice` and a scalar nonnegative numeric.

Data Types: `double`

Optional HeynenKat Name-Value Arguments

`DividendType` — Stock dividend type
`"continuous"` (default) | string with value `"continuous"` | character vector with value `'continuous'`

Stock dividend type, specified as `DividendType` and a string or character vector.

Data Types: `char` | `string`

`DividendValue` — Dividend yield for underlying stock
`0` (default) | scalar numeric

Dividend yield for the underlying stock, specified as `DividendValue` and a scalar numeric.

Data Types: `double`

`PricingMethod` — Analytic pricing method
default pricer associated with `BlackScholes` model (default) | string with value `"HeynenKat"` | character vector with value `'HeynenKat'`

Analytic pricing method, specified as `PricingMethod` and a string or character vector.

Note The default pricing method for a `BlackScholes` model is a `BlackScholes` pricer.

Data Types: `double`

Properties

`DiscountCurve` — `ratecurve` object for discounting cash flows
object

This property is read-only.

`ratecurve` object for discounting cash flows, returned as a `ratecurve` object.

Data Types: `object`

`Model` — Model
`BlackScholes` model object

Model, returned as a `BlackScholes` model object.

Data Types: `object`

`SpotPrice` — Current price of underlying asset
nonnegative numeric

Current price of the underlying asset, returned as a scalar nonnegative numeric.

Data Types: `double`

`DividendType` — Stock dividend type
`"continuous"` (default) | string with value `"continuous"`

This property is read-only.

Stock dividend type, returned as a string.

Data Types: `string`

`DividendValue` — Dividend yield for underlying stock
`0` (default) | scalar nonnegative numeric

Dividend yield for the underlying stock, returned as a scalar numeric.

Data Types: `double`

`PricingMethod` — Analytic pricing method
default pricer associated with `BlackScholes` model (default) | string with value `"HeynenKat"`

Analytic pricing method, returned as a string.

Data Types: `string`

Object Functions

price Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

Examples

Use Heynen-Kat Pricer and Black-Scholes Model to Price Partial Lookback Instrument

This example shows the workflow to price a `PartialLookback` instrument when you use a `BlackScholes` model and a `HeynenKat` pricing method.

Create `PartialLookback` Instrument Object

Use `fininstrument` to create an `PartialLookback` instrument object.

```
PartialLookbackOpt = fininstrument("PartialLookback",ExerciseDate=datetime(2022,9,15),Strike=100
```

```
PartialLookbackOpt =
  PartialLookback with properties:

     MonitorDate: 15-Sep-2021
    StrikeScaler: 1
      OptionType: "put"
          Strike: 100
     AssetMinMax: NaN
   ExerciseStyle: "european"
    ExerciseDate: 15-Sep-2022
            Name: "partial_lookback_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",Volatility=0.32)
```

```
BlackScholesModel =
  BlackScholes with properties:

    Volatility: 0.3200
   Correlation: 1
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,Basis=12)
```

```
myRC =
  ratecurve with properties:
```

```
                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create HeynenKat Pricer Object

Use `finpricer` to create a `HeynenKat` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",Model=BlackScholesModel,DiscountCurve=myRC,SpotPrice=100,Divider
```

```
outPricer =
  HeynenKat with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 100
    DividendValue: 0.0500
     DividendType: "continuous"
```

Price PartialLookback Instrument

Use `price` to compute the price and sensitivities for the `PartialLookback` instrument.

```
[Price, outPR] = price(outPricer,PartialLookbackOpt,["all"])
```

```
Price = 31.4405

outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×7 table
    Price     Delta        Gamma       Lambda      Vega      Theta       Rho
    _____    ________    _________    _______    ______    _______    _______

    31.44    -0.37693    0.0042263    -1.1989    76.886    -1.6249    -259.77
```

IkedaKunitomo

Create `IkedaKunitomo` pricer object for `DoubleBarrier` instrument using `BlackScholes` model

Description

Create and price a `DoubleBarrier` instrument object with a `BlackScholes` model and a `IkedaKunitomo` pricing method using this workflow:

1. Use `fininstrument` to create a `DoubleBarrier` instrument object.
2. Use `finmodel` to specify a `BlackScholes` model for the `DoubleBarrier` instrument object.
3. Use `finpricer` to specify a `IkedaKunitomo` pricer object for the `DoubleBarrier` instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a `DoubleBarrier` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
IkedaKunitomoPricerObj = finpricer(PricerType,'Model',model,'
DiscountCurve',ratecurve_obj,'SpotPrice',spotprice_value)
IkedaKunitomoPricerObj = finpricer( ___ ,Name,Value)
```

Description

`IkedaKunitomoPricerObj = finpricer(PricerType,'Model',model,'DiscountCurve',ratecurve_obj,'SpotPrice',spotprice_value)` creates a `IkedaKunitomo` pricer object by specifying `PricerType` and sets properties on page 11-3165 using the required name-value pair arguments `Model`, `DividendType`, and `SpotPrice`.

`IkedaKunitomoPricerObj = finpricer( ___ ,Name,Value)` sets optional properties on page 11-3165 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `IkedaKunitomoPricerObj = finpricer("Analytic",'Model',BSModel,'DiscountCurve',ratecurve_obj,'SpotPrice',100,'DividendValue',0.025,'PricingMethod',"IkedaKunitomo")` creates a `IkedaKunitomo` pricer object. You can specify multiple name-value pair arguments.

Input Arguments

PricerType — Pricer type

string with value `"Analytic"` | character vector with value `'Analytic'`

Pricer type, specified as a string with the value `"Analytic"` or a character vector with the value `'Analytic'`.

Data Types: `char` | `string`

`IkedaKunitomo` Name-Value Pair Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `IkedaKunitomoPricerObj = finpricer("Analytic",'Model',BSModel,'DiscountCurve',ratecurve_obj,'SpotPrice',100,'DividendValue',0.025,'PricingMethod',"IkedaKunitomo")`

Required IkedaKunitomo Name-Value Pair Arguments

`Model` — `IkedaKunitomo` model object
object

Model object, specified as the comma-separated pair consisting of `'Model'` and the name of a previously created `BlackScholes` model object using `finmodel`.

Data Types: `object`

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

`ratecurve` object for discounting cash flows, specified as the comma-separated pair consisting of `'DiscountCurve'` and the name of the previously created `ratecurve` object.

Note Specify a flat `ratecurve` object for `DiscountCurve`.

Data Types: `object`

`SpotPrice` — Current price of underlying asset
scalar nonnegative numeric

Current price of the underlying asset, specified as the comma-separated pair consisting of `'SpotPrice'` and a scalar nonnegative numeric value.

Data Types: `double`

Optional IkedaKunitomo Name-Value Pair Arguments

`DividendValue` — Dividend yield
`0` (default) | scalar nonnegative numeric

Dividend yield, specified as the comma-separated pair consisting of `'DividendValue'` and a scalar nonnegative numeric value.

Data Types: `double`

`DividendType` — Dividend type
`"continuous"` (default) | string with value `"continuous"` | character vector with value `'continuous'`

Dividend type, specified as the comma-separated pair consisting of `'DividendType'` and string or character vector.

Data Types: `char` | `string`

`Curvature` — Curvature levels of the upper and lower barriers
`[0 0]` (default) | vector

Curvature levels of the upper and lower barriers, specified as the comma-separated pair consisting of `'Curvature'` and a vector where the first level is the upper barrier curvature (d1) and second level is the lower barrier curvature (d2). The possible curvature levels are as follows:

- d1 = d2 = 0 corresponds to two flat boundaries.
- d1 < 0 < d2 corresponds to an exponentially growing lower boundary and an exponentially decaying upper boundary.
- d1 > 0 > d2 corresponds to a convex downward lower boundary and a convex upward upper boundary.

Data Types: `char` | `string`

`PricingMethod` — Analytic pricing method
default pricer associated with `BlackScholes` model (default) | string with value `"IkedaKunitomo"` | character vector with value `'IkedaKunitomo'`

Analytic pricing method, specified as the comma-separated pair consisting of `'PricingMethod'` and a character vector or string.

Note The default pricing method for a `BlackScholes` model is a `BlackScholes` pricer.

Data Types: `string` | `char`

Properties

`Model` — Model
model object

Model, returned as a model object.

Data Types: `object`

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

This property is read-only.

`ratecurve` object for discounting cash flows, returned as a `ratecurve` object.

Data Types: `object`

`SpotPrice` — Current price of underlying asset
nonnegative numeric

Current price of the underlying asset, returned as a scalar nonnegative numeric value.

Data Types: `double`

`DividendValue` — Dividend yield
`0` (default) | scalar nonnegative numeric

Dividend yield, returned as a scalar nonnegative numeric.

Data Types: `double`

`DividendType` — Dividend type
`"continuous"` (default) | string with value `"continuous"`

This property is read-only.

Dividend type, returned as a string.

Data Types: `string`

`Curvature` — Curvature levels of the upper and lower barriers
`[0 0]` (default) | vector

Curvature levels of the upper and lower barriers, returned as a vector where the first level is the upper barrier curvature (d1) and second level is the lower barrier curvature (d2).

Data Types: `char` | `string`

`PricingMethod` — Analytic pricing method
default pricer associated with `BlackScholes` model (default) | string with value `"IkedaKunitomo"`

Analytic pricing method, returned as a string.

Data Types: `string`

Object Functions

price Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

Examples

Use Ikeda-Kunitomo Pricer and Black-Scholes Model to Price Double Barrier Instrument

This example shows the workflow to price a `DoubleBarrier` instrument when you use a `BlackScholes` model and an `IkedaKunitomo` pricing method.

Create `DoubleBarrier` Instrument Object

Use `fininstrument` to create a `DoubleBarrier` instrument object.

```
DoubleBarrierOpt = fininstrument("DoubleBarrier",'Strike',100,'ExerciseDate',datetime(2020,8,15),
```

```
DoubleBarrierOpt =
  DoubleBarrier with properties:

       OptionType: "call"
           Strike: 100
     BarrierValue: [110 80]
    ExerciseStyle: "european"
```

```
     ExerciseDate: 15-Aug-2020
      BarrierType: "dko"
           Rebate: [0 0]
             Name: "doublebarrier_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes","Volatility",.3)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.3000
    Correlation: 1
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2017,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2017
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `IkedaKunitomo` Pricer Object

Use `finpricer` to create an `IkedaKunitomo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("Analytic","DiscountCurve",myRC,"Model",BlackScholesModel,'SpotPrice',100,
```

```
outPricer =
  IkedaKunitomo with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 100
    DividendValue: 0.0290
     DividendType: "continuous"
        Curvature: [0.0300 -0.0300]
```

Price DoubleBarrier Instrument

Use `price` to compute the price and sensitivities for the `DoubleBarrier` instrument.

```
[Price, outPR] = price(outPricer,DoubleBarrierOpt,["all"])
```

```
Price = 5.6848e-04
```

```
outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×7 table
      Price          Delta          Gamma        Lambda       Vega          Theta          Rho
    __________    ___________    ___________    _______    _________    _________    ___________

    0.00056848    -3.7713e-05    -4.2071e-06    -6.6339    -0.031332    0.0008912    -0.00035113
```

VannaVolga

Create `VannaVolga` pricer object for `Vanilla`, `Barrier`, `DoubleBarrier`, `Touch`, or `DoubleTouch` instrument using `BlackScholes` model

Description

Create and price a `Vanilla`, `Barrier`, `DoubleBarrier`, `Touch`, or `DoubleTouch` instrument object with a `BlackScholes` model and a `VannaVolga` pricing method using this workflow:

1. Use `fininstrument` to create a `Vanilla`, `Barrier`, `DoubleBarrier`, `Touch`, or `DoubleTouch` instrument object.
2. Use `finmodel` to specify the `BlackScholes` model for the `Vanilla`, `Barrier`, `DoubleBarrier`, `Touch`, or `DoubleTouch` instrument object.
3. Use `finpricer` to specify the `VannaVolga` pricer object for the `Vanilla`, `Barrier`, `DoubleBarrier`, `Touch`, or `DoubleTouch` instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a `Vanilla`, `Barrier`, `DoubleBarrier`, `Touch`, or `DoubleTouch` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
VannaVolgaPricerObj = finpricer(PricerType,'DiscountCurve',ratecurve_obj,'
Model',model,'SpotPrice',spot_price,'VolatilityRR',volatilityrr_value,'
VolatilityBF',volatilitybf_value)
```

Description

`VannaVolgaPricerObj = finpricer(PricerType,'DiscountCurve',ratecurve_obj,'Model',model,'SpotPrice',spot_price,'VolatilityRR',volatilityrr_value,'VolatilityBF',volatilitybf_value)` creates a `VannaVolga` pricer object by specifying `PricerType` and sets properties on page 11-3171 using the required name-value pair arguments `DiscountCurve`, `Model`, `SpotPrice`, `VolatilityRR`, and `VolatilityBF`. For example, `VannaVolgaPricerObj = finpricer("VannaVolga",'DiscountCurve',ratecurve_obj,'Model',BSModel,'SpotPrice',Spot,'VolatilityRR',VolRR,'VolatilityBF',VolBF)` creates a `VannaVolga` pricer object.

`VannaVolgaPricerObj = finpricer(___,Name,Value)` sets optional properties on page 11-3171 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `VannaVolgaPricerObj = finpricer("VannaVolga",'DiscountCurve',ratecurve_obj,'Model',BSModel,'SpotPri`

ce','Spot','VolatilityRR',VolRR,'VolatilityBF',VolBF,'DividendValue',0.0210) creates a VannaVolga pricer object. You can specify multiple name-value pair arguments.

Input Arguments

PricerType — Pricer type

string with value "VannaVolga" | character vector with value 'VannaVolga'

Pricer type, specified as a string with the value "VannaVolga" or a character vector with the value 'VannaVolga'.

Data Types: char | string

Required VannaVolga Name-Value Pair Arguments

Specify required pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: VannaVolgaPricerObj = finpricer("VannaVolga",'DiscountCurve',ratecurve_obj,'Model',BSModel,'SpotPrice',Spot,'VolatilityRR',VolRR,'VolatilityBF',VolBF,'DividendValue',0.0210)

DiscountCurve — ratecurve object for discounting cash flows

ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of a previously created ratecurve object.

Data Types: object

Model — Model object

BlackScholes model object

Model object, specified as the comma-separated pair consisting of 'Model' and the name of a previously created BlackScholes model object using finmodel.

Data Types: object

SpotPrice — Current price of underlying asset

numeric

Current price of the underlying asset, specified as the comma-separated pair consisting of 'SpotPrice' and a scalar numeric.

Data Types: double

VolatilityRR — 25-delta risk reversal (RR) volatility

numeric

25-delta risk reversal (RR) volatility, specified as the comma-separated pair consisting of 'VolatilityRR' and a scalar numeric.

Data Types: double

`VolatilityBF` — 25-delta butterfly (BF) volatility
numeric

25-delta butterfly (BF) volatility, specified as the comma-separated pair consisting of `'VolatilityBF'` and a scalar numeric.

Data Types: `double`

Optional VannaVolga Name-Value Pair Arguments

`DividendType` — Dividend type
`"continuous"` (default) | string with value of `"continuous"` | character vector with value of `'continuous'`

Dividend type, specified as the comma-separated pair consisting of `'DividendType'` and a string or character vector for a continuous dividend yield.

Data Types: `char` | `string`

`DividendValue` — Continuous dividend yield
`0` (default) | scalar numeric

Continuous dividend yield, specified as the comma-separated pair consisting of `'DividendValue'` and a scalar numeric.

Note When pricing currency (FX) options, specify the optional input argument `'DividendValue'` as the continuously compounded risk-free interest rate in the foreign country.

Data Types: `double`

Properties

`DiscountCurve` — `ratecurve` object for discounting cash flows
object

`ratecurve` object for discounting cash flows, returned as a `ratecurve` object.

Data Types: `object`

`Model` — Model
`BlackScholes` model object

Model, returned as a `BlackScholes` model object.

Data Types: `object`

`SpotPrice` — Current price of underlying asset
numeric

Current price of the underlying asset, returned as a scalar numeric.

Data Types: `double`

`VolatilityRR` — 25-delta risk reversal (RR) volatility
numeric

25-delta risk reversal (RR) volatility, returned as a scalar numeric.

Data Types: `double`

`VolatilityBF` — 25-delta butterfly (BF) volatility
numeric

25-delta butterfly (BF) volatility, returned as a scalar numeric.

Data Types: `double`

`DividendType` — Dividend type
`"continuous"` (default) | string with value of `"continuous"`

This property is read-only.

Dividend type, returned as a string.

Data Types: `string`

`DividendValue` — Continuous dividend yield
`0` (default) | scalar numeric

Continuous dividend yield, returned as a scalar numeric.

Data Types: `double`

Object Functions

price Compute price for equity instrument with VannaVolga pricer

Examples

Use Vanna Volga Pricer and Black-Scholes Model to Price Double Barrier Instrument

This example shows the workflow to price a `DoubleBarrier` instrument when you use a `BlackScholes` model and a `VannaVolga` pricing method.

Create `DoubleBarrier` Instrument Object

Use `fininstrument` to create a `DoubleBarrier` instrument object.

```
DoubleBarrierOpt = fininstrument("DoubleBarrier",'Strike',100,'ExerciseDate',datetime(2020,8,15),
```

```
DoubleBarrierOpt =
  DoubleBarrier with properties:

       OptionType: "call"
           Strike: 100
     BarrierValue: [110 80]
    ExerciseStyle: "european"
     ExerciseDate: 15-Aug-2020
      BarrierType: "dko"
           Rebate: [0 0]
             Name: "doublebarrier_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes","Volatility",0.02)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.0200
    Correlation: 1
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2019,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `VannaVolga` Pricer Object

Use `finpricer` to create a `VannaVolga` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
VolRR = -0.0045;
VolBF = 0.0037;
RateF = 0.0210;
outPricer = finpricer("VannaVolga","DiscountCurve",myRC,"Model",BlackScholesModel,'SpotPrice',100
```

```
outPricer =
  VannaVolga with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 100
     DividendType: "continuous"
    DividendValue: 0.0210
     VolatilityRR: -0.0045
     VolatilityBF: 0.0037
```

Price DoubleBarrier Instrument

Use `price` to compute the price and sensitivities for the `DoubleBarrier` instrument.

```
[Price, outPR] = price(outPricer,DoubleBarrierOpt,["all"])
```

```
Price = 1.6450

outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×7 table
    Price     Delta     Gamma     Lambda     Vega      Theta      Rho
    _____    _______    _____    ______    ______    _______    _____

    1.645    0.82818    75.662    50.346    14.697    -1.3145    74.666
```

More About

Vanna-Volga Method

The Vanna Volga method is an empirical procedure based on adding an analytically derived correction to the Black-Scholes price of the instrument.

The Vanna-Volga method consists of adjusting the Black-Scholes theoretical value (BSTV) by the cost of a portfolio which hedges three main risks associated to the volatility of the option: the Vega, the Vanna and the Volga.

The general formulation of the Vanna-Volga method suggests that the Vega, Vanna, and Volga values can be replicated by the weighted sum of at-the-money (ATM), risk-reversal (RR), and butterfly (BF) strategies.

$$X_i = \omega_{ATM} ATM_i + \omega_{RR} RR_i + \omega_{BF} BF_i \; (i = vega, vanna, volga)$$

Here, the weights are obtained by solving the system $x = A\omega$

$$A = \begin{matrix} ATM_{vega} & RR_{vega} & BF_{vega} \\ ATM_{vanna} & RR_{vanna} & BF_{vanna,} \\ ATM_{volga} & RR_{volga} & BF_{volga} \end{matrix} \quad \omega = \begin{matrix} \omega_{ATM} \\ \omega_{RR,} \\ \omega_{BF} \end{matrix} \quad X = \begin{matrix} X_{vega} \\ X_{vanna} \\ X_{volga} \end{matrix}$$

Given this replication, the Vanna-Volga method adjusts the Black-Scholes price of the option by the smile cost of the above weighted sum:

$$X^{VV} = X^{BS} + \omega_{ATM}(ATM^{mkt} - ATM^{BS}) + \omega_{RR}(RR^{mkt} - RR^{BS}) + \omega_{BF}(BF^{mkt} - BF^{BS})$$

$$= X^{BS} + x^{T}(A^{T}I$$

$$= X^{BS} + X_{vega}\Omega_{vega} + X_{vanna}\Omega_{vanna} + X_{volga}\Omega_{volga}$$

where $I = \begin{matrix} ATM^{mkt} - ATM^{BS} \\ RR^{mkt} - RR^{BS} \\ BF^{mkt} - BF^{mkt} \end{matrix}$, $\Omega_{vanna} = (A^{T}I$ Ω_{vega} Ω_{volga}

The resulting correction or overhedge turns out to be too large. So, the option value is modified as follows:

$$X^{VV} = X^{BS} + X_{vega}\Omega_{vega} + X_{vanna}\Omega_{vanna} + X_{volga}\Omega_{volga}$$

where, $\rho_{vega} = \frac{1}{2} + \frac{1}{2}\rho$, and $\rho_{volga} = \frac{1}{2} + \frac{1}{2}\rho$.

ρ is the risk-neutral probability of not hitting the barrier.

Heston

Create `Heston` pricer object for `VarianceSwap` instrument using `Heston` model

Description

Create and price a `VarianceSwap` instrument object with a `Heston` model and a `Heston` pricing method using this workflow:

1. Use `fininstrument` to create a `VarianceSwap` instrument object.
2. Use `finmodel` to specify the `Heston` model for the `VarianceSwap` instrument object.
3. Use `finpricer` to specify the `Heston` pricer object for the `VarianceSwap` instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a `VarianceSwap` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
HestonPricerObj = finpricer(PricerType,'DiscountCurve',ratecurve_obj,'
Model',model)
```

Description

`HestonPricerObj = finpricer(PricerType,'DiscountCurve',ratecurve_obj,'Model',model)` creates a `Heston` pricer object by specifying `PricerType` and sets properties on page 11-3178 using the required name-value pair arguments `DiscountCurve` and `Model`. For example, `HestonPricerObj = finpricer("Analytic",'DiscountCurve',ratecurve_obj,'Model',HWModel)` creates a `Heston` pricer object.

Input Arguments

`PricerType` — Pricer type

string with value `"Analytic"` | character vector with value `'Analytic'`

Pricer type, specified as a string with the value `"Analytic"` or a character vector with the value `'Analytic'`.

Data Types: `char` | `string`

`Heston` Name-Value Pair Arguments

Specify required pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `HestonPricerObj = finpricer("Analytic",'DiscountCurve',ratecurve_obj,'Model',HWModel)`

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

`ratecurve` object for discounting cash flows, specified as the comma-separated pair consisting of `'DiscountCurve'` and the name of a previously created `ratecurve` object.

Note The software uses the `Basis` value of the specified `ratecurve` object to calculate both the discounting and accrual for the `VarianceSwap` instrument object.

Data Types: `object`

`Model` — Model object
`Heston` model object

Model object, specified as the comma-separated pair consisting of `'Model'` and the name of the previously created `Heston` model object using `finmodel`.

Data Types: `object`

Properties

`DiscountCurve` — `ratecurve` object for discounting cash flows
object

`ratecurve` object for discounting cash flows, returned as a `ratecurve` object.

Data Types: `object`

`Model` — Model
`Heston` model object

Model, returned as a `Heston` model object.

Data Types: `object`

Object Functions

price Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

Examples

Use Heston Pricer and Heston Model to Price Variance Swap Instrument

This example shows the workflow to price a `VarianceSwap` instrument when you use a `Heston` model and a `Heston` pricing method.

Create `VarianceSwap` Instrument Object

Use `fininstrument` to create a `VarianceSwap` instrument object.

```
VarianceSwapInst = fininstrument("VarianceSwap",'Maturity',datetime(2020,9,15),'Notional',100,'S
```

```
VarianceSwapInst =
  VarianceSwap with properties:

           Notional: 100
    RealizedVariance: 0.0200
             Strike: 0.1000
          StartDate: 15-Jun-2020
           Maturity: 15-Sep-2020
               Name: "variance_swap_instrument"
```

Create `Heston` Model Object

Use `finmodel` to create a `Heston` model object.

```
HestonModel = finmodel("Heston",'V0',0.06,'ThetaV',0.1,'Kappa',0.9,'SigmaV',0.7,'RhoSV',-.3)
```

```
HestonModel =
  Heston with properties:

       V0: 0.0600
    ThetaV: 0.1000
     Kappa: 0.9000
    SigmaV: 0.7000
     RhoSV: -0.3000
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2020, 1, 1);
ZeroTimes = calmonths(3);
ZeroRates = 0.05;
ZeroDates = Settle + ZeroTimes;
Basis = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates,'Basis',Basis)
```

```
ZeroCurve =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 1
               Dates: 01-Apr-2020
               Rates: 0.0500
              Settle: 01-Jan-2020
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `Heston` Pricer Object

Use `finpricer` to create a `Heston` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("Analytic",'DiscountCurve',ZeroCurve,'Model',HestonModel)

outPricer =
  Heston with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.Heston]
```

Price `VarianceSwap` Instrument

Use `price` to compute the price and fair variance for the `VarianceSwap` instrument.

```
[Price, outPR] = price(outPricer,VarianceSwapInst,["all"])

Price = 6.0054

outPR =
  priceresult with properties:

       Results: [1x2 table]
    PricerData: []
```

```
outPR.Results

ans=1×2 table
    Price     FairVariance
    ______    ____________

    6.0054      0.07039
```

Algorithms

Variance swaps can be priced with the calibrated Heston model by using the following closed-form expression for the fair variance:

$$K_{\text{var}} = \frac{1 - e^{-kT}}{kT}(n_0 - \theta) + \theta$$

Here:

- ν_0 is the initial variance of the underlying asset at $t = 0$ $\nu_0 > 0$.
- θ is the long-term variance level $\theta > 0$.
- k is the mean reversion speed for the variance ($k > 0$).

Once the fair variance is computed, the actual price paid in the market at time t for the variance swap with a start date at time 0 is computed as follows:

$$VarianceSwap(t) = Notional \times Disc(t,T) \times \left[\frac{t}{T}RealizedVariance(0,t) + \frac{T-t}{T}FairVariance(t,T) - StrikeVariance\right]$$

Here:

- t is the time from the start date of the variance swap to the settle date.
- T is the time from the start date to the maturity date of the variance swap.
- $Disc(t,T)$ is the discount factor from settle to the maturity date.
- $RealizedVariance(0,t)$ is the realized variance from start date to the settle date, in basis points.
- $FairVariance(t,T)$ is the fair variance for the remaining life of the contract as of the settle date, in basis points.
- *StrikeVariance* is the strike variance predetermined at inception (start date), in basis points.

ReplicatingVarianceSwap

Create `ReplicatingVarianceSwap` pricer object for `VarianceSwap` instrument using `ratecurve` object

Description

Create and price a `VarianceSwap` instrument object with a `ratecurve` object and a `ReplicatingVarianceSwap` pricing method using this workflow:

1. Use `fininstrument` to create a `VarianceSwap` instrument object.
2. Use `ratecurve` to specify a curve model for the `VarianceSwap` instrument object.
3. Use `finpricer` to specify a `ReplicatingVarianceSwap` pricer object for the `VarianceSwap` instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a `VarianceSwap` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
ReplicatingVarianceSwapPricerObj = finpricer(PricerType,'
DiscountCurve',ratecurve_obj,'VolatilitySmile',volatilitysmile_value,'
SpotPrce',spotprice_value)
ReplicatingVarianceSwapPricerObj = finpricer( ___ ,Name,Value)
```

Description

`ReplicatingVarianceSwapPricerObj = finpricer(PricerType,'DiscountCurve',ratecurve_obj,'VolatilitySmile',volatilitysmile_value,'SpotPrce',spotprice_value)` creates an `ReplicatingVarianceSwap` pricer object by specifying `PricerType` and sets properties on page 11-3184 using the required name-value pair arguments `DiscountCurve`, `VolatilitySmile`, and `SpotPrice`.

`ReplicatingVarianceSwapPricerObj = finpricer( ___ ,Name,Value)` sets optional properties on page 11-3184 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `ReplicatingVarianceSwapPricerObj = finpricer("ReplicatingVarianceSwap",'DiscountCurve',ratecurve_obj,'VolatilitySmile',smiletable,'SpotPrice',1000,'CallPutBoundary',"forwardprice",'InterpMethod',"cubic")` creates a `ReplicatingVarianceSwap` pricer object. You can specify multiple name-value pair arguments.

Input Arguments

`PricerType` — Pricer type

string with value `"ReplicatingVarianceSwap"` | character vector with value `'ReplicatingVarianceSwap'`

Pricer type, specified as a string with the value `"ReplicatingVarianceSwap"` or a character vector with the value `'ReplicatingVarianceSwap'`.

Data Types: `char` | `string`

`ReplicatingVarianceSwap` Name-Value Pair Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `ReplicatingVarianceSwapPricerObj = finpricer("ReplicatingVarianceSwap",'DiscountCurve',ratecurve_obj,'VolatilitySmile',smiletable,'SpotPrice',1000,'CallPutBoundary',"forwardprice",'InterpMethod',"cubic")`

Required `ReplicatingVarianceSwap` Name-Value Pair Arguments

`DiscountCurve` — `ratecurve` object for discounting cash flows

`ratecurve` object

This property is read-only.

`ratecurve` object for discounting cash flows, specified as the comma-separated pair consisting of `'DiscountCurve'` and the name of a `ratecurve` object.

Note

- Specify a flat `ratecurve` object for `DiscountCurve`. If you use a nonflat `ratecurve` object, the software uses the rate in the `ratecurve` object at `Maturity` and assumes that the value is constant for the life of the equity option.
- The software uses the `Basis` value of the specified `ratecurve` object to calculate both the discounting and accrual for the `VarianceSwap` instrument object.

Data Types: `object`

`VolatilitySmile` — Volatility smile table

table | matrix

Volatility smile table, specified as the comma-separated pair consisting of `'VolatilitySmile'` and a table with the columns `"Strike"` and `"Volatility"` or a `NumVols`-by-2 matrix where the first column is the strikes and the second column is the volatilities in decimals.

Data Types: `table` | `double`

SpotPrice — Spot price of underlying asset
nonnegative numeric

Spot price of the underlying asset, specified as the comma-separated pair consisting of `'SpotPrice'` and a scalar nonnegative numeric.

Note `SpotPrice` must be covered by the range of strikes in `VolatilitySmile`.

Data Types: `double`

Optional ReplicatingVarianceSwap Name-Value Pair Arguments

`CallPutBoundary` — Boundary strike for call and put options
`"spotprice"` (default) | scalar numeric | character vector with value `'spotprice'` or `'forwardprice'` | string with value `"spotprice"` or `"forwardprice"`

Boundary strike for call and put options, specified as the comma-separated pair consisting of `'CallPutBoundary'` and a scalar numeric or one of the following character vectors or strings:

- `"spotprice"` — The call and put option boundary strike is the spot price.
- `"forwardprice"` — The call and put option boundary strike is the forward price.

Note `CallPutBoundary` must be covered by the range of strikes in `VolatilitySmile`.

Data Types: `double` | `char` | `string`

`InterpMethod` — Interpolation method for `SmileTable`
`"linear"` (default) | string with value `"linear"`, `"cubic"`, `"next"`, `"previous"`, `"pchip"`, `"v5cubic"`, `"makima"`, or `"spline"` | character vector with value `'linear'`, `'cubic'`, `'next'`, `'previous'`, `'pchip'`, `'v5cubic'`, `'makima'`, or `'spline'`

Interpolation method for `SmileTable`, specified as the comma-separated pair consisting of `'InterpMethod'` and a scalar string or character vector using a supported value. For more information on interpolation methods, see `interp1`.

Data Types: `char` | `string`

Properties

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

`ratecurve` object for discounting cash flows, returned as the `ratecurve` object.

Note The software uses the `Basis` value of the specified `ratecurve` object to calculate both the discounting and accrual for the `VarianceSwap` instrument object.

Data Types: `object`

`VolatilitySmile` — Volatility smile table
table | matrix

Volatility smile table, returned as a table with the columns `"Strike"` and `"Volatility"` or a `NumVols`-by-2 matrix where the first column is the strikes and the second column is the volatilities in decimals.

Data Types: `table` | `double`

`SpotPrice` — Strike price of underlying asset
nonnegative numeric

Strike price of the underlying asset, returned as a scalar nonnegative numeric.

Data Types: `double`

`CallPutBoundary` — Boundary strike for call and put options
`"spotprice"` (default) | scalar numeric | string with value `"spotprice"` or `"forwardprice"`

Boundary strike for call and put options, returned as a numeric or as a string with the value `"spotprice"` or `"forwardprice"`.

Data Types: `double` | `char` | `string`

`InterpMethod` — Interpolation method
`"linear"` (default) | string with value `"linear"`, `"cubic"`, `"next"`, `"previous"`, `"pchip"`, `"v5cubic"`, `"makima"`, or `"spline"`

Interpolation method, returned as a scalar string.

Data Types: `string`

Object Functions

price Compute price for equity instrument with ReplicatingVarianceSwap pricer

Examples

Use Replicating Variance Swap Pricer and `ratecurve` to Price Variance Swap Instrument

This example shows the workflow to price a `VarianceSwap` instrument when you use a `ratecurve` and a `ReplicatingVarianceSwap` pricing method.

Create `VarianceSwap` Instrument Object

Use `fininstrument` to create a `VarianceSwap` instrument object.

```
VarianceSwapInst = fininstrument("VarianceSwap",'Maturity',datetime(2021,5,1),'Notional',150,'Sta
```

```
VarianceSwapInst =
  VarianceSwap with properties:

            Notional: 150
    RealizedVariance: 0.0500
              Strike: 0.1000
           StartDate: 01-May-2020
```

```
            Maturity: 01-May-2021
                Name: "variance_swap_instrument"
```

Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```
Settle = datetime(2020, 9, 15);
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
Basis = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates,'Basis',Basis)
```

```
ZeroCurve =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 1
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2020
        InterpMethod: "linear"
   ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

Create ReplicatingVarianceSwap Pricer Object

Use finpricer to create a ReplicatingVarianceSwap pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
Strike = (50:5:135)';
Volatility = [.49;.45;.42;.38;.34;.31;.28;.25;.23;.21;.2;.21;.21;.22;.23;.24;.25;.26];
VolatilitySmile = table(Strike, Volatility);
SpotPrice = 100;
CallPutBoundary = 100;

outPricer =  finpricer("ReplicatingVarianceSwap",'DiscountCurve', ZeroCurve, 'VolatilitySmile', V
'SpotPrice', SpotPrice, 'CallPutBoundary', CallPutBoundary)
```

```
outPricer =
  ReplicatingVarianceSwap with properties:

     DiscountCurve: [1x1 ratecurve]
      InterpMethod: "linear"
   VolatilitySmile: [18x2 table]
         SpotPrice: 100
   CallPutBoundary: 100
```

Price VarianceSwap Instrument

Use price to compute the price and fair variance for the VarianceSwap instrument.

```
[Price, outPR] = price(outPricer,VarianceSwapInst,["all"])
```

```
Price = 8.1997

outPR =
  priceresult with properties:

       Results: [1x2 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×2 table
    Price     FairVariance
    ______    ____________

    8.1997      0.21701
```

```
outPR.PricerData.ReplicatingPortfolio
```

```
ans=19×6 table
    CallPut    Strike    Volatility      Weight       Value     Contribution
    _______    ______    __________    __________    _______    ____________

      ⋮
```

More About

Replicating Variance Swap

A replicating variance swap uses a portfolio of options.

The variance swap replication is accomplished using a portfolio of options with different strikes.

Algorithms

The fair value of the future variance *Kvar* is approximated in terms of the following portfolio of options Π_{CP}:

$$K_{\text{var}} = \frac{2}{T}\left\{rT - \left(\frac{S_0}{S_*}e^{rT} - 1\right) - \log\frac{S_*}{S_0} + e^{rT}\Pi_{CP}\right\}$$

$$\Pi_{CP} = \sum_i w(K_{ip})P(S, K_{ip}) + \sum_i w(K_{ic})C(S, K_{ic})$$

Here:

- Call option strikes — The call option strike are $K_0 < K_{1c} < K_{2c} < K_{3c} \ldots < K_{nc}$.
- Put option strikes — The put option strikes are $K_{mp} < \ldots < K_{3p} < K_{2p} < K_{1p} < K_0 = S_*$.
- K_{var} — is the fair value of future variance
- Π_{CP} — is the portfolio of call and put options
- S_0 — is the current asset price
- S_* — is the boundary between the call and put option strikes (for example, the spot price S_0 or forward price S_0e^{rT})
- $P(K)$ — is the current put option price with strike K
- $C(K)$ — is the current call option price with strike K

If the options portfolio Π_{CP} has an infinite number of options with continuously varying strikes, it has the following payoff function at maturity:

$$f(S_T) = \frac{2}{T}\left[\frac{S_T - S_*}{S_*} - \log\frac{S_T}{S_*}\right]$$

Since it is not possible to construct such a portfolio with an infinite number of options and continuously varying strikes, the appropriate weights $w(K_{ip})$ and $w(K_{ic})$ for a portfolio with a finite number of options and discretely varying strikes can be computed by approximating the continuous payoff function $f(S_T)$ in a piecewise linear fashion. Starting with the strike at K_0, the first call option weight can be computed as the slope of the first piecewise linear function:

$$w_c(K_0) = \frac{f(K_{1c}) - f(K_0)}{K_{1c} - K_0}$$

The next call option weight with the strike K_{1c} is computed as the slope of the next piece-wise linear function minus the previous weight:

$$w_c(K_{1c}) = \frac{f(K_{2c}) - f(K_{1c})}{K_{2c} - K_{1c}} - w_c(K_0)$$

This procedure is continued for the remaining call option strikes:

$$w_c(K_{n,c}) = \frac{f(K_{n+1,c}) - f(K_{nc})}{K_{n+1,c} - K_{n,c}} - \sum_{i=0}^{n-1} w_c(K_{i,c})$$

To compute the put option weights, a similar procedure can be used in the opposite direction (starting from K_0):

$$w_p(K_{m,p}) = \frac{f(K_{m+1,p}) - f(K_{mp})}{K_{m,p} - K_{m+1,p}} - \sum_{i=0}^{m-1} w_p(K_{i,p})$$

Once the fair variance is computed, the actual price paid in the market at time t for the variance swap with a StartDate at time 0 is computed as follows:

$$VarianceSwap(t) = Notional \times Disc(t,T) \times \left[\frac{t}{T}\text{Re}alizedVariance(0,t) + \frac{T-t}{T}FairVariance(t,T) - StrikeVariance\right]$$

Here:

- t is the time from the start date of the variance swap to the settle date.
- T is the time from the start date to the maturity date of the variance swap.
- $Disc(t,T)$ is the discount factor from settle to the maturity date.
- $RealizedVariance(0,t)$ is the realized variance from start date to the settle date, in basis points.
- $FairVariance(t,T)$ is the fair variance for the remaining life of the contract as of the settle date, in basis points.
- *StrikeVariance* is the strike variance predetermined at inception (start date), in basis points.

Version History

Introduced in R2020b

BjerksundStensland

Create `BjerksundStensland` pricer object for `Vanilla` or `Spread` instrument using `BlackScholes` model

Description

Create and price a `Vanilla` or `Spread` instrument object with a `BlackScholes` model and a `BjerksundStensland` pricing method using this workflow:

1. Use `fininstrument` to create a `Vanilla` or `Spread` instrument object.
2. Use `finmodel` to specify a `BlackScholes` model for the `Vanilla` or `Spread` instrument object.
3. Use `finpricer` to specify a `BjerksundStensland` pricer object for the `Vanilla` instrument (American exercise) or `Spread` instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a `Vanilla` or `Spread` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
BjerksundStenslandPricerObj = finpricer(PricerType,'Model',model,'
DiscountCurve',ratecurve_obj,'SpotPrice',spotprice_value)
BjerksundStenslandPricerObj = finpricer( ___ ,Name,Value)
```

Description

`BjerksundStenslandPricerObj = finpricer(PricerType,'Model',model,'DiscountCurve',ratecurve_obj,'SpotPrice',spotprice_value)` creates a `BjerksundStensland` pricer object by specifying `PricerType` and sets the properties on page 11-3192 for the required name-value pair arguments `Model`, `DividendType`, and `SpotPrice`.

`BjerksundStenslandPricerObj = finpricer( ___ ,Name,Value)` to set optional properties on page 11-3192 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `BjerksundStenslandPricerObj = finpricer("Analytic",'Model',BSModel,'DiscountCurve',ratecurve_obj,'SpotPrice',[100;105],'DividendValue',[2.5,2.8],'PricingMethod',"BjerksundStensland")` creates a `BjerksundStensland` pricer object.

Input Arguments

`PricerType` — Pricer type
string with value `"Analytic"` | character vector with value `'Analytic'`

Pricer type, specified as a string with the value of `"Analytic"` or a character vector with the value of `'Analytic'`.

Data Types: `char` | `string`

BjerksundStensland Name-Value Pair Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `BjerksundStenslandPricerObj = finpricer("Analytic",'Model',BSModel,'DiscountCurve',ratecurve_obj,'SpotPrice',[100;105],'DividendValue',[2.5,2.8],'PricingMethod',"BjerksundStensland")`

Required BjerksundStensland Name-Value Pair Arguments

`Model` — Model
object

Model, specified as the comma-separated pair consisting of `'Model'` and the name of the previously created `BlackScholes` model object using `finmodel`.

Data Types: `object`

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

`ratecurve` object for discounting cash flows, specified as the comma-separated pair consisting of `'DiscountCurve'` and the name of the previously created `ratecurve` object.

Note Specify a flat `ratecurve` object for `DiscountCurve`. If you use a nonflat `ratecurve` object, the software uses the rate in the `ratecurve` object at `Maturity` and assumes that the value is constant for the life of the equity option.

Data Types: `object`

`SpotPrice` — Current price of underlying asset
scalar nonnegative numeric | vector of nonnegative numerics

Current price of the underlying asset, specified as the comma-separated pair consisting of `'SpotPrice'` and a scalar or vector of nonnegative numeric values. Use a vector for `SpotPrice` when pricing a `Spread` instrument.

Data Types: `double`

Optional BjerksundStensland Name-Value Pair Arguments

`DividendValue` — Dividend yield
`[0,0]` (default) | scalar nonnegative numeric | vector of nonnegative numerics

Dividend yield, specified as the comma-separated pair consisting of `'DividendValue'` and a scalar or vector of nonnegative numeric values. Use a 1-by-2 vector of nonnegative values for `DividendValue` when pricing a `Spread` instrument.

Data Types: double

DividendType — Dividend type
"continuous" (default) | string with value "continuous" | character vector with value 'continuous'

Dividend type, specified as the comma-separated pair consisting of 'DividendType' and string or character vector.

Data Types: char | string

PricingMethod — Analytic pricing method
default pricer associated with BlackScholes model (default) | string with value "BjerksundStensland" | character vector with value 'BjerksundStensland'

Analytic pricing method, specified as the comma-separated pair consisting of 'PricingMethod' and a character vector or string.

Note The default pricing method for a BlackScholes model is a BlackScholes pricer.

Data Types: string | char

Properties

Model — Model
object

Model, returned as a model object.

Data Types: object

DiscountCurve — ratecurve object for discounting cash flows
ratecurve object

This property is read-only.

ratecurve object for discounting cash flows, returned as a ratecurve object.

Data Types: object

SpotPrice — Current price of underlying asset
nonnegative numeric | vector of nonnegative numerics

Current price of the underlying asset, returned as a scalar or vector of nonnegative numeric values.

Data Types: double

DividendValue — Dividend yield
scalar nonnegative numeric | vector of nonnegative numerics

Dividend yield, returned as a scalar or vector of nonnegative numeric.

Data Types: double

DividendType — Dividend type
"continuous" (default) | string with value "continuous"

This property is read-only.

Dividend type, returned as a string.

Data Types: `string`

`PricingMethod` — Analytic pricing method
default pricer associated with `BlackScholes` model (default) | string with value `"BjerksundStensland"`

Analytic pricing method, returned as a string.

Data Types: `string`

Object Functions

price Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

Examples

Use Bjerksund-Stensland Pricer and Black-Scholes Model to Price Spread Instrument

This example shows the workflow to price a European exercise `Spread` instrument when you use a `BlackScholes` model and a `BjerksundStensland` pricing method.

Create Spread Instrument Object

Use `fininstrument` to create a `Spread` instrument object.

```
SpreadOpt = fininstrument("Spread",'Strike',5,'ExerciseDate',datetime(2021,9,15),'OptionType',"pu
```

```
SpreadOpt =
  Spread with properties:

       OptionType: "put"
           Strike: 5
    ExerciseStyle: "european"
     ExerciseDate: 15-Sep-2021
             Name: "spread_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',[0.2,0.1])
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: [0.2000 0.1000]
    Correlation: [2x2 double]
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)

myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `BjerksundStensland` Pricer Object

Use `finpricer` to create a `BjerksundStensland` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPrice',[100

outPricer =
  BjerksundStensland with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: [100 105]
    DividendValue: [0.0900 0.1700]
     DividendType: "continuous"
```

Price Spread Instrument

Use `price` to compute the price and sensitivities for the `Spread` instrument.

```
[Price, outPR] = price(outPricer,SpreadOpt,["all"])

Price = 7.0596

outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: []

outPR.Results

ans=1×7 table
    Price            Delta                    Gamma                   Lambda                Vega
    _____    ____________________    ______________________    ________________    ___________
```

```
    7.0596    -0.23249     0.27057    0.0069887    0.0055319    -3.2932     3.8327    41.938
```

Use Bjerksund-Stensland Pricer and Black-Scholes Model to Price an American Exercise Vanilla Instrument

This example shows the workflow to price an American exercise `Vanilla` instrument when you use a `BlackScholes` model and a `BjerksundStensland` pricing method.

Create `Vanilla` Instrument Object

Use `fininstrument` to create an American exercise `Vanilla` instrument object.

```
VanillaObj = fininstrument("Vanilla",'Strike',120,'ExerciseDate',datetime(2019,1,30),'OptionType
```

```
VanillaObj =
  Vanilla with properties:

       OptionType: "put"
    ExerciseStyle: "american"
     ExerciseDate: 30-Jan-2019
           Strike: 120
             Name: "vanilla_instrument"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',.2)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.2000
    Correlation: 1
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
       Compounding: -1
             Basis: 12
             Dates: 15-Sep-2023
             Rates: 0.0350
            Settle: 15-Sep-2018
      InterpMethod: "linear"
```

```
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `BjerksundStensland` Pricer Object

Use `finpricer` to create a `BjerksundStensland` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPrice',120,
```

```
outPricer =
  BjerksundStensland with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 120
    DividendValue: 0.0500
     DividendType: "continuous"
```

Price `Vanilla` Instrument

Use `price` to compute the price and sensitivities for the `Vanilla` instrument.

```
[Price, outPR] = price(outPricer,VanillaObj,["all"])
```

```
Price = 6.1080
```

```
outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×7 table
    Price     Delta       Gamma       Lambda      Vega      Theta       Rho
    _____    ________    ________    _______    ______    _______    _______

    6.108    -0.48471    0.026611    -9.5227    28.781    -8.3418    -24.115

“Choose Instruments, Models, and Pricers” on page 1-53

Black

Create Black pricer object for Cap, Floor, or Swaption instrument using Black model

Description

Create and price a Cap, Floor, or Swaption instrument object with a Black model and a Black pricing method using this workflow:

1. Use fininstrument to create a Cap, Floor, or Swaption instrument object.
2. Use finmodel to specify a Black model for the Cap, Floor, or Swaption instrument object.
3. Use finpricer to specify a Black pricer object for the Cap, Floor, or Swaption instrument object.

Note If you do not specify ProjectionCurve when you create a Cap, Floor, or Swaption instrument with the Black pricer, the ProjectionCurve value defaults to the DiscountCurve value.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a Cap, Floor, or Swaption instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
BlackPricerObj = finpricer(PricerType,'DiscountCurve',ratecurve_obj,'
Model',model)
```

Description

`BlackPricerObj = finpricer(PricerType,'DiscountCurve',ratecurve_obj,'Model',model)` creates a Black pricer object by specifying PricerType and the required name-value pair arguments for DiscountCurve and Model to set properties on page 11-3199 using name-value pairs. For example, `BlackPricerObj = finpricer("Analytic",'DiscountCurve',ratecurve_obj,'Model',BlackModel)` creates a Black pricer object.

Input Arguments

PricerType — Pricer type

string with value "Analytic" | character vector with value 'Analytic'

Pricer type, specified as a string with the value of "Analytic" or a character vector with the value of 'Analytic'.

Data Types: `char` | `string`

`Black` Name-Value Pair Arguments

Specify required pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `BlackPricerObj = finpricer("Analytic",'DiscountCurve',ratecurve_obj,'Model',BlackModel)`

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

`ratecurve` object for discounting cash flows, specified as the comma-separated pair consisting of `'DiscountCurve'` and the name of the previously created `ratecurve` object.

Data Types: `object`

`Model` — Model
`Black` model object

Model, specified as the comma-separated pair consisting of `'Model'` and the name of a previously created `Black` model object using `finmodel`.

Data Types: `object`

Properties

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

`ratecurve` object for discounting cash flows, returned as the `ratecurve` object

Data Types: `object`

`Model` — Model
`Black` model object

Model, returned as a `Black` model object.

Data Types: `object`

Object Functions

price Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

Examples

Use Black Pricer and Black Model to Price Cap Instrument

This example shows the workflow to price a `Cap` instrument when you use a `Black` model and a `Black` pricing method.

Create Cap Instrument Object

Use `fininstrument` to create a `Cap` instrument object.

```
CapOpt = fininstrument("Cap",'Strike',.02,'Maturity',datetime(2021,12,30),'Reset',4,'Principal',1
```

```
CapOpt =
  Cap with properties:

                     Strike: 0.0200
                   Maturity: 30-Dec-2021
                ResetOffset: 0
                      Reset: 4
                      Basis: 12
                  Principal: 100
             ProjectionCurve: [0x0 ratecurve]
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                   Holidays: NaT
                       Name: "cap_option"
```

Create Black Model Object

Use `finmodel` to create a `Black` model object.

```
BlackModel = finmodel("Black",'Volatility',0.09,'Shift',0.002)
```

```
BlackModel =
  Black with properties:

    Volatility: 0.0900
         Shift: 0.0020
```

Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2020,9,14);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
       Compounding: -1
             Basis: 0
             Dates: [10x1 datetime]
             Rates: [10x1 double]
            Settle: 14-Sep-2020
      InterpMethod: "linear"
    ShortExtrapMethod: "next"
```

```
     LongExtrapMethod: "previous"
```

Create Black Pricer Object

Use `finpricer` to create a `Black` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'Model',BlackModel,'DiscountCurve',myRC)
```

```
outPricer =
  Black with properties:

            Model: [1x1 finmodel.Black]
    DiscountCurve: [1x1 ratecurve]
```

Price Cap Instrument

Use `price` to compute the price for the `Cap` instrument.

```
Price = price(outPricer,CapOpt)
```

```
Price = 4.6412e-29
```

Version History

Introduced in R2020a

BlackScholes

Create `BlackScholes` pricer object for `Vanilla`, `Barrier`, `Touch`, `DoubleTouch`, or `Binary` instrument using `BlackScholes` model

Description

Create and price a `Vanilla`, `Barrier`, `Touch`, `DoubleTouch`, or `Binary` instrument object with a `BlackScholes` model and a `BlackScholes` pricing method using this workflow:

1. Use `fininstrument` to create a `Vanilla`, `Barrier`, `DoubleTouch`, `Binary` or , `Touch` instrument object.
2. Use `finmodel` to specify a `BlackScholes` model for the `Vanilla`, `Barrier`, `Touch`, `DoubleTouch`, or `Binary` instrument object.
3. Use `finpricer` to specify a `BlackScholes` pricer object for the `Vanilla`, `Barrier`, `Touch`, `DoubleTouch`, or `Binary` instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a `Vanilla`, `Lookback`, `Barrier`, `Asian`, `Spread`, `Touch`, `DoubleTouch`, or `Binary` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
BlackScholesPricerObj = finpricer(PricerType,'DiscountCurve',ratecurve_obj,'
Model',model,'SpotPrice',spotprice_value)
BlackScholesPricerObj = finpricer(___,Name,Value)
```

Description

`BlackScholesPricerObj = finpricer(PricerType,'DiscountCurve',ratecurve_obj,'Model',model,'SpotPrice',spotprice_value)` creates a `BlackScholes` pricer object by specifying `PricerType` and sets properties on page 11-3204 using the required name-value pair arguments `DiscountCurve`, `Model`, and `SpotPrice`.

`BlackScholesPricerObj = finpricer(___,Name,Value)` sets optional properties on page 11-3204 using additional name-value pair arguments in addition to the required arguments in the previous syntax. For example, `BlackScholesPricerObj = finpricer("Analytic",'DiscountCurve',ratecurve_obj,'Model',BSModel,'SpotPrice',1000,'DividendType',"continuous",'DividendValue',100)` creates a `BlackScholes` pricer object. You can specify multiple name-value pair arguments.

Input Arguments

`PricerType` — Pricer type

string with value `"Analytic"` | character vector with value `'Analytic'`

Pricer type, specified as a string with the value `"Analytic"` or a character vector with the value `'Analytic'`.

Data Types: `char` | `string`

`BlackScholes` Name-Value Pair Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `BlackScholesPricerObj = finpricer("Analytic",'DiscountCurve',ratecurve_obj,'Model',BSModel,'SpotPrice',1000,'DividendType',"continuous",'DividendValue',100)`

Required BlackScholes Name-Value Pair Arguments

`DiscountCurve` — `ratecurve` object for discounting cash flows

`ratecurve` object

`ratecurve` object for discounting cash flows, specified as the comma-separated pair consisting of `'DiscountCurve'` and the name of a previously created `ratecurve` object.

Note Specify a flat `ratecurve` object for `DiscountCurve`. If you use a nonflat `ratecurve` object, the software uses the rate in the `ratecurve` object at `Maturity` and assumes that the value is constant for the life of the equity option.

Data Types: `object`

`Model` — Model object

`BlackScholes` model object

Model, specified as the comma-separated pair consisting of `'Model'` and the name of a previously created `BlackScholes` model object using `finmodel`.

Data Types: `object`

`SpotPrice` — Current price of underlying asset

nonnegative numeric

Current price of the underlying asset, specified as the comma-separated pair consisting of `'SpotPrice'` and a scalar nonnegative numeric.

Data Types: `double`

Optional BlackScholes Name-Value Pair Arguments

`DividendType` — Stock dividend type
`"continuous"` (default) | string with value `"continuous"` | character vector with value `'continuous'`

Stock dividend type, specified as the comma-separated pair consisting of `'DividendType'` and a character vector or string.

Note When you price currencies using a `Vanilla` instrument, `DividendType` must be `"continuous"` and `DividendValue` is the annualized risk-free interest rate in the foreign country.

Data Types: `char` | `string`

`DividendValue` — Dividend amount or dividend schedule for underlying stock
`0` (default) | scalar numeric | timetable

Dividend amount or dividend schedule for the underlying stock, specified as the comma-separated pair consisting of `'DividendValue'` and a scalar numeric for a dividend amount or a timetable for a dividend schedule.

Note When you price currencies using a `Vanilla` instrument, the `DividendType` must be `"continuous"` and `DividendValue` is the annualized risk-free interest rate in the foreign country.

Data Types: `double` | `timetable`

Properties

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

`ratecurve` object for discounting cash flows, returned as a `ratecurve` object.

Data Types: `object`

`Model` — Model
`BlackScholes` model object

Model, returned as a `BlackScholes` model object.

Data Types: `object`

`SpotPrice` — Current price of underlying asset
nonnegative numeric

Current price of the underlying asset, returned as a scalar nonnegative numeric.

Data Types: `double`

`DividendType` — Stock dividend type
`"continuous"` (default) | string with value `"continuous"`

This property is read-only.

Stock dividend type, returned as a string.

Data Types: `string`

`DividendValue` — Dividend amount or dividend schedule for underlying stock

`0` (default) | scalar nonnegative numeric | timetable

Dividend amount or dividend schedule for the underlying stock, returned as a scalar numeric for a dividend amount or a timetable for a dividend schedule.

Data Types: `double` | `timetable`

Object Functions

price Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

Examples

Price Vanilla Instrument Using Black-Scholes Model and Black-Scholes Pricer

This example shows the workflow to price a `Vanilla` instrument when you use a `BlackScholes` model and a `BlackScholes` pricing method.

Create `Vanilla` Instrument Object

Use `fininstrument` to create a `Vanilla` instrument object.

```
VanillaOpt = fininstrument("Vanilla",'ExerciseDate',datetime(2018,5,1),'Strike',29,'OptionType','
```

```
VanillaOpt =
  Vanilla with properties:

       OptionType: "put"
    ExerciseStyle: "european"
     ExerciseDate: 01-May-2018
           Strike: 29
             Name: "vanilla_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.25)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.2500
    Correlation: 1
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,1,1);
Maturity = datetime(2019,1,1);
```

```
Rate = 0.05;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',1)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 1
               Dates: 01-Jan-2019
               Rates: 0.0500
              Settle: 01-Jan-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `BlackScholes` Pricer Object

Use `finpricer` to create a `BlackScholes` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'DiscountCurve',myRC,'Model',BlackScholesModel,'SpotPrice',30,'D
```

```
outPricer =
  BlackScholes with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 30
    DividendValue: 0.0450
     DividendType: "continuous"
```

Price `Vanilla` Instrument

Use `price` to compute the price and sensitivities for the `Vanilla` instrument.

```
[Price, outPR] = price(outPricer,VanillaOpt,["all"])
```

```
Price = 1.2046
```

```
outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta       Gamma      Lambda      Vega       Rho       Theta
    ______    _________    ________    _______    ______    _______    _______

    1.2046    -0.36943    0.086269    -9.3396    6.4702    -4.0959    -2.3107
```

Use Black-Scholes Pricer and Black-Scholes Model to Price Vanilla Instrument for Foreign Exchange

This example shows the workflow to price a `Vanilla` instrument for foreign exchange (FX) when you use a `BlackScholes` model and a `BlackScholes` pricing method. Assume that the current exchange rate is $0.52 and has a volatility of 12% per year. The annualized continuously compounded foreign risk-free rate is 8% per year.

Create `Vanilla` Instrument Object

Use `fininstrument` to create a `Vanilla` instrument object.

```
VanillaOpt = fininstrument("Vanilla",'ExerciseDate',datetime(2022,9,15),'Strike',.50,'OptionType
```

```
VanillaOpt =
  Vanilla with properties:

       OptionType: "put"
    ExerciseStyle: "european"
     ExerciseDate: 15-Sep-2022
           Strike: 0.5000
             Name: "vanilla_fx_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
Sigma = .12;
BlackScholesModel = finmodel("BlackScholes",'Volatility',Sigma)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.1200
    Correlation: 1
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
```

```
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create BlackScholes Pricer Object

Use `finpricer` to create a `BlackScholes` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument. When you price currencies using a `Vanilla` instrument, `DividendType` must be `'continuous'` and `DividendValue` is the annualized risk-free interest rate in the foreign country.

```
ForeignRate = 0.08;
outPricer = finpricer("analytic",'DiscountCurve',myRC,'Model',BlackScholesModel,'SpotPrice',.52,
```

```
outPricer =
  BlackScholes with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 0.5200
    DividendValue: 0.0800
     DividendType: "continuous"
```

Price Vanilla Instrument

Use `price` to compute the price and sensitivities for the `Vanilla` FX instrument.

```
[Price, outPR] = price(outPricer,VanillaOpt,["all"])
```

```
Price = 0.1123
```

```
outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×7 table
     Price      Delta      Gamma     Lambda      Vega        Rho        Theta
    _______    ________    ______    _______    _______    _______    _________

    0.11229    -0.59114    1.5562    -3.7706    0.20212    -1.6799    -0.023676
```

Version History

Introduced in R2020a

ConzeViswanathan

Create `ConzeViswanathan` pricer object for `Lookback` instrument using `BlackScholes` model

Description

Create and price a `Lookback` instrument object with a `BlackScholes` model and a `ConzeViswanathan` pricing method using this workflow:

1. Use `fininstrument` to create a `Lookback` instrument object.
2. Use `finmodel` to specify a `BlackScholes` model for the `Lookback` instrument object.
3. Use `finpricer` to specify a `ConzeViswanathan` pricer object for the `Lookback` instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a `Lookback` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
ConzeViswanathanPricerObj = finpricer(PricerType,'
DiscountCurve',ratecurve_obj,'Model',model,'SpotPrice',spotprice_value)
ConzeViswanathanPricerObj = finpricer(___,Name,Value)
```

Description

`ConzeViswanathanPricerObj = finpricer(PricerType,'DiscountCurve',ratecurve_obj,'Model',model,'SpotPrice',spotprice_value)` creates a `ConzeViswanathan` pricer object by specifying `PricerType` and sets the properties on page 11-3212 for the required name-value pair argument `Model`, `DiscountCurve`, and `SpotPrice`.

`ConzeViswanathanPricerObj = finpricer(___,Name,Value)` to set optional properties on page 11-3212 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `ConzeViswanathanPricerObj = finpricer("Analytic",'DiscountCurve',ratecurve_obj,'Model',BSModel,'SpotPrice',1000,'DividendType',"continuous",'DividendValue',100,'PricingMethod',"ConzeViswanathan")` creates a `ConzeViswanathan` pricer object.

Input Arguments

PricerType — Pricer type

string with value `"Analytic"` | character vector with value `'Analytic'`

Pricer type, specified as a string with the value of `"Analytic"` or a character vector with the value of `'Analytic'`.

Data Types: `char` | `string`

ConzeViswanathan Name-Value Pair Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Specify required and optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `ConzeViswanathanPricerObj = finpricer("Analytic",'DiscountCurve',ratecurve_obj,'Model',BSModel,'SpotPrice',1000,'DividendType',"continuous",'DividendValue',100,'PricingMethod',"ConzeViswanathan")`

Required ConzeViswanathan Name-Value Pair Arguments

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

`ratecurve` object for discounting cash flows, specified as the comma-separated pair consisting of `'DiscountCurve'` and the name of the previously created `ratecurve` object.

Note Specify a flat `ratecurve` object for `DiscountCurve`. If you use a nonflat `ratecurve` object, the software uses the rate in the `ratecurve` object at `Maturity` and assumes that the value is constant for the life of the equity option.

Data Types: `object`

`Model` — Model
`BlackScholes` model object

Model, specified as the comma-separated pair consisting of `'Model'` and the name of a previously created `BlackScholes` model object using `finmodel`.

Data Types: `object`

`SpotPrice` — Current price of underlying asset
nonnegative numeric

Current price of the underlying asset, specified as the comma-separated pair consisting of `'SpotPrice'` and a scalar nonnegative numeric.

Data Types: `double`

Optional ConzeViswanathan Name-Value Pair Arguments

`DividendType` — Stock dividend type
`"continuous"` (default) | string with value `"cash"` or `"continuous"` | character vector with value `'cash'` or `'continuous'`

Stock dividend type, specified as the comma-separated pair consisting of `'DividendType'` and character vector or string. `DividendType` must be `"cash"` for actual dollar dividends or `"continuous"` for a continuous dividend yield.

Data Types: `char` | `string`

`DividendValue` — Dividend amount or dividend schedule for underlying stock
`0` (default) | scalar numeric | timetable

Dividend amount for the underlying stock, specified as the comma-separated pair consisting of `'DividendValue'` and a scalar numeric for a dividend amount or a `timetable` for a dividend schedule.

Note Specify a scalar if `DividendType` is `"continuous"` and a timetable if `DividendType` is `"cash"`.

Data Types: `double` | `timetable`

`PricingMethod` — Analytic pricing method
default pricer associated with `BlackScholes` model (default) | string with value `"ConzeViswanathan"` | character vector with value `'ConzeViswanathan'`

Analytic pricing method, specified as the comma-separated pair consisting of `'PricingMethod'` and a string or character vector.

Note The default pricing method for a `BlackScholes` model is a `BlackScholes` pricer.

Data Types: `double`

Properties

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

`ratecurve` object for discounting cash flows, returned as the `ratecurve` object.

Data Types: `object`

`Model` — Model
`BlackScholes` model object

Model, returned as a `BlackScholes` model object.

Data Types: `object`

`SpotPrice` — Current price of underlying asset
nonnegative numeric

Current price of the underlying asset, returned as a scalar nonnegative numeric.

Data Types: `double`

`DividendType` — Stock dividend type
`"continuous"` (default) | string with value `"cash"` or `"continuous"`

This property is read-only.

Stock dividend type, returned as a string. `DividendType` is `"cash"` for actual dollar dividends or `"continuous"` for a continuous dividend yield.

Data Types: `string`

`DividendValue` — Dividend amount or dividend schedule for underlying stock
`0` (default) | scalar nonnegative numeric | timetable

Dividend amounts or dividend schedule for underlying stock, returned as a scalar numeric for a dividend yield or a timetable for a dividend schedule.

Data Types: `double` | `timetable`

`PricingMethod` — Analytic pricing method
default pricer associated with `BlackScholes` model (default) | string with value `"ConzeViswanathan"`

Analytic pricing method, returned as a string.

Data Types: `string`

Object Functions

price Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

Examples

Use Conze-Viswanathan Pricer and Black-Scholes Model to Price Lookback Instrument

This example shows the workflow to price a fixed strike `Lookback` instrument when you use a `BlackScholes` model and a `ConzeViswanathan` pricing method.

Create Lookback Instrument Object

Use `fininstrument` to create a fixed strike `Lookback` instrument object.

```
LookbackOpt = fininstrument("Lookback",'Strike',90,'ExerciseDate',datetime(2021,9,15),'OptionType
```

```
LookbackOpt =
  Lookback with properties:

       OptionType: "put"
           Strike: 90
      AssetMinMax: NaN
    ExerciseStyle: "european"
     ExerciseDate: 15-Sep-2021
             Name: "lookback_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',.358)

BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.3580
    Correlation: 1
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)

myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `ConzeViswanathan` Pricer Object

Use `finpricer` to create a `ConzeViswanathan` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPrice',95,'D

outPricer =
  ConzeViswanathan with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 95
    DividendValue: 0.0250
     DividendType: "continuous"
```

Price `Lookback` Instrument

Use `price` to compute the price and sensitivities for the `Lookback` instrument.

```
[Price, outPR] = price(outPricer,LookbackOpt,["all"])

Price = 29.6209

outPR =
  priceresult with properties:
```

```
       Results: [1x7 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta        Gamma       Lambda      Vega      Theta       Rho
    _____    _________    _________    _______    ______    _______    _______

    29.621    -0.49834    0.0085048    -1.5983    78.578    -3.4045    -163.55

Credit

Create `Credit` pricer object for `CDS` instrument using `defprobcurve`

Description

Create and price a `CDS` instrument object with a `defprobcurve` and a `Credit` pricing method using this workflow:

1. Create a default probability curve object using `defprobcurve`.
2. Use `finpricer` to specify a `Credit` pricer object for the `CDS` instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a `CDS` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
CreditPricerObj = finpricer(PricerType,'DiscountCurve',ratecurve_obj,'
DefaultProbabilityCurve',defprobcurve_object)
```

Description

`CreditPricerObj = finpricer(PricerType,'DiscountCurve',ratecurve_obj,'DefaultProbabilityCurve',defprobcurve_object)` creates a `Credit` pricer object by specifying `PricerType` and the required name-value pair arguments `DiscountCurve` and `DefaultProbabilityCurve` to set properties on page 11-3217 using name-value pairs. For example, `CreditPricerObj = finpricer("Credit",'DiscountCurve',ratecurve_obj,'DefaultProbabilityCurve',defprobcurve_obj)` creates a `Credit` pricer object.

Input Arguments

`PricerType` — Pricer type

string with value `"Credit"` | character vector with value `'Credit'`

Pricer type, specified as a string with the value of `"Credit"` or a character vector with the value of `'Credit'`.

Data Types: `char` | `string`

`Credit` Name-Value Pair Arguments

Specify required pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `CreditPricerObj = finpricer("Credit",'DiscountCurve',ratecurve_obj,'DefaultProbabilityCurve',defprobcurve_obj)`

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

`ratecurve` object for discounting cash flows, specified as the comma-separated pair consisting of `'DiscountCurve'` and the name of the previously created `ratecurve` object

Data Types: `object`

`DefaultProbabilityCurve` — Default probability curve
`defprobcurve` object

Default probability curve, specified as the comma-separated pair consisting of `'DefaultProbabilityCurve'` and the name of a previously created `defprobcurve` object.

Data Types: `object`

Properties

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

`ratecurve` object for discounting cash flows, returned as the `ratecurve` object

Data Types: `object`

`DefaultProbabilityCurve` — Default probability curve
`defprobcurve` object

Default probability curve, returned as a `defprobcurve` object.

Data Types: `object`

Object Functions

price Compute price for credit derivative instrument with Credit pricer

Examples

Use Credit Pricer and Default Probability Curve to Price CDS Instrument

This example shows the workflow to price a `CDS` instrument when you use a `defprobcurve` model and a `Credit` pricing method.

Create `CDS` Instrument Object

Use `fininstrument` to create a `CDS` instrument object.

```
CDS = fininstrument("cds",'Maturity',datetime(2027,9,20),'ContractSpread', 50,'Name',"CDS_instru
```

```
CDS =
  CDS with properties:
```

```
          ContractSpread: 50
                Maturity: 20-Sep-2027
                  Period: 4
                   Basis: 2
            RecoveryRate: 0.4000
  BusinessDayConvention: "actual"
                Holidays: NaT
      PayAccruedPremium: 1
                Notional: 10000000
                    Name: "CDS_instrument"
```

Create `defprobcurve` Object

Create a `defprobcurve` object using `defprobcurve`.

```
Settle = datetime(2017, 9, 20);
DefProbTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
DefaultProbabilities = [0.005 0.007 0.01 0.015 0.026 0.04 0.077 0.093 0.15 0.20]';
ProbDates = Settle + DefProbTimes;
DefaultProbCurve = defprobcurve(Settle,ProbDates,DefaultProbabilities)
```

```
DefaultProbCurve =
  defprobcurve with properties:

                 Settle: 20-Sep-2017
                  Basis: 2
                  Dates: [10x1 datetime]
    DefaultProbabilities: [10x1 double]
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates)
```

```
ZeroCurve =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 20-Sep-2017
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `Credit` Pricer Object

Use `finpricer` to create a `Credit` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
CDSpricer = finpricer("credit",'DiscountCurve',ZeroCurve,'DefaultProbabilityCurve',DefaultProbCu
```

```
CDSpricer =
  Credit with properties:

              DiscountCurve: [1x1 ratecurve]
                   TimeStep: 10
    DefaultProbabilityCurve: [1x1 defprobcurve]
```

Price CDS Instrument

Use `price` to compute the price for the `CDS` instrument.

```
outPrice = price(CDSpricer, CDS)
```

```
outPrice = 6.9363e+04
```

CDSBlack

Create CDSBlack pricer object for CDSOption instrument using CDSBlack model

Description

Create and price a CDSOption instrument object with a CDSBlack model and a CDSBlack pricing method using this workflow:

1. Use fininstrument to create the CDSOption instrument object. By default, this creates a single-name CDS option. You can create a CDS index option by specifying the optional name-value argument AdjustedForwardSpread.
2. Use finmodel to specify the CDSBlack model for the CDSOption instrument object.
3. Use finpricer to specify the CDSBlack pricer object for the CDSOption instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a CDSOption instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
CDSBlackPricerObj = finpricer(PricerType,'DiscountCurve',ratecurve_obj,'
Model',model,'DefaultProbabilityCurve',defaultprobabilitycurve_obj)
```

Description

`CDSBlackPricerObj = finpricer(PricerType,'DiscountCurve',ratecurve_obj,'Model',model,'DefaultProbabilityCurve',defaultprobabilitycurve_obj)` creates a CDSBlack pricer object by specifying PricerType and the required name-value pair arguments for DiscountCurve, Model, and DefaultProbabilityCurve to set properties on page 11-3221 using name-value pairs. For example, `CDSBlackPricerObj = finpricer("Analytic",'Model',CDSBlack,'DiscountCurve',ratecurve_obj,'DefaultProbabilityCurve',defaultprobabilitycurve_obj)` creates a CDSBlack pricer object.

Input Arguments

PricerType — Pricer type

string with value "Analytic" | character vector with value 'Analytic'

Pricer type, specified as a string with the value of "Analytic" or the character vector with a value of 'Analytic'.

Data Types: char | string

CDSBlack Name-Value Pair Arguments

Specify required pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `CDSBlackPricerObj = finpricer("Analytic",'Model',CDSBlack,'DiscountCurve',ratecurve_obj,'DefaultProbabilityCurve',defaultprobabilitycurve_obj)`

Required CDSBlack Name-Value Pair Arguments

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

`ratecurve` object for discounting cash flows, specified as the comma-separated pair consisting of `'DiscountCurve'` and the name of the previously created `ratecurve` object.

Data Types: `object`

`Model` — Model
`CDSBlack` model object

Model object, specified as the comma-separated pair consisting of `'Model'` and the name of a previously created `CDSBlack` model object using `finmodel`.

Data Types: `object`

`DefaultProbabilityCurve` — Default probability curve
`defprobcurve` object

Default probability curve, specified as the comma-separated pair consisting of `'DefaultProbabilityCurve'` and a name of a previously created `defprobcurve`.

Data Types: `object`

Properties

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

`ratecurve` object for discounting cash flows, returned as the `ratecurve` object.

Data Types: `object`

`Model` — Model
`CDSBlack` model object

Model, returned as a `CDSBlack` model object.

Data Types: `object`

`DefaultProbabilityCurve` — Default probability curve
object

Default probability curve, returned as a `defprobcurve` object.

Data Types: `object`

Object Functions

price Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

Examples

Use CDS Black Pricer and CDS Black Model to Price CDS Option Instrument

This example shows the workflow to price a `CDSOption` instrument when you use a `CDSBlack` model and a `CDSBlack` pricing method.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2017,9,20);
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve("zero", Settle, ZeroDates ,ZeroRates)

ZeroCurve =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 20-Sep-2017
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `defprobcurve` Object

Create a `defprobcurve` object using `defprobcurve`.

```
DefProbTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
DefaultProbabilities = [0.005 0.007 0.01 0.015 0.026 0.04 0.077 0.093 0.15 0.20]';
ProbDates = Settle + DefProbTimes;
DefaultProbCurve = defprobcurve(Settle, ProbDates, DefaultProbabilities)

DefaultProbCurve =
  defprobcurve with properties:

                 Settle: 20-Sep-2017
                  Basis: 2
                  Dates: [10x1 datetime]
    DefaultProbabilities: [10x1 double]
```

Create CDS Instrument Object

Use `fininstrument` to create an underlying `CDS` instrument object.

```
ContractSpreadBP = 0; % Contractual spread is determined on ExerciseDate
CDS = fininstrument("CDS",'Maturity',datetime(2027,9,20),'ContractSpread',ContractSpreadBP)
```

```
CDS =
  CDS with properties:

          ContractSpread: 0
                Maturity: 20-Sep-2027
                  Period: 4
                   Basis: 2
            RecoveryRate: 0.4000
    BusinessDayConvention: "actual"
                Holidays: NaT
        PayAccruedPremium: 1
                Notional: 10000000
                    Name: ""
```

Create CDSOption Instrument Object

Use `fininstrument` to create a `CDSOption` instrument object.

```
ExerciseDate = datetime(2017, 12, 20);
Strike = 50;
CDSOption = fininstrument("CDSOption",'Strike',Strike,'ExerciseDate',ExerciseDate,'OptionType',"
```

```
CDSOption =
  CDSOption with properties:

              OptionType: "put"
                  Strike: 50
               Knockout: 0
    AdjustedForwardSpread: NaN
             ExerciseDate: 20-Dec-2017
                      CDS: [1x1 fininstrument.CDS]
                     Name: ""
```

Create CDSBlack Model Object

Use `finmodel` to create a `CDSBlack` model object.

```
SpreadVolatility = 0.3;
CDSOptionModel = finmodel("CDSBlack",'SpreadVolatility',SpreadVolatility)
```

```
CDSOptionModel =
  CDSBlack with properties:

    SpreadVolatility: 0.3000
```

Create CDSBlack Pricer Object

Use `finpricer` to create a `CDSBlack` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
CDSOptionpricer = finpricer("analytic",'Model',CDSOptionModel,'DiscountCurve',ZeroCurve,'DefaultI

CDSOptionpricer =
  CDSBlack with properties:

                      Model: [1x1 finmodel.CDSBlack]
              DiscountCurve: [1x1 ratecurve]
    DefaultProbabilityCurve: [1x1 defprobcurve]
```

Price `CDSOption` Instrument

Use `price` to compute the price for the `CDSOption` instrument.

```
outPrice = price(CDSOptionpricer,CDSOption)

outPrice = 6.5054
```

Use CDS Black Pricer and CDS Black Model to Price CDS Index Options

This example shows the workflow to use a `CDSOption` instrument to price CDS index options when you use a `CDSBlack` model and a `CDSBlack` pricing method.

Set Up Data for CDS Index

```
% CDS index and option data
Recovery = .4;
Basis = 2;
Period = 4;
CDSMaturity = datetime(2017, 6, 20);
ContractSpread = 100;
IndexSpread = 140;
BusDayConvention = 'follow';
Settle = datetime(2012, 4, 13);
OptionMaturity = datetime(2012, 6, 20);
OptionStrike = 140;
SpreadVolatility = .69;
```

Create `ratecurve` Object for Zero Curve Using `irbootstrap`

Create `ratecurve` object for a zero curve using `irbootstrap`.

```
% Zero curve data
DepRates = [0.004111 0.00563 0.00757 0.01053]';
DepTimes = calmonths([1 2 3 6]');
DepDates = Settle + DepTimes;
nDeposits = length(DepTimes);

SwapRates = [0.01387 0.01035 0.01145 0.01318 0.01508 0.01700 0.01868 ...
    0.02012 0.02132 0.02237 0.02408 0.02564 0.02612 0.02524]';
SwapTimes = calyears([1 2 3 4 5 6 7 8 9 10 12 15 20 30]');
SwapDates = Settle + SwapTimes;
nSwaps = length(SwapTimes);

nInst = nDeposits + nSwaps;

BootInstruments(nInst,1) = fininstrument.FinInstrument;
```

```
for ii=1:length(DepDates)
    BootInstruments(ii) = fininstrument("deposit","Maturity",DepDates(ii),"Rate",DepRates(ii));
end

for ii=1:length(SwapDates)
    BootInstruments(ii+nDeposits) = fininstrument("swap","Maturity",SwapDates(ii),"LegRate",[Swap
end

ZeroCurve = irbootstrap(BootInstruments,Settle)
```

```
ZeroCurve =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [18x1 datetime]
               Rates: [18x1 double]
              Settle: 13-Apr-2012
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Bootstrap Default Probability Curve

Use `defprobstrip` to bootstrap default probability curve assuming a flat index spread.

```
ProbDates = datemnth(OptionMaturity,(0:5*12)');
MarketCDSInstruments = fininstrument("cds", ...
    'ContractSpread', ContractSpread, 'Maturity', CDSMaturity);
DefaultProbCurve = defprobstrip(ZeroCurve, MarketCDSInstruments, IndexSpread, 'ProbDates', ProbDa
```

```
DefaultProbCurve =
  defprobcurve with properties:

                 Settle: 13-Apr-2012
                  Basis: 2
                  Dates: [61x1 datetime]
    DefaultProbabilities: [61x1 double]
```

Compute Spot and Forward RPV01s

Compute the spot and forward RPV01s using `cdsrpv01`.

```
ProbData = [datenum(DefaultProbCurve.Dates) DefaultProbCurve.DefaultProbabilities];

% RPV01(t,T)
RPV01_CDSMaturity = cdsrpv01(ZeroCurve,ProbData,Settle,CDSMaturity)
```

```
RPV01_CDSMaturity = 4.7853
```

```
% RPV01(t,t_E,T)
RPV01_OptionExpiryForward = cdsrpv01(ZeroCurve,ProbData,Settle,CDSMaturity,...
    'StartDate',OptionMaturity)
```

```
RPV01_OptionExpiryForward = 4.5972
```

```
% RPV01(t,t_E) = RPV01(t,T) - RPV01(t,t_E,T)
RPV01_OptionExpiry = RPV01_CDSMaturity - RPV01_OptionExpiryForward

RPV01_OptionExpiry = 0.1882
```

Compute Spot Spreads

Compute the spot spreads using `cdsspread`.

```
% S(t,t_E)
Spread_OptionExpiry = cdsspread(ZeroCurve,ProbData,Settle,OptionMaturity,...
    'Period',Period,'Basis',Basis,'BusDayConvention',BusDayConvention,...
    'PayAccruedPremium',true,'recoveryrate',Recovery)

Spread_OptionExpiry = 139.8995

% S(t,T)
Spread_CDSMaturity = cdsspread(ZeroCurve,ProbData,Settle,CDSMaturity,...
    'Period',Period,'Basis',Basis,'BusDayConvention',BusDayConvention,...
    'PayAccruedPremium',true,'recoveryrate',Recovery)

Spread_CDSMaturity = 139.9999
```

Compute Forward Spread

Compute the forward spread using the spot spreads and RPV01s.

```
% F = S(t,t_E,T)
ForwardSpread = (Spread_CDSMaturity.*RPV01_CDSMaturity - Spread_OptionExpiry.*RPV01_OptionExpiry

ForwardSpread = 140.0040
```

Compute Front-End Protection

Compute the front-end protection (FEP).

```
FEP = 10000*(1-Recovery)*ZeroCurve.discountfactors(OptionMaturity)*DefaultProbCurve.DefaultProbal

FEP = 26.3108
```

Compute Adjusted Forward Spread

Compute the adjusted forward spread to use when creating an `CDSOption` instrument.

```
AdjustedForwardSpread = ForwardSpread + FEP./RPV01_OptionExpiryForward

AdjustedForwardSpread = 145.7273
```

Compute CDS Option Prices with Adjusted Forward Spread

Use `fininstrument` to create a `CDSOption` instrument for a single-name CDS option.

```
CDS = fininstrument("cds",'ContractSpread', ContractSpread, 'Maturity', CDSMaturity)

CDS =
  CDS with properties:

           ContractSpread: 100
```

```
                Maturity: 20-Jun-2017
                  Period: 4
                   Basis: 2
            RecoveryRate: 0.4000
    BusinessDayConvention: "actual"
                Holidays: NaT
        PayAccruedPremium: 1
                Notional: 10000000
                    Name: ""
```

Use `fininstrument` to create a `CDSOption` instrument for two CDS index option instruments.

```
CDSCallOption = fininstrument("cdsoption", 'Strike', OptionStrike, ...
    'ExerciseDate', OptionMaturity, 'OptionType', 'call', 'CDS', CDS, ...
    'Knockout',true, 'AdjustedForwardSpread', AdjustedForwardSpread)
```

```
CDSCallOption =
  CDSOption with properties:

              OptionType: "call"
                  Strike: 140
                Knockout: 1
    AdjustedForwardSpread: 145.7273
            ExerciseDate: 20-Jun-2012
                     CDS: [1x1 fininstrument.CDS]
                    Name: ""
```

```
CDSPutOption = fininstrument("cdsoption", 'Strike', OptionStrike, ...
    'ExerciseDate', OptionMaturity, 'OptionType', 'put', 'CDS', CDS, ...
    'Knockout',true, 'AdjustedForwardSpread', AdjustedForwardSpread)
```

```
CDSPutOption =
  CDSOption with properties:

              OptionType: "put"
                  Strike: 140
                Knockout: 1
    AdjustedForwardSpread: 145.7273
            ExerciseDate: 20-Jun-2012
                     CDS: [1x1 fininstrument.CDS]
                    Name: ""
```

Create CDSBlack Model Object

Use `finmodel` to create a `CDSBlack` model object.

```
CDSOptionModel = finmodel("cdsblack",'SpreadVolatility',SpreadVolatility)
```

```
CDSOptionModel =
  CDSBlack with properties:

    SpreadVolatility: 0.6900
```

Create CDSBlack Pricer Object

Use finpricer to create a CDSBlack pricer object and use the ratecurve object for the zero curve for the 'DiscountCurve' name-value pair argument.

```
CDSOptionpricer = finpricer("analytic",'Model',CDSOptionModel,'DiscountCurve',ZeroCurve,'DefaultI
```

```
CDSOptionpricer =
  CDSBlack with properties:

                     Model: [1x1 finmodel.CDSBlack]
             DiscountCurve: [1x1 ratecurve]
    DefaultProbabilityCurve: [1x1 defprobcurve]
```

Price CDS Index Options

Use price to compute the price for the CDS index options.

```
outPrice = price(CDSOptionpricer, [CDSCallOption;CDSPutOption]);
fprintf('    Payer: %.0f   Receiver: %.0f  \n',outPrice(1),outPrice(2));
```

```
    Payer: 92   Receiver: 66
```

NumericalIntegration

Create `NumericalIntegration` pricer object for `Vanilla` instrument using `Heston`, `Bates`, or `Merton` model

Description

Create and price a `Vanilla` instrument object with a `Heston`, `Bates`, or `Merton` model and a `NumericalIntegration` pricing method using this workflow:

1. Use `fininstrument` to create a `Vanilla` instrument object.
2. Use `finmodel` to specify a `Heston`, `Bates`, or `Merton` model for the `Vanilla` instrument object.
3. Use `finpricer` to specify a `NumericalIntegration` pricer object for the `Vanilla` instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a `Vanilla` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
NumericalIntegrationPricerObj = finpricer(PricerType,'Model',model,'
DiscountCurve',ratecurve_obj,'SpotPrice',spotprice_value)
NumericalIntegrationPricerObj = finpricer(___,Name,Value)
```

Description

`NumericalIntegrationPricerObj = finpricer(PricerType,'Model',model,'DiscountCurve',ratecurve_obj,'SpotPrice',spotprice_value)` creates a `NumericalIntegration` pricer object by specifying `PricerType` and sets the properties on page 11-3232 for the required name-value pair arguments `Model`, `DiscountCurve`, and `SpotPrice`.

`NumericalIntegrationPricerObj = finpricer(___,Name,Value)` sets optional properties on page 11-3232 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `NumericalIntegrationPricerObj = finpricer("NumericalIntegration",'Model',NIModel,'DiscountCurve',ratecurve_obj,'SpotPrice',1000,'DividendValue',100,'VolRiskPremium',0.9)` creates a `NumericalIntegration` pricer object. You can specify multiple name-value pair arguments.

Input Arguments

`PricerType` — Pricer type

string with value `"NumericalIntegration"` | character vector with value `'NumericalIntegration'`

Pricer type, specified as a string with the value of "NumericalIntegration" or a character vector with the value of 'NumericalIntegration'.

Data Types: char | string

NumericalIntegration Name-Value Pair Arguments

Specify required and optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: NumericalIntegrationPricerObj = finpricer("NumericalIntegration",'Model',NIModel,'DiscountCurve',ratecurve_obj,'SpotPrice',1000,'DividendValue',100,'VolRiskPremium',0.9)

Required NumericalIntegration Name-Value Pair Arguments

Model — Model
model object

Model, specified as the comma-separated pair consisting of 'Model' and the name of a previously created Merton, Bates, or Heston model object using finmodel.

Data Types: object

DiscountCurve — ratecurve object for discounting cash flows
ratecurve object

This property is read-only.

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of a ratecurve object.

Note Specify a flat ratecurve object for DiscountCurve. If you use a nonflat ratecurve object, the software uses the rate in the ratecurve object at Maturity and assumes that the value is constant for the life of the equity option.

Data Types: object

SpotPrice — Current price of underlying asset
nonnegative numeric

Current price of the underlying asset, specified as the comma-separated pair consisting of 'SpotPrice' and a scalar nonnegative numeric.

Data Types: double

Optional NumericalIntegration Name-Value Pair Arguments

DividendValue — Dividend yield
0 (default) | scalar numeric

Dividend yield, specified as the comma-separated pair consisting of 'DividendValue' and a scalar numeric.

Data Types: `double`

`VolRiskPremium` — Volatility risk premium
`0` (default) | numeric

Volatility risk premium, specified as the comma-separated pair consisting of `'VolRiskPremium'` and a scalar numeric value.

Data Types: `double`

`LittleTrap` — Flag indicating Little Heston Trap formulation
`true` (default) | logical with values `true` or `false`

Flag indicating Little Heston Trap formulation by Albrecher et al., specified as the comma-separated pair consisting of `'LittleTrap'` and a logical:

- `true` — Use the Albrecher et al. formulation.

  For more information on the `LittleTrap`, see [1] and also the Little Trap formulation is defined by C_j and D_j, see "Heston Stochastic Volatility Model" on page 11-3235 and "Bates Stochastic Volatility Jump Diffusion Model" on page 11-3237.
- `false` — Use the original Heston formation.

Note `LittleTrap` is supported only for `Heston` and `Bates` models.

Data Types: `logical`

`AbsTol` — Absolute error tolerance for numerical integration
`1e-10` (default) | numeric

Absolute error tolerance for numerical integration, specified as the comma-separated pair consisting of `'AbsTol'` and a scalar numeric value.

Data Types: `double`

`RelTol` — Relative error tolerance for numerical integration
`1e-6` (default) | numeric

Relative error tolerance for numerical integration, specified as the comma-separated pair consisting of `'RelTol'` and a scalar numeric value.

Data Types: `double`

`IntegrationRange` — Numerical integration range used to approximate continuous integral over `[0 Inf]`
`[1e-9 Inf]` (default) | vector

Numerical integration range used to approximate the continuous integral over `[0 Inf]`, specified as the comma-separated pair consisting of `'IntegrationRange'` and a 1-by-2 vector representing `[LowerLimit UpperLimit]`.

Data Types: `double`

`Framework` — Framework for computing option prices and sensitivities using numerical integration of models
`"heston1993"` (default) | string with values `"heston1993"` or `"lewis2001"` | character vector with values `'heston1993'` or `'lewis2001'`

Framework for computing option prices and sensitivities using the numerical integration of models, specified as the comma-separated pair consisting of `'Framework'` and a scalar string or character vector with the following values:

- `"heston1993"` or `'heston1993'` — Method used in Heston (1993)
- `"lewis2001"` or `'lewis2001'` — Method used in Lewis (2001)

Data Types: `char` | `string`

Properties

`Model` — Model
model object

Model, returned as a model object.

Data Types: `object`

`DiscountCurve` — `ratecurve` object for discounting cash flows
object

`ratecurve` object for discounting cash flows, returned as a `ratecurve` object.

Data Types: `object`

`SpotPrice` — Current price of underlying asset
nonnegative numeric

Current price of the underlying asset, returned as a scalar nonnegative numeric.

Data Types: `double`

`DividendValue` — Dividend yield
`0` (default) | scalar numeric

Dividend yield, returned as a scalar numeric.

Data Types: `double`

`VolRiskPremium` — Volatility risk premium
`0` (default) | numeric

Volatility risk premium, returned as a scalar numeric value.

Data Types: `double`

`LittleTrap` — Flag indicating Little Heston Trap formulation
`true` (default) | logical with value `true` or `false`

Flag indicating Little Heston Trap formulation by Albrecher et al., returned as a logical.

Data Types: `logical`

`AbsTol` — Absolute error tolerance for numerical integration
`1e-10` (default) | numeric

Absolute error tolerance for numerical integration, returned as a scalar numeric value.

Data Types: `double`

`RelTol` — Relative error tolerance for numerical integration
`1e-6` (default) | numeric

Relative error tolerance for numerical integration, returned as a scalar numeric value.

Data Types: `double`

`IntegrationRange` — Numerical integration range used to approximate continuous integral over `[0 Inf]`
`[1e-9 Inf]` (default) | vector

Numerical integration range used to approximate the continuous integral over `[0 Inf]`, returned as a 1-by-2 vector representing `[LowerLimit UpperLimit]`.

Data Types: `double`

`Framework` — Framework for computing option prices and sensitivities using numerical integration of models
`"heston1993"` (default) | string with value `"heston1993"` or `"lewis2001"`

Framework for computing option prices and sensitivities using the numerical integration of models, returned as a scalar string.

Data Types: `string`

Object Functions

price Compute price for equity instrument with NumericalIntegration pricer

Examples

Use Numerical Integration Pricer and Merton Model to Price Vanilla Instrument

This example shows the workflow to price a `Vanilla` instrument when you use a `Merton` model and a `NumericalIntegration` pricing method.

Create `Vanilla` Instrument Object

Use `fininstrument` to create a `Vanilla` instrument object.

```
VanillaOpt = fininstrument("Vanilla",'ExerciseDate',datetime(2020,3,15),'ExerciseStyle',"europea
```

```
VanillaOpt =
  Vanilla with properties:

       OptionType: "call"
    ExerciseStyle: "european"
     ExerciseDate: 15-Mar-2020
           Strike: 105
```

```
             Name: "vanilla_option"
```

Create Merton Model Object

Use `finmodel` to create a `Merton` model object.

```
MertonModel = finmodel("Merton",'Volatility',0.45,'MeanJ',0.02,'JumpVol',0.07,'JumpFreq',0.09)
```

```
MertonModel =
  Merton with properties:

    Volatility: 0.4500
         MeanJ: 0.0200
       JumpVol: 0.0700
      JumpFreq: 0.0900
```

Create ratecurve Object

Create a flat `ratecurve` object using `ratecurve`.

```
myRC = ratecurve('zero',datetime(2019,9,15),datetime(2020,3,15),0.02)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: 15-Mar-2020
               Rates: 0.0200
              Settle: 15-Sep-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create NumericalIntegration Pricer Object

Use `finpricer` to create a `NumericalIntegration` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("numericalintegration",'Model',MertonModel,'DiscountCurve',myRC,'SpotPrice
```

```
outPricer =
  NumericalIntegration with properties:

                Model: [1x1 finmodel.Merton]
        DiscountCurve: [1x1 ratecurve]
            SpotPrice: 100
         DividendType: "continuous"
        DividendValue: 0.0100
               AbsTol: 0.5000
               RelTol: 0.4000
     IntegrationRange: [1.0000e-09 Inf]
    CharacteristicFcn: @characteristicFcnMerton76
            Framework: "lewis2001"
       VolRiskPremium: 0.9000
```

```
           LittleTrap: 0
```

Price `Vanilla` Instrument

Use `price` to compute the price and sensitivities for the `Vanilla` instrument.

```
[Price, outPR] = price(outPricer,VanillaOpt,["all"])
```

```
Price = 10.7325

outPR =
  priceresult with properties:

       Results: [1x6 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×6 table
    Price     Delta      Gamma       Theta      Rho       Vega
    ______    ______    _________    _______    ______    ______

    10.732    0.5058    0.012492    -12.969    19.815    27.954
```

More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

Here:

St is the price of the underlying asset at time t.

K is the strike price.

For more information, see “Vanilla Option” on page 3-27.

Heston Stochastic Volatility Model

The Heston model is an extension of the Black-Scholes model, where the volatility (square root of variance) is no longer assumed to be constant, and the variance now follows a stochastic (CIR) process. This allows modeling the implied volatility smiles observed in the market.

The stochastic differential equation is

$$dS_t = (r - q)S_t dt + \sqrt{v_t} S_t dW_t$$

$$dv_t = \kappa(\theta - v_t)dt + \sigma_v \sqrt{v_t} dW_t^v$$

$$\mathrm{E}\left[dW_t dW_t^v\right] = pdt$$

Here:

r is the continuous risk-free rate.

q is the continuous dividend yield.

S_t is the asset price at time t.

v_t is the asset price variance at time t.

v_0 is the initial variance of the asset price at $t = 0$ for ($v_0 > 0$).

θ is the long-term variance level for ($\theta > 0$).

κ is the mean reversion speed for the variance for ($\kappa > 0$).

σ_v is the volatility of the variance for ($\sigma_v > 0$).

p is the correlation between the Weiner processes W_t and $W^v{}_t$ for ($-1 \le p \le 1$).

The characteristic function $f_{Heston_j}(\phi)$ for $j = 1$ (asset price measure) and $j = 2$ (risk-neutral measure) is

$$f_{Heston_j}(\phi) = \exp(C_j + D_j v_0 + i\phi \ln S_t)$$

$$C_j = (r - q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2}\left[\left(b_j - p\sigma_v i\phi + d_j\right)\tau - 2\ln\left(\frac{1 - g_j e^{d_j \tau}}{1 - g_j}\right)\right]$$

$$D_j = \frac{b_j - p\sigma_v i\phi + d_j}{\sigma_v^2}\left(\frac{1 - e^{d_j\tau}}{1 - g_j e^{d_j\tau}}\right)$$

$$g_j = \frac{b_j - p\sigma_v i\phi + d_j}{b_j - p\sigma_v i\phi - d_j}$$

$$d_j = \sqrt{\left(b_j - p\sigma_v i\phi\right)^2 - \sigma_v^2\left(2u_j i\phi - \phi^2\right)}$$

where for $j = 1, 2$:

$$u_1 = \frac{1}{2}, u_2 = -\frac{1}{2}, b_1 = \kappa + \lambda_{VolRisk} - p\sigma_v, b_2 = \kappa + \lambda_{VolRisk}$$

Here:

ϕ is the characteristic function variable.

$\lambda_{VolRisk}$ is the volatility risk premium.

τ is the time to maturity ($\tau = T - t$).

i is the unit imaginary number ($i^2 = -1$).

The definitions for C_j and D_j for the Little Heston Trap by Albrecher et al. (2007) are

$$C_j = (r-q)i\phi\tau + \frac{\kappa\theta}{\sigma_v{}^2}\left[\left(b_j - p\sigma_v i\phi - d_j\right)\tau - 2\ln\left(\frac{1-\varepsilon_j e^{-d_j\tau}}{1-\varepsilon_j}\right)\right]$$

$$Dj = \frac{b_j - p\sigma_v i\phi - d_j}{\sigma_v^2}\left(\frac{1-e^{-d_j\tau}}{1-\varepsilon_j e^{-d_j\tau}}\right)$$

$$\varepsilon_j = \frac{b_j - p\sigma_v i\phi - d_j}{b_j - p\sigma_v i\phi + d_j}$$

Bates Stochastic Volatility Jump Diffusion Model

The Bates model (Bates 1996) is an extension of the Heston model where, in addition to stochastic volatility, the jump diffusion parameters similar to Merton (1976) are also added to model sudden asset price movements.

The stochastic differential equation is

$$dS_t = (r - q - \lambda_p\mu_J)S_t dt + \sqrt{v_t}S_t dW_t + JS_t dP_t$$

$$dv_t = \kappa(\theta - v_t)dt + \sigma_v\sqrt{v_t}dW_t$$

$$\mathrm{E}\left[dW_t dW_t^{\mathrm{v}}\right] = pdt$$

$$\mathrm{prob}(dP_t = 1) = \lambda_p dt$$

Here:

r is the continuous risk-free rate.

q is the continuous dividend yield.

S_t is the asset price at time t.

v_t is the asset price variance at time t.

J is the random percentage jump size conditional on the jump occurring, where `ln`$(1+J)$ is normally distributed with mean $\ln(1+\mu_J) - \frac{\delta^2}{2}$ and the standard deviation δ, and $(1+J)$ has a lognormal distribution:

$$\frac{1}{(1+J)\delta\sqrt{2\pi}}\exp\left\{\frac{-\left[\ln(1+J) - \left(\ln(1+\mu_J) - \frac{\delta^2}{2}\right]^2\right.}{2\delta^2}\right\}$$

v_0 is the initial variance of the asset price at $t = 0$ ($v_0 > 0$).

θ is the long-term variance level for ($\theta > 0$).

κ is the mean reversion speed for ($\kappa > 0$).

σ_v is the volatility of variance for ($\sigma_{\mathrm{v}} > 0$).

p is the correlation between the Weiner processes W_t and W_t^v for (-1 ≤ p ≤ 1).

μ_J is the mean of J for (μ_J > -1).

δ is the standard deviation of $\ln(1+J)$ for ($\delta \geq 0$).

λ_p is the annual frequency (intensity) of Poisson process P_t for ($\lambda_p \geq 0$).

The characteristic function $f_{Bates_j(\phi)}$ for $j = 1$ (asset price mean measure) and $j = 2$ (risk-neutral measure) is

$$f_{Bates(\phi)} = \exp(C_j + D_j v_0 + i\phi \ln S_t)\exp\left(\lambda_p \tau (1+\mu_J)^{m_j + \frac{1}{2}}\left[(1+\mu_j)^{i\phi} e^{\delta^2 (m_j i\phi + \frac{(i\phi)^2}{2})} - 1\right] - \lambda_p \tau \mu_J i\phi\right)$$

$$m_j = \begin{Bmatrix} m_1 = \frac{1}{2} \\ m_2 = -\frac{1}{2} \end{Bmatrix}$$

$$C_j = (r-q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2}\left[\left(b_j - p\sigma_v i\phi + d_j\right)\tau - 2\ln\left(\frac{1-g_j e^{d_j\tau}}{1-g_j}\right)\right]$$

$$Dj = \frac{b_j - p\sigma_v i\phi + d_j}{\sigma_v^2}\left(\frac{1-e^{d_j\tau}}{1-g_j e^{d_j\tau}}\right)$$

$$g_j = \frac{b_j - p\sigma_v i\phi + d_j}{b_j - p\sigma_v i\phi - d_j}$$

$$d_j = \sqrt{\left(b_j - p\sigma_v i\phi\right)^2 - \sigma_v^2\left(2u_j i\phi - \phi^2\right)}$$

where for $j = 1, 2$:

$$u_1 = \frac{1}{2}, u_2 = -\frac{1}{2}, b_1 = \kappa + \lambda_{VolRisk} - p\sigma_v, b_2 = \kappa + \lambda_{VolRisk}$$

Here:

ϕ is the characteristic function variable.

$\lambda_{VolRisk}$ is the volatility risk premium.

τ is the time to maturity for ($\tau = T - t$).

i is the unit imaginary number for ($i^2 = -1$).

The definitions for C_j and D_j for the Little Heston Trap by Albrecher et al. (2007) are

$$C_j = (r-q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2}\left[\left(b_j - p\sigma_v i\phi - d_j\right)\tau - 2\ln\left(\frac{1-\varepsilon_j e^{-d_j\tau}}{1-\varepsilon_j}\right)\right]$$

$$Dj = \frac{b_j - p\sigma_v i\phi - d_j}{\sigma_v^2}\left(\frac{1-e^{-d_j\tau}}{1-\varepsilon_j e^{-d_j\tau}}\right)$$

$$\varepsilon_j = \frac{b_j - p\sigma_v i\phi - d_j}{b_j - p\sigma_v i\phi + d_j}$$

Merton Jump Diffusion Model

The Merton jump diffusion model (Merton 1976) is an extension of the Black-Scholes model, where sudden asset price movements (both up and down) are modeled by adding the jump diffusion parameters with the Poisson process.

The stochastic differential equation is

$$dS_t = (r - q - \lambda_p \mu_j) S_t dt + \sigma S_t dW_t + J S_t dP_t$$
$$\text{prob}(dP_t = 1) = \lambda_p dt$$

Here:

r is the continuous risk-free rate.

q is the continuous dividend yield.

W_t is the Weiner process.

J is the random percentage jump size conditional on the jump occurring, where $\ln(1+J)$ is normally distributed with mean $\ln(1 + \mu_J) - \frac{\delta^2}{2}$ and the standard deviation δ, and $(1+J)$ has a lognormal distribution

$$\frac{1}{(1+J)\delta\sqrt{2\pi}} \exp\left\{ \frac{-\left[\ln(1+J) - \left(\ln(1+\mu_J) - \frac{\delta^2}{2}\right]\right]^2}{2\delta^2} \right\}$$

μ_J is the mean of J for (μ_J > -1).

δ is the standard deviation of $\ln(1+J)$ for ($\delta \geq 0$).

λ_p is the annual frequency (intensity) of Poisson process P_t for ($\lambda_p \geq 0$).

σ is the volatility of the asset price for ($\sigma > 0$).

The characteristic function $f_{Merton76_j}(\phi)$ for $j = 1$ (asset prices measure) and $j = 2$ (risk-neutral measure) is

$$f_{Merton76_j} = f_{BS_j} \exp\left(\lambda_p \tau \left(1 + \mu_j\right)^{m_j} + \frac{1}{2} \left[\left(1 + \mu_j\right)^{i\phi} e^{\delta^2 \left(m_j i\phi + \frac{(i\phi)^2}{2} \right)} - 1 \right] - \lambda_p \tau \mu_j i\phi \right)$$

where for $j = 1, 2$:

$$f_{BS_1}(\phi) = \frac{f_{BS_2}(\phi - i)}{f_{BS_2}(-i)}$$

$$f_{BS2}(\phi) = \exp\left(i\phi \left[\ln S_t + \left(r - q - \frac{\sigma^2}{2} \right) \tau \right] - \frac{\phi^2 \sigma^2}{2} \tau \right)$$

$$m_1 = \frac{1}{2}, m_2 = -\frac{1}{2}$$

Here:

ϕ is the characteristic function variable

τ is the time to maturity ($\tau = T - t$).

i is the unit imaginary number ($i^2 = -1$).

Numerical Integration Method Under Heston (1993) Framework

Numerical integration is used to evaluate the continuous integral for the inverse Fourier transform.

The numerical integration method under the Heston (1993) framework is based on the following expressions

$$Call(K) = S_t e^{-q\tau} P_1 - K e^{-r\tau} P_2$$

$$Put(K) = Call(K) + K e^{-r\tau} - S_t e^{-q\tau}$$

$$P_j = \frac{1}{2} + \frac{1}{\pi} \int_0^{\infty} \mathrm{Re}\left[\frac{e^{-i\phi \ln(K)} f_j(\phi)}{i\phi} \right] d\phi$$

Here:

r is the continuous risk-free rate.

q is the continuous dividend yield.

S_t is the asset price at time t.

K is the strike.

τ is time to maturity ($\tau = T - t$).

$Call(K)$ is the call price at strike K.

$Put(K)$ is the put price at strike K.

i is a unit imaginary number ($i^2 = -1$).

ϕ is the characteristic function variable.

$f_j(\phi)$ is the characteristic function for $P_j (j = 1,2)$.

P_1 is the probability of $S_t > K$ under the asset price measure for the model.

P_2 is the probability of $S_t > K$ under the risk-neutral measure for the model.

Where $j = 1,2$ so that $f_1(\phi)$ and $f_2(\phi)$ are the characteristic functions for probabilities P_1 and P_2, respectively.

Choose this framework by specifying the default value `"Heston1993"` for the `Framework` name-value pair argument.

Numerical Integration Method Under Lewis Framework

Numerical integration is used to evaluate the continuous integral for the inverse Fourier transform.

The numerical integration method under the Lewis (2001) framework is based on the following expressions:

$$Call(k) = S_t e^{-q\tau} - \frac{\sqrt{K}e^{-\tau t}}{\pi}\int_0^{\infty} \mathrm{Re}\left[K^{-iu} f_2\left(\phi = \left(u - \frac{i}{2}\right)\right)\frac{1}{u^2 + \frac{1}{4}}\right]du$$

$$Put(K) = Call(K) = Ke^{-\tau t} - S_t e^{-q\tau}$$

Here

r is the continuous risk-free rate.

q is the continuous dividend yield.

S_t is the asset price at time t.

K is the strike.

τ is time to maturity (τ = T-t).

$Call(K)$ is the call price at strike K.

$Put(K)$ is the put price at strike K.

i is a unit imaginary number (i^2= -1).

ϕ is the characteristic function variable.

u is the characteristic function variable for integration, where $\phi = \left(u - \frac{i}{2}\right)$.

$f_2(\phi)$ is the characteristic function for P_2.

P_2 is the probability of $S_t > K$ under the risk-neutral measure for the model.

Choose this framework by specifying the value `"Lewis2001"` for the `Framework` name-value pair argument.

Version History

Introduced in R2020a

Discount

Create `Discount` pricer object for `Deposit`, `FRA`, `Swap`, `FixedBond`, `FloatBond`, `OISFuture`, `STIRFuture`, and `OvernightIndexedSwap` using `ratecurve` object

Description

Create and price a `Deposit`, `FRA`, `Swap`, `FixedBond`, `FloatBond`, `OISFuture`, `STIRFuture`, and `OvernightIndexedSwap` instrument object with a `ratecurve` and a `Discount` pricing method using this workflow:

1. Create an interest-rate curve object using `ratecurve`.
2. Use `finpricer` to specify a `Discount` pricer object for the `Deposit`, `FRA`, `Swap`, `FixedBond`, `FloatBond`, `STIRFuture`, `OISFuture`, or `OvernightIndexedSwap` instrument object.

Note If you do not specify `ProjectionCurve` when you create a `Swap` or `FloatBond` instrument with the `Discount` pricer, the `ProjectionCurve` value defaults to the `DiscountCurve` value.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a `Deposit`, `FRA`, `Swap`, `FixedBond`, or `FloatBond` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
DiscountPricerObj = finpricer(PricerType,'DiscountCurve',ratecurve_object)
```

Description

`DiscountPricerObj = finpricer(PricerType,'DiscountCurve',ratecurve_object)` creates a `Discount` pricer object by specifying `PricerType` and the required name-value pair argument `DiscountCurve` to set properties on page 11-3244 using name-value pairs. For example, `DiscountPricerObj = finpricer("Discount",'DiscountCurve',ratecurve_obj)` creates a `Discount` pricer object.

Input Arguments

`PricerType` — Pricer type

string with value `"Discount"` | character vector with value `'Discount'`

Pricer type, specified as a string with the value of `"Discount"` or a character vector with the value of `'Discount'`.

Data Types: `char` | `string`

`Discount` Name-Value Pair Arguments

Specify required pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `DiscountPricerObj = finpricer("Discount",'DiscountCurve',ratecurve_obj)`

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

`ratecurve` object for discounting cash flows, specified as the comma-separated pair consisting of `'DiscountCurve'` and the name of a previously created `ratecurve` object

Data Types: `object`

Properties

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

`ratecurve` object for discounting cash flows, returned as the `ratecurve` object.

Data Types: `object`

Object Functions

price Compute price for interest-rate instrument with Discount pricer

Examples

Use Discount Pricer and `ratecurve` to Price Swap Instrument

This example shows the workflow to price a `Swap` instrument when using a `ratecurve` and a `Discount` pricing method.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve` for the underlying interest-rate curve for the `Swap` instrument.

```
Settle = datetime(2022,1,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:
```

```
                Type: "zero"
        Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Jan-2022
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create Swap Instrument Object

Use `fininstrument` to create a Swap instrument object.

```
SwapOpt = fininstrument("Swap",'Maturity',datetime(2027,1,15),'LegRate',[0.024 0.015],'LegType',
```

```
SwapOpt =
  Swap with properties:

                     LegRate: [0.0240 0.0150]
                     LegType: ["fixed"    "float"]
                       Reset: [2 2]
                       Basis: [0 0]
                    Notional: 100
          LatestFloatingRate: [NaN NaN]
                 ResetOffset: [0 0]
    DaycountAdjustedCashFlow: [0 0]
             ProjectionCurve: [1x2 ratecurve]
       BusinessDayConvention: ["actual"    "actual"]
                    Holidays: NaT
                EndMonthRule: [1 1]
                   StartDate: NaT
                    Maturity: 15-Jan-2027
                        Name: "swap_instrument"
```

Create `Discount` Pricer Object

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("Discount", 'DiscountCurve',myRC)
```

```
outPricer =
  Discount with properties:

    DiscountCurve: [1x1 ratecurve]
```

Price Swap Instrument

Use `price` to compute the price and sensitivities for the Swap instrument.

```
[Price, outPR] = price(outPricer, SwapOpt,["all"])
```

```
Price = -1.3834
```

```
outPR =
  priceresult with properties:

      Results: [1x2 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×2 table
     Price       DV01
    _______    ________

    -1.3834    0.048336
```

Future

Create `Future` pricer object for `BondFuture`, `CommodityFuture`, `EquityIndexFuture`, and `FXFuture` using `ratecurve` object

Description

Create and price a `BondFuture`, `CommodityFuture`, `EquityIndexFuture`, and `FXFuture` instrument object with a `ratecurve` object and a `Future` pricing method using this workflow:

1. Create an interest-rate curve object using `ratecurve`.
2. Use `fininstrument` to create a `BondFuture`, `CommodityFuture`, `FXFuture`, or `EquityIndexFuture` instrument object.
3. Use `finpricer` to specify a `Future` pricer object for the `BondFuture`, `CommodityFuture`, `FXFuture`, or `EquityIndexFuture` instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a `BondFuture`, `CommodityFuture`, `EquityIncomeFuture`, or `FXFuture` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
FuturePricerObj = finpricer(PricerType,DiscountCurve=ratecurve_object,
SpotPrice=spot_price)
```

Description

`FuturePricerObj = finpricer(PricerType,DiscountCurve=ratecurve_object, SpotPrice=spot_price)` creates a `Future` pricer object by specifying `PricerType` and the required name-value arguments for `DiscountCurve` and `SpotPrice` to set properties on page 11-3248. For example, `FuturePricerObj = finpricer("Future",DiscountCurve=ratecurve_obj,SpotPrice=125)` creates a `Future` pricer object.

Input Arguments

`PricerType` — Pricer type
string with value `"Future"` | character vector with value `'Future'`

Pricer type, specified as a string with the value of `"Future"` or a character vector with the value of `'Future'`.

Data Types: `char` | `string`

Future Name-Value Pair Arguments

Specify required pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `FuturePricerObj = finpricer("Future",DiscountCurve=ratecurve_obj,SpotPrice=125)`

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

`ratecurve` object for discounting cash flows, specified as `DiscountCurve` and the name of a previously created `ratecurve` object

Data Types: `object`

`SpotPrice` — Quoted spot price for underlying asset to be delivered
numeric

Quoted spot price for underlying asset to be delivered, specified as `SpotPrice` and a numeric value that depends on the type of future instrument being priced:

- `BondFuture` instrument — Clean spot price quoted for $100 face value of underlying bond
- `CommodityFuture` instrument — Spot price for underlying commodity quantity specified in contract
- `EquityIndexFuture` instrument — Spot equity index value
- `FXFuture` instrument — Spot price quoted in domestic currency for one unit of foreign currency

Data Types: `double`

Properties

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

`ratecurve` object for discounting cash flows, returned as the `ratecurve` object.

Data Types: `object`

`SpotPrice` — Quoted spot price for underlying asset to be delivered
numeric

Quoted spot price for underlying asset to be delivered, returned as a numeric value that depends on the type of future instrument being priced.

Data Types: `double`

Object Functions

price Compute price for interest-rate instrument with Future pricer

Examples

Use Future Pricer and ratecurve to Price BondFuture Instrument

This example shows the workflow to price a BondFuture instrument when you use a ratecurve object and a Future pricing method.

Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2022,3,1);
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates,Compounding=2);
```

Create Underlying FixedBond Instrument Object

Use fininstrument to create a FixedBond instrument object.

```
FixB = fininstrument("FixedBond",Maturity=datetime(2032,9,1),CouponRate=0.05,Name="fixed_bond_ins
```

```
FixB =
  FixedBond with properties:

                 CouponRate: 0.0500
                     Period: 2
                      Basis: 0
                EndMonthRule: 1
                   Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                    Holidays: NaT
                   IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 01-Sep-2032
                        Name: "fixed_bond_instrument"
```

Create BondFuture Instrument Object

Use fininstrument to create a BondFuture instrument object.

```
BondFut = fininstrument("BondFuture",Maturity=datetime(2022,9,1),QuotedPrice=86,Bond=FixB,Convers
```

```
BondFut =
  BondFuture with properties:

           Maturity: 01-Sep-2022
        QuotedPrice: 86
               Bond: [1x1 fininstrument.FixedBond]
    ConversionFactor: 1.4300
           Notional: 100000
               Name: "bondfuture_instrument"
```

Create Future Pricer Object

Use `finpricer` to create a `Future` pricer object and use the `ratecurve` object with the `DiscountCurve` name-value argument.

```
outPricer = finpricer("Future",DiscountCurve=ZeroCurve,SpotPrice=125)
```

```
outPricer =
  Future with properties:

    DiscountCurve: [1x1 ratecurve]
        SpotPrice: 125
```

Price BondFuture Instrument

Use `price` to compute the price and price result for the `BondFuture` instrument.

```
[Price,outPR] = price(outPricer,BondFut)
```

```
Price = -151.9270

outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×4 table
     Price     FairDeliveryPrice    FairFuturePrice    AccruedInterest
    _______    _________________    _______________    _______________

    -151.93       1.2283e+05            85.893                0
```

FFT

Create FFT pricer object for Vanilla instrument using Merton, Heston, or Bates model

Description

Create and price a Vanilla instrument object with a Heston, Bates, or Merton model and an FFT pricing method using this workflow:

1. Use finstrument to create a Vanilla instrument object.
2. Use finmodel to specify a Heston, Bates, or Merton model for the Vanilla instrument object.
3. Use finpricer to specify an FFT pricer object for the Vanilla instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a Vanilla instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
FFTPricerObj = finpricer(PricerType,'Model',model,'
DiscountCurve',ratecurve_obj)
FFTPricerObj = finpricer( ___ ,Name,Value)
```

Description

`FFTPricerObj = finpricer(PricerType,'Model',model,'DiscountCurve',ratecurve_obj)` creates an FFT pricer object by specifying PricerType and sets the properties on page 11-3254 for the required name-value pair arguments Model and DiscountCurve.

`FFTPricerObj = finpricer( ___ ,Name,Value)` sets optional properties on page 11-3254 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `FFTPricerObj = finpricer("FFT",'Model',FFTModel, 'DiscountCurve',ratecurve_obj,'SpotPrice',1000,'DividendValue',0.01,'VolRiskPremium',0.9)` creates an FFT pricer object. You can specify multiple name-value pair arguments.

Input Arguments

PricerType — Pricer type
string with value "FFT" | character vector with value 'FFT'

Pricer type, specified as a string with the value of "FFT" or a character vector with the value of 'FFT'.

Data Types: char | string

FFT Name-Value Pair Arguments

Specify required and optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: FFTPricerObj = finpricer("FFT",'Model',FFTModel, 'DiscountCurve',ratecurve_obj,'SpotPrice',1000,'DividendValue',0.01,'VolRiskPremium',0.9)

Required FFT Name-Value Pair Arguments

Model — Model
model object

Model, specified as the comma-separated pair consisting of 'Model' and the name of the previously created Merton, Bates, or Heston model object using finmodel.

Data Types: object

DiscountCurve — ratecurve object for discounting cash flows
ratecurve object

This property is read-only.

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of the ratecurve object.

Note Specify a flat ratecurve object for DiscountCurve. If you use a nonflat ratecurve object, the software uses the rate in the ratecurve object at Maturity and assumes that the value is constant for the life of the equity option.

Data Types: object

SpotPrice — Current price of underlying asset
nonnegative numeric

Current price of the underlying asset, specified as the comma-separated pair consisting of 'SpotPrice' and a scalar nonnegative numeric.

Data Types: double

Optional FFT Name-Value Pair Arguments

DividendValue — Dividend yield
0 (default) | scalar nonnegative numeric

Dividend yield, specified as the comma-separated pair consisting of 'DividendValue' and a scalar nonnegative numeric in decimals.

Data Types: double

`VolRiskPremium` — Volatility risk premium
`0` (default) | numeric

Volatility risk premium, specified as the comma-separated pair consisting of `'VolRiskPremium'` and a scalar numeric value.

Data Types: `double`

`LittleTrap` — Flag indicating Little Heston Trap formulation
`true` (default) | logical with value `true` or `false`

Flag indicating Little Heston Trap formulation by Albrecher et al., specified as the comma-separated pair consisting of `'LittleTrap'` and a logical:

- `true` — Use the Albrecher et al. formulation.

  For more information on the `LittleTrap`, see [1] and also the Little Trap formulation is defined by C_j and D_j in "Heston Stochastic Volatility Model" on page 11-3258 and "Bates Stochastic Volatility Jump Diffusion Model" on page 11-3259.
- `false` — Use the original Heston formation.

Note `LittleTrap` is supported only for `Heston` and `Bates` models.

Data Types: `logical`

`NumFFT` — Number of grid points in characteristic function variable
`4096` (default) | numeric

Number of grid points in the characteristic function variable and in each column of the log-strike grid, specified as the comma-separated pair consisting of `'NumFFT'` and a scalar numeric value.

Data Types: `double`

`CharacteristicFcnStep` — Characteristic function variable grid spacing
`0.01` (default) | numeric

Characteristic function variable grid spacing, specified as the comma-separated pair consisting of `'CharacteristicFcnStep'` and a scalar numeric value.

Data Types: `double`

`LogStrikeStep` — Log-strike grid spacing
`2*pi/NumFFT/CharacteristicFcnStep` (default) | numeric

Log-strike grid spacing, specified as the comma-separated pair consisting of `'LogStrikeStep'` and a scalar numeric value.

Note If (`LogStrikeStep*CharacteristicFcnStep`) is `2*pi/NumFFT`, FFT is used. Otherwise, FRFT is used.

Data Types: `double`

`DampingFactor` — Damping factor for Carr-Madan formulation
`1.5` (default) | numeric

Damping factor for the Carr-Madan formulation, specified as the comma-separated pair consisting of `'DampingFactor'` and a scalar numeric value.

Data Types: `double`

`Quadrature` — Type of quadrature
`"simpson"` (default) | string with value `"simpson"` or `"trapezoidal"` | character vector with value `'simpson'` or `'trapezoidal'`

Type of quadrature, specified as the comma-separated pair consisting of `'Quadrature'` and a scalar string or character vector.

Data Types: `char` | `string`

Properties

`Model` — Model
model object

Model, returned as a model object.

Data Types: `object`

`SpotPrice` — Current price of underlying asset
nonnegative numeric

Current price of the underlying asset, returned as a scalar nonnegative numeric.

Data Types: `double`

`DividendValue` — Dividend yield
0 (default) | scalar nonnegative numeric

Dividend yield, returned as a scalar nonnegative numeric in decimals.

Data Types: `double`

`VolRiskPremium` — Volatility risk premium
`0` (default) | numeric

Volatility risk premium, returned as a scalar numeric value.

Data Types: `double`

`LittleTrap` — Flag indicating Little Heston Trap formulation
`true` (default) | logical with value `true` or `false`

Flag indicating Little Heston Trap formulation by Albrecher et al., returned as a logical.

Data Types: `logical`

`NumFFT` — Number of grid points in the characteristic function variable
`4096` (default) | numeric

Number of grid points in the characteristic function variable and in each column of the log-strike grid, returned as a scalar numeric value.

Data Types: `double`

`CharacteristicFcnStep` — Characteristic function variable grid spacing
`0.01` (default) | numeric

Characteristic function variable grid spacing, returned as a scalar numeric value.

Data Types: `double`

`LogStrikeStep` — Log-strike grid spacing
`2*pi/NumFFT/CharacteristicFcnStep` (default) | numeric

Log-strike grid spacing, returned as a scalar numeric value.

Data Types: `double`

`DampingFactor` — Damping factor for Carr-Madan formulation
`1.5` (default) | numeric

Damping factor for the Carr-Madan formulation, returned as a scalar numeric value.

Data Types: `double`

`Quadrature` — Type of quadrature
`"simpson"` (default) | string with value `"simpson"` or `"trapezoidal"`

Type of quadrature, returned as a string.

Data Types: `string`

Object Functions

price Compute price for equity instrument with FFT pricer

Examples

Use FFT Pricer and Heston Model to Price Vanilla Instrument

This example shows the workflow to price a `Vanilla` instrument when you use a `Heston` model and an `FFT` pricing method.

Create `Vanilla` Instrument Object

Use `fininstrument` to create a `Vanilla` instrument object.

```
VanillaOpt = fininstrument("Vanilla",'ExerciseDate',datetime(2022,9,15),'Strike',105,'ExerciseSty
```

```
VanillaOpt =
  Vanilla with properties:

       OptionType: "call"
    ExerciseStyle: "european"
     ExerciseDate: 15-Sep-2022
           Strike: 105
```

```
             Name: "vanilla_option"
```

Create Heston Model Object

Use `finmodel` to create a `Heston` model object.

```
HestonModel = finmodel("Heston",'V0',0.032,'ThetaV',0.1,'Kappa',0.003,'SigmaV',0.2,'RhoSV',0.9)
```

```
HestonModel =
  Heston with properties:

       V0: 0.0320
    ThetaV: 0.1000
     Kappa: 0.0030
    SigmaV: 0.2000
     RhoSV: 0.9000
```

Create ratecurve Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create FFT Pricer Object

Use `finpricer` to create an `FFT` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("fft",'DiscountCurve',myRC,'Model',HestonModel,'SpotPrice',100,'Characteris
```

```
outPricer =
  FFT with properties:

                  Model: [1x1 finmodel.Heston]
          DiscountCurve: [1x1 ratecurve]
              SpotPrice: 100
           DividendType: "continuous"
          DividendValue: 0
                 NumFFT: 8192
    CharacteristicFcnStep: 0.2000
```

```
        LogStrikeStep: 0.0038
    CharacteristicFcn: @characteristicFcnHeston
        DampingFactor: 1.5000

More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

Here:

St is the price of the underlying asset at time t.

K is the strike price.

For more information, see “Vanilla Option” on page 3-27.

Heston Stochastic Volatility Model

The Heston model is an extension of the Black-Scholes model, where the volatility (the square root of the variance) is no longer assumed to be constant, and the variance now follows a stochastic (CIR) process. This process allows modeling the implied volatility smiles observed in the market.

The stochastic differential equation is

$$dS_t = (r - q)S_t dt + \sqrt{v_t} S_t dW_t$$

$$dv_t = \kappa(\theta - v_t)dt + \sigma_v \sqrt{v_t} dW_t^v$$

$$\mathrm{E}\left[dW_t dW_t^v\right] = p dt$$

Here:

r is the continuous risk-free rate.

q is the continuous dividend yield.

S_t is the asset price at time t.

v_t is the asset price variance at time t.

v_0 is the initial variance of the asset price at $t = 0$ for ($v_0 > 0$).

θ is the long-term variance level for ($\theta > 0$).

κ is the mean reversion speed for the variance for ($\kappa > 0$).

σ_v is the volatility of the variance for ($\sigma_v > 0$).

p is the correlation between the Weiner processes W_t and $W^v{}_t$ for ($-1 \le p \le 1$).

The characteristic function $f_{Heston_j}(\phi)$ for $j = 1$ (asset price measure) and $j = 2$ (risk-neutral measure) is

$$f_{Heston_j}(\phi) = \exp(C_j + D_j v_0 + i\phi \ln S_t)$$

$$C_j = (r - q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2}\left[\left(b_j - p\sigma_v i\phi + d_j\right)\tau - 2\ln\left(\frac{1 - g_j e^{d_j \tau}}{1 - g_j}\right)\right]$$

$$D_j = \frac{b_j - p\sigma_v i\phi + d_j}{\sigma_v^2}\left(\frac{1 - e^{d_j\tau}}{1 - g_j e^{d_j\tau}}\right)$$

$$g_j = \frac{b_j - p\sigma_v i\phi + d_j}{b_j - p\sigma_v i\phi - d_j}$$

$$d_j = \sqrt{\left(b_j - p\sigma_v i\phi\right)^2 - \sigma_v^2\left(2u_j i\phi - \phi^2\right)}$$

where for $j = 1, 2$:

$$u_1 = \frac{1}{2}, u_2 = -\frac{1}{2}, b_1 = \kappa + \lambda_{VolRisk} - p\sigma_v, b_2 = \kappa + \lambda_{VolRisk}$$

Here:

ϕ is the characteristic function variable.

$\lambda_{VolRisk}$ is the volatility risk premium.

τ is the time to maturity ($\tau = T - t$).

i is the unit imaginary number ($i^2 = -1$).

The definitions for C_j and D_j in the Little Heston Trap by Albrecher et al. (2007) are

$$C_j = (r-q)i\phi\tau + \frac{\kappa\theta}{\sigma_v{}^2}\left[\left(b_j - p\sigma_v i\phi - d_j\right)\tau - 2\ln\left(\frac{1-\varepsilon_j e^{-d_j\tau}}{1-\varepsilon_j}\right)\right]$$

$$Dj = \frac{b_j - p\sigma_v i\phi - d_j}{\sigma_v^2}\left(\frac{1-e^{-d_j\tau}}{1-\varepsilon_j e^{-d_j\tau}}\right)$$

$$\varepsilon_j = \frac{b_j - p\sigma_v i\phi - d_j}{b_j - p\sigma_v i\phi + d_j}$$

Bates Stochastic Volatility Jump Diffusion Model

The Bates model (Bates 1996) is an extension of the Heston model where, in addition to stochastic volatility, the jump diffusion parameters similar to Merton (1976) are also added to model sudden asset price movements.

The stochastic differential equation is

$$dS_t = (r - q - \lambda_p\mu_J)S_t dt + \sqrt{v_t}S_t dW_t + JS_t dP_t$$

$$dv_t = \kappa(\theta - v_t)dt + \sigma_v\sqrt{v_t}dW_t$$

$$\mathrm{E}\left[dW_t dW_t^v\right] = pdt$$

$$\mathrm{prob}(dP_t = 1) = \lambda_p dt$$

Here:

r is the continuous risk-free rate.

q is the continuous dividend yield.

S_t is the asset price at time t.

v_t is the asset price variance at time t.

J is the random percentage jump size conditional on the jump occurring, where $\ln(1+J)$ is normally distributed with mean $\ln(1+\mu_J) - \frac{\delta^2}{2}$ and the standard deviation δ, and $(1+J)$ has a lognormal distribution:

$$\frac{1}{(1+J)\delta\sqrt{2\pi}}\exp\left\{\frac{-\left[\ln(1+J) - \left(\ln(1+\mu_J) - \frac{\delta^2}{2}\right]^2\right.}{2\delta^2}\right\}$$

Here:

v_0 is the initial variance of the asset price at $t = 0$ ($v_0 > 0$).

θ is the long-term variance level for ($\theta > 0$).

κ is the mean reversion speed for ($\kappa > 0$).

σ_v is the volatility of variance for ($\sigma_v > 0$).

p is the correlation between the Weiner processes W_t and W_t^v for ($-1 \le p \le 1$).

μ_J is the mean of J for ($\mu_J > -1$).

δ is the standard deviation of $\ln(1+J)$ for ($\delta \ge 0$).

λ_p is the annual frequency (intensity) of Poisson process P_t for ($\lambda_p \ge 0$).

The characteristic function $f_{Bates_j(\phi)}$ for $j = 1$ (asset price mean measure) and $j = 2$ (risk-neutral measure) is

$$f_{Bates(\phi)} = \exp(C_j + D_j v_0 + i\phi \ln S_t)\exp\left(\lambda_p \tau(1+\mu_J)^{m_j} + \frac{1}{2}\left[(1+\mu_j)^{i\phi} e^{\delta^2\left(m_j i\phi + \frac{(i\phi)^2}{2}\right)} - 1\right] - \lambda_p \tau \mu_J i\phi\right)$$

$$m_j = \begin{Bmatrix} m_1 = \frac{1}{2} \\ m_2 = -\frac{1}{2} \end{Bmatrix}$$

$$C_j = (r-q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2}\left[\left(b_j - p\sigma_v i\phi + d_j\right)\tau - 2\ln\left(\frac{1 - g_j e^{d_j\tau}}{1 - g_j}\right)\right]$$

$$Dj = \frac{b_j - p\sigma_v i\phi + d_j}{\sigma_v^2}\left(\frac{1 - e^{d_j\tau}}{1 - g_j e^{d_j\tau}}\right)$$

$$g_j = \frac{b_j - p\sigma_v i\phi + d_j}{b_j - p\sigma_v i\phi - d_j}$$

$$d_j = \sqrt{\left(b_j - p\sigma_v i\phi\right)^2 - \sigma_v^2\left(2u_j i\phi - \phi^2\right)}$$

where for $j = 1, 2$:

$$u_1 = \frac{1}{2}, u_2 = -\frac{1}{2}, b_1 = \kappa + \lambda_{VolRisk} - p\sigma_v, b_2 = \kappa + \lambda_{VolRisk}$$

Here:

ϕ is the characteristic function variable.

$\lambda_{VolRisk}$ is the volatility risk premium.

τ is the time to maturity for ($\tau = T - t$).

i is the unit imaginary number for ($i^2 = -1$).

The definitions for C_j and D_j in the Little Heston Trap by Albrecher et al. (2007) are

$$C_j = (r-q)i\phi\tau + \frac{\kappa\theta}{\sigma_v{}^2}\left[\left(b_j - p\sigma_v i\phi - d_j\right)\tau - 2\ln\left(\frac{1-\varepsilon_j e^{-d_j\tau}}{1-\varepsilon_j}\right)\right]$$

$$Dj = \frac{b_j - p\sigma_v i\phi - d_j}{\sigma_v^2}\left(\frac{1-e^{-d_j\tau}}{1-\varepsilon_j e^{-d_j\tau}}\right)$$

$$\varepsilon_j = \frac{b_j - p\sigma_v i\phi - d_j}{b_j - p\sigma_v i\phi + d_j}$$

Merton Jump Diffusion Model

The Merton jump diffusion model (Merton 1976) is an extension of the Black-Scholes model, where sudden asset price movements (both up and down) are modeled by adding the jump diffusion parameters with the Poisson process.

The stochastic differential equation is

$$dS_t = (r - q - \lambda_p\mu_j)S_t dt + \sigma S_t dW_t + JS_t dP_t$$
$$\text{prob}(dP_t = 1) = \lambda_p dt$$

Here:

r is the continuous risk-free rate.

q is the continuous dividend yield.

W_t is the Weiner process.

J is the random percentage jump size conditional on the jump occurring, where $\ln(1+J)$ is normally distributed with mean $\ln(1+\mu_J) - \frac{\delta^2}{2}$ and the standard deviation δ, and $(1+J)$ has a lognormal distribution:

$$\frac{1}{(1+J)\delta\sqrt{2\pi}}\exp\left\{\frac{-\left[\ln(1+J) - \left(\ln(1+\mu_J) - \frac{\delta^2}{2}\right]^2\right.}{2\delta^2}\right\}$$

Here:

μ_J is the mean of J for ($\mu_J > -1$).

δ is the standard deviation of $\ln(1+J)$ for ($\delta \geq 0$).

λ_p is the annual frequency (intensity) of the Poisson process P_t for ($\lambda_p \geq 0$).

σ is the volatility of the asset price for ($\sigma > 0$).

The characteristic function $f_{Merton76_j}(\phi)$ for $j = 1$ (asset price measure) and $j = 2$ (risk-neutral measure) is

$$f_{Merton76_j} = f_{BS_j}\exp\left(\lambda_p\tau\left(1+\mu_j\right)^{m_j+\frac{1}{2}}\left[\left(1+\mu_j\right)^{i\phi}e^{\delta^2\left(m_j i\phi+\frac{(i\phi)^2}{2}\right)}-1\right]-\lambda_p\tau\mu_j i\phi\right)$$

where for $j = 1, 2$:

$$f_{BS_1}(\phi) = \frac{f_{BS_2}(\phi - i)}{f_{BS_2}(-i)}$$

$$f_{BS2}(\phi) = \exp\left(i\phi\left[\ln S_t + \left(r - q - \frac{\sigma^2}{2}\right)\tau\right] - \frac{\phi^2\sigma^2}{2}\tau\right)$$

$$m_1 = \frac{1}{2}, m_2 = -\frac{1}{2}$$

Here:

ϕ is the characteristic function variable.

τ is the time to maturity ($\tau = T - t$).

i is the unit imaginary number ($i^2 = -1$).

Carr-Madan Formulation

The Carr-Madan (1999) formulation is a popular modified implementation of Heston (1993) framework.

Rather than computing the probabilities P_1 and P_2 as intermediate steps, Carr and Madan developed an alternative expression so that taking its inverse Fourier transform gives the option price itself directly.

$$Call(k) = \frac{e^{-\alpha k}}{\pi}\int_0^\infty \mathrm{Re}\left[e^{-iuk}\psi(u)\right]du$$

$$\psi(u) = \frac{e^{-r\tau}f_2(\phi = (u - (\alpha+1)i))}{\alpha^2 + \alpha - u^2 + iu(2\alpha+1)}$$

$$Put(K) = Call(K) + Ke^{-r\tau} - S_t e^{-q\tau}$$

Here:

r is the continuous risk-free rate.

q is the continuous dividend yield.

S_t is the asset price at time t.

τ is time to maturity (τ = T-t).

$Call(K)$ is the call price at strike K.

$Put(K)$ is the put price at strike K

i is a unit imaginary number (i^2= -1)

ϕ is the characteristic function variable.

α is the damping factor.

u is the characteristic function variable for integration, where ϕ = (u - (α+1)i).

$f_2(\phi)$ is the characteristic function for P_2.

P_2 is the probability of $S_t > K$ under the risk-neutral measure for the model.

To apply FFT or FRFT to this formulation, the characteristic function variable for integration u is discretized into `NumFFT`(N) points with the step size `CharacteristicFcnStep` (Δu), and the log-strike k is discretized into N points with the step size `LogStrikeStep`(Δk).

The discretized characteristic function variable for integration u_j(for j = 1,2,3,...,N) has a minimum value of 0 and a maximum value of (N-1) (Δu), and it approximates the continuous integration range from 0 to infinity.

The discretized log-strike grid k_n(for n = 1, 2, 3, N) is approximately centered around `ln`(S_t), with a minimum value of

$$\ln(S_t) - \frac{N}{2}\Delta k$$

and a maximum value of

$$\ln(S_t) + \left(\frac{N}{2} - 1\right)\Delta k$$

Where the minimum allowable strike is

$$S_t \exp\left(-\frac{N}{2}\Delta k\right)$$

and the maximum allowable strike is

$$S_t \exp\left[\left(\frac{N}{2} - 1\right)\Delta k\right]$$

As a result of the discretization, the expression for the call option becomes

$$Call(k_n) = \Delta u \frac{e^{-\alpha k_n}}{\pi} \sum_{j=1}^{N} \mathrm{Re}\left[e^{-i\Delta k \Delta u (j-1)(n-1)} e^{iuj\left[\frac{N\Delta k}{2} - \ln(S_t)\right]} \psi(u_j)\right] w_j$$

Here:

Δu is the step size of the discretized characteristic function variable for integration.

Δk is the step size of the discretized log strike.

N is the number of FFT or FRFT points.

w_j is the weights for quadrature used for approximating the integral.

FFT is used to evaluate the above expression if Δk and Δu are subject to the following constraint:

$$\Delta k \Delta u = \left(\frac{2\pi}{N}\right)$$

Otherwise, the functions use the FRFT method described in Chourdakis (2005).

GoldmanSosinGatto

Create `GoldmanSosinGatto` pricer object for `Lookback` instrument using `BlackScholes` model

Description

Create and price a `Lookback` instrument object with a `BlackScholes` model and a `GoldmanSosinGatto` pricing method using this workflow:

1. Use `fininstrument` to create a `Lookback` instrument object.
2. Use `finmodel` to specify a `BlackScholes` model for the `Lookback` instrument object.
3. Use `finpricer` to specify a `GoldmanSosinGatto` pricer object for the `Lookback` instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a `Lookback` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
GoldmanSosinGattoPricerObj = finpricer(PricerType,'
DiscountCurve,ratecurve_obj,'Model,model,'SpotPrice',spotprice_value)
GoldmanSosinGattoPricerObj = finpricer(___,Name,Value)
```

Description

`GoldmanSosinGattoPricerObj = finpricer(PricerType,'DiscountCurve,ratecurve_obj,'Model,model,'SpotPrice',spotprice_value)` creates a `GoldmanSosinGatto` pricer object by specifying `PricerType` and sets the properties on page 11-3267 for the required name-value pair arguments `DiscountCurve`, `Model`, and `SpotPrice`.

`GoldmanSosinGattoPricerObj = finpricer(___,Name,Value)` to set optional properties on page 11-3267 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `GoldmanSosinGattoPricerObj = finpricer("Analytic",'DiscountCurve',ratecurve_obj,'Model',BSModel,'SpotPrice',1000,'DividendType',"continuous",'DividendValue',500,'PricingMethod',"GoldmanSosinGatto")` creates a `GoldmanSosinGatto` pricer object.

Input Arguments

PricerType — Pricer type

string with value `"Analytic"` | character vector with value `'Analytic'`

Pricer type, specified as a string with the value of `"Analytic"` or a character vector with the value of `'Analytic'`.

Data Types: `char` | `string`

GoldmanSosinGatto Name-Value Pair Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `GoldmanSosinGattoPricerObj = finpricer("Analytic",'DiscountCurve',ratecurve_obj,'Model',BSModel,'SpotPrice',1000,'DividendType',"continuous",'DividendValue',500,'PricingMethod',"GoldmanSosinGatto")`

Required GoldmanSosinGatto Name-Value Pair Arguments

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

`ratecurve` object for discounting cash flows, specified as the comma-separated pair consisting of `'DiscountCurve'` and the name of the previously created `ratecurve` object.

Note Specify a flat `ratecurve` object for `DiscountCurve`. If you use a nonflat `ratecurve` object, the software uses the rate in the `ratecurve` object at `Maturity` and assumes that the value is constant for the life of the equity option.

Data Types: `object`

`Model` — Model
`BlackScholes` model object

Model, specified as the comma-separated pair consisting of `'Model'` and the name of a previously created `BlackScholes` model object using `finmodel`.

Data Types: `object`

`SpotPrice` — Current price of underlying asset
nonnegative numeric

Current price of the underlying asset, specified as the comma-separated pair consisting of `'SpotPrice'` and a scalar nonnegative numeric.

Data Types: `double`

Optional GoldmanSosinGatto Name-Value Pair Arguments

`DividendType` — Stock dividend type
`"continuous"` (default) | string with value `"cash"` or `"continuous"` | character vector with value `'cash'` or `'continuous'`

Stock dividend type, specified as the comma-separated pair consisting of `'DividendType'` and a character vector or string. `DividendType` must be `"cash"` for actual dollar dividends or `"continuous"` for a continuous dividend yield.

Data Types: `char` | `string`

`DividendValue` — Dividend amount or dividend schedule for underlying stock
`0` (default) | scalar numeric | timetable

Dividend amount for underlying stock, specified as the comma-separated pair consisting of `'DividendValue'` and a scalar numeric for a dividend amount or a timetable for a dividend schedule.

Note Specify a scalar if `DividendType` is `"continuous"` and a timetable if `DividendType` is `"cash"`.

Data Types: `double` | `timetable`

`PricingMethod` — Analytic pricing method
default pricer associated with `BlackScholes` model (default) | string with value `"GoldmanSosinGatto"` | character vector with value `'GoldmanSosinGatto'`

Analytic pricing method, specified as the comma-separated pair consisting of `'PricingMethod'` and a character vector or string.

Note The default pricing method for a `BlackScholes` model is a `BlackScholes` pricer.

Data Types: `double`

Properties

`DiscountCurve` — `ratecurve` object for discounting cash flows
object

`ratecurve` object for discounting cash flows, returned as a `ratecurve` object.

Data Types: `object`

`Model` — Model
`BlackScholes` model object

Model, returned as a `BlackScholes` model object.

Data Types: `object`

`SpotPrice` — Current price of underlying asset
nonnegative numeric

Current price of the underlying asset, returned as a scalar nonnegative numeric.

Data Types: `double`

`DividendType` — Stock dividend type
`"continuous"` (default) | string with value `"cash"` or `"continuous"`

This property is read-only.

Stock dividend type, returned as a string. `DividendType` is either `"cash"` for actual dollar dividends or `"continuous"` for a continuous dividend yield.

Data Types: `string`

`DividendValue` — Dividend amount or dividend schedule for underlying stock
`0` (default) | scalar nonnegative numeric | timetable

Dividend amount or dividend schedule for the underlying stock, returned as a scalar numeric for a dividend amount or a timetable for a dividend schedule.

Data Types: `double` | `timetable`

`PricingMethod` — Analytic pricing method
default pricer associated with `BlackScholes` model (default) | string with value `"GoldmanSosinGatto"`

Analytic pricing method, returned as a string.

Data Types: `string`

Object Functions

price Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

Examples

Use Goldman-Sosin-Gatto Pricer and Black-Scholes Model to Price Lookback Instrument

This example shows the workflow to price a floating-strike `Lookback` instrument when you use a `BlackScholes` model and a `GoldmanSosinGatto` pricing method.

Create Lookback Instrument Object

Use `fininstrument` to create a floating-strike `Lookback` instrument object where the `Strike` argument is specified as `NaN`.

```
LookbackOpt = fininstrument("lookback",'Strike',NaN,'ExerciseDate',datetime(2021,9,15),'OptionTy
```

```
LookbackOpt =
  Lookback with properties:

       OptionType: "put"
           Strike: NaN
      AssetMinMax: NaN
    ExerciseStyle: "european"
     ExerciseDate: 15-Sep-2021
             Name: "lookback_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',.358)
```

```
BlackScholesModel =
  BlackScholes with properties:
```

```
     Volatility: 0.3580
    Correlation: 1
```

Create ratecurve Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                 Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create GoldmanSosinGatto Pricer Object

Use `finpricer` to create a `GoldmanSosinGatto` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPrice',100,
```

```
outPricer =
  GoldmanSosinGatto with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 100
    DividendValue: 0.0250
     DividendType: "continuous"
```

Price Lookback Instrument

Use `price` to compute the price and sensitivities for the floating-strike `Lookback` instrument.

```
[Price, outPR] = price(outPricer,LookbackOpt,["all"])
```

```
Price = 53.3720
```

```
outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta        Gamma        Lambda     Vega      Theta       Rho
    _____    ________    ___________    ______    ______    _______    ________

    53.372    0.53372    -1.4211e-06       1      181.36    -8.7793    -213.01
```

“Choose Instruments, Models, and Pricers” on page 1-53

HullWhite

Create `HullWhite` pricer object for `Cap`, `Floor`, or `Swaption` instrument using `HullWhite` model

Description

Create and price a `Cap`, `Floor`, or `Swaption` instrument object with a `HullWhite` model and a `HullWhite` pricing method using this workflow:

1. Use `fininstrument` to create a `Cap`, `Floor`, or `Swaption` instrument object.
2. Use `finmodel` to specify the `HullWhite` model for the `Cap`, `Floor`, or `Swaption` instrument object.
3. Use `finpricer` to specify the `HullWhite` pricer object for the `Cap`, `Floor`, or `Swaption` instrument object.

Note If you do not specify `ProjectionCurve` when you create a `Cap`, `Floor`, or `Swaption` instrument with the `HullWhite` pricer, the `ProjectionCurve` value defaults to the `DiscountCurve` value.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a `Cap`, `Floor`, or `Swaption` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

```

Description

`HullWhitePricerObj = finpricer(PricerType,'DiscountCurve',ratecurve_obj,'Model',model)` creates a `HullWhite` pricer object by specifying `PricerType` and the required name-value pair arguments `DiscountCurve` and `Model` to set properties on page 11-3272 using name-value pairs. For example, `HullWhitePricerObj = finpricer("Analytic",'DiscountCurve',ratecurve_obj,'Model',HWModel)` creates a `HullWhite` pricer object.

Input Arguments

`PricerType` — Pricer type

string with value `"Analytic"` | character vector with value `'Analytic'`

Pricer type, specified as a string with the value of `"Analytic"` or a character vector with the value of `'Analytic'`.

Data Types: `char` | `string`

`HullWhite` Name-Value Pair Arguments

Specify required pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `HullWhitePricerObj = finpricer("Analytic",'DiscountCurve',ratecurve_obj,'Model',HWModel)`

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

`ratecurve` object for discounting cash flows, specified as the comma-separated pair consisting of `'DiscountCurve'` and the name of a previously created `ratecurve` object.

Data Types: `object`

`Model` — Model
`HullWhite` model object

Model object, specified as the comma-separated pair consisting of `'Model'` and the name of the previously created `HullWhite` model object using `finmodel`.

Data Types: `object`

Properties

`DiscountCurve` — `ratecurve` object for discounting cash flows
object

`ratecurve` object for discounting cash flows, returned as a `ratecurve` object.

Data Types: `object`

`Model` — Model
`HullWhite` model object

Model, returned as a `HullWhite` model object.

Data Types: `object`

Object Functions

price Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

Examples

Use Hull-White Pricer and Hull-White Model to Price a Floor Instrument

This example shows the workflow to price a `Floor` instrument when you use a `HullWhite` model and a `HullWhite` pricing method.

Create `Floor` Instrument Object

Use `fininstrument` to create a `Floor` instrument object.

```
FloorOpt = fininstrument("Floor",'Strike',0.02,'Maturity',datetime(2019,1,30),'Reset',4,'Principa
```

```
FloorOpt =
  Floor with properties:

                     Strike: 0.0200
                   Maturity: 30-Jan-2019
                ResetOffset: 0
                      Reset: 4
                      Basis: 8
                  Principal: 100
             ProjectionCurve: [0x0 ratecurve]
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                   Holidays: NaT
                       Name: "floor_option"
```

Create `HullWhite` Model Object

Use `finmodel` to create a `HullWhite` model object.

```
HullWhiteModel = finmodel("HullWhite",'Alpha',0.032,'Sigma',0.04)
```

```
HullWhiteModel =
  HullWhite with properties:

    Alpha: 0.0320
    Sigma: 0.0400
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = "zero";
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
       Compounding: -1
             Basis: 0
             Dates: [10x1 datetime]
             Rates: [10x1 double]
            Settle: 15-Sep-2018
      InterpMethod: "linear"
    ShortExtrapMethod: "next"
```

```
     LongExtrapMethod: "previous"
```

Create `HullWhite` Pricer Object

Use `finpricer` to create a `HullWhite` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'Model',HullWhiteModel,'DiscountCurve',myRC)
```

```
outPricer =
  HullWhite with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.HullWhite]
```

Price `Floor` Instrument

Use `price` to compute the price for the `Floor` instrument.

```
Price = price(outPricer,FloorOpt)
```

```
Price = 0.5809
```

Version History

Introduced in R2020a

Topics

“Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22
“Choose Instruments, Models, and Pricers” on page 1-53

IRMonteCarlo

Create `IRMonteCarlo` pricer object for interest-rate instruments using `HullWhite`, `BraceGatarekMusiela`, `BlackKarasinski`, or `LinearGaussian2F` model

Description

Create and price a `Cap`, `Floor`, `Swap`, `Swaption`, `FloatBond`, `FixedBond`, `FixedBondOption`, `FloatBondOption`, `OptionEmbeddedFixedBond`, or `OptionEmbeddedFloatBond` instrument object with a `HullWhite`, `BraceGatarekMusiela`, `SABRBraceGatarekMusiela`, `BlackKarasinski`, or `LinearGaussian2F` model and a `IRMonteCarlo` pricing method using this workflow:

1. Use `fininstrument` to create a `FixedBond`, `FloatBond`, `Cap`, `Floor`, `Swap`, `Swaption`, `FixedBondOption`, `FloatBondOption`, `OptionEmbeddedFixedBond`, or `OptionEmbeddedFloatBond` instrument object.
2. Use `finmodel` to specify a `HullWhite`, `BlackKarasinski`, or `LinearGaussian2F` model for the `Cap`, `Floor`, `Swap`, `Swaption`, `FloatBond`, `FixedBond`, `FixedBondOption`, `FloatBondOption`, `OptionEmbeddedFixedBond`, or `OptionEmbeddedFloatBond` instrument object.

   Use `finmodel` to specify a `BraceGatarekMusiela` or `SABRBraceGatarekMusiela` model for the `Cap`, `Floor`, `FloatBond`, `FixedBond`, `FixedBondOption`, `FloatBondOption`, `OptionEmbeddedFixedBond`, or `OptionEmbeddedFloatBond` instrument object.
3. When using a `HullWhite`, `BlackKarasinski`, or `LinearGaussian2F` model, use `finpricer` to specify an `IRMonteCarlo` pricer object for the `Cap`, `Floor`, `Swap`, `Swaption`, `FloatBond`, `FixedBond`, `FixedBondOption`, `FloatBondOption`, `OptionEmbeddedFixedBond`, or `OptionEmbeddedFloatBond` instrument object.

   When using a `BraceGatarekMusiela` or `SABRBraceGatarekMusiela` model, use `finpricer` to specify an `IRMonteCarlo` pricer object for the `Cap`, `Floor`, `FloatBond`, `FixedBond`, `FixedBondOption`, `FloatBondOption`, `OptionEmbeddedFixedBond`, or `OptionEmbeddedFloatBond` instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for `Cap`, `Floor`, `Swap`, `Swaption`, `FloatBond`, `FixedBond`, `FixedBondOption`, `FloatBondOption`, `OptionEmbeddedFixedBond`, or `OptionEmbeddedFloatBond` instruments, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
IRMonteCarloPricerObj = finpricer(PricerType,Model=model,
DiscountCurve=ratecurve_obj,SimulationDates=simulation_dates)
```

```
IRMonteCarloPricerObj = finpricer( ___ ,Name=Value)
```

Description

`IRMonteCarloPricerObj = finpricer(PricerType,Model=model, DiscountCurve=ratecurve_obj,SimulationDates=simulation_dates)` creates an `IRMonteCarlo` pricer object by specifying `PricerType` and sets the properties on page 11-3277 using the required name-value arguments `Model`, `DiscountCurve`, and `SimulationDates`.

`IRMonteCarloPricerObj = finpricer( ___ ,Name=Value)` sets optional properties on page 11-3277 using additional name-value arguments in addition to the required arguments in the previous syntax. For example, `IRMonteCarloPricerObj = finpricer("irmontecarlo",Model=HWModel,DiscountCurve=ratecurve_obj,SimulationDates=[datetime(2018,1,30); datetime(2019,1,30)],NumTrials=500)` creates an `IRMonteCarlo` pricer object using a `HullWhite` model. You can specify multiple name-value arguments.

Input Arguments

`PricerType` — Pricer type
string with value `"IRMonteCarlo"` | character vector with value `'IRMonteCarlo'`

Pricer type, specified as a string with the value `"IRMonteCarlo"` or a character vector with the value `'IRMonteCarlo'`.

Data Types: `char` | `string`

`IRMonteCarlo` Name-Value Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `IRMonteCarloPricerObj = finpricer("irmontecarlo",Model=HWModel,DiscountCurve=ratecurve_obj,SimulationDates=[datetime(2018,1,30); datetime(2019,1,30)],NumTrials=500)`

Required IRMonteCarlo Name-Value Arguments

`Model` — Model object
`HullWhite` object | `BlackKarasinski` object | `LinearGaussian2F` object | `BraceGatarekMusiela` object | `SABRBraceGatarekMusiela` object

Model object, specified as `Model` and the name of a previously created `HullWhite`, `BlackKarasinski`, `LinearGaussian2F`, `BraceGatarekMusiela`, or `SABRBraceGatarekMusiela` model object. Create the model object using `finmodel`.

Data Types: `object`

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

`ratecurve` object for discounting cash flows, specified as `DiscountCurve` and the name of a previously created `ratecurve` object.

Note Specify a flat `ratecurve` object for `DiscountCurve`. If you use a nonflat `ratecurve` object, the software uses the rate in the `ratecurve` object at `Maturity` and assumes that the value is constant for the life of the interest-rate option.

Data Types: `object`

`SimulationDates` — Simulation dates
datetime array | string array | date character vector

Simulation dates, specified as `SimulationDates` and a scalar or a vector using a datetime array, string array, or date character vectors.

To support existing code, `IRMonteCarlo` also accepts serial date numbers as inputs, but they are not recommended.

Optional IRMonteCarlo Name-Value Arguments

`NumTrials` — Simulation trials
`1000` (default) | scalar

Simulation trials, specified as `NumTrials` and a scalar number of independent sample paths.

Data Types: `double`

`RandomNumbers` — Dependent random variates
`[ ]` (default) | structure

Dependent random variates, specified as `RandomNumbers` and an `NSimulationDates`-by-`NBrownians`-by-`NTrials` 3D time series array. The 3D time series array has the following field:

- `Z` — `NSimulationDates`-by-`NBrownians`-by-`NTrials` 3D time series array of dependent random variates used to generate the Brownian motion vector (that is, Wiener processes) that drive the simulation.

Data Types: `struct`

Properties

`Model` — Model object
object

This property is read-only.

Model object, returned as an object.

Data Types: `object`

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

`ratecurve` object for discounting cash flows, returned as a `ratecurve` object.

Data Types: `object`

`SimulationDates` — Simulation dates
datetime

Simulation dates, returned as a datetime array.

Data Types: `datetime`

`NumTrials` — Simulation trials
`1000` (default) | scalar

Simulation trials, returned as a scalar number of independent sample paths.

Data Types: `double`

`RandomNumbers` — Dependent random variates
`[ ]` (default) | structure

Dependent random variates, returned as an `NSimulationDates`-by-`NBrownians`-by-`NTrials` 3D time series array.

Data Types: `struct`

Object Functions

price Compute price for interest-rate instrument with IRMonteCarlo pricer

Examples

Use IRMonteCarlo Pricer and Hull-White Model to Price Fixed Bond Instrument

This example shows the workflow to price a `FixedBond` instrument when using a `HullWhite` model and an `IRMonteCarlo` pricing method.

Create FixedBond Instrument Object

Use `fininstrument` to create a `FixedBond` instrument object.

```
FixB = fininstrument("FixedBond",Maturity=datetime(2022,9,15),CouponRate=0.05,Name="fixed_bond")
```

```
FixB =
  FixedBond with properties:

                 CouponRate: 0.0500
                     Period: 2
                      Basis: 0
                EndMonthRule: 1
                   Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                    Holidays: NaT
                   IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 15-Sep-2022
                        Name: "fixed_bond"
```

Create HullWhite Model Object

Use finmodel to create a HullWhite model object.

```
HullWhiteModel = finmodel("HullWhite",Alpha=0.32,Sigma=0.49)
```

```
HullWhiteModel =
  HullWhite with properties:

    Alpha: 0.3200
    Sigma: 0.4900
```

Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2019,1,1);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 01-Jan-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create IRMonteCarlo Pricer Object

Use finpricer to create an IRMonteCarlo pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("IRMonteCarlo",Model=HullWhiteModel,DiscountCurve=myRC,SimulationDates=Zero
```

```
outPricer =
  HWMonteCarlo with properties:

          NumTrials: 1000
      RandomNumbers: []
      DiscountCurve: [1x1 ratecurve]
    SimulationDates: [01-Jul-2019    01-Jan-2020    01-Jan-2021    ...    ]
              Model: [1x1 finmodel.HullWhite]
```

Price FixedBond Instrument

Use price to compute the price for the FixedBond instrument.

```
[Price,outPR] = price(outPricer,FixB,["all"])

Price = 115.0303

outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: [1x1 struct]

outPR.Results

ans=1×4 table
    Price      Delta     Gamma     Vega
    _____    ________    _____    ____

    115.03    -397.13    1430.4     0
```

Use IRMonteCarlo Pricer and LinearGaussian2F Model to Price Cap Instrument

This example shows the workflow to price a `Cap` instrument when using a `LinearGaussian2F` model and an `IRMonteCarlo` pricing method.

Create Cap Instrument Object

Use `fininstrument` to create a `Cap` instrument object.

```
CapOpt = fininstrument("Cap",Maturity=datetime(2022,9,15),Strike=0.01,Reset=2,Name="cap_option")

CapOpt =
  Cap with properties:

                     Strike: 0.0100
                   Maturity: 15-Sep-2022
                ResetOffset: 0
                      Reset: 2
                      Basis: 0
                  Principal: 100
             ProjectionCurve: [0x0 ratecurve]
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                   Holidays: NaT
                       Name: "cap_option"
```

Create LinearGaussian2F Model Object

Use `finmodel` to create a `LinearGaussian2F` model object.

```
LinearGaussian2FModel = finmodel("LinearGaussian2F",Alpha1=0.07,Sigma1=0.01,Alpha2=0.5,Sigma2=0.

LinearGaussian2FModel =
  LinearGaussian2F with properties:

         Alpha1: 0.0700
```

```
         Sigma1: 0.0100
         Alpha2: 0.5000
         Sigma2: 0.0060
    Correlation: -0.7000
```

Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2019,1,1);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 01-Jan-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create IRMonteCarlo Pricer Object

Use `finpricer` to create an `IRMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("IRMonteCarlo",Model=LinearGaussian2FModel,DiscountCurve=myRC,SimulationDa
```

```
outPricer =
  G2PPMonteCarlo with properties:

          NumTrials: 1000
      RandomNumbers: []
      DiscountCurve: [1x1 ratecurve]
    SimulationDates: [01-Jul-2019    01-Jan-2020    01-Jan-2021    ...    ]
              Model: [1x1 finmodel.LinearGaussian2F]
```

Price Cap Instrument

Use `price` to compute the price and sensitivities for the `Cap` instrument.

```
[Price,outPR] = price(outPricer,CapOpt,["all"])
```

```
Price = 1.2156

outPR =
  priceresult with properties:
```

```
       Results: [1x4 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×4 table
    Price     Delta     Gamma          Vega
    ______    ______    _____    _______________

    1.2156    131.37    11048    126.5    -157.38
```

Use IRMonteCarlo Pricer and BraceGatarekMusiela Model to Price Floor Instrument

This example shows the workflow to price a `Floor` instrument when using a `BraceGatarekMusiela` model and an `IRMonteCarlo` pricing method.

Create Floor Instrument Object

Use `fininstrument` to create a `Floor` instrument object.

```
FloorOpt = fininstrument("Floor",Maturity=datetime(2022,9,15),Strike=0.05,Reset=1,Name="floor_op
```

```
FloorOpt =
  Floor with properties:

                     Strike: 0.0500
                   Maturity: 15-Sep-2022
                ResetOffset: 0
                      Reset: 1
                      Basis: 0
                  Principal: 100
             ProjectionCurve: [0x0 ratecurve]
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                   Holidays: NaT
                       Name: "floor_option"
```

Create BraceGatarekMusiela Model Object

Use `finmodel` to create a `BraceGatarekMusiela` model object.

```
BGMVolFunc = @(a,t) (a(1)*t + a(2)).*exp(-a(3)*t) + a(4);
BGMVolParams = [.3 -.02 .7 .14];
numRates = 20;
VolFunc(1:numRates-1) = {@(t) BGMVolFunc(BGMVolParams,t)};
Beta = .08;
CorrFunc = @(i,j,Beta) exp(-Beta*abs(i-j));
Correlation = CorrFunc(meshgrid(1:numRates-1)',meshgrid(1:numRates-1),Beta);
BGM = finmodel("BraceGatarekMusiela",Volatility=VolFunc,Correlation=Correlation,Period=1);
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2019,1,1);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [9x1 datetime]
               Rates: [9x1 double]
              Settle: 01-Jan-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create IRMonteCarlo Pricer Object

Use `finpricer` to create an `IRMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("IRMonteCarlo",Model=BGM,DiscountCurve=myRC,SimulationDates=ZeroDates)
```

```
outPricer =
  BGMMonteCarlo with properties:

         NumTrials: 1000
      RandomNumbers: []
      DiscountCurve: [1x1 ratecurve]
    SimulationDates: [01-Jul-2019    01-Jan-2020    01-Jan-2021    ...    ]
              Model: [1x1 finmodel.BraceGatarekMusiela]
```

Price Floor Instrument

Use `price` to compute the price and sensitivities for the `Floor` instrument.

```
[Price,outPR] = price(outPricer,FloorOpt,["all"])
```

```
Price = 14.7975

outPR =
  priceresult with properties:

       Results: [1x3 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×3 table
    Price      Delta     Gamma
    ______    _______    ______
```

```

Use IRMonteCarlo Pricer and Black-Karasinski Model to Price Fixed Bond Instrument

This example shows the workflow to price a `FixedBond` instrument when using a `BlackKarasinski` model and an `IRMonteCarlo` pricing method.

Create FixedBond Instrument Object

Use `fininstrument` to create a `FixedBond` instrument object.

```
FixB = fininstrument("FixedBond",Maturity=datetime(2022,9,15),CouponRate=0.05,Name="fixed_bond")
```

```
FixB =
  FixedBond with properties:

                 CouponRate: 0.0500
                     Period: 2
                      Basis: 0
                EndMonthRule: 1
                   Principal: 100
   DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
                   Holidays: NaT
                  IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 15-Sep-2022
                        Name: "fixed_bond"
```

Create BlackKarasinski Model Object

Use `finmodel` to create a `BlackKarasinski` model object.

```
BlackKarasinskiModel = finmodel("BlackKarasinski",'Alpha',0.02,'Sigma',0.34)
```

```
BlackKarasinskiModel =
  BlackKarasinski with properties:

    Alpha: 0.0200
    Sigma: 0.3400
```

Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2019,1,1);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 01-Jan-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create IRMonteCarlo Pricer Object

Use `finpricer` to create an `IRMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("IRMonteCarlo",Model=BlackKarasinskiModel,DiscountCurve=myRC,SimulationDate
```

```
outPricer =
  BKMonteCarlo with properties:

          NumTrials: 1000
      RandomNumbers: []
      DiscountCurve: [1x1 ratecurve]
    SimulationDates: [15-Mar-2019    15-Sep-2019    15-Mar-2020    ...    ]
              Model: [1x1 finmodel.BlackKarasinski]
```

Price FixedBond Instrument

Use `price` to compute the price for the `FixedBond` instrument.

```
[Price,outPR] = price(outPricer,FixB,["all"])
```

```
Price = 113.3046
```

```
outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×4 table
    Price     Delta     Gamma      Vega
    _____    _______    ______    ______
```

```
    113.3    -310.39    -26741    2.0294
```

Version History

Introduced in R2021b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `IRMonteCarlo` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

Support for Black-Karasinski model

Behavior changed in R2022b

The name-value argument option for `Model` supports a `"BlackKarasinski"` binomial tree model.

`fininstrument` | `finmodel`

Topics

“Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22
“Choose Instruments, Models, and Pricers” on page 1-53

IRTree

Create `IRTree` pricer object for `Cap`, `Floor`, `Swap`, `Swaption`, `FloatBond`, `FixedBond`, `FixedBondOption`, `FloatBondOption`, `OptionEmbeddedFixedBond`, or `OptionEmbeddedFloatBond` instrument

Description

Create and price a `Cap`, `Floor`, `Swap`, `Swaption`, `FloatBond`, `FixedBond`, `FixedBondOption`, `FloatBondOption`, `OptionEmbeddedFixedBond`, or `OptionEmbeddedFloatBond` instrument object with a `HullWhite` or `BlackKarasinski` model and an `IRTree` pricing method using this workflow:

1. Use `fininstrument` to create a `Cap`, `Floor`, `Swaption`, `Swap`, `FloatBond`, `FixedBond`, `FixedBondOption`, `FloatBondOption`, `OptionEmbeddedFixedBond`, or `OptionEmbeddedFloatBond` instrument object.
2. Use `finmodel` to specify a `HullWhite`, `BlackKarasinski`, or `BlackDermanToy` model for the `Cap`, `Floor`, `Swaption`, `Swap`, `FixedBond`, `FloatBond`, `FixedBondOption`, `FloatBondOption`, `OptionEmbeddedFixedBond`, or `OptionEmbeddedFloatBond` instrument object.
3. Use `finpricer` to specify an `IRTree` pricer object for a BK, BDT, or HW trinomial tree model for the `Cap`, `Floor`, `Swaption`, `Swap`, `FixedBond`, `FloatBond`, `FixedBondOption`, `FloatBondOption`, `OptionEmbeddedFixedBond`, or `OptionEmbeddedFloatBond` instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a `Cap`, `Floor`, `Swaption`, `Swap`, `FixedBond`, `FloatBond`, `FloatBondOption`, `OptionEmbeddedFixedBond`, or `OptionEmbeddedFloatBond` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
IRTreePricerObj = finpricer(PricerType,'Model',model_type,'
DiscountCurve',ratecurve_obj,'TreeDates',tree_dates)
```

Description

`IRTreePricerObj = finpricer(PricerType,'Model',model_type,'DiscountCurve',ratecurve_obj,'TreeDates',tree_dates)` creates a `IRTree` pricer object by specifying `PricerType` and the required name-value pair arguments for `Model`, `DiscountCurve`, and `TreeDates` to set properties on page 11-3289 using name-value pair arguments. For example, `IRTreePricerObj =`

`finpricer("IRTree",'Model',HullWhite,'DiscountCurve',ratecure_obj,'TreeDates',['jan-30-2018';'jan-30-2019'])` creates an `IRTree` pricer object.

Input Arguments

`PricerType` — Pricer type

string with value `"IRTree"` | character vector with value `'IRTree'`

Pricer type, specified as a string with the value of `"IRTree"` or a character vector with the value of `'IRTree'`.

Data Types: `char` | `string`

`IRTree` Name-Value Pair Arguments

Specify required pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `IRTreePricerObj = finpricer("IRTree",'Model',HullWhite,'DiscountCurve',ratecure_obj,'TreeDates',['jan-30-2018';'jan-30-2019'])`

`Model` — Model type

`HullWhite` object | `BlackKarasinski` object | `BlackDermanToy` object

Model type, specified as the comma-separated pair consisting of `'Model'` and the name of a previously created `HullWhite`, `BlackKarasinski`, or `BlackDermanToy` model object. Create the model object using `finmodel`.

Note When you use a `HullWhite` model, the `IRTree` pricer uses the HW2000 algorithm [1].

Data Types: `object`

`DiscountCurve` — `ratecurve` object for creating `IRTree` and discounting cash flows

`ratecurve` object

This property is read-only.

`ratecurve` object for creating `IRTree` and discounting cash flows, specified as the comma-separated pair consisting of `'DiscountCurve'` and the name of a `ratecurve` object.

Data Types: `object`

`TreeDates` — Dates marking the cash flow dates of the tree

vector

Dates marking the cash flow dates of the tree, specified as the comma-separated pair consisting of `'TreeDates'` and an `NLEVELS`-by-`1` vector of dates. Cash flows with these dates will fall on tree nodes. The `TreeDates` argument determines the number of levels, or depth, of the tree. List dates in increasing order.

Data Types: `double` | `cell` | `datetime`

Properties

`Tree` — HW or BK trinomial tree

struct for HW or BK tree

HW or BK trinomial tree, returned as a struct with the following properties:

- `tObs` contains the time factor of each level of the tree.
- `dObs` contains the date of each level of the tree.
- `Probs` contains a cell array of 3-by-`N` numeric arrays with the up, mid, down probabilities of each node of the tree except for the last level. The cells in the cell array are ordered from root node. The arrays are 3-by-`N` with the first row corresponding to an up move, the mid row to a mid-move, and so on. Each column of the array represents a node starting from the top node of a given level.
- `CFlowT` is a cell array with as many elements as levels of the tree. Each cell array element contains the time factors (`tObs`) corresponding to its level of the tree and those levels ahead of it.
- `Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.
- `Connect` contains a cell array with connectivity information for each node of the tree. The arrangement is similar to `Probs`, with the exception that it has only one row in each cell. The number represents the node in the next level to which the middle branch connects to. The top branch connects to the value above (minus one) and the lower branch connects to the value below (plus one).
- `FwdTree` contains the forward spot rate from one node to the next. The forward spot rate is defined as the inverse of the discount factor.
- `RateTree` contains the interest rate from one node to the next.

Data Types: `struct`

`TreeDates` — Tree dates

datetime

Tree dates, returned as a scalar datetime or datetime array.

Data Types: `datetime`

`Model` — Model type

`HullWhite` object | `BlackKarasinski` object | `BlackDermanToy` object

Model type, returned as an object.

Data Types: `object`

`DiscountCurve` — `ratecurve` object for creating `IRTree` and discounting cash flows

`ratecurve` object

This property is read-only.

`ratecurve` object for creating the `IRTree` object and discounting cash flows, returned as a `ratecurve` object.

Data Types: `object`

Object Functions

price Compute price for interest-rate instrument with IRTree pricer

Examples

Use Hull-White Tree Pricer and Hull-White Model to Price FixedBondOption Instrument

This example shows the workflow to price a `FixedBondOption` instrument when you use a `HullWhite` model and an `IRTree` pricing method.

Create `FixedBond` Instrument Object

Use `fininstrument` to create a `FixedBond` instrument object as the underlying bond.

```
BondInst = fininstrument("FixedBond",'Maturity',datetime(2029,9,15),'CouponRate',0.025,'Period',
```

```
BondInst =
  FixedBond with properties:

                 CouponRate: 0.0250
                     Period: 1
                      Basis: 0
                EndMonthRule: 1
                   Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                    Holidays: NaT
                   IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 15-Sep-2029
                        Name: "fixed_bond_instrument"
```

Create `FixedBondOption` Instrument Object

Use `fininstrument` to create a `FixedBondOption` instrument object.

```
FixedBOption = fininstrument("FixedBondOption",'ExerciseDate',datetime(2025,9,15),'Strike',98,'Bo
```

```
FixedBOption =
  FixedBondOption with properties:

       OptionType: "call"
    ExerciseStyle: "european"
     ExerciseDate: 15-Sep-2025
           Strike: 98
             Bond: [1x1 fininstrument.FixedBond]
             Name: "fixed_bond_option_instrument"
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2019,9,15);
Type = 'zero';
ZeroTimes = [calyears([1:10])]';
ZeroRates = [0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307 0.0310]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create HullWhite Model Object

Use `finmodel` to create a `HullWhite` model object.

```
HullWhiteModel = finmodel("HullWhite",'Alpha',0.01,'Sigma',0.05)
```

```
HullWhiteModel =
  HullWhite with properties:

    Alpha: 0.0100
    Sigma: 0.0500
```

Create IRTree Pricer Object

Use `finpricer` to create an `IRTree` pricer object and use the `ratecurve` object with the `'DiscountCurve'` name-value pair argument.

```
HWTreePricer = finpricer("irtree",'Model',HullWhiteModel,'DiscountCurve',myRC,'TreeDates',ZeroDa
```

```
HWTreePricer =
  HWBKTree with properties:

            Tree: [1x1 struct]
       TreeDates: [10x1 datetime]
           Model: [1x1 finmodel.HullWhite]
   DiscountCurve: [1x1 ratecurve]
```

```
HWTreePricer.Tree
```

```
ans = struct with fields:
        tObs: [0 1 1.9973 2.9945 3.9918 4.9918 5.9891 6.9863 7.9836 8.9836]
        dObs: [15-Sep-2019    15-Sep-2020    15-Sep-2021    ...    ]
      CFlowT: {1x10 cell}
       Probs: {1x9 cell}
     Connect: {1x9 cell}
```

```
     FwdTree: {1x10 cell}
    RateTree: {1x10 cell}
```

Price FixedBondOption Instrument

Use `price` to compute the price and sensitivities for the `FixedBondOption` instrument.

```
[Price, outPR] = price(HWTreePricer,FixedBOption,["all"])
```

```
Price = 11.1739

outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×4 table
    Price      Delta     Gamma      Vega
    ______    _______    ______    ______

    11.174    -272.19    3667.6    243.09
```

Use Black-Karasinski Tree Pricer and Black-Karasinski Model to Price FixedBondOption Instrument

This example shows the workflow to price a `FixedBondOption` instrument when you use a `BlackKarasinski` model and an `IRTree` pricing method.

Create FixedBond Instrument Object

Use `fininstrument` to create a `FixedBond` instrument object as the underlying bond.

```
BondInst = fininstrument("FixedBond",'Maturity',datetime(2029,9,15),'CouponRate',0.025,'Period',1
```

```
BondInst =
  FixedBond with properties:

                 CouponRate: 0.0250
                     Period: 1
                      Basis: 0
                EndMonthRule: 1
                  Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                   Holidays: NaT
                  IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 15-Sep-2029
```

```
                    Name: "fixed_bond_instrument"
```

Create FixedBondOption Instrument Object

Use `fininstrument` to create a `FixedBondOption` instrument object.

```
FixedBOption = fininstrument("FixedBondOption",'ExerciseDate',datetime(2025,9,15),'Strike',100,'
```

```
FixedBOption =
  FixedBondOption with properties:

       OptionType: "call"
    ExerciseStyle: "european"
     ExerciseDate: 15-Sep-2025
           Strike: 100
             Bond: [1x1 fininstrument.FixedBond]
             Name: "fixed_bond_option"
```

Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2019,9,15);
Type = 'zero';
ZeroTimes = [calyears([1:10])]';
ZeroRates = [0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307 0.0310]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
       Compounding: -1
             Basis: 0
             Dates: [10x1 datetime]
             Rates: [10x1 double]
            Settle: 15-Sep-2019
      InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create BlackKarasinski Model Object

Use `finmodel` to create a `BlackKarasinski` model object.

```
BlackKarasinskiModel = finmodel("BlackKarasinski",'Alpha',0.02,'Sigma',0.34)
```

```
BlackKarasinskiModel =
  BlackKarasinski with properties:

    Alpha: 0.0200
    Sigma: 0.3400
```

Create IRTree Pricer Object

Use `finpricer` to create an `IRTree` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
BKTreePricer = finpricer("IRTree",'Model',BlackKarasinskiModel,'DiscountCurve',myRC,'TreeDates',
```

```
BKTreePricer =
  HWBKTree with properties:

             Tree: [1x1 struct]
        TreeDates: [10x1 datetime]
            Model: [1x1 finmodel.BlackKarasinski]
    DiscountCurve: [1x1 ratecurve]
```

```
BKTreePricer.Tree
```

```
ans = struct with fields:
        tObs: [0 1 1.9973 2.9945 3.9918 4.9918 5.9891 6.9863 7.9836 8.9836]
        dObs: [15-Sep-2019    15-Sep-2020    15-Sep-2021    ...    ]
      CFlowT: {1x10 cell}
       Probs: {1x9 cell}
     Connect: {1x9 cell}
     FwdTree: {1x10 cell}
    RateTree: {1x10 cell}
```

Price FixedBondOption Instrument

Use `price` to compute the price and sensitivities for the `FixedBondOption` instrument.

```
[Price, outPR] = price(BKTreePricer,FixedBOption,["all"])
```

```
Price = 0.5814
```

```
outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×4 table
     Price      Delta     Gamma     Vega
    _______    _______    ______    _____

    0.58143    -15.842    45.702    2.793
```

Use Hull-White Tree Pricer and Hull-White Model to Price Vanilla FixedBond Instrument

This example shows the workflow to price a vanilla `FixedBond` instrument when you use a `HullWhite` model and an `IRTree` pricing method.

Create FixedBond Instrument Object

Use `fininstrument` to create a `FixedBond` instrument object.

```
Maturity = datetime(2024,1,1);
Period = 1;
VBond = fininstrument("FixedBond",'Maturity', Maturity,'CouponRate', 0.025,'Period',Period)
```

```
VBond =
  FixedBond with properties:

                 CouponRate: 0.0250
                     Period: 1
                      Basis: 0
                EndMonthRule: 1
                   Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                    Holidays: NaT
                   IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 01-Jan-2024
                        Name: ""
```

Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,1,1);
ZeroTimes = calyears(1:10)';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
Compounding = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates, "Compounding",Compounding);
```

Create HullWhite Model Object

Use `finmodel` to create a `HullWhite` model object.

```
VolCurve = 0.01;
AlphaCurve = 0.1;

HWModel = finmodel("HullWhite",'alpha',AlphaCurve,'sigma',VolCurve);
```

Create IRTree Pricer Object

Use `finpricer` to create an `IRTree` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
HWTreePricer = finpricer("IRTree",'Model',HWModel,'DiscountCurve',ZeroCurve,'TreeDates',ZeroDates
```

```
HWTreePricer =
  HWBKTree with properties:

            Tree: [1x1 struct]
       TreeDates: [10x1 datetime]
```

```
            Model: [1x1 finmodel.HullWhite]
    DiscountCurve: [1x1 ratecurve]
```

Price FixedBond Instrument

Use `price` to compute the price and sensitivities for the vanilla `FixedBond` instrument.

```
[Price, outPR] = price(HWTreePricer, VBond,["all"])
```

```
Price = 107.7023
```

```
outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×4 table
    Price     Delta     Gamma     Vega
    _____    _______    ______    ____

    107.7    -602.56    4086.4     0
```

Use Hull-White Tree Pricer and Hull-White Model to Price Vanilla FloatBond Instrument

This example shows the workflow to price a vanilla `FloatBond` instrument when you use a `HullWhite` model and an `IRTree` pricing method.

Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,1,1);
ZeroTimes = calyears(1:10)';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
Compounding = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates, "Compounding",Compounding);
```

Create FloatBond Instrument Object

Use `fininstrument` to create a vanilla `FloatBond` instrument object.

```
Spread = 0.03;
Reset = 1;
Maturity = datetime(2024,1,1);
Period = 1;
Float = fininstrument("FloatBond",'Maturity',Maturity,'Spread',Spread,'Reset',Reset,'ProjectionCu
```

```
Float =
  FloatBond with properties:
```

```
                    Spread: 0.0300
              ProjectionCurve: [1x1 ratecurve]
                  ResetOffset: 0
                        Reset: 1
                        Basis: 0
                 EndMonthRule: 1
                    Principal: 100
      DaycountAdjustedCashFlow: 0
         BusinessDayConvention: "actual"
            LatestFloatingRate: NaN
                     Holidays: NaT
                    IssueDate: NaT
              FirstCouponDate: NaT
               LastCouponDate: NaT
                    StartDate: NaT
                     Maturity: 01-Jan-2024
                         Name: ""
```

Create HullWhite Model Object

Use `finmodel` to create a `HullWhite` model object.

```
VolCurve = 0.01;
AlphaCurve = 0.1;

HWModel = finmodel("HullWhite",'alpha',AlphaCurve,'sigma',VolCurve);
```

Create IRTree Pricer Object

Use `finpricer` to create an `IRTree` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
HWTreePricer = finpricer("IRTree",'Model',HWModel,'DiscountCurve',ZeroCurve,'TreeDates',ZeroDates
```

```
HWTreePricer =
  HWBKTree with properties:

              Tree: [1x1 struct]
         TreeDates: [10x1 datetime]
             Model: [1x1 finmodel.HullWhite]
     DiscountCurve: [1x1 ratecurve]
```

Price FloatBond Instrument

Use `price` to compute the price and sensitivities for the vanilla `FloatBond` instrument.

```
[Price, outPR] = price(HWTreePricer,Float,["all"])
```

```
Price = 117.4686
```

```
outPR =
  priceresult with properties:

        Results: [1x4 table]
     PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×4 table
    Price      Delta     Gamma     Vega
    _____    ________    _____    ____

    117.47    -60.007    315.09     0
```

Use BlackDermanToy Tree Pricer and Black-Derman-Toy Model to Price FixedBondOption Instrument

This example shows the workflow to price a `FixedBondOption` instrument when you use a `BlackDermanToy` model and an `IRTree` pricing method.

Create FixedBond Instrument Object

Use `fininstrument` to create a `FixedBond` instrument object as the underlying bond.

```
BondInst = fininstrument("FixedBond",Maturity=datetime(2029,9,15),CouponRate=.024,Principal=100,I
```

```
BondInst =
  FixedBond with properties:

                 CouponRate: 0.0240
                     Period: 1
                      Basis: 1
                EndMonthRule: 1
                   Principal: 100
   DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
                   Holidays: NaT
                  IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 15-Sep-2029
                        Name: "fixed_bond"
```

Create FixedBondOption Instrument Object

Use `fininstrument` to create a `FixedBondOption` instrument object.

```
FixedBOption = fininstrument("FixedBondOption",ExerciseDate=datetime(2025,9,15),Strike=800,Bond=F
```

```
FixedBOption =
  FixedBondOption with properties:

      OptionType: "put"
   ExerciseStyle: "american"
    ExerciseDate: 15-Sep-2025
          Strike: 800
            Bond: [1x1 fininstrument.FixedBond]
            Name: "fixed_bond_option"
```

Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2019,9,15);
Type = 'zero';
ZeroTimes = [calyears(1:10)]';
ZeroRates = [0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307 0.0310]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates,Basis=5)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 5
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create BlackDermanToy Model Object

Use finmodel to create a BlackDermanToy model object.

```
BlackDermanToyModel = finmodel("BlackDermanToy",Sigma=0.14)
```

```
BlackDermanToyModel =
  BlackDermanToy with properties:

    Sigma: 0.1400
```

Create IRTree Pricer Object

Use finpricer to create an IRTree pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
BKTreePricer = finpricer("IRTree",Model=BlackDermanToyModel,DiscountCurve=myRC,TreeDates=ZeroDate
```

```
BKTreePricer =
  BDTTree with properties:

            Tree: [1x1 struct]
       TreeDates: [10x1 datetime]
           Model: [1x1 finmodel.BlackDermanToy]
    DiscountCurve: [1x1 ratecurve]
```

```
BKTreePricer.Tree
```

```
ans = struct with fields:
        tObs: [0 1 2 3 4 5 6 7 8 9]
        dObs: [15-Sep-2019    15-Sep-2020    15-Sep-2021    ...    ]
```

```
     FwdTree: {1x10 cell}
    RateTree: {1x10 cell}
```

Price FixedBondOption Instrument

Use `price` to compute the price and sensitivities for the `FixedBondOption` instrument.

```
[Price, outPR] = price(BKTreePricer,FixedBOption,"all")

Price = 705.2729

outPR =
  priceresult with properties:

       Results: [1x4 table]
    PricerData: [1x1 struct]

outPR.Results

ans=1×4 table
    Price     Delta      Gamma        Vega
    ______    ______    _______    __________

    705.27    844.75    -8084.8    7.0486e-08
```

Version History

Introduced in R2020a

Support for Black-Derman-Toy model

Behavior changed in R2022b

The name-value argument option for `Model` supports a `"BlackDermanToy"` binomial tree model.

AssetTree

Create `AssetTree` pricer object for `Vanilla`, `Barrier`, `Asian`, or `Lookback` instrument

Description

Create and price a `Vanilla`, `Barrier`, `Asian`, or `Lookback` instrument object with a `BlackScholes` model and an `AssetTree` pricing method using this workflow:

1. Use `fininstrument` to create a `Vanilla`, `Lookback`, `Barrier`, or `Asian` instrument object.
2. Use `finmodel` to specify a `BlackScholes` model for the `Vanilla`, `Barrier`, `Asian`, or `Lookback` instrument object.
3. Use `finpricer` to specify an `AssetTree` pricer object for a Cox-Ross-Rubinstein (CRR), equal-probability (EQP), Leisen-Reimer (LR), or Standard Trinomial (ST) lattice tree model for the `Vanilla`, `Barrier`, `Asian`, or `Lookback` instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a `Vanilla`, `Barrier`, `Asian`, or `Lookback` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
AssetTreePricerObj = finpricer(PricerType,'Model',model_type,'
DiscountCurve',ratecurve_obj,'SpotPrice',spot_price)
AssetTreePricerObj = finpricer(___,Name,Value)
```

Description

`AssetTreePricerObj = finpricer(PricerType,'Model',model_type,'DiscountCurve',ratecurve_obj,'SpotPrice',spot_price)` creates an `AssetTree` pricer object by specifying `PricerType` and the required name-value pair arguments for `Model`, `DiscountCurve`, and `SpotPrice`.

`AssetTreePricerObj = finpricer(___,Name,Value)` sets optional properties on page 11-3304 using additional name-value pair arguments in addition to the required arguments in the previous syntax. For example, `AssetTreePricerObj = finpricer("AssetTree",'Model',BlackScholes,'DiscountCurve',ratecure_obj,'SpotPrice',1000)` creates an `AssetTree` pricer object.

Input Arguments

`PricerType` — Pricer type
string with value `"AssetTree"` | character vector with value `'AssetTree'`

Pricer type, specified as a string with the value of "AssetTree" or a character vector with the value of 'AssetTree'.

Data Types: char | string

AssetTree Name-Value Pair Arguments

Specify required and optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: AssetTreePricerObj = finpricer("AssetTree",'Model',BlackScholes,'DiscountCurve',ratecure_obj,'Spot Price',1000)

Model — Model
BlackScholes object

Model, specified as the comma-separated pair consisting of 'Model' and the name of the previously created BlackScholes model object using finmodel.

Data Types: object

DiscountCurve — ratecurve object for creating AssetTree object and discounting cash flows
ratecurve object

This property is read-only.

ratecurve object for creating the AssetTree object and discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of a ratecurve object.

Data Types: object

SpotPrice — Underlying spot price
scalar numeric

Underlying spot price, specified as the comma-separated pair consisting of 'SpotPrice' and a scalar numeric.

Data Types: double

Optional AssetTree Name-Value Pair Arguments

PricingMethod — Asset pricing method
"CoxRossRubinstein" (default) | string with value "CoxRossRubinstein", "EqualProbability", "LeisenReimer", or "StandardTrinomial" | character vector with value 'CoxRossRubinstein', 'EqualProbability', 'LeisenReimer', or "StandardTrinomial"

Asset pricing method, specified as the comma-separated pair consisting of 'PricingMethod' and a string or character vector.

Data Types: char | string

Maturity — Maturity date
datetime scalar | string scalar | date character vector

Maturity date, specified as the comma-separated pair consisting of `'Maturity'` and a scalar datetime, string, or date character vector.

To support existing code, `AssetTree` also accepts serial date numbers as inputs, but they are not recommended.

If you use a date character vector or string, the format must be recognizable by `datetime` because the `Maturity` property is stored as a datetime.

`NumPeriods` — Number of levels or time steps of the tree
`10` (default) | numeric

Number of levels or time steps of the tree, specified as the comma-separated pair consisting of `'NumPeriods'` and a scalar.

Data Types: `double`

`DividendType` — Stock dividend type
`"continuous"` (default) | string with value `"cash"` or `"continuous"` | character vector with value `'cash'` or `'continuous'`

Stock dividend type, specified as the comma-separated pair consisting of `'DividendType'` and a string or character vector. `DividendType` must be `"cash"` for actual dollar dividends or `"continuous"` for a continuous dividend yield.

Data Types: `char` | `string`

`DividendValue` — Dividend amount or dividend schedule for underlying stock
`0` (default) | scalar numeric | timetable

Dividend amount or dividend schedule for the underlying stock, specified as the comma-separated pair consisting of `'DividendValue'` and a scalar numeric for a dividend amount or a timetable for a dividend schedule.

Note `DividendValue` must be a scalar for a `"continuous"` `DividendType` or a timetable for `"cash"` `DividendType`.

Data Types: `double` | `timetable`

`Strike` — Option strike used with Leisen-Reimer pricing method
`SpotPrice` (default) | nonnegative numeric

Option strike used with the Leisen-Reimer pricing method, specified as the comma-separated pair consisting of `'Strike'` and a scalar nonnegative numeric.

Data Types: `double`

`InversionMethod` — Inversion method for Leisen-Reimer pricing method
`'PP1'` (default) | string with value `"PP1"` or `"PP2"` | character vector with value `'PP1'` or `'PP2'`

Inversion method for the Leisen-Reimer pricing method, specified as the comma-separated pair consisting of `'InversionMethod'` and a string or character vector.

- `'PP1'` — Peizer-Pratt method 1 inversion

- `'PP2'` — Peizer-Pratt method 2 inversion

Data Types: `string` | `char`

Properties

`InversionMethod` — Inversion method for Leisen-Reimer pricing method

`'PP1'` (default) | string with value `"PP1"` or `"PP2"`

Inversion method for the Leisen-Reimer pricing method, returned as a string.

Data Types: `string`

`Strike` — Option strike used with Leisen-Reimer pricing method

`SpotPrice` (default) | nonnegative numeric

Option strike used with the Leisen-Reimer pricing method, returned as a nonnegative numeric.

Data Types: `double`

`Tree` — CRR, EQP, LR binomial tree or STT trinomial tree

structure

CRR, EQP, LR binomial tree or STT trinomial tree, returned as a structure with the following properties:

- `Probs` contains a 2-by-`NumLevels` numeric array with the up and down probabilities that apply to each level of the tree except for the last one. All nodes in a given level share the same up and down probabilities. The columns of the `Probs` array are ordered from the root node. The first row of the array corresponds to the probability of an up move, while the second row corresponds to a down move.
- `ATree` contains the price tree for the underlying asset.
- `dObs` contains the date of each level of the tree.
- `tObs` contains the time factor of each level of the tree.

Data Types: `struct`

`NumPeriods` — Number of levels or time steps of the tree

numeric

Number of levels or time steps of the tree, returned as a numeric.

Data Types: `datetime`

`Model` — Model type

object

Model type, returned as an object.

Data Types: `object`

`DiscountCurve` — `ratecurve` object for creating `AssetTree` object and discounting cash flows

`ratecurve` object

This property is read-only.

`ratecurve` object for creating the `AssetTree` object and discounting cash flows, returned as a `ratecurve` object.

Data Types: `object`

`SpotPrice` — Current price of underlying asset
nonnegative numeric

Current price of the underlying asset, returned as a scalar nonnegative numeric.

Data Types: `double`

`DividendType` — Stock dividend type
`"continuous"` (default) | string with value `"cash"` or `"continuous"`

This property is read-only.

Stock dividend type, returned as a string. `DividendType` is either `"cash"` for actual dollar dividends or `"continuous"` for a continuous dividend yield.

Data Types: `string`

`DividendValue` — Dividend amount or dividend schedule for underlying stock
`0` (default) | scalar nonnegative numeric | timetable

Dividend amount or dividend schedule for the underlying stock, returned as a scalar nonnegative numeric for a dividend yield or a timetable for a dividend schedule.

Data Types: `double` | `timetable`

`TreeDates` — Tree dates
datetime

Tree dates, returned as a scalar datetime or datetime array.

Data Types: `datetime`

Object Functions

price Compute price for equity instrument with AssetTree pricer

Examples

Use Leisen-Reimer Tree Pricer and Black-Scholes Model to Price Vanilla Instrument

This example shows the workflow to price a `Vanilla` instrument when you use a `BlackScholes` model and an `AssetTree` pricing method.

Create `Vanilla` Instrument Object

Use `fininstrument` to create a `Vanilla` instrument object.

```
VanillaOpt = fininstrument("Vanilla",'ExerciseDate',datetime(2019,5,1),'Strike',29,'OptionType','
```

```
VanillaOpt =
  Vanilla with properties:
```

```
       OptionType: "put"
    ExerciseStyle: "european"
     ExerciseDate: 01-May-2019
           Strike: 29
             Name: "vanilla_option"
```

Create BlackScholes Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.25)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.2500
    Correlation: 1
```

Create ratecurve Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,1,1);
Maturity = datetime(2020,1,1);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',1)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 1
               Dates: 01-Jan-2020
               Rates: 0.0350
              Settle: 01-Jan-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create AssetTree Pricer Object

Use `finpricer` to create an `AssetTree` pricer object for an LR equity tree and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
LRPricer = finpricer("AssetTree",'DiscountCurve',myRC,'Model',BlackScholesModel,'SpotPrice',30,'
```

```
LRPricer =
  LRTree with properties:

    InversionMethod: PP1
             Strike: 30
               Tree: [1x1 struct]
        NumPeriods: 15
              Model: [1x1 finmodel.BlackScholes]
      DiscountCurve: [1x1 ratecurve]
```

```
          SpotPrice: 30
       DividendType: "continuous"
      DividendValue: 0
          TreeDates: [02-Feb-2018 08:00:00    06-Mar-2018 16:00:00    ...    ]
```

Price `Vanilla` Instrument

Use `price` to compute the price and sensitivities for the `Vanilla` instrument.

```
[Price, outPR] = price(LRPricer,VanillaOpt,"all")
```

```
Price = 2.2542

outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta       Gamma       Vega     Lambda      Rho       Theta
    ______    ________    ________    ______    ______    _______    ________

    2.2542    -0.33628    0.044039    12.724    -4.469    -16.433    -0.76073
```

Use Standard Trinomial Tree Pricer and Black-Scholes Model to Price Vanilla Instrument

This example shows the workflow to price a `Vanilla` instrument when you use a `BlackScholes` model and an `AssetTree` pricing method for a Standard Trinomial (STT) tree.

Create `Vanilla` Instrument Object

Use `fininstrument` to create a `Vanilla` instrument object.

```
VanillaOpt = fininstrument("Vanilla",'ExerciseDate',datetime(2019,5,1),'Strike',29,'OptionType','
```

```
VanillaOpt =
  Vanilla with properties:

       OptionType: "put"
    ExerciseStyle: "european"
     ExerciseDate: 01-May-2019
           Strike: 29
             Name: "vanilla_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.25)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.2500
    Correlation: 1
```

Create ratecurve Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,1,1);
Maturity = datetime(2020,1,1);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',1)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 1
               Dates: 01-Jan-2020
               Rates: 0.0350
              Settle: 01-Jan-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create AssetTree Pricer Object

Use `finpricer` to create an `AssetTree` pricer object for an Standard Trinomial equity tree and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
STTPricer = finpricer("AssetTree",'DiscountCurve',myRC,'Model',BlackScholesModel,'SpotPrice',30,
```

```
STTPricer =
  STTree with properties:

            Tree: [1x1 struct]
       NumPeriods: 15
            Model: [1x1 finmodel.BlackScholes]
    DiscountCurve: [1x1 ratecurve]
        SpotPrice: 30
     DividendType: "continuous"
    DividendValue: 0
        TreeDates: [02-Feb-2018 08:00:00    06-Mar-2018 16:00:00    ...    ]
```

Price Vanilla Instrument

Use `price` to compute the price and sensitivities for the `Vanilla` instrument.

```
[Price, outPR] = price(STTPricer,VanillaOpt,"all")
```

```
Price = 2.2826
```

```
outPR =
  priceresult with properties:
```

```
       Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta      Gamma      Vega     Lambda       Rho       Theta
    _____    ________    _________    _____    _______    _______    _________

    2.2826    -0.2592    0.030949    12.51    -3.8981    -16.516    -0.73845
```

Version History

Introduced in R2021a

Support for Standard Trinomial Tree model

The name-value argument option for `PricingMethod` supports a `"StandardTrinomial"` lattice tree model.

Serial date numbers not recommended

Not recommended starting in R2022b

Although `AssetTree` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

KemnaVorst

Create `KemnaVorst` pricer object for `Asian` instrument using `BlackScholes` model

Description

Create and price a `Asian` instrument object with a `BlackScholes` model and a `KemnaVorst` pricing method using this workflow:

1. Use `fininstrument` to create an `Asian` instrument object.
2. Use `finmodel` to specify a `BlackScholes` model for the `Asian` instrument object.
3. Use `finpricer` to specify a `KemnaVorst` pricer object for the `Asian` instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for an `Asian` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
KemnaVorstPricerObj = finpricer(PricerType,'DiscountCurve',ratecurve_obj,'
Model',model,'SpotPrice',spotprice_value)
KemnaVorstPricerObj = finpricer(___,Name,Value)
```

Description

`KemnaVorstPricerObj = finpricer(PricerType,'DiscountCurve',ratecurve_obj,'Model',model,'SpotPrice',spotprice_value)` creates a `KemnaVorst` pricer object by specifying `PricerType` and sets the properties on page 11-3313 for the required name-value pair arguments `DiscountCurve`, `Model`, and `SpotPrice`.

`KemnaVorstPricerObj = finpricer(___,Name,Value)` to set optional properties on page 11-3313 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `KemnaVorstPricerObj = finpricer("Analytic",'DiscountCurve',ratecurve_obj,'Model',BSModel,'SpotPrice',1000,'DividendType',"continuous",'DividendValue',100,'PricingMethod',"KemnaVorst")` creates a `KemnaVorst` pricer object.

Input Arguments

`PricerType` — Pricer type

string with value `"Analytic"` | character vector with value `'Analytic'`

Pricer type, specified as a string with the value of `"Analytic"` or a character vector with the value of `'Analytic'`.

Data Types: char | string

KemnaVorst Name-Value Pair Arguments

Specify required and optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: KemnaVorstPricerObj = finpricer("Analytic",'DiscountCurve',ratecurve_obj,'Model',BSModel,'SpotPrice',1000,'DividendType',"continuous",'DividendValue',100,'PricingMethod',"KemnaVorst")

Required KemnaVorst Name-Value Pair Arguments

DiscountCurve — ratecurve object for discounting cash flows
ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of the previously created ratecurve object.

Note Specify a flat ratecurve object for DiscountCurve. If you use a nonflat ratecurve object, the software uses the rate in the ratecurve object at Maturity and assumes that the value is constant for the life of the equity option.

Data Types: object

Model — Model
BlackScholes model object

Model, specified as the comma-separated pair consisting of 'Model' and the name of a previously created BlackScholes model object using finmodel.

Data Types: object

SpotPrice — Current price of underlying asset
nonnegative numeric

Current price of the underlying asset, specified as the comma-separated pair consisting of 'SpotPrice' and a scalar nonnegative numeric.

Data Types: double

Optional KemnaVorst Name-Value Pair Arguments

DividendType — Stock dividend type
"continuous" (default) | string with value "cash" or "continuous" | character vector with value 'cash' or 'continuous'

Stock dividend type, specified as the comma-separated pair consisting of 'DividendType' and a string or character vector. DividendType must be "cash" for actual dollar dividends or "continuous" for a continuous dividend yield.

Data Types: char | string

`DividendValue` — Dividend amount or dividend schedule for underlying stock
`0` (default) | scalar numeric | timetable

Dividend amount for the underlying stock, specified as the comma-separated pair consisting of `'DividendValue'` and a scalar numeric for a dividend amount or a timetable for a dividend schedule.

Note `DividendValue` must be a scalar for a `"continuous"` `DividendType` or a timetable for `"cash"` `DividendType`.

Data Types: `double` | `timetable`

`PricingMethod` — Analytic pricing method
default pricer associated with `BlackScholes` model (default) | string with value `"KemnaVorst"` | character vector with value `'KemnaVorst'`

Analytic pricing method, specified as the comma-separated pair consisting of `'PricingMethod'` and a string or character vector.

Note The default pricing method for a `BlackScholes` model is a `BlackScholes` pricer.

Data Types: `double`

Properties

`DiscountCurve` — `ratecurve` object for discounting cash flows
object

This property is read-only.

`ratecurve` object for discounting cash flows, returned as a `ratecurve` object.

Data Types: `object`

`Model` — Model
`BlackScholes` model object

Model, returned as a `BlackScholes` model object.

Data Types: `object`

`SpotPrice` — Current price of underlying asset
nonnegative numeric

Current price of the underlying asset, returned as a scalar nonnegative numeric.

Data Types: `double`

`DividendType` — Stock dividend type
`"continuous"` (default) | string with value `"cash"` or `"continuous"`

This property is read-only.

Stock dividend type, returned as a string. `DividendType` is either `"cash"` for actual dollar dividends or `"continuous"` for a continuous dividend yield.

Data Types: `string`

`DividendValue` — Dividend amount or dividend schedule for underlying stock
`0` (default) | scalar nonnegative numeric | timetable

Dividend amount or dividend schedule for the underlying stock, returned as a scalar numeric for a dividend yield or a timetable for a dividend schedule.

Data Types: `double` | `timetable`

`PricingMethod` — Analytic pricing method
default pricer associated with `BlackScholes` model (default) | string with value `"KemnaVorst"`

Analytic pricing method, returned as a string.

Data Types: `string`

Object Functions

price Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

Examples

Use Kemna-Vorst Pricer and Black-Scholes Model to Price Asian Instrument

This example shows the workflow to price an `Asian` instrument when you use a `BlackScholes` model and a `KemnaVorst` pricing method.

Create `Asian` Instrument Object

Use `fininstrument` to create an `Asian` instrument object.

```
AsianOpt = fininstrument("Asian",'ExerciseDate',datetime(2022,9,15),'Strike',105,'OptionType',"pu
```

```
AsianOpt =
  Asian with properties:

         OptionType: "put"
             Strike: 105
        AverageType: "geometric"
       AveragePrice: 0
   AverageStartDate: NaT
      ExerciseStyle: "european"
       ExerciseDate: 15-Sep-2022
               Name: "asian_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.32)
```

```
BlackScholesModel =
  BlackScholes with properties:
```

```
     Volatility: 0.3200
    Correlation: 1
```

Create ratecurve Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create KemnaVorst Pricer Object

Use `finpricer` to create a `KemnaVorst` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPrice',100,
```

```
outPricer =
  KemnaVorst with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 100
    DividendValue: 0.0500
     DividendType: "continuous"
```

Price Asian Instrument

Use `price` to compute the price and sensitivities for the `Asian` instrument.

```
[Price, outPR] = price(outPricer,AsianOpt,["all"])
```

```
Price = 18.1186
```

```
outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta        Gamma       Lambda     Vega       Rho        Theta
    ______    ________    _________    ______    ______    _______    _______

    18.119    -0.44689    0.0087391    -3.025    64.582    -251.23    -1.5738
```

Kirk

Create `Kirk` pricer object for `Spread` instrument using `BlackScholes` model

Description

Create and price a `Spread` instrument object with a `BlackScholes` model and a `Kirk` pricing method using this workflow:

1. Use `fininstrument` to create a `Spread` instrument object.
2. Use `finmodel` to specify a `BlackScholes` model for the `Spread` instrument object.
3. Use `finpricer` to specify a `Kirk` pricer object for the `Spread` instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a `Spread` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
KirkPricerObj = finpricer(PricerType,'DiscountCurve',ratecurve_obj,'
Model',model,'SpotPrice',spotprice_value)
KirkPricerObj = finpricer(___,Name,Value)
```

Description

`KirkPricerObj = finpricer(PricerType,'DiscountCurve',ratecurve_obj,'Model',model,'SpotPrice',spotprice_value)` creates a `Kirk` pricer object by specifying `PricerType` and sets the properties on page 11-3319 for the required name-value pair arguments `DiscountCurve`, `Model`, and `SpotPrice`.

`KirkPricerObj = finpricer(___,Name,Value)` to set optional properties on page 11-3319 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `KirkPricerObj = finpricer("Analytic",'DiscountCurve',ratecurve_obj,'Model',BSModel,'SpotPrice',[100;105],'DividendValue',[2.5,2.8],'PricingMethod',"Kirk")` creates a `Kirk` pricer object.

Input Arguments

`PricerType` — Pricer type

string with value `"Analytic"` | character vector with value `'Analytic'`

Pricer type, specified as a string with the value of `"Analytic"` or a character vector with the value of `'Analytic'`.

Data Types: char | string

Kirk Name-Value Pair Arguments

Specify required and optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: KirkPricerObj = finpricer("Analytic",'DiscountCurve',ratecurve_obj,'Model',BSModel,'SpotPrice',[100;105],'DividendValue',[2.5,2.8],'PricingMethod',"Kirk")

Required Kirk Name-Value Pair Arguments

DiscountCurve — ratecurve object for discounting cash flows
ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of a previously created ratecurve object.

Note Specify a flat ratecurve object for DiscountCurve. If you use a nonflat ratecurve object, the software uses the rate in the ratecurve object at Maturity and assumes that the value is constant for the life of the equity option.

Data Types: object

Model — Model
BlackScholes model object

Model object, specified as the comma-separated pair consisting of 'Model' and the name of a previously created BlackScholes model object using finmodel.

Data Types: object

SpotPrice — Current price of underlying asset
scalar nonnegative numeric | cell array of nonnegative numerics

Current price of the underlying asset, specified as the comma-separated pair consisting of 'SpotPrice' and a scalar or cell array of nonnegative numerics.

Data Types: double

Optional Kirk Name-Value Pair Arguments

DividendType — Dividend type
"continuous" (default) | string with value "continuous" | character vector with value 'continuous'

Dividend type, specified as the comma-separated pair consisting of 'DividendType' and a string or character vector for a continuous dividend yield.

Data Types: char | string

`DividendValue` — Dividend yield for underlying asset
`[0,0]` (default) | scalar nonnegative numeric | vector of nonnegative numerics

Dividend yield for the underlying asset, specified as the comma-separated pair consisting of `'DividendValue'` and a scalar or a vector of nonnegative numerics. Use a vector of nonnegative values for `DividendValue` when pricing a `Spread` instrument.

Data Types: `double`

`PricingMethod` — Analytic pricing method
default pricer associated with `BlackScholes` model (default) | string with value `"Kirk"` | character vector with value `'Kirk'`

Analytic pricing method, specified as the comma-separated pair consisting of `'PricingMethod'` and a string or character vector.

Note The default pricing method for a `BlackScholes` model is a `BlackScholes` pricer.

Data Types: `double`

Properties

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

This property is read-only.

`ratecurve` object for discounting cash flows, returned as a `ratecurve` object.

Data Types: `object`

`Model` — Model
`BlackScholes` model object

Model, returned as a `BlackScholes` model object.

Data Types: `object`

`SpotPrice` — Current price of underlying asset
required input (default) | scalar nonnegative numeric | vector of nonnegative numerics

Current price of the underlying asset, returned as a scalar or vector of nonnegative numeric values.

Data Types: `double`

`DividendType` — Dividend type
`"continuous"` (default) | string with value `"continuous"`

This property is read-only.

Dividend type, returned as a string.

Data Types: `string`

`DividendValue` — Dividend yield for underlying stock
`[0,0]` (default) | scalar nonnegative numeric | vector of nonnegative numerics

Dividend yield for the underlying stock, returned as a scalar or vector of nonnegative numerics.

Data Types: `double`

`PricingMethod` — Analytic pricing method
default pricer associated with `BlackScholes` model (default) | string with value `"Kirk"`

Analytic pricing method, returned as a string.

Data Types: `string`

Object Functions

price Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

Examples

Use Kirk Pricer and Black-Scholes Model to Price Spread Instrument

This example shows the workflow to price a `Spread` instrument when you use a `BlackScholes` model and a `Kirk` pricing method.

Create `Spread` Instrument Object

Use `fininstrument` to create a `Spread` instrument object.

```
SpreadOpt = fininstrument("Spread",'Strike',5,'ExerciseDate',datetime(2021,9,15),'OptionType',"pu
```

```
SpreadOpt =
  Spread with properties:

       OptionType: "put"
           Strike: 5
    ExerciseStyle: "european"
     ExerciseDate: 15-Sep-2021
             Name: "spread_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',[0.2 , 0.1])
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: [0.2000 0.1000]
    Correlation: [2x2 double]
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
```

```
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create Kirk Pricer Object

Use `finpricer` to create a `Kirk` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPrice',[103
```

```
outPricer =
  Kirk with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: [103 105]
    DividendValue: [0.0250 0.0280]
     DividendType: "continuous"
```

Price Spread Instrument

Use `price` to compute the price and sensitivities for the `Spread` instrument.

```
[Price, outPR] = price(outPricer,SpreadOpt,["all"])
```

```
Price = 17.8614
```

```
outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×7 table
    Price            Delta                   Gamma                   Lambda                Vega
    _____    ____________________    ____________________    ________________    ____________
```

```
    17.861    -0.44663     0.58229    0.0093493     0.008195    -2.5756     3.3578    59.518    2
```

Levy

Create `Levy` pricer object for `Asian` instrument using `BlackScholes` model

Description

Create and price a `Asian` instrument object with a `BlackScholes` model and a `Levy` pricing method using this workflow:

1. Use `fininstrument` to create an `Asian` instrument object.
2. Use `finmodel` to specify a `BlackScholes` model for the `Asian` instrument object.
3. Use `finpricer` to specify a `Levy` pricer object for the `Asian` instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for an `Asian` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
LevyPricerObj = finpricer(PricerType,'DiscountCurve',ratecurve_obj,'
Model',model,'SpotPrice',spotprice_value)
LevyPricerObj = finpricer(___,Name,Value)
```

Description

`LevyPricerObj = finpricer(PricerType,'DiscountCurve',ratecurve_obj,'Model',model,'SpotPrice',spotprice_value)` creates a `Levy` pricer object by specifying `PricerType` and sets the properties on page 11-3325 for the required name-value pair arguments `DiscountCurve`, `Model`, and `SpotPrice`.

`LevyPricerObj = finpricer(___,Name,Value)` to set optional properties on page 11-3325 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `LevyPricerObj = finpricer("Analytic",'DiscountCurve',ratecurve_obj,'Model',BSModel,'SpotPrice',1000,'DividendType',"continuous",'DividendValue',100,'PricingMethod',"Levy")` creates a `Levy` pricer object.

Input Arguments

`PricerType` — Pricer type

string with value `"Analytic"` | character vector with value `'Analytic'`

Pricer type, specified as a string with the value of `"Analytic"` or a character vector with the value of `'Analytic'`.

Data Types: char | string

Levy Name-Value Pair Arguments

Specify required and optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: LevyPricerObj = finpricer("Analytic",'DiscountCurve',ratecurve_obj,'Model',BSModel,'SpotPrice',1000,'DividendType',"continuous",'DividendValue',100,'PricingMethod',"Levy")

Required Levy Name-Value Pair Arguments

DiscountCurve — ratecurve object for discounting cash flows
ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of a previously created ratecurve object.

Note Specify a flat ratecurve object for DiscountCurve. If you use a nonflat ratecurve object, the software uses the rate in the ratecurve object at Maturity and assumes that the value is constant for the life of the equity option.

Data Types: object

Model — Model
BlackScholes model object

Model, specified as the comma-separated pair consisting of 'Model' and the name of a previously created BlackScholes model object using finmodel.

Data Types: object

SpotPrice — Current price of underlying asset
nonnegative numeric

Current price of the underlying asset, specified as the comma-separated pair consisting of 'SpotPrice' and a scalar nonnegative numeric.

Data Types: double

Optional Levy Name-Value Pair Arguments

DividendType — Dividend type
"continuous" (default) | string with value of "continuous" | character vector with value of 'continuous'

Dividend type, specified as the comma-separated pair consisting of 'DividendType' and a string or character vector for a continuous dividend yield.

Data Types: char | string

`DividendValue` — Dividend yield or dividend schedule for underlying stock
`0` (default) | scalar numeric | timetable

Dividend yield for the underlying stock, specified as the comma-separated pair consisting of `'DividendValue'` and a scalar numeric for a dividend yield or a timetable for a dividend schedule.

Note Specify a scalar if `DividendType` is `"continuous"` and a timetable if `DividendType` is `"cash"`.

Data Types: `double` | `timetable`

`PricingMethod` — Analytic pricing method
default pricer associated with `BlackScholes` model (default) | string with value `"Levy"` | character vector with value `'Levy'`

Analytic pricing method, specified as the comma-separated pair consisting of `'PricingMethod'` and a character vector or string.

Note The default pricing method for a `BlackScholes` model is a `BlackScholes` pricer.

Data Types: `double`

Properties

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

`ratecurve` object for discounting cash flows, returned as a `ratecurve` object.

Data Types: `object`

`Model` — Model
`BlackScholes` model object

Model, returned as a `BlackScholes` model object.

Data Types: `object`

`SpotPrice` — Current price of underlying asset
nonnegative numeric

Current price of the underlying asset, returned as a scalar nonnegative numeric.

Data Types: `double`

`DividendType` — Dividend type
`"continuous"` (default) | string with value of `"continuous"`

This property is read-only.

Dividend type, returned as a string.

Data Types: `string`

`DividendValue` — Dividend yield or dividend schedule for underlying stock
`0` (default) | scalar nonnegative numeric | timetable

Dividend yield or dividend schedule for the underlying stock, returned as a scalar numeric for a dividend yield or a timetable for a dividend schedule.

Data Types: `double` | `timetable`

`PricingMethod` — Analytic pricing method
default pricer associated with `BlackScholes` model (default) | string with value `"Levy"`

Analytic pricing method, returned as a string.

Data Types: `string`

Object Functions

price Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

Examples

Use Levy Pricer and Black-Scholes Model to Price Asian Instrument

This example shows the workflow to price an `Asian` instrument when you use a `BlackScholes` model and a `Levy` pricing method.

Create `Asian` Instrument Object

Use `fininstrument` to create an `Asian` instrument object.

```
AsianOpt = fininstrument("Asian",'ExerciseDate',datetime(2022,9,15),'Strike',105,'OptionType',"pu
```

```
AsianOpt =
  Asian with properties:

          OptionType: "put"
              Strike: 105
         AverageType: "arithmetic"
        AveragePrice: 0
    AverageStartDate: NaT
       ExerciseStyle: "european"
        ExerciseDate: 15-Sep-2022
                Name: "asian_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.32)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.3200
    Correlation: 1
```

Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create Levy Pricer Object

Use finpricer to create a Levy pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPrice',100,
```

```
outPricer =
  Levy with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 100
    DividendValue: 0
     DividendType: "continuous"
```

Price Asian Instrument

Use price to compute the price and sensitivities for the Asian instrument.

```
[Price, outPR] = price(outPricer,AsianOpt,["all"])
```

```
Price = 13.0014
```

```
outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta       Gamma      Lambda      Vega      Theta        Rho
```

```
    ______    _______    _________    _______    ______    ________    _______

    13.001    -0.3749    0.0094403    -2.8836    44.586    -0.71607    -121.97
```

Use Levy Pricer and Black-Scholes Model to Price Asian Instrument for Foreign Exchange

This example shows the workflow to price an `Asian` instrument for an arithmetic average currency option when you use a `BlackScholes` model and a `Levy` pricing method. Assume that the current exchange rate is $0.52 and has a volatility of 12% per annum. The annualized continuously compounded foreign risk-free rate is 8% per annum.

Create `Asian` Instrument Object

Use `fininstrument` to create an `Asian` instrument object.

```
AsianOpt = fininstrument("Asian",'ExerciseDate',datetime(2022,9,15),'Strike',.50,'OptionType',"pu
```

```
AsianOpt =
  Asian with properties:

          OptionType: "put"
              Strike: 0.5000
         AverageType: "arithmetic"
        AveragePrice: 0
    AverageStartDate: NaT
       ExerciseStyle: "european"
        ExerciseDate: 15-Sep-2022
                Name: "asian_fx_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
Sigma = .12;
BlackScholesModel = finmodel("BlackScholes",'Volatility',Sigma)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.1200
    Correlation: 1
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create Levy Pricer Object

Use `finpricer` to create a `Levy` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument. When you price currencies using a Asian instrument for an arithmetic average currency option, `DividendType` must be `"continuous"` and `DividendValue` is the annualized risk-free interest rate in the foreign country.

```
ForeignRate = 0.08;
outPricer = finpricer("analytic",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPrice',.52,
```

```
outPricer =
  Levy with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 0.5200
    DividendValue: 0.0800
     DividendType: "continuous"
```

Price Asian FX Instrument

Use `price` to compute the price and sensitivities for the `Asian` FX instrument.

```
[Price, outPR] = price(outPricer,AsianOpt,["all"])
```

```
Price = 0.0535
```

```
outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×7 table
     Price       Delta       Gamma      Lambda       Vega        Theta         Rho
    ________    ________    _______    ________    ________    _________    ________
```

```
    0.053516    -0.62792    3.8371    -6.1014    0.15613    -0.010917    -0.82694
```

Functions

`fininstrument` | `finmodel` | `timetable` | `ratecurve`

Topics

“Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22
“Choose Instruments, Models, and Pricers” on page 1-53

Normal

Create `Normal` pricer object for `Cap`, `Floor`, or `Swaption` instrument using `Normal` model

Description

Create and price a `Cap`, `Floor`, or `Swaption` instrument object with a `Normal` model and a `Normal` pricing method using this workflow:

1. Use `fininstrument` to create a `Cap`, `Floor`, or `Swaption` instrument object.
2. Use `finmodel` to specify a `Normal` model for the `Cap`, `Floor`, or `Swaption` instrument object.
3. Use `finpricer` to specify a `Normal` pricer object for the `Cap`, `Floor`, or `Swaption` instrument object.

> **Note** If you do not specify `ProjectionCurve` when you create a `Cap`, `Floor`, or `Swaption` instrument with the `HullWhite` pricer, the `ProjectionCurve` value defaults to the `DiscountCurve` value.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a `Cap`, `Floor`, or `Swaption` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
NormalPricerObj = finpricer(PricerType,'DiscountCurve',ratecurve_obj,'
Model',model)
```

Description

`NormalPricerObj = finpricer(PricerType,'DiscountCurve',ratecurve_obj,'Model',model)` creates a `Normal` pricer object by specifying `PricerType` and the required name-value pair arguments `DiscountCurve` and `Model` to set properties on page 11-3332 using name-value pair arguments. For example, `NormalPricerObj = finpricer("Analytic",'DiscountCurve',ratecurve_obj,'Model',NormModel)` creates a `Normal` pricer object.

Input Arguments

`PricerType` — Pricer type

string with value `"Analytic"` | character vector with value `'Analytic'`

Pricer type, specified as a string with the value of `"Analytic"` or a character vector with the value of `'Analytic'`.

Data Types: `char` | `string`

`Normal` Name-Value Pair Arguments

Specify required pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `NormalPricerObj = finpricer("Analytic",'DiscountCurve',ratecurve_obj,'Model',NormModel)`

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

`ratecurve` object for discounting cash flows, specified as the comma-separated pair consisting of `'DiscountCurve'` and the name of a previously created `ratecurve` object.

Data Types: `object`

`Model` — Model
`Normal` model object

Model, specified as the comma-separated pair consisting of `'Model'` and the name of a previously created `Normal` model object using `finmodel`.

Data Types: `object`

Properties

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

`ratecurve` object for discounting cash flows, returned as a `ratecurve` object.

Data Types: `object`

`Model` — Model
`Normal` model object

Model, returned as a `Normal` model object.

Data Types: `object`

Object Functions

price Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

Examples

Use Normal Pricer and Normal Model to Price Cap Instrument

This example shows the workflow to price a `Cap` instrument when you use a `Normal` model and a `Normal` pricing method.

Create Cap Instrument Object

Use `fininstrument` to create a `Cap` instrument object.

```
CapOpt = fininstrument("Cap",'Strike',0.02,'Maturity',datetime(2019,6,25),'Reset',4,'Principal',1
```

```
CapOpt =
  Cap with properties:

                     Strike: 0.0200
                   Maturity: 25-Jun-2019
                ResetOffset: 0
                      Reset: 4
                      Basis: 8
                  Principal: 100
             ProjectionCurve: [0x0 ratecurve]
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                   Holidays: NaT
                       Name: "cap_option"
```

Create `Normal` Model Object

Use `finmodel` to create a `Normal` model object.

```
NormalModel = finmodel("Normal",'Volatility',0.063)
```

```
NormalModel =
  Normal with properties:

    Volatility: 0.0630
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2018
        InterpMethod: "linear"
   ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

Create Normal Pricer Object

Use finpricer to create a Normal pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic",'Model',NormalModel,'DiscountCurve',myRC)
```

```
outPricer =
  Normal with properties:

    DiscountCurve: [1x1 ratecurve]
            Shift: 0
            Model: [1x1 finmodel.Normal]
```

Price Cap Instrument

Use price to compute the price for the Cap instrument.

```
Price = price(outPricer,CapOpt)
```

```
Price = 0.4828
```

RollGeskeWhaley

Create `RollGeskeWhaley` pricer object for American exercise `Vanilla` instrument using `BlackScholes` model

Description

Create and price a `Vanilla` instrument object with a `BlackScholes` model and a `RollGeskeWhaley` pricing method using this workflow:

1. Use `fininstrument` to create a `Vanilla` instrument object.
2. Use `finmodel` to specify a `BlackScholes` model for the `Vanilla` instrument object.
3. Use `finpricer` to specify a `RollGeskeWhaley` pricer object for the `Vanilla` instrument object (American exercise).

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a `Vanilla` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
RollGeskeWhaleyPricerObj = finpricer(PricerType,'Model',model,'
DiscountCurve',ratecurve_obj,'SpotPrice',spotrate_value,'
DividendType',dividendtype,'DividendValue',dividendvalue)
RollGeskeWhaleyPricerObj = finpricer(___,Name,Value)
```

Description

`RollGeskeWhaleyPricerObj = finpricer(PricerType,'Model',model,'DiscountCurve',ratecurve_obj,'SpotPrice',spotrate_value,'DividendType',dividendtype,'DividendValue',dividendvalue)` creates a `RollGeskeWhaley` pricer object by specifying `PricerType` and sets the properties on page 11-3337 for the required name-value pair arguments `Model`, `DiscountCurve`, and `SpotPrice`.

`RollGeskeWhaleyPricerObj = finpricer(___,Name,Value)` to set optional properties on page 11-3337 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `RollGeskeWhaleyPricerObj = finpricer("Analytic",'Model',BSModel,'DiscountCurve',ratecurve_obj,'SpotPrice',1000,'DividendValue',timetable(datetime(2021,6,15),2.5),'DividendType',"cash",'PricingMethod',"RollGeskeWhaley")` creates a `RollGeskeWhaley` pricer object. You can specify multiple name-value pair arguments.

Input Arguments

PricerType — Pricer type

string with value "Analytic" | character vector with value 'Analytic'

Pricer type, specified as a string with the value of "Analytic" or a character vector with the value of 'Analytic'.

Data Types: char | string

RollGeskeWhaley Name-Value Pair Arguments

Specify required and optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: RollGeskeWhaleyPricerObj = finpricer("Analytic",'Model',BSModel,'DiscountCurve',ratecurve_obj,'SpotPrice',1000,'DividendValue',timetable(datetime(2021,6,15),2.5),'DividendType',"cash",'PricingMethod',"RollGeskeWhaley")

Required RollGeskeWhaley Name-Value Pair Arguments

Model — Model

BlackScholes model object

Model, specified as the comma-separated pair consisting of 'Model' and the name of a previously created BlackScholes model object using finmodel.

Data Types: object

DiscountCurve — ratecurve object for discounting cash flows

ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of a previously created ratecurve object.

Note Specify a flat ratecurve object for DiscountCurve. If you use a nonflat ratecurve object, the software uses the rate in the ratecurve object at Maturity and assumes that the value is constant for the life of the equity option.

Data Types: object

SpotPrice — Current price of underlying asset

nonnegative numeric

Current price of the underlying asset, specified as the comma-separated pair consisting of 'SpotPrice' and a scalar nonnegative numeric.

Data Types: double

DividendValue — Cash dividend for underlying stock

timetable

Cash dividend for the underlying stock, specified as the comma-separated pair consisting of `'DividendValue'` and a timetable.

Data Types: `timetable`

Optional RollGeskeWhaley Name-Value Pair Arguments

`DividendType` — Stock dividend type
`"cash"` (default) | string with value `"cash"` | character vector with value `'cash'`

Stock dividend type, specified as the comma-separated pair consisting of `'DividendType'` and a string or character vector.

Data Types: `char` | `string`

`PricingMethod` — Analytic pricing method
default pricer associated with `BlackScholes` model (default) | string with value `"RollGeskeWhaley"` | character vector with value `'RollGeskeWhaley'`

Analytic pricing method, specified as the comma-separated pair consisting of `'PricingMethod'` and a string or character vector.

Note The default pricing method for a `BlackScholes` model is a `BlackScholes` pricer.

Data Types: `double`

Properties

`Model` — Model
`BlackScholes` model object

Model, returned as a `BlackScholes` model object.

Data Types: `object`

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

`ratecurve` object for discounting cash flows, returned as a `ratecurve` object

Data Types: `object`

`SpotPrice` — Current price of underlying asset
nonnegative numeric

Current price of the underlying asset, returned as a scalar nonnegative numeric.

Data Types: `double`

`DividendValue` — Cash dividend for underlying stock
timetable

Cash dividend for the underlying stock, returned as a timetable.

Data Types: `timetable`

`DividendType` — Stock dividend type
`"cash"` (default) | string with value `"cash"`

Stock dividend type, returned as a string.

Data Types: `char` | `string`

`PricingMethod` — Analytic pricing method
default pricer associated with `BlackScholes` model (default) | string with value `"RollGeskeWhaley"`

Analytic pricing method, returned as a string.

Data Types: `string`

Object Functions

price Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

Examples

Use a Roll-Geske-Whaley Pricer and Black-Scholes Model to Price Vanilla Instrument

This example shows the workflow to price an American exercise `Vanilla` instrument when you use a `BlackScholes` model and a `RollGeskeWhaley` pricing method.

Create `Vanilla` Instrument Object

Use `fininstrument` to create a `Vanilla` instrument object.

```
VanillaOpt = fininstrument("Vanilla",'ExerciseDate',datetime(2022,9,15),'Strike',105,'ExerciseSty
```

```
VanillaOpt =
  Vanilla with properties:

       OptionType: "call"
    ExerciseStyle: "american"
     ExerciseDate: 15-Sep-2022
           Strike: 105
             Name: "vanilla_american_instrument"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.07)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.0700
    Correlation: 1
```

Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
myRC = ratecurve("zero",Settle,datetime(2023,9,15),.05,'Basis',12);
```

Create RollGeskeWhaley Pricer Object

Use finpricer to create a RollGeskeWhaley pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPrice',100,'
```

```
outPricer =
  RollGeskeWhaley with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 100
    DividendValue: [1x1 timetable]
     DividendType: "cash"
```

Price Vanilla Instrument

Use price to compute the price and sensitivities for the Vanilla instrument.

```
[Price, outPR] = price(outPricer,VanillaOpt,["all"])
```

```
Price = 14.9582
```

```
outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta      Gamma      Lambda      Vega      Theta      Rho
    _____    ________    ________    ______    ______    ________    _____

    14.958    0.87494    0.01471    5.8493    41.184    -3.9873    290.2
```

SABR

Create SABR pricer object for Swaption instrument using SABR model

Description

Create and price a Swaption instrument object with a SABR model and a SABR pricing method using this workflow:

1. Use `fininstrument` to create a Swaption instrument object.
2. Use `finmodel` to specify a SABR model for the Swaption instrument object.
3. Use `finpricer` to specify a SABR pricer object for the Swaption instrument object.

> **Note** If you do not specify `ProjectionCurve` when you create a Swaption instrument with the SABR pricer, the `ProjectionCurve` value defaults to the `DiscountCurve` value.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a Swaption instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
SABRPricerObj = finpricer(PricerType,'DiscountCurve',ratecurve_obj,'
Model',model)
```

Description

`SABRPricerObj = finpricer(PricerType,'DiscountCurve',ratecurve_obj,'Model',model)` creates a SABR pricer object by specifying `PricerType` and the required name-value pair argument `Model` to set properties on page 11-3342 using name-value pairs. For example, `SABRPricerObj = finpricer("Analytic",'DiscountCurve',ratecurve_obj,'Model',SABRModel)` creates a SABR pricer object.

Input Arguments

`PricerType` — Pricer type
string with value `"Analytic"` | character vector with value `'Analytic'`

Pricer type, specified as a string with the value of `"Analytic"` or a character vector with the value of `'Analytic'`.

Data Types: `char` | `string`

SABR Name-Value Pair Arguments

Specify required pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `SABRPricerObj = finpricer("Analytic",'DiscountCurve',ratecurve_obj,'Model',SABRModel)`

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

`ratecurve` object for discounting cash flows, specified as the comma-separated pair consisting of `'DiscountCurve'` and the name of a previously created `ratecurve` object.

Data Types: `object`

`Model` — Model
SABR model object

Model, specified as the comma-separated pair consisting of `'Model'` and the name of a previously created SABR model object using `finmodel`.

Data Types: `object`

Properties

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

`ratecurve` object for discounting cash flows, returned as a `ratecurve` object

Data Types: `object`

`Model` — Model object
SABR model object

Model, returned as a SABR model object.

Data Types: `object`

Object Functions

price	Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer
volatilities	Compute implied volatilities when using SABR pricer

Examples

Use SABR Pricer and SABR Model to Price Swaption Instrument

This example shows the workflow to price a `Swaption` instrument when you use a SABR model and a SABR pricing method.

Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create Swap Instrument Object

Use fininstrument to create the underlying Swap instrument object.

```
Swap = fininstrument("Swap",'Maturity',datetime(2023,1,30),'LegRate',[0.018 0.24],'LegType',["fix
```

```
Swap =
  Swap with properties:

                   LegRate: [0.0180 0.2400]
                   LegType: ["fixed"    "float"]
                     Reset: [2 2]
                     Basis: [1 1]
                  Notional: 100
         LatestFloatingRate: [NaN NaN]
                ResetOffset: [0 0]
   DaycountAdjustedCashFlow: [0 0]
           ProjectionCurve: [1x2 ratecurve]
      BusinessDayConvention: ["actual"    "actual"]
                  Holidays: NaT
              EndMonthRule: [1 1]
                 StartDate: 30-Mar-2020
                  Maturity: 30-Jan-2023
                      Name: "swap_instrument"
```

Create Swaption Instrument Object

Use fininstrument to create a Swaption instrument object.

```
Swaption = fininstrument("Swaption",'Strike',0.275,'ExerciseDate',datetime(2021,7,30),'Swap',Swap
```

```
Swaption =
  Swaption with properties:
```

```
       OptionType: "put"
    ExerciseStyle: "european"
     ExerciseDate: 30-Jul-2021
           Strike: 0.2750
             Swap: [1x1 fininstrument.Swap]
             Name: "swaption_instrument"
```

Create SABR Model Object

Use `finmodel` to create a SABR model object.

```
SABRModel = finmodel("SABR",'Alpha',0.032,'Beta',0.04,'Rho',.08,'Nu',0.49,'Shift',0.002)
```

```
SABRModel =
  SABR with properties:

            Alpha: 0.0320
             Beta: 0.0400
              Rho: 0.0800
               Nu: 0.4900
            Shift: 0.0020
    VolatilityType: "black"
```

Create SABR Pricer Object

Use `finpricer` to create a SABR pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'Model',SABRModel,'DiscountCurve',myRC)
```

```
outPricer =
  SABR with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.SABR]
```

Price `Swaption` Instrument

Use `price` to compute the price for the `Swaption` instrument.

```
Price = price(outPricer,Swaption)
```

```
Price = 10.3771
```

FiniteDifference

Create FiniteDifference pricer object for Barrier, DoubleBarrier, or Vanilla instrument using a BlackScholes, Heston, Merton, or Bates model

Description

Create and price a Vanilla, Barrier, or DoubleBarrier instrument object with a BlackScholes, Heston, Bates, Merton, or Dupire model and a FiniteDifference pricing method using this workflow:

1. Use fininstrument to create the Barrier, DoubleBarrier, or Vanilla instrument object.
2. Use finmodel to specify the BlackScholes model for a Barrier or DoubleBarrier instrument or a Heston, Bates, Dupire, or Merton model for the Vanilla instrument object.
3. Use finpricer to specify the FiniteDifference pricer object for the Barrier, DoubleBarrier, or Vanilla instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a Vanilla, Barrier, or DoubleBarrier instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
FiniteDifferencePricerObj = finpricer(PricerType,'Model',model,'
DiscountCurve',ratecurve_obj,'SpotPrice',spotprice_value)
FiniteDifferencePricerObj = finpricer(___,Name,Value)
```

Description

`FiniteDifferencePricerObj = finpricer(PricerType,'Model',model,'DiscountCurve',ratecurve_obj,'SpotPrice',spotprice_value)` creates a FiniteDifference pricer object by specifying PricerType and sets the properties on page 11-3349 for the required name-value pair arguments Model, DiscountCurve, and SpotPrice.

`FiniteDifferencePricerObj = finpricer(___,Name,Value)` sets optional properties on page 11-3349 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `FiniteDifferencePricerObj = finpricer("FiniteDifference",'Model',BSModel,'DiscountCurve',ratecurve_obj,'SpotPrice',100,'DividendValue',.025,'DividendType',"cash")` creates a FiniteDifference pricer object. You can specify multiple name-value pair arguments.

Input Arguments

PricerType — Pricer type
string with value "FiniteDifference" | character vector with value 'FiniteDifference'

Pricer type, specified as a string with the value of `"FiniteDifference"` or the character vector with a value of `'FiniteDifference'`.

Data Types: `char` | `string`

`FiniteDifference` Name-Value Pair Arguments

Specify required and optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `FiniteDifferencePricerObj = finpricer("FiniteDifference",'Model',BSModel,'DiscountCurve',ratecurve_obj,'SpotPrice',100,'DividendValue',.025,'DividendType',"cash")`

Required FiniteDifference Name-Value Pair Arguments

`Model` — Model object
object

Model object, specified as the comma-separated pair consisting of `'Model'` and the name of the previously created `Merton`, `Bates`, or `Heston` model object using `finmodel`.

Data Types: `object`

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

This property is read-only.

`ratecurve` object for discounting cash flows, specified as the comma-separated pair consisting of `'DiscountCurve'` and the name of the `ratecurve` object.

Note Specify a flat `ratecurve` object for `DiscountCurve`. If you use a nonflat `ratecurve` object, the software uses the rate in the `ratecurve` object at `Maturity` and assumes that the value is constant for the life of the equity option.

Data Types: `object`

`SpotPrice` — Current price of underlying asset
nonnegative numeric

Current price of the underlying asset, specified as the comma-separated pair consisting of `'SpotPrice'` and a scalar nonnegative numeric.

Data Types: `double`

Optional FiniteDifference Name-Value Pair Arguments

`DividendValue` — Dividend yield or dividend schedule
`0` (default) | scalar | timetable

Dividend yield or dividend schedule, specified as the comma-separated pair consisting of `'DividendValue'` and a scalar for a dividend yield or a timetable for a dividend schedule.

Data Types: double | timetable

DividendType — Dividend type
"continuous" (default) | string with value "cash" or "continuous" | character vector with value 'cash' or 'continuous'

Dividend type, specified as the comma-separated pair consisting of 'DividendType' and a character vector or string. DividendType must be "cash" for actual dollar dividends or "continuous" for a continuous dividend yield.

Note When you use a Barrier instrument, you must set DividendType to "cash".

Data Types: char | string

SpotGridSize — Size of spot grid for finite difference grid
400 (default) | scalar numeric

Size of the spot grid for the finite difference grid, specified as the comma-separated pair consisting of 'SpotGridSize' and a scalar numeric.

Data Types: double

SpotPriceMax — Maximum price for price grid boundary
if unspecified, SpotPrice values are calculated using asset distributions at maturity (default) | positive scalar

Maximum price for the price grid boundary, specified as the comma-separated pair consisting of 'SpotPriceMax' and a positive scalar.

Data Types: single | double

VarianceGridSize — Number of nodes of variance grid for finite difference grid
200 (default) | scalar numeric

Number of nodes of the variance grid for the finite difference grid, specified as the comma-separated pair consisting of 'VarianceGridSize' and a scalar numeric.

Note VarianceGridSize is supported only when you use a Heston or Bates model.

Data Types: double

VarianceMax — Maximum variance for variance grid boundary
1.0 (default) | scalar numeric

Maximum variance for the variance grid boundary, specified as the comma-separated pair consisting of 'VarianceMax' as a scalar numeric.

Note VarianceMax is supported only when you use a Heston or Bates model.

Data Types: double

`TimeGridSize` — Number of nodes of time grid for finite difference grid
`100` (default) | positive numeric scalar

Number of nodes of the time grid for the finite difference grid, specified as the comma-separated pair consisting of `'TimeGridSize'` and a positive numeric scalar.

Data Types: `double`

`InterpMethod` — Method of interpolation for estimating the implied volatility surface from `ImpliedVolData`
`'linear'` (default) | string with value `"linear"`, `"makima"`, `"spline"`, or `"tpaps"` | character vector with value `'linear'`, `'makima'`, `'spline'`, or `'tpaps'`

Method of interpolation for estimating the implied volatility surface from `ImpliedVolData` for use only with a `Dupire` model, specified as the comma-separated pair consisting of `'InterpMethod'` and a string or character vector with one of the following values:

- `'linear'` — Linear interpolation
- `'makima'` — Modified Akima cubic Hermite interpolation
- `'spline'` — Cubic spline interpolation
- `'tpaps'` — Thin-plate smoothing spline interpolation

Note The `'tpaps'` method uses the thin-plate smoothing spline functionality from Curve Fitting Toolbox.

The `'makima'` and `'spline'` methods work only for gridded data. For scattered data, use the `'linear'` or `'tpaps'` methods.

For more information on gridded or scattered data and details on interpolation methods, see “Gridded and Scattered Sample Data” and “Interpolating Gridded Data”.

Data Types: `char` | `string`

Properties

`Model` — Model
object

Model, returned as a model object.

Data Types: `object`

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

This property is read-only.

`ratecurve` object for discounting cash flows, returned as the `ratecurve` object.

Data Types: `object`

`SpotPrice` — Current price of underlying asset
nonnegative numeric

Current price of the underlying asset, returned as a scalar nonnegative numeric.

Data Types: `double`

`DividendValue` — Dividend yield or dividend schedule
`0` (default) | scalar | timetable

Dividend yield or dividend schedule, returned as a scalar for a dividend yield or a timetable for a dividend schedule.

Data Types: `double` | `timetable`

`DividendType` — Dividend type
`"continuous"` (default) | string with value `"cash"` or `"continuous"`

This property is read-only.

Dividend type, returned as a string. The `DividendType` is either `"cash"` for actual dollar dividends or `"continuous"` for a continuous dividend yield.

Data Types: `string`

`GridProperties` — Grid properties
`400` (default) | scalar numeric

Grid properties, returned as a struct.

For a `Dupire` model, `GridProperties` contains the following fields:

- `SpotGridSize` — Size of the spot grid for the finite difference grid, returned as a scalar numeric.
- `SpotPriceMax` — Maximum price for price grid boundary, returned as a positive scalar.
- `TimeGridSize` — Number of nodes of the time grid for the finite difference grid, returned as a positive numeric scalar.
- `InterpMethod` — Method of interpolation for estimating the implied volatility surface, returned as a string.

For a `Heston` or `Bates` model, `GridProperties` contains the following fields:

- `VarianceGridSize` — Size of the variance grid for the finite difference grid, returned as a scalar numeric.
- `VarianceMax` — Maximum variance for the variance grid boundary, returned as a scalar numeric.

Data Types: `struct`

Object Functions

price Compute price for equity instrument with FiniteDifference pricer

Examples

Use Finite Difference Pricer and Black-Scholes Model to Price Barrier Instrument

This example shows the workflow to price a `Barrier` instrument when you use a `BlackScholes` model and a `FiniteDifference` pricing method.

Create Barrier Instrument Object

Use `fininstrument` to create a `Barrier` instrument object.

```
BarrierOpt = fininstrument("Barrier",'Strike',105,'ExerciseDate',datetime(2019,1,1),'OptionType'
```

```
BarrierOpt =
  Barrier with properties:

       OptionType: "call"
           Strike: 105
      BarrierType: "do"
     BarrierValue: 40
           Rebate: 0
    ExerciseStyle: "american"
     ExerciseDate: 01-Jan-2019
             Name: "barrier_option"
```

Create BlackScholes Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.30)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.3000
    Correlation: 1
```

Create ratecurve Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,1,1);
Maturity = datetime(2023,1,1);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',1)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
       Compounding: -1
             Basis: 1
             Dates: 01-Jan-2023
             Rates: 0.0350
            Settle: 01-Jan-2018
      InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create FiniteDifference Pricer Object

Use `finpricer` to create a `FiniteDifference` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("FiniteDifference",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPric
```

```
outPricer =
  FiniteDifference with properties:

     DiscountCurve: [1x1 ratecurve]
             Model: [1x1 finmodel.BlackScholes]
         SpotPrice: 100
    GridProperties: [1x1 struct]
      DividendType: "continuous"
     DividendValue: 0
```

Price `Barrier` Instrument

Use `price` to compute the price and sensitivities for the `Barrier` instrument.

```
[Price, outPR] = price(outPricer,BarrierOpt,["all"])
```

```
Price = 11.3230
```

```
outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta      Gamma      Lambda      Theta       Rho        Vega
    _____    ________    _______    _______    ________    _______    _______

    11.323    0.54126    0.0132     4.7802     -7.4408     42.766     39.627
```

TurnbullWakeman

Create `TurnbullWakeman` pricer object for `Asian` instrument using `BlackScholes` model

Description

Create and price a `Asian` instrument object with a `BlackScholes` model and a `TurnbullWakeman` pricing method using this workflow:

1. Use `fininstrument` to create an `Asian` instrument object.
2. Use `finmodel` to specify a `BlackScholes` model for the `Asian` instrument object.
3. Use `finpricer` to specify a `TurnbullWakeman` pricer object for the `Asian` instrument object.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for an `Asian` instrument, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
TurnbullWakemanPricerObj = finpricer(PricerType,'
DiscountCurve',ratecurve_obj,'Model',model,'SpotPrice',spotprice_value)
TurnbullWakemanPricerObj = finpricer( ___ ,Name,Value)
```

Description

`TurnbullWakemanPricerObj = finpricer(PricerType,'DiscountCurve',ratecurve_obj,'Model',model,'SpotPrice',spotprice_value)` creates a `TurnbullWakeman` pricer object by specifying `PricerType` and sets the properties on page 11-3355 for the required name-value pair arguments `DiscountCurve`, `Model`, and `SpotPrice`.

`TurnbullWakemanPricerObj = finpricer( ___ ,Name,Value)` to set optional properties on page 11-3355 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `TurnbullWakemanPricerObj = finpricer("Analytic",'DiscountCurve',ratecurve_obj,'Model',BSModel,'SpotPrice',1000,'DividendType',"continuous",'DividendValue',100)` creates a `TurnbullWakeman` pricer object.

Input Arguments

`PricerType` — Pricer type

string with value `"Analytic"` | character vector with value `'Analytic'`

Pricer type, specified as a string with the value of `"Analytic"` or a character vector with the value of `'Analytic'`.

Data Types: char | string

TurnbullWakeman Name-Value Pair Arguments

Specify required and optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: TurnbullWakemanPricerObj = finpricer("Analytic",'DiscountCurve',ratecurve_obj,'Model',BSModel,'SpotPrice',1000,'DividendType',"continuous",'DividendValue',100,'PricingMethod','TurnbullWakeman')

Required TurnbullWakeman Name-Value Pair Arguments

DiscountCurve — ratecurve object for discounting cash flows
ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of a previously created ratecurve object.

Specify a flat ratecurve object for DiscountCurve. If you use a nonflat ratecurve object, the software uses the rate in the ratecurve object at Maturity and assumes that the value is constant for the life of the equity option.

Data Types: object

Model — Model
BlackScholes model object

Model, specified as the comma-separated pair consisting of 'Model' and the name of a previously created BlackScholes model object using finmodel.

Data Types: object

SpotPrice — Current price of underlying asset
nonnegative numeric

Current price of the underlying asset, specified as the comma-separated pair consisting of 'SpotPrice' and a scalar nonnegative numeric.

Data Types: double

Optional TurnbullWakeman Name-Value Pair Arguments

DividendType — Stock dividend type
"continuous" (default) | string with value "cash" or "continuous" | character vector with value 'cash' or 'continuous'

Stock dividend type, specified as the comma-separated pair consisting of 'DividendType' and a character vector or string. DividendType must be "cash" for actual dollar dividends or "continuous" for a continuous dividend yield.

Data Types: char | string

`DividendValue` — Dividend yield or dividend schedule for underlying stock
`0` (default) | scalar numeric | timetable

Dividend yield for the underlying stock, specified as the comma-separated pair consisting of `'DividendValue'` and a scalar numeric for a dividend yield or a timetable for a dividend schedule.

Note `DividendValue` must be a scalar for a `"continuous"` `DividendType` or a timetable for a `"cash"` `DividendType`.

Data Types: `double` | `timetable`

`PricingMethod` — Analytic pricing method
default pricer associated with `BlackScholes` model (default) | string with value `"TurnbullWakeman"` | character vector with value `'TurnbullWakeman'`

Analytic pricing method, specified as the comma-separated pair consisting of `'PricingMethod'` and a string or character vector.

Note The default pricing method for a `BlackScholes` model is a `BlackScholes` pricer.

Data Types: `double`

Properties

`DiscountCurve` — `ratecurve` object for discounting cash flows
`ratecurve` object

`ratecurve` object for discounting cash flows, returned as a `ratecurve` object.

Data Types: `object`

`Model` — Model
`BlackScholes` model object

Model, returned as a `BlackScholes` model object.

Data Types: `object`

`SpotPrice` — Current price of underlying asset
nonnegative numeric

Current price of the underlying asset, returned as a scalar nonnegative numeric.

Data Types: `double`

`DividendType` — Stock dividend type
`'continuous'` (default) | string with value `"cash"` or `"continuous"`

This property is read-only.

Stock dividend type, returned as a string. `DividendType` is either `"cash"` for actual dollar dividends or `"continuous"` for a continuous dividend yield.

Data Types: `string`

`DividendValue` — Dividend yield or dividend schedule for underlying stock
`0` (default) | scalar nonnegative numeric | timetable

Dividend yield or dividend schedule for the underlying stock, returned as a scalar nonnegative numeric for a dividend yield or a timetable for a dividend schedule.

Data Types: `double` | `timetable`

`PricingMethod` — Analytic pricing method
default pricer associated with `BlackScholes` model (default) | string with value `"TurnbullWakeman"`

Analytic pricing method, returned as a string.

Data Types: `string`

Object Functions

price Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

Examples

Use Turnbull-Wakeman Pricer and Black-Scholes Model to Price Asian Instrument

This example shows the workflow to price an `Asian` instrument when you use a `BlackScholes` model and a `TurnbullWakeman` pricing method.

Create `Asian` Instrument Object

Use `fininstrument` to create an `Asian` instrument object.

```
AsianOpt = fininstrument("Asian",'ExerciseDate',datetime(2022,9,15),'Strike',105,'OptionType',"pu
```

```
AsianOpt =
  Asian with properties:

          OptionType: "put"
              Strike: 105
         AverageType: "arithmetic"
        AveragePrice: 0
    AverageStartDate: NaT
       ExerciseStyle: "european"
        ExerciseDate: 15-Sep-2022
                Name: "asian_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.35)
```

```
BlackScholesModel =
  BlackScholes with properties:
```

```
     Volatility: 0.3500
    Correlation: 1
```

Create ratecurve Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 12
               Dates: 15-Sep-2023
               Rates: 0.0350
              Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create TurnbullWakeman Pricer Object

Use `finpricer` to create a `TurnbulllWakeman` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPrice',100,
```

```
outPricer =
  TurnbullWakeman with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 100
    DividendValue: 0
     DividendType: "continuous"
```

Price Asian Instrument

Use `price` to compute the price and sensitivities for the `Asian` instrument.

```
[Price, outPR] = price(outPricer,AsianOpt,["all"])
```

```
Price = 14.3431
```

```
outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta        Gamma       Lambda      Vega      Theta        Rho
    ______    ________    _________    _______    ______    ________    _______

    14.343    -0.37004    0.0085706    -2.5799    44.864    -0.86257    -125.73
```

defprobcurve

Create `defprobcurve` object for credit instrument

Description

Create a `defprobcurve` object for a credit instrument.

After creating a `defprobcurve` object, you can use the associated functions `survprobs`, `hazardrates`, and `defprobstrip`.

To price a `CDS` instrument, you must create a `defprobcurve` object and then create a `Credit` pricer object.

For more information on the available instruments, models, and pricing methods, see “Choose Instruments, Models, and Pricers” on page 1-53.

Creation

Syntax

```
DefaultProbCurve = defprobcurve(Settle,ProbDates,DefaultProbabilities)
DefaultProbCurve = defprobcurve( ___ ,Name,Value)
```

Description

`DefaultProbCurve = defprobcurve(Settle,ProbDates,DefaultProbabilities)` creates a `defprobcurve` object.

`DefaultProbCurve = defprobcurve( ___ ,Name,Value)` sets properties on page 11-3361 using name-value pairs and any of the arguments in the previous syntax. For example, `DefaultProbCurve = defprobcurve(datetime(2017,1,30),[datetime(2018,1,30);datetime(2019,1,30)], [0.005 0.007],'Basis',2)` creates a default probability curve object. You can specify multiple name-value pair arguments.

Input Arguments

`Settle` — Settle date for curve

datetime scalar | string scalar | date character vector

Settle date for curve, specified as a scalar datetime, string, or date character vector.

To support existing code, `defprobcurve` also accepts serial date numbers as inputs, but they are not recommended.

If you use a date character vector or string, the format must be recognizable by `datetime` because the `Settle` property is stored as a datetime.

`ProbDates` — Dates corresponding to `DefaultProbabilities`

datetime array | string array | date character vector

Dates corresponding to `DefaultProbabilities`, specified as an `NPOINTS`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `defprobcurve` also accepts serial date numbers as inputs, but they are not recommended.

If you use a date character vector or string, the format must be recognizable by `datetime` because the `ProbDates` property is stored as a datetime.

`DefaultProbabilities` — Default probability data for the curve
vector

Default probability data for the curve, specified as a numeric vector.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `defprobcurve = defprobcurve(datetime(2017,1,30), [datetime(2018,1,30);datetime(2019,1,30)],[0.005 0.007],'Basis',2)`

`Basis` — Day count basis
`2` (actual/360) (default) | integer from `0` to `13`

Day count basis, specified as the comma-separated pair consisting of `'Basis'` and a scalar integer.

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

Properties

`Settle` — Settlement date

datetime

Settlement date, returned as a datetime.

Data Types: `datetime`

`Basis` — Day count basis

2 (actual/360) (default) | integer from `0` to `13`

This property is read-only.

Day count basis of the instrument, returned as a scalar integer.

Data Types: `double`

`Dates` — Dates corresponding to rate data

datetime

Dates corresponding to the rate data, returned as a datetime.

Data Types: `datetime`

`DefaultProbabilities` — Default probabilities for the curve

vector

Default probabilities for the curve, returned as a vector.

Data Types: `double`

Object Functions

survprobs	Compute survival probability based on default probability curve
hazardrates	Compute hazard rates based on default probability curve
defprobstrip	Bootstrap defprobcurve object from market CDS instruments

Examples

Create `defprobcurve` Object

Create a `defprobcurve` object using `defprobcurve`.

```
Settle = datetime(2017,9,20);
DefProbTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
DefaultProbabilities = [0.005 0.007 0.01 0.015 0.026 0.04 0.077 0.093 0.15 0.20]';
ProbDates = Settle + DefProbTimes;

DefaultProbCurve = defprobcurve(Settle,ProbDates,DefaultProbabilities,'Basis',2)
```

```
DefaultProbCurve =
  defprobcurve with properties:

                 Settle: 20-Sep-2017
                  Basis: 2
```

```
                Dates: [10x1 datetime]
    DefaultProbabilities: [10x1 double]
```

Version History

Introduced in R2020a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `defprobcurve` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

survprobs

Compute survival probability based on default probability curve

Syntax

```
outSurvProbs = survprobs(obj,inDates)
```

Description

`outSurvProbs = survprobs(obj,inDates)` computes the survival probability based on the default probability curve object.

Examples

Calculate Survival Probability Based on Default Probability Curve

Create a `defprobcurve` object using `defprobcurve` and then use `survprobs` to calculate the survival probability.

```
Settle = datetime(2017,9,20);
DefProbTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
DefaultProbabilities = [0.005 0.007 0.01 0.015 0.026 0.04 0.077 0.093 0.15 0.20]';
DefProbDates = Settle + DefProbTimes;

DefaultProbCurve = defprobcurve(Settle,DefProbDates,DefaultProbabilities,'Basis',5)
```

```
DefaultProbCurve =
  defprobcurve with properties:

                  Settle: 20-Sep-2017
                   Basis: 5
                   Dates: [10x1 datetime]
    DefaultProbabilities: [10x1 double]
```

```
SurvProbTimes = [calmonths([6 12 18])];
SurvProbDates = Settle + SurvProbTimes;
outSurvProb = survprobs(DefaultProbCurve, SurvProbDates)
```

```
outSurvProb = 3×1

    0.9950
    0.9930
    0.9915
```

Input Arguments

`obj` — `defprobcurve` object
`defprobcurve` object

`defprobcurve` object, specified as a previously created `defprobcurve` object.

Data Types: `object`

`inDates` — Survival probability dates
datetime array | string array | date character vector

Survival probability dates, specified as a vector using a datetime array, string array, or date character vectors.

To support existing code, `survprobs` also accepts serial date numbers as inputs, but they are not recommended.

Output Arguments

`outSurvProbs` — Survival probability
numeric

Survival probability, returned as a numeric.

Version History

Introduced in R2020a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `survprobs` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```

hazardrates

Compute hazard rates based on default probability curve

Syntax

```
OutRates = hazardrates(obj)
```

Description

`OutRates = hazardrates(obj)` computes hazard rates based on a `defprobcurve` object.

Examples

Calculate Hazard Rates Based on Default Probability Curve

Create a `defprobcurve` object using `defprobcurve` and then use `hazardrates` to calculate the hazard rates.

```
Settle = datetime(2017,9,20);
DefProbTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
DefaultProbabilities = [0.005 0.007 0.01 0.015 0.026 0.04 0.077 0.093 0.15 0.20]';
ProbDates = Settle + DefProbTimes;

DefaultProbCurve = defprobcurve(Settle,ProbDates,DefaultProbabilities,'Basis',5)
```

```
DefaultProbCurve =
  defprobcurve with properties:

                  Settle: 20-Sep-2017
                   Basis: 5
                   Dates: [10x1 datetime]
    DefaultProbabilities: [10x1 double]
```

```
hazardrates(DefaultProbCurve)
```

    0.0058
    0.0065
    0.0061
```

Input Arguments

obj — defprobcurve object
defprobcurve object

defprobcurve object, specified as a previously created defprobcurve object.

Data Types: object

Output Arguments

OutRates — Hazard rates
numeric

Hazard rates, returned as a numeric.

defprobstrip

Bootstrap `defprobcurve` object from market CDS instruments

Syntax

```
OutCurve = defprobstrip(ZeroCurve,MarketInstruments,MarketQuotes)
OutCurve = defprobstrip( ___ ,Name,Value)
```

Description

`OutCurve = defprobstrip(ZeroCurve,MarketInstruments,MarketQuotes)` bootstraps a `defprobcurve` object from market CDS instruments.

`OutCurve = defprobstrip( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to any of the input argument combinations in the previous syntax.

Examples

Bootstrap Default Probability Curve from Market CDS Instruments

This example shows how to use `defprobstrip` to bootstrap a `defprobcurve` object based on market CDS instruments.

Create `ratecurve` Object for Zero-Rate Curve

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2017,9,15);
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates);
```

Market CDS Spreads and Vector of Market CDS Instruments

Define the market CDS spreads and use `fininstrument` to create a vector of market CDS instrument objects.

```
SpreadTimes = [1 2 3 4 5 7 10 20 30]';
Spread = [140 175 210 265 310 360 410 460 490]';
MarketDates = datemnth(Settle,12*SpreadTimes);

NumMarketInst = length(MarketDates);
ContractSpreadBP = zeros(NumMarketInst,1);

MarketCDSInstruments(NumMarketInst,1) = fininstrument("cds", ...
      'ContractSpread', ContractSpreadBP(end), 'Maturity', MarketDates(end));
  for k = 1:NumMarketInst
      MarketCDSInstruments(k,1) = fininstrument("cds", ...
          'ContractSpread', ContractSpreadBP(k), 'Maturity', MarketDates(k));
  end
```

Use `defprobstrip` to create a `defprobcurve` object.

```
DefaultProbCurve = defprobstrip(ZeroCurve,MarketCDSInstruments, Spread)
```

```
DefaultProbCurve =
  defprobcurve with properties:

                  Settle: 15-Sep-2017
                   Basis: 2
                   Dates: [9x1 datetime]
    DefaultProbabilities: [9x1 double]
```

Input Arguments

`ZeroCurve` — Zero-rate curve

`ratecurve` object

Zero-rate curve, specified by a previously created `ratecurve`.

Data Types: `object`

`MarketInstruments` — Market CDS instruments

vector

Market CDS instruments, specified as an `NINST`-by-`1` vector.

Data Types: `double`

`MarketQuotes` — Market spread

vector

Market quotes, specified as an `NINST`-by-`1` vector.

Data Types: `double`

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `DefaultProbCurve = defprobstrip(ZeroCurve, MarketInstruments, MarketQuotes,'QuoteType',"upfront")`

`QuoteType` — Market quote type

`"fairspread"` (default) | string with value of `"fairspread"` or `"upfront"` | character vector with value of `'fairspread'` or `'upfront'`

Frequency of payments per year, specified as the comma-separated pair consisting of `'QuoteType'` and a scalar character vector or string.

- `"fairspread"` — CDS break-even spread for zero upfront price
- `"upfront"` — CDS upfront price for a given contractual spread

Data Types: `char` | `string`

`ProbDates` — Dates for probability data
`NINST`-by-`1` vector of maturity dates in `MarketInstruments` input (default) | datetime array | string array | date character vector

Dates for probability data, specified as the comma-separated pair consisting of `'ProbDates'` and a `P`-by-`1` vector of dates for the output `defprobcurve` object, given as a datetime array, string array, or date character vectors.

To support existing code, `defprobstrip` also accepts serial date numbers as inputs, but they are not recommended.

Output Arguments

`OutCurve` — Default probability curve
`defprobcurve` object

Default probability curve, returned as a `defprobcurve` object with the following properties:

- `Settle`
- `Basis`
- `Dates`
- `DefaultProbabilities`

Version History

Introduced in R2020a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `defprobstrip` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

A

Derivatives Pricing Options

Pricing Options Structure

In this section...

Introduction

The MATLAB `Options` structure provides additional input to most pricing functions. The `Options` structure

- Tells pricing functions how to use the interest-rate tree to calculate instrument prices.
- Determines what additional information the Command Window displays along with instrument prices.
- Tells pricing functions which method to use in pricing barrier options.

The pricing options structure is primarily used in the pricing of interest-rate-based financial derivatives. However, the `BarrierMethod` field in the structure allows you to use it in pricing equity barrier options as well.

You provide pricing options in an optional `Options` argument passed to a pricing function. (See, for example, `bondbyhjm`, `bdtprice`, `barrierbycrr`, `barrierbyeqp`, or `barrierbyitt`.)

Default Structure

If you do not specify the `Options` argument in the call to a pricing function, the function uses a default structure. To observe the default structure, use `derivset` without any arguments.

```
Options = derivset

Options =

    Diagnostics: 'off'
       Warnings: 'on'
      ConstRate: 'on'
  BarrierMethod: 'unenhanced'
```

The `Options` structure has four fields: `Diagnostics` on page A-2, `Warnings` on page A-2, `ConstRate` on page A-3, and `BarrierMethod` on page A-3.

Diagnostics Field

`Diagnostics` indicates whether additional information is displayed if the tree is modified. The default value for this option is `'off'`. If `Diagnostics` is set to `'on'` and `ConstRate` is set to `'off'`, the pricing functions display information such as the number of nodes in the last level of the tree generated for pricing purposes.

Warnings Field

`Warnings` indicates whether to display warning messages when the input tree is not adequate for accurately pricing the instruments. The default value for this option is `'on'`. If both `ConstRate` and

`Warnings` are `'on'`, a warning is displayed if any of the instruments in the input portfolio have a cash flow date between tree dates. If `ConstRate` is `'off'`, and `Warnings` is `'on'`, a warning is displayed if the tree is modified to match the cash flow dates on the instruments in the portfolio.

ConstRate Field

`ConstRate` indicates whether the interest rates should be assumed constant between tree dates. By default this option is `'on'`, which is not an arbitrage-free assumption. So the pricing functions return an approximate price for instruments featuring cash flows between tree dates. Instruments featuring cash flows only on tree nodes are not affected by this option and return exact (arbitrage-free) prices. When `ConstRate` is `'off'`, the pricing function finds the cash flow dates for all instruments in the portfolio. If these cash flows do not align exactly with the tree dates, a new tree is generated and used for pricing. This new tree features the same volatility and initial rate specifications of the input tree but contains tree nodes for each date in which at least one instrument in the portfolio has a cash flow. Keep in mind that the number of nodes in a tree grows exponentially with the number of tree dates. So, setting `ConstRate 'off'` dramatically increases the memory and processor demands on the computer.

BarrierMethod Field

When using binomial trees to price barrier options, this may require many tree steps to achieve an accurate result when tree nodes do not align with the barrier level. With the `BarrierMethod` field, the toolbox provides an enhancement method that improves the accuracy of the results without having to use large trees.

The `BarrierMethod` field can be set to `'unenhanced'` (default) or `'interp'`. If you specify `'unenhanced'`, no correction calculation is used. Otherwise, if you specify `'interp'`, the toolbox provides an enhanced valuation by interpolating between nodes on barrier boundaries.

You specify the barrier method in the last input argument, `Options`, of the functions `barrierbycrr`, `barrierbyeqp`, `barrierbyitt`, `crrprice`, `eqpprice`, `ittprice`, `crrsens`, `eqpsens`, or `ittsens`. `Options` is a structure that you create with the function `derivset`. Using `derivset`, you specify whether to use the enhanced or the unenhanced method.

For more information about this algorithm, see Derman, E., I. Kani, D. Ergener and I. Bardhan, “Enhanced Numerical Methods for Options with Barriers,” *Financial Analysts Journal*, (Nov. - Dec. 1995), pp. 65–74.

Customizing the Structure

Customize the Options structure by passing property name/property value pairs to the `derivset` function.

As an example, consider an Options structure with `ConstRate 'off'` and `Diagnostics 'on'`.

```
Options = derivset('ConstRate', 'off', 'Diagnostics', 'on')
```

```
Options =

  Diagnostics: 'on'
     Warnings: 'on'
    ConstRate: 'off'
BarrierMethod: 'unenhanced'
```

To obtain the value of a specific property from the Options structure, use `derivget`.

```
CR = derivget(Options, 'ConstRate')

CR =
Off
```

Note Use `derivset` and `derivget` to construct the Options structure. These functions are guaranteed to remain unchanged, while the implementation of the structure itself may be modified in the future.

Now observe the effects of setting `ConstRate 'off'`. Obtain the tree dates from the HJM tree.

```
TreeDates = [HJMTree.TimeSpec.ValuationDate;...
HJMTree.TimeSpec.Maturity]

TreeDates =

     730486
     730852
     731217
     731582
     731947

datedisp(TreeDates)

01-Jan-2000
01-Jan-2001
01-Jan-2002
01-Jan-2003
01-Jan-2004
```

All instruments in `HJMInstSet` settle on January 1, 2000, and all have cash flows once a year, except for the second bond, which features a period of 2. This bond has cash flows twice a year, with every other cash flow consequently falling between tree dates. You can extract this bond from the portfolio to compare how its price differs by setting `ConstRate` to `'on'` and `'off'`.

```
BondPort = instselect(HJMInstSet, 'Index', 2);

instdisp(BondPort)

Index Type CouponRate Settle      Maturity     Period Basis...
1     Bond 0.04       01-Jan-2000 01-Jan-2004  2      NaN...
```

First price the bond with `ConstRate 'on'` (default).

```
format long
[BondPrice, BondPriceTree] = hjmprice(HJMTree, BondPort)

Warning: Not all cash flows are aligned with the tree. Result will
be approximated.

BondPrice =

  97.52801411736377

BondPriceTree =
FinObj: 'HJMPriceTree'
 PBush: {1x5 cell}
```

```
AIBush: {[0]  [1x1x2 double] ... [1x4x2 double]  [1x8 double]}
  tObs: [0 1 2 3 4]
```

Now recalculate the price of the bond setting `ConstRate 'off'`.

```
OptionsNoCR = derivset('ConstR', 'off')

OptionsNoCR =

Diagnostics: 'off'
   Warnings: 'on'
  ConstRate: 'off'

[BondPriceNoCR, BondPriceTreeNoCR] = hjmprice(HJMTree,...
BondPort, OptionsNoCR)

Warning: Not all cash flows are aligned with the tree. Rebuilding
tree.

BondPriceNoCR =

  97.53342361674437

BondPriceTreeNoCR =

FinObj: 'HJMPriceTree'
 PBush: {1x9 cell}
AIBush: {1x9 cell}
  tObs: [0 0.5000 1 1.5000 2 2.5000 3 3.5000 4]
```

As indicated in the last warning, because the cash flows of the bond did not align with the tree dates, a new tree was generated for pricing the bond. This pricing method returns more accurate results since it guarantees that the process is arbitrage-free. It also takes longer to calculate and requires more memory. The `tObs` field of the price tree structure indicates the increased memory usage. `BondPriceTree.tObs` has only five elements, while `BondPriceTreeNoCR.tObs` has nine. While this may not seem like a large difference, it has a dramatic effect on the number of states in the last node.

```
size(BondPriceTree.PBush{end})

ans =

     1 8

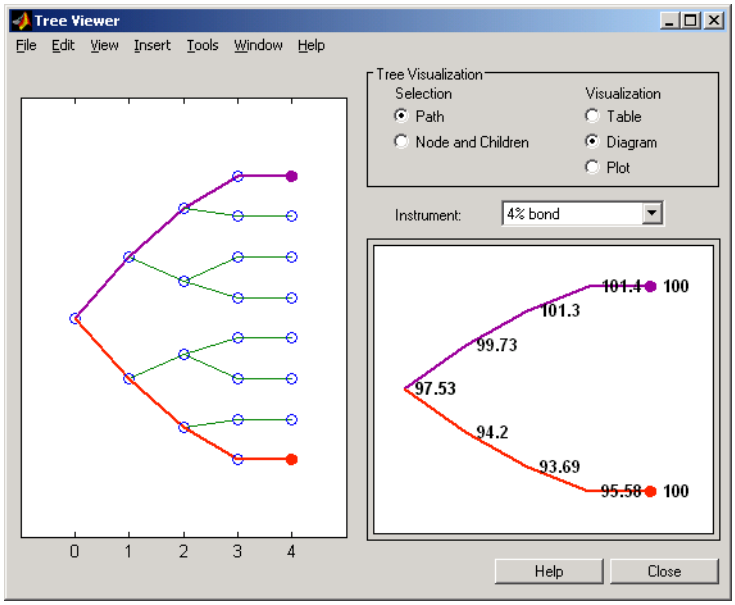
size(BondPriceTreeNoCR.PBush{end})

ans =

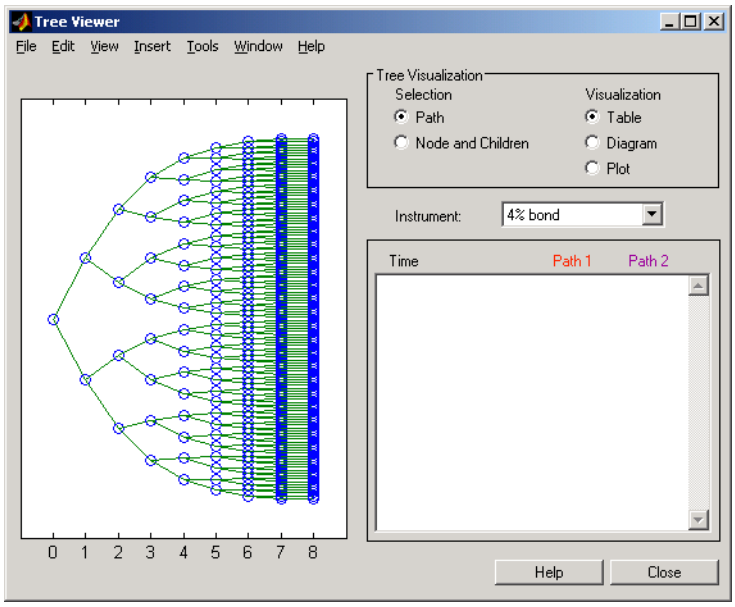
     1 128
```

The differences become more obvious by examining the price trees with `treeviewer`.

```
treeviewer(BondPriceTree, BondPort)
```



```
treeviewer(BondPriceTreeNoCR, BondPort)
```



```
All = [Delta ./ Price, Gamma ./ Price, Vega ./ Price, Price]
```

```
All =

         -2.76         10.43          0.00         98.72
         -3.56         16.64         -0.00         97.53
       -166.18      13235.59        700.96          0.05
         -2.76         10.43          0.00         98.72
         -0.01          0.03             0        100.55
         46.95       1090.63         14.91          6.28
       -969.85     173969.77       1926.72          0.05
         -76.39        287.00          0.00          3.690
```

Bibliography

Bibliography

Black-Derman-Toy (BDT) Modeling

A description of the Black-Derman-Toy interest-rate model can be found in:

[1] Black, Fischer, Emanuel Derman, and William Toy. "A One Factor Model of Interest Rates and its Application to Treasury Bond Options." *Financial Analysts Journal.* January - February 1990.

Heath-Jarrow-Morton (HJM) Modeling

An introduction to Heath-Jarrow-Morton modeling, used extensively in Financial Instruments Toolbox software, can be found in:

[2] Jarrow, Robert A. *Modelling Fixed Income Securities and Interest Rate Options.* McGraw-Hill, 1996, ISBN 0-07-912253-1.

Hull-White (HW) and Black-Karasinski (BK) Modeling

A description of the Hull-White model and its Black-Karasinski modification can be found in:

[3] Hull, John C. *Options, Futures, and Other Derivatives.* Prentice-Hall, 1997, ISBN 0-13-186479-3.

You can find additional information about the Hull-White single-factor model used in this toolbox in these papers:

[4] Hull, J., and A. White. "Numerical Procedures for Implementing Term Structure Models I: Single-Factor Models." *Journal of Derivatives.* 1994.

[5] Hull, J., and A. White. "Using Hull-White Interest Rate Trees." *Journal of Derivatives.* 1996.

Cox-Ross-Rubinstein (CRR) Modeling

To learn about the Cox-Ross-Rubinstein model, see:

[6] Cox, J. C., S. A. Ross, and M. Rubinstein. "Option Pricing: A Simplified Approach." *Journal of Financial Economics.* Number 7, 1979, pp. 229–263.

Implied Trinomial Tree (ITT) Modeling

To learn about the Implied Trinomial Tree model, see:

[7] Chriss, Neil A., E. Derman, and I. Kani. “Implied trinomial trees of the volatility smile.” *Journal of Derivatives.* 1996.

Leisen-Reimer Tree (LR) Modeling

To learn about the Leisen-Reimer model, see:

[8] Leisen D.P., M. Reimer. “Binomial Models for Option Valuation – Examining and Improving Convergence.” *Applied Mathematical Finance.* Number 3, 1996, pp. 319–346.

Equal Probabilities Tree (EQP) Modeling

To learn about the Equal Probabilities model, see:

[9] Chriss, Neil A. *Black Scholes and Beyond: Option Pricing Models.* McGraw-Hill, 1996, ISBN 0-7863-1025-1.

Closed-Form Solutions Modeling

To learn about the Bjerksund-Stensland 2002 model, see:

[10] Bjerksund, P. and G. Stensland. “Closed-Form Approximation of American Options.” *Scandinavian Journal of Management.* Vol. 9, 1993, Suppl., pp. S88–S99.

[11] Bjerksund, P. and G. Stensland. *“Closed Form Valuation of American Options.”*, Discussion paper, 2002.

Financial Derivatives

You can find information on the creation of financial derivatives and their role in the marketplace in numerous sources. Among those consulted in the development of Financial Instruments Toolbox software are:

[12] Chance, Don. M. *An Introduction to Derivatives.* The Dryden Press, 1998, ISBN 0-030-024483-8.

[13] Fabozzi, Frank J. *Treasury Securities and Derivatives.* Frank J. Fabozzi Associates, 1998, ISBN 1-883249-23-6.

[14] Wilmott, Paul. *Derivatives: The Theory and Practice of Financial Engineering.* John Wiley and Sons, 1998, ISBN 0-471-983-89-6.

Fitting Interest-Rate Curve Functions

[15] Nelson, C.R., Siegel, A.F. "Parsimonious modelling of yield curves." *Journal of Business.* Number 60, 1987, pp 473–89.
